200,000 kw. Reheat Boiler Design

for the Hydro-Electric Power Commission of Ontario, Richard L. Hearn Station

F. W. Cranston,

Sales Manager, Babcock-Wilcox & Goldie McCulloch Limited, Galt, Ont.

M. G. Ireland,

Asst. Contract Manager, Babcock & Wilcox Co., Barberton, Ohio.

Read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May 1956

Many new problems in the last ten years have caused rapid change in the design of boiler units. The authors discuss some of the factors involved and describe the considerations that led to the design of the 200,000 kw. reheat boiler (no. 5) for Ontario Hydro's Richard L. Hearn Station.

BY WAY OF introduction it may be well to mention a few reasons why Canada's phenomenal industrial growth during the past fifteen years has not, up to 1956, justified a decision to install a thermal station equipped with units larger than 100,000 kilowatts capacity.

The greatest concentrations of population and of industry in Canada have developed in provinces and areas which were abundantly provided with water power resources. This is particularly true of Quebec, Ontario and British Columbia. One has only to recall that Niagara Falls and the St. Lawrence power scheme now being developed, are located in Southern Ontario, and that Quebec has even more favourable water power resources. The B.C. hydro potential, which has attracted an industry of the magnitude of the Aluminum Company of Canada operation at Kitimat, needs no more than a passing reference.

But, it is evident that we are now approaching the economic limits of hydro-electric development in Ontario and that we will, in the forseeable future, do so in the other provinces.

In the past, Ontario has been in a position to consider thermal stations more in the nature of peak load plants to be operated in conjunction with hydro installations, but the fast growing annual increment of its base load power requirements has dictated that the Hydro-Electric Power Commission of Ontario should proceed with the installation for service in 1958 of the first 200,000 kw. steam turbo generator and single reheat steam generator to be installed in Canada.

There are still many undeveloped water power sites in Canada and as new areas and industries are developed these will undoubtedly, if economically justified, provide their quota of power. Nevertheless, in the future, Canada's growing needs for electrical energy will depend on thermal stations.

In the other Canadian provinces where fossilized fuels are available thermal stations of sizes up to 60,000 kw. have been or are being installed, and it is apparent that industrial development in those provinces is dictating a trend toward larger units which will approach or exceed the size discussed here.

At the end of 1950, there were approximately 300 thermal generating stations in Canada capable of developing a total of 642,000 kw. The majority of these stations were located in the east and middle west where fuels are available. During the following four years the power requirements increased considerably and the rate of increase within this period and projected to the year 1958 is shown on Fig. 1.

Although the power generated by thermal stations in Canada is not yet great and represents only approximately 7 per cent of total power generated, the expected increase from 642,000 kw. in 1950 to 2,295,000 kw. in 1958 shows an increase of over 350 per cent during this period.

At December 1954 the thermal stations in this country were capable of developing a total of 1,441,000 kw., and this total is shown graphically by provinces on Fig. 2.

This curve refers specifically to the kilowatts generated in thermal stations, and does not represent the total power load growth that has occurred in these provinces and which has partially or wholly been provided for by additions or expansions of existing hydro plants.

To illustrate further the relative kilowatt load growth forecast for the Canadian thermal power station, Fig. 3 shows the comparison between thermal and hydro generation from 1950 to 1954 and what it is expected to be in 1958.

In relation to total generating capacity thermal generation represented 7.0 per cent in 1950, 11.0 per cent in 1954 and is forecast to be 14.0 per cent in 1958.

In the field of thermal power gen-

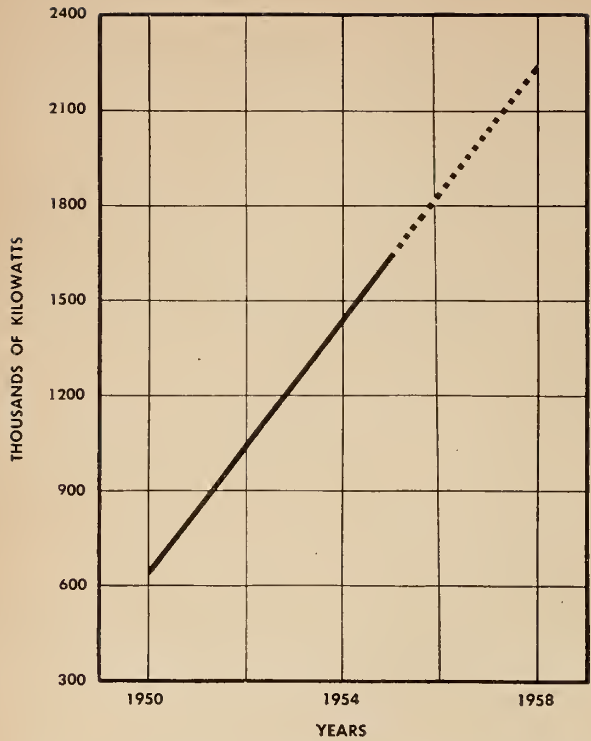

Fig. 1. Available Canadian thermal supply 1950-1958.

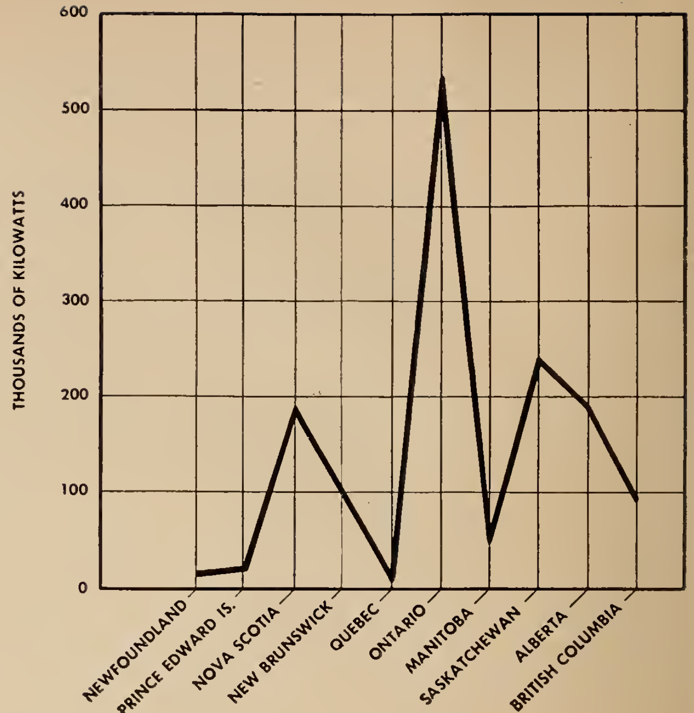

Fig. 2. Available Canadian thermal supply, 1954, by provinces.

eration a thorough knowledge of the characteristics and economics of all available fuels is essential. It is not the intention in this paper to discuss the possibilities of nuclear fuel nor the relative merits of any one fuel, but rather to refer briefly to the better known fossil type fuels abundantly available in certain areas of Canada.

In the Maritimes and along the eastern seaboard are large quantities of bituminous coals which principally serve the generating plants in that area. These medium volatile coals are high in sulphur — sometimes exceeding 4 or 5 per cent — with ash softening temperatures often below 2050 deg. F. so that slag-proof boiler furnaces and convection heating surfaces are required in steam generating units for their successful use. Liquid fuels imported by pipe line and sea-going tankers are also available in the Maritimes.

In the prairie provinces of Manitoba, Saskatchewan, and Alberta, recent discoveries of large quantities of oil and natural gas are being increasingly used for central stations in western Canada. These sources, with existing bituminous and lignite fields, afford the prairie provinces a combination of fuel supply of unlimited scope for future thermal power developments in that area.

The Province of Ontario, because of its proximity to the coal fields of Pennsylvania and West Virginia, uses American bituminous coals widely in steam generation.

British Columbia is abundantly supplied with water power sites, but many of these are so remote from present centres of industry as to make their development uneconomical except for such outstanding enterprises as Kitimat. This province has large deposits of bituminous coal, often of high ash and low heating value, and oil fuel is widely available by sea transport.

The basis of economical steam generation is the efficient liberation and absorption of heat. Boiler and turbine designers have made a tremendous contribution to the power station industry through their continuing search for better and more efficient equipment, which has reduced fuel consumption per kilowatt. Since the first steam-electric plant went into service great changes have taken place in the design of boilers and firing equipment and in pressures and temperatures. We have seen the evolution from boilers of limited capacity fired by underfeed or chain grate stokers, to the modern radiant design units of over one million lb/hr. capacity, with complete furnace cooling and pulverized fuel, gas or oil firing, and up to 300,000 lb/hr. for continuous ash discharge spreader stokers.

In Canada, the design of steam generating units is affected not only by fuel but also by the amount and character of the electrical load, whereas in the United States, for example, electricity is generated chiefly by steam so that most of the generating plants are base loaded. Many of our central generating systems in Canada have a large percentage of their capacity in hydroelectric equipment and less in thermal equipment. Steam plants are, therefore, very often used for peaking in Canada and so must be designed not only for efficient use of fuel, which everywhere is becoming more expensive, but for high and constant steam temperature over a very wide range of loads and for quick and frequent re-start with high steam temperature quickly available to reduce stress on the turbine. These conditions, while by no means unique, are an unusually common problem in Canada.

As the use, and proportion, of steam generation increases in this country, these peaking characteristics may be less essential in design than they are at present but the need for more efficient use of fuel will continue with increasing fuel costs. Here, the advantages of the reheat cycle become very apparent, particularly as this cycle allows a marked reduction in the amount of condenser water required; the supply of this is already a serious problem in large areas of the prairie provinces.

This field of major steam generating units, of advanced pressures and temperature, built for the reheat cycle, for constant temperature over a very wide load range, and for rapid high-temperature start-up, has been entered for the first time in Canada by H.E.P.C. of Ontario in its recently purchased No. 5 unit for the Richard L. Hearn station in Toronto. (Advanced and modern as this new unit is, the ever-pressing need for cheaper power leads us toward supercritical pressure generating units — the first of which in this hemisphere will go in service during this summer at the Philo plant of the Ohio Power Company on the American Gas & Electric System.)

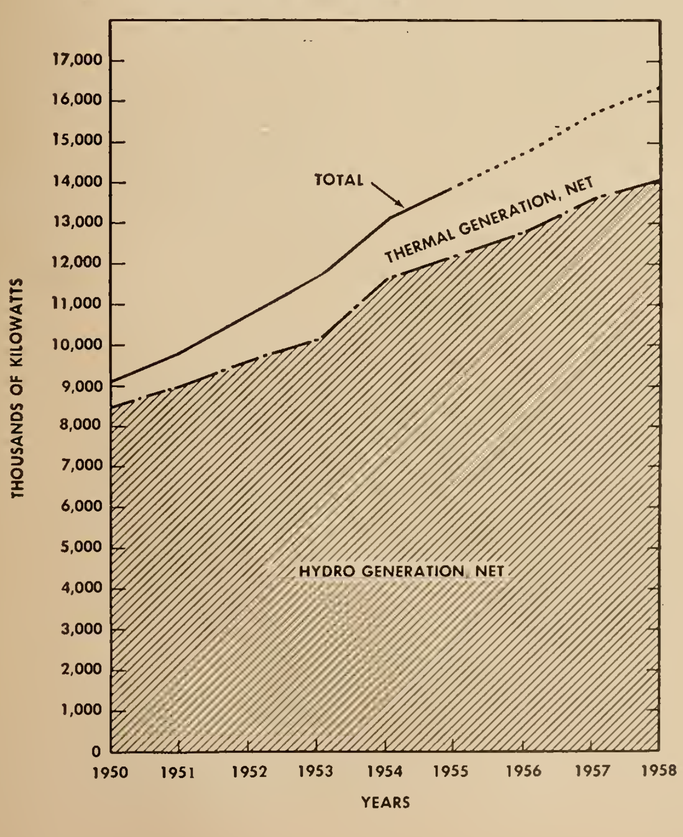
A further advance in the technique of fuel burning has been the development of the cyclone furnace, which is especially suited for low grade, low ash fusion coals, and brings with this outstanding design efficiency and freedom from ash and slag problems. The first installation of this unit in Canada will be at the Nova Scotia Light and Power Corporation in Halifax, which, at present, has two such cyclone fired boilers under construction, each capable of delivering 450,000 pounds of steam per hour at 925 pounds per square inch operating pressure and 915 deg. F. steam temperature.

The principal factors favouring the cyclone furnace were the abundance of low fusion ash coals and the suitability of this method of burning such fuels, demonstrated on similar units.

Figure 4 illustrates this boiler. Incidentally, the first North American supercritical steam generating unit is fired by cyclone furnaces, thus combining two of the most outstanding advances in steam generation.

Though the use of lignite for steam generation throughout western Canada has prevailed for many years, it was not until recently that this fuel became important in pulverized form, although in the last 25 years a couple of small installations had been tried. Perhaps the first major installation in Canada was made at the City of Winnipeg hydro plant in 1950, comprising a fully water cooled, controlled superheat unit of 175,000 pounds of steam per hour capacity, and this successful plant was followed in 1954 by an additional similar unit of 30,000 pounds of steam per hour capacity. This is illustrated in Fig. 5.

Fig. 3. Canadian net generating capability 1950-1958.



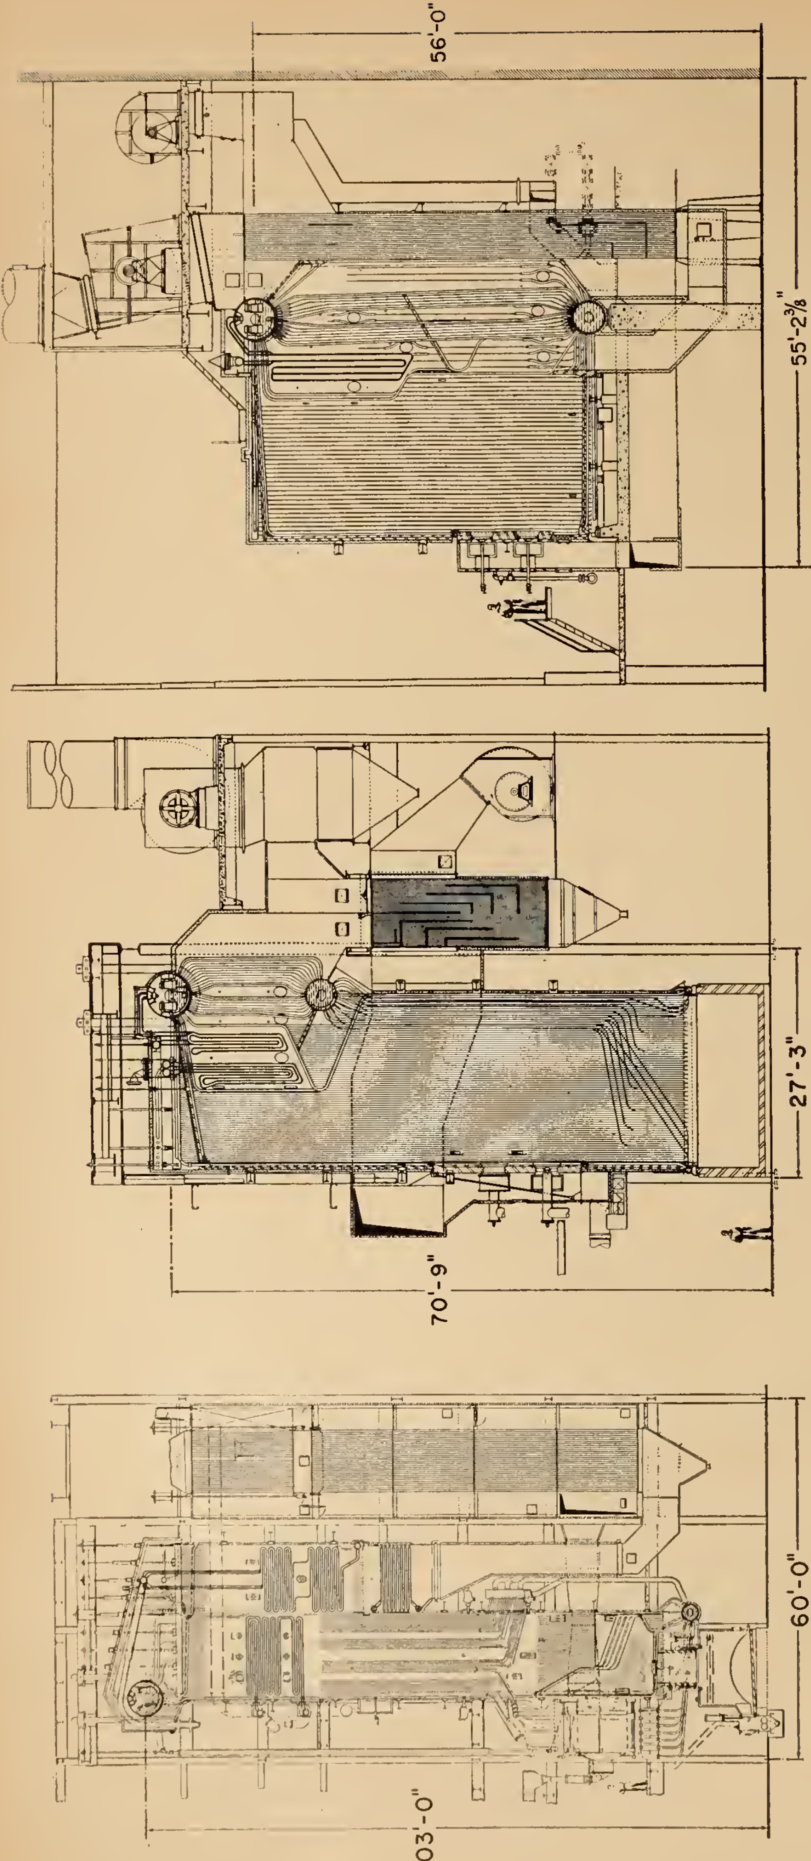
Tests on these units, and the observed results, confirm the efficient and easy utilization of high-moisture lignite in a pulverized direct firing system. Today, units of much larger capacity are in process for other plants due to these satisfactory results.

Figure 6 illustrates another typical Canadian central station boiler; this one recently installed at the generating station of the City of Edmonton, Alberta, to burn natural gas. This unit delivers 330,000 pounds of steam per hour at 415 psig. and 750 deg. F. and is one of 7 somewhat similar units in this station having a total output of nearly 1,500,000 pounds of steam per hour.

Figure 7 shows a unit now approaching completion at the Wabamun plant of Calgary Power Company, near Edmonton, to burn natral gas, or sub-bituminous pulverized coal, or oil, and generate 625,000 lb. steam/hour at 850 psig. and 900 deg. F.; this temperature to be constant from 250,000 lb./hr. output to full capacity.

As already mentioned, broad knowledge of load conditions and of available fuels is essential to the design of steam generating equipment, and this guided the consulting engineer's decision when the Hydro-Electric Power Commission of Ontario some years ago launched their thermal station projects now known as the J. Clark Keith generating station, in Windsor, and the Richard L. Hearn generating station at Toronto. These large boilers, of which there are four in each station, all of similar design, use the direct fired pulverized fuel system and have controlled superheat. The Windsor units are each designed to deliver 650,000 lb. steam per hour at 875 p.s.i., 900 deg. F. total steam temperature; and the Toronto units are each designed to deliver 850,000 lb. steam per hour, at 875 p.s.i. and total temperature of 900 deg. F. Figure 8 illustrates the design of the latter units.

Because of increased power demand, the Commission has found it necessary to expand the Richard L. Hearn station by a further 200,000 kw. and to achieve this has purchased boiler No. 5 which is capable of delivering 1,350,000 lb. steam per hour, at 1900 p.s.i., with steam temperature 1000 deg. F., and a reheat temperature of 1000 deg. F. As this



is the first reheat boiler and by far the largest unit to be installed in Canada, a detailed description may be of interest. (Fig. 9.)

Fuel Considerations[1]

In determining the overall design of the boiler, the first consideration is the fuel. Coal has been selected as the fuel for this unit, after considering market conditions which are constantly changing because of such factors as price fluctuations, seasonal variations in the availability of natural gas, and temporary shortages of coal or fuel oil.

The wide variation in the properties of coal and coal ash are well known, and it is necessary to adapt each boiler design to the particular kinds of coal which will be burned with proper allowance for reasonable deviation from the anticipated coal analysis. Coal with high ash fusion temperatures is inherently suitable for burning in a dry-ash removal hopper bottom furnace. Coal with low ash fusion temperatures requires so much more heat absorbing surface in the furnace for satisfactory dry ash operation that it is more economical to design for slag tap operation with pulverized coal supplied to burners or with crushed coal supplied to a cyclone furnace. The final decision as to furnace design is based on a combination of technical factors, engineering judgment, and at times personal preference.

Design and Functional Requirements

The unit selected for this plant will supply steam for a 200,000 kw. turbo-generator and is to be designed for a capacity of 1,350,000 pounds steam per hour, design pressure of 2200 p.s.i., and operating at 1900 p.s.i. at the superheater outlet, with a temperature of 1000 deg. F. The reheater will be designed for a pressure of 600 p.s.i. at a boiler output of 1,350,000 pounds per hour, the flow through the reheater will be 1,227,000 pounds per hour, with an inlet pressure of 450 p.s.i. and an outlet pressure of 419 p.s.i. The entering steam temperature will be 682 deg. F., and the outlet temperature 1000 deg. F.

The steam temperature at the superheater and the reheater outlet will be held at 1000 deg. F., over an operating range of about 2 to 1.

Fig. 4, 5, 6 (at left, bottom to top of page) Boiler installations at: Nova Scotia Light and Power Corporation, Halifax; City of Winnipeg Hydro-electric System; and City of Edmonton.

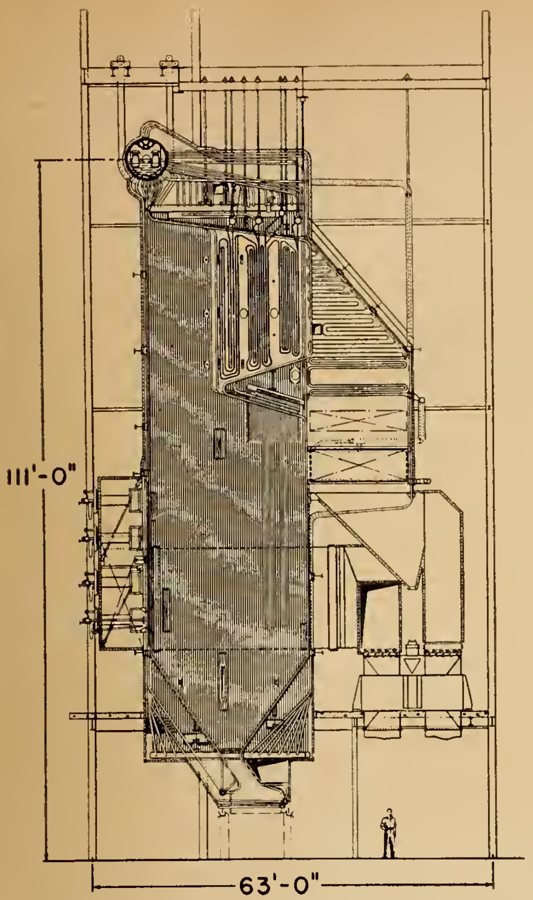


Fig. 7. Calgary Power Co., Lake Wabamun Plant.

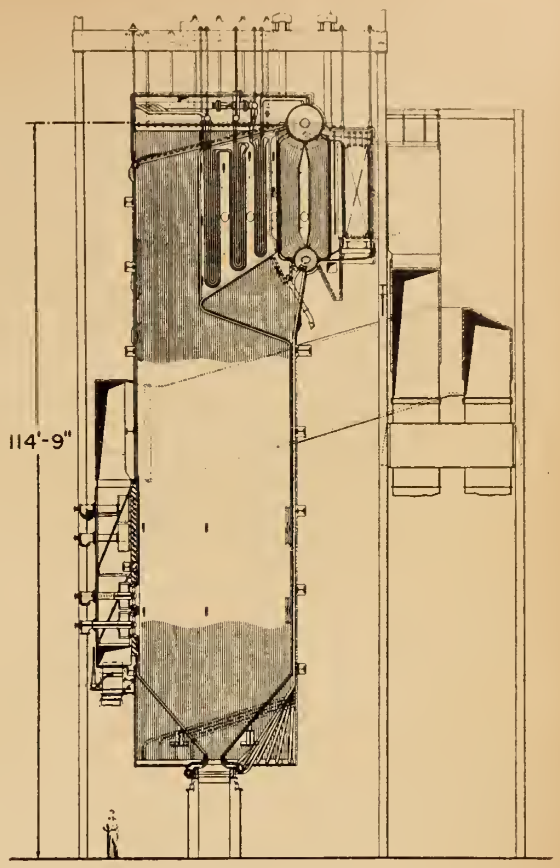

Fig. 8. Richard L. Hearn station, boiler nos. 1 to 4.

Having determined the design and functional requirements of the boiler, the physical size is determined by the total heat absorption. The design of the boiler furnace, where the fuel is burned and the products of combustion are cooled sufficiently to prevent slag difficulties in the convection surfaces, is one of the most important phases of the design, in order to ensure economical steam generation with high availability and low maintenance.

Natural Circulation in Boilers[2]

This boiler is designed for natural circulation, and will have a steam drum equipped with cyclone steam separators which not only makes possible operation with natural circulation at pressures approaching the critical, but has also provided circulation improvements at all pressures, and effected economies in the size and cost of boilers by facilitating the use of smaller drums, furnace division walls, and fewer downcomers.

Boiler circulation, in its elementary form, can be likened to a single U-tube (Fig. 10) connected to an overhead source or reservoir of water. If both legs of the U-tube are filled with water at the same temperature, the system is static. When heat is applied to one leg of the U-tube the temperature of the water in that leg increases and, with sufficient heat, some steam is formed; the weight or density of the water-steam mixture is less than that of the water in the unheated leg and circulation results as the lighter mixture rises and is displaced by a heavier mixture. Flow is from the reservoir, down the cold supply leg, up the heated riser leg, and thus circulation is established.

At low pressures, the difference between the density of the water in the downcomers and that of the water-steam mixture in the riser tubes is appreciable. (Fig. 10.) However, as the operating pressure is increased the steam in the risers is compressed and becomes denser. As a result, the differential density head between the supplies and the risers is reduced and the force available to produce circulation is decreased. In addition, the saturation temperature increases with pressure and, since the water in the downcomers is at, or slightly below, saturation temperature, this causes the density of water in the downcomers to decrease as pressure is increased. This trend to lighter downcomer water density and heavier riser steam density, as saturation temperatures and pressures increase, continues until finally at the critical pressure (3207 p.s.i.) the densities are the same—and it is impossible to obtain natural circulation.

At pressures below the critical the difference between the densities of water and dry steam at the saturation temperature corresponding to a given pressure is the maximum theoretically available for producing circulating head. However, a boiler cannot operate with dry steam in the generating or riser tubes since sufficient water must also pass through these tubes to conduct the heat from the tube walls and carry the steam generated into the steam drum. Thus, the maximum available difference between boiler downcomer and riser densities always is less than that theoretically possible; but the available density differential, even in the pressure range above 2000 p.s.i., is still substantial. Further, if this available density differential can be fully utilized, it is sufficient to produce an adequate and satisfactory circulating force.

Cyclone Steam Separators[2]

In order to ensure steam-free water in the downcomers, it is necessary to provide an efficient method of separation. About 1936 a new design—the cyclone steam separator (Fig. 11)—was developed to remove the steam from the water-steam mixture in the steam drum. These separators are installed in single or double rows in the steam drums, and all steam and circulating water from the risers is collected behind a manifold baffle and then discharged into the cyclones at high velocity; part of the circulating energy is utilized to produce a centrifugal force many times greater than the gravity separating force. This centrifugal action forces the water toward the periphery of the cyclones and the lighter steam flows up the central portion of the cyclone to the top outlet, whence it leaves at a velocity sufficiently low to prevent the pick-up of water; the steam quality is not affected by large variations in the water-steam ratios. Directional vanes at the bottom of the cyclone guide the water into the drum and utilize the velocity energy in the water to overcome the head of water outside the cyclone. This prevents flooding of the cyclones, even when the water level in the steam drum is close to the top of the cyclone, and permits wide variations in water level without affecting circulation or steam quality.

The cyclone steam separator has no moving parts and simply transforms a small portion of the circulating force into the centrifugal force required to separate the steam and water. Thus, there is adequate natural force left, even at very high pressures, to maintain satisfactory circulation without resorting to mechanical devices for assistance.

The first cyclone steam separator installations were so successful that it was decided to build natural circulation boilers for operation at pressures in excess of 2000 p.s.i.

This decision resulted in two industrial installations which have been operating for more than fifteen years, and analyses of their successful performance have provided considerable design data for use in subsequent high-pressure boiler designs. Because of the success of these pioneering developments, the authors' company has installed (or on order at end-April, 1956) 126 boilers designed for pressures above 2000 p.s.i. and averaging more than 1,000,000 lb. steam per hour per unit at rated capacity. Three of the most significant of these are reheat units, designed for a pressure of 2825 p.s.i., which will deliver 2,000,000 lb. steam per hour at 1053 deg. F. and reheat steam to 1053 deg. F. Seven units have a design pressure of 2700 p.s.i.

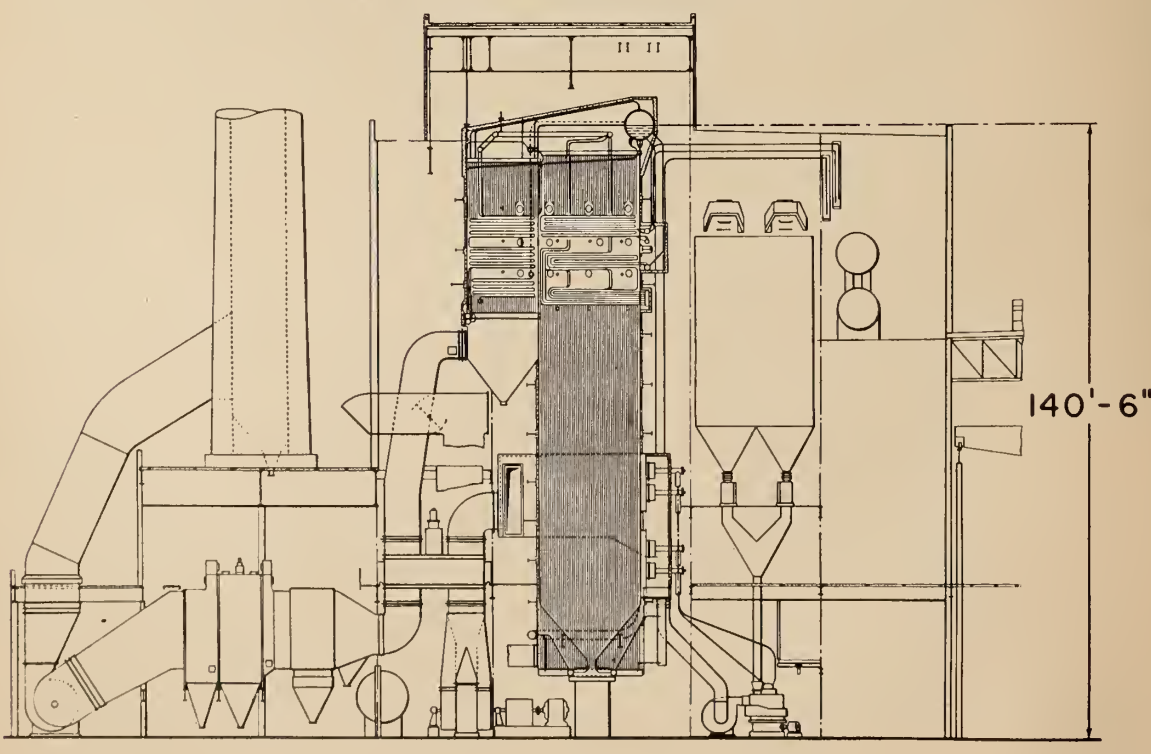
Steam Washers for Silica Removal[3]

One of the problems at present facing the power industry is that of carry-over of vaporous silica, which deposits in turbines. A solution to this problem is a steam washer which removes silica from the steam in the boiler by absorption in wash water such as condensate or feed water.

Manufacturers of power boilers guarantee that solids in the steam will not exceed 1 p.p.m., provided the total solids in the boiler water are held within certain limits, which depend on pressure. However, a boiler may deliver steam well within the guarantee value for total solids, but the turbine may become fouled with silica deposits. Though the problem can be solved with feed water treatment, this solution may not be economically practical.

Model washer tests have resulted in the development of a washer illustrated in Fig. 12. This consists of upper and lower perforated trays, which in addition to their function as part of the washing process, assure proper distribution of steam and water through a small-diameter stainless

Fig. 9. Richard L. Hearn station, boiler no. 5.



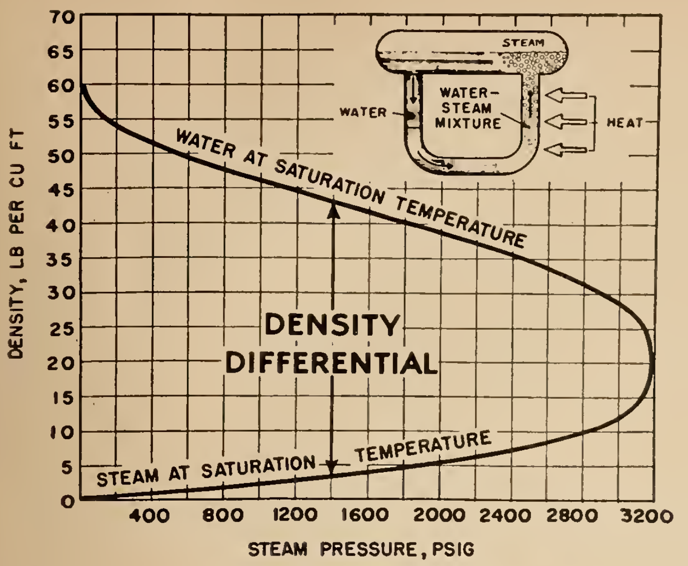


Fig. 10. Effect of pressure on density of steam and water at saturation temperature. Inset, U-tube analogy of natural circulation in boilers.

Fig. 11. Cyclone steam separator.

steel wire-mesh pad several inches thick. Such washers have reduced silica by approximately 90 per cent.

The advantages to be gained by steam washing depend on prevailing conditions, such as silica content of feed water, operating pressure, and the amount of blow-down that can be tolerated. The use of steam washers will permit appreciable reduction in blow-down rates used to control turbine deposits. Tests have indicated that turbine deposits of silica can be controlled by a steam washer at a saving of as much as 80 per cent in the blow-down rate.

A steam washer will be installed in the steam drum of the boiler being discussed, in the space normally occupied by the secondary steam scrubber.

Several high-pressure boilers, now being designed and erected will have steam washers. Figure 13 shows a typical installation. In view of the low initial cost and the large savings offered in turbine maintenance and reduced blow-down with steam washing, it is anticipated that a large percentage of future high-pressure boilers will be so equipped.

Description of Unit

The boiler selected (Fig. 9) is of the radiant type, fired with pulverized coal through circular burners in the front wall at four elevations. The furnace is designed for dry-ash operation, and provided with a hopper bottom for easy ash removal. The secondary superheater and reheater are located in the up-flow convection pass above the furnace. The primary superheater and the economizer are in the down-flow convection pass, below which are two regenerative air-preheaters at the rear of the unit.

The steam drum and all headers for the water walls, superheater, reheater, and economizer will be provided with shop-welded stubs to which all tubes will be strength-welded in the field. This precludes leakage, since the headers will not have gasketed hand-hole fittings. Each header will be provided with expanded and seal-welded nipples which can be removed for inspection.

The furnace width is 49 ft. 6 in. between side wall tubes, and the depth is 24 ft. 0 in. from the front or burner wall tubes to the rear wall tubes. The distance from the bottom of the hopper to the lower row of tubes in the secondary superheater is approximately 82 feet. The over-all height of the unit is about 140 feet, or the height of a 12-storey building.

The boiler is provided with a division wall at the centre of the furnace, extending from the front of the rear furnace wall except for a 2 ft.-0 in. opening at the centre of the division wall. An additional wall section will also be installed at the rear of the furnace midway between the division wall and each side wall. Each wall section will extend into the furnace about 5 feet for the full furnace height.

Supports

The entire unit is top supported by hanger rods attached to headers and tubes with the steam drum supported at each end by laminated straps. All rods and straps will extend to horizontal structural steel at the same level, which permits equal downward expansion of all pressure parts, eliminating the need for expansion joints.

The Boiler Furnace

The boiler furnace serves two primary functions: (a) it provides sufficient volume to facilitate complete combustion; and (b) it introduces ahead of the convection surface sufficient radiant heat absorbing surface to reduce the gas temperature entering the convection surface to a satisfactory level. Generally, for a given fuel and method of firing, this design temperature does not vary appreciably with capacity requirements and, therefore, in similar types of boilers the furnace heat-absorbing surfaces increase proportionately with capacity.

If all the surface is placed in the furnace boundaries, an increase in boiler capacity necessitates an increase in either the furnace width, depth or height; or an increase in combinations of these three dimensions. However, by employing one or more division walls in the furnace, the necessary heat-absorbing surface can be installed while effecting a substantial reduction in boiler size and, consequently, building volume. The use of furnace division walls increases the heat absorbing surface without increasing the furnace volume, and results in a more uniform

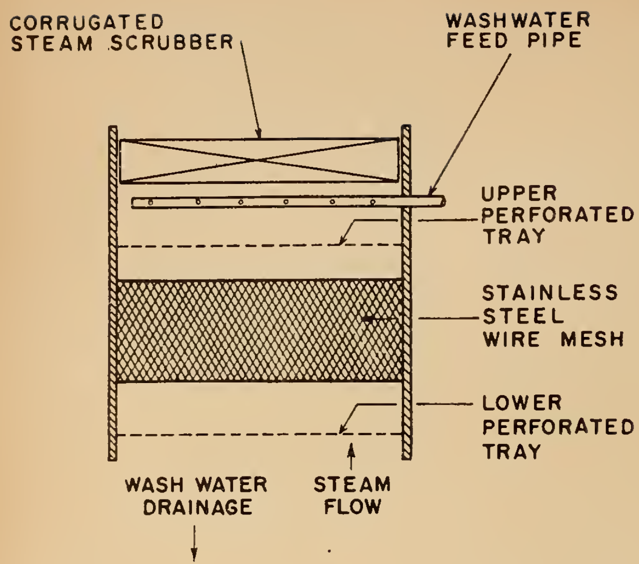

Fig. 12. Wire mesh steam washer.

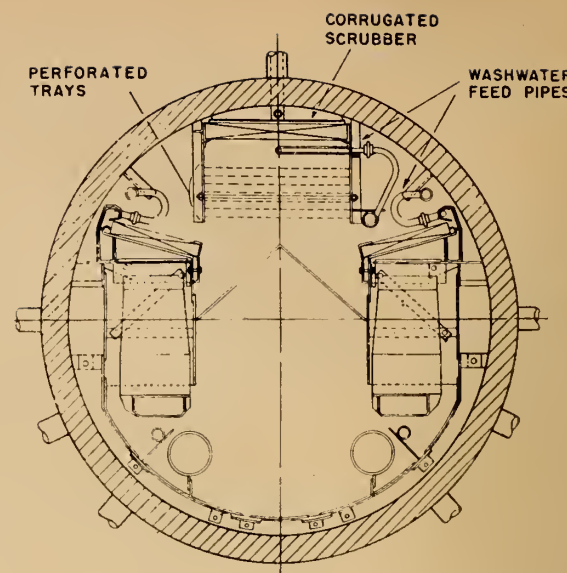

Fig. 13. Combination perforated tray and scrubber washers in high-pressure boilers.

gas temperature entering the convection heat absorbing surfaces (Fig. 14).

In all boiler furnaces there is usually a considerable variation in width of the unit. The tendency is toward temperatures higher than average at the centre of the furnace and well below average at the furnace sides. The differences between the maximum and minimum furnace exit gas temperatures also tend to increase with boiler width. However, the use of a division wall provides, in effect, two smaller-width furnaces and, consequently, reduces the differential. This is most important in the operation of the boiler, since the expected performances are predicted on average furnace exit gas temperatures. Large variations from this average could result in excessive metal temperatures and slagging in those zones of the superheater that receive furnace gases at temperatures well above the average.

Description of Pressure Parts

Steam Drum — The steam drum (weighing some 170 tons) will have a nominal inside diameter of 66 in.; the plate will be 6½ in. thick, and the overall length approximately 62 feet. It will be equipped with cyclone separators and washers as previously described. Four large downcomer pipes (one at each end of the drum, and two along the horizontal axis) will supply water to the various saturated circuits at the lower end of the unit.

Boiler Walls — All furnace and convection heating surfaces are completely enclosed with tangent tube bare walls. No refractory or spaced tubes in the perimeter of the boiler are exposed to hot gases.

The two side walls, the front and rear walls, including the hopper floor, and the division walls will be formed by tangent tubes.

The entire unit will be double cased; the inner casing, of No. 10 gauge plate, will be applied directly against the tangent tubes and seal-welded to minimize air infiltration into the boiler. This casing, being at saturation temperature, moves integrally with the expansion of the pressure parts, so avoiding damage by temperature differentials.

Economizer — The continuous-tube type economizer is located at the outlet end of the down-flow convection pass and will have sufficient capacity to pass all feed water required by the unit without an excessive pressure drop.

All surfaces of economizer, superheater, and reheater tubes and headers are drainable, the headers being provided with drain connections.

Primary Superheater — The primary superheater is at the top of the down-flow convection pass. It has two outlets, each equipped with a spray-type attemperator which is a part of the steam temperature control system.

Secondary Superheater — Steam from the primary superheater passes to the secondary superheater at the lower end of the up-flow convection pass. In this superheater, the lower section will have platens of tubes on 18 in. horizontal centres, and the upper section platens on 9 in. horizontal centres. The outlet tubes end in an outlet header outside the boiler.

Reheater — The reheater is at the top of the up-flow convection section and will be supplied with steam from the high pressure turbine. Steam will enter the header at each end and be distributed through platens of tubes. A spray-type attemperator is located at each of the reheater inlets.

The horizontal spacing of the superheater, reheater, and economizer tubes will minimize the accumulation of slag and ash. Furthermore, cavities provided for the installation of soot blowers will be spaced to facilitate the cleaning of all heating surfaces.

Superheater and Reheater Outlet Connections — Steam at 1000 deg. F. will be taken from the superheater and reheater headers in the vestibule at the front of the boiler to their respective manifold headers, approximately 40 feet from the boiler, by means of multiple tubes. These tubes will have sufficient flexibility to let the outlet headers move vertically 9 inches, for vertical expansion of the main steam pipe to the high and low pressure turbines.

The supply pipes and outlet headers will be supported by spring hangers designed for a predetermined load and motion.

Air Preheater

The unit will be served by two air preheaters, each 24 ft. diameter with 48 in. deep heating elements, the lower or cold air inlet end of which will be made of corrosion-resistant alloy steel. All heating elements will be mounted in baskets which can be readily removed.

These heaters are sized to preheat air from 40 deg. F. to 550 deg. F. at the rated capacity of 1,350,000 lb. steam/hr.

Each heater can be steam-cleaned.

Soot Blowers

The boiler will be provided with soot blowers, using steam as the blowing medium. The superheater, reheater, and economizer will have 8 retractable blowers at each side of the boiler, or a total of 16 blowers spaced between tube banks to provide complete coverage of all surfaces at either side of the tube supports which run vertically through the tube banks.

Twenty-four rotating-type wall blowers will clean the four furnace walls, in the area below the secondary superheater. In the blowing position the nozzle extends into the furnace a short distance beyond the face of the wall tubes. At the end of the blowing cycle the nozzle is retracted from the wall.

The entire soot blowing system is designed for automatic sequential operation and has electric-driven retracting mechanism.

Pulverizers, Feeders and Primary Air Fans

The coal bunker will be at the front of the boiler and directly above the pulverizers. The coal will pass through scales and directly to a feeder which is integral with each pulverizer; rate of feed is automatically controlled by the combustion control system or independently by the operator.

Six type EL-70 pulverizers will each deliver approximately 22,700 lb. coal per hour, at the rated capacity of 1,350,000 lb. steam per hour; 136,000 lb. coal will be burned per hour.

One pulverizer may be operated with its respective burners at a minimum load of 75,000 lb. steam per hour.

Individual motors will drive each pulverizer, primary air fan and coal feeder.

The primary air fan for each pulverizer will be designed to deliver sufficient heated air to the pulverizer to dry and carry the coal to the burners.

Coal Burners and Lighters

There will be 24 circular coal burners in the front wall, 12 on each side of the furnace division wall (6 burners in each of 4 horizontal rows). The burners will be placed to avoid impingement or scouring action on the furnace walls, or the lower row of superheater tubes.

It is possible to increase the steam temperature control range by firing only the upper burners at low loads.

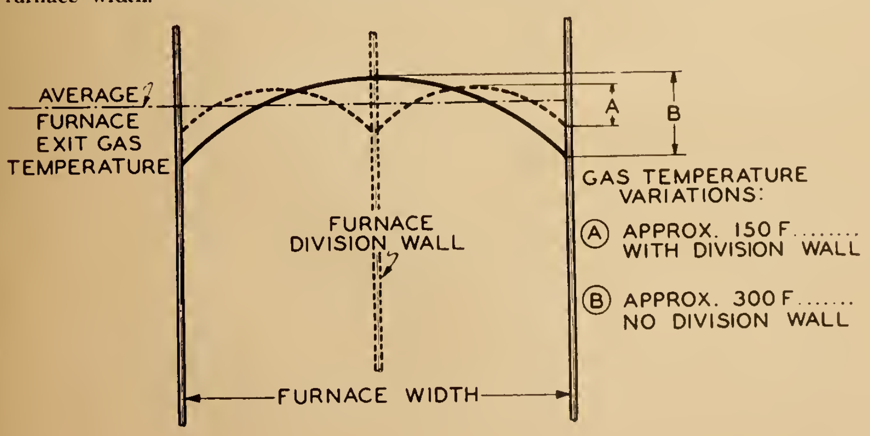
Each pulverizer will serve four burners, two on each side of the furnace division wall. Thus it is possible to operate any number of pulverizers with equal firing on either side of the wall.

The burners are in a secondary air housing, attached to the front wall tubes. This housing will have sufficient cross-section to give equal air distribution to each burner. Heated air from the preheaters will be delivered to each end of the burner housing through two insulated ducts, one at each side of the boiler.

Automatic oil lighting equipment for each burner is interlocked to ensure that the spark is functioning before oil is supplied to the burner.

Remote operating and indicating equipment is provided for each burner to centralize the controls for: operating the oil-fired lighters; retracting or injecting burner impellers; opening and closing air register doors; and operating the valves in the coal-air pipes between the pulverizers and the burners.

Fig. 14. Effect of furnace division wall on variation in gas temperatures across furnace width.



Flue and Duct Arrangement

The gas leaving the economizer enters a plenum compartment (provided with a hopper) from which the gas passes through a flue to the inlet side of the two air preheaters. From the outlet of the air preheaters the gas enters dust collectors through a flue, also provided with a hopper, and leaves through the induced draught fan to the stack.

Manually operated isolating dampers are provided in the gas duct to each air preheater.

Gas for recirculation is taken from the flue between the economizer outlet and the air preheater inlet. This gas passes through a flue to the gas recirculating fan and then to a plenum compartment under the adjacent hopper floor. From this compartment the gas is distributed through the hopper opening and over the furnace wall tubes.

The forced draught fan, at the rear of the unit, has an inlet duct so arranged and dampered that air may be taken from outside or inside the building. The fan discharges air through the two preheaters into ducts, at each side of the boiler, which supply combustion air to the burner windbox at the front of the boiler. A common hot air duct at the rear of the boiler will connect the two ducts at either side, permitting an even distribution of hot air to the burner windbox with one preheater out of service.

All flues and ducts will be supported on hanger rods, and provided with adequate expansion joints.

Steam Temperature Control

When superheated steam is generated for power or process use, it is desirable that the final steam temperature be maintained within specified limits over a range of steam output from the boiler. In power generation this is important in order that maximum turbine efficiency and minimum last stage moisture may be attained without exceeding safe metal temperatures in the superheater, reheater, steam piping or first stages of the turbine, and also to minimize temperature fluctuations.

The addition of a reheater, which is just another superheater, has not complicated operation, but has extended the requirements of steam temperature control. When this control is required over a wide range, as in this case from full to half load, it is necessary to combine control methods.

The automatic controls for draught, combustion, pulverizing equipment, and feedwater flow are conventional and need not be discussed. Since this is the first reheat installation in Canada, the steam temperature control system will be briefly described. There are many installations using this system successfully in the United States.

The basic operating variables influencing steam temperature with this design of boiler, assuming a constant degree of fouling, are:

(1) Superheated and reheated steam temperatures will rise with increased load and fall with decreased load.

(2) Increase in excess air has the effect of shifting heat absorption from the furnace to the convection pass, thereby increasing steam temperatures. Increase in excess air also increases the quantity of gas up the stack, reducing boiler efficiency.

(3) Admission of recirculated flue gas to the ash hopper has an effect on steam temperature similar to excess air, but does not increase the quantity of gas up the stack.

(4) Spray attemperation between the primary superheater outlet and the secondary superheater inlet, and at the reheater inlet, can be used to reduce superheated and reheated steam temperatures respectively.

(5) At fractional loads fuel can be supplied to the upper rows of burners to minimize absorption of heat in the furnace, thereby increasing furnace outlet gas temperature and the temperatures of both superheated and reheated steam, or the lower rows of burners can be fired with the reverse affect.

(6) Reduction in feed water temperature with a feed water heater out of service results in an increase in steam temperature due to the necessity of a higher heat input at a given steam output.

Because of the loss in boiler efficiency, increasing excess air to raise steam temperature is usually uneconomical. Flue gas recirculation and spray attemperation are the basic variables in the automatic steam

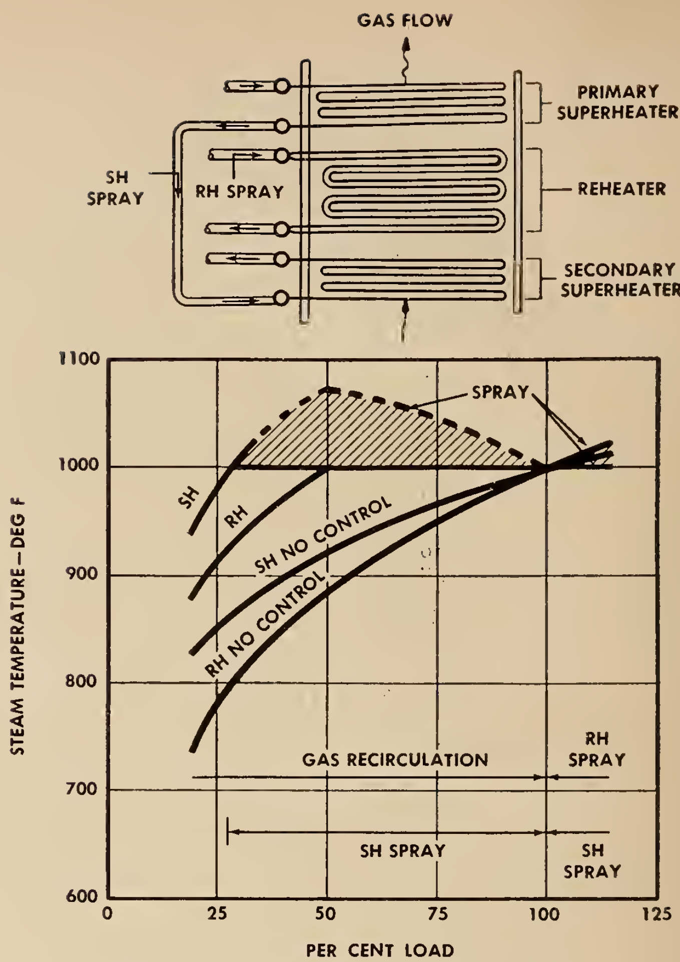


Fig. 15. Steam temperature control diagram.

temperature control system. Results achieved by the steam temperature control system are indicated in Fig. 15 and described below.

Flue gas is withdrawn from a low temperature zone by a fan and is delivered to the lower part of the furnace hopper. The introduction of flue gas at this point has the effect of blanketing the furnace walls, diluting the combustion gas and decreasing the residence time of the combustion gas. This leads to reduced furnace heat absorption and increased convection pass heat absorption, shifting part of the heat absorption from the evaporative to the superheating surface.

The boiler is designed to deliver superheated and reheated steam at a temperature of 1000 deg. F. at full load without flue gas recirculation or attemperation. During periods of overload, when the uncontrolled steam temperatures would rise above 1000 deg. F., spray attemperation is used to maintain the desired steam temperatures. At lower loads, when the uncontrolled steam temperatures would fall below 1000 deg. F., flue gas recirculation is used to increase superheater and reheater absorption and maintain the desired temperatures. If enough gas is recirculated to keep the reheated steam temperature up to 1000 deg. F., the superheater absorption will be excessive and the superheater attemperator must be operated. As load reduction is continued the point of maximum gas recirculation will be reached and further load reduction will cause reheated steam temperature to drop below 1000 deg. F. while superheat attemperation is reduced. Further load reduction will permit less and less superheat attemperation to be used, until zero superheat attemperation is reached, and then the superheated steam temperature also will fall below 1000 deg. F.

The steam temperature control equipment is shown schematically in Fig. 16. Steam flow, which is an index of boiler heat output, serves as the anticipating element for regulating the gas recirculating fans. The product (gas flow x gas temperature) in the superheater region, which is an index of heat flow over the superheater, provides an impulse which depends upon the actual amount of recirculation. Final adjustment of gas recirculation is made by an impulse from the lower of the two reheater outlet steam temperatures through the selective relay. The recirculating fan is kept running at all times, the quantity of gas recirculated being controlled by hydraulic coupling drive and dampers. Solenoids connected to the recirculating fan motor circuit serve to close the recirculating fan shut-off dampers and to open the damper which admits cooling air to the recirculating system when the recirculating fans are out of service.

The Babcock & Wilcox Company have developed the spray type attemperator (Fig. 17), for reducing and controlling the temperature of a superheated vapour or liquid. This consists of a spray nozzle, in the superheated steam line, through which a spray of low-solids-concentration water is injected into the steam which it cools by evaporation. A thermal sleeve protects the steam piping from quenching stresses.

That part of the total steam output which is supplied as spray water does not pass through the economizer nor through the superheater section preceding the attemperator, a fact which is important in design calculation of performance and superheater tube temperatures. Attemperator water is usually taken from the boiler feed line at a point ahead of the feed control valves.

Spray attemperation in the reheater, required only during overload, is regulated solely by reheater outlet steam temperature. Spray attemperation in the superheater is governed by an anticipating impulse from the product of gas flow rate x gas temperature, and by an impulse from attemperator outlet steam temperature which depends upon the actual amount of attemperation. Final adjustment of superheater attemperation is made by impulses from secondary superheater outlet steam temperatures.

Quick Starting

In recent years the load characteristics of some utility systems have made it economically desirable to remove large units from service after the evening peak, hold them idle overnight (or over weekend), and return them to service in the morning, picking up load at a rapid rate.

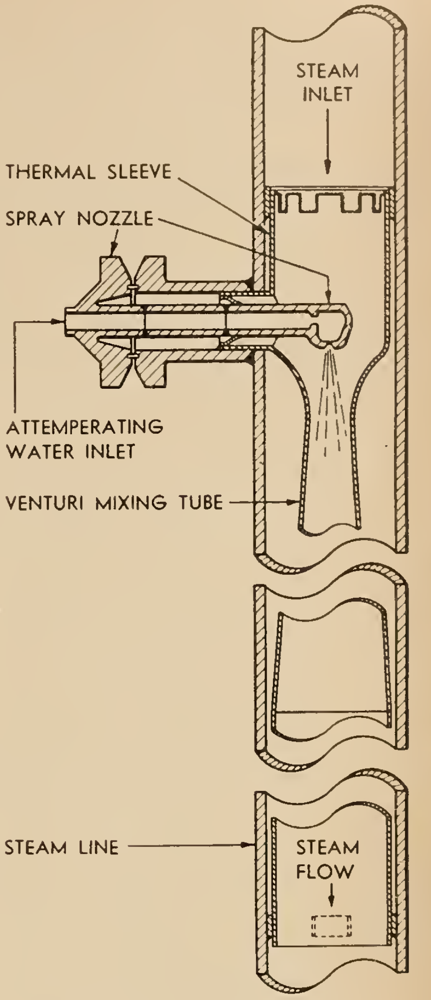

Fig. 17. Spray type attemperator.

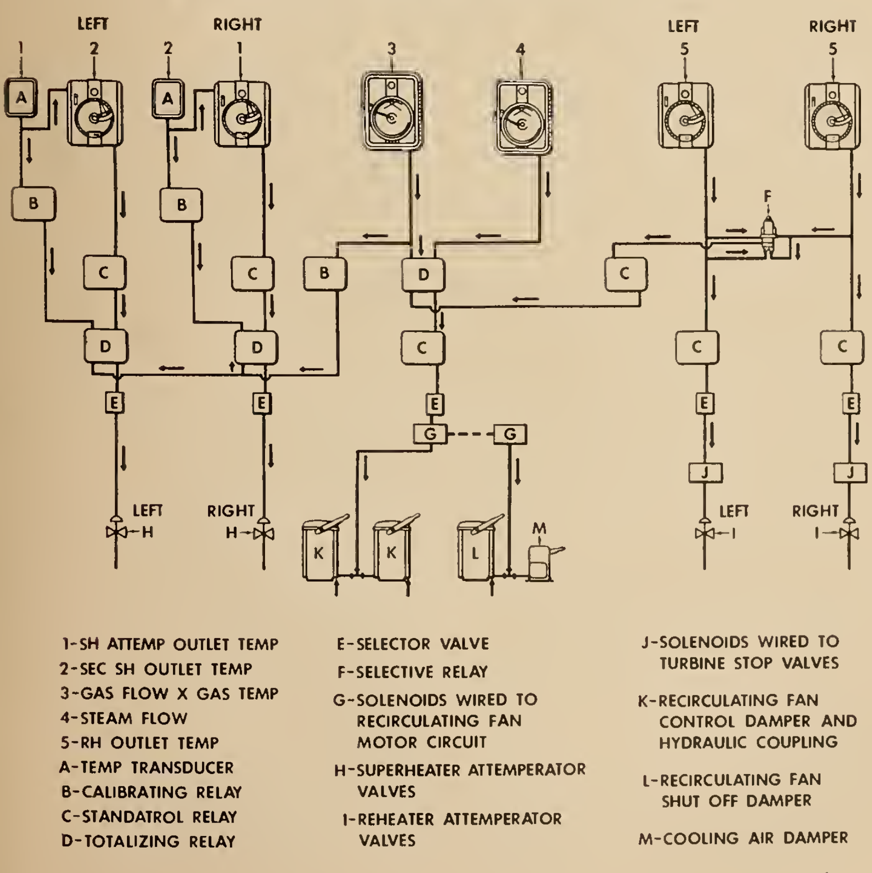
Fig. 16. Schematic steam temperature control diagram.



This practice is known as quick starting. Much pioneer work in this phase of operation has been done by Consolidated Edison Company of New York.[4,5,6]

When a boiler is brought from no load and low pressure to full load and full pressure in a short time precautions must be taken to avoid the following difficulties:

(1) Excessive thermal stresses resulting from extreme temperature differentials in the drum metal during the transient period.

(2) Excessive differential expansion in the remainder of the unit because of extreme temperature inequalities.

(3) Overheating the superheater and reheater metals during the no-flow and low-flow periods.

(4) Damaging the turbine by admitting steam at temperatures too different from that of the turbine metal parts at the steam admission end.

Firing a boiler when it is completely cold after a prolonged outage causes circulation of water within the circuits, and therefore heats the lower half of the drum with which the water comes in contact. The part of the drum above the water line receives very little heat from the water, but may receive heat from steam bubbles released in the drum, or from steam generated by vaporization of condensate in the superheater. The top and bottom of the drum therefore change temperature at diferent rates. When saturation pressure of the water reaches atmospheric pressure, the air within the drum is rapidly purged from the drum through the vent and replaced by saturated steam, which condenses on the metal of the top part of the drum. Since condensing steam provides very rapid heat transfer, the inside metal of the top part of the drum quickly approaches saturation temperature. During the subsequent pressure-raising period the inside surface of the drum, both top and bottom, rises in temperature almost as fast as saturation temperature, while the outside temperature of the drum rises more slowly as dictated by the laws of unsteady state heat conduction. Temperature differences in the drum metal induce two sorts of stresses: inequalities between top and bottom of the drum produce axial tension and compression stresses which are partially relieved by drum bowing; inequalities between inside and outside of the drum shell produce circumferential stresses. Heat input to the furnace and rate of saturation temperature rise may have to be restricted to keep these stresses within acceptable limits. However, when starting a 2200 p.s.i. boiler at an initial pressure between 500 p.s.i. and 1500 p.s.i. following a relatively short out-of-service period, the drum is already hot (467 to 545 deg. F.) so that rates of saturation temperature change, as limited by other considerations, will not cause excessive stresses in the drum metal.

Differential expansion in other parts of the boiler is rarely a problem, since boiler designers incorporate sufficient flexibility to avoid this difficulty. By inducing more vigorous circulation as a consequence of the higher input, quick starting produces a more uniform temperature distribution throughout the boiler, and therefore smaller differential expansion stresses, than a conventional slow start.

Protection of superheater and reheater tubes during start up requires:

(1) that the maximum gas temperature entering the superheater and reheater sections be restricted to approximately 950 deg. F. during period of no steam flow;

(2) that heat input to these tubes be limited to acceptable values during periods of low steam flow, particularly at reduced pressures where steam film conductances are less than normal.

During start-up temporary thermocouples should be positioned in the gas stream ahead of the superheater to monitor the gas temperature entering the superheater. With a nondrainable superheater, thermocouples installed on the outlets of the tubes are required to indicate whether or not the tubes are completely clear of condensate before the boiler goes on the line. In some cases the rate of firing must be restricted for several hours until the last tube has cleared. With a drainable superheater, such as is being furnished on this boiler, it will take only a few minutes to drain the headers of condensate, and it will not be necessary to wait for loops to clear.

Thermocouples installed on the tubes at the steam outlet header to indicate steam temperatures from the individual tubes are still desirable, however, to assure the safety of superheater and reheater tubes during operation. If steam pressure is held steady, or is increased only slowly during initial loading of the boiler, superheater and reheater tubes will operate at safe metal temperatures provided the indicated unbalanced steam temperatures do not exceed design limits. However, overfiring to raise pressure rapidly can result in overheating of the tube metals even if steam temperatures from individual tubes are within proper limits, since under these circumstances a major fraction of the heat absorbed by the water-cooled surfaces is being used to increase the pressure instead of generating steam which would normally flow through and cool the superheater and reheater tubes. A prudently restricted rate of steam pressure rise is not prejudical to fast starting, since it is satisfactory, and actually advantageous, to admit steam initially to the turbine at reduced pressure.

When a turbine is taken off the line it will cool gradually. Elston's data[7] show that during an eight-hour out-of-service period the steam chest of a 1000 deg. F. machine may cool to 600 deg. F. and the reheat admission space to 710 deg. F. Turbine manufacturers usually wish to have steam temperature 100 deg. F. above steam chest temperature during restarting after a cooling off period. To provide the desired temperature, which will vary for different operating and out-of-service periods, it is necessary to have a flexible steam temperature control system such as that supplied for this unit. The actual operating procedures which will be desirable to give the required steam temperatures can be determined only by experience.

Quick Pick-Up

Because suitable water power sites are usually remote from electrical load centres, hydro-electric systems tend to have long transmission lines which are vulnerable to interruptions. Steam plants operating near the load centres in parallel with hydro-electric units are therefore designed to accept sudden large load increases. Special features can be incorporated in the boiler, its auxiliaries, and its controls to meet rapid load pick-up needs [8, 9, 10, 11, 12].

When the steam demand on a boiler is suddenly increased there is a short period of rapid pressure reduction before the firing equipment can again supply heat to the steam generating unit as rapidly as it is removed. The pressure reduction has two effects:

(1) the volume of existing steam bubbles increases;

(2) some of the water in the circulating system flashes into steam.

The resulting increase in volume of the steam-water mixture causes the water level in the drum to rise. A large drum can therefore be used to minimize water level surge. To keep the water level variation within permissible operating limits, a long gauge glass should be supplied and water level controls adjusted to carry a low level at low loads and a high level at high loads. A three-element feedwater regulator can easily be so adjusted.

If fast load fluctuations are to be properly handled, firing equipment must have rapid response characteristics. On this unit the air-swept ball-bearing type pulverizers, which respond very rapidly, are supplemented by remote operation of lighters, burners, and coal valves so that, if necessary, additional burners can be quickly put into service. Firing and draughting equipment must be generously sized so that the extra heat

Co-operative Research in the British Electrical Industry

J. Miedzinski

Development Engineer, Department of National Defence, Navy, Ottawa

Read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada, Montreal, May, 1956

Co-operative research in Great Britain is carried out through several organizations, but specialized research associations are responsible for most of the work. There are forty such associations, half of them with over thirty years' experience. They are maintained by industry, with the help of Government grants. The electrical industry reorganized its earlier research committees into the form of the British Electrical and Allied Industries Research Association (E.R.A.) in 1920. The E.R.A. research program is arranged to avoid projects which could be carried out economically by the private research of her members. It is therefore mainly concerned with initial examination of new concepts on the one hand, with marginal improvements of established techniques on the other, and with testing, standardization, co-ordination of effort, etc. Examples given in the paper illustrate E.R.A.'s work on the characteristics of cables and overhead lines, study and abatement of radio interference (including a fundamental investigation of electro-magnetic shielding), and the development and operation of a large analogue computer (network analyser).

THE GROWTH OF the co-operative research movement within British industry dates from the 1914-1918 war when the need for applied research became apparent. Few industrial firms were large enough to run an effective research department and the Universities were fully occupied with fundamental research. It was recognized that much of the applied research was of interest to many firms in the same industry and so research committees were formed to ensure that the scarce research facilities were not wasted by duplication of efforts. The Government decided to stimulate this industrial co-operation by grants so that an industry could set up a research association, under its own control, to deal with common problems. Twenty such associations were formed from 1918 to 1926 and the number is now forty. The industries covered range from purely craft and processing, such as the ceramic, baking, hat and felt making industries, to the highly scientific, such as the shipbuilding, iron and steel, steam turbine manufacturing, and electrical industry.

Those of particular interest to engineers are:

- Cast Iron Research Association
- Coke Research Association
- Iron and Steel Research Association
- Non-Ferrous Metals Research Association
- Steel Castings Research Association
- Coal Utilisation Research Association
- Hydromechanics Research Association
- Internal Combustion Engine Research Association
- Electrical Research Association
- Parsons and Marine Engineering Turbine Research and Development Association
- Motor Industry Research Association
- Production Engineering Research Association
- Shipbuilding Research Association
- Welding Research Association
- Scientific Instrument Research Association
- Coil Spring Federation Research Organisation.

These sixteen associations between them have a present income of some 2.5 million pounds, of which roughly four-fifths is subscribed by the members of the various industries and the remaining one-fifth consists of grant from the Government. The conditions of grant are usually so arranged that, though considerable support is given to a newly-formed research association, there is an incentive to increase the ratio of industrial income to that derived from the Government. The size of the research associations listed above varies greatly. The smallest has an income of about £15,000, the largest £500,000. Each maintains a central co-ordinating committee structure and central laboratories, and each to some extent supports fundamental research in the Universities.

In addition, the engineering industry in Britain has recourse to Government research establishments which, although not directly associated with any particular industry, maintain programs continually kept in step with the trends of development in the industries falling within their scope. Such Government laboratories are —

- Building Research Station
- Fuel Research Station
- Hydraulics Research Station
- Mechanical Engineering Research Laboratory
- National Physical Laboratory
- Radio Research Board
- Road Research Station
- Forest Products Research Laboratories

The British Electrical and Allied Industries Research Association, commonly known as the Electrical Research Association or E.R.A., serves primarily the electrical industry. The latter, by virtue of its very widespread interests, contributes also to many other research associations. Similarly the E.R.A. derives support from many sources which have only a partial, and sometimes minor, direct interest in electrical matters, e.g., the coal and transport industries, paper manufacturers, and oil refineries.

Development and Structure of E.R.A.

The conception of the E.R.A. dates back to 1913 when the Research Committee of the Institution of Electrical Engineers was established to organize research on the heating of buried cables, on mica, porcelain, and insulating oils. It was followed in 1915 by the Research Committee of the British Electrical and Allied Manufacturers Association which studied composite insulants, fibrous materials and ebonite, condenser corrosion and turbines. These two bodies were fused in 1917 as the Electrical Research Committee, the direct predecessor of the E.R.A. The latter was incorporated in 1920, with Government support through the Department of Scientific and Industrial Research under the scheme to which reference has already been made. To the scope of its predecessor was added work on basic principles of invention exemplified at the outset by the circuit-breaker researches.

The broad aim of the E.R.A. is to promote research in the general interest for the progress and development of the electrical and allied industries. The type of research concerned is that for which the industrial reward would not justify individual action and must therefore be pursued collectively, together with that which, in any case, must be applied collectively. Within these limits the particular objects include:

(1) conduct of fundamental and empirical researches leading to better understanding of underlying principles affecting design, manufacture and use;

(2) preparation of surveys of the state of knowledge to assist members in ascertaining useful avenues for new developments;

(3) development of new, improved and cheaper apparatus and materials;

(4) investigation of factors affecting the life, reliability, safety, efficiency and economical utilization of equipment and materials;

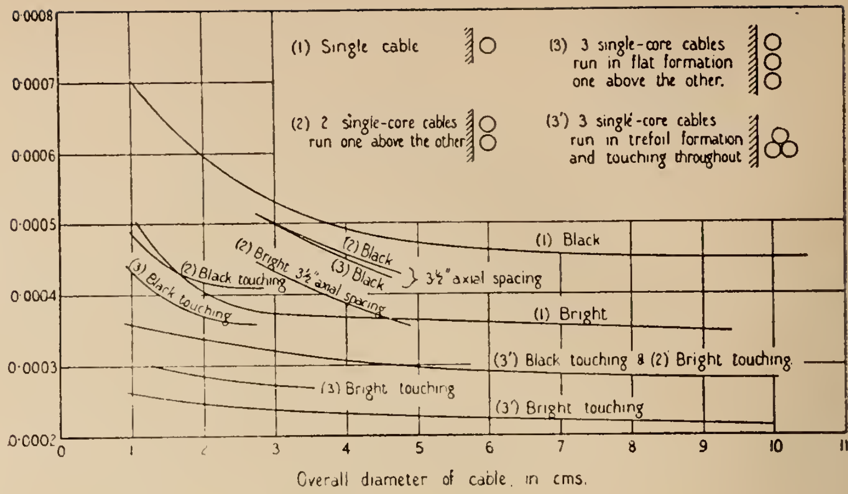

Fig. 1. Curves showing the constant of heat emission h for both black and bright surfaces.

(5) development of methods of testing; and

(6) experimental establishment of common bases of evidence upon which standard specifications, rules and regulations can be formulated.

The membership of the E.R.A. is open to supply undertakings, manufacturers, consultants, and nationalized or other semi-official bodies. It now includes nearly all the British electrical industry, with representatives for the majority of the members of the Commonwealth. Each of the supporting organizations is represented on the council. The council establishes sectional committees, each of which deals with a major field of work. The function of a sectional committee, which consists of eminent persons representative of all the interests concerned in its field, is mainly advisory. It sets up subcommittees of experts who, under its supervision, give more detail consideration to individual research projects. Sub-committee members are chosen from member organizations and firms, or they may be independent experts from Universities, Ministries, Government departments and laboratories or other research associations.

It can be seen that at both administrative and executive levels the organization is such as to ensure truly co-operative effort by assembling together on neutral ground scientific and industrial experts representing all the interests involved.

The co-operative principle extends also to the placing of research programs. The E.R.A. is in close contact through its committees and otherwise with the Universities, with the research departments of its members, and with Government and other research laboratories. Therefore, where it is economical to make use of existing facilities in such laboratories for the conduct of a particular research, this can often be arranged. Indeed, in the early stages of the E.R.A.'s existence the majority of its work was done extra-murally. In 1955, however, only 30 per cent of the total research expenditure was for extra-mural programs.

Nature of E.R.A. Researches

The structure is such that the range of subjects covered is wide. Those fields tend to be excluded in which there is the likelihood of substantial and rapid advances of commercial importance, since these naturally tend to be adequately covered in the laboratories of member firms. Co-operative research has its best application either at an earlier or later stage, as when a conception requires proper examination and basic research before handing over to industry; when marginal improvements in utilization of long established material or processes can be secured either by a short or a continuous programme of research; or when characteristics of commonly used plant or materials require determination.

Some examples in each category may be cited. Over the past few years, co-operative research has sponsored an investigation into the hydrogen-oxygen fuel cell, in which electricity is produced directly from the combination of oxygen and hydrogen. This was taken up when it was, at best, capable of demonstration as a scientific curiosity, on a very small scale. It has been brought to the stage when application on an industrially useful scale can be demonstrated. Commercial evaluation is now in progress but whether or not the matter is pursued, co-operative research will have fulfilled its proper function in providing the information on which such a decision can properly be taken. Similarly co-operative research has, since the war, continuously carried on a program of research on high voltage transmission by direct current, so that British industry has at all times been in a position to proceed, if the economic situation so warranted, with the commercial development of the necessary plant.

The best example in the second category is the study of insulation. This was early recognized as a proper and fruitful subject for study, and major programs have been maintained for over thirty years. Academic physicists working on programs supported by E.R.A. have made important contributions to the theory of dielectrics as, for example, in the classical work of Frohlich, and have also taken a leading part in the discovery of electronic intrinsic breakdown and in much of the work carried out since. A quantitative theory of ionic discharges in insulation, due in considerable measure to the E.R.A., has proved the way to most insulation failures in high voltage equipment. New methods for the detection of, and increasing resistance to, discharges have been developed. The theory of the electro-chemical breakdown of low voltage insulation has been developed and one application, the addition of protective substances, can increase life 20 times under certain conditions. The applied research has led to 12 British Standards, but more important is the influence of both fundamental and applied research on the better selection of materials, the introduction of new and the improvement of early materials.

The third category is exemplified by the E.R.A.'s study of the properties of steam. This may appear a peculiar subject of study for co-operative research in the electrical industry. It is, however, steam plant for the electrical industry which is always in the van as concerns use of the highest possible steam temperatures and pressures. Thus in 1939, because electricity supply required higher temperatures and pressures in turbines, the E.R.A. published the Callendar and Egerton steam tables, up to 1,000 degrees F., and this is still the limit of international agreement. Reliable tables up to 1,300° F. and 6,000 lb./sq. in. are now urgently needed and the E.R.A. has constructed extra-murally a unique plant for the accurate measurement of the properties of steam, in which work has started on investigating higher steam conditions. This work on the properties of steam is accompanied by a study of the properties of steels for pipework.

The researches on switchgear, the first undertaken by the Association in its own laboratories, had quite remarkable results. They were the first sustained and systematic investigation of this kind in the world, and appear to have set the pattern for all such investigations elsewhere. In the late twenties they resulted in the invention and patenting of the air-blast breaker, the baffle breaker, and the differential piston breaker, which were rapidly taken up by industry and constitute the great majority of all high voltage breakers built within the past twenty years.

It is not possible to deal here with all the E.R.A. activities; attention will therefore be confined to a few fields in which achievements have been specially notable, which are thought to be of particular interest to Canada, or with which the author has been directly concerned.

Cables and Overhead Lines

In what are essentially common problems the aim is to secure the best uniform practice. An example is the research on ratings for paper-insulated cables, which initially was inherited from one of the E.R.A.s predecessors. This first involved fixing permissible operating temperatures having regard both to deterioration of insulation and to strains imposed on the cable and its joints by thermo-mechanical forces. These had to be associated with appropriate ambient conditions, and the thermal constants of the cable materials and of the surrounding medium determined to enable the heat dissipation to be calculated.

Experimental work has included determination of: thermal resistivities of cable materials, skin and proximity effects, sheath and armour losses, thermal resistivity of the soil and investigation of the factors which affect it, thermal resistivity of duct material and thermal resistance of

multiway duct structures with varying degrees of occupation, overall dissipation constants for typical configuration, and modes of installation of cable circuits in air. The latter are illustrated in Fig. 1. These have enabled ratings to be computed for known conditions, but in many cases check tests were made.

The conductor and ambient temperatures adopted in the first comprehensive rating tables published in 1941 together with revised values recently agreed for the current edition [1] are given in Table I. The soil resistivity [2] for which ratings for cables laid direct and in ducts were tabulated in 1941 was 120° C. cm./W; in 1955 tables were included for both 90 and 120° C. cm./W.

The first standard ratings issued were estimated to save the supply industry many millions of pounds by improving the utilization of cable systems in existence at the time and by reducing expenditure on subsequent extensions. The later relaxations for modern cables have permitted increased ratings, shown for typical cases in Table II and these, together with full use of cyclic rating factors which can now be computed for practical load curves [3] will result in further substantial economies.

In addition to the work on continuous and cyclic ratings extensive investigations have been carried out on the effects of short circuits on cables. [4]

Similar work has been done in connection with installations for buildings. Ratings and corresponding voltage drop data for cables with paper, rubber or plastic insulation, and bare copper busbar systems for all the common modes of installation have been determined and incorporated in the I.E.E. wiring regulations. [5]

As regards bare overhead line conductors no generally accepted limit for operating temperatures has been agreed. Ratings have, however, been determined for a range of temperatures up to those at which long term annealing of the materials concerned is likely to occur. Data on forced convection related to conductors of the size and type considered were lacking for weak cross winds, up to 1 mile per hour, which are likely to occur on even a calm day. Laboratory tests to establish the effect of such winds were made and typical results are given in Fig. 2. The investigation has been fully reported [6] and the ratings incorporated in a book [7] which also deals comprehensively with the theoretical considerations that decide the electrical characteristics of overhead power lines and the practical estimation and application of those characteristics. In this book the practical data are presented as tables and alignment charts from which the main electrical characteristics of a line can be easily and quickly obtained with sufficient accuracy for transmission engineering purposes.

Radio Interference

In 1930 an *ad hoc* conference of interested international organizations took place in Paris to decide how the subject of radio interference should be dealt with internationally. Arising from this the C.I.S.P.R. (Comité International Spécial des Perturbations Radioélectriques) was formed under the aegis of the I.E.C. and the U.I.R. and its first meeting was held in 1934. In the U.K. a committee of the Institution of Electrical Engineers met in 1933 to discuss radio interference from the national viewpoint. The E.R.A. may be said to have been aotively associated with the problem from that date. In co-operation with the G.P.O., the B.B.C., and the electrical and radio manufacturers, definitions were sought for the tolerable degree of interference, the standard of transmission and also of receiver to be protected, and for the means of measuring and assessing the interfering signals. In addition, examination was made of the various methods available for the correction of interfering appliances and installations, and how these methods could be used, bearing in mind the need for compliance with the codes of safety and good engineering practice of the Home Office, Ministry of Transport, Institution of Electrical Engineers, Lloyds, and other bodies.

Considerable advances were made during the pre-war years and the state of the art by 1938 is admirably summarized in the paper by A. J. Gill and S. Whitehead which was read before the wireless section of the Institution in April of that year.

By 1939 a number of British Standards had been prepared, notably those dealing with the characteristics of measuring equipment; the permissible limits of radio interference from appliances (broadcast bands), motor vehicles (television band I), and trolley buses (broadcast band); the quality of components to be used for suppression purposes. A number of standards were also in course of preparation, including one related to the anti-interference characteristics of broadcast receiving installations and one concerned with industrial and medical radio frequency equipment.

During the war years full use was made of the Association's knowledge and experience by the Ministry of Supply and the Admiralty. The high standard of communications achieved by the land and coastal forces may be said to be due largely to the E.R.A. work on the suppression of radio interference in armoured fighting vehicles and coastal assault craft.

After the war the general work on radio interference was resumed. With increased interest in services at the higher frequencies the pre-war standards became out-dated and most have now been completely revised. In addition new standards and codes of practice have been produced and in all to date some seven standards and four codes of practice have been issued, based largely on

Table II. Comparative Ratings for Paper-Insulated Cables, 1941-1955

*Voltage and Type	Size	Laid direct 1941	Laid direct 1955	In ducts 1941	In ducts 1955	In air 1941	In air 1955
1.1 kv.

° 1941 ratings are for cables up to 1 kv. and for 3 kv.

Note:

1. Three single-core cables are laid in trefoil with servings touching when direct in ground or in air, or drawn singly into trefoil ducts.
2. Ratings laid direct and in ducts assume a soil of 120°C. cm/W thermal resistivity.

the work of the Association. Further, the Association in the person of the director, has assisted on the advisory committees set up by the I.E.E. for the purpose of advising the Postmaster General on legislation in respect of interference caused by the ignition systems of internal combustion engines, by refrigerators, and by small electric motors.

In the international field the E.R.A. has been closely connected with the work of the C.I.S.P.R. since its inception, the director having been for several years chairman of the committee. In this sphere agreement may now be said to have been reached on the methods of measurements to be used up to 25 Mc./s. or 30 Mc./s. and the ground work for measurement at higher frequencies well prepared. Some measure of agreement has also been obtained as to what may be regarded as a tolerable limit for radio interference in the broadcast bands.

From the wide range of subjects studied it is difficult to select representative examples. One which may be of particular interest is concerned with measuring equipment. The measuring equipment used in the U.K. and on the Continent differs significantly from that used on this side of the Atlantic. Though basically a quasi-crest type of valve voltmeter is used at the output of a constant bandwidth receiver, as in North America, the general conception of the function of measuring equipment in Europe differs from that in America and Canada.

All who have had experience in the measurement of radio interference are aware of the great variety of signal which must be measured and the large and rapid variations which take place in the amplitude of any one type of interference. For these reasons the quasi-crest type of meter found universal adoption. In Canada and the U.S.A. the variability of the signals to be measured was offset by the wide-range compressed scale of the logarithmic type obtained on the meter by A.G.C. circuits, associated with the main time constant circuits of the meter, and covering a range of 50-60 db. This however, inevitably results in a non-linear behaviour of the receiver and considerable difficulties arise where certain kinds of signal are being measured. In particular, slowly repeated impulses cannot be measured adequately on this type of receiver since overloading of one or more stages of the receiver

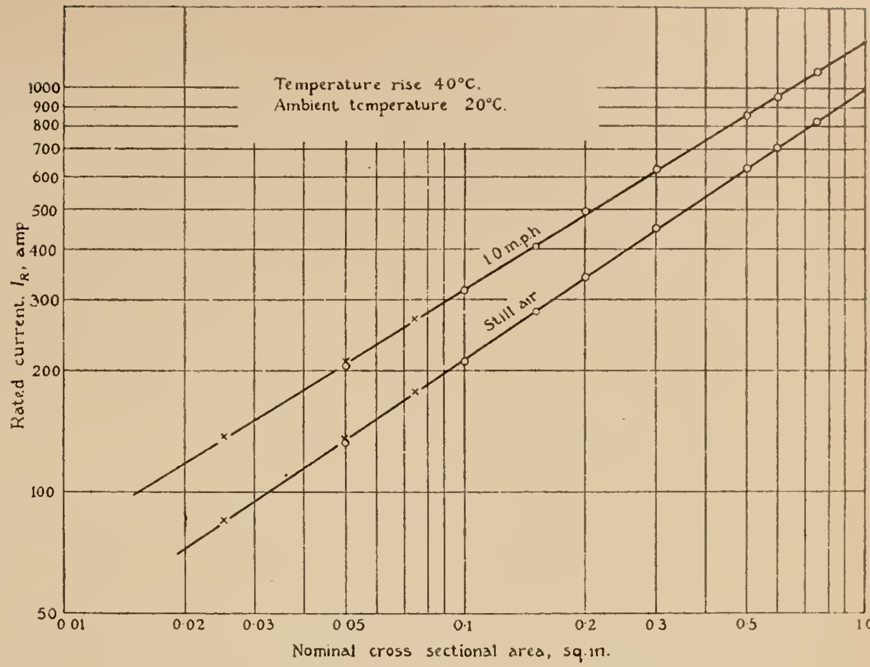

Fig. 2. Variation of current carrying capacity with area. For bright copper conductors. (Shielded from sun.)

occurs for almost any readable indication on the meter scale.

In Europe, on the other hand, small range instrument scales are used, of about 10 db. range and even, in some cases, only a single reference deflection. At the same time the gain of the receiver, the sensitivity of its metering circuits and the signal handling capacity of its output stages are so proportioned that a sufficient overload factor is obtained to allow of a single valued assessment of a single impulse to be made. No A.G.C. is used and the gain of the receiver is only adjusted manually by means of close ratio attenuators or continuously variable attenuators.

It is interesting to note that despite the above differences, measurements made with either equipment of the interference generated by possibly the most prevalent cause — the small electric motor — will as often as not differ by no more than repeated measurements made with either equipment or, say, measurements made with two equipments of the same type.

Electromagnetic Shielding *

Reference might also be made to work on interference caused by industrial and medical radio frequency equipment. In this field, the major effort was directed towards the design of satisfactory shielding enclosures. The subject of shielding offers a particularly suitable field for the application of co-operative research. This is so because the manufacturing of a shielded enclosure is a simple process, whereas highly advanced technical and experimental studies involving the use of complicated test equipment are required to evolve the most economical designs, simple but adequate methods of testing, and sound ways of installation and utilization. The economic factor is of great importance since the cost of a large shielded enclosure can vary from a few hundred to many thousand dollars depending on the method of construction and the materials employed. The primary purpose of the E.R.A. work on shielding was therefore to investigate the performance (i.e. the frequency dependence of insertion loss) of simple enclosures made of least expensive materials, to determine under what condition they may be as satisfactory as the more costly structures. This meant that the investigation was concerned mainly with single-skin enclosures, made of openwork materials like wire mesh, expanded sheet metal, etc.

A relatively simple fundamental analysis [8] can show that two distinct phenomena can give rise to shielding; namely, reflection and absorption of the field energy. Attenuation by absorption in a conducting shield is easily calculable since, in

* Shielding is referred to as screening in British publications.

most practical cases, it depends only on the thickness of the shielding material, measured in terms of the wavelength in that material. Unfortunately, absorption loss in openwork materials is normally negligibly small, so that they can only attenuate by reflection, which is a much more complicated phenomenon. For example, it would not be prudent to calculate the reflection loss of an enclosure without a prior experimental verification of theoretical deductions regarding its dependence — or otherwise — on the following factors:

(1) size and shape of enclosure;

(2) size, shape and position of internal equipment;

(3) earthing and other connections to the shielding material both inside and outside the enclosure;

(4) field component being measured (electric or magnetic), its uniformity and direction of polarization;

(5) direction of measurement (i.e. polar diagram of enclosure) and distance from external source or receiver;

(6) direction of power flow through the shield (inward or outward);

(7) directional properties of shielding material;

(8) quality of bonding;

The above list indicates the extent of investigation required before the results of measurements made with various shielding materials and types of construction can lead to a reliable estimate of their relative efficacy.

The E.R.A. investigation of attenuation by reflection covered the frequency range 0.2 - 150 Mc/s. and included a variety of shielding materials tested under strictly controlled conditions. The results of this investigation and of the simultaneous theoretical study and survey of literature have been presented in a number of research reports issued to members of E.R.A. Some salient points from these results are:

(1) Shielded enclosures of simple design, using openwork materials, can easily be made with bonding so good that the insertion loss is determined by the parameters of the material itself and not by the contact impedance.

(2) The frequency characteristic of insertion loss is then calculable for reasonably simple shapes of enclosure, even if the geometry of the shielding material itself is involved (e.g., the diamond-shaped mesh of expanded sheet metal).

(3) The calculation must be made separately for electric and for magnetic waves. It is quite simple for enclosures small compared to the wavelength, and can be extended even to the region in which cavity resonance effects are present.

(4) There are several types of resonance and some resonant frequencies are critically dependent on internal loading and/or external connections to the enclosure.

(5) Calculation of insertion loss makes it possible to choose the most economical shielding material and form of construction (e.g., single or double skin) which will satisfy a given specificaton.

(6) The insertion loss of enclosures small compared to the wavelength can be found from graphs of the inherent properties of shielding materials. These are now available in the form of frequency characteristics for a wide range of practical materials.

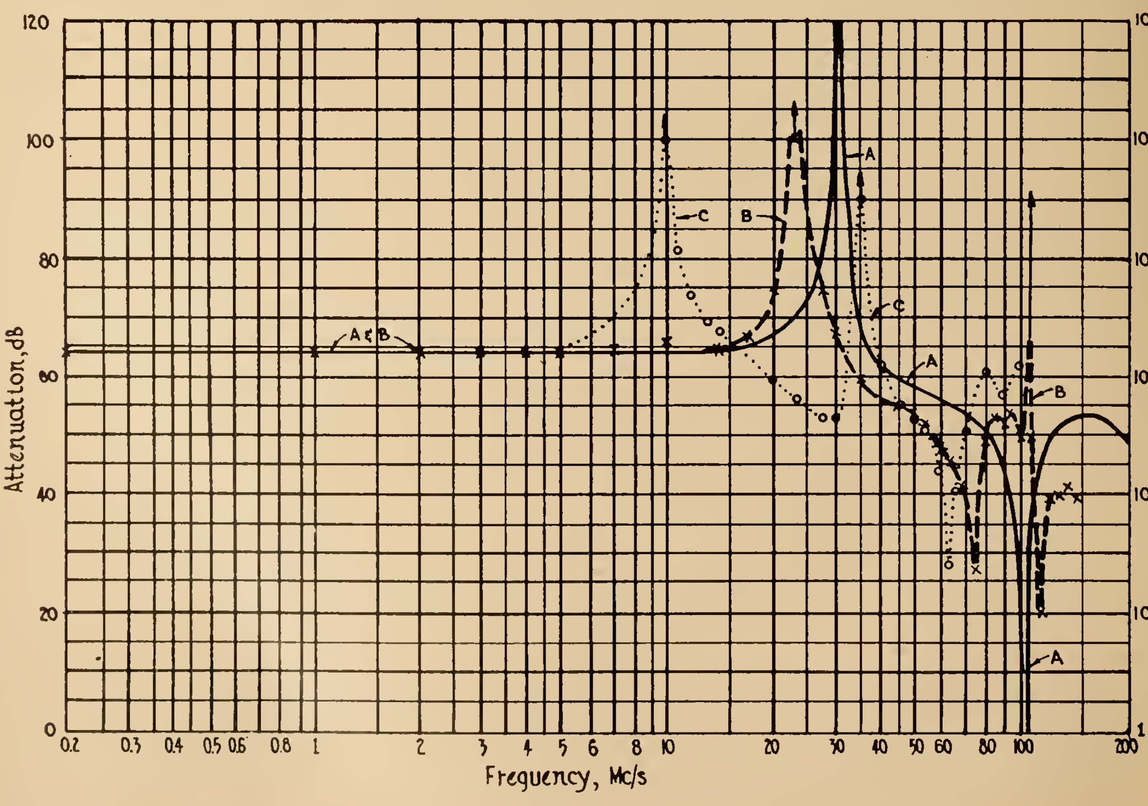
(7) A simple correlation has been established between the properties of shielding materials determined by laboratory measurements on small samples in a test jig, and the performance of complete enclosures, operated under specified conditions.

(8) The method of analvsis developed in the above investigation is also applicable to multi-skin shielding structures.

Performance of a Practical Enclosure

As an illustration of the above, calculated and measured values of elec-

Fig. 3. High frequency resonance effects in electric mode. A, theoretical curve for isolated, empty encl.; B and C, exp. results.



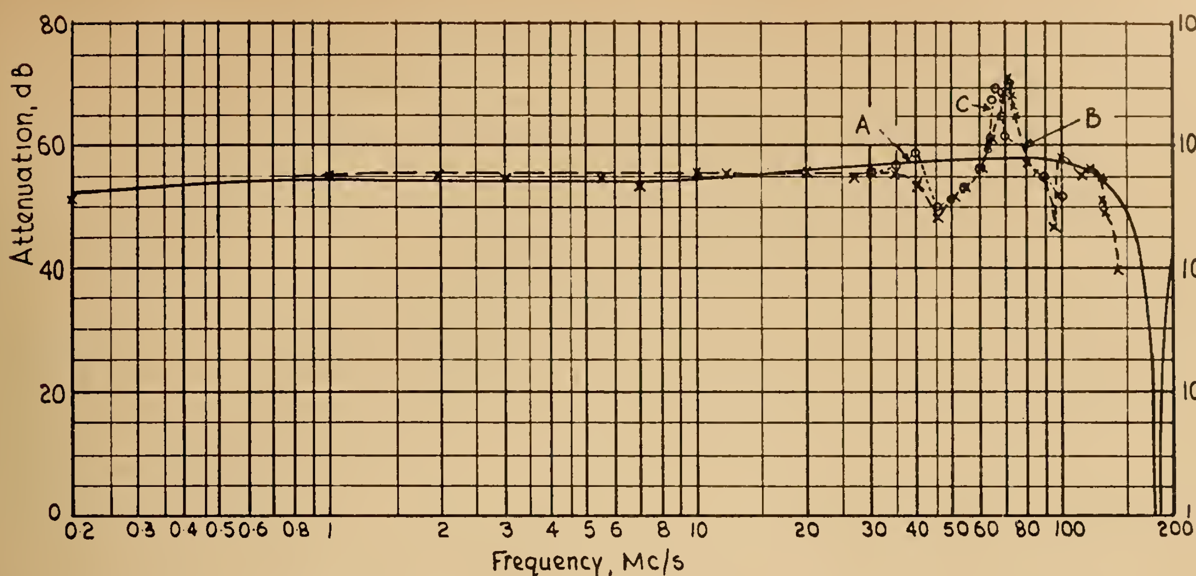


Fig. 4. High frequency resonance effects in magnetic mode. A, theoretical curve for isolated, empty encl.; B and C, exp. results.

tric and magnetic insertion loss are shown in Fig. 3 and 4, curves A and B. These were obtained for a typical small enclosure, of about 6 ft. cube, made of a fairly coarse copper wire mesh (0.04 in. diameter, 0.25 in. spacing). Agreement of theory with experiment is seen to be very good, with a few notable exceptions. These are not due to any shortcomings of the general theory but result from certain deliberate oversimplifications, made to indicate the magnitudes of possible errors. The calculation refers to the inherent properties of the enclosure when empty and isolated, while the experimental results show to what extent these are modified under practical operating conditions. The minimum of electric attenuation at 74 Mc/s. is due to the foreshortened transission line resonance, introduced by the presence of test equipment inside the enclosure. The maximum of electric attenuation at 109 Mc/s. is due to the impedance reflected by the shield into the internal aerial. The maximum of magnetic attenuation at 72 Mc/s. results from a coupling between electric and magnetic modes of oscillation.

The extent to which the insertion loss may be affected by the connection of ungrounded conductors to the shield is indicated by the results of curves C. The only difference in the test condition for curves B and C was that in the latter case the internal receiver and an external steel frame (mechanically supporting the enclosure) were electrically connected to the centre of the shield floor. The observed effect, due mostly to the external connection, is startlingly large in the electric case. The frequency of the first maximum* is altered by 13 Mc/s. from 23 Mc/s. to 10 Mc/s. and a new sharp maximum appears in the response. The attenuation of the magnetic field is little altered by connections not creating new closed circuits, as would be expected.

The above examples indicate the importance of interaction occurring at certain frequencies between a shield and the enclosed equipment. This aspect of shielding received relatively little consideration in practical literature on the subject and in published designs. It should be remembered that a shielded enclosure might provide infinite insertion loss and yet be useless instead of being perfect if, at the same time, it seriously affected the performance of the equipment which it was supposed to protect. This has a bearing on the methods of testing shielded enclosures, a subject which received special attention in the E.R.A. investigation.

Network Analysis

A computer is one of the more important tools in modern research and development work. Small specialized computers can be obtained or constructed at a moderate cost and can be operated by any engineer, but there is also a growing demand for a more exact, more extensive or faster analysis of performance of more and more complex systems. This demand can be satisfied by the use of a large, versatile computer, operated by an equally versatile team of engineers. Here again a co-operative effort is indicated as a good way of supporting a computing centre. This was recognized by the members of the E.R.A. who requested and supported a research and development effort to construct and operate an analogue computer of exceptional versatility. The equipment is of the network analyser type in which electric networks are studied by direct modelling of their electrical parameters, while other systems are represented by means of their electric analogue networks. It is interesting to note that active supporters of the project include members who themselves already operate network analysers on a commercial basis. Far from fearing competition, they expect to gain by being able to pass on to the E.R.A. certain problems requiring special treatment, while utilizing their own equipment more economically on problems suitable for solution by means of routine procedures.

Versatility in a network analyser ([9]) means that the equipment must be applicable to all three fundamental types of network problems, namely:

(i) steady-state, fixed frequency studies;
(ii) frequency response, i.e. steady state, variable frequency studies;
(iii) transient response, i.e. multi-frequency studies.

In addition, the number, range and accuracy of network elements, the accuracy of the measuring system and the flexibility of interconnections should cover the requirements of a large variety of problems.

* This maximum is due to a phenomenon not previously described, named "surface resonance" by the author.

Network analysers are used most frequently on problems arising in the electrical supply industry. There the research problems requiring greater versatility than is usually available in commercial analysers originate mainly in connection with the design of systems and the diagnosis of faults.

Design problems often require diverse studies to be made on a single proposed or existing system. For instance, in a power system it may be desirable to study any or all of the following: load flow, voltage regulation, fault currents and voltages, restriking voltage characteristics, generation and propagation of harmonics, and transmission of surges. Clearly there must be great advantages in having all such studies made by a single team, operating a single equipment, particularly as the results of any one study may necessitate the repetition of some others in altered system conditions. Furthermore, the availability of a versatile equipment encourages full investigations which might otherwise be so reduced in scope that some important details are overlooked.

The advantages of a versatile analyser in applied research show themselves most strikingly in problems involving the diagnosis of a fault on a power system. It is not unusual for several phenomena to be associated with the occurrence of a fault and it may be important to find which of them initiated the sequence of events. In such a problem it is often the combination of results from diverse studies which, when directly available to a single operating team, give the inspiration for the most profitable course of further investigation.

Resources made available by cooperation permitted the development and construction of equipment having the required versatility, in spite of its fairly high cost. The general view of the equipment is shown in Fig. 6. One quarter of the passive elements (one plugboard and two wings of racks) and the steady state control desk have been operational since March 1954. Equipment for transient response studies is also operating and further network elements are steadily being added.

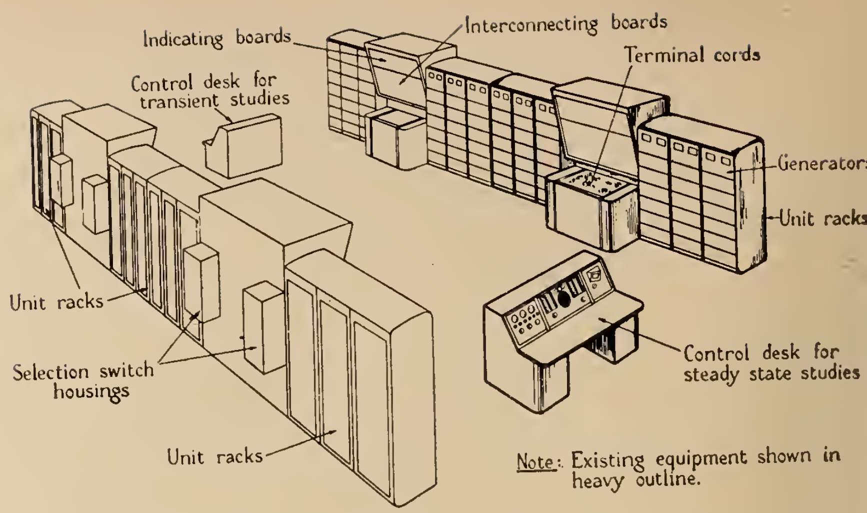

Fig. 5. E.R.A. network analyser. Layout of complete equipment.

A fairly detailed technical description of the analyser has already been published. (10, 11). The only features to be discussed now will therefore be those specifically aimed at overcoming some limitations of the more conventional designs. The main limitations in question are: narrow bandwidth, low accuracy of measurement, low purity of network elements and high cost of providing a sufficiently large number of elements.

Main design parameters

Normal operating frequency	1592 c/s ($\omega = 10^4$)
Frequency range	159 c/s to 15.9 kc/s
Base impedance	100 ohms
Base inductance	10 millihenrys.
Base capacitance	1 microfarad
Base voltage	500 millivolts
Base current	5 milliamperes
Base power	2.5 milliwatts

Each base quantity is numerically represented by 100 units. At normal (i.e. mid-band) frequency, 100 units of capacitance and inductance have 100 units of impedance. The number of network elements of various types and their details are given in Table III. A number of mutual-conductance and non-linear elements not listed in the table, are also available.

The base values of R, L, and C are sufficiently high to make the effect of strays introduced by interconnections very small at the normal frequency, e.g. a stray shunt capaci-

Table III. Details of Network Elements

Type of Unit	Resistance R Max.	Resistance R Steps	Reactance X Max.	Reactance X Steps	Susceptance B Max.	Susceptance B Steps	Connections	Number Available Final	Number Available Present
High impedance (load)	10100	10	1900	5	..	..	Series & Parallel	60	33

Low impedance (line)	110	0.1	110	¼	..	..	Series	126	36
Low susceptance	..	..	..	..	109	¼	..	72	30
High susceptance			..	..	1000	100	..	48	12
π Network	110	0.1	110	¼	2 x 109	¼	π	48	12
Steady state generators			E = 0 – 400%					18	6
Autotransformers, coarse (system transformers)			100% ± 30% in steps of 0.5%					18	8
Autotransformers, fine (load adjusters)			100% ± 10% in steps of 0.2%					64	2
Mutual Transformers			Ratio 1 : 1					12	2
Mutual Transformers			Ratio 2 : 1 or V3 : 1					8	1
Amplifiers and Buffers			Gain 10 : 1 or 1 : 1					12	6

Note: — 48 autotransformers, 24 high impedance units and 24 medium impedance units will be combined into 48 load units provided with individual voltmeters.

Generators and autotransformer units incorporate two-decade reactances.

tance as high as 1000$\mu\mu$F. represents only 0.1 unit, i.e. 0.1 per cent of the base value of capacitance and reactance. Also, a relatively high mid-band frequency facilitates the attainment of reasonably high Q (about 100) in inductive elements. These factors together result in a useful frequency range of 100:1 and a bandwidth of nearly 16 kc/s. for the passive elements. The exceptionally low power level permits the use of small dust-cored inductors, and of miniature vacuum tubes, without loss of linearity. Thus standard small telecommunication components are used throughout the equipment, their low cost and bulk making the provision of a large number of elements an economical proposition.

The use of the low power level was made possible by the development of a suitable measuring system. Fig. 6 shows the control desk for steady state studies, fixed or variable frequency. This desk permits remote selection of measuring points, and displays simultaneously the following quantities:

(i) Complex current I (amplitude and phase) in a selected network element
(ii) complex voltage V (amplitude and phase) between any two selected nodes
(iii) direct phase difference ϕ between V and I
(iv) product $P = VI \cos \phi$ (watts)
(v) product $Q = VI \sin \phi$ (vars)

These quantities, measured by servo-operated a.c. potentiometers, are displayed on dials having a scale length of 50 cm. The design of these potentiometers, one of which can resolve a symmetric voltage of 0.1 microvolt in the presence of an asymmetric voltage of 2 volts (at the same frequency) over 100:1 frequency range, might be of general interest to servo-system designers.

In spite of the low operating levels, the main measuring system has a resolution of 0.1 unit, V and I, i.e. 0.1 per cent for magnitudes around the base value of 100 units. The phase resolution is 0.1° for amplitude levels greater than 10 units. The overall accuracy of measurement depends on the mutual effect of a number of variables, but is normally better than 1 unit and 1 degree at normal frequency, or 2 units and 2 degrees at extreme frequency limits.

Frequency response and transient response studies

The steady state test frequency can be varied over the whole range of 0.1 to 10 times the normal frequency. It is selected by setting of the synchronizing oscillator which determines both the frequency of the energizing units and the frequency to which the measuring system responds. When this frequency is varied slowly, the servo system automatically indicates the corresponding variation of V, I, ϕ, etc., at the selected points, i.e. it indicates the frequency response if the input is kept constant. This facility, inherent in many computers, but unusual in a network analyser, not only extends greatly the usefulness of the analyser for power system studies but is also expected to open new applications for this type of communication and control engineering.

By virtue of its wide bandwidth, the passive system of the analyser can also be used for transient response studies with a suitable energizing and display equipment. Transients containing up to the 100th harmonic of the lowest frequency of interest may be observed with a single modelling factor. Direct superposition of the transient on the steady state response is possible. The possibility of correlating the transient response and the frequency response of a given system is particularly instructive.

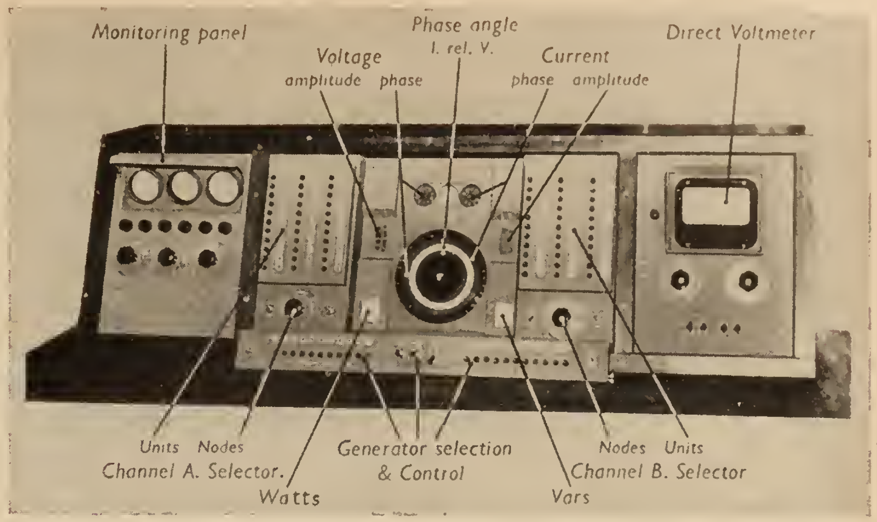

Fig. 6. Control desk for steady state studies.

Example of application

The list of studies made in an actual investigation may serve as a good example of the way in which various facilities provided by the analyser are used to obtain sufficient information about the properties of a system.

Several faults occurred on a system comprising a power station, generating at 20 kilovolt level, grid infeed and a 20 kilovolt cable network. It was required to know if these faults should be attributed to deterioration of insulation, the presence of overvoltages, or the combined effect of both factors. The following studies were found necessary before giving an answer to the question.

(1) Overvoltages and fault currents at system frequency, caused by a solid fault.

(2) Transient voltage at 20 kilovolt busbar on occurrence and clearance of fault.

(3) Frequency response at 20 kilovolt busbars to:

(a) Frequencies generated by fault arc.
(b) Generator harmonics in fault condition.
(c) Generator harmonics in balanced condition.
(d) Triple harmonics generated in an earthing transformer in fault and in balanced condition.
(e) Non-triple harmonics generated in earthing transformer in fault condition.

In conclusion something should be said about the utilization of results. Co-operative research cannot hide its light under a bushel. It is essential that the results should be made available to all the members interested, in such a way that they are clearly understood and can be properly used in industry.

Accordingly an important part of the E.R.A.'s organization is the Information Bureau and Technical Liaison Department. The former which also controls the library facilities deals with the dissemination of existing knowledge including E.R.A. reports of which about 100 a year are now

(Continued on page 40)

Precast Panels as Formwork for a Gravity Dam

J. S. Ellis, JR.E.I.C.
Department of Engineering, University of Cambridge, England

THIS ARTICLE describes the use of precast concrete formwork for the construction of a large gravity dam. The structure, the Cluanie Dam in Scotland (Fig. 1), is the first large project in Britain to use such formwork. The following points will be considered: a description of the panels, their advantages and disadvantages, and sources of information. (Fig. 1, general view, above.)

Description of the Panels

Figures 2 to 4 show the panels and Figure 3 clearly indicates the differences between the three types. The upstream panels are each 4,480 lb. in weight while the downstream ones are somewhat heavier at 7,280 lb., and the contraction joint panels are 3,360 lb.

The sizes of the panels are dictated by: (a) depth of lift—the vertical height of a panel is equal to the depth of a lift of concrete; (b) weight—the capacity of the small mobile crane used for erection limited the size; (c) final adjustment—this was done by hand and it was considered easier to adjust several small panels than one large one.

The panels were cast in moulds assembled on a vibrating table; the moulds were stripped generally after 5 hours and the panels were then cured for 7 days. The panels were inspected before use, and the number of rejections was small and resulted mainly from mishandling during stripping. The peak output was in excess of 500 per week.

In erecting the upstream panels a layer of mortar was placed in groove A (Fig. 2) of the lower panel to form a seal. (Bituminous filler was tried in the early stages but became badly deformed during erection and its use was therefore discontinued.) Then precast concrete cylinders, called joggles, were placed in grooves B. The upper panel was lowered into position so that the grooves G fitted over the joggles and so that the tail C of the upper panel fitted loosely into pocket D of the lower one. Thus the upper panel was located and yet possessed a limited amount of pivotal movement about the upper edge of the front face of the lower panel. Concrete wedges were inserted round the tail and when the panel was set truly the pocket D was filled with grout to make a solid joint. The joints between the panels were then pointed.

During the course of the concreting operations, concrete was rammed down channel E to ensure that no voids were left at the back of the tails.

The procedure for the contraction joint and downstream panels was the same, except that in the latter case precast struts were placed behind the panels to support them at their correct slope (see Fig. 4). A study of Fig. 4 will reveal that the downstream panels had no tails.

Only the upstream and contraction joint panels were reinforced and the reinforcement was placed in the tail and around the top pocket. This

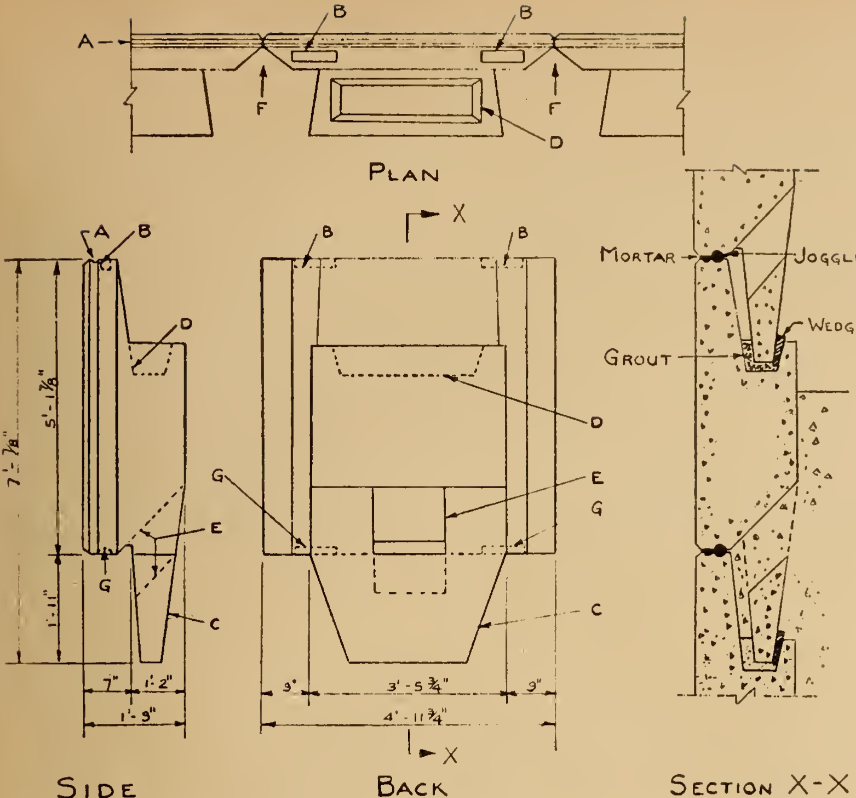

Fig. 2. Diagram of layout of upstream panel

Fig. 3. View along the dam showing panels in position

steel was put in to strengthen the panel against damage due to handling and erection.

Advantages and Disadvantages

The economic factors which favour the use of precast panels are: (a) a project of sufficient size to warrant the expense of setting up a block-casting yard; (b) difficulty in obtaining carpenters; (c) a relatively high price of dressed timber which is used in normal wooden formwork; and (d) a shortage of steel, which is against the use of steel forms.

The panels were erected without the use of external scaffolding; this saved money and promoted safety. As they extended above the upper level of the dam during construction the panels served to protect the workmen.

It was not considered advisable to eliminate the rich mix of concrete on the upstream side of the dam as it was feared that with the panels there would be more potential joints to permit leakage. On the downstream side, however, the rich mix was not used.

There was no evidence to show that the mass concrete shrank upon

setting and induced cracks between the panels and the mass concrete.

The use of these panels was considered by the contractor to be justified economically and it was felt that they would certainly be used again to build another dam in the same conditions.

Sir William Halcrow & Partners, M.M.I.C.E., of London, England, who were the consulting engineers for this project, provided the writer with the information contained in this article. The patent specification for the precast panels is held by the Mitchell Eng. Ltd., of London and by J. W. Moore, of Stamford. The contractors were the Mitchell Construction Co., and the owner is the North of Scotland Hydro-Electric Board.

Acknowledgments

The writer wishes to acknowledge gratefully the generosity of the Athlone Fellowship Committee for financing his visit to the Scottish dams where he saw the use of the precast panels. He is also indebted to C. M. Roberts, M.I.C.E., a partner of Sir William Halcrow & Partners, and the North of Scotland Hydro-Electric Board for their assistance in the preparation of this article.

200,000 kw. Reheat Boiler *(continued from page 14)*

input required for pressure regain after the load pick-up may be supplied while full steam output is being delivered to the turbine.

To protect the turbine from excessive steam temperature fluctuations during severe load swings the boiler must be able to maintain full load steam temperature at fractional loads, and must have sensitive and fast steam-temperature regulating devices. The combination of boiler design, flue gas recirculating to the hoppers, and spray attemperation on both superheater and reheater provide these features for this unit.

In conclusion, we may summarize some of the major considerations which guide boiler design[1]. The fuel to be burned and the approximate size of the unit required fix the general design of a steam generating unit. The specified performance at full load and at partial loads determines the sizes and to some extent the arrangement of the furnace, superheater, reheater, economizer, air heater, and firing equipment. Available building space, indoor or outdoor service, anticipated load cycle, draught loss, provision for soot blowing equipment, and other matters affect the arrangement details.

There has been a very rapid change in the design of units in the last ten years. Operators have been confronted with new problems, increases in the cost of fuel, changes in generating cycles and in the size of units. These requirements have received intensive study, and present-day designs have been developed to meet these changed conditions. A good design today will provide a unit from which reliable, efficient and reasonably trouble-free operation can be confidently expected.

Ore Transfer Facilities at Contrecoeur, Quebec

D. H. Sharp, M.E.I.C.,

Assistant Manager, C. D. Howe Company Limited, Montreal

DURING 1956, iron ore mined at Knob Lake by the Iron Ore Company of Canada Limited was shipped from their port at Seven Islands (described in the January 1955 issue of *The Engineering Journal*) in ships varying in size from 9,000-ton canallers to 45,000-ton ocean-going ore carriers.

The Seven Islands port opened on July 31st, 1954 and before the close of navigation at the end of November, had shipped 1,700,000 long tons. In 1955, 7,500,000 long tons were shipped, and in 1956, 12,000,000 long tons were shipped. The design capacity is 10,000,000 long tons. In 1956, 2,750,000 tons of this ore came up the St. Lawrence on its way to lake ports in the U.S.A. in ships too large to get through the canal system, and the ore was reloaded into smaller ships and railroad cars at the ore transfer facilities built for this purpose at Contrecoeur, Quebec; 2,206,000 tons were loaded into canallers and 460,000 tons into railroad cars, the balance of 84,000 tons remaining in the stock pile over the winter. These facilities are about 25 miles downstream from Montreal, on the south shore.

The sketch above shows the general layout of the dock area with a large vessel and a canaller berthed.

The facilities consist of a dock with capacity for unloading a 28,000-ton ship and loading canallers averaging 2,275 tons at the same time, or of loading two canallers at once if no large ship is berthed; two travelling unloading towers each equipped with a clamshell bucket capable of lifting 12 long tons of iron ore; conveying equipment to transfer from the unloading towers to a canaller loading tower and to railroad cars; and a storage pile area where the unloaders may place ore if no ships are available in which to load it. Provision is made to erect a 150-ton stiff leg derrick at the downstream end of the dock and for the loading of ships with it, should this be required. A small administrative office, machine shop and pump house are the only buildings.

An approach channel 300 feet wide and providing a minimum of 35 feet of water allows large loaded ships to berth. After they are unloaded and their draught reduced, they may turn around in the area between the dock and St. Lawrence river channel. Small ships, such as canallers have great freedom of manoeuvre as they are of very shallow draught and can approach without using the channel.

Unloading starts as soon as lines are made fast — the sequence of emptying holds being set by the ship's crew. The unloader tower operator has good vision into the hold and his rate of unloading is mainly governed by his dexterity. A 35 to 45-second cycle is maintained when unloading from ship to conveyor belt and a 55-second cycle when unloading to the stockpile. Before arrival of vessels, the aprons of the unloaders overhanging the water are raised to clear the ships' superstructures, and this is also necessary during unloading operations, to allow the towers to move past the superstructures to the forward hatches.

The clam shell bucket of 12 long ton capacity dumps into a 150-ton hopper over a 48 in. manganese pan feeder feeding the 36 in. dock conveyor. This conveyor in turn reloads on to an inclined belt feeding into the canaller loading tower. The ore is weighed on the inclined belt by a standard conveyor weigher.

The canaller loading tower consists of a 42 in. retractable horizontal "shuttle" belt conveyor mounted on a moveable frame, motor - driven through a rack and pinion. All conveyors start and stop in sequence and are protected from being fed when not running at full speed by the use of centrifugal switches. The canaller is moved to maintain trim fore and aft as the tower is fixed. The shuttle conveyor may be moved while operating to trim athwart ship.

As the canaller is a small ship, loading with one tower at a time at maximum capacity (1,000 long tons/hour) is fast enough. Therefore, while towers are unloading freely, only one of them feeds the dock conveyor and the other unloads to the stockpile. During cleanup, when unloader capacity is reduced, both may feed the dock conveyor. Average capacity for unloading an ore carrier with properly designed cargo space is 800 tons per hour per rig. As soon as the large ship is unloaded, the stock pile is rehandled back to the dock conveyor. This arrangement is convenient and necessary since so many 2,200-ton canallers are required to equal a 20,000- or 28,000-ton ship, and time must be available through use of a "surge pile" to allow for the arrival and departure of canallers and the moving of them during loading. In this way, unloading of the large ships may take place at maximum speed whatever is happening at the canaller berth.

The dock has three dolphins in line with its face on the downstream end, and one set back towards the shore at right angles with the others. Dredging has provided a turning basin here to receive the stern of a ship leaving the dock. The ship may warp downstream and pivot around the last dolphin with a line to the one ashore to assist the manoeuvre; this enables it to leave the dock heading upstream and at an angle to the current.

Fig. 2. View of the dock conveyor (left) and inclined belt feeding the canaller loading tower (right centre).

Should a ship wish to load at the 150-ton derrick, it may use the dolphins and the dock for mooring. A siding ends at the derrick so that cars, locomotives, and freight may be loaded. The siding connects with the C.N.R. track feeding Sorel from Montreal. A road runs parallel to the railroad siding part of the way, connecting the dock area to No. 3 highway. This road is at the same elevation as the top of the dock and has been run to the upstream end of the dock, so that its embankment will serve as protection against flood water which could otherwise flow behind the stockpile area to the railroad siding.

Water is pumped from the river and filtered and treated to provide the domestic supply for the small staff. A well was considered but the experience gained at a neighbouring property where brackish water and gas were encountered, was not encouraging. A prefabricated building provides office space, stores, and a small machine shop.

The dock is of steel sheet pile construction, the unloading face being 751 ft. 5 in. long, piling being 83 ft. long and driven in clay with bands of sand. A rock blanket and gravel and sand filter are placed against it and the area behind filled with sand brought in from elsewhere. The piling is tied back with one row of tie rods.

Fig. 3. Discharging from loading tower. Empty canaller moored at left.

Dredging of the channel and turning basin was done by a suction dredge with cutting head, the material being clay with some small boulders. This material was piled ashore downstream from the dock as it could not be used for fill. It was possible to walk on it shortly after it had been deposited.

Dolphins were constructed of groups of hollow piles, each made up of 3 steel sheet piles. These were encased in concrete caps 10 ft. thick x 20 ft. x 10 ft. and connected by tie rods, which also served to support wooden walkways connecting the dolphins. There is a bollard on each dolphin. The inshore dolphin is tied back to the downstream wing wall of the dock by cable. The river bottom was such that it appeared advisable to tie the dolphins together and to the dock.

Foundations for the 12-ton unloader rails consist of concrete walls on timber piling with cross wall ties every 25 feet. Foundations for the conveyors are spread footings on the rock fill and the administration and shop building (120 ft. x 40 ft.) is built on a monolithic reinforced concrete slab on fill material which was built up about a foot above the surrounding yard level. The storage area is of sand placed on clay. The 100,000 long ton storage area is permanently floored with a layer of lean ore about 2 feet thick. The elevation of this floor is about 2 feet below the yard level. A concrete wall separates the storage area from the dock area and also supports the steel structure supporting the power supply to the unloaders. Power for the project is received from the utility at 33 kv. and stepped down to 600 volts by means of a 2000 kva. substation. Three single-phase 667 kva., 33 kv., 600-volt transformers are used with a fourth spare transformer installed. Main low-voltage switching equipment and utility metering equipment consists of a switchboard located in a small prefabricated building adjacent to the transformers.

Each of the two unloading towers has two 300 h.p. W.R. bucket motors, a 150 h.p. W.R. trolley motor, two 40 h.p. W.R. propelling motors, a 5 h.p. S.C. rail clamp motor, a 60 h.p. W.R. apron hoist motor. In addition, each tower has an apron feeder powered by a 15 h.p. S.C.T.E.F.C. motor.

Power to both unloading towers is taken over a 3-conductor extruded aluminum system, each conductor being paralleled with a 750 m.c.m. copper booster cable, and the system rated 1500 amperes continuous. Power pickup to each unloading tower is by means of graphite collector shoes rated 1000 amp. for each conductor. In addition, each unloading tower has two control wires taken to it over a cable reel for sequence operation of the apron feeder.

The dock conveyor and inclined conveyor are equipped with 75 h.p. T.E.F.C. S.C. motors and fluid couplings. The dock conveyor is equipped with a thrustor brake so that its long decelerating time will not result in a pile-up of material at the transfer point.

The shuttle belt and shuttle transfer drives are also equipped with totally enclosed S.C. motors. The shuttle belt and apron feeders are equipped with traction type fluid couplings. All conveyors and the apron feeders are interlocked so that they may be started and stopped in correct sequence from the "all start — all stop" pushbutton in the ship loader. Double voltage relaying and centrifugal switch interlocks ensure that material will not pile up in the event of the failure of one drive. Each apron feeder may be stopped independently of the other conveyors from the ship loader.

Each conveyor and the apron feeders can be run independently of all sequencing from the "hand-off —automatic" selector switch near each drive motor. "Emergency stop" switches are placed at strategic locations along the various conveyors.

An 80-foot steel tower serves to accommodate flood lights for night operations. Floodlights on each unloading tower and on the ship loader supplement the tower lights.

The unloader towers are 91 ft. 6 in. high and about 30 ft. wide and are supported on dual 132 lb. rails. The total span of the arms is some 210 feet and the total lateral travel of the clam shell is 180 feet. The bottom chord of the arm is 62 ft. 10 in. above the rail, and vertical clam shell travel is about 90 feet. Bucket hoist speed is 308 feet per minute. Horizontal or trolley speed is 720 feet per minute, maximum.

The clam shell may be turned through 90 deg. by the operator to facilitate unloading from ship's hatches. The towers may be moved along the dock at 75 feet per minute and can approach to within 42 feet of each other. Bumpers are provided in case of collision. Warning horns sound while towers are travelling along the dock.

Communication between the office and tower operator and other personnel is by radio. Loud-speakers are placed at the back and front, in the cab, machinery room, and at the hopper of each unloader, and at the reload point between the dock conveyors and in the canaller loading tower. All conversations are heard over all loud-speakers. A portable radio is used which allows the user to speak over the loud-speaker system, in which case he also hears his reply over the loud-speakers.

All hoisting and traversing machinery is housed in the towers on one floor about 73 feet above top of rail. One and one-eighth inch diameter steel wire rope is used and is bought on a large reel which is supported in the tower so that new rope may be fed off it into the rope system as required; the rope deemed unserviceable is cut off at the clam shell end. This saves replacing all rope when one spot becomes worn.

Fig. 4. Dolphins, spaced 80 ft. apart, at Contrecoeur transhipment area allow large ships to manoeuvre without tugs.

Meeting the shortage of Engineers and Scientists

J. W. Barker, M.E.I.C.

President, The American Society of Mechanical Engineers
Chairman and President, Research Corporation, New York

Address to the ASME-EIC Engineering Education Conference, London, Ont., October 19, 1956

CANADA and the United States are facing a most serious problem which threatens to place limitations on their rapid technological progress. In neither country are we training sufficient numbers of those highly qualified engineers and scientists so essential to meet the demands of government, education, and industry as these institutions expand to service the requirements of our rising standard of living. Nor are we training sufficient numbers of technicians to support and amplify the work of the engineers and scientists.

I want to stress from the very beginning that it is more important for both our countries to emphasize "quality" rather than sheer numbers of engineers and scientists. Although it is true that we require *more* engineers and scientists, it will be the "quality" — the creativeness, the ingenuity, the comprehensiveness of background — which will determine the rate of technological progress.

Our North American continent is in fact an entity, complete in itself even if divided by imaginary boundaries into two political units. It interacts, it is true, with other national entities but nevertheless contains within itself all the ingredients necessary for its growth and success — or for its decline and failure. Nowhere else do we find two nations more closely linked in their economics, more closely linked in their way of life, their thinking and their actions, yet completely independent politically. We are truly an entity.

This is a fact we cannot repeat too often, for it may help to clear up some of the present confusion about our competition with the Soviet Union in the training of scientists and engineers. You have all heard the figures that tell how the Russians are outstripping us in this respect. Those figures are valid and they are significant. I should be the last person in the world to ridicule them. But, I think it is more important for us to look at our engineer shortages in terms of the difference between what we have and what we need, in terms of the "quality" of our educational and professional training. After all, it should be our purpose to solve this problem in terms of our own requirements, and not in terms of a frantic contest to make our statistics look better than those of the communists.

Let us first examine this numerical shortage, therefore, in terms of the only index that amounts to anything —the ratio between the number of engineers available and soon to be available, on the one hand, and, on the other hand, the numbers needed and soon to be required.

Using that index we know that these shortages are now severe and probably will become worse before they can become better. In both our countries, we had a low birth rate in the mid-1930's and we have had a steeply rising curve of births since the mid 1940's. Our present production of qualified engineers can only come from those age groups born in the mid-1930's, yet our industries must expand to service the rapidly growing population due to the higher birth rates of the last ten to twelve years as well as to supply our expanded "standard of living" and our phenomenal technological progress. Added to all this are the production demands to meet our mutual defence needs in the "cold war."

Every advance in technological progress and every demand of mutual defence creates a fantastic increase in the demand for engineers. Every modernization of existing plant, every application of automation, every new product, every new defence weapon, all these increase the demand for engineers and scientists. And the growing school population arising from our increased birth rates creates a simultaneous demand for more qualified teachers of all types but particularly a severe demand for teachers of science and mathematics which can only be supplied from those same age groups of the 1930's which have to supply the industrial and governmental demands. The schools have been and are having very severe problems in securing qualified teachers to train our potential engineers, for their salary scales are much lower than those of industry and the teacher shortage means a reduction in our ability to train more engineers. It is a vicious cycle and can mean trouble for both our countries' continued progress.

So much, for the moment, on the numerical shortage. Let us now consider the quality question. The extremely rapid technological advances of the post war years have resulted from our ability, first, to make new scientific discoveries; second, to visualize or rather to create the means to apply them to practical uses; third, to create the demand for these new products or means of production and.

finally, to seek constantly for means to improve them either in terms of greater usefulness or in terms of lower costs. Increases purely in the numbers of engineers and scientists, though essential, will not keep our technology in the forefront of world progress. Just as the adoption of automation in a production line increases the need for skilled operators and reduces the demand for unskilled workers, so, too, does technological advance increase the need for ever higher qualified and more creative engineers and scientists to pioneer the way to continued technological advances.

The ancient Egyptian civilization, which was a marvel of its age, was built by hundreds of thousands of peasant farmers and slave labourers guided by a handful of rulers and engineers. Our North American standard of living is operated by a working force of some 75 million men and women, of whom only a fifth could possibly be classified as "unskilled workers."

Lee Du Bridge, the president of California Institute of Technology recently said "This great civilization of ours has one terribly important property that we often fail to recognize —it cannot be operated by dopes! The key figure of the future will not be the frustrated automaton, but the educated man with his feet on the desk — thinking!" It is highly probable that some future historian will describe our technology as "a master plan designed by a few geniuses for execution by a great many geniuses."

To revert again to the numerical shortage problem, in the United States the Special Survey Committee of the Engineers Joint Council recently published results from the answers to questionnaires received from 363 industrial and 51 governmental organizations which employed on 1 January, 1956 about 140,000 engineering graduates or about 25 per cent of the U.S. total. From the 140,000 employed on 1 January they expected to lose from all causes, including military draft, 10,800; they expected, or rather *hoped*, to hire from the 1956 graduating classes 11,300 B.S., 1,100 M.S., and 600 Ph.D. graduates, a total of 13,000; while from earlier classes (which can only mean hiring away from somebody else) they expected to hire 9,500. From military leave they expected 2,000 to return to employment, making total *net expected* engineering accessions for the complete year of 1956 to be 14,100 — a net increase of 10.1 per cent. But, in the same survey these same organizations stated their requirements as 14,500 B.S., 1,400 M.S., 964 Ph.D's from current classes and 11,700 from earlier classes or a total *net requirement* of 20,000, leaving a stated shortage of about 6,000 engineers in a 25 per cent sample of all U.S. industrial and governmental engineering employment. Hence, if the same ratios exist in the remaining 75 per cent, then the engineer shortage must be about 24,000. And it must be remembered that educational and scientist shortages are *not* included in such computations.

It was expected that 30,000 B.S. degrees in engineering would be

J. W. Barker, M.E.I.C.

awarded last June but some 6,000 of these were expected to return for graduate study and hence would not be available for full-time employment. With a net of 24,000 available and industry and government *expecting* to hire 45,000 B.S. graduates it is evident that some were seriously disappointed in their recruiting results. Although I have seen no comparably detailed studies in Canada, my Canadian colleagues assure me that your situation is almost exactly the same as ours.

This, then, is a reasonably accurate picture of the present-day numerical shortages based on present production levels.

Returning to the "quality" problem, I want to point out from these survey reports that the reporting organizations were seeking 2,300 advanced degree men in comparison with 14,500 bachelor degree graduates, or 16 per cent advanced degree men. If an advanced degree is an indication of "quality" training, then it must be evident that the reporting industry and government organizations were seeking to improve the quality as well as to increase the numbers of their staffs. I am not going to argue whether advanced degree instruction does *ipso facto* increase the creativeness of the student or whether it simply crams his head with more theories. Neither am I going to argue whether it is always the more qualified B.S. graduate who goes on in the engineering school or university to an advanced degree nor whether the graduate school faculties eliminate the uncreative, less qualified students and carry on to the graduate degree only the truly qualified engineer or scientist. I am prepared to argue that all these facts indicate that we should give great weight to improving the quality of our entire instructional practices.

Will the demand for engineers remain in the near future as high as it is at present? For both Canada and the United States it is reliably reported that gross national product, though it has levelled off somewhat after its sensational rise to over 400 billion dollars per annum for the U.S., will continue for 1957 at least at its present rate. There are almost no economists who are predicting a serious drop in our gross national product during 1957. Whether or not this rate can be maintained indefinitely will depend somewhat on whether or not the cold war remains at its present temperature and whether or not inflationary processes continue. But, every increase in wage rates makes an increase in automation more probable, every new process and every improvement in production practice makes more and more demand for engineers and scientists.

It has been stated that the phenomenal rise in gross national product and the present tendency for this rise to level off above the 400 billion annual rate for the United States mean that even if we have had some engineering shortage, it has not hindered production of goods and services. I have considerable doubt whether such an argument can hold water. Although gross national product is the best, possibly the only index available, it must be remembered that it measures not only the actual quantity of goods and services produced but also the price which those goods and services command on the world market. Any serious monetary inflation must of necessity move the gross national product index higher; even with no increase in the quantity of goods and services produced.

Our American experiences in the depression of the 1930's have demonstrated that companies which shorten sail by reducing research and engineering take longer to recover from the depression than those which increase their research engineering in hard times.

When we put all these factors together it seems most improbable that there will be a material slackening in the demand for engineers for some considerable number of years ahead. Even when we can meet the numerical shortage there will still be a tremendous need for a higher percentage of more highly qualified engineers and scientists.

We have already seen that our educational systems are not producing enough to meet present demands. We have seen the need for improving our educational processes. We have seen that education will require additional competent teachers. We have seen that not until the increased birth rate of the 1940's begins to increase the number of B.S. graduates will we begin to meet the annual demand. We have seen that present and past shortages have left large gaps in the various levels of engineering staffs. We have seen that the teaching requirements to handle the increased school populations resulting from increased birth rate will require large numbers of highly qualified teachers, particularly in science, mathematics and engineering. We have also seen that not only do we require more engineers and scientists but that we seriously need to improve the quality and to seek out and increase the number of highly qualified, creative engineers and scientists.

What Can Be Done

Now what can be done to break this vicious cycle and permit both our countries to maintain and even to increase our technological progress and to make possible a constantly rising standard of living, which I believe can only be achieved by constantly increasing production of goods and services at prices the consumers can afford to pay.

First, I believe we must critically examine and ruthlessly weed out any practices which tend to use our trained engineers and scientists at less than their full scale capacity. We cannot afford to use any engineers or scientists on any tasks which can be performed by trained technicians. We cannot afford to use creative engineers on more or less routine engineering tasks.

Second, we must establish and strengthen programs to provide technicians qualified to undertake the more routine practices under the direction of engineers and scientists. And this relief of our trained engineers and scientists from sheer routine means we must use qualified secretarial help in increasing proportion.

Strengthen Teaching

Third, we must strengthen and actively support the highly qualified teaching of science and mathematics throughout our secondary education. Such instruction is vital for those who will undertake engineering or science as a career but it is also important for all our children who will live in a civilization built by engineers and scientists if the remaining portion of the adult population is to appreciate, to understand, and to utilize the possibilities of technological contributions to an improved standard of living. To me it is heartbreaking to hear reports from one of our great U.S.A. state universities, which for some three years administered achievement tests to all entering freshmen, that nearly 30 per cent failed to pass even fifth grade arithmetic! How can they expect to balance a check book, let alone comprehend what impacts technology is making on our entire civilization? It is truly said that technology must be related to social progress, but it is equally true that social sciences must understand technology.

Fourth, we must improve the social and financial position of our teachers both in secondary and collegiate level education. When you stop to think that the teachers have contact more hours per day with, and hence more influence upon, the children and youth than do the parents or the church, surely those to whom we thus commit the intellectual growth of our youth should be recognized as among the most important citizens in our community. When discussing this problem recently with President Eisenhower, he told me of one of his experiences while president of Columbia University. He had been invited to speak befor a group of well-to-do parents on "the problems of our public schools." He said that he commenced his talk by asking any parents to rise who had entertained in their home during the past year any teacher of their children. Not one stood up! Then he went after them hard on the basis that as long as the teachers were second class citizens, not worthy of being invited to their homes, how did they expect to be able to improve public school instruction. There is a great lesson for all of us to learn out of this story.

Fifth, what about our engineering and science colleges? Here is the apex of our formal educational system for training engineers and scientists. Yet these colleges, whether privately or publicly supported, are having a desperate time retaining sufficient qualified staff against the higher stipends and opportunities offered by industry and government. I know of one U.S. state engineering school department of mechanical engineering which lost 40 staff members last May and which, in spite of increased enrollments and a slightly increased salary scale, has only been able to secure 30 replacements so far this academic year. This is by no means an isolated example. Should such a trend be continued for long we would certainly decrease the quality of education afforded our student engineers when the great essential is to improve quality. Even highly dedicated teachers who remain on college staffs because they love to teach cannot carry excessive teaching loads and still give first class instruction to the coming generation.

Approaching the Problem

However, the topic assigned me for this joint E.I.C.-ASME meeting was "meeting the shortage of engineers." So far I have only sketched out how serious this shortage is, how the demand for engineers is most probably going to continue at least at its present level, how this must now and for the immediate future be met from age groups coming from a low birth rate, how the technological progress is apt to maintain the present demands as a minimum, and how the increasing birth rate since the war has tended to accentuate the shortage problem and prevent its solution in the near future. I have touched upon the necessity for industry and government to reassess uses of engineers and scientists, and the desirability of substituting wherever possible other personnel in any work now being done by engineers and scientists which can possibly be done by others. I have stressed the desirability of improved quality rather

DISCUSSION

of Technical Papers and Other Articles

LATERAL RIGIDITY OF STEEL BUILDING FRAMES

J. L. de Stein, M.E.I.C., and J. O. McCutcheon, M.E.I.C.

The Engineering Journal, 1956, October, p. 1343

Chas. W. Deans, M.E.I.C.[1]

The article dealing with lateral stability and rigidity of steel building frames is verv timelv as presented by Messrs. de Stein and McCutcheon in view of the growing use of lightweight floors and panel type light weight building facings in metal and glass flexibly attached to the building frame.

In the Vancouver area recently the post office building and the Burrard buildings presented interesting problems. Both of these buildings were designed for earthquake and wind forces as well as the dead loads peculiar to each type of structure and their functional uses. The heavy floor and equipment loadings of the post office made earthquake forces of prime importance due to the weights involved and the 8 to 9 storey height. Here the lateral deflections were not a major consideration.

In the case of the Burrard building however, we have a structure with transverse bavs of 25 ft. 6 in. x 18 ft. 0 in. x 25 ft. 6 in. with a height of about 225 ft. in 20 stories. The floor was of a metal ribbed type with thin concrete slab and the outer wall cladding of the glass and aluminium construction, very light indeed. Here we find that wind is a major consideration in the lower stories while earthquake is a design criterion in the upper stories, all as far as stresses are concerned. However, when a deflection calculation is made under the assumption of full wind forces according to the National Building Code, it is found that many column and beam sections have to be increased in stiffness merely to satisfy a certain maximum tolerable deflection in keeping with natural frequency characteristics and actual physical sensation of the human body to repetitive large displacements.

It was felt that the limiting displacements per 11 ft. to 12 ft. 6 in. stories should be limited to about ⅛ in. and 3/16 in. This amounts to approximately 1/800 to 1/1000 of the height. As the Burrard building was on firm sand-clay-gravel this order of displacement ratio was deemed satisfactory. It may be that for other foundation conditions of a more yielding nature the limitation of displacement would be of the order of 1/1500 of the height.

As the authors rightly point out, the designer has to consider many factors in the design of modern building frames in steel. In the taller types it would seem imperative to use the all-welded beam to column connection developing the beam stiffness at the column face or even overdeveloping this stiffness to give additional over-all stiffness to the frame.

The newer concept of applying plastic limit design methods to such tall and lightly loaded building frames with light floors and wall cladding certainly will have to be checked by a proper elastic deflection analysis to ensure that lateral displacements do not exceed those beyond which the human body can tolerate or the occupants can experience without discomfort.

In tall buildings one must also consider the added lateral displacements due to column shortening and lengthening due to a vertical cantilever action of the building frame. The total displacement at each storey is also required to determine the natural frequency of the building frame. I feel that this is an important calculation when comparing frame frequency with natural ground frequency for the different kinds of foundation conditions encountered.

As the authors remark the whole question of permissible lateral displacements and natural frequencies is very complex and much research needs to be done in this field and the information from field measurements at many sites throughout the world should be gathered and distributed to all structural engineers and architects who will have to deal with such design problems.

AN HISTORICAL REVIEW OF THE SEAWAY

The Engineering Journal, 1956, September, p. 1126

General A. G. L. McNaughton, M.E.I.C.[2]

In reading the "Historical Review of the Seaway" I was very interested to observe that the map at the head of the article shows the boundary line as north of Adams Island, leaving the Gut Channel in United States territory. Adams Island is the small island to the north of the west end of Isle aux Galops.

The passage between Adams and Galops is called the Gut Channel and it, together with the Gut Dam, was a subject of very serious controversy during the proceedings of the International Joint Commission on the St. Lawrence Power Applications in 1952. Actually the dispute over the Gut Dam might have prevented the issue of the Order, but in actual fact agreement for its removal provided a last gesture by the Canadian Commissioners which induced two of our United States colleagues to vote with us.

Despite the authority of the Office of Public Works, Toronto, 1856 (who published the map referred to above —Ed.) the boundary in this troublesome region runs down the middle of the Gut Channel and always has done so since the demarcation carried

[2]Chairman, Canadian Section, International Joint Commission.

out by the Commissioners under the Treaty of Ghent and recorded both in the Treaty itself and in their declaration signed at Utica on 18 June, 1822.

I have verified this by looking at the original certified reproductions held by Canada and now in the possession of the Canadian Section of the International Boundary Commission. The Commission has kindly undertaken to provide a reproduction which, because of its interest, I propose to send to you for the Engineering Institute Library.

The Commission also provided me with a copy of the boundary as revised under Article IV of the Treaty of 11 April, 1908, which was adopted by the International Waterways Commission at Buffalo, N.Y., on 15 August 1913. The revision which is the present boundary substitutes straight lines from point to point for the rather complicated lines at a fixed distance, generally 100 yards from the nearest shore, which was adopted by the Treaty of Ghent Commissioners.

This area is now traversed by the Galop Cut for the St. Lawrence power and navigation project and the various islands will be lost by the disposition of the fill. In consequence I thought this information might prove to be of interest to the members of the Institute.

Editorial Note

General McNaughton's interesting comments are greatly appreciated, as is his valued contribution of the two maps to which he refers, and which have been received at Institute headquarters.

RIPPLE ROCK, B.C. (Canadian Developments)

The Engineering Journal, 1956, August, 1037.

F. G. Goodspeed, M.E.I.C.[1]

I was closely connected with the attempt to remove Ripple Rock in 1943-45, and was a member of the Research Council Board which recommended the method being undertaken at present. This method has been given consideration when the work was originally undertaken and was not suggested by a student at the University. Over the years it has been suggested by numerous people.

There is a fear that too much is expected from the 'removal' of Ripple Rock, which of course only entails the removal of that portion of the rock above the 40 foot depth at low tide. The reduction in tidal velocity will be infinitesimal and the whirlpool above the rock will still exist. Small vessels will have the same difficulty in navigating Seymour Narrows as they have at present.

No doubt the current velocity or the whirlpool, rather than the rock itself, have been responsible for a number of the deaths which have been attributed to the rock. These will continue to exist. During the former attempt to remove the pinnacle of the rock nine men were lost when their boat overturned in the swift current.

DESIGN OF FROBISHER'S YUKON PROJECT

The Engineering Journal, 1956, September, p. 1183

Referring to page 1183 of September 1956 issue of the Engineering Journal, and in particular to the continuation on page 1324, we have the following comment:

J. M. Wardle, M.E.I.C.[2]

Page 1324, col. 3, para. 1: article two of the Boundary Waters Treaty of 1909 states that, ". . . each of the High Contracting Parties reserves the exclusive jurisdiction and control over the use and diversion, whether temporary or permanent, of all waters on its own side of the line which in their natural channels would flow across the boundary or into boundary waters . . ."

The treaty further states that "neither of the high contracting parties surrenders any right . . . to object to any . . . diversion of water, the effect of which would be productive of material injury to navigation interests on its side of the boundary." The effect of the latter clause was carefully considered in 1953 before any great expenditure was made on Yukon River investigations.

Meantime commercial navigation on the Yukon, both in Canada and the United States, has come practically to an end; also material injury can be remedied by storage reservoirs on Yukon tributaries. . . the only permission Northwest Power Industries must obtain is from the Dominion Government under the 1955 Act providing for control of structures and improvements on international waters.

Page 1324, col. 3, para 3: Grease Harbour was one of the sites examined in October 1955, but was found unsatisfactory and the site selected is 10 miles up-river from Grease Harbour.

[2]Consulting Engineer, Northwest Power Industries, Ltd.

Meeting the Shortage of Engineers and Scientists

(continued from page 32)

than just increasing the numbers of engineers and scientists.

Yet it is my firm personal conviction that these generalities will not suffice and, further, it is my conviction that each industry and each community will find attacks on these problems to be purely unique to that industry and to that community.

Engineers are by calling and training expert in analyzing problems, locating the essential and critical and basic questions, applying their peculiar knowledge in synthesizing possible solutions, and then finding that one best answer for the particular problem at hand. Yet when it comes to the peculiar problem of finding, stimulating, and educating our successors in our profession we have in general abdicated. We have washed our hands, saying isn't it too bad that our youth cannot or will not see what glorious opportunities lie ahead in engineering and science. We have left to the professional educationist —I don't want to call them "educators" —the preliminary education of our youth and the stimulation to consider engineering or science as a career. We have failed to place the dedicated teacher in a position of high stature within our community. We have taken halting steps to ensure that our engineering school staffs have opportunities to keep fully abreast of the advances in technology and to maintain those staffs in sufficient numbers. We do little to encourage or stimulate our engineering students to improve their creative abilities and to dedicate themselves to higher quality of engineering and science.

Let us stop "crying in our beer" and put our hearts and minds to work on the problems of improving our profession and improving its contributions to the society in which we live.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

NATIONAL RESEARCH COUNCIL HIGH VOLTAGE SYMPOSIUM

A successful high voltage symposium, sponsored by the National Research Council of Canada, was held in Ottawa in September, 1956. Some 19 papers were presented by an international body of authors; the titles are given below.

Although abstracts of all the papers cannot be published here, because space is limited, copies of abstracts may be obtained on application to *The Engineering Journal.* The papers will not be available separately, but the National Research Council is going to publish all of them in one volume, which should be available early in 1957. There will be a small charge for this publication.

(1) Electrical Breakdown in High Vacuum; A. S. Denholm, National Research Laboratories, Ottawa.

(2) The Peculiarities of H. V. Cable Dielectrics; H. D. Short, Canada Wire and Cable Co., Ltd., Toronto.

(3) High Voltage Transformer Insulation Co-ordination; J. R. Meador, General Electric Company Ltd., Pittsfield, Mass.

(4) The Mechanism of the Electrical Breakdown of Triggered Spark Gaps of the Trigatron Type; P. K. Watson, formerly Nat. Res. Laboratories.

(5) A New Approach to the Calculation of the Lightning Performance of Transmission Lines; C. F. Wagner, Westinghouse Electric Corp., East Pittsburgh, Pa.

(6) Economics of Long Distance Power Transmission in Ontario; P. L. Dandeno and H. Teekman, Hydro-Electric Power Commission of Ontario.

(7) Problems of High Voltage Power Transmission; Ivar Herlitz, ASEA, Sweden.

(8) Limitations of A.C. Power Transmission; Ivar Herlitz, ASEA, Sweden.

(9) Characteristics of D.C. Transmission; Uno Lamm, ASEA, Sweden.

(10) High Voltage Measurements and Equipment — Surges on Transmission Lines and Stations; J. W. Skooglund, Westinghouse Electric Corp., East Pittsburgh, Pa.

(11) Impulse Voltage Measurement; F. C. Creed, Nat. Res. Laboratories.

(12) Measuring Steep-Front Impulse Voltages; H. Linck, H.E.P.C. of Ontario.

(13) Testing Insulators with Steep-Front Surges; H. M. Ellis, H.E.P.C. of Ontario.

(14) Impulse Failure Detection Methods in Transformer Testing; W. J. Purvis, Nat. Res. Laboratories.

(15) The Ultra Corona Discharge, A New Discharge Phenomenon Occurring on Thin Wires; C. A. E. Uhlig, Nat. Res. Laboratories.

(16) A.C. Corona Current and Losses on Thin Wires from Onset to Spark-over; C. A. E. Uhlig, Nat. Res. Laboratories.

(17) Factors Influencing the Corona Inception Voltage of Extra High Voltage Transmission Lines; G. K. Lambert, Northern Electric Company, Ltd., Lachine, Que.

(18) Corona Type Noise and Its Measurements; T. W. Liao, General Electric Company Ltd., Pittsfield, Mass.

(19) Radio Noise Testing of High Voltage Line Equipment; A. S. Denholm, Nat. Res. Laboratories.

THE IMPACT OF AUTOMATION ON SOCIETY

T. Burns, Senior Lecturer, Dept. of Social Study, University of Edinburgh.

Inst. Production Engineers Journal, 1956, October

Everybody who discusses automation is aware it is a word for developments as old as industry itself, yet there is an irresistible tendency to make it a crisis point. What are the social pressures making for this dramatization? Possible clues lie in the following:

(1) Occupational status has come to be the chief designation of social status.

(2) Outside the work-place differences in status as being reflected in clothes, activities, possessions, are becoming gilded. The traditional social structure is being overlaid by another structure of elite group and mass audience connected by mass communication industries.

(3) We remain a society dominated by the idea of success. Possibilities of success are being more and more restricted to educational and occupational promotions.

In discussing automation in the factory, what we are talking about are the changes likely to arise, or be needed, from an accelerated expansion of: *(a)* automatic machinery and transfer; *(b)* automatic process, product and quality control; *(c)* computer-controlled machinery; *(d)* rapid processing of information about costs, progress, stores, etc.; of these, the third is the most important.

There are certain changes which may be fairly safely counted on. These are:

(1) A large increase in the functions of programming, production, costing and planning operations.

(2) A considerable change in required skills and a much higher standard of competence.

(3) A considerable movement away from divisions of labour into individual, semi-autonomous jobs and towards interlocking service functions.

(4) A development of plant hiring schemes.

Present discussion about the social consequences of technical change hinges inevitably on technological unemployment. There is probably a considerable fluctuation in the demand of a particular industry or factory for individual skills, a fluctuation which would be wider than that in the total demand for labour. A factory will need a complement of craftsmen who could act as fitters, maintenance men, toolmakers, inspection controllers, at different times of the year.

Two possible consequences of automation, therefore, are a larger population of skills than of work people, and a heightened need for adaptability and mobility of labour.

Summarizing, the possible repercussions on people inside industry are: *(a) a much greater need for information, for people to collect and process it; (b) a need for workers with multiple skills; (c) a need for managers with more and more varied technical qualifications; (d) a need for more elaborate forms of programming; (e) a breakdown of traditional status divisions between management and workers.*

We are in for a period of considerable structural change in the social organization of industry. The system we live in has to be adjusted so that there is less discrepancy between the two. It must involve more fundamental reorganization of the roles of people at work and a recasting of the institutional structure of the workplace.

LET'S TAKE THE WASTE OUT OF STRUCTURAL DESIGN

Civil Engineering, 1956, Aug. 1, p.43.

Like all other professions, engineering can't always be reduced to a formula. The human factor looms large, and nowhere is it more in evidence than in structural design. This year a fortune will be spent in the study of building materials. But in spite of this many engineers will needlessly waste materials by over-designing their structures.

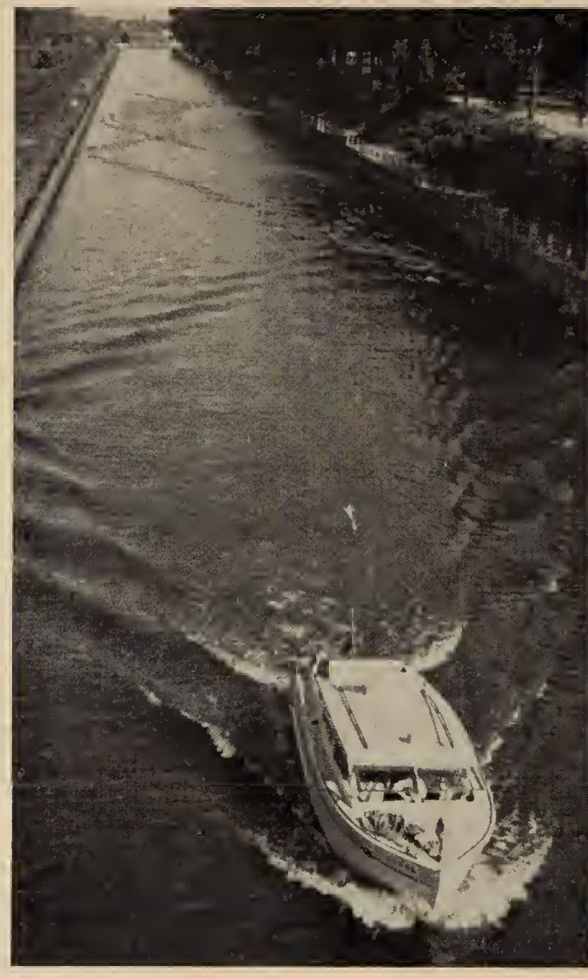
Because of the uncertainties to be found in most designs safety factors between 2.0 and 4.0 are commonly used. Sometimes these high factors are justified. But to overcome this all too-prevalent practice of overdesigning structures, the following suggestions are offered. Engineering societies should undertake two studies:

(1) First an appraisal should be made of existing knowledge. Second, case histories of thousands of existing structures should be studied. Reports of these findings would have a ready cash value among engineers.

(2) Technical and professional periodicals should feature more articles on economic designs.

(3) Engineers should continually endeavour to keep up to date on progress by reading the publications made available to them.

These suggestions, if followed, should lead to economical engineering. Let's take the guesswork out of design, with its resulting waste.



REFLECTED RIPPLES IN THE RIDEAU CANAL

This picture of the Rideau canal at Ottawa, taken from the Laurier Avenue bridge, near Union Station, shows an interesting pattern of ripples reflected by the vertical banks of the canal. The photographer, W. John Fletcher M.E.I.C., is prompted to wonder what factors determine the angle subtended by the two lines of the ripples—perhaps a member familiar with ship design would comment on this. (Taken on 35 mm. film, f8, 1/125 sec.)

ULTRASONIC TECHNIQUES IN INDUSTRIAL CLEANING

Dr. W. McCracken, Director of Research, Detrex Corp.

Inst. Production Engineers Journal, 1956, October

For several years, the use of ultrasonics in the fields of industrial application has been unduly exaggerated; wide areas of research still remain for development of practical and useful ultrasonic processes.

To understand the application of ultrasonics to industrial cleaning it is necessary to review the types of soil usually found on metal. This discussion is limited to soils such as grease and oil or grinding, polishing and drawing compounds and other organic or inorganic substances including finely divided adherent material known as smut.

The electro-strictive method using barium titanate as a transducer is the leading technique at the present time. A RF generator of some 400 kc/s. is required, with capacity varying from ½ kw. to 10 or more kw., pending on the application. For best results and maximum efficiency from ultrasonic energy, the technique must be employed as a tool in conjunction with a well designed cleaning process.

In summary, it can be said that the ultrasonic technique can, and is, being used as a powerful tool in the field of industrial cleaning; that it is best employed as the last stage of a well designed cleaning process; that it is adaptable to the process of solvent degreasing using chlorinated hydrocarbon solvents; that barium titanate transducers are far more adaptable than other types; that ultrasonic technique can, and is, being adapted to production line cleaning; and lastly that the best results are being obtained by ultrasonics in conjunction with solvent degreasing.

BRAKE ON A SATELLITE

Engineering, 1956, November 9

An electrical braking force, the existence of which has been proved by Dr. Bo Lehnert, of the Stockholm Polytechnical Institute, is likely to threaten the experiments with the satellites that are to be sent out into space during the International Geophysical Year 1957-58. The Swedish scientist's findings have led to an extensive correspondence with the American research workers who are planning the satellite programme.

According to the Swedish calculations the satellite will be electrically charged when bombarded by electrons and ions during its passage through the ionosphere. This charge will in itself have a retarding effect on the satellite—to what extent it is not possible to estimate at present—and also give rise to an electrically charged "wake" with unforeseeable effects on the satellite. The cautious wording of Dr. Lehnert's comments on the calculations runs: "Should it prove that the satellite does not behave in the manner foreseen, the electrical charge may offer part of the explanation to the deviation."

From Dr. Lehnert's correspondence with the American scientists it looks as if they had not previously paid attention to this phenomenon. The current research work at the Institution for Electronics of the Stockholm Polytechnical Institute has opened up many aspects related to this problem.

INTERCOMMUNICATION AND THE APPLICATION OF IDEAS

Civil Engineering, 1956, August, 60.

In spite of today's great engineering achievements, many signs indicate the recent past is only the beginning of an even greater engineering age. To support this volume of work with new methods and materials much research and development will be needed. The rate of progress in the arts and sciences of our profession will be a function of two dependent variables: efficiency of dissemination of basic research, and speed with which new useful development will flow from basic research.

Progress in achievement seems often dependent on accidental stumbling on right ideas when needed. Does this slow down our technical advancement, and what can we do about it? The primary purpose of this article is to provoke discussion so as to ascertain the extent of the problem and perhaps to start work towards resolving it.

We should establish a committee served by and answering to all engineering and scientific societies, to act as a central agency, whose functions should be to:

(1) Receive, summarize, and collate all new information.

(2) Distribute these to the proper technical groups.

(3) Maintain a board of experts for critical analysis.

Would the value of such an up-to-date indexed compilation outweigh the costs of such an organization? Can we afford not to do something along these lines?

THE DIDO TECHNIQUE FOR EFFECTIVE COMMUNICATION

Felton Koch, Prudential Insurance Co., Newark.

Advanced Management, 1956, October

All levels of management can be seriously handicapped by poorly transmitted communications, written or oral. Weak and badly interpreted information can bring about bad decisions and adversely affect company policy, administrative procedures and organization morale.

Define: You cannot communicate effectively when either talking or writing unless your words and symbols have established definitions known to you and your listener or reader.

Index: A custom of indexing clarifies and specifies references in communication. Practice indexing to develop the awareness of differences as a better way to understanding.

Date: Omitting time, degree, measurement, date, etc., often cause confusion or misunderstanding about the intention of the speaker or writer.

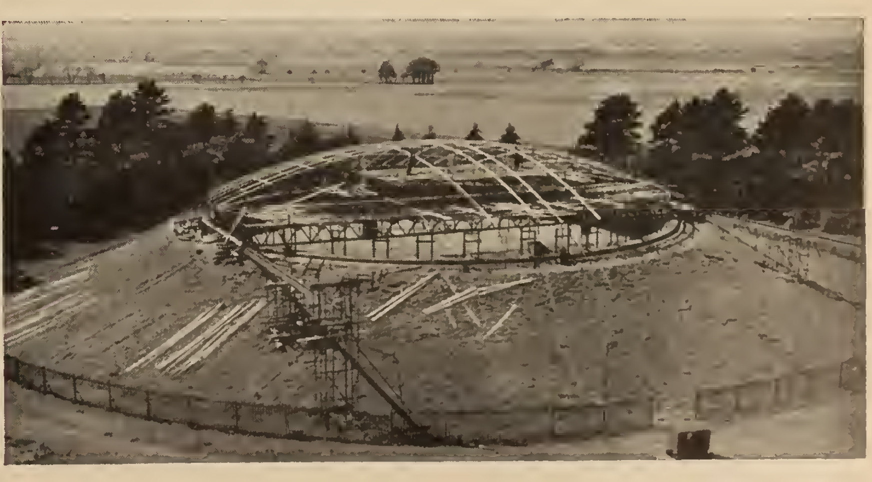
Orient: The purpose of communication consists of your attempt to convey a thought pattern from your mind to the mind of your listener or reader to turn off his mental 'record player' when he should have his 'mental recorder' operating.

If you want to communicate effectively, Define, Index, Date, and Orient your statements to eliminate semantic blockage. This method promotes understanding and agreement. If you use this formula you will create a style for your subordinates to follow, and it will improve the lines of communication in your company.

ROOF CONSTRUCTION FOR CIRCULAR RESERVOIRS

United Kingdom Information Service

New reservoirs for immediate supplies of filtered water for communities are now generally roofed over to prevent pollution by airborne impurities. Traditional roofing methods often use support columns from the reservoir floor, which entails draining during construction and other difficulties such as added risk of contamination. One answer to the problems, for new or old reservoirs, is the use of self-supporting domed aluminum roofs, of which two examples have recently been installed, without draining, in Bedfordshire, England. These are shallow spherical domes consisting of a grid of box-section ribs located on two series of great circles; they are clad with flat 16 S.W.G. aluminum alloy sheet.



RESPONSIBILITIES OF THE ENGINEER EMPLOYER

H. Weirsema, M.ASCE., Assistant Chief Engineer, Tennessee Valley Authority

Civil Engineering, 1956, October

From 13 years of experience in collective bargaining with employees in T.V.A., and from observation of the experience of others, the author has come to certain conclusions:

Professional societies have had little influence on employee relationships, and this little has had small effect on raising the economic status of engineers.

The employer no longer has the personal contact necessary for complete understanding. Because of this lack of personal influence, young engineers in increasing numbers have joined unions with the hope of national benefit — such unions have helped increase the salaries of engineers to raise their economic status.

There is not necessarily any irreconcilable conflict between the professional status of engineers and the efforts of unions to improve their economic status. Whether we like it or not, we are going to see more rather than less unionization of engineers in the coming years. Any amount of persuasion and discouragement of unionization will be ineffective in the future. Instead of worrying about employee unions the employer should be working for better economic status for his employees.

As a result of his experience with younger engineers, the author is certain they will respond to the efforts of their employers to improve their professional status.

SPACE HEATING WITH THE ATOM (USE OF WASTE ENERGY)

S. L. Nelson,

General Electric Review, 1956, November

Getting motive power from the atom claims so much attention that engineers and scientists overlook one important potential; utilizing raw energy as it comes from the atom nucleus in the form of heat.

For ten years Hanford engineers watched tremendous amounts of heat energy literally go down the drain. Because the reactors were built to produce plutonium, heat energy became a troublesome by-product requiring the simplest possible method of disposal. So it was dumped back into the Columbia river after allowing time for decay of radioactivity induced by neutron bombardment of the water molecules passing through the reactor cooling tubes.

The paradox of running hot water into the river while burning coal to heat buildings challenged G.E. engineers. With the T. C. Main Company, of Boston, they pioneered in the design of a space heating system. The main components are: (1) an outdoor central exchanger to extract heat from water after it has passed the reactor; (2) a mixture of ethylene glycol and water, heated in the central heat exchanger; and (3) a distribution system to circulate the ethylene glycol through the radiating coils and exchangers used to heat the plant buildings.

The significance of the atomic furnace lies in its wide potential application and relative simplicity in design. This does not mean that in 10 or 20 years smokeless atomic furnaces will replace combustion furnaces. It does mean the use of atomic energy for heating large hotels, office buildings and other compact areas with large space heating requirements is feasible now. Though not enough work has been done on all the economic aspects of atomic space heating to make any evaluation, the AEC has already laid the groundwork for standardization and control. Details of the design are given.

THE MEASURE OF AIR POWER

Canadian Aviation, 1956, October

A revolution in air arms! That's the measure of achievement by the aircraft industry in the United States during the 1950's.

Some seven years after the first successful jet flights, the bulk of U.S. air power was still built around the piston engine. After World War II production, employment dropped from over a million to about 235,000. With the exception of a few projects, research and development was similarly stymied.

In June 1950, U.S. Air Force combat strength consisted of 47 wings. Equipment was mainly piston driven aircraft. The Navy's situation was comparable. By mid-1957, the Air Force will have reached its goal of 137 wings, all flying the latest production aircraft suited to their role —the vast majority of them jets. Naval air power now consists of 17 similarly well-equipped air groups plus three Marine Air Corps wings.

The next really major task already underway, will be re-equipment of commercial carriers with the latest jet equipment. The end of the crash program has undoubtedly sharpened competition.

Commercial airplane orders on the books of American aircraft manufacturers now stand at an all-time high figure. The horizon of accomplishment continues to widen with each new advance. There is no doubt that aviation's greatest years still lie ahead. Achievements of the American rocket industry over the past decade have been previously unequalled. They will be mild in comparison with what will be accomplished in the next decade.

Canadian Aviation contacted officials of leading American companies for their frank appraisal of conditions in the U.S. aviation industry and an evaluation of the prospects for their individual firms. Some 17 of these interviews are given in condensed form.

GAS LUBRICATED BEARINGS

Engineering, 1956, November 2

Gas lubrication, which has recently undergone considerable development under the stimulus of the atomic energy programme, may well have applications to half a dozen other branches of engineering, and this is borne in mind by the authors of a paper "Principles and Applications of Hydrodynamic-Type Gas Bearings", presented at the Institution of Mechanical Engineers on October 26. The authors, G. W. K. Ford, M.B.E., D. M. Harris, and D. Pantall, are all members of the United Kingdom Atomic Energy Authority. The call for gas bearings arose from the need to install moving parts within enclosed gas circuits where contamination of the gas is undesirable, the parts themselves are largely inaccessible and the formation of oxide films is impossible; this occurs in gas-cooled reactors such as those at Calder Hall. In addition, pumps for liquid metals, which may be at high temperatures, require a lubricant that does not deteriorate under the action of heat and will not contaminate the metals being pumped; bismuth, which may serve as a solvent for nuclear fuels in future reactors, is chosen by the authors as an example. However, high temperatures, gas circuits, inaccessibility, particulate matter in suspension, and the need to exclude contaminating materials are requirements not unique to atomic engineering. To place gas bearings in the context of other applications, the authors outline their features and limitations, and name some other fields of engineering — machine tools and chemical industry for example — in which they may be used. The paper is concerned mainly with hydrodynamic as distinct from hydrostatic bearings and covers both thrust and journal types.

THE RUSSIAN EXAMPLE

The Times Science Review, Winter, 1956

Science is international, but also competitive. It is international by necessity, as well as tradition; it depends for its progress on the exchange of knowledge and ideas, without restriction from language race or culture. The course of exchange between the Soviet Union and the West has been more free during the past year than for a long time. As Professor P. B. Moon, F.R.S. wrote: "From ignorance of Russian work, we are swinging through rivalry to possible cooperation." The ideal of cooperation in research is indeed worthy. But it is the competitive element which, in Britain, needs most to be emphasized. And the competition which matters is not that between one scientist, or one laboratory, and another, but between nations.

Science, for most working scientists, is an end in itself. It is also the foundation on which most material progress is based. The need for scientists and engineers has been realized from the start in the Soviet Union. The pace set was a hot one, and the emphasis was on quantity to begin with. The fact that quality was being achieved also, at least in the physical sciences, has penetrated only slowly to outsiders.

There has been evidence, and to spare, of progress. Much, admittedly, has been imitative — for example, in methods of building dams on alluvial rivers, and in the early development of jet aircraft — but much also has been independent. In one field, that of atomic energy, the preparatory meetings for the Geneva conference of August, 1955 led to the beginnings of reassessment. The process was accelerated and completed at the conference proper. The quality — and independence — of much of the Russian work was perforce recognized. But it was still a

A Guide for Authors

Authors of articles for publication in *The Engineering Journal* should be guided by the following notes.

MANUSCRIPT

Two copies are required, double-spaced, typewritten on one side of 8½ x 11 in. paper, with a wide margin (1½ in.). Author's name, professional affiliation, and a 100-word summary of the paper should be given on a separate sheet.

References

Superior reference figures are used; e.g. . . . Artz[3]

References and bibliography are collected at the end of the paper. The style used is: author, title, publication (abbreviated), volume no., page; e.g.,

[3]Artz, M. Frequency Modulation of RC Oscillators; *Proc. I.E.E.*, 1944, vol. 32, 409.

Mathematical Work

Complex formulae should be hand-printed unless a special typewriter is available. The relative positions and sizes of symbols must be distinguished (e.g., between Eo and EO, E_2 and E^2).

Identify any special symbols (e.g. Greek letters). Keep mathematical work and equations separate from the main text as far as possible — e.g. numbered in a separate appendix.

Abbreviations

The practice followed is that of the Canadian Government Style Manual. Most abbreviations are in lower case with periods (m.p.h., kv., kwh.); singular and plural the same (12 lb., 20 in.).

ILLUSTRATIONS

These notes are a general guide; the editorial staff will be glad to give more detailed advice on preparing illustrations.

Photographs

Glossy prints, preferably 10 x 8 in.; not less than 5 in. on longest dimension.

Diagrams

Black ink on white paper or tracing cloth; not more than 12 x 16 in. Usual *Engineering Journal* size for cuts is 4½ in. or 6¾ in. wide; original lettering must be big enough to appear not less than 1/16 in. high after reduction.

All diagrams, particularly maps and scale drawings, must be simplified to essentials. Graphs must not be drawn on "graph paper", but with the fewest necessary cross-lines (not more than 8 lines per inch after reduction). The weight of the finest line, after reduction, should be not less than a clear typescript letter 1.

Blueprints, coloured diagrams and pictures, and diagrams with solid tints or shading are not accepted for publication.

Legends (captions)

Figures and tables should be identified (Fig. 1, 2, etc.; Table I, II, etc.) and relevant legends listed on a separate sheet.

surprise to most British physicists to learn from Academician I. V. Kurchatov, in July 1956, of the scale and excellence of the research done in Russia on the approach, by one particular method, to the realization of the high temperatures needed to bring about thermonuclear, or fusion, reactions under controlled conditions in a laboratory. The investigation so fully prosecuted must have been done in the main for its own sake; in relation to its primary object, it must have been virtually written off at an early stage.

In the meantime there had been visits by British and American scientists to Moscow. These were not the first; but most of the earlier visitors had been enthusiasts, sometimes uncritical in their reports. Now a more general impression was possible. To travellers' tales and the information that the Soviet Academy of Science employed more than 10,000 scientists of university standard in roughly 100 research institutes, it could be added that laboratories and teaching facilities had been viewed by relevant specialists and that especially in the physical sciences they had come away greatly impressed. That is not to say that all Russian work is good, or even that the average of it is as high as, for example, in Britain. Nor has Russia yet more scientists and engineers than the United States. But the output of trained men is greater, equipment lavish, opportunities for research wide, and the volume of good work substantial and growing.

Among these organized visitors to Russia were delegates to a conference on high-energy nuclear physics, held in Moscow; they visited the Institute of Nuclear Studies at Bolshoya Volga. (The issue contains an illustrated article on this Institute.) The impression is, again, one of size, energy and determination to push ahead. They have built the largest nuclear accelerator of one kind, then of another, and now are planning a third. They are also very ready to discuss — much more so than in the period of building up and preparation. The stage, as it were, has been set, and criticism of the production can be invited freely. It is not longer necessary, as in the past, to rely on the making of dubious claims to priority. The impression should be as much stimulating as alarming.

In nuclear physics, especially, Britain has a unique record in discovery and, even since the war, has made a surprisingly big proportion of contributions. In the application of discovery she can point to the Calder Hall nuclear power station. But in the training of scientists and engineers there has been more of lip service than performance. There has been a lack of appeal in schools, and later, to many who, with more of encouragement and interest, might have been among the best material available. There has been a lack of incentives — in Government departments, in teaching, even in some sections of industry. There has been too much talk about the best means of expanding technological education at the higher levels, too little done. It is time that the lesson of Soviet progress was learnt. If Britain is to survive in a world which year by year becomes technologically more competitive, it must be learnt soon.

FRANCE MOVES FORWARD

An illustrated booklet, entitled France Moves Forward, describes the economic and technical progress made in the French Union in the years 1946 to 1955. Atomic power, the coal and steel industries, hydro-electric power and hydraulics, and thermal power are among the subjects covered. Advances have been made in transportation by land, sea, and air; in metals and their fabrication; and in petroleum. French achievements in several fields overseas are also described.

Co-Operative Research in the British Electrical Industry *(continued from page 23)*

issued. Technical enquiries are answered by reference to the Bureau's own classified data, an expert on the technical staff or an extra-mural associate. There is a weekly abstract service and loans of periodicals and books to members have risen to over 4,000 a year. The Technical Liaison Department is responsible in general for guarding the interests of members. It organizes personal visits for discussion with a view to ascertaining the problems which arise in industry where the E.R.A. can be of assistance, and bringing these problems to the attention of the departments or committees concerned. It also organizes informal meetings to which representatives of members are invited for the discussion of specific fields of research which are ripe for industrial application. The endeavour is always to establish a personal link which will go further than that which can be achieved by the normal issue of reports. A further step which has recently been taken in this direction is the issue of a house journal comprising articles on general and specific subjects related to the work of the Association, designed particularly to appeal to directors and others who are in a position to make the fullest use of the results of the E.R.A.'s researches.

Acknowledgments

It is a pleasure to acknowledge the help received in the preparation of this paper, without which it could never have come to be. Thanks are due to the director of the E.R.A., Dr. S. Whitehead, for permission to draw freely on the content of his paper* "Co-operative Research in the Electrical Industry" and to reproduce figures and tables from E.R.A. reports; also to Messrs. L. Gosland, E. E. Hutchings, W. Nethercot, and S. F. Pearce of the E.R.A. who have prepared sections not directly related to the author's personal experience and are therefore factual co-authors of this paper.

* Paper read before the British Electrical Power Convention, June, 1952.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

The weather continued generally favourable for construction work throughout the month, and good progress was made.

Progress By Ontario Hydro

The total work force in the Ontario Hydro section was 4,100 persons.

Work began during November on removal of Iroquois Point, one of the major channel improvement contracts. An excellent start was made on this contract with approximately 45,000 cubic yards of material removed and placed in the temporary cofferdam. This cofferdam will act as a dividing dike between Iroquois control dam and the seaway work at Iroquois Point.

At Galop Island, the south dike was extended east to Dixon and Kellogs Islands. The north cofferdam had been extended. Excavation on the west end of Galop Island proceeded well. Earth removal to date has amounted to 7,350,000 cubic yards, and rock excavation to month end amounted to 500,000 cubic yards.

At the power-house site, splendid progress was made in concrete placing operations. By the end of November a total of 370,000 cubic yards of concrete had been placed, or 40 per cent. Five draught tubes had been poured and two more started. Mechanical parts were being installed. The draught tube liner was installed in unit No. 2 and work was well advanced on the installation of the speedring.

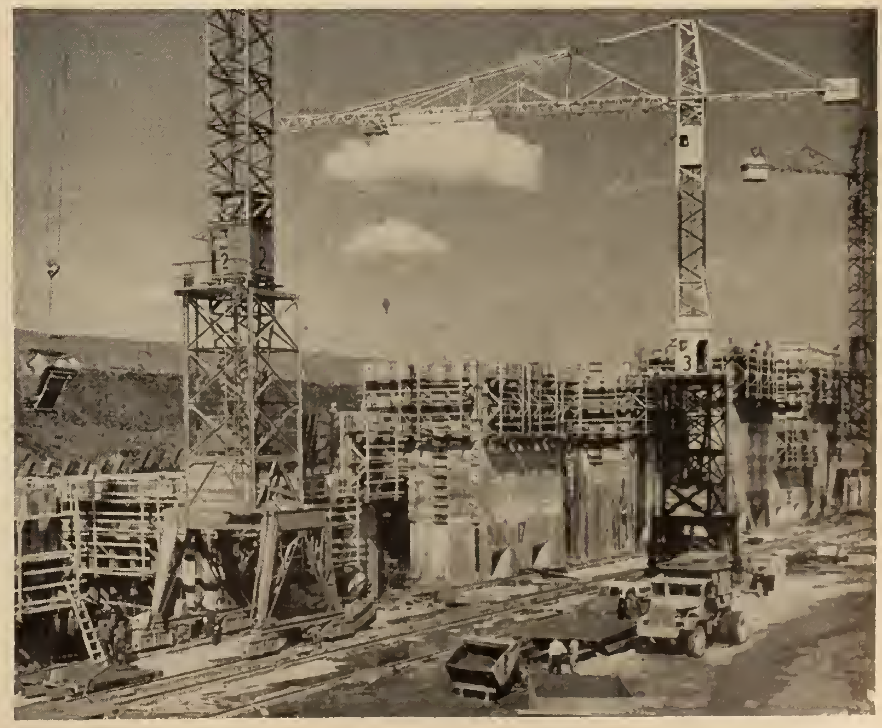
The concrete walls of the Cornwall diversion canal closure structure were finished during the month. Approximately 75 per cent of the excavation of the mile-long diversion canal had been done by the end of November.

Till placing and compacting on Cornwall dike was terminated in mid-November. Only the granular course on the top and the rip rap on the slopes remains to be done in section 3. Approximately 55 per cent of the till in section 2 had been placed and compacted and that work had also ceased for the season. All stripping had been completed in section 1.

On the C.N.R. relocation, work on grading contracts was completed early in the month. All the double track had been laid for the entire 40 miles and about 75 per cent of the ballast had been placed. Work was in progress installing telegraph equipment and block signals.

Concrete footings had been com-

Cote Ste. Catherine lock in the Lachine Section. Three gantry cranes of French design are being used. Placing of monoliths for about one-half of the photographed side of the lock was complete, and work was being done on the opposite side also. Filling and emptying ports and culverts can be seen.



The high level suspension bridge over the south channel of the St. Lawrence River from the U.S. mainland at Massena, to Cornwall Island, is to be ready for traffic on November 30, 1958. Contracts were awarded recently to The American Bridge Division of United States Steel Corporation for the superstructure on their bid of $4,759,045; and to McNamara Construction Company, Ltd., Toronto, for the substructure, at $1,240,550. D. B. Steinman, M.E.I.C., of New York prepared the design and specifications. The cost of the bridge will be shared by Canada and the United States, with SLSDC administering the superstructure contract, and the SLSA in charge of the contract for the substructure.

pleted for the 1957 phase of the St. Lawrence transformer station construction. The second relay building, scheduled for completion next year, was virtually completed.

House moving operations began in new town No. 1 (Ingleside) in November and eight houses were moved. Already the water lines and sewers had been completed and the subgrade for the entire road pattern was finished. Construction continued on the Roman Catholic church and the public school. Footings and walls for the shopping centre were being constructed. The water pumping station and sewage pumping station both were in operation, while the sewage plant was nearly finished.

At new town No. 2 (Long Sault), all major house moving operations were completed. A total of 106 houses had been relocated. Building of the shopping centre was started during the month. Footings for the water tower were completed and the sewage treatment plant was under way.

Sewer and water lines were completed for the new sub-division at Morrisburg. Basements were under construction for 30 homes and a limited house moving program is underway. At Iroquois, main activity was on the shopping centre, the high school, public school, the Presbyterian and Roman Catholic Churches.

Progress by NYSPA

November progress was underscored by the release of water into the completed Stage 1 of Long Sault dam, with 20 per cent of the river flow passing through at month's end. Overall construction passed the halfway mark as concrete placement to date exceeded 900,000 cubic yards and excavation for all features exceeded 31 million cubic yards. Employment averaged 4,450 for the month.

At Long Sault dam, excavation of the river bed above the dam and erection of the upper sections of the spillway gates were completed. The removal of the sheet steel piling was continued from the Stage 1 cofferdams. Excavation of Cut "F" progressed to 90 per cent of completion and seeding of spoil areas was started. Placing of rockfill for cofferdam "E" was resumed.

Concrete placement in Barnhart Island power-house increased the total placed to 430,000 cubic yards, or nearly half the total. Intakes on two units were poured to the top. Eight draught tubes were poured and stripped and some concrete placed on all 16, with some completed. Excavation for the switchyard equipment foundations and concrete placement for the various structures was continued. Embankment work for the south forebay dike had been discontinued for the season, and concrete operations will be closed down by Christmas for the winter.

At Iroquois dam, twenty-three of the forty stage 2 cofferdam cells had been placed. Removal of the upstream and downstream stage 1 cofferdams was in progress. 75 per cent of the river flow was passing through stage 1 at the month-end.

All stage 1 concrete for Massena intake had been placed. Excavation for the channel upstream and downstream of the structure continued and stage 2 cofferdam cells were being placed. Work on the temporary water line upstream from the structure was in progress. Excavation under the five channel improvement contracts had passed the half way mark. Seeding and mulching of the Red Mills Point spoil area was completed. Work was in progress on the three reservoir clearing contracts between Waddington and the St. Lawrence power dam. Cleaning of the reservoir as a whole was approximately 25 per cent completed. Clearing and chemical treatment of the Barnhart-Plattsburgh transmission line right-of-way was progressing. Continued progress was made on the rehabilitation of the Massena-Taylorville transmission line.

Production of construction drawings continued at a high rate. Much effort has been put into expediting various equipment items to insure their arrival on the project in time to avoid any delays in the tight construction schedule.

Progress by SLSA

Progress on construction of the seaway this summer and fall has been good, and is marked by the completion of several contracts and a change in emphasis from excavation to the building of structures, announced SLSA president Lionel Chevrier on November 20. All general contracts in the Lachine, Soulanges and Lake St. Francis sections had been awarded, as well as most of the contracts for bridges and lock equipment. Still to be awarded were one contract for dredging approaches to the Iroquois canal and lock, and two dredging contracts for deepening of the Welland Ship canal.

The overall progress as of the end

of October showed 30 million cubic yards of excavation completed out of a total of 65 million, or 46 per cent; 5½ million cubic yards of dike construction completed out of a total of 9 million, or 60 per cent; 250,000 cubic yards of concrete had been placed out of a total of 1,800,000, or 15 per cent, he stated. During the peak of activity this year a total of nearly 4,000 men were employed by the contractors on the construction of Canadian locks, channels and bridges. At the end of November construction and equipment contracts to a value of some $178 million had been awarded by Canada's Seaway Authority.

During the summer contractors began placing concrete at Canadian locks, and by year's end substantial quantities of concrete would be placed. Excavation work should be largely complete a year from now, and next year and 1958 would be generally devoted to the completion of concrete work, installation of lock gates and equipment, erection of equipment, and erection of bridges. There was little visible sign as yet of bridge construction, but various steel mills were producing the steel, while steel fabricating firms were preparing the steel work and planning for erecting the bridges and lock equipment at the sites.

Lachine Section

Work in the Lachine section was covered by 12 general contracts worth 65 million dollars, explained Mr. Chevrier. These included contracts for the two locks at St. Lambert and Côte Ste. Catherine, eight contracts for 16 miles of channel excavation and dike construction from below Jacques Cartier bridge to Lake St. Louis, and two contracts for dredging at the Montreal harbour approach and in Lake St. Louis.

Other contracts had been let for raising of Jacques Cartier bridge, for lift spans at Victoria bridge, for the first stages of the new high level approaches to Honoré Mercier bridge, and for the lift spans at the Canadian Pacific Railway bridge at Caughnawaga. Contracts had also been awarded for most of the lock equipment, gates, fenders, valves, machinery and other items.

Construction was actively under way on Lachine section general contracts from deep water in Montreal harbour to deep water in Lake St. Louis, a distance of 20 miles. Dredging of the Montreal harbour approach to the seaway channel was on schedule. The first stage of the work for raising the Jacques Cartier bridge was almost complete.

Progress on the two contracts for channel and dike from Montreal harbour up to Victoria bridge had been good, said Mr. Chevrier. Construction of St. Lambert lock and the sub-structure work for the modifications to Victoria bridge were making good progress. First concrete was placed in the lock structure in May and about a third of the south wall had been completed. Concrete was also being placed for the downstream entrance wall.

Excavation of the channel and construction of dike for the seven-mile stretch around Laprairie Basin to Côte Ste. Catherine lock was showing good progress. The work was being done in two contracts and both would be approximately half completed by the end of the year. At Côte Ste. Catherine lock excellent work by the contractor had resulted in this work being close to scheduled status. At the end of November concrete for the north lock wall had been almost completed and a good start made on the south wall.

Immediately upstream of the lock the first completed major contract was finished last February, for excavation of the channel and construction of dike for some three-quarters of a mile, overland. Next upstream was three miles of channel excavation and dike construction involving a total of 7½ million cubic yards of excavation. Progress had been maintained at scheduled rates.

Contracts had been awarded for work in connection with the extension southward of the Honoré Mercier bridge and with highway work involved in this. A clearance of 120 feet overhead at bridges had to be provided for vessels. At the C.P.R. Caughnawaga bridge, lift spans would be provided.

Work was being done in two contracts to provide the channel from below Honoré Mercier bridge to the Lake St. Louis entrance, upstream.

The St. Lawrence Seaway Authority inaugurated its Hydraulic Laboratories at Ville LaSalle, Que., on December 13. The object of the models already housed in these laboratories is to prove mathematically by tests the effect of works in the Lachine Section. Part of the Lachine Rapids model is shown below; another one reproduces the conditions to be dealt with in Montreal harbour; they were built by Neyrpic Canada Limited. The Authority has models of other important parts of the seaway in laboratories at the National Research Council.

All steps had to be planned to avoid interference with rail or highway traffic. The channel will skirt the river shore in front of Caughnawaga village for about two miles. Here two miles of cofferdam were being constructed in fast water in the river parallel to the shore, of which about 60 per cent had been completed. The dredging of the channel in Lake St. Louis was ahead of schedule.

Soulanges and Lake St. Francis

Work in the Soulanges section was covered in four general contracts valued at some $32 million, Mr. Chevrier reported. These included the lower and upper Beauharnois locks, a large part of preliminary excavation work and cofferdam construction, and a contract for crushing excavated rock for aggregates. Others would be let for a railway swing bridge for the New York Central Railroad across the upper Beauharnois lock, a lift bridge at St. Louis for combined highway and rail traffic. and a lift bridge at Valleyfield for combined highways and rail traffic.

At Beauharnois, the three general contractors were actively excavating rock at a combined rate of 10,000 cubic yards of solid rock per day. Excavation for the highway tunnel under the upper entrance to the lower lock had been completed, and the construction of the concrete tunnel was just getting started.

Work in the Lake St. Francis section had been covered in three dredging contracts totalling some 4½ million cubic yards valued at some $6 million. This work was now more than 60 per cent complete.

International Rapids Section

Improvements in the Cornwall Island channels would be done soon and a contract would also be let for the substructure of new high level highway bridge from the U.S. mainland to Cornwall Island.

The contract for the lock and canal at Iroquois Point had been the first lock contract to be awarded, and was the first on the schedule for completion. Early completion was a necessary factor in the coordinated development of the upper part of the river by power and seaway entities. A large and deep excavation across Iroquois Point had to be made before much could be done on construction of the lock or its entrance walls. Over 3½ million cubic yards of material had been excavated, and the concrete structure to date had 100,000 cubic yards of concrete placed. This work would continue during the winter. Start of erection of the lock equipment at Iroquois was planned for January 1957.

Welland Ship Canal

In this section, three contracts were awarded for excavation in the dry. This work is to be completed during the winter seasons of 1956 and 1957, while navigation is closed. One contract had been awarded in the Port Colborne area for dredging part of the canal from 25 to 27 feet. There remained a contract to dredge the entrance to the canal from Lake Ontario, to be let shortly. No other work was required in this section, since all the locks are of the dimensions approved for the new locks under construction in Canada and on the United States side in the International Rapids section.

Contract Awards by SLSA

The Russell Construction Co. Ltd., of Toronto, was awarded a contract on November 20 for dredging, and guard gate to station 710, Welland ship canal, at a price of $7,280,575. Other contracts awarded during November included one for supply and installation of Taintor lock valves at all locks and Taintor regulating valves at upper Beauharnois lock, to Bridge and Tank Co. Ltd., Hamilton, Ont., at $773,660; and another for lighting standards and lighting units for lighting the locks and canal prisms of the seaway, to Canadian Westinghouse, Montreal, at a price of $145,997.

The contract awarded to Russell Construction Co. was the first major contract awarded by SLSA to a British-owned firm, and was signed by Sir Andrew McTaggart, president of Balfour Beatty and Co. (Canada), and chairman of the British firm Balfour Beatty and Co., and by A. B. Sharp, president of Russell Construction Co., a wholly-owned subsidiary.

Dredging Controversy

The deadlock concerning the dredging in the International Rapids section for the channel on the north side of Cornwall Island may soon be resolved. An exchange of notes between the United States and Canadian governments appears to be clearing the way.

Dredging of the seaway channel south of Cornwall Island increases the flow from 66 per cent to 80 per cent, contrary to provisions of the Boundary Waters Treaty. Canada claims right to dredge a 27-ft. channel north of the island from Lake St. Francis to Cornwall, to restore the natural balance of flow. The United States has objected to this, fearing a duplicate seaway channel on the Canadian side would result.

Meantime the two seaway authorities, wanting to get on with the construction, worked out a plan to divide the cost of all this dredging on a 50/50 basis of $17 millions each, less $6 million credits to each from Hydro and NYSPA, and a start was made in October on work at the two extreme ends, avoiding the areas of acute controversy.

Jacques Cartier Bridge

Work was started the last week of November on the raising of Jacques Cartier Bridge to provide the required 120 foot clearance above the ship channel. The two piers on either side of the channel have to be raised fifty feet and an inclined roadway built on either side.

Progress By SLSDC

At the end of November, excavation on the upstream part of Long Sault channel over the islands was 95 per cent complete; section over the mainland 45 per cent complete and excavation for the two locks 65 per cent complete. The dikes at Richards Landing, Long Sault canal, Eisenhower lock, south forebay and Long Sault dam were 60, 70, 90, 70 and 15 per cent completed, respectively.

Concrete for the Eisenhower lock was 45 per cent done, with 240,000 cubic yards in place. The south lock wall was built to 2/3 of its height for full length and the north wall to half height for part of its length. Concrete for the Grass River lock with 220,000 cubic yards placed, was 40 per cent completed; most of the work done was in the lock structure, with both walls built to half their height. Placing of concrete was discontinued in November for both locks, but digging on the navigation channel will continue through part of the winter season.

Canadian Pipeline Projects

Westcoast Transmission

More than 407 miles of pipe had been welded on Westcoast's 650-mile main line by mid-November. Good progress was being made all along the line, in spite of early winter sleet and snow in some parts of the interior. On spread No. 1 in the north, Dutton-Williams Brothers had welded 86 miles. Bechtel Construction Division, responsible for spread 2, had welded 143 miles. Conyes Construction Corporation had welded 114 miles; and Mannix Limited, spread No. 4 on the south end, had welded 64 miles.

More than 490 miles of 30-inch pipe had been received. Pipe was being delivered at the rate of 20 miles a month, and it is expected deliveries will be completed by July, 1957. Shipments received during the winter will be stockpiled at strategic points along the line in preparation for the 1957 construction season. Pipe for the gathering lines was being received and stockpiled. Meanwhile, the completed sections were being tested. More than 7 million tons of earth and rock must be handled on the 650 miles of main line alone.

One of the trunk lines of the gathering system near Fort St. John, consisting of eight miles of 18-inch pipe, and grading of other portions of the gathering system, was well under way. Fifty miles had been graded. Full-scale pipelining on the gathering system starts in the spring. Work was moving forward on three compressor stations; at Taylor Flats in the Peace River Block; and near Quesnel. Foundations were between 60 and 70 per cent complete. Work on the stations will continue throughout the winter.

There are 13 crossings on the main line over navigable waters, seven of them submarine crossings and the others aerial. Construction of the first crossing of the Peace River at Taylor Flats was virtually complete, with foundations, bridge structure, towers and cables in readiness for pipe, which will be installed next year. The Fraser crossing at Shelley, near Prince George, was 98 per cent complete, with pipe installation 70 per cent complete. Crews on the Quesnel River crossing near Quesnel had erected towers and were stringing bridge cables.

The Huntingdon meter station had been completed, except for paint. This station is in reality two stations in one. There is equipment for metering gas for B.C. Electric, and one for Pacific Northwest. The equipment is designed to meter gas in either direction. Gas is now flowing from south to north, and upon the completion of the Westcoast Transmission line, the flow will be from north to south.

B.C. Electric Gets Natural Gas

Mid-November saw the first flow of New Mexico gas trickling across the British Columbia border to serve the B.C. Electric's Vancouver distribution system. The company spent $10 million in 1956 to lay its 36-mile pipeline from Huntington to a gas terminal at Patullo bridge, and for revising and expanding many of its distribution lines in the metropolitan area. It was also spending another $3 million to convert gas appliances already in use from manufactured to natural gas. Total company expenditures on natural gas will reach $30 million.

A fever of gas-furnace installations had hit Vancouver, with the Company's services pressed to keep up with demand. Spurring it was the increasing scarcity of supplies of sawdust for furnaces using "hog-fuel", during winter months. Faced thus with a possible serious gas shortage, home owners were being advised to keep their oil burners for the time being.

The company had successfully applied to the Federal Power Commission through its temporary supply source, Pacific Northwest Pipeline Corp., for an additional 20 million cubic feet per day, in addition to the 12 million feet daily originally contracted for. The FPC was quick to grant its permission to Pacific Northwest for this additional temporary export.

Financing for Inland Gas

Early November saw the offering of 250,000 shares of 5%, $20 par cumulative redeemable preferred stock of Inland Natural Gas at $17.50 a share, or a total of $4,375,000. Each share carries one warrant for one share at $7.25 after March 1, 1957. Proceeds will go towards building the Company's distribution system. Further financing will be needed later for the company's program which will cost a total of close to $25 million.

Inland has announced its rates will be approximately the same as those for major B.C. coast centres served by Westcoast. These rates are expected to spur industry and improve living conditions over a large area in interior British Columbia.

El Paso to Buy Pacific Northwest System

Canadian gas is seen gaining almost continent - wide distribution through the recent proposal of El Paso Natural Gas Co. to acquire the Pacific Northwest Pipeline System. As a result of the record expansion and development program this year in British Columbia and the Peace River area of Alberta, reserves have expanded very rapidly and government and gas company officials are seeking greater market outlets.

If and when FPC approval of the deal is forthcoming, Pacific Northwest will mesh perfectly with El Paso operations. When the flow of gas is reversed southward in about seven years time Canada will be the major source of gas for California, supplemented by San Juan reserves.

Trans Canada Pipelines

By Mid-November, Trans Canada had awarded a contract for the 98½-mile fifth section between Miniota river crossing and mile 498.3 just north of McGregor, to Price-Poole Construction, Ltd. This contractor had set up a field office at Brandon, and had started on clearing and grading. No pipe laying will be started until spring.

By late November a contract had also been awarded for the 86 miles of section six betweeen McGregor and the east side of the Red River, exclusive of the river crossing east of St. Norbert, to Canadian Bechtel, Ltd. The contractor was setting up a jointing yard two miles east of Portage la Prairie and planned to clear and level the right of way this winter, possibly do some double-jointing and stringing as well.

Dunn Brothers of Dallas will string for Price-Poole, while Universal and Canadian Bechtel will do their own stringing. Some 13 miles of pipe had been delivered at Portage la Prairie and some at Oakshela.

Work was still proceeding on Universal, Dutton-Williams and Price-Poole spreads, while some 230 miles of pipe on spreads one and two had been welded and 220 laid in the ground.

Sites had been chosen for compressor stations, one at Ile des Chênes where the 34-inch pipe terminates, and the other just west of the Portage la Prairie crossing of the Assiniboine river. One of the dual 34-inch pipes 2600 feet in length had been pulled across the Assiniboine near Miniota, soon to be followed by the second pipe. Dual crossings of the same river will also be made near Portage la Prairie at an early date by the same contractor, Marine Pipeline and Dredging Ltd., of Vancouver.

Estimated First and Fifth Year Deliveries

Latest estimate of expected deliveries of natural gas to areas along the Trans-Canada route, in billions of cubic feet yearly the first and fifth years of full operation, respectively, are as follows: Moosomin to Swift Current, 4 and 4; Brandon to Portage, 3 and 5½; Greater Winnipeg, 7 and 14; Keewatin to Lakehead, 7 and 10; Lakehead to Toronto, 13 and 26; Toronto (Consumers Gas Franchise area), 24 and 48; Southern Ontario (Union, United and Dominion), 16½ and 28; Ottawa-Hull, 10 and 12; Toronto to Montreal, 4 and 7; Metropolitan Montreal, 15 and 42. Totals, 103 and 196½ billion cubic feet.

Trans Canada is reported to have recently signed a 20-year sales contract with a newly formed company, Provincial Gas and Northern Quebec, Ltd. Some $4 million may be spent to pipe the gas to Rouyn, Que., and other areas near the Ontario-Quebec border.

Alberta Gas Trunkline

The Alberta Gas Trunk Line Co., incorporated in Alberta to build the gathering grid for the Trans-Canada pipeline, has awarded its first contract for the crossing of a gathering lateral under the Red Deer River near Cavendish. The lateral will bring production from the Bindloss, Provost and Sibbald fields to the main pipeline at the Field Gate. Length of the crossing is 2600 feet.

The Annacis Industrial Estate

In the past few years there has been a steadily growing demand for industrial lands to accommodate the expansion of secondary industry in British Columbia. The focal point of industrial development has been in the lower mainland area surrounding Greater Vancouver, which presents outstanding advantages with two major sea ports, one in Burrard Inlet and the other at New Westminster on the Fraser River.

Good transportation, moderate climatic conditions, and the many advantages for good living and recreation, make it a most attractive spot. Markets in Western Canada have been rapidly increasing over the past 10 years. Nearly 2,500,000 live in British Columbia and Alberta. Latest B.C. figure is 1,320,000. South of the border lies an American market with a population exceeding that of the whole of Canada.

Taking all these points into consideration, the Grosvenor Estates of London, England purchased Annacis Island in the harbour of New Westminster, and commenced development of this 1200-acre plot of land, and thus began Annacis Industrial Estate. The whole island is being developed for the accommodation of light and heavy industries, bulk breaking and packaging plants and warehousing.

The first of a series of four areas has already been completed. This area was filled with sand from adjacent river channels, presenting a good bearing for light and heavy construction. Excellent drainage facilities as well as sewerage systems have been installed along with an adequate water supply. Permanent, wide, main and secondary roadways are being progressively developed. Annacis maintains its own engineering and construction teams. Companies may have buildings designed by their own architects.

Spurs are provided to industries requiring rail service, while a strip of land flanking the channel has been set aside for industries requiring deep sea shipping facilities. A general cargo docking area is planned. Vancouver airport lies only 20 minutes from the Estate by car or bus. A heliport is also planned.

A most attractive feature is the landscaping of the areas bordering main roadways and buildings to give a parklike atmosphere. Power and cheap natural gas are available. Piped oxygen, display centres, shopping facilities, medical services, banks, clubs, fire protection and other services and amenities will be provided.

Architectural designing of all buildings will conform to a high standard of appearance. The Estate provides factory space and erects factories and warehouses to the specifications of the tenant, developed on a terrace basis under one roof which can be divided into units of 6000 square feet. Buildings are also erected to specification on separate sites according to the tenant's requirements.

Annacis is being developed on a leasehold basis. Upon signing the lease, the Estate guarantees delivery of a complete building or buildings and site. It is also possible for a tenant to lease the site and erect his own factory.

Since the official opening in July, 1955, there has been a steadily increasing tempo of development. 21 tenants have signed leases, 19 are already occupying premises. With more buildings being rushed to completion, and leases in various stages of negotiation, Annacis is thus well launched on the first 200-acre stage of development.

Within ten years the management expects half the island will be covered with factories, compared with about one sixth developed to date.

Though it was originally planned to encourage British industrialists to open Canadian branches at Annacis, of the twenty firms on the island today only two are British. Six are American, three are Canadian subsidiaries of U.S. firms and the other nine are Canadian.

N. P. D. Building

The contract for the construction of the building to house Canada's first power reactor has been awarded to The Foundation Company of Ontario Limited, it was announced recently by Canadian General Electric Company, Ontario Hydro, and Atomic Energy of Canada Limited.

Total amount of the contract for station building work is slightly in excess of $1,000,000. Work consists of site development, setting up of a construction camp, excavation, and carrying out of concrete and superstructure construction.

The Nuclear Power Demonstration station building will be located on the Ottawa River a few miles downstream from Ontario Hydro's Des Joachims generating station. The building will be 200 feet by 200 feet in size, with a steel frame and asbestos siding. The structure will be 40 feet above ground at its highest point and will have concrete works extending to 60 feet below ground level. It is scheduled for completion in the fall of 1957.

The N.P.D., with a capacity of 20,000 kw., is scheduled to come into operation in 1959. It is a joint undertaking of three organizations. Atomic Energy of Canada Limited is supplying basic research and nuclear engineering knowledge; Ontario Hydro is providing the site, is responsible for the engineering of the conventional features of the plant and will operate the station on completion; and Canadian General Electric is responsible for the engineering design and development of the reactor and acts as prime contractor for the whole project.

Canadian Oil and Gas Pipelines

Besides the two great pipeline projects, Westcoast Transmission and Trans Canada Pipelines, progress of which is being reported monthly in the *Journal*, great activity in laying pipe for both natural gas and crude oil pipelines has been occurring elsewhere during 1956, most of it in the three priairie provinces.

During 1956, including the expected 450 miles for Westcoast and 200 for Trans Canada, a total of some 1,350 miles of natural gas mains and laterals have been laid in the ground. Added thereto will be some 800 miles of distribution systems in various cities and towns from Vancouver of Toronto.

Although crude oil pipelines fell into a secondary position, some 775 miles of crude oil pipeline were also built during the year, opening up new markets in Saskatchewan and Alberta and readjusting the geographical allocation of fields to markets in both provinces.

Natural Gas Pipelines

Midwestern Industrial Gas Ltd. and North Canadian Oils Ltd. built a 10-inch composite gas line 170 miles long from the Alexander Indian Reserve field in Alberta to Wabamun and Hinton, in northern Alberta, to serve a large power plant and paper mill there.

South Alberta Pipelines Ltd. completed a 55-mile, 10-inch gas pipeline at a cost of $1.7 million from the Etzikom gas field in southern Alberta to serve the new Nitro-Chemicals Ltd. petro-chemical plant at Medicine Hat with 9 million cubic feet per year. The line will supply the city of Medicine Hat with 1 billion feet the first year and up to 3 billion feet the seventh year.

In the south west corner of the province British American Oil Company's 7-mile gas pipeline to the company's recycling plant neared completion.

Canadian Western Natural Gas and Northerwestern Utilities Ltd. made extensions to their existing systems of 109 miles and 68 miles respectively, tying in a number of large towns in Alberta not previously served with natural gas.

The Saskatchewan Power Commission laid 249 miles of main line and laterals, of which 120 miles of 12-inch gas pipeline from the Success field to serve the city of Moose Jaw, was the largest undertaking.

City and town distribution systems for natural gas at various points from Vancouver to Winnipeg and in Toronto's metropolitan area will add another four million feet or approximately 800 miles either completed or under way.

Crude Oil Pipelines

In Alberta, the Peace River Oil Pipeline Co. completed its system with 45 miles of 12-inch and 16-inch main line and 33 miles of 8- and 4-inch gathering lines. Cremona Pipelines Ltd. put into operation its 60-mile, 8-inch line with 10 miles of 6- and 4-inch feeders, to connect Calgary refineries with the Westward Ho, Sundre and Harmattan-Elkton oilfields.

Britmol Pipeline Co. Ltd. added 33 miles of 8-inch crude oil pipeline to the south end of its system to tie in the West Drumheller field with the line which now serves the Joffre and Fenn-Big Valley fields. Texaco Exploration Co. laid 22 miles of new 12-inch line to extend its present system from the Westerose area south to the Holmglen Rimbey field. Here it would connect with the new 44-mile line being built by Rangeland Pipeline Co.

Also in Alberta, Pembina Pipeline Ltd. was extending its large gathering system and raising its main line throughput to a level which was not originally expected to be attained before 1960. The construction schedule calls for 170 miles to bring total mileage up to 352 miles. This status should be achieved in 1957.

Further east, the Westspur Pipeline Co. laid 109 miles of 12-inch crude oil pipe, 10 miles of 8-inch pipe and 50 miles of gathering lines from fields in southwestern Saskatchewan to the interprovincial pumping station at Cromer, Manitoba.

Transprairie Pipelines received a permit to build 17 miles of 8-inch crude oil pipeline from the Halbrite field to Weyburn, Sask. It will link up with the Midale terminal.

The South Saskatchewan Pipeline Co. laid 59 miles of 12-inch and 7½ miles of 8-inch pipeline, including one river crossing, extending its existing line from Cantuar to Dollard, Sask., to take in four additional oil fields in the area.

Closely related to both these Saskatchewan projects is the expansion program of Interprovincial Pipeline Co., which looped its bottleneck section in the central part of its Manitoba division. The job consisted of 67 miles of 24-inch loop and 2 miles of 26-inch loop — the first leg in Manitoba of a continuous 30-mile loop of its Minnedosa line section operated by Lakehead Pipeline Co.

Interprovincial also added a seventh pumping unit at Cromer and further tank capacity at Cromer and Gretna. Throughput from Gretna was soon to be increased from 29,000 to 38,000 barrels per day in the 75-mile line of the Winnipeg Pipeline Co., an Imperial Oil subsidiary.

In Eastern Canada, products pipelines continued to expand their traffic volume faster than expected, and plans to loop one major products pipeline in Ontario were completed. Interprovincial announced firm plans to extend its line from Sarnia to a new destination at Port Credit, with construction to be done in 1957.

Research and Engineering

The new research and engineering facilities of Imperial Oil Limited at Sarnia, Ont., were opened in October.

At this time a symposium, attended by deans and professors of chemistry and engineering from across Canada as well as leaders of industry and government, was arranged to discuss research and engineering problems of mutual interest. Subjects of discussion included the role of industrial and institutional research, the use of scientific manpower, and the selection and training of technical personnel. At its conclusion Dr. E. W. R. Steacie, president of the National Research Council officially opened the new building.

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE ELECTIONS AND TRANSFERS

What Can Be Done About It?

The supply of engineers and scientists for Canada's future is now and will be for several years quite inadequate. The picture is so clear and so alarming that it is hard to know why something more isn't being done about it.

More words have been spoken and printed about this situation than about almost anything else, with the possible exception of the international situation, and the latest sporting events. Many organizations have studied the situation and reported their findings. Many voices have proclaimed the urgency but after years of talk no one has done anything of consequence that will improve the situation quickly.

The full answer is not easy to find or to apply, but surely there can be some long distance thinking that will start a movement in the right direction.

In case the seriousness of the situation is not appreciated, the *Journal* presents herewith some of the latest information, which should convince anyone that the present troubles will be multiplied and aggravated beyond all reason, if we do not tackle the problem now. We have played with it long enough.

Let us look at the picture. There are three angles from which it must be regarded before it can be seen in all its seriousness. Firstly, what is the need? Secondly, how many are we graduating? And thirdly, how many are we getting by immigration?

First, the need. No one can say precisely how many engineering openings there are, but a partial answer can be developed, that is sufficiently disturbing to command attention. Taking the word of various engineering deans and staff members who have something to do with employment, it is safe to say that after eliminating duplications, this Spring each graduate had at least three jobs he could take. There were 1,600 graduates, so let's call the need at that time as 5,000.

Bear in mind this figure is for new graduates only. Add to it the need for experienced engineers and we have at least 1,000 more.

Secondly. — How many graduates will there be? In 1957 the figure will not be above 1,900. There will be a slow rise in numbers for several years and in 1965 it is indicated enrolment figures will double those of 1955.

Thirdly — How many come here from other parts of the world? Counting both engineers and scientists there were 1,900 in 1953. There were 500 who left Canada in the same year, so the net gain was 1,400. Graduates in engineering that year numbered 1,300. It will surprise many to know that for a short time Canada was gaining more by immigration than by graduation.

Now if immigration is added to graduation in 1953, we would have 2,700 new acquisitions that year. The demand at that time was about 6,000, so even under those favourable conditions we were short at least 50 per cent of the requirement.

A serious trend is now becoming apparent. Acquisition by immigration is falling off alarmingly. In 1953 it exceeded graduation but in 1955 it amounted to only 60 per cent of the number of graduates, or about 800. The economic conditions in other countries are improving to the point that their engineers and scientists are content to stay home. Barring some serious upheaval, immigration never again will be so important a factor in the Canadian picture.

Now let us look ahead to 1965 which is the target date for so many plans and conjectures. According to Dr. Sheffield of the Dominion Bureau of Statistics, university enrolment then will be double that of 1955. If such is the case, the maximum number of engineering graduates in 1965, will not be more than double the 1955 number, or 2,600.

If immigration figures follow their trend, the number available from this source in 1965 will not exceed 500, and in all probability will be much less.

Putting these two figures together, there will be in 1965 about 3,100 new acquisitions.

Now what will be the demand then? A recent survey of over 700 employers of Canadian engineers shows that they expect to increase their needs by 10 per cent per year for the next three years. If this carries on until 1965 the need will be at least 12,000 per year at that time.

The arithmetic is simple; the answer impressive. With a need of 12,000 engineers and a graduation class of 2,600, the situation becomes startlingly clear. Some will argue that industry will not require 10 per cent more graduates each year, but the figure is definite for at least three years. It is not unreasonable to assume that in this growing country with its great potential, industry, government and universities will require that many.

To meet the argument of those who think these figures are unrealistic, let us examine the situation as if industry's requirements remain just as they are today, that is to say, that the need would be about 6,000, as it is now. The graduating class, if it doubles the 1955 figure, would be 2,600. There is still a shortage of almost 50 per cent and even that is a matter so serious that more attention should be given to it—atten-

Cover Picture

tion that will produce some changes quickly.

The Answers

Who knows the answers? Apparently everybody and nobody. This situation has been foreseen by many people over a period of years, long enough to have brought about some worthwhile improvement, if those who have the power had seen fit to do anything about it.

At long last there is an increase in the tempo of the thinking, but alas, the possibility of bringing about improvements in the near future is not encouraging. University officials are almost powerless to do anything by themselves, but they are now planning in terms of the immediate needs. However, they need money — money for buildings, for increased salaries, for increased staff, for additional and improved equipment. There is some promise now that government and industry will help, but the needs appear to be away beyond any sums that are being mentioned as available shortly. The planning needs to be expanded greatly or the situation will not be met.

Technicians

One of the quickest and best methods of overcoming the shortage is to train more technicians. Many hours of work now done by professional workers could be done equally well by properly trained technicians, but the supply of technicians is just as inadequate as is the supply of engineers. Here too there are but few signs that anything is being done about it.

The Province of Ontario has made a fine start with its Ryerson Institute of Technology at Toronto, but the number of graduates is hopelessly small in terms of the needs. Fortunately the province is expanding its teaching facilities in this field and there is excellent promise of worthwhile improvements shortly.

Effects

Through the survey of employers referred to earlier it was discovered that the shortage was having adverse effects on production, research and expansion. Out of over 700 firms surveyed, 360 reported that their operations had suffered from the shortage. They mentioned such effects as delay in new projects, inability to tender on new projects, reduced expansion, research retarded, no opportunity to train young executives, expanded use of improperly qualified personnel, overwork of professional employees with corresponding reduction in efficiency and so on.

So —

As admitted earlier, there appears to be no means of meeting this situation immediately, but surely some better planning can be done and more active support can be offered than has been apparent so far. The situation is serious and merits treatment as an emergency.

Hungarian Refugee Engineers

Indications are that several thousand refugees from the Hungarian terror will come to Canada. They will represent a cross-section of the Hungarian population and there will be engineers among them. Council has directed that the Institute give all possible help to refugee engineers in their efforts to find work and to become members of the Canadian community.

Immigration Offices and National Employment Service are the government agencies concerned with the refugees, assisted by various welfare organizations. So far, efforts to find out how the Institute could assist most effectively have not been too successful. There is still some organizing to be done.

The Institute has already made available the facilities of the Employment Service and of the *Journal*. When arrival and dispersal points are known in advance, branches at these points are advised and asked to help. However, advance information is not always obtained and all branches are asked to be on the lookout for arrivals in their communities.

The branches can help in two ways: First by asking to be advised of the names and qualifications of engineers among the refugees to help them find employment, then by inviting them to branch meetings where they can meet prospective employers and make friends with their Canadian colleagues.

Individual members may help by rounding up some of the jobs they intend to get done but postpone time after time because no one can be spared to do them. Perhaps a refugee can do one of these jobs or relieve a Canadian engineer of some of the routine details of his work. Such assignments, even for temporary periods, will help the refugees to become familiar with our language, our methods and our customs.

Most Europeans with college educations have studied English and French. Nevertheless, there will be serious language difficulties in many cases. For those who speak neither language it may be necessary to find work at sub-engineering level, at least for a while. Temporary jobs as draftsmen, technicians or machine operators will be more suitable and useful than the jobs these trained refugees might otherwise have to take.

Headquarters will help the branches as much as possible, but most of the work will have to be done where the refugees are. The branches are asked to keep headquarters informed of the assistance given these refugees in order that progress reports may be published in the *Journal*.

At present, enthusiasm is very high. Welfare agencies are receiving many offers of help, to the point where they do not quite know what to do with them. But enthusiasm tapers off. For this reason, the efforts of the Institute will need to be sustained to assure the late comers an even break.

End hardening rails at the plant of Dominion Steel and Coal Corporation, Sydney, N.S. This photograph received an award of merit in the E.I.C. photographic exhibit, 1956.

A Proposal for a Survey of the Engineering Profession

From the report of the ECPD-EJC Joint Task Committee on Engineering Profession Survey

Editor's Note :

One of the most important things the profession in North America will have to face in the immediate future is outlined in the following article. In the minds of many people who have studied the situation it is essential that this survey go forward.

If it is undertaken the Engineering Institute will become deeply concerned with it. As the only Canadian member of the Engineers' Council for Professional Development it will fall to the Institute to carry out or supervise all the phases that will have to do with Canada.

This is a serious matter. Never before has there been a proposal so far-reaching, so comprehensive and so significant to the profession of engineering. It will pay the readers of *The Engineering Journal* to study it.

The ever accelerating pace at which expanding scientific knowledge and discovery is rendered useful by the engineer has stimulated a world-wide revolution. By force of momentous advances that are still in progress, the engineering profession has assumed broad responsibilities, among which its traditional concern with individual professional competence is only one. The engineering profession today is the most complex of all. The present shortage in engineering manpower, serious enough by itself, has served further to underscore many other major problems confronting the profession. It has raised more questions than have been answered.

Critical problems have arisen in every facet of the profession: education, utilization of manpower, organization, and social and economic factors, all of which intimately concern the national welfare. It therefore seems appropriate, necessary, and, in fact, urgent that the engineering profession at this time make the first searching and comprehensive self-study in its history.

If it were a matter of numbers alone, the engineering profession and the nation would face a somewhat less formidable problem. But the pattern of the future is already being drawn in the affairs of today. Society and technology have not only utilized the professional competence of the engineer, they look to him to supply managerial and executive ability as well. To cite just one example, answers to the problem of natural resources will almost certainly hinge on the decisions and accomplishments of engineers. The engineer often works without the spur of public concern that, for example, accompanies medical research. More than ever today the engineer must possess the technical and intellectual discernment to anticipate problems and solve them almost before others think of them. Inevitably, engineers make policy in a host of industries and vast government agencies which a decade or two ago looked to the corporation lawyer, the financier, or a political figure for the lead. Just as inevitably, in a period when the battle between freedom and totalitarianism is waged with bread and know-how, national policy must be drafted with the aid of engineers.

The Time Is Now

The decision toward an undertaking so immense as a Survey of the nation's largest profession is not easy and ought not to be made with undue haste. Five years of informal and formal deliberation and introspection lie behind this call for the Survey. It is issued not only because the time is propitious, but also in the belief that delay will do injury to the living and to generations to come. Action born of crisis can be precipitious; but if that action springs from competence, integrity, and authority, it is likely to lead to vast strides forward.

Enlightened Self-Interest As Well

Among the great professions, engineering may take justifiable pride in its reputation. It has been uniquely free of mistrust, scandal, ridicule, and charges of incompetence or inertia. Having earned universal respect, the profession must not complacently assume that this is a permanent grant. If in the future shortcomings should bring deserved criticism upon the profession (to say nothing of abuse and threats to professional freedoms) it will have only itself to blame. Assuming this concern to be, frankly, one motivated by self-interest, it is nevertheless interwoven with the primary obligation of the profession to society.

To measure up to the tasks required of it, the profession must be assured that it is properly training, utilizing, rewarding, and attracting men of the highest competence and potentialities. No responsible person can honestly say that all is well in these areas today. Only a top-to-bottom Survey can determine the nature of the mission, the extent to which it is being fulfilled, and the steps necessary to maximize our efforts in the most effective manner.

The Personality of the Profession

The profession is composed of individuals. The danger that this will be forgotten grows as the proportion of engineers to other groups increases inexorably. Indeed, neglect of the individual has always been a tendency in a profession distinguished from many others by the fact that most of its members are employees rather than self-employed. Despite emphasis on quantity, society and technology now clearly demand of engineers a high order of intellectual capability, individuality, imagination, and ability to assume responsibility. The Survey must therefore probe not only the day-to-day tasks of the engineer but also his attitudes, hopes, ambitions, disappointments, and fears.

The Spirit of the Survey

Other professions have surveyed themselves thoroughly — under less pressing circumstances than face the engineering profession today. The two most recent studies yielded significant pictures of the American architect and the American lawyer. These are cited merely as a matter of record; only to a minor extent could they serve as models for the Survey of engineering. Engineering's needs seem to call for a type of investigation more akin to the Hoover Commission's study on governmental operations.

The Scope and Uses of the Survey

In each of the great areas the Survey will:

Seek comprehensive knowledge of the facts of the existing situation.

Formulate answers to many penetrating questions arising from the facts.

Make recommendations for future action.

Provide ways and means of putting the recommendations into actual practice.

If it truly penetrates every aspect and level of engineering, the Survey's constructive conclusions may well be expected to provide guides for the profession for the next quarter-century. Not that engineering should straightjacket itself, for it is by nature dynamic and changing. But the great problems this Survey will attack are of a kind that not only will remain with us for the next generation but may be expected to come into sharper focus and carry even greater significance than now.

Following are the areas with which the survey must be concerned, together with an indication, not intended to be complete, of questions in each area that cry for investigation and solution.

1. Professional Services and Responsibilities

Today the essential of individual technical competence is but a starting point of the engineer's role in society. Past concepts, performance, and evolution of the profession should be analyzed to obtain an up-to-date perspective on present and future problems. Therefore,

What are the strictly professional responsibilities of the engineer?

To what extent do engineers influence the application of their professional efforts?

What are the gaps in intellectual leadership that could be, should be, filled by engineers?

To what extent should professional education and organization be altered to equip the engineer for new, untraditional services and responsibilities?

2. The Supply of Brain Power

To meet the spiralling demands for both capital and consumer goods, the productivity of human effort must be rendered increasingly more effective. At the same time the intricacies and refinements of modern production take a growing percentage of engineering man-hours from inception of an idea to the fabrication and assembly. For example, a 1940 fighter plane took 17,000 man-hours of engineering, a 1955 took 1,410,000, and a 1960 promises to take 2,000,000. Engineering must share with the other professions and intellectual occupations a relatively small reservoir of talented youths. Of the mere 17% of high school graduates intellectually suited to engineering education, engineering colleges are drawing one-fourth of the male portion. A single profession enlisting so great a proportion of this precious human resource assumes grave obligations and responsibilities. Therefore,

From a completely objective and unemotional study, what are the specific shortages, present and projected? Careful statistical studies should deal not alone with the over-all situation but with industries, branches of engineering, and professional levels (consulting, industrial, teaching, and research).

What are the demands of the other professions on the national supply of brain-power? Will these brains have to be rationed? If so, what should be the order of priority?

In general terms, and in case studies, how are engineers utilized?

Depending on the specific shortages disclosed, how can they be alleviated: by regimentation, incentives, better utilization, changes in education, variation of standards, or by other means?

If the growing concentration of numbers in this one profession tends to depress the morale and initiative of its members, how may this be remedied?

3. The Individual Engineer

Because he often works in teams and is usually an employee, the individual engineer is too often anonymous. The tributes he has earned are frequently paid to his profession in the mass. Therefore,

What is an engineer? Who is he, and what are his origins and his social, cultural, and economic background? For the purposes of outlining an operable framework for the Survey, the Survey Committee must first establish a definition of who shall be termed "an engineer" and therefore be included in the study. To do this, the areas of activity of engineers and those of scientists must be delineated.

Why did he choose engineering? What was the nature of his intellectual preparation, and how did it affect his subsequent career?

What made him choose his particular branch or level of engineering?

How much does he earn, and how much can be expected to earn throughout his career? What are his living standards?

What are his personality traits, and how do they affect his professional performance?

Does the fact that so many engineers are employees adversely affect their professional outlook? Is there a different outlook among those who are self-employed or in policy-making positions?

What are his initimate feelings about his profession, about the organizational pattern in which he functions? How does this pattern encourage or discourage his individual talents, initiative, and imagination?

What do his employers and nonprofessional colleagues, family and friends think of him? How does he rate in his community or in the business world compared with members of other professions?

All other factors being equal, is he more valuable for having remained in one job for many years or having switched often?

What are the effects of pension systems, and other devices to make employment more attractive and reduce turnover, on the freedom and development of the individual engineer?

Does he attempt to advance himself after he leaves college, and by what means?

Does he have nonprofessional interests, in individual pursuits and in his community?

4. Subprofessional Engineering Services

Like the brain in the central nervous system, the engineer triggers activity by men and women in a greater number of allied occupations and skills: at the same time, he receives information and services from them in order to perform the tasks requiring his particular professional ability and judgment. This is true of other professions, though their allied subprofessional services seem to be more thoroughly and rationally organized. It is ludicrous to imagine a cardiologist or other medical specialist performing the functions of a nurse, an X-ray technician, or a bacteriological aide. Yet many professional engineers are found in comparable situations. Therefore, What are the specific types of subprofessional services allied to professional engineering? Should more women as well as men be enlisted into them?

To what extent are professional engineers engaged in them?

What are the educational requirements for subprofessional services? What are the existing and needed educational facilities for them?

What kind of people should be attracted to these services?

What recognition can be given them? What opportunities should they have for transfer to professional status?

What mechanical, as well as human, aids are given to the engineer?

To what extent can expanded and better apportioned subprofessional activities alleviate shortages in the profession?

5. Engineering Education

The ink is scarcely dry on the last extensive survey of engineering education. More spadework having been done in this area than in any other aspect of the engineering profession, the job of the Survey will be to crystallize the basic problems of engineering education as they relate to other areas of the Survey and to make comprehensive, detailed, and realistic recommendations for solutions. Among the following questions, the Survey will have considerable information on some, may choose to examine others in still greater detail, and may want to put others to thorough examination by eminent laymen as well as by engineers:

What do we mean by engineering education?

What is the contribution of the educational system to the development of the professional engineer from secondary school through postgraduate study?

Is engineering education too formal, stereotyped, and rigid? Does it foster or inhibit originality and creativity?

What is the actual cost of educating an engineer? How is it paid?

How are engineering schools financed, staffed, and equipped?

What is the composition, ability, and morale of engineering faculties? How may schools retain outstanding faculties in the face of competition from other areas?

What are the causes and implications of the heavy mortality in engineering students?

To what extent should social and humanistic studies be effectively integrated into engineering education?

Should some engineering studies be introduced into educational programs for other professions?

How far should formal graduate work go? Who should pursue it?

To what extent is the advancement and utilization of older engineers (those out of college five years or more) impeded by lack of opportunity or incentive for keeping abreast of new advances in engineering and science?

What procedures can encourage continuing education stimulating to the engineer, not restrictive of his family life and finances, and advantageous to his employer?

6. Registration and Unionization

Compared to his invaluable contributions and widespread prestige, the legal status of the engineer and his personal relationship with his profession lag far behind and are relatively ambiguous. The fact that 48 states have registration laws fails to meet the hard truth that while a doctor is a doctor, a lawyer a lawyer, a minister a minister, too often an engineer is all things to all men. Of all the professions, engineering has the most members of labor unions. Therefore,

Should mandatory licensing be expanded? Should engineers be licensed broadly or in particular fields?

Why do engineers register or not register?

Has registration improved engineering ethics and the level of engineering services to the public?

What problems arise from the practice of engineering through the corporate form of business?

What is the nature and extent of unionization?

Why do engineers join unions? How does union membership affect their professional competence and subsequent careers?

What is the organized profession's attitude toward unionization?

Are there advantages and disadvantages in unionization that affect the profession's role in society?

7. Organization of the Profession

Many societies, organized along branch lines, flourish within the engineering profession. The societies are organized in two federations. The profession has no true counterpart to the American Medical Association and the American Bar Association. On the other hand, those national organizations are comparatively new institutions in the history of their professions and their function and value, if related to the Survey of engineering, should be studied rationally and objectively. Therefore,

For meaningful organization purposes, what are the major branches of engineering?

Is the engineering profession cohesive?

What is professional unity and how does it affect maximum professional service?

Are changes in the organization of the engineering profession desirable?

What is the political, social, and economic status of the profession?

What are its relationships to scientific organizations, industrial associations, labor and political organizations, the military, and other professional organizations?

The Role of the Societies

A Survey of the engineering profession will require at least two years. It will cost on the order of $1 million.

The details of organization and procedure of the Survey clearly cannot be spelled out in advance. For one thing, they require long and careful planning. For another, they demand a plan for consultation with all of the constituent societies, a step requiring that the societies first endorse this proposal in general terms.

Generally, however, this joint committee suggests the establishment of a Committee on the Survey of the Engineering Profession under the joint auspices of ECPD and EJC.

Following the lead of recent self-studies by other professions it seems logical to organize the Survey so that various groups would investigate specific items on which they are best qualified. Such groups need not be composed solely of engineers since engineering embraces a spectrum of activities much broader than the technical competence of the individual engineer. The calibre and distinction of the directing committee should be of a level to arouse enthusiasm and support in areas outside as well as within the profession.

The Committee Would

△ Outline a form of organization to conduct the Survey, using the present proposal and supplementary suggestions from the constituent societies as a basis. It will doubtless be desirable to explore the extent to which one or another problem is peculiar to a given segment of the profession, so that special groups in one or more constituent societies may become special agents of the committee.

△ Appoint a director and small staff to assist in detailing the program and later administering it under the committee's auspices.

△ Make progress reports to the Executive Committee of ECPD and the Board of Directors of EJC, so that constituent societies may be continuously informed through their representatives.

Manifestly, the Survey cannot and should not be undertaken without the enthusiastic endorsement and support of the national engineering societies. The unity of the profession on the desirability of the Survey must be unmistakable before others are asked to lend their support.

The Reason Within Us

The future pattern of engineering will, to an extent undreamed of by many, influence day-to-day schedules in factories and mines, the size and shape of the national product, the face of the city and countryside, conditions in homes here and abroad, and the respect with which American words are heard at conference tables the world over. This is verified by historical and technological reality and by a sense of great works — wonders, if you will — that lie somewhere in the traditionally unemotional engineer. It is the preservation and extension of that sense that we cite as our final reason for the Survey of the engineering profession.

Manpower Conference

The Advisory Committee on Professional Manpower had another meeting in Ottawa on Monday, October 29. This is an Advisory Committee of the Department of Labour and therefore the meeting was opened with a welcome and expression of thanks from the Deputy Minister, Mr. Arthur Brown. The Minister, the Honourable Milton Gregg, V.C., joined the group in the afternoon and stayed throughout that session.

The agenda provided for nine topics of discussion and each topic was introduced by an official of the Department of Labour or some other government department and was followed by a very general discussion. Herewith are the topics and the persons who presented the papers and led in the discussions.

Introductory remarks, Mr. A. H. Brown, Deputy Minister of Labour.
The long-term outlook of professional personnel, Dr. W. R. Dymond, Department of Labour.
1956 Survey of Requirements for Professional Personnel, Mr. A. M. Sargent, Department of Labour.
Technical Personnel Register and other developments since the last meeting, Dr. P. H. Casselman, Department of Labour.
Professional health personnel, Miss B. J. Stewart, Department of National Health and Welfare.
Economic status of engineers and scientists, Mr. F. L. McKim, National Research Council.
Comments on program of university expansion, Dr. F. Stiling, National Conference of Canadian Universities.
Comments on Industrial Foundation for the Advancement of Education, Mr. S. H. Deeks, Executive Director, Foundation.
Comments on shortage of science teachers in high schools, Dr. Garnet Page, Chemical Institute of Canada.
Other business.

There were about fifty persons at the meeting, which by the way took place in the Liberal Caucus Room in the House of Commons building. It certainly must have been inspirational, at least to some of the persons in the room, to be surrounded with busts and portraits of such distinguished Liberals as Sir Wilfrid Laurier, Mackenie King and Louis St. Laurent.

For this meeting the membership of the committee was extended substantially over previous meetings. For instance, there were two delegates from the Canadian Chamber of Commerce, two from the Canadian Manufacturers Association and one from the newly formed Industrial Foundation for Education. Other organizations and departments which were represented are as follows:—

Representatives to the Advisory Committee on Professional Manpower Meeting—October 29, 1956

Mr. L. W. J. Hurd, Agricultural Institute of Canada
Mr. C. J. G. Carroll, Royal Architectural Institute of Canada
Dr. Garnet Page, Chemical Institute of Canada
Mr. J. M. Muir, The Dominion Council of Professional Engineers
Dr. L. Austin Wright, The Engineering Institute of Canada
Mr. J. D. Coats, Canadian Institute of Forestry
Mr. C. Gerow, Canadian Institute of Mining and Metallurgy
Dr. A. E. Douglas, Canadian Association of Physicists
Dean F. Stiling, National Conference of Canadian Universities
Dr. C. T. Bissell, National Conference of Canadian Universities
The Very Rev. R. Normandin, National Conference of Canadian Universities
Mr. W. H. Evans, Canadian Manufacturers Association
Dr. J. R. Whitehead, Canadian Manufacturers Association
Mr. W. J. McNally, Canadian Chamber of Commerce
Mr. E. R. Complin, Canadian Chamber of Commerce
Mr. S. H. Deeks, Industrial Foundation on Education
Mr. F. G. Patten, Canadian Educational Association
Mr. T. W. Morison, Atomic Energy of Canada Limited
Mr. M. Lamontagne, Economic Adviser to the Prime Minister
Mr. G. D. Mallory, Technical Adviser, Department of Trade and Commerce
Dr. E. F. Sheffield, Director, Educational Division, Dominion Bureau of Statistics
Dr. F. T. Rosser, Director, Division of Administration, National Research Council
Dr. J. B. Marshall, Chief, Awards Branch, National Research Council
Mr. F. L. McKim, Chief, Personnel Branch, National Research Council
Dr. H. W. Jamieson, Director of Personnel, Defence Research Board
Miss B. J. Stewart, Research and Statistics Division, Department of National Health and Welfare
Col. G. M. Morrison, Supervisor, Executive and Professional Division, National Employment Service
Mr. A. H. Brown, Deputy Minister, Department of Labour
Dr. G. V. Haythorne, Assistant Deputy Minister, Department of Labour
Mr. A. W. Crawford, Director, Canadian Vocational Training, Department of Labour
Miss M. V. Royce, Director Women's Bureau, Department of Labour
Mr. W. E. Duffett, Director, Economics and Research Branch, Department of Labour
Dr. W. R. Dymond, Chief, Manpower Division, Department of Labour
Dr. P. H. Casselman, Chief, Specialized Manpower Resources Section, Department of Labour
Mr. J. P. Francis, Department of Labour
Mr. J. A. Wedge, Department of Labour
Mr. P. B. Wolfe, Department of Labour
Mr. A. M. Sargent, Department of Labour
Mr. K. N. Williams, Department of Labour
Mrs. E. M. Glavin, Department of Labour
Miss J. Marlow, Department of Labour

One subject which was of considerable interest was related to the Canadian undergraduates and graduates who go to the United States for further study. The problem here is how to get them back to Canada after they have completed their studies. Efforts are now being made to prepare lists of such persons and it is hoped that the Department of Labour may keep in touch with them through their national register and offer them encouragement to return to their native land.

It was agreed by the three Institutes that they would supply the Department with the names of their young members who made the Institutes aware of their transfer to the United States. In many instances these young men send in a change of address, in other instances they ask for the privilege of paying students' fees only while they are at college and in some cases they offer their resignation. It was felt that if this information were passed to Ottawa, close contact could be maintained with them, which may be influential in preventing their loss to the United States.

Survey of 1956 Needs

A. M. Sargent presented a report in the 1956 survey of needs of industry for professional workers. There were some startling figures and graphs but the group were informed that this whole report was still confidential and permission was not given to publish any or all of it at the moment. Suffice it to say that the demands for the future are substantial and there is every indication that there is nothing that anybody can do in this country that will develop a supply of engineers sufficient to meet the needs.

The enrolment in engineering this year is greatly increased over last year, but it will be between four and five years before this effect is felt and even then it is expected that the demands will have increased to such an extent that the additional supply will still fall short of the requirements.

The work of the Advisory Committee is extremely interesting. To some extent this group is similar to the Advisory Board established during the war as part of the Wartime Bureau of Technical Personnel. The register which is now maintained also is an outcome of that same effort. Members will recall that registration was compulsory during the war and that the Wartime Bureau of Technical Personnel was manned almost entirely by engineers, the director being E. M. Little, M.E.I.C., and the assistant director being L. Austin Wright, the general secretary of the Institute. The records set up at that time are the basis of the present registration.

Elections and Transfers

At the meeting of council held at Montreal, December 8, 1956, a number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected.

MEMBERS

R. Baldur, Montreal; J. J. E. Barcelo, Montreal; J. R. Crerar, Leamington; H. A. Delcellier, Ottawa; J. A. Desbaillets, Montreal; G. Finnie, Montreal; G. N. Fisher, Montreal; R. G. Griffith, Montreal; E. R. Gustafson, Fort William; R. E. Hughes, Montreal; E. Kraulis, Toronto; C. Langlois, Sherbrooke.

D. C. Musgrave, Ottawa; R. D. Mutch, Montreal; L. K. Narod, Vancouver; J. Norman, Montreal; C. G. Poulton, Three Rivers; A. Poumbouras, Sherbrooke; J. J. Russo, Montreal; D. M. C. Saunders, Whitehorse; G. N. Sheetikoff, Hamilton; J. Soare, Montreal; C. E. Stockman, Toronto; H. B. Tryhorn, Toronto.

FOR ADMISSION AS JUNIOR

R. H. Baylis, Montreal; P. Epp, Calgary; J. R. Griffin, Whitehorse; G. Heroux, Brownsburg; J. S. Howard, Montreal; D. M. Johnson, Hamilton; T. E. Lawson, Montreal; H. P. MacMaster, Arnprior; E. W. Thorne, St. Catharines; A. A. Tsapras, Montreal.

FOR TRANSFER FROM JUNIOR TO MEMBER

C. R. Baker, Washington; R. Burns, Montreal; M. J. Coady, Whitehorse; A. G. Hyde, Montreal; A. F. Joplin, Revelstoke; W. G. Mayberry, Galt; H. J. T. Patterson, Beaconsfield; D. W. Stairs, Kenogami; S. Thomson, Whitehorse; L. Trudel, Charlesbourg; D. Zavitzianos, Toronto.

FOR TRANSFER FROM STUDENT TO JUNIOR

P. T. Beauchemin, Montreal; D. C. J. H. Meredith, Scotland.

THE FOLLOWING STUDENTS WERE ADMITTED:

McGill University

J. A. R. Abbott, P. N. S. Annand, J. G. Anthopouloj, D. G. Barclay, P. Y. Beauparlant, N. M. Benoit, C. H. Bergstrom, O. Bernaus, A. G. Bible, G. Y. Bloomstone, S. R. Borenstein, W. H. Borlase, J. J. A. Boutin, K. R. Bradley, R. C. Brereton, I. R. Brunet, L. D. Burpee, D. H. Bush, G. C. Campbell, D. T. W. Chin, H. W. Clarke, H. A. Condy, C. S. Cook, J. Corej, R. Cross, B. A. Culham, E. A. Dainius, R. F. Darlington, E. J. Derome, J. R. Derome, G. M. Desjardins, E. Deskin, M. O. Diorio, E. Di Salvo, L. A. Donolo, D. A. Dorrance, G. Drupals, J. T. Dunn, A. Economides, W. H. Ellis, J. G. Feltrin, R. Foisy, J. Fong, W. Friedlander, D. B. Galuga, T. Gertin, A. Giannetti, R. F. Gosine, H. G. Griffith, D. E. Guitton, A. Haddad, G. S. Hamilton, N. Handiak, O. Hawaleshka, K. A. Henderson, D. I. Hughes.

C. F. Judson, H. W. Katz, D. J. Keenan, E. Keller, E. B. Kenwood, E. A. Kersulis, E. Kolankowsky, D. P. Komery, E. Konigsberg, R. Korol, K. Y. Kwong, Y. Kyssa, J. P. Laberge, R. Lajzerowicz, A. I. E. Lapin, R. A. Lapinas, A. E. Lapointe, M. A. LeBlanc, R. Lee, C. G. Leger, D. M. Lewis, A. L. Lippay, A. I. MacDougall, J. D. MacIntosh, T. Matsushita, J. Mazutis, P. Mermelstein, J. A. Michaud, G. E. Milburn, N. C. Morantz, L. P. Morey, M. Morin, S. E. Muir, W. E. Muir, F. J. Muszynski, J. G. Nault, R. C. Neapole, I. M. Nitkin, R. A. C. Noel, E. Norak, B. L. Novak.

S. P. Olsen, G. L. G. Oulton, G. Pajuk, V. Paulius, F. S. Philpott, A. B. Pusarauskas, F. J. Raimondo, J. P. Richard, C. S. Robertson, G. W. Ross, H. S. Rothman, F. Rousseau, M. Rozen, A. F. A. Ryan, J. P. Safford, V. Schecter, M. Schneerer, H. H. Schwartz, J. A. Sebastyan, B. M. Segal, D. J. Shlien, R. A. Simons, O. M. Skorzewski, R. P. Smithers, K. Soosaar, B. Sowinski, J. W. Storr, L. Strucchelli, C. K. Tanaka, R. Tanaka, J. N. Tilley, P. Tondi, B. Toporowski P. Tzimas, E. Vernigora, J. J. Wallace, D. G. Wallwork, M. Wein, R. A. Westoby, D. A. Wheeler, C. F. White, M. A. Wolanyk, Jr., H. Wong, D. T. Yamadka, R. E. Young.

Nova Scotia Technical College

H. K. Beatty, G. H. Brennan, K. D. Coleman, H. T. Doane, G. K. Fleming, B. S. Fulmore, R. L. Fulton, R. S. Giffin, M. A. Ibrahim, T. L. Jeary, J. J. A. Lefebvre, R. L. Neil, F. L. Rhyns, D. A. Seamone, C. L. Sherman, W. G. S. Smith, S. R. Stephenson.

University of Toronto

P. M. Anderson, H. Balodis, W. T. A. Beardwood, Jr., P. L. Beck, D. J. Beesley, D. A. Elliott, M. D. Freedman, Y. T. Huang, J. Kruus, A. B. Redekopp, E. J. Schiller, J. P. Stewart, D. Vidinsh (Miss).

University of British Columbia

W. M. Calderwood, J. D. N. Cheeke, G. L. Clements, W. J. P. Crawford, G. R. Douglas, R. E. Elcox, E. A. Lund, N. W. Fletcher, M. Sydor, K. G. VanSacker, J. P. West, G. T. Wong.

University of New Brunswick

J. R. Ainsworth, A. S. Blanchard, R. M. Chiasson, B. R. H. Kishbaugh, J. M. Lowe, G. C. MacTavish, E. Motluk, A. N. Olyarchuk, W. G. Paterson, L. O. Pertus, R. G. Scott.

University of Alberta

I. H. Anderson, P. N. Balko, J. A. Brown, C. N. Ellert, G. C. Fuerst, O. J. Hahn, P. Kupin, J. P. O'Dwyer, D. J. Pawluk, B. H. Schultz.

McMaster University

H. Cipywnyk, A. E. Kozak.

Laval University

J. C. M. Lagace, J. D. Provencher, J. R. LaHaye.

Mount Allison University

E. H. Gilroy, W. T. Hopkins.

Royal Military College

J. M. Lebel.

Queen's University

R. Priolo.

University of Illinois

G. Eng.

Graduates

Geo. T. Harrap, B.Sc. (Chem.), Toronto, 1956; A. Opstad, B.Sc. (Elec.), Alberta, 1956; V. M. Cossette, B.Eng. (Civil), McGill 1956; B. W. Little, B.Eng. (Mech.), McGill 1956.

Ecole Polytechnique

THIRTY-FIVE YEARS AGO

Comment on the Journal of January, 1922

Thirty - five years is half man's Scriptural life span; much can happen in it. This is brought to mind by the leading paper in the *Journal* for January, 1922, "General Oil Refining Practice," by C. D. Dean, M.E.I.C. The methods described in this paper would seem pretty crude to any petroleum chemist of today, but presumably they were quite up to date, since they were those of Canada's largest oil company.

Not being particularly interested in the oil industry, even as a speculator in a modest way in the hope of becoming rich overnight, the current ambition of a good many Canadians, this writer is certainly not qualified to discuss in detail the advances in oil technology since 1922. But it will occur to anybody that we are squeezing a great deal more out of crude oil and gas than we used to. Polyethylene plastics, liquid gases and by-product sulphur come to mind as comparatively new products in this field.

Speaking of natural gas, Dr. J. A. L. Henderson advised the Moncton Branch against using it for space heating "on account of waste". How many billions of cubic feet of natural gas do you suppose were used for just this purpose in 1956? The figures are not at hand, but must be astronomical.

W. P. Dobson, M.E.I.C., had a paper in this *Journal* dealing with electrical standardizing and inspection as carried out by the Hydro-Electric Power Commission of Ontario. And P. E . Biggar, S.E.I.C., wrote on "The Aeroplane Engine", an excellent paper, as true within its limits today as it was when written. Of course, there is no reference to jet or turbojet engines. The lightest of Biggar's engines was the 450-hp. Bristol Jupiter, which weighed 1.74 lb/hp.

Man's memory is short. A note in this *Journal* reminds the writer that he addressed the Montreal Section of the Society of Chemical Industry in late 1921 on a topic in which he was then interested. If it were not for the black and white evidence of this note, he would say that he never did any such thing.

Three members advertised that they were seeking employment, one at $160 per month, and Civil Service had a mining engineering job open at $2100-$2580 per year, about forty per cent of today's scale.

The Officers

J. G. Sullivan, M.E.I.C., of Winnipeg, was the president-elect to be inducted at the annual meeting in Montreal on January 24 and 25, 1922. He had also just been re-elected an alderman of his city. J. M. R. Fairbairn, M.E.I.C., the sitting president, had recently received "an engrossed memento" from the American Railway Engineering Association as a token of appreciation for courtesies extended to the A.R.E.A. during its Montreal meeting of July, 1921.

The agitation over registration seems pretty much to have subsided. There is only a single editorial reference to it in this number of the *Journal* and that quoted from *The Electrician* of London, to some extent questioning its advantages. This quotation must have given quite a fillip to the morale of a substantial number of Canadian engineers who were still not as enthusiastic about the value of registration as were the more vocal proponents of the scheme.

The Winnipeg Branch offered the conclusions of its Committee on Foundations in this *Journal*, which were that there was no uniformity in foundation conditions in Winnipeg, not even very locally. A soil load of 4,000 lb/sq. ft. was recommended as a general maximum, though it was admitted that some buildings had shown no distress at loadings as great as 7,000 lb./sq. ft.

The Lethbridge Branch announced its organization as of December 3, 1921, with S. G. Porter, M.E.I.C., as chairman, C. M. Arnold, M.E.I.C., as secretary-treasurer, and G. N. Houston, M.E.I.C., C. D. MacKintosh, M.E.I.C., and H. W. Meech, A.M.E.I.C., as members of the executive committee.

The city engineer of Peterborough, R. H. Parsons, M.E.I.C., and the Ontario Department of Health were at odds over the type of sewage disposal plant which should be built by the city, so the local Branch expressed its confidence in Mr. Parsons in a resolution published in this *Journal*. It would be interesting to know who won he argument.

Among the thirty-eight applicants for admission to the *Institute* or for promotion to a higher grade, onlv a bare dozen are still members. Thus doth time efface us all.

R. DeL. F.

Elections and Transfers

(Continued from page 54)

G. Martel, R. M. Martin, J. R. G. Martineau, D. Martinoli, R. Martinoli, Y. Masse, C. Melancon, G. Mercier, J. D. M. Morin, L. J. R. G. Morin, G. Neron.

J. G. Niquette, A. Paquette, G. Paquette, F. Paquin, M. Parise, A. Payette, A. C. Pellerin, R. Pelletier, A. R. Penelle, Y. H. Picard, Y. Pichette, A. Placas, R. Plouffe, G. Proulx, J. A. J. Plourde, R. Poirier, R. G. J. Pronovost, R. Provencher, J. E. G. Prud'Homme, C. Racine, J. G. Rene, J. Richard, J. L. J. P. Riel, C. Riendeau, Y. Rivest, F. Roberge, J. P. Y. Rouette, J. M. Roussel, J. C. Roy, J. J. Roy, G. Sauve, G. Scott, J. P. Senay, J. P. Simard, J. Tellier, R. C. Terreault, J. C. Tetreault, D. Tremblay, J. G. Theriault, F. Toutant, D. Tremblay, J. C. Tremblay, C. Tupinier, J. C. S. Trudeau, L. Valiquette.

Applications Through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Junior—I. D. Finnan.

Junior to Member—R. B. Kerr, A. L. Stirling.

Student to Junior—D. E. Lee.

SASKATCHEWAN

Members

R. A. Collie, V. L. Moore, J. W. Stevenson, L. F. Swann, J. I. M. Wells.

Students

L. N. Adamache, R. A. Anderson, J. P. Baker, W. M. Beard, M. J. Belak, R. M. Book, G. A. Bowman, R. C. Brewer, R. K. Broeder, J. R. Brooks, C. G. Burns, M. Chorney, M. F. Clark, G. A. Cork, G. F. Cox, S. Dzuba, C. D. Fairburn, F. D. Friedrich, G. G. Galbraith, D. V. Gilewich, R. M. Girling, R. J. Gotts, V. J. Gross, M. M. Hawrysh, E. D. Hoffman, R. C. Holfeld, E. P. Horton, T. E. Huta, D. W. Johnson.

J. A. Kavanagh, H. Keller, R. G. Kessler, N. L. King, G. A. Koss, S. B. Kowalski, A. W. Kruger, R. W. Kyle, R. G. Lloyd, W. D. McKay, W. B. McLean, J. P. Melin, D. A. Meneley, G. Meyrink, J. Molchan, D. E. O'Leary, K. C. G. Pritchard, E. A. Rindt, J. H. Roddick, J. R. S. Sadler, R. B. Snyder, E. L. Steacy, J. J. Syrnyk, R. N. Thompson, A. T. Torgrimson, A. M. Toth, I. S. Turnbull, C. C. Vallance, R. J. Wieser, D. M. Wilson, E. Wiwchar.

Junior to Member—L. S. R. Ely, G. T. Haig.

Student to Junior—J. M. McNeil, K. H. Thompson.

MANITOBA

Member—J. G. Johnson.

Student to Junior—D. D. Elliott.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

Employers of Engineers

Bell Telephone Company of Canada is the largest employer of professional engineers practising in the province of Quebec; as of November 9, 1956, there were 244 P.Eng.'s in Bell's employ in Quebec. Other important employers of Quebec professional engineers are: City of Montreal, 219; Northern Electric Company, 209; Aluminum Company of Canada, 172; Hydro-Quebec, 144.

It is worth pointing out that at one time Bell engineers took their interests in their own hands in drawing to the attention of personnel executives that only competent engineers should be given a title of engineer by the Company. The natural and easiest way to determine who is a competent engineer was to make sure that all company engineers holding a position of professional responsibility at the Bell were legally entitled to do so by being registered with the Corporation of Professional Engineers of Quebec.

Of course the same spirit of professionalism and the same consideration for the engineer's exclusive right to his title exists in other firms as well. For instance, both the City of Montreal and the Quebec-Hydro Commission require that any person who wishes to serve them as an engineer should have his qualifications recognized by the Corporation of Professional Engineers of Quebec and be regularly licensed by it.

Shortage of Engineers

When the president, L. Roy, P.Eng., visited with the members of the Lake St. John region in early October, he had this to say about the shortage of engineers: "For some time now, you have heard about the shortage of engineers attributable to the extraordinary industrial boom of our country in general, to say nothing of the present expansion in the province of Quebec in particular. But how long is this shortage of engineers going to last? This is an extremely important and serious question which confronts the profession

Not that the number of engineers we train in this country is negligible; on the contrary, the number of engineering graduates has been growing considerably, year after year. Our neighbors to the south have recorded a similar increase—the number of engineers as compared with labour has soared from a ratio of 1 to 140 in 1940 to a ratio of 1 to 80 today.

At home as well as in the U.S.A., the number of engineers has grown more rapidly than that of labour and the demand for engineers in industry has skyrocketed. Today, the needs in this field are far from satisfied.

However, the situation is not without remedy, provided we manage to take more advantage of some technical talents now being squandered in jobs that are not connected with the engineering profession as such.

Nevertheless, I feel that if we worry about the actual shortage of engineers today we should not worry too much about the future shortage of engineers. Being naturaly inclined to optimism, I agree with the Financial Post editor, Michael Barkway, who said: "For practical purposes, the next five years count more, there will definitely be a serious shortage and these years will count more than perhaps the next ten. By 1960, we shall have in Canada about a quarter of a million more children between fifteen and nineteen. Probably a larger proportion of them will also be going to university. You can then assume a sharp increase in the supply of engineers from 1961 on. Hang on for another five years, and the worst of our troubles should be over.

And it suggests a word of warning to the young. Shortage in the next few years and the high rates of pay which it causes could go on tempting an increasing proportion of lads to take an engineering courses. So it is by no means impossible that engineers might be in over supply in the 1960's.

It would be a very short-sighted policy on the part of our youth to envisage the problem with only remuneration in view. The real problem is that of training engineers so as to satisfy the demand and to keep abreast of the expanding Canadian industry.

ONTARIO

Engineers in the News

E. Gordon Murphy has been made general sales manager, industrial products with the Linde Air Products Company, Division of Union Carbide Canada Ltd., with the responsibility for all direct user sales of Linde gases, electric and gas welding equipment and supplies. **F. L. Neuman**, has been named general sales manager, special products, covering marketing activities on Union Carbide silicones and Linde crystal products, molecular sieves, rare gases and flame plating.

Robert J. Anderson becomes manager, engineering and sales service with full responsibility for sales engineering and for the operation of Linde sales offices and warehouses, forming part of a staff realignment program of Linde Air Products Company, Toronto. A University of Toronto graduate in electrical engineering, he has for some years held the post of manager, engineering services, for the company. **Richard A. Schmidt** likewise becomes manager, production, with full responsibility for the operation of Linde's eighteen manufacturing establishments across Canada. Mr. Schmidt is a graduate of the University of Notre Dame in chemical engineering and has recently held the position of general superintendent of the organization.

G. E. Lindsay has been made sales manager of the Exide industrial division of Electric Storage Battery Company (Canada) Ltd.

The Exide industrial division will continue to manufacture in its present location on Warden Ave., Scarboro, Toronto, with general offices at 153 Dufferin St., Toronto.

C. E. Marshall has been appointed staff engineer of Automatic Electric Sales (Canada) Ltd., Brockville, Ont. Formerly supervisor of equipment engineering, Mr. Marshall has had wide experience in the design and layout of automatic telephone exchanges and switching systems in Canada. In his new position he will be engaged in field engineering service and will be available for consultation and technical assistance to independent telephone systems.

Bertram A. Wilson has acquired the control of J. A. Wilson Lighting and Display Incorporated of Buffalo, N.Y., and likewise has become its president and general manager.

Dr. A. J. Paszyc has resigned his appointment with H. A. Simons Ltd., consulting engineer of Vancouver, B.C., and has accepted the position of project manager with Ralph M. Parsons Company, 617 South Olive St., Los Angeles 14, Cal.

J. Carl Wilson has acquired control of J. A. Wilson Lighting and Display Ltd., Toronto and becomes president and general manager.

J. R. McGovern has been elected to the position of managing director of Sola Electric (Canada) Ltd., 102 Laird Drive, Toronto 17, Ont. This is a newly formed subsidiary of Sola Electric Co., Chicago, and will market fluorescent lighting ballasts, mercury vapor lamp transformers, dc power supplies, constant voltage transformers and other specialty transformer products.

A graduate in electrical engineering of McGill, Mr. McGovern has been associated with the specialty transformer field in Canada and for the past two years has been district sales engineer for the Sola Electric Company.

J. J. Harris and **C. J. Jamieson** have announced the formation of the firm of Harris and Jamieson, mining consultants. The head office is located at 537 Craig St. West, Montreal, Que., and a branch at Chibougamau, Que., in the Perraylt Building.

W. R. Petri has left the employ of Magor Aviation, Galt, and is now practicing as a consulting engineer in the spheres of aviation, aerodynamics, hydrodynamics, stress analyses, vibration problems and other branches of mechanical engineering.

Mr. Petri has offices at Magor Aviation, Argyle Rd., Galt, Ont., and at 250 King St. North, Waterloo, Ont.

Dr. Maurice Adelman has joined the faculty of Assumption University of Windsor, Ont., as associate professor of chemistry of Essex College.

Dr. Adelman was born in Welland, Ont., and later in 1937 obtained his B.A.Sc. degree in chemical engineering at the University of Toronto. Remaining at Toronto for post-graduate studies he was awarded his Master's degree in 1940 and his Ph.D. in 1946. During the period 1937-45 he was a demonstrator and instructor in the department of chemical engineering.

For the past nine years Dr. Adelman has conducted his own business as a consulting chemical engineer under the name "Starkman Analytical Laboratories". Last year the firm's name was changed to "Adelco Laboratories". Apart from his consulting work he has published articles of a general scientific nature as well as some devoted to chemical research in technical journals. He has also developed several patents.

J. H. Bleaney is employed in the engineering department of the Township of North York as roads engineer.

Hugo Vajk, Jr. is resigning from his position of assistant to the president of Standard Iron and Steel Works Ltd., Toronto, to move to New York, to join the Joy Manufacturing Co. Export, 60 East 56th. St., New York 22.

W. Alex Shaw, chief engineer of the hydro division, The Windsor Utilities Commission, Windsor, Ont., retired on November 1, after thirty-six years' service with Hydro in Windsor. He is now living in Clearwater, Fla.

Mr. Shaw obtained his degree in engineering from Queen's University, Kingston, in 1921, his course being broken by service during World War I. He joined the Windsor Hydro in May, 1920.

C. S. Purser of the Department of Transport of Canada, has moved to St. Catharines, Ont., where he is assistant superintending engineer, Welland Canal.

Charles H. Gerenraich of St. Thomas, Ont., has been elected president of the Kiwanis Club of that city. G. Duncan Black, has been appointed to the executive of the same organization for 1957.

Donald C. Redpath has moved to Boston, Mass., where he is employed with the research and advanced development division of Avco Manufacturing Corp., 750 Commonwealth Ave.

David H. Clegg, formerly with the DuPont Co. of Canada Ltd. in Montreal, is now a process engineer at the Port Alice, B.C., mill of the Alaska Pine and Cellulose Co. Ltd.

D'Arcy B. G. Dutton has succeeded Ernest E. W. Oke, as city engineer of Waterloo, Ont. While Mr. Oke has retired from his city engineer's responsibilities, he is continuing in consulting and advisory work.

Mr. Dutton graduated in civil engineering from the University of Manitoba in 1949 and for the three ensuing years was a field engineer in the engineering department of Port Arthur, Ont. In 1952 he was appointed assistant township engineer for the Township of Etobicoke, Ont. and a little over a year ago he moved to the Waterloo engineering department, first serving as assistant city engineer and since last April as deputy city engineer.

Harvey F. Hurlbut has moved from London, Ont. to Manitoba where he is the assistant brewmaster of The Kiewel Brewing Co. Ltd. in St. Boniface, Man.

Donald Blackburn of Martin Paper Products Ltd., a subsidiary of the Powell River Company, has been appointed to the head office staff as director of production. He was formerly production manager at the company's Winnipeg plant.

Mr. Blackburn, who graduated in 1948 in engineering and business from the University of Toronto, was in the management consulting field before entering the corrugated paper box industry in 1953.

P. C. Toft, who was previously on the engineering staff of Imperial Oil Ltd., at Sarnia, Ont., is employed with the Canadian General Electric Co. Ltd., Peterboro, Ont., in the atomic power department.

D. E. McGregor and **C. E. Beynon** inform us that the firm of McGregor and Beynon Ltd., consulting engineers, have moved to new and larger premises at 2510 Yonge Street, Toronto 12, Ont. The telephone number is HUdson 1-5688.

Norman F. Parkinson will retire at the end of this year, as executive director of the Ontario Mining Association and the Mines Accident Prevention Association, which offices he has held since 1942. He is taking up residence in Victoria, B.C.

In referring to the retirement, M. L. Urquhart, president of the Ontario Mining Association stated: "We in the mining business in Ontario feel a great sense of loss through Mr. Parkinson's well-earned retirement. He has made an extraordinary contribution to the industry and to Canada as a whole."

Mr. Parkinson graduated in engineering from the University of Toronto. Following service with the Canadian Field Artillery in World War I, he became director of Veteran's Training in 1919 and the next year was appointed deputy minister of the Department of Soldiers' Civil Re-establishment. In 1927 he resigned his post to supplement his Master's degree in civil engineering with geological studies. Until assuming his recent position with O.M.A., he was engaged in the mining field, being the first secretary-treasurer of Ventures Ltd., and holding offices and directorates in a number of other companies, including Falconbridge Nickel and Fahralloy Canada Ltd.

Hudson Mossop, formerly chief engineer of the Sterling Electrical Company Limited, St. Catharines, Ont., has been appointed vice-president and general manager of the company. He is also a graduate of the University of Toronto, class of 1949.

E. L. Dodington has been named president of the Sterling Electrical Company Limited, St. Catharines, Ont. Previously vice-president and general manager, he is a 1938 graduate of the University of Toronto.

John Beattie, manager of Delnite Mines Ltd., Timmins, Ont., has resigned this position to take up the duties of executive director of the Ontario Mining Association, Toronto. He succeeds Norman F. Parkinson, who retires from the post December 31, 1956.

Mr. Beattie obtained his B.A.Sc. in

mining engineering at the University of Toronto in 1924 and in the following year was awarded his Master's degree. In 1925 he joined McIntyre-Porcupine Mines, subsequently becoming manager of Delnite Mines with which he has been connected for a number of years.

Eber A. Pollard, assistant chief engineer of Federal Wire and Cable Company Limited, Guelph, Ont., has been appointed chief engineer in place of R. G. Oldham, now in England.

Mr. Pollard is a graduate in engineering physics of the University of Saskatchewan and following his graduation in 1941 worked for the National Research Council, first at the University of Toronto in conjunction with the RCAF on equipment for high altitude flying, and later in Montreal on the atomic energy project. In 1945 he joined the engineering research department of the Massey-Harris Co., and later transferred to the engineering department where he became assistant to the chief engineer, tractor section. In 1950 he joined Federal Wire and Cable.

A. V. W. Stenson, is now employed as an electrical engineer in the Directorate of Engineer Development, Department of National Defence, Elgin Annex, Elgin Street, Ottawa, Ont.

W. J. Fletcher, has resigned from his position as electrical design engineer with the Canadian General Electric Company Limited, to assume the post of chief engineer of the power equipment development section on the staff of the electrical engineer-in-chief, Royal Canadian Navy, Ottawa, Ont.

R. M. Gair, of the British American Oil Co., Ltd., is now a process engineer in the manufacturing engineering department of the company at 800 Bay Street, Toronto.

BRITISH COLUMBIA

Association's Annual Meeting

A record number of newly registered engineers, eighty-five in all, were presented with certificates at this year's annual meeting of the Association of Professional Engineers of B.C., held at the Hotel Vancouver, November 30 and December 1.

In addition, two professional engineers received Life memberships in the Association and a number of special prizes and awards were made to engineering pupils. The presentations took place at the Association's annual awards luncheon on Friday, November 30.

Seventeen Victoria engineers were also eligible for certificates of registration and one for Life Membership. Presentations to these members was made at the annual meeting of the Victoria branch of the Association, held November 22.

Guest speaker at the two-day annual meeting of the Association was Paul H. Robbins of Washington, D.C., executive director of the National Society of Professional Engineers in the United States. Widely known throughout Canada and the United States as a capable, interesting speaker, Mr. Robbins was able to draw upon a long and varied engineering career for material. He addressed a luncheon meeting Saturday, 1 December.

Life memberships will be presented to R. T. Blair, Vancouver, and E. H. Orser, Vancouver, at the awards luncheon. Winners of the Ingleow prize awards, announced earlier this year, will be introduced at the meeting. The awards presented annually to the outstanding student in each year of the engineering courses at U.B.C., were won by Kenneth Charles Wilson, Todd Garrett, and George Alexander Wilson, all of Vancouver. The fourth winner, J. J. F. Loewen of Vancouver is attending Harvard University and will be unable to attend the meeting.

Winners of the annual Association of Professional Engineers of B.C. book prizes, presented each year to the third year U.B.C. engineering students writing the best summer essay in each branch, was presented at the meeting. They are Egon J. P. Matzen, Vancouver, (Chemical); Gary S. Grais, Vancouver, (Civil); Malcolm M. McKenzie, Vancouver, (Electrical); Gordon Mah, Vancouver, (Mechanical); and George C. Wooton, Vancouver, (Metallurgy).

The Association's new executive, elected during the convention, were installed on Saturday evening at the close of the convention. Following the final session, members and their wives attended a dinner dance in the hotel ballroom. Music was supplied by Dal Richards.

Engineers in the News

R. C. Pybus, has been named president and general manager of Commonwealth Construction Co. Mr. Pybus, who had been director and Western manager of the company, was also recently elected vice-president of the Canadian Chamber of Commerce.

F. J. Dwyer has joined the Vancouver Branch of Canadian Johns-Manville Co. Ltd. in a sales capacity to serve the plumbing and heating trade. Mr. Dwyer was previously with Blain Boiler Works as sales manager.

J. S. Kendrick of the Aluminum Co. of Canada, has returned from Montreal and has taken up residence at Kitimat.

Eric Anderson, previously with the B.C. Engineering Co., is now with the B.C. Power Commission in Victoria.

J. A. Eddleston, formerly residing in North Vancouver, is now in Kelowna with Kelowna Bridge Contractors Ltd.

R. C. B. Henderson has resigned his post with the Aluminum Company of Canada and has taken a position as senior office engineer with the International Engineering Company of San Francisco. He is presently in East Pakistan on a hydroelectric project.

D. G. Tapley who was with Electric Power & Equipment Ltd. in Vancouver is now in Bellevue, Wash. He is working for the Boeing Airplane Co. at their Renton plant.

L. W. Locke is now employed as an electrical design engineer in the transport division of the Boeing Airplane Co., of Seattle, Washington. Mr. Locke had been in Nanaimo as maintenance engineer with the B.C. Power Commission.

R. J. Pinder recently left the employment of Crown Zellerbach Canada Ltd. at Ocean Falls and is now employed with MacMillan & Bloedel (Alberni) Ltd., Alberni Pulp & Paper Division.

Keith Wallis is now with the B.C. Engineering Co. as supervisor station electrical design. He had been with the consulting firm of Simpson & McGregor.

R. H. Johnston is now with Jeanette Minerals, Santiago, Cuba.

Hugh Coleopy has accepted a position with Canadian Forest Products, Howe Sound Pulp Division, at Port Mellon. Mr. Coleopy was previously with the Gas Production Department, B.C. Electric, in Vancouver.

R. H. Ansley, assistant Pacific manager of Commonwealth Construction Co., was recently appointed a director of the company.

A. R. Shrumm has accepted a job with the Boeing Airplane Co. in Seattle, Washington. He had been in Vancouver working for the Department of Public Works.

A. J. Paszyc recently accepted the position of project manager with Ralph M. Parsons Company of Los Angeles. Dr. Paszyc has been project engineer with H. A. Simons Ltd. in Vancouver.

R. S. Taylor is now with the engineering and board of works departments of the City of Trail. Mr. Taylor, a 1951 civil graduate of U.B.C. relinquished a position in municipal works at Kitimat in order to accept his new appointment.

M. Chercover, previously with J. L. Miller, consulting engineer, is now with Western Canada Steel.

G. F. Winterburn, until recently, with the Bay Co. (B.C.) Ltd., is now mechanical engineer in charge of construction for the Electric Reduction Company of Canada Ltd.

E. H. Tarrant has accepted a position with Canadian Collieries (Dunsmuir)

(Continued on page 63)

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Frederick Percy Shearwood, President, 1934

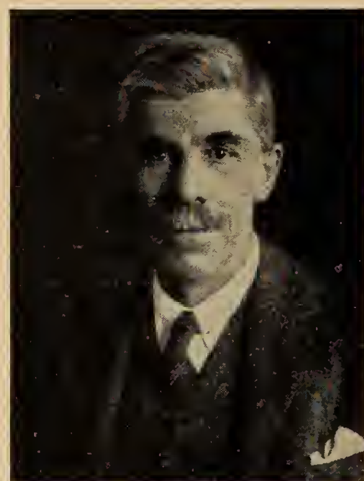
Frederick Percy Shearwood, HON.-M.E.I.C., retired chief engineer with the Dominion Bridge Company Limited, Montreal, and past president of the Institute, died on November 22, 1956, at Montreal.

From London, Eng., he was born there on November 2, 1866. After an engineering education received through private tuition, he went to Brazil in 1884 to work as a junior engineer for the Sao Paulo Railway Company. Three years later, in 1887, he came to Canada to begin his long and noteworthy career in this country, with Dominion Bridge Company Limited, Lachine, Que. Appointed chief engineer in 1921, he became a consulting engineer with the firm in 1937. Finally, in 1948, he retired from active professional duties.

Widely known in engineering circles for his part in the design and erection of a number of the important bridges and other structures in Canada, in 1955 he was, in his ninetieth year, awarded the Gzowski medal of the Institute for the best paper of the year on a civil engineering subject. He was a 1935 winner of the King's Jubilee Medal.

Memorable as a yachtsman and yacht designer, Mr. Shearwood was associated with G. H. Duggan, M.E.I.C., for ten years in building and racing the boats which brought the Seawanhaka cup to Canada, and for nine years, during the eighteen eighties and nineties, successfully defended that trophy. Adding to his skill in this field as in the field of structural design and erection, Mr. Shearwood was responsible for many other successful yacht designs. He was a life member of the Royal St. Lawrence Yacht Club.

Always an active member of the Institute, he became an Associate Member in 1892 and transferred to member in 1904. Elected to Council in 1909 and again in 1921-23, he was vice-president from 1923 to 1925 and chairman of the finance committee at the same time. Treasurer of the Institute in 1926, he held that office until 1930. He was elected president of the Institute for the year 1934. Honorary membership was conferred on him in 1953. He was a member of the American Society of Civil Engineers, the American Railway Engineering Association and the Corporation of Professional Engineers of Quebec. He also served on various committees of the Canadian Engineering Standards Association.



F. P. Shearwood, Hon. M.E.I.C.

Henry Augustus Dupre, M.E.I.C., retired official of the Electricity and Gas Inspection Department of Trade and Commerce, Ottawa, died in August, 1956.

Born in London, Eng., on September 6, 1877, Mr. Dupre studied civil and mechanical engineering at the Associate City and Guilds of London Institute, which is now London University. He also followed studies in Germany.

Beginning his engineering career in 1901 he was associated with the firm of Armstrong Whitworth and Company, Newcastle on Tyne, where he was in charge of the electrical testing department for a period of five years. He was also engaged for a time in perfecting the auto electric cab signalling system on the Great Central Railway.

In 1913 Mr. Dupre was appointed assistant to the chief engineer with the Department of Inland Revenue, Ottawa. However, he spent the war years overseas, returning to his duties at Ottawa in 1919 in the position of acting assistant director of electricity and gas inspection.

Elected a Member of the Canadian Committee of International Electro-Technical Commissions and the Incandescent Lamp sub-committee of Canadian English Standards Committee in 1920, he was also named assistant director of Electricity and Gas Inspection, with the Department of Trade and Commerce at that time.

Mr. Dupre joined the Institute in 1914 as an Associate Member and transferred to Member in 1920. He attained Life membership in 1944.

Norman Leroi Crosby, M.E.I.C., retired engineer with the Hamilton Bridge Company Limited, died suddenly at Ancaster, Ont., on November 1, 1956.

A maritimer, Mr. Crosby was born at Hebron, N.S., on August 15, 1880. He enrolled in an arts course at Acadia University in 1899 and then went on to a civil engineering course at the School of Practical Science in 1902. He was awarded the degree B.A.Sc. at the University of Toronto in 1906.

Chief draftsman with the Halifax and Eastern Railway on graduation, he had also taken part in the construction of the Halifax and Southwestern Railway and worked with the Dominion Bridge Company while still a student. In 1908 Mr. Crosby went on to design and estimating work for the firm of McClintic-Marshall Construction Company, Pittsburgh. He became associated with the Hamilton Bridge Company in 1923, working as a district representative in Toronto. In his latter years with the firm he had been located at Hamilton and engaged in sales engineering work. Active in the organization for thirty years, Mr. Crosby retired early in 1954.

A Student member of the Institute in 1902, Mr. Crosby was transferred to Associate Membership in 1909 and became a Member of the Institute in 1940. He attained Life membership in 1949.

John Starley Lochhead, M.E.I.C., administrative engineer and director of Racey-MacCallum and Associates Limited, consulting engineers of Montreal, Toronto and Vancouver, died in an automobile accident at Lancaster, Ont., on November 14, 1956.

Born in Montreal on December 26, 1913, he was educated at McGill University where he obtained a B.Eng. degree in civil engineering in 1937. At the beginning of his career employed with Dominion Bridge Company, Montreal, he also had experience with Defence Industries Limited, during the war years, and with Canadian Vickers Limited, aircraft division. He served as a planning engineer with Canadair Limited, Montreal, in 1945.

An independent consultant and manufacturers agent for five years, he was appointed Canadian director of Consulting Designers for Industry, Inc., Cleveland, Ohio, and was also associated with the Montreal firm of McDougall and Friedman as consulting engineer during this period. Later he held the position of sales engineer and special projects engineer for Charles, Warnock and Company Limited.

One of the founders of the firm of Racey, MacCallum and Associates, in 1952, he was elected a director and appointed a vice-president. Until a recent transfer brought him to Montreal, Mr. Lochhead had been responsible for the Vancouver operations of the firm. He then took on the additional duties of administrative engineer, which duties he performed until the time of his death.

Mr. Lochhead was a member of the Association of Professional Engineers of Quebec, Alberta, and British Columbia.

He joined the Institute as a Student member in 1934, transferred to Junior in 1941 and was elected a Member in 1945.

Aurel G. Jarry, M.E.I.C., president of Jarry and Frere Ltee, Montreal, died in Montreal on November 2, 1956.

A native of Montreal, Mr. Jarry was born there on January 11, 1916. He received his engineering training at McGill University, graduating with a B.Eng. degree in civil engineering in 1940. He was also a graduate of the Royal Military College, Kingston, Ont., class of 1938.

Beginning his graduate career as a navigation instructor in the R.C.A.F., in 1940, he later served overseas as a pathfinder navigator in the closing year of the war.

In 1947 Mr. Jarry became co-proprietor, service manager and industrial division manager for the firm of Jarry and Frere, Montreal. His appointment as president was made in May of this year.

A student member of the Institute in 1940, he transferred to Junior in 1943 and became a Member in 1949.

Joseph Henry Hamel, AFFIL.E.I.C., retired president of the Provincial Paint and Supply Company, Montreal, died in Montreal on November 20, 1956.

A native of Quebec City, Que., he was born on November 2, 1887, and received his education at St. Dunstan's University, P.E.I. In 1903 he was awarded a bachelor of arts degree followed by a bachelor of science degree in 1905.

Associated with the Canadian National Railways for the first six years of his career, Mr. Hamel later worked for the Department of Marine and Fisheries, Province of Quebec, for three years. He served with the Canadian Army from 1915 to 1918. The following year he returned to his position with the Province of Quebec. In the ensuing years, until 1936 he was also associated with the C.N.R., at Edmunston, N.B., and with the Quebec Harbour Commission. He joined the Department of National Defence at Valcartier in 1939, and held a position as superintendent and engineer for the Department at Lauzon, Que., in 1941. He served in the same position for E. G. M. Cape and Company of Montreal in 1942 on National Defence work at St. John's, Nfld. In 1945 he held the appointment of engineer and inspector general of the Department of Roads, Province of Quebec.

Mr. Hamel's association with the Provincial Paint and Supply Company, Montreal, dates to 1951. He joined the firm at that time as vice-president and general manager, becoming secretary in 1953 and president of the organization in 1955.

He joined the Institute in 1942.

NEWS OF THE ASSOCIATIONS

(Continued from page 61)

Ltd. Mr. Tarrant had been on the electrical engineering staff of H. A. Simons Ltd.

Dennis Duncan, an engineering pupil, won a Dow Chemical of Canada Scholarship of $500 awarded to a student entering final year of chemical engineering.

J. C. Taylor of Kamloops, an engineering pupil, won the Heavy Construction Scholarship of $250 for civil engineering.

R. F. Heckman, previously with Western Consulting Ltd., is now working with the B.C. Engineering Co. as a designer.

A. P. Martinez, formerly with Cemco Electrical Manufacturing Co. has accepted the position of chief engineer of Johnson & Phillips Ltd., manufacturers and distributors of electrical equipment.

F/O H. P. Burden, now with the R.C.-A.F., has been transferred from Camp Borden to the big armament base at Cold Lake, Alberta.

ALBERTA

Unity — Confederation

Reprinted from "Presidentialities" — in the November issue of The Alberta Professional Engineer.

"The Plan for Unity" and "Confederation" are two phrases that are being discussed by many professional engineers today, both in committee and in any place where two or more of them may meet. All who discuss the proposal appear to be in favour of it as I have yet to hear of one who is not just a little anxious to see it move forward as quickly as possible.

Herbert J. Smith of the Association of Professional Engineers of Ontario, is the author of the "Plan for Unity" as we know it today. The Engineering Institute of Canada refers to the subject as "Confederation". Both titles have been used, in all of the discussions that I have heard, synonymously. You too, may have heard something like this: "Plan for Unity — Confederation? It doesn't matter what you call it you know what we mean. We only wish they would get along with the job. It's been talked about long enough, now let's hear of some action."

It would seem to me that the only thing that all of us are discussing is the desirability of having one Engineering Organization in Canada that would, in short, take over the roles of both Dominion Council and the Engineering Institute. The general way in which this is to be done has not been discussed by many, other than those on the committees set up to do that job.

The two titles have essentially different meanings and suggest to me that two different types of a National Organization could result, depending on which title is accepted. Just which one is decided upon depends on you and I. Hence I believe that we should consider the implications of each title.

Unity among the Professional Engineers of Canada will mean one new National Organization in which the identities of our present bodies will be submerged. The individual organizations would disappear completely in favour of one new one that would carry on all of the phases presently covered, plus any new ones that are possible through such unity. The actual organization is more than likely to be different to any one now existing.

Confederation on the other hand suggests that existing groups will combine into a National Organization while still retaining a great deal of their original identities. The individual organizations might not completely disappear and the various functions would continue much as they do now. Here are examples of the two results. Unity might result in the formation of a new headquarters in Ottawa, staffed by a relatively small group, financed by national fees collected and rebated by the provincial bodies, and responsible for the overall operation of the organization under a national council. A national professional publication might be their responsibility also. The provincial bodies might finance and operate the branches.

Confederation could result in the retention of the present headquarters in Montreal along with the Engineering Journal in its present form, the library and the employment service. Financing of the branches and their control could also remain with it. The national fees would be a larger rebate from the Provincial bodies so that a rebate could be returned to the branches. This larger staff would also be responsible for the operation of the organization under a National Council.

With these two brief examples before you I hope that you will recognize the possibilities in the formation of a National Organization. You may like one or the other, or even perhaps you have no preference. Whether you have a preference or not for either of these examples or for a compromise of the two, I hope only that you will think about the question and discuss it with others so that when you are asked to decide you may know whether you want "Unity" or "Confederation".

Personals

News of the Personal Activities of Members of the Institute.

Dr. R. L. Hearn, M.E.I.C., chairman of the Hydro Electric Power Commission of Ontario, has retired from office. Continuing his service to Hydro as a consultant, however, he intends to establish a private engineering practice.

The long and notable engineering career of Dr. R. L. Hearn began in 1913 when he graduated from the University of Toronto. Briefly with the City of Toronto roads and works department and Dominion Bridge Company Limited, he had by 1921 attained the post of assistant engineer of construction for the Commission, on a hydro-electric power plant. At one time the world's largest, this plant is now known as the Adam Beck-Niagara Generating Station No. 1. Positions with the Washington Power Company, Spokane, as assistant chief engineer, and with the firm of H. G. Acres Company Limited, St. Catharines, Ont., as chief engineer and secretary-treasurer followed, in the nineteen-twenties. During the early period of the next decade he earned the position of consulting engineer for Dominion Construction Company and H. F. McLean Limited and continued as chief engineer with the firms until 1942.

Returning to the Commission in 1942 as an executive assistant to the chairman, his services, in demand elsewhere during the war years, were loaned to the Polymer Corporation's synthetic rubber plant at Sarnia. Chief engineer in charge of construction there, he was later in 1944 asked to serve as Canadian technical advisor to the Public Utilities Division of the Combined Production and Resources Board at Washington, D.C. At war's end, returning to the Commission, he assumed the duties of engineer of design and construction. Named general manager and chief engineer in 1947, his appointment as chairman of the Commission was announced early in 1955.

A member of many technical organizations in Canada, the U.S. and Great Britain, Dr. Hearn was in 1952 appointed a director of Atomic Energy of Canada Limited. Also in 1952 he was awarded an honorary degree of Doctor of Engineering by the University of Toronto. In 1955 the Engineering Institute awarded him the Julian C. Smith Medal for achievement in the development of Canada.

On many occasions openly acclaimed for his contribution to Ontario's publicly owned hydro enterprise and the Canadian engineering field, he was given lasting recognition in 1951 when Canada's largest fuel-electric power plant, the Richard L. Hearn Generating Station, was named in his honour.

In the period of more than forty years since first joining the commission, Dr. Hearn has played a major part in the growth of the organization, with its unprecedented power expansion program, embracing major hydro-electric projects and Canada's largest steam generating installations.

Dr. Hearn joined the Institute in 1920 as an Associate Member.

G. R. Connor, M.E.I.C., and **C. B. Jackson,** M.E.I.C., of Alchem Limited, have been jointly appointed to the position of assistant vice-president. In the service of the company for more than fifteen years, in the field and home office, their most recent positions were those of managers of the industrial and production departments, respectively.

Mr. Connor joined Alchem in 1939, with a B.A.Sc. degree in chemical engineering, gained at the University of Toronto.

Mr. Jackson graduated from the University of Saskatchewan in 1931 with the degree of B.Sc. in civil engineering. He joined the staff of Alchem in 1941 and has since then held positions as district engineer, resident engineer and plant engineer with the organization.

G. R. Connor, M.E.I.C.

C. B. Jackson, M.E.I.C.

J. G. Notman, M.E.I.C., president of Canadair, has recently been elected a director of the Crown Trust Company and has accepted the presidency of the Air Industries and Transport Association. He is senior vice-president of Canadair's parent company, General Dynamics Corporation, New York; chairman of the board of Atlas Copco Canada and S. F. Products Limited; a director of the Canadian Bank of Commerce, Canadian Marconi, Montreal Locomotive Works, Canadian Arsenals Limited, Canadian Industrial Preparedness Association and the Quebec Industrial Relations Institute.

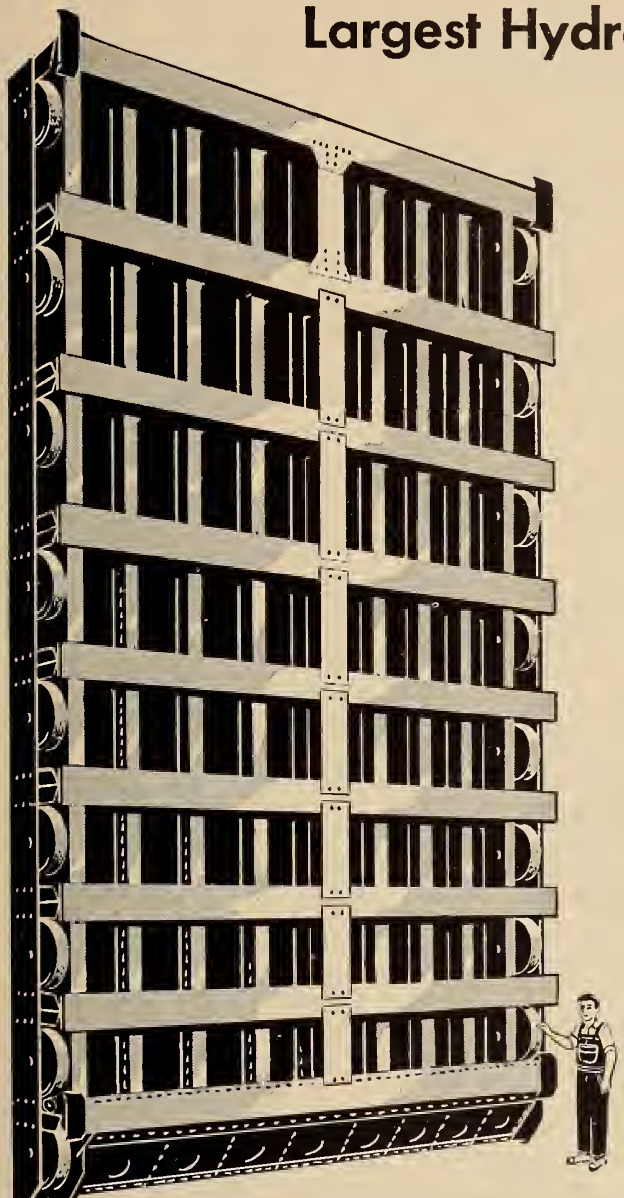
D. B. Steinman, M.E.I.C., consulting engineer, New York City, has been retained by the government of Iraq to design and supervise the construction of a suspension bridge over the Tigris River in Baghdad. It is estimated to cost $5,000,000.

G. A. Cunningham, M.E.I.C., has been named assistant manager of the technical services and transferred to the head office staff of Imperial Oil Limited, Toronto, Ont.

Formerly located at Halifax, N.S., Mr. Cunningham took an active part in the affairs of the Institute, and was chairman of the Halifax Branch at the time of his recent appointment.

W. H. Price, M.E.I.C., formerly assistant general manager of Mid-Western Industrial Gas Limited, Edmonton, has been appointed general manager of the company.

Mr. Price joined Mid-Western in 1952 as chief engineer. He is a graduate in chemical engineering from the University of Alberta in 1949.



Largest Hydraulic Regulating Gate Order Ever Placed in Canada

Illustrated at left is a scale drawing of one of 48 head gates for the Canadian section of the Barnhart Island Power House — a part of the St. Lawrence power project.

These gates comprise the largest order of the kind ever placed in Canada and are now being fabricated for Ontario Hydro. With bedded parts and hoists, they are designed by Dominion Bridge for 17 ft. wide by 37 ft. high openings. Each will withstand a pressure of 3,000,000 lbs. with 93 ft. head at sill.

By its association with most of the large power projects built in Canada, Dominion Bridge has accumulated a wealth of experience, making it a leading authority in this specialized field.

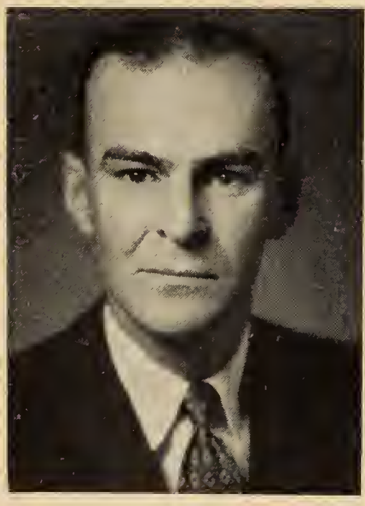
• PERSONALS

S. D. Cavers, M.E.I.C., formerly research engineer with the B.C. Research Council, now holds the position of associate professor of chemical engineering at the University of British Columbia.

Mr. Cavers is a University of British Columbia graduate in chemical engineering, class of 1942. He became employed with the University of Saskatchewan as an associate professor of chemical engineering in 1952.

J. A. Beauchemin, M.E.I.C.



W. H. Beaton, M.E.I.C.

Jules Armand Beauchemin, M.E.I.C., has announced an expansion in the Montreal firm of J. A. Beauchemin and Associates, in the formation of a partnership to include W. H. Beaton, M.E.I.C., H. Lapointe, M.E.I.C., R. O. Beauchemin, M.E.I.C., and P. T. Beauchemin, JR.E.I.C., who will carry on the practice of the consulting engineering firm under the new name of Beauchemin-Beaton-Lapointe.

A past-chairman of the Montreal Branch of the Institute, Mr. Beauchemin is also a past-councillor representing the Montreal Branch, and a past-president of the Alumni Association of Ecole Polytechnique.

W. H. Beaton, M.E.I.C., an associate in J. A. Beauchemin and Associates, consulting engineers of Montreal, has become a partner in the firm, Beauchemin-Beaton-Lapointe.

Mr. Beaton is a graduate in civil engineering of McGill University, class of 1947, and has since been occupied in the consulting field.

H. Lapointe, M.E.I.C., an associate in J. A. Beauchemin and Associates, consulting engineers of Montreal, has become a partner in the firm, renamed Beauchemin-Beaton-Lapointe.

Mr. Lapointe graduated in civil engineering from McGill University in 1951, and has since been occupied on consulting work in the field of municipal engineering.

R. O. Beauchemin, M.E.I.C., of J. A. Beauchemin and Associates, consulting engineers of Montreal, has become a partner in the firm, Beauchemin, Beaton-Lapointe.

Mr. Beauchemin graduated from the Ecole Polytechnique in 1950, and was previously with Canada Cement Company Limited.

P. T. Beauchemin, JR.E.I.C., of J. A. Beauchemin and Associates, consulting engineers of Montreal, has also become a partner in that firm.

A. C. Dalrymple, M.E.I.C., has accepted a position as civil engineer, class II, in the power development division of the B.C. Power Commission, Victoria, B.C.

Earlier this year, Mr. Dalrymple, who is originally from Great Britain, was employed as a structural design engineer with Standard Iron and Engineering Works, Edmonton.

W. W. Brumby, M.E.I.C., has accepted employment with Malartic Gold Fields Limited, at Halet, Que., where his position is that of mechanical and electrical superintendent.

Mr. Brumby was associated with the English Electric Company of Canada Limited at St. Catharines, Ont., for a number of years, and has served the Canadian Westinghouse Company Limited, at Winnipeg, since 1952.

In 1945 Mr. Brumby was a member of the British Admiralty Technical Mission at Ottawa.

Allan W. Gilmour, M.E.I.C., has left the employ of the Powell River Paper Company of Canada and is employed as an electrical engineer with Machinery Designers Incorporated, at Hoquiam, Washington, U.S.A.

An Edinburgh University graduate, class of 1948, Mr. Gilmour was formerly associated with the B.C. Electric Company Limited, at Victoria, B.C. shortly after coming to this country.

Major K. F. Collins, M.E.I.C., has left the appointment of officer commanding, armament company, R.C.E.M.E. school at Barriefield, Ont., and has been appointed general staff officer, grade II, with the directorate of weapons and development, at Army headquarters, Ottawa.

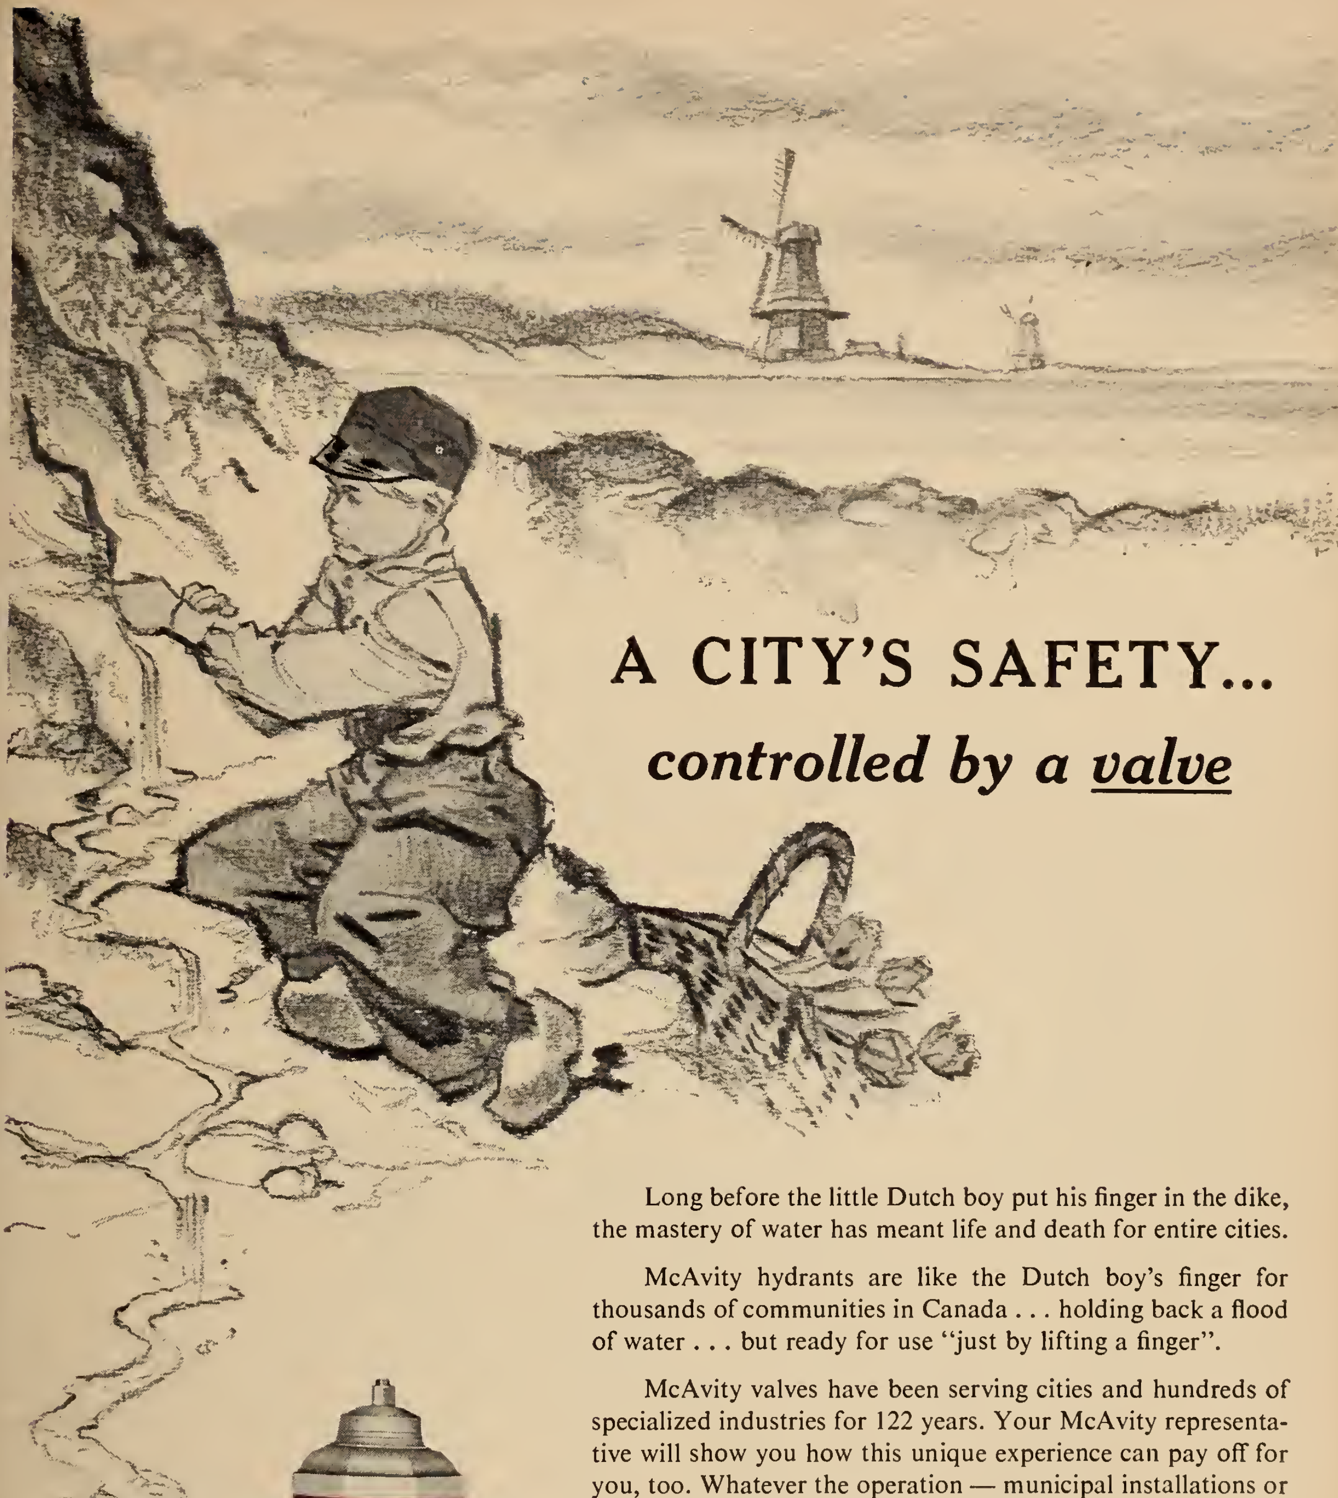
Major Collins is a 1941 graduate of Queen's University, in chemical engineering.

C. T. Aitken, M.E.I.C., has accepted a position with the American Flange and

H. Lapointe, M.E.I.C.

P. T. Beauchemin, JR.E.I.C.

R. O. Beauchemin, M.E.I.C.



Manufacturing Company, Inc., at Linden, N.J.

Mr. Aitken was formerly planning engineer in the special contracts department of the Bell Telephone Company, at Montreal.

L. J. Macdonald, M.E.I.C., of Montreal, superintendent of rolling stock with the Montreal Transportation Commission, Montreal, since 1946, has resigned from office. He has accepted an appointment as general manager of the Ottawa Transportation Commission, Ottawa, Ont.

Beginning his career in Canada at the conclusion of World War II, Mr. Macdonald brought with him sixteen years' experience in the field of mechanical engineering. This includes responsibility with the Corporation Transport of Aberdeen, Scotland, 1930-35, and a period of four years as a supervisor concerned with high speed experiments on road, rail and marine diesel engines, with the Associated Equipment Company, Middlesex, Eng. After six years' war service Mr. Macdonald retired from the R.A.F. with the awards of D.F.C. and Bar, and D.F.M.

W. J. Dyck, M.E.I.C., who was in 1955 at work with the General Petroleum Corporation, Torrance, Calif., has taken a position with Hydrocarbon Research Inc., New York. He will be stationed at Duesseldorf, Germany as project engineer.

With Hydrocarbon Inc., in Germany at an earlier date in his career, in 1952, he has also held positions with the Lummus Company, N.Y., as process engineer and with the British Columbia Research Council, Vancouver, as a chemical engineer.

Mr. Dyck graduated from the University of Saskatchewan, class of 1942.

G. D. Zimmerman, M.E.I.C., has been elected president and general manager of the firm of Fischer and Porter (Canada) Limited, at Toronto.

Previously vice-president and managing director of the company, Mr. Zimmerman joined Fischer and Porter Company of Hatboro, Pennsylvania, in 1946, in the capacity of sales engineer. The following year he opened the first office for the U.S. Company in Montreal, with the subsequent incorporation of the Canadian company in 1949.

Mr. Zimmerman is a graduate of the University of Toronto in chemical engineering.

Larry Murphy, M.E.I.C., distribution engineer with Ferranti Electric Limited, has recently been appointed maritime district manager for the organization.

Mr. Murphy graduated with a B.Eng. degree from the Nova Scotia Technical College in 1949 and after a two-year training course joined the Nova Scotia Light and Power Company, where he held the position of distribution engineer, until joining Ferranti Electric in August 1956.

C. B. R. Macdonald, M.E.I.C., general manager of John Howard and Company (Africa) Limited, building and civil engineering contractors, Lusaka, Northern Rhodesia, has resigned from this appointment and is at present residing at Hindhead, Surrey, England.

Practising engineering for many years in Canada, South America, the West Indies, Europe, and the Middle East, Mr. Macdonald went to Africa several years ago. Within the last ten years he has been associated with Raymond Concrete Pile Company of Venezuela, and with Humphreys Limited, London, at Gibralter, as resident engineer.

He is a graduate of the Royal Military College, Kingston.

D. E. Doxsee, M.E.I.C., of the M. W. Kellogg Company, construction department, has concluded an assignment at Grande Prairie, Alta., and has been transferred to the firm's American parent company as a special studies engineer. He expects to spend a number of months in the United States.

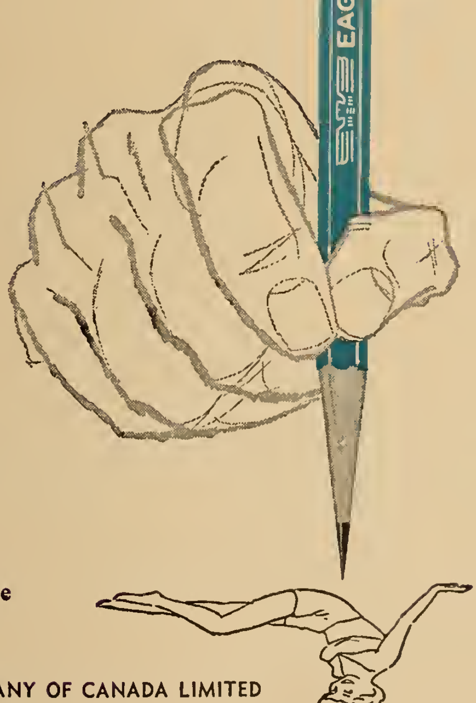
Mr. Doxsee is a mechanical engineering graduate of the University of British Columbia, class of 1951.

W. K. Clawson, M.E.I.C., of the M. M. Dillon and Company, London, Ont., has been transferred to the Toronto office of the firm.

Mr. Clawson has been employed with the company for a number of years.

Turquoise transfers ideas to paper more quickly, clearly, accurately

. . . thanks to 100% *"ELECTRONIC" GRAPHITE



"Electronic" is Eagle's trade name for a blend of crystalline graphites of highest purity, reduced to particles of micronic fineness in our patented Attrition Mill. 100% "Electronic" graphite in every Turquoise lead gives you super-service in four important ways:

Super-Smoothness! Turquoise leads are smoother, faster. No harsh impurities slow your line or scratch the paper.

Super-Strength! Turquoise points don't crumble. The microscopic graphite particles combine with the clay binder to form the strongest, longest-wearing lead structure ever made.

Super-Blackness! Because millions more of super-fine graphite particles are compacted in every inch of its lead, Turquoise deposits denser, blacker, more even lines that reproduce to perfection.

Super-Grading! 17 individual, exactly controlled formulas of "Electronic" graphite and clay make 17 evenly spaced degrees that are uniform from end to end, from lead to lead, from year to year.

He is a 1940 graduate of the University of Toronto in civil engineering, and earlier in his career was associated with the County of Middlesex, Ont., as county engineer and road superintendent, on his return from service with the R.C.E. in World War II.

A. R. Bonnell, M.E.I.C., district engineer for the New Brunswick Department of Public Works, is the 1956-57 choice of the members of the Northern New Brunswick Branch of the Institute for chairman.

Born at Sussex, N.B., Mr. Bonnell received his engineering training at the University of New Brunswick, from which he graduated in civil engineering in 1935.

After five years experience in highway construction with the Province of New Brunswick, Mr. Bonnell, was engaged for another five-year period in oilfield, mining and defence construction in the West Indies.

On his return to Canada he spent eight years as city engineer at Lancaster, N.B.

W. A. Ker, M.E.I.C., has recently established a consulting engineering practice at Victoria, B.C. Formerly deputy comptroller of Water Rights for the Province of British Columbia, he served with the Water Rights Branch in various capacities for the past ten years, gaining experience in the field of water resource investigation and development. He plans to continue in this field, specializing in water supply and hydraulics. Mr. Ker is a graduate in civil engineering from the University of British Columbia, class of 1945. Earlier in his career he was employed by Northern Construction and J. W. Stewart Limited.

He is a past chairman of the Central B.C. Branch of the Institute.

Stanley, Grimble, Roblin Limited

Three E.I.C. members comprise the firm of Stanley, Grimble and Roblin, consulting engineers, of Edmonton.

A. R. Bonnell, M.E.I.C.

W. A. Ker, M.E.I.C.

Donald R. Stanley, M.E.I.C., formerly of the firm of D. R. Stanley and Associates, consulting engineers, Edmonton is a University of Alberta graduate, class of 1940, in civil engineering. In 1952 he obtained a Doctor of Science degree in sanitary engineering from Harvard University.

Dr. Stanley's experience includes two years spent on the hydro-electric power development of the Calgary Power Company, as supervisor of construction, and three and a half years in the R.C.A.F. as an engineering officer. For four years director of the division of sanitary engineering, with the Department of Public Health for the Province of Alberta he was also a member of the Provincial Board of Health, responsible for the approval of plans and specifications for all waterworks and sewage construction in Alberta. Dr. Stanley also held Rockefeller Foundation and Dominion Government Fellowships for post graduate study at Harvard University, conducting research studies on water filtration. Principal member of the firm of Associated Engineering Services Limited, for two years, he was special consultant to the Dominion Provincial Board, Fraser River Basin, on the pollution of the Fraser River.

Louis G. Grimble, M.E.I.C., holds a Master of Science degree from the University of Illinois, in structural engineering, and has had two years experience on bridge design and construction with the United States Federal Bureau of Roads, and two years as a pilot in the R.C.N.V.R. He spent eight years in the service of the Alberta Department of Highways, resigning in 1954 as chief bridge engineer. Since then he has been employed as a construction engineer with Burns and Dutton Concrete and Construction Company.

He is originally a graduate of the University of Alberta in civil engineering.

Herbert L. Roblin, M.E.I.C., councillor representing the Edmonton Branch of the Institute for the current year was associated with the Canadian National and Canadian Pacific Railways for many years. He was engaged in railway location construction work for ten years, and spent thirty years in railway maintenance and operation. He retired from the duties of division engineer at Edmonton in 1955 to become a member of the firm of Hanley, Grimble, Roblin Limited.

H. L. Roblin, M.E.I.C.

D. R. Stanley, M.E.I.C.

L. G. Grimble, M.E.I.C.

Alkylation unit of the new Petrofina Refinery at Pointaux-Trembles, Quebec.

• PERSONALS

A veteran of two World Wars and a graduate of the University of Toronto he served with the Canadian Expeditionary Force during World War I and received the Military Cross. In the more recent conflict he was in command of the 13th Field Company of the R.C.E. at Regina, Sask., retiring in 1945 with the permanent rank of major.

T. Dumas, M.E.I.C., who was formerly associated with the firm of Lawrason's and Company, London, Ont., has accepted employment with the Department of Agriculture, London, Ont., as a research chemist at the science service laboratory.

R. A. de Villers, M.E.I.C., since 1945, president of Lumber Products Manufacturing and Export Company, Princeville, Que., and secretary and general manager of Paul de Villers and Sons Inc., Princeville, has opened a private practice as a consulting engineer at Montreal.

Mr. de Villers graduated from the Ecole Polytechnique in 1942 in civil engineering. Early in his career gaining experience with Canadian Marconi Company, Montreal, he later joined the Canadian National Railways as an assistant engineer in the Bureau of Research. He remained with the company until 1953, resigning as assistant district engineer at Levis, Que.

Bernard D. Wood, M.E.I.C., has left the staff of the University of Manitoba, department of mechanical engineering, and is now associated with Syracuse University in that department.

Mr. Wood obtained an M.A.Sc. degree from the University of Toronto in 1952.

D. R. Bakewell, M.E.I.C., has accepted the appointment of general manager of C. D. Schultz, a firm of engineers, foresters and consultants, with headquarters in Vancouver and Seattle.

Formerly operations manager with the company, Mr. Bakewell has been responsible for all projects undertaken by it since 1952.

He is a forestry engineering graduate of the University of British Columbia, class of 1946.

Robert M. Rice, M.E.I.C., who formerly held the position of industrial sales representative for Imperial Oil Limited, at Sydney, N.S., has been transferred to Halifax. His new position is that of supervisor of the industrial and commercial sales, for the maritimes.

He is a University of Manitoba graduate, class of 1950, in electrical engineering.

John A. Havers, M.E.I.C., has for a number of months been employed at Honolulu, Hawaii. He is with the firm of Harland Bartholomew and Associates, city planners, civil engineers and landscape architects.

Mr. Havers graduated from the University of Saskatchewan in 1947 with a B.Eng. degree in civil engineering, and then went on to Purdue University, Lafayette, Indiana, where he obtained an M.Sc. degree, specializing in soil mechanics, in 1953.

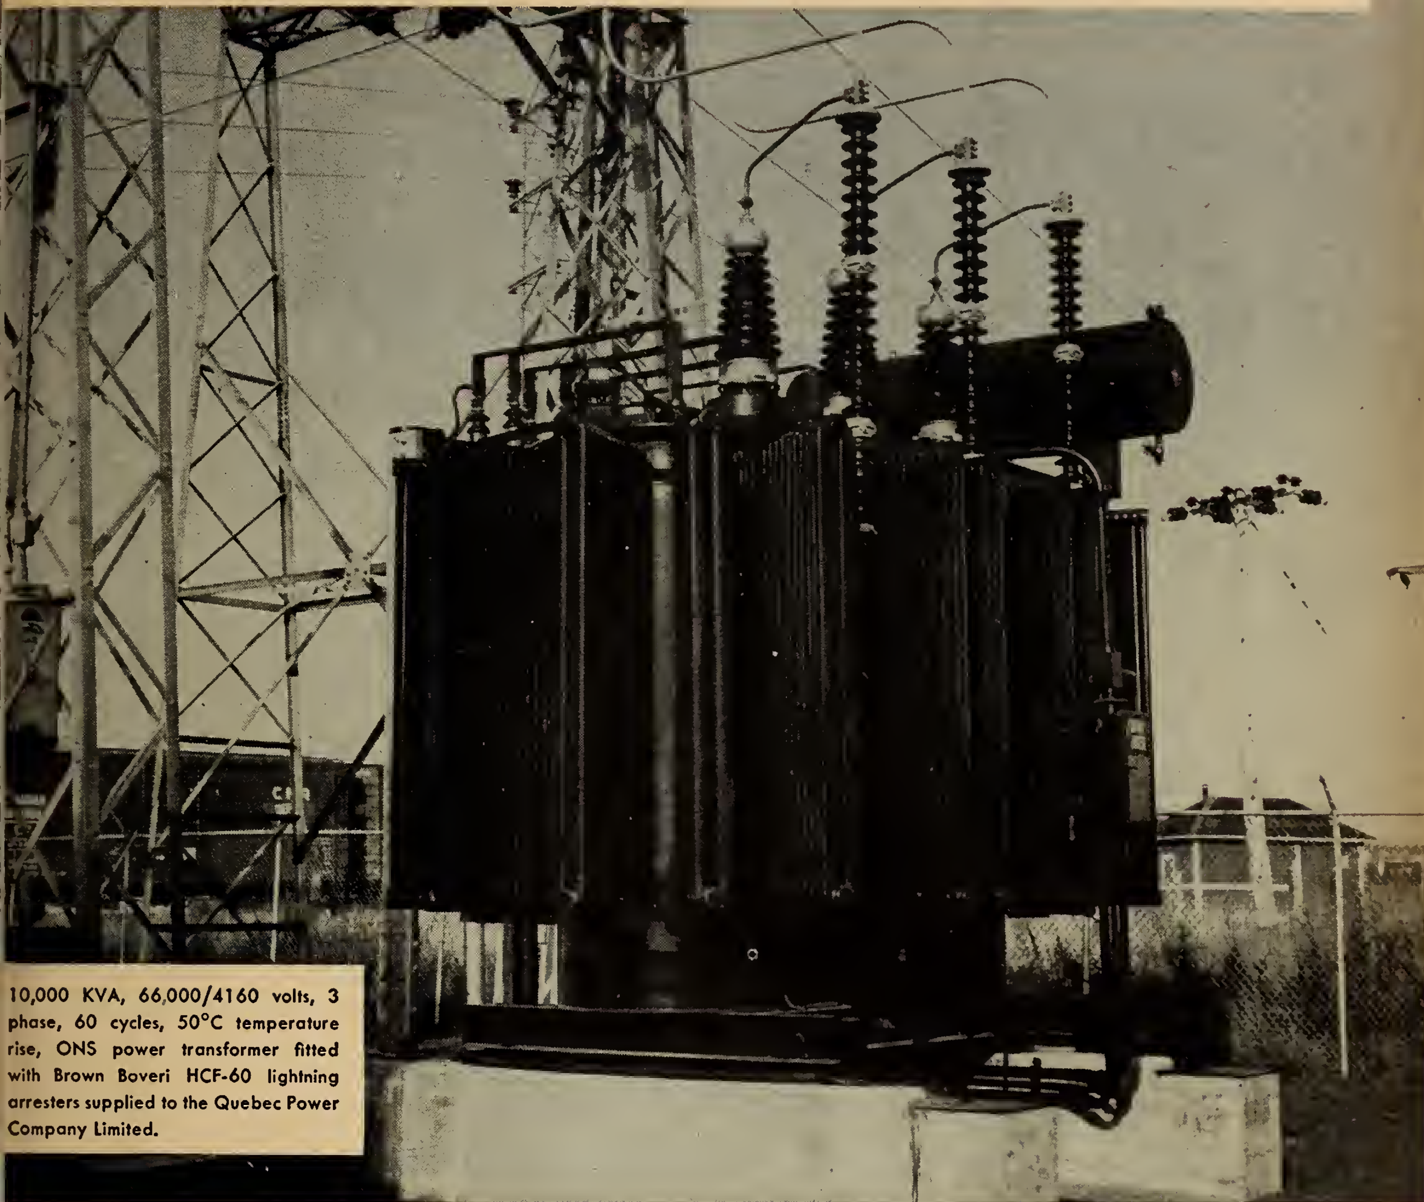
Karl E. Buchmann, M.E.I.C., for eleven years designer and draughtsman for McIntyre Porcupine Mines Limited, Schumacher, Ont., has accepted an appointment as resident engineer for Kilborn Engineering Limited at the Spanish American Mine, Elliot Lake, Ont.

Through the years working for various mining concerns, Mr. Buchmann has, in more recent times been associated with the Normetal Mining Corporation, Toronto, and with the Buffalo Ankerite Mine, South Porcupine, Ont.

He is a University of Toronto graduate.

Merritt M. Davis, M.E.I.C., has joined the staff of the Department of civil engineering of the University of Toronto, as an assistant professor. He is also assistant-director of the joint highway research program of the University of To-

FOR POWER TRANSFORMERS



10,000 KVA, 66,000/4160 volts, 3 phase, 60 cycles, 50°C temperature rise, ONS power transformer fitted with Brown Boveri HCF-60 lightning arresters supplied to the Quebec Power Company Limited.

get a quotation from BROWN BOVERI

There are many advantages to selecting Brown Boveri Power Transformers for new or expanding power system facilities:

* *custom-built, incorporating the latest developments in design and materials*
* *lower losses, smaller size, less oil, lower weights*
* *substantial savings effected in operation, transportation and handling costs*
* *every design backed by sixty years of transformer-manufacturing experience*
* *proved in service with major utilities throughout Canada.*

WRITE FOR BULLETIN C-PT-1

When in Montreal, we will be happy to arrange a visit to our St. Johns Plant to show you the scope of our manufacturing facilities.

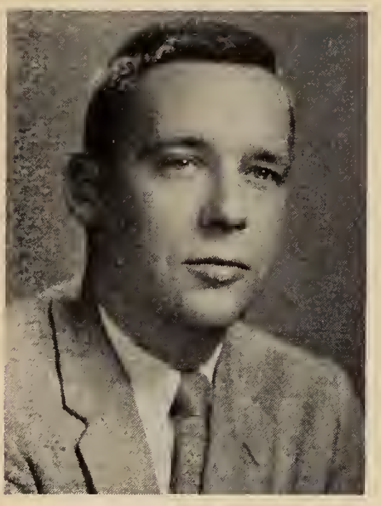
ronto and the Ontario Department of Highways.

Prof. Davis obtained his B.Sc. in civil engineering from Queen's University, Kingston, in 1945, and then served with the Canadian Army in Canada and Europe as a lieutenant. In 1947, he joined the Ontario Department of Highways and remained in this work until his recent appointment to the University of Toronto. Granted leave-of-absence by the Department in 1947-48 to undertake post-graduate studies at Purdue University, majoring in highway engineering he obtained the degree of M.Sc. in 1949.



M. M. Davis, M.E.I.C.

D. G. Dawson, JR.E.I.C., is employed with the British Thomson-Houston Company (Canada) Limited, Toronto, following a period of two years spent in Great Britain at the main works of British Thomson-Houston Company, under the provisions of an Athlone Fellowship.

Mr. Dawson received a B.Sc. degree in electrical engineering from the University of Alberta in 1954.

H. S. Ragan, JR.E.I.C., has joined the firm of Stanley, Grimble, Roblin Limited, consulting engineers of Edmonton, as chief design engineer. He will make his headquarters in Edmonton.

A native of Calgary, Mr. Ragan had his early education at Edmonton and obtained a B.Sc. degree in civil engineering from the University of Alberta. Employed by the Department of Highways, of Alberta, bridge branch, from 1950 to 1956, he was engaged in the design and construction of numerous large bridges. During the past three years he was the chief design engineer in that department.

H. S. Ragan, JR.E.I.C.

Paul-Emile Drouin, JR.E.I.C., for a number of years associated with the hydraulic laboratory, Ecole Polytechnique, has joined the staff of Hydro-Quebec, servicing the power development division, hydraulic section.

An Ecole Polytechnique graduate, class of 1947, in civil engineering, he also holds an M.Eng. degree, from McGill University gained in 1952.

L. A. Quinn, JR.E.I.C., has left the sales engineering staff of American-Marsh Pumps (Canada) Limited, Stratford, Ont., to take a position with the Demerara Bauxite Company Limited, Mackenzie, British Guiana, as a mechanical engineer.

A University of Toronto graduate in mechanical engineering, he obtained his degree in 1953.

Earl W. Fee, JR.E.I.C., an Athlone Fellowship winner of 1953, has concluded his studies abroad, and has accepted a position with Atomic Energy of Canada Limited, Deep River, Ont.

Mr. Fee spent the first year of his fellowship with the English Electric Company Limited, at Rugby, Eng., later proceeding to the Atomic Energy Research Establishment at Harwell, Eng., where he studied atomic power plant design.

Mr. Fee received a B.A.Sc. degree from the University of Toronto in 1953.

G. J. MacHutchin, JR.E.I.C., who has elected a director and appointed executive vice-president of Diamond Flooring Limited, specialists in the design and installation of concrete floor finishes. Mr. MacHutchin has been with the firm since his graduation from McGill University as a civil engineer in 1952.

G. J. MacHutchin, JR.E.I.C.

T. H. Legg, JR.E.I.C., a graduate of the University of British Columbia, class of 1953 in engineering physics, has left Montreal and is employed with the Radio Physics Laboratory of the Defence Research Board, at Ottawa.

E. Davis Christian, JR.E.I.C., formerly employed with the New Brunswick Electric Power Commission, Fredericton, N.B., has joined the Federal Department of Trans-Canada Highways, engineering staff. He is presently employed on the Cabot Trail, Cape Breton Highlands National Park, at Cheticamp, N.S.

A B.Sc. graduate in civil engineering from the University of New Brunswick, he obtained his degree in 1954.

G. Lepinay. JR.E.I.C., a Laval University graduate, class of 1953 is presently working with the firm of Michaud and Semard Inc., general contractors, Quebec City, Que.

Mr. Lepinay joined the Department of Public Works, Province of Quebec, on graduation and carried out the duties of assistant district engineer.

Michael E. M. Gibson, JR.E.I.C., a 1954 graduate in civil engineering of the University of Dublin, formerly associated with the firm of Proctor, Redfern and Laughlin, Scarboro, Ont., has recently accepted a position at Niagara Falls, Ont. He is engaged in design engineering with H. G. Acres and Company Limited.

A. D. Scothorn, JR.E.I.C., is employed with the Department of National Defence, Directorate of Works, at Ottawa.

Mr. Scothorn has had previous experience with the firm of Margison, Babcock and Associates, Toronto, and with Canadian Arsenals Limited, Montreal, Que.

He is a 1951 graduate in mechanical engineering from the Nova Scotia Technical College.

Richard N. Outhouse, JR.E.I.C., has returned to this country after spending some time in Great Britain with the educational department of Metropolitan Vickers Electrical Company Limited, Manchester.

He is at present at work as a sales engineer with the firm of Peacock Brothers Limited, Montreal.

Mr. Outhouse is a Nova Scotia Technical College graduate, class of 1953 in mechanical engineering.

J. S. Coopman, JR.E.I.C., has accepted employment with the firm of Joice-Sweanor Electric Limited, at Port Hope, Ont.

A Queen's University graduate of the class of 1954, Mr. Coopman has held

• PERSONALS

professional association with the English Electric Company of Canada Limited and with Mutual Boiler and Machinery Inc., at Toronto, as an electrical inspection engineer.

C. R. Vivian, JR.E.I.C., has transferred from the engineering staff of the Newfoundland Light and Power Company, Limited, at St. John's to the position of superintendent of the company's central division, with headquarters at Grand Falls.

Mr. Vivian has been associated with the Nfld. Light and Power Company on various construction projects since graduation from the Nova Scotia Technical College in 1950.

A. G. MacDonald, JR.E.I.C., has accepted employment with Burns and Company, engineering department at head office, Calgary.

Mr. MacDonald is originally from Eastern Canada, where he graduated from McGill University in 1953 and held several positions in the electrical engineering field.

Before embarking on his present duties, Mr. MacDonald was associated with Wirtanen Electric Company Limited, Edmonton and with K. Siemens, a consulting mechanical engineer, also at Edmonton, as an electrical engineer.

R. D. Hall, JR.E.I.C., utility engineer with the City of Lethbridge, has been re-elected to serve as secretary-treasurer of the Lethbridge Branch of the Institute. This is his sixth term of office. A native of Camrose, Alta, Mr. Hall received his public and high school education in Alberta, and graduated from the University of Alberta with a B.Sc. degree in electrical engineering in 1948. He also spent two years in the Canadian Army.

Following graduation Mr. Hall was employed in the station section of the Hydro Electric Power Commission of Ontario at Toronto and in 1950 transferred to the communications section of the same organization.

In 1951 he accepted employment with the City of Lethbridge and also began his lengthy term of office with the Lethbridge Branch of the Institute.

R. D. Hall, JR.E.I.C.

Guy Pelletier, S.E.I.C., a 1956 graduate of Laval University in chemical engineering is technical assistant to the operating superintendent of plastics, with Monsanto Canada Limited, Montreal.

Robert L. Wright, S.E.I.C., a B.Eng. graduate from McGill University, class of 1956, has accepted employment as a junior engineer with Horton Steel Works Limited, Fort Erie, Ont.

Mr. Wright won the 1956 students prize of the Montreal Branch of the Institute.

R. D. Boyd,, S.E.I.C., a 1956 graduate in civil engineering from McGill University, has accepted a position with Dominion Bridge Company Limited, Montreal.

Tour of Shepody Dam

On Sunday, October 28, a party of branch members, their wives, and a few guests visited the Shepody dam, at Albert, N.B.

The Shepody dam is the largest single structure built to date by the Maritime Marshland Rehabilitation Administration under Canada Agriculture. It consists of a rock-fill dam; a by-pass section closed by rock fill and timber core; and gate structures. The overall length is approximately 1600 feet, with a maximum vertical height of about 55 feet. The water flow is controlled by two steel vertical lift gates 20 feet wide and 16 feet high, and water diverted through the by-pass on March 5, and the by-pass was closed on March 22, 1956. A very important factor in the successful closure was the detailed study on a scale model in the hydraulics laboratory in Amherst.

Project Described. J. D. Conlon, chief engineer, M.M.R.A., and C. D. Carter, resident engineer, explained the project to the party. Mr. Carter also briefly outlined the work necessary for the final completion, including the rock facing of heavy adjoining dykes, and other protective works.

After visiting the dam, the party drove around the district to see the 5,576 acres of land now protected from the tide by the new works. The trip was concluded by dinner in Moncton.

BELLEVILLE

Secretary-treasurer

What is a Silicone?

The Belleville Branch of the E.I.C. held its first meeting for the 1956-57 season on November 12, 1956.

The guest speaker was H. D. Hamilton who is manager of electrical and silastic sales of Dow Corning Silicones Ltd. at Toronto. He delivered a very comprehensive talk on silicones, supplementing his remarks with slides and a film entitled "What's a Silicone".

The speaker outlined the history of the formation of Dow Corning Silicones Ltd. The need for an electrical insulating material having good stability at fairly high temperatures led the Corning Glass Works to turn to the Dow Chemical Company for assistance. A subsidiary company consisting of members from both parent companies was organized in 1942. One year later the first product was produced.

Three Silicone Groups. Silicone products, in general, come under one of three groups, namely fluids or oils, silastics, and resins.

Silicone oils having either extremely high or extremely low viscosities can now be produced. On the other hand, oils having a stable viscosity over a wide temperature range are also manufactured. They are used as a damping fluid in various kinds of meters and as a low temperature lubricant. As a lubricant, the non-sludging property of silicone oil, and the fact that the chemical composition is such that oxidation is practically inhibited, are of particular importance. The use of these oils as a protective coating for glass is rather interesting. Such a coating leaves the surface of the glass so well lubricated that an inadverdent contact or blow, is translated into sliding action thereby avoiding breakage. Silicone greases, which are basically silicone oils with fillers added, naturally display most of the same desirable properties.

Silastics, the rubbery type of materials, which because of their non-carbonizing property and their high thermal conductivity, are used extensively as the insulating medium for power and control cables on ships. On account of the excellent thermal properties displayed, the addition of 5 - 10% of silastic "rubber" to automotive tires increases their life considerably.

The third group of silicones namely, resins, are used extensively for insulating the windings of motors and generators because of the desirability of using a fire-resistant material and particularly because of the inherent thermal properties. A motor, thus insulated, can have its horse power rated upwards by as much as 50%.

The speaker was thanked by Mr. Sillitoe.

CORNWALL

V. A. HARRISON, M.E.I.C.,
Publicity Chairman

Commonwealth Study Conference

The second fall meeting of the Cornwall Branch was held October 3 at the Cornwall Golf and Country Club. R. D. Archibald, secretary of Dominion Textiles Ltd. gave a compehensive outline of the Duke of Edinburgh's Study Conference held in England last July.

Mr. Archibald, a Canadian representative, described it as an enriching and broadening experience and one of the best organized conferences he had ever attended.

Also present at the meeting was Sir John Hanbury-Williams, chairman of the Board of Courtaulds Limited, who was honorary treasurer of the council set up by the Duke to organize the conference. Sir John described how the idea of the conference had grown out of the Duke's experiences in visiting hundreds of industrial concerns throughout the Commonwealth.

Differences Noted. The Duke had been struck by the difference in attitudes he found in the various plants he visited, and by the differences in the relationships between industries and communities. After discussion, a conference of representatives from all parts of the Commonwealth and Empire was decided upon, "The Duke of Edinburgh's Study Conference on Human Problems of Industrial Communities within the Commonwealth and Empire".

"The whole program was focussed on the individual living in an industrial community," Mr. Archibald said. A second aim of the conference was to give some help to the newer industrial coun-

• BRANCH NEWS

tries like Pakistan, which might be able to avoid some of the mistakes made in the older industrial communities.

At the end of the three-week period of lectures, study groups and tours to factories in many parts of England, Mr. Archibald said one of his chief impressions was that "the factories where the employees seem to be the happiest, where they put the most into and get the most out of their jobs, are those where they know what is going on . . . These are the plants where the line managers make people the principal part of their jobs."

Another impression, said Mr. Archibald, was that in the Western world's industrial democracy, it was absolutely essential that equipment be kept up to date.

The speaker also had praise for the hospitality of all the people he had met on the conference, and remarked on the fine reception they received in all the plants they visited. They were given free access, he said, and permitted to move about the plants asking any questions they wanted.

Broad Representation. It was also a broadening experience, he said. For detailed study the conference of 280 persons was broken down into 20 groups of 14 persons, each with its own chairman. These were carefully "mixed". His own group, said Mr. Archibald, had included a director of a Pakistan tobacco plant, a trade union organizer from Yorkshire, a lathe operator from Ireland, a coloured plantation manager from Nigeria and a civil servant from Singapore who was also a union leader.

The Duke of Edinburgh, who had presided for most of the plenary sessions that opened the conference impressed Mr. Archibald as being highly alert, with a good sense of humour and deep sincerity — "All the qualities you would look for in a leader."

Speakers were top industrialists who usually gave hour-long papers to the whole group, which would then break up into 14-man sessions to consider them. About 10 days of the conference were spent in visiting industrial sites in various parts of the country.

CALGARY

R. G. PRICE, M.E.I.C.,
Branch News Editor

Brian McNally is Speaker

The Calgary Branch of the E.I.C. held an evening meeting in the Palliser Hotel on Thursday, November 8. Brian McNally described the new N.W. Nitro-Chemical Plant at Medicine Hat, Alberta, in which he is employeed as plant engineer. This new $21.5 million fertilizer manufacturing plant was just getting into production and had produced its first sack of fertilizer the day of Mr. McNally's address.

Imperial Oil Research Centre

Personnel of the new million dollar Imperial Oil Research Centre in S. E. Calgary were hosts to the Calgary Branch on the evening of November 22 and about 150 members took the opportunity to examine the Centre. Jim Young of Imperial, who is in charge of the Centre and his very obliging assistants served refreshments at the conclusion of the tour.

Engineering Education

On Monday evening, November 5, the Fredericton Branch held a very enjoyable dinner meeting chaired by Ira Beattie, president of the branch. It was highlighted by the presentation of a paper on Engineering Education by Prof. James O. Dineen, head of the electrical engineering department of the University of New Brunswick.

Prof. Dineen was introduced by R. E. Tweeddale, assistant chief engineer, of the N.B.E.P.C. Mr. Tweeddale mentioned that every engineer should take an interest in the training of future engineers and should also keep abreast of modern developments in the scientific world.

Prof. Dineen began his talk by saying that there were two types of knowledge, social knowledge and material knowledge. He stated that social knowledge has been rather gradual through the years, and that "man has gradually evolved from the barbaric tribes of early ages to the relatively civilized society of the present day."

The remainder of Prof. Dineen's paper dealt with material or scientific knowledge from the time the Egyptians first developed and applied geometry, up to the present day.

In his history of the development of engineering, Prof. Dineen mentioned the contributions of such men as Galileo and Leonardo di Vinci in the middle ages. In the 19th century, he said, the fundamental discoveries of men like Volta, Oerstead, Ampere, Gauss and Faraday laid the foundation for practical applications of Morse, Maxwell, Edison, Bell, Stanley, Westinghouse, Flemming, Marconi and many others. Because of the feverish race to convert these fundamental discoveries into commercial enterprises, engineering schools arose. U.N.B., one of the first engineering schools in the country began giving instruction in engineering in 1854.

Prof. Dineen then traced the development of the engineering profession from 1900. He then outlined some of the demands and problems that have to be met by the engineers of today. The civil engineer has five great problems facing him: traffic congestion, municipal rehabilitation, adequate water resources, industrial pollution, and highway reconstruction and safety. The mechanical engineer deals with the production of power, and the conception, design and manufacture of devices. The commodity of the electrical engineer, electricity, cannot be observed as can the works of the civil engineer and the machine tools and products of the mechanical engineer. "Its study requires emphasis on imagination, and understanding of classical and modern physics and a heavy reliance on mathematical analysis," he stated.

Educational Trends. Prof. Dineen then outlined some trends in under-graduate curricula and outlined the graduate programs of the universities. He said that we should provide the graduate with sound training in fundamentals and develop his ability for creative thinking, and leave the more specialized training to graduate schools. He also mentioned that many companies give the new graduate a one or two year training course. This gives the graduate an opportunity to become familiar with all phases of the company's work. In the United States many companies make provision for selected employees to attend advanced courses at local universities.

In conclusion Prof. Dineen stated that there comes a time in each career when formal education ceases. Then it is up to the individual to keep abreast of the developments in his own field of endeavour and to cultivate a habit of self education.

Knob Lake — Sept Iles

Our second meeting of the 1956-57 season, attended by some 50 members, students and guests, was held at R.M.C. on the 20th of November.

The speaker for the evening was Mr. J. A. Little, general manager of the Quebec North Shore and Labrador Railway at Sept Iles, Quebec. Mr. Little discussed the historical background of the Knob Lake — Sept Iles area and then described in detail the building of the railroad linking the ore body at Knob Lake

Branch News Editor

Water Resources

A. M. Snider of Kitchener, chairman of the Ontario Water Resources Commission, addressed the branch at the November meeting. The commission was established this year by provincial legislation, with guiding principles similar to those of the Hydro Electric Power Commission.

The functions of the commission are:

(a) To develop and make available supplies of water.

(b) To construct and operate systems for the supply and purification and distribution of water and for the disposal of sewage.

c) To enter into agreements with respect to the supply of water or the disposal of sewage.

(d) To conduct research programs and to prepare statistics for its purpose.

(e) To perform such other functions or discharge such other duties as may be assigned to it from time to time by the Lieutenant Governor in Council.

Mr. Snider said, "This act is a departure from practices followed here in the past, and is without parallel elsewhere in Canada or United States. In general the Commission is authorized to build, finance and operate water supply and sewage disposal projects. This is a comprehensive program designed to ensure water resources that will be adequate for the needs of the development of this Province."

Advantages Outlined. There are advantages to be derived from the Commission's operations:

1) Money is borrowed by Provincial Commission at rates usually lower than municipalities, and at longer term than for municipal borrowing —thirty year basis usually. There is no increase in municipal debt — money is borrowed by the Commission.

(2) Best engineering assistance available ensures excellent modern design. Operation of plant is under modern scientific control at all times with latest improvements introduced regularly.

Referring to importance of regional planning, Mr. Snider said: "An agreement to supply works is not to be restricted to single municipalities. Water supply and waste disposal must be considered as area or regional problems rather than be restricted to municipal boundaries. It is not always easy for communities to agree among themselves on joint programs, regardless of the advantages of such compacts. The Water Resources Commission is prepared to consider services to all municipalties in an area whether there be a water works pumping plant or a sewage treatment plant. The allocation of costs among the municipalities or areas served can be made by the Commission without undue difficulty."

Some idea of the magnitude of the task facing Ontario in the next twenty years was given by the estimate of $2.4 billion for water and sewage works projects to keep pace with requirement of homes and industry.

• BRANCH NEWS

Plant Tours

For the October meeting, the branch members and friends inspected the plants of Sheldons Engineering Ltd., and Joy Manufacturing Company (Canada) Ltd.

In the Sheldons plant the visitors inspected a wide range of air moving equipment, as well as the installations for testing, dynamic balancing, and some new manufacturing techniques.

At the Joy plant the role of air in engineering was seen in another way—the manufacture of compressors and compressed air tools, particularly for the mining industry. At the close of the tour, refreshments were served in the plant cafeteria.

The Kitchener branch records its appreciation to the managements of these companies for two most interesting tours.

NIPISSING AND UPPER OTTAWA

J. W. MILLAR, M.E.I.C.,
Branch News Editor

Dinner Meeting

The Nipissing and Upper Ottawa Branch held its November dinner meeting in the Dragon Room of the Golden Dragon Restaurant in Ferris, Ont., on November 22. Chairman T. C. Macnabb presided at the well attended meeting.

After dinner, Dick Booey introduced the speaker Douglas Walkington, Montreal, of the chemicals division of Canadian Industries Limited and who at the present is particularly interested in market research and public relations.

Mr. Walkington started his talk by pointing out what chemistry had done for industry and how chemistry had provided the material and the engineer had put it to use. He cited the heavy industries such as pulp and paper, mining and construction where chemistry played a large part in providing materials to be used in the processes for producing wood pulp and paper and refining ores. Agriculture uses a great many chemicals and these included insecticides and Mr. Walkington pointed out that insects soon become immune to insecticides and new ones have to be developed.

Use of Plastics. He then dealt with plastics, and saying there were twenty major plastics, each with many variations. In order to properly use plastics, industry must understand that each had special properties and the proper plastic must be used to obtain the best results. Mr. Walkington illustrated his talk with a variety of articles made from plastics, including polythene rope, plastic water pipe, toys, plumbing fixtures, etc. He also had an assortment of textiles and enlarged on the contribution of chemistry to the textile industry in the development of rayon, nylon, dacron, orlon and terylene all of which have their special uses and are generally used in combination with wool and cotton.

A discussion period followed, and Mr. Walkington ably answered many questions put to him by the engineers. The speaker was thanked by J. W. Millar.

NORTHERN NEW BRUNSWICK

BERNARD BEATON, JR.E.I.C.,
Branch News Editor

Power for New Brunswick

A general meeting of the Northern New Brunswick Branch of the Engineering Institute of Canada was held at the Miramichi Golf and Country Club at 8:00 p.m., November 3, 1956. There were twenty-two engineers and guests present.

The meeting was called to order by the chairman, A. R. Bonnell. B. Beaton was appointed executive member for Restigouche to fill the vacancy left by A. R. Bonnell when he moved up to the chairmanship of the Branch.

The chairman introduced the speaker of the evening, Reginald Tweeddale, assistant chief engineer of the New Brunswick Electric Power Commission. Mr. Tweeddale extended greetings from the Fredericton Branch of the Institute.

"Power for New Brunswick" is a topic, he said which has not been fully appreciated by the people of this province. Consequently, the commission, being a public utility, has instituted a program of education on this subject.

Mr. Tweeddale expanded his subject on the following topics with the aid of a map of the N.B. Power System, and a physical cardex-graph system of the power growth of the Province:

1. The existing generating stations.
2. The new 69- and 138-kv. overlay transmission systems.
3. The six rural distribution districts of the Province.
4. Future buildup of system to meet average 10% increase per annum.
5. The installation of larger generators and tie-ins with heavy industry.
6. Two new thermal plants for the province.
7. Power will be the key to development of the mining industry in the north of the province and about Woodstock.
8. The potential of the St. John River hydro developments; example at hand is the 135,000 hp. development at Beechwood.
9. The integration of hydro with thermal with our eyes on new sources of power, such as d-c, high voltage transmission from Hamilton Fall, atomic power plants and tidal power.

A colour film was shown on Beechwood construction to date with explanatory comments by Mr. Tweeddale.

OTTAWA

STEWART G. FROST, JR.E.I.C.,
Branch News Editor

NATO is Discussed

NATO must be maintained as a tangible deterrent to Russian aggression and Canadians must set an example in supporting its principles and armed forces. This was the thought expressed by Donald C. MacCallum, president of Racey-MacCallum and Associates, Montreal, who spoke at a special Junior Section luncheon meeting of the Ottawa Branch on November 15.

Mr. MacCallum, recently returned from a tour of NATO establishments in Europe, warned against any relaxation of vigilance in maintaining a state of preparedness against a Russian attack. The New Look, assumed by Russia since the relegation of Stalin, has prompted some to suggest the abolition of the atomic bomb and the withdrawal of armed forces from Europe. Under no circumstances, emphasized Mr. MacCallum, must we be led astray by such fuzzy thinking, for we are probably faced with a more dangerous Russia than ever before.

NATO's Organization. As one of a group of members of the Canadian Industrial Preparedness Association, Mr. MacCallum was privileged to meet and confer with those responsible for keeping NATO an efficient and effective body. Lord Ismay, vice-chairman and general secretary of NATO, together with his staff, thoroughly briefed the group on the philosophy, set-up, and functioning of the organization. Similarly General Gruenther outlined the extensiveness of the military force under his command at SHAPE. Mr. MacCallum was particularly impressed by the state of training and morale of the Canadian forces. These forces consist of an air division under Air Vice-Marshal Brandy Godwin and an army brigade under Brigadier Rober Rowley.

Having been fortunate enough to gain this first hand information Mr. MacCallum welcomed this opportunity to pass on the impressions he had formed. NATO, he said, has been highly successful in confining Russian operations and is absolutely essential if the status quo is to be maintained; it must receive the full support of all Canadians.

Herb Gladish, chairman of the Junior Section, presided at the luncheon and introduced the speaker. At the head table with Mr. MacCallum were Professor R. H. Galbraith and student representative John Belanger of Ottawa University, Professor E. E. Goldsmith and student representative Richard Baird of Carleton College, and Brig. J. P. Carriere, vice-chairman of the Ottawa Branch. The speaker was thanked by Stewart G. Frost.

Aklavik

"The New Aklavik—Search for the Site" was the subject of a paper presented by R. F. Legget and J. A. Pihlainen to the Ottawa Branch on October 18. Mr. Legget is director of the Division of Building Research of the National Research Council and Mr. Pihlainen is head of the Permafrost Section of that Division. Together with C. W. Merrill, now district administrator for the Department of Northern Affairs and National Resources at Fort Smith, they had participated actively in the search for the new site for Aklavik and had pooled their experiences in preparing the paper.

The growth and development of Aklavik and the reasons for moving it were first discussed by Mr. Legget. Originating as a fur trading post, as recently as 1918, Aklavik gradually grew with the establishment there of an Anglican Mission, an R.C.M.P. station, a Hudson Bay post, a Roman Catholic Mission, and a signal station of the Royal Canadian Corps of Signals. Today Aklavik boasts a permanent population of about 400.

Its location north of the 68th parallel and on the delta of the Mackenzie River causes Aklavik to be of importance as an administrative centre for the Canadian Northwest. It is not surprising, therefore, that the Government of Canada should take an active interest in the growth and development of the site.

Paradoxically, those factors which make the town important are also responsible for hindering its development. The organic silt of the delta and the arctic climate have combined to make soil conditions impossible for permanent buildings. The "permafrost" at Aklavik has been shown to contain 60 per cent ice. Other features such as poor drainage and lack of a good site for an air strip combined to make it necessary to find a new site.

Criteria for New Site. The new Aklavik would have to be acceptable from the commercial and social point of view, it should be close to navigation, it should have a first class airfield and it should have water and sewage. These and many other essential factors provided a guide for those who conducted the survey.

Mr. Pihlainen reported that preparations for the survey were started as early as January 1954 and were coordinated by Mr. Merrill. A preliminary appraisal of the delta area was made using air photographs. Land form patterns were established stereoscopically and identified by soil sampling in strategic locations. Twelve possible townsites were located in this way.

To examine these sites in the field extensive use was made of the helicopter. From the air it was possible to reject eight of the sites as unsuitable. Using special light weight equipment, soil sampling was carried on at the other sites. Much difficulty was experienced in judging the proper amount of wash water, too much water would melt and wash away the ore while too little would freeze the core barrel. Samples were tested and coloured photographs of split representative samples were made for future reference. After the spring break up further sampling was carried out at two of the most promising sites. One site known as "East Three" located about 80 miles by water but only 35 by air from the old town was finally chosen.

The speakers were introduced by the Branch chairman, Colonel E. B. Pennock and thanked by the vice-chairman, Brigadier J. P. Carrier. Guests at this dinner meeting were G. W. Rowley, secretary of the Advisory Committee on Northern Development and F. I. G. Cunningham, Director of Northern Administration and Land Branch of the Department of Northern Affairs and National Resources.

Junior Section Active

On October 25, the Junior Section of the Ottawa Branch commenced its activities this season with a visit to the plant of Computing Devices of Canada at Bell's Corner near Ottawa. Jim Boucher, an executive member of the Junior Section, had invited the juniors and students in the Ottawa area to inspect the new plant.

About 50 juniors and 15 students took part in the outing. Dave Knudson, public relations officer of Computing Devices of Canada was in charge of the plant tour. He, together with other members of his staff guided small groups through the various phases of activity and explained in detail the operation of much that was being done.

Computors Demonstrated. In the data processing the room the groups were given a demonstration on the operation of a digital computor and had the fundamentals of an analog computor explained to them. The wonders of the transistor were demonstrated and other electronic equipment was displayed.

Impressed with the marvels of the electronic age groups returned to the cafeteria where they were treated to coffee and doughnuts. Mr. Gladish, chairman of the Junior Section took this occasion to announce the program of the Junior Section for the coming season and to extend a special welcome to the students of Carleton and Ottawa University to all functions. Mr. Frost thanked Mr. Boucher and Mr. Knudson for a most interesting evening and for their generous hospitality.

Visit to Seaway

The St. Lawrence Seaway and Power Project was visited for a second time on October 27 by four bus loads of members and friends of the Ottawa ranch. This cavalcade left Ottawa at 9:30 a.m. and arrived at Cornwall for luncheon at the Cornwallis Hotel. The group was met there by Charles McIntosh of the Ontario Hydro and was guided by him through the various phases of the work going on between Cornwall and Iroquois.

Power House. Construction work on the power house being built between the Canadian mainland and Barnhart Island was observed from the top of the downstream cellular cofferdam. Next the group proceeded to the arched dam being built at the foot of the Gallop Rapids and to the Eisenhower Lock. The relationship of these structures one to another and the schedule for placing them in operation was clearly explained by Mr. McIntosh.

Control Dam and Townsite. The group then proceeded to Iroquois to view the new control dam being built there and to inspect the new townsite. At the time of this visit the gates of the control dam were near completion and preparations were being made to start work on the second half of the dam. At the new Iroquois townsite the group were taken

Shown below are . . . some of the gentlemen who sat at the head table, on the occasion of the November 15 luncheon meeting of the Ottawa Branch, addressed by D. C. MacCallum, president of Racey-MacCallum and Associates Limited, Montreal. They are, left to right: Prof. E. E. Goldsmith, Carleton College; Prof. R. H. Galbraith, Ottawa University; Herb Gladish, chairman of the Ottawa Junior section; D. C. MacCallum, and Brigadier Carriere, vice-chairman of the Ottawa Branch.

• **BRANCH NEWS**

through the streets of the relocated community and were impressed with the condition of the old houses which had been moved from their old location along the riverfront to this new development.

Before leaving Mr. McIntosh for the return journey home, Mr. Brown, proceedings committee chairman, expressed to him the sincere thanks of the group for his fine explanation and guidance.

TORONTO

EIC-ASCE-ICE Joint Area Committee

B. HARDCASTLE, M.E.I.C.,
Secretary

ACI Building Code

A meeting of the Joint Area Committee was held on October 18, 1956 in Toronto, at which there were approximately eighty members present. H. Fealdman introduced the speaker, Professor Frank Kerekes, dean of faculty, Michigan College of Mining and Technology, and president of the American Concrete Institute.

Professor Kerekes reviewed briefly the organization of the Committee for Revision of the Building Code of the American Concrete Institute, of which he was chairman, and elaborated on the functions of each subcommittee.

The basic approach to structural design developed by this committee dealt with the use of load factors applied to structural analysis based on ultimate strength.

The speaker outlined the difficulties facing the Committee in revising the Building Code of the ACI, dealing in detail with individual problems. He stressed the necessity of treating any code with discretion, and using it in conjunction with fundamental design principles.

Professor Kerekes' address was interspersed with examples taken from his own wide experience.

The wide interest in the paper was evidenced by the stimulating discussion and question period which followed.

B. Hardcastle proposed a vote of thanks to the speaker.

VANCOUVER ISLAND

W. G. McINTOSH, M.E.I.C.,
Branch News Editor

Road Design

The Vancouver Island Branch opened its fall season on October 3 with a joint dinner meeting held in conjunction with the Victoria Branches of the B.C. Association of Professional Engineers and the C.I.M.M. The guest speaker was W. A. Johnson, engineer of soils and foundations, Highway Research Board, Washington, D.C., who spoke on "A Practical Approach to the Design of a Road Section". Mr. Johnson discussed a number of highway research projects at present being undertaken in the United States.

Agassiz Bridge

A second joint meeting was held on October 19, at which Gerald Koster, resident engineer, Bridge Department, Province of B.C., gave an illustrated paper on the new Agassiz-Rosedale Bridge.

Reception for National Officers

On November 10, the Branch held a dinner meeting in connection with the annual visit of the president and the general secretary, to which the ladies were invited. Unfortunately, President V. A. McKillop was unable to be present. In his place, Dean Hardy of the University of Alberta attended and presented a short address. Dr. Wright then gave us an informal account of the present state of Institute affairs. After the dinner, music was provided for dancing.

VANCOUVER

A. D. CRONK, M.E.I.C.
Secretary-treasurer

Structural Section

Second Meeting

The second regular monthly meeting of the structural section was held on Tuesday, October 16, 1956, in the Willingdon Cafe and was attended by thirty members.

The chairman, Peter Jones, introduced the report of the Douglas Committee on prestressed concrete criteria. These criteria were distributed to those present, who were asked to comment or send comments in before the end of that week. These criteria were then to be submitted to the Consulting Engineers Division of the Association of Professional Engineers for action. Mr. Faliszewski spoke briefly on the work of the committee.

Officers.

Following dinner, the election of officers took place, those elected being: chairman, Dr. Roy Hooley, vice-chairman, Gordon Ellis, secretary-treasurer, Steve Faliszewski.

Mr. Robert Wannop introduced the main speaker, Len Narod, who gave a very interesting talk on the design of the La Conner bridge, a fixed arch steel bridge for which he was the designer. A number of interesting design problems were clearly illustrated, and their solutions outlined. His talk provoked a lively question period. Frank Leighton thanked the speaker.

WINNIPEG

C. S. LANDON, M.E.I.C.,
Secretary Treasurer

Electrical Section

Visit to Cable Plant

Sixty members of the electrical section visited the newly opened Winnipeg plant of the Canada Wire & Cable Company and its subsidiary company Telecables & Wires Limited. The combined plant occupies an area of some 92,000 square feet and incorporates the most modern wire and cable manufacturing machinery. The plant is located on 14 acres of ground in suburban Fort Garry.

Space does not allow a complete technical description but production includes the manufacture of telephone and other communication cables; solid bare copper wire, solid aluminum wire, stranded aluminum wire, A.C.S.R., polyethylene covered line wire, flame seal, N.M.W.10 and triplex. Complete testing facilities are provided.

Thanks are due to the company for an interesting and informative visit.

The Electrical Section held its annual dinner dance at the Marlborough Hotel on Friday evening, November 16. Approximately 210 members, their ladies and other guests attended.

The guest speaker, Miss Mildred McMurray of the Provincial Health and Welfare Department delivered an entertaining and at times thought provoking address entitled "Leaves from a Lawyer's Diary". Miss McMurray's experiences in private law practice and her present concern with family welfare provided some interesting reminiscences.

The Electrical Section dance is an established and popular event in the E.I.C. social calendar. This year we were again fortunate in having our general secretary, Dr. L. Austin Wright with us. Unfortunately the President Mr. V. A. McKillop, who had hoped to attend, was unable to do so because of a business emergency.

News of Other Societies

International Aeronautical Meeting

Toronto was the location chosen for the 1956 fall meeting of the Canadian Aeronautical Institute and the Institute of the Aeronautical Sciences, of U.S.A., held on Monday and Tuesday, November 26-27. Despite the blizzard conditions which prevailed over the weekend, the total registration of around 450 was a tribute to the vitality and spirit of this young Canadian institution.

The Program

The technical program consisted of the W. Rupert Turnbull Lecture, together with twelve papers in four groups under the general headings of Test Flying, Quality Control, Electronics, and Missiles. The titles of these papers, and their authors, were as follows:

1. *The Canadian Test Flying Scene*—Donald H. Rogers, Chief Test Pilot, Avro Aircraft Limited.
2. *Flight Testing of High-Speed Aircraft* — Richard Johnson, Chief Engineering Test Pilot, Convair, San Diego, A Division of General Dynamics Corporation.
3. *RCAF Test and Development* — S/L Owen B. Philp, RCAF. Formerly Chief Test Pilot, Central Experimental and Proving Establishment.
4. *Quality Control Policy in the Royal Canadian Air Force* — G/C Robert McMillan, Chief of Quality Control, RCAF.
5. *Applications of Ultrasonics in Aircraft* — Charles P. Albertson, Supervisor of Sonic Testing; Philip Melara, Supervisor, Quality Control Laboratory, Grumman Aircraft Engineering Corporation.
6. *Control of Deviating Material* — Harold G. Dickie, Supervisor, Quality Review, Canadian Pratt and Whitney Aircraft Company, Limited
7. *Operational Use of TACAN* — Murray Block, Air Traffic Control Specialist, Federal Telephone and Radio Co., 'Div. of International Telephone. and Telegraph Corp.
8. *A Survey of the Advantages of Transistors in Air-Borne Electronic Equipment* — Earl F. Johnson, Head, Semiconductor Engineering Dept., Computing Devices of Canada, Limited.
9. *Airport and Airways Surveillance Radar for Canadian Air Traffic Control* — Bruce McCaffrey, Project Engineer, Radar Dept., Raytheon Manufacturing Company.
10. *Guidance and Control of Missiles* —A. G. Carlton, TRITON Division Supervisor, Applied Physics Laboratory, The Johns Hopkins University.
11. *The Technology of Guided Missiles and Its Effect on Industry* — R. D. Richmond, Chief Development Engineer; J. F. Perrier, Missiles Systems Engineer, Canadair, Limited.
12. *A Method for Evaluating Jet-Propulsion-System Components in Terms of Missile Performance* — R. J. Weber, Roger Luidens, Aeronautical Research Scientists, Lewis Flight Propulsion Laboratory, NACA.

Guided Missile

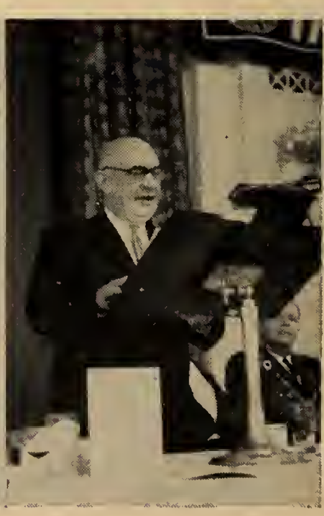
The W. Rupert Turnbull Lecture, presented on Monday afternoon before the whole convention, was given by Simon Ramo, executive vice-president of the Ramo-Wooldridge Corporation of the United States. Mr. Ramo, who has had a distinguished career in aeronautical development, spoke on the subject of "The Guided Missile as a Systems Engineering Problem".

He explained first that his lecture was really on two topics, guided missiles and systems engineering, and it was his endeavour to tie the two together. The lecturer then went on to deal with systems engineering in rather general terms, after which he added some specific examples—in particular the guided missile —and then concluded with ways of how we can improve our knowledge and use of these special engineering techniques.

One interesting aspect of the application of systems engineering, developed by Mr. Ramo in his lecture, was what he called the "arrangement making problem". By this he meant that in some cases the technical problem involved could be solved easier than the problems arising from the introduction of the proposed system itself. The alternate approaches must therefore be carefully examined, he stressed.

The speaker merited congratulations on presenting a most complicated sub-

At the CAI-IAS dinner meeting November 27, l. to r.: T. E. Stephenson, president of the Canadian association, Dr. E. R. Sharp, president of Institute of the Aeronautical Sciences, and C. C. Furnas of the United States, the speaker for this meeting.



ject in clear and understandable language.

At dinner, also on the first day, places were laid for over 600 delegates and guests. The evening program was under the chairmanship of the C.A.I. president, T. E. Stephenson, who called first upon Dr. E. R. Sharp, president of the I.A.S., who is director of the Lewis Flight Propulsion Laboratory. Dr. Sharp brought to the meeting the greetings and good wishes of the society he represents from south of the border.

International Cooperation

Then followed the principal speaker, Clifford C. Furnas, assistant secretary of defense for research and development, U.S.A.

In his beautifully modulated voice Mr. Furnas, author of "The Next 100 Years", opened his talk with a review of what he feels is one of best examples of post war Western integration. He illustrated, with very apt anecdotes and incidents, the fine co-operation that has existed and continues to function between the aeronautical men of the United States, Canada, and Great Britain.

The speaker then pointed up the gravity of the present situation facing mankind. He felt that the problem is twofold: man against nature, and man against man, which is after all an age-old concept of existence. He then expressed the view that Canada and the U.S.A. are engaged on an unprecedented effort of tackling both sides of the task at the same time. In other words, to have both "guns *and* butter". Research and development are going on, both civil and military, on a scale which is bringing about the most rewarding technological advances.

Mr. Furnas could also see that, as we go on into the future, Canada and the United States will have many other new problems in common — problems dealing with our natural resources, and the use of them. We will be faced with building an industrial structure necessary to support the expected vast world population increase of the next several generations. He could see our engineers and scientists turning to sea water, atomic energy, and solar energy for the answers.

Mr. Furnas also reminded the audience of the growing need to pass on the benefits of our advances to the "have-nots" of the rest of the world. He concluded with the warning that this is a critical generation in human history, with a special responsibility.

Tuesday, the second day, was taken up with three more sessions of technical papers, and the meeting then ended. The *Journal* salutes the council, staff, and all those concerned in the C.A.I., for their energy and initiative in adding another successful meeting to their institute's young but impressive record.

International Scientific Radio Union

Letter from Canadian secretary

The twelfth general assembly of the International Scientific Radio Union (known as URSI) will be held at Boulder, Colorado, August 22 to September 5, 1957, by invitation of the U.S.A. National Committee of URSI and the National Academy of Sciences.

Participation in the Assembly, including attendance at technical sessions and special features, is limited to representatives officially designated by the National Committees of the member countries. Canada has many competent scientists in the field of radio science, who are not at present members of the Canadian National Committee of URSI or its Technical Commissions. Any scientist wishing to attend the General Assembly may get in touch with the chairman of any of the Canadian Commissions covering a field in which he is interested. He should "enroll" with one chairman only, to simplify the bookkeeping, even though he may be interested in other fields as well. His name will then be added to the "Canadian delegation" for the purpose of admitting him to the conference with full privileges. This action is proposed solely to meet the administrative requirements of URSI, and there is no membership fee. Travelling expenses, hotel accommodations, and all the other incidentals of the trip will be the "delegate's" own responsibility.

The Canadian Commissions and their chairmen are as follows:

Commission I — Radio Measurements and Standards: Chairman, Dr. J. T. Henderson, National Research Council, Ottawa.

Commission II — Radio and Troposphere: Chairman, Dr. J. S. Marshall, Physics Department, McGill University, Montreal.

Commission III — Ionospheric Radio: Chairman, J. C. W. Scott, Defence Research Board, Ottawa.

Commission IV — Radio Noise of Terrestrial Origin: Chairman, J. C. W. Scott, Defence Research Board, Ottawa.

Commission V — Radio Astronomy: Chairman, A. E. Covington, National Research Council, Ottawa.

Commision VI — Radio Waves and Circuits: Chairman, Dr. G. Sinclair, Department of Electrical Engineering, University of Toronto, Toronto.

Commission VII — Radio Electronics: Chairman, Dr. H. P. Koenig, Physics Department, Laval University, Quebec.

It would be appreciated if any interested persons would, at their earliest convenience, communicate with the appropriate Commission chairman, so that the names of all participants may be sent to the URSI 1957 General Arrangements Committee not later than February 1, 1957, as we have been requested to do. It is realized that many persons will not have crystallized their plans by that time, of course, and the Canadian Committee is hopeful that flexible arrangements can be made to add names up to the last moment.

A brochure covering the coming general assembly has been issued by the U.S.A. Committee. We believe that you may obtain a copy by writing to: URSI 1957 General Arrangements Committee, National Academy of Sciences, 2101 Constitution Avenue, Washington 25, D.C.

This office would be pleased to attempt to answer any questions you may have regarding the twelfth General Assembly.

J. M. Ann Marshall,
Secretary, Canadian National
Committee of URSI

Calendar

Electrical Engineering

Meetings of all sections in the three divisions of the Canadian Electrical Association, in both Eastern and Western Zones, will be held in Quebec, Que., January 28-31, 1957, and in Vancouver, B.C., March 18-20, 1957.

Information is available from the C.E.A. managing director, B. C. Fairchild, Room 714, Tramways Building, Montreal 1.

Civil Engineering

The American Society of Civil Engineers (33 West 39th St., New York 18) will hold a meeting in Jackson, Miss., February 18-22, 1957.

Materials Testing

Committee week of the American Society for Testing Materials (1916 Race Street, Philadelphia 3, Pa.) is scheduled for February 4-8, 1957 at the Benjamin Franklin Hotel, Philadelphia.

Chemical Engineering

The Chemical Institute of Canada (18 Rideau Street, Ottawa 2) announces meetings as follows:

February 21, 1957, the eleventh Divisional Conference, Protective Coatings Subject Division, in Toronto.

February 22, 1957, Montreal. The eleventh Divisional Conference, Protective Coatings Subject Division.

March 11-13, 1957, seventh Divisional Conference, Chemical Engineering Subject Division, Kingston, Ont.

BOOK REVIEW

American civil engineering practice, vols. 1 and 2.

R. W. Abbett, ed. New York, Wiley, 1956. illus., $15.00 per volume.

Written as a successor to Merriman's American Civil Engineers' Handbook, the latest edition of which appeared in 1930, this new comprehensive reference work will be welcomed by all engineers. It presents the fundamentals and techniques of civil engineering planning, design and construction. It is a completely new work, not merely another revision of Merriman's book, and its scope has been considerably enlarged.

Each of the three volumes into which it is divided covers a broad field of civil engineering, and is complete in itself. There are thirty-four sections, each written by an expert. The list of contributors include some of the most distinguished engineers in the United States.

The first volume covers metropolitan and community planning, surveying, highways, airports, railroads, soil mechanics, site planning, foundations, earthworks, tunnels, and mathematical tables. Volume II deals with hydraulic, sanitary and harbour engineering, while the third volume will be concerned with masonry, reinforced concrete, steel, and timber structures.

This volume, used in conjunction with two other works also published by Wiley, Handbook of Engineering Fundamentals, edited by O. W. Eshbach, and Handbook of Engineering Materials, edited by D. F. Miner and J. B. Seastone, will cover nearly all the usual problems, encountered in civil engineering. S.C.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada.

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

***Aerodynamics propulsion structures and design practice.**

E. A. Bonney, M. J. Zucrow and C. W. Besserer. Toronto, Van Nostrand, 1956. 595 p., diagrs. $11.00.

The series, "Principles of guided missile design", of which this is the second volume, is intended to provide engineers and graduate students with basic information on missile technology. The present volume consists of three sections. Section 1, on general supersonic aerodynamics, deals with such problems as skin friction, shock waves, and loads, and contains material on wind tunnels, ballistic ranges, and flight testing. Section 11 discusses the thermodynamic and aerodynamic principles governing the operating characteristics of jet propulsion engines. Section III covers the design of the airframe and the packaging of its contents. Each section includes a bibliography.

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

LIBRARY HOURS

Monday to Friday

9 a.m. — 5 p.m.

Saturday 9 a.m. - 12 noon.

Automatic digital calculators, 2nd ed.

A. D. and K. V. Booth. Toronto, Butterworth, 1956. 261 p., illus.

In this second edition the text has been revised and brought up to date by the inclusion of new material, such as the ferro-electric matrix store and certain automatic coding procedures which have recently been introduced.

The book is intended to serve as a guide to the theory, design, construction and use of digital calculators. The first part contains an historical introduction and an account of the nature and function of the machines. The second part considers the design of calculating machines and their components. The last chapters cover coding and programming, and the uses to which calculating machines have already been put.

The book provides a good clear coverage of the subject, and contains a lengthy bibliography for further reading. It is unfortunate, however, that more detailed references were not given, as some of the items listed are practically impossible to identify.

***Automatic digital computers.**

M. V. Wilkes. London, Methuen, 1956. 305 p., 42/-.

Emphasizing general principles, this book covers design, principles of programming, relay computers, storage, switching circuits, and computing circuits. An introductory chapter surveys the development of computers from Babbage to EDVAC, and the last chapter deals with special problems of design and operation, the organization of a computer center, and applications in business and industrial processes. A detailed description of EDSAC and brief descriptions of other computers are included.

***Aircraft materials and processes, 5th ed.**

G. F. Titterton. Toronto, Pitman, 1956. 398 p., illus., $6.00.

This is a compilation, for engineers and designers, of essential information on metals, wood, plastics, rubber and other materials, and on heat treating, surface hardening, joining, forming and other processes. Numerous suggestions are included on the choice of materials or processes for specific applications. Emphasis has been placed, in this edition, on the effects on materials of heat from aerodynamic heating and jet engines, and changes have been made throughout the text in order to take into account recent advances.

Appraising and integrating employee benefits.

R. D. Gray. Pasadena, California inst. of tech., 1956. 24 p., $1.00 (U.S.) (BIRC pub. no. 3)

Every employer must deal with the problem of employee benefits, and this publication considers how an integrated

program may be developed to serve the needs of both employees and the employer. Since no one system is applicable to every case, the principles of developing such a program are presented.

*Atmospheric pollution, its origins and preventions.

A. R. Meetham. London, Pergamon, 1956. 302 p., illus., 63/-.

This is a general approach to the subject, intended to provide engineers, public health officials and other interested readers with a foundation for more technical studies. It includes discussion of fuel, fuel burning appliances, and industrial processes as sources of pollution, as well as information on measurement, distribution, effects, and remedial measures. This edition includes a new chapter covering pollution in fogs, pollution from nuclear reactions, and recent trends in Great Britain. A bibliography has also been added.

Canadian universities and colleges, 5th ed.

London, National conference of Canadian universities, 1956. 194 p., $2.00.

A directory of Canadian institutions of higher education giving the following information for each: a brief history, lists of administrative officers, degrees and diplomas conferred, grading systems, and special facilities such as graduate scholarships offered, and affiliated schools. Two sections cover special curricula and summer schools. A useful reference book for any library.

Electronic metal locators.

H. S. Renne. Indianapolis, Sams, 1956. 117 p., illus., $2.50 (U.S.)

Although originally developed as mine detectors, metal locators now have a variety of uses ranging from metal prospecting to the detection of metal in food.

This book discusses the three basic types of locator, and explains their operation, construction and application.

A list of manufacturers of electronic metal locators is included in the appendix, as well as a bibliography of periodical articles and books, including a section on the location of buried treasure.

Encyclopaedia of the iron and steel industry.

A. K. Osborne. London, Techincal press, 1956. 558 p., 90/-.

This Encyclopaedia provides, in dictionary form, a concise description of the materials, plant, tools and processes used in the iron and steel industry, and in allied industries, from the preparation of the ore to the finished product.

The work is based on information collected by the author in the twenty-odd years she has been librarian of Brown-Firth in Sheffield.

There are concise definitions of the many terms involved, and a thirty-page bibliography listing the source of many of the definitions.

The appendices include conversion tables, tables of weights and measures, the properties of steels, and a list of societies related to the iron and steel industries.

This is an invaluable work, and should be in the library of anyone connected with the industry — it is, indeed, almost a library in itself.

*Engineering as a career.

R. J. Smith. Toronto, McGraw-Hill, 1956. 365 p., $5.70.

This book introduces the beginning engineering student to the nature of the profession, to the type of studies in which he will be engaged during his four years of college, and to selected topics in civil, electrical, and mechanical engineering. The qualifications, duties, and responsibilities of the engineer are indicated, and the profession is described both in terms of the major branches and in terms of functions—research, design, construction, management, etc. Materials, mechanics, thermodynamics, electrodynamics, and engineering economy are the engineering subjects introduced.

Engineering dynamics. v.2. Elastic problems of single machine elements.

C. B. Biezeno and R. Grammel. London, Blackie, 1956. 527 p., 90/-.

Intended as a graduate text, the four volumes of this work presuppose a knowledge of elementary mechanics and the mathematics connected with it. The book deals with some of the static and kinetic problems which have to be solved by means of the scientific methods of mechanics. The solutions of the problems are given in great detail; consequently there is a limited number presented.

The other volumes in the series have covered the theory of elasticity, steam turbines and internal-combustion engines. This present volume is concerned with the elastic problems of single machine elements, and the topic is considered under four headings: beam and shaft; spring and ring; plate and shell; and problems of elastic instability.

The four volumes are translated from the second German edition which appeared in 1953, and are a valuable addition to the literature on the subject.

*Flow of gases through porous media.

P.C. Carman. Toronto, Butterworth, 1956. 182 p., $6.00.

An integrated and, as far as possible, quantitative account of flow in and through fine-pored media, with emphasis on theory and experimental methods rather than specific applications. Approaching the subject from the Kozeny theory, the author deals in seven concise chapters with such topics as flow through unconsolidated beds, the permeability method of surface measurement, the separation of gas mixtures, diffusional flow, and the transition to turbulent flow. References are listed after each chapter.

*An introduction to fluvial hydraulics.

Serge Leliavsky. Toronto, Longmans Green, 1955. 257 p., illus., $6.00.

A brief summary of various theories, methods, and facts relating to the flow of water in erodible channels. The subjects dealt with include sediment transportation; the difference between traction and suspension; correlation between surface slope and particle size; dunes and ripples; scour criteria; bed-load; side slope stability; and three-dimensional characteristics of the water flow in rivers.

James Brindley: the pioneer of canals.

Laurence Meynell. Toronto, Ambassador, 1956. 190 p., illus., $3.00.

With so much attention focused on the St. Lawrence Project and its attendant ship canal, it is interesting to read this account of the self-taught millwright who was the first great canal engineer in England, and whose first canal was completed in 1761, ushering in a new era in transportation in England. This, the Bridgewater canal, was made even more remarkable by the fact that it was carried on an aqueduct across a navigable river.

Anyone interested in the history of navigation canals would find this an absorbing book, telling as it does of the difficulties encountered in their early financing and construction.

Lectures on the icosahedron and the solution of equations of the fifth degree, 2nd ed. rev.

F. Klein, tr .by G. G. Morrice. New York, Dover, 1956. 289 p., pa. $1.85 (U.S.)

This book covers the solution of quintics in terms of the rotations of regular icosahedron around the axis of its symmetry. It is a basic source book on the mathematics of equations of the fifth degree, and the mathematics of crystallography.

Mass communication.

Erik Barnouw. Toronto, Clarke, Irwin, 1956. 280 p., $4.50.

Television, radio, films and the press are the media covered, with specific application to the United States, although naturally many of the statements apply equally to Canada.

● LIBRARY NOTES

The work is divided into four sections covering history, psychology, the media themselves, and the sponsors of mass communication. This final section includes case histories showing the success experienced through mass communication by businesses, government agencies and non-profit organizations. There are useful bibliographies appended to each section.

The history of mass communication is relatively short, and it is well to be reminded that this is so. The author points out how our way of life is influenced by the constant bombardment to which we are subjected, and how it is largely made possible by the various means of mass communication.

*Mechanics of the roller chain drive.

R. C. Binder with the collaboration of the Engineering Staff of the Diamond Chain Company. Englewood Cliffs, Prentice-Hall, 1956. 204 p., illus., $5.00 (U.S.)

This mathematical analysis of the dynamics and statics of roller chains operating over sprockets provides a basis for developing the power capacity, or rating, of roller chain drives. Among the factors analyzed are centrifugal force, tooth pressure angle, roller velocity, sprocket velocity, chain strand vibration, and the path of the chain strand. The last chapter is an analytical study of a simple type of roller chain drive, made in order to outline a general method for rating drive.

Numerical integration of differential equations.

A. A. Bennett and others. New York, Dover, 1956. 108 p., $1.35 (U.S.)

New methods of integration of differential equations are presented in considerable detail by the authors. These include methods for partial differential equations, transition from difference equations to differential equations, and solution of differential equations to non-integral values of a parameter. The emphasis is on step by step methods of integration.

Oil accounting: principles of oil exploration and production accounting in Canada.

R. E. Waller. Toronto, University press, 1956. 99 p., $5.50.

The rapid growth of oil and gas exploration and production in Canada has resulted in accounting methods being adopted in many cases without due consideration being given to the fundamentals underlying them.

In this book the author outlines the more significant features of oil exploration and production accounting practices, and the concepts on which they are based. Some of the topics covered include cost allocation, depletion and depreciation, income measurement, and statement disclosure.

This book will fill a gap in the published material relating to the Canadian oil industry. It has been produced as part of the programme of the Canadian institute of chartered accountants which is trying to develop accounting literature, especially in fields of special significance to Canadian practice.

Oil pipe line measurement and storage practices.

Austin, Texas University, Petroleum extension service, 1955. 134 p., illus., $3.25 (U.S.)

Published in co-operation with the American petroleum institute, this third volume in a series on oil pipe line transportation practices covers tank construction, strapping tanks, tank gauging and measurement and the quantity measurement of liquid petroleum with meters. An appendix covers the cleaning of petroleum storage tanks.

The book is clearly written and illustrated and should prove useful to all those in, or entering, the petroleum industry.

*Power plants, 2nd ed.

A. H. Zerban and E. P. Nye. Scranton, International Textbook, 1956. 655 p., illus., $8.50 (U.S.)

The new edition of this text, previously published under the title STEAM POWER PLANTS, has been broadened in scope to provide a coordinated treatment of all types of power-generation equipment. The material on internal combustion plants has been expanded, a new chapter on hydro plants has been added, and recent developments such as supercritical vapor cycles and nuclear power are discussed.

*Practical petroleum engineers handbook, 4th ed.

Joseph Zaba and W. T. Doherty. Houston, Gulf Publishing Co., 1956. 818 p., $14.00 (U.S.)

An extensive compilation of tables, charts and formulas connected with drilling and production practice, including sufficient explanatory text material for practical use. There are also separate chapters on general engineering data. About one hundred and fifty pages of new material have been added in this edition.

The physics of nuclear reactors.

London, Institute of physics, 1956. 112 p., 25/-. (British Journal of Applied Physics, suppl. no. 5)

This volume contains the papers and discussions presented at a conference on the subject held in July 1956 by the Institute of physics.

The majority of the papers are by British experts, and cover such topics as the physics of advanced reactors, the zero-energy fast breeder reactor, ZEPHYR; the roles of chemistry and metallurgy in a nuclear energy project; shielding for reactors; the instrumentation of reactors, and United Kingdom research reactors and their uses.

As Sir John Cockroft wrote in his foreword, this is a record of the present state of knowledge of the subject, and of the gaps still to be filled.

Réaumur's memoirs on steel and iron.

Translated by A. G. Sisco. Toronto, University press, 1956. 396 p., illus., $6.00.

Although his name is now best known in connection with a temperature scale and a station on the Paris underground,

● LIBRARY NOTES

Réaumur was an important figure in eighteenth century France. Trained as a mathematician, he was interested in all branches of pure and applied science, and in his Memoirs, which appeared in 1722, is the first published description of the method of changing iron into steel. In this work he also describes the manufacture of malleable cast iron.

In addition to their scientific value, which is considerable, Reaumur's memoirs throw interesting side-lights on the France of the period. Their first appearance in English translation will be welcomed by those interested in the history of science, and by all metallurgists.

Rayleigh's principle and its applications to engineering.

G. Temple and W. G. Bickley. New York, Dover, 1956. 152 p., pa. $1.50 (U.S.)

In this study Rayleigh's Principle is developed to provide upper and lower estimates of the true value of the fundamental period of a vibrating system, or the condition of stability of an elastic system. In this way a useful means of determining frequencies and critical loads is provided.

°Robert Maillart.

Max Bill, ed. Zurich, Girsberger, New York, Heinman, 1955. 184 p., illus., $11.00 (U.S.)

This volume consists mainly of reproductions of photographs and cross section drawings of the structures designed by the Swiss engineer Maillart (1872-1940). Brief comments on the structures and extracts from Maillart's writings, for the most part given in French, German, and English, accompany the illustrations. Although most of the book is devoted to bridges, one section covers other structures, especially those with mushroom column construction.

This is a beautifully produced book, and will be of interest to all our members connected in any way with the design and construction of bridges.

°Science and economic development; new patterns of living.

R. L. Meier. New York, Wiley, 1956. 266 p., $6.00.

The author briefly reviews world needs and resources and discusses possible means of attaining a reasonable level of living for the world's population by the application of recent discoveries in science and technology, particularly in the areas of foods and fuels. He also deals with the possible effects of new technologies on social and industrial organization, and suggests that a "mutant type of scientist and engineer", a scientist-executive, may achieve dominance in the resulting society. Fundamental problems needing solution – the protein supply, low-grade ore utilization, means of transport, and others are listed in an appendix.

Timber design and construction handbook.

Timber engineering co. New York, Dodge, 1956. 622 p., illus., $12.75 (U.S.)

The results of advances in timber design procedures and construction practice are found in this reference book which has been prepared by a research organization long active in the field.

The first chapters discuss the basic properties of wood—its types, grades and methods of preservation. The chapters on design and construction cover preliminary considerations such as load, choice of fastenings, etc.; post-and-beam construction; roof trusses; arches, including lamella roof construction; special framing; outdoor structures; plywood; fabrication, assembly, erection and maintenance. There is a chapter on specification forms, and a compilation of reference data, including weights of different woods, loads, maximum spans, etc.

The final section of the book reproduces the design standards issued by the National lumber manufacturers association, the Timber engineering company, the American standards association and the American society for testing materials. This, needless to say, is a very useful and valuable section.

Much of the material in the book has not been previously published, and certainly little of it has appeared before in such a compact and usable form.

Structural geology of Canadian ore deposits.

Montreal, Canadian institute of mining and metallurgy, 1948. 948 p., illus., $10.00.

This symposium was published to commemorate the fiftieth anniversary of the founding of the Institute. It provides a valuable source of information on Canadian geology, especially those features which control the deposition of ore.

Each chapter is written by an expert, and describes the geology of a particular mine or district. These chapters are grouped together into geographical units, and arranged in three main groups corresponding to the geological regions of the country – the Cordilleran region, the Precambrian Shield and the Appalachian region. There are also general papers on each region, and on the relationship of minor structures to gold deposition.

The book is illustrated with many diagrams, and is well indexed. There are bibliographical references at the ends of many of the chapters.

A technology for the analysis, design, and use of textile structures as engineering materials.

W. J. Hamburger. Philadelphia, American society for testing materials, 1955. 50 p., diagrs., $1.50 (U.S.)

A brief review of the development of textile technology introduces this lecture, which considers the applications of engineering principles to textile research including the elastic behavior of textile materials in tension, compression, binding and torsion. Objective and subjective functional performance characteristics of textile structures are also considered. This is the twenty-ninth Edgar Marburg lecture.

°Transport processes in applied chemistry.

R. C. L. Bosworth. New York, Wiley, 1956. 387 p., $12.00.

This is a theoretical treatment in which the author's concept of a "carrier" is used to explain the mechanism of transport processes: electric current, the flow of heat, diffusion, the transfer of momentum, etc. Among major topics dealt with are coupled transport processes, transport by molecular motion, radiant and convective transfer, turbulent and interphase transport, and irreversibility. The author suggests that unit operations or entire factory operations may be treated as a single, equivalent transport process, and also deals with feedback, cascade operations, and chemical similarity.

In plant after plant across Canada, B & W boilers are providing the steam for heating, power or lighting . . . every installation a particular achievement in itself. The ability to engineer and construct steam generating units, which will **reliably** and **economically** perform the task of supplying steam, for either a modest load or for a giant public utility project, has only been made possible by the competent staff, the relentless research and the modern manufacturing method employed in the shops and the field by Babcock-Wilcox and Goldie-McCulloch Limited.

Take advantage of this experience — ask **first** for the recommendations of a B. & W. engineer for your next steam generating problem.

Workshop for management.

Systems and procedures association of America. Greenwich, Management publishing, 1956. 499 p., $19.00 (U.S.)

Reproduced in this volume are the proceedings of the eighth annual systems meeting sponsored by the Systems and procedures association of America. The Association, founded in 1944, has as its objective the improvement of management in business and industry. Its conferences are designed to keep its members, and others concerned, abreast of current developments in the field.

The emphasis at the conference was on electronic equipment, and some of the topics covered were: surveying present methods and costs before considering the installation of electronic equipment; selecting the right electronic system for the office; training personnel to use the new equipment; organizing the company for an electronics operation; what to expect from the equipment; and when to use manual rather than electronic equipment.

Some of the other subjects discussed were: operations research as applied to production control and inventory management; forms control; work measurement; office incentive plans; records management, etc.

The speakers and seminar participants at the conference were all leading executives, management consultants and electronic office experts: consequently, the information presented is based on actual experience, and represents some of the latest and best information on the subject. The value of the book is increased by the inclusion of a detailed index.

Nuclear power plants.

Nuclear engineering. Calder Hall number Oct. 1956.

Petroleum products.

Storage and handling of liquefied petroleum gases. (Dominion board of insurance underwriters. Standard No. 58)

Sanitary engineering.

STANDARDS REVIEWED

British Standards, British standards institution, 2 Park St., London, W.1. Also available from the Canadian standards association.

B.S. 84:1956—Parallel screw threads of Whitworth form.

This standard includes tables of basic sizes, limits and tolerances for B. S. Whitworth and B. S. Fine screw threads. An allowance (minimum clearance) is provided on certain classes of bolts of sizes up to and including ¾ in. diameter; the recommended associations of classes of bolts and nuts include nuts having larger effective diameter tolerances than the corresponding sizes of bolts. Three classes of tolerance are provided for bolts, two classes for nuts. No change has been made in the formulae used as a basis for tolerancing effective diameters and other thread elements. 10/-.

B.S. 2772: 1956—Iron and steel for colliery haulage and winding equipment. Part 1—Wrought iron; Part 2—Wrought steel.

These standards cover the requirements of the mining industry in respect of materials for types of load-carrying components of haulage and cage-suspension gear. General requirements for both parts deal with dimensional and weight tolerances, the marking and provision of material for testing, and tensile and bend test requirements. Specific requirements for Part 1 cover "Best Yorkshire", "Special" grade and Grade A wrought iron. Specific requirements for Part 2 cover 25/30 ton carbon steel, 1.5 per cent manganese steel and 50/70 ton tensile steel. The appendices include tables of metric equivalents, forms of B.S. test pieces, and information on "ruling sections". Pt. 1 6/-; Pt. 2 4/-.

The Aviation and Associated Industries

THERE ARE many Canadians, we suppose, who think of our aviation industry as one of our newer and smaller industrial activities. The truth, of course does not bear this out. Right within the borders of our own country, the construction, operation, and maintenance of aircraft have reached proportions which make the field of aviation one of Canada's most important and complex activities. The numbers of personnel engaged, and the millions of dollars spent annually on aviation by this nation, place it well in the front rank of our economy, taking its place with the older ones.

All of this has come about, of course, within the last fifty years, and indeed most of it inside the span of the last fifteen or so—since the beginning of the second world war. Much of the requirement, but by no means all of it, has been military. The war itself, and the long chain of events since, have kept the pressure on for more and more of the latest aircraft capable of carrying out adequate national defence. This demand still goes on, and when it may end is anyone's guess.

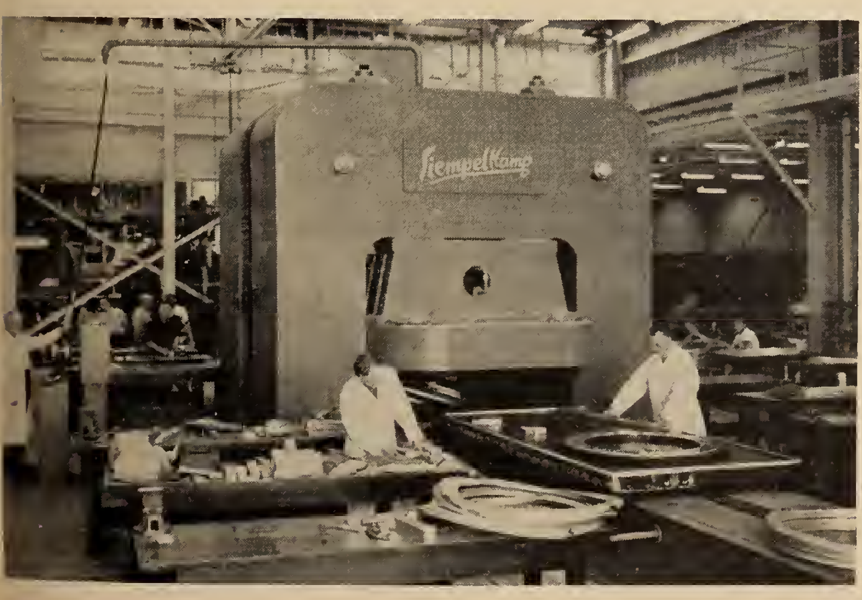
The New Aircraft Industry

The beneficial result of this, so far as the Canadian economy is concerned, has been the creation and expansion of a string of plants for the construction, modification, and repair of aircraft — together with their engines and other equipment—which have commanded the admiration of experts from countries far larger and more experienced than ours. Postwar developments now include the design and production of both aircraft and engines that are wholly Canadian, engineered entirely in this country.

Northern Development

At the same time, another impetus has been added to the aviation industry's expansion in Canada by the new conquest of the North, which is rolling forward with ever increasing momentum. This has brought with it the demand for new and better "bush" type planes, rugged freighters, helicopters, and aircraft specially equipped for mineral exploration. In these fields we have become the acknowledged leaders — Russia of course dissenting!

A large metal-forming press used in the Canadian aircraft manufacturing industry. Sheet metal is shaped over a form by hydraulic pressure, in this case through a 10 ft. by 5 ft. rubber pad at 400 lb. per square inch. Total pressure is 15,000 tons.



Civil Air Transport

While all this has been going on, we must not overlook the developments that have been taking place in our civilian air transport industry. From small beginnings, not too many years ago, Canadians have developed their air carrier business to an enviable position, both domestic and international. Planes of our major air line fleets are familiar sights on any airport in Canada, and on most of the important ones of the free world abroad.

That this varied activity requires hundreds of engineers, and will continue to require them in substantial numbers, is most obvious. It is a technical industry in nearly all of its phases, with places for engineers from several branches — principally aeronautical, civil, mechanical, and electrical. The challenge and adventure of it will appeal to a great many of our young men.

Some of the fields in which engineers are needed are outlined below.

Manufacturing

The manufacturing industries, which are steadily expanding, produce airframes and aero-engines. Associated industries also produce a great range of further equipment which goes into the make-up of a complete aircraft.

The industry is constantly looking forward in design of airframes and engines, and many design engineers are needed in both these fields. Throughout the industry, in fact, designs are constantly being advanced.

Manufacturing processes use much heavy mechanical equipment, such as hydraulic presses for forming sheet metal for airframes, and a wide range of usual and specialized machine tools. Many mechanical and electrical engineers are on operating and maintenance staffs, and other engineers are usually responsible for carrying out the often complex production schedules.

The quality of materials and components in an aircraft must be of the highest order, and quality control is another important field for the engineer.

Operating

The operation of civil airlines also involves engineering staffs. There are many operators, from the large passenger- and freight-carrying lines to those who use aircraft for special purposes, such as survey work. In all cases aircraft must be maintained by technical staffs under the supervision of engineers, though some of the major work may be carried out by the manufacturers.

Mechanical engineers play their part in this work and electrical engineers are widely concerned in the maintenance of radio, radar, and other electrical equipment.

Directly concerned with the operation of aircraft are the airfields and airports which must constantly be developed to keep pace with the expansion of operations. Not only are new areas being opened up, requiring first airfields for the movement of men and materials and later regular airports, but existing facilities rapidly become obsolete if they are to continue to handle an increased volume of traffic and the heavier and faster aircraft being developed, particularly with the wider use of the jet engine.

Though not always directly a part of the aviation industry, many civil engineers are concerned with the building and extension of runways and the construction of airport buildings and facilities, as are engineers in other fields, for example, the provision and maintenance of electrical power supplies and equipment.

Special Operations

Mention has been made of operators of aircraft for special purposes such as survey work. In a great and relatively undeveloped land area such as Canada, exploration and mapping from the air are very important. The discovery and development of mineral resources, abundant in remote areas, is the concern of a rapidly growing industry that uses various aerial survey methods, often with specially-equipped aircraft.

In addition to the engineering staffs required to maintain the flying operations, there is much specialized work in the design and development of, for example, electromagnetic and other survey instruments, and also in the interpretation of survey results.

Aviation plays a great part in the development of Canada's remote territories and mineral resources, which can often only be approached by air until other routes are made. Aerial survey methods represent one of the specialized means of mapping territory and finding mineral deposits. Here, a helicopter handles an aerial electromagnetic survey device with its 20-ft. long "bird".

Research and Development

There is an intense international race for air supremacy, both in the military field and that of civil aviation. As higher speeds and longer ranges are attempted, so must new materials, manufacturing methods, and means of propulsion be developed. Design staffs are working on advanced jet engines and rocket motors. Flight at speeds many times the speed of sound poses countless problems to be solved by the aerodynamics and structural engineers. Complex instrumentation and electronic equipment, for example, for flight control, and so on are the province of the electrical engineer and the engineering physicist.

Administration

Within all the fields mentioned so far there is scope for the engineer to advance through supervisory positions to the higher levels of management. In a specialized industry such as this, the senior managerial posts are often filled by professional engineers.

Training

Most organizations in the industry take undergraduates for summer work.

For the graduate first joining a company, training is always provided to give him the necessary general and specific knowledge to fit him for his future in the industry. Some organizations have set up their own training schools to help to provide the properly trained manpower needed by the industry.

Salaries and Benefits

Salaries start at least at the prevailing industrial level and rise through various scales to the upper levels of management.

Such benefits as paid vacations, pension and health schemes, are usual throughout the industry. Bonus may be paid in certain cases, and some companies, particularly the airline operators, offer travel concessions.

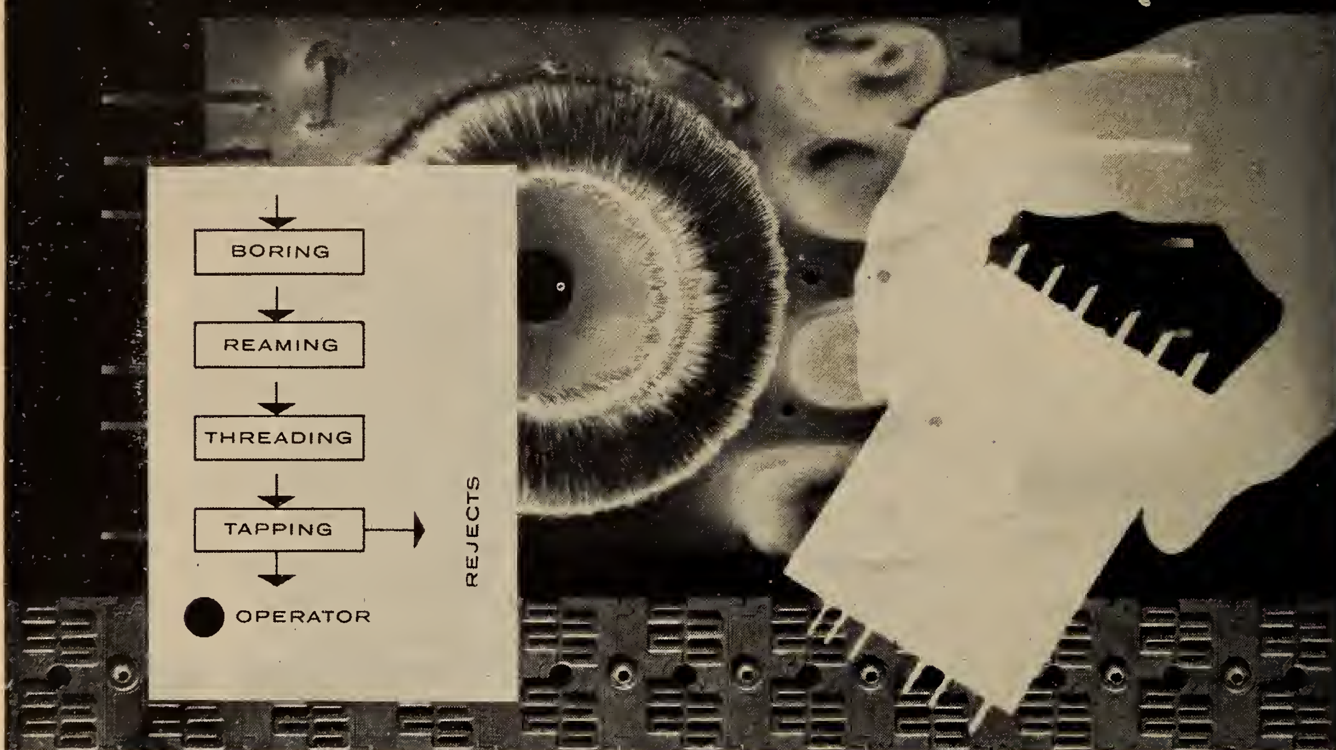
CYPAK
AT WORK...



More reliable, automatic control for machine tools

Fast reaction without a moving part . . . a control that maintenance men can walk by without ever touching—these are some of the benefits you get from CYPAK control systems on machine tools. By eliminating the causes of relay failure—wear, jamming, corrosion—CYPAK gives you greater control dependability and none of the usual control maintenance costs. And CYPAK'S greater speed in handling signals often permits a wider range of work on machine tools than from those equipped with conventional controls.

CYPAK'S elements are encased in solid, plastic blocks which are plugged-in—locked-in to a common power channel. Slip-on connecting wires join the signal terminals. This modern control design permits addition or a recombination of control functions at minimum time and cost and gives you greater adaptability if change-over is necessary.

This is how CYPAK control systems back up machine-tool production. Your Westinghouse representative has more information on steel, paper, rubber, and other industrial applications. Call him today. Or write Canadian Westinghouse Company Limited, Industrial Control Department, Hamilton, Canada.

Canada's Approach to the Economic Fuelling of Nuclear Power Reactors

A. J. Mooradian

Superintendent, Engineering Development Branch, Atomic Energy of Canada Limited

Read at the Biennial Meeting of the Atlantic Provinces Professional Engineers, St. Andrews, N.B., September 1956

The author believes that it is possible to fuel a power reactor to compete economically with present thermal power stations; the heavy-water reactor promises best to give low fuel costs. Work done on fuel problems, particularly at Chalk River, is described in the paper. Results encourage the view that problems will soon be solved.

WE FIND ONE thing in common among all participants in the development of nuclear power. This common focal point is the vision of nuclear power supplying the world with virtually a limitless supply of power at a cost which will allow an unlimited industrial expansion. No serious thinking scientist or engineer will deny this vision.

The popular press and technical publications have allowed the public to share this hope for the future. The 1955 boom in the uranium market is proof of the public's willingness to participate in the development of nuclear power.

However, one cannot help but sense that within the last year some confusion has settled over the clear vision we had in the past. This is nothing more than an indication that the whole field is trying to mature very quickly.

Following the Geneva Conference, there was a flood of declassified information on nuclear power reactors. In the wake of this tidal wave of data, the reactor designers of all countries quietly started to compare their respective approaches to the ultimate goal of the economic power reactor.

Where we found in the past one clear vision, we now found a confusion in the number of approaches to its fulfilment. Where all scientists agreed that it was possible, most designers differed in their approach.

The public, on the other hand, had been so conditioned to the high yield of energy from nuclear fuels that it came as a surprise that anyone should have to make a case for a reactor which would just meet costs of present day coal-fired stations.

There are at least half a dozen different types of reactors which are being seriously considered as power producers. The fundamental variations are largely the result of differences in technical judgment. The same mathematical precision which predicted the possibility of a self-sustaining reactor cannot be brought to bear on the decision as to the best design approach.

It is apparent to those of us in the field that the time is at hand when the nuclear physicist must gracefully relinquish his pre-eminent position in the field of fission reactors.

I would like to quote a passage from a paper prepared by Rear Admiral Rickover, delivered before a meeting of the American Society for Metals, October 20th, 1955. Admiral Rickover is the man responsible for the successful development of the nuclear powered submarine:

> "It is a common belief that atomic power development is primarily the province of the nuclear physicist. Nothing could be further from the truth. What actually faces us is how to determine by calculation and by experiment, the best way to remove heat from a reactor and then to design and build all of the components of the reactor system so that they will operate safely and reliably under the most rigorous conditions."

Economic nuclear power is now dependent on the best answers to the following type of questions:

(*a*) How can a fuel element be made cheaply which will stand up in a nuclear reactor?

(*b*) How can a leak-free system be made cheaply?

(*c*) How can a pressure vessel be made large enough to be economic?

(*d*) What is the cheapest way to get fuel in and out of the reactor?

(*e*) How can irradiated fuel be processed cheaply enough to warrant recovery of fissionable material?

These and a hundred other such questions must be answered by the engineers, chemists, metallurgists, physicists, biologists, and so on.

It is not my intention today to try to cover the whole picture, but rather to give you an idea of how we in Canada are attempting to answer one of the most important of these questions — that of the type of fuel elements which we expect to see in the reactor of tomorrow.

The one aim which all approaches to nuclear power have in common is that of attaining low fuel costs.

The Canadian approach to nuclear power possibly weighs this factor more heavily than most other alternative approaches.

The Chalk River program is based on natural uranium heavy-water moderated reactors. Although it is recognized that heavy water moderation is more economic of fuel than any other type, opponents of the scheme base their criticism largely on the fact that leakage of heavy water from the system at $28/lb. can constitute a crippling expense. Alternatively Canada's confidence in her approach is based on 10 years of successful containment of heavy water and the confidence that the engineering problems of containment in a high pressure system can be solved economically.

The public has been faced by such a barrage of stunning comparisons between the comparative amounts of energy which can be obtained from uranium and from coal that now when nuclear power is asked to compete with conventional fossil fuel stations, it comes as a shock that fuel costs should even appear on the nuclear power balance sheet.

The simple facts are these:

(1) The capital cost of a power reactor will be higher than that of a comparable coal-fired station. For example, the capital cost of a conventional coal-fired station of 100 megawatt capacity today will fall in the range of $120-$160 per kilowatt of installed capacity. The first power reactors of this capacity are expected to fall in the range of $500 to $600 per kw. of installed capacity. It is expected that development of simpler designs and less expensive construction materials and methods should cut this down to $250 per kw. However, it is not likely that reactors will be installed as cheaply as thermal stations in the foreseeable future.

(2) It is also unlikely that the operating cost of a power reactor will be cheaper than that of a coal-fired station. The equipment, controls, maintenance, fuel charging, etc., are all considerably more complex than a conventional thermal station — at least for the foreseeable future.

(3) With operating and capital costs higher than a coal-fired station, the fuel costs will have to be lower than coal in order to make nuclear energy competitive with present day fuel costs.

This then gives us a starting point for a fuel development program by defining the upper acceptable limit of fuel costs. Large base-load thermal power stations burning coal at $8/ton give power at about 5.4 mills/kwh., of which the coal cost is about 3 mills.

To be competitive with coal-fired stations, the fuel cost allowance for power reactors varies according to the optimism of the estimator, but falls in a range covering 1 to 2 mills/kwh.

Now let us see what is being done in Canada to achieve this goal of nuclear fuel costs between 1 to 2 mills/kwh. and to look at the problems which we face in aiming at such a target.

Early in the short history of nuclear development, it was pointed out that the fission of a pound of uranium would yield three million times as much energy as a pound of coal. Even with the higher cost of uranium taken into account, on this basis, it works out that uranium would be about a thousand times cheaper than coal as a fuel.

Now if this were the whole story, the problem would be licked and we could expect nuclear stations to spring up like mushrooms.

Obviously, there is something more to the story.

It turns out that there are a great many expensive problems standing in the way of extracting all of the energy available in the uranium. Some of the limitations are fundamental in nature and some of them are practical.

Fundamental Problems

Natural uranium as mined is a mixture of two isotopes, U^{238} and U^{235}, both of which behave so much alike chemically that there is no separation of the two isotopes in the course of normal chemical processing. Thus, we can take uranium ore and convert it all the way to metal and the relative percentages of the U^{238} and U^{235} do not change.

Now these two isotopes occur in natural uranium in the ratio of 140/1 with U^{238} being 140 times more abundant than the U^{235}. The sad part about these figures is that the most useful of the two isotopes is the one which is the least abundant — the U^{235}.

The fundamental essence of economy in a reactor is the conservation of neutrons. Any neutron which is captured without ultimately being responsible for a fission is a dead loss.

With regard to neutron economy, there is an important difference in the behaviour of the two isotopes of natural uranium. When a neutron is captured by U^{235}, atomic fission occurs, with the expected enormous release of energy. On the other hand, when an atom of U^{238} captures a neutron, it is quietly transformed into an atom of plutonium (Pu^{239}). However, this is not a complete loss because Pu^{239} is itself as fissile as U^{235}. That this, when Pu^{239} captures a neutron it too will release an enormous burst of energy. The net effect is this:

> It takes one neutron to cause fission of U^{235} but it takes two neutrons eventually to cause fission of U^{238}. Thus, U^{235} is called a fissile material, and U^{238} is called a fertile material —fertile because it can be converted into a fissionable material.

With this in mind, we should be in a position to take a look at the important events which are taking place in natural uranium fuel inside a reactor with regard to the fundamental limitations on fuel economy.

(1) The U^{235} is being burned up to give energy which shows up as heat.

(2) U^{238} is being converted to Pu^{239}.

(3) Some of the Pu^{239} is being burned to give energy.

(4) Because the Pu^{239} is not being burned as quickly as it is being formed, there is a net accumulation of plutonium in the fuel element.

In a well designed reactor, it is possible to produce 8 atoms of Pu^{239} for every 10 atoms of U^{235} which are burned. If no other factors were involved in limiting the fuel life, it would be possible to burn about 3 per cent of the total uranium. If we could get the uranium into the reactor at $25/lb. and gave ourselves a 25 per cent thermal to electrical efficiency, the fuel cost would be 0.33 mills/kwh. — well within our target cost.

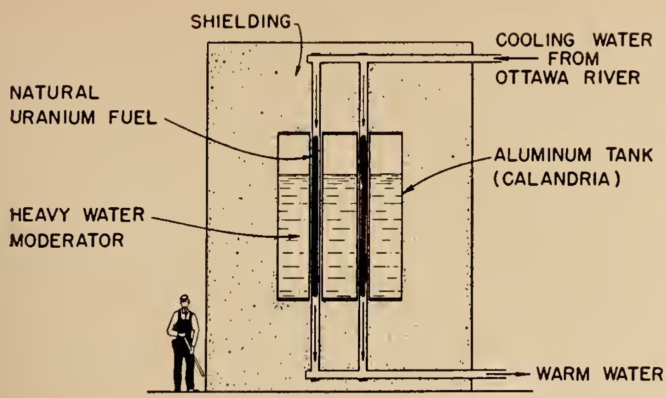
However, another fundamental factor is involved which prevents the attainment of such high burn-up in a single irradiation. This limitation is imposed by the accumulation of the so-called "atomic ash" — the products of fission.

The fission products are neutron parasites. They absorb neutrons without giving rise to either fertile or fissile material. Clearly there is an economic limit to the allowable accumulation of fission products in the reactor.

The nuclear physicists set this fission product poison limit between a burn-up of 4,000 megawatt days/tonne and 6,000 megawatt days/tonne. This corresponds to a cost of between 1.5 - 2.3 mills/kwh., which is within the range of the target figure for fuel.

At this limit, there is a large accumulation of Pu^{239} in the fuel which cannot be economically used because it is associated with the parasitic fission products.

Thus, if the Pu^{239} could be economically separated from the fission products, it would again be a useful fuel. Because Pu^{239} is chemically different from both uranium and fission products, it is possible to make



NRX TYPE REACTOR

Fig. 1. Schematic diagram of the NRX type of reactor.

such a separation by a suitable chemical process.

At Chalk River, we are sufficiently attracted by the possibility of improving the fuel economy by recycling the plutonium that it has given rise to two of our more vigorous programs —that of fuel processing, and that of Pu fuel rod development.

Obviously, there is a practical limit to the number of times the plutonium may be recycled, but it appears likely that fuel processing costs can be made sufficiently attractive to warrant at least a single recycle. One such recycle would allow a net uranium burn-up of 10,000 to 15,000 Mw. days/tonne, giving us fuel costs between 0.6 and 0.9 mills/kwh.

Thus far we have only looked at the fundamental economic aspects of the fuel itself. Other fundamental limitations exist which arise from the necessity of sheathing and cooling the fuel material. These limitations arise because all materials other than fissile or fertile materials are neutron parasites exactly in the same way that fission products are neutron parasites.

Table I shows the price which must be paid to have fuel sheathing and fuel cooling media present in the pile. A similar table was prepared for

Table I*. Irradiation Costs

Material	Irradiation Cost per neutron/kilobarn $/lb.
Lead	0.64
Zirconium	1.5
Magnesium	1.7
Aluminum	5.9
Iron	30
Stainless steel	37
Nickel	55
Oxygen	0
Heavy water	0
Natural water	26

* Based on uranium at $25/lb.

presentation at the Geneva Conference by Dr. Lewis, the vice-president in charge of research and development at Chalk River.

The term neutron/kilobarn needs some explanation. An irradiation of one neutron/kilobarn would be achieved in 116 days (4 months) at 10^{14} neutrons per square centimetre per second. This would correspond to an irradiation of about one year in NRX. The power reactors of the future will probably have neutron fluxes in this order of magnitude.

This means that for every pound of one of these materials we find in the NRX reactor, for example, it would cost the corresponding figure per year of reactor operation.

It is obvious that we are economically limited in the choice of the sheathing and cooling materials which can be used. There are, of course, other technical criteria which further limit the choice of materials.

The comparison in cost between light water and heavy water is also very interesting in that it forms the basis for Chalk River's approach to economic power reactors.

Let me now summarize the fundamental limitations on fuel economy.

First, natural uranium can be taken to a burn-up of 4,000-6,000 Mw.d./tonne before the accumulation of fission products makes further irradiation uneconomic. Assuming we can put natural uranium in the reactor at $25/lb., this would make it possible to produce power at a fuel cost of between 1.5 and 2.3 mills/kwh. if we did nothing more than throw away the spent fuel rod.

However, a further fuel economy can be achieved if the plutonium is separated from the fission products in the spent fuel rod and recycled to the reactor. On such a basis, it is expected that the fuel costs may easily be brought down to 0.6 - 0.9 mills/kwh.

The achievement of maximum burn-up is important in order to get the maximum benefit from recycling plutonium. The longer fuel is in the reactor, the more plutonium will accumulate.

It is clear from what has been said thus far that it is possible for uranium to compete with coal as a fuel within the fundamental limitations of uranium burn-up, but that at present day costs, the advantage is not large.

Practical Problems

Thus far we have talked about the theoretical limits on fuel economy. Now let us see what problems we face in trying to approach these limits in practice.

The primary objective of any fuel rod development program is to produce a fuel rod which will withstand the demanding conditions inside a reactor long enough to attain the fundamental limit on economic irradiation.

The Canadian fuel development program started with the NRX reactor (Fig. 1).

NRX is a heterogeneous reactor composed of uranium rods arranged in a lattice within a tank of heavy water. Each uranium rod is equipped with a cooling channel so that light water can carry away the heat produced in the uranium by fission. The fuel element in this reactor is 10 feet long. Figure 2 shows a cross-section of the NRX fuel element.

The core is pure uranium metal. Surrounding this we have a sheath of aluminum metal and a second aluminum tube. Between the sheath and the tube is the cooling channel which is filled with natural water.

Why aluminum? From Table I, lead, zirconium, and magnesium are more desirable from the neutron economy standpoint. Lead we can discard because it has insufficient mechanical strength and too low a melting point. Magnesium is not sufficiently corrosion-resistant. That leaves zirconium as the chief contender. Zirconium is both corrosion-resistant and sufficiently strong — however, at the time NRX was designed, the technology was not sufficiently advanced to permit the fabrication of such sections.

The light water coolant was selected as a measure to simplify the design.

Probably the most important problem faced by any fuel designer is how to get the heat safely out of the fuel and into the coolant. The heat fluxes involved have never before been faced in this kind of service. A section of an NRX fuel rod about one foot in length, placed in the heart of NRX would generate enough heat to keep seven houses warm through a Canadian winter. Now, if you found that your furnace had suddenly been replaced by a small bulge in the hot water line, you would think that furnace technology had made a tremendous step forward. The NRX reactor is in fact burning up uranium at such a rate and has been doing so for about ten years.

However, although we have been successful in designing for such high heat fluxes, the best we have been able to achieve thus far in NRX is a burn-up of 4000 Mw.d./tonne, and this only infrequently.

Here are some of the problems:

1. *Integrity of the Sheath* — The chief reason that the sheath is provided on the fuel rod is to protect the uranium from corrosion. Uranium metal is very susceptible to corrosion in water, especially when it is hot. In fact chips, turnings, and powder must be kept under oil because of their pyrophoric nature. Now, if for any reason the sheath should rupture, we have a problem on our hands. Not only would the fuel rod quickly corrode away but the cooling system would become highly radioactive.

This faculty of fission products (particularly the fission product gases) to leak through pinholes or small ruptures in the sheathing has enabled the detection of a faulty fuel rod before the fuel element has had an opportunity to cause serious damage.

The hazard of a leak in the sheathing is most serious when the corrosion products build up sufficiently to block the cooling channel. If this happens, the uranium core would quickly melt along with the sheathing and serious damage would result in the reactor.

This problem of sound sheaths has required the development of special test procedures and the most rigid control of production methods. Experience has shown that the seal welds are an important source of failure. To overcome this, Chalk River has developed a crew of aluminum welders whose skill is unsurpassed in Canada.

However, with every conceivable precaution taken to provide sound sheaths, the fuel rods still have to be pulled from the reactor before the theoretical limit of radiation has been achieved. Why?

The reason lies with the effect that radiation and thermal cycling have on the uranium core itself.

2. *Behaviour of Fuel Core Under Reactor Conditions* — Uranium metal behaves peculiarly when irradiated. For example, in the early history of NRX, it was found that some fuel rods shortened, some lengthened, some did not change at all. Not a few thousandths of an inch, but changes in the order of several inches over only a ten-foot length.

Because the reactor itself has to be built to fine tolerances, these dimensional changes have a profound effect on the allowable life in the reactor. If a rod fattens too much, it becomes very difficult to pull it out of the reactor. If it lengthens too much, it can block off the cooling ports.

Obviously, in the early days, there was much information missing which made it impossible to correlate the metallurgy of the preparation of the fuel with its in-reactor performance.

Unfortunately, the only way to proof-test a fuel is to irradiate it in a reactor. The process of accumulating the answers to this problem of fuel life is, therefore, a very costly and time consuming business. However, with NRX, we in Canada are in an excellent position to pursue such important investigations. The NRX reactor is one of the best test reactors in operation in the world today. Sufficient foresight was used in the design to allow for the testing of complete fuel assemblies. Furthermore, the flux density is high enough to give the required data very quickly compared with most other reactors. This explains why NRX has been used so extensively on a co-operative basis by both the United Kingdom and the United States atomic energy authorities. It will interest you to know that the selection of the fuel for the large American power reactor, the so-called PWR, has been made largely on the basis of co-operative experiments conducted in Canada's NRX.

Thanks to reactors such as NRX, we are pretty well in a position to be able to predict the behaviour of a given bar of uranium if we have all of the metallurgical history of the metal. The most striking confirmation of this may be found in the increased life expectancy of NRX fuel elements. In 1947, NRX fuel rods were expected to fail at an irradiation of only 300 Mw.d./tonne, whereas today they have been taken to as high as 4,000 Mw.d./tonne.

The work on NRX fuels has been invaluable in pointing the way to the desirable qualities which we are looking for in power reactor fuels.

Fuelling Problems

We in Canada believe that the route to economic atomic power lies through the heavy-water moderated, heavy-water cooled reactor. This poses some fuelling problems not yet mentioned. For example:

(1) The pure aluminum used for sheathing NRX rods cannot stand up under power reactor conditions. Aluminum (1S) begins to suffer localized intergranular corrosion above 212° F. This corrosion becomes much more serious with increasing temperatures. In power reactors we are asking for corrosion-resistance to water at 600° F.

(2) If the sheath rupture in NRX, the corrosion rate of the exposed uranium is low enough in the cooling water at 70°F. to allow us to shut-down the reactor and remove the damaged fuel before the cooling system has been contaminated or damaged. In 600° F. water, the corrosion of the uranium metal is much too fast to allow a shut-down in time to avoid contamination or damage. Uranium corrodes in water about 100,000 times faster at 600° F. than at 70° F.

Answering The Problems

At Chalk River we are trying to arrive at answers to these two imposing problems. A positive program of development required one important decision at the outset — whether or not the sheath alone was enough protection against fuel corrosion.

On the basis of our own experience and that of other similar projects around the world, it was decided that the risk of sheath failure was too high and that a double line of protection was required. That is, not only would the sheath have to be corrosion-resistant to 600° F. water but the fuel would also have to be considerably more corrosion resistant than the pure uranium metal.

Sheath Materials

Thanks to the vigorous work of the Americans in the development of the *Nautilus* submarine, we have available today commercial quantities of zirconium metal. Table I shows that zirconium is an attractive material as it absorbs only about one-quarter as many neutrons as an equivalent weight of aluminum.

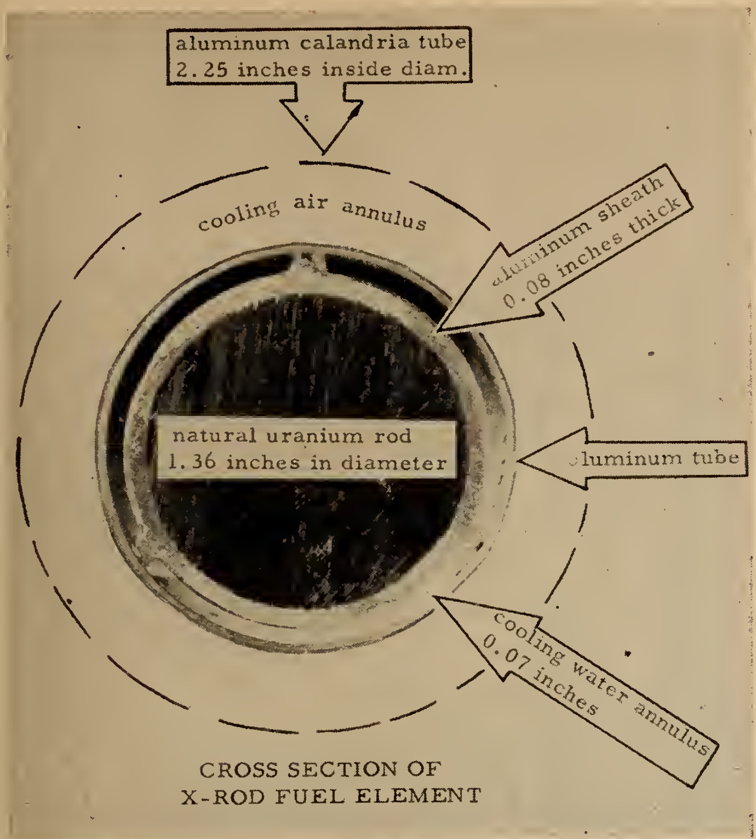


Fig. 2. Cross-section of a fuel element in the NRX reactor.

Furthermore, a zirconium-rich alloy called Zircaloy-II is very corrosion-resistant to 600° F. water.

It would appear that the sheath problem was well in hand. However, this does not prove to be the case. With our aim set at the target figure for economic reactor fuel, fabricated Zircaloy-II at today's prices is prohibitively high in cost, so that sheathing would cost as much as or more than the uranium fuel itself.

However, zirconium technology has advanced very quickly and it is not impossible that costs can be brought within the target range as the technology advances. For example, as late as 1955, the price of zirconium sponge was about $14/lb. On May 3rd, 1956, the *Wall Street Journal* announced that three major 5-year contracts for zirconium had been let by the USAEC for a total of 11 million lb. at an average price of about $6.80/lb. In the face of such remarkably fast development, it is not too much to hope for zirconium at a price which will allow economic sheathing in the foreseeable future.

However, the situation at present is stimulating a search for a lower-cost alloy.

At Chalk River, we have been engaged in such an alloy development program which looks very encouraging. Certain aluminum-rich alloys containing small amounts of nickel and iron have been developed which show remarkable resistance to 600° F. water. Where aluminum itself completely disintegrates under such conditions, this alloy exhibits a corrosion rate of only 1 to 2 mils/yr. However, there is a dependence of corrosion rate on water velocity which arises from the erosion effect. Whether or not this limitation can be overcome will be answered by work which is now in progress. We are very hopeful of a satisfactory solution. This would mean a major break-through in power reactor material technology.

Summarizing the sheath situation, we can say this:

Zirconium exists today and answers the immediate problem of providing something that works. There is considerable hope that zirconium costs can eventually be cut to a level which will make its use economic. This is not so at present; however, developments are in progress which may result in lower-cost alloys which may replace zirconium as a power fuel sheathing material.

Fuel Developments

Now we come to the fuel proper. We have decided, above, that uranium metal has to be replaced by some other form of fuel which will not corrode as quickly as the pure metal in hot water in the event that the sheathing fails.

In the United States there are active programs of uranium alloy development which make use of such alloying constituents as molybdenum to increase the corrosion-resistance of uranium metal. These have resulted in some excellent materials. However, we in Canada hold that it is too costly to introduce such neutron parasites into the fuel and that it would be much more difficult to hit the fuel target costs with such alloys.

The line of reasoning which has been followed is something like this. If the uranium metal is too corrosive, why not corrode the metal first and use a suitable form of the corrosion product as the fuel?

We in Canada are not alone in this approach. Most other atomic power projects have had the same idea.

When uranium metal is exposed to high-temperature water, the resulting corrosion product turns out to be uranium dioxide (UO_2). Oxygen is one of the elements we can introduce into a reactor with practically no absorption of neutrons. This means that uranium oxide is very nearly as efficient a fuel as uranium alone.

The problem is to produce it cheaply enough in the proper form so that we can get the heat out of it without undue distortion of the fuel rod.

Chalk River has joined hands with the Bureau of Mines and a number of industrial firms in order to find an answer. It is not as straightforward as it may first appear.

First, space in the reactor is very expensive. This, combined with nuclear considerations, asks that the best uranium oxide fuels would be those exhibiting the highest densities.

However, it turns out that uranium oxide is an extremely refractory material with a melting point of about 5000° F. so that it is impractical to melt and cast it as fully dense material. The alternative route of compacting and sintering the powder offers a much more attractive possibility. The technology is just at the stage now where various methods are under investigation for producing dense sintered compacts. On a laboratory scale, it has been possible to produce UO_2 at 95 per cent of theoretical density, (approximately 10.59). This density is acceptable

Plastic Design of Structural Steel

Bruno Thurlimann

Fritz Engineering Laboratory, Lehigh University, Bethlehem, Pa.

Read at a Conference on "Plastic Design of Steel Structures" (Royal Military College, Queen's University, and Canadian Institute of Steel Construction), at Kingston, Ontario, May 1956

PLASTIC DESIGN HAS not yet much of a history. To take a look into its future may appear somewhat premature. However, such an undertaking offers a possibility to focus attention on this new approach to the general design problem, particularly if we contrast it with present-day elastic methods. In discussing this outlook I would like to distinguish three different aspects:

(1) Theoretical implications
(2) Practical developments
(3) Plans for the immediate future in the United States.

Theoretical Implications

Present-day elastic design methods are completely governed by the concept of allowable stress. This concept is so much hammered into the minds of our students that some honestly believe a stress of more than 20,000 p.s.i. will lead to the immediate collapse of a structure. Even experienced designers are alarmed by some local yielding in a structure. Concentrating all our ingenuity and efforts on more and more refined methods of elastic analysis we forget the actual purpose of design as such.

The purpose of design is not to keep all the stresses in a structure below 20,000 p.s.i — but to produce a structure which will fulfil its intended use without endangering the life of the occupants, the value of the goods stored, and so on.

Elastic design is one approach to the solution of this problem; and, I will admit, a successful one. The great number of existing structures are a visible and convincing proof of its usefulness. Nevertheless, this fact does not imply that it is the only approach possible nor that its application leads to the most economical use of materials.

Let us first take a critical look at the significance of elastic stress calculations. With great accuracy — and very often with considerable mental pain — we determine the stresses in a complicated structure under all imaginable loading conditions. These nominally computed stresses are supposed never to exceed the prescribed allowable design stresses. However, in actual performance under full design loads, some parts will be greatly understressed compared with this analysis while others will be overstressed even to the point where actual yielding occurs. There is ample experimental evidence of the considerable difference between nominally computed stresses and actually induced stresses [1]. However, we should not be astonished about this discrepancy. Firstly, in the stress computations, the presence of residual stresses were not taken into account. Rolled beams for instance, have locked-in cooling residual stresses of from 10,000 to 15,000 p.s.i [2]. Welding produces stresses as high as the yield point value of the material. Furthermore, fabrication operations such as cold bending, cambering, punching of holes, etc., induce additional stresses not accounted for in the analysis. Secondly, during erection, stresses are produced by forcing members into place. The actual sequence of erection causes a different stress distribution than that given by the analysis based on the dead load applied to the completed structure. Assumed simplifications in the analysis constitute a third source of variance between calculated stresses and those actually present. For instance framed structures under lateral loads are commonly analyzed by using either the so-called "portal" or "cantilever" method. Applying both methods to the same problem leads to quite different results. It can be easily shown that the actual stresses do not follow either method.

Concerning the design of connections (either bolted, riveted, or welded) it may appear, at first glance, that it is also based on prescribed stresses which should never be exceeded. Examining the problem more closely will show immediately that parts of the connections will be above, other parts below, these prescribed values. For instance, the end rivets in a row of four to five rivets carry a load considerably above the computed nominal load. Many more examples could be cited in which our present-day concept of allowable stresses is grossly violated.

Considering all these facts you may be compelled to ask "Why then do our buildings actually stand?" May I first answer negatively by stating, "Certainly not because no actual stress exceeds the nominally computed stresses." Recourse must be made to one of the outstanding properties of structural steel — ductility. Steel is able to deform plastically and, therefore, will relieve overstressed parts and bring into play understressed portions. Without this remarkable property our present-day practice of neglecting residual stresses, of using simplified design procedures, and in designing connections could not be justified.

Plastic design philosophy [3] is essentially a conscious acceptance of subconsciously implied justifications of elastic design. The ability of steel to deform plastically is clearly recognized. By forming so-called "plastic hinges" the individual members will develop their full plastic moment value and the structure is able to redistribute its moments. Design is no longer based on an allowable stress concept but on the maximum load carrying capacity — the strength — of the structure as such. By limiting the working loads to a chosen percentage of this ultimate load a safe structure is obtained. It should be mentioned that checks on deflections, stability, etc., are sometimes necessary, as in present-day elastic design, to ensure the proper performance of the structure. However, the essential design criterion for plastic design is the load carrying capacity of the structure.

At present, methods of plastic analysis are fairly well developed for framed structures. All these methods assume that failure will occur due to formation of sufficient plastic hinges to transform the structure into a mechanism. To ensure such a type of failure precaution must be taken to avoid failure by instability. A considerable amount of our efforts at Lehigh is being spent on this problem. We think we have solved the problem of local buckling of rolled sections [4,5]. Work on lateral buckling is in progress. Considerable additional efforts seem necessary in the field of column buckling, especially for cases of framed columns.

Taking a look somewhat beyond the immediate future I feel the biggest progress in structural engineering can be made by a re-examination of the concept of safety. A look back into the past shows that civil engineers should not be too proud about the progress made in this particular field. Around 1820 the French engineer Louis Navier wrote his famous work "Resumé des Leçons" [6], proposing design stresses which should not be exceeded (*loc.cit.* p. 112 to 120). His approach consisted of limiting the elastically computed stresses to a chosen fraction of the ultimate tensile strength of the material. In the case of bending, the stresses computed from the formula $f = Mc/I$ should not exceed 1/10, 1/6, and ¼ of the tensile strength of oak, wrought iron, and cast iron respectively. He arrived at the above given fractions by analyzing the hardiest buildings of his time and comparing their working stresses to the ultimate tensile strength of the material. It should be pointed out that the important building materials of his time were stone, timber, and cast iron; materials having relatively little ductility. By limiting the stresses and hence the maximum strains, the possibility of brittle fracture was eliminated. However, he mentions that ". . . one has not yet conclusive experiments on the resistance of wrought iron against fracture in case of bending" (*loc.cit.* p. 92). In modern terminology we would say that the ductility of wrought iron allows the formation of a plastic hinge.

Today, after more than a century of immense technological progress, we still essentially follow Navier's approach. Even the safety margin for A-7 steel of roughly 20/65 = 1/3.25 (allowable stress/tensile strength) does not differ too much from Navier's recommendations. The major change has been the switch from the ultimate strength to the yield strength as a basis for design.

A re-examination of the safety concept may be started with the question: Why do we need a factor of safety?" In principle a simple answer

> **The author presents the basic thoughts behind the concept of plastic design. Experimental evidence shows that plastic methods can predict the ultimate load of a steel frame with a degree of accuracy on which design can be safely based.**

is possible. A structure should fulfil its intended use without the possibility of collapse, excessive deformations, or any other limit one may choose to specify. Factors influencing this performance are possible variations of material properties, variations in dimensions, quality and control of workmanship, possibility of corrosion, simplifications in design assumptions, possible overloads, etc. All these factors combine to affect the safety of a structure. At present, we use a constant factor of 33/20 = 1.65 against nominal yielding indiscriminately for all types of structures. However, it seems to me not justified to design, for example, a water tank with the same safety factor as a warehouse. The water tank cannot be overloaded (the water will simply overflow), whereas the warehouse may very well be overloaded sometimes during its lifetime. This is just one of many examples indicating that the safety factor should be dependent on the type of structure.

Plastic design philosophy allows a much more realistic approach as it provides methods to compute the actual load carrying capacity of structures. Elastic methods are unable to predict the ultimate load of statically indeterminate structures. They can only specify a nominal load at which first yielding will occur. I have already shown the rather questionable accuracy of such a prediction.

The years ahead should see considerable progress in this field, clarifying the basic issue and leading to a more realistic approach of the safety problem. Important theoretical studies have been made already [7,8]. Especially from the field of aircraft design a good deal of valuable basic information can be obtained. I would like to mention that within our own field new developments in reinforced concrete design take a much more realistic approach [9]. The time has arrived where steel design can no longer afford to relax on its successful past but must get prepared for the future.

Practical Developments

The acceptance of the ultimate load carrying capacity as a new basis for design and with it the introduction of plastic analysis, will bring about changes in the conception, the design, and the fabrication of steel structures. It may be of interest to speculate on this subject.

A strong tendency should develop toward statically indeterminate structures. There are several reasons for such a development. Plastic methods of analysis are much easier and shorter in such cases than corresponding elastic methods. There should be little excuse for avoiding indeterminancy on the bases of too cumbersome an analysis. Even in cases of possible foundation settlements indeterminate systems can be used, for plastic analysis shows that such movements — kept within reasonable limits — do not influence the carrying capacity. Continuity and especially the constant safety factor against ultimate load introduced through plastic analysis will reduce the total tonnage of steel to a considerable extent. May I explicitly point out that elastic methods are unable to furnish a constant safety margin against ultimate load for different statical systems. The higher resistance of statically indeterminate structures against unexpected loads such as earthquakes, bomb blasts, severe damage of individual members should be mentioned as a very desirable feature.

As members, rolled sections will be used primarily. There should be less need for built-up sections with variable moment of inertia, haunched knees, cover-plates, often used in elastic design to reduce peak stresses. Plastic design recognizes the fact that through formation of yield hinges the structure redistributes its forces, relieving overstressed parts and loading understressed portions. For large structures offering difficult conditions for lateral supports — for example, sport arenas, airplane hangars — built-up box sections may offer an elegant and economic solution. Such sections require little lateral support due to their great torsional stiffness. To provide the required continuity of the connections welding is necessary, at least for shop work. At present welding is all too often used as a simple substitute for riveting without giving careful consideration to details. Continuous corner connections, interior two- and four-way connections will present a new challenge to the designer and detailer. Much will depend on the successful solutions of such details to turn the saving in overall weight into a saving of costs. Shop welding should be used to the widest extent possible in building up large sub-assemblies. For instance, an interior four-way connection can be made by welding four beam stubs to the column. In erection, the beam splices, placed at location of low moment, offer considerably less difficulty than a fully continuous beam-column splice. High-tensile bolts may offer a very economical solution for field splicing. Even today high-tensile bolts compete successfully with riveting and welding in field work. In some instances simpler details may be obtained by changing from the usual practice of shear connections (friction between the clamped plates) to direct tension — compression connections, with the bolts in the direction of the forces.

In fabrication, proper care must be taken to conserve the ductility of the material. Punching of holes must be avoided in the tension zones of potential plastic hinges. In the neighborhood of such holes the material is very brittle due to plastic deformations caused by the punching operation. Relatively small strains are sufficient to cause brittle fracture (see, e.g., ref. (10) for informative tests). The same reasons exclude shearing of plates, cold bending of parts and other operations leading to the embrittlement of the material. Small plastic deformations, however, caused by straightening or cambering of members can be tolerated as the material will not lose its ductility.

The general problem of brittle fracture [11] is still with us in spite of the extensive research done since the much publicized failures of the liberty ships during World War II. The structural designer should not expect that the metallurgists will solve this problem completely for him. "Foolproof" steels which will never fail in a brittle manner can be produced. However, their cost is prohibitive for structural application. The present A-7 steel is a perfectly good material if the designer is aware of a few simple facts and pays attention to detail problems. Stress raisers should be eliminated. Special attention must be given to complicated welding details in order to avoid states of triaxial tension [12]. Translated into simplified language this means that material stressed in tension should be able to "breath" at least in one transverse direction. As a consolation to the worried designer I would like to mention that it is extremely hard to produce brittle fracture of A-7 steel, provided the material thickness does not exceed about ¾ inch. Fortunately a large part of our structures fall into this category.

U.S. Plans for the Immediate Future

You may rightly wonder how plastic design may enter the actual design field. I can report to you on the immediate outlook in the U.S.A.

Within the A.S.C.E. a "committee on plasticity related to design" (chairman, Dr. L. S. Beedle, Lehigh University, Bethlehem, Pa.) is working on a "commentary" on plastic design. This document is intended to include (1) the basic assumption of plastic design; (2) experimental data substantiating those assumptions; (3) experimental results of tests on component parts and entire structures; (4) a summary of design recommendations and the background therefor. It is hoped that this commentary can be used by specification writing groups as a basis for a "plastic design" code.

The A.I.S.C. (T. R. Higgins, director of engineering and research) is at present working on a "design manual". (In this connection I would like to mention that the A.I.S.C. together with the A.I.S.I. and the U.S. Navy have been supporting our research efforts at Lehigh University for the past ten years and are continuing their sponsorship.) This book will contain specific examples giving the loading, analysis, detail designs, etc. By introducing an enabling clause into the AISC specification authorizing the use of plastic design if recognized procedures are followed, it is hoped that the new method will find its way into the design offices. It can be expected that such a clause may be incorporated in the specifications within the next one or two years.

After some practical experience in actual application, the A.I.S.C. expects to draft a "plastic design specification" which will be presented as an alternate to its present "elastic" specifications.

Without exaggeration, I say that we have reached a turning point in basic design philosophy. Navier introduced in the early eighteen hundreds the concept of allowable working stresses. For brittle materials such as stone, timber, cast iron — the most important building materials of that time — such a procedure gave a fair estimate of the load-carrying capacity of a structure. As steel found its introduction in building construction during the second half of the 19th century the same basic reasoning was applied without giving due consideration to the great ductility of this new material. Plastic design recognizes this important property by virtue of which a steel structure is able to form plastic hinges and redistribute its moments. It provides a simple tool for determining the actual load carrying capacity on which design can be based. The question "What are the maximum fibre stresses?" is replaced by "What is the ultimate load?" Elastic procedures can only give an answer to the first question — and in most cases a very rough one. Experimental evidence shows that plastic methods can predict the ultimate load of a steel frame with a fair degree of accuracy on which design can safely be based.

Design and Construction of Earth Dams in Western Canada

R. Peterson, M.E.I.C.

Prairie Farm Rehabilitation Administration, Saskatoon, Sask.

THE PRAIRIE FARM Rehabilitation Administration (P.F.R.A.) was established in 1935 under the Federal Department of Agriculture. One of its main objectives was the creation of irrigation and water development projects to alleviate drought conditions in the three prairie provinces. The original act applied only to that portion of the prairie area known as the Palliser Triangle, but P.F.R.A. activities have been extended to include projects in British Columbia being developed by the Department of Veterans' Affairs.

As most of the projects involved earth structures in the form of dams or canals, it was apparent that engineering soil studies would be required.[6] Consequently a complete Soil Mechanics Division was set up and made responsible for field exploration, laboratory testing, design studies, construction control and, finally, observations of the earth structures in service.

The designs are not based entirely upon theoretical considerations but rather on a mixture of precedent, experience and theoretical soil mechanics.[4] In many instances semi-empirical methods are used to save time and money in the investigation and design stages.

This paper discusses briefly some major points in the design and construction of earth dams with particular emphasis on problems encountered by P.F.R.A. in Western Canada. An attempt is made to cover important recent developments in earth dam engineering rather than repeat information available in existing texts. Typical cross-sections of existing and proposed dams are shown.

With the exception of the smaller dams, where an earth spillway is often adequate, most earth dam projects require a permanent spillway, as well as diversion works and outlet works. These structures usually represent a large portion of the total cost and frequently present formidable design problems. However these considerations are not within the scope of this paper.

Table I is a summary of P.F.R.A. earth dam projects during the period 1935 to 1955 and illustrates the scope of the work.

Table I. P.F.R.A. Earth Dam Projects: 1935-1955.

Height in Feet	No. of Sites Investigated Preliminary	Detailed	Number of Dams Completed	Total
0 – 25	13	70	6500	6583
25 – 75	21	65	76	162
75 – 150	14	17	7	38
150 – 225	6	9	2	17
Total	54	161	6585	6800

Most of the 6500 dams in the height range of 0 - 25 ft. are located on farms and were, in fact, constructed by farmers with only a limited amount of direction and engineering assistance. Soil studies have been made only occasionally for embankments in the 0 - 25 ft. group whereas they have nearly always been required for fills greater than 25 ft. in height. This latter group has involved over 200 sites.

The Travers Dam, typical of the larger earth dams, is shown in Fig. 1. It is a key structure on the Bow River project which will irrigate a quarter of a million acres of dry land in Southern Alberta. The dam is a compacted embankment with a maximum height of 150 ft. in the stream-bed (Fig. 9 (i)) and containing nearly five million cubic yards of fill.

Geology

The entire prairie area with the exception of the Cypress Hills was glaciated and this has resulted in characteristic foundation and borrow problems. Two typical valley cross-sections are shown in Fig. 2. The cross-section at the left shows a valley which has been eroded through the overlying glacial or lacustrian soil into the underlying bedrock; whereas the valley at the right has resulted from down cutting into the overburden only. The bedrock is generally sedimentary; usually soft shale and sandstone with clay shales predominating. In both instances the valleys are filled with river deposited alluvial soils consisting of clay, silt, sand and gravel.

In general, the deposits are relatively soft, stratified and variable and therefore more acceptable as foundations for earth dams than for concrete dams? The variable nature of these formations makes it difficult to establish representative strength, compressibility, and permeability characteristics and consequently the values used in design are often approximations. Terzaghi[12] clearly points out the important effect of minor geologic details on the safety of dams and his definition of 'minor geologic details' as "features that can be predicted neither from the results of careful investigations of a damsite nor by means of a reasonable amount of test borings", is therefore disconcerting.

Medium plastic glacial clay is often plentiful and has proved satisfactory borrow material for the construction of impervious cores and acceptable for homogeneous earth embankments of a limited height. Pervious material in the form of sand and gravel is often scarce and therefore costly.

In order to obtain a better understanding of foundation conditions the geology of all major P.F.R.A. sites is studied by the Geology and Air Photo Division. In addition to providing information on the characteristics of the foundation strata areas of potential borrow material are outlined from a study of air photos.

Design

A satisfactory earth dam design must provide for seepage control through, and stability of, the embankment, foundation and abutments.

Seepage Control

In designing for seepage control, consideration must be given to the quantity of seepage and also to the water pressure and possibility of erosion as a result of the flow.[15] In order to illustrate a number of typical designs, several cross-sections are shown in Fig. 3. These are based on an embankment height of about 60 ft. and it is assumed that the side slopes shown are required from the standpoint of stability.

Impervious Foundation — A zoned embankment with a positive cut-off to impervious foundation material is shown in Fig. 3(a). This arrangement is ideal from the standpoint of seepage control but can be used only where conditions are favourable. The central section of the embankment consists of compacted impervious soil and provides an effective water barrier through the fill. The outer shoulders of granular material provide stability on both sides and drainage on the downstream side. The cut-off consists of an open trench through the shallow pervious material backfilled with compacted impervious soil.

The design shown in Fig. 3(b) is similar to that of 3(a) except that a homogeneous embankment rather than a zoned embankment has been used. This case is common on the prairies where there is often a lack of pervious material and an abundance of impervious material which can be utilized for the homogeneous embankment. In such a design the core or central section is sometimes placed wetter than the optimum moisture content so that it will be able to deform much more than the shoulders without cracking and will also be less pervious. In addition a horizontal filter of screened or select sand and gravel is generally used and a narrow sloping or stepped drain extending at least to maximum reservoir water level has been frequently provided in recent designs.

Fig. 1. Travers Dam; spillway and outlet canal from reservoir in foreground.

Pervious Foundation — A foundation consisting of a considerable depth of pervious sand or gravel as shown in Fig. 3(c) is generally the most difficult from the standpoint of seepage control. Frequently the ground water level is relatively high in such a formation making it costly to construct a cut-off trench to any appreciable depth. It has been established that partial cut-offs are relatively ineffective, and therefore an upstream blanket and downstream drainage is the most feasible method of reducing the quantity of seepage and providing pressure relief. Downstream drainage may be provided by a granular section, filters within the dam, toe drains or relief wells as shown in Fig. 3 or by an inverted filter as shown in Fig. 9(g).

For this type of foundation it is desirable to carry out field permeability or pumping tests to establish the coefficient of permeability. If a reliable estimate of the permeability can be made the proportions of a blanket to reduce seepage to tolerable quantities can be determined by existing methods[14]. Of particular importance in this type of problem is the relation between the horizontal and vertical permeability of the foundation. Where it is impossible or too expensive to establish reliable permeability values the blanket is generally proportioned on the basis of empirical rules. For the average case a blanket equal in length to approximately 10 times the water head is utilized. Among the important considerations in proportioning the blanket are the permissible seepage loss through the foundation, the effectiveness of the natural blanket in the upper layers of the foundation at the site and the possibility of silting in the reservoir.

During the past few years the use of relief wells[18] has increased and this method appears to offer very satisfactory seepage control, particularly where the surface soil is less previous than the underlying material. The U.S. Engineer Corps has carried out extensive research in connection with design and construction of relief wells. These studies have indicated that substantial penetration into the pervious foundation layer and length of screen are more important variables than well size and spacing in achieving maximum pressure relief. In order to avoid corrosion problems the Engineer Corps are utilizing slotted wood stave pipes surrounded by gravel packing. At the present time the P.F.R.A. is carrying out tests to determine the best type of well for use under western conditions. Installations to date have included standard well screens and slotted steel and plastic pipes—with and without gravel packing. For limited depths risers fabricated by nailing four 1 x 4 plywood strips (slotted with a circular saw) into a rectangular conduit have proved very satisfactory. Perhaps one of the most important advantages of relief wells for seepage control beneath dams is the fact that a few wells can be installed in the early stages and more added if the need for further relief is indicated by high pressures in the toe area. Inverted filters can also be added at the downstream toe to stabilize boils and prevent erosion due to seepage flow.[16, 20]

The gradation of interior filters, weighted filters and packing around relief wells must be such as to retain the particles of the material to be drained but coarse enough to be many times more permeable than the material to be drained. These requirements will be met if the 15 per cent size of the drainage medium is at least four times the 15 per cent size of the layer to be drained and is not more than four times the 85 per cent size of this layer.[35] In order to protect embankment and foundation material, it is sometimes necessary to use several filter layers based on the above rules. However, on the majority of projects where the material to be protected is fairly well graded, one filter layer is considered sufficient. Where two filter layers are required an attempt is often made to utilize a similar gradation to fine concrete aggregate and to coarse concrete aggregate as these sizes are generally easily available. In some cases, however, special gradations are absolutely essential but are difficult to produce, particularly in the sand sizes. One point of considerable importance in the design of filters and weighted filters has to do with the relative permeability of a pervious foundation layer and the filter itself. It should be remembered that the foundation material is quite frequently in the loose or medium density state and stratified. The horizontal permeability is therefore considerably greater than praise the situation at two other dams at which sheet piling was used. At the Fort Randall dam an upstream blanket and relief wells were used instead of a sheet pile cut-off and reports indicate that this design is performing very well.

In commenting on the effectiveness of steel sheet pile cut-offs Bureau of Reclamation Engineers state.[22] "Steel sheet piling was used at both Pine View and Rye Patch Dams, but exploration and operation exper-

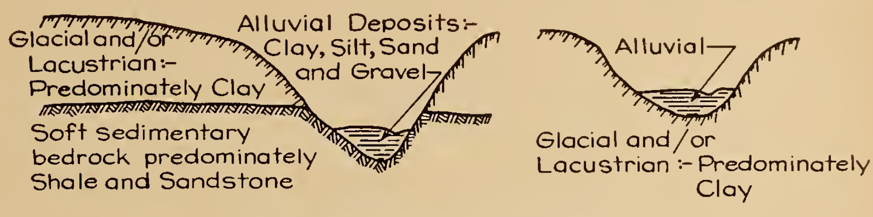

Fig. 2. Typical valley cross-sections.

the permeability of the same material when mixed and compacted to even a medium density. This generally means that if foundation sands and gravels are to be considered for filters they must be washed or processed in order to make them many times more pervious than the foundation material in place.

Sheet Pile and Concrete Cut-offs —On early projects in the west considerable use was made of wood sheet piling for cut-offs. In some instances this sheeting was driven, in others it was dug in and backfilled. Steel sheet piling has also been used and its effectiveness is being studied. The initial studies were required in order to design a 200 ft. earth embankment resting on a foundation of 100 ft. of fine to medium sand (Fig. 9(a)). Laboratory tests indicated that the interlocks of commercial steel sheet piling were far from watertight and that the sheet piling would be relatively ineffective, particularly where the seepage path beneath the dam was great.[17] On the other hand observations on the drop in water pressure across a sheet pile wall beneath an existing 16 ft. dam indicate that the wall is completely effective. In connection with appraising the effectiveness of steel sheet piling a review of the designs for the major dams on the Missouri River was particularly informative. At the Fort Peck Project steel sheet piling was used; however, observations indicated that it was not effective and relief wells were required at the downstream toe.[19] Sufficient records are not yet published to apiences have shown this device to be relatively ineffective."

On P.F.R.A. earth dam projects concrete core walls or concrete cut-offs have not been used. In only one instance has it been necessary to grout the bedrock beneath a compacted earth cut-off.

Abutments — Abutment treatment has proven to be important and critical on many projects. Frequently the soil or bedrock in the abutments is stratified and this may permit horizontal flow around the end of the cut-off. In addition the contact zone between the overburden and the bedrock is often pervious due to the presence of sand and gravel and because of weathering in the bedrock material. Such conditions require the use of special drains on the abutments. However, it is often necessary to wait until the reservoir is filled in order to determine the required size and location of these drains.

Stability

In general terms, the stability of an earth dam means the ability of the structure to retain its shape. It is common practice to check the stability of a dam by one of several methods of analysis. The general procedure is to select a segment or slice at right angles to the axis of the embankment and assume a potential sliding surface in the dam or the dam and the foundation. A major problem is the choice of the shear strength[27, 33] that can be mobilized in the several soil types involved and the pore water pressures that might exist due to seepage or compression of the soil. In the case of a compacted embankment, an estimate of the shear strength can be made in advance of construction but it must be recognized that this strength may or may not be realized. For example the water content and degree of compaction may vary during the placing operation from that assumed in design and this will result in a different strength and different density from that anticipated.[8] Also the type of fill material used may differ somewhat from that initially envisioned. Similarly the actual strength of the foundation may be at variance with that estimated for design purposes. Rate of construction and the resultant consolidation exerts a great influence on the shear strength of soils and if this and drainage conditions are not accurately envisioned, the selected design shear strength may be considerably in error. When the choice of shear strength has been made the stability analysis is more or less routine.

Methods Used for Stability Studies — The Swedish method which assumes a potential slide on a circular arc is commonly used in stability studies. In cases where the shear strength of each soil strata is assumed constant the stability is evaluated by taking moments about the centre of the arc as shown in Fig. 4(a). The overturning moment is the weight of the soil mass times the moment arm and the resisting moment is the total shear strength along the arc times the radius. For the more complicated case where it is assumed that

$$s = c + (p - u) \tan \varnothing$$

(s = shear strength, c = cohesion, p = total unit pressure on the surface of sliding, u = pore water pressure, and $\varnothing$ = true angle of internal friction) it is necessary to consider the variation of shear strength along the arc. This is done by dividing the segment into slices and summing up the forces on the individual slices or else resorting to the integration or area method.[28, 34] The most critical arc is found by trial and error.

Another method which can be used is the sliding block analysis. This method applies particularly to the case of spreading on a weak horizontal layer in the foundation.[23, 35] The forces involved are shown in Fig. 4(b). The active earth pressure (which tends to produce movement) is equated with the passive

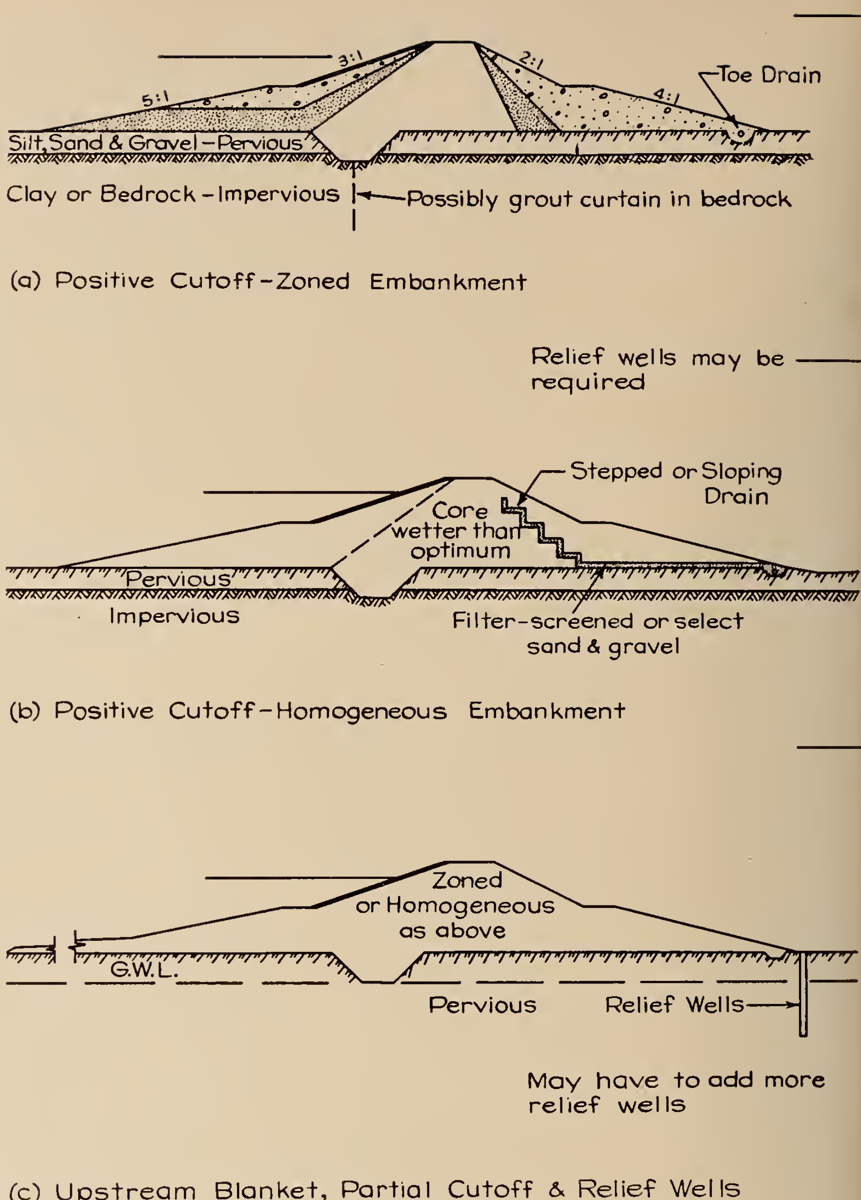

Fig. 3. Typical methods of seepage control.

pressure plus the shearing strength of the soil on the assumed plane, both of which tend to resist movement. The most critical condition is determined by trial and error.

A third method of evaluating stability is known as the elastic analysis in which the stresses within the foundation are computed on the basis of the theory of elasticity and these stresses are compared with the available soil strength.[31] There is always some question as to whether or not the foundation behaves in an elastic manner and this method has been used only for special conditions.

Conditions Checked — Any, or all, of the above methods can be used to check several critical conditions which may occur during the construction or operation of an earth dam. Frequently the most critical condition is the stability immediately after construction, particularly where clay soils are used in the embankment or thick clay layers occur in the foundation. For such an analysis it is generally assumed that the shear strength of clay is equal to one-half the quick or undrained compressive strength and the computations are carried out using total stresses. Based on experience in Western Canada it would seem that this method is on the unsafe side when applied to highly plastic clay foundations as several slides have occurred where the estimated factor of safety was in excess of 1.5.[2, 32, 36] The reasons for this are not yet evident and research is being carried on in an effort to explain this apparent discrepancy.[24] It would appear that the strength of the clay at very low rates of strain or under sustained load at constant water content may be appreciably less than that determined by conventional quick or undrained laboratory shear tests[25]. Furthermore there is a possibility of progressive failure or incompatibility between the foundation material and the embankment material when they have different stress-strain characteristics. Quite frequently embankment materials are placed at lower moisture contents and may be more brittle than the wetter foundation clays. There is also some reason to believe that the embankment material may become more brittle with the passage of time. Where such conditions exist the foundation may deform and before the full strength of this soil is mobilized, failure may occur in the more brittle embankment. Following this the entire load must be carried by the foundation and deformation is certain to increase with the likely possibility of failure.

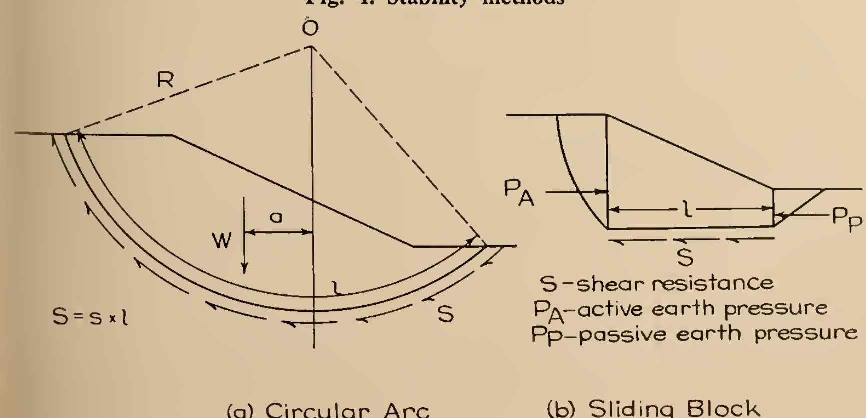
The second condition which may be critical is the case of a dam with a full reservoir and the seepage line developed through the embankment. In such an analysis the effective stresses are generally used and the pore pressure is estimated by means of a flow net. In order to apply the method of effective stresses, it is necessary to know the true cohesion and angle of internal friction of the soil which can be determined by the slow or drained shear test. These tests are time consuming and some investigators in the past have estimated the value of the true angle of internal friction $\varnothing$ since it did not appear to vary greatly for different soils. Frequently estimates of $\varnothing = 30°$ have been utilized. However, recent studies at Harvard [24] have indicated that this value may be 20° or even lower for some of the highly plastic clays.

The third condition which should be considered is the effect of rapid drawdown on the upstream slope. The results of consolidated quick tests are required when this analysis is carried out on the basis of total stresses. It is interesting to note that the overturning moment is almost doubled following rapid drawdown whereas the strength of clay soils remains approximately the same. A failure of this type would not be as serious as the others and therefore a lower factor of safety is justified.

Factor of Safety — A numerical value for the factor of safety in some cases implies a degree of accuracy which does not exist. First of all there are inconsistencies in the definition of safety factor. If it is defined as the ratio of the resisting moment to the overturning moment the value will vary depending on whether the resisting moment includes only the resistance due to soil strength or due to both soil strength and that portion of the mass which tends to resist the overturning moment. In order to avoid this inconsistency it has been suggested [2] that the safety factor be defined as the ratio of the soil strength available to the soil strength required. There are also many variables affecting shear strength, and other important conditions which must necessarily be neglected in making a stability analysis. Consequently the numerical value obtained is really only an estimate of the relative safety.

A review of the literature leaves one with the impression that the computed safety factor of an earth dam should be at least 1.5 for the condition immediately after construction or with seepage developed as a result of a full reservoir. This would seem to apply for granular soils and other types where the characteristics can be predicted with reasonable accuracy. Where the soils are more erratic, of a clay type, or where less desirable conditions prevail, then higher values of the factor of safety should be used. In view of the discrepancy between theoretical analyses and field behaviour, and until such time as more complete information is obtained, P.F.R.A. is attempting to use factors of safety of at least 2 and preferably 2.5 for cases where highly plastic clay foundations are involved. This is based on conventional tests applied in the usual manner; if adjustments are made in the shear value for slow rates of strain and progressive failure the above suggestions are undoubtedly too conservative.

Fig. 4. Stability methods



Settlement — Compression of the embankment and settlement of the foundation can generally be predicted with reasonable accuracy from the results of consolidation tests, at least where soil conditions are uniform. However, the rate of consolidation is much more difficult to predict because rate of drainage through sand lenses, fissures, etc., is difficult to evaluate or predict from laboratory tests.

Slope Protection — Slope protection is of major concern on the portion of the upstream slope between low water level and the crest of the embankment. In this zone dumped riprap placed on a coarse gravel blanket appears to be the most desirable method of protection.[26] The downstream slope and the upstream slope below operating water level are generally left unprotected or are protected with gravel blankets or the gravel of a zoned embankment. In some instances the downstream slope is covered with topsoil and seeded.

Embankment Cracks — One of the most important points brought to light in recent years is the possibility of cracks forming through an embankment at right angles to the axis. This danger has been pointed out by Casagrande [3] and by Sherard.[11] Fig. 5 shows the areas where cracks might occur. In the case of one otherwise well constructed dam Sherard attributes the formation of a transverse crack to stretch which occurred along the longitudinal axis. Reference points had been placed 100 ft. apart along the crest and a stretch or elongation of as much as 6 in. was measured between two successive stations. It would appear that differential settlement within a fill, or adjacent to steep abutments or closure sections, can cause tension along the top of the embankment resulting in elongation of the crest and crack formation. Sherard's studies of a considerable number of dams seem to indicate that certain silt and clay soils compacted on the dry side of the optimum are most susceptible. Fig. 6 shows a photograph of cracks which have developed due to non-uniform settlement within a homogeneous embankment 30 ft. in height. The cracks shown are two to three inches in width and resulted from a subsidence of approximately one foot in an area about 30 ft. to the left of the photograph.

In order to avoid such cracks in embankments uniform compaction and moisture content are desirable. Abutment treatment to eliminate steep slopes and overhangs is important in eliminating the danger of differential movements conducive to cracking. It has been suggested that the best protection against piping through such cracks would be the use of a zoned fill. However, where it is necessary to use homogeneous fills it is believed that a central section compacted wetter than optimum may form a plastic core which will not crack as a result of movement.[3] Another precaution that might be taken in connection with homogeneous embankments is the use of a pervious filter layer extending for the full height of the embankment. Such a layer would intercept any seepage through cracks and would likely prevent failure due to piping.

Abutments — The treatment of abutments is of major concern on many projects where glacial material or unstable clay shale [10] is involved. Fillets between the embankment and abutments or widening the ends of the dam can be used to stabilize weak abutments. The strength and stability of abutment materials are quite frequently evaluated on the basis of the long time performance of the existing slopes making due allowance for altered water conditions which will result from reservoir seepage; rather than by laboratory testing and theoretical studies.

Construction

Foundation Treatment

Foundation treatment is difficult and controversial in the case of many of the sedimentary bedrocks encountered.[42] Frequently where the bedrock is soft shale or sandstone the foundation and cut-off trench is trimmed with ordinary earth moving equipment and the first layer of embankment placed directly upon this surface. However, where the foundation consists of harder interbedded shale and sandstone which is fractured and weathered, the preparation and clean-up is troublesome and frequently decisions regarding the required depth of excavation are difficult. In such cases a hand clean-up is generally specified and it would appear desirable to place a layer of Gunite, such as was used at the Kenny Dam [37], particularly if there is any possibility of grouting being required at a later date. It is important to place the first few layers of impervious embankment somewhat wetter than optimum with a view to securing better compaction and contact against the foundation.

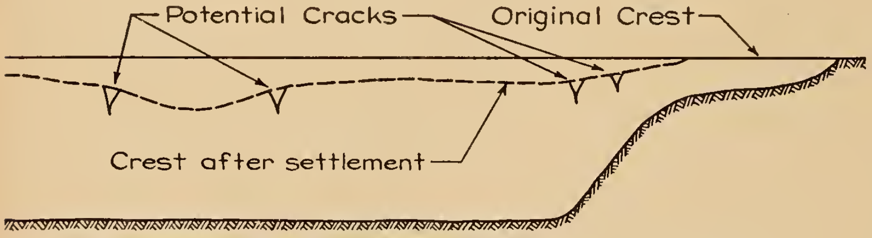


Fig. 5. Embankment profile showing areas of potential cracks.

Placement of Embankment Material

Impervious — The placement of impervious embankment material is perhaps the most important construction consideration.[43] When the P.F.R.A. began its program of earth dam construction in the drought period of the thirties there was very little water available to moisten impervious soils to the proper water content for ideal compaction. Because many of the earlier and lower dams were of necessity compacted without the addition of water and therefore below the optimum moisture content, a few failures were experienced.[40]. These failures generally occurred on the first filling of the reservoir by piping through dry poorly compacted layers. Fig. 7 is a downstream view of a pipe through a low earth dam in which compaction was poor due to low placement moisture content. As the program developed special precautions were taken to ensure moisture control during compaction. It was found that irrigation of the borrow pits in advance of construction was by far the most satisfactory method where more than 3 or 4 per cent moisture had to be added. Experience indicated that when a borrow pit was excavated a few weeks after irrigation the moisture content would be almost at the optimum for typical medium plastic glacial soils. In the case of higher dams, however, it is most important that the moisture content be no greater than optimum otherwise there is a danger of high pore pressures within the fill during construction.[30, 39]

Compaction of impervious soils for earth dam construction by means of sheepsfoot rollers would seem to be more desirable than compaction by other methods. However, in recent years the use of rubber tired rollers has become more prevalent.[38] When using a sheepsfoot roller it is common practice to compact the material in 6 in. lifts by 8 to 12 passes of the roller whereas for the heavy rubber tired rollers, the thickness of lift can be doubled and the number of passes reduced to about half. However, uniformity of the soil as placed is of paramount importance and the sheepsfoot roller is somewhat superior to the rubber tired roller in this regard as it produces a more intimate mixing of the soil and the moisture within the material. In addition the "puckered" surface left by the roller feet results in better bond between layers.

Pervious—The placement of pervious fill has not involved any serious problems and compaction is generally carried out in layers about one foot in thickness utilizing either crawler tractors, earth moving equipment or rubber tired rollers.

The addition of moisture has not proved necessary with most sand and gravel selected for embankment use. In some instances the finer more uniform sands would perhaps have benefited considerably from the addition of water during compaction.

However, where structures have been placed on compacted sand and gravel moisture control and thin layers have always been used.

Test Apparatus

Special emphasis is placed upon the use of observational or test apparatus to study the behaviour of earth embankments and this equipment is generally installed during construction. The several types now being used are shown in Fig. 8.

The Bureau of Reclamation has successfully developed a good deal of apparatus used for this purpose.[1] The B. of R. settlement gauge which has been adopted by P.F.R.A., makes it possible to determine the settlement of the surface of the foundation and also the compression within the embankment by lowering a measuring bob through a gauge consisting of telescoping pipe with cross arms.

Piezometer equipment [1] consisting of tips within the embankment and foundation is utilized to measure pore pressures. The tips are connected by double lines of plastic tubing to a terminal well located at the toe where the pressures can be read continuously on bourdon gauges. In addition perforated standpipes and piezometers are used to check the water level in the downstream portion of the embankment and in the vicinity of the downstream toe in the foundation. In order to study surface movements on the crest of the dam, on berms and at the downstream toe, alignment pins as shown in Fig. 8 are being used. A more recent development utilizes plastic casing and an inclinometer to detect horizontal movements at any point along the length of the casing within the embankment, foundation or abutments. This method was developed by Wilson and is being tried on several projects.[41]

Stage Construction

Many earth dams are founded on soft alluvial materials, with highly plastic clay being predominant. If there is any possibility of gain in strength due to consolidation within a reasonable length of time, stage construction is always considered, although the results are often uncertain until field observations are available. At the present time six embankments utilizing stage construction have been recently completed or are being built by P.F.R.A. (Fig. 9(e)) and an equal number are proposed (Fig. 9 (c)). The importance of having readings of test apparatus available is obvious in making decisions with regard to the safe rate of construction.

Concluding Remarks

It is probable that the soil mechanics literature may leave one with an incorrect perspective of the limitations of soil mechanics theories in practice.[3] This perhaps is more often the fault of the reader or student rather than the writer, as the authorities on the subject invariably warn of the practical limitations of the theories as a result of erratic soil conditions and other considerations which might not comply with the basic assumptions. It would appear that the student masters the theory and in his zeal to apply it often neglects to consider fully the many limitations imposed by variable and indeterminate soil conditions.

There is no doubt that the science of soil mechanics has resulted in tremendous progress in the field of earth dam engineering. However, very serious gaps in our knowledge still exist. Perhaps the most important of these is the shear strength of clays and particularly the time effects associated with these soils. Much study and research coupled with field observations are required for a better understanding of these problems. One must be careful not to rely upon new methods or procedures until they have been proved in practice. In the case of earth dams, where failures may involve high property damage and loss of life, it is generally impossible within a limited period to check the validity of theories by study of full scale models. If there is any reason to suspect the theory or the experience on which a design is based or to question the safety of an earth structure, the wise course is to rely heavily upon field observations to warn of dangerous conditions. This makes it possible to modify the design to include berms, flatter slopes, relief wells or stage construction and thus achieve a safe yet economical structure.

In conclusion, P.F.R.A. design and construction methods are based on soil mechanics, accumulated experience, and precedent, with consider-

able reliance being placed upon observations during construction and operation.

Acknowledgments

The writer would like to express appreciation to G. L. MacKenzie, chief engineer, P.F.R.A., for permission to publish this paper and to G. N. Munro, assistant chief engineer, W. L. Foss, supervising construction engineer, St. Mary Irrigation Project, and N. L. Iverson, soil mechanics engineer, for reviewing the manuscript and making a number of helpful suggestions.

Economic Fuelling of Nuclear Power Reactors

(Continued from page 127)

to the nuclear physicists. The problem remains to develop the commercial methods for achieving such densities on a production scale.

The second major problem is that the sheath must make good contact with the oxide fuel for good heat transfer. This too is at present under investigation. Preliminary experiments on prototype oxide fuel elements have been very encouraging.

In experiments, the sheath has been artifically ruptured with no apparent detrimental effect on the fuel under irradiation. Also, the oxide has shown a remarkable dimensional stability under reactor conditions.

We have confidence in this aproach to an economic power reactor fuel. This confidence is indicated by the recent decision to use uranium dioxide as the fuel for the forthcoming NPD reactor. NPD is the Nuclear Power Demonstration reactor being designed and built through the co-operative efforts of Atomic Energy of Canada Limited, the Ontario Hydro-Electric Power Commission, and the Canadian General Electric Company.

Summary

In summary, I would like to make the following points.

First, the economic fuelling of a power reactor which can compete with present day thermal power stations is possible.

Second, the choice of the heavy-water reactor offers the most attractive promise for achieving low fuel costs.

Third, work at Chalk River encourages the belief that the practical limitation on achieving economic fuelling costs can be overcome, probably in the near future.

Finally, there is no doubt in the minds of those who are working in the field that nuclear power is here to stay. The most authoritative prediction I can give you is that of our president, W. J. Bennett, in a statement made before the parliamentary committee on research on 5 June 1956—

> ". . . nuclear energy will play a quite modest part in supplying power demands up until 1971. During the 1970's, it is probable that several million kilowatts of nuclear capacity will be installed. By 1981, nuclear power plants may conceivably account for as much as 10 - 15% of the total generating capacity in this country and beyond that period this percentage will increase . . ."

There is a good deal of work to be done to make this prediction come true. It will require the best efforts of both research establishments and Canadian industry. However, the need is there and the vision is strong. I have no doubt that it can be achieved.

Management's New Tool —

Automatic Computers

W. Smuck,
International Business Machines Company Limited

Read at a meeting of The Engineering Institute of Canada, Montreal Branch, Management Section, November, 1956.

THE TERM "automation," fundamentally applicable to a process in which machines operate other machines, has been associated in recent years with mechanized production line operations.

With the introduction of electronic data processing machines, many have associated a parallel revolutionary development in office procedures; however a review of the growth of large electronic computers will show that they are just another step in the evolution of the ultimate — the "automatic office."

For many years, man was restricted to the use of his fingers for counting purposes. The introduction of the "abacus," however, gave him a more practical device for performing arithmetic operations. In 1642, Pascal introduced the principle of the "toothed" wheel in an adding mechanism — a device to add one with a turn of one notch; this concept, with modification, has been utilized in the functions of present day adding and calculating machines. During the 1830's, Charles Babbage attempted, without success, to develop a calculating machine with automatic sequence controls; i.e., to perform a number of operations in sequence and automatically.

Although these ideas have shown a significant influence on the development of computing devices we should recognize that a concept, introduced by Dr. Herman Hollerith in 1887, has dictated the trend in the mechanization towards the automated office. The idea was to record data into a card as a combination of holes in preassigned locations and to engineer machines to process these cards, subject to the information contained therein. This was the basis for research in the past half century by many business equipment organizations.

Let us at this time review briefly the basic accounting machine equipment, utilizing the punched card.

The basic record for the equipment is a card (7⅜ in. by 3¼ in.) which is capable of storing permanently 80 characters of information (alphabetical or numerical) in the form of punched holes. Being so registered, a punched hole can function in many ways; such as:

(1) add itself to something else;
(2) multiply itself by something else;
(3) classify itself;
(4) file itself;
(5) list itself;

and others.

The initial registration and the above mentioned operations are mechanically controlled.

"Card punching" is the basic method of converting source data into the punched cards. This is followed by preparatory operations, such as arranging the cards in a specific sequence, adding additional cards, and selecting cards, which can be done automatically by different machines.

The "card sorter" is capable of grouping cards in sequence — numerical or alphabetical — according to any classification punched in them. Individual cards can be selected automatically either by the sorter or collator according to the type of selection; for example; all cards higher than a specific number; cards between two specific numbers; cards out of sequence, etc.

Merging is an automatic operation, performed in the collator, of combining two sets of punched cards, each in the same sequence, into one set of that sequence. Matching is the term applied to the function of checking the agreement between two sets of cards, by a comparing procedure on the collator.

These preliminary operations prepare the card records for processing through other machines.

Information, punched in the card, can be interpreted in report form by the use of an accounting machine. Other operations possible during printing are addition, subtraction, cross-addition, cross-subtraction, printing of totals and the automatic conversion into punched-hole form of information developed within the machine by attaching another unit.

For many years, business, finance and accounting organizations used these basic machines to produce various reports automatically. Increase in business since World War II accentuated the restrictions imposed by the type of arithmetic possible on the accounting machines.

The demand for machines to do

more complicated arithmetic resulted initially in the production of electromechanical calculators with limited automatic sequence control. With the harnessing of the electron for counting devices, a small digital electronic calculator was made available by the author's company for business and research. This electronic calculating punch can read and punch data at the rate of 100 cards per minute, and for each card up to 60 individual steps of arithmetic may be performed; for example add, subtract, multiply, divide, or logical tests such as "is a number negative?"

In a mechanical system, incorporating components of the type described, the punched card becomes a control link for data processing. Conventional punched card equipment has been and is used successfully in the processing of many business applications — payroll, sales accounting, cost accounting, inventory, customer billing, public utilities, and others; and in scientific computing—correlation and regression analysis, matrix problems.

The increase in record keeping, management's demands for more accurate and current reports, and the proposed mechanization of new applications were only a few of the factors that affected the engineering of machines with increased processing speeds, input-output media to balance the processing speeds, and additional memory storage. These are the electronic data processing machines.

Before the introduction of the machines for accounting and record-keeping applications, a computer with the features mentioned was designed primarily for engineering and research calculating.

Here is a brief review of the fundamentals of the electronic data processing machine, type 705.

Memory

The memory, although not as compact and efficient as the human brain, is capable of storing 40,000 characters of information, any one of which can be located and transferred in seventeen millionths of a second.

The storage device consists of magnetic cores; tiny doughnut-shaped objects that can "remember" information indefinitely.

The memory stores the input data to be processed, data to be recorded on some output device, tabular values, and the program (series of instructions) to be followed by the machine in the processing.

Control Unit

Associated with the memory is the control unit which tells the machine where to get data, what operations it is to perform and where to place the answer. The control unit functions in accordance with the sequence of operations contained in the program.

Arithmetic Unit

The arithmetic unit does the actual processing of data under the direction of the operation interpreter — the control unit. The 705 machine performs all the arithmetic in the decimal system and has the ability to perform comparisons. Calculating speeds: 504,000 additions or subtractions, 50,000 multiplications, 24,000 divisions, render 1,765,000 logical decisions in one minute.

The electronic data processing machine can prove to be an invaluable tool to management, according to the author, who outlines the operations of a typical instrument. Electronic machines are "only hardware" until man applies his creative thinking; their function is to relieve mental drudgery, not to subjugate it.

Operator's Console

The operator's console is both an operator's control of the machine by use of a keyboard and a machine's control of the operator by use of the typewriter.

Using the keyboard and console, the operator can enter data directly into the machine or control its operations. The information recorded on the typewriter by the machine is subject to the control of the program.

Input Devices

In addition to the keyboard on the console, information can be accepted from: (a) punched cards at the effective rate of 20,000 characters per minute; (b) magnetic tape at the rate of 15,000 characters per second.

Magnetic tape is a plastic film, ½-inch wide, with a thin layer of iron-oxide on one surface. Information is recorded in the form of magnetized spots at a density of 200 characters (alphabetic or numeric) per inch. One reel of tape, 2400 feet in length, can store permanently the equivalent of 25,000 distinct punched card records. Magnetic tapes can be processed thousands of times without signal deficiencies.

Output Device

In addition to the typewriter, which can print 900 characters per minute from memory, information can be recorded in the following ways:

(a) punched cards at the rate of 8,000 characters per minute.

(b) magnetic tape at the rate of 15,000 characters per second. The "write" operation on tape has a dual function — that of erasing (demagnetizing) the previously stored data and of recording the new information from memory.

(c) Line-printers of various speeds: 18,000, 60,000, or 120,000 characters per minute which is the equivalent to 1,000 lines of 120 characters each.

The electronic data processing machine is a general purpose data processing system, with a multiplicity of input and output devices: card readers, magnetic tape units, card punches, line printers. The machine becomes an efficient special purpose machine by merely changing the program stored in the memory and connecting the appropriate input and output units. To retain a state of optimum operation, the processing of voluminous files should be directly from magnetic tape to magnetic tape. Conversion of punched cards to magnetic tape, or magnetic tape to printed documents or punched cards, is an ancillary operation; i.e., independent of the memory.

In the preceding paragraphs is described a large electronic data processing machine capable of processing from basic data to final results subject to a predetermined series of operations in a short period of time without the intervention of an operator — a major advance towards the automated office.

With mechanisms of this calibre or of smaller classification, such as the IBM Type 650 magnetic drum data processing machine, the concept of integrated data processing has become a reality.

The underlying theme in the concept of integration or automation is "one-time recording" of source data. This is accomplished by the development of machines such as "typewriter card punch" — the automatic punching of a card at the time of typing a document; "typewriter tape punch" — the automatic punching of a paper tape, to be converted to cards by a subsequent operation while typing a document; "transceivers" — the automatic and direct transmission over telephone or telegraph circuits of punched card information.

Further review of machine advancements would only emphasize the fact that electronic machines are here to stay, and that we must recognize their potentiality in Canadian business for applications such as production control, perpetual inventory, insurance, billing and sales, railway revenue, and others.

The natural question that may arise in everyone's mind at this time is "won't this do away with many jobs?" It is conceivable that these machines would directly influence the type of jobs; i.e., replace tedious routine jobs by positions requiring the ingenuity of the human brain.

Thos. J. Watson, one of the great pioneers in the office equipment field, has this to say: "Automation will develop as all other forms of power have developed. Primitive man had only his hands, then animal power, then wind power, then came steam, and electric power, then gasoline and oil power and now atomic power. Man power became more valuable than ever. Never in history has man received higher rates of pay for his work than he is getting today."

Comments such as "automation and mechanization in offices will cause mass unemployment" become meaningless when we note that, in Canada, the relative increment in the clerical force since 1900 has been over 800 per cent, despite the fact that the rise of business equipment has increased each year. Another significant factor is that in 1900, the clerical classification represented only 3 per cent of the total labour force in comparison to the 10 per cent ratio existing at present.

Theoretical mathematics has played a major part in the solution of major business problems, such as, "to determine the location of distributing warehouses in order to minimize shipping costs and to make the products available to the market in those areas" or "the correlation of past experience with present conditions for anticipation of the future." Problems of this type are categorized under the new field of "operations research."

To date, solution of such problems was a manual trial and error procedure. In the future, the results will be computed automatically and accurately by using electronic data processing machines.

The concept of integrated data processing is a challenge to management and it will have a profound effect on the way in which we will operate in the future. The trend in labour will be a reduction in unskilled personnel, but a demand for highly trained staff to develop the procedures for and to process the information from the electronic data processing machines.

The function of these machines is such that office operations will be unified and centralized under direct management control; it is no longer a departmental operation. The "logical" ability allows these machines to make decisions, subject to a predetermined program and limits, on volumes of records and to isolate only the records, not in agreement with all the restrictions. In this way, it is possible to process all records, but only report the items requiring immediate action. Such an approach is "management by exception."

Now is the time for management to consider electronic data processing systems. The preliminary studies and implementation of such a system is a major program and may require a period of several months. Although automation in your office may appear more as a fantasy than a reality, failure to assess the merits of an integrated system or to capitalize on the information available at this time can jeopardize the status of the company in the future.

Since the system affects the overall organization and crosses departmental lines, it is essential that the program be controlled at management level.

Electronic systems have found the punched card the most economical and suitable medium for entering basic data. With this in mind, utilization of punched card procedures should be expanded before implementation of the new system. It is also essential that existing routines be itemized in a "procedure outline" with the idea of streamlining these operations by revised clerical operations or punched card mechanization; such a procedure may show considerable savings.

I think that we can all be very enthusiastic about these machines and what can and will be done with them. Electronic machines are not "brains," but only hardware, which remains lifeless until man induces some of his creative thinking to the "memory." These mechanisms are really slaves to the human race, with the sole function to relieve mental drudgery not to subjugate it.

Engineering Properties v. Composition in Simple Binary Alloys

L. M. Elijah
Metallurgical Engineer, Ford Motor Company of Canada

D. J. Mack
Department of Mining and Metallurgical Engineering, University of Wisconsin, Madison, Wis.

Investigations were made to show qualitatively how engineering properties vary with gross composition in mechanical mixture alloy systems. Results obtained are discussed in this paper.

IT IS A WIDELY accepted fact that the engineering properties of metallic materials are structure sensitive. That is, as we vary the structure of an alloy, either by heat treatment, mechanical working or a change in composition we expect that the hardness, ductility, electrical resistance, and other properties of the alloy will exhibit (in most cases) a corresponding change. The changes in properties attendant upon microstructural changes induced by heat treatment and/or mechanical working have been thoroughly investigated quantitatively for all types of alloy systems. This is not true, however, for changes in these properties caused only by gross variations in composition of the alloy, as for example, entirely across a simple eutectic alloy system.

These relationships of gross composition *v.* the engineering properties are well documented for steel, cast iron, and single-phase solid solutions. For other materials, principally alloys whose structure is of the mechanical mixture type, there is almost no information available in the literature. What experimental data exist are seemingly contradictory. This is not surprising if one considers the complex of factors determining, say, the ultimate tensile strength of a mechanical mixture type alloy. Within this complex there would be such contributing factors as: the flow and fracture characteristics of each phase and how these affect each other; the mean free path over which each could operate; the size, topology and overall distribution of the metallographic phases; the cohesion between phases, etc., not to mention the common metallurgical variables such as: amount and kind of working, segregation, and others. Attempts have been made, based largely upon analogy and empirical reasoning, to predict qualitatively the relationship between composition and properties in such systems. The more reasonable attempts have been made by Johnson[1] and Harrington[2]. Examples can also be found in most textbooks on physical metallurgy. Because of this lack of quantitative information, it was decided to measure the common engineering properties as functions of composition in several different mechanical mixture type alloy systems.

Experimental Procedure

Five different simple binary alloy systems were finally selected for study, the selection being based on the consideration that all the component metals were cheap and readily available in a high state of purity (to avoid extraneous solid solution effects), and that they all melted at fairly low temperatures, thus facilitating melting and casting. Since these alloys were all to be of the mixture type it was realized that segregation during freezing would be a serious problem. Accordingly, all alloys were centrifugally chill cast as one-inch bars, four bars of each analysis being cast in a cluster. Three of the bars were used for property determinations, the fourth being held as a reference bar. The procedure followed was that each bar was machined to a ¾ x 6 inch cylinder and its electrical resistance determined, after which it was machined to a standard 0.505 inch test bar with threaded ends, and its tensile properties determined.

Despite all precautions and numerous attempts, it was found impossible to prepare sound test bars of the complete range of compositions in the monotectic Cu-Pb and Zn-Pb systems. The Cu-Pb system was abandoned but a series from the Zn-Pb system was ultimately prepared. Finish machining revealed that they were sufficiently unsound, however, to use for mechanical property determination and so only electrical resistance was measured. Because of the brittleness of the Sb-rich alloys, the Pb-Sb alloys were prepared only up to 25 per cent Sb.

The results are shown by means of graphs, the composition being plotted against the various properties. In each case, the phase diagram is also shown for reference.

The Al-Sn system. The eutectic in

*Extracted from a thesis presented by Leo M. Elijah to the Graduate Faculty at the University of Wisconsin in partial fulfilment of the requirements for the degree of Master of Science, Metallurgical Engineering.

this system (Fig. 1) occurs so close to the Sn axis that its effect on the microstructure and properties as determined here seems negligible as do the very slight terminal solid solubilities at both ends. Accordingly, all alloys can be regarded essentially as a mixture of aluminum and tin, the tin in all cases being the continuous phase in the structure. On this basis the properties should obey the rule of mixtures and be linear functions of composition. Only the electrical resistivity and hardness conform to the prediction. Elongation and reduction in area are curvilinear and both show minima, suggesting that because of the difference in properties of the aluminum and tin the topology of the microstructure is important. The tensile strength curve is linear down to about 20 per cent aluminum, after which it drops in a smooth curve to the value for pure tin. This also indicates a critical distribution of the micro-constituents. Although the analogy is far-fetched and probably illogical, a study of the flow characteristics of alloys in the region of this break point might be of interest in boundary microflow mechanisms.

The Zn-Pb system. As previously stated, due to the difficulties of casting sound specimens only the electrical resistivity of alloys in this system was measured. The results are shown in Fig. 2 and are as one would anticipate, the electrical conductivity being a linear function of composition.

The Sn-Pb system. The system, as shown in Fig. 3, consists of a eutectic with terminal solid solutions at both ends. It is somewhat unusual because, despite the extensive solid solubility decreasing markedly with temperature at each end, almost no age-hardening effects occur. This is fortuitous for property determination because variations in cooling rates or storage time amongst the various alloys become unimportant and it also means that probably no significant strain ageing effects will occur.

The properties are also shown in Fig. 3. The strong effect of solid solution formation on properties is well illustrated at both ends of the diagram. The ductility as measured by elongation and reduction in area is a minimum at the eutectic composition. Paradoxically, the hardness is also near a minimum at the eutectic composition and the tensile strength seems nearly unaffected by the relative amount of the finely divided eutectic structure present. The reason for this behaviour is known. The electrical conductivity behaves normally in that it is a linear function of the relative amounts of the two solid solutions present.

The Pb-Sb system. The effect of Sb in inducing age hardening in Pb is well known as is the fact that rapidly cooled alloys age at room temperature. Accordingly, all alloys were thoroughly aged before property determination, thus ensuring that the effect of the gross composition (microstructure) would be

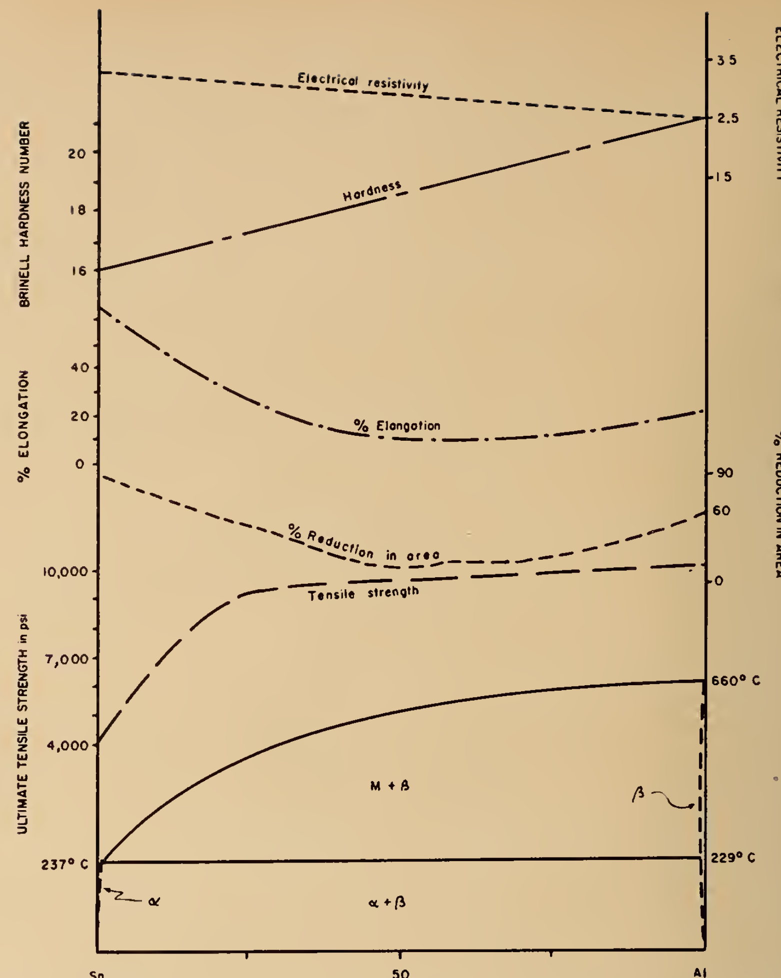

Fig. 1 Properties as a function of composition in the aluminum-tin system.

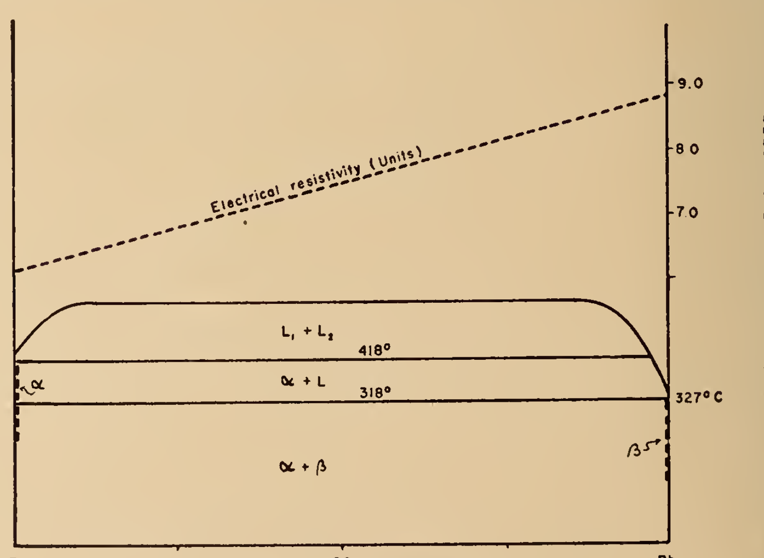

Fig. 2. The zinc-lead system.

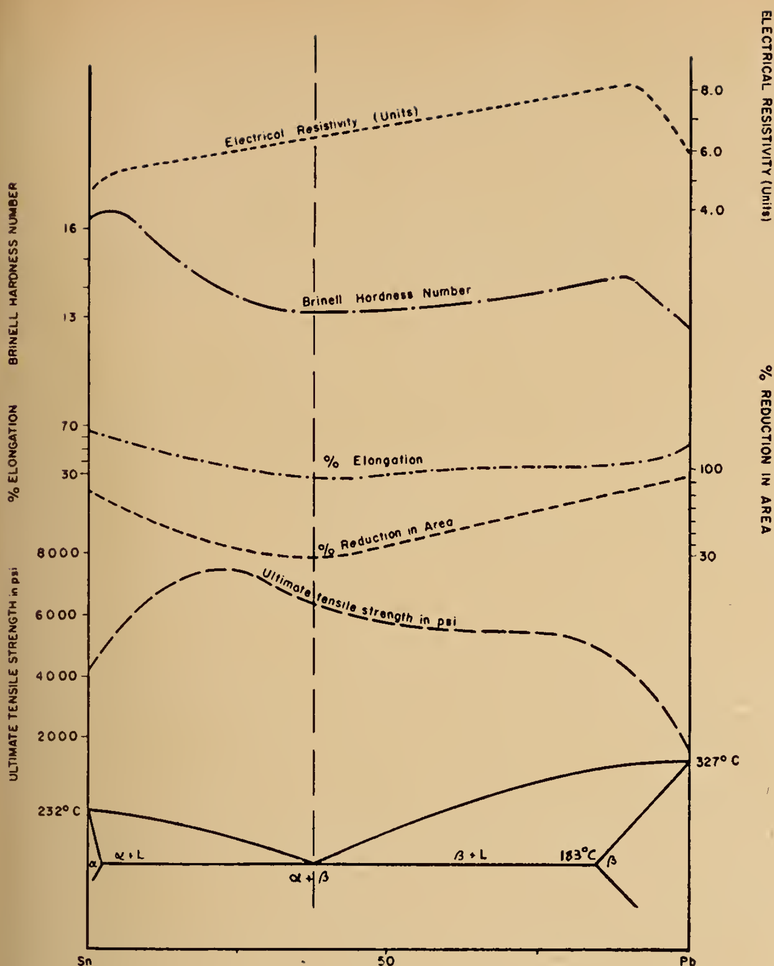

Fig. 3. The tin-lead system.

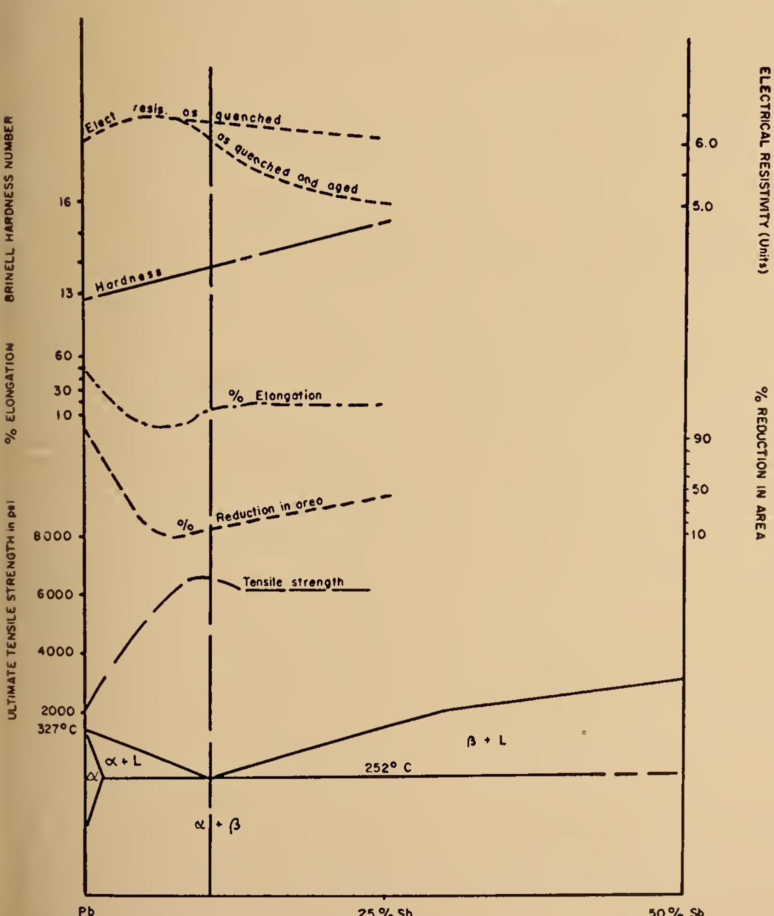

Fig. 4 (Below)
The lead-antimony system.

measured as unaffected by transitory ageing phenomena. The results are shown in Fig. 4.

Two curves are shown for electrical conductivity which illustrate how necessary it is in this system to control ageing if reproducible properties are desired. The resistivity is shown to be higher in the freshly quenched state than in the overaged condition, which is normal behaviour. That the two curves get farther apart with increasing Sb content is probably due to the fact that the Sb-rich phase which is present in increasing amounts is more affected by ageing than is the Pb-rich phase.

In general, the properties behave as one might expect. The elongation and reduction in area both show minima near the eutectic but on the lead-rich side, whereas the tensile strength maximum is at the eutectic composition. Why the minima in ductility and the maximum in tensile strength do not coincide is uncertain, but may be associated with some slight irregularities in ageing. The bumps shown on some published tensile strength curves in the region of 4-5 per cent lead are believed due to a lack of appreciation of the extent to which Pb-Sb alloys of this composition will age- and strain-harden.

The hardness curve which is linear is interesting because it serves to emphasize the danger of trying to correlate hardness with other properties in systems where the correlation has not been extensively studied.

Conclusions

These very brief results show that the attempts which have been made to picture qualitatively how the engineering properties vary with gross composition in a mechanical mixture alloy system have been moderately successful. They also show that the nature of the phases is more important than their gross amount or distribution in the microstructure of an alloy and that any attempt to picture the property curves as breaking sharply at phase field boundaries or at eutectic compositions is unwarranted.

Symposium on the

Transatlantic Telephone Cable

A meeting of the Institution of Electrical Engineers, the American Institute of Electrical Engineers, and the Engineering Institute of Canada, held simultaneously in London, New York, and Montreal, on 24 January, 1957, using the first transatlantic telephone cable.

THE TRANSATLANTIC telephone cable service was officially inaugurated on 25 September 1956 at simultaneous ceremonies in London, New York, and Ottawa (reported in the November issue of *The Engineering Journal).*

On 24 January, 1957, the cable links between Britain and the North American continent were once again used to enable a simultaneous meeting to be held in London, New York, and Montreal between the engineers and executives associated with the project, under the auspices of the Institution of Electrical Engineers, the American Institute of Electrical Engineers, and the Engineering Institute of Canada.

Greetings were exchanged between M. S. Coover, president, A.I.E.E., V. A. McKillop, president, E.I.C., and Sir Gordon Radley, president, I.E.E., who acted as chairman of the joint meeting.

The carefully organized and strictly timed program continued with the introduction of the authors from the three countries who had prepared papers on various technical aspects of the cable project. The authors spoke briefly of the work.

As a demonstration of the excellent quality of reproduction made possible by the cable, there followed an interlude of high-fidelity recorded music which amply demonstrated the great advance in quality that had been achieved.

Speakers in the three cities then had an opportunity of discussing the subjects of the technical papers before the meeting closed with remarks from particular sections of the three engineering organizations and from their respective presidents.

The Canadian group met in the auditorium of the Bell Telephone Company of Canada, in Montreal. Among the distinguished participants were T. W. Eadie, president, the Bell Telephone Company of Canada, and D. F. Bowie, president and general manager, Canadian Overseas Telecommunication Corporation.

Background to the Cable

An agreement covering the provision of a submarine cable system for transatlantic telephone service between the United States and Canada, on the West, and the United Kingdom, on the East, was made on 2 November 1953, between the principals concerned. These were: the British Postmaster-General; the American Telephone and Telegraph Company, New York (A.T. & T.); Canadian Overseas Telecommunication Corporation, Montreal (C.O.T.C.); and Eastern Telephone and Telegraph Company, Halifax, N.S. (of which the outstanding capital stock is owned by A.T. & T.). The agreement defines the share of the principals in the construction, maintenance, and operation of the service. Work started on the east-bound cable on 28 June 1955, and laying of some 2100 nautical miles was completed in three stages by September 1955. The corresponding west-bound cable was laid in three stages between June and August, 1956. During this time, other facilities were also completed.

Symposium Papers

The titles of the papers prepared for this symposium, and their authors, are listed below. Copies of the papers may be obtained from the Institute library, and some may subsequently be published in full. (Numbers in parentheses identify preprints of the papers issued by the Institution of Electrical Engineers.

A Foreword to the Symposium

Mervin J. Kelly,

President, Bell Telephone Laboratories, Inc.

Sir Gordon Radley,

President, The Institution of Electrical Engineers

A SERIES of technical papers will describe the design, manufacture and installation of the first transatlantic telephone cable system in all its component parts, including the connecting microwave radio-relay system in Nova Scotia. The purpose of this introduction is to set the scene in which this project was undertaken and to discuss the technical contribution it has made to the development of world communications.

Electrical communication between the two sides of the North Atlantic started in 1866. In that year the laying of a telegraph cable between the British Isles and Newfoundland was successfully completed. Three previous attempts to establish transatlantic telegraph communication by submarine cable had failed. These failures are to-day seen to be the result of insufficient appreciation of the relation between the mechanical design of the cable and the stresses to which it is subjected as it is laid in the deep waters of the Atlantic. The making and laying of deep-sea cables was a new art, and designers had few experiments to guide them.

During the succeeding ninety years, submarine telegraph communication cables have been laid all over the world. Cable design has evolved from the simple structure of the first transatlantic telegraph cable — a stranded copper conductor, insulated with gutta-percha and finished off with servings of jute yarn and soft armouring wires — to the relatively complex structure of the modern coaxial cable, strengthened by high-tensile-steel armouring for deep-sea operation. The coaxial structure of the conducting path is necessary for the transmission of the wide frequency bandwidth required for many telephone channels of communication. The optimum mechanical design of the structure for this first transoceanic telephone cable has been determined by many experiments in the laboratory and at sea. As a result, the cable engineer is confident that the risk of damage is exceedingly small, even when the cable has to be laid and recovered under conditions which impose tensile load approaching the breaking strength of the structure.

The great difference between the transatlantic telephone cable and all earlier transoceanic telegraph cables is, however, the inclusion of submerged repeaters as an integral part of the cable at equally spaced intervals and the use of two separate cables in the long intercontinental section to provide a separate transmission path for each direction. The repeaters make possible a very large increase in the frequency bandwidth that can be transmitted. There are 51 of these submerged repeaters in each of the two cables connecting Clarenville in Newfoundland with Oban in Scotland. Each repeater provides 65 db. of amplification at 164kc./s., the highest transmitted frequency. The working frequency range of 144kc./s., will provide 35 telephone channels in each cable and one channel to be used for telegraph traffic between the United Kingdom and Canada. Each cable is a one-way traffic lane, all the 'go' channels being in one cable and all the 'return' channels in the other.

The design of the repeaters used in the North Atlantic is based on the use of electronic valves and other components, initially constructed or selected for reliability in service, supported by many years of research at Bell Telephone laboratories. Nevertheless, the use of so many repeaters in one cable at the bottom of the ocean has been a bold step forward, well beyond anything that has been attempted hitherto. There are some 300 valves and 6,000 other components in the submerged repeaters of the system. Many of the repeaters are at depths exceeding 2,000 fathoms (2¼ miles) and recovery of the cable and replacement of a faulty repeater might well be a protracted and expensive operation. This has provided the incentive for a design that provides a new order of reliability and long life.

On the North Atlantic section of the route, the repeater elements are housed in flexible containers that can pass around the normal cable-laying gear without requiring the ship to be stopped each time a repeater is laid. The advantages of this flexible housing have been apparent during the laying operations of 1955 and 1956. They have made it possible to continue laying cable and repeaters under weather conditions which would have made it extremely difficult to handle rigid repeater housings with the methods at present available.

Single Cable

A single connecting cable has been used across Cabot Strait between Newfoundland and Nova Scotia. The 16 repeaters in this section have been arranged electronically to give both-way amplification, and the single cable provides 'go' and 'return' channels for 60 circuits. 'Go' and 'return' channels are disposed in separate frequency bands. The design is based closely on that used by the British Post Office in the North Sea. Use of a single cable for both-way transmission has many attractions, including that of flexibility in providing repeatered cable systems, but no means has yet been perfected of laying as part of a continuous operation the rigid repeater housings that are required because of the additional circuit-elements. This is unimportant in relatively shallow water, but any operation that necessitates stopping the ship adds appreciably to the hazards of cable laying in very deep water.

The valves used in the repeaters between Newfoundland and Scotland are relatively inefficient judged by present-day standards. They have a mutual conductance of 1000 micromhos. Proven reliability, lower mechanical failure probability, and long life were the criteria that determined their choice. Valves of much higher performance with a mutual conductance of 6000 micromhos are used in the Newfoundland-Nova Scotia cable, and it is to be expected that long repeatered cable systems of the future will use valves of similar performance. This will increase the amplification and enable a wider frequency band to be transmitted, thus assisting provision of a greater number of circuits. If every advantage is to be taken of the higher-performance valves, it will be necessary to duplicate (or parallel) the amplifier elements of each repeater, in the manner described in a later paper, in order to assure adequately long trouble-free performance. This has the disadvantage of requiring the use of a larger repeater housing.

Large Capacity

During the three years that have elapsed since the announcement in December, 1953, by the American Telephone and Telegraph Company, the British Post Office, and the Canadian Overseas Telecommunication Corporation, of their intention to construct the first transatlantic telephone cable system, considerable progress has been made in the development and use of transistors. The low power drain and operating voltage required will make practicable a cable with many more submerged repeaters than at present. This will make possible a further widening of the transmission band, which could provide for more telephone circuits with accompanying decrease in cost per speech channel, or the widened band could be utilized for television transmission. Much work, however, is yet to be done to mature the transistor art to the level of that of the thermionic valve and thus ensure the constancy of characteristics and long trouble-free life that this transatlantic service demands.

The present transatlantic telephone cable whose technical properties are presented in the accompanying papers, however, gives promise of large reduction in costs of transoceanic communications on routes where the traffic justifies the provision of large-traffic-capacity repeatered cables. The thirty-six 4kc./s. channels, which each cable of the 2-way system provides, are the equivalent of at least 864 telegraph channels. A modern telegraph cable of the same length without repeaters would provide only one channel of the same speed. The first transatlantic telegraph cable operated at a much lower speed, and transmitted only three words per minute. The greater capacity of future cables will reduce still further the cost of each communication circuit provided in them. Such considerations point to the economic attractiveness, where traffic potentials justify it, of providing broad-band repeatered cables for all telephone, telegraph and teletype service across ocean barriers.

The new transatlantic telephone cable will supplement the service now provided by radio telephone between the European and North American continents. It will add greatly to the present traffic-handling capacity of this service. The first of these radio circuits was brought into operation between London and New York in 1927. As demands for service have grown, the number of circuits has been increased. We are, however, fast approaching a limit on further additions, as almost all possible frequency space has now been occupied. The submarine telephone cable has come, therefore, at an opportune time; further growth in traffic will not now be limited by traffic capacity.

Technical Development

Technical developments over the years by the British Post Office and Bell Telephone Laboratories have brought continuing improvement in the quality, continuity, and reliability of the radio circuits. The use of high-frequency transmission on a single sideband with suppressed carrier and steerable receiving aerial are typical of these developments. Even so, the route, because of its location on the earth's surface is particularly susceptible to ionospheric disturbances which produce quality deterioration and at times interrupt the service completely. The cable transmission will be free of all such quality and continuity limitations. In fact, service of the quality and reliability of the long-distance service in America and Western Europe will be possible. This quality and continuity improvement may well accelerate the growth in transatlantic traffic.

The British Post Office and Bell Telephone Laboratories are continuing vigorous programmes of research and development on submarine cable systems. Continuing technical advance can be anticipated. Broader transmission bands, lower-cost systems and greater assurance of continuous, reliable and high-quality services will surely follow.

The Engineering Technician

A panel discussion held as Session 1 of the joint Conference of the American Society of Mechanical Engineers and the Engineering Institute of Canada, University of Western Ontario, October 1956

Dr. L. S. Beattie

Superintendent of Secondary Education, Province of Ontario
Moderator of the Session.

Radical changes in production methods, combined with our industrial expansion, have created an acute demand for scientists, engineers, and technicians. Formerly, the technician received all of his training on the job. It has been claimed that modern industrial engineering has substituted "operations" for "jobs" and hence has eliminated the work processes by which the technicians were trained. Under these changing conditions, therefore, it may be necessary to give the potential technician a basic technical education before he enters employment, thus enabling him to progress more rapidly in his on-the-job training. Moreover, in today's industry there is a strong trend to transfer the less creative and the more routine work of the engineer to the engineering technician who has received in a technical institute or a junior college an education the content of which is briefer, more technical, and less theoretical than engineering curricula.

To discuss the problems related to the enginering technician and his training, the members of this panel have been chosen from the fields of industry and technical education in both the United States and Canada. Light and heavy industry is represented by Mr. Kimball C. Cummings, associate director of aero research, Minneapolis - Honeywell Co., Minneapolis, and Mr. Robert S. Eadie, vice - president and general manager, Eastern Division, Dominion Bridge Co., Montreal. These two speakers will deal with the following questions:

(1) How does industry define the engineering technician?

(2) In what ways does his work compare with or differ from that of the graduate engineer?

(3) What is an ideal ratio of engineers to technicians?

(4) To what extent is the technician being trained on the job?

(5) How can industry assist and cooperate with schools of technology?

The education of the engineering technician will be presented by Mr. Howard H. Kerr, principal, Ryerson Institute of Technology, Toronto, and Mr. Karl O. Werwath, president, Milwaukee School of Engineering, Milwaukee. These speakers will attempt to answer the following questions:

(1) What are the qualifications for an entrant to the course in enginering technology?

(2) What specialized courses are offered?

(3) What is the nature of their content and presentation?

(4) In what ways does the school gain the co-operation of industry?

(5) To what extent do the graduates meet the present demand for engineering technicians?

R. S. Eadie

Vice-President and General Manager, Eastern Division,
Dominion Bridge Company Limited, Montreal, Que.

To discuss this or any other subject intelligently, it is first necessary to be sure that all those interested place the same meaning on the words used in defining the particular matter under discussion. The definition for an engineering technician adopted by the Conference of Commonwealth Engineering Institutes is:

"An engineering technician is one who can apply in a responsible manner proven techniques which are commonly understood by those who are expert in a branch of engineering or in those techniques especially prescribed by professional engineers. The techniques employed demand acquired experience and knowledge of a particular branch of engineering combined with the ability to work out details of a task in the light of well-established practice."

This definition appears to be complete but, after discussing the subject with representatives of several industries, it appears to me that it does not enable one to pinpoint the jobs held by engineering technicians in Canadian industry, in which there seems to be a difference of opinion among engineers and management as to what an engineering technician is and what type of jobs he can handle. I will try to define what I think is meant by the term by discussing actual examples of those I believe are and are not technicians.

First, I would eliminate from the class of technician all skilled mechanics and tradesmen such as machinists, toolmakers, pattern makers, etc. This is not a slur on these occupations because many of these men are very highly skilled and, in some cases, may be promoted to other positions where they may, in my opinion, be properly classed as technicians. For example, a highly skilled tool maker may, with additional training and with the necessary natural ability, be advanced to the position of inspector or methods layout man where he would be properly classified as a technician. We, of course, also eliminate all graduate engineers, although some may occupy positions which could be filled by technicians, particularly in the years immediately following graduation when they are obtaining the necessary basic practical experience in industry, or later due to a lack in the individual which cannot be overcome by training.

Since I am most familiar with the heavy engineering industry, I am selecting from the employees in that type of industry the following classes of engineering technician.

Structural and Mechanical Draughtsmen — These men make layout drawings, assembly drawings and, finally, the detail drawings which completely describe the finished product to be turned out in the shop.

Estimators — Men with ability to read drawings and to take off quantities from them so that these estimates may be used as the basis for the estimate of labour required to produce the finished product. Some estimators' previous training may enable them to estimate the labour allowance necessary for fabrication.

X-ray Operators — Men trained to set up and take the necessary x-ray or gamma-ray pictures of welded or other fabricated units so as to show up defects. In some cases, their extensive experience may qualify them to interpret the x-ray film and prescribe the method of repair. They work under the direction of a qualified welding engineer.

Welding Supervisors — In our operations men who have had long and varied experience as welders are used to supervise and control welding operators. They are concerned solely with the methods and techniques employed and the qualitative results obtained. They have no control on discipline or production. They work under the direct supervision of the shop welding engineer.

Service Men — All producers of heavy machinery and equipment must maintain contact with their customers to observe the operation of their equipment in the field and report to the designing engineers and shop personnel any improvements which they consider should be made to operation or maintenance. This is a position that may be filled by a graduate engineer, but, in many cases, as good or better results can be obtained by the use of a man, trained either in the shop or office, who has the faculty of observing and recording troubles and is able to suggest ways of overcoming or improving defective design.

Time Study Men — Time study can, and properly should, be controlled by a graduate engineer but the actual work of gathering, recording, and compiling the information can be done by technicians trained in the particular methods to be used.

Methods Lay Out Men — In all engineering shops, whether of the production or job type, the methods to be used in the manufacture of any piece must be pre-determined before the drawings are issued to the production shops. This work can usually best be done, again under the supervision of an engineer, by a man with shop training who has imagination and skill in the application of the machines and tools available in the shop.

Inspectors — In all engineering shops, some form of inspection must be maintained on the jobs as they progress and when they are finally completed. In jobbing shops this probably requires a man with a higher degree of skill than in production shops, as practically every job is unique and continuous reference must be made to the drawings.

During the panel session. From left: Karl O. Werwath; Dr. H. H. Kerr; Dr. L. S. Beattie, moderator; R. S. Eadie; and Kimball C. Cummings, addressing the session.

The foregoing examples may be sufficient to show the type of employee who, I think, should be classed as an "engineering technician".

It would appear essential, in all cases, that such employees should have a basic education equivalent to Junior Matriculation. This basic education may, of course, be obtained partially after leaving school by means of night classes or correspondence courses but, without it, a technician is not likely to go far. Of course, for the positions mentioned above there can be a difference in the emphasis on the subjects which are taken in this basic training.

Draughtsmen and Estimators

As draughtsmen and estimators form probably the largest group of the technicians referred to, I would like to discuss the possible methods of training these men.

A good draughtsman should have: (*a*) A thorough knowledge of arithmetic, geometry and trigonometry; (*b*) skill in the use of pencil, scale and tee-square; (*c*) preferably, some knowledge of descriptive geometry; and (*d*) knowledge of the detail standards and shop practice used in the particular plant or industry.

How are these men to receive the necessary training? There are at least three methods which may be followed.

If a boy has completed his matriculation course, including mathematics, he has acquired a good part of the knowledge required in item (a). With this background he can be taken into the drawing office where, in a special squad of trainees, he is taught the fundamentals of mechanical drawing and is introduced to the standards used in the industry. As his knowledge increases, he is gradually put on productive work.

If a boy has not completed matriculation, he can still be taken into the drawing office trainee squad and, if he is willing to make the effort, he can obtain the necessary basic training in mathematics which he lacks by correspondence course, night classes at technical or other schools, or by lectures given by the employer's staff. In some cases, instead of attending high school, boys enter technical schools operated in some of the provinces. These schools give a grounding in mathematics and some training in basic drawing and other basic skills. Depending on the school, some of the graduates can be quickly made into productive draughtsmen. In other cases, it may be necessary to give additional draughting instruction before trying to incorporate these people into the productive squad.

Staff Lectures

No matter by which line of approach a student draughtsman has come up, all new employees should receive some lectures given by the employer's staff to instruct them in the standards and practices which are peculiar to that industry or plant. Men that receive such a training are essential to industry and from the point of view of the individual there is good opportunity for promotion to positions which are rewarding both financially and as to responsibility.

Some draughtsmen with a special interest in mathematics may be further trained as estimators and as designers of simple structures. These men can take off quantities of material for estimating, make estimates of labour hours required, and do other such repetitive work. Some may also advance further and, by study, gain a very sound knowledge of machine and/or structural design. Such men, in many cases, are more useful to a manufacturer as a designer than a graduate engineer who has not too much practical experience.

We have, through the years, employed a large number of draughtsmen trained in the British apprentice system, which includes a very complete course in both shop and office. These men are very satisfactory and, in many cases, can do a considerable amount of design work, particularly if they have secured the National Higher Certificate issued in Britain.

In some cases, of course, a technician may proceed to take the necessary examinations and obtain registration as a professional engineer.

Training of the other types of technicians which I have mentioned, may be varied. It may be via technical school, tradesman's apprenticeship course, or by training in the special technique in the shop. In all cases, however, the trainee must have a basic knowledge equivalent to high school matriculation together with an ability and a desire to study and to apply himself.

With respect to the ideal ratio of engineers to technicians, I would certainly not hazard a guess for the heavy manufacturing industry.

As already stated, I think that a large part of a technician's specialized training must be done on the job. I think, however, that technical schools do serve a useful purpose and that industry should and can cooperate with them. As an example, I would suggest that the trips of teachers to plants, such as arranged by the Montreal Board of Trade every year, serve a very useful purpose in acquainting the teachers with what industry needs and expects from the graduates. Also, I think that further use could be made, in night schools especially, of instructors from industrial plants to cover the practical and some theoretical courses.

Kimball C. Cummings
Associate Director, Aero Research, Minneapolis-Honeywell Company, Minneapolis, Minn.

Considerable emphasis has been given to the shortage of engineers and the role of the engineering technician in partial relief of this shortage. Perhaps not so widely recognized is that the engineering technician has a rightful and not just a substitute place on the industrial engineering team. The effect of the engineering shortage has created a greater need for higher qualified men as technicians thereby amplifying the technician's role. Part of this panel will discuss what the technical institutes are doing to fulfill the demand for the higher quality product. This talk covers how American industry is utilizing technicians, what it is doing to upgrade the quality of its current technician staff, some ways schools can cooperate, and what is the outlook for technicians.

Definition of the Engineering Technician

One can find many definitions for technicians. Yet, none seem to be exact enough. The technician's job is really a continuum of jobs, each one overlapping several others. At one end of this spectrum of jobs lies the craftsman. The other extreme is represented by the engineering aide. In between lies a juxtaposition of skills and abilities creating a skein of jobs.

When we speak of the engineering technician, we'll have to assume that he works in an engineering department, and that he has some contact with an engineer who is the source of work for the technician. As an example, draughtsmen are sometimes not considered engineering technicians, although many companies classify them generally as such. Many draughtsmen, however, by outside and on-the-job training develop their ability to where they can be classified as engineering technicians in every sense of the meaning. The same is true of machinists and other craftsmen who are normally thought of as being in tradesman areas.

The American Society of Engineering Education defines* the engineering technician as one who engages in work that requires some of the knowledge and skills of both the professional engineer and the skilled craftsman. The type of industry, the job assignment, and the abilities of the person determine the composition of the job, and its real definition.

Bell Telephone Laboratories defines** three technical aide classifications. The lowest is the technical assistant, which requires technical institute or equivalent training. These work under close direction of more senior members, and in a supporting capacity. The second, the technical staff associate, requires greater experience on the job, demonstrated ability to carry on work of greater degree of complexity and with less supervision than is given the technical assistants, and sometimes more formal training. The third, senior technical associate, is a classification carrying sufficient responsibility and latitude for the exercise of independent judgment to make it qualify for exemption under the Fair Labour Standards Act. In general, it requires a formal preparation equivalent to a four year college course. It involves the ability to undertake work independently on a project basis.

It may not be necessary to make a limiting definition, since so much depends on the type of work and other factors. A clearer understanding of the engineering technician can be obtained by examining the types of work he does in industry. I cannot, of course, speak for all American industry, but will try to give you some examples.

General Motors, as described by Mr. DeMause in the *Wall Street Journal*, has a "balanced engineer-technician team." They use "service" departments which cut across broad areas such as engines, exhaust, fuels, and cooling. One service department may handle all testing, for example. Each department has many technicians, working group leaders, and junior engineers.

* The Engineering Technician, booklet available from Editor, **Technical Education News**, 330 West 42nd Street, New York 36, N.Y.

• ASME-E.I.C. CONFERENCE

One company, in constructing a large electrical generating station, uses technicians for directing construction and erecting operations, for inspecting material and finished work, and for installing machinery and electrical apparatus.

At Minneapolis-Honeywell we have pool-type operations such as model shop, draughting and technician shop. However, part of the men in the latter two groups are given team assignments which may last for a long time or sometimes for short periods. In addition to the pools, many technicians are employed directly on the engineering or research teams.

Examples of Work Assignments

It is difficult to give representative examples of the work performed by engineering technicians because of the broad spectrum I mentioned earlier. Perhaps I can pick out a few jobs within this spectrum and give some details on them. It is to be assumed that all of these jobs come under the direction of engineers or appropriate work directors.

Engineering craftsman engages primarily in manipulative skills in making a part or a device from a finished drawing, and uses freedom in the construction process to arrive at the final designated form. He may make suggestions to the engineer to change the design so that the fabrication may be easier.

Design technician engages primarily in manipulative skills, but works from rough sketches or verbal instructions and often supplies his own concepts as to the final form of the device.

Computist does calculations for the engineer. He may operate a desk calculator, slide rule, use charts, graphs, and tables for solving equations, draw graphs, reduce data, wire panels for computer operation, and other tasks which are essentially of a computational nature.

Test Technician assists engineer in environmental tests on components and complete systems; sets up equipment, runs tests, prepares data for report, and may even analyse data and write a test report on routine tests.

Design aide assists design engineers in his work. He expedites and coordinates building of duplicate engineering models, does design computational work, makes minor engineering studies, does routine design changes, assists in design data releases, parts lists, drawings, follows progress of equipment through service organizations and does repetitive engineering work once accomplished by the design engineer.

Research aide assists the research engineer in his experimental or analytical studies. He may perform research experiments, collate data, assist the engineer in setting up and solving problems on analogue or digital computers, program and code instructions for the computers and analyse and present results to the engineer. He may solve a complete problem of a repetitive nature by himself. During the computer solution the research aide assists the engineer in more of the repetitive operations. In many cases, he will be able to carry on the computer analysis alone, and where only a slight modification is required, he can probably carry on the whole analysis by himself.

Flight technician prepares equipment and instrumentation for flight test. He may design the necessary fixtures to fasten the equipment to the airplane, and arrange the instrumentation system to get the required data.

Technical writers write reports and instruction manuals from data supplied by engineers. One company relieves the engineer of all report writing, whereas others supply a technical editor.

Production technician helps prepare methods analysis, assists in design of production tooling and production control functions, assists in production operations and construction and maintenance of complex production equipment.

Levels of Responsibility

One of the problems apparent on the engineering team is the division of responsibility between the engineer and the technician. The engineer must develop the ability to assign work to the technician so that he is fully effective. Too much delegation can lead to possible compromises in the engineering design, whereas too little can create a clerk out of the technician. Training and coaching of both the engineer and technician is required to achieve harmony, and probably most of it has to be done on the job rather than in the academic classroom.

There is no sharp line of demarcation between the responsibility of the technician and the engineer. Some like to use the terms "how" and "why" to differentiate between the technician and the engineer. Any way of looking at this still depends on the particular situation and on the individuals concerned. I believe we should continue to increase the technical responsibilities of all groups, and encourage formal and informal training to make this possible.

Training Activities

On-the-Job Training

The simplest method is on-the-job training. This is the training where a man learns by doing and by making mistakes. One of the important factors then is assignment of jobs so that a man has to learn more if he is to put in good performance. This would seem to hold true for either engineers or technicians.

Some companies intensify on-the-job training by giving formal courses relating directly to the job. For example, our company recently obtained a large digital computer for research use. We knew that we would need coders, programmers and mathematicians with proper training to make effective use of the computer when it arrived. We sent people out to learn the operation of this style of computer, and they instituted an in-hours course to train the people who would be working with it. This formal training continued after the equipment arrived, and now is done informally as part of the job.

After-Hours Courses

The Minneapolis plants of Minneapolis-Honeywell are fortunate in being close to the University of Minnesota where many basic courses are available and the company does not have to engage in teaching courses normally found in a university. In fact, along with hundreds of other U.S. companies, we offer tuition aid to employees who wish to take formal training which would benefit them in their present or future work. The after-hours courses which are taught on company premises are free to the students and cover courses for technicians, engineers, and others.

Special Training Programs

Some companies offer full tuition and, in certain cases, time off with pay to attend school. An article in the September 7th issue of the *Wall Street Journal* cited some of the training programs offered by companies to increase the technical ability of their technicians. For example, International Business Machines conducted a concentrated twelve weeks training program for technicians who can now handle some tasks formerly done by professional engineers.

Thus the educational opportunities

are there and those who wish to accept greater responsibilities need only to ask and act.

Relations with Technology Schools

With the shortage of engineers and technicians, the question can be asked, "What can industry do to assist and cooperate with schools training technicians?" Unfortunately, I am not familiar with the practice of American industry, but I can say what we at Honeywell have done in this direction.

Our problem was that we wanted to hire more technicians, and the supply of the type of technicians we required was not available in Minneapolis.

The first step made was to get acquainted with the sources of supply. Personnel representatives visited technical institutes to make personal contacts and gain an understanding of the school and the type and quality of graduates. We also contacted the junior colleges in Minnesota to see how their educational facilities and technical courses could fulfil industry's needs. We found all the schools eager to help and the main problem was communication — both internal and external.

The various engineering and research departments were asked to establish their technician requirements. Their requirements and the demand for manpower, and even specific individual needs, were outlined to the schools.

In the case of the junior colleges, where the curricula were not so well established in the areas we wanted, we arranged further contact with the faculties. After our representatives had visited all the colleges, the college presidents were invited to visit Honeywell. After a panel discussion of how technicians are utilized, a plant tour was arranged. The outcome of these contacts and meetings were course changes designed to meet ours and other industrial needs.

We have also arranged summer work for faculty members so that they can get a better understanding of our operations.

Finally, we are arranging cooperative programs and scholarships for students.

The Future for the Technician

Ratio of Technicians to Engineers

We speak of the shortage of engineers; less well known is that there is a greater shortage of engineering technicians. The ratio of technicians to engineers varies considerably in industry. A recent survey† shows ratios from 0.20 in the chemical and allied fields to 3.18 in the fabricated metal products field. The average for the 363 industries was 0.73. However, the hiring practice of 1956 shows the ratio to be over 1.00, which indicates the demand is about the same for technicians as it is for engineers. This ratio is expected to increase because of the compounding effect created by utilizing technicians more effectively on the engineering team.

Demand for Technicians

I know of no source where the yearly demand for engineers can be accurately found, nor where the demand for engineering technicians can be found. Various sources lead me to believe that 50,000 engineers and an equal number of technicians approximate the current annual demand for these groups in the United States. Engineering graduates will number this year about 30,000, fulfilling about 60 per cent of the demand.

It is more difficult to determine the supply of engineering technicians. The survey* made by Leo F. Smith, dean of instruction for the Rochester Institute of Technology, shows 11,350 graduates of technology courses one year or more in length. To these must be added the technological graduates of the terminal courses in the junior colleges. I am not aware of any available data on the number of graduates from the junior colleges. Mr. Smith mentions old data in his book**, but was unable to give up-to-date figures. Even if their graduates equalled the Technical Institute graduates, the supply of technicians would barely satisfy half the present needs.

These figures assume an average ratio of one technician to one engineer. Minneapolis - Honeywell is increasing their ratio and many other companies are doing likewise. One can only conclude that the technician shortage is going to get worse, before it gets better.

Personal Goals

One important point has to do with the outlook from the personal point of view of the technician. This point is that artificial barriers should not be put in the way of a technician such that he cannot enter into an engineering position in industry. We have several men who have, by virtue of their demonstrated proficiency on the job (which required outside study and devotion to his work), entered the engineering ranks. Most of these people tend to be specialists and do not have the flexibility of an engineer when switching jobs, but they do perform work of engineering calibre. The fact that advancement beyond technician ranks is possible often serves as a powerful motivation.

Future Role

The future of the engineering technician is tied to these three conclusions:

(1) The complexity of our times is increasing and will continue to increase. This will require more engineers and technicians.

(2) The current scarcity of engineers has created new opportunities for lesser trained people, and with the compounding of the increased need for engineers, the need for technicians will continue to grow.

(3) Automation will raise the skill required of the laboring force; hence more training will be required.

Dr. H. H. Kerr

Principal, Ryerson Institute of Technology, Toronto.

In an address last January on the subject of education, Sir Anthony Eden said: "The prizes will not go to the countries with the largest population. Those with the best systems of education will win. Science and technical skill give a dozen men the power to do as much as thousands did fifty years ago. Our scientists are doing brilliant work. But if we are to make full use of what we are learning, we shall need many more scientists, engineers and technicians. I am determined that this shortage shall be made good."

The shortage of scientists, engineers, and technicians is just as great in Canada as in England; and here as in England industry and all levels of Government are endeavouring to find an acceptable solution. There are many causes for this dearth of engineering manpower but one important factor is that the ratio between engineers and other types of employees is rising. Fifty years ago this ratio in the manufacturing industries was 1 to 300. Because of the tremendous changes that have taken place in production methods, the

---

† "Demand for Engineering Graduates", **Electrical Engineering**, 1956. Vol. 75, No. 10, October, pp. 886-889.

* Annual Survey of Technical Institutes for 1955-1956, **Technical Education News**, 1956, vol. XV, no. 4, September, pp. 16-17.

** The Technical Institute, L. F. Smith, L. Lipsett; McGraw-Hill Book Company, New York, 1956.

ratio is now 1 to 50. Here is a prime reason for the shortage of engineers and the requirements for engineering personnel at all levels is such that the ratio may go even higher.

Recent Recognition

Only during the past few years have the capabilities of the engineering technician or engineering assistant, as he is sometimes classified, become recognized. For the past fifty years, the engineering faculties attached to many of our universities have offered excellent courses on both the under-graduate and the graduate levels. We have also had various good schemes for the training of our skilled craftsmen but the education of the engineering technician has been neglected, probably because it was only recently that Canada evolved an industrial economy. Since its establishment in 1948, however, the Ryerson Institute of Technology with its impressive growth has helped to direct attention to the training of the engineering technician and his potential value to a company. Since that date, moreover, there has developed a great shortage of professional engineers, and employers generally have turned to this new source for assistance to fill their engineering needs.

In January 1956 at a meeting of the Engineers Joint Council General Assembly, held in New York City, the engineering technician received national recognition. One-quarter of the time of the meeting was devoted to a discussion of the topic "Extending engineering manpower by utilizing balanced teams of engineers and engineering technicians".

Dr. Eric A. Walker, now president of the Pennsylvania State University, who delivered the opening address, was not overly enthusiastic about proposals suggesting that the way to solve the engineering manpower problem was to build and staff more and larger engineering colleges. Only a comparatively small percentage of the secondary school population had the native ability to absorb an engineering education and there did not seem to be much hope of increasing that percentage.

The intelligence quotient is by no means the only yardstick for prognosticating a successful career. Such qualities as determination, integrity, personality, attitude, and motivation are all highly important, but the I.Q. does apparently give a good indication of the student's ability to do abstract reasoning, the type of thinking required in an engineering course, as well as in many other courses.

Surveys have indicated that candidates with an I.Q. of less than 120 should not under-estimate the possibility of failure if they decide to embark on a full engineering course. It is estimated that only 10 per cent of the male secondary school graduates in the United States (figures are not available for Canada) have an I.Q. rating of 120 or more. About one-third of this group do not wish to proceed to college as they plan to enter industry or business directly from high school. Others cannot finance a university course, leaving only about one-half of the original 10 per cent ready and willing to go on to a degree in one of the recognized professions. If standards are to be maintained, therefore, there is a limit to the expansion of engineering colleges.

The Technical Institute

The technical institute, on the other hand, offers different types of curricula designed to produce persons who will make good engineering assistants or who will occupy other positions on the same level in the production, installation, or maintenance fields. Candidates for admission should be practical-minded individuals, but since they will not be called upon to produce the intricate designs or to make decisions involving highly technical data, it is not necessary for them to take the advanced theoretical subjects, a knowledge of which is required of the engineer. The I.Q. entrance requirement, therefore, could be dropped to possibly 110. This figure is still well above the average. Indeed, it is often used as a guide by persons giving advice to prospective college students but it is necessarily high since a good engineering technician must possess a keen mind and the ability to perform competently the work required of him if he is to act successfully as an aide to a fully qualified engineer.

A second source of recruitment is from the pool of able students who for one reason or another do not wish to undertake a full engineering course. A third source is from industry itself. There are always a number of persons who are forced to leave school before graduating and seek employment. A few years later they may find themselves financially able to resume their education.

It would appear, therefore, that it should not present too much difficulty to recruit students for engineering technician curricula. Actually, there are a number of obstacles that only time and imaginative careful planning will remove. Over the years, the universities have, quite rightly, built up an enormous economic and social prestige. The average parents, if not the average student, are determined in their efforts to send their sons or daughters to the university with its beautiful campus and buildings and offering all that is usually associated with college life. They feel that such an experience is worth almost any sacrifice and they hesitate to encourage their children so to plan their lives that they will complete their formal education in a non-degree-granting institution lacking the prestige and amenities of a college.

If technical institutes are to develop and take their rightful place on the educational ladder, they must be given at least the same status as would be accorded a junior college. The salaries paid to the instructional staff must be sufficient to attract highly qualified teachers. The buildings must be attractive and commodious enough, for instruction cannot thrive in inadequate quarters. From the point of view of the taxpayer, the cost per student at an institute is a great deal less than that at a university, but it costs the student's parents just as much, aside from fees, to send a son or daughter to an institute as it does to a university. Hence the educational environment must be acceptable.

Proportion of Technicans

It must not be assumed that engineering technicians should be graduated by the tens of thousands. A reasonable ratio in the United States is estimated to be 1½ technicians for each engineer. In Canada, many of our factories are branches of industries whose home plants are across the border. Consequently, a good deal of engineering work which ordinarily would be done here is performed at the head office. There is a possibility, therefore, that the ratio in Canada could be increased to 2 to 1.

The Canadian universities graduated in 1956 about 1,800 engineers, which means that between 2,700 and 3,600 additional engineering technicians should have been prepared this year to take their places in Canadian industry. Actually, the number was less than 300, which surely emphasizes that in this country we have a very unbalanced ratio of engineers and engineering technicians.

Ryerson Institute

The Ryerson Institute of Technology is one of the few institutions in Canada that is staffed and equipped to provide suitable training for the prospective engineering technician. It is a provincially owned and operated institution and, while the instruction is on the junior college level, the courses are terminal in character. This means that they are not specificially designed to provide the necessary requirements for entrance to a university course, although each year a number of our graduates do seek admission to engineering colleges. On the other hand, very few students who do not make their year at the university enrol at Ryerson. This is unfortunate and it would appear to be a wastage of manpower.

The Ryerson engineering technician courses — electronic, electrical, chemical, mechanical, metallurgical, instrument, architectural, and aeronautical technology — are of three years' duration, and the minimum entrance requirement is the Ontario secondary school graduation diploma obtained at the end of Grade XII. The first six of these courses have been accredited for technical institute purposes by The Engineering Institute of Canada.

Our failure rate is high; 35 per cent of our first year either drop out or fail in their final examinations. In the second year, this figure is 15 per cent, and in the third year 5 per cent. We have endeavoured to establish and maintain good educational standards. That these standards are acceptable to industry may be judged from the fact that this year there were almost four job opportunities for each graduate.

We have tried to keep our courses as broad as possible in order to ensure that our students will have some concept and understanding of the world around them, and of the opinions and thoughts of the great men of the world, both past and present. Our students, therefore, receive instruction in English for three hours a week during the three years of their course. They also take such subjects as economics, related science and mathematics, industrial organization and management. We insist on neatness and tidiness in dress and manner, for we believe such things are important.

Although almost two-thirds of the total enrolment is in the engineering technician curricula, Ryerson offers courses on the same level in such non-engineering fields as the graphic arts, business, hotel administration, and the furniture industry. The number of courses listed in the day school calendar is 22 and the 1956-57 registration is 1,982 students. The evening school consists largely of upgrading courses for employed persons, and last year's enrolment was 4,200.

Advisory Committees

Ryerson maintains a close contact with the industrial and business world by means of advisory committees. These committees are composed of prominent individuals in various firms connected with the industries we serve. The members favour us with a constant examination of our technological curricula. They assist us in securing scholarships and equipment, in establishing standards of attainment, and in organizing new courses to meet the needs of the industry concerned. Acting as liaison officers between the Ryerson Institute and the business and industrial world, they endeavour to interpret the work of the Institute to industry and obtain support for it in a variety of ways. The number of scholarships and bursaries provided our students by various firms is a source of pride and satisfaction to us.

Ryerson is serving a wide field: 50 per cent of the total enrolment comes from Metropolitan Toronto, 45 per cent from centres in the province outside the boundaries of Metro, and 5 per cent from other provinces. Thus, in its own way, the Institute is endeavouring to meet the need for trained personnel on both a provincial and national basis.

The professional engineering organizations in England, such as the Institution of Mechanical Engineers, and the Institution of Electrical Engineers, in co-operation with the Ministry of Education, have developed a system whereby the bright ambitious student who could not afford a college education can progress by various means from the Ordinary National Certificate to the Higher National Certificate, and then on to professional status. The Association of Professional Engineers in the Province of Ontario has done an outstanding job of encouraging qualified individuals to write their professional engineer's examinations, but there is not a clear-cut road as is the case in England. It is sincerely hoped that in time such a system will develop here, perhaps in a modified form. Without such a system, the technical institute is handicapped, for there are always a number of bright, young graduates who would make good engineers if they were given an opportunity, and it would make a difference in the mental outlook of the engineering technician if he knew he could advance himself to the top of the ladder, provided he had the determination and ability.

Automation and increased industrialization will need more and more technical institute graduates whose thoroughly practical and theoretical training enables them to step into responsible positions in factories and laboratories. Proposals have frequently been made for the establishment of more such institutions in other sections of the country, for the health of our economy demands it. Perhaps the time has come, however, when alternative methods of financing technical institutes should be investigated. Industry, commerce, and all levels of government benefit from the product of these courses. It seems hardly just that the duty of financing both the capital and operating costs should be the sole responsibility of the provincial government.

Present Predicament

There are few people who do not recognize the problems for our country created by the shortage of engineering personnel. Satisfactory solutions will require careful planning and it is encouraging to note the steps that are being taken to rectify the situation. The present predicament was ably summarized by Dr. James R. Killian, president of the Massachusetts Institute of Technology, in a recent article:

"The nation's technological work requires a broad spectrum of abilities and skills ranging from the technician, who does not need a degree, to the creative scientist or engineer whose education has carried him through the Ph.D. or even post-doctoral study. Men are in short supply throughout the entire spectrum but our greatest current shortages are at the extremes. We need more technicians to back up the professional scientist and more technical institutes to train them. At the other end of the spectrum, we need more graduate education and more graduate study opportunities to make this possible."

Most people will agree that this statement of Dr. Killian's mirrors the situation in Canada.

Karl O. Werwath
President, Milwaukee School of Engineering, Milwaukee, Wis.

A. What educational and personal qualifications do we look for in an entrant to a course in engineering technology?

Referring to the scientific and engineering technician, a statement incorporating these qualifications was developed for use by the working group for technical supporting personnel for scientists and engineers of the National Committee for the Development of Scientists and Engineers, as follows:

"The scientific technician and the engineering technician, although not new to the American industrial scene, are currently being employed in increasing numbers and are being given increasing responsibility to help alleviate the growing demand for engineering and scientific products and services. When utilized by industry or government, the scientific or engineering technician is usually employed in (1) research, design or development; (2) production, operation, or control; (3) installation, maintenance or sales. When serving in the first of these functional categories (research, design or development), he usually acts as direct supporting personnel to an engineer or scientist. When employed in the second categories (production, operation or control) he usually follows a course prescribed by a scientist or engineer but may not work closely under his direction. When active in the third categories (installation, maintenance or sales) he is frequently performing a task that would otherwise have to be done by an engineer.

"In executing his function the scientific or engineering technician is required to use a high degree of rational thinking and employ post-secondary school mathematics and the principles of physical and natural science. He thereby assumes the more routine engineering functions necessary in the growing technologically-based economy. He must effectively communicate scientific or engineering ideas mathematically, graphically and linguistically."

Specifically, the 1953 report of the recognition committee of the Engineers' Council for Professional Development defines the engineering technician as follows:

"An engineering technician is one who can carry out in a responsible manner either proven techniques which are common knowledge among those who are technically expert in his branch of engineering, or those specially prescribed by professional engineers. Under general professional engineering direction, or following established engineering techniques, he shall be capable of carrying out duties which may comprise: working on design and development of engineering plant; draughtsmanship; the erecting and commissioning of engineering equipment or structures; estimating, inspecting and testing engineering equipment; use of surveying instruments; maintaining engineering machinery or engineering services and locating faults; operating, maintaining and repairing engineering plant; or activities connected with research and development, sales engineering and representation, servicing, and testing of materials and components, advising consumers; training and education.

In carrying out many of these duties, the competent supervision of the work of skilled craftsmen will be necessary. The techniques employed demand acquired experience and knowledge of a particular branch of engineering, combined with the ability to work out the details of a job in the light of well-established practice.

"An engineering technician, therefore, requires a background sufficient to enable him to understand the reasons and purposes of the operations for which he is responsible."

While the engineer plans, the technician makes and does: while the engineer creates, the technician applies. This engineering technician is often the liaison between the professional man and the craftsman. He has the same basic characteristics and fundamental educational requirements as the engineer, except that his interest and education are more in the direction of application, with less mathematical and theoretical depth, combined with the ability to understand the instructions of the professional engineer and translate these to action either by applying his own abilities or in the direction of other supporting technicians and craftsmen.

B. What are the specialized fields of technology in which courses are offered?

There are some 100 courses accredited by the Engineers' Council for Professional Development or approved by the National Council of Technical Schools in ten fields in which engineering technicians have become prominent and in which technician employment opportunities have demanded course development. These fields include aeronautical design, maintenance and production; air conditioning, heating and refrigeration; architecture and building construction, civil technology; electronics and radio-television; electrical power and control; instrumentation and watchmaking; metal fabrication and tool design; photographic; and steam, diesel and automotive technology. In addition, there are some seven other miscellaneous highly specialized fields listed in the 1956 College Blue Book, such as gas fuel technology, fire protection, industrial technology, stationary engineering, surveying technology, chemical technology, and welding technology.

C. What is the nature of the content and presentation of those courses?

This type of instruction is in the broad area of technical education and lies between professional engineering on one side and vocational education on the other and is conducted by several types of institutions. Curricula are offered by one or more schools in the following categories:

Technical institutes, endowed or publicly supported.

Junior colleges offering terminal programs.

Evening sessions and extension divisions of colleges and universities.

Proprietary schools, operated by individuals or corporations.

Schools or training divisions associated with industries.

Specialized schools operated by divisions of government.

Correspondence schools.

Courses are from one to three years in length but generally require two academic years of full-time study. High school graduation or equivalent is required for admission and most courses have specific additional academic matriculation stipulations. These programs are briefer and more technical in content than are professional engineering curricula. They include a heavy schedule of specialized technical subjects which make up approximately one-half of the curriculum in class time and total company effort. These are integrated with and balanced by related studies in mathematics, physical sciences, graphics, English, economics, industrial commerce and general studies. Such courses now generally lead to an associate degree in engineering or applied science.

This is a specific type of higher education leading to specific occupations. Transfers from technical institute to other curricula or from one technical institute curriculum to another are relatively few. Credits are generally transferable for comparable subject matter.

D. In what ways does the school gain the co-operation of industry?

Relations with industry vary with each individual school, but in general there are some ten areas of co-operation which exist to a greater or lesser degree depending upon the individual organization.

(1) Where such schools are privately endowed, there is industrial leadership represented in the corporation membership and on the boards of control. Proprietary schools are generally owned by technical specialists who are consulting professional people and who have a close relationship with the industry which they serve. Thus, basic policy is conceived and controlled in an influence conducive to good relations with industry.

(2) Courses and subjects in publicly supported, privately endowed, or proprietary schools, are generally reviewed by industrial advisory committees. In some instances this takes the form of a formal board of visitors; in others, informal committees of laymen from industry, and professional and technical societies who are invited to review particular programs.

(3) Most schools have some form of applied industrial research conducted in conjunction with industry, especially in applied technical phases of research.

(4) Instructors, particularly those engaged in presenting the technical specialty subjects, are selected with consideration for practical industrial experience as well as academic training and teaching experience. In some instances, industry supplies teachers either for regular classes or for evening and extension classes, on a volunteer or a payroll basis.

(5) Industry supplies instruction aids, particularly laboratory equipment and apparatus for specialized laboratory experience. These are either donated outright or made available on a loan or grant basis, with opportunities for replacement for obsolescence or depletion. Visual instruction aids which implement classroom presentations, particularly films and equipment models, are also supplied by industry.

(6) Programs of part-time employment, either on a formal or informal basis, are quite general. Such programs often provide the additional revenue which makes it possible for students to complete day school courses. Late afternoon and evening courses lead to the same certificates or degrees in most metropolitan areas and fit into the plans of those who are employed full-time.

(7) Full-time placement service is maintained by the staffs of most technical institutes to aid graduates in finding appropriate first jobs in the field of their specialized training.

(8) Guest lecturers from industry augment the regular faculty, generally in highly specialized technical courses, and particularly for presentation of new developments.

(9) Field trips become an important part of a technical institute curriculum to convey specific information on scientific and industrial operations; they are preceded by pre-visit orientation and followed by formal or informal students' reports on such visits.

(10) Aid of members of professional societies and trade organizations, particularly through student branches of technical societies, alumni relations and participation in trade show and similar events, flow back into the school as a continuous source of ideas for integration into the program.

E. To what extent do your graduates meet the present demand for technicians?

There are various estimates as to the needs of engineering technicians in proportion to engineers; these range from 1 to 1 and 5 to 1, depending upon the industry and the area encompassed in the analysis. On the strong side, our best analysis shows the need for 35,000 four-year engineering graduates per year. This is about 200 per million population and parallels closely the existing ratios of other modern industrial nations of the world today.

If the ratio of technicians to engineers is 5 to 1, this would call for an annual production of some 160,000 technicians per year. In contrast, we graduated last year some 11,350 from courses in 66 schools. To meet the need, technicians have been developed through other sources, including evening programs and on-the-job training.

That there is a shortage in the nation's requirements is emphasized by the following report of the National Committee for the Development of Scientists and Engineers.

"A. The fact that there is a shortage of scientists and engineers, and that the ratio of technical to the whole labor force is rising, indicates a continuing and probably a growing demand for the skills of scientific and engineering technicians.

"B. The Department of Labor currently lists a number of these technical skills on the "critical occupations list".

"C. The experience of the working group indicates that competent graduates of engineering technician schools receive many offers of jobs and that salary levels are rising.

"D. Fragmentary local data indicate that there are more jobs than applicants in most instances checked. One large firm reports successful hiring of only 1/3 of its expressed needs for 1956.

"E. Many technical schools are now supported in part by industry and public agencies to assure a flow of trained technicians. Demand has forced the development of technical institute type curricula in the major fields.

"F. Industrial advertising in newspapers, technical publications, school newspapers, and handbills and other media is evident in almost all major industrial centers.

"G. Despite extensive training programs and various improvements in career incentives, the military services are faced with persistent shortages of technicians who are urgently needed to man and maintain our complex new weapons systems. The military services are constantly losing such people to industry, which also needs them. The problem is national in scope. Increased training to improve our supply and quality of technicians is, therefore, necessary to meet national defense needs as well as of a healthy civilian economy."

DISCUSSION

of Technical Papers and Other Articles

LATERAL RIGIDITY OF STEEL BUILDING FRAMES

J. L. de Stein, M.E.I.C., and J. O. McCutcheon, M.E.I.C.

The Engineering Journal, 1956, October, 1943

T. R. Higgins[1]

Quite apart from what lateral deflection limitation ought to be placed on rigid frames having frangible cladding, the extensive data contained in the article "Lateral Rigidity of Steel Building Frames" serves a very useful purpose in evaluating the stiffening effect of semi-rigid connections used in lieu of full continuity. It will come as no surprise to most engineers that web connections alone are seriously deficient where frame action is required to resist horizontal forces. The much more favourable behaviour of the flange type semi-rigid connectons, in the case of buildings of usual span-to-column height ratio, may not have been as well understood.

The authors' designs call for columns having flanges approximately equal to their depth, i.e., "column" shapes, together with girders of greater depth. This may have been dictated by the details of the semi-rigid connections. It should be noted, however, that in present-day practice in rigid frame design, the girders and exterior columns are generally proportioned to have approximately the same depth and moment of inertia. This practice tends to reduce the lateral deflection resulting from horizontal loading, without increasing the weight of the frame. Hence, the deflections given in Table I are somewhat in excess of those we might expect using typical rigid frame designs.

For example, Frame S 20-1-15 might have employed a 10WF 25 for the rafter instead of a 12WF 27, and a 10WF 29 for the columns instead of an 8WF 28. In fact, a 10WF 25 would be "overstressed" less than 7 per cent, if used for the columns. The total weight, even using the heavier 29 lb. shape for the columns, would be 0.7 per cent less than the authors' frame S 20-1-15. The lateral deflection would be 18 per cent less.

The authors' conclusion (4) should be re-examined on the basis of the more general practice of employing the same rolled shape for the exterior columns and girders. Using a load factor of 1.88 for vertical loading only, and 1.41 for combined wind and gravity loading, plastic design would give a 10WF 25 for the entire frame. At working loads the lateral deflection of such a plastically designed frame would be slightly less than for the authors' design.

The Engineering Journal, 1956, June, 769

G. G. Fintak‡

The author's interesting presentation of the advantage of the Kaplan turbine should greatly encourage and increase the application of the Kaplan type adjustable-blade turbine in the future development of Canada's hydro - electric potential. However, there are a few items in connection with this paper that might be brought out or further stressed.

The author calls attention to the development of the fixed-blade propeller turbine in 1913 and the Kaplan type adjustable-blade turbine in 1919 with the first fully automatic Kaplan type adjustable-blade turbine installed in this hemisphere in 1929 at the Lake Walk plant of the Central Power and Light Company, of San Antonio, Texas.

It should be added that as early as 1923 an adjustable blade propeller turbine was built by Allis-Chalmers Mfg. Co. for the Inca Mining Copany, Peru. The blades were seasonaly adjusted at the hub by means of bolts and dowels after the casing was unwatered.

In 1925, the first manually adjustable blade propeller turbine, where the blades were mechanically adjusted at the turbine-generator coupling without unwatering the casing but with the turbine at rest, was installed.

In 1926, the first manually adjustable blade propeller turbine in Canada was built by Canadian Allis-Chalmers, Ltd. and installed at the Canada Cement Co., Lakefield, Ontario. This turbine was a 138-inch four bladed runner rated to develop 3,100 h.p., 16 ft. net head, 112.5 r.p.m. In 1927, the 192 in. four-bladed, manually adjustable propeller turbine, installed at the Montreal Island Power and Light Co., Back River plant, set the world's record for physical size for adjustable blade propeller turbines.

In 1930, the Allis-Chalmers Mfg. Co. introduced the "Motormatic" adjustable blade propeller turbine which incorporated an electric motor inside the shaft for adjusting the blade tilt while at rest or in motion.

During the years 1925 to 1932, the writer's company built 40 adjustable blade propeller turbines of the manual or electrically operated type.

The largest physical Kaplan type adjustable blade propeller turbine in this hemisphere today are the six Allis-Chalmers units installed at the Pickwick Landing plant of the Ten-

‡ Application engineer, Hydraulic Department, Allis-Chalmers Manufacturing Company, Milwaukee, Wisconsin.

nesee Valley Authority, each having a 292-inch runner rated 55,000 h.p., 818 r.p.m., 43 ft. net head.

Several high head Kaplan type adjustable blade turbines are in operation in the United States today. The Shepaug Plant of the Connecticut Light and Power Co., built by the writer's company, operates under a maximum head of 99 feet. The Cabinet Gorge plant of the Washington Power Co. operates under a maximum head of 100 feet. It should be noted that the Kaplan turbine at the Shepaug plant has a rivetted plate steel full spiral casing.

Unlike the case in Europe, the Kaplan type turbine for high heads (over 100 feet) has not gained favour over the Francis turbine due to the low settings required and the correspondingly high excavating costs.

The author mentions that considerable leakage of water into the runner hub has been experienced. The double seal arrangement at the blade trunnion of the Allis-Chalmers design has reduced leakage to a minimum requiring little maintenance and negligible seal and oil replacement. The minimum leakage also eliminates the necessity for automatically recharged air pressure tanks to maintain definite pressure inside the hub.

Recent index tests of the Kaplan type adjustable blade propeller turbine at the Rock Island plant of the Washington Power Co., Box Canyon plant, PUD No. 1, Pend Oreille County, Washington and Shepaug plant, Connecticut Light and Power Company, give further emphasis to the author's illustration of the flat efficiency horsepower curves for wide head ranges obtainable by modern Kaplan turbines.

The importance of the hydraulic laboratory investigations cannot be stressed enough, not only model testing for new plants under construction, but equally important for plants being modernized.

Usually, the physical dimensions of the plant considered for modernization restricts the draft tube and casing proportions which are important factors affecting the performance of the turbine. Therefore, it is essential that the complete turbine, inlet and discharge water passages, draft tube and setting of the plant be model tested in the laboratory and contract performance based on these tests.

We agree with the author's statement that it is practically impossible to conduct a reasonably accurate field acceptance test in accordance with any approved test code on units having a concrete semi-spiral casing. Recent field tests made on concrete semi-spiral casings with properly installed Gibson piezometers have decidedly shown unequal velocities in the inlet channels to the turbine which indicates unequal flows, tending to make a Gibson test inaccurate on this type of casing.

Research and experience with the Gibson method has also shown that turbulence near the Gibson piezometers can have a large effect on the accuracy of the discharge measurements. Since the upstream piezometers on concrete semi-spiral casings by necessity usually have to be located near the intake where considerable entrance and rack turbulence is present, the accuracy of Gibson tests on this type of casing seems to be in question.

J. G. Warnock **

Mr. Johnson's paper, "The Kaplan Turbine in Canada", gives a very useful survey of the present status and future possibilities of the application of this type of design to Canadian installations. I find that the paper corroborates many of my own sympathies in this direction, and I certainly hope it will stimulate further thought by those responsible for selecting type of plant, particularly for marginal applications.

Mr. Johnson mentions the advantage of Kaplan type units in maintaining automatically maximum station efficiency, even with slight variation in demand, head or flow, and it is agreed that this is an advantage to be considered when contemplating the use of Kaplans for a large multi-unit installation. Even where head, total output, and flow variations are not great, the inherent overload of the unit at "full tilt" capacity may conveniently be called on to provide extra plant capacity for use on occasions when one of the units may be out of service for maintenance. For example, application of 28 Kaplan machines to a development similar to the St. Lawrence power project would perform a similar function to say 32 fixed blade propellers without change in physical size of unit, and ensure maximum efficiency operation for by far the major proportion of the time. Resistance to cavitation pitting would also be greater due to the use of the precisely correct blade angle for each output condition. Admittedly, even with the reduction in the number of Kaplan units, generators and associated equipment, the total plant cost would be higher, but instances will certainly arise where the additional capital cost can be fully justified by additional revenue from higher average operating efficiency.

In the future application of Kaplan units in Canada, heads of up to 200 feet may certainly be considered with conventional axial flow units and considerably higher heads with the more recent diagonal flow variable pitch propeller unit.

A 28,000 h.p. Kaplan unit, under 188 foot head, is among the highest head applications in operation in Europe. A particularly large hub to tip ratio, eight blades, and full spherical skirt over the running clearance with the blade tips are all special features associated with the high head Kaplan unit.

The blade control mechanism of all Kaplans manufactured by the firm with which I am associated, is located within the hub itself, and no special servomotor in the main shaft or heavy linkage is required.

Turning now to even higher head applications, Mr. Johnson has developed his excellent description of the hydraulic aspects of the Kaplan from consideration first of the fixed blade propeller associated, until a few years ago, with heads of under 60 feet. In the alternative approach, the principles of the mixed flow Francis type wheel commonly applied to heads of from 50 to 1500 feet have been applied to the standard Kaplan axial flow, which is quite at home, as we have seen, between 20 and 200 feet, to produce the mixed flow variable pitch design, or Deriaz runner, after its inventor, our chief hydraulic designer. This design is applicable to heads of 300 to 350 feet and even higher.

The first application of this form of design following generally Kaplan principles will be for reversible pump - turbine duty as listed and mentioned by Mr. Johnson in his paper. Six of these units developing 45,500 b.h.p. at 92.3 r.p.m. under 83 feet will be installed by the Hydro-Electric Power Commission of Ontario at their Sir Adam Beck - Niagara development. In this case the diagonal flow principles have been necessary to develop the 90 foot pumping head in a single stage from a runner following Kaplan principles.

With both these high head Kaplan applications, steel plate scroll cases are, of course, used. From hydraulic

** Head of Hydraulic Department, English Electric Company of Canada Limited.

design considerations the complete and circular spiral form presents no additional problems than arise with the concrete semi scroll case which has been commonly associated with Kaplan applications.

We are fully in agreement with Mr. Johnson's emphasis on the importance and value of hydraulic laboratory tests in the design and development of Kaplan type turbines. The design of high head and Deriaz runners for the Niagara units have been possible only after the most exhaustive testing of various forms of turbine and blade shapes in our extensive laboratories in Rugby, which are largely engaged on development work for the Canadian market.

It has been found from both aerodynamic and hydraulic model testing at these laboratories that the semi scroll case as well as the draft tube design may have appreciable bearing on ultimate efficiency, and may show substantial deviations from open flume tests. We would, in fact, recommend that development programs, too, include tests with completely homologous water passages from inlet to discharge. We would agree that the draft tube form is also particularly important as it is on the efficiency of this vital part of the Kaplan turbine that recovery of the shock losses in the kinetic energy at discharge depends.

I am particularly interested in the references to means of restricting runaway speeds as it is the firm with whom I am associated that has applied the use of a hydro brake for this purpose. As mentioned by Mr. Johnson, present practice in generator design appears to have largely overcome the problem by a careful distinction between "theoretical" or off-cam and "practical" or on-cam runaway speeds. There will, however, be cases in the future where very wide head variations on low head developments will cause runaway speeds of perhaps 4 to 5 times normal, resulting in excessively high runaway stresses. We have in mind particularly tidal projects where the full tidal ranges must be utilized. When the time comes to develop these tidal projects with their enormous potential there may arise a very definite need for some reliable means of restricting runaway speeds.

I would like to congratulate Mr. Johnson on an excellent presentation of this most interesting paper. The occasion of its presentation is timely in that the plentiful resources of water power, particularly in Ontario, are diminishing, and more attention will have to be applied to sites with less attractive hydraulic considerations, where the Kaplan turbine may well give the optimum selection of plant.

R. S. Sproule †

The author should be congratulated on this paper, which should achieve its object: "To encourage increased use of the Kaplan adjustable blade propeller turbine in the continuing development of Canada's hydro-electric potential." The writer is also enthusiastic about the future of the Kaplan turbine but not quite to the same extent as the author. Exception must be taken to the statement that "because of the resulting high average operating efficiencies the use of the Kaplan runner instead of Francis or propeller wheels permits a considerable reduction in the number of units in any particular power house without any reduction in the total annual power output from the available supply of water." Where flow conditions are steady, the fixed blade propeller is superior to the Kaplan because of its lower cost and higher peak efficiency. The cost is lower because of greater simplicity. The peak efficiency is higher because with a fixed blade propeller turbine more favourable shapes of hub and throat ring are possible, the hub can be smaller, and the running clearances can be smaller. For a turbine designed for peak efficiency at a given power and a given head the Kaplan turbine has to be fully as large as the fixed blade propeller, and even somewhat larger because of the relatively larger hub required for the Kaplan. If some sacrifice in efficiency at rated power is permissible then the Kaplan turbine can be made smaller.

Reference to the author's Figure 3 will demonstrate that at any given power and head the Kaplan turbine operates as a fixed blade propeller turbine and the high unit powers, or high powers for a given turbine size, obtained with Kaplan turbines are accompanied by some loss in efficiency compared to the point of peak efficiency. For example, a fixed blade propeller turbine of the design on which Figure 3 is based with the runner blade set at 28 degrees, would give 129,000 h.p. at 89 feet head with an efficiency of 93 per cent. Somewhat better could be expected from a fixed blade turbine designed to operate at this point only. Figure 3 also demonstrates graphically how much superior the Kaplan turbine is to the fixed blade propeller when operation is desired over a range in power or when high power is wanted at reduced head and the accompanying loss of efficiency is acceptable.

†Manager, Hydraulic Division, Dominion Engineering Works.

The Editor invites written discussion of articles that appear in *The Engineering Journal* or other subjects.

S. Logan Kerr*

The only question that I would raise is the one discussed by the author under the heading "Contract Model Tests and Field Tests" (on pages 775 and 776) which is somewhat broader than the actual conditions that exist and is not accepted as standard practice to eliminate field tests and use the laboratory model tests exclusively for establishing guarantees.

The ASME Code, paragraph 4, (reference 8 in the paper), is very specific about this and does not specify the Moody formula for stepping up the results, but only mentions that "the method of allowing for scale effect should be agreed upon by the representatives of both parties to the contract." In the supplement covering Index Tests, paragraph 4, it is very specific in stating "the Index method of testing should not be used as an acceptance test of a hydraulic turbine to determine whether it meets the contract guarantee."

I feel that this matter should be pointed out clearly and not indirectly infer that such procedure as outlined in the third paragraph under "Contract Model Tests and Field Tests" (page 776) is covered by the ASME Power Test Code. This, of course, is not the case and the words "actual prototype efficiency horsepower curves" are really the estimated prototype efficiency curves. There is a great difference between the actual and estimated curve, particularly since the so-called Moody formula or the Ackeret formula have not been confirmed by extensive comparisons on field tests and are empirical formulas only.

* International president, TC4/IEC—Hydraulic Turbines, Flourtown, Penna.

Further discussion of "The Kaplan Turbine in Canada" will appear in the March issue.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

PAPERS OF THE INSTITUTIONS OF CIVIL, ELECTRICAL, AND MECHANICAL ENGINEERS

Copies of many of the papers of the respective Institutions of Civil, Electrical, and Mechanical Engineers, in Britain, are made available to the Engineering Institute of Canada and form a valuable addition to the Institute library. It is proposed to publish abstracts of those papers which appear to have particular interest for the professional engineer in Canada.

In the meantime, there appears below a list of the papers received recently of which a copy is held in the Institute library.

The Institution of Civil Engineers
The Institution of Mechanical Engineers
The Institution of Electrical Engineers

The second Graham Clark Lecture: The impact of engineering on society; Sir Maurice Bowra, warden of Wadham College, Oxford.

The Institution of Electrical Engineers

The dual-input describing function and its use in the analysis of non-linear feedback systems; J. C. West, J. L. Douce and R. K. Livesley.

A bridge for the measurement of permittivity; A. M. Thompson.

The indirectly heated thermistor as a precise a.c.-d.c. transfer device; F. C. Widdis.

Time sharing as a basis for electronic telephone switching (A switched-highways system); L. R. F. Harris.

Temperature rises in electrical machines as related to the properties of thermal networks; J. J. Bates and Prof. A. Tustin.

Nuclear - reactor - control ionization chambers; W. Abson and F. Wade.

Temperature rises in electrical machines on variable load and with variable speed; Prof. A. Tustin and J. J. Bates.

Underground lighting in coal mines; C. D. J. Statham.

Performance and heating curves for motors on short-run duties; Prof A. Tustin, D. F. Nettell, and R. Solt.

Some design aspects of nuclear-reactor control mechanisms; G. E. Lockett.

The application of transistors to the trigger, ratemeter and power-supply circuits of radiation monitors; E. Franklin and J. B. James.

The control and instrumentation of a nuclear reactor; A. B. Gillespie.

A point-contact transistor scaling circuit with 0-4 microsec. resolution; G. B. B. Chaplin.

The control of nuclear reactors; R. J. Cox and J. Walker.

The Crystal Palace television transmitting station; F. C. McLean, A. N. Thomas, and R. A. Rowden.

The Broadcasting House-Crystal Palace television link; A. R. A. Rendall and S. H. Padel.

Band I television-transmitter design, with particular reference to the transmitters at Crystal Palace; V. J. Cooper and W. J. Morcom.

A junction - transistor scaling circuit with 2 microsec. resolution; G. B. B. Chaplin and A. R. Owens.

Mine locomotives; T. E. Green.

The Institution of Mechanical Engineers

Behaviour of rubber in compression under dynamic conditions; H. McCallion and D. M. Davies.

Heat transfer in pipe flow at high speeds; J. E. Bialokoz and Prof. O. A. Saunders.

Symposium on nuclear energy: (1) Nuclear reactors for power generation; B. L. Goodlet. (2) Steam cycles and nuclear power plant; R. E. Zoller. (3) Heat removal from nuclear power reactors; Prof. J. Diamond and W. B. Hall. (4) Shielding against nuclear radiation; C. E. Iliffe

A standard gas turbine to burn a variety of fuels; G B. R. Feilden, J. D. Thorn, and M. J. Kemper.

Fatigue under triaxial stress: development of a testing machine and preliminary results; Prof J. L. M. Morrison, B. Crossland, and J. S. C. Parry.

The fatigue strength of specimens containing cracks; N. E. Frost and C. E. Phillips

Front suspension and tyre wear (Automobile Division); V. E. Gough and G. R. Shearer.

Forces on a brake block and brake chatter; H. R. Broadbent.

An approach to the techniques of graduate training; D. L. Marples, J. F. A. Radford, and J. L. Reddaway

Crankcase explosions: an investigation into some factors governing the selection of protective devices; H G. Freeston, J. D. Roberts, and A. Thomas.

Crankcase explosions: development of new protective devices; W. P. Mansfield.

A servo-controlled continuous feeder; J. C. R. Heydenrych and U. A. Luoto.

Three-dimensional motion in axial-flow impellers; S. P. Hutton. The performance of an axial-flow pump; E. A. Spencer.

The influence of the gas-turbine axial-flow aero-engine on blade manufacturing methods; R. R. Whyte.

PRECAST BRIDGE UNITS SAVE TIME AND COST

E. F. Bespalow, vice-president and chief engineer, Choctaw, Inc.

Civil Engineering, 1956, November

One of the major road blocks in the highway department is the shortage of civil engineers experienced enough to design the many bridges and structures needed for high standard roads. Since 1936, when efforts were first being made to promote the use of precast units in the United States, it has taken 20 years to reach the stage of development we are in today, the beginning of the utilization of precast and prestressed concrete construction.

Precast concrete bridge units have proved a boon to maintenance engineers. On emergency work they could be delivered from stock and erected at once, thus saving the building and maintaining of detours and avoiding complaints. It is now possible to produce precast units of much better quality and to deliver them at less cost than that of conventional cast-in-place concrete.

They have almost complete salvage value. If the location is changed units can be unbolted and transferred to a new location without loss. For widening a bridge, additional units can be inserted as required. Precast units are ideal for use in detour bridges required during construction of new highways. Standardization in the various states would help reduce their costs. There is a serious need for a realistic specification covering the manufacture of precast units when made up in recognized manufacturing plants.

The economy of this type of construction is demonstrated by the fact that when alternate bids have been taken against other types of construction, in most cases the precast type has proved to be cheaper. Bridges built under contract with precast type units have shown a construction cost in place, completed, of $4 to $5 per square foot, depending on the type of construction used.

TRAINING FACTORY WORKERS

The Times Review of Industry, 1956, Aug.

The report summarized in this article recommends general principles of the utmost value for those training semi-skilled and unskilled workers. The survey was undertaken in the manufacturing industry of Britain as part of a larger investigation organized in seven western European countries by the European Productive Agency, which will issue a general report.

Factories visited include those manufacturing food, beverages, footwear, tobacco, textiles, clothing, footwear, furniture, paper, pottery. vehicles, machinery, steel, chemicals, and goods made of wood, leather, rubber, and petroleum products. Only in eleven of the schemes studied were both financial and non-financial incentives deliberately applied to trainees, while in 113 cases there were no such arrangements.

The general conclusion of the survey is that success depends on suiting the training scheme to the firm and, in particular, to the number of trainees and the nature of the work. A detailed appendix shows how schemes have been applied to a wide range of jobs. The survey, as was intended, must be only the beginning of a determined drive to improve the present haphazard, wasteful and scattered efforts at systematic training which it reveals.

GEODESIC STRUCTURES

R. Buckminster Fuller, well-known American architect, is a pioneer in the design and use of geodesic dome structures, which combine the properties of the tetrahedron and the sphere. Recently, Mr. Buckminster Fuller visited McGill University and supervised the erection of a geodesic dome structure by architectural students of the university. The frame members and panels were aluminum.

TECHNICAL PUBLICATIONS ON PETROLEUM

Many technical papers on petroleum subjects are written each year by the staffs of the companies within the Royal Dutch-Shell Group and form a valuable contribution to the literature. Many of the papers are based on research work done at the laboratories at Amsterdam and Delft, in Holland, and at Thornton, in the United Kingdom. These papers are listed in a catalogue "Technical Papers, 1955" under various sections from history of science and engineering, through various fields of physics and chemistry, to chemical engineering and production processes. There are also papers on industrial and agricultural applications of petroleum products. It is proposed to publish a similar catalogue in subsequent years. Information about the catalogue and papers may be had from the Shell Oil Company of Canada Limited, P.O. Box 400, Terminal A, Toronto 1, Ont.

PENSION WITHOUT TIES

Engineering, 1956, December 7

The Engineers' Guild (in Britain) have brought out a new form of group insurance. The scheme is designed to enable the professional engineer to make arrangements for death cover or pension which will be independent of the continuity of his employment in any one organization, or, if self-employed, which will benefit from the lower rates open to group schemes. No longer need pension considerations deter engineers from "striking out into new fields to widen their experience and to gain opportunities for using their abilities to the full." Conversely, companies will be freed from the difficulties of fitting older, experienced engineers into existing group pension schemes.

Various features of the scheme combine to make it attractive, especially to the young engineer who wishes to gain experience with several firms before settling down. The employer can pay all or part of the contributions as he wishes; all contributions qualify for income tax relief; individual evidence about health is not required for the first £2,000 insured; and the age at which a pension is payable can be selected (within certain limits). It would thus seem to offer all the advantages of company-run schemes without any of their disadvantages.

The scheme is open to members of the Guild, or to those eligible for membership: namely, members of the Institutions of Civil, of Mechanical, and of Electrical Engineers aged between 21 and 60. The details are set out in a booklet "Pensions for Professional Engineers", published by the Engineers' Guild Limited, 78 Buckingham-gate, London, S.W.1.

WORLD'S LARGEST DISCHARGE TUNNEL

A discharge tunnel two-and-a-half miles long with a section of 4200 square feet, said to be the largest in the world at present, is a feature of Sweden's biggest power station (390,000 kw, installed capacity) now under construction at Stornorrfors by the Swedish State Power Board. More than two million cubic yards of material will have to be excavated for the tunnel. The picture shows thirteen chain-fed drills carried on a rig on one of the two final stages of the benching operation in which crews were drilling 500 feet per man-shift. Lightweight rock drills mounted on pusher legs were used to drill the 1720 sq. ft. top heading. (Atlas Copco Canada Limited.)

ACCOUNTING RATIOS FOR INTERFIRM COMPARISONS

Times Review of Industry, 1956, November

There are a number of ways in which firms can make use of reasonable, simple ratios drawn from their accounts, but probably most businessmen look for a major indication of business success in their return on capital. A primary ratio is the return on capital employed. This should be represented in current money terms, which usually means adjusting the book values of fixed assets to bring them in line with current replacement costs. If the firm carries on more than one homogeneous business, separate statements of capital employed should be prepared for each.

Return on capital can be expressed in terms of net profit. If a firm finds its return on capital employed is lower than that of most other firms in its own industry then it should look for reasons by examining how it stands in relation to secondary ratio comparisons. This it will look to see whether other firms have achieved a faster turnover of capital by inspecting the rates of sales income to operating capital employed.

On another plane of reference, secondary ratios should be used to investigate whether other firms have obtained higher profits on sales because they operated on lower cost levels.

The primary purpose of interfirm comparisons of accounting ratios is to indicate to the management of firms in the same industry significant variations between the internal accounting ratios of the firm and similar ratios of other firms, to reveal any weaknesses in the financial structure or deficiencies in the profitability of the firm.

In examination of the principles and purposes of accounting ratios, it must be realized they will indicate no more than the direction in which improvements within a business must be sought, and a broad guide to the possible scaled improvement. No one ratio should be relied upon in isolation. It is desirable to keep to a few selected strategic ratios, and upon the interdependence of accounting aggregates by assuming that all other sub-relationships will more or less respond within the constraints of the accounting framework.

THE EXECUTIVE JOB AND THE ENGINEER

Dr. F. J. Gaudet, Stevens Institute of Technology

The American Engineer, 1956, Dec.

Fifty per cent of all major executives in American business are now at the age where they have to be replaced in the next few years. Who will replace these top executives? The group aged 35 to 45 is poorly represented. Ten or fifteen years from now there will be even a greater dearth of available top management.

In the last ten years, the greatest emphasis in recruiting for industry has been placed upon the engineering graduate. But some industries have found engineers are not solving all their management problems. Some top executives say: "Engineers are too specialized" . . . "They know too little about human relations," and so on.

The author, who has been consultant to many companies in evaluation development of management personnel, summarizes in this article his ideas about the training of the potential executive, what he should know and what background he should have. Whether it be engineering, law, business administration or the liberal arts, he points out, it is not the school which makes the man narrow or broad in his range of interest.

All schools have some students who are rigid personalities and some who are flexible. What industry or business will get from any of these schools will depend upon their method of selection and, having selected the right man, the opportunities for growth and development that are afforded him while he is in their employ.

doubling that quantity. Mechanical pulp will be manufactured first, and chemical pulp bought as semi-bleached kraft; eventually chemical or semi-chemical pulp will be made and bleached at Tuxtepec.

The paper machine will be a 181-in. fourdrinier with submerged screens, a pressure inlet, conventional open-transfer press section, enclosed dryers, calender, reel and winder, all driven by a line-drive shaft and variable speed steam turbine at a rated speed of 1150 feet per minute.

Process steam will be generated in two oil-fired low pressure boilers; electric power will be purchased. Process water will come from shallow wells in the gravel beds of the adjoining river, fed by gravity from a reservoir.

Main process equipment will be in a single two-storey reinforced concrete structure, serviced by travelling cranes from pulpwood grinding to paper finishing area. Storage areas, repair shops, laboratories, and mill offices will be in a parallel annex. The main structure will have a unique system of criss-crossed column and multiple-arch thin shell roofs, with suspended aluminum ceilings forming an integral part of the ventilating system. All walls will be lined inside and out with domestic tile.

Construction is scheduled for the mill to be ready for operation early in 1958. Building contractors are Ingenieros Civiles Asociados, of Mexico City.

INFLUENCE OF NAIL DESIGN ON JOINT STRENGTH

A. B. Dove, M.E.I.C., The Steel Company of Canada Limited

Wire and Wire Products, 1955, June

The full title of this paper, which won the 1955 award of The Wire Association as the most meritorious paper on wire manufacture or fabrication, is "The influence of nail design and manufacturing practices on joint strength".

Research conducted during the development of an improved common nail gave a close study of some of the factors that influence the strength of nailed timber joints. The paper deals with the investigations and the results obtained with various different types of nail, of which the characteristics are given. Some of the subjects considered are: wood structure and the effect of nail penetration; holding power of nails; the influence of extent and type of deformation; bending during driving; effect of heat treatment; flooring nails; splitting effect; and the lateral strength of nailed joints.

PASSENGER AIRLINE ECONOMICS

Lloyd B. Aschenback, Douglas Aircraft Co. Inc.

Aeronautical Engineering Review, 1956, December

In this article, market research techniques are used to study the factors affecting the air travel industry, with specific reference to the problem of traffic forecasting.

As an industry, the author finds, common carrier traffic is losing in the competitive race for a share of the consumer dollar. Air travel purchased per dollar of national income is increasing, but the amount of surface travel is decreasing. Present indications are that air will continue to increase its percentage of total common carrier travel. As this occurs it may be possible for common carrier travel to regain its competitive position for the consumer dollar.

Based on a national income forecast developed by the Joint Committee on Economic Report of the Congress, by the use of numerous graphs and charts, travel trends are forecast with the resulting relative values for each type of transportation.

The CAA has grouped all cities served by airlines into four classes: marketing, institutional, balanced, and industrial. By the use of several economic factors a symptomatic index of the buying potential of a city can be assigned. Elements of the index are population of the area, retail sales and disposable income.

For instance, a city classified as industrial will not, as a rule, generate as many passenger miles as a city classified as marketing or institutional. By relating the growth rate of a region to the economic and air-travel growth rates for the nation, an air passenger traffic forecast can be made for a specific region.

The article concludes with a discussion dealing with the equipment needs of the specific airline, both for short-to-medium range and long range flight segment lengths. Having the best equipment available to do the most economical job, the airline turns to the scheduling and type of service requirements in its region of operation, paying close attention to the desires of its customers. When all these elements are considered and properly weighted, the purchase of suitable airplanes may be made.

THE TUXTEPEC PULP AND PAPER PROJECT

J. S. Motherwell, Sandwell International Limited

Papermaking, in the European sense, has been carried on in Mexico since 1580, though paper had been made from the inner bark of trees in the Aztec empire — an art which still survives in places. Now, a modern newsprint paper mill is being constructed near the village of Tuxtepec, in the Papaloapan basin, an area of some 17,000 square miles north-east of the Isthmus of Tehuantepec.

The mill, of the Fabricas de Papel Tuxtepec, is the first major industry since the government-established Comision del Papaloapan introduced flood control and power production to the area. The project owes much to Canadian experience, the consultants being Sandwell International Limited and the equipment contractors Parsons and Whittemore Development Company, of St. John, N.B.

Initial rated annual capacity of the mill will be 30,000 metric tons of newsprint, with a provision for at least

ADVANCED STEAM CONDITIONS

The most advanced steam conditions ever commercially used in Britain will be in operation in a new extension to the B power station at the Margam steelworks in South Wales. The plant will generate 240,000 lb. steam per hour at 3300 p.s.i. and a temperature of 1060 deg. F. with reheat to 840 deg. F. using a Benson forced-circulation boiler. This is a joint project of the Steel Company of Wales and Simon-Carves Ltd.

FIRST SWEDISH NUCLEAR POWER PLANT

Bureau de Presse Suédo-Internationale, Stockholm, 1956, Dec. 12

The first nuclear plant in Sweden for the production of heat and power will be built to serve Farsta, a new autonomous suburb of Stockholm with a population of 50,000. The program is to be completed in 1960.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Ontario Hydro's new chairman, James S. Duncan, C.M.G., has made a first-hand inspection tour of the St. Lawrence development. In December, he visited the construction work on both sides of the International Rapids section. He also toured the new townsites on the north shore and saw the rehabilitation work in progress.

Mr. Duncan inspected the power-house site, the Long Sault and Iroquois dams, and channel improvement work. He also saw construction work at Eisenhower lock and Iroquois Point.

"I am sure from what I have seen in my inspection trip, that this power development will be constructed on schedule and meet the target date for first power in the summer of 1958", Mr. Duncan stated.

Progress by Ontario Hydro

Throughout December, variable weather conditions offered some difficulties for construction. The work force amounted to 3,900 persons. Excavation for all features exceeds 24 million cubic yards and concrete placement exceeds 575,000 cubic yards.

Placing of concrete on the Canadian half of the power-house site continued despite winter weather of varying degrees of severity. On the average, 10,000 cubic yards of concrete were placed each week throughout December and by month end a total of 405,000 cubic yards had been put into the power-house.

Installation was well under way at the end of December on the first and second turbine units. Erection of No. 6 draught tube form was completed early in the month and placing of concrete in that area was started.

Paving operations on new No. 2 highway had been commenced in the vicinity of Long Sault (town No. 2). The contractor had completed ten miles between Long Sault and the Aultsville road intersection.

At Galops Island, rock and earth excavation work had proceeded well despite the unfavourable weather conditions. The big 14-cubic-yard dragline "The Gentleman" had been added to the contractor's equipment and was ready for operation throughout the winter months. A total of 7,520,000 cubic yards of rock had been removed in this contract.

Splendid progress had been made in excavation work at Iroquois Point. The cofferdam there had been joined to the seaway canal cofferdam. Closure of the river was completed during the month.

In other areas of the project, good progress was made. The ballast laying had been fully completed for the Canadian National Railways double track section between Iroquois and Cornwall. On the diversion canal, the excavation both east and west of the closure structure was essentially completed.

Some 20 homes had been transported to Ingleside (town No. 1) by the end of December. Erection of the water tower was about 90 per cent completed and the sewage treatment plant was almost ready for operation. In Morrisburg area, five houses were moved to clear the access road. Work was continuing on water and sewage pumping stations and services. Foundations for the new shopping centre were completed.

At Iroquois, construction mainly was centred on the shopping centre. Some stores would be ready for occupancy early in the New Year. Work of building schools and churches in New Iroquois was progressing well. At Long Sault (new town No. 2), construction of the shopping centre footings was under way. Work in the new town site was being centred on completion of improvement work on new houses moved there, and on general clean-up. To date, 284 of the required 500 houses had been moved to the various town sites.

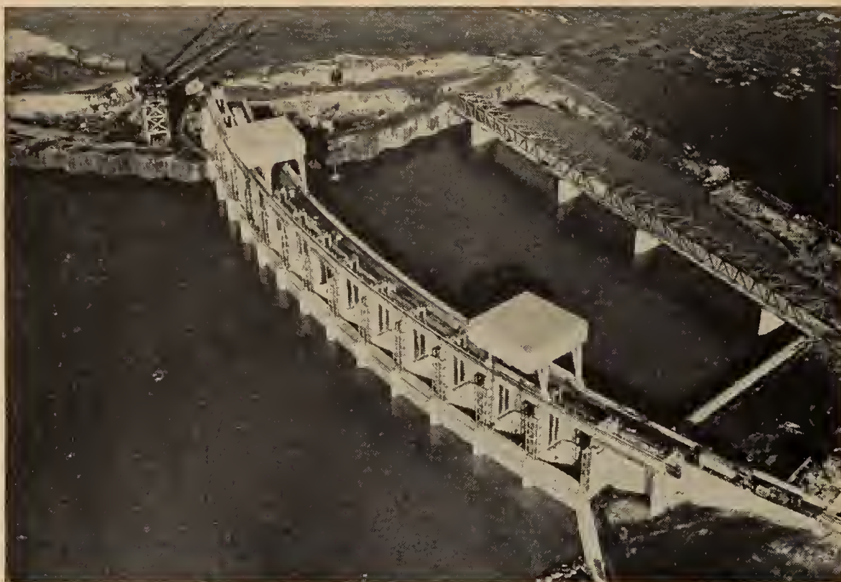
Hydro's Winter Concreting

Winter will not halt concrete placing operations on the power-house site in the Ontario Hydro section of the St. Lawrence development. This work will proceed around the clock all winter long with an average of some 10,000 cubic yards of concrete placed per week. Already, a total of some 400,000 cubic yards or about 40 per cent of the total for the Ontario Hydro half of the power-house, has been placed.

The greatest care and vigilance must be maintained at all times, day and night, to assure that there is no thermal shock which may damage the concrete. But, with experienced concrete control engineers and construction men on the job to check conditions, successful concrete placing operations can be carried out even in the severest winter weather.

Progress by NYSPA

December was marked by diversion of the entire flow of the river through the completed portion of Iroquois dam. Overall construction was on schedule as concrete placement to date exceeded 910,000 cubic yards and excavation for all features exceeded 33 million cubic yards. Employment averaged 3,100 for the month.



Long Sault dam. Stage I construction area had been flooded.

At Long Sault dam, removal of cofferdams A and B was completed, cut C was plugged, and the entire flow of the south channel was diverted through the completed portion of the dam on December 3, 1956. Balancing of the head on both sides of the upstream plug at cut F was completed and breaching of the plug was initiated on December 26, 1956, by blasting the first section of the plug.

Concrete placement in the American half of the Barnhart Island powerhouse increased the total placed to date to 438,000 cubic yards. Concrete was placed in the scroll case walls, stay ring erection piers, and in the ice sluices.

At Iroquois dam, thirty-five of the forty stage II cofferdam cells had been placed to the end of December. Removal of the downstream stage I cofferdam was completed. The rock groin dike was closed on the Canadian shore, diverting the main river flow through the completed portion of the dam.

At Massena intake, Stage II cofferdam cells were being placed. Structural items, piping, and mechanical and electrical equipment were being installed in the pump room, control room, and stairway.

Excavation under the five channel improvement contracts was approximately 56 per cent completed. The contractor for the Chimney Island area stopped dredging operations for the season on December 17, 1956. Channel improvement work at the other areas is continuing.

Construction work on the relocated highway routes 37 and 37B was progressing ahead of schedule. Concrete placement for the abutments of the Big Sucker Brook bridge and the piers of the Brandy Brook bridge is being continued.

Work continued on the rehabilitation of the Massena-Taylorville transmission line. Continued progress was being made by the four reservoir clearing contractors as well as the contractor clearing the Barnhart-Plattsburgh transmission line right-of-way.

As the design work moves into its final phase, there is much activity in the preparation of specifications for purchasing various pieces of auxiliary equipment.

Progress by SLSDC

At the end of the year, with 200,000 cubic yards of concrete placed in the Grasse River lock and 250,000 yards in the Eisenhower lock, and progress well up to schedule, excavation on the $6½ million Long Sault canal contract was the only portion of the work on which concern was felt for the rate of progress achieved. Here the contractors have put in a claim for an extra $5½ million, claiming that the glacial till was found to be "cemented".

Work on channels and locks on the American side was closed down for the holiday period. Work on clearing will continue throughout the winter however, as well as on certain portions of the channel excavation.

Progress By SLSA

SLSA President Lionel Chevrier, in a year-end announcement, stated: "At year's end we can say that nearly half the work on navigation channels, locks and bridges on the Canadian portion of the seaway has been completed". Contract awards at year end totalled $190 million out of an estimated total of some $205 million.

Of an estimated total of some 51 million cubic yards of excavation about 60 per cent had been moved. Of an estimated total of some 18 million cubic yards of dredging, 40 per cent had been dredged to date. Out of a total of two million yards of concrete in locks, bridge piers and abutments nearly 20 per cent had been placed.

Freeze-up had closed down dredging operations for the winter months, though some rock excavation was being continued. Placing of concrete for the Iroquois and St. Lambert locks will continue during the winter. Work will be continued on three contracts for excavating the Welland ship canal in the dry during the winter season while navigation is closed.

Construction of Bailey bridges, commenced in late November to permit diversion of highway traffic between the south end of the Jacques Cartier bridge and the navigation channel, was continuing. As soon as completed, work will commence on a new abutment on the Longueuil shore and on the long task of gradually raising the bridge itself.

At Victoria bridge a lift-span for rail and highway traffic will be provided across the St. Lambert lock, while a second lift span for road traffic only will permit vehicles to to be diverted along one of the lock walls and to cross the lock further upstream at times when ships are holding up traffic over the main rail-highway lift span.

Opposite Lachine, a new lift-span will carry rail traffic on the CPR Caughnawaga bridge across the seaway channel, while the south end of the Honore Mercier bridge will be raised in a pattern similar to that being followed on the Jacques Cartier bridge, to give 120 feet clearance for ocean shipping. Work is already under way on construction of approach roads at the south end.

SLSA Contract Awards

A contract for the supply and erection of the vertical lift span superstructures of two bridges was awarded on December 6 to Dominion Structural Steel Limited, of Montreal, at a price of $6,343,146. The bridges are the St. Louis bridge and the Valleyfield bridge. Each carries railway and highway traffic over the

Beauharnois canal. The work is to be entirely completed by November 15, 1958.

A contract for the substructure of a high level suspension bridge across the south channel of the St. Lawrence at Cornwall Island, was awarded November 30 to McNamara Construction company, Limited, of Toronto, at a total estimated cost of $1,240,550.

It is to be completed by August 31, 1957. The bridge, for which the SLSDC is building the superstructure, will be a two-lane highway crossing between the United States mainland, approximately 8 miles northeast of Massena, N.Y., and Cornwall Island.

Assurance has been given by SLSDC and SLSA engineers that this bridge, to be completed for July 1958, will meet schedule requirements.

McNamara Construction Company Limited, was awarded the contract on December 21, for dredging in the north channel of the St. Lawrence River, at Cornwall Island. Value of the contract is $3,574,000, the work to be completed by October 31, 1958.

Dredging under this contract extends from a point near the eastern end of Cornwall Island up to a point just short of the downstream entrance to the Cornwall canal. A contract for dredging the seaway channel in Lake St. Francis, previously awarded, abuts this new contract on the east.

Alternate Canadian Channel

Terminating a controversy of many months duration respecting the dredging of an alternate navigation channel through Canadian territory on the north side of Cornwall Island, the United States was told formally early in December that Canada intended to override American objections to an all-Canadian seaway. At the same time Canada assured the United States she would not complete this all-Canadian channel for at least ten years, or unless traffic became great enough to warrant the opening of a second route. Any formal moves towards completing an all-Canadian seaway would be taken only after Canada had consulted fully with American authorities.

While dredging this Canadian channel now will add some $17 million to the overall cost of the project, carrying out the work now to a depth of 27 feet will mean an ultimate cost to Canada of some $50 million for the alternate channel including lock facilities, as against a possible cost of upwards of $100 million several years from now.

The controversy regarding an all-Canadian channel to duplicate that portion of the seaway now being built on the American side of the International Rapids section, including two locks, arose from the question of the imposition of tolls. The United States favours high tolls as a form of protection for the American merchant fleet which is being subsidized by the U.S. government.

Canada, on the other hand, favours low tolls to permit low-cost foreign shipping to operate economically on the Great Lakes. A foreign customer for Canadian wheat, for example, pays for its transportation. Thus payment for wheat carried in a Canadian ship is proportionally higher than if the customer used his own vessel. Some incentive must be present in the form of navigation facilities at low cost. But U.S. policy on shipping differs from that of Canada because of the insistence that overseas shipping is an essential industry and because the American government must be in a position to supply shipping needs in the event of a war.

Joint Statement by the Two Seaway Authorities

Following a meeting in New York on December 6, it was announced jointly that the Saint Lawrence Seaway Development Corporation and the St. Lawrence Seaway Authority would call for tenders for major dredging and excavation in the channels south and north of Cornwall Island. Bids were to be opened on approximately January 22, 1957.

SLSDC will undertake the dredging in the south channel between mile 107.5 and mile 110 involving work both upstream and downstream of the existing Roosevelt (International) bridge. This channel enlargement will provide a seaway channel of 27 ft. depth leading to the Grasse River lock at the lower end of the Long Sault canal.

SLSA will undertake dry excavation on south part of Cornwall Island in the vicinity of Roosevelt bridge and dredging in the south channel from below mile 109 to mile 112.5 to complete the 27 ft. seaway channel. The Canadian authority will also carry out dredging and dry excavation in the north channel to maintain the natural distribution of flow in the two channels.

It was also announced that the two toll committees representing Canada and the United States are rapidly approaching agreement on principles pertaining to toll rates. However, the committee members agree that studies and discussion of this subject will occupy them for some months ahead.

Seaway News

The U.S. Supreme Court has approved a temporary increase in the amount of water diverted from the Great Lakes into the Illinois River to 10,000 cubic feet per second for a period of 100 days. It is estimated this additional diversion would lower Lake Michigan by about ½ an inch, and would raise levels in the Mississippi River about one foot on the average, thus benefiting river navigation.

Construction progress at Ontario Hydro's power-house project.

Burlington Beach Skyway

The Burlington Skyway

The $13 million Burlington skyway, now being built to replace the Queen Elizabeth way across Burlington Beach at Hamilton, Ontario, is the largest bridge project ever undertaken by the Ontario Department of Highways. Work on the various elements of the substructure are now well along toward completion and erection of the steel superstructure will be carried out throughout 1957. The skyway will be opened for traffic by the end of 1957.

The first road leading from Toronto to Burlington Beach was built in 1808. Since completion of the Queen Elizabeth Way, some 14 years ago, the six-mile, two-lane section of it between Burlington and Hamilton has been a dangerous bottleneck. The 50-mile speed limit on the highway is reduced to 30 through the semi-urban beach area. Local traffic, and heavy truck traffic around north and south shores of Hamilton harbour, have added to the congestion.

Obsolete Bridge Added To Congestion

The existing swing bridge at Burlington beach, or what is left of it, was not erected until 1896. It had to be frequently opened to allow freighters and smaller craft through the ship channel into the harbour. Weekend and holiday traffic during the navigation season is often backed-up for miles in both directions. Then early in 1952 the bridge was wrecked by a ship and had to be replaced by a temporary roll-beam structure on steel piles, closing off half of the 300-foot wide channel.

Discussions between the Ontario Department of Highways and the Federal Department of Public Works resulted in the appointment in August 1954 of Foundation of Canada Engineering Corporation Ltd. as engineers for the design and supervision of a high level bridge across the channel, to be tied in with a new dual-lane highway on a new right of way west of the existing road. Dr. P. L. Pratley, M.E.I.C., of Montreal and Wm. R. Sonter and Associates of Hamilton were engaged to act in association with Fenco on bridge design and on architectural features respectively. Work started in March, 1955.

Foundations

Typical soil conditions disclosed by site investigations showed some 10 feet of loose grey sand, overlaying an average depth of 30 feet of dense sand and gravel, then 80 to 100 feet of compact fine silty material, followed by stiff clayey silt. Since the ground under the bridge was 6 feet or less below water level, it was decided to fill the entire area behind a rock dike with hydraulic sand fill pumped from the harbour, to a height 6 feet above water level. This decision has simplified the entire construction procedure, providing ready access to all points along the site. An estimated half a million dollars has been saved thereby.

To keep differential settlement of the pier foundations within tolerable limits, design criteria based on pier bases at least 7½ feet below ground level and with at least 20 feet of compact sand beneath the base, called for:

(a) untreated class A timberpiles wherever average "N" value of the soil is lower than 15.
(b) maximum load on piles, 22½ tons.
(c) maximum load with no allowance for material excavated, 18 tons.
(d) bottom of pier base not to be above El. 241.5 with top of base not above El. 249.
(e) net increase in soil pressure not to exceed 3,000 psi. on the average or 3500 psi. maximum.

Design of the Superstructure

The bridge structure itself embodies a central span section 1045 feet in length comprising an arch-

like span 495 feet long over the ship channel with two flanking spans each 275 feet in length. On either side of this three-span central section are eleven steel-deck truss spans, followed by nine plate-girder spans each 85 feet long. Total length of the bridge is thus 8,400 feet. It forms part of an extensive dual highway relocation 4.37 miles in length.

Basic requirements for the bridge call for a horizontal clearance of 300 feet across the channel; a vertical clearance of 120 feet above high water in the channel; maximum gradients of 3 per cent as fixed by the Department of Highways; two 24-foot roadways with a 6-foot centre strip; and two 3-foot walkways, one on each side. Design called for safe passage of trucks having a loaded weight of 40 tons or double the loading called for by CSA 1952 specifications. Turnout or parking bays are to be provided for in each directional lane at both ends of the 3-span central unit.

Construction

The concrete work, which covers bridge decking and asphalt as well as the piers, was let under three contracts. Pigott Construction of Hamilton was awarded two contracts comprising separate jobs and the other went to another Hamilton firm, S. McNally & Sons. The total amount of the three contracts is slightly over $2,500,000.

Five separate firms are under contract to the Ontario Highways Department to build the project. Seven different contracts involve six contractors. Different kinds of fabricated steel are necessary, so contracts were awarded three different firms, Bridge and Tank Company and Dominion Bridge of Hamilton and the Toronto firm of Runnymede Structural Steel Ltd.

Dominion Bridge has the contract for the centre span at a cost of $2,405,000. The Bridge and Tank Co. contract amounting to $1,598,700 calls for parquette steel. The largest of the steel contracts and the biggest single contract ever awarded by the Highways Department goes to the Runnymede firm, amounting to $3,932,000.

Building of the skyway involves the placing of some 90,000 cubic yards of concrete and the fabrication and erection of some 20,000 tons of structural steel. Total cost of the entire project, including the controlled access highway at both ends of the bridge, will be approximately $16 million.

Allumette Island Bridges

The end of November saw the completion of the Allumette Island bridge project, a joint effort of the Federal, Quebec and Ontario governments.

The total length of the project is approximately 2 miles. The Ottawa River, at this point, is nearly 1¾ miles wide, and is divided by a group of islands into three channels.

Four Bridges

The Ontario section contains two small bridges. Proceeding from Highway No. 17 near Pembroke, the first bridge is a 172-foot, 3-span, continuous-reinforced concrete overpass which crosses the transcontinental line of the C.P.R. A short stretch of highway connects this bridge with a second smaller bridge of 101 feet overall length. This is a 3-span, reinforced concrete, rigid frame structure spanning Hazley's Bay between the Ontario mainland and Moffat Point. A ½-mile stretch of highway follows on Moffat Point. Bridges and roads in this section have been built and supervised by the Province of Ontario.

The interprovincial channel bridge was built by the Federal Government, Department of Public Works. This is the largest bridge, spanning the interprovincial boundary line and joining Moffat Point to Morrison Island. It is 1,018 feet long, a 7-span continuous steel truss construction, with a concrete roadway slab.

The Quebec section starts with a ¾-mile stretch of highway on Morrison Island. The bridge over the Allumette rapids joining Morrison Island to Allumette Island is 653 feet long. It is a 5-span reinforced concrete structure located entirely in Quebec, with bridge and highway links supervised by the Quebec government.

The north-easterly end of the project terminates at a point between Chapeau and Waltham.

Highway Research

A joint highway research program is in effect in Ontario, the participants being the Ontario Department of Highways, the University of Toronto and Queen's University. Under the plan, started in October, the universities will conduct research on highway engineering problems for which the Department is providing $85,000 to cover costs for the first year.

Minister of Highways the Hon. Jas. N. Allan states that it is hoped that the highway research program will result in economies in the development and operation of the provincial highway system and will interest university students in highway engineering as a career.

Direction of the program will be under a committee with John Walter, design engineer, Department of Highways, as chairman, and F. C. Brownridge, soil and material engineer, as secretary. Other members of the committee are W. J. Fulton, W. Q. Macnee and R. E. Clarke, of the department; Prof. C. F. Morrison, Prof. O. J. Marshall and Prof. M. M. Davis of the University of Toronto; Dr. S. D. Lash, Dr. R. O. Martin and Prof. H. M. Edwards, of Queen's University; A. K. Hay, Ottawa, general manager of the Federal District Commission; and E. W. Jones, president of the County Engineers Association of Ontario. Dr. Lash will direct the work at Queen's, with Prof. Edwards as associate director. Prof. Morrison will be the director at the University of Toronto with Prof. Davis as associate director.

Aircraft Contract

Canadair Limited, Montreal, will supply 225 Canadian Sabre Mark VI aircraft to the Federal Republic of Germany.

The Department of Trade and Commerce announced the conclusion of an agreement in December on the order valued at $75,000,000.

Allumette Island Bridge Project

The production of these aircraft and spare parts will provide employment for more than 3,000 people for approximately two years, and will retain special skills within the industry, while new aircraft programs are being developed.

The effect of this substantial business will be felt from coast to coast in Canada, where there are about 2,000 subcontractors and suppliers serving the aircraft industry. Among the larger subcontractors are: Orenda Engines, Limited, of Toronto; Lucas Rotax Limited, of Toronto and Montreal; York Gears Limited, Toronto.

Athabasca Oil Sands Development

Royalite Oil Company, Limited, Calgary, and its associates plan a $50 million development program in the Athabasca oil sands of northern Alberta.

During two years of intensive research, conducted at a pilot plant at Bitumount, Alta., the company has worked with Can-Amerc Oil Sands Development Company, Calgary, perfecting the Coulson centrifuge process as an economical method of separating the oil from the sands. These oil soaked sands are known by reputation in the exploration and development branches of the oil industry.

Royalite's initial plans call for the construction of a separation plant and a 20,000 barrel per day processing plant on the Company's 50,000 acre lease at Mildred Lake, halfway between Bitumount and Fort McMurray. The Company's property contains, by conservative estimate, a potential one billion barrels of oil.

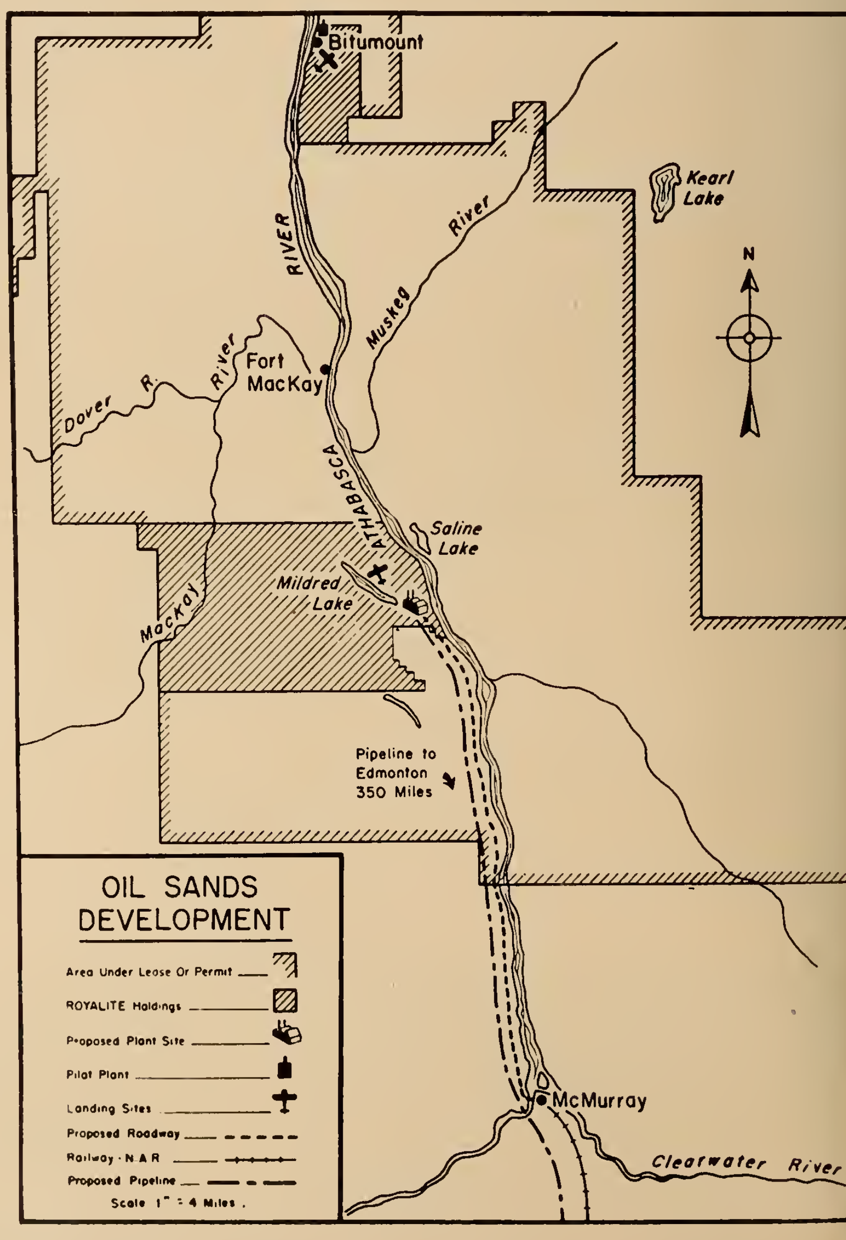
Construction, to begin at spring break-up this year, will be handled by Caribou Engineering Company, Calgary. The greatest part of the work this year will be in engineering and design. In 1958 the processing and separator equipment will be installed. Heavy construction would be concentrated in 1959, with the building of the plant and a 350-mile pipeline to Edmonton. Royalite estimates the entire project will be ready for operation by 1960, having cost a minimum of $50 million.

The Coulson centrifuge process, invented by Gordon Coulson, of Calgary, spins the sand from the oil. The oil sands will be mined and transported to the separation plant. Here banks of giant centrifuges will automatically separate the oil, sand and minute particles of clay. Clean waste sand will be pumped out to the low-lying river bank.

The oil, which is approximately 7° gravity (API) will be transferred to a nearby processing plant to undergo a coking process. It will then be pumped to a sulphur plant which will produce an estimated 140 tons of sulphur per day.

The resulting crude will test 20° to 30° gravity (API), thus permitting normal flow through an oil pipe line. The oil will yield high value products, ranging from premium gasoline to jet and diesel fuel. There will be no waste.

Preliminary engineering and design has been prepared by Pipe Line Technologists of Calgary and Houston.



Bersimis Montreal Microwave Link

Hydro-Quebec's 440-mile microwave link has been completed, the longest private commercial microwave system in Canada. It joins Montreal with Labrieville in northeastern Quebec, site of the Bersimis River hydro-power generating plant.

Other points linked in the 15-station electronic system include Beauharnois, Charlesbourg, Forestville, and the site of the projected Bersimis No. 2 power plant, 18 miles down-river from Bersimis No. 2.

The primary purpose of the $1 million system is to provide communication and control circuits between the Hydro-Quebec offices in Montreal and the Bersimis generating stations and also to provide mobile radio coverage to maintenance crews on the highway along the 330 kv. power transmission line. The system also provides circuits between Montreal and the existing generating station at Beauharnois.

The facilities provided are:

22 voice channels between the main drop points in the system.

2 party line teletype circuits linking these stations.

6 telemetering circuits terminating in Montreal from Beauharnois, Charlesbourg, Bersimis I, and eventually Bersimis II, for automatic remote measurement of conditions.

2 load frequency control circuits originating in Montreal, to allow remote control operation of certain equipment.

The mobile channel ties in to base station equipment at every location except Beauharnois and provides communication from operators at the four control points to mobiles along the route, as well as mobile to mobile communications.

The order wire channel allows party line communication between all stations for maintenance personnel, and, at main locations, for the local operator.

The fault alarm system automatically reports fault conditions from all stations to attended control points at three locations.

Engineering and construction of the system were handled by RCA Victor Company, Ltd., of Montreal. It fills the Hydro's requirements for a number of different voice, teletype, control and mobile facilities in a developing area.

There is other microwave construction under way in Canada. On the west coast a system was recently completed between Vancouver, Burnaby Mountain and Ingledow for B.C. Electric Company. In Alberta a system linking Brooks and Empress is finished, and another linking Edmonton-Valleyview-Peace River and Valleyview-Grand Prairie is being started; both are for the Alberta Government Telephones. In Manitoba RCA has been awarded a contract by the Manitoba Telephone System to connect Swan River and Flin Flon.

Nickel Development In Manitoba

Plans for the development over the next three or four years of a $175 million nickel project in the Mystery-Moak Lake areas in northern Manitoba were announced early in December by Premier Douglas Campbell of Manitoba and President Henry S. Wingate of the International Nickel Co. of Canada Ltd. It will include the opening of two new nickel mines, to be known as the Thompson and the Moak. Production is scheduled for 1960.

Exploration for the new project has lasted ten years and has cost some $10 million to date. When completed, it will constitute the biggest nickel producing operation in the world, next to INCO's operations in the Sudbury district of northern Ontario. Together with the Sudbury development, it will raise INCO's annual nickel producing capacity by 130 million pounds.

As presently planned INCO's investment in Manitoba excluding exploring and pre-production costs will be approximately $15 million. This will include cost of opening and developing the two mines, building concentrator, smelter, refinery, transportation facilities and a townsite for an ultimate population of 15,000.

The amount excludes the cost of a power plant at Grand Rapids on the Nelson River, to be built by the Manitoba Hydro-Electric Board at a cost of between $32 and $35 million. Here 200,000 horse power could be developed. The arrangement reflects the long standing desire of the government to develop the site. Also excluded is the cost of a 30-mile railway branch to be built by the CNR and some $20 million of homes and buildings.

The new town, plant site and adjacent mine will be named Thompson, in honor of Dr. John F. Thompson, board chairman of INCO, who this year completed 50 years of service with the company. The town will be set up as an industrial townsite under the Manitoba laws, and will cost an estimated $20 million.

INCO will assist in financing the power plant by a 4-year 2-per cent loan during the construction period. To get the program under way immediately the company with its own funds will finance all initial capital costs but expects to be reimbursed for its advances for the power plant and any advances made for the railway.

President Wingate said the project would contribute greatly to the much larger supply of nickel which the free world can expect by 1960. But he emphasized that since the Manitoba ores carry much smaller copper values, INCO's copper production capacity will not be increased correspondingly with the large increase for nickel. In view of the cost of separating and refining the copper, the copper content is not regarded as a commercial asset. Minor quantities of cobalt, platinum, palladium, silver and gold are present to assist in making the project successful.

Canadian Pipeline Projects

Westcoast Transmission

Dutton Williams Ltd. had virtually completed section one, extending 120 miles from Peace River to Azouetta Lake by Christmas, thanks to the early exceptionally mild winter break. Without it, most of the men and machines would have had to be retained until spring. A mass exodus for home followed, some on holidays and others leaving permanently, leaving about 35 on the site. Heavy equipment was being marshalled for shipment south to either the Trans Canada pipeline, or for the distribution systems of Inland Natural Gas. The contractors estimate early completion had saved them $50 to $60 thousand.

Though more than 70 per cent of the main line mileage, or 455 miles from Taylor, B.C., to the Fraser valley was thus complete, work was continuing on river crossings, aerial bridges, compressor stations and on the gas scrubbing plant. River Construction Corporation Ltd., had already started laying the 150-mile gathering system in the Peace River area of Alberta and B.C.

Westcoast has contracted to buy 65 million cubic feet of gas per day from Phillips Petroleum in British Columbia. Phillips will supply an additional 150 million feet daily when the demand justifies it. The line will begin next fall to deliver 400 million cubic feet daily.

Savanna Creek Gas for Export

It was announced at year-end that Westcoast had signed a contract with Phillips Petroleum Co. of Bartlesville, Oklahoma, for gas in the Savanna Creek area in southern Alberta, near the British Columbian border. Another contract has been signed with Pacific Northwest Pipeline Corp., the company with which Westcoast has a contract to deliver gas from its Peace River line, for export of Savanna Creek gas to the United States via Kingsgate, B.C.

The program will be divided into two stages. In the first phase, $55 million will be spent to increase capacity of the 30-inch Peace River line from the presently planned 400 million cubic feet daily capacity, to 660 million cubic feet daily, by additional compressor stations and other facilities. Prime user will be Pacific Northwest Pipeline in the U.S., but both B.C. Electric and Inland Natural Gas have also increased their planned volume.

The second phase, costing $45 million, will conclude a 174-mile, 30-inch pipeline from the Savanna Creek field to southeastern B.C. and the U.S. border. Also included is construction of a 500-ton daily sulphur plant in southwestern Alberta.

Pacific Northwest Pipeline completed its main line from the San Juan Basin to the Canadian border early in December. The work involved 1481 miles of main line and 884 miles of laterals and gathering lines.

Inland Natural Gas had completed its survey for their main line through the interior of B.C. by mid-December. A start on pipe laying is planned for February. The work will include 304 miles of main and 73 miles of laterals and feeder lines, as well as distribution systems. Three spreads will operate; — one between Kamloops and Kelowna and between Kelowna and Penticton, a second between Penticton and Kootenay and a third between Okanagan and Nelson. Dutton Williams Ltd. has been awarded the contract for the work.

Premier W. A. C. Bennett of British Columbia announced in December that the B.C. government plans to establish one of the most modern and competent petroleum and natural gas divisions on the North American continent. The announcement was made at the annual meeting of the Canadian Petroleum Association.

Trans Canada Pipelines

A severe prairie blizzard on December 9/10 just about called a complete halt to further clearing. On section 3, Universal Pipeline Ltd. had completed clearing the right of way by mid-December, but lack of pipe for installing the road crossings made further work impossible. On section 4, Dutton Williams Ltd. was continuing with clearing but had stopped grading and stringing. On section 5, Price-Poole Ltd. had closed down early in December. Canadian Bechtel Ltd. on section 6 had cleared 26 miles as far as the Assiniboine crossing near Portage la Prairie, and though no grading was possible some clearing was continuing.

Though survey crews were still working on section 7 east of the Red River, no contract award had been announced. There was little progress to report from the Bechtel Ltd. double jointing yard, though some ten miles of pipe had been delivered at Portage la Prairie siding. The first section of the river crossing at Portage la Prairie was completed on December 17. This was the first of two 560-feet sections to be laid in the river. The second section would be completed after Christmas, weather permitting. Another major river crossing is at Miniota, where work was nearing completion.

Trans Canada had until February 1, 1957 to prove financial ability to build its line. This, the third hoist for the deadline, was granted by the Board of Transport Commissioners on November 1. Because the U.S. midwestern market for Canadian gas was not now available, the financing had been rearranged to provide for a deficit for the first three to five years of operation.

Dominion Natural Gas Co., of Brantford, Ont., is planning a $2½-million expansion program for 1957, double the company's 1956 program which included acquisition of the properties of the Port Colborne Welland Gas Co. The company brought in 29 new producing wells in 1956.

Consumer's Gas Company of Toronto

President A. L. Bishop of Consumer's Gas Co. of Toronto, told the Company's annual meeting in November, that the Company continued to experience an appreciable gain in sales last year from the addition of commercial, residential and industrial load, both on Consumer's Gas and Provincial Gas systems.

The company's annual report for year ending September 30, 1956, showed natural gas deliveries of over 9 billion cubic feet, as compared with 4,878,617,000 cubic feet the previous year and 3,831,450,000 cubic feet the last year manufactured gas was sold. Net income amounted to 82 cents per common share, compared with 66 cents the previous year.

Union Gas to Expand Services

With arrangements now completed for large, long-term volumes of natural gas, Union Gas Co. of Chatham now plans a program for construction of pipelines and other facilities to carry this gas to waiting markets. It will represent the largest single expansion program in the company's history.

Preliminary engineering plans are completed and work has been under way for some time on other preliminary phases such as obtaining franchises and contacting landowners regarding right-of-way. Orders are placed for all the necessary pipe and some of the smaller sizes are already being delivered.

However, completion of the project depends on how soon pipe mills can deliver the 140 miles of large diameter pipe required for the main line. The company hopes to complete the line from its underground storage area in Lambton County to the vicinity of Hamilton by the fall of 1957.

Automobile-Passenger Ferry

At high tide in November 29, the automobile-passenger ferry "Lord Selkirk" was launched at Pictou, N.S. The $2,000,000 vessel will ply between Cariboo, Nova Scotia and Wood Islands, Prince Edward Island.

The Cariboo-Wood Island route is part of the Trans Canada Highway system and the ship has been constructed to specifications. It is a double-ended ferry — a drive-through type to reduce loading and unloading time. It is 260 feet long, 52 feet wide and will have a service speed of 12 knots.

The main deck will handle a capacity of 60 automobiles or other vehicles in five lanes and accommodation is provided for 300 passengers. Four propellers (two forward and two aft) are designed so that the pitch of the blades may be changed while the ship is in operation. This will permit ease in maneuvring.

COMMENT AND CORRESPONDENCE
ELECTIONS AND TRANSFERS

Expansion of Institute Technical Activities

This report has been prepared by the chairman of the Institute's Committee on Technical Operations, F. L. Lawton. Members are urged to read it in order to satisfy themselves that the Institute is prepared to expand greatly its interest in the development of technical studies and activities. Mr. Lawton is writing to all branches to solicit their support in the set-up of committees. It is hoped that the membership will support the committee in the huge task which they have assumed under Council's direction.

The Editor

Report of Committee on Technical Operations

At the annual meeting of Council on May 22, 1956, after lengthy prior consideration, Council adopted the report of its special Committee on Technical Operations.

This report was as follows:—

"Council, at its meeting in Hamilton on February 26, 1955 adopted a report which recommended the setting up of a Committee on Technical Operations, which was duly appointed, with the following scope or terms of reference:—

(a) Keep all technical activities of the Institute under constant review.

(b) Recommend to Council the establishment of such subcommittees of the Committee on Technical Operations as necessary to carry out reviews of specific fields of technical activity and also such special or standing committees of the Institute as may appear warranted by developing needs, in technical areas.

(c) Recommend to the Papers Committee a particular subject or field of endeavour which should be treated in a paper or papers.

(d) Recommend to the Publications Committee particular papers for publication.

(e) Report quarterly to Council on technical activities of the Institute.

(f) Do such work as desirable to encourage the formation of technical sections in the branches.

This report deals with that section of the scope relating to (f) — "Do such work as desirable to encourage the formation of technical sections in the branches".

Need for Improvement

Many members of the Institute, from one end of Canada to the other, recognize that now, as never before, there is a real need to undertake constructive work to improve the technical activities of the Institute, in order to achieve, on the scale necessary, our basic objectives, which are:—"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interest, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

Why is there this need? The answer is embraced in the following observations:

1. Canada is experiencing a period of rapid growth, with a substantial influx of new Canadian engineers into Canada and into the Institute. If the Institute does not provide the means whereby the professional needs of these new members are adequately met by the calibre and scope of technical activities of the Institute they will turn elsewhere.
2. For some time there has been a greatly increased tendency to go outside Canada for consultants whenever major industrial and other undertakings are being planned.
3. There has long been a tendency for many Canadian engineers to look to the professional societies in specialized fields in the U.S.A.

Cover Picture

A stage in the manufacture of the transatlantic telephone cable (page 144 of this issue). The picture shows adjustments being made to the machine which applies to the insulated conductor simultaneously, the copper return tapes and the jute bedding for the armouring wires.

Photo courtesy Submarine Cables Limited which with large memberships, have tended to splintering the profession in Canada.

4. Lack of adequate and well-organized provision for technical activities in the Institute has resulted in many excellent presentations of Canadian engineering achievements being initially presented before U.S.A. societies, to the detriment of the Canadian engineering literature as well as the Institute and the long-range interests of Canadian engineers.

5. Canada's growing industrial stature and prestige abroad both require the development of the strongest possible technical recognition, which can be achieved by the creation of a distinctive Canadian engineering literature.

The Institute has done much in the field of technical activities but there is a wealth of opportunities to do more, thus serving the members of the Institute and Canada. How can this be done?

Certain branches have shown how this can be accomplished. For instance, Winnipeg Branch has a strong Electrical Section. Montreal Branch, for several years, has had a number of technical sections, which have gradually assumed greater significance than the traditional meetings, insofar as diversified membership interest and participation are concerned.

Your Committee on Technical Operations in a report to Council under date of March 26, 1956, has recommended certain action relative to technical activities on the nation-wide Institute level.

Four Recommendations

Your Committee now recommends, further, measures concerned with the encouragement of technical activities in the Branches. These recommendations are:—

1. That, in the proposals embodied in the report of March 26, 1956, the words "subcommittee" and "Subcommittees" be replaced by the words "Division" and "Divisions" respectively.

2. That there be added to the scope of Divisions of the Committee on Technical Operations a sentence reading "The Division on . . . Engineering shall encourage the formation of Technical Sections dealing with its area of engineering in the Branches, assist such Technical Sections in their work, and coordinate activities of such Technical Sections in the various Branches."

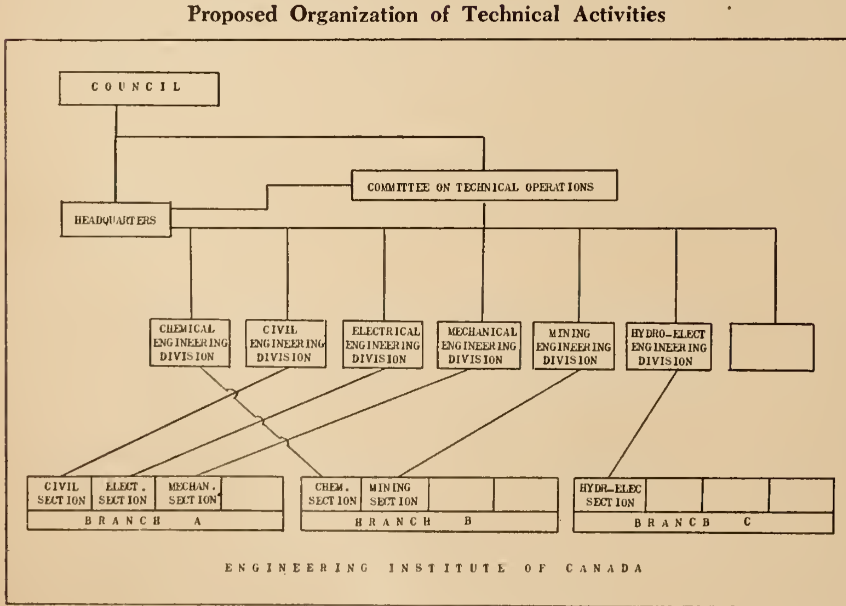
3. That, in pursuance of (2) above, each Division of the Committee on Technical Operations shall:—
   (a) Encourage the formation of branch technical sections by presentation to branch executive committees of data on procedures found to be effective by branches with successful technical sections and on results achieved thereby.
   (b) Make available to branch technical sections up-to-date lists of speakers (and their subjects) who can be secured in the various fields of engineering activities.
   (c) Co-ordinate and make available to branch technical sections the practices and experiences of the various branch technical sections within the scope of a division.
   (d) Promote the preparation and presentation of papers on technical subjects by branch members.

4. That there be a member of the Headquarters staff who shall act as secretary of the Committee on Technical Operations and as secretary of the several Divisions of the Committee on Technical Operations.

The above report was the result of long deliberation by the special Committee on Technical Operations. These deliberations were directed towards achievement of the technical aims expressed in the by-laws.

Your Council is desirous of enhancing the calibre of the technical activities of the Institute, both at the national and branch levels, with the dual aim of widening the scope and improving the quality of technical activities in the branches, thus developing an engineering literature of distinctly Canadian character and of the highest quality.

Proposed Organization of Technical Activities



Experience of Other Societies

The character of the development which it is hoped to achieve is similar to that which has been accomplished by sister societies in the United States, exemplified by the divisional organization of the American Society of Mechanical Engineers and the American Society of Civil Engineers. These two societies entrust the promotion and control of technical activities within the several divisions of interest to their respective divisional organizations. The American Institute of Electrical Engineers has had for some years a somewhat similar divisional setup which has now been extended by the transformation of the former committee responsible for technical operations into the Technical Operations Department. This is operated by appointed members working on a purely voluntary basis. The results have been outstanding. One of the principal objectives is to promote liaison between the technical groups in the various Sections (Branches), and the national technical committees.

As the diagram showing proposed organizations of technical activities indicates, your Committee on Technical Operations initially plans only six divisions, but this may be added to any time as needs arise.

The Committee consists of the following members: B. G. Ballard, Ottawa, C. E. Frost, Montreal, R. M. Hardy, Edmonton, A. R. Harrington, Halifax, W. H. Paterson, Toronto, D. L. Rigsby, Kingston, S. Sillitoe, Belleville, E. R. Smallhorn Montreal, F. L. Lawton, Chairman, Montreal.

You will be hearing more about the plans of your Committee on Technical Operations in the future through the medium of the *Journal*. This is an initial progress report.

Hydraulic Engineering

The Netherlands Universities Foundation for International Cooperation will offer to graduates in engineering from all parts of the world, starting in October 1957, an "International Course in Hydraulic Engineering".

There is an expectation on the part of the Delft Technological University and the Foundation, jointly initiating the course, of a favourable response. They plan to offer a well organized and responsible scientific treatment. There is also good opportunity for visual illustration in the vast hydraulic engineering projects now under construction or planned.

The course will start on Tuesday, October 22, 1957, and will last for a twelve-month period with four intervals for holidays. Instruction will be in the English language.

There is a copy of the prospectus of the course in the Library of The Engineering Institute. This gives information about requirements for admission, the award of a diploma in hydraulic engineering, fees and expenses, fellowships, and the particular subjects of courses. More complete information can be obtained from the Netherlands Universities Foundation for International Cooperation, 27 Molenstratt, The Hague, The Netherlands.

Correspondence

A New Member Writes

Dear Dr. Wright,

Thank you very much for your letter of December 13 advising of my election as a member of the Institute and particularly for the very warm welcome expressed by you.

I count it as a great privilege to be numbered with those who already are members and, while I hope and believe that there are many advantages accruing to myself, I trust that I may be able to contribute something, however small, to the growing body of Canadian engineers and engineering.

R. Douglas Mutch, m.e.i.c.

Montreal.

Value of Membership

Dear Dr. Wright:

I am in receipt of your letter and wish to say that it inspired me sufficiently so that I now plan to begin catching up on past dues and maintain my membership in the Institute. Originally I felt that I resided too far from Canada or any Institute branch to make it worthwhile. But after thinking about it and realizing that the engineering profession has given me my share of personal satisfaction plus worldly goods, I now believe the Engineering Institute of Canada should be supported by all those who have benefitted or might benefit from it.

I came to the Boston area in 1951 by virtue of an ad I ran in the *Journal* for employment, which was answered by a well known Boston engineering company. Without that service I might be still running a transit for a department of highways.

I hope you do not feel that I am speaking disparagingly of those noble fellows who get the road construction done, but if an individual feels he can improve both his personal and professional standing by going into some other branch of engineering, such as structural design for example, which I am now practising, he may never be happy unless he does. Everyone to his own liking, but he who is dissatisfied and knows he can do better should make a move, and being an Institute member may be a big help.

Thank you for not having my name removed. I was very much relieved when I saw in your letter that you had not at that time presented it for removal.

m.e.i.c., Massachusetts.

Sanitary Engineers
(Is it necessary to advertise the fact)

To the Editor,

A short time ago a prominent B.C. newspaper headed an article with "Sanitary Inspectors go to Winnipeg". The men mentioned were to attend the National Convention of Sanitary Inspectors. I find that there are a number of professional engineers calling themselves Sanitary Engineers, also a number of towns have in their list of officers a "Sanitary Engineer".

That these men are sanitary must be a great advantage at a crowded meeting. This unfortunate nomenclature also became prevalent in England and a recent cutting from one of their papers read as follows:

> "LONDON — Sanitary inspectors will in future be known in Britain as 'public health inspectors' because they strongly object to their present name."

The joke that one bath per month was the qualification for an Associate and two for full membership proved too much for them.

Sanitation is the devising and application of means for the improvement of sanitary conditions. Hence sanitate: to put in a sanitary condition.

In my opinion these men should be called *Sanitation Engineers and Inspectors.*

The sloppy nomenclature in using the word "sanitary" instead of "sanitation" should not, I think, be tolerated by a professional body.

Perhaps our Sanitary Engineers exercise the same privilege as Her Majesty in giving the "Order of the Bath" to its members.

A. J. Gayfer, m.e.i.c.

Professional Engineer (Alta.) (Retired) also Sanitary.

The Index, 1956

Reprints have been made of the Index of *The Engineering Journal* for the year 1956, which appeared in the January issue, and copies are available from the Institute Library.

Elections and Transfers

At a meeting of Council held at Montreal on January 26, 1957, a number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected:

MEMBERS

R. L. J. Beccat, Montreal; J. A. Boa, Montreal; D. A. Burnett, Rossland, B.C.; P. T. Christoffersen, Vancouver; C. R. Crocker, Ottawa; R. E. Diefenbach, Montreal; E. E. Embacher, Hamilton; R. A. Hanright, St. Catharines; J. L. Haydock, Niagara Falls; J. R. K. Hickman, Peterborough; R. F. Hooley, Vancouver; H. B. Johnson, Toronto; B. Justewicz, Montreal; C. E. King, Corner Brook; E. Kuhi, Montreal; J. G. Livland, Vancouver; U. Matiss, Ottawa; O. Meyer, Quebec; H. N. Muller, Hamilton; W. C. Pietz, Toronto; A. G. Roberts, Toronto; J. C. Robinson, Edmonton; P. D. Rossiter, Montreal; K. Slesers, Sarnia; D. A. Sloan, Montreal; P. S. Smith, London; J. W. Thomson, Toronto; D. D. Urquhart, London; W. E. Van Steenburgh, Ottawa; A. R. Walker, Toronto; G. L. Wilson, Sudbury; W. B. Workman, North Bay; M. S. Yolles, Toronto; J. M. Zarzycki, Ottawa; G. R. Zethner, Toronto.

JUNIORS

G. C. Bellamy, North Bay; P. G. Jones, Maitland; R. J. Lapum, Ottawa; R. W. Lowe, Montreal; C. F. Smale, Ottawa; P. G. Stein, Toronto; J. Weatherall, Kingston.

JUNIOR TO MEMBER

C. M. Armstrong, Windsor; L. F. Bresolin, Toronto; E. H. Lambert, Toronto; D. K. Lawson, Toronto; M. Lupu, Montreal; G. J. O'Sullivan, Toronto; J. G. Ouellette, Montreal; J. N. Pritchard, Ottawa; D. Quan, Toronto; D. M. Ripley, Montreal; R. F. Routledge, Sarnia; J. E. Rymes, Fort William; R. J. Sheridan, Toronto; A. T. Sherrett, Dryden; G. C. Simpson, Montreal; H. C. Sylvia, Montreal.

STUDENT TO MEMBER

M. F. Oster, Toronto.

STUDENT TO JUNIOR

G. J. T. North, Sarnia.

STUDENTS ADMITTED:

University of Manitoba

G. D. Balacko, H. J. Berry, R. P. Bukata, L. L. Charriere, R. Diamond, G. B. Dyer, P. J. Fulford, F. S. Gira, F. H. Gunston, L. P. Haberman, R. J. Herbertson, R. C. Isaak, D. K. Johnson, D. A. THIRTY-FIVE YEARS AGO

Comment on the Journal of February, 1922

They say that anything can be proved by a judicious juggling of statistics. Fortunately, we do not wish to prove anything in analyzing the Institute's position in December 31, 1921, reported in the *Journal* for February 1922, and its position on December 31, 1955, thirty-four years later: because these notes are necessarily written some months in advance of their publication, we cannot wait for the results of 1956's operations. We are interested only in interesting points which may be brought out by a comparison of the two sets of data.

Let us look at the state of the Institute's finances, first as to totals. In 1921 income was $47,497.53 and expenditure was $37,183.80, leaving a favourable balance of $10,313.73. The corresponding figures for 1955 were $496,820.23, $437,839.67 and $58,980.56. In 1921 the Institute had $335.50 invested in revenue producing securities; in 1955, this figure had risen to the very respectable sum of $192,375.80, including $20,644.19 held in trust for various medal funds and the like. Our total assets increased during this period from $115,088.55 to $292,708.10.

One excellent reason for accumulating a surplus is that before too many years the natural growth of the Institute is going to compel it to find larger headquarters. Anybody familiar with the anthill conditions in our present offices will readily grant that conclusion. When the time comes for expansion, its financing will be immensely easier if we can assume a substantial proportion of it ourselves, no matter whether we put up a new building for our own exclusive use, build one for joint occupancy with some of our sister societies, or arrange for a long lease of space in some commercial structure. And, of course, the income from invested surplus, $4,152.35 in 1955—could be used to pay for something we would otherwise feel we could not afford.

Getting back to the balance sheets we are comparing, let us look at a few selected items. Members' fees, excluding arrears, rose from $34,267.29 in 1921 to $186,380.82. More interesting figures — arrears dropped from about fourteen per cent of the total billed in 1921 to about four per cent in 1955, partly a reflection of economic conditions, we imagine, though perhaps our financial wizards are tougher now than they used to be.

In 1921 the *Journal* produced a net revenue of $6,204.89; in 1955, the comparable figure for the *Journal* and Directory was $38,239.40, not at all a bad record, reflecting the position the *Journal* has attained as that of the leading Canadian engineering periodical.

Financial statistics are notoriously dull for anybody except those directly responsible for them, so let us look at membership figures. At the end of 1921 there were 4,879 members of all grades, of whom 899 were students and 3,980 of higher grade. At the end of 1955, the Institute had 2,630 students, and 13,440 members of higher grade, a total of 16,070.

In themselves, such figures do not mean much. One would expect our membership to increase with Canada's population and with the rising proportion of engineers in it. The question is "are we keeping up with the procession?" R.DeL.F.

WORLD POWER CONFERENCE

The Transactions of the Fifth World Power Conference held in Vienna in June, 1956, will be published shortly. The theme of the Conference was "World energy resources in the light of recent technical and economic developments" and the twenty volumes of the Transactions contain, in either German, French or English, according to the choice of the author, all the 276 papers presented. They may be ordered from the Canadian Committee of the World Power Conference, T. M. Patterson, M.E.I.C., Room 500, 150 Wellington Street, Ottawa 4, Ont. The prepublication price is 3500 Austrian sch. (approximately $135.00) plus carriage. The price after publication is 3700 Austrian sch. plus carriage. In either case a discount of 20% is allowed when the order is placed through the National Committee.

Irving R. Tait retired from Canadian Industries Limited in December 1956. Here he is shown at a reception, receiving a gift camera from H. Greville Smith, C-I-L president. Left to right: T. W. Smith, formerly of C-I-L, Mr. Smith, Mr. Tait, former chief engineer, H. W. Umphrey, present chief engineer, and W. T. D. Ross, C-I-L vice-president. Mr. Tait is a past vice- president of the Institute, a past chairman of the Finance Committee, and currently a member of the Committee on Professional Interests.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

"On This Matter of Shortage"

Taken from the Bulletin of the Corporation of Professional Engineers of Quebec, December 1956. This article is an excerpt from a speech delivered by the president of the Corporation, Leo Roy, M.E.I.C., *before the members of the Lake St. John Region at a meeting held in Chicoutimi on October 4, 1956.*

"For some time now, you have heard about the shortage of engineers attributable to the extraordinary industrial boom of our country in general, to say nothing of the present expansion in the province of Quebec in particular. But how long is this shortage of engineers going to last? This is an extremely important and serious question which confronts the profession.

Not that the number of engineers we train in this country is negligible; on the contrary, the number of engineering graduates has been growing considerably year after year. Our neighbors to the south have recorded a similar increase — the number of engineers as compared with labour has soared from a ratio of 1 to 140 in 1940 to a ratio of 1 to 80 today.

At home as well as in the U.S.A., the number of engineers has grown more rapidly than that of labour and the demand for engineers in industry has skyrocketed. Today, the needs in this field are far from satisfied.

However, the situation is not without remedy, provided we manage to take more advantage of some technical talents now being squandered in jobs that are not connected with the engineering profession as such.

Nevertheless, I feel that if we worry about the actual shortage of engineers today we should not worry too much about the future shortage of engineers. Being naturally inclined to optimism, I agree with Financial Post editor Michael Barkway, who said: For practical purpose the next five years count more, there will definitely be a serious shortage and these years will count more than perhaps the next ten. By 1960, we shall have in Canada about a quarter of a million more children between 15 and 19. Probably a larger proportion of them will also be going to university. You can then assume a sharp increase in the supply of engineers from 1961 on. Hang on for another five years, and the worst of our troubles should be over.

And it suggests a word of warning to the young. Shortage in the next few years and the high rates of pay which it causes could go on tempting an increasing proportion of lads to take engineering courses.

So it is by no means impossible that engineers might be in over supply in the 1960's.

It would be a very short-sighted policy on the part of our youth to envisage the problem with only remuneration in view. The real problem is that of training engineers so as to satisfy the demand and to keep abreast of the expanding Canadian industry . . . ."

Members Opinions

It is understood that the opinions expressed hereunder are personal and are not necessarily those of the Corporation.

Considering the importance of our feature article on the utilization of engineers, we canvassed several members of the Corporation with a view to presenting their opinions for consideration. While we found that there was no shortage of opinion, there was an unwillingness to be quoted directly. Most of the members approached felt that any shortage or surplus of engineers was tied so tightly to the national economy that it was necessary to make assumptions regarding this which might prove untenable.

Assuming that our present expanding economy continues, all members agreed that there was a shortage of engineers. There was not such a unanimous agreement on the reasons for the shortage. It is generally agreed that an engineering training prepares a man for many fields of endeavor and that several graduates from our universities take advantage of this training to advance on other lines. There was no criticism levelled at this, although there was some made about graduates who emigrate immediately after graduation, to the United States. One unique opinion was that since the country had invested a great deal of money in giving engineering students their education, these students should enter into a committment to work for five years in this country, or for a Canadian company abroad.

One prominent Montreal engineer suggested that the graduates of recent years do not have the competence nor do they acquire the wide experience of earlier engineers. He felt that it now takes three engineers to do the work that two were doing twenty years ago. This engineer also made a point that was repeated several times by other members; that is that engineers are being used in great numbers for jobs requiring nothing more than competent technicians. In this category he would put engineers employed as draftsmen, checking off material, doing routine testing, or any other occupation which merely necessitated collecting facts without having either to analyze them or to apply them.

Amongst younger engineers there was a feeling that a lack of recognition was driving them away from the field of straight engineering. In general these engineers hoped to stay in the same company but to transfer from an engineering department to a commercial one. The lack of recognition was basically a complaint about salaries, although as one design engineer put it, "Last week one of our sales engineers got a very good order. He was congratulated and shared in the dinner which was held to celebrate the event. He not only had a good time and was made to feel more important but he had the opportunity of meeting our company executives at a social gathering." He then brought up the part that hurt. "We worked hard to solve the problems connected with the piece of equipment. It was our design which made it practical and economical, yet we received no recognition at all."

The role of "sales engineer" was criticized by several members as using up available talent and returning little. It was felt that at the present time there is a great incentive to buy only on price. Some said that under these conditions a company could send a tender to a customer by means of the office boy since technical considerations only too often got little consideration. Some of the sales engineers interviewed felt frustrated under these conditions. Most however were ambitious and recognized that the chances for promotion were greater in the commercial departments. This ambition then kept them on the sales side although they had little opportunity to apply their training, and it was this same ambition which attracted good designers as referred to above, to break from pure engineering. The greatest cynicism came from one engineer who gave the definition of a sales engineer as a "person who engineers a sale." He went on to suggest that if all the drug manufacturing companies employed a large number of doctors on their staff to sell to hospital and retail outlets, there would be a grea hue and cry about the wastage of doctors. He also doubted that a term such as "sales doctor" would be acceptable to the Medical Association.

Summarizing therefore, the general opinion was that there is no shortage of people with engineering training, but there is a very real shortage of people doing engineering work. This has been brought about by the fact that pure engineering does not appear to be an attractive lifetime occupation from either the social or financial point of view in the eyes of the engineers whose opinions were sought.

Persons with a different opinion wishing to express other views on the subject were invited to contact the Association of Professional Engineers of Quebec.

ONTARIO

Engineers in The News

M. A. Elson, has resigned as deputy minister of the Ontario Department of Highways to rejoin the Russell Construction Ltd., Toronto, as a director and executive vice-president of that company.

Mr. Elson, who graduated in civil engineering from the University of Toronto in 1933, was appointed deputy minister of Ontario Highways in 1954 and during his tenure of that office has played an important role in effecting important changes in the department's organization.

Mr. Elson has spent a number of years of his career in the consultation field. During World War II he served with the R.C.E. and in 1945 was in command of the R.C.E. of the Canadian Army overseas. His service included anti-invasion defence work in England, tunnelling in Gibraltar, and field action in France, Belgium and Holland

Following his retirement from the Army he was assistant project manager for the Carter, McNamara, Mannis, Morrison and Knudsen companies (CMMK) in the Quebec-Labrador iron field development. Just prior to his Highways appointment Mr. Elson was general superintendent of construction of the Russell Construction Co. Ltd.

Dr. W. P. Dobson of Toronto has left Canada for a trip to the United Kingdom and India and was one of two Canadian delegates representing the Government of Canada and the Canadian Standards Association at the Commonwealth Standards Conference which took place at New Delhi, India, from January 21 to February 3, 1957. The other Canadian delegate is J. S. Cameron, of Montreal, president of C.S.A.

The conference will deal with standards for materials and equipment with the object of promoting uniform standards in the Commonwealth.

For many years director of the research laboratories of Ontario Hydro, and now chairman of the administrative board of CSA Testing Laboratories, Dr. Dobson is planning to visit several of the atomic energy establishments in the British Isles. His program also includes a visit to K.E.M.A. Laboratories in Arnheim, Holland, which carries on the test work for C.S.A. on the continent

J. H. Fox Elected

New president of the Association of Professional Engineers of Ontario is John H. Fox, vice-president in charge of sales for Honeywell Controls Limited.

J. H. Fox, O.B.E., M.E.I.C.

As president, Mr. Fox will head the largest association of its kind in Canada and the licensing body for Ontario's engineering profession.

A graduate, in mechanical engineering, of the University of Toronto, class of 1927, and a native of Toronto, he has been associated with Honeywell since 1935 when he joined the company as a sales and application engineer on electric and pneumatic controls and systems for heating, refrigeration and air conditioning. His appointment followed employment as a demonstrator in hydraulics at the University of Toronto and as an engineer with a firm designing steam heating systems and plants for all types of buildings.

Mr. Fox has had a distinguished military as well as business career. He joined the R.C.E.M.E. shortly after the outbreak of war and held various staff and unit command appointments while serving in Britain and Northwest Europe. He ended the war as a colonel.

His military service earned for him the O.B.E.

Returning to Honeywell at the end of the war, he was promoted to sales manager of the commercial controls division and from 1951 until his appointment as vice-president last September he was successively manager central division and general sales manager.

His professional memberships include the Engineering Institute of Canada, an associate membership in the Institute of Mechanical Engineering, London, Eng. He is a member of the Council of the American Society of Heating and Air Conditioning Engineers and a past president of the Ontario Chapter of that organization. He is also a member of the Canadian Construction Association.

William J. Fulton of Toronto, has been appointed Deputy Minister of the Department of Highways of Ontario.

Mr. Fulton has been with the Department for 35 years, joining it a short time after his graduation in civil engineering from the University of Toronto.

During his service with Ontario Highways Mr. Fulton has held a number of posts of engineering responsibility. Latterly he has been head of the planning and design department and directed the compilation of a master plan for Ontario highway development for the next twenty years.

Also announced by the Minister of Highways, the Hon. James Allan, was the appointment of John Walter to succeed Mr. Fulton as head of planning and design, and of Hugh W. Adcock, as manager of operation under the chief engineer, W. A. Clarke.

Peter R. Pettit has returned to Australia, where he plans to continue his professional work. He is now living in Mosman, N.S.W. Australia.

Mr. Pettit graduated in civil engineering from the University of Sydney, Australia, in 1950. Coming to Canada some three or four years ago he was first employed as assistant to the superintendent of construction at the University of Toronto. More latterly he has been with the Toronto firm of consultants, Morrison, Hershfield, Millman and Huggins.

A. S. Williamson was recently appointed to the position of town engineer and works manager of the town of Dundas, Ont. Before this appointment he was employed by MacKay & MacKay, engineers and surveyors, in Hamilton.

Everett B. Allen has left Beaucage Mines Ltd., of North Bay, Ont., and is an assistant research fellow at the Ontario Research Foundation in Toronto.

Robert D. Burns is assistant geologist at Geco Mines Ltd., Manitouwadge, Ont.

John G. Gill of Canadian Steel Improvement Ltd., Long Branch, Toronto, has been appointed a director and vice-president in charge of operations of the Company.

Milton M. Hamburger is employed by E. S. & A Robinson (Canada) Ltd., in Toronto. He was earlier with Courtalds (Canada) Ltd.

Robert B. Allison is county engineer for the County of Prince Edward and has his headquarters in Picton, Ont. A graduate in engineering from Queen's University, Kingston, he was formerly assistant distict municipal engineer with the Ontario Department of Highways at

(Continued on page 178)

Chatham, Ont.

R. W. Lewkowitz has moved from Toronto, where he was with Powertronic Equipment, Ltd., and is now living in St. Catharines, Ont. He is employed as a design engineer with Packard Electric Co. Ltd., of that city.

Edward J. Adams, formerly with John Inglis Co. Ltd., in Toronto, is now a design engineer in the civilian atomic power department of the Canadian General Electric Co. Ltd., at Peterborough, Ont.

MANITOBA

Association's Fall Frolic

A capacity crowd turned out for the first Fall Frolic held by the Association. Members violating the rules of the dance floor were arrested and tried by the judge, who was complete with gown and wig. If found guilty offenders were placed in a small "jail" to remain there until fines were paid.

Jack Hoogstraten, the Association president was awarded the prize for design. This was a pair of rubber gloves for having solved the problem of how to clean small ducks when one has large hands. The good housekeeping award, an apron shaped like a pair of bloomers, went to Craig Sommerville. The award for animal training, a box of sawdust, was presented to W. J. Adams, who house-broke his dog in thirty-eight and a half days. W. Y. Lynn won the award for courage for having successfully refrained from giving in to his wife's plea for a new hat at $40.00. He was presented with veiling and two feathers to make one for her. R. E. Gottfred won the style award, an umbrella shaped hat, recognizing him as the best dressed golfer at a recent tournament.

All the awards were a complete surprise to the recipients.

Engineers in the News.

L. A. Bateman, council member of the Association attended the 37th annual meeting of the B.C. Association of Professional Engineers held in Vancouver.

W. A. Green, has been appointed vice-president and director of Hudson Bay Mining and Smelting Co. Limited at Flin Flon, Man.

Angus G. MacKenzie has been appointed assistant chief engineer of Sherritt Gordon Mines Ltd. at Lynn Lake.

C. L. Fisher was elected a director of the Canadian Good Roads Association at the thirty-seventh annual convention held in Quebec City.

M. Lasko has been appointed Winnipeg district engineer of the new district office opened by CSA Testing Laboratories in Winnipeg.

I. B. Henderson has been appointed general superintendent of the Greater Winnipeg Water District.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Col. D. H. McDougall, M.E.I.C., chairman of the board of MacKinnon Steel Corporation and president of the Frontenac Tile Company, died on December 4, 1956, at Montreal.

Donald Hugh McDougall was born in Sydney, N.S., on September 15, 1879, and was educated at public schools, the Government Mining School at Glace Bay, and Dalhousie College. In 1905 he undertook the management of the Dominion Iron and Steel Company's Wabana iron ore mines. Three years later he became general superintendent of ore

Col. D. H. McDougall, M.E.I.C.

mines and quarries for the same company. Named general superintendent in 1910 and general manager of the Dominion Coal Company in 1912, he was general manager of both these coal and steel companies in 1916. President of the Nova Scotia Steel and Coal Company in 1919, he received the appointment of vice-president of the British Empire Steel Company in 1921.

Three years later, in 1924, he severed direct connection with the twin industries of Nova Scotia and opened an office in Montreal as a consulting mining engineer. Over the past thirty years he originated, designed and developed many mining and engineering projects, not only in Canada but throughout the entire continent.

Colonel McDougall served as a director of many Canadian companies such as the McIntyre Porcupine Gold Mines, Steep Rock Iron Mines, Malartic Gold Fields, Inspiration Mining Company, Beaucage Mining Company, Canadian National Railways, Atlantic Sugar Refineries, Eastern Trust Company and Fleet Aircraft Limited.

In recognition of his contributions to the development of the Coal and Steel Industries of Nova Scotia, St. Francis Zavier University, in 1916, conferred on him an honorary degree of Doctor of Laws. On the Coronation of Queen Elizabeth II, Her Majesty was pleased to bestow on him the Coronation Medal.

Col. McDougall not only held the high office of president of the Mining Society of Nova Scotia, 1918-1919, and the Canadian Institute of Mining, 1919-1920, but gave unstintingly of his service and wise guidance as a member of the Councils of both, over a period of many years. First elected to the Council of the Canadian Institute of Mining in 1915 he served five separate appointments in this office for a total period of twenty-five years. Since 1941 until the time of his death he had served fifteen consecutive years as chairman of the executive committee of council. In 1955 named an honorary member of the Mining Society of Nova Scotia, he was, in 1956, at the time of his death, nominated for honorary membership in the Canadian Institute of Mining. He was a Life member of the organization.

He was also a member of the A.I.M.E., the American Iron and Steel Institute, and the Mining Institute of Scotland.

Col. McDougall joined the Institute in 1913 as a member and became a Life Member in 1948.

John Kirby Wyman, M.E.I.C., retired as-assistant to the port manager of Montreal Harbour for the National Harbour Board, died November 3, 1956, at Victoria, B.C., where he had been resident for the past six years.

Born at Hawkesbury, Ont., on July 31, 1883, Mr. Wyman received his engineering education at McGill University graduating in civil engineering in 1910. Beginning hs career with the Canadian eneral Development Company, St. Timothee, Que., on a canal for the Canadian Light and Power Company he was for five years associated with the John S. Metcalf Company on grain elevator construction, with the Bathurst Lumber Company and the Foundation Company of Canada.

At the outbreak of World War I he joined the Royal Engineers in England, winning a distinguished war record, and mention in despatches. After the war he continued to serve the Royal Engineers for an additional four years in India as an assistant director of military works at Lahore. He held the rank of major.

Returning to Canada in 1924, he worked for a time with the Department of Railways and Canals, in St. John, N.B., and Ottawa. Later in 1928, he was superintendent of the Port Colborne, Ont., grain elevator, and when an elevator was opened at Prescott, Ont., he became the first superintendent.

In 1938 he held the post of general superintendent of grain elevators, with the National Harbours Board, Montreal, and in 1949 became assistant to the port manager of the Montreal Harbours Board, the position he held until his retirement in 1950.

Mr. Wyman joined the Institute in 1907 as a Student member, was transferred to Associate Member in 1912 and became a member in 1940. He attained Life Membership in 1948.

Raphael Belanger, M.E.I.C., formerly vice-president of the contracting engineering firm of Deschamps and Belanger Limited, Valleyfield, Que., died on December 5, 1956, at Montreal.

Closely linked with Valleyfield, for many years, Mr. Belanger was born there on May 25, 1899. On gaining a B.A. degree at Valleyfield Seminary, he went on to engineering studies at the Ecole Polytechnique, Montreal, graduating with a B.Sc. degree in 1923.

City engineer at Valleyfield for a number of years, at the beginning of his career, he later went into private practice in the construction field in that district and finally in 1954 became a partner in the firm, Deschamps and Belanger Limited. He was appointed vice-president of the company in 1954.

Mr. Belanger joined the Institute as a Student Member in 1921, transferred to Associate Member in 1927, and became a Member in 1940.

Howard Fellows, M.E.I.C., formerly chief engineer with the Nova Scotia Power Commission, Halifax, and lately consulting engineer with the organization, died suddenly on November 17, 1956, at Halifax.

A native of Nova Scotia, Mr. Fellows was born at Stellarton, on August 3, 1894. He attended Mount Allison University from 1913 to 1915, and after four years machine shop and drafting room experience he enrolled at McGill University in 1919, graduating two years later with the degree B.Sc. in electrical engineering. Mr. Fellows joined the Nova Scotia Power Commission at Halifax in 1921 and continued to serve the company throughout his lifetime. Assistant chief engineer with the Commission in 1930, he was named chief engineer in 1946, and eventually became consulting engineer to the organization.

Mr. Fellows joined the Institute in 1930, as an Associate Member, and transferred to member in 1940.

Edward Stanley Carpenter, M.E.I.C., surveys engineer with the Dominion Department of Agriculture, P.F.R.A., at Regina, Sask., died on November 22, 1956 at Regina.

Mr. Carpenter was born at Gamebridge, Ont., on June 2, 1904. Brought up in Regina, he attended public and high schools in that city and then went on to study engineering at the University of Saskatchewan. He was awarded a B. Eng. degree in 1929, and during the first few years of his career gained experience as resident engineer with the Department of Highways, Province of Saskatchewan. After a number of years with P.F.R.A. at Regina, Mr. Carpenter joined the R.C.E., at the beginning of World War II and served overseas with the 14 Canadian A Fd. Coy. Returning to Canada in 1944 with the rank of captain, he was an instructor at the School of Military Engineering, Chilliwack, B.C., and in 1946 resumed his position as district engineer with P.F.R.A., located for a time at Saskatoon and later at Regina.

Joining the Institute as an Associate Member in 1931, he transferred to Member in 1940.

An active member of the Institute, he served the executive of the Saskatchewan Branch in 1947 and 1948.

He was also active in the Association of Professional Engineers of Saskatchewan.

Edwin Gerald Wyckoff, M.E.I.C., who was for many years a member of the staff of Otis Elevator Company, in Hamilton, Ont., died on November 13, 1956, at London, Eng., where he had been for a short time associated with Waygood-Otis Limited.

Born at Vittoria, Ont., on October 5, 1907, and educated at Simcoe High School and later at the University of Toronto, Mr. Wyckoff gained a B.A. Sc. degree in electrical enginering in 1930.

Employed with the Hydro Electric Power Commission of Ontario and the Otis Elevator Company Limited as a student, he remained with the latter firm after graduation and was employed at the Hamilton works, in charge of various manufacturing departments. Eventually administrative engineer in 1947 and head of the engineering department at Hamilton, he was later associated with the Warsaw Elevator Company as chief engineer. Works manager with Elevadoes Otis S.A. in Sao Paulo, Brazil in 1952, he was associated with the Otis Company at Bombay, India in 1955, before going to England.

Mr. Wyckoff served on the executive of the Hamilton Branch in 1946 and was elected chairman in 1948.

He joined the Institute in 1938, as an Associate Member, and was transferred to Member in 1940.

Gregoire Gareau, M.E.I.C., formerly chief engineer with Saguenay Electric Company Limited at Chicoutimi, Que., died on September 6, 1956 at Chicoutimi.

Born at St. Faustin, Terrebonne County, Que., on May 20, 1919, Mr. Gareau attended the Seminaire St. Therese de Blainville. Continuing his studies at Laval University, he graduated with a B.A.Sc. degree in electrical engineering in 1944.

He remained at Laval University in the capacity of professor from 1944 to 1948, and the following year joined Saguenay Electric Company at Chicoutimi.

Mr. Gareau was an active member of the Institute and was a member of the executive committee of the Saguenay Branch of the Institute. He was a member of the Corporation of Professional Engineers of Quebec.

Mr. Gareau joined the Institute as a Student Member in 1944, transferred to Junior in 1946 and became a Member in 1951.

Andrew J. Kowalchuk, JR.E.I.C., chief engineer for Brent Construction Company Limited, Edmonton, was killed in an auto accident on October 27, 1956. Mr. Kowalchuk was born in Poland on November 15, 1923. He followed his engineering studies at the University of Alberta, graduating with a B. Sc. degree in civil engineering in 1950.

First employed as a laboratory technician at the university, he accepted a position as field engineer with Brown and Root Limited, Edmonton in 1951. He joined the firm of Brent Construction Company Limited in 1955.

Mr. Kowalchuk joined the Institute in 1949 as a Student Member and in 1952 transferred to Junior member.

He was also a member of the Association of Professional Engineers of Alberta.

John Burton Gilliatt, M.E.I.C., retired chief engineer with Dominion Steel and Coal Corporation Limited at Wabana, Nfld., for many years, died at Annapolis Royal, N.S., on November 22, 1956.

Born at Granville Centre, N.S., on February 1, 1880, Mr. Gilliatt attended the University of New Brunswick and Dalhousie University, graduating with a B. Eng. degree from the latter in 1908.

Engaged in railway construction engineering with the National Transcontinental Railway throughout eastern Canada for the initial eight years of his career, except for a short term spent in the city engineer's office at Halifax after graduation, he joined the Dominion Steel and Coal Corporation Limited as resident engineer of the Wabana Mines in 1916 and held that position for the following six years. In 1922 he assumed the duties of chief engineer, which he continued to fulfill until his retirement in 1952.

Later, Mr. Gilliatt served on several engineering projects for the town of Annapolis Royal, on a part-time basis.

He joined the Institute as a Member in 1954.

CORRECTION

The Journal regrets the error which occurred in the obituary of J. E. Mikkelson in the November issue. It was stated that Mrs. Mikkelson was an engineer and had returned to practice in San Francisco. This is not correct. However Mrs. Mikkelson is employed in the engineering field.

Personals

News of the Personal Activities of Members of the Institute.

C. K. McLeod, M.E.I.C., of Montreal has been elected to the board of directors of the Permutit organization.

Earlier this year his election as president of Walter Kidde and Company of Canada Limited was announced. He has been associated with that organization as well as the Permutit Company since 1925.

Mr. McLeod is a former councillor of the Institute, 1940, and a past chairman and secretary-treasurer of the Montreal Branch from 1934 to 1936.

R. L. Dobbin, M.E.I.C., and **L. F. Grant,** two past-presidents of the Institute have been elected as aldermen in their respective cities.

Mr. Dobbin, of Peterborough, Ont., was formerly general manager of Peterborough Utilities.

Mr. Grant, Field Secretary of the Institute resides at Kingston, Ont.

Also elected to aldermanship at Kingston was **G. Vosper,** JR.E.I.C.

A. J. Lawrence, M.E.I.C., recently elected an alderman of Beaconsfield, Que., by acclamation, has also been elected to the advisory town planning commission of that district.

For many years employed with the Northern Electric Company Limited, Montreal, he is in charge of apparatus engineering standards with the organization.

J. M. Breen, M.E.I.C., president and general manager of Canada Cement Company Limited, Montreal, has been elected to the board of directors of Canadian General Electric Company Ltd.

He is also a director of Du Pont of Canada Securities Limited and its operating company, Du Pont Company of Canada Limited, the Montreal Trust Company, Canadian Refractories Limited, and the North American Life Assurance Company.

Mr. Breen has been associated with Canada Cement since 1922. He became president and general manager of the company in 1949.

R. S. Eadie, M.E.I.C., who has been appointed vice-president and manager of Dominion Bridge Company Limited, eastern division, is a graduate of McGill University.

Interrupted in his education during World War I, he joined the Canadian Engineers as a lieutenant and served in Canada and overseas. He resumed his studies on discharge and obtained his B.Sc. degree in civil engineering in 1920 and was awarded an M.Sc. degree shortly afterwards.

Lecturer in the Department of Applied Mechanics at McGill University on graduation, he held the position until 1924 when he joined Dominion Bridge Company in Montreal.

In 1935, Mr. Eadie was appointed design engineer and in 1937 was named assistant chief engineer. He became chief engineer of the Eastern division in 1944 and held this post until his recent appointment.

Thomas A. Somerville, M.E.I.C., has been appointed vice-president of E. G. M. Cape and Company, Montreal.

A B.Eng. graduate in civil engineering from McGill University, class of 1948, he has been with the firm since that date, serving at Halifax and Montreal. He now directs the Ontario operations of the company.

In 1953 he was named general superintendent of the organization at Montreal.

James Wheatley, M.E.I.C., former chief engineer of the shops and transportation department of the Quebec Hydro-Electric Commission has retired following eighteen years in this position.

Originally from New York state, Mr. Wheatley received his engineering qualifications at McGill University, obtaining a degree in mechanical engineering in 1912. Beginning his career with the Northern Electric Company upon graduation, he gained three years' experience in the design and manufacturing field and then accepted a position with the British Munition Company Limited of Verdun where he was engineer in charge of the design of tools and manufacturing, during World War 1. He also served for a short period of time with the Canadian Engineers in Canada.

Rejoining the staff of Northern Electric Company at the end of hostilities, he was employed in the power apparatus sales division for some time.

Assistant superintendent of the bolt and nut department of the Steel Company of Canada at Montreal in 1923 he remained with the firm for three years.

In 1926 he became associated with Domestic Gas Appliances Limited, a subsidiary of the Montreal Light, Heat and Power Consolidated, at Montreal, which firm was later in 1944 to become known

C. K. McLeod, M.E.I.C.

R. S. Eadie, M.E.I.C.

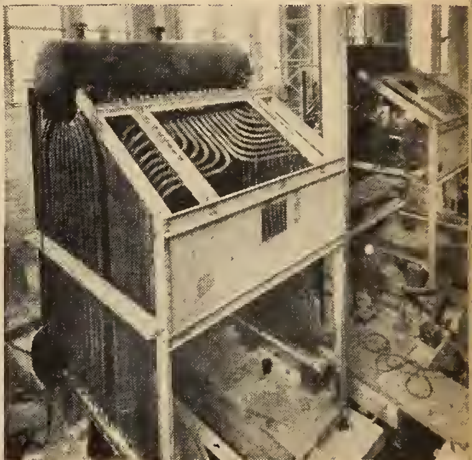
J. M. Breen, M.E.I.C.

Microwave parabolic reflector for transmitting ultra-high frequency waves. Mechanical design, fabrication and erection by Dominion Bridge for RCA Victor Company Limited.

On the job...

Completely enclosed 250-ton gantry crane, with 60-ton crane at right. Both are installed at the Peribonka power house of the Aluminum Company of Canada. We are now building a 300-ton crane of same type for St. Lawrence power project — largest ever built in Canada.

This rotary kiln is 450 ft. long, 12 ft. diam. and weighs approx. 700 tons. Largest in Canada — it is capable of producing 1,500,000 barrels of cement annually. Fabricated and erected by Dominion Bridge for Canada Cement Company, Fort Whyte, Man.



Three 25,000 pph Dominion Bridge water tube boilers installed in St. Justine Hospital, Montreal.

• PERSONALS

as the Quebec Hydro-Electric Commission.

In 1938 he was transferred to the industrial department of Montreal Light, Heat and Power Consolidated as manager of the gas division of the firm. In the same year he was transferred to the shops department as mechanical superintendent and general superintendent of shops and the garage department, prior to assuming the duties of chief engineer of the shops and transportation department.

Mr. Wheatley was elected a Life Member of the Institute in 1954.

Garth Griffiths, M.E.I.C., of Victoria, B.C., is the choice of the Vancouver Island Branch of the Institute as chairman for the coming season.

Last year appointed assistant to the general manager and also director of administration with the British Columbia Power Commission, Victoria, Mr. Griffiths has been associated with that organization since its inception in 1946.

At that time he was discharged with the rank of major from the R.C.E.M.E. technical staff, following three years' military service. This included liaison work with the design and production authorities and with British Army Staff in Ottawa and Washington, and a short tour of duty in the United Kingdom and northwest Europe.

Mr. Griffiths is a graduate of the University of British Columbia in electrical engineering, class of 1941.

C. G. J. Luck, M.E.I.C., who retired from his position as assistant engineer with the National Harbours Board at Churchill, Man., in 1955, now lives at Saanichton, Vancouver Island, B.C. He is an assistant engineer with the British Columbia Forest Services.

Engaged in engineering since 1905, the date of his graduation from the Central Technical College, London, Eng., his career has entailed a variety of experience. In Canada as early as 1920, he had behind him several years' military service with the British Expeditionary Force. At the end of the war in 1919, also with the B.E.F., he was instrumental in the reconstruction of the Murman Railway, in Northern Russia. Mr. Luck was awarded the M.C. with Bar on his discharge from the Army.

J. H. Wheatley, M.E.I.C.

G. Griffiths, M.E.I.C.

Employed with the firm of Ewing, Lovelace and Tremblay, Montreal, in 1920, he also held appointments with Fraser-Brace Engineering Company Limited during the 1920's, and the Gatineau Power Company.

He was associated with the Ontario Hydro-Electric Commission, the Beauharnois Construction Company at Beauharnois, Que., and the C.P.R., at St. John, N.B., in the following decade.

His association with northern Canada began in the mid-thirties, when, turning to engineering projects with the Department of Northern Development, he was employed at Kenora, Hudson and Port Arthur, Ont. Later in 1940 he went to Churchill, Man., to accept a post with the National Harbour Board as an assistant engineer.

Mr. Luck was elected a Life Member of the Institute in 1956.

Edward R. Zacharias, M.E.I.C., has been named general manager of engineering and manufacturing services for the Thermoid Company, Trenton, N. J.

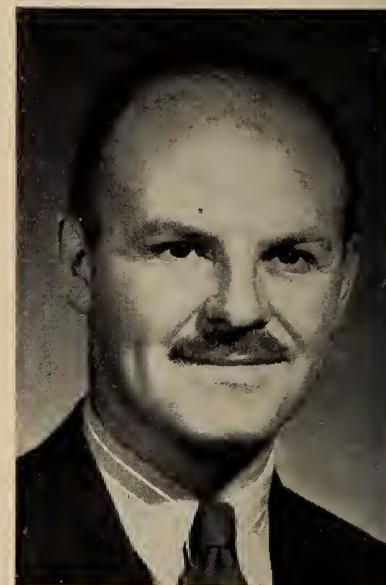
With Thermoid since 1950, he was for eleven years prior to that time factory manager of the Stokes division, General Tire Rubber Company, Welland, Ont.

A graduate of the University of Saskatchewan, class of 1935, he has a B.Eng. degree in civil enginering.

Harry S. Spark, M.E.I.C., port engineer with the National Harbours Board at Montreal has retired after more than thirty-three years' service.

A native of Scotland, Mr. Spark came to Canada in 1912 following two and a half years' apprenticeship with a Dundee engineering and shipbuilding firm, on completion of his engineering studies.

Initially employed in Canada with Canadian Explosives Limited, in the design field, until 1914, he then joined the Montreal Filtration and Aqueduct Works and took part in the preparation of hydraulic studies and designs for re-



P. B. French, M.E.I.C.

taining walls and a power house at the low level pumping station at Montreal.

With Canadian Vickers Limited from 1917 to 1921, he was employed as an assistant chief draughtsman, before joining the Harbour Commissioners of Montreal as an assistant engineer.

He became assistant chief engineer in 1944 and in 1947 assumed the top position of port engineer.

Mr. Spark has been largely responsible for the extensive building program now under way in the harbour in preparation for the opening of the Seaway.

John M. Hansen, M.E.I.C., town engineer at Fort Frances, Ont., in 1955, has accepted an appointment as resident engineer with the Department of Public Works, Banff, Alta.

A Danish engineer from the Royal Technical College, Copenhagen, Mr. Hansen has had varied experience in this country, working on the staff of W. M. Barnes, general contractor in Edmonton, as designer and draughtsman, and later in 1949 with Sparling and Davis, Edmonton, in the general contracting field. He has also been associated with the City of Edmonton engineering department, and in 1951 joined Defence Construction Limited at Edmonton. In 1954 he became town engineer for Dauphin, Man.

Vassyl Nakonechny, M.E.I.C., of Canadian Vickers Limited, Montreal, has been

promoted from senior draughtsman, Marine drawing office, to estimator, in the industrial drawing office.

With Canadian Vickers for a number of years Mr. Nakonechny came to this country originally from Belgium where he studied engineering at the University of Louvain, Belgium.

Philip B. French, M.E.I.C., of Lyman Tube and Bearings Limited, Montreal, has been recently appointed vice-president in charge of sales with the firm.

Mr. French, who has been with the firm for a number of years, as bearings sales manager and branch manager, has also had experience with the Ahlberg Bearing Canada Limited, Montreal and with Canadian SKF Co. Ltd., since graduating from McGill University in 1934.

H. Chaput, M.E.I.C., of the Ottawa Transportation Commission has been named manager of equipment and power following several years' service with the organization.

Mr. Chaput graduated from Queen's University in 1941 with a B.Sc. in electrical engineering, and completed the test course with the Canadian General

H. Chaput, M.E.I.C.

Electric Company the following year. With the R.C.A.F. as a signal officer and pilot, from that time until the end of the war, his next engineering assignment was with the English Electric Company, St. Catharines, Ont. as a design engineer. In 1949 he was appointed electrical engineer with the Ottawa Transportation Commission. He became assistant to the general manager in 1952.

C. C. Purves, JR.E.I.C., a 1950 graduate of the University of New Brunswick, in civil engineering is working with the British Columbia Power Commission at Victoria, as an assistant generation planning engineer.

Mr. Purves had previously been associated with the Montreal Engineering Company Limited, Montreal.

J. A. Dake, JR.E.I.C., a 1954 graduate of the University of Edinburgh, in electrical engineering, and formerly a design engineer with the Bell Telephone Company of Canada, has found employment with International Business Machines Company. Located at Don Mills, Ont., he is concerned with the plant engineering department.

John R. Challis, JR.E.I.C., has resigned from the staff of James F. MacLaren and Associates, consulting engineers, Toronto and has taken a position with the Saint Lawrence Seaway Authority, as specifications writer.

He is a University of Toronto graduate in civil engineering, class of 1951.

Dr. John Duby, JR.E.I.C., holds a sessional appointment with the University of Alberta electrical and civil engineering departments.

A graduate of that University, he was awarded a B.Sc. degree in chemical engineering in 1952, later attending Brasenose College, Oxford, Eng.

J. A. Cowlin, JR.E.I.C., of Victoria, B.C., has been elected secretary-treasurer of the Vancouver Island Branch of the Institute for the 1956-57 season.

An assistant engineer on the design of municipal services, he began work in this field in 1954 when he joined the engineering department of the municipality of Saanich as an engineering assistant on sewer construction.

Mr. Cowlin has also been employed with the Consolidated Mining and Smelting Company at Trail, B.C., since graduating from the University of British Columbia in 1952. He was awarded a B.A.Sc. degree in civil engineering.

R. G. Nicholls, JR.E.I.C., is with the Great Plains Development Company, Calgary. He was formerly associated with the Shell Oil Company, gas division, in that city. He is a 1954 graduate in mechanical engineering, University of Manitoba.

D. P. Murray, JR.E.I.C., has severed his connections with the Otis Elevator Company Limited and has accepted a position as sales engineer with the American Air Filter Company of Canada, located at Hamilton. He is a 1949 graduate of the University of Manitoba.

B. F. Willson, M.E.I.C., of Edmonton, has been appointed vice-president of operations with the Canadian Western

---

Correction: The *Journal* regrets that in the January issue of the *Journal* it was incorrectly stated that H. D. Scothorn, JR.E.I.C., is employed with the Department of National Defence, Directorate of Works, Ottawa.

Mr. Scothorn is a mechanical engineer on loan to the Dominion Government from the firm of A. D. Margison and Associates Ltd., Toronto.

• PERSONALS

Natural Gas Company Limited, Edmonton, and with Northwestern Utilities Limited.

On graduation from the University of Alberta in civil engineering in 1943, Mr. Willson joined the Royal Canadian Engineers. On discharge in 1945, he joined the staff of Northwestern Utilities Limited in Edmonton and became assistant general manager of that company in 1953.

A year later he was transferred to Calgary to assume the post of director of administrative services, an inter-company department of Canadian Western Natural Gas Company Limited and Northwestern Utilities Limited. Election to the board of directors of both companies followed in April 1956.

H. M. Hunter, M.E.I.C., of the Canadian Western Natural Gas Company Limited, Edmonton, has been named general manager with the organization.

A graduate of the University of Alberta, class of 1927, he joined the geological department of the gas company at that time.

Mr. Hunter served overseas with the Royal Canadian Enginers from 1939 to 1945, and on his return to Canada with the rank of major, was appointed general superintendent of the company in 1946.

In 1955 he was appointed manager of the plant division.

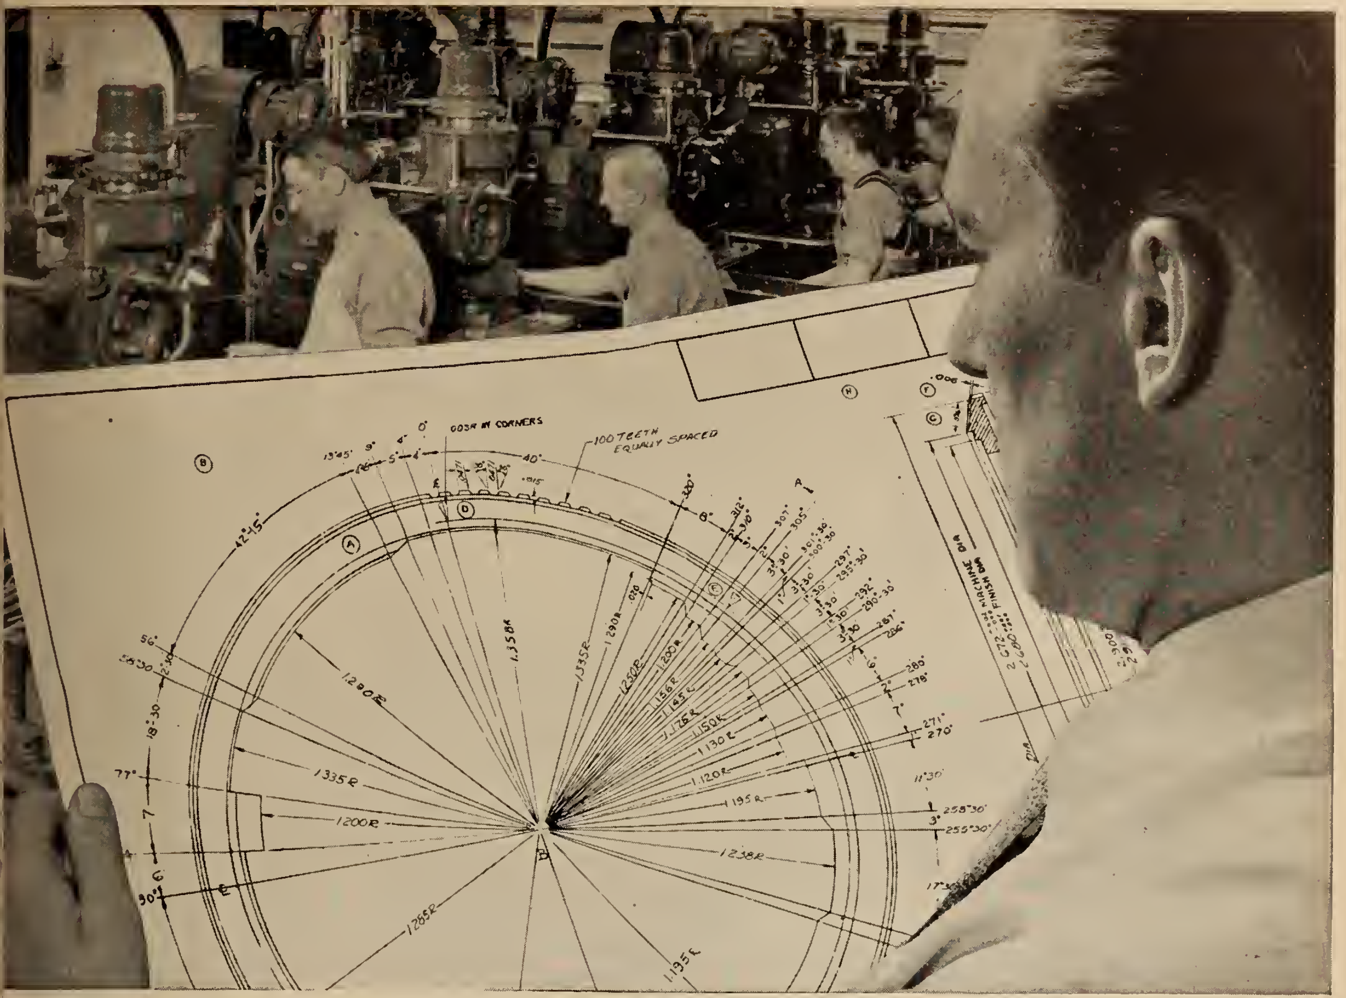
Robert B. McRuer, M.E.I.C., is methods and scheduling supervisor with Du Pont of Canada Limited, Maitland, Ont., on a new plant being constructed for the manufacture of acrylic fibre.

Mr. McRuer is a 1948 graduate of Queen's University in chemical engineering.

H. D. Brydone-Jack, M.E.I.C., of Montreal, engineer of construction with the Canadian Pacific Railway, whose employment with the organization dates to 1911, has retired and is living in Montreal.

Mr. Brydone-Jack joined the C.P.R. staff as an assistant engineer in 1911 on receiving a B.Sc. degree from McGill University. With the outbreak of World War I he went to England in 1915 and joined the Royal Horse and Royal Field Artillery. In the closing year of the war he was captain of the 29 Battery, R.F.A., with the Third Division Artillery. For his part in the battle of Loos he received mention in despatches and was awarded the Military Cross in 1918.

At war's end returning to his position as an assistant engineer with the C.P.R., he later in 1920 obtained leave of absence from the company to undertake the duties of superintendent of Sydney Junkins Company Limited, engineers and constructors. Active with the C.P.R. in



• PERSONALS

1927 he was promoted to the position of assistant manager of personnel in 1932, to acting manager of personnel in 1942 and in 1946 was named manager of that department. The following year he took over the duties of engineer of construction, the position he held at the time of his retirement.

J. A. Beveridge, M.E.I.C., city commissioner at Red Deer, Alta., since 1952, has transferred his services from that locality to the southern Saskatchewan city of Moose Jaw.

Mr. Beveridge is originally from British Columbia, where he obtained a B.A. Sc. degree at the University of British Columbia in 1947. Furthering his studies at John Hopkins University, and specializing in sanitary engineering and soil mechanics, he attained the degree of master of science in 1950. He enrolled in the management training course at the Banff School of Fine Arts in 1956.

A junior engineer with Canadian Industries Limited, he worked on plant construction during 1947-48. Later, on leaving John Hopkins University in 1950 he was for two years sanitary engineer for the province of Alberta.

During that time he was a member of the Alberta provincial board of health, a director of the Western Canada Water and Sewage Conference, and a lecturer at the University of Alberta.

Within the last few years he has served as a member of the Legislative Committee of the Union of Alberta Municipalities; as a member of an Associate Committee working on the National Building Code; and as district representative of the Community Planning Association of Canada.

M. Eagle, M.E.I.C., formerly of Sorel Que., with Quebec Iron and Titanium Corporation, has accepted a position in Western Canada with Pioneer Electric Alberta Ltd., at Red Deer, Alta.

A graduate of the University of British Columbia, class of 1948, Mr. Eagle has since that time held appointments with the Manitoba Paper Company, Pine Falls, Man., as an assistant to the electrical superintendent, and with the Canadian Brazilian Traction, Light, and Power Company, at Rio de Janeiro, before joining the Quebec firm in 1953.

J. S. MacDonald, M.E.I.C., who was last year associated with the Tide Water Oil Company, Regina in the capacity of geologist, has gone to South America. He is employed with the Venezuelan Atlantic Refining Company.

John G. Kerfoot, M.E.I.C., 1956-57 chairman of the Brockville Branch of the Institute is a Queen's University graduate, class of 1936, and is employed as a plant engineer with Automatic Electric (Canada) Limited, at Brockville, Ont.

Mr. Kerfoot began his engineering

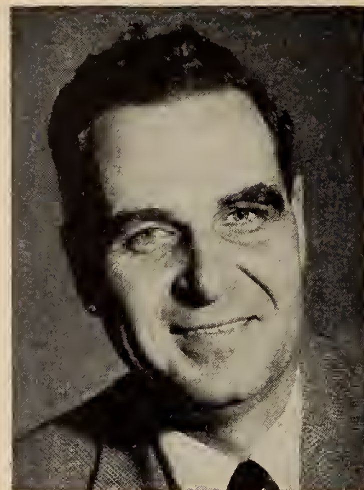
career with Phillips Electrical Works Limited in Brockville in the telephone manufacturing department shortly after his graduation. From this position he moved on to work for Defence Industries Limited during the early war years, as a supervisor on production and on tool design and process. Later, he served the Royal Canadian Navy at sea.

Associated as a partner in a small precision manufacturing business in Kitchener, Ont., at the end of hostilities, Mr. Kerfoot gave this up in 1948 to rejoin the staff of Phillips Electrical Works Limited, as an assistant plant engineer. In 1951 he transferred his services to the Kaiser Aluminum Corporation at Newark, N.J., as an assistant plant engineer.

He has been associated with the Automatic Electric (Canada) Limited since 1953.

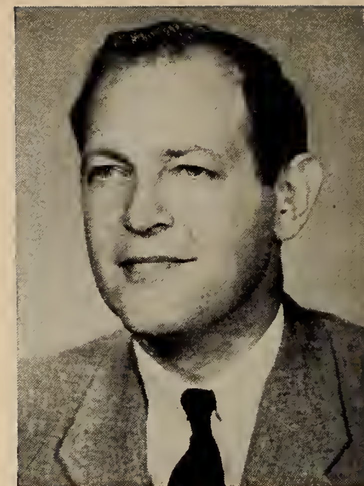


L. W. Locke, M.E.I.C.

Lorne W. Locke, M.E.I.C., now resides in Seattle and is employed with The Boeing Airplane Company as an electrical design engineer in the transport division at Renton, Wash.

Previously maintenance engineer with the B.C. Power Commission, he has also practised engineering in Winnipeg where he was on the engineering staff of the City of Winnipeg Hydro Electric System and served in various capacities in the production and engineering design division, holding the position of operating engineer from 1951 to 1955.

A graduate of the University of Manitoba, he received his degree in electrical engineering in 1948.



D. C. R. Miller, M.E.I.C.

D. C. R. Miller, M.E.I.C., has been named vice-president of Dow Corning Silicones Limited at Toronto.

Holding a professional degree in mechanical engineering from the University of Toronto, Mr. Miller was formerly associated with Duplate Canada Limited and with Fiberglas Canada Limited. He managed sales of Dow Corning Silicones at Toronto, for Fiberglas from 1948 until the formation of the present company in 1953 at which time he was appointed general manager.

He will continue as general manager of Dow Corning Silicones Limited in addition to assuming his new duties as vice-president.

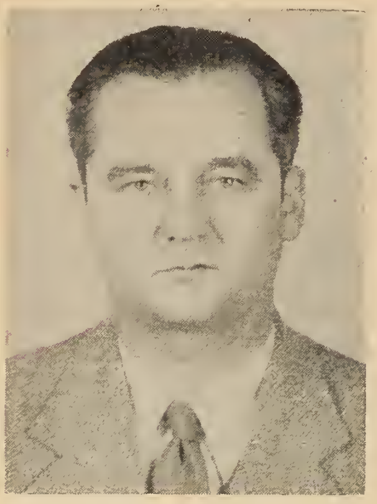
Stanley A. Barnas, M.E.I.C., supervisory civil engineer in the office of the area engineer, Corps of Engineers, U.S. Army, Goose Bay, Labrador, is engaged on the construction of the Goose Air

• PERSONALS

Base, the Pinetree Line and Mid-Canada Line.

Resident in Canada since 1954, he is a native of Poland, and had his engineering training in England after World War II. He graduated from the South West Technical College and School of Art, London, class of 1951, on completion of a four-year course in civil and structural engineering.

Mr. Barnas served with the Polish Army during the war, in the Middle East and in Italy.



S. A. Barnas, M.E.I.C.

Following his graduation Mr. Barnas was employed with the Lummus Company Limited, designing engineers and constructors for petroleum and chemical industries, of London, England, as a structural engineer, and also with Orlit Limited, Colnbrook, Eng., as senior engineer.

He is an engineer-member of the Society of American Military Engineers, and an Associate Member of the Institution of Structural Engineers.

E. Heaton, M.E.I.C., a graduate of the National University of Ireland, class of 1947, has accepted a position with the Montreal Engineering Company, consulting and operating engineers, civil engineering section, at Montreal.

Mr. Heaton was formerly associated with the St. Lawrence Seaway Authority, hydraulics section, at Montreal and carried on the work of investigation engineer.

N. F. Stewart, JR.E.I.C., is the choice of the Prince Edward Island Branch of the Institute for chairman, for the term 1956-57. He was elected to the executive in 1955.

After a war record in which Mr. Stewart served with the Royal Canadian Artillery, and with the R.C.A.F., he enrolled at Dalhousie University to begin engineering studies. Awarded a diploma in engineering from that college in 1949, he went on to further studies at the Nova Scotia Technical College and in 1951 obtained the degree of Bachelor of Engineering.

Field engineer with H.M.C. Dockyard, Halifax, in the civil engineering and maintenance department, for the next two years, he accepted his present position with the County Construction Company Limited in 1953 and serves as construction engineer and estimator with the firm.

S. Cherry, JR.E.I.C., formerly on the staff of the University of Manitoba civil engineering department, has gone to Vancouver where he is at work at the University of British Columbia, also in the civil engineering department.

Mr. Cherry graduated in 1949 from the University of Manitoba, and carried out graduate research work at the University of Illinois. Later he was associated with the University of Bristol engineering laboratories.

Dr. C. R. Cupp, JR.E.I.C., has left the International Nickel Company of Canada, Copper Cliff, Ont., research department and has accepted a position with the Canadian Westinghouse Company Limited, Grimsby, Ont.

Senior metallurgist, in the metallurgical-mechanical section, research and development laboratories, Dr. Cupp is a University of Toronto graduate. He was awarded a B.A.Sc. degree in metallurgy in 1950, followed by a Ph.D. in 1953.

V. G. MacWilliam, JR.E.I.C.

E. J. Grant, JR.E.I.C.

V. G. MacWilliam, JR.E.I.C., of Atholville, N.B., secretary-treasurer of the Northern New Brunswick Branch for the present term of office, is a native of Petitcodiac, N.B., and a 1949 graduate of the Nova Scotia Technical College.

Mr. MacWilliam, who also has an engineering diploma, gained at Dalhousie University prior to enrolling at N.S.T.C., worked for three years as a machinist in St. John, N.B., before commencing his studies.

With the Nova Scotia Power Commission as a construction engineer on mill renovation at Trenton, N.S., from 1949 to 1951, he has since then spent a number of years in the same type of work with Irving Pulp and Paper Limited, as a construction engineer at Lancaster, N.B.

At present Mr. MacWilliam is associated with the Restigouche Company Limited, Atholville, which he joined in 1955.

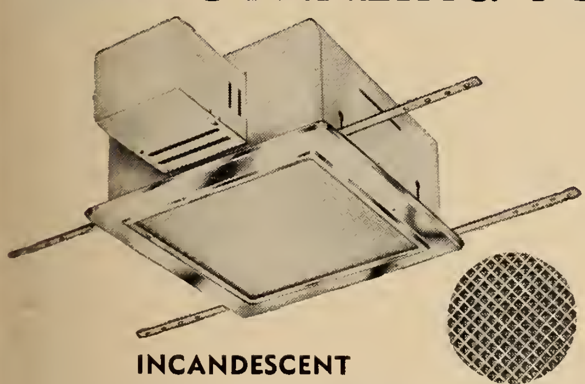
Active in the Canadian Pulp and Paper Association, Atlantic Branch, technical section, as mill representative for Irving Pulp and Paper Limited, in 1954, he also acted as mill representative for the Restigouche Company, Limited during 1956.

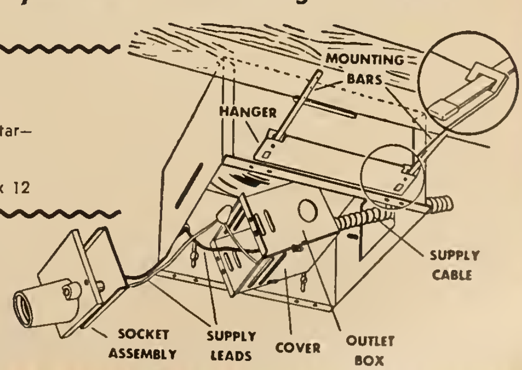
E. J. Grant, JR.E.I.C., a 1954 graduate of the University of New Brunswick, for the past two years studying in Great Britain under the provisions of an Athlone Fellowship, returned to Canada a number of months ago and is employed with the Foundation of Canada Engineering Corporation, Montreal, as a structural engineer.

While in Great Britain, Mr. Grant spent one year at Imperial College, London University, where he specialized in the study of pre-stressed concrete, under the supervision of Dr. A. L. L. Baker. He was honored in the award of the D.I.C. (Diploma of Imperial College).

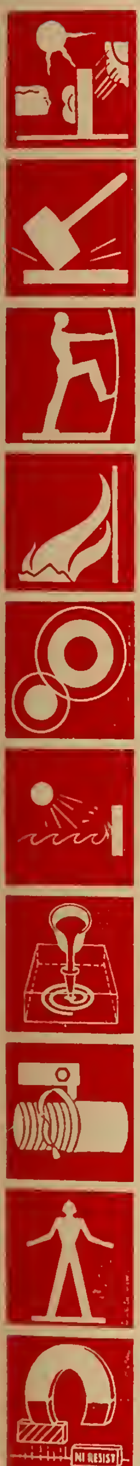
During his second year he was asociated with a consulting engineering firm, also located in London.

While abroad Mr. Grant had the opportunity to visit industrial plants, touring several European countries.





ɔ other cast metal provides ɛeful engineering properties



Corrosion Resistance: Countless problems involving the handling of acids, alkalies and salts have been satisfactorily solved by ductile Ni-Resist austenitic irons.

Toughness: The impact resistance of ductile Ni-Resist irons is comparable to that of steel at ordinary temperatures. Also like other nickel-containing austenitic alloys, it suffers no appreciable embrittlement at sub-zero temperatures.

Ductility: Ductile Ni-Resist irons provide appreciable elongation in the tensile test (4 to 40%), and can be bent and twisted like mild steel.

Heat Resistance: Up to 1300°F., with some types as high as 1500°F. Ductile Ni-Resist Irons greatly reduce the oxidation rate but enable the oxidation products to adhere to base metals, making them especially useful in engine manifolds and superchargers.

Wear Resistance: Engine and pump liners, pistons, bearings, glands and other metal-to-metal rubbing parts last longer and perform better, especially under corrosion conditions, when made of ductile Ni-Resist irons.

Erosion Resistance: Corrosive slurries, wet steam, etc., are extremely erosive on most metals. The ductile Ni-Resist series of alloys shows economical service under many erosion conditions.

Fluidity (Castability): The good flowing quality of ductile Ni-Resist irons in the molten state permits making intricate designs which are difficult to provide in some other cast metals.

Machinability: The machinability rates of ductile Ni-Resist irons are of the same order as those of conventional pressure type gray iron. Both of these factors aid materially in producing finished parts economically.

Controlled Expansion: Expansivities from 4.5 to 10.4 millionths per °F are available with various types of ductile Ni-Resist Irons. Metals of different expansivities can be matched with selected Ni-Resist types.

Non-Magnetic: Some types of ductile Ni-Resist irons are non-magnetic and therefore are useful in many applications in the electrical and allied fields where this quality, plus machinability, heat resistance, etc., are required.

Controlled Volume Pumping

J. W. Halls of Consolidated Engines and Machinery Company, Montreal, delivered a comprehensive talk supplemented with slides, on controlled volume pumping, at the general meeting of the Belleville Branch, held December 10, 1956.

The pumps used are almost invariably the piston type having adjustable stroke length. The volume pumped is generally controlled using thymotrols for varying the speed of the D.C. motor driving the pump. The thymotrol unit itself is activated by a flow recorder of various types. Of particular interest was the method in which air could be employed as the medium for controlling the output of the pumps.

While controlled volume pumping could no doubt be accomplished by other means such as a variable speed centrifugal pump, the extreme accuracy (tolerance of less than 1 per cent) of the piston type of pumps together with a duplicate valve system makes them highly preferable for formulating products in the chemical and allied industries.

Mr. Halls brought with him two types of controled volume pumps, one of which he dismantled in order to show the component parts. Considerable interest was shown by the group in the two models displayed.

CAPE BRETON

W. L. DODSON, M.E.I.C.,
Secretary-Treasurer

E. J. PRINCE, M.E.I.C.,
Branch News Editor

Annual General Meeting 1956

The annual general meeting of the Cape Breton Branch was held on Friday, December 14, 1956, at the officers' mess, Victoria Barracks, Sydney, N.S. E. Jack Prince was in the chair at the beginning of the meeting, his place being taken later by W. A. MacDonald, newly elected chairman for 1957.

Mr. Prince thanked the 1956 committee for their whole-hearted support during the year. He also thanked Branch members for their enthusiasm in attending meetings. A successful year in every way for the Branch, meetings had been well attended in 1956 and a variety of technical and engineering subjects dealt with by a number of capable speakers.

The secretary then gave his report and this was followed by the reports of the sub-committee chairmen. The thanks of the branch were extended by the entertainments sub-committee chairman to all those companies who had materially helped in making the dinner meetings a success.

The secretary then gave his report Park and Cliff Roach, reported that the following Branch officers and executive had been duly elected for 1957: W. A. MacDonald, Branch chairman; V. Palmer, vice-chairman; W. A. Dodson, secretary; C. A. Campbell, treasurer.

The executive committee consists of D. Wilson, R. Bradley, J. Richard, H. Aspinall, G. W. Ross, H. Maitland, and F. MacDonald.

M. R. Campbell has been chosen as the Member of Council and J. R. Wallace elected to the nominating committee.

Publicity Chairman

Cornwall Student Bursary

Friday, December 7, 1956 was the date of an interesting and important event in the history of the Cornwall Branch, and indeed in the affairs of the Institute. Before a dinner meeting of branch members and their ladies, E.I.C. president, V. A. McKillop presented for the first time the Colonel W. H. Magwood Bursary.

These cash grants are for the purpose of assisting engineering students to obtain a course at a university of their choice. Candidates are restricted to residents of the three counties surrounding Cornwall, and high academic standing is not the only criterion for selection. The eligible students must also be financially deserving of help, and with a

The presentation of the Colonel Magwood bursary. Shown together, left to right, are: Drummond Giles, chairman of the bursary committee, Kent Plumley, H. R. Sills, of Peterborough, V. A. McKillop, president of the Institute, Jack Morris, chairman of the Cornwall Branch, John Hawkes, councillor, and Donald Plumley.

recognizable zeal for a higher engineering education. The bursary has been named to honour Colonel W. H. Magwood, a retired engineer living in the same city, and a well known and greatly respected citizen of the Cornwall area. He became a leading figure in the professional life of that community, and served for many years as the city engineer.

President's tour of the St. Lawrence Seaway Power Project. Left to right are: V. A. Harrison, D. C. McEwan, W. Rothwell, Jack Morris, chairman, Cornwall Branch, G. Mitchell, director of the Project, all of Cornwall, and E. C. Luke, Associate Editor of the Journal, President V. A. McKillop, and William Hogg, field project engineer.

On this occasion the recipients were two brothers, Kent and Donald Plumley, and each one was given a certificate and the sum of $600.00 to pursue his studies at Queen's University, Kingston. Those who attended the presentation could not help being impressed with the high calibre of the young men selected.

The funds to create this bursary were collected locally by the Cornwall Branch, through a committee under the chairmanship of Drummond Giles, M.E.I.C., a past vice-president and councillor of the Institute, and prominent member of the Branch.

The *Journal* and the officers of the Institute wish to pay a special tribute to those of the Cornwall Branch whose imagination and initiative have brought this fine bursary into being. We think it makes a fine target for other branches to aim at in their similar endeavours.

President's Visit

On the occasion of the president's visit to the Cornwall Branch, December 7, President McKillop, accompanied by E. C. Luke, Assistant General Secretary, joined the executive of the Cornwall Branch, headed by chairman Jack Morris, for a luncheon at the Cornwallis Hotel.

NOVA SCOTIA PENSTOCK

Engineered and installed by the Nova Scotia Power and Light Company, Ltd., this 66″ line was covered from 4′ to 17′ deep. Pipe was made by Halifax Ship Yard; pipe and couplings were bituminous coated. Wall thicknesses range from $3/8''$, $1/2''$, $9/16''$ to $5/8''$ for line pressures of up to 195 psi.

BIG JOB, SMALL WRENCH

From a reservoir served by the Nictaux River, 100 miles southwest of Halifax, water now flows via canal and wood stave pipe to this 3312′ Dresser-Coupled steel penstock.

The lighter weight, high-strength steel pipe was delivered to the job with Dresser Coupling middle rings and followers already in place. It was a simple matter to swing the long pipe lengths into the ditch. Then workmen put in the bolts and tightened the end nuts. *A wrench was the only joining tool required.*

That's how it is on all Dresser-Coupled jobs. No expensive skills or equipment are needed. Work can proceed in any weather at an average of only two man-minutes per bolt. And there's no need for exact pipe fitting or alignment. The resilient rubber gasket in every Dresser Coupling absorbs line stresses, strains and movement . . . permits expansion and contraction . . . keeps joints bottle-tight and trouble-free for life!

BEFORE YOUR NEXT PENSTOCK PROJECT, **write for helpful, interesting engineering data on the many successful and varied Dresser-Coupled, steel-pipe penstock installations.**

DRESSER® ONE OF THE DRESSER INDUSTRIES

Dresser Manufacturing Company, Ltd., 1211 Bathurst St. Toronto 4, Ontario; 1210 11th Ave., W., Calgary, Alberta. Distributors: B.C. Equipment Co., Vancouver, B.C.; J. T. McAvity, Winnipeg, Manitoba.

• BRANCH NEWS

A brief but lively discussion on the question of Confederation took place during the affair.

Later the group drove west of Cornwall to Ontario Hydro's administration building, headquarters for the St. Lawrence Power Project. The president met Gordon Mitchell, M.E.I.C., project director, and renewed acquaintances with W. M. Hogg, M.E.I.C., field project engineer

Tour of Project — Mr. Mitchell and Mr. Hogg conducted the president and his party on a tour of the Project which included the main dam and power house at Barnhardt Island, the Long Sault control dam on the American side of the St. Lawrence River and the Eisenhower lock on the U.S. section of the St. Lawrence Seaway. On returning to the Canadian side the president was shown the house moving operation, where houses were being removed from the village of Wales which will be completely flooded by the head pond of the power house. The new town of Long Sault was the last point of interest. This town, which will replace the villages of Mille Roches and Moulinette, is now well established with over 100 houses having been already moved into it.

In the evening, the dinner meeting at the Northway Hotel was very well attended by the branch membership.

After a most enjoyable meal and the presentation of the Colonel Magwood bursary, the president delivered an interesting address on the Engineering Institute of Canada under three main headings; Its Ambitions, Its Achievements and Avenues Ahead.

Mr. McKillop also expressed a keen interest in seeing the confederation of engineers become a reality. 'The problem presently facing the Associations in each of the provinces is not unlike that faced by the Fathers of Confederation," he said. "We should, like them, emphasize the common ground and minimize our differences and proceed with confederation with faith in its ultimate success." It was, he felt, becoming increasingly essential to have unified representation of all professional engineers in Canada on both national and international questions.

The president was thanked by John Hawkes, Branch councillor, who expressed the very real pleasure the presidential visit had afforded.

Mr. Luke expressed the thanks of the Montreal headquarters and himself for the hospitality which had been so evident. He also, on behalf of the head office of the Institute, expressed their desire to be of service to all members whenever possible.

Branch chairman, Jack Morris, subsequently adjourned the meeting.

Corrosion Film Discussed

Members of the Hamilton Branch have expressed interest in having dinner meetings with guest speakers. The first such meeting was held on November 15 when fifty members gathered for dinner and heard R. J. Law, of the International Nickel Co. comment on the company film "Corrosion in Action". There are few products today which are sold in their natural state that is, without some protective coating. The prime material for the purpose is paint. However, there are many conditions under which paint is not applicable, for example, where moving parts are involved in machinery. It is in this field of protection that alloys play an essential role. Nickel is one of the basic corrosion resistant metals. Its main use is in alloys, hence International Nickel is vitally concerned with research to further the application of its product. At Kure Beach, North Carolina, Inco has established a large corrosion testing station where over 25,000 test samples are exposed to marine atmosphere. By observing the reactions of these samples to weathering, facts are obtained which lead to action in research, producing in turn advances in protective coatings.

The three part film covered the nature of corrosion, electrical potential between anode and cathode with the resultant flow of electrons, the origin and characteristics of corrosion current, and finally, passivity or resistance to corrosion, and protective films. The movies were extremely well edited in colour and time-lapse photography was used to great advantage.

J. J. Kelly, branch chairman, presided over the meeting, and A. E. Archibald, executive committee member, expressed the appreciation of the meeting to Mr. Law.

Ladies' Night

The Professional Development Program has another first. A 'Ladies' Night' was held on November 23 at the Royal Hamilton Yacht Club. To insure that the ladies would be invited to attend the dance, a letter was sent by the executive giving details of the event. The response was very encouraging, nearly 100 couples attended and enjoyed dancing, a skit by some of the talented members and a buffet supper. The evening was so successful that it is expected that the Ladies' Night will become an annual event.

The P.D.P. has outlined its constitution in a 16-page booklet which will be dis-

tributed across Canada as a guide to other programs.

Uranium Development Outlined

The second dinner meeting of the fall program was held on December 13, 1956, with R. M. Way of R. M. Way and Company Ltd., Toronto, as guest speaker. This consulting engineering firm is responsible for seventy-five per cent of the uranium development in Canada. Mr. Way emphasized the importance of Canadian uranium in the world today. With one of the world's largest sources of uranium at Blind River, Ont., Canada will be by 1958 the top supplier of this mineral. The extent of our supply of uranium is indicated by the fact that from 1958 to 1963 Canada will export 350 million dollars worth of U308 to the United States annually. It is felt that the advent of atomic energy will bring about an industrial revolution with new applications of this new form of energy being developed continually. The United States is spending 25 million dollars a month on atomic energy.

Four Main Sources — There are four principal sources of uranium in Canada. These are Beaver Lodge, Northern Saskatchewan, Bancroft, in Ontario, Eldorado in the Northwest Territories and Blind River, near Sault Ste. Marie, Ont., where 33,000 tons of ore are mined a day. The cost of refining the ore is tremendous, one ton of uranium U308 ore is worth $10.00 and one pound of pure uranium costs $5200.00.

In Canada today the ore is mined, crushed and ground, and leeched with caustic soda or sulphuric acid. This ore is then shipped to the United States where it is refined to produce pure uranium.

This subject "Canadian Uranium Developments" is a topic of vital interest and much of the information has been released only in the past month. Mr. Way is an authority in this field and

A joint dinner meeting of the Eastern Townships Branch and the Corporation of Professional Engineers of Quebec was held at Sherbrooke, Que., on Friday, Nov. 23, 1956. Among those attending were, left to right; A. Crepeau, G. Piette, G. M. Dick, J. Bourque, Leo Roy, G. Masse, and J. Lemieux.

provided a very interesting and informative evening.

J. J. Kelly, branch chairman, presided over the meeting and H. E. Seely, executive committee member thanked Mr. Way on behalf of the forty members in attendance.

LETHBRIDGE

R. J. D. GARDNER, JR.E.I.C.,
Branch News Editor

R. D. HALL, JR.E.I.C.,
Secretary-Treasurer

Dr. L. A. Wright Guest of Honor

A combined dinner meeting and ladies' night was held on November 15 in the El Rancho banquet room at Lethbridge. Dr. L. Austin Wright, general secretary of the Institute was the guest of honor and expressed the regrets of the president, V. A. McKillop, called back from his Western tour in being unable to attend.

He then went on to review the history of the Institute, pointing out that it is the largest society of its kind in Canada, and that the production of the *Journal* is the biggest publishing job of its kind in Canada today.

Commenting on the shortage of engineers, Dr. Wright quoted The Honorable C. D. Howe as saying that there should be a slight shortage of engineers, this being evidence of an advancing economy. The shortage should not, however, be allowed to become too severe.

Although freshman registration in engineering is up 18 per cent this year and overall engineering student registration is up 12 per cent, the demand for engineers still far exceeds the supply. Immigration of engineers, which until recently exceeded graduation, is now dropping of, and this will also contribute to the shortage, which in a few years could reach serious proportions.

Answer to Shortage — The answer to the shortage of engineers, Dr. Wright felt, is the engineering technician. These men, trained in mathematics and engineering design, would release many engineers for more advanced work. Engineering technicians would be easier to train than engineers, but so very few schools offer such a course. It is felt that the provincial governments should institute such courses and thereby materially reduce the present and future shortage of engineers.

During the evening an excellent musical program was enjoyed. This included duets by Temple Sinclair and Mrs. Sinclair, accompanied by Mrs. R. D. Hall, vocal numbers by Miss Ella Findlay, and piano and violin numbers by George Brown and Mrs. Brown.

Another guest of the evening was Mayor T. R. Haig, who welcomed Dr.

• BRANCH NEWS

Wright to Lethbridge. Dr. Wright was introduced by N. H. Bradley and thanked by E. A. Lawrence.

Branch chairman A. J. Branch presided at the meeting, and R. D. Hall introduced guests.

Secretary-Treasurer

Engineers' Wives Association

The first meeting of the Engineers' Wives Association was held recently at the home of Dr. and Mrs. G. T. Leighton.

The thirty-four members present were welcomed by Mrs. Wickwire, wife of R. M. Wickwire, chairman of the Moncton Branch, who announced that the slate of officers will act until the annual meeting next May.

Elected president was Mrs. M. F. K. Leighton; vice-president, Mrs. G. Peck, and secretary-treasurer, Mrs. V. C. Blackett.

In addressing the members Mrs. Leighton spoke of the activities of wives' associations active in the Maritimes at St. John and Halifax, and outlined plans for the coming season.

Highlight of the evening was a film entitled 'Iceland Today'. Later, bridge was played and refreshments served.

NORTHERN NEW BRUNSWICK

V. G. MACWILLIAM, JR.E.I.C.,

F. M. Ross Addresses Meeting

The December meeting of the Northern New Brunswick Branch of the Engineering Institute of Canada was held in the New Florence Hotel, Campbellton, N.B., on Saturday, December 8. Engineers from Northumberland, Gloucester and Restigouche Counties were in attendance. The meeting which included a short business session was presided over by the chairman of the Northern New Brunswick Branch, A. R. Bonnell.

Guest speaker for the evening, F. M. Ross, supervisor of the pilot plant in the Restigouche Co. Ltd. research department at Atholville, was introduced by V. G. MacWilliam. He gave a very interesting talk on the operation and control of pulpwood processing and described, with supporting graphic tabulations, some of the projects that are being studied in this department. His topic was a familiar one to many of the engineers in this area who are associated with the pulp and paper industry.

A buffet lunch was served during the discussion period which followed.

OTTAWA

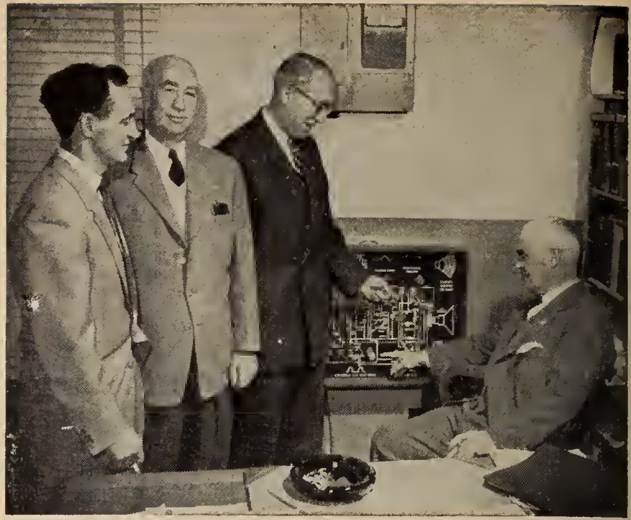
President Visits Ottawa

Young engineers rise to responsible positions more quickly in Canada than in the United States. This encouraging news was revealed by president V. A. McKillop to the engineering students of the University of Ottawa and Carleton College during his visit to the Ottawa Branch on December 6, 1956.

Accompanied by Assistant General Secretary E. C. Luke and later joined by the General Secretary Austin Wright, President McKillop was introduced to the many activities of the local branch

during his brief visit to the nation's capital. After speaking to the students of the two local engineering schools the president held a press conference and attended a regular luncheon meeting of the Branch. In the afternoon he sat in on a meeting of the management committee and, with Mrs. McKillop, joined the committee members and their wives at supper. Later in the evening he met and addressed the general membership of the Branch at a reception.



During the president's visit to the University of Ottawa, vice-Dean Dr. R. U. Lemieux, Col. W. P. Pennock, Branch chairman, and Mr. McKillop, standing, chat with Professor R. H. Galbraith.

Engineering Future in Canada — President McKillop met with Vice-Dean Dr. R. U. Lemieux and Professor R. H. Galbraith at the University of Ottawa. Speaking to the engineering students in the auditorium of the new medical building, he told them to look to Canada if they aspired to a real future in engineering. Jean Belanger, speaking on behalf of his fellows, thanked the president for his interest in their future.

Carleton College — Dean S. G. Takaberry and Professor E. E. Goldsmith welcomed the president to Carleton College. This was the seventh group of students that the president had addressed during his term of office and he urged them to aim high, but with true perspective, when planning their career in engineering. G. C. Langdon, student, introduced the president and M. Ross Jackson, also of the student body, moved a vote of appreciation.

The president was accompanied on his visits by Col. W. B. Pennock, Branch chairman, and Stewart B. Frost, vice-chairman of the Junior Section.

Canadian Shipbuilding — Richard Lowery, president of Davie Shipbuilding Limited, painted a gloomy future for Canadian Shipbuilding in his luncheon address to the Ottawa Branch. Without federal government help and assistance he warned that shipbuilding in Canada could not be maintained virile and ready for the emergency of war.

Mr. Lowery pointed out that our coasting trade must be restricted to ships owned and built in Canada. This would prevent vessels of U.K. registry, with their lower operating and capital costs, from competing with our own ships. The deepening of the St. Lawrence would under our present policy of free trade, deal a crippling blow to Canadian Great Lakes shipowners and to the builders of their ships.

With Mr. Lowery at the head table was President McKillop who spoke briefly. Other guests of honour were Mrs. E. M. Lett, executive secretary of the Canadian Shipbuilding Association, L. C. Audette, chairman of the Canadian Maritime Commission, and Rear Admiral W. W. Porteous, chief of Royal Canadian Naval Technical Services. Mr. Lowery was thanked by B. G. Ballard past vice-president of the E.I.C.

Supper at Chateau Laurier — At an informal supper in the Canadian Grill of the Chateau Laurier, the president and Mrs. McKillop dined and danced with the wives and members of the Ottawa Branch management committee. Following the supper the group proceeded to the R.C.A.F. Officers' Mess where Mr. and Mrs. McKillop received the members of the local branch. In his address the president commended the Ottawa Branch for its most active part in erecting the memorial to Colonel By.

Mr. McKillop advised that engineers might be better guided in choosing their way of life by asking themselves what other people want rather than what they want themselves. He pointed out that as employees (97 per cent) we tend to concern ourselves only with technical matters and leave the social implications of our work to employers and politicians.

Shown enjoying the reception held in Ottawa are, left to right: Col. W. B. Pennock, Ottawa, Branch chairman, Mrs. V. A. McKillop, Dr. Austin Wright, General Secretary, Mrs. Pennock and President McKillop.

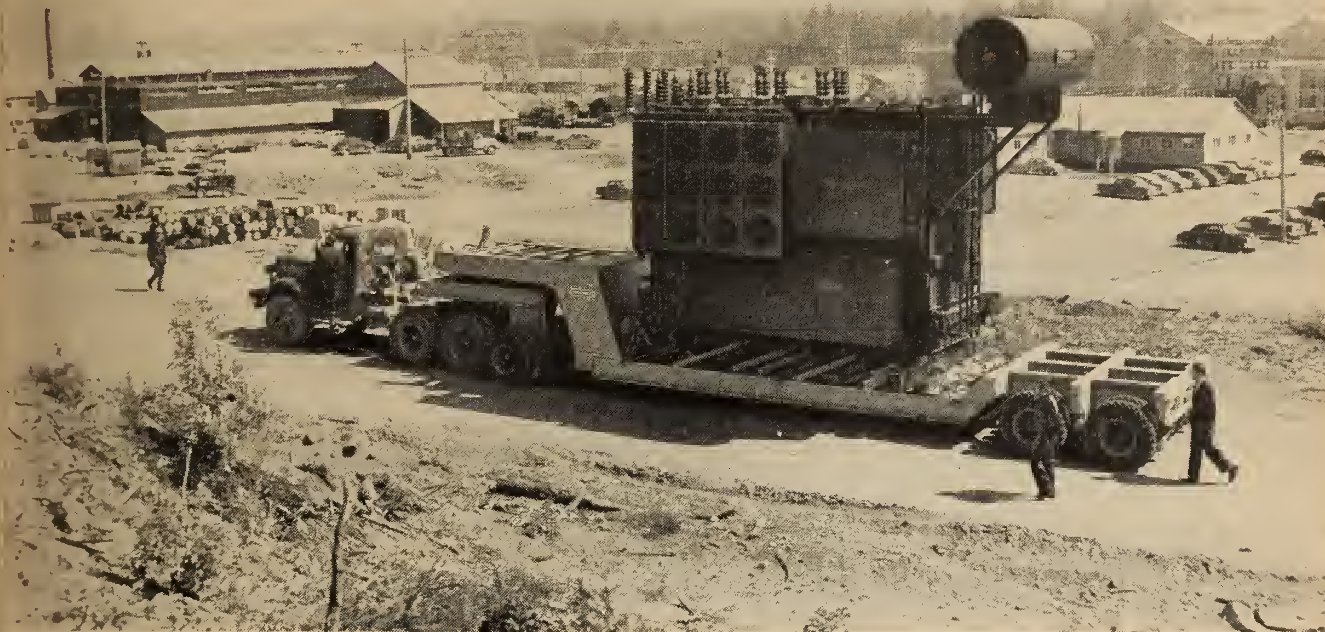
L. F. MASON-TULBY, M.E.I.C.,
Secretary-Treasurer

Mackinac Straits Bridge Construction

Guest speaker at the November meeting of the Branch was J. W. Kinney, resident engineer for the Mackinac Straits giant bridge construction project, representative for the State Bridge Authority, and for Dr. D. B. Steinman, the designer and consultant.

Introduced by L. Mason-Tulby, secretary-treasurer of the Branch, the speaker gave an interesting technical address on the second phase of construction of the giant Mackinac bridge, starting after virtual completion of the abutments, piers and anchorages, and covering erection of the great towers, a large proportion of the approach spans of structural steel, and the threading across and spinning of the huge steel cables for the central suspension span.

The address was graphically illustrated with coloured slides, and some interesting and unusual features of design emerged. As a matter of interest some broad comparisons were made with the famous Golden Gate bridge at San Francisco. Whereas the central suspension span of Mackinac is 3,800 feet, being shorter by 400 feet, the total bank-to-bank gap of four miles here involves a



• BRANCH NEWS

greater total of approach spans. Furthermore the gulley is much deeper, which posed special engineering problems.

While the San Francisco structures incorporates eight lanes, including railroad lanes, the Mackinac Bridge has only four lanes, without railways but with provision for their future inclusion. *Design for Safety and Stability* — For the sake of lightness, easy snow clearance and greater stability under wind loads, the two inner roadways are to be of open grating, with serrations to ensure good traction. In such matters a new bridge presently under construction benefits by the elimination of undesirable factors, and the inclusion of advantageous features culled from experience. As is now becoming widely known, the outstanding design of Dr. Steinman includes some most important features for safety and stability, such as the system of cross-bracing which is being employed.

After covering the technical field, Mr. Kinney added a few facts of general interest. At any one time the number of men on the site reaches one thousand. The present target date for completion of the bridge for actual passage of traffic is November 1957. To cover the cost of this structure the bond issue is $99,800;000 and the expected toll charge will be similar to the present ferry charge. In regard to maintenance, the State Bridge Authority has undertaken to contribute around $400,000 annually.

Accompanying Mr. Kinney to the Branch meeting were Mr. Bell, assistant public relations officer for the Mackinac Bridge Authority and also Mrs. Kinney and Mrs. Bell.

SUDBURY

H. M. WHITTLES,
Secretary-Treasurer

H. F. COFFIN, JR.E.I.C.,
Branch News Editor

H. D. Hamilton is Speaker

The regular monthly dinner meeting of the Sudbury Branch was held on November 15 at the Granite Club with about 30 members present.

The guest speaker, H. D. Hamilton, manager of Electrical and Silastic Sales for Dow-Corning Silicones Limited, was introduced by E. Savage. Mr. Hamilton's subject was "What's the Silicone".

Mr. Hamilton had given this lecture at Belleville on November 12, and since it is summarized in the Belleville Branch report, January issue, it will not be repeated here.

Telephone Switching Systems

The December meeting of the Sudbury Branch was held in the Legion Memorial Hall, Sudbury, Ont., on December 6, 1956. About 25 members attended.

Guest speaker of the evening was R. W. Vowcott, equipment engineer of the western area of the Bell Telephone Company, who spoke on "Telephone Switching Systems". Mr. Vowcott outlined the progress made in telephone systems from the magneto party line to the present step-by-step dial systems, with the aid of slides. The manual boards were restricted in capacity so that in the larger centres they have been replaced by automatic equipment which performs all the functions formerly done by operators.

The speaker went on to describe the crossbar system that is just coming into use. It is an improvement over the step-by-step dial system in that less equipment is required to do the same amount of work and hence less maintenance and office space.

Mr. Vowcott also discussed the Electronic Switching System being developed to make possible long distance sta tion to station dialing without the assistance of an operator. He concluded his talk by saying, "All this progress has gradually come about because of the telephone company's desire to give better and increased service at the lowest cost."

The speaker was introduced by T. C. Robertson and thanked by W. Ibbotson.

TORONTO

L. F. BRESOLIN, JR.E.I.C.,
Secretary-Treasurer

A. C. DAVIDSON, M.E.I.C.,
Branch News Editor

Report on Seaway Progress

About seventy members and guests heard D. M. Ripley, JR.E.I.C., give a report on seaway progress at a meeting held December 6, 1956. Mr. Ripley, the senior assistant engineer for hydraulics of the St. Lawrence Seaway, was introduced by Lance Farrand, of the Toronto Branch.

The report was as up to date as Mr. Ripley could make it. He had obtained a number of aerial views of the work about three weeks previously which greatly enhanced the exposition.

Halfway Mark Reached — Mr. Ripley, who listed a great many interesting facts about the seaway reported that the seaway was at about the halfway mark. At present the construction was in the most interesting stage. Variius parts were still evident, but would soon be hidden by ponded waters or earth dikes.

Some $160,000,000 worth of contracts had been awarded in the Canadian works of which $45 million were complete. American totals were $13 million and $74 million respectively.

It was interesting to note that views of the construction of the compensating channel at Cornwall, had just been released that evening. This compensating channel would make Cardinal a deep water port, and retain water on the Canadian side of the river, which would otherwise be diverted by the American works. The presence of the channel would also make construction of an all Canadian seaway comparatively easy.

To be Ready in 1959 — It was hoped that the seaway would be completely finished in 1959. A 14-foot channel would be ready in 1958 with power being produced.

Necessity of Iroquois Dam — In the discussion a point was made clear concerning the necessity of the Iroquois dam. Mr. Ripley pointed out that for one thing, the dam was necessary because it separates two ice forming regions in the river; for another, the Iroquois dam would be in operation before the downstream structures were finished and would therefore control the river level during the construction. The power house forebay would be at elevation, 238 for some 10 years, so the head at Iroquois would be perhaps 7 feet.

Thanks for a most interesting paper were tendered by E. R. Davis.

Talk on Semi-Conductors

On November 2, Professor V. G. Smith of the University's electrical engineering department spoke before an audience of sixty members, at an evening meeting held in the mechanical building, University of Toronto. The talk was intended for those who know the fundamentals of electrical phenomena, and was eminently successful in making clear exactly how the transistor or semi-conductor works.

History of Phenomena — Professor Smith traced the history of phenomena connected with semi-conductors, from Faraday's experiment with the negative temperature co-efficient of Silver Sulfate, to the transistor itself which appeared in commercial form in 1946.

Professor Smith dwelt for some time on the underlying electronic phenomena. In summing up, he told of the applications of semi-conductors where weight and space are at a premium, such as in aircraft and in hearing aids, to contrast two extremes.

Speculation on Future — It is interesting to speculate on the future of the semi-conductor. Even now the space and weight saving features and the low power consumption are causing a revolution in the field of computer construction.

The thanks of the group was tendered by H. Patterson.

Ladies' Night

On November 8, the annual Ladies' Night was held at the Embassy Club on Bloor Street. A very pleasant informal evening of dining, dancing and conversation was enjoyed by some 200 people. Arrangements for the evening were under the able direction of Tom Denby, and Ross Norgrove. The Branch chairman, Ken Tupper, made everyone welcome, and helped materially to promote the informal atmosphere of the evening.

R. L. Hearn is Speaker

Dr. Richard L. Hearn, M.E.I.C., of the Hydro Electric Power Commission of Ontario addressing members of the Joint Committee of the E.I.C. and the I.C.E. in Cody Hall, at the University of Toronto, November 13, spoke on the subject, "The Sir Adam Beck Generating Station No. 2, A Major Canadian Hydro Electric Development". An interesting evening was spent by an audience of fifty people who learned of some of the ingenious arrangements in the design of the development. The hydraulics of the canal cross-over were an important feature of the whole scheme. Other phases of the design were of considerable interest also, notably the curtain of air bubbles used to protect the headrace of the existing station during blasting.

Program of the Joint Area Committee

The 1956 program concluded on December 13 with a paper on "Engineering Aspects of Municipal Subdividing", by M. Couse, Jr. E.I.C., chief engineer, Scarborough Branch, Proctor, Redfern and Laughlin.

Meetings were scheduled for Feb. 7 and March 7. A paper on "Planning for Future Highways in Ontario", was given by W. J. Fulton, Dir. of Planning, Dept. of Highways of Ont. "Application of Computing Machines to Civil Engineering Design Problems" is to be given in March.

April 4, 1957, will be an "Open Night". For this occasion, original papers of civil engineering interest are invited. Any member wishing to present a paper should write the Secretary; B. Hardcastle, c/o McColl Frontenac Oil Co. Ltd., 8 Spadina Road, Toronto, Ontario.

Miles Green Presents Paper

On November 28, 1956, the Vancouver Branch heard a paper presented by Miles Green, chief engineer of the North West Telephone Company, entitled, "The Trans-Canada Micro Wave System". The paper has been summarized by S. S. Lefeaux, Branch chairman, as follows: "Mr. Green described in general terms the construction of the trans-continental micro wave system which will carry simultaneously three television programs and hundreds of telephone conversations when completed. The British Columbia section of the micro wave system will be the final line to be put into operation and should be completed in the fall of 1957. Mr. Green illustrated his talk with a most interesting set of coloured slides.

The problems encountered in the selection of route and providing access to the sites for the B.C. section were tremendous.

Surveys were made through the mountains by means of aerial photography and with the use of lights and mirrors.

Miles Green

Provision of access to the sites of the stations proved very costly. An aerial tramway is under construction for access to the station at Hope, B.C., as the cost of road access to this mountainous location proved too costly. Access to the station in Manning Park will be by means of a tracked vehicle over a very rough mountain roadway. Stations must be inspected at least once each week for adjustment and possible repairs. Each station is equipped with a fully automatic generating set and storage batteries, together with public power supply, except in one instance."

Structural Section

A structural section formed within the Branch in 1956 has so far attracted an average of twenty-five to forty members to its meetings. With a promising looking future, the meetings take the form of dinner meetings at which a local speaker delivers a paper on a technical subject in the structural field.

WINNIPEG

C. S. LANDON, M.E.I.C.,
Secretary-Treasurer

W. A. Snodgrass Addresses Electrical Section

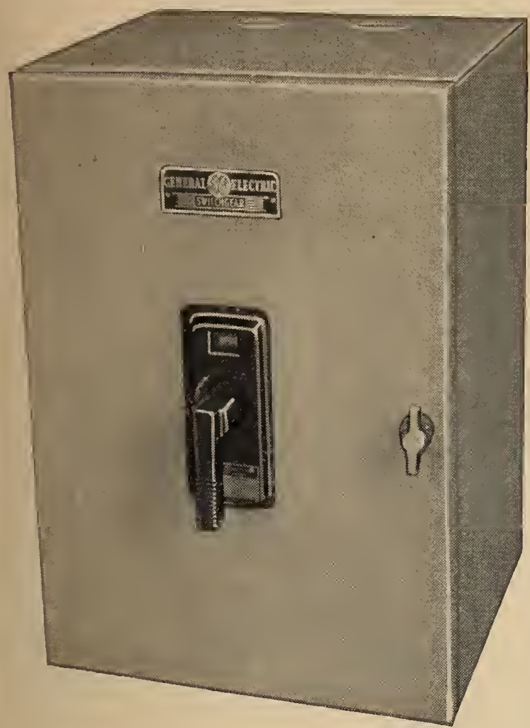
On December 6, the Electrical Section of the Winnipeg Branch was addressed by W. A. Snodgrass, switchgear division, English Electric Co., of Canada on the subject "Circuit Breaking".

Mr. Snodgrass outlined the development of the circuit breaker and discussed the merits of the various types under the broad divisions of bulk oil, minimum oil, magnetic air break and air blast. None of the designs was discussed in great detail but Mr. Snodgrass had obviously selected the illustrations with great care and the result was a concise but very complete coverage of a broad field.

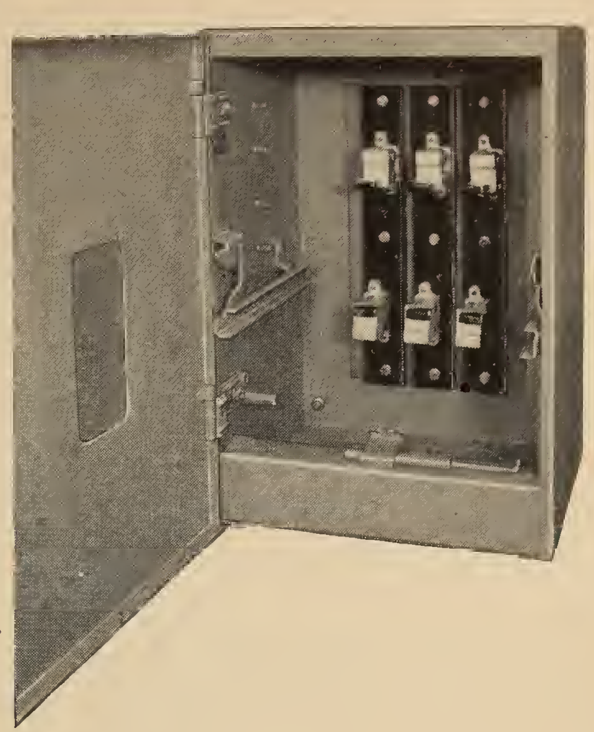
Mr. Snodgrass then discussed various standards relating to the short circuit testing of circuit breakers and outlined the main features of European anc North American procedures in ratin; and testing. The North American prac tice of circuit breaker selection is basec upon an asymmetrical rating, while ii Europe selection is based upon symmet rical rating. Mr. Snodgrass discussed th methods in some detail but suggestec the European method was basically mor logical in its approach.

Film Shown — In conclusion, Mr. Snod grass showed a short film, made with a high speed motion picture camera, whicl showed the action of a low current ar in a magnetic air circuit breaker. Sev eral shots were made, with currents o the order of 50 amperes, with and with out the arc puffer in operation. Withou a puffer, arc extinction was extremel slow, there being insufficient magneti action to force the arc into the arcin chute. With the puffer in operation, th arc was pushed into the chute ver quickly and arc extinction was rapic The arc chute used in the test wa transparent and it was possible to se the way in which the arc was elon gated and finally extinguished. It wa even possible to see the pulsations i the arc corresponding to the 50-cycl frequency.

A lively discussion period followec mainly concerned with the compariso of European and American specification



‹bove is closed view of the type DAK Air Circuit Breaker showing its ‹ompact design and sturdy construction. The single-unit—either manually ‹r electrically operated—eliminates the necessity for a disconnect switch.



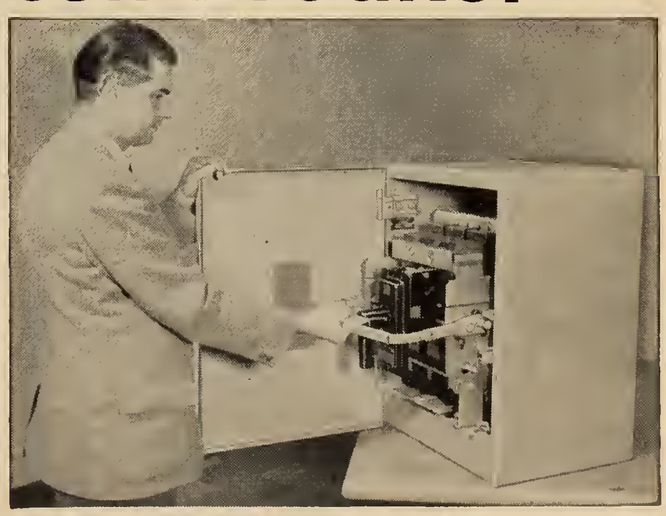
The Wall-mount Housing with the breaker mechanism removed shows clearly the silver-tipped breaker points, and the sturdy splash-proof construction of the housing.

‹LECTRIC Air Circuit Breaker ‹ircuit's broken

tripping devices which do not require current transformers.

This is the first time any electrical manufacturer has offered Canada's mining industry a device for complete circuit isolation in one compact, single unit, and in compliance with the mining code. These breakers are available for either manual or electrical operation. Ratings are available from 15 to 600 amps, with Interrupting Capacities of 15,000 amps, and 25,000 amps.

For further information on ratings, specifications and other data, contact your nearest C-G-E Office or write: Apparatus Department, Canadian General Electric Co. Ltd., 107 Park St. N., Peterborough, Ontario.



The DAK 1-25 Air Circuit Breaker, showing the easy accessibility of all parts, once the breaker is "pulled out". All components are extremely accessible for easy maintenance. Interlock arrangement makes it impossible to draw out breaker mechanism when circuit is closed.

News of Other Societies

Canadian Geographical Society

President's Letter to Engineers

As a member of the Engineering Institute of Canada, I would like to extend to fellow engineers an invitation from the board of directors of The Canadian Geographical Society to become members of that Society.

Founded in 1929, the Society, a nonprofit organization, not supported by Government, has endeavoured to further its objectives in advancing geographical knowledge and in disseminating information on the geography, resources and people of Canada, through its official monthly publication, *The Canadian Geographical Journal;* through five million reprint booklets purchased and widely distributed by government and industrial clients; through special supplementary publications such as the set of ten booklets entitled "Geographical Aspects of the Provinces of Canada", and "Industry in Action in La Province de Quebec"; and through other educational media such as lectures, the production and sponsoring of documentary films, scholarship awards, etc.

Unique Publication

For those who may not be familiar with the *Canadian Geographical Journal,* a brief word may be of interest: In both form and content this magazine is unique in Canada. Its interest is in every phase — historical, physical, economic and cultural — of the geography, primarily of Canada, but also of the British Commonwealth and the world at large. It seeks to publish articles which are of popular current interest and the greatest care is taken that the information given is dependable and the views expressed authoritative. It is profusely and admirably illustrated and is attractive both to mature and to younger readers.

The society through its *Journal* strives to convey to readers everywhere a true conception of Canada's immense resources and the epic manner of their development, to spotlight practices and research programs designed to effectively conserve and perpetuate renewable resources and stimulate the optimum use of land and water for posterity. In this we feel that the Society shares a joint interest with members of the Engineering Institute of Canada — in fact, that we are virtually the picture window for the work of engineers.

Should you desire fuller information, and I hope you will, regarding the effectiveness of the Society's work, we will be glad to send you statements made in the past few months by our honorary patron, The Governor General of Canada; by Dr. L. W. Brockington; and by members of parliament as recorded in Hansard; as well as a sample copy of the *Journal.*

It is the earnest hope of our directors that members of the Engineering Institute of Canada will accept this invitation to become members of The Canadian Geographical Society. Annual fee for membership is $5.00, and all correspondence and fees should be addressed to the Society at 54 Park Avenue, Ottawa 4.

H. A. Young, M.E.I.C.,
President.

Society for Nondestructive Testing

Activities of the Society for Nondestructive Testing, Inc., in Canada are arranged by two groups, the Ontario and Eastern Canada chapters.

The program of the Ontario Section for early 1957 is as follows: A meeting was held on February 12 in Toronto, which was addressed by Mr. Deans of Canadian Inspection and Testing. His subject was the inspection of the Imperial Oil Building in Toronto.

On March 12 a meeting will be held at the Royal Connaught Hotel in Hamilton, with Dr. McGonnagle, Argonne National Laboratories, as speaker.

There will be another meeting of the Ontario chapter on April 19.

The Eastern Canada Section lists the following meetings for early 1957:

At a meeting on January 17, P. K. Bloch, Branson Ultrasonic Corp., Stamford, Conn., spoke on "Ultrasonic Resonance Testing for Thickness, Measurement and Flaw Detection"; on February 14, S. Rybb, Dawe Instrument Company, Ottawa, discussed "Vibration Measurements".

A meeting will be held jointly with the Canadian Welding Society Montreal Chapter on March 11, at which Dr. W. J. McGonnagle, Argonne National Laboratories, Lemont, Ill., will speak on "Nondestructive Testing of Welds".

In April a meeting will be arranged for a panel discussion. On May 16 Dr. G. H. Tenney, of Los Alamos Scientific Laboratories, will give an address on "International Activities of the Non-Destructive Testing Profession".

The secretariat of the Society for Nondestructive Testing is at 1109 Hinman Avenue, Evanston, Illinois. Information on Canadian groups can be obtained from: J. F. McGuire, M.E.I.C., treasurer for the Eastern Canada section, c/o Racey MacCallum and Associates Limited, 5890 Monkland Ave., Montreal; or P. J. Stewart, secretary, Ontario Chapter, c/o Isotope Products Ltd., Oakville, Ont.

Engineering Centre New York

United Engineering Trustees, Inc., the joint corporate agency of the four major American national engineering societies signed a contract late in 1956 for preliminary architectural plans and studies for a new Engineering Centre in mid-Manhattan, New York.

The new centre will replace the Engineering Societies Building, which houses the four "Founder Societies", the

• Other Societies

American Society of Civil Engineers, the American Institute of Mining, Metallurgical and Petroleum Engineers, The American Society of Mechanical Engineers and the American Institute of Electrical Engineers. A fifth, The American Institute of Chemical Engineers will be included in the Centre project.

The location, cost or time of completion was not announced.

Soil Mechanics Conference

Dr. Karl Terzaghi of Harvard University was guest of honour at the tenth Canadian Soil Mechanics Conference held in Ottawa on December 17 and 18. More than 200 were present, including visitors from the United States, the United Kingdom, India and Burma.

In addition to participating actively in the conference, Dr. Terzaghi spoke at a special dinner held during the conference. He chose as his subject the High Dam at Assouan giving a detailed account of the remarkable design developed for this structure by the International Board of Consultants of which he is a member. He told of the unusual test boring which revealed the deep buried gorge, and of the plans for compacting the dune sand on which the dam is to be built. He expressed the view that, despite all recent political events the dam must be built unless Egyptians in large numbers are to starve.

The Hon. R. H. Winters, M.E.I.C., Minister of Public Works, and Dr. E. W. R. Steacie, president of National Research Council attended this dinner meeting.

The first day of the conference was devoted to landslides in Canada, a subject studied during recent years by a special group under the chairmanship of N. D. Lea. Participating in the discussion were Dr. Nelson Gadd, on the geological aspects; P. M. Bilodeau on the Nicolet slide, with supplementary information by Prof. Jacques Hurtubise and P. A. Rochette; W. J. Eden on a landslide at Hawkesbury, Ont.; Dr. G. G. Meyerhof, on the theoretical aspects of flows; and Dean R. M. Hardy on Landslides in Preconsolidated Clays and Shales. Further examples of landslides were noted by J. D. Mollard, C. F. Ripley, R. Peterson and A. S. Ringheim.

On the second day, M Bozozuk described studies of settlement of structures and R. F. Legget spoke on Soil Mechanics around the World. Sponsor of the Conference is the Associate Committee on Soil and Snow Mechanics of National Research Council, and particularly the Subcommittee, on Soil Mechanics.

It was reported that seven Canadian papers will be submitted to the fourth international conference of the International Society of Soil Mechanics and Foundation Engineering in August of 1957. Progress reports were presented to the Ottawa conference by groups functioning under the auspices of the Associate Committee in many parts of Canada, and by researchers whose work has been supported by grants.

Proceedings of the Tenth Conference will be published by N.R.C. and will be available as a Technical Memorandum of the Associate Committee on Soil and Snow Mechanics. Application for copies should be addressed to the Secretary of the Committee, c/o National Research Council, Ottawa, Canada.

French Chapter of ASHAE

A chapter of the American Society of Heating and Air Conditioning Engineers was inaugurated in Quebec City on December 13, 1956.

Gathering at a special dinner to launch the activities of the new group were engineers and technicians, including the following guests of honour: Guy Dubeau, representing the Illuminating Engineering Society; Dr. Albert Cholette, of Laval University; Louis-Philippe Bonneau, of Laval, chairman of the Quebec Branch of the Engineering Institute of Canada; Lorne Lindsay, past president of the Montreal Chapter of ASHAE; A. V. Hutchinson, executive-secretary of ASHAE; Maurice Paquet, interim treasurer of the Quebec Chapter; R. F. Queer, vice-president, ASHAE; Philippe Lamarche, interim president of the Quebec Chapter; John W. James, of Chicago, president, ASHAE; Jean Veilleux, president of the Quebec Branch, Institute of Power Engineers; John W. Fox, president of the Ontario Association of Professional Engineers; Pierre Bournival, general secretary of the Corporation of Professional Engineers of Quebec; Gerard Venne, vice-president of the Association of Architects of Quebec; W. C. Hole, Montreal chapter, ASHAE; A. DeBreyne, secretary of the Montreal chapter; H. C. S. Murray, Norman K. Smith, and R. J. Kerr, of the Montreal chapter.

Officers of the new Quebec Chapter, numbering 30 members, are: Jean Veilleux, president, Philippe Lamarche, vice-president, Roland Harnois, secretary, Maurice Paquet, treasurer; and directors, L. P. Bonneau, O. Dorval, E. Fournier, M. Royer, and Y. Tasse.

Uniform Traffic Control

The Joint Committee on Uniform Traffic Control Devices for Canada met in Quebec City, on October 5.

J. O. Martineau, M.E.I.C., assistant chief engineer, of the Department of Roads, Quebec, had earlier been appointed as the representative of the Engineering Institute to this Committee.

At this meeting the chairman of the committee, Walter Q. Macnee, reported progress of the plans to develop a uniform system of traffic control devices for streets and highways throughout Canada. It was planned to have a draft uniform manual prepared by April, 1957, with the hope that the manual can be completed at the 1957 annual meeting of the Canadian Good Roads Association.

Reports of the Subcommittees on Signs, Markings, Signals, Islands, Research, and of the French Language Subcommittee, and the Editing Subcommittee were heard. The support of several organizations was reported, including that of the Canadian Federation of Mayors and Municipalities.

Future meetings of the Joint Manual committee are scheduled as follows: on April 22, the day preceding the opening of the convention of the Canadian Highway Safety Conference at the Chateau Frontenac, Quebec; September 28, 1957, a meeting in Saskatoon, after the close of the CGRA convention.

Calendar

Nuclear Congress

The 1957 Nuclear Congress, to be held in Philadelphia, March 11-15, is sponsored by more than 20 engineering and technical societies. It will include a program of two hundred technical papers, two days of conferences for people interested in atomic energy, and an International Atomic Exposition, where new developments related to peacetime nuclear operations will be displayed. The Engineers Joint Council is coordinating the program.

More than forty major topics will be considered, including nuclear generating stations, reactors for ship propulsion, disposal of radioactive wastes, production of atomic fuels, legislative and legal problems, atomic energy developments abroad, and practical commercial applications of the atom in such fields as chemical production and food processing.

Copies of the advance Congress program may be obtained by writing to the Engineers Joint Council, 29 West 39th St., New York 18, N.Y.

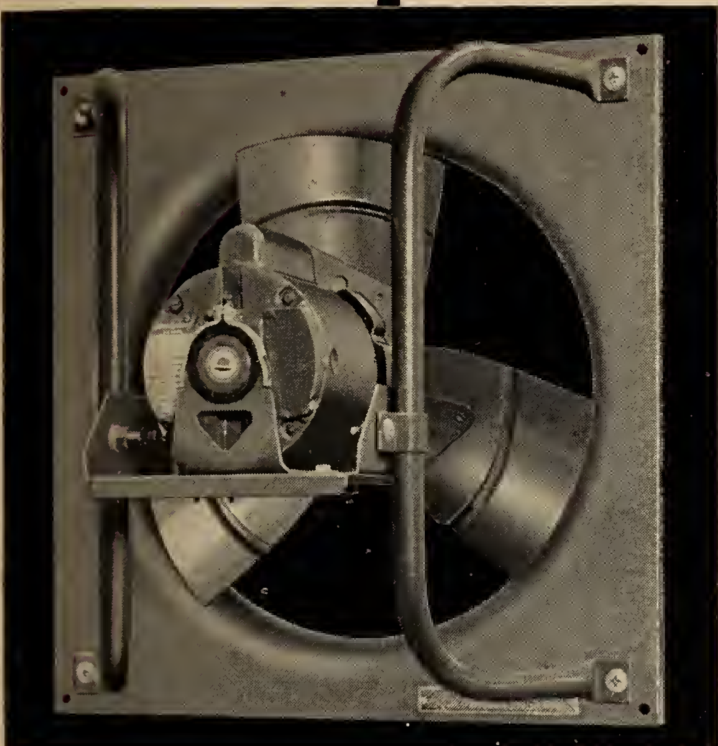
Canadian Sirocco Ventura Fans offer you

top performance and economical ventilation



Canadian Sirocco Model K Ventura Fan

You can count on Canadian Sirocco Ventura Fans to do the job they are designed for, with high efficiency and a minimum of maintenance. They are built for long life and top performance. All ratings are certified.

Canadian Sirocco Model K Ventura Fans are ruggedly constructed, heavy-duty propeller fans for tough industrial applications. They offer the power you need . . . when you need it, and will operate against static pressures up to ⅝″. Request Bulletin 6514-C.

Canadian Sirocco Ventura Fans are attractively designed, quality built, and easy to install . . . *yet competitively priced.* Ventura Fans come in a wide range of sizes and capacities — with constant-speed and two-speed direct drives, totally enclosed motors — to satisfy your exact requirements.

Certified Ratings

Air deliveries are in accordance with Standard Test Code for Centrifugal and Axial Fans adopted by Canadian Fan Manufacturers and American Society of Heating & Ventilating Engineers.

CANADIAN SIROCCO PRODUCTS

AMERICAN-Standard PRODUCTS CANADA

the Illuminating Engineering Society, announces that the fourteenth Canadian regional conference of the Society will be held in the city of Niagara Falls, Ontario, on May 16 and 17, 1957. The host society will be the Hamilton chapter, under the general direction of John H. Mills, general conference chairman.

The conference will include papers by well-known illuminating engineers from Canada and the United States, dealing with such subjects as new light sources, progress in lighting, and other pertinent technical papers.

L. K. Hart, of Canadian Westinghouse Company Limited, (P.O. Box 510, Hamilton, Ont.) is in charge of public relations and information.

Corrosion

The thirteenth annual conference and exhibition of the National Association of Corrosion Engineers (1061 M and M. Bldg., Houston 2, Texas) will be in the Kiel Auditorium, St. Louis, Mo., March 11-15, 1957.

Timber Construction

The convention and annual meeting of the Canadian Institute of Timber Construction (Ottawa 4) will be held at the Hotel Vancouver, Vancouver, March 25-28, 1957.

Mechanical Engineering

Meetings of the American Society of Mechanical Engineers (29 West 39th St., New York 18, N.Y.) are scheduled in the first half of 1957 as follows; Nuclear Congress (in association with the Engineers Joint Council), March 10-16, Philadelphia; Gas Turbine Power Conference, March 18-21, Detroit; Engineering Management Conference, March 27-28, Pittsburgh; Spring Meeting, April 8-10, Birmingham, Ala.; Instruments and Regulators Conference, April 7-10, Chicago; Railroad Conference, April 25-26, Chicago; Management-SAM Conference, April 25-26, New York; Wood Industries Conference, May 16-17, Winston-Salem, S.C.; Oil and Gas Power Conference, May 19-23, Louisville, Ky.; Design Engineering Conference, May 20-23, New York; Semi-annual Meeting, June 9-13, San Francisco, Calif.

For the Gas Turbine Power Conference in Detroit, March 18-21, the program will deal with a number of aspects of gas turbines including automotive use. Among the speakers will be representatives of European automobile manufacturers. An exhibit will display new developments in gas turbines.

Tool Engineering

Information is available from the American Society of Tool Engineers (10700 Puritan Avenue, Detroit 38, Mich.) about the silver anniversary convention and annual meeting. It will be at Houston, Texas, March 23-28, 1957.

BOOK REVIEW

Records and research in engineering and industrial science, 3rd ed.

J. E. Holmstrom. Toronto, British Book Service, 1956. 491p., $10.25.

The flood of technical information appearing in books, periodicals and individual reports often serves as a deterrent rather than an inspiration to the engineer in search of data on a problem in which he is interested. With such a multiplicity of sources, he is usually at a loss to know where to begin his search.

The aim of this book, now in its third edition in sixteen years, is to bring some order into the apparent confusion, and serve as a guide to the available resources — reports, translations, abstracts, indices, libraries and institutions.

The first three chapters discuss research methods, the relation of science and technology, the classification of the sciences, including a very interesting chart showing some of the relations between the various branches of science and technology.

The following three chapters discuss the various organizations, societies, institutions, government and industrial research bodies, etc., connected in any way with research and/or the propagation of the information resulting therefrom. The chapters cover British organizations, those elsewhere in the world, arranged by country and international oganizations.

Various types of records are discussed in the seventh chapter ranging from note-taking to reference books. The many bibliographical aids available are covered in the next chapter. These include indexes of all types, abstract services, book reviews, etc.

The final chapter deals with the actual procuring of books, periodicals, etc., and their organization so that they may be fully utilized. There is an extensive bibliography, keyed to the different chapters.

This is a most valuable work, concerned wholly with engineering and scientific material, and should be in the library of every engineer.

S.C.

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

LIBRARY HOURS

Monday to Friday

Saturday 9 a.m. — 12 noon.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada.

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

***The aerothermopressor.**

A. H. Shapiro. Nottingham, University, Departments of Civil and Mechanical Engineering, 1956. Various paging, $10.00.

The first lecture in this series of five lectures is a survey of the principles of one-dimensional gas dynamics necessary for an understanding of the Aerothermopressor, a device for atomizing water into a high-speed, hot stream of air, with the objective of realizing the rise in stagnation pressure which is theoretically possible. The second and third lectures are summaries of the theoretical and experimental work done on the device. The last two lectures deal with a deceleration probe for measuring properties of a droplet-laden gas stream, with the evaporation of a cloud of particles of non-uniform size.

Analysis of bistable multivibrator operation; the Eccles-Jordon flip-flop circuit.

P. A. Neeteson. Eindhoven, Philips, 1956. 84p., $2.15 (U.S.)

Written for a doctor's degree in applied physics at the Technical University, Delft, this thesis presents a thorough analysis of the dynamic behaviour of the bistable multivibrator which plays such an important role in electronic apparatus. This is the first such analysis to be published, although the Eccles-Jordon flip-flop circuit was conceived in 1919. The book also contains a summary of previous papers written on the subject.

Analysis of deformation. v. 3, Fluidity.

Keith Swainger. Toronto, British Book Service, 1956. 266p., $11.10.

The first two volumes of this work covered the mathematical theory and experiment and applied theory connected with the analysis of deformation. This present volume considers the fluidity aspects of the deformation problem under the headings of mathematical and classical mathematical formulation; viscous, plane flow; three dimensional, viscous flow; stress fluidity; and boundary conditions and their influence on the flow. Apendices cover vector analysis and rigid body motion.

The author has kept the use of mathematics to a minimum, although mathematical expressions are essential to the representation of the analysis of deformation. The work is based on standard histories and texts, and on periodical articles and other original reports. The author has listed his sources in a bibliography.

***Biological treatment of sewage and industrial wastes. v.I. Aerobic oxidation.**

J. McCabe and W. W. Eckenfelder, eds. New York, Reinhold, 1956. 393p., illus., $10.00 (U.S.)

The thirty-three papers contained in this volume are arranged in four parts

We put Turquoise *leads over the jumps*

SO THEY WON'T BIND IN YOUR HOLDER!

To assure you of perfectly straight, symmetrical Turquoise Drawing Leads, we send them down this "ski jump" in the Eagle Pencil plant.

The slightest unevenness in a lead makes it wobble and careen off the end of the jump into the "reject chamber". Only the true, perfectly formed leads clear the gap, and land in your holder.

Turquoise leads are of "*Electronic" graphite — reduced to micronic size. Millions more of these finer graphite particles are compacted in every inch of lead. That's why Turquoise deposits a denser, blacker line that reproduces to perfection . . . gives you the strongest, smoothest, longest-wearing point that ever met paper. 17 degrees, 6B to 9H.

*TURQUOISE

DRAWING PENCILS, LEADS AND HOLDERS

HEADQUARTERS FOR QUALITY PENCILS
100 YEARS
EAGLE PENCIL COMPANY
1856 · 1956

NEW LEAD HOLDER! Eagle's *new* 3379 Turquoise Lead Holder is precision-made for trouble-free operation. The *Prestomatic* button releases the lead—and a spring relocks the rifled jaws to hold the lead firmly in place. Red, yellow, and green release buttons identify the degree of lead contained.

• LIBRARY NOTES

Part 1 reviews the basic pinciples of bio-oxidation and discusses their application to waste treatment processes. Part II describes the mechanism of oxygen transfer and its application to the design of aeration equipment. Parts III and IV deal with the design and operation of typical biological processes for the treatment of municipal and industrial waste waters. Pulp and paper, dairy, pharmaceutical, petroleum, and cannery waste treatment methods are discussed in separate papers.

***Chemical engineering practice. v. 1, General; v. 2, Solid state.**

H. W. Cremer and T. Davies, eds. Toronto, Butterworth, 1956. 494p., 632p., illus., $13.30 each.

These are the first two volumes of a twelve - volume reference work which will deal with the various stages of chemical manufacturing processes from the laboratory to the completed factory, emphasizing, throughout, the underlying physico -chemical principles. Volume 1 contains brief discussions of the origins and nature of the chemical engineering profession, and deals fully with the economics of production, production planning, pilot plants, and flow diagrams. Volume 11 covers basic solid state theory, metals and alloys, corrosion, powder metallurgy, and porous masses. Considerable space is devoted to the uses of porous masses in filtration, purification of coal gas, water and sewage treatment, and transpiration cooling. Chapter references are given, and a 16-page bibliography on pilot plants is included in the first volume.

Chemical process economics in practice.

J. J. Hur, ed. New York, Reinhold, 1956. 115p., $3.95 (U.S.)

The papers in this publication are those presented at the fourth Experience in industry symposium sponsored by the American institute of chemical engineers and the University of Pennsylvania. Topics covered include: total initial capital required for a process unit and pitfalls of cost accounting; indirect investment and costs of services attending a processing plant and methods used to distribute them; methods of financing the original cost and operation of a new plant.

The symposium was intended primarily for the young engineer, and the emphasis throughout is on the practical aspects of the subject.

***Contracts, specifications and engineering relations, 3rd ed.**

D. W. Mead, rewritten by Mead and Hunt, Inc., with J. R. Ackerman. Toronto, McGraw Hill, 1956. 427p., $7.80.

The first part of this standard text deals with the training and work of the engineer, factors determining professional success, engineering ethics, and the writing of letters and reports. The second part deals, briefly, with the engineer in various legal situations, (as an agent, as an expert witness, etc.), and, in more detail, with construction by direct employment and by contract; advertising and letting contracts; and contract documents. The last part of the book covers the preparation of specifications for materials, processes, machinery, and engineering work. Forms, as well as a complete set of specifications for a construction job, are included.

***Disposal of sewage and other water-borne wastes.**

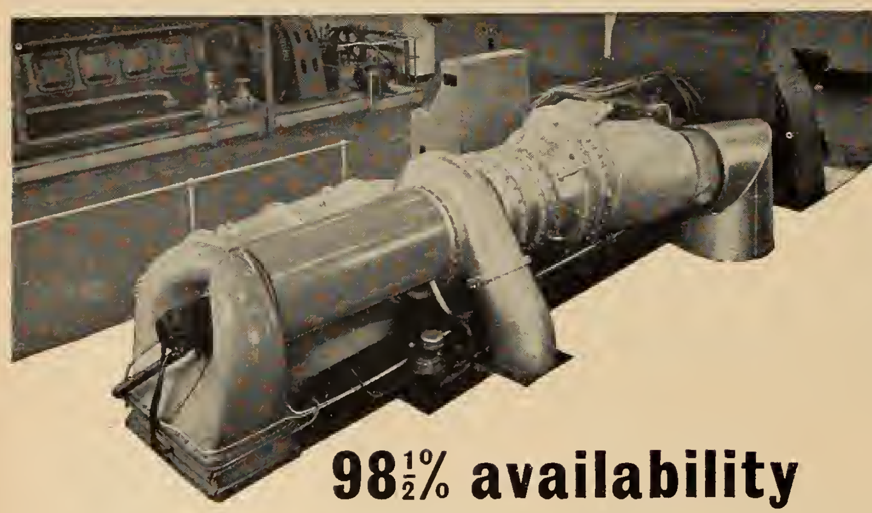
K. Imhoff, W. J. Muller and D. K. B. Thistlewayte. Toronto, Butterworths, 1956. 347p., diagrs., $9.00.

The contents of this book differ from the original German work by Imhoff upon which it was based, in the greater emphasis placed on practices common in countries of the British Comonwealth and in America. Intended as a practical manual for engineers and public officials, it deals in detail with techniques for the treatment of all ordinary water-borne wastes, including domestic or municipal sewage and industrial wastes. Brief sections cover basic data, methods of disposal, and disposal and treatment of wastes in unsewered areas.

Electrical engineering (general)

A. T. Dover and others. Toronto, Longmans Green, 1956. 489p., $9.00.

The first of a new series of undergraduate textbooks, this volume deals with the theory connected with electric circuits, instruments, apparatus and materials for use with direct currents, and with alter-



• LIBRARY NOTES

nating currents of power frequencies.

The treatment of magnetic fields is restricted to static fields, and does not cover the movement of electro-magnetic energy in space. Circuits are covered in detail, and the solution of simple network problems is discussed. Measuring instruments, both laboratory and industrial are also considered.

This series, to which the volume **Electrical machines** also belongs, should prove extremely useful to students, as it will concentrate on the fundamentals of the subject.

Electrical machines

A. Draper. Toronto, Longmans, Green, 1956. 346p., $7.20.

An undergraduate textbook intended for the majority of students who will not actually become designers of electrical machines, the book covers the fundamental principles behind their theory and operation which it is essential that those whose work may involve the use of electric machines should understand.

Among the topics covered in detail are the transformer, windings, the magnetic circuit, the induction motor, synchronous generators and motors. D.C. machines, and mercury-arc rectifiers.

Encyclopedia of instrumentation for industrial hygiene.

C. D. Yaffe, ed. Ann Arbor, University of Michigan, 1956. 1243p., illus., $22.50 (U.S.)

Two years in preparation, this large volume contains the information presented at a 1954 Symposium on instrumentation for industrial hygiene, together with descriptions of over eight hundred instruments. The information is divided into seven sections, covering various fields of instrumentation. These are: instruments for measuring air velocity, sound, vibration, ionizing radiations and ultraviolet, visible and infra-red energy; instruments for sampling and analyzing air for contaminants in industrial environments; laboratory type instruments of specific application to industrial hygiene; instruments for atmospheric pollution evaluation.

Each section includes a review of the instrumentation in that area; technical papers on special problems or types of instruments used; description of instruments used in the field.

This volume should prove of particular interest and value to air pollution specialists.

Fatigue of metals and structures.

H. J. Grover and others. Toronto, Longmans, Green, 1956. 399p., illus., $6.50.

The results of a survey conducted by the Battelle Memorial Institute, this volume is intended for the designer or engineer who has a limited practical experience of fatigue problems. It presents a summary of present-day information, and provides references to the published literature on the subject.

Some of the topics covered by the survey are: the nature of fatigue failures; fatigue damage; stress concentrations; effect of size and shape upon the fatigue strength of a part; effect of high temperatures on fatigue strength; methods of using fatigue data in design; methods of detecting and combating fatigue.

°Flow measurement by the differential pressure method, 2nd. ed.

Luton, George Kent Ltd., 1956. 136p., illus., 10/-.

This small book contains simplified orifice tables and related information useful to the oil field engineer, to the engineer in testing equipment, and to the process engineer in measuring piped supplies of water, air, gas, or steam. Although the data apply mainly to ordinary straight iron pipes with non-pulsating flows and of the usual industrial size, one section of the book is devoted to flow under abnormal conditions. The last part of the book is a catalog of the products of the publisher.

°Induction heating practice.

D. Warburton-Brown. New York, Philosophical Library, 1956. 192p., illus., $10.00 (U.S.)

The general principles and specific practical applications of induction soldering, brazing, and hardening are discussed, and detailed information is given on the design of coils, inductors, and handling fixtures. Factors to be considered in selecting the process are also treated, and one chapter is devoted to the design of components for production by the induction heating method.

°Industrial engineering handbook.

H. B. Maynard, ed. Toronto, McGraw-Hill, 1956. Various paging, $17.40.

This comprehensive reference book for practising industrial engineers contains fifty-eight chapters grouped in the following eight sections: the industrial engineering function; methods; work measurement; predetermined-elemental-time standards; wage payment; control procedures; plant facilities and design; and other aspects. The individual chapters, each prepared by an authority in the field covered, deal with a wide range of techniques and functions, including organizing for industrial engineering, process charts; curves and nomographs; planning and measuring maintenance and construction work, product classification, and the preparation of reports.

Maintenance of high-speed diesel engines, 4th ed.

A. W. Judge. Toronto, British Book Service, 1956. 422p., illus., $9.75.

Largely re-written, this new fourth edition also contains many new illustrations to bring the information up-to-date. The new material added includes a chapter on engine testing after overhaul.

Much of the information is based on the practices of leading English manufacturers of engines and equipment, and is mostly concerned with the automobile type of compression-ignition engine. However, the information is applicable to stationary, marine, agricultural, locomotive and tractor engines.

Massivbrucken. Teil 1. Platten und Balkenbrucken.

Hans Unger. Leipzig, Teubner, 1956. 400p., diagrs., 26 DM.

A new text on concrete bridges, this book covers their design in great detail, and includes many diagrams.

The topics covered include pavements, piers, abutments, hinges, supports, etc. There is a bibliography, most of the works listed being in German.

Metallurgical analysis, by means of the Spekker photoelectric absorptiometer, 2nd ed.

F. W. Haywood and A. A. R. Wood. London, Hilger and Watts, 1956. 292p., illus., £2.

The Spekker absorptiometer is widely used in metallurgical laboratories for analysis, and in this book the authors present information on the use of the instrument and on developments in absorptiometric analysis.

The first part of the book considers the role of absorptiometric analysis, and the construction, operation and maintenance of the Spekker absorptiometer.

The second section discusses the methods used in applying absorptiometry to metallurgical analysis of aluminum alloys, copper alloys, steels, magnesium alloys and zinc alloys. There is a useful bibliography.

• LIBRARY NOTES

***The metropolitan transportation problem.**

W. Owen. New York, Brookings Institution, 1956. 301p., illus., $4.50 (U.S.)

This is a broad and critical survey covering such aspects of the subject as trends in population and economic activity; the failure of urban planning to take into account the increased use of private vehicles; the decline of mass transportation; current attempts to remedy the situation by expressways, terminals and off-street parking; methods of financing and organizing transportation systems; and city redevelopment. The author sees the solution to the problem in a program combining metropolitan redevelopment and the coordinated utilization of all methods of transportation.

A primer to the automatic office.

William Eustis and others. Westboro, Automation Management, Inc., 1956. 93p., $7.50 (U.S.)

Commencing with its own definition of automation, the authors proceed to show how automation can be applied to all types and sizes of offices, emphasizing that a thorough analysis of the present system should be made before any particular automatic machine is considered, as sometimes manual or mechanical systems prove more economical.

Suggestions are presented for the correct method to use in analysing and solving the problem of whether or not to use automatic machines. There is a history of calculating and accounting machinery, and a description of the workings of electronic computers. Descriptions are given of the various computers available, and examples are given of actual applications of automatic office machines in various fields. A bibliography concludes this useful book on a subject of increasing importance.

***Principles of guided missile design. v. 3, Operations research, armament, launching.**

Edited by Grayson Merrill and others. Toronto, Van Nostrand, 1956. 508p., illus., $11.00.

The major part of the first section of this book is a review of the mathematics of operations research, illustrated by examples of operational analysis as applied to missile performance. The second section deals with important considerations in armament design: target characteristics, warheads, fuses and arming device. This section also discusses problems of systems engineering of particular importance to armament and includes a chapter on testing. The final section covers load analysis and other basic concepts in the design of launchers, the systems concept as applied to launching, launcher mechanisms, and general principles of design.

Progress in semiconductors.

A. F. Gibson, ed. New York, Wiley, 1956. 200p., diagrs., $8.00

The seven articles in this volume deal with recent advances in silicon; the germanium filament in semiconductor research; the theory of the Seebeck effect in semiconductors; the electrical properties of phosphors; the design of transistors to operate at high frequencies; and the photo-magneto and field effects in semiconductors.

This is the first of a projected series of annual review volumes in the field of semi-conductors. It is hoped that these volumes will enable workers in this and allied fields to keep abreast of current developments. It is hoped that the contributors will include specialists from all over the world. Those contributing to this volume are from the United States, England and France.

Spannbetonbau, Teil 1.

Wolfgang Herberg. Leipzig, Teubner, 1956. 286p., illus., 21.80 DM.

This text for students and practising

engineers on prestressed concrete construction commences with an historical introduction covering the last fifty years. Following chapters cover the principles of prestressed concrete, the materials used, and calculations for design.

The author gives a clear picture of the subject, and the value of the book is increased by the many diagrams and tables, and the bibliography.

***Symposium on powder metallurgy.**

London, Iron and steel institute, 1956. 390p., illus., 65/- (Special report no. 58).

The fifty papers included in this volume are presented in four groups covering the manufacture, properties, and testing of powders; the principles and control of compacting and sintering; the manufacture and properties of structural engineering components, and the powder metallurgy of high-melting-point materials. Some of the papers, such as those on manufacturing methods, the powder metallurgy of zirconium, and powders for magnetic applications, are review papers; others deal with specific processes or materials; testing of ceramal materials, porous stainless steel, hot compacting, etc.

Unit operations of chemical engineeering.

W. L. McCabe and J. C. Smith. Toronto, McGraw Hill, 1956. 945p., diagrs., $12.60.

This textbook for junior and senior undergraduates presents unit operations of the chemical process industries, from the theoretical and practical standpoint. The operations covered are: fluid mechanics; transportation of fluids; size reduction; handling of solids; mixing; mechanical separations; flow of heat; evaporation; mass transfer; gas absorption; distillation; leaching and extraction; crystallization; air-water contact operations; and drying.

In the section on fluid mechanics the boundary layer theory is included and used to connect various problems of fluid flow. The less usual operations, for example, adsorption, have been omitted so that the topics at hand would be fully treated, and kept at undergraduate level. There are problems and references at the end of each section.

STANDARDS REVIEWED

A.S.T.M. Standards, American society for testing materials, 1916 *Race St., Philadelphia* 3.

Rubber products

Every ASTM standard relating to rubber and related products is included in this latest compilation. It contains pocessibility tests, chemical tests for vulcanized rubber, physical tests for vulcanized rubber, aging and weathering tests, and low temperature tests. Standards for automotive and aeronautical rubber, packing and gasket materials, hose and belting, tape, electrical protective equipment, rubber coated fabrics, insulated wire and cable, and hard rubber are also included. Various standards for latex foam, sponge and expanded cellular rubber, rubber adhesives, rubber latex, and non-rigid plastics are also to be found in the compilation. Electrical tests, nomenclature and definitions, and general tests are mentioned. In addition, there are in the appendices proposed methods for testing rubber threads. 746 p., $5.75 (U.S.)

British Standards, British standards institution, 2 Park St., London, W.1. Also available from the Canadian standards association.

B.S. 24: Part 1: 1956.
Axles, railway rolling stock material. 4/-.

B.S. 24: Part 4: 1956 – Steel billets, blooms, bars and forgings, railway rolling stock material. 3/-.

B.S. 760:1956—Wire armoured paper-insulated cables for use in mines. 5/-.

B.S. 2737: 1956—Terminology of internal defects in casting as revealed by radiography. 12/6.

Canadian standards. Canadian standards association, National research building, Ottawa.

A8—1956–Specification for masonry cement.

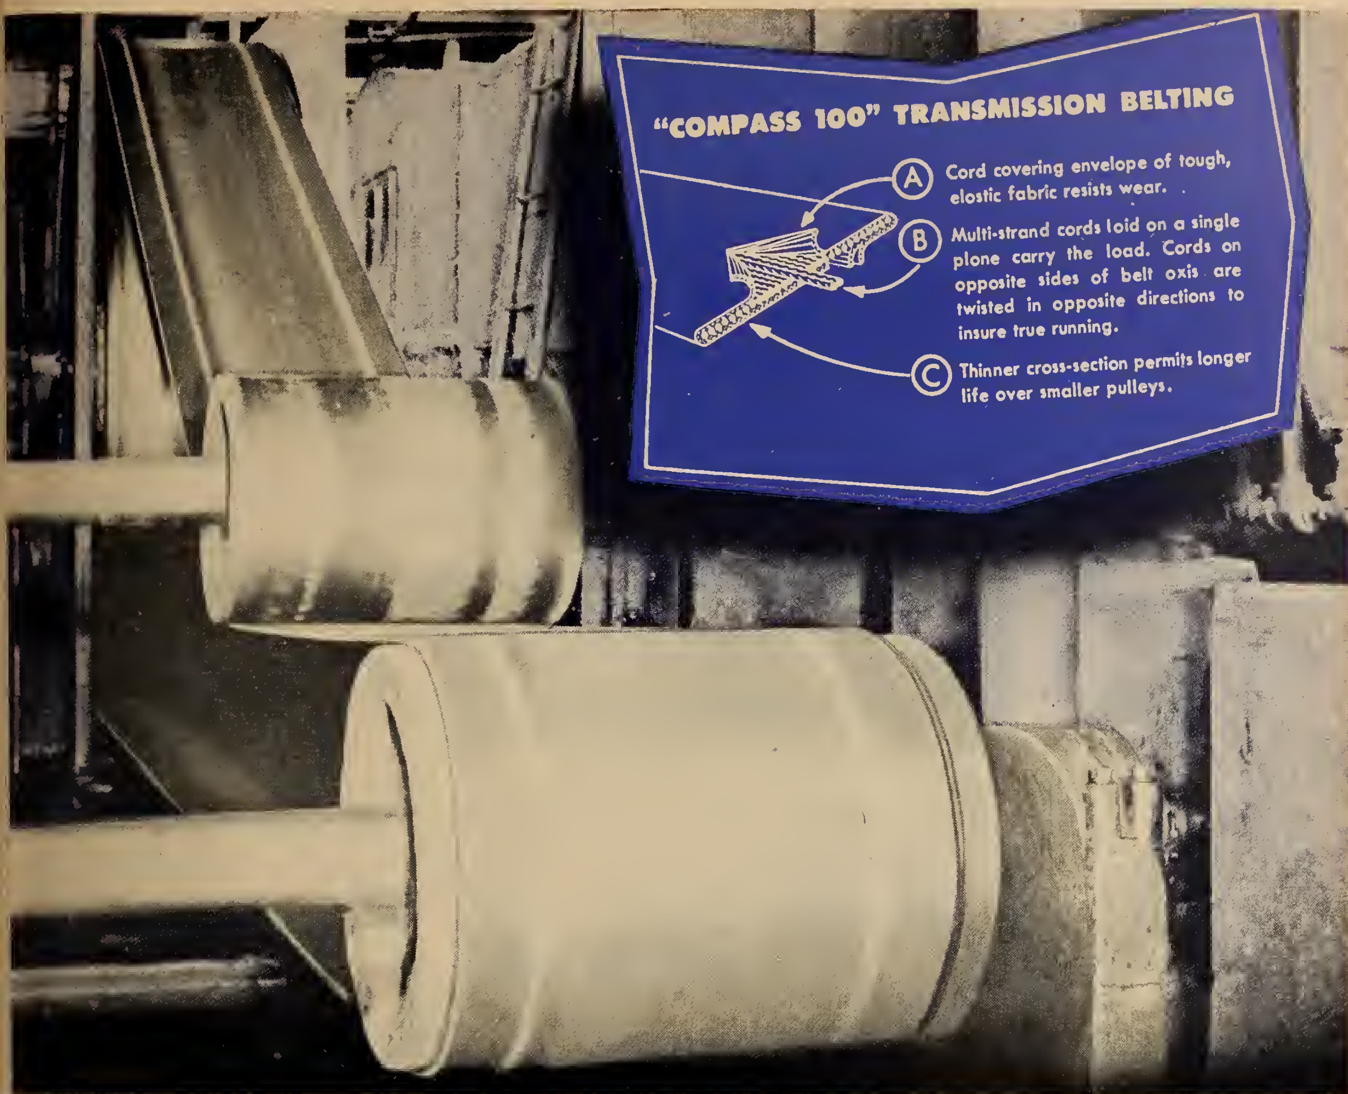
Based largely on the ASTM standard C91-53 (Specification for masonry cement), this specification is written as a performance standard and does not refer to any particular composition of masonry cement, but gives requirements of time of set, strength, soundness, water retention, etc. $1.50

B89.3-1956 — Automobile fire fighting apparatus, 3rd ed.

The third edition includes a number of revisions which have been approved since the publication of the second edition. The specification is intended to cover the minimum requirements and performance of three types of automobile fire fighting apparatus; pumper (triple combination), ladder truck (aerial), and ladder truck and pumper (quadruple combination). It covers the following: provisions applying to all types of apparatus; general construction, carrying capacity, rating of pumpers, fire pump, pump control, booster pump, gasoline engine cooling system, lubricating system, carburetor, ignition, electrical equipment, and other pertinent parts. Acceptance tests regarding pumping and road requirements are also covered. In addition, general information for municipal officials using the specification; conditions of tender and acceptance; and special provisions for all three types of apparatus, have been included. $1.75.

C128—1956—Specification for asbestos-cement conduit.

This specification is intended to include the necessary provisions for the supply and manufacture of a uniformly high quality asbestos-cement conduit. Contents include types, sizes and dimensions, test requirements and procedures, etc. 75 cents.



How belt costs were cut 60%

Belting replacement expense and high maintenance costs plagued management of a Toronto paper processing plant. Transmitting power on a beater drive to agitate 30 tons of reclaimed paper mash, 24 hours a day, 6 days a week at 500 r.p.m. by a 250 Hp. motor, added up to a belt-killing drive.

Troubles ended, however, when a Goodyear Representative stepped in and recommended a "Compass 100" Belt. For 2½ years, this 30" "Compass 100" has successfully absorbed the gruelling punishment of this tough operation.

The cost of "Compass 100" for 2½ years' service was approximately equal to the cost per year of the previous belt.

The Goodyear "Compass 100" Belt now on the job looks like it's going to stay on the job for a long, long time, cutting costs at every turn.

Every inch of Goodyear belting is backed by 50 years of experience in producing rubber products. This vast store house of know-how is available to help you solve problems of power transmission or material handling thru' industrial rubber products.

The Heavy Metal-Fabricating Industries

IN THE DEVELOPMENT of Canada's great natural resources of minerals, forests, water-power and waterways, and in the general industrial expansion, there is needed a great amount and diversity of heavy plant and equipment.

This article deals with the industries that fabricate from iron, steel, and other materials, components and equipment for such fields as hydro-electric and other power plants; mineral, chemical, and petroleum process industries; the pulp and paper industry; shipbuilding, waterways, and port facilities (such as cranes and other materials handling equipment). Many of the organizations that supply these fields also engage in the construction of such structures as bridges, which may be considered here, though the construction industry proper is the subject of a separate article.

Capital investment in the metal-working industries generally has increased greatly in recent years and the expansion of the heavy fabricating industries is likely to continue at a high rate. The reasons are not hard to find and have already been briefly outlined in terms of the country's general development. In particular, mention might be made of such developments as the St. Lawrence seaway, which requires new locks, new or reconstructed bridges, and a wide expansion of equipment associated with inland port facilities.

The power project on the St. Lawrence is only one of many current or planned hydro-electric developments in Canada that will make heavy demands on the industry for equipment. In areas such as the province of Ontario, where industry is growing rapidly, but hydro-electric power is approaching the limits of further expansion, there will be a major increase in thermal power production; this will have to be met by the provision of more facilities for the manufacture of modern high-pressure boilers and associated equipment. Just entering the field, but undoubtedly due to have considerable significance in the country's power economy within a generation, is the nuclear power reactor, which poses special problems for the heavy engineering industry in the design and fabrication of reactor and other pressure vessels, heat exchangers, and other plant.

The growth of the mining industry means the growth of the demand for heavy mineral dressing and handling equipment, extraction, smelting, and processing plant, and so on. The petroleum and natural gas industries, comparatively speaking, are still in their infancy and are already large customers for refinery equipment and great quantities of pipe; though the largest diameters of pipe for gas and oil lines still have to be imported.

Like petroleum, the chemical and other process industries make wide use of pressure and other vessels, pipe, and storage tanks. The pulp and paper industry depends to a great extent on heavy equipment for pulping, processing, and paper-making; this, too, is a continually expanding demand.

These few examples will show that probably the biggest problem that the heavy metal-fabricating industries have to face is the need to keep up with the general growth and to expand their own manufacturing facilities. Not the least of these facilities is the engineer.

Generally speaking, the greatest demand of the industry is for mechanical engineers, though there is some need for engineers in other fields, particularly metallurgical, chemical, electrical and civil. In al

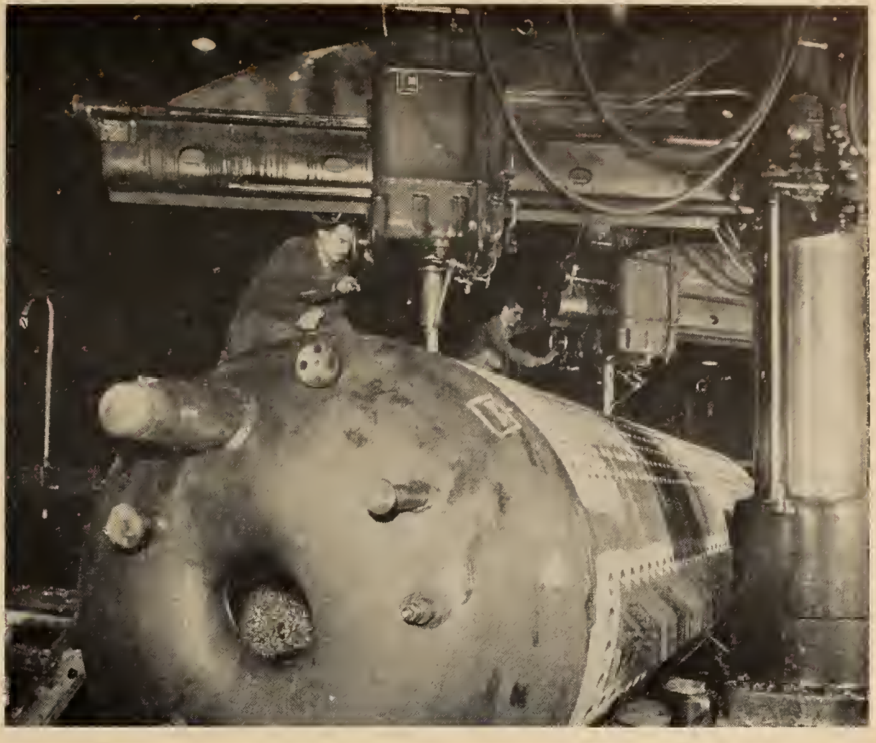
A typical item for the hydro-electric power industry is this Y-piece for a penstock. Large units are often partly shop-fabricated and later assembled in the field.

branches of the industry the prospects for suitable engineers are very good.

Fabricating Techniques

The techniques used by the fabricating industries include forming, by rolling, stamping, forging, and other methods; casting, by a variety of foundry techniques; cutting, which covers a very wide field of machine tool operations (drilling, broaching, milling, etc.); and joining, including the important and growing field of welding, brazing, rivetting, and so on. Some industries specialize in a certain field, for example, in the production of castings or the fabrication of equipment by welding; others employ a variety of techniques in the manufacture of their products.

Considerable engineering development work is involved as new materials are brought into use and new methods of fabrication, or adaptions of the usual methods, are required. An example of this is the increasing use in recent years of stainless steels and other alloys, and the non-ferrous metals, of which the metallurgical properties have to be investigated from the point of view of design behaviour and methods of fabrication.



Several fabricating techniques are used in the manufacture of equipment such as boilers. Here, a large welded boiler drum is being drilled in the machine shop.

Design and Production

As well as the physical expansion of the fabricating industries there must be considered the advances made in the fields that they supply. As capacities of equipment increase and new processes develop, so must the design of the plant and material supplied by the fabricating industries be advanced. Design engineering is therefore an important phase of their operations.

The manufacture of equipment, involving the techniques outlined previously, needs engineering staffs for plant, production, and industrial engineering, and specialists such as welding engineers and tool engineers.

After manufacture, some organizations may provide the engineering supervision for the installation of their equipment in the customer's plant or they may be responsible for a whole project, such as a bridge, from design to final construction. In such cases the industry will have teams of project and structural engineers whose work extends beyond the stages of design and manufacture.

An extension of this, which is so closely associated with the heavy fabricating industries that it may be considered here, is the firm that specializes in the design and construction of part or complete plants for industry (for example, petroleum refineries) though it may not have its own manufacturing facilities. Such engineering companies employ teams of engineers who work from initial design to final installation of equipment in close cooperation with the equipment manufacturers and the final customer, often as residents in the respective plants. These engineers require much the same experience as those who are actually with a fabricator of heavy equipment.

Other Fields

There is quite a wide field for the engineer with other companies which are not specifically heavy manufacturers, yet are very closely associated. These include makers and suppliers of welding equipment who frequently have engineers who can advise the manufacturing industries on the best techniques to use and who work closely with other companies' welding engineers. Similarly, there are firms specializing in foundry techniques or other fields who have suitably qualified engineers, though they do not necessarily themselves engage in manufacture.

Administration and Sales

In this group of engineering industries the only limit to the advance of the individual engineer is his own capability. A very high proportion of senior administrative and top management positions in many companies in this field are filled by professional engineers, who have advanced through various levels of responsibility and supervision.

The sales engineering activities of these industries are also widespread.

Training

Most companies accept engineering students for summer work. There are some that emphasize apprentice training schemes.

For the graduate engineer, the scheme of training varies somewhat with the particular industry, but it is generally designed to give him the basic essential experience followed by any necessary specialized training. This may extend from on-the-job experience to company support of outside advanced courses.

Salaries and Benefits

Starting salaries are generally in line with other major industries. Subsequent advances depend largely on the qualifications of the individual but industry scales are broadly guided by the rates suggested by the provincial associations of professional engineers.

EMPLOYMENT SERVICE

This service is operated for the benefit of members of The Engineering Institute of Canodo ond for industriol ond other orgonizotions employing technically troined men—without charge to either porty. It would be appreciated if employers would moke the fullest use of these focilities to list their requirements—existing or estimoted.

NOTICES appearing in the SITUATIONS WANTED column will be discontinued ofter three insertions. They will be reinstated on request, ofter o lapse of one month.

REPLIES to odvertisements should be addressed to File No. 000, Employment Service, The Engineering Institute of Conada, 2050 Mansfield Street.

INTERVIEWS with the Institute Employment Service, 2050 Mansfield Street, Montreal—Telephone PLoteau 5078—moy be orronged by oppointment.

SITUATIONS WANTED

ELECTRICAL ENGINEER, M.E.I.C., P. Eng. (Alberta) with twenty-five years' selling experience in Western Canada plus some administrative duties desires a wider opportunity for creative effort. Familiar with electrical rotating and static machinery and similar types of equipment. File No. 1854-W.

GRADUATE ENGINEER, M.E.I.C., P.Eng., age 44, married, with family; has substantial experience in home appliance (refrigerator) field. Is seeking position with scope for further growth in refrigeration or allied art. File No. 1958-W.

GRADUATE ENGINEER, M.E.I.C., P.-Eng. (Ont.), B.Sc. (C.E.), UNB '41, age 38, married with one child. Diversified background in structural, heating and electrical design and draughting, preparation of architectural and engineering specifications, and administration of contracts in an architect-engineer firm. Seeking a responsible position with a progressive architect-engineer or consulting firm. Presently employed and available on reasonable notice. File No. 2477-W.

ENGINEER, B.Sc., P.Eng., twelve years' experience, plant, equipment and general engineering, including design, development and layout. Cost estimating, methods, production, maintenance, correspondence and report writing. Presently employed, seeks increased responsibility at administrative level. File No. 2644-W.

ELECTRICAL MECHANICAL ENGINEER. Available for appointment as chief engineer, assistant works manager, or plant engineer. Thorough knowledge of production principles, plant layout and construction, production machinery and plant services. Natural leader with highly successful record established in administration and supervision of engineering and maintenance of large plants. Complete details and references available. Prefer location in Eastern Canada. File No. 2728-W.

MECHANICAL ENGINEER, M.E.I.C., P.Eng., B.Sc., married with children, with 11 years' intensive experience since graduation in the design and construction of utility systems for heavy industries, natural gas distribution, thermal power stations, heat treating furnaces. Experience includes project supervision, contract negotiation, engineering sales. Wishes to associate with progressive capable management as staff member or representative. Your enquiry will bring a prompt reply. File No. 2990-W.

CIVIL ENGINEER, age 34, bilingual, married, presently employed in construction division of large public utility as assistant superintendent engineer, desires position of administrative or supervisory capacity with construction company. Further details on request. File No. 3774-W.

PRODUCTION ENGINEER, Jr.E.I.C., P.Eng. (Ont.) McGill Mechanical Graduate, completed 2/3 of master's degree course in business administration at University of Michigan, age 37, married, holds current commercial pilot's licence. Desires position as head of a production engineering or manufacturing engineering department, or to take charge of production, or both, in a metal working manufacturing plant. Experience includes administrative and supervisory background in the engineering functions of process planning, tool design, plant layout, cost reduction; and also the shop services of tool room, cutter grind, tool inspection, tool cribs and tool procurement. Location not important, with a preference for Ontario or B.C. Presently employed, available on reasonable notice. File No. 3958-W.

SALES ENGINEER, M.E.I.C., age 38, married, presently employed as Sales Engineer in materials handling industry to large industrial concerns. Also, extensive experience in sales, product development, manufacturing, in electrical hardware industry. Seeks connection with medium sized company in managerial position, or interested in partnership in agency dealing with materials handling products to industrial accounts. Preferred location southern Ontario. File No. 4039-W.

CORROSION ENGINEER, M.E.I.C., P.Eng., N.A.C.E. Many years of industrial experience including cathodic protection, coatings, tapes, surveying, testing etc. Desires responsible position with oil, gas or chemical industry. Preferred location in western Canada or U.S. Available on reasonable notice to present employer. File No. 4359-W.

CIVIL ENGINEER, M.E.I.C., B.Sc., Queen's 1943, age 37, married. Experience includes five years' consultant design work on hydro-electric developments and 1½ years' foreign field work on hydro-electric project. Presently engaged in structural design of buildings and structures in reinforced concrete, steel, and timber. Desires change, available on reasonable notice to present employer. File No. 4061-W.

ELECTRICAL ENGINEER, B.Sc. 1946, age 33, married with family. Ten years' experience in electric utility industry on construction, operation and maintenance of substations, transmission and distribution facilities. Active in E.I.C. and Professional Association. Interested in responsible position where abilities and experience may be fully utilized. Prefer location in Eastern Canada. Full details on request. File No. 4397-W.

COST CONSCIOUS CONSTRUCTION MANAGER presently employed seeks change. P.Eng. (Civil); graduate in business administration. Last 5 years manager of general contracting firm. Thoroughly conversant with estimating, costing, tendering, job supervision and general administration. Desires senior position in medium sized construction company or similar appointment. File No. 4640-W.

MECHANICAL ENGINEER, B.Sc.A. P.Eng., Jr.E.I.C. Ecole Polytechnique '55. Married, one child, equivalent of three years' experience in the industrial field: heating, ventilating & air conditioning systems, process piping, oil tanks installation and pumping set, boiler houses, compressed air installation. Specification of equipment. Seeks a position as salesman in the region of Montreal. Owns car. Bilingual. Available with reasonable notice. File No. 4669-W.

ADMINISTRATIVE ENGINEER, Jr.E.I.C., B'industrial engineering, (McGill), extra-curricular studies in accounting and business administration. Over 5 years' industrial experience in U.S. and Canada in manufacturing operations: plant layout, methods studies, material handling, inventory and production control, labour standards, office systems and accounting controls. Canadian citizen, age 28. Interested in responsible position in technical sales or factory management as aide to executive. Willing to travel as required and relocate U.S. or Canada. Further details on request. File No. 4792-W.

MECHANICAL ENGINEER, P.Eng. (Ont.) M.E.I.C., married, age 29; 5 years' apprenticeship, 3 years' design and development of wind turbines and industrial equipment in U.K. 3½ years' technical sales estimating and tendering with 1 year in charge engineering department. Presently employed; 1 year as design engineer on special trailers and their ancillary equipment. Seeking position as project engineer or similar with prospects of advancement. Full details on request. File No. 4796-W.

MANAGEMENT ENGINEER, Jr.E.I.C., B.Sc. electrical 1952, candidate for master's, business administration May 1, 1957, age 27. Diversified experience in power plant construction, electrical plant maintenance and financial analysis. Looking for an opportunity within a small or medium sized company. File No. 4850-W.

ELECTRICAL ENGINEER, Jr.E.I.C., P.-Eng., (Ontario), Graduated 1949 London, England, 34 years of age, maried, presently employed with a prominent electrical manufacturer desires responsible position in industry or with a consulting engineering firm. Experienced in design and development of a-c and d-c machines (also fractional), special drives, navy work, electrical design for industrial plants and oil refineries. Available on one month's notice to present employer. File No. 4937-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., presently taking O.L.S., age 29, married with two children. Four years' varied construction and estimating experience, one year with consultant doing land subdivision municipal and hydrological work. Desires position where both engineering and land surveying experience helpful. Will answer all enquiries promptly. Would prefer the Kitchener area but this is not a limiting factor. Free to start work November 15th 1956. File No. 4982-W.

GRADUATE CIVIL ENGINEER, London England, class 1951, age 36, married, in Canada since May 1954, P.Eng., M.E.I.C. A.M.I. Struct. E., experienced in design

Ground Temperature Investigations in Canada

C. B. Crawford, JR.E.I.C. and R. F. Legget, M.E.I.C.

National Research Council, Canada, Division of Building Research

This paper describes the program of work undertaken by the Division of Building Research, of N.R.C., to determine ground temperature variations in Canada. Some of the practical results and theoretical problems are discussed.

THE VARIATION OF temperature in the ground, with time, and with increasing depth from the surface, is a natural phenomenon with which civil engineers come into contact in many special branches of work. Determination of the depth at which service pipes should be installed, the design of road and airport pavements, calculation of heat losses from structures in contact with the ground, the design and operation of heat pumps — these and similar projects can be carried out efficiently only if the appropriate ground temperature regime is known with reasonable accuracy.

At some depth below the surface, the temperature of the ground ceases to be affected by daily and monthly changes in the surface temperature. In many parts of Canada this depth is of the order of 20 feet. Below this depth ground temperatures usually increase slowly with increasing depth. This phase of the phenomenon is related to the problem of high temperatures in deep mines. Much has been written about the practical aspects of this problem and with corresponding scientific deductions from deep ground-temperature observations.

Between the critical depth noted and the ground surface, the effect of changing surface temperature will be evident to a steadily increasing degree as the ground surface is approached. The increase is not linear; major variations in temperature are greatly reduced within the first two or three feet from the surface. Following the basic laws of heat transfer, there should be a steadily increasing time lag for maximum and minimum temperature conditions. Observations show that in Canada the lag is six months, as the critical depth of approximately steady temperature is approached. These basic features of the over-all phenomenon are shown in graphs accompanying this paper which will be discussed later.

This outline of the pattern of ground temperature variation indicates that the problem of theoretically computing the ground temperature, at any particular depth, in any particular location, at any specified time, is a complex one — so complex that it can be said to be insoluble except on the basis of a number of simplifying assumptions. Variations in soil type, variations in groundwater level, variations in surface vegetation and even in the colour of this vegetation, variation in snow cover, variation in rainfall — these are but some of the factors which will affect the ground temperature regime for anv selected locality. Although generalized solutions can be obtained theoretically for ideal conditions, the study of ground temperature variation is one which must be based, at the start, upon field observations. This is reflected in the literature of the subject which is extensive despite the restricted and special nature of the problem. It has been critically analysed by Crawford (1952)[3]. An early paper of unusual interest records observations made in Edinburgh as early as 1837, by Professor Forbes[5], who used glass bulb thermometers with stems 25 feet long.

Early Measurements in Canada

The first known ground temperature measurements in Canada were made at McGill University by Prof. H. L. Callendar, beginning in October 1894. Electrical resistance bulbs were installed in the side of a trench from the surface to a depth of 9 feet and readings were made for several years (Callendar 1897)[2].

During the years 1921 to 1923 ground temperatures were observed at depths of 1 to 8 feet at 1-foot intervals on the campus of the University of Saskatchewan in Saskatoon. Electrical resistance thermometers were used and temperatures were recorded continuously (Harrington 1928)[7]. From 1929 to 1934 ground temperatures were measured at the University of Manitoba in Winnipeg at various depths from the surface to a depth of 15 feet. Frost penetration was computed from these measurements (Thomson 1934)[15].

During the period 1924 to 1939 ground temperatures were measured in Toronto with electrical resistance thermometers at the surface and at intervals to a depth of 15 feet in sandy soil at the Canadian Meteorological Office. From 1945 until 1952 further readings were obtained at the same site at depths of 4, 6, and 8 feet using a recording mercury bulb instrument supplied by the University of Toronto.

Records of shallow ground temperatures have been obtained for many years and in many locations by the Experimental Farms Service of the Department of Agriculture. Most of these observations have been made in connection with problems of crop culture and the results are not directly applicable to engineering problems. At present a general study of ground temperatures is being carried out at the experimental farms at Ottawa and Fort Vermilion.

Some earth temperature measurements have been made at great depths to study vertical temperature gradients and heat flow (Misener, Thompson and Uffen 1951)[11]; similar work has been done in some of the deeper Canadian mines.

Studies by the Division of Building Research

Shortly after the formation of the Division of Building Research a project was started to determine ground temperature variations in Canada. This project was prompted by a request to the Division to install an experimental heat pump and by an urgent problem relating to frost penetration in the City of Ottawa. Early Divisional work in the north of Canada showed that an accurate knowledge of ground temperature variations was essential in permafrost research. These and other demands for practical information were linked with an increasing appreciation of the necessity for study of the over-all theoretical problem, arising from earlier work of the senior author and from the clear necessity for a long-term study of frost action in soils.

Accordingly, the Division of Building Research has developed a steadily increasing number of field observing stations for ground temperature variations jointly with other organizations. The records so far obtained are already proving to be of much practical value. At the same time they indicate that little is to be gained by a much wider extension of such field observations. The time seems ripe, therefore, for the presentation of a review of the work that has been done in this field, not only to tell the engineering profession in Canada of the information that is available for public use, should it be needed, but also to place on record in convenient form a summary of this extensive field program against which more detailed and theoretical studies can be assessed. This paper is a statement of the field research work into this problem which the Division has carried out, in association with other research agencies noted in the descriptions of the individual installations. The locations of ground temperature installations are shown in Fig. 1.

Current Temperature Measurements

Ottawa, Ontario

Following the severe winter of 1947-48 during which the City of Ottawa had many difficulties with frozen water lines, the Division began co-operatively with the City, a study of ground temperatures under city streets. In the fall of 1948, recording thermometer bulbs were placed under two streets; one in a sandy area and one in a clay area. Readings were taken for two and three years respectively.

In 1949 thermocouples were placed in a vertical profile at 1-foot intervals to a depth of 15 feet in undisturbed clay and to a depth of 8 feet in test pits (Fig. 2) in both sand and clay. These installations were designed to evaluate the effect of air temperatures, soil type, soil density and snow cover on ground temperatures. This work was extended in 1952 with the installation of thermocouples under a snow-cleared roadway and under adjacent grass cover near the Building Research Centre at Ottawa. Readings have been made weekly at these sites.

During the winter of 1954-55 temperatures at 2-inch intervals through natural snow cover were measured to evaluate the thermal properties of snow and its effect on ground temperatures. This study will soon include the measurement of heat flow in the snow.

Aishihik, Y.T.

As part of an international study of temperatures in permanently frozen ground (permafrost), arrangements were made with the U.S. Corps of Engineers and the Dominion Meteorological Service to provide and maintain a ground temperature installation at the air field at Aishihik in the Yukon Territory. In October 1952, thermocouples were placed at three locations: from the surface to a depth of 10 feet at 1-foot intervals in a wooded area and in a brush area; from the surface to 10 feet at 1-foot intervals; and from 10 to 20 feet at 2-foot intervals in a grassed area. Weekly temperature readings have been made.

Aklavik, N.W.T.

During the summer of 1953 the Permafrost Section of the Division installed a number of thermocouples for measuring ground temperatures

FIGURE: 1

LOCATION OF SOIL TEMPERATURE INSTALLATIONS at Aklavik. One string of thermocouples was placed in natural ground under grass cover at intervals of 1-foot from the surface to a depth of 10 feet and at 12.5, 15 and 20 feet. Temperature readings and snow cover measurements have been made every week since August 1954. At the same time twelve additional thermocouple strings were installed on the sites of two proposed buildings: a ten-room school and a teacherage (Pihlainen and Johnston 1954)[13]. These installations were established to study the effects of buildings on permafrost but due to the subsequent decision to relocate the town of Aklavik, the buildings have not been constructed and no temperature readings have been made. It is expected, however, that some of these thermocouples will be read beginning in 1956.

During 1953 thermocouples were also located on the perimeters of four wooden piles immediately after they had been steam-jetted into permafrost. Observations on these thermocouples have given information on the refreezing of such steam-jetted piles in permafrost.

Yellowknife, N.W.T.

In 1951 seven temperature measuring installations were made at Yellowknife by the Department of National Health and Welfare in co-operation with the Division of Building Research. One three-point mercury-bulb recording thermometer was used; thermocouples were used in the remaining installations.

In addition to the general collection of ground temperature information in this area, these installations were planned to give data necessary for the engineering design of municipal services in northern regions where heat input to the system is required. Analysis of the data revealed that for a satisfactory solution of the design problem more precise ground temperature measurements are necessary as well as measurements of water temperatures, flow rates, heat input and a complete understanding of thermal properties of the soil. The complexity of this problem may delay its solution for many years. Meanwhile some guidance for design can be obtained by reference to the data which have been obtained. This information is now being processed for publication.

The Yellowknife installations include two reference stations: one beneath a roadway and one under natural cover. Other installations have been made around water and sewer pipes with temperature measurements recorded above, below, and in and around the pipes (Fig. 3). Temperature measurements have been made since 1951 although, owing to various difficulties, these were not continuous during the first two years of operation. The data confirm that the installation of service pipes has a significant effect on ground temperatures. The topography of Yellowknife is shown with the instrument huts in Fig. 4.

Fort Smith, N.W.T.

One three-point mercury-bulb recording thermometer has been in continuous operation at Fort Smith since May 1952 to provide information for the control of heating of the municipal water supply. This instrument was installed and is maintained by the Department of Northern Affairs and National Resources in co-operation with the Division of Building Research.

Fig. 3. Thermocouples around water main, Yellowknife, N.W.T.

(Photo S. C. Copp)

Fig. 2. Thermocouples located in test pit in clay; Ottawa, Ont.

Resolute Bay, N.W.T.

In 1948 thermistors (electrical resistance type thermometers) were established at shallow depths in the ground at the weather station at Resolute Bay which is situated just south of the 75th parallel and is operated jointly by the Meteorological Division of the Department of Transport and the U.S. Weather Bureau. Later the Dominion Observatory and the National Research Council of Canada joined with the Meteorological Division and the U.S. Geological Survey to establish deep ground temperature observations as a means of estimating the depth of permanently frozen ground and to record long-term changes in permafrost temperatures. Owing to the many practical difficulties of boring through frozen rock this program required four seasons to complete the main deep hole to 650 feet deep.

Temperature measurements have now been made in shallow holes at various depths down to 5 feet since 1948. Since September 1950 readings have been obtained at 5-foot intervals to a depth of 98 feet and this was extended in May 1952 to points at 300 feet and 450 feet. In August 1953 readings began at 50-foot intervals to a depth of 650 feet.

Data from these installations show that the ground temperature at a depth of 20 feet varies annually from about +5° F. to +13° F. At 50 feet the variation is about 1° F. and averages about +8° F. during the year. This temperature remains fairly constant to a depth of about 150 feet where it begins to increase at a rate of about 2° F. per 100-foot depth. Preliminary estimates place the depth of permafrost at between 1,000 and 1,500 feet.

Uranium City, Saskatchewan.

At the request of the Provincial Government of Saskatchewan, the Division of Building Research loaned two three-point mercury-bulb recording thermometers to the Provincial Department of Natural Resources for installation at Uranium City. These instruments were located to obtain design information in advance of the proposed installation of municipal services and to study an unusual permafrost condition which caused problems in road construction at this new townsite. In 1951 both instruments were installed at the Uranium City townsite. During the summer of 1952 one instrument was relocated in the townsite and the other was moved to a location known as "Ice Hill" on the main road near the town to obtain information on an unusual occurrence of permafrost. A typical installation is shown in Fig. 5.

Fig. 5. Typical mercury-bulb recording thermometers, Uranium City, Sask.

(Photo S. C. Copp)

Fig. 4. Typical topography and instrument huts, Yellowknife, N.W.T.

During September 1954 the instrument at the townsite was replaced with a thermocouple installation measuring temperatures under a snow-cleared driveway and under natural snow cover. Because of instrument difficulties satisfactory readings of the thermocouples were not obtained until the summer of 1955.

Saskatoon, Saskatchewan

The Prairie Regional Laboratory of the Division of Building Research made several thermocouple installations on the University Campus at Saskatoon in 1949 to study the effect of a heated building on ground temperatures. Unfortunately the leads from the neutral reference station, extending to a depth of 35 feet, were destroyed shortly after installation. There remain a number of thermocouple strings under and around the building. One string with points at the surface, 1, 2, 4, 6, 8, and 10 feet in depth and located 20 feet from the building will approximate natural ground temperatures. Readings have been made weekly since March 1950.

Winnipeg, Manitoba

In the fall of 1952 many thermocouples were installed in the ground in connection with an experimental basementless house which was constructed on the University of Manitoba Campus by the Division as a joint research project. Temperatures are measured at various depths under and around the slab and at a considerable distance from the slab to a depth of 15 feet. The data from these installations allow study of the effect of the slab on thermal conditions in the ground.

London, Ontario

Dr. A. D. Misener, working at London, Ontario, in co-operation with the Division of Building Research, has installed thermocouples in a grid under the floors of two school buildings to study the effect of floor panel heating on ground temperatures. Additional thermocouples were placed in the ground outside the influence of the buildings. *In situ* field tests for thermal properties of the soil were made.

Labrador

In co-operation with the Iron Ore Company of Canada and the Quebec North Shore and Labrador Railway, several installations for the measurement of ground temperatures were made in 1953 to obtain information for construction and operations. At mile 266 on the railway non-recording remote - reading mercury - bulb thermometers were placed to a depth of 13 feet in a typical granular fill, to a depth of 6 feet in a typical silty cut and at depths of 1.5 and 3.75 feet in muskeg. Weekly temperature readings were made during the first winter but due to inaccessibility further readings are not anticipated. It is hoped that these instruments can be moved to a position in the roadbed near a permanent camp.

At Knob Lake, site of the Iron Ore Company town, recording mercury-bulb thermometers were located under a snow-cleared road to a depth of 9 feet and to a depth of 5 feet under natural cover. This installation was relocated in the fall of 1954 owing to the unexpected extreme penetration of frost in the dry granular soil, and bulbs were placed to a depth of 15 feet under a roadway and to 12 feet under natural cover. Thermocouples were installed with the mercury-bulbs to allow periodic checking of the instruments. Continuous ground temperature readings have been obtained at Knob Lake since 1953.

Results of Field Observations

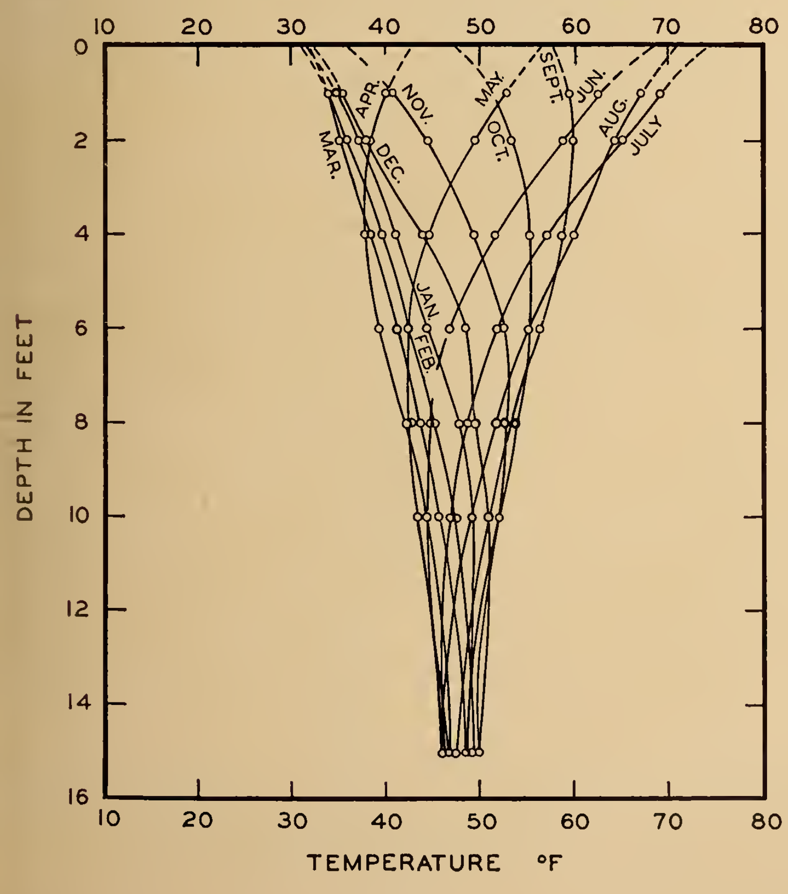
This paper does not record detailed results or even average results of all the temperature installations described; these will be published in individual papers. Some general results, however, are shown in Figs. 6 to 9. Figure 6 shows monthly average ground temperature profiles with depth under natural grass and snow cover in undisturbed clay at Ottawa during one year. These curves illustrate the decreasing mean annual temperature amplitude with depth (43° F. at the surface, 4° F. at a depth of 15 feet).

Temperature lag with depth is also illustrated (coolest in July, warmest in December at 15 feet). Figure 7 shows similar monthly averages in disturbed clay soil with the snow cover removed. Removal of the snow cover causes an increase in temperature amplitude and a decrease in the mean ground temperature. Figure 8 illustrates temperature profiles at Knob Lake in Labrador in a coarse granular soil under a snow-cleared roadway. More severe climatic conditions cause much greater temperature amplitudes (more than 10° F. at 15 feet).

Figure 9, which summarizes Figs. 6, 7, and 8, shows that the mean annual temperature under natural conditions (based on weekly observations) to a depth of 15 feet at Ottawa is approximately constant at 48° F., and increases to 48.4° F. in the upper 3 feet (curve A). The effect of snow cover is illustrated by the decrease in mean annual temperature under snow-cleared ground in the upper 6 or 8 feet (curve B). The depth to which this effect extends will depend on the boundaries of snow clearance, in this case a radius of about 6 feet. The mean annual ground temperature under a snow-cleared road at Knob Lake decreases from 33.5° F. at a depth of 15 feet to about 30.3° F. at the surface (curve C). Boundary conditions for this curve are similar to those for curve B. Mean annual ground temperatures at Knob Lake suggest that this is a region not far removed from permafrost; in the iron ore mining operations some permafrost has been observed.

The most significant feature of these curves of mean annual ground temperatures is the wide variation,

Fig. 6. Monthly average ground temperature in clay soil at Ottawa, Ont., from May 1954 to April 1955 (under natural surface cover).



even without snow cover, between mean surface temperatures and air temperatures. This variation will be discussed in some detail later. It may be appropriate to consider first the main results of the field studies.

Discussion of Results

Much valuable information related to ground temperatures has been published within the last 100 years: information on the thermal properties of soil, the effect of surface cover, precipitation, soil type, water content, organic content and various weather elements notably air temperature. For the most part this information is qualitative or applies to specific cases and is therefore difficult to apply to engineering operations. Probably the greatest single development, for engineering, is the simple empirical relationship between air temperature and frost penetration, first suggested by Casagrande (1931)[1] and later developed by the U.S. Corps of Engineers (1947)[14]. It is recognized that this relationship is an oversimplification with limiting conditions of a complex phenomena but it can be used to estimate frost penetration. A "freezing index" map of Canada (Wilkens and Dujay 1954)[16] can be used with the empirical curve to make a first approximation of frost penetration (Crawford 1955)[4]. The field measurements outlined in this paper have generally confirmed the accuracy of the empirical relationship but it is also important to note that in one case (Knob Lake) the frost penetration was twice as great as the estimate. Many field observations will be required to improve the accuracy of this method.

The field studies have added to our knowledge of the effect of soil type on ground temperatures and have illustrated the great effect of snow cover in preventing the penetration of frost (Legget and Crawford 1952)[9]. More is being learned about the general effect of basementless houses on ground temperatures and heat loss from the slab. It is apparent that the various service pipes greatly affect subsurface temperatures. Perhaps the most important result of field observations is an appreciation of the complexity of the thermal regime in the ground. This leads to consideration of a combined empirical and theoretical approach to the problem.

Evaluation

When one considers the influence which the thermal properties of the soil must have upon ground temperature variations, it becomes evident that the final understanding of this phenomenon must be guided by the theories of heat transfer. Theoretical solutions are complicated because the problem involves transient heat flow in a material with constantly changing thermal properties. On the other hand, field measurements alone will not suffice because it would be necessary to obtain results to cover every possible combination of climate and soil in sufficient numbers for statistical analysis.

In the first approach to the problem by the Division of Building Research, it was planned that study should include theory, laboratory experiments, and field observations. Field observations were begun immediately since a year of measurement is required for one complete weather cycle and because these measurements could provide interim answers to practical problems. During 1955 equipment has been developed and constructed at the Building Research Centre, Ottawa, in which small samples of soil can be subjected to various controlled temperature, density, and moisture conditions. Experiments to study the effects of freezing on various soils are continuing (Penner 1956)[12]. Work and laboratory heat transfer studies is also being planned.

In empirical approaches to ground temperature studies, it has been customary to simplify the problem by neglecting most of the variables which are known to affect temperatures to arrive at workable relationships such as the simple relationship of frost penetration to degree-days of freezing air temperature. This neglects important variables such as thermal properties of the soil (which depend greatly on water content), water movement (with its tremendous potential as a heat transfer mechanism), nature of the ground surface and all of the weather elements except air temperature. To obtain engineering design data the problem must be simplified in this way but it appears to be equally necessary to consider all the variables to achieve a satisfactory understanding of the problem.

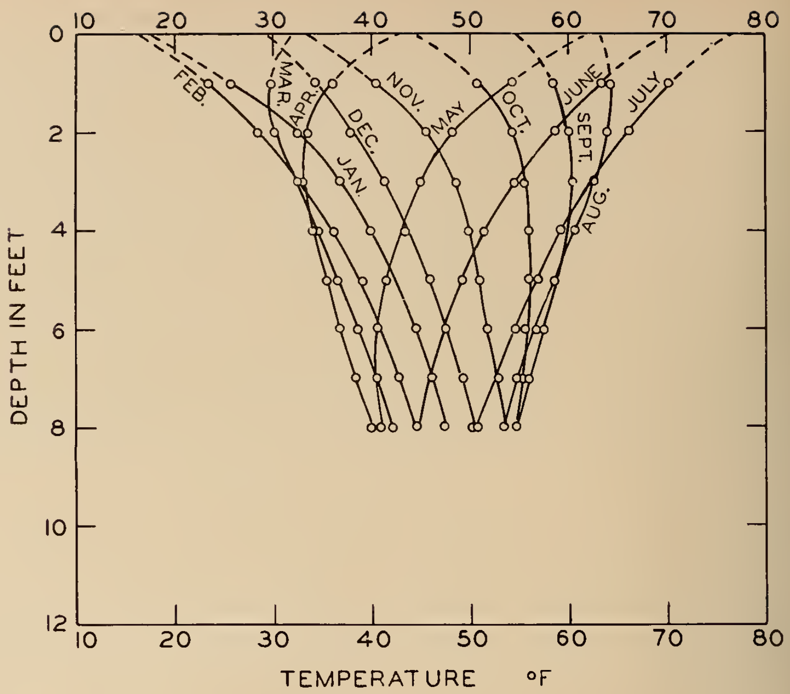


Fig. 7. Monthly average ground temperature in clay soil at Ottawa, Ont., from May 1954 to April 1955 (under snow cleared surface).

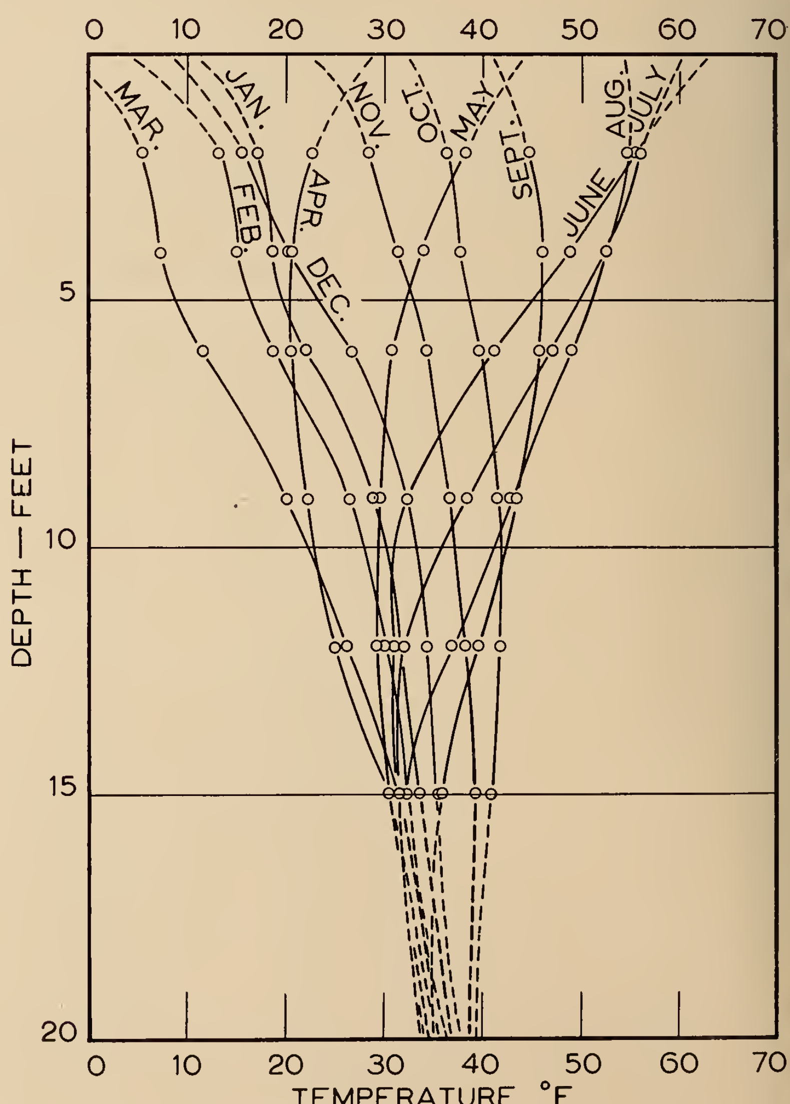

Fig. 8. Monthly average ground temperature at Knob Lake from October 1954 to September 1955 (under snow cleared road).

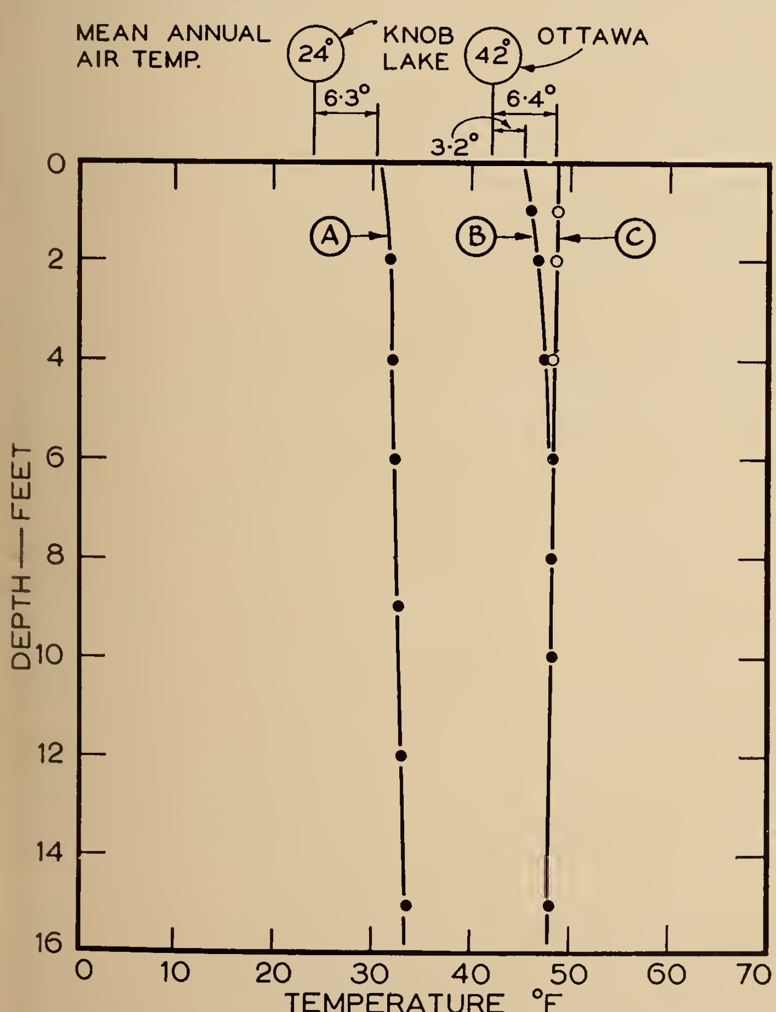
From Fig. 9 it can be seen that the mean annual temperature of the upper 15 feet of the earth at Ottawa is more than 6° F. warmer than the mean annual air temperature. Even under conditions of no snow cover the difference is more than 3° F. at Ottawa and more than 6° F. at Knob Lake. These curves clearly indicate the influence of snow cover, the effect of climate between Ottawa and Knob Lake, and the fact that there does not exist a simple direct relationship between air and ground temperatures as has generally been supposed to exist.

Further consideration of air temperature as a variable is therefore warranted. Air temperature is chosen as representing the effect of climate on ground temperatures because it is a simple variable, easily understood, and a weather element of long-term record. Further study, however, shows that ground temperature is not wholly a function of air temperature. If mass air movements are neglected the air temperature may equally well be regarded as the result of heat exchange with the earth rather than the reverse. This is caused by the fact that practically all of the heat reaching the surface of the earth results from short wave (high temperature) radiation by the sun, of which only a small amount is absorbed by the atmosphere (Geiger 1950)[6]. About 40 per cent of the radiant energy from the sun is lost to space by reflection from clouds and by diffuse scattering. The remainder, except for the small amount absorbed by the atmosphere arrives at the earth's surface by direct solar radiation and by sky radiation, having had almost no effect on atmospheric temperature. The intensity of this radiation depends on altitude, slope and orientation of the receiving ground surface, inclination of the sun and on various atmospheric conditions. At Winnipeg during 1952, for example, the average cloudless day insolation ranged from about 500 B.t.u. per square foot per day in winter to nearly 3,000 B.t.u. per square foot per day in mid-summer (Mateer, 1955)[10].

Fig. 9. Relationship between mean annual air temperature and mean annual ground temperature.



Examination of the heat exchange at the earth's surface shows that only part of the radiation that reaches the ground results in a net heat gain to the ground. Part of it is reflected directly; the amount of reflection may be largely dependent on the colour of the ground surface. Some is re-radiated as long wave (low temperature) radiation which is absorbed much more readily by the atmosphere than is the incoming radiation and therefore greatly affects the air temperature. Some radiation is used in the evaporation of moisture; this can have a marked effect on both air and ground temperatures. In the net heat exchange, condensation may balance the effect of evaporation. Minor losses to the net heat gain by radiation include convection losses to the atmosphere. During the day there is a net heat gain to the earth and at night there is a net heat loss, the balance between the two depending greatly on the season and on atmospheric conditions. Radiation from the ground surface is particularly important during the long, clear, winter nights. For practical purposes, smudge-pots are often placed in orchards to provide an artificial haze to trap this heat loss.

It is evident from the above, and supported by the curves of Fig. 9, that simple heat conduction theory does not apply at the air-to-surface interface although it may be correct within the ground, except for the complications of heat transfer by moisture movements. Field work by the Corps of Engineers and at the University of Minnesota (Kersten and Johnson 1955)[8] indicated a discrepancy in using air temperature to compute frost penetration and this has resulted in an air-surface correction factor to obtain a "pavement freezing index". This may prove to be the most practical engineering approach for estimating frost penetration. For research studies designed to understand the ground temperature regime, however, it will be essential to consider all the basic climate factors.

Research on ground temperatures has not yet answered the question of when to make field measurements and when to attempt theoretical analysis. Field measurements give a quick answer without requiring a basic understanding of the problem.

The Design of Sorel Stadium

with special reference to its foundations

G. G. **Meyerhof,** M.E.I.C.
Head, Department of Civil Engineering, Nova Scotia Technical College

L. A. **Fraikin,** M.E.I.C.
Vice-President and Managing Director, Franki of Canada Limited

In spite of unfavourable soil conditions collaboration between client, consulting engineers, and foundation specialists enabled a safe and economical design of superstructure and foundations of the Sorel stadium to be obtained. The 3-hinged steel arch ribs, seating, and walls rest on groups of caisson piles of 30 feet length in a fine silty sand with clayey silt varves and a high ground water table. A detailed site investigation included dynamic and static penetration tests and obtaining undisturbed soil samples for triaxial compression and consolidation tests in the laboratory. From these tests and recent bearing capacity theory the ultimate bearing capacity of the caisson piles was estimated, and a check of the safe load was obtained from a loading test on a typical pile. Test results were also used to estimate the probable movement of the pile groups under the maximum working load, and an allowance for the corresponding settlement and spread of the support was made in the design of the arch ribs. Settlement observations showed that the actual movements were less than estimated and that the foundations were entirely satisfactory.

THE NEW SOREL Stadium which serves as an amphitheatre and arena is located adjacent to the old open stadium in the southeast part of the town of Sorel, Que. The structure has an arched roof with glazed gable ends and presents a pleasing appearance enhanced by the layout of the brick walls (Fig. 1). The superstructure embodies six steel arch ribs of 3-hinged construction in order to accommodate some foundation movement. The ribs have a span of 130 feet and are spaced at 38 feet centres. The site of the arena is practically level and is underlain by a fine sand of great depth.

During the installation of the caisson piles (see below) the foundation conditions turned out to be less favourable than had been anticipated from a preliminary soil exploration. It became necessary, therefore, to carry out a more detailed site investigation in order to ascertain the mechanical properties of the underlying soil and to estimate the bearing capacity and probable movement of the caisson piles under the load. As part of this work, a loading test was made on one of the piles and the behaviour of the foundation was observed during and after construction as described in this paper.

Soil Exploration

Dynamic and static penetration tests were made at four locations on the site to obtain information about the relative density of the soil and the bearing capacity of the piles. In addition three boreholes were put down using a foil sampler to obtain sensibly undisturbed and continuous soil samples to a depth of about 5[illegible] feet; the samples were carefully transported to the laboratory for testing. The boring records and results of the penetration tests showed that the soil was fairly uniform over the site and consisted of some 5 feet of compact light-grey medium san[illegible] underlain by a fluvio-glacial dark-grey fine silty sand with clayey silt varves (Fig. 2 and 3). The water table was about 5 feet below ground level in the boreholes at the time when the observations were made.

In the upper 15 feet, approximately, of the silty sand stratum, the varves were ⅛ to ¼ inch thick and occurred at ¼ to ½ inch intervals (Fig. 4). The sand was in a compact state (standard penetration resistance of 10 to 15 blows per foot of penetration) and had an average porosity of about 43 per cent. The minimum and maximum porosities which could be obtained in the laboratory were 46 and 57 per cent respectively. Between a depth of about 15 and 25 feet, the clayey silt varves increased to a thickness of ¼ to ½ inch at intervals of 1 to 2 inches and the soil became somewhat softer. A soft silty clay layer was found between about 21 and 23 feet depth below ground level. Below a depth of about 25 feet the clayey silt varves were similar to those found in the upper portion of the stratum. There were, however, some softer sections up to about 1 foot thick at irregular intervals. The sand was generally in a compact state with an average porosity of 44 per cent.

Triaxial compression tests were made in the laboratory on full-sized specimens of about 2½ inches diameter and 8 inches length. The results of consolidated-undrained and drained tests indicated a minimum angle of internal friction of 38 and 40 degrees, respectively, within the pressure range of 0 to 5 tons per square foot. Consolidation tests were made on the silty sand samples. Typical consolidation - time curves showed that the major portion of the movement took place during the first minute. While the compressibility of the sandy portion of the soil was very low, the compressibility of the silty material was appreciable as shown by the void ratio-pressure relationships.

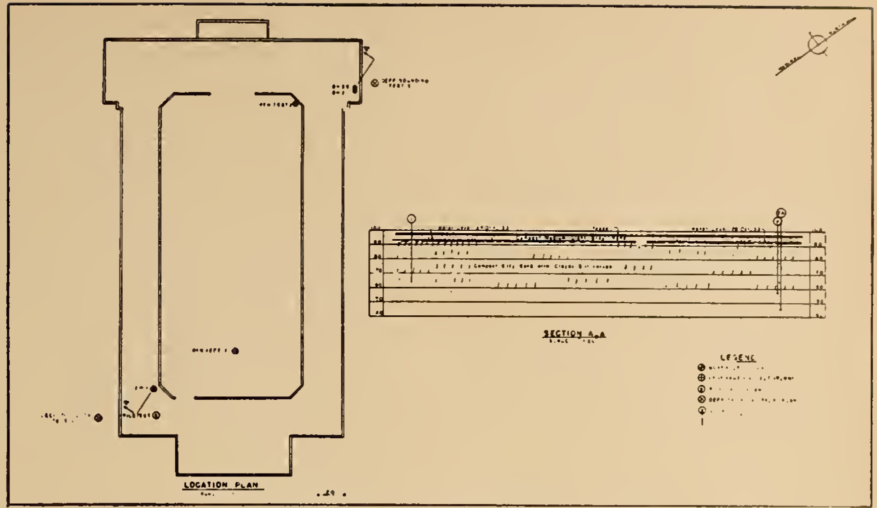

Fig. 2. Plot plan and stratigraphy of site.

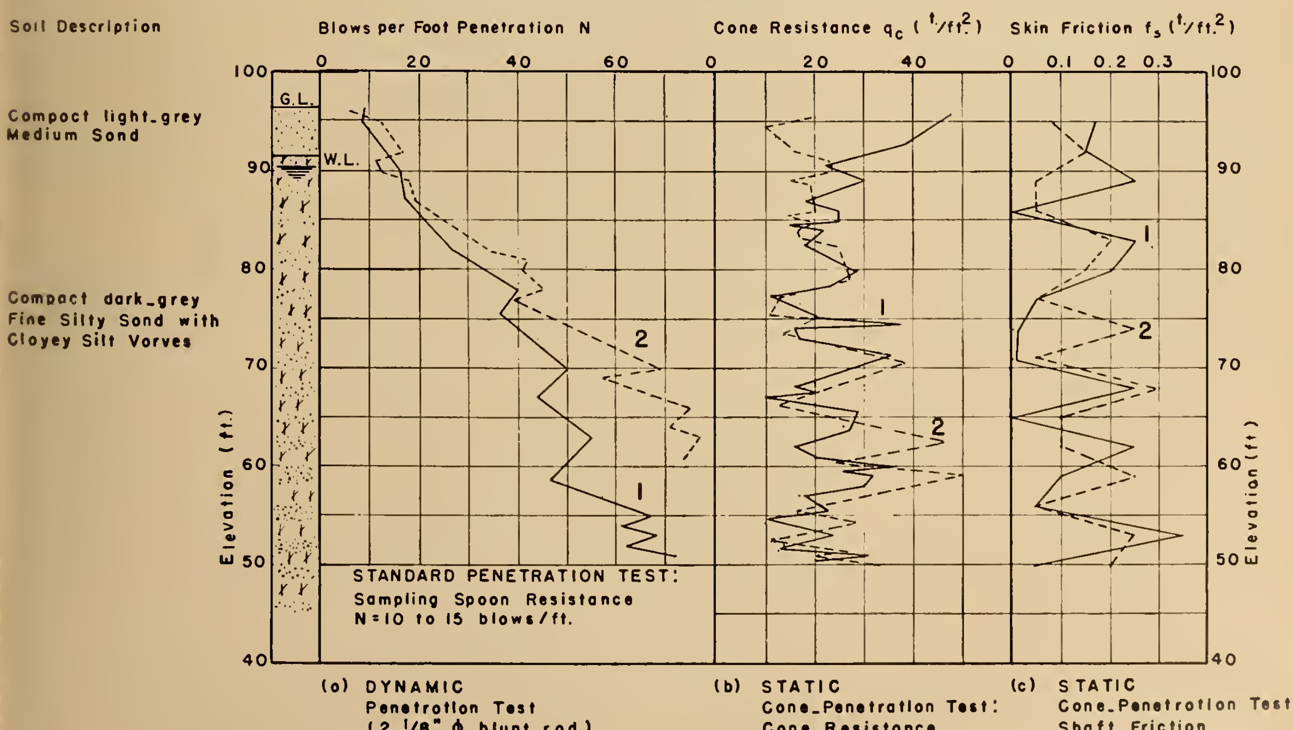
Design of Foundations

When selecting the best type of foundation for a particular building, the soil conditions encountered should not be the only concern of the engineer. He has to take into account the rentability of the building and design the superstructure, keeping in mind that he has to achieve a balanced distribution of costs between this superstructure and the hidden part of the building, the foundations. If costs of foundations giving full rigidity to the structure are such that a project has to be abandoned, the engineer is not fulfilling his obligations towards his

Fig. 3. Results of dynamic and static penetration tests.



client, if he does not suggest an alternative solution for the foundations requiring perhaps the re-design of a superstructure permitting some movement of the foundations. The design of the Sorel stadium was an opportunity to show that full cooperation can be obtained between the client, the engineer in charge of the project, and the engineer called in to design the foundations.

It was known that no heavy building could be contemplated in the area of the town chosen as the best location for the stadium, unless the owners were willing to pay for very deep foundations. The first soil investigation made rapidly indicated firm bearing soil at a depth of 90 feet or more. This meant that the whole project would have to be abandoned if foundations could not be established successfully at depth of about 30 feet below the surface, even if this meant re-designing the superstructure to take care of possible movements, these movements being estimated and kept under control due to the advanced stage of the science of soil mechanics.

Accordingly, the client and the engineer in charge of the design of the superstructure, approached the Franki Compressed Pile Company, to see whether their system of foundations could be suggested for this project. The problem was then solved by this company as follows. First, as the original soil investigation indicated a granular soil formation into which the expanded base of the caisson piles could be formed with success, a rig (Fig. 5) was brought to the site of the stadium and a test caisson pile was concreted (Fig. 6). Second, since the driving and concreting of this pile indicated that soil conditions as originally known were not encountered, additional soil investigations and laboratory tests were carried out. Third, a loading test was made on the caisson pile in order to determine its bearing capacity under the actual subsoil conditions.

Fig. 4. Section of borehole sample of varved silty sand.

Fig. 5. Rigs for installation of caisson piles.

The results of these various tests are given below. From these the safe bearing capacity of the caisson piles was determined, and the design of the foundation thereafter did not present any particular difficulty. The arch ribs were carried by groups of five 30-feet long caisson piles, four piles on a batter of 17½ degrees and one pile vertical in order to take care of the dead loads during construction (Fig. 7). Only the batter piles were reinforced.

Bearing Capacity of Caisson Piles

For the purpose of estimating the bearing capacity of the caisson piles, the diameter and length of the shaft were taken as 2 feet and 27 feet, respectively, while the base (bulb) of the pile was taken as 4 feet diameter. The bearing capacity of this pile depends on the shearing strength of the sand between a depth of about 25 and 35 feet. Because of the low permeability of the clayey silt varves in the sand, the angle of internal friction governing the bearing capacity will be between the values of 38 and 40 degrees obtained in the consolidated-undrained and drained triaxial compression tests. On the basis of bearing capacity theory[1] the ultimate bearing capacity of the caisson piles was estimated to be about 150 tons per square foot of base area. This value is about the same as the compressive strength to the concrete of the shaft and may, therefore, be considered as the upper limit of the theoretical bearing capacity.

It is of interest to compare this estimate with the point resistance observed in the penetration tests. The average cone resistance determined in the static (deep sounding) penetration tests at a depth of some 30 feet was about 30 tons per square foot (Fig. 3), which corresponded to a loose state of packing and was considerably less than estimated above; the difference may be due to the low shear strength of the silty clay varves. On the other hand, the dynamic (standard) penetration test gave an average of 12 blows per foot at a depth of 30 feet which would indicate a bearing capacity of about 50 tons per square foot on the basis of recent field investigations[2]. These estimates give thus an average of 40 tons per square foot, which may be taken as the lower limit of the theoretical bearing capacity because of the negligible soil compression in penetration tests compared with the large compaction of the soil by the expanded base of a full-scale caisson pile[1]. The bearing capacity of the caisson piles estimated from the driving resistance of the 20-inch diameter pile tube was of the order of 90 tons per square foot according to Hiley's pile driving formula. This latter estimate is between the values determined from bearing capacity theory and the penetration test results. The various estimates indicate therefore an average value of the base resistance of 90 tons per square foot.

Unfortunately, it is not possible to compare these estimates with the results of the loading test on the test caisson pile, because the test was stopped long before the ultimate bearing capacity of the pile had been reached (Fig. 8). The maximum load applied was 90 tons or about 7 tons per square foot of base area when the settlement was only about 0.3 inch. At the ultimate load, the settlement is likely to be several inches. Since the actual load on the caisson piles supporting the structure did not exceed about 60 tons or 5 tons per square foot, an adequate factor of safety was provided against shearing failure of the soil.

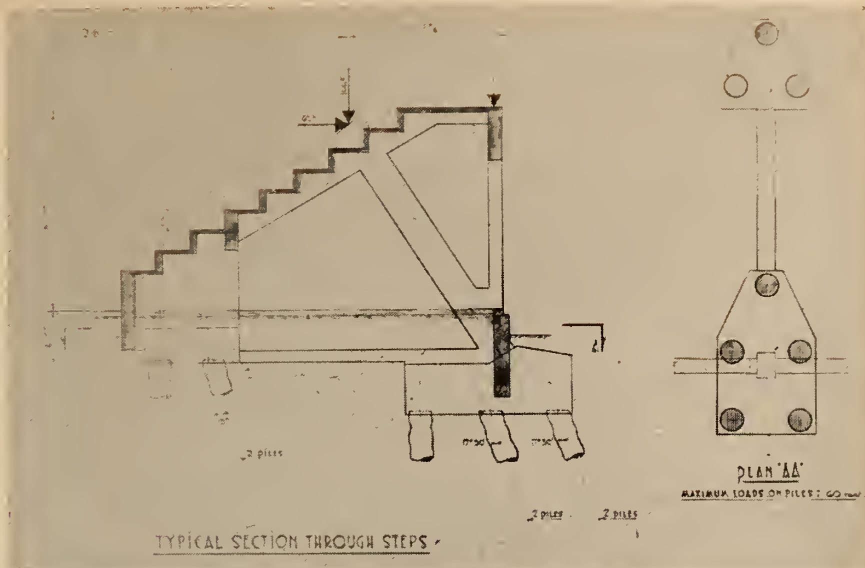


Fig. 7. Typical section of seating and pile group.

Settlement of Caisson Piles

The vertical reaction and horizontal thrust from the arch ribs are combined with the vertical loads from the walls, seating, and supports to give a maximum structural design load of 235 tons inclined at 1 in 3 to the vertical and distributed on a group of five caisson piles (Fig. 7). Since the resultant load acts practically on the centroid and in the direction of the four batter piles, they may be considered as taking the full load. The maximum working load per caisson pile was therefore 60 tons or 5 tons per square foot of base area. On account of the close spacing of these piles in the group, its effective base diameter may be taken as 8 feet.

The total movement of the caisson piles consists of immediate movement, which can be estimated from triaxial compression tests, and consolidation movement, which is estimated from consolidation tests. On that basis, the theoretical immediate movement was about ¼ inch, while the theoretical consolidation movement was about 1½ inches; the total estimated movement was thus of the order of 2 inches. On account of the rapid consolidation, most of the movement would occur on application of the load. This movement, which takes place in a direction of 1 in 3 to the vertical, would lead to a vertical movement (settlement) of the pile group of the order of 1¾ inches and a corresponding horizontal movement (spread) of the order of ½ inch. Accordingly, in the design of the arch ribs an allowance for 2 inches settlement and 1 inch total spread was made.

As a check of the estimated foundation movements, levels were taken on the pile groups of the foundation during and after construction of the stadium. The first observations were made at the beginning of June 1954 after the caisson piles had been installed, but before any load from the superstructure was applied. The second observations were made during the second half of that month when the concrete work of the seating had

Fig. 6. Base of typical caisson pile.

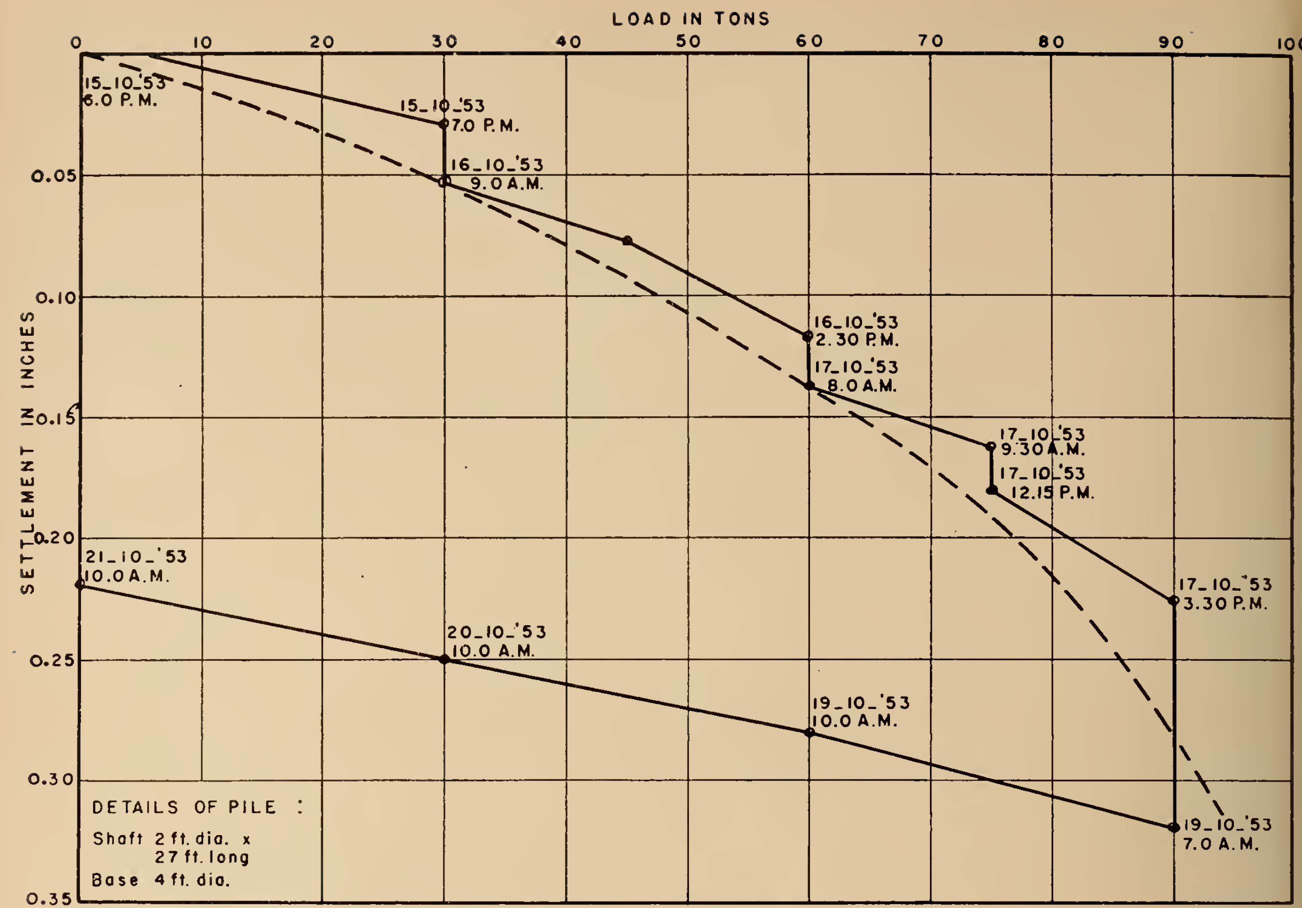

Fig. 8. Result of pile loading test.

been finished. At that time the maximum pile load was about 30 tons, or one-half of the full amount. No significant movements were recorded along the outside rows of the caisson piles, but the inside rows of piles had settled from about ⅛ to ½ inch. The third settlement observations were made in January 1955 after completion of the superstructure and under snow load on the roof, when the maximum pile load was about 60 tons. The total settlement varied from ¼ to ¾ inch (maximum differential settlement of ½ inch) and was greater in the south end than in the north or entrance end of the stadium. This confirms the results of penetration tests which had indicated somewhat better soil conditions in the latter portion.

It is of interest to compare the results of these settlement observations with the movements estimated from theoretical considerations and the results of the pile loading test. The maximum settlement of ¾ inch is approximately one-half of that estimated from settlement theory. This difference is partly due to the probability that the full design load does not always act on the foundation, partly due to a necessarily conservative estimate and partly due to the compaction of the soil within a large zone by the formation of the caisson piles.

It is believed that the last two factors are the main reasons why the observed settlements are less than the theoretical estimates in the present case. Thus, the estimates were conservative because in a compact fine varved sand the soil structure is particularly sensitive to disturbance so that it is very difficult to obtain completely undisturbed samples for laboratory tests. The slightest, almost unavoidable disturbance loosens the structure of the soil samples and thus leads to a greater compressibility being recorded in laboratory consolidation tests than corresponds to the soil below the foundations. Moreover, when the large expanded bases of caisson piles are formed in a granular soil as underlying the present site, the density of the soil is increased, especially where the caisson piles are arranged in groups as in the stadium foundations. This compaction of the soil from installation of the caisson piles reduces the compressibility of the soil near the piles and cannot yet be considered in theoretical settlement estimates.

The observed settlement is about five times that indicated by the pile loading test. This indicates the usual shortcoming of such a test on a single pile which always settles considerably less than a whole group especially where the soil contains some silt and clay as on the present site. No observations were made on the lateral movement of the pile groups. But since the main caisson piles were inclined at a batter of 1 in 3, it may be assumed that the horizontal movement was about one-third of the vertical movement or approximately ¼ inch maximum. The observed movements were well within the limits that could be tolerated by the superstructure and showed that the design and construction of the foundations were entirely satisfactory.

Acknowledgment

The consulting engineers for the Stadium were Messrs. Brouillet and Carmel, Montreal, Que., who also made the settlement observations. The soil investigation was carried out by the Foundation Company of Canada, Limited, Montreal. Que.

Modernization of a Paint Finishing Area

W. J. Flynn, JR.E.I.C.

Northern Electric Company Limited, Belleville, Ont.

HOW MANY persons buying an item look beyond its appearance? Very few people can understand the complicated mechanisms of to-day. Hence, they look wise while the salesman discusses the different technical points and then base their decision on the appearance. Although the primary function of the finish is protection from corrosion, the appearance, hence finish, quite often can either make or break the product.

Because of competition it is necessary to strive for the best product at the lowest price. As a result finishing cost must be held down while quality is maintained or improved. An investigation was undertaken in 1954 to determine the finishing cost at Northern Electric's Belleville plant and to determine what steps could be taken to reduce it and to improve quality.

Faults of Old Area

This investigation disclosed serious errors and omissions in the construction and location of the original finishing area. It was situated in the middle of the plant and was not separated from the remainder by an adequate fire-resistant partition. It was also crowded, and adequate space around the equipment for proper fire protection and maintenance did not exist.

A survey of rejected finishes for the period between October 1st, 1953 and October 1st, 1954, indicated an average of 15 per cent of the items were rejected for inferior finishes. This was due to the high standard of quality called for on JCNAAF specification of the Canadian Military Electronic Standards Agency of the Department of National Defence, and also the high quality demanded in Bell Telephone and Northern Electric equipment.

Investigation showed rejected finishes resulted from dust and foreign material embedded in the painted surfaces. This was traceable to a condition of negative pressure arising from exhausting more air from the area than was being introduced to it through the filters. This caused dust-laden air to be drawn through any cracks and openings in the walls.

In tangible terms this meant that out of about 14,000 hours spent on finishing 2000 hours were spent on re-working the rejected parts and an extra 2576 hours were spent in stripping and rubbing down. In addition $2,400 worth of materials were used in refinishing.

Design Principles

Three main points were considered in designing a paint finishing area to correct these conditions.

(*a*) Provision of an adequate space with maximum fire protection for plant and personnel.

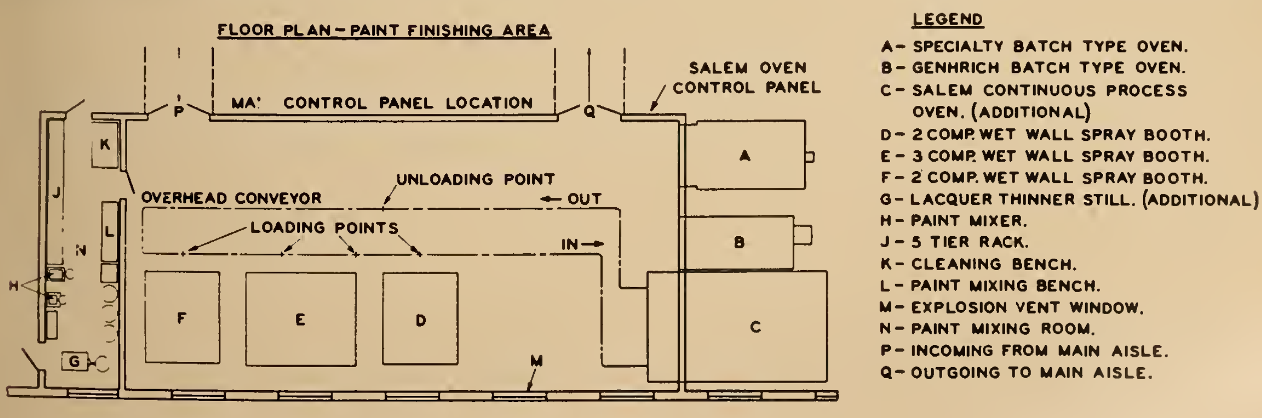
(*b*) Provision of equipment to produce the best quality finish.

(*c*) Provision of equipment and arrangement of work flow to ensure finishing would be done at the lowest cost.

Fire Protection to Plant

Maximum fire protection to the plant is achieved by having the area on an outside wall and enclosed by a concrete block wall with a minimum of two hours fire resistance. All doors and duct openings are equipped with automatic fire doors

Fig. 1. Floor plan of paint shop finishing area, showing arrangement of equipment and work flow pattern.



to contain a fire. Protection from explosive force is accomplished by having all windows of an explosion-venting type which automatically open to relieve the force. The venting area for these windows is designed on the basis of one square foot for every fifty cubic feet of room volume; this is in accordance with the Fire Underwriters and Department of Labour requirements.

Fire Protection of Personnel and Equipment

Protection of equipment and personnel is provided by an automatic sprinkler system with fog type nozzles spaced for coverage of 90 square feet per sprinkler. The floor is sloped one inch in six feet to scuppers in the outside wall permitting the sprinkler run-off to leave the building directly, thereby decreasing the explosion potential. The base floor is covered with marblette, a non-sparking, non-skidding material impervious to acids and alkalies.

To minimize fire or explosion hazard due to electrical apparatus, all motors and switches in the room are of the explosion-proof type for Class 1, group "D" locations. Only three motor switches, for the vacuum still and paint shakers, are inside, all others are located on a control panel outside the area. Light fixtures for the paint mixing room are of the explosion-proof type, due to the greater risk in the dispensing area, whereas the fixtures for the spray area are vapour proof. To insure that all apparatus will be turned off if a fire or explosion should occur, all motor starters are controlled by three Sprink-la-stats, set for 135 deg. F, which will open, closing off the master control circuit and opening all switches.

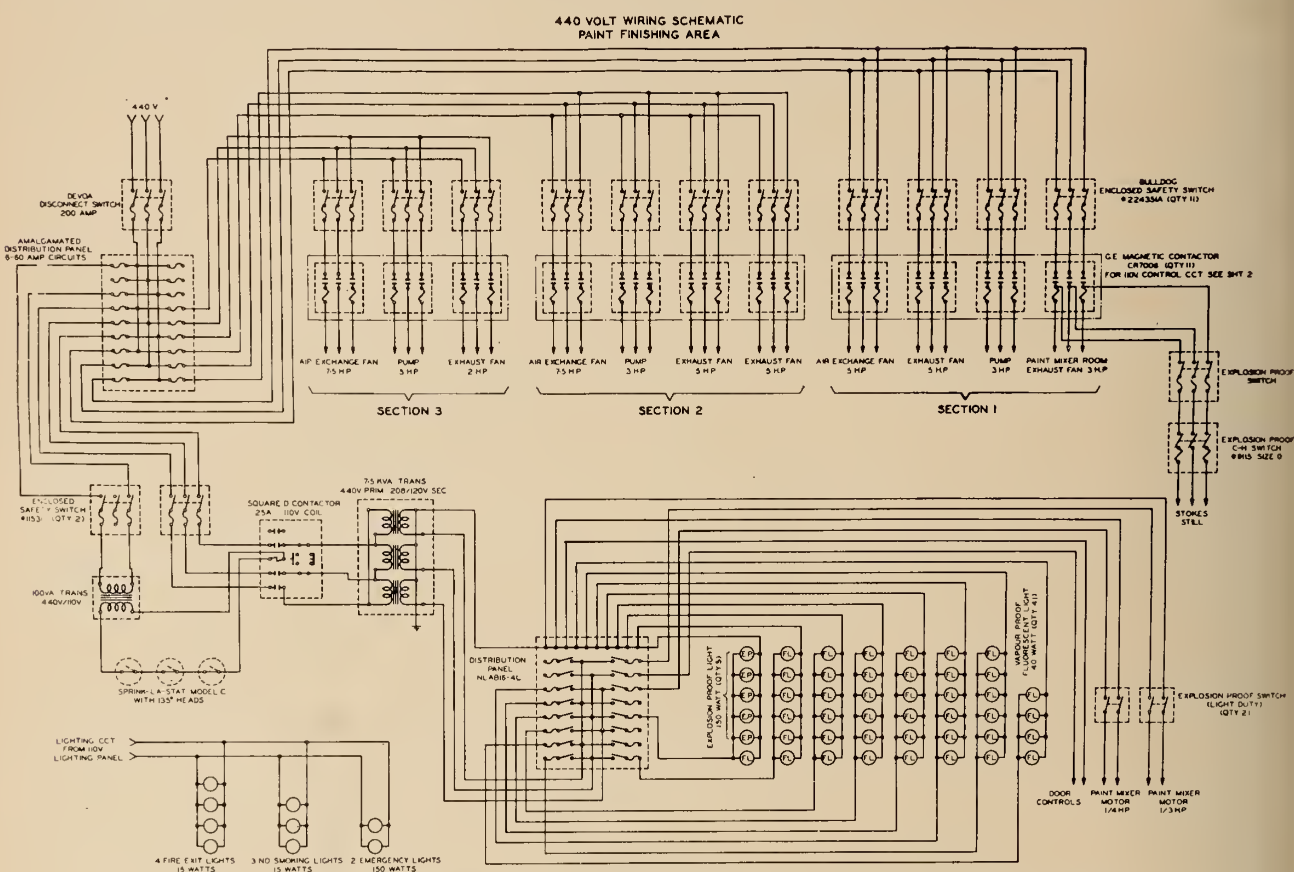


Fig. 2. Wiring schematic, 440 volt. Sprinklers are operated by temperature controlling all electrical apparatus in area. Note also emergency lights, which are on a separate circuit.

Maintenance

All equipment in the area is spaced three feet apart for greater fire protection and ease of maintenance. Periodic inspections and cleaning cycles have been arranged to keep all equipment in good operating condition, thereby minimizing costly production delays and also eliminating the risk of possible fires caused by worn-out apparatus.

Correction of Dust Problem

Presence of dust or foreign material embedded in the painted surface constitutes a main cause of rejected or inferior finishes, as stated previously. Pressurizing the area by supplying an excess of dust-free air from three air intake units minimizes this condition. The first step in accomplishing this was to ensure that all paint booths had proper exhaust. For booth type hoods our standard is a velocity of 150 feet per minute across the booth opening; this is the minimum requirement as stated by the American Society of Heating and Ventilating Engineers. The second step was checking all other exhausts, such as cleaning bench and ovens to ensure they had the minimum ventilation requirements. Lastly, the sum total of all the exhausts was found and increased 5 per cent to allow for leakage. This figure represented the total input of dust-free air required. The ventilation was then checked to the minimum requirements of the Fire Underwriters and Department of Labour, which is 0.25 c.f.m. per sq. ft. floor area, and was found to be adequate.

As the design required three ovens and three booths it was decided to use three air replacement units and to interconnect them to ensure that no air could be exhausted without dust-free air being drawn in. This latter was accomplished by installing a pressure operated switch in the dis-

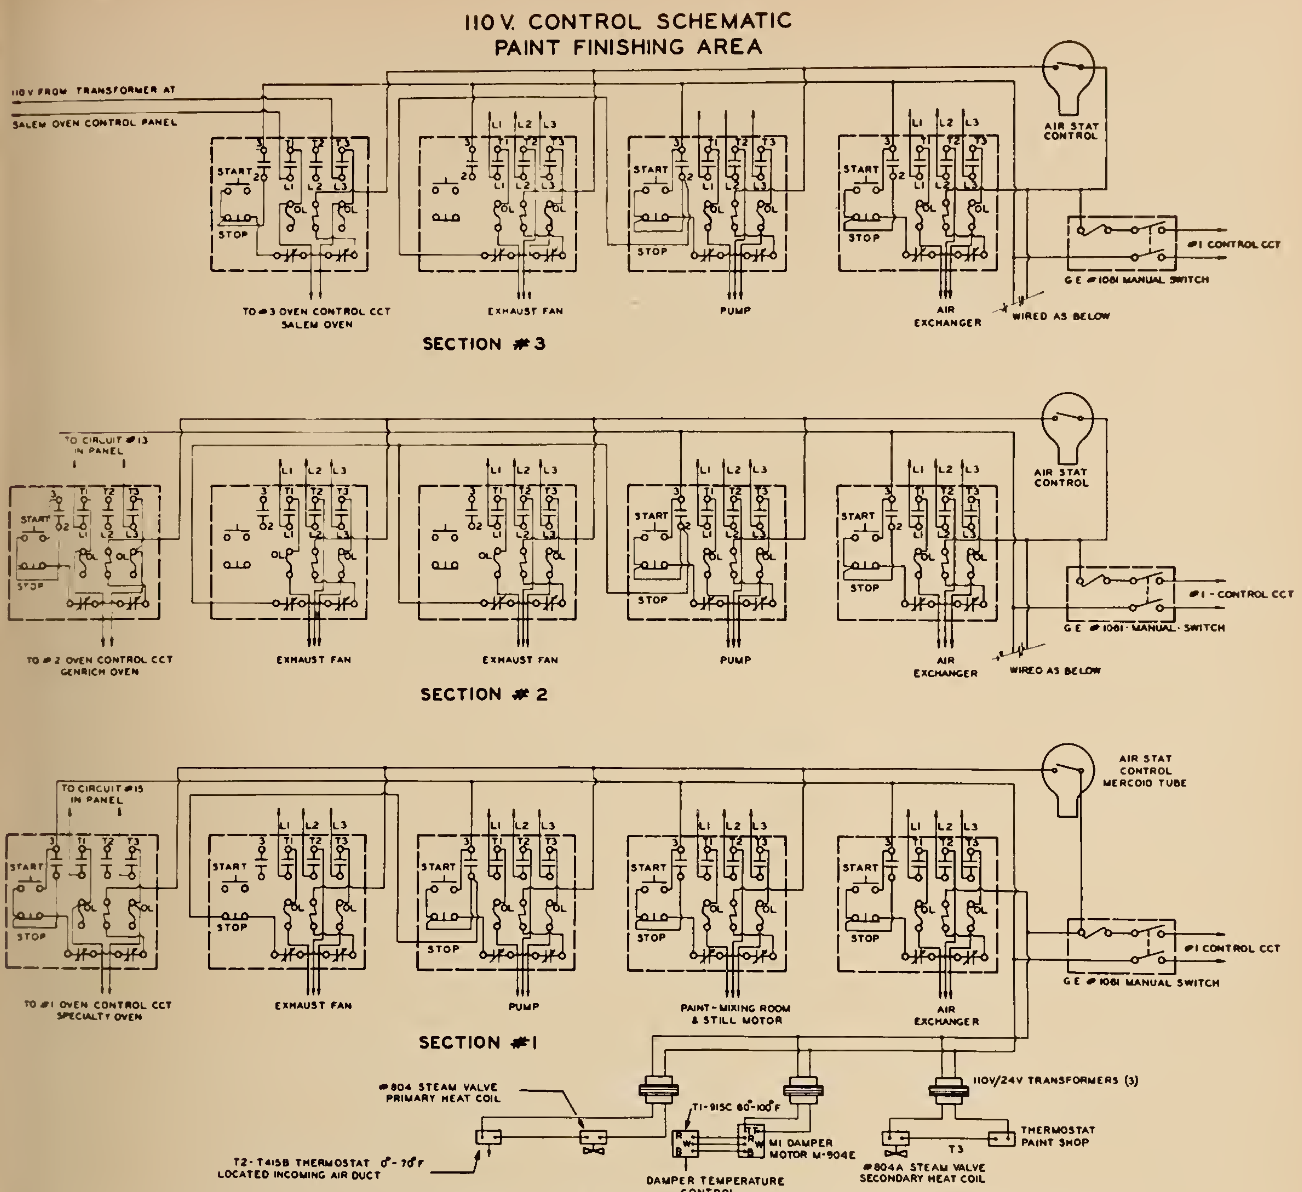

Fig. 3. Schematic wiring diagram of the 110 volt control circuit showing interconnection of motor starters, which prevent air from being exhausted without filtered air being drawn in.

charge duct of the replacement units controlling the motor starters of the exhaust fans. Thus, unless air is being pushed into the area and operating the switch the exhaust fan will not operate.

The ceiling of the plant consists of dressed 2-in. x 3-in. planks on edge and it was thought this type of construction constituted a definite fire hazard, and that some preventive action would be required. However, on checking the revised fire regulations it was found that no ceiling treatment was necessary. The regulations had been changed after the "Levonia" fire when it was shown it is better for the fire to burn through the roof and burn itself out rather than be contained below where it can be supported by the built-up roof. Due to the numerous cracks and crevices inherent in a plank roof it was felt this type of ceiling might provide us with a dust problem. It was therefore decided to install aluminum foil over the deck as a vapour barrier. This was then covered with Masonite to present a smooth ceiling. The new roof has proved very effective and in addition is easily cleaned. An added step to minimize the possibility of fire has been the provision of 3-in. clearance around the ducts passing through the ceiling. This space has been packed with asbestos.

Uniform Temperature

Consistent quality in gloss and uniform paint film thickness are necessary from piece to piece. This is achieved by maintaining a constant temperature in the area, thereby permitting constant paint viscosity and a greater control in paint mixing. The temperature is held to 78 deg. ± 2 deg. F. by thermostats controlling the steam flow to the coils of each air intake unit.

Lighting

The lighting is arranged to provide a minimum of 50-foot candles in the paint mixing room and the paint booths and 35-foot candles in the remaining area. Adequate lighting has not only cut down operating fatigue but, in addition, has minimized streaking of the product by enabling the operators readily to distinguish demarcation lines in the spray pattern.

Results

The foregoing measures have resulted in a sharp reduction in the cost of finishing. Since all painting, baking and air drying is done in the dust free area of the paint shop, rejects have been decreased to 5 per cent. This has decreased the reworking the rejected finishes from 2,000 to 660 hours. In the meantime, however, actual quality standards have been raised with the effect that only two-thirds of the originally estimated savings on the old quality standards have been realized.

New Equipment

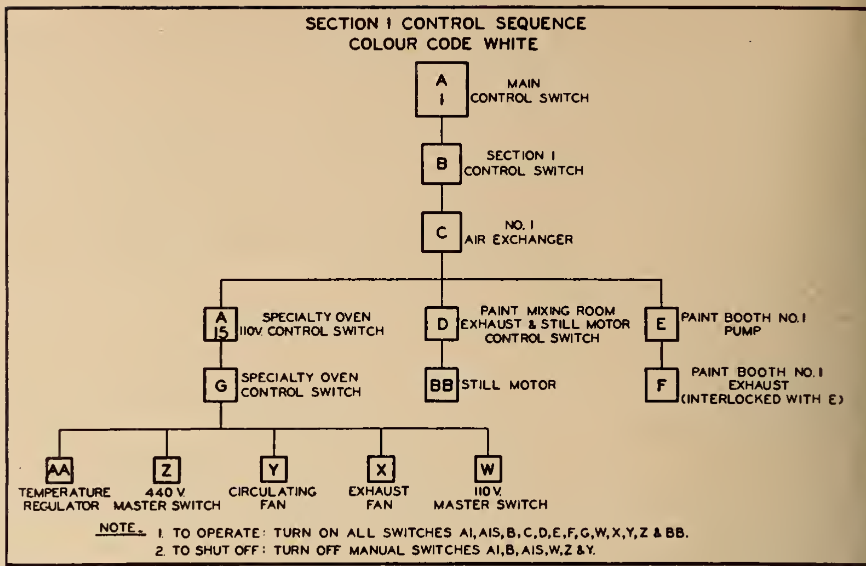
Further savings have been effected by the provision of a conveyor oven and a vacuum still. An average of 3500 gallons per year of lacquer thinners are used to clean guns, cups, and equipment. About 75 per cent of this material is recovered and reused, after the solids have been removed, by the vacuum still. The operation is automatic and very economical since the paint mixer loads and unloads the still in his free time. An interesting and unexplainable point is that reclaimed thinners have been found to do a better job of cleaning than the original thinners.

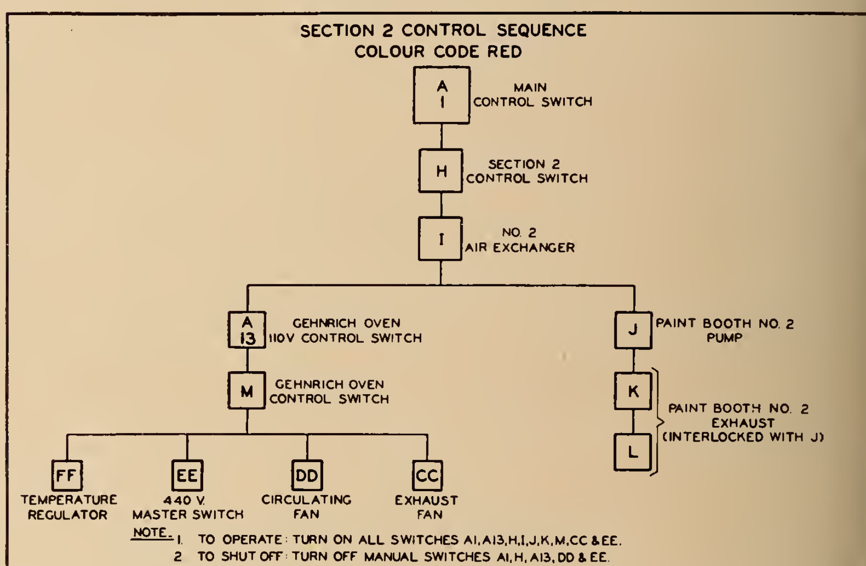
Ovens

Previously the output of the paint finishing area was dependent on the oven capacity. As this was low, it tended to reduce the production rate. Installation of an additional oven has made the output dependent on the painters with a resultant significant increase in production. Also, as the new oven has a conveyor, interruptions from loading and unloading have been decreased. From studies made before and after the completion of the area it has been found production increased 40 per cent making possible a saving of approximately 4500 hours.

All ovens are installed with their fronts flush with the inside wall of the area and oven proper extending through the wall into the surrounding shop. This provides an increased area in a dust-free location for air dried finishing, presents a neater layout and reduces a source of dust which in turn lessens the cleaning time for the paint shop.

A further slight saving has been achieved by the installation of power operated doors. A study indicated the doors are opened and closed some 41,000 times per year. The time to open and close the doors has been decreased from 30 seconds to 10 seconds with a resultant saving of 228 hours.





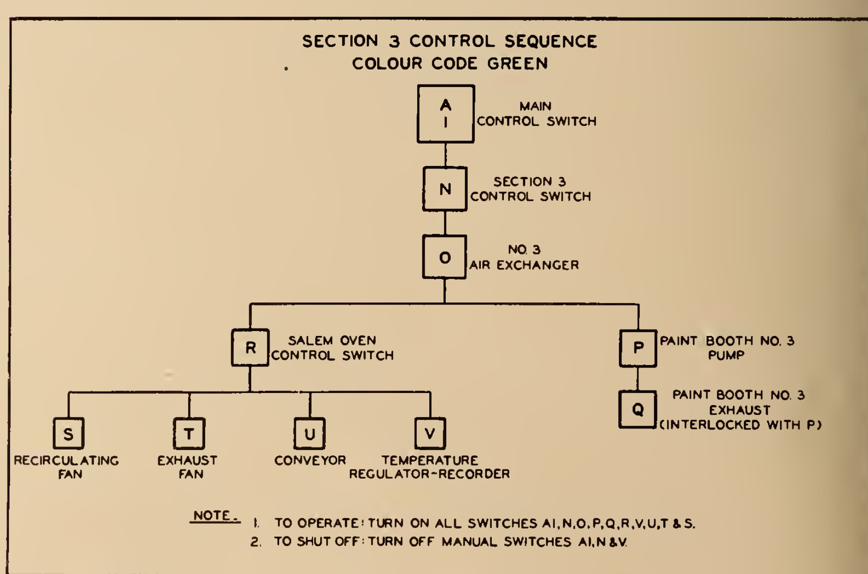


Fig. 4, 5, 6 (from top). Control sequences for sections 1, 2, and 3, indicating sequence in which switches must be turned on to operate units. All switches are painted in the section colour and codified for easy identification.

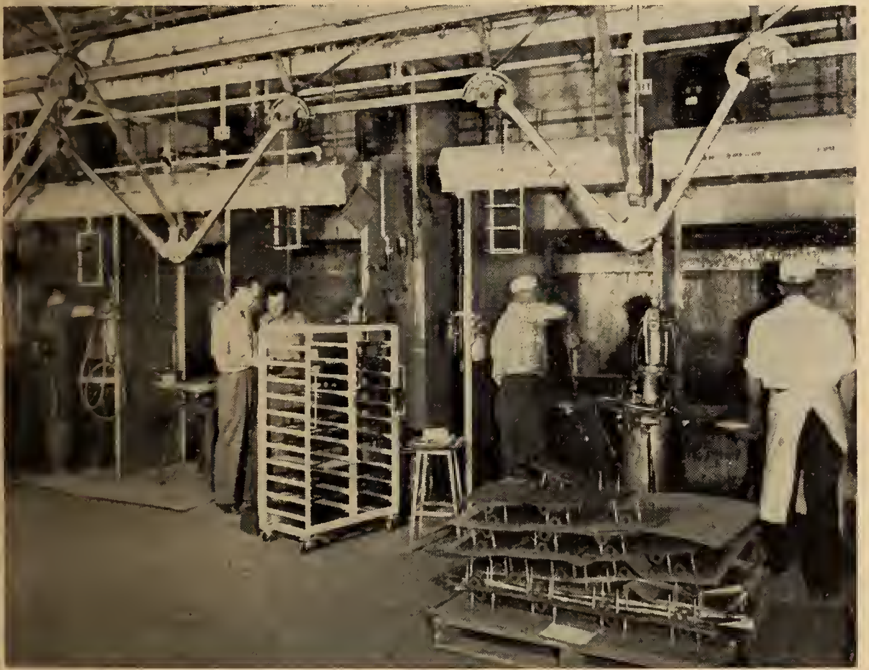
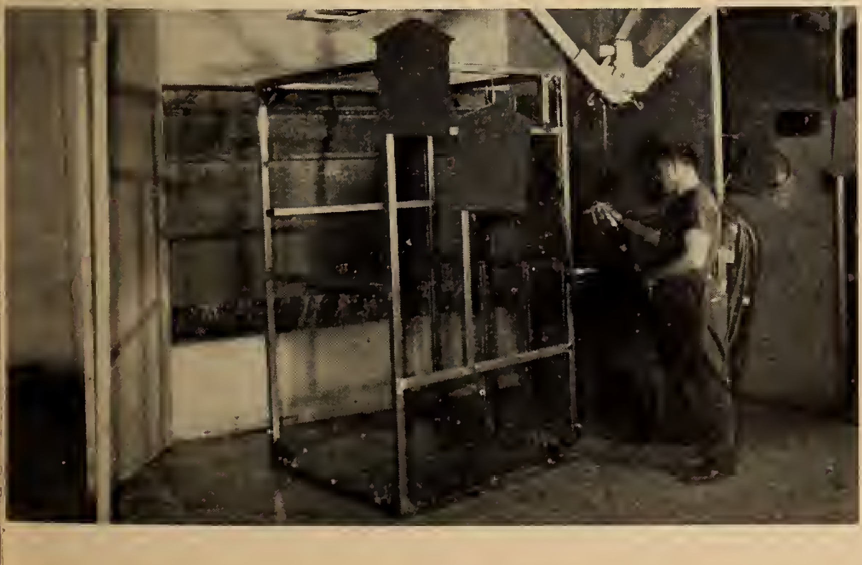




The locations of the doors were selected for good work flow. All parts enter through the "in" door and are distributed to the booths. From there they proceed to the curing area at the opposite end of the room. After curing they leave the area through the "out" door for inspection and lettering. In this way, crossover of traffic is held to a minimum.

The paint shop itself is ideally located for work flow since it is situated adjacent to lettering, inspection, and packing areas and close to mechanical assembly and stockrooms.

Adaptability of Area and Equipment

An outstanding point not covered so far is the adaptability of the paint shop to meet changing loads, parts and finishes. For this reason only convection type ovens are used. Also, although there are positions for seven painters since two two-compartment and one three-compartment spray booths are available, partitions in booths are removable to permit entry of extra large parts. To handle even larger parts the side of the number 3 booth is arranged to swing open to make an opening 10 ft. high by 10 ft. wide. Only water wall spray booths are used to minimize the contamination of outside air and also reduce the fire potential.

In line with the provision for large parts one door of the paint shop was made 10 ft. high while the other was held to 8 ft.

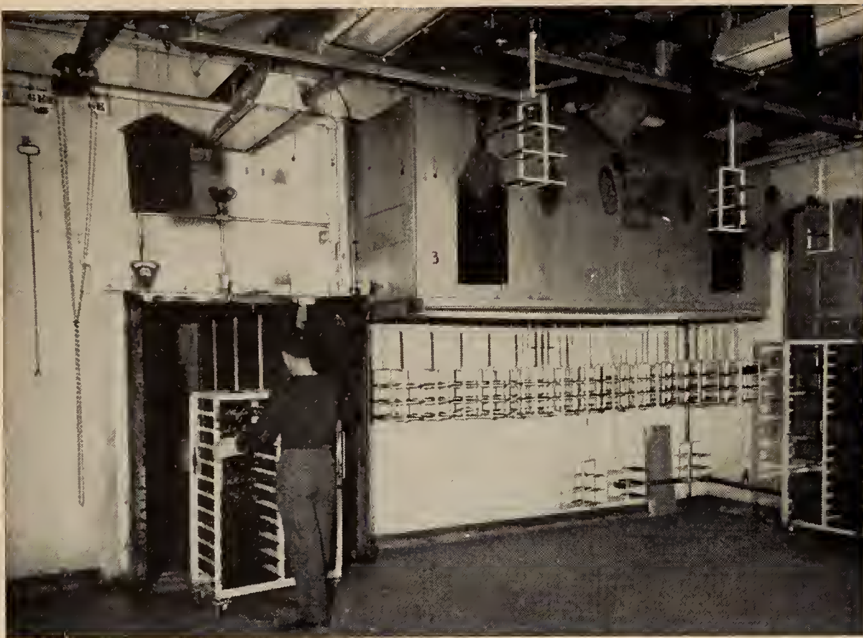
Conclusion

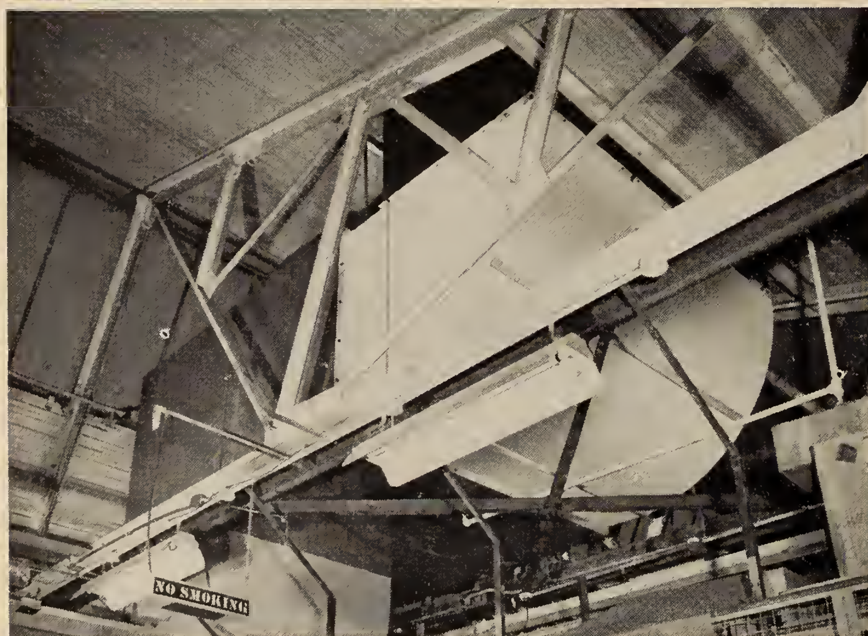
Since installation we have had trouble with the air intake units freezing. No complete explanation can be given but the theory is that although the traps were designed with a factor of safety of 5 a sudden surge was encountered which was over the trap capacity. This surge could have resulted from a higher steam demand which reduced the steam pressure at the trap, consequently reducing its condensate capacity. This allowed condensate to collect and freeze, bursting the tubes. This situation was corrected by installing larger traps away from the units so the pipes can act as a reservoir for any surplus of condensate the trap cannot handle.

Fig. 7 (top). General view of paint mixing room. Vacuum still for thinner reclamation can be seen in background.

Fig. 8. Booth and conveyor arrangement.

Fig. 9. No. 3 spray booth with centre partition removed and opened for entry of extra large parts.





On starting one unit, with no air being exhausted, hot air was forced up the intake stacks of the other units. This caused the controlling thermostats (owing to their location) to close the steam valves and cause a freeze-up.

In conclusion, after a year of operation, it can be definitely stated the installation has measured up to expectations. Quality has been vastly improved and there is little hazard in the operation of the area.

The overall cost of the project was approximately $60,000 and the annual savings due to decreased rejection and improved efficiency was estimated at $24,000. However, the latter actually amounts to $30,000 because of the increased work load which the area easily handles. Operating costs however, have increased slightly due to the additional oven and the vacuum still. Heating cost is approximately the same, as the amount of exhausted air has not increased appreciably.

Electrical Power Measurements

at the National Research Council

J. Hart

Division of Applied Physics, National Research Council

ENGINEERS and scientists are planning for a continuous expansion of the supply of electrical power, and technical journals are filled with papers on novel methods of generation, distribution and switching. Meters are very necessary adjuncts to our power systems, but their importance tends to be eclipsed in print by articles on more spectacular electrical matters; a highly specialized and important aspect of metering which is concerned with the art of standardization and calibration is all too often taken for granted, and this article seeks in some small measure to remedy this deficiency.

Power authorities, defence departments, meter manufacturers and similar industrial organizations maintain their own a.c. laboratories which contain excellent secondary instruments whose calibration is known to remain constant for many months or even years, and the comparison with the laboratory standard of meters from production or the field, perhaps through other intermediate instruments, can be carried out on an assembly line basis.

The calibration of precision laboratory master instruments is quite another problem, and may require considerable finesse. Many of the better equipped laboratories carry a group of standard cells, resistors and potentiometers for high precision d.c. comparisons, but it is very rare to find an even vaguely comparable precision in a.c. work: the reason for this gulf between a.c. and d.c. precision will become evident later in the article.

The power frequencies at which calibration facilities are made available depends on the nature of the industry: 60 cps. and 25 cps. are still overwhelmingly popular as general distribution frequencies, but the trend in airborne and other portable systems is to frequencies that would have been considered impossibly high a few years ago, and high precision calibrations at 4000 cps. are usual, if not commonplace. This state of affairs presents quite a challenge to the calibration laboratory, for it is a truism to say that the higher the frequency, the farther away the calibration gets from the d.c. standard cell and ohm, and the more difficult does the technique become.

The Applied Physics Division of N.R.C. is responsible for the maintenance of existing physical and electrical standards, and research into new ones. This paper describes the a.c. power measuring equipment that is being built in the electricity and mechanics section of the division.

Responsibility of N.R.C.

A uniform and true system of metering is possible only if the laboratory standard instruments, *including cells and resistors*, belonging to industries across the country are compared at regular intervals with master standards that are known to be accurate; it is precisely this function of correlation that the National Research Council is required by law to undertake.

This responsibility is not by any means confined to electrical standards and in the applied physics division very active research is being pursued into primary standards for all fields; a variety of industrial measuring devices ranging from gauge blocks through thermometers to nuclear radiation sources are accepted for comparison with our standards. These facilities are heavily used by industries with their own standardization laboratories, and by firms who specialize in calibration.

An absolute measurement is strictly speaking the direct comparison of a quantity with the basic standards of mass and length of which the National Research Council is the legal custodian, and time which is kept by the Dominion Observatory. Electrical units are established by a series of transfers in the electricity and mechanics section. Starting with a standard physically measured inductor used in a bridge at a standard frequency, it is possible to establish a standard resistor in terms of length and time to a few parts in a million. A standard ampere (d.c.) can be similarly established, with about the same precision in terms of the force between two coils of known physical dimensions (here, mass, length and time are involved). The standard ampere passing through a standard ohm establishes a standard d.c. potential which is readily available in a Weston cell. These standards of resistance and potential are portable and can be used for national and international calibrations and comparisons.

A. C. Standards

The problem of a.c. measurements is on a rather different plane. It is not, with present techniques, possible to make an absolute a.c. calibration since the quantity to be measured is of necessity transitory in nature. A practicable alternative is to derive primary a.c. standards of current, potential, and their product, power, in terms of the well-established absolute d.c. measurements. (A broad definition of a primary measurement would be a comparison made with the highest accuracy against an international or absolute standard).

It is now 60 years since electrical power was first measured with high precision and it is a great tribute to Kelvin and to far-sighted people like Rayner that the most precise measurement of a.c. power is still made with a quadrant electrometer that is substantially the same as Kelvin's original. This instrument, however, has disadvantages, and dynamometer or thermal converter instruments are necessary for some power standardization purposes. I shall explain the presence of these diverse types of instruments, some of very old design (but of excellent vintage), in the electricity section of the National Research Council's applied physics division, and follow that with a more detailed description of the equipment. This facet of the standardization facilities at the Council is a new, but very necessary development; the immediate objective is the establishment of a.c. power measurements of a quality equal to those of any other national standards laboratory; the industrial expansion of our country has made the continuing development of primary a.c. standards in Ottawa imperative.

In almost all physical measurements the most accurate result can be obtained if the unknown quantity is compared with the known one in such a way as to give a null upon a deflecting instrument. Unfortunately there is no single circuit which can be used in this way to compare a.c. and d.c. quantities with precision. It is possible to build a wattmeter which has two similar systems, one a.c. and one d.c. connected in such a way that the d.c. couple acts as an "electrical spring", and counteracts the a.c. deflecting torque so that when the a.c. and d.c. quantities are equal there is no deflexion of the detector. Electrostatic instruments have been made on this principle, and we have a dynamometer which can be so used.

In practice, however, complications are introduced by trying to set up such an instrument and the traditional method of making primary a.c. measurements is to use an instrument which has nearly the same response to d.c. and a.c. The amount by which a given d.c. current, voltage or power and the same a.c. quantity differ for the same indication of the instrument is the a.c./d.c. transfer error of the instrument at that particular frequency: a primary instrument is designed to have this error calculable and very small. It is always used in such a way that the same scale indication is obtained successively on both directions of d.c. and on a.c.: under these circumstances the transfer is independent of relatively slow mechanical and thermal drifts. Once the a.c./d.c. transfer error has been established, this information can be used throughout the lifetime of the instrument. As with any other standardization the proof that the transfer error is small can be demonstrated only by using more than one method of transfer, and it is for this reason that a well-established national laboratory uses several types of instruments. Once the a.c./d.c. transfer error of the primary standard instrument has been established the calibration of other a.c. instruments although not necessarily a matter of routine, is quite straightforward. This article is concerned mainly with power measurements, but the same principle holds for current and voltage measurements.

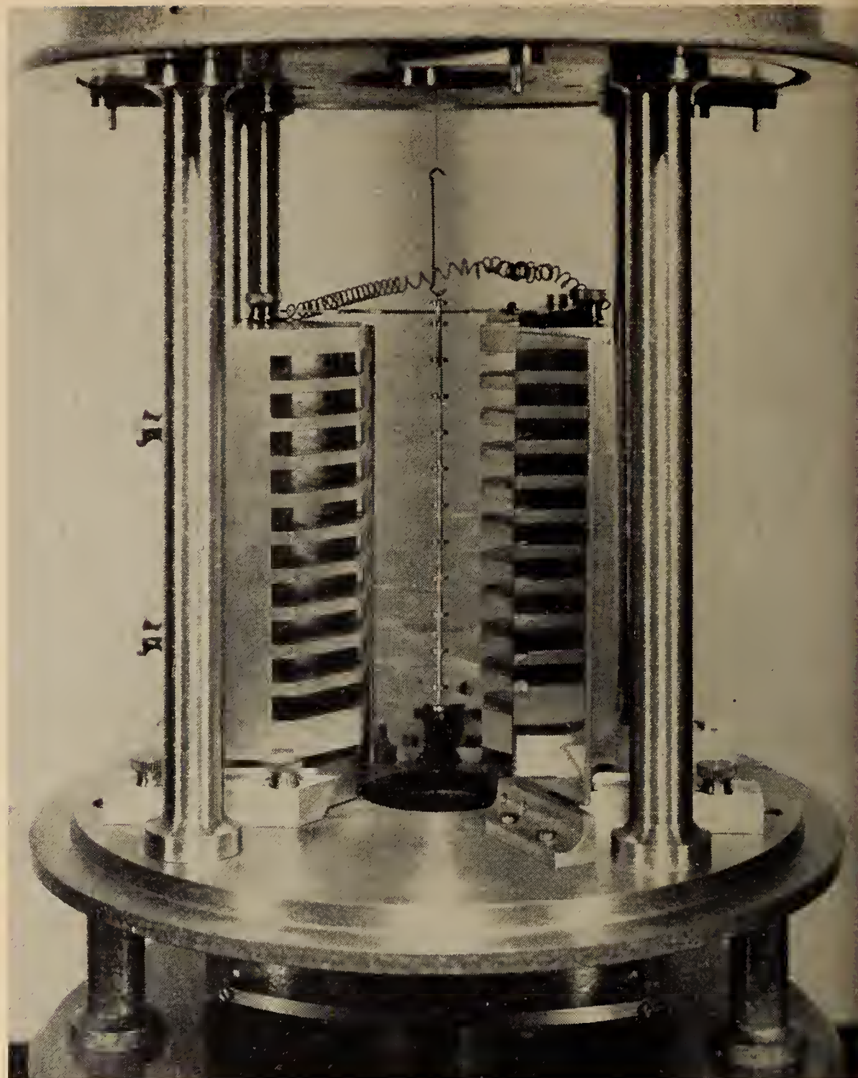

Figure 1. The Kelvin electrostatic voltmeter movement. The instrument has a bifilar suspension about two feet long. The mirror which is in the lower compartment is attached to the moving vanes by the metal rod. The fixed electrodes run on tracks, and their position determines the sensitivity and linearity. Construction is almost completely of aluminum: the main baseplate is about 7 in. in diameter.

Standard Laboratory Instruments

There are three main types of laboratory transfer instruments: (a) electrostatic, (b) electrodynamic, and (c) electrothermal. There is another reliable method of transfer so far used for potentials only; this involves the comparison of a.c. peak with d.c. voltages but it is of strictly limited application. Methods (a) and (b) can be made to depend upon the instantaneous products of two potentials or currents to a high degree of precision and are suitable for standard voltmeters, ammeters or wattmeters. Thermal or, more recently, luminous converters can be made to read power directly only by ingenious circuitry, so that they have not been widely employed as wattmeters. To measure power by thermal methods, independent precise measurements of potential and current have to be made using a pure waveform, with the additional complication of a very difficult phase angle measurement. All three types of instruments are capable of accuracies of better than 0.01 per cent when carefully used, at any power frequency. Each type of instrument has its own limitations and these will be discussed in detail.

The laboratory has deliberately been very conservative in the choice of instruments, for our immediate objective has been the rapid establishment of unimpeachable a.c. standards.

Electrostatic Instruments

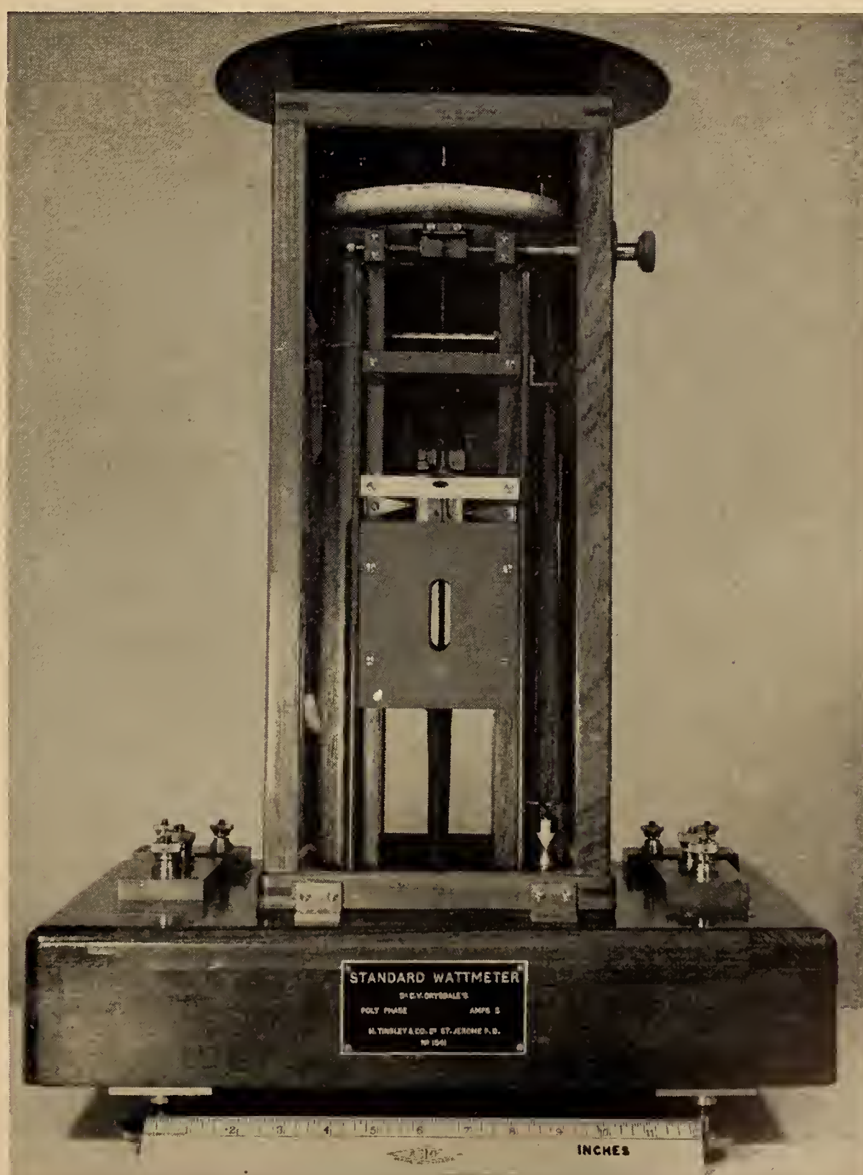
The laboratory has a Kelvin electrostatic voltmeter, and a quadrant electrostatic wattmeter based upon the British National Physical Laboratory design is being constructed in the physics workshop at the National Research Council. An electrostatic instrument is difficult to handle, since the torques developed are small and thermal or mechanical disturbances can be very troublesome. The voltmeter, which is a multiplate instrument with a bifilar suspension is less critical in this respect than the wattmeter, which has a very thin aluminized mica needle on a single wire suspension. Both instruments have optical pointers and are capable of an ultimate accuracy of the order of a few parts in 100,000. The full-scale deflexion of the voltmeter is 120 volts; the wattmeter requires a potential of 120 volts on the needle and about 2 volts on the quadrants obtained by dropping the current across an a.c. standard resistor; the indication is proportional to the integrated instantaneous product of these two potentials and therefore to average power.

Electrostatic instruments are of course essentially sensitive to differences of potential. They have practically zero inductance and small capacitance, so that they are transfer instruments *par excellence* at all audio frequencies, but small contact potentials may be troublesome. To reduce these, the same metal (aluminum) is used throughout and the machine finish is carefully controlled; despite these precautions very slight surface corrosion can exert a detectable rectifying action which increases the transfer error. The only way of removing this error, which may not be constant with frequency, is to subject the working parts to mild chemical treatment. In the past, electrostatic voltmeters with working parts of different metals with different finishes have been used to examine these effects in some detail and there is no necessity for us to repeat this work.

Electrodynamometer Instruments

The dynamometer is essentially a current-sensitive device and of necessity has appreciable inductance. The laboratory has two precision dynamometers, both with optical pointers. One has a high permeability core and has to be corrected with auxiliary capacitances for a.c. operation. Although capable of great precision it is not truly an a.c./d.c. transfer instrument since the transfer error is not

Figure 2. The Drysdale dynamometer wattmeter. Two pairs of fixed coils are perpendicular to each other and the moving coils are suspended from a torsion head by a spiral phosphor bronze spring. The moving coils are individually wound astatically, and as a result each pair of fixed coils has to be connected with the fields of the two individual coils opposing each other. The moving coil therefore moves in a far from uniform field. Construction is almost completely of wood and bakelite.



amenable to calculation and (without compensation) is large.

The other instrument, designed many years ago by Drysdale, has no iron whatever in its construction. It has two identical systems mechanically coupled and suspended by a spiral spring of phosphor-bronze, so that it can be used for two and three phase measurements and if necessary as a single phase a.c. instrument with a d.c. electrical spring. The interaction between the two systems is negligible, current-potential interaction is also small since the torsion head is adjusted so that the coils are always in a position of practically zero mutual inductance with respect to the fixed coils. The moving potential coil is in series with a resistive multiplier of relatively high value and the inductance of the coil is negligible; there are no large masses of metal or closed loops so that eddy currents are kept to a minimum; the a.c./d.c. transfer error is therefore small and calculable at frequencies up to a few kilocycles per second. The instrument is rugged compared with the electrostatic instrument, for the operating torque is relatively high, and it is invaluable for more routine calibrations. The precision obtainable is of the order of 1 part in 50,000 with 100 volts on the moving coil and its associated potential divider and 5 amp. through the field coils.

Thermal Converters

A thermal converter is essentially a filament of resistive material which is heated by the current to be measured; the temperature attained is read by using a thermo-couple or by some other method. Commercial converters are readily available and we use these without modification either in a self-contained transfer volt ammeter designed at the National Bureau of Standards or in our own circuits. In this laboratory, thermocouple potentials are compared on oil-filled microvolt potentiometers; no absolute measurement of the filament temperature is required when the converter is being used as a transfer instrument. The more sensitive converters are sealed in vacuo.

Thermal converters suffer from d.c. reversal errors if the thermocouple is not in the thermal centre of the heater, and they are inclined to drift fairly rapidly so that it is difficult to make a measurement more precisely than about one part in 10,000. On the other hand, they have a response right through the audio

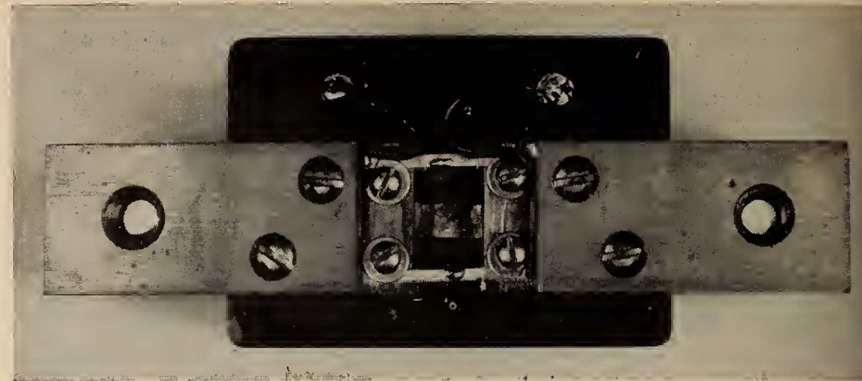


Figure 3. A high-current thermal convertor. The thermocouple is welded to the centre of the resistance element and is connected to the potential terminals via the two metal strips which are isolated by mica spacers.

frequency range for current between 5 ma. and 20 amp.; their self-inductance and capacitance are virtually zero. Precise measurements of power have to be made by measuring current and phase angle independently using a very pure sinusoidal waveform. This can be achieved without difficulty at unity power factor but the phase angle measurement becomes very difficult at lower power factors; we hope to develop a phase bridge which will be adequate for power factors down to 50 per cent.

Laboratory Equipment Is Flexible

Electronic generators supply the power source for calibrations. An audio frequency oscillator feeds three audio frequency amplifiers by way of a phase shifter which controls the relative phases of the amplifier inputs. Single phase wattmeters are normally calibrated on phantom loading using two amplifiers to supply the potential and current respectively with a variable phase angle between them. The third amplifier is a standby which is paralleled into the current output for high current measurements and may also be used to supply a third phase if required.

The output from this equipment is 200 watts per phase, with less than 1 per cent harmonic distortion at frequencies between 200 and 20,000 cycles per second; amplitude drift is of the order of 0.2 per cent per minute and is the most troublesome feature of the generators. Potentials up to 1 kv. and currents up to 20 amp. are available.

In addition there is a 1.8 kw. self-contained single phase electronic generator with an output of 110 volts, 1 per cent distortion between 20 and 4,000 cycles per second. This is normally used to power the other three amplifiers at 75 cps. to avoid various complications that occur when they are powered directly from the mains, but it is available separately for calibrations requiring higher powers.*

The generators are mounted in standard racks together with a monitoring oscilloscope, phase meter and wave analyser, in front of which there is a low bench for the potentiometers and portable meters; the bench is narrow and the generator controls can be reached by people seated at the benches. The primary standard meters are mounted on wall brackets or other benches and the potentiometer, galvanometers for routine work stand on anti-vibration mounts in the equipment racks or supported by wall brackets.

Associated with the equipment already mentioned there are a.c. standard resistors in an oil bath, standard cells in an air thermostat, decade resistance boxes and capacitors. Direct current supplies are obtained from batteries in a ventilated cabinet, and the direct potential supplies come from a Glynn type stabilizer.

The laboratory is air-conditioned and is maintained at 72 degrees F., 40 per cent to 50 per cent r.h.

Calibration And Intercomparison

All the instruments described respond to d.c. and to r.m.s. a.c. when used to measure current and potential: the wattmeters respond to average power. These are the quantities which are normally of most interest, and they are not critically dependent upon the applied waveform provided that high order harmonics outside the range of the instrument are not present in large quantities.

The comparison of current voltage or power by an a.c./d.c. transfer requires the connection of the stand-

* Current and potential transformers used for high power work are calibrated in the National Research Council's electrical engineering section.

ard and other meter in a circuit with provision for switching between a.c. and both directions of d.c., which is itself standardized against a standard cell by ordinary potentiometer techniques. It is emphasized that the calibration is independent of the electro mechanical properties of the standard and depends only upon its a.c./d.c. transfer characteristics which are for all practical purposes constant and known. Errors caused by effects like the self-heating of a potential coil are examined separately.

The measurement of power by thermal methods is difficult and is still in the experimental stage. Thermal wattmeters which are usable throughout the audio frequency range are not high precision instruments. It is possible to measure current and voltage separately and the phase angle between them, but in this case the apparent power is given by the product of the r.m.s. current and voltage and the power factor and this is not the true power unless current and potential wave forms are sinusoidal. The precision is limited by the waveform of the generator and the accuracy of the phase angle measurement.

Future Work Depends Upon Demand

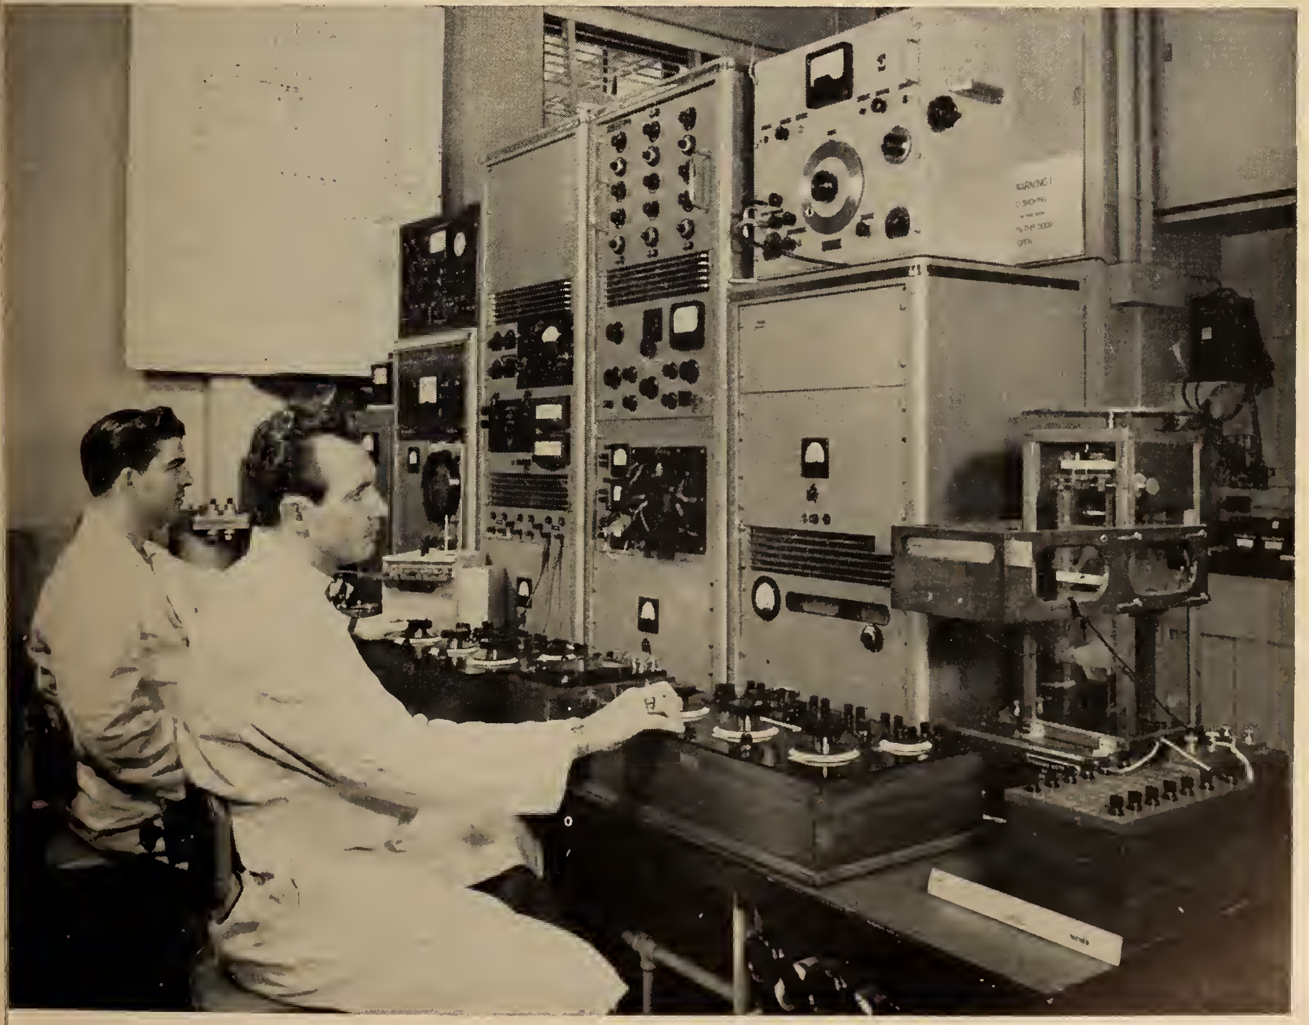
Ever higher power frequencies are being used in diverse applications, ranging from missiles to induction furnaces and we intend to devote a considerable part of our energies to the study of new methods of power measurement that can be used at these elevated frequencies. The demand upon the a.c./d.c. transfer system will increase at "ordinary" frequencies and we know that the country's standard rests upon a sound classical foundation.

In spite of the vast improvement in standardization techniques and calibration facilities in the last few years, there are still too many instruments in the country in which the users have completely unjustified confidence. It is our hope and duty to encourage every meter user to confirm the calibration of his instrument at regular intervals, whether he be interested in illumination, photogrammetry or, in our case, electricity.

It is our function to calibrate laboratory standard meters from commercial standardization laboratories. It is not our function to calibrate quantities of ordinary meters for industry; these may be sent to firms who specialize in that business, or, in appropriate circumstances to the Department of Trade and Commerce. They

(Continued on page 290)

Figure 4. A general view of the calibration racks. The 1.8 kw. power supply is hidden at the far left: the next rack contains a distortion monitor, the phase meter and an oscilloscope. The phasc bridge, output monitoring meters and one 200 watt amplifier are in the centre rack. From top to bottom in the fourth rack are the phase shifter, oscillator, ac/dc switches and the second amplifier. The fifth rack carries the wave analyser, the third amplifier and the d.c. galvanometers. On the bench arc the thermostat containing standard cells, a portable wattmeter, two potentiometers, an a.c. volt box and a primary wattmeter. The heavy batteries are in the cupboard behind the racks. A heavy duty oil cooled standard current shunt can be seen between the technicians.



An appraisal of the potentiality of

High Voltage D.C. Transmission

E. V. Leipoldt, M.E.I.C.

Vice-President, The Shawinigan Engineering Company Limited, Montreal

Based on papers read at meetings of the Atlantic Provinces Professional Engineers, St. Andrews, N.B., September 1956, and the Engineering Institute of Canada, Montreal Branch, October 1956.

TECHNICAL interest in the possibilities of long distance transmission of power by high voltage direct-current has been sustained for over half a century. This continued interest is somewhat puzzling in view of the meagre accomplishments in this field to date. Only two relatively small installations, both government sponsored, have been recently constructed after a lapse of some 60 years since the so-called Thury system of d.c. transmission was commissioned in 1890.

The Thury system was based on constant current transmission at variable voltage. The high voltage was attained by connecting a number of d.c. generators in series with insulated bed plates and drive shafts. To utilize this power at the receiving end of the line, the motors were similarly arranged. It is obvious that this system had limited application and it was used to a degree only in North America on d.c. traction systems at 2500-3000 volts. Subsequently these d.c. generators were replaced by mercury arc rectifiers.

In order to place it in the proper perspective and historical background, it should be observed that the Thury system was initiated in France during the period that the polyphase alternating-current system and the induction motor were being developed in America and in Europe. From this point on great strides were made in the perfection of a.c. motors, generators and transformers, and transmission of power by high voltage a.c. soon took the lead, a position it has never relinquished. As the magnitude of power to be transmitted and the required transmission distance have increased with time, technique in the design and construction of a.c. equipment and lines has kept pace and thus far imposed no limitation on practical requirements. Several systems in European countries are now operating at 400 kv. and new lines are being projected for 500 kv. In these upper ranges of transmission voltage, a single circuit line would be capable of transmitting a million kilowatts over a distance of 400 to 500 miles. Capability of this order should satisfy all practical requirements in the foreseeable future.

Where then does d.c. transmission enter the picture as a possible contender, and why has interest been maintained in d.c. transmission in the face of such overwhelming achievements in the a.c. field? The answer may be found in technical criteria which favour the use of d.c. and which have stirred the imagination of many eminent engineers. Some of the leading manufacturers in Europe and the U.S.A. have spent millions of dollars in research and on the construction of experimental lines to demonstrate the practicability of d.c. high voltage transmission. With possibly one exception, these companies have all abandoned active development in this field due to the apparent limited application of d.c. transmission to the rapidly expanding network of a.c. lines which cover most industrialized areas.

Technical Comparisons

A review of some of the technical advantages which the d.c. system offers in comparison with the conventional a.c. transmission system is given hereunder.

(1) *Conductors* — Self-induction of alternating current creates the so-called "skin effect", the crowding of current to the periphery of the conductor. The economical utilization of metal for conducting heavy alternating currents suggests the use of a hollow core conductor, unless mechanical or other considerations apply, such as steel reinforced aluminum conductor. The smaller diameter of conductor, permissible for direct current of equal rating, is of particular significance in the comparative cost of submarine cables.

(2) *Insulation* — Since the nominal or effective voltage of alternating current is the r.m.s. value of the sinusoidal voltage wave, it is apparent that all insulating materials will be subject to stresses equal to the peak value of the wave. This factor of approximately 1.4 of the effective to the peak values of a.c. voltage permits a corresponding lowering of the insulation levels for d.c. transmission lines and cables of equivalent voltage classification. A further reduction in the thickness of paper insulation for d.c. cables is permissible due to the unidirectional stress imposed by the d.c. voltage.

(3) *Submarine Cables* — The capability of any submarine cable to carry the rated ampere load for which it has been designed is governed mainly by thermal considerations. The energy loss generated in the conductor must be dissipated through the insulation, the sheath and the mechanical armouring at a temperature gradient which would not exceed specified temperature limits at the surface of the conductor. When alternating current is transmitted, certain other losses, in addition to that of the conductor, must be accounted for in calculating the ther-

mal flow. There are, for example, the dielectric loss in the insulation caused by alternations of the direction of stress; induced circulating current losses in the metallic sheath; and electro-magnetic losses in the external steel armouring of the cable. None of these supplementary losses applies to d.c. transmission; moreover, the reduced radial thickness of the insulation belt (item 2) permits a greater transfer of heat, or conversely a lower temperature at the surface of the conductor.

(4) *Transmission Lines* — The construction of a transmission line for high voltage d.c. offers a simpler solution in structural design than a conventional three phase a.c. transmission line of comparable voltage and transmission capacity. The two-conductor d.c. system with grounded midpoint, relatively shorter insulator strings and smaller tower clearances (item 2) permits the use of a simple and compact steel mast with ground wire at the apex and balanced side arms carrying one conductor on each side.

(5) *Transmission Stability* — For comparative purposes, the electrical stability of the transmission system may be considered in the following two cases. The first concerns the long distance transmission of a large amount of energy from a generating source to a load consuming area; the second concerns the transmission of a limited amount of energy from one large power system to another. In the first case with a.c. transmission, instability may arise due to a disturbance in the connected load system causing a momentary drop in voltage or frequency. In the second case, overloading and resulting instability of the tie line may occur due to a sudden loss of load or of generating capacity in either of the two major systems, with resultant differences in frequency and voltage. The d.c. transmission system is inherently stable as it is independent of frequency and of voltage fluctuations of the connected a.c. systems. It will tend to maintain the power flow for which it has been adjusted, provided the connected a.c. systems are able to supply or absorb the energy transmitted. The d.c. tie line is also an effective method of inter-connecting two a.c. systems of different frequencies for the interchange of power.

(6) *Line Capacitance* — In long distance a.c. lines, and particularly in the very high voltage ranges, the line charging current due to the capacitance effect presents a serious operating problem in many respects. Unless compensated by the switching of shunt reactors in the line, it imposes special requirements in the generator design, complicates the regulation problem and requires higher insulation at the line terminal for open circuit conditions. In long a.c. high voltage cables, this condition becomes more severe, since the charging current may easily exceed the normal load current. The line capacitance has no similar effect on d.c. transmission. Compensating equipment with associated losses must therefore be considered an added burden to the cost of a.c. transmission of large blocks of power.

(7) *System Fault Currents* — When a system with large concentration of power is connected to a smaller system by an a.c. tie line, a substantial increase in the magnitude of fault current of the smaller system results. This condition seriously affects the interrupting ratings of circuit breakers on the smaller system. The d.c. tie line, on the other hand, contributes in short circuit current little more than the nominal rating for which it has been adjusted. A supplementary increase in fault current may arise however from the synchronous condenser capacity required to supply the reactive component on the load. The combination of these two will still be much less in effect than that resulting from an a.c. line of comparable capacity.

The author discusses advantages and drawbacks to the use of high voltage direct current transmission, with particular reference to some of the experience gained in Europe. Transmission at operating ranges of some 200 kv. is commercially feasible.

Consideration of the foregoing technical advantages indicates that items (1) to (4) inclusive have a most significant bearing on the economy of d.c. transmission, particularly where long submarine cables form a part of the transmission system. In view of these apparent advantages of d.c. transmission, the question may well be asked: why has so little use been made of this practical means of reducing the cost of long distance-power transmission?

The answer is simple. The economical "break-even" point for long distance a.c. and d.c. transmission of large blocks of power is considered to be approximately 400 miles. While few lines have been constructed or even considered for this length, it is apparent that present experience with d.c. transmission lies on the wrong side of the fence. Not many engineers would be willing to assume the risk of making the large capital commitments necessary for a million or more kw. transmission scheme based on the now available performance data of relatively small capacity d.c. systems.

The cost of the a.c. to d.c. conversion equipment at each end of the line remains a formidable item, also the design and construction of the converters and associated control gear are more complex than the conventional equipment required for switching a.c. lines. Many utility engineers fear that the added complications would require a much higher order of technical skill and training on the part of their operating staff.

An appreciation of the general design features and operating principles of the d.c. transmission system may be helpful at this stage in appraising the prospects and potentiality in regard to future developments of the power industry.

Direct-Current Conversion Equipment

The converters which transform the a.c. to d.c. are, in principle, similar to the mercury arc rectifiers so extensively used for electrolytic purposes and for electric railways. They are reversible in their functions so that power can be transmitted in either direction, i.e. the converter can become the inverter. This is accomplished simply by shifting over a range of 90 electrical degrees the controlled pulses to the grids, which time the firing cycle of the valves.

Each converter station contains a number of valves arranged in groups of six connected to a three phase circuit with the anode and cathode forming the negative and positive d.c. supply. The connections are so arranged that each phase discharges alternately through one of two connected valves with each reversal of current, thus giving six d.c. pulses per cycle (see Fig. 1). Where two groups of valves are used in series, the second group could be connected to a separate transformer winding having a 60 degree phase shift. This gives twelve d.c. pulses per cycle and reduces the ripple effect in the d.c. circuit.

Each rectifier valve is so designed that it allows current to pass in one direction only. The main body of the valve consists of a steel shell supporting one or more insulated anodes at the top and contains a pool of mercury at the base which forms the cathode. A control grid, separately excited, is supported between the anodes and cathode, and serves to regulate the power through-put by advancing or retarding the ignition.

Whereas rectifiers for industrial use are of relatively low voltage and capacity, the valves for high voltage d.c. transmission must necessarily be designed for much higher voltages in order to transmit economically large amounts of energy. Individual valves are at present in operation at a nominal 50 kv. and experimental units for over 100 kv. have been designed and tested. At these higher voltages, the rectifier valves have a transmitting efficiency of approximately 99.8 per cent.

D.C. System Operation and Control

The principles employed in the control of d.c. transmission systems contain elements that are novel to the operator of conventional a.c. systems. For many years the relative merits of constant voltage versus constant d.c. current have been debated. At present, the constant voltage system appears to have gained the upper hand, and the control procedures described herein are based on this method of operation.

First of all, it must be understood that a d.c. transmission system, with its complement of terminal equipment, converters and inverters, cannot function unless there is a source of a.c. voltage available at the receiving end. This voltage may be derived from a synchronous condenser or a power network, the former being normally required to supply the reactive component of the inverter station. The reactive requirements amount to approximately 50 per cent of the energy transmitted, or the equivalent of an 85 per cent power factor at the receiving station.

This reactive requirement is due to the "margin of commutation", i.e., the time interval between the selected firing point on the phase voltage wave and the instant where the incoming and outgoing phase voltages are equal. If this margin is reduced to a minimum, there is a possibility that one of the valves may fail to "commutate", resulting in a short-circuit of the d.c. supply. Increasing the margin of commutation improves the stability of the inverters but also increases the amount of reactive power which must be supplied.

The transmitting station is normally set to maintain a predetermined d.c. voltage by regulation of the on-load tappings of the main transformers. The receiving station, on the other hand, takes over the function of control of the frequency and current, i.e. the load. However, the control functions and responses of the sending and receiving stations are complementary, and it is therefore essential to connect the stations by a radio link or pilot wire for transmitting the control signals.

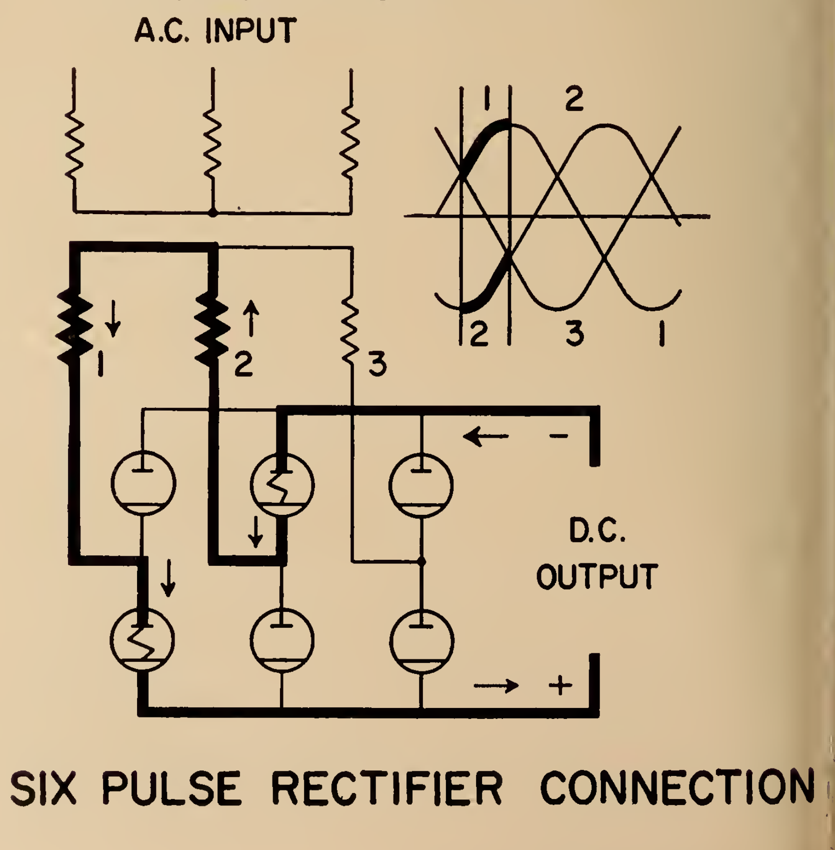
Where the d.c. transmission line is the sole source of power supply for a load area, regulation of the a.c. system voltage is accomplished by adjustment of the field of the synchronous condenser, precisely as in the case of a single generator supplying an isolated load. Power flow to the a.c. system is regulated by means of a frequency sensitive relay, which transmits "raise" or "lower" signals to the sending station when the system frequency deviates from normal. The transmitted signal is transferred through a relay which adjusts the grid control to raise or lower the d.c. voltage supplied by the rectifier, and actuates a follow-up relay to check and re-adjust the transformer taps to maintain the required margin of control on the grids.

For the alternative condition, where a d.c. line supplies power to an a.c. network having its own generating plant, the supply is controlled by a d.c. current regulator which can be adjusted to limit the amount of power transmitted. The d.c. supply will simultaneously assist in maintaining the system frequency by means of the frequency relay, but only to the extent that the maximum pre-set load is not exceeded. In the event of failure of the carrier or radio signalling system, the converters at the sending end continue to regulate for constant d.c. voltage, whereas the inverters automatically take over frequency or load control but under less favourable conditions.

Economic Studies

The capital cost of the terminal installations only for d.c. transmission has been recently considered to be in the order of \$40 to \$50 in Canada per kw. of transmission capacity. If this were to be expressed in terms of physical assets, the conversion

Fig. 1. Six pulse rectifier connection. Passage of current during interval between vertical lines on phase voltage curve is shown by heavy lines in diagram.



equipment for one million kw. transmission capacity would equal the cost of two separate 400 kv. three-phase a.c. lines approximately 250 miles long and capable of transmitting the same amount of energy. However, due to recent improvements and refinements in the d.c. converters now operating, it is anticipated that manufacturing allowances for development work could be shaded, with resultant lower prices to the industry. Reports from Japan(1), where d.c. converter stations have been installed for interconnecting their 50-cycle and 60-cycle systems, indicate a considerably lower cost for the conversion equipment as the "break-even" point in comparisons between a.c. and d.c. transmission costs is estimated to be 200 miles compared with the European estimates of approximately 400 miles.

Exhaustive studies have been made to establish an acceptable basis for comparison of costs for d.c. versus a.c. transmission. Assumptions have been postulated and examples calculated on a prescribed basis, covering a range of loads from 100 to 1500 Mw. and distances from 100 to 1000 kilometres for overhead lines, also 30 to 100 kilometres for submarine cables. The work (2) was undertaken by an international Study Committee appointed by the International Conference on Large Power Systems (CIGRE) and presented in report form (No. 417) at the Paris Conference, June, 1956.

Using European costs for line construction and conversion equipment, the "break-even" distance for overhead lines varies from 320 miles to 380 miles. The applicable distances for submarine cables are 22 miles for 750 Mw. and 18 miles for 100 Mw. It may be assumed that the "break-even" point would be somewhat greater in Canada due to the higher landed cost of conversion equipment.

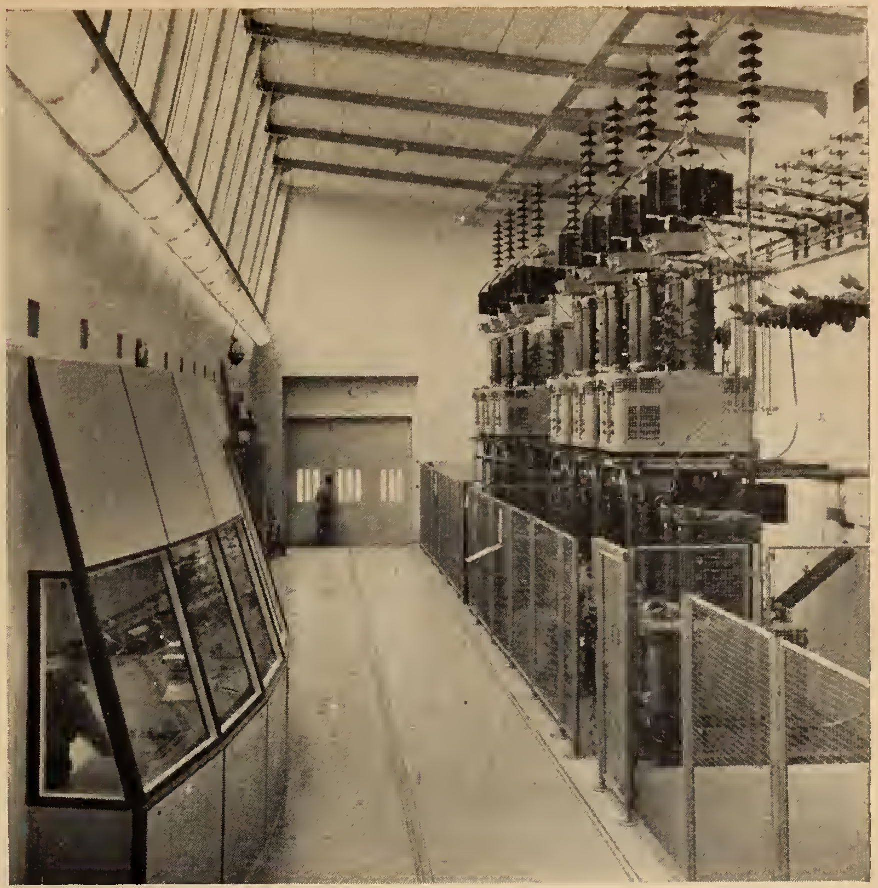


Fig. 2. Converter installation for the Gotland system. Rated output 20 Mw. at 100 kv., d.c. The two groups of rectifier valves are referred to in the text below.

Operational Experience

The Gotland scheme (60 miles of submarine cable) was constructed in two stages and operated for some months at 50 kv. with one set of valves. After the installation of the second group, the voltage was raised to the nominal rating of 100 kv. for an output of 20 Mw. over a single cable with return through the earth. Ultimately, a second cable will be laid and the installation duplicated to give 200 kv. between positive and negative and a transmission capacity of 40 Mw. Since the spring of 1954 when the system was placed in service, there have been two cable failures, one of which was due to a ship's anchor fouling the cable.

It was anticipated that the major source of trouble would arise from "back-firing" of the rectifier valves. This fault condition is provided for in the layout by the addition of a bypass valve for each group of six, which would shunt out the defective valve. This operation reduces the voltage to half normal and permits the valve to recover in a fraction of a second and be restored to service with a barely perceptible flicker. Figure 2 illustrates the two groups of rectifier valves at Gotland.

Experience to date has been more favourable than anticipated. Less than 10 "back-fires" have occurred during the first year of operation. The ageing of the valves, due to the deposit of metallic dust on the insulation, also has been less than expected and it is now believed that five years' continuous operation can be obtained before it is necessary to open the valves for removal of the deposits. A number of minor troubles in the secondary and control wiring have been eliminated and adjustments made to the regulating devices, which may be considered part of the normal "tuning up" operation of any newly developed equipment. This d.c. system is now considered so reliable that the thermal generating station on the island of Gotland has been shut down and the entire supply is taken over the single cable.

Russia has also been able to contribute information submitted in report form (3) to the CIGRE Conference. This covers the operation of an experimental-industrial 200 kv. d.c. transmission system. This d.c. system was commissioned in 1950 and supplies 30 Mw. to the Moscow power system from a generating station 70 miles away over two buried cables. The valves used in this installation are single anode type rated at 100 kv. and are arranged on an insulated platform which is normally grounded. In the event of a cable failure, the midpoint grounding is removed and the full output at 200 kv. is transmitted over the sound cable. The equipment and line were subjected to various artificial faults for development purposes and a number of improvements made which have resulted in stable operation. It is reported that the system operated with only three minor faults during 1955 and for a period of over 1000 hours continuously without an incident.

New Projects

With the recent signing of an agreement for transfer of power between the Central Electricity Authority of Britain and the Electricité de France, the Channel transmission scheme is now being actively developed. The d.c. system is favoured on account of the magnitude of the two networks to be connected by a relatively weak tie. The d.c. committee studies, previously referred to, would indicate that this installation would be a marginal case from the economic viewpoint.

Russia is definitely embarking on a large d.c. scheme for transmission from Stalingrad to Donbass to be completed by 1960. The voltage proposed is 400 kv. but no reports have been published as to the projected capacity of the line.

In Japan considerable progress has been made in d.c. transmission due to the two frequencies (50-cycle and 60-cycle) in common use and the necessity of cable crossings to the various islands. Several schemes are being actively studied and the manufacturers have produced suitable rectifier valves in ratings up to 100 kv.

Conclusions

(1) The design and construction of the d.c. conversion equipment, in the operating range of 200 kv. between positive and negative poles, has been demonstrated as a commercial proposition with normal expectancy of satisfactory and economical operation.

(2) Transmission of large amounts of energy in the order of 1000 Mw. or more from point to point and which would require an operating voltage of 400 kv., is still in the unproven stage. Unless government sponsored schemes are developed and operated to provide the necessary background, it is unlikely, that private industry would be prepared to finance the experimental installations and trial operating period which must precede the actual capital commitments for the construction of the d.c. transmission system.

(3) Transmission by underground or submarine cable, or where a cable forms part of the transmission system, is a field in which the application of d.c. could be advantageous for several reasons. If the distance is such as to make d.c. the economical choice, the d.c. system offers additional reliability for continuity of service. With a single circuit for both a.c. and d.c., failure of one cable or a conductor would reduce the d.c. transmission to 50 per cent of the rated capacity, whereas a similar fault on a.c. would cause a total interruption. Provision could also be made to increase temporarily the d.c. capacity by reconnection of the converter circuit, if one cable is out of service for an extended period.

(4) Direct-current transmission is decidedly advantageous for a tie line between two large systems on account of its inherent stability under system fault conditions and due to its limited contribution to system fault currents which affect circuit breaker ratings.

Ground Temperature Investigations in Canada

(Continued from page 269)

but not without a significant margin of error; this should be reduced as more data become available. The success of theoretical study, directed toward a basic understanding of the problem, will depend on the development of ability to measure correctly the thermal properties of the ground, to deal with the complications of moisture flow, and to assess properly all the relevant climatic influences. It is in this direction that the studies of the Division of Building Research are now proceeding.

Electrical Power Measurements at N.R.C.

(Continued from page 285)

send their standard instruments to Ottawa and we issue to them a routine form of report.

Problems which arise from the introduction of high precision instruments with unusual or novel characteristics should be discussed before the calibration is started: it is essential that the ultimate actual user of the instrument should take part in the discussion.

Finally, I should like to emphasize that the only primary Canadian calibration standards are those maintained by the National Research Council in Ottawa. It is a major part of ou[r] responsibility to make internationa[l] comparisons and this we achieve b[y] a regular exchange of tangible standards like the ohm. We define ou[r] own power measurements in term[s] of these standards and this is [a] function that must of necessity be carried out by one authority alone.

The Product of the Engineering Baccalaureate Curriculum

A panel discussion held as Session 2 of the joint Conference of the American Society of Mechanical Engineers and the Engineering Institute of Canada, University of Western Ontario, October 1956

G. Ross Lord

Head, Dept. of Mechanical Engineering, University of Toronto.

Moderator of the Session

The Panel members at this Session are: J. T. Rettaliata, president, Illinois Technical Institute; A. M. Anderson, manager of technical education, General Electric Company, Schenectady, N.Y.; E. T. W. Bailey, combustion engineer Steel Company of Canada; Professor S. Lauchland, head, department of engineering science, University of Western Ontario.

President Rettaliata describes the operation of his institute in considerable detail showing that his facilities (not necessarily staff) are employed from about 8:30 a.m. to 10:00 p.m. five days a week, 12 months a year with good results. In fact if it were not for the extra hours used per day, it would not be possible to operate at all. The undergraduate student has a well rounded program of fundamentals and humanities in his early training, with analysis and design added in his final two years. Most of the post-graduate study is done in the later afternoon and evening.

Mr. Anderson contrasts the work of the engineer with that of the scientist. Where the engineer uses knowledge to improve the lot of man, the scientist is adding to the store of knowledge. He also distinguishes lore from knowledge and understanding, and shows how all these factors may be combined to show how the engineer fits into the world of industry. Research, both basic and applied, require a discipline oriented engineer with post-graduate study qualifications. Mr. Anderson has conducted an interesting study of his own to see how engineers compared with liberal arts graduates concerning personality conflicts with others as a measure of their command of English. There was no detectable difference between the groups.

Mr. Bailey examines two aspects of university education. All year operation *v.* two-term operation, and the special (i.e., civil, electrical, mechanical) option *v.* a general course.

Professor Lauchland has the unique position of designing his own engineering curriculum for the new engineering sciences course at Western. He is also greatly concerned with this same problem of general *v.* special courses. What evolves at Western will be very interesting.

John T. Rettaliata

President, Illinois Institute of Technology, Chicago, Ill.

The recent report of the ASEE Committee on Evaluation of Engineering Education states "the ultimate goal of engineering education is the development of able and responsible men" who are "fully capable to practice on a professional plane, especially those who will lead the profession to new heights of accomplishment through creative practice or research."

Of course, this goal is stated from the point of view of the engineering profession and its educators, but all discerning people understand that its achievement will create necessary and useful individuals for the times in which we live.

The advancement of civilization, our standards of living, and even the preservation of life, are so dependent upon our industrial system that "the products of our engineering baccalaureate curriculum" will have a great effect on the future of mankind.

Predictions from informed sources reveal a future economy for the United States of almost limitless proportions. Each successive year, forecasts indicate, can be a better year. Such optimistic prognostications are certainly pleasant to contemplate. But, it must be understood that the kind of economy being prophesied cannot be attained with the now conventional methods of operation. Because of this, we will be wise to attempt a forecast of what will be needed from the engineer in the future and determine how the products of engineering education may be best prepared and accommodated.

In the United States, it is now expected that the population, now about 168 million people, will double in 50 years; the gross national product, now 400 billion dollars, will double in 25 years; and that electric energy production will double in 10 years. This tremendous expansion anticipates the use of new methods and new adaptations of more of the natural resources. The need for more research to develop new knowledge, and to apply it, is obvious.

Since implementation of these things must originate in the minds of men, the individual who is equipped to achieve the increased productivity that is necessary to our future existence is the key to their accomplishment.

The scientist and the engineer must bear the major burden in bringing into reality the potential in store for us. Competent management, as always, will also be invaluable in furnishing the medium through which creative forces ultimately produce a useful result; but the basic dependence of the economy will be upon science and technology.

Hence, continued progress will be contingent, primarily, upon an adequate supply of qualified scientists and engineers. We must not only produce more scientists and engineers but we must especially strive to develop creative men who will be able to make the greatest contribution toward reaching our future objectives. As we approach the area of diminishing returns in the effectiveness of existing procedures and processes, the thinker becomes increasingly important.

As always, the magnitude of our advancing stride will be dependent upon the human dimension, not the mechanical. The various new aids at our disposal — such as electronic computers — remarkable as they are, cannot think. Their effectiveness is related to the competence of their conceivers and operators. If we are to meet the challenge of the tremendous task ahead, we should make most effective use of gifted individuals and stimulate the creativeness of every future engineer.

The frontiers of science and technology are now advancing more rapidly than at any previous time in history; many will be reduced to routine engineering practice within a few years. The future engineer will have to recognize new developments that have significant potentialities in engineering. Indeed, the rate at which new scientific knowledge is incorporated into engineering practice will depend upon the engineering graduate's capacity to understand new science as it develops. We must facilitate this translation into practice by emphasizing the unity in scientific subject matter to the future engineers now in the classroom. When a student understands there is a great deal of similarity among the generalizations of heat flow, electromagnetic fields, mechanics of fluids and vibration theory, for example, he will gain a concept of systematic orderliness in many fields of science and engineering; he will know how to solve problems in widely diverse fields, with the same basic methods.

Because new situations will arise continually, engineering educators must help students to learn how to deal with each of the situations in terms of fundamental principles, on their own initiative, with self-confidence and sound judgement.

The future engineer must not only be a competent professional but also a well-educated man, with understanding in the humanities and the social sciences as well as in his own field. He will need to be able to deal with the economic, human, and social factors of his professional problems.

An increasing number of engineers are progressing into managerial and top executive positions in industry and government. As manufacturing becomes more complex, and industrial research more common, the proportion will grow. Such men must get their original preparation on the campus. Their future ability will be influenced by the extent to which their technical education is broadened, and perspective and judgement sharpened.

Considerable thought has been given in recent years to the curriculum pattern in the technological institutions to produce the better engineers needed in the future.

Most engineering educators are in agreement that scientifically-orientated curricula which emphasize the basic sciences, the fundamentals of engineering, and which provide for the integration of courses in the humanistic and social sciences should produce the best product. These educators are seeking time to fit into the tight class schedules the opportunity for more students to enroll in more elective courses. They are also concerned about the performance of students in the communication of ideas.

Specialization

For many years, the curricula have been split by the occupational objectives of students who want to specialize because students do have varying interests and will serve different functions in society. We must produce such diverse personalities as production men, designers, technical editors, engineering salesmen, patent attorneys, and promoters. Too much specialization is very expensive for the educational institution to provide and the too-specialized may risk his adaptability for future needs and cheat both himself and society.

The perfect curriculum is still a dream, but there is growing conviction that a good broad education in science and technology, engineering analysis and design, and certain non-engineering subjects is the best one.

The emphasis on fundamentals will result in an approach to unification of the various engineering disciplines. There will be less distinction between different engineering curricula through the bachelor degree level. The tendency will be toward having the majority of the program the same for all engineers, with those courses defining the major not exceeding several semesters out of the four years.

By keeping our engineering education fundamental in nature we should be able to help the employers of our product. For example, electrical, civil and mechanical engineers are too often regarded as specialists. The employer who insists he can consider only an electrical engineer for employment, for instance, will benefit — especially when there is a shortage of engineers — if he can use an adaptable mechanical engineer. It is obvious that, as basic science and engineering grow more important and intermingled, the educational institutions will be able to produce more graduates who are well-fitted to perform a variety of engineering duties.

Preparation for the engineering profession is receiving critical analysis, and only through continual self-examination will progress be made. Specialization is being gradually diminished in the undergraduate program, and is moving more appropriately into the graduate area.

For many years the bachelor's degree has been the accepted badge of admission to the engineering profession. But in a world of increasing complex technology, it is becoming more difficult to prepare a student adequately at the undergraduate level. If engineering is to remain a profession of stature, we might also reflect whether it, like the sciences, has now reached the state where a graduate degree represents the proper minimum preparation. It would appear timely to consider this if the student is to possess the proper fundamental background and also acquire some of the specialization needed to advance the practice of engineering. This is not a matter of concern only to educational institutions; the engineering profession itself must take a leading part.

Engineering and science will be hard pressed to meet the increasing challenge presented by our expanding economy. Alfred North Whitehead summed up the situation of our century as long ago as 1917 when he wrote:

"In the conditions of modern life the role is absolute . . the race which does not value trained intelligence is doomed. Not all your heroism, not all your social charm, not all your wit, not all your victories on land or sea, can move back the finger of fate. Today we maintain ourselves. Tomorrow science will have moved forward yet one more step and there will be no appeal from the judgement which will then be pronounced on the uneducated."

As science and technology move ahead, the product of our technological institutions must also move ahead — not only to keep pace but to set the pace.

A. M. Anderson

Manager of Technical Education, General Electric Company. Schenectady, N.Y.

Before I can provide adequate impressions of current engineering graduates, I feel it is quite important that we adopt a mutually understandable frame of reference against which we can measure these people. In establishing this reference, I will rely on some of the work done by Dr. D. E. Chambers of the General Electric Company although, of course, I am not speaking for Dr. Chambers in this connection.

First, I intend to dwell principally on matters relating to the graduate's understanding of physical principles and will devote little attention to the engineer's ability to read or write or get along with his fellow man. There are many popular and some ill-conceived notions in this latter category which are being espoused by many people but I would prefer to by-pass most of these at this time.

(1) Systematized fund of knowledge and understanding
(2) Lore

On the one hand is the systematized fund of knowledge and understanding which includes the physical principles which are utilized by these people. These are the descriptions of physical phenomena which have been proved useful over the years since they can be used to predict events when varied circumstances under which these events transpire are postulated. Some of the simple principles we know as things like Newton's laws, Maxwell's equations, the laws of hydrodynamic motion, etc. The second body of information is that of lore. These are the myriad bits of information which are largely uncodified and which some people include in the term "industrial arts." Included in this are the practices which have proved useful in making a product — practices which have been stumbled across quite by accident and which on the surface at least have but a very weak foundation in the body of understanding.

Now the scientist as he undertakes his work addresses his attention to increasing and further unifying the systematized funds of knowledge and understanding. In addition, as another example he attempts to transfer pieces from the fund of lore to the fund of knowledge and understanding. He is primarily motivated by a curiosity about physical things and a desire to synthesize new principles which will correlate observations and phenomena more succinctly. The engineer, on the other hand, is primarily responsible for extracting from the funds of understanding and the funds of lore to synthesize products and services which will satisfy the needs and wants of customers

During the second session. From left: E. T. W. Bailey; Prof. J. T. Rettaliata; Prof. G. Ross Lord, the moderator; Prof. J. Stuart Lauchland; and A. M. Anderson.

at the market place. However, either the scientist or the engineer in the process of doing his work might also and usually quite by accident does some of the things which the other generally does. For instance, it is not uncommon for an engineer to find in his work a different principle with a direct unifying ability and this in turn adds to the fund of knowledge. Conversely,it is not uncommon for the scientist in his explorations to perceive new products and services which can be sold at the market place.

It is necessary to go one step further in this description of technical work and outline the various facets of both research and engineering, the research work being dominantly a scientific endeavour.

Shown in the accompanying table are definitions of work — not necessarily of organization, although there are certain advantages in organizing the technical work approximately in this way. (Table on page 294)

From the foregoing it should be obvious that the body of knowledge and understanding which is studied academically by the engineer and the scientist should be roughly the same. Usually, however, the engineering educational institutions devote a little more time in their curricula to the industrial arts or the things which we have classified as lore although I personally believe this is not the correct thing to do and that these ingredients are better learned at work than in the classroom.

Now to the product of the current baccalaureate curriculum. In general the undergraduate excursion into the systematized fund of knowledge and understanding is roughly adequate to undertake the work of product design engineering, or some of the work of advanced manufacturing engineering, and of most of the work of application engineering judged in terms of the businesses of the General Electric Company. To undertake the advanced product engineering work, the advanced marketing engineering work, and some aspects of the advanced manufacturing engineering work, a greater penetration into this fund is required than one gets in the ordinary B.S. curriculum, and in general this means that graduate work or additional courses offered by the industrial enterprise itself are necessary to proper performance in these areas. In the research phases it is quite important that the majority of the professional people have an education level ap-

THE TECHNICAL WORK OF INDUSTRY

Research developing scientific understanding and obtaining scientific knowledge	➧	**Basic Research** developing scientific understanding of nature		**Applied Research** obtaining scientific knowledge about nature
Engineering applying understanding, knowledge and experience to determining, manufacturing, and marketing products	➧	**Advance Engineering** demonstrating technical feasibility	**Design Engineering** designing new products, processes and applications whose technical feasibility has been proven	**Production Engineering** improving existing products, processes and applications

proximating that of the doctoral degree, although there are many ways of doing this including just working on the job and learning as one works. For technical work entitled product production engineering, manufacturing production engineering, and installation and service engineering, the technical content of the undergraduate curriculum in mechanical engineering is probably more than is required and for people who work dominantly in this area it is possible to substitute some of the more subjective courses for some of the technical courses given in the normal curriculum.

From this vantage point, I hope I have made it clear that the product of the baccalaureate curriculum is reasonably adequate for today's work. About the only changes I can suggest are to spend more time on the body of principles and less time on the so-called industrial arts for the great majority of the students since this is about the only way that the educational institutions can remain abreast of technological acceleration.

E. T. W. Bailey

Combustion Engineer,
Steel Company of Canada,
Hamilton, Ont.

Products which win consistent demand through good and bad times must have qualities which satisfy the purchaser. The engineering graduate has been such a product. It seems reasonable to conclude that the curriculum which moulded his thinking was basically satisfactory.

For years the curriculum, which embodies specialization into civil chemical, electrical, mechanical, and other groups at the beginning of the second or third years, has been used by many Canadian universities. Well-meaning people have advocated earlier specialization and equally well-meaning people have held out for no specialization. The latter contend that a common course would best serve the profession.

Actually, a youth starts to specialize when he charts his course through high school. He takes another big step when he enrolls in a particular university or faculty. Entering second or third year, he again has had the opportunity to chart his training into the channels he likes and for which he feels he has an aptitude. This pattern can be compared to the sturdy tree which develops strongest branches when they leave the trunk at the earliest time.

W. Scott Hill, manager of engineering recruiting, writing in the September *General Electric Review*. says:

"Engineering colleges for the past 20 years have tended to turn out graduates equipped with the practical knowledge to begin work immediately in some specialized field. This seemingly meets the needs of many industries at the moment, but only a slight backward glance shows that many of the technologies of even a few years ago are already superseded.

"This realization led to a search for programs that would not be obsolete by the time the senior student took his degree in hand and accepted a job.

"Certain basic technical material underlies most technical work. From this search evolved a greater emphasis on these common understandings. They begin with physics and chemistry, build up to the engineering sciences, seek the true meaning and understanding of mathematics, and end with some concentrated study experience in one or more of the engineering fields.

"Most of the advanced colleges have revised their thinking: delay specialization until the individual reaches the very end of his undergraduate work; keep it relatively minor in character even then. The truly specialized knowledge will come later — either in graduate school or through some advanced education process associated with work experience."

This view might be carried still further and advocate that all faculties of a university have a common first, second, third or even fourth year curriculum.

Usually, in these matters, the most satisfactory solution is found somewhere in between the extremes. In general, the existing curricula used in Canada's leading universities meet the "somewhere in between" specification.

The common, or unspecialized, graduate might be more acceptable to industrial giants who already have built-in colleges in their organizations. But what about the thousands of small industries and consulting firms which cannot offer or afford such training facilities? On the one hand, we are repeatedly told that this is an age of specialization while, on the other hand, plausible reasons are being advanced for withholding specialized training from the curricula.

The basic technical material, physics, chemistry, and mathematics, with few exceptions, have not changed in the last twenty years. The technologies embodying the application of basic principles have, on the other hand, experienced phenomenal growth and changes. The methods of engineering approach, which employ the changing technologies, are fundamentally more constant. Nevertheless, engineering or applied science has within itself wide variations of approach so that specialization becomes mandatory. Earlier specialization offers a better opportunity for the student to grasp these special techniques under the guidance of an expert teacher once the basic subjects have been mastered.

The following simple questionnaire was submitted to engineers of the Steel Company of Canada, Limited. No arguments for or against various curricula were given.

"Mark ..... which of the following type of curriculum, leading to the bachelor degree in engineering, you consider is the better.

(a) Specialized curriculum, that is, chemical, civil, electrical, mechanical, metallurgical and mining.

(b) Common curriculum, for all the above, which might turn out a product which industry would accept and train in their own special fields."

The results showed 61 per cent favoured the specialized, while 39 per cent favoured the common curriculum; 134 answered the questionnaire. The result is an interesting spot check for one company.

Other Changes

The press recently told of other projected changes in the engineering curriculum. One aviation company, for example, plans to give training equivalent to a university engineering degree, confirmed with examinations by the Association of Professional Engineers of Ontario. Instructors will be company engineers who will have to leave their regular duties to teach classes about nine hours per week. How many years it will take the student worker to obtain the engineering degree equivalent, was not disclosed. It will indeed be difficult to bring the quality of this instruction, however well meant, up to that of seasoned professors. It would appear that the ultimate cost might be greater than if the company sent the student directly to college where he can also benefit from the many useful extra-curricular advantages.

The press has also featured headlines about our crowded universities and the urgent need for more engineering colleges. These projected colleges have strong advocates of the common curriculum, as it would reduce their costs.

The net time a student spends in an engineering college at present is six months. The rest of the year valuable physical teaching facilities lie idle.

In an 8,760-hour year, a steel company uses its major facilities 8,688 hours. Engineering colleges use their facilities approximately 1,144 hours to turn out a product. By installing some air-conditioning equipment, giving the staff extra help and raising their salaries, a summer semester could be established. This would require a fraction of the capital required to establish new colleges, complete with staffs and physical facilities. Such an arrangement would double the usefulness of existing facilities to 2,288 hours per year.

Further doubling the hours of use by inaugurating two shifts might achieve the maximum potential of 4,576 useful hours per year. It is not likely, however, that a night shift college course would be very popular. There might be reasonable hope for the success of a summer semester, especially if industry and others got behind it and offered jobs to these people during the winter months. Longer paid vacations for industrial workers are becoming more common and may have to be taken in winter, and the help of college people may become as useful in winter as it now is during the summer. It would be interesting to know if the Russians allow their engineering educational facilities to be used as few hours in the year as we do.

A modern engineering curriculum, whether specialized or common, should feature the possibilities of adventure in order to attract a greater number of students. Colleges would do well to make more use of idea stimulation techniques; creative thinking themes should be integrated with presentations of regular material or given separately. Applied imagination would give students a wonderful interest boost. More and more the engineer must do the broad, creative thinking and leave the details and repetitive work to others. The student would delight in the intellectual free-for-alls similar to those being conducted by some of the larger industrial concerns.

There are few experiences in life so satisfactory as getting good ideas. Quite often they burst into the mind, glowing with the heat and delight of creation. How they do is a complete mystery. We do, however, have methods for stimulating their birth and frequency, with which every student should become familiar.

Let us not take this subject of curriculum arrangement too seriously, for, after many hours of concentrated research, I found someone has solved the whole matter, as indicated in the Dartmouth College Song:

Eleazer Wheelock was a very pious man;
He went into the wilderness to teach the Indian,
With a Gadus ad Parnassum, a Bible and a drum,
And five hundred gallons of New England rum . . . .
Eleazer was the faculty, and the whole curriculum
Was five hundred gallons of New England rum.

Professor L. Stuart Lauchland

Head, Department of Engineering Science,
University of Western Ontario,
London, Ont.

The last member of an unrehearsed panel often finds himself in an unenviable position. I am no exception to the general rule. Last week I discovered that many of the things I intended to say this afternoon are going to be said in better words after dinner this evening by the president of this university. Not many minutes ago I mentally tore up my second set of notes while listening to the president of the Illinois Institute of Technology. The remarks I am going to make now are my third, and last, effort.

There will be general agreement in this room on most of the contents of the A.S.E.E. Committee Report on Engineering Education After the War (Hammond Report, 1944) and of the A.S.E.E. Committee Report on Evaluation of Engineering Education (Grinter Report, 1955). All of us will agree, I think, that our complex industrial world needs engineering specialists. Most of us will agree, I think, that an engineering education has been a satisfactory general education for many individuals who have gone on to successful and satisfying careers in non-engineering fields.

At this point we divide. Some of us believe in specialized undergraduate curricula. Some of us believe in more general undergraduate curricula. There are few neutrals.

I am a supporter of the more general programmes. However, I must admit that the existence of two schools of thought has made me re-examine my own philosophy of engineering education. I have come to the conclusion that the differences in the two kinds of undergraduate curricula are not as great, and may not be as important, as the differences in motivation, ability, enthusiasm, intelligence, and cultural background of our raw material — the graduates of the high schools.

Questions for Industry

The following remarks and questions are intended to promote discussion and pleasant argument. I am more interested in the reactions of the industrial representatives than in those of the university representatives.

(1) A student's time during his undergraduate course is so valuable that none of it should be spent in the acquisition of skills and knowledge that can be and should be gained in industry after graduation and in the acquisition of skills and knowledge that may soon become obsolete.

(2) The graduates of highly-specialized courses may not find the highly-specialized jobs for which they are "trained" and may not be suitable for alternative jobs.

(3) The knowledge and the attitudes with which a student leaves the university must last him for a lifetime in a world that is always changing. We are preparing students for about 40 years of professional life — 40 years of self-education and self-development — and all of these years are in the future.

(4) Has too much attention been paid to the demands that an engineer must be immediately useful on graduation? Most large firms have training programmes. Should the firm hiring its first engineer consider only one who has had some experience after graduation?

(5) The engineering schools will be doing a good job if their graduates (a) know the basic sciences, (b) know the engineering sciences, (c) have some knowledge of some of the humanities and the social sciences, (d) can communicate ideas in the oral, written, and graphical forms, (e) have studied some of the aspects of analysis and synthesis of engineering systems, with some emphasis on one broad field of engineering, and (f) can use a library.

(6) In addition to the undergraduate curriculum, there are other influences at work. The benefits of extra-curricular activities and of life-long friendships are more important than the presence or absence of certain subjects in the curriculum.

(7) The four-year course is satisfactory for the majority of students. Study at the graduate level will provide for any desired specialization.

(8) What can we in the engineering schools do to encourage and develop creative thinking? We must never forget that engineering is a creative profession and that the members and members-to-be of the profession must, while not forgetting the past and ignoring the present, look toward the future.

Engineering at Western

Professor Lauchland then outlined the development of engineering education at The University of Western Ontario. The Department of Engineering Science was established in 1954 to offer a two-year course designed to prepare students for admission with advanced standing to certain engineering courses at other Canadian universities. In 1956 the Board of Governors approved the expansion of the two-year course to a four-year course leading to a degree and started planning for the construction of an engineering science building. The planning is based on a first-year enrolment of 150 and a total undergraduate enrolment of about 475. The department will, in the course of time, become a separate school or faculty.

Subsequent Discussion

The moderator noted that many interesting points were raised during the discussion that followed the presentations by panel members.

These included: Is the graduate immediately useful? What should be the training program of the large firm? Since the university has the student for 28 months at most in four years, nothing in the way of skill or technique should be taught in college which could just as well be taught in industry. Should there be required summer reading? A discussion developed on lecturing (passive) *v.* tutorial (active) methods of teaching: the undergraduate is taught by lecture and by recitation (problem periods) while the graduate gets tutorial and seminar methods. The lecture (passive) system does have the one outstanding advantage in that it is possible to expose the student to great scholars.

DISCUSSION

of Technical Papers and Other Articles

THE KAPLAN TURBINE IN CANADA

G. Dugan Johnson, *S. Morgan Smith Company, York, Pa.*

The Engineering Journal, 1956, June, 769

Discussion of this paper by Messrs. Fintak, Kerr, Sproule, and Warnock (referred to below by the author) was published in the Feb., 1957, issue.

D. E. Brainard[1]

The Kaplan turbine has had a deep effect on the hydro industry in the past quarter century. None are more aware of this than the suppliers of generators for hydraulic turbine drive. Mr. Johnson's summary of history and attainment over that period is most interesting. His remarks on future trends require some comments.

As generally recognized in the hydro industry, mechanical design of the rotor is the most important single limit to the permissible size of generator at a given rated speed. As the specified overspeed increases, this factor becomes more restrictive. In this day of large units, there will be increasing pressure on purchasers to specify something less than the "off-cam" overspeed.

There has been a tendency to consider that the design overspeed is a nominal condition but that no serious harm would result if the rotor attained an overspeed such as to give calculated stresses up to or even exceeding the yield point. The author describes this as "present practice." The position of purchasers and generator suppliers alike has been and, I believe, should be that the generator must never be expected to exceed the specified overspeed. The "factor of safety" represented by limiting calculated stresses at that overspeed to two-thirds of the yield point is generally required by purchasers to allow for differences between calculated and actual stresses. Only if the turbine builder can develop design features that will limit the overspeed and can demonstrate their validity, may the purchaser be justified in specifying the resulting reduced value for generator design.

In the matter of thrust bearing design, the industry has cause for real pride. The ten Bonneville bearings, each carrying 3,000,000 pounds, represented a 50 per cent increase in load carried. Another increase, this time of 33 per cent, brought the load per bearing to 4,000,000 pounds at McNary. It may be added that the twelve domestic bearings in this plant have gone into service without a single failure.

The most difficult duty on a thrust bearing occurs at starting and unit pressures have hitherto been governed by this fact. The use of high pressure oil at starting is effective in removing this limitation, and thrust bearings for loads of 6,000,000 lb. to 7,000,000 lb. appear entirelv feasible. We believe, therefore, that rotor design rather than thrust bearing capacity is most likely to limit the increase in size of units.

Norman R. Gibson[2] M.E.I.C.

I would like to ask Mr. Johnson two questions.

(1) If general practice is to accept results of model tests as a basis of contract, what assurance can be given that the prototype will be manufactured in exact proportion to the model?

(2) Is the author able to state that there is a tendency toward lower efficiency as the specific speed of Kaplan turbines is increased?

H. R. Sills[3] M.E.I.C.

Mr. Johnson in his paper hints at problems in connection with the design of generators attached to Kaplan turbines. I may say they are substantial. The worst problem is concerned with the offcam overspeed which appears to be a hypothetical rather than an actual hazard. For usual generator proportions the maximum generator capacity is limited directly as the 3/2 power of the permissible rim stress and inversely as the r.p.m. and the cube of the overspeed ratio.

For the type of construction ordinarily used for generators connected to Kaplan turbines the maximum permissible size can be approximated from the following formula:

$$\text{Max. kva.} = \frac{K \times 3 \times 10^5 \times S^{3/2}}{\text{r.p.m.} \times (OS)^3}$$

where K = output constant (from 8 to 11 x 10^{-5} depending on reactance and power factor)
S = maximum permissible rim stress in lb/sq. in.
r.p.m. = rated speed
OS = over speed ratio = runaway speed/rated speed

The Kaplan turbine with both high speeds and higher overspeed ratios has an exponential advantage on the only recourse available to the generator designer, rim materials of higher strength.

The rim stress the generator designer must contend with varies as the 2/3 power of the r.p.m. and the square of the overspeed ratio. A reduction of even 10 per cent in the overspeed ratio would reduce the rim stresses 21 per cent for the same kva. or permit a 33 per cent larger machine for the same stress. This, I suggest, is a prime incentive to find ways of limiting these overspeeds.

With the off-cam overspeed largelv a theoretical condition, as the author suggests, it would appear that substantial advantage would accrue to all concerned if permissible rim stresses at this speed were accepted as 95 per cent of proportional limit rather than the present conventional limit of 66 per cent. Such a practice would permit the design of machines 1.73 times larger than the present practice permits or a less expensive machine (if capacity is not a limit), and yet provide normal factor of safety at proven overspeeds. This is by

[1]General Electric Company, Schenectady, N.Y.
[2]Consulting engineer, Niagara Falls, N.Y.
[3]Canadian General Electric Company, Limited, Apparatus Department, Peterborough, Ont.

no means as outrageous as it may sound. Maximum stresses may be accurately calculated, there always exists a margin of the actual proportional limit above the minimum specified for the material and no appreciable strain occurs until the yield point is reached, usually 10 to 15 per cent higher than the proportional limit. Even here the rim does not burst but stretches like an overstressed chain which will cause the poles to rub against the stator, braking the rotor to a slower speed. The stators are designed and anchored to withstand maximum short circuit stresses and it is reasonable to assume that the braking effort will not reach this value before speed has reduced enough to limit the stress. This condition is not much different from recognized practice in steam turbines where a runaway usually terminates due to the blades coming off and choking the casing.

Thrusts are also a problem. Presumably they will increase as the size of turbines increases. As yet there does not seem to be a limit to size of thrust bearings but shipping limits may cause problems with the supporting structure. I suspect this limit will apply equally to the turbine head-cover. If the upward pressure on the head-cover always coincides with the downward hydraulic pressure on the thrust bearing some mutual advantage may be gained by connecting columns between the hubs of the head-cover and thrust bracket. I tend to agree with the author that American and Canadian preference in respect to accessibility of parts will prevent European practice of mounting the thrust bearing on the head cover from becoming popular on this continent. Present machine designs permit as close coupling of the turbine and generator as the scroll case passages will permit.

I would that the turbine designers could do something about removing the oil head from the top of the generators. After years of endeavour the generator designers have managed to design oil tight bearings and so keep oil out of their windings and thereby reduce the worst fire hazard; and now come these oil heads! With the greatest respect for their efficient functioning I do wish they were put below where there is no possibility of an electrical fault.

If essential we would accept the compensating mechanism but we would prefer a tape, that could be decently buried, to the present crank rod. Most generator manufacturers have developed means to expedite the maintenance of their machines by methods for quick removal of top covers and other components. The oil heads and compensating mechanism, to put it bluntly, foul this up. Moreover after years of endeavour decently to enclose piping and the other intestines of the generators and give them sex appeal I have a very jaundiced view of the plumbing that the turbine designers drape over the side and top of the generators to their oil head.

E. B. Strowger[4]

The author has stated that the Kaplan turbine is especially well suited to run-of-river developments with wide variations of flow and head and little or no storage. This is an important consideration and may be shown by means of duration curves like those of Figure 1. These curves show the flow, power and length of time of daily peak operation in duration form for a hydro-electric project on a river having an average flow of about 2500 c.f.s., the head at the site being 76 feet and the usable pondage small. The flow varies from a maximum corresponding to the 100 year flood value estimated at 30,000 c.f.s. to a minimum of 1100 c.f.s. From the most economic installation, a one-unit plant with a relatively high discharging capacity is indicated. The c.f.s. capacity contemplated for a one unit Francis installation is shown by line A and that of a one unit Kaplan installation of comparable size by line B. (Fig. 1 is on page 299.)

The utility system to utilize the project requires 8-hour operation of this plant except during the flood season when operating time of the station increases to 24 hours per day. The figure shows the following advantages of a Kaplan installation.

(1) Greater annual energy generation due to the large overload capacity of the Kaplan turbine. This is shown by the cross hatched areas.

(2) Higher capacity available in the low flow season due to the higher part gate efficiency of the Kaplan.

(3) Based on what is considered to be the dependable December flow, a larger firm capacity supplied to the system.

(4) Smaller drop-off in capacity than in the case of a Francis installation when, in the flood season, the head is low.

The value of the additional peak capacity may be as great or even greater to the utility system than that of the additional annual generation of kwh. For instance, on a 20,000 kw. installation with a 50 per cent annual capacity factor a gain of 5 per cent in dependable peak capacity is approximately equivalent in value to a gain of 10 per cent in annual energy generation when evaluated by $25.00 per kw. of peak and 3 mills per kwh. of energy, these values representing the cost of equivalent steam power in the area. This may be shown as follows:

Value of 10 per cent energy gain·
8760 x 0.50 x 0.10 x 20,000 x 0.003
=$26,000.

Value of 5 per cent gain in peak
20,000 x 0.05 x 25
=$25,000

If, instead of the very limited pondage available as shown by Figure 1, the pondage is adequate for operation at the daily capacity factor required under the conditions defining dependable capacity, then it might be advantageous to install a fixed blade propeller turbine and operate it every day at the point of maximum efficiency, reducing the time on peak as the river flow reduces. Regulating capacity would, of course, be sacrificed with this type of operation.

Of course, the setting of the Kaplan turbine must be low enough to be sure the cavitation limit is beyond the 4,000 c.f.s. capacity shown by line B on the chart and the additional capacity required for the Kaplan generator will increase its cost and will offset to some extent the advantage of its higher speed. However, all factors considered, economic studies show many sites, with the characteristics of the one described, to be favourable to a Kaplan installation.

R. A. Sutherland[5]

Mr. Johnson's paper is a very useful compendium of advantages of the Kaplan turbine. Inasmuch as "the object of this paper is to encourage increased use of the Kaplan adjustable blade propeller turbine," it is to be regretted that Mr. Johnson had not given more definite information relating to the cost in money, materials or work which is required to obtain the benefits of the Kaplan turbine. The writer has several times had occasion to evaluate the merits of us-

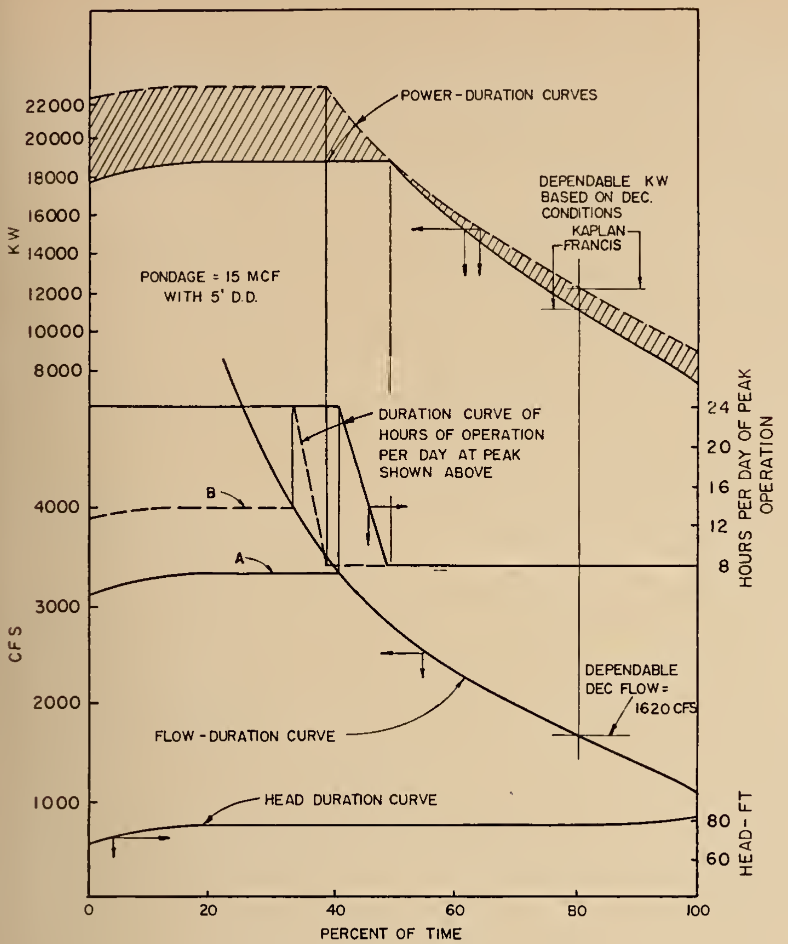

FIG. I
DURATION CURVES OF RUN OF RIVER PROJECT
--- KAPLAN
—— FRANCIS

ing one or more Kaplan turbines for a given installation, and has found all the features are susceptible of being evaluated. Some of these features are as follows:

(1) *Cost of Turbine* — In the writer's experience, a Kaplan turbine costs from 20 to 50 per cent more than a fixed blade propeller turbine of equal capacity.

(2) *Cost of Generator* — Some additional cost will ordinarily be applicable to the generator due to higher overspeed, provision of oil head, and other details of a special nature.

(3) *Setting of Turbine* — The Kaplan turbine may require to be set at a lower elevation which will usually entail additional costs in the powerhouse excavation, structure and other features.

(4) *Operating Advantages* — With a given known or assumed method of operation, it is possible to compute for the Kaplan turbine and the alternative turbines, the net results over a period of time and to evaluate the greater output of energy and the increased capability, particularly at times of high tailwater.

Each case must obviously be treated on its own merits, and the fact that the Kaplan turbine is not necessarily always the ideal unit is shown by the choice in some cases of Francis or fixed blade units as a result of a comprehensive study such as outlined. More generally, however, it is true that the use of at least one Kaplan in a plant with a head up to or perhaps over 100 feet is distinctly advantageous. The capacity to carry additional load beyond the rating is a feature particularly relished by operating engineers who come to depend on a Kaplan unit to tide them over their most severe peaks.

T. Zowski[6]

The author's paper reviews in a concise manner the basic characteristics, design developments, and application of Kaplan turbines. The writer would like to offer a few comments based on his company's association with the design of a number of interesting Kaplan unit installations which include the first Kaplan turbine installation in America, the first high head (105 feet) installation in the Western Hemisphere located on the Rio Negro in Uruguay, and several other plants in which new turbine features were introduced.

Bids are being taken in Canada for a Kaplan turbine rated 30,300 h.p. under a net head of 112 feet, for the Centre Falls plant of the Great Lakes Power Company, Limited. The rated head of 112 feet is, to the best of the writer's knowledge, the highest rated head specified to date for Kaplan turbines in Canada and the United States.

In discussing protection against cavitation, the author mentions the use of solid cast stainless steel blades on small runners and includes the 110-inch runners at Lower Great Brook in Nova Scotia as an example. It may be of interest to mention that solid cast stainless steel Kaplan runners of nearly twice this size (208-inch) have been in operation for about one year now at the Box Canyon Plant in the United States, with outstanding performance results, especially in the overload range. Under the rated head of 41 feet, the turbines operate satisfactorily with loads 17 per cent in excess of the corresponding guaranteed cavitation limit, and about 7 per cent beyond the cavitation limit indicated by the model tests, without any evidence of pitting damage. This overload is appreciably greater than has been found practical on most Kaplan runners protected against pitting in the usual manner by prewelded stainless steel coatings. The Box Canyon turbine contract specified blades of carbon cast steel with welded stainless coatings, but in view of the large amount of costly welding work required on the blades, the turbine manufacturer found that the relative cost of solid cast chromium stainless steel blades would not be much greater, and actually furnished them at no additional cost to the purchaser.

Cast stainless steel blade inserts welded to portions of the blades were used on nine 110-inch Kaplan units at the Petenwell and Castle Rock plants designed by the writer's company for the Wisconsin River Power Company. These units have given good service, although under sustained overload operation the un-

[6]Chief Mechanical Engineer, Harza Engineering Company, Chicago, Ill.

protected blade surfaces along the inserts eventually suffered cavitation damage requiring welding repairs. Our experience indicates that solid cast stainless steel blades are far superior and should be given serious consideration for all future Kaplan installations except low head units.

Hydro plant operating experience indicates that it is economically feasible to operate Kaplan turbines for substantial periods of time with loads somewhat greater than the actual cavitation limit. The practical limit of loading is largely a matter of economics involving the value of the additional output and the cost of pitting repairs and associated outages, as well as a matter of acceptable vibration limits, but the writer believes it is generally feasible to exceed the cavitation limits by about 5 to 7 per cent. The author's views on this would be of interest.

The use of concrete semi-spiral cases for heads up to 100 feet is mentioned by the author. The experience of the writer's company in the design of concrete spiral and semi-spiral cases indicates that the considerable structural design problems, complicated construction work, and difficulties in maintaining watertightness tend to make the use of concrete spiral cases questionable for heads greater than about 80 feet, except for extremely large turbines. In our design of the Scott Falls plant in Ontario for the Great Lakes Power Company, Limited, it was found less costly to use plate steel spiral cases for the two 104-inch, 10,000 h.p. Kaplan turbines which operate under a maximum head of 75 feet.

The Author

The author is extremely grateful for the large number and high quality of the discussions, which supplement the information given in the paper and add greatly to its value. This is particularly true of those by Messrs. Sills and Brainard, who represent generator manufacturers, as well as those of Messrs. Strowger, Sutherland and Zowski, who represent designers and/or owners of hydro plants. The general agreement from the other turbine manufacturers' representatives, Messrs. Fintak, Sproule, and Warnock, is significant, and the questions raised by Dr. Gibson and Mr. Kerr are certainly worthy of serious consideration. Although time does not permit a detailed examination of each point raised by these gentlemen, the author is indeed thankful that their discussions are hereby available in printed form to "complete" the presentation of the original paper.

Mr. Sutherland has emphasized the need for a careful evaluation of the various economic factors involved for each specific installation, and Mr. Strowger has presented an actual example of the operating advantage of a Kaplan turbine. In addition to the increased annual energy output, Mr. Strowger has clearly indicated the practical value of the additional dependable peak capacity attainable with the Kaplan.

Mr. Zowski has pointed out that the "extra" capacity of the Kaplan turbine is even greater than that calculated from the model tests in the laboratory, since it is possible to operate at loads greater than the cavitation limits indicated by the model. Actually, experience has shown that 5 to 7 per cent additional capacity can be obtained from a large prototype unit without loss of efficiency due to cavitation and substantial additional capacity can usually be realized before objectionable vibration or excessive cavitation pitting is experienced. It is interesting to note that it is economically feasible to cast fairly large Kaplan blades entirely of stainless steel in order to take advantage of this additional capacity with minimum cavitation pitting.

DISCUSSION

The Editor invites discussion of technical papers and other articles in *The Engineering Journal.*

Messrs. Sills and Brainard both state that maximum generator capacities are limited by mechanical design of the rotors, rather than by permissible thrust bearing loads. Mr. Sills agrees with the author's statement that "present practice *seems* to indicate acceptance of the idea that the generator must never be expected to exceed the specified overspeed," which can be limited by dependable automatic design features as mentioned by the author.

Mr. Sills' objection to the Kaplan oil head with attached plumbing and compensating mechanism dangling therefrom is certainly understandable. Possibly what he has in mind is an arrangement similar to that shown in figure 1-7 of reference no. 11 with an oil transfer unit around the turbine shaft, but with the blade servo-motor and generator thrust bearing located as in arrangements 1, 2 or 3 of that figure. Although not yet popular in Canada or the United States, such oil transfer units are feasible and have been successfully used by the author's company for controllable-pitch ship propeller applications.

Mr. Fintak's account of his company's early experience with manually adjustable runner blades is interesting, but was not mentioned in the paper because a "true" Kaplan has blades that can be automatically adjusted during operation. The author agrees with Mr. Sproule that a fixed-blade propeller turbine would be more economical and more efficient than a Kaplan for an installation with essentially constant head and discharge conditions. Mr. Warnock's comments, especially those referring to his company's experience with high-head Kaplan and diagonal-flow turbines, are extremely interesting and worthwhile additions to the author's paper.

The answer to Dr. Gibson's second question is that no "tendency toward lower efficiency as the specific speed of Kaplan turbines is increased" has been observed by the author's company to date, except when the increase has been obtained merely by increasing the inclination of an existing blade design to increase the unit capacity. The moderate loss in efficiency as the blade inclination is increased beyond the best efficiency point is shown by the McNary "index" test curves on Fig. 3 of the paper. However, when the specific speed is increased by designing for the actual conditions of a particular installation, the efficiency could be approximately the same at the higher specific speed. As mentioned in the paper, draft tube design is also intimately associated with Kaplan turbine efficiencies.

The answer to Dr. Gibson's first question is that the laboratory model and the prototype units are manufactured from geometrically proportioned (homologous) drawings within reasonably exact tolerances. Templates are used for the critical turbine components, such as runner blades and wicket gates, and the water passages to and from the turbines are easily constructed so nearly homologous that any differences in flow patterns and hydraulic losses are negligible, except for the

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

CONSTRICTED TUNGSTEN-ARC CUTTING OF ALUMINUM

Ayler, O'Brien, and Maier — *Welding Journal*, 1956, Dec.

An argon-hydrogen gas shield is being used with a constricted tungsten-arc for the cutting of aluminum, magnesium and copper. Although the mechanical metal cutting methods of shearing or sawing produce high quality severance edges, often their use is limited and it becomes necessary to resort to drilling or chipping. The tungsten-arc has proven to be a much faster means of cutting than any of the mechanical methods and at the same time it provides high quality kerf walls. With a manual cutting torch, aluminum plate ¼ in. thick can be cut at 60 i.p.m. and 1½ in. at 15 i.p.m. A machine operated torch permits these speeds to be increased to 100 and 35 i.p.m. respectively. Greater speeds can be obtained when cutting magnesium, due to its lower thermal conductivity, and conversely the rates are less for copper.

Tungsten-arc cutting employs a constricted arc between a tungsten electrode and the workpiece, in conjunction with a high velocity gas stream. The arc is concentrated and localized upon a small area so that the intense heat melts the metal. The gas which is preheated by the arc expands greatly and is forced through the constricted orifice. Molten metal is then continuously removed to form a kerf by the jet action of the gas stream. The cutting gas also protects the kerf walls from oxidation and a high quality saw-like cut free of dross is obtained.

The depth of the heat-affected zone is approximately the same for ¼ to 1½ in. thick plates providing that maximum cutting speeds are used for a given power input. Hardness readings indicate that the approximate normal hardness of the plate is reached beyond a depth of 0.064 inch. Welds subjected to tensile, guided bend, and free-bend tests showed that arc-cut edges are equivalent to saw-cut edges.

Tungsten electrodes similar to those used for inert gas tungsten-arc welding are used in the cutting torch and electrodes of ⅛ in. dia. cover the complete range of aluminum thickness up to 1½ in. The rate of electrode consumption is very low. High operating voltages are needed; 400 amp. at 70 to 85 arc volts. Motor-generators with a rated capacity of 600 amp. and an open-circuit voltage of 100 volts have proved satisfactory. Water cooling of the torch nozzle is necessary to prolong its life.

Two different mixtures of argon and hydrogen are used with this process: 65 per cent argon and 35 per cent hydrogen for machine operated torches; 80 per cent argon and 20 per cent hydrogen for manual cutting. The lower hydrogen content for manual cutting provides the operator with a greater latitude of arc length. For best results this should be ¼ in. If the hydrogen content is greater than 20 per cent the arc is extinguished should the nozzle-to-work distance exceed ¾ in. Argon is used in these gas mixtures because it is inert and an arc can be readily established in an argon atmosphere. Hydrogen is used because it yields a high arc voltage due to its high resistance, producing greater heat at a given current.

ENERGY FROM THE SEA

Water Power, 1956, Nov. and Dec.

These articles contain a description of the design and construction problems which are being solved in order to harness tidal energy near the French seaport of St. Malo. The project, which is to be in full commission by 1960, involves the erection of a tidal dam across the north of the River Rance where it enters the sea, and depends upon a combination of tidal power generation and pumping operations.

The dam will be 2329 ft. long and 157 ft. wide with the height of the crest above the highest tide level 4.92 ft. and the enclosed surface about 7¾ sq. miles at high tide. Both generation and pumping are to be accomplished by 38 totally submerged upstream bulb type turbine units each of 9000 kw. capacity, immersed in orifices in the dam with their centre line 18 ft. below low water level. Controls and switch gear are accommodated in the hollow upper part of the dam while the top serves as a bridge across the river. The dam will also contain a number of sluices and on the west bank locks are to be provided for river navigation.

Extensive studies involving much detailed calculation and model testing were used to prove the scheme to be practicable. It proposes to generate power both during the filling and emptying of the estuary over a greater and more flexible time period than that of the normal tide ebb and flow. It utilizes energy from the national electrical supply network at off-peak periods to provide an artificially greater head by pumping water into the basin at high tide or out of the basin at low tide. This requires a water turbine which will operate efficiently both as a pump and a turbine under variable head and with water flow in either direction.

Such a machine has been developed by the French engineers after years of research and experiment. It is of the monobloc type with the following characteristics: speed 88.2 r.p.m., maximum operating head 11 metres, maximum pumping head 6 m., nominal rating 9000 kw. with direct or reverse water flow for variable head between 11 and 5.5 m. with flows between 100 and 270 cu. m. per sec.

The difference of level between high and low tides for this region is about 44 ft. at exceptional tidal periods and the tidal range is 36 ft. at spring tides, 29 ft. at average tides and 18 ft. at ebb tides. The cycle of operation is as follows. If high tide exists on both sides of the dam and if energy can be borrowed from the electrical supply system for pumping purposes (presuming an off-peak period exists) it is possible to raise the level within the estuary; as the tide falls away outside the dam a head becomes available which is greater at any given state of the tide than would have been the case without pumping. Generation starts as soon as the minimum head is reached and this occurs earlier in relation to the tide movement because of pumping.

Generation continues until the head is reduced to the minimum level, at which time the turbine blades are feathered and the units act as valves, each turbine passing 180 cu. m. per sec. under a head of 1m. as compared to the main sluice valves each of which permits a flow of 420 cu. m. per sec. under the same conditions. By converting the 38 turbines into straight - through valves and opening all sluices the water within the basin can be rapidly evacuated near the time of low tide by gravity means. Since the machines are totally submerged, further water can be pumped out if electrical energy is available. As the tide rises on the outside of the dam a generating head is reached earlier than would have been the case if the water level had not been artificially lowered. As the tide continues to rise generation will take place until sufficient water has entered the estuary to destroy the minimum generating head. Rapid opening of all turbine passages and sluices then permits high tide level to be reached within the basin and the cycle can restart.

A most important feature of the cycle is that it can be greatly varied by means of pumping during off-peak hours so that tidal power can always be made available to the electrical distribution network when most needed. Full details of the cycle studies are given. The total capacity of the plant will be 342 Mw. with the annual output of energy exceeding 800 million kwh. over and above that borrowed for pumping purposes. The estimated cost of the project is about 95 million dollars.

This development is considered to be a pilot scheme for other large tidal-power proposals. One under study is a possible enclosure of the Baie du Saint Mont Michel adjacent to St. Malo. This dam would be 23.4 miles long enclosing a basin of 270 to 300 sq. miles and would contain 1200 generating units with a total estimated capacity of 8 to 10 million kw. giving an annual supply of electrical energy about half that presently used in France. If carried out it is expected to take 15 years to complete.

It is pointed out that this method of harnessing tidal energy would be well suited to work in conjunction with atomic power plants. Such plants are restricted to continuous operation to avoid poisoning by xenon 135 which is caused by shut-down. It is foreseen that nuclear power could reach such a proportion of the total power developed that the shutting down at nights of all thermal and water-power stations would still not load the nuclear plants sufficiently. Instead of dissipating the energy or selling at a loss it could be usefully diverted to pumping operations in tidal power plants.

METAL FORMING WITH EXPLOSIVES

American Machinist, 1957, January

Several aircraft companies are working with explosive manufacturers in experimental investigations of metal forming using explosive charges as a source of pressure. Previously, cartridge-actuated devices have been employed for many purposes such as firing rescue lines, fishing lines, pilots on ejection seats, parachutes, etc.; and to tack rugs, drive studs into steel or concrete, start jet engines, or cut cables. However, present experiments indicate that cartridges may be used to punch holes in high strength alloys, to flare and bulge tubing, to form "non-formable" alloys of stainless steel, to avoid spring-back in forming titanium alloys; as well as to swage, upset, and cup shapes and materials for which no other process has been successful.

Limited research has shown that most metals react differently under an impulsive loading compared to the conventional loading that occurs under a hydraulic press or a drop hammer. The energy of explosion is absorbed partly, or often completely, by the metal being formed so that work hardening characteristics are changed and grain structure may be altered. The velocity at which the load is applied has important effects. Each alloy has its own critical velocity. Too fast a shock wave may shatter it to fragments while a reduction of a few hundred feet per second will give good plastic flow. Elongation far beyond that possible by conventional methods has been obtained. There are two types of explosives employed: low explosives are powders such as those used in ammunition which burn rather than explode; and high explosives are those which decompose rather than burn, some developing shock wave velocity well over 4 miles per second.

This method has also been successfully applied to the punching of clean holes in sheet steel of 250,000 p.s.i. tensile strength without cracking the surrounding metal and without dimpling if a die is used.

THYRATRONS CONTROL DIE-CUTTING MACHINE

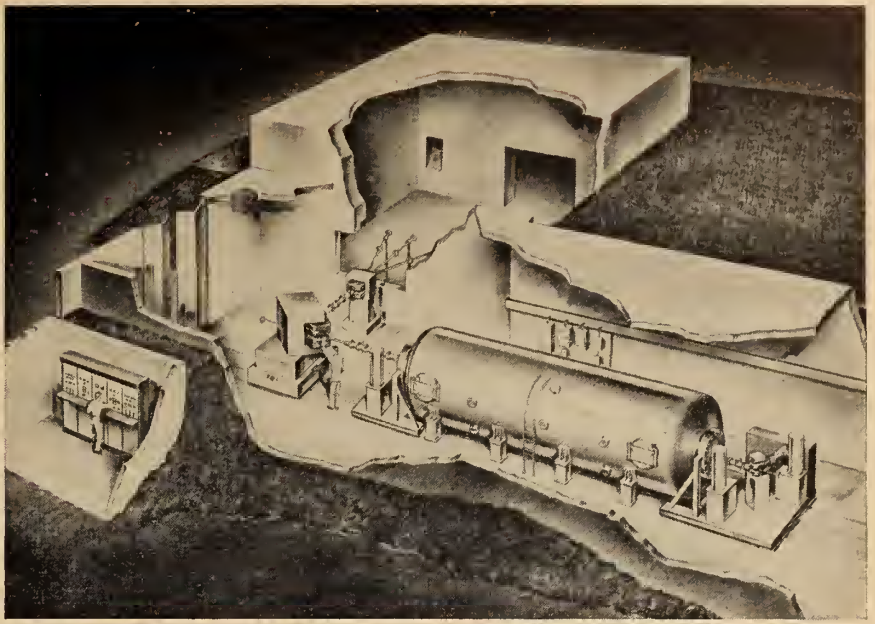
R. W. Bradley, *Electronics,* 1957, January

Adaptation of electronic control to a swinging-beam die-cutting machine used for cutting leather, plastic, light sheet metal or metallic cloth has resulted in more efficient operation with greater operator safety. Machines which utilize only a mechanical linkage system with a fixed stroke from a flywheel crank, produce high impact forces with consequent high stress and vibration, and also require that die sets be of the same height to prevent die sticking or incomplete cutting.

The new machine has an electronically controlled cutter stroke which limits the force developed to that required for the particular cutting operation. This is accomplished by means of a hydraulic pressure system actuating the cutting head. Sharp fluid cut-off is provided by a solenoid-operated valve in a closure period of approximately 10 milliseconds. The cutting stroke is terminated electronically when the cutting die completes the electrical circuit between the beam striking plate and the conductive cutting surface plate. The striking plate is attached to the bottom of the beam but electrically insulated from it, and the rest of the machine including the cutting surface plate is at ground potential. With this arrangement the beam height position is relatively unimportant and dies of different heights can be used in sequence without machine adjustment. Elimination of die sticking and die damage, a longer life of cutting surface, improved cutting performance, and reduced operator fatigue are claimed.

The control stops the beam travel in a manner to give regulated die penetration into the conductive cutting surface ensuring accurate cutting with a minimum expenditure of energy. It also includes an accurately repetitive time delay giving deeper cutting surface plate penetration to permit the pressure build-up necessary for cutting soft fibrous materials such as metallic cloth.

An important safety feature is the use of the hand to hand electrical resistance of the operator's body as a triggering device to stop the beam travel and prevent injury if one hand should contact the striking plate while the other holds the bare metal handle of the machine actuating switch. The electronic assembly is carried on a shock mounted printed circuit board. Thyratron tubes are used instead of the vacuum type because of their longer life, sturdier construction, greater grid-cathode distance, and satisfactory operation at reduced heater voltage. A control circuit schematic is presented and the operation described.



TANDEM ACCELERATOR FOR CHALK RIVER

An artist's conception of the 10-million volt "tandem accelerator" which is to be installed at the Chalk River project of Atomic Energy of Canada Limited early in 1958. The machine, which is being designed and built by High Voltage Engineering Corporation, Burlington, Mass., will be the world's highest energy accelerator working on the Van de Graaf principle. Chalk River at present has a three million volt Van de Graaf accelerator; this is used to bombard materials with a beam of particles to determine the structure of the nuclei of certain light elements. The new machine, which consists of two specially designed Van de Graaf accelerators coupled together and housed horizontally in a tank, will considerably extend the field of measurements possible both for light nuclei and for a large number of heavy elements.

SMALL TELEVISION CAMERA

French Economic and Technical Bulletin, 1956, no. 9-10

The Compagnie Generale de T.S.F. has developed a miniature television camera which is portable and fully independent of external power sources. The whole equipment weighs only 17 pounds, including the camera (2.8 lb.) and two cases containing batteries and other equipment (about 14 lb.).

The range of the unit depends on topography, but under favourable conditions, especially from an aircraft, perfect results are obtainable over 20 to 30 miles.

Industrial and military, as well as commercial, applications are being studied. The camera was used by CBS during their television coverage of the 1956 political conventions in the United States.

RECENT DEVELOPMENT LOANS BY THE WORLD BANK

Chile, Nicaragua, Australia, Japan, and India are among recent recipients of loans from the International Bank for Reconstruction and Development, perhaps better known as the World Bank.

Chile has received $15 million for electric power development during 1956-62. This will provide some 166,000 kw. of an overall program for 400,000 kw. of additional generating capacity, mostly hydro-electric. This is the second such loan.

A loan of $1.6 million to Nicaragua will supplement an earlier loan of $7.1 million towards constructing a 30,000 kw. thermal power plant and extension of the distribution system in Managua. The first 15,000 kw. unit should be ready for commercial operation in March 1958.

The Commonwealth of Australia has borrowed $27 million, of which $9,230,000 from the World Bank, towards buying (in dollars) Boeing and Lockheed aircraft and parts for Qantas Empire Airways Ltd., the international airline owned by the Commonwealth Government.

Two loans were made to Japan. The first, equivalent to $4.3 million, will largely be used to import equipment which will be used on pilot projects to test the feasibility of land reclamation in Japan by modern mechanical methods. The second loan will finance part of the cost of constructing a modern strip mill at the Kawasaki Steel Corporation's plant near Tokyo; when the new mill is in operation, now scheduled for 1959, Kawasaki will be one of the most modern and efficient steel producers in Japan.

The loan of $20 million to India is also for the expansion of the steel industry. It will help to finance additional rolling capacity for The Indian Iron and Steel Company Ltd. (IISCO), a privately owned company which is the second largest steel producer in India. Output of semi-finished and finished steel will be raised to 800,000 tons annually by the added rolling capacity.

ABSTRACTS OF PAPERS PRESENTED TO THE ENGINEERING INSTITUTIONS IN BRITAIN

As mentioned in the February issue of The Engineering Journal (p. 159) it is proposed to publish abstracts of some of the papers presented to the British Institutions of Civil, Electrical, and Mechanical Engineers.

Institution of Civil Engineers

The analysis of prestressed concrete structures and the application of recent research. P. B. Morice.

Structural and Building Paper No. 51

The paper illustrates the application of some results of recent research on the behaviour of prestressed concrete structures. A simple set of expressions is developed for the elastic design and ultimate load-carrying capacity of prestressed members in both statically determinate and indeterminate structures. The use of these expressions in the analysis of continuous beams, portal frames, and bridge decks is discussed in the light of the results of experimental work. Some aspects of research on the effects of friction between prestressing tendons and their ducts in post-tensioned members are included, together with the principal results of a study of the transmission length in factory-made pretensioned units.

The design and construction of a laboratory for research in underwater ballistics. C. L. Champion, R. J. R. Hancock, M.B.E., and M. Woolfson.

Works Construction Paper No. 34

The paper describes research facilities recently completed for the Admiralty. These consist of a rotating arm for propelling models round an annular tank and a cavitation tunnel. Various problems arising in the design and construction of this very unusual plant and the associated civil engineering works are considered.

Institution of Electrical Engineers

Mechanical strength of power transformers in service. E. T. Norris. (No. 3244)

The mechanical stresses in power transformers have steadily increased with transformer size and supply system capacity. Short-circuit currents are generally based on the rupturing capacity of circuit breakers which has increased in 25 years from 1500 Mva. to 25,000 Mva.

The position has been accentuated by the established practice of auto-reclosing which makes repeated switching on to possible faults a normal practice, and the introduction of fault throwing for inter-tripping purposes where dead short-circuits are deliberately created under normally controlled conditions.

Using only simple mathematics, it is shown that the mechanical strength of a transformer is not a simple single value as is implied in the short-circuit clauses of standard transformer specifications. Some of the strains are progressive and some of the stresses cumulative leading to short term and long term characteristics. The resulting categories of mechanical strength are defined as initial, critical, and ultimate, the last named being usually the crucial one in service.

It is shown how the performance in service can be predetermined and the expectation of life, in terms of number of short-circuits, predicted for any given operating conditions.

Service records of failures on short-circuit are analysed and found to support the predicted values.

Methods of improving the expectation of life are considered.

A deep electrolytic tank for the solution of two and three dimensional field problems in engineering. E. R. Hartill, J. G. McQueen, and P. N. Robson. (No. 3131)

The electrolytic tank is playing an increasing part in electrical engineering design departments, particularly for the analogous solution of two dimensional field problems. The paper describes the design, construction, and operation of a general purpose deep tank for solving both two and three dimensional problems. Details are also given of the precision electronic potential and gradient measuring equipment, together with an assessment of the accuracy achieved and the precautions required.

The use of the tank is illustrated by typical applications which have been studied by the computation group within a large electrical engineering organization.

DISCUSSION — The Kaplan Turbine in Canada

(Continued from page 300)

universally-accepted increase in prototype efficiency because of the relatively smaller skin friction loss as the turbine size increases.

Apparently, Mr. Kerr questions the author's statement that "*current* practice is to specify accurately conducted laboratory tests on homologous models . . . and the contract guarantees are based on model performance." Actually, this procedure has been followed for all of the large Kaplan installations in the United States (except Safe Harbor) and the author's statement is not a personal opinion but an observed fact. The balance of the section on "Contract Model Tests and Field Tests" also consists of observed facts rather than personal opinions, except for the poor choice of the word "actual", as pointed out by Mr. Kerr, which could be replaced by the word "estimated" or left out entirely, without changing the sense of the statement. Actually, since the efficiency guarantees have previously been satisfied by the model tests, it is not significant whether the Moody or the Ackeret step-up formula, or something in between, or even no efficiency step-up at all, is used in connection with the field "index" tests to draw the prototype performance curves. The important point is that it is not economically feasible to measure the large water flow rates with sufficient accuracy to base the contract guarantees on a so-called "absolute" acceptance test so that recourse to "index" tests (in accordance with the ASME Test Code) is the only practical procedure.

The author wishes to thank all of the discussers for their valuable contributions, which have added greatly to the satisfaction of presenting a paper on a subject of current interest in Canada. He also wishes to thank the officers and members of the Engineering Institute of Canada for the opportunity to present the paper and for their courtesy and friendship extended to him at the Montreal meeting.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Severe cold weather slowed down construction work considerably during January. There was also a period of extremely mild weather which also interfered with the work progress. In general, the weather was unfavourable for construction. The total number of workers on the Ontario Hydro section of the project was 3,550 persons.

Progress By Ontario Hydro

Excavation of the mile-long Cornwall diversion canal was virtually completed in January. A total of 1,100,000 cubic yards of material was removed from this new channel. It will take ship traffic through the power-house construction area while the dike is being completed over the old canal, and will be used until the time of flooding the headpond area.

Construction of the concrete closure structure had been completed in November. Removal of the plugs at either end of the canal was getting underway. At end of January only the placing of rip-rap on the slopes of the canal remained to be done to prepare the diversion waterway for shipping in April.

Despite extremes in weather, concrete placing continued around the clock on the Ontario Hydro half of the power-house. To the end of the month, a total of 430,000 cubic yards of concrete had been placed in the permanent structures on the power-house site. Concrete placing was proceeding in all units out to No. 8, and also in the three ice sluices. The draught tube form was erected in unit No. 7 and concrete placing was getting underway.

Draught tube liners had been installed in units 3 and 4. Erection of the fourth gantry crane on an 85-ft. gantry on the downstream side of the power-house was completed at month end. This will help to speed up concrete placing operations on the downstream side of the power-house, and also the installation of mechanical parts. At the west end of the project, excellent progress was made on the removal of Iroquois Point. The total excavation now amounts to 700,000 cubic yards, with the material going to disposal areas at Iroquois townsite and dikes in the area. Reinforcing of the swing bridge over the canal at Iroquois was in progress to handle heavy traffic engaged in construction work at Iroquois Point.

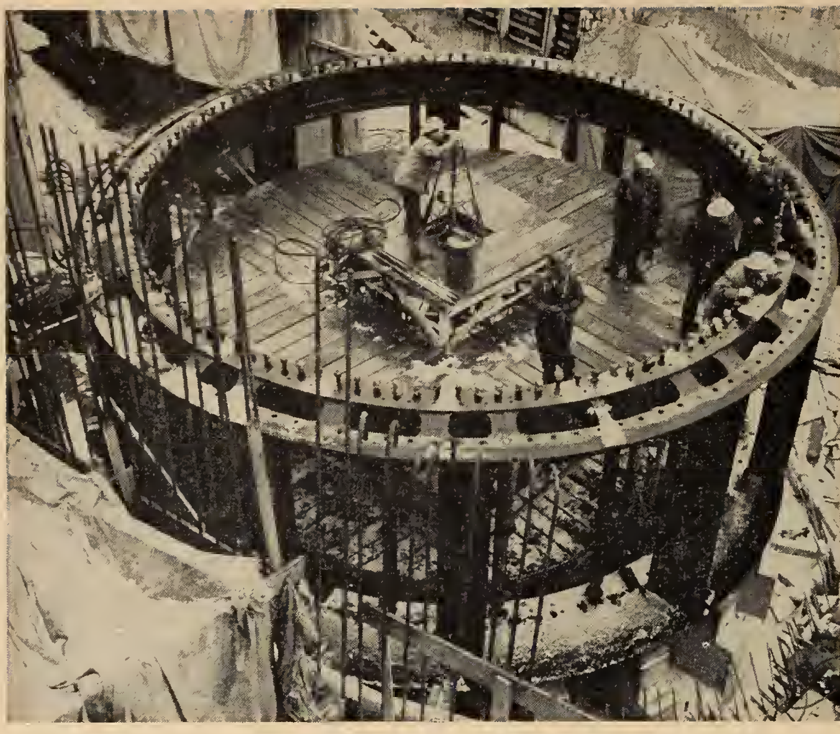
Erection of the new railway bridge to carry the relocated Canadian National Railways double track over Hoople Creek had been completed. Work was about to commence on the bridge over Nash Creek, one of three such structures on the 40-mile stretch of new railway line. Construction of the highway bridge over Hoople Creek also was proceeding favourably. The paving contractor had added five additional miles of base paving to new No. 2 highway west of Ingleside to the Aultsville Road.

Some work was in progress in preparation for dike construction in the spring. The contractor was excavating in the marine clay areas in the vicinity of Mille Roches.

Limited house moving operations were carried out in Morrisburg in January to clear access routes for the major moving program to commence in April. Ten homes had been moved by the end of the month. In the new industrial area of Morrisburg, all services had been installed, and a new track spur had been laid.

At Iroquois, work was concentrated on the new shopping centre. Store fronts were virtually completed and interior installation work was proceeding. Conversion of houses into apartments was in progress, with approximately 30 apartments ready for occupancy. Work was continuing on schools and churches.

An artist's conception of the St. Lawrence power project, when completed in 1960.



St. Lawrence power dam. The stay ring for unit 32 is leveled and aligned

House moving operations were in progress throughout the month at town No. 1 with a total of 32 homes moved by month end. Work was essentially completed on the storage tank, and construction of the sewage treatment plant was virtually completed. At town No. 2, the major program was cleaning up and repairs and renovations to houses recently moved. Some 25 houses remained to be moved into the townsite.

Progress by NYSPA

Despite January's extreme subzero temperatures, progress continued on almost all features of the project. Overall construction was on schedule, as concrete placement to month's end exceeded 34.5 million cubic yards. Employment averaged 2,150 for the month.

At Long Sault dam, removal of the plug at the upstream end of cut F was progressing on a twenty-four hour day basis, concurrently with placing rock fill in cofferdam E. All the flow of the south channel, and part of the flow of the north channel, was being diverted through Long Sault dam. Concrete placement in the St. Lawrence power dam (Barnhart Island power-house) was continued at a reduced rate due to low temperature conditions, as concrete placed to date exceeded 440,000 cubic yards. Concentrated efforts were made to push the placement of concrete in ice sluices 5 and 6 and in the intake piers. Concrete continued to be placed in the switchyard walls and in transmission line tower footings.

At Iroquois dam, the stage II cellular cofferdam to the Canadian shore was completed, the construction area unwatered, and excavation started. Removal of the upstream stage I cofferdam continues.

At Massena intake, cofferdam cells were being driven and excavation for the upstream diversion channel continued. Installation of electrical and mechanical equipment inside the structure progressed satisfactorily. The elevator hoist machinery was installed.

Excavation under the five channel improvement contracts was hampered during part of the month by extremely cold temperatures. Due to difficulty in ferrying personnel and supplies to Toussaints Island, equipment was moved to the mainland and placed in operation on Sparrowhawk Point.

Construction work on the relocated highway routes 37 and 37B continued during the first half of January, but at month end both contractors had suspended all construction activities until spring. Progress on both highways was ahead of schedule. Work continued at a reduced pace on the rehabilitation of the Massena-Taylorville transmission line due to the severe weather. Clearing of the right-of-way for the Barnhart-Plattsburgh transmission line was progressing on schedule. Bids were received for a 200-Mva. auto-transformer to be located at Plattsburgh.

Continued progress was made by the four reservoir clearing contractors, as 3,000 acres of the required 11,000 acres had been cleared.

Heavy Construction to End This Year

Completion of heavy construction work on the St. Lawrence power project by the end of 1957 was forecast by NYSPA. Another goal cited was the opening of the river between Montreal and Lake Ontario to 27-foot draught vessels at the start of the 1959 navigation season.

These and several other predictions were contained in an illustrated 52-page progress report prepared by the Authority for Governor Averell Harriman and the state legislature.

Present plans call for the flooding of the power pool on July 1, 1958, he said, with the first power being produced by September 1, 1958.

In addition, the report said the authority has assured a market for all St. Lawrence project power.

Robert Moses, Authority chairman, said that contracts had been signed with Aluminum Company of America, the state of Vermont, the city of Plattsburgh and the Plattsburgh air base. Also, he said, "contracts have been negotiated with Reynolds Metals Company and Niagara Mohawk Power Corporation, thus assuring a market for all St. Lawrence power and sufficient revenue to pay for maintenance."

Progress by SLSA

With the labour force reduced to some 3,500, most of the work on navigation channels during January was on the locks. At the Iroquois lock 161,000 yards of concrete had been placed to date on the upper approach wall and the upstream end of the lock. Nearly four million yards of excavation was completed. No concrete was poured during January at the Cote Ste. Catherine lock. At the upper Beauharnois lock 310,000 yards of earth and 343,000 yards of rock had been excavated to date and the mixing plant was ready to operate. On the lower lock 230,00 yards of rock had been taken out to date and 22,000 cubic yards of concrete poured in the underpass. At the St. Lambert lock placing of concrete was just being resumed after a two-month shut down.

At Mercier bridge, the contractor was working on the embankments for the approach roads, and had started pouring concrete pedestals. At the Jacques Cartier bridge, temporary southbound and northbound lanes were opened for traffic, and cladding of the piers was virtually completed. Work had started on the new south shore abutment and preparations were being made for lifting the superstructure spans. At the Welland ship canal, with work completed between locks 1 and 2 and between locks 3 and 4, work was continuing between locks 2 and 3 in the dry and drilling was proceeding at the Port Colborne end.

A contract to John Entwistle of Cornwall was awarded January 4 for the construction of a temporary water supply installation to supply clean water to the Courtaulds plant at Cornwall, during construction of the seaway. The contract is valued at $176,000 and the work is to be completed by April 30, 1957.

Award of a contract for supply and erection of the steel superstructure from pier 14 to pier 29 of the proposed south extension to Honoré Mercier bridge near Montreal was announced January 8. This superstructure will be some 1883 feet in length. The contract was awarded to Dominion Bridge Company Limited, of Montreal. It is valued at $2,503,-218. Purpose of the extension is to provide a high-level crossing for motor traffic over the seaway channel.

By November 30, 1957, the contractor will complete fabrication to such state that erection may actively proceed, at which date the concrete piers are scheduled for completion by another contractor. The work is to be entirely completed by May 31, 1958.

A contract for suction dredging of 9,400 feet of the Welland ship canal in Port Weller harbour at the Lake Ontario entrance was awarded on January 9 to the J. P. Porter Company Limited, of Montreal, at a price of $642,600. Dredging at the lower entrance to lock No. 1 is to be done during the non-navigation season this winter. The whole of the work is to be completed by July 31, 1957.

(Continued on page 313)

What Goes On

Canadian Car and Foundry, Limited

A three-year, $15,000,000 plant construction and integrated modernization program, was announced at the end of January by E. J. Cosford, president and managing director of Canadian Car and Foundry, Limited. Can-Car is a member of the A. V. Roe Canada Limited, and Hawker Siddeley Group of Companies.

By this program the company's Dominion plant at Ville St. Pierre, Que., will be enlarged to nearly double its present manufacturing area, with new facilities for the production of stainless steel equipment. Production capacity of stainless steel cars is estimated at 80 units a year.

Canadian Steel Foundries (1956) Limited

Construction of a plant in Montreal for the production of wrought steel wheels for railway freight and passenger cars and for diesel locomotives is announced by Canadian Steel Foundries (1956) Limited. New equipment valued at $4,000,000 will include a battery of heavy machines for forging, pressing, rolling and heat treating; the latest equipment in mechanical and materials handling; electric furnaces and machining facilities.

The firm is a relatively new member of the A. V. Roe Canada Limited and Hawker Siddeley Group of Companies. It was formerly a division of Canadian Car and Foundry Company, Limited.

Shawinigan Water and Power Company

The Shawinigan Water and Power Company and the Power Corporation of Canada Limited, jointly announced recently that agreement had been reached on the terms of an offer by Shawinigan to acquire Power Corporation's holdings of 199,975 shares (49.9 per cent interest) in Southern Canada Power Company, Limited's common stock on a share exchange basis. The same exchange offer will be extended shortly to all other Southern Canada common shareholders. The preferred shareholders of Southern Canada will not be affected.

The effect will be the ownership by Shawinigan of 70 per cent of Southern Canada's common shares.

It is believed the closer relationship of Shawinigan and Southern Canada companies will be of benefit to the territories served by both companies.

International Nickel Company of Canada, Limited

Preliminary construction was commenced in December on a new 12-million dollar concentrating plant for the International Nickel Company of Canada, Limited.

Located on a site adjacent to the Company's Levack Mine, the mill will have a rated capacity of 6,000 tons per day. It will form part of a continuing program to provide for more effective utilization and efficient treatment of the Sudbury ores. It will produce both nickel sulphide and copper sulphide concentrates.

Contract for the new mill building has been let to the Foundation Company of Canada.

Dominion Bridge Company, Limited

A $20 million expansion program announced by Dominion Bridge company as a four-year project, will affect the whole company network, increasing productive capacity by approximately 40 per cent.

In the Eastern Division there will be an office extension at the Lachine plant, a plain steel warehouse and additions to the structural steel fabrication shop; new fabrication facilities at Robb Engineering Works, Limited, Amherst, N.S.; a new plant in Ottawa.

The Ontario Division will receive a new steel fabrication shop in Toronto.

Principal expansion in the Western Division will be in the Edmonton area, a large structural fabrication, shop. At Calgary a fabrication aisle will be enlarged.

In the Pacific Division, the program will follow several expansion stages which have already taken place during the past few years at the company's two Vancouver plants.

Tender for Fertilizer Plants

A request for tenders has been received from the Commercial Secretary, Office of the High Commissioner for India, in Ottawa. This tender may be of interest to Canadian engineering companies.

The tenders are invited for supplying a group of fertilizer plants, designed for the production of nitrolimestone (20.5% nitrogen) starting from hydrogen, of electrolytic purity, and limestone.

The request for tenders, with full details and specification, is available for inspection at Institute headquarters. Tenders are to be received by parties in New Delhi, India, and in New York, N.Y., by May 15, 1957.

Canadian Pipeline Project

Westcoast Transmission

Frank McMahon, president, announced in mid-January that at the close of the 1956 construction season more than 70 per cent of the pipe was laid in the ground, and that the entire project, including river crossings, compressor stations and measuring stations, was on schedule. He said his company would provide the sales outlet for the largest potential gas producing area served by one natural gas pipeline.

Mr. McMahon believes the proposed union of El Paso Natural Gas and Pacific Northwest companies will, when completed, provide increased market areas for Westcoast gas supplies from Alberta and B.C. fields. This new deal, whereby El Paso acquires full ownership of Pacific Northwest for $150 million, gives the former company ownership of 11 trillion cubic feet of reserves, over 2,300 miles of pipeline with 339 billion cubic feet daily of capacity, 304,000 acres of leases and 246 producing gas wells, making it the world's largest pipeline system. The company holds a 25% interest in Westcoast Transmission.

A Canadian financial house has estimated that Westcoast's earnings in its first 12 months of regular operation commencing in 1958, will reach approximately $14½ million or $2.90 per share outstanding. Revenue is predicated on the assumption that movement of gas under present contracts for firm deliveries, for additional option purchases and for still further extra amounts, will total around 750 million cubic feet daily in the 12-month sample period. Firm and option deliveries are slated to rise to 849½ million cubic feet daily starting in 1961, but growth in demand and pipe facilities are seen as making it possible that deliveries will rise to 1 billion cubic feet daily in 1961 and to 1½ billion feet by 1963. On this basis it is calculated earnings would increase to $4.10 per share in 1961 and to $5.80 per share in 1963.

Inland natural gas planned to start work on its distribution systems on February 1. First on the program was the Penticton system, with Kelowna following on February 15. The Nelson system was to be started on March 15; work will start at Williams Lake and Quesnel early in April and at Trail in July. Award of a $9 million contract to build the main pipeline was awarded last September. Prior to that, orders had been placed for pipe, to be manufactured in Canada, amounting to $6½ million.

Already enthusiasm for modern firing of industries with natural gas has raised Inland's commitments to Westcoast. No rate structure has yet been announced but it has been stated that rates will be competitive and as low as those paid by users in the coastal areas of British Columbia.

Completion of Inland's entire pipeline system is expected by September this year.

Savanna Creek Gas

The Northern Natural Gas Co. will apply to the Petroleum and Natural Gas Conservation Board of Alberta for permission to take natural gas from the Savanna Creek field to destinations in northern states, including Minneapolis. Northern's Canadian subsidiary has a 32½% interest in the Savanna Creek field. The proposed pipeline would presumably be in substitution for the one projected recently by Westcoast Transmission Co. for export of Savanna Creek gas to the Pacific northwest.

The Westcoast announcement had referred to a contract with Phillips Petroleum Co., which holds 27½% interest in the field. The new Northern Natural Gas plan would take the gas via Coutts, Montana, to connect with Northern's large existing system. No agreement has so far been reached on compromise plans in connection with a proposal for export of Canadian gas by Trans Canada Pipelines to a subsidiary of Tennessee Gas Transmission. Trans Canada officials had made no comment up to the end of January.

Trans Canada Pipelines

J. L. Parrish, chief engineer, speaking for Charles S. Coates, executive vice president and general manager of Trans Canada, told the Pipeline Contractors' Association meeting in Florida, on January 15 that his company expects to have 1300 miles of its 2250 mile pipeline in the ground by the end of this year. This means laying 1000 miles during 1957. To date some 230 miles had been laid on the line to Winnipeg and contracts awarded for the balance of the 574 miles. Digging of the pipe trench might not be resumed until June, he said, but gas would reach Winnipeg by August or September. Two vital events in the immediate future were the financing of the project and FPC approval of export-import proposals.

Mr. Coates' report also stated that the 30-inch pipe would be laid as far as Port Arthur during the current year, as well as the 310-mile Toronto-Montreal 20-inch leg. The Port Arthur-Toronto gap would be bridged in 1958. Thus gas services from the all-Canadian line would be available at all points along the initial system by the fall of 1958.

According to an announcement last September, Montreal deliveries by Trans Canada are to be taken and distributed in this area by a new company, to be formed to acquire producing and distributing facilities of Hydro-Quebec. This company could presumably be formed this year and could commence distribution of gas supplies which are presently being purchased for use in Toronto (via Buffalo) from Tennessee Gas Transmission Co.

Meantime, the Tennessee-Midwestern case, on which FPC hearings are being conducted at Washington, remains where it stood last November when the Federal Power Commission rejected applications from the competing natural gas companies to throw out the Tennessee-Midwestern proposal to import 204 million cubic feet of Canadian gas daily via Emerson, Manitoba.

In addition, Tennessee-Midwestern want to export gas to Eastern Canada to build up the Montreal market pending the arrival of Alberta gas. The way the hearings are going at Washington many months may pass before a decision is handed down, and after that the case may be appealed before the Supreme Court of the United States. Thus the all-Canadian pipeline may be built and operating before the case is resolved.

Crown Company Gets 'Go-Ahead'

The federal government on January 30 announced it had authorized a start on construction of the northern Ontario leg of the pipeline. The Crown Corporation will complete laying of the pipe from the Manitoba boundary to Port Arthur by November 1, 1957, and the rest of its portion to Kapuskasing by November 1, 1958. On its part, Trans Canada has agreed to complete the prairie leg to the Ontario boundary by Nov. 1, 1957, and to complete the rest of the line from Kapuskasing to Montreal by November 1, 1958. The government is now satisfied that Trans-Canada has completed arrangements for financing of all the costs for its portion of the construction.

The Saskatchewan Power Corporation is seeking to purchase the output of natural gas from the Many Island gas field just west of the Saskatchewan-Alberta border. It claims gas from this field would be cheaper than gas purchased from the Trans-Canada pipeline. The intention would be to connect the field up with the 120-mile gas pipeline built in 1956 to bring gas to the city of Moose Jaw from the Success field in southwestern Saskatchewan.

The City of Medicine Hat, Alberta, opposes this purchase however, and even if the Alberta Conservation Board should decide in favour of the Saskatchewan proposal, the Corporation must apply to the Transport Board for approval of a pipeline route, before approval will be given by the Alberta Government for export.

The First "Argus" Completed

The first flight of the Argus is scheduled for April 1957.

Canadair Limited, Montreal, has developed the CL-28, now named the Argus, to meet the exacting requirements of the Royal Canadian Air Force for a long range maritime patrol aircraft. The first two craft will remain at Canadair for testing purposes, and the RCAF will take over the third later in the year.

"The primary role of the airplane" it was explained by E. H. Higgins, Canadair's chief project engineer "has been stated by the RCAF to be the shore based air seaward defence of Canada, in the Canadian Atlantic sub-area, in conjunction with the R.C.N."

Although the Argus has been developed from the basic design of the Bristol Britannia series of transport aircraft, the military requirements have resulted in very extensive changes for its specialized role.

The complex equipment provided for communication, navigation and submarine detection requirement; includes an extensive number of separate electronic systems and a wide range of the most recent armament equipment.

The giant aircraft is 128 feet long, with a wing span of 142 feet, a height of 36 feet. Its cruising range is more than 4,000 miles, cruising speed, 175 to 200 m.p.h., maximum altitude 20,000 feet.

It is powered by four Wright piston turbo-compounded engines, instead of the Britannia's turbo-prop engines. This power change will give the Argus very long range at low levels and moderate speed, as required for its special tactical mission.

The Bristol Britannia was completely redesigned, employing North American standards and materials, to ensure that the Argus can be produced and maintained in Canada under wartime conditions. Its completion was preceded by a vigorous program of laboratory testing of the major systems, the airframe components and power plant.

The Argus, it is reported by the RCAF, will be the best fitted anti-submarine aircraft in the world with respect to modern electronic and other equipment. With its coming into service the Avro Lancaster, a wartime bomber, now being used by RCAF's Maritime Air Command, will be gradually retired. The recently acquired Lockheed P2V-7 Neptune, medium range patrol aircraft, will remain in service.

The Argus will be capable of flying more than 1000 miles from its base and remaining there for a considerable time on patrol. If necessary it can divert to an alternate field within a radius of 500 miles from base with normal fuel reserves. It has a combat range of more than 4000 miles. It will carry torpedoes, depth bombs and a variety of weapons, as required for patrol mine laying or torpedo bombing.

The program of the Engineering Institute's annual meeting this year at Banff, Alta., June 12-14, will include a technical paper on the Argus.

Transatlantic Telephone Cable

The Canadian Overseas Telecommunication Corp., is considering further transatlantic telephone cable facilities, Douglas F. Bowie, president and general manager, said recently.

Mr. Bowie was commenting on a London dispatch quoting the *Financial Times* as saying the United States and Canada have under discussion the possibility of a second cable because of the great volume of calls that followed completion of the first cable.

Mr. Bowie's statement said:

"Public use of the transatlantic telephone cable which was launched on September 25, 1956, has exceeded all expectations and it has become necessary to give serious consideration to providing more facilities".

(CP. Report, Feb. 20, 1957)

E.I.C. Annual Meeting

Banff, June, 1957

"Overseas Telecommunications" wilil be the subject of a paper by R. G. Griffith, M.E.I.C., of Canadian Overseas Telecommunication Corporation.

Presenting views of New York, London, and Montreal groups, meeting simultaneously on January 24, 1957, and with proceedings linked by transatlantic telephone cable service. This unique meeting was reported in the February issue, page 144.

London. Here the meeting was arranged by the Institution of Electrical Engineers. Sir Gordon Radley, president, is seen (left) expressing greetings of I.E.E. Also shown: Dr. R. C. G. Williams, chairman of the Radio and Telecommunication Section, Dr. R. A. Brockbank and R. J. Halsey, of the British Post Office, authors of papers.

Montreal. At the meeting sponsored by the Engineering Institute of Canada the participants were: Douglas Bowie (left) president of the Canadian Overseas Telecommunication Corporation; Thomas W. Eadie, president of The Bell Telephone Company of Canada; R. G. Griffith, chief engineer of C.O.T.C., and V. A. McKillop, president of the E.I.C.

The New York end of the conference took place at the winter general meeting of the American Institute of Electrical Engineers. Those participating in New York are (left to right): M. J. Kelly, president, Bell Telephone Laboratories; T. F. Gleichmann, Bell Laboratories; J. S. Jack, A. T. & T. Long Lines Division; H. A. Lewis, Bell Labs; A. N. Lebert and E. T. Mottram, of Bell Labs, and M. S. Coover, president of AIEE.

Power Developments in Newfoundland

St. John's, Corner Brook, Grand Falls

The Newfoundland Light and Power Company Limited, St. John's, has reported an expected total load growth in 1957 of close to 22 million kwh., in the St. John's, Corner Brook, and Grand Falls areas. The company has been reporting rapid load growths in the past ten or twenty years.

In 1956 a 10,000-kw. steam generating plant at St. John's was completed, the first steam turbine station in the system. The installation, costing $1,990,000, and developing a site that can be used for two more units of 20,000 each, features a new electronic system of boiler control, the first of its kind in Canada.

Future planning for the St. John's division of the company, as reported by V. A. Ainsworth, general manager, includes the addition of a 10,000-kva. generator at the Pierre's Brook hydro plant to provide peak capacity in 1958, and the addition of a 20,000-kw. steam unit at the St. John's steam plant in 1959. There is also a plan that will give remote control of all plants and substations from a central load dispatching point by 1961.

It is anticipated that the load in St. John's will reach 270,000,000 kwh. per year, with a peak of 63,000 kw., by the end of 1961.

In the Grand Falls area, construction is to start in the spring of 1957 on a power plant on Rattling Brook, Norris Arm, about twenty miles from Grand Falls. Completion date is scheduled for late in 1958 at this site, which is capable of 8500 hp. continuous. This development is the result of the agreement, made when the distribution system in this area was purchased from the Anglo Newfoundland Development Company, that the Power Company would develop a source of power immediately.

In the Corner Brook area, where power is purchased from Bowaters for distribution, plans are for urban and rural distribution extensions only.

Trinity Bay and Conception Bay

Two more power developments into operation in December, 1956, in Newfoundland, the New Chelsea power house at Trinity Bay, and the project at Manuel's River on the shore of Conception Bay.

These new installations of the United Towns Electric Company Limited, designed to expand its power resources, will add, in 1957, 20 million kwh. to the company's annual output. The company is affiliated with the Avalon Telephone Company, of St. John's, Nfld.

The Avalon company, through W. J. Carew, reports expansion of United Towns' operations during 1956 to 55,138,590 kwh. generated. There are other expansions being contemplated for Lookout Brook, on the West Coast, and in Burin Peninsula.

The $2 million New Chelsea project was developed in three stages.

Two areas totalling nearly seven square miles, in the vicinity of Crooked Pond and Ocean Pond, are adjacent to Big Brook, and their outlets formerly drained into Conception Bay. These waters have been turned into Pitmans Pond and the combined resources of all these headwaters are now fed into the powerhouse at Big Brook.

The work at Manuel's River consisted of the creation of a reservoir, five sq. mi. in area. A compacted earth fill dam, 37 ft. high, raises the water surface to a height of 30 feet, which is sufficient to divert it into a 3,600-ft.-long canal, into an existing reservoir and penstock which feeds the power plant at Topsail. This plant is thus ensured of a continuous 24-hour production, and its output is increased to 8,260,000 kwh. annually.

This development as well as the New Chelsea one was carried out by the Power Corporation of Canada.

New Brunswick Power

Exploration work being carried on in New Brunswick is continuing to reveal valuable new ore bodies, rating the province's mineral finds as some of the richest in North America, it is reported by the N.B. Electric Power Commission.

The commission, planning to provide economical power to domestic customers, and to light and heavy industry, lists as potential power users the mining companies at present either processing, consolidating or expanding their mineral discoveries. Chemical industries, pulp and paper mills, and others must be served also.

The demands for large blocks of power are already known. The immediate and longer term plans feature a pattern of interconnection of generating facilities within the province, and within the whole maritime area and a tie-in with a utility in the State of Maine.

In the past year a reciprocal arrangement interconnecting the Commission's grid system with five of the major pulp and paper companies for the purchase and sale of surplus power was mutually beneficial. The Commission thus obtained 29 million kwh. for resale, while 44 million kwh. of off-peak power from the Commission generating stations was supplied to the paper companies.

Actual hook-up of N.B. Power Commission with facilities of the Maine Public Services, a privately owned utility, is set for an early date this year.

The power pool idea has been endorsed in principle by the three Maritime governments, and a special committee has been set up by the Atlantic Provinces Economic Council to study and report on the plan. Only New Brunswick and Nova Scotia are now represented in this special power group. Though Prince Edward Island is not now in the plan, the theory is that a hook-up with P.E.I. could be accomplished by submarine cable across the Straits of Northumberland or via the proposed causeway.

The potential market for power is great. Even after the 102,000-kw. Beechwood hydro development begins transmitting its power, the Province may require a further 532,000 kw. to supply the demand in the next decade.

An orderly program of construction of generating facilities has been designed. Steam units are planned, to be integrated with developments on the St. John and other rivers.

A thermal plant at Chatham was added in December 1956. Work on the Beechwood hydro development on the St. John River is going forward well ahead of the original plan of construction. Construction of the 30 million development, with contractors Foundation Maritime Ltd. in charge, continued through the fall and winter.

Tidal power as a source of electrical energy, long a subject of speculation, received particular attention in 1956. The International Joint Commission has authorized a comprehensive study of the technical and economic feasibility of the Passamaquoddy Tidal Power project.

CF-100 Flight Simulator

Acceptance of the first production model of the CAE CF-100 Flight and Weapons Systems Simulator on February 12 by the government and the air force marked an advance in Canada's aviation and electronics industries.

The simulator reproduces on the ground the flight, engine and weapons systems characteristics of the actual aircraft. Eleven models will be built at the Canadian Aviation Electronics Company plant in Montreal.

The Rt. Hon. C. D. Howe, Minister of Defence Production, for the government, and Air Marshal C. R. Slemon, Chief of Air Staff, for the Royal Canadian Air Force, accepted the first model from K. R. Patrick, president of CAE.

The simulator consists of an exact replica of the CF-100 cockpit, an instructor's console, and a number of computers. It is a training device familiarizing the aircrew with the behaviour of a specific aircraft rather than with general flight and instrument performance. Basically a computer of the "analogue" type, it will allow three distinct types of aircrew training: transition and familiarization; training in emergencies; tactical training in interception techniques.

Operation and Techniques

During simulator operation, controls and instrumentation provide complete information concerning flight conditions, engine performance, enemy activity and so on. The flight and radar instructors are provided with duplicate sets of instruments together with a scoring system that measures crew proficiency.

Instrument readings, from which the operational data of an aircraft are taken, are basically instantaneous solutions to the complex differential equations that govern the behaviour of an aircraft in motion. Individual terms of these equations are derived primarily from displacement of the aircraft controls such as control column, throttle, rudder bar, etc., and in flight are added, multiplied and integrated automatically by the aircraft itself. Analogue computers make possible the solution of these equations and their display upon real or simulated flight instruments and recorder charts.

Variable quantities, such as lift, drag, weight, angle of attack, etc., are presented to analogue computers as "machine variables" or voltages and shaft rotations which are made to obey the same mathematical relationships existing between the original variables. The processes used in computing occur at the same rate as the processes they represent in the actual aircraft.

Civilian Application

Recently Canadian Pacific Airlines placed an order for a DC-6B simulator with Canadian Aviation Electronics, the first Canadian airline to order a full simulator. This will be the first commercial model to be built in Canada.

Mineral Industry in Nova Scotia

Increased production marked the progress of the mineral industry in Nova Scotia in 1956.

The total value of the industry well exceeded the $66 million mark, of which coal accounted for $50 million. Coal production is again on the increase after a slight recession felt in recent years. Aiding in the improvement have been several factors. Increased mechanization has reduced mining and transportation costs; new washing and screening methods have been introduced, and a new downdraft automatic coal burning furnace is being marketed.

Nova Scotia produced during 1956 more than 80 per cent of the total Canadian output of gypsum. Production reached 4 million tons, practically all of which is shipped in crude form to mills on the Atlantic seaboard of the United States.

The Canadian Gypsum Company is investing $2½ million in a new quarry; the National Gypsum (Canada) Ltd., has developed a new quarry and has extended shipping facilities. The Bestwall Gypsum company has obtained property at Cheverie and at Milford, and development will proceed. The Johns Manville Company is reported to have taken options on tracts in the vicinity of Milford.

The province produces 90 per cent of the Canadian output of barytes. A new development is the plan to adopt the underground mining method; a contract has been let for a new 900-foot shaft to tap large tonnages of proven barytes ore reserves.

The Malagash Salt Company Ltd is developing a new salt deposit at Pugwash, and will invest $1 million in new buildings, machines and marketing arrangements.

Production of sandstone, granite and clay products continues profitably. Petroleum field exploration has been undertaken over large tracts by Imperial Oil Co. Ltd. Prospecting for base metals continued at a high level.

Ontario Hydro's Golden Jubilee Year

Ontario Hydro observed its Golden Jubilee in 1956.

During Hydro's first fifty years, the population of Ontario has more than doubled, to over 5 million. The gross value of manufactured products has jumped to over $9 billion and mineral production to $584 million.

Primary power requirements for all systems were 4½ million kilowatts in 1956. This would more than absorb the output of the additions to the Commission's power resources and its modest reserves. This situation will be improved as resources now under construction are placed in service during 1957. For the time being, it emphasizes the value of Ontario Hydro's interconnections with neighbouring states and provinces.

Construction presently under way on nine separate projects, including new plants and additions, will add over 2 million kilowatts to present resources within the next four years. By 1980, power demands may be four to five times what they are today, which means that resources totalling more than twenty million kilowatts will be required, much of which will be provided from thermal sources.

In the light of these facts, the ceremonies on September 19, 1956, launching construction of Canada's first nuclear-electric plant on a site near the Commission's Des Joachims station on the Ottawa River, assume the highest significance. It is expected that the operation of the 20,000-kw. NPD plant will provide valuable information and experience for future development of electric power from nuclear sources on a much larger scale.

Further evidence of the active role which Hydro is playing in nuclear research is to be found in the financial assistance being given to McMaster University for work associated with reactor installation, operation and studies. Ontario Hydro provided a grant of $100,000 during 1956 and will give a further $100,000 in 1957. In addition, $5,000 per annum will be provided for over ten years to assist in the operating costs, associated with the reactor.

Progress at Niagara

In the Niagara area, four additional 75,000-kilowatt units of the Sir Adam Beck-Niagara Generating Station No. 2, are scheduled to be in service by 1958. These, along with the 170,000-kilowatt pumping generating station, scheduled for service in 1957, will bring the installed capacity of this plant to its ultimate of 1,370,000 kilowatts.

Considerable headway was also made during the year on the remedial works program being undertaken jointly by Ontario Hydro and the Corps of Engineers, U.S. Army.

News of still further expansion of Hydro's southern Ontario system came during 1956 with the announcement that three 200,000-kilowatt units will be added to the Richard L. Hearn generating station at Toronto. Already this is the largest thermal-electric plant in Canada, and the additional units will bring its total capacity to one million kilowatts. At the same time, the Commission is considering the possibility of building a steam plant at Hamilton using a site which is owned by the Commission at the waterfront.

Northern Ontario

In northwestern Ontario, an area which comprises more than half the province, Hydro's power demands had increased in December, 1956 by 6.1 per cent over the corresponding period of a year ago.

This part of the province, from the standpoint of its potential development, is described as "the richest area in the world", and its population should double in the next 20 years.

New Power Plants

At Whitedog Falls on the Winnipeg, a 54,000-kilowatt plant is being built, scheduled to come into initial service in December, 1957. The following year, the 67,500-kilowatt Caribou Falls station on the English River is scheduled for first operation. Extensions are being made to the Alexander and Cameron Falls plants on the Nipigon River that will increase the resources of the northwestern division by 30,400 kilowatts by 1958. Looking even farther ahead Hydro crews have test-bored the lakehead area for possible thermal-electric generating station sites.

In October, 1956, arrangements were completed for the first exchange of power between the facilities of Ontario Hydro's Northwestern Division and the Manitoba Hydro-Electric Board. It is now possible for these two systems to exchange power and to co-operate in utilizing the flows of the Winnipeg and English Rivers to the best possible advantage. The interconnection was made through Ontario Hydro's new switching station at Kenora.

Frequency Standardization

During 1956, the 60-cycle frequency standardization program in southern Ontario advanced substantially. From October, 1949, when it was started, up to November 1, 1956 a total of nearly five million appliances had been changed from 25 to 60 cycles for 739,202 Hydro customers. It is estimated that over six million appliances will have been altered by the time the southern Ontario changeover program has been completed in 1959. Plans for 60-cycle frequency standardization in Hydro's northeastern division were announced in September.

St. Lawrence Seaway

(Continued from page 307)

The Hon. George Marler, Federal Minister of Transport, announced that tenders would be called in the spring for the proposed new highway bridge across the St. Lawrence at Nun's Island opposite Montreal, if all formalities could be cleared by that time. The National Harbours Board would also consider adding a fifth traffic lane over the Jacques Cartier bridge when conditions warrant it, he said, but not before better approaches are provided on the Montreal side.

The speaker intimated that the federal government would be spending a total of some $40 million on improvement of highway communications between the island of Montreal and the south shore arising out of seaway development.

Discussing seaway traffic, he expressed the view that American ports would handle the bulk of overseas shipping using the Great Lakes when the seaway opens. Traffic on the lakes had increased substantially since 1945 and would be further developed when the seaway is finished. He predicted that U.S. Great Lakes ports, rather than Canadian ports, would be the terminus for more goods, because of the greater population on the American side of the Lakes.

Month to Month

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE
ELECTIONS AND TRANSFERS

E.I.C. Conference on Engineering Education (1956)

Since the Institute's Engineering Education Conference was held in May, 1956, the committee consisting of Deans R. E. Jamieson, H. Gaudefroy and H. Conn have been busy working on the verbatim and the resolutions.

The committee has met at least three times at three different centers and has recenty produced documents which mark the second stage in the conference development.

In the first place, the committee has circulated an abstract of the very voluminous verbatim. A copy of this has gone to every one of the sixty people who attended the conference. The verbatim itself has been circulated to each university so that each person may have an opportunity to study what was said, thereby refreshing his own recollections of the conference.

Recently the committee circulated a very exhaustive questionnaire — eight pages in length. This questionnaire has gone to every dean of engineering in Canada, with the suggestion that the information be compiled carefully and then returned to committee for study.

The questionnaire provides graphs wherein may be recorded information such as undergraduate degree, and sessional fee, admission requirements, maximum number of students in teaching groups, draughting room sections, laboratory groups, staff teaching load, attendance records, amount and type of shopwork, surveying field work, draughting hours, laboratory reports per student per session, industrial experience requirement, academic standing and promotion, record of academic performance, —from first, to second, to third, to fourth and to final years, and so on.

At the conference itself it was noticed that practices varied considerably from institution to institution.

Once this questionnaire has been completed and analyzed, the differences in teaching methods and procedures can be readily noted and the methods of one institution as compared to another can be studied.

The committee plans to compile all the information and then to recirculate it to every person who participated in the conference. It is believed that under these circumstances the educators will have in their possession for the first time the real story of how engineering is taught in Canada. From such basic information the conference will be able to plan very wisely for the future.

It is expected that when the information is finally compiled it will be published in the *Engineering Journal* so that it will be available not only to the educators themselves but to all members of the profession.

Historical Biography

Shortly the Institute will be in the book publishing business. A four hundred and sixty page biography of two great Canadian engineers is being published under the Institute auspices and will be on the market by late Spring.

For some time people within the Institute have been talking about the possibility of bringing back to the public's attention, the careers of distinguished engineers who helped build up this great country. In some instances distinguished people such as Sir Casimir Gzowski and Sir Sanford Fleming have had their biographies published but there were many other giants of the profession associated with them whose records have been buried for almost a hundred years.

Some time ago the Council of the Institute agreed that the Institute would sponsor some worthwhile biographies of this nature. At the moment there are two in hand. One is now being printed and the other is in manuscript form and at this moment is up for final checking and approval.

Cover Picture

Jets of industrially clean water are sprayed on to rolled steel plate in the final cooling process at the Dominion Foundries and Steel Company rolling mill in Hamilton, Ont.

The first book will deal with the lives of Walter and Francis Shanly. Walter Shanly was a founder member of the Engineering Institute of Canada and was a vice-president in 1887. His brother was more concerned with the business side of their various enterprises but between them, they did much to shape the character of Canada.

The story of the Shanlys is a fascinating one and is an integral part of the history of railroad building and Canada's development. They did tasks both in the United States and Canada that put them in a special class of engineers and contractors. They completed successfully projects which had had to be abandoned by other firms because of inability to complete them.

In the process of doing all this they became wealthy men and Walter was a member of Parliament for Upper Canada.

The story has been told fascinatingly by Dr. Frank N. Walker of Toronto. Dr. Walker's degree is in medicine and not in engineering and members of the engineering profession are indeed greatly indebted to him for the fine work which he and Mrs. Walker have done and which they have made available to the Institute.

It is hoped that the biography will be available by the first of May.

It will be an impressive publication and probably will sell in the neighborhood of six dollars. It will be unique in the history of Canadian pioneers and in the history of The Engineering Institute.

To make the book a success commercially it will be necessary to have the support of the members of the Institute. It is hoped that the general public, too, will be interested but the principal field must lie within the profession itself.

In later issues of the *Journal* there will be extracts from the biography so that the membership may bit by bit get to know in advance something of the great men who fill its pages. This will be done in the hope that by the time the book becomes available many appetites will have been whetted.

The second biography has to do with the life of Sir Casimir Gzowski who like Francis Shanly was a vice-president of the Institute in 1887. This will be a complete story telling perhaps for the first time most of the great events of a great man's life. It is hoped that this second biography will be available before the end of the year.

The President Visits Quebec City

The president's visit to Quebec City coincided with the annual meeting of the branch. At this time Ben O. Baker became branch chairman. In this photograph, left to right, Mr. Baker and Louis-Philippe Bonneau, retiring chairman, and President McKillop. The decoration was keyed to the Quebec Carnival, then in progress.

Visitors to Quebec (at right) are Mr. and Mrs. Keith Leighton, of Moncton, and Mr. and Mrs. M. A. Montgomery, of Kitchener, Ont.

Mr. McKillop took this opportunity to present an E.I.C. prize to Jean Real LaHaye, an engineering student at Laval University.

At the annual meeting of the branch: Ben O. Baker, President V. A. McKillop, L. P. Bonneau, and Roger Desjardins, secretary-treasurer.

Transactions to be Published

Another publication of the Institute will make its appearance in the spring or early summer this year. Titled, "Transactions of The Engineering Institute of Canada", it will actually be the resumption of publication of "Transactions" which was interrupted in 1930, and later continued for a time with five "Technical Papers".

This activity received the final approval of Council at the Quebec meeting in January. It had been under consideration by the Publication Committee earlier and the decision was reached that there are now the means and the technical material to present to the membership a useful publication.

The production and editing is now in the hands of the editorial department, and suitable material is being selected for the first issue. Initially, distribution will be free to all members.

Technical Papers

Original technical articles submitted to the Engineering Institute of Canada are reviewed by authorities in the field of engineering concerned, and considered by the publication committee. If acceptable, papers may be published in the regular monthly issues of *The Engineering Journal* or in the *Transactions*.

The *Journal* would receive papers of general interest or of wide application; descriptive articles (e.g. industrial and other installations); papers on subjects that are likely to have a wide readership; papers on designs or processes not too technical in nature.

Papers of specialized technical interest and limited potential readership would be published in *Transactions;* as well as fundamental work of lasting value, likely to be used as a reference paper on the subject (e.g. theory of design); or papers too long for *Journal* use.

Members who have, or know of, papers which might be suitable for the *Journal* or for *Transactions* are invited to inform headquarters.

General Secretary is Society President

The general secretary of the Institute, L. Austin Wright, was elected president of the Council of Engineering Society Secretaries at the annual meeting of the Society in January.

Dr. Wright has represented the Engineering Institute in the activities of C.E.S.S. for many years. He is the first Canadian to hold the highest office in the Society whose 70 member institutions represent some 400,000 engineers in the United States and Canada. His election follows service as vice-president for the past year.

This 32nd annual meeting was held in New York City, on January 14, 15, 16, 1957. The next meeting will be in Cleveland in May, 1958.

Athlone Fellowships

Once again the Institute had the honour and privilege of entertaining Dr. H. H. Burness of the Ministry of Education, London, England, who for several years has come to Canada to select young engineers to whom may be awarded Athlone Fellowships.

Dr. Burness met with the selection committees at Ecole Polytechnique and McGill. Throughout his entire journey across Canada he will be accompanied by Robert Belgrave of the United Kingdom High Commissioner's office at Ottawa.

The persons attending the luncheon in Montreal in addition to Dr. Burness and Mr. Belgrave were Arnold Heckle, United Kingdom Senior Trade Commissioner of Montreal, R. E. Heartz, past-president of the Institute and president of the Shawinigan Engineering Company, E. D. Gray-Donald, chairman of the Montreal branch and vice-president and chief engineer of Shawinigan Water and Power Company, and the following representatives of the selection teams:—

Ecole Polytechnique: Henri Gaudefroy, J. C. Bernier, Robert Brais, Pierre Paul Vinet, Jacques Laurence, Leon A. Duchastel, (representing industry).

McGill: R. E. Jamieson, J. J. O'Neill, G. A. Wallace, D. L. Mordell, J. U. MacEwen, Irving R. Tait, (representing industry).

Unfortunately the luncheon date clashed with an important meeting of the Montreal Board of Trade, of which the Institute's Montreal vice-president, R. L. Dunsmore, is president. Under these circumstances past-president R. E. Heartz presided at the luncheon.

After Dr. Heartz had given the Institute's welcome to Dr. Burness, an opportunity was afforded the guest to tell something of the Athlone Fellows in England and the prospect for more Fellows through the various universities across Canada this year. It was nice to hear that the Canadians had done so well in the Old Country and that the candidates for this year were well up to standard.

The meeting was held at the University Club.

Award of Merit

At each Triennial Reunion, the Engineering Alumni Association of the University of Toronto presents two medals to two outstanding graduates in engineering. To be the recipient of such a medal is an honour which is highly prized.

The purpose of the "Award" is to recognize the accomplishments of engineers, graduates in applied science of the University of Toronto who in a quiet way have contributed greatly to engineering knowledge, or who through their patient and skilful application of their engineering training have been successful in developing methods or machinery for the advancement of Canadian industry, or whose accomplishments had contributed to the comfort, convenience or welfare of humanity.

The Engineering Alumni Association has appointed a committee, representing the different branches of engineering, to receive nominations for this "Award". In sending forward a nomination, details of the achievements and merits of the nominee must be given. This would include such information as the year of graduation, the department from which he graduated; any specialized post graduate courses taken; the special field in which he has worked and particulars of his contributions to the science of engineering and public welfare.

Nominations should be sent before July 31, 1957 to J. Dudley Barnes, secretary, Engineering Alumni Medal Committee, c/o Canadian Standards Association, Box 506, Weston, Toronto 15, Ont.

E.I.C. Annual Meeting, 1957

■■ Principal theme of the technical meeting this year is Production and Distribution of Natural Gas and Oil in Canada. On this subject there will be a total of eight papers.

■■ Some other highlights of the technical program are papers on:

Kelowna-Westbank Floating Bridge, W. Pegusch, JR.E.I.C.

Problems of Highway Location in Rogers Pass, J. P. Hague

The Canada-India Reactor, F. J. Bleackley, M.E.I.C.

Future Power Development in B.C., T. Ingledow, M.E.I.C.

Bersimis St. Lawrence Under-Water Cable, O. W. Titus, M.E.I.C.

Engineering The RCAF Maritime Reconnaissance Aircraft, CP-107, W. K. Ebel and E. B. Schaefer

Management Panel.

■■ A program of special interest will be provided for the ladies.

■■ The Alberta annual meeting committee is arranging special projects. A post-convention trip around an oil field may be provided if sufficient interest develops.

■■ In addition to what has been mentioned, the glorious location of Banff itself will have a wide appeal to those who enjoy mountain air and unsurpassed scenic beauty. June is usually a fine month in the Rockies.

■■ Members who plan to travel on the fast C.P.R. train, The Canadian, are urged to make reservations as soon as possible. It is understood that no extra service will be provided on that train for the meeting.

■■ More information will be given in the April issue. Advance notices can be expected by members during April.

Banff, Alberta, June 12 to 14, 1957

Salary Structure for Teachers

The *Journal* continues to publish frequently informational material on education. This article is from the Engineering and Scientific Manpower Newsletter of December 6, 1956. In part it refers to a project on teacher education which is of interest, though it does not apply to universities directly.—Ed.

Once again the Research Division of the National Education Association has given us an invaluable document under the title "Salaries Paid and Salary Practices in Universities, Colleges, and Junior Colleges, 1955-56" (NEA Research Bull., Vol. 34, No. 3, October 1956). The investigation was concerned with conditions in academic year 1955-56, and the report covers 730 institutions of higher learning. Attention was restricted to the full-time instructional personnel teaching nine months of the year. Some of the figures are worth recording. The average salary paid in all colleges and universities surveyed, and for all ranks of teaching personnel, was $5,243. Distribution by rank was as follows:

Professors	$7,076
Associate professors	5,731
Assistant professors	4,921
Instructors	4,087
Median	$5,243

Still more definitive information bearing upon the teaching problem may be anticipated from a research project in progress under the direction of John B. Whitelaw, Chief for Teacher Education in the Office of Education. A pilot study of problems relating to the staffing of the nation's schools and colleges was completed July 30, 1956, and a summary report of results was issued on that date. The pilot study concludes that eight foundation problem factors "must be taken fully into account in any attempts to get more good teachers and to keep them in the profession." The eight are listed as follows:

1. The economic status of teachers;
2. The social status of teachers;
3. Teaching as predominantly tax-supported, public employment;
4. Teaching as predominantly a female occupation;
5. The quality and costs of education that teachers receive;
6. The effect of technology on society and therefore on the function of the school;
7. The current conceptions of the teaching process and what goes on in the school;
8. What society really requires of the school.

A critical inspection of these factors suggests that the study group was more concerned with elementary teaching than it was with teaching in the secondary schools and colleges. In the latter, teaching is not predominantly a female occupation, and the profession as a whole becomes one only by inclusion of the very large numbers of elementary teachers required for our rapidly growing school-age population. If it is proposed to examine the content of the high school curriculum and the quality of the training that teachers receive in subject matter, this intention might profitably receive more emphasis in the summary report. A large and growing segment of the public has serious misgivings about the philosophy of education, which seems to be out of joint with the times and blind to the fact that over 30 per cent of our young people of college age are now entering college, and therefore require sound college preparatory instruction in our secondary schools. This changing pattern is of vast significance in any project that proposes to deal with the staffing of the nation's schools and colleges.

And From New York City

The Advisory Committee on Science Manpower, appointed earlier this year by Hon. Charles H. Silver, President of the New York City Board of Education, recently submitted its report to Dr. William Jansen, Superintendent of Schools. Of unique interest are the Committee's recommendations to provide a suitable climate which would attract science and mathematics teachers and enable them to grow professionally.

The Committee, composed of outstanding persons from the schools, industry and higher education, under the chairmanship of Dr. John R. Dunning, recognized the fact that an adequate salary was one of the most important factors contributing to a suitable environment and it must reflect general economic conditions as well as the status, preparation and professional competence of the teachers. In addition, it recommended a series of specific steps designed to increase the supply of secondary school science and mathematics teachers and to utilize the present staff more effectively. Following are the recommendations considered most crucial and requiring immediate action:

1. Postpone preservice education course requirements for a science and mathematics substitute's license to enable the immediate employment of college graduates. Require each substitute to take a minimum of six semester hours in approved courses each year to qualify for the annual renewal of his substitute's license. Permit the substitute to become eligible to take the examination for a regular teacher upon the completion of 24 semester hours in approved courses.
2. Encourage qualified and interested elementary school teachers to take examinations to teach science and mathematics in the junior and senior high schools.
3. Add an additional period of science or mathematics where necessary to the program of a highly qualified teacher and compensate him on a pro-rata basis.
4. Provide more laboratory assistants for assignment to senior high schools and to junior high schools.
5. Better supervision of science teaching at all levels. More time for supervision should be permitted each chairman to take care of the increased load.
6. All Board of Education in-service training should be carefully planned, subsidized and supervised. Supervisors and competent teachers giving these courses should be compensated. A special fund should be established for this purpose.
7. Provide summer employment for science and mathematics teachers and for interested students through the co-operation of industry (I-E Committee).
8. Provide television reception for all schools and provide model lessons in science as useful in-service training. Wider use of radio and television would bring important scientific lessons to the attention of pupils.
9. Improve and extend the science program in the elementary schools.
10. Improve and extend the science program in the junior high schools.

THIRTY-FIVE YEARS AGO

Comment on the Journal of February, 1922

The *Journal* for March, 1922, might vell be called a "Shawinigan num-ıer" since its two principal papers vere "The Generation of Steam by ˡlectricity", by F. T. Kaelin, .M.E.I.C., chief engineer of the hawinigan Water & Power Co., and The New 41,000 h.p. Unit at hawinigan Falls", by Julian C. mith, M.E.I.C., the company's presi-ent.

Mr. Kaelin's paper appears to have ›een the first description of the lectric boiler which bears his ame. This had some novel features, hough in the main it followed prece-lents set in the design and construc-ion of the 300-odd electric boilers hen in use in Italy, Switzerland, weden and France. Mr. Kaelin was irmly convinced that his boiler would ill a useful place in industry. "One f the cheapest ways of (utilizing lle electric current) is to produce team, which in most cases can be sed in conjunction with other steam enerating apparatus and where a ystem of piping for the purpose of eating or using steam for manufac-uring purposes already exists . . . t was shown by an investigation nade lately that the saving of coal luring the fifty-two Sundays and hree holidays (shut down time of a ›ulp mill) would easily pay for the nstallation of the (electric) steam enerator in less than one year."

Several of Mr. Kaelin's boilers had lready been built when this paper vas written, including one rated at 8,000 kw. and 6,600 v. and produc-ng up to 60,000 lb. of steam at 135 b. gauge pressure per hour. Two 5,000 kw. generators were also ınder construction. A good many of hese boilers were built and in gen-ral they seem to have met the laims made for them.

The new turbine and generator at hawinigan Falls were notable hiefly for their size. Compared to nodern units, 41,000 h.p. does not trike one as very big, but by the tandards of the time it was enorm-ous; 52,000 h.p. was the largest unit hen in use, though the Hydro-Elec-ric Power Commission of Ontario was onsidering larger ones for its Queen-ton-Chippewa development. The original 1903 turbines at Shawinigan Falls were of 6,000 h.p., the biggest that could then be had; the 1910 units used 18,500 h.p. wheels. Both were of the horizontal shaft type, but this new 1922 unit was a vertical one. Between 1910 and 1922 the turbine makers had developed reliable thrust bearings for heavy loads, making vertical turbines practicable.

Perhaps the most eye catching feature of the 1922 Shawinigan development was the giant Johnson-Larner valve in the penstock just back of the turbine, the largest built up to that time. It was about 23 ft. in diameter and 27 ft. long and weighed 150 tons.

Business and Research

Business was not too good in 1922. Prices were high and going up, leading, among other things to wage increase demands and consequent frequent strikes and much labour unrest. It seems to take a crisis such as this to get most engineers to thinking along economic lines. H. A. Goldman, A.M.E.I.C., of Toronto, writes in this *Journal* of "The Rise and Fall of Prices". He concluded that engineers must use their talents to analyze and control economic conditions so far as possible if we were to avoid trouble in future. He proposed that the Toronto Branch, to which his paper was addressed, should follow the time honoured practice — appoint a committee to consider the matter.

The National Research Council of which R. A. Ross, M.E.I.C., was then chairman, persuaded this *Journal* to list a few of its problems. Some are still problems, as their titles show — wheat rust; diet of black foxes (!); uses for helium; national fuel supply; utilization of lignite and of peat; utilization of low grade iron ore; and disposal of saw mill and pulp mill waste and of straw.

Institute Affairs

Secretaries of the eastern branches of the Institute, twelve in all, met in Montreal in January, 1922. As reported in the *Journal*, they discussed uniform bylaws, publicity, programs and finances, but without coming to any positive conclusions, save that they did ask Council to arrange for the preparation of uniform bylaws.

Somebody gathered a mass of personals for this *Journal*, four solid pages of them, a step in the right direction. Although this writer was reasonably active in Institute affairs at that time, he must confess that he can find only six names among all those mentioned that mean anything at all to him. *Sic transit gloria mundi!*

According to this *Journal* the Vancouver Branch was promoting the formation of "a general engineering council composed of delegates from existing organizatio ıs, to function when concerted action in the interests of all engineers is needed." It was also arguing with the city authorities over an annual tax of $25 just imposed on every engineer in private practice in the city. Naturally, engineers objected to this tax, as did doctors, dentists, lawyers, chartered accountants and other professional men subject to it. The Winnipeg Branch was also getting set to object to a proposed provincial income tax and to the tax proposals which would affect engineers.

There were forty applicants for admission to membership and twenty-one for promotion to a higher grade. Fifteen of these sixty-one are still members of the Institute.

R.DEL.F.

WORLD POWER CONFERENCE

The Transactions of the Fifth World Power Conference held in Vienna in June, 1956, will be published shortly. The theme of the Conference was "World energy resources in the light of recent technical and economic developments" and the twenty volumes of the Transactions contain, in either German, French or English, according to the choice of the author, all the 276 papers presented. They may be ordered from the Canadian Committee of the World Power Conference, T. M. Patterson, M.E.I.C., Room 500, 150 Wellington Street, Ottawa 4, Ont. The prepublication price is 3500 Austrian sch. (approximately $135.00) plus carriage. The price after publication is 3700 Austrian sch. plus carriage. In either case a discount of 20% is allowed when the order is placed through the National Committee.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

Decisions of Council

A technique currently used in Ontario by T. C. Keefer, Field Secretary of the Ontario Association, will be carried out in our own province under the responsibility of B. R. Lachapelle, Engineers' Service Officer. This technique is intended to help the Corporation increase its effectiveness in influencing the remuneration of engineers.

Bursary for Sherbrooke

Quebec's newest university, Sherbrooke University, has a school of engineering, providing the first three years of the required course. It now contemplates offering the last two years, in the not too distant future.

Council will do everything it can to assist this young university. It has decided among other things to grant a deserving student of Sherbrooke University a bursary of two hundred dollars, such as is being offered at McGill, Ecole Polytechnique and Laval.

Letter to a Mayor

The following is a letter sent recently by the General Secretary to the Mayor of a Quebec municipality.

Dear Mr. Mayor,

We understand that you are attempting to have a group of consulting engineers enter into competitive bidding for their professional services. You are asking that each of these firms of consultants stipulate in advance what their professional fees would amount to in rendering your municipality engineering services for a preliminary study of a water work and sewage disposal system.

You will readily appreciate that it is not possible for a professional man to account in advance for the time he will have to devote to his client. Hence, it is not possible to establish the exact amount of his fees in advance. These will vary with the amount of work involved and its difficulty which must be taken into consideration when the statement of fees is computed in accordance with the By-Laws governing the practice of our profession.

As for the practice of competitive bidding for professional services which your Council would follow by looking for the cheapest services they can get, it is an entirely unethical and unprofessional method which is not tolerated in any of the professions. It is quite detrimental to the public itself. That is why the Corporation of Professional Engineers of Quebec is forbidding this procedure.

Consequently, we have advised all consulting engineers from whom you have requested bids that the Code of Ethics and the Tariff of Minimum Fees of the Corporation of Professional Engineers of Quebec does not allow them to comply with your request.

May I stress that professional services should be retained on the basis of competence, integrity and accomplishment. These are the significant criteria in the selection of any professional man, be he a physician, a lawyer or an engineer.

Yours very truly,

Pierre Bournival,
General Secretary.

Speech Workshop

John D. Richards, was selected as the student who showed the most progress in the fall session of the speech workshop. On January 14, Mr. Richards and the nineteen other members of the class delivered their graduation speeches and received certificates in the auditorium of Ecole Polytechnique.

On the following Monday, the winter session of the workshop got under way with an enrolment of nineteen professional engineers. V. G. Baker continues to act as instructor.

ONTARIO

Annual Meeting

More than 1000 members of the Association of Professional Engineers of Ontario gathered at the Royal York Hotel, Toronto, on January 26, 1957, to hear and discuss the policies and reports of Association activities during the past year. In his presidential address, retiring president Merritt W. Hotchkin, of Kirkland Lake, Ont., outlined the growth of the profession in Ontario from a membership of 3000 in 1945 to its present enrolment of 15,500. He described the Association as "a power in the affairs of Canada" and added that it was the duty of the professional man to contribute his specialized knowledge for the general welfare whenever the occasion arose.

He also referred to a renewal of the joint professional engineer-architect committee and said he looked forward to co-operation and valuable discussion between the two groups.

Educational Stand

Declaring that "This Association should be prepared to be outspoken on matters of education," Mr. Hotchkin remarked on the establishment of new engineering courses at the University of Western Ontario, Ottawa University, and Assumption College, and singled out "the completely new type of school for Canada which is being studied by Waterloo College". Noting the shortage of secondary school teachers, he added that the situation had not yet become as severe in Canada as in the United States, where no physics courses are taught in 60 per cent of high schools, due to a shortage of teachers.

Report on Gerontology

Among those reports presented at the annual meeting was an announcement to the effect that the first Ontario Conference on Aging will take place in Toronto, from May 31 to June 3, 1957. The conference will bring together authorities and interested representatives from the many fields concerned with the problems of the aged, such as labor, industry, education, the professions, social services and churches.

Council Discusses Technician

The Executive Council of the Association, meeting on January 24, 1957, prior to the annual meeting, has approved a plan to establish standards of qualification for engineering technicians and also set up a system of voluntary registration for them as such.

The engineering technicians would be examined by the Association and classified in four grades which would be determined by their educational qualifications and technical experience.

The Association points out that at present there is no registering body for engineering technicians in the province, and that such a system would be of great value both to industry and to the technician.

The A.P.E.O. emphasized that this move did not mean that engineering technicians would become members of the Association, but pointed out that such technicians by self-improvement, further education and experience, advance through the various stages and finally secure registration as members of the Association.

Submits Report

A report, prepared by a special committee studying the engineering technician problem was tabled at the meeting.

The committee, headed by Dr. George B. Langford, of the University of Toronto, noted in its report that: engineering technicians were invaluable assistants to professional engineers in taking over some of the non-professional duties of an engineer, and allowing the latter to carry out full-time professional work; that there was a need for a rapid increase in the number of such technicians to keep pace with the demand for their services, that many industries now are employing four or more technicians for every professional engineer; and that there was evidence within the engineering technician body of a desire for recognition and the establishment of accepted standards of technical qualifications.

Dr. Langford said there was an urgent need for such a system of registration for technicians. It would, he added, encourage them to progress, and would also serve industry as a method of defining the upgrading of their technical employees, employment requirements and salary structure.

Dr. Lord — Maths Are Basis

The Association of Professional Engineers of Ontario is concerned with "a very real threat to the profession" in the form of a decline in the teaching standards of Ontario's high school mathematics and science teachers.

The Professional Engineers' salary survey, compiled by the Association during 1956, attracted wide interest during the annual meeting. Shown here left to right are: W. E. Rose and P. S. Reavill, both of Sarnia; E. E. MacPhail, Toronto; and J. Klassen, Ottawa.

In referring to mathematics as "the basis for engineering", Dr. G. Ross Lord, head of the department of mechanical engineering of the University of Toronto, told the Association's executive council here today that "one-half of those graduating from the Ontario College of Education who could be teaching mathematics in the high schools, have only their Grade XIII maths".

It was pointed out at the meeting that a recent survey of Ontario's high schools showed that of 630 mathematics and science teachers, 400 had not taken maths and science courses beyond Grade XIII.

"They're not taking the courses at university because they think they'll fail them," said Dr. Lord, "with the result that the pupils they are teaching are not getting sufficient grounding in these subjects." But he conceded that the situation was worse in the United States where high school students have an option on taking maths and sciences. Less than 25 per cent of the students are taking these subjects.

"How does the U.S. expect to keep pace in the engineering race with Russia when there aren't enough students taking maths to continue on into university?" Dr. Lord asked.

He said the engineering profession in Ontario had to take stock of this alarming situation and do something to improve it.

"It's the educational background that makes the profession," he added, pointing out that there were signs that students were losing respect for their teachers as authorities in maths and sciences.

Brigadier C. D. Quilliam, long-time soldier, and for a number of years since World War II, chief Middle East correspondent of the London Times, presented a first-hand picture of Middle East problems in his address to the annual luncheon meeting of the Ontario Association. Flanking Brig. Quilliam are, left to right: John H. Fox, Toronto, Association president; C. T. Carson, Walkerville, first vice-president, and L. F. Grant, Toronto, Field Secretary of the Institute.

Would End Discrimination

The Executive Council of the Association has called upon the Department of National Defence to end its discrimination of professional engineers who are serving in the armed services, particularly in the Army.

The Council asked that professional engineers in the Army be accorded the same financial recognition currently received by medical and dental officers.

Medical and dental officers receive $60.00 per month professional pay up to the rank of colonel. There is no provision for professional pay to Army engineers.

The A.P.E.O. also feels that there should be more scope in engineering projects for the Army professional engineers.

Engineers in the News

S. T. Bieniada has left the Department of Highways of Ontario and has moved from Toronto to Ottawa, where he is employed by the Department of National Defence (Army) as a structural engineer in the design division of the structures section.

George C. Chernish has moved from Niagara Falls, Ont. to Santa Ana, Calif., where he holds the post of chief engineer with B. J. Electronics, Borg-Warner Corporation.

Peter A. Livingston has left the employ of Abitibi Power and Paper Co. Ltd., in Toronto, and is with the K.V.P. Company Ltd., at Espanola, Ont.

S. G. Petursson, is sales equipment supervisor with Dewey and Almy Chemical Company of Canada Ltd, 1244 Dufferin Street, Toronto. Mr. Petursson who graduated in mechanical engineering from the University of Manitoba in 1951, was earlier on the engineering staff of the John Inglis Co. Ltd., of Toronto.

W. H. Bates, of the Canadian Westinghouse Co. Ltd., has been transferred from Ottawa to the head office of the company in Hamilton, where he is with the electronics division, Hamilton Plant No. 2, Longwood Road.

S. M. Peterkin & Associates, Ltd., consulting engineers, have moved to 21 Sultan Street, Toronto from the previous address: 116 Bloor Street West, in the same city.

W. E. Emmerson has joined the air conditioning division of Canadian Ice Machine Co. Ltd., 95 Villiers St. Toronto. Mr. Emmerson was formerly division engineer in the new work division of the Underwriters' Laboratories of Canada, Toronto.

A. N. Campbell, of the Du Pont Company of Canada Ltd., has been transferred from Montreal, Que., to Kingston, Ont., where he has assumed the responsibilities as assistant works manager of the company's nylon plant in that city.

F. R. Thompson, has moved from Asbestos, Que., to Trail, B.C. where he is with the Consolidated Mining and Smelting Company of Canada Ltd., Mr. Thompson was formerly employed by Canadian Johns Manville Coompany, Ltd. at Asbestos.

C. S. LeClair has recently joined Peacock Bros. Ltd., in Montreal, as chief engineer of the company's new project and development department. Mr. Le Clair came to Canada from England in 1951 and until taking over his new post practiced in Toronto a a consulting engineer.

J. C. R. Punchard, manager of the Belleville Plant of the Northern Electric Co. Ltd., has been appointed as Canadian member of the Awards Committee of the Inistute of Radio Engineers.

Marlin D. Smith, has left Sarnia, Ont. where he was with the Canadian Oil Refineries Ltd., and is now on the Engineering Staff of Lago Oil & Transport Co. Ltd., Aruba, Netherlands Antilles.

Robert G. Martinek has been appointed chief engineer of the Eclipse Fuel Engineering Co. of Canada Ltd., manufacturers of industrial process heating equipment at Toronto.

Mr. Martinek graduated in engineering from the University of Vienna in 1939 and has been in Canada since 1943. He joined the staff of Eclipse in 1954.

H. G. McHaffie, general manager of the British Thomson-Houston Co. (Canada) Ltd., has announced the purchase by the company of new premises at 766 King Street West, Toronto, where the firm's head office is located. An office has also been opened in Vancouver, B.C., at 326 West Pender Street.

William J. R. Thomson, of the Ontario Department of Highways has moved from Owen Sound to Ottawa where he is assistant engineer with the department.

R. C. Fraser, has left the employ of the Corporation of the City of Hamilton to become a design engineer with C. C. Parker & Associates, Hamilton, Ont.

MANITOBA

Election of Officers

At the thirty-seventh annual meeting of the Association of Professional Engineers of Manitoba, held recently, the following members were elected to office: N. S. Bubbis, President; L. A. Bateman, vice-president, and C. S. Landon, secretary-treasurer.

Retiring President Interviewed

Retiring president of the Association, Professor Jack Hoogstraten, in an interview declared that more attention must be paid the developing high school student displaying a mechanical aptitude and good marks in mathematics and science.

Dr. Hoogstraten advocated that the need for engineers be stressed at an earlier period in the student's school life, at least at the high school level. Although Russia is now turning out more engineers than North America, Canada would be wise in producing sufficient engineers to coincide with her rapidly expanding growth and economy.

Professor Tweedie Guest Speaker

Professor A. S. R. Tweedie, in addressing the annual meeting, dealt with the problem of future enrolment of engineering students in universities and colleges across the country.

With the infants of the early forties now at university entrance level, it was felt that if the percentage increase remains constant, by 1970 enrolment will have climbed 85 per cent above the present record. As no Canadian university is equipped to handle this flood, a building program must be undertaken in the next two or three years. With no ready reserves in cash or staff, universities are unable to expand their staff or facilities.

The Canada Council

Professor Tweedie felt that the Canada Council was a modest step in the right direction. All Canadian provinces are seeking to augment their support of the universities, and are predicting a marked increase in support of higher education.

The university instructor is beginning to realize that he is now in a buyer's market, and that he is in a position where he is much in demand, and at a higher salary. The University of Toronto requires an additional staff of 400 in the next decade. Dr. Tweedie stressed that just where they are to be found is difficult to ascertain unless it is by dangling the everpresent cheque book.

He added that while building of a non-residential nature is twenty-three times greater than in the past decade and construction for centres of higher education increased only four times, Canada cannot be accused of squandering new found wealth on higher education.

BRITISH COLUMBIA

Engineers in the News

R. C. B. Henderson, formerly with the Aluminum Company of Canada at Kitimat, B.C., is now engaged on a large hydro-electric project in East Pakistan.

Now an employee of the International Engineering Company Inc., of San Francisco, Mr. Henderson is senior office engineer on the firm's Karnafuli hydro-electric project in the Chittagong Hill Tracts in East Pakistan. Consisting of an 1800 foot impervious rolled fill earth dam, a large spillway capable of discharging nearly 600,000 cubic feet of water per second and a powerhouse with an estimated initial capacity of 107,000 h.p., it is roughly equivalent to the output of the B.C. Electric's Buntzen development.

Mr. Henderson expects to be engaged on the project for two years.

F. R. R. Jones, until recently genera[l] superintendent, MacIntyre Development Tahawus, New York, has resigned fro[m] the National Lead Company to accep[t] the position of mine manager, Stanroc[k] Uranium Mines Ltd., Toronto.

P. G. Wolstenholme has sent word tha[t] he is now assistant construction manage[r] with Sprostons (Jamaica) Ltd., and i[s] engaged in work on the extensio[n] to the aluminum ore plant of Alumin[a] (Jamaica) Ltd.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

C. A. Waterous, M.E.I.C., retired vice-president and general manager of the firm of Waterous Limited, a Brantford, Ont., company, died on December 7, 1956, in that city.

A native of Brantford, he was born on April 6, 1877. He attended Montreal high schools and graduated from McGill University with a degree in mechanical engineering in 1898. He was at that time the youngest man ever to be admitted to a B.Sc. degree at that college. Returning to his home that year he joined the family firm of Waterous Limited. From 1925 to 1935, a period of notable expansion for the company, particularly in the manufacturing of pulp and paper mill machinery, he was vice-president and general manager.

Mr. Waterous retired from public office in 1949.

A member of the Board of Water Commissioners of Brantford he served that body almost continually from 1917 to 1944.

Mr. Waterous was a member of the American Society of Mechanical Engineers and was awarded the "Gold Card" of that organization. He was a charter member of the Grand Valley Group of professional engineers. He was also a member of the Association of Professional Engineers of Ontario.

He joined the Institute as a Student member in 1898, became an Associate member in 1903, and transferred to Member in 1909. He attained Life membership in 1947.

Frederick William Paulin, M.E.I.C., president and owner of the Canadian Engineering and Contracting Company Limited, Hamilton, Ont., died in hospital at Hamilton on January 18, 1957.

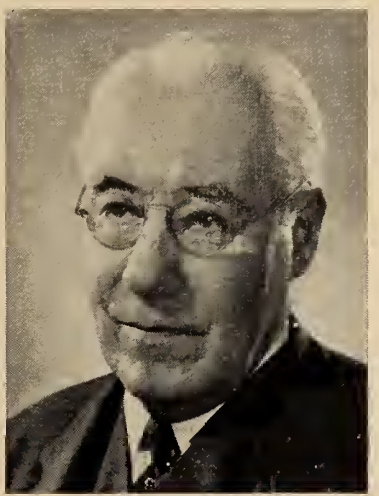
Mr. Paulin was born at Arthur, Ont. on September 16, 1882. He followed his engineerinfg studies at Toronto University, graduating in 1907 from the School of Practical Science.

Some of his early engineering experience gained as an Ontario Land Surveyor he also took part in laying the Great West and T. and N.O. Railway, now a part of the Canadian National Railway System. He was employed as City engineer at Niagara Falls in the early days and was engaged in the installation of the Whirlpool Rapids Cable Car. A founder of the Canadian Engineering and Contracting Company Limited in 1914, he moved to Hamilton at that time.

During the years of the depression he transferred his activities to Buffalo, N.Y., and formed the F. W. Paulin Contracting Company Limited. Later he was appointed president of the District Improvement Corporation and of the Great Lakes Concrete Pipe Company Inc. of Buffalo. He had the signal honour of being the first Canadian elected president of the American Concrete Pipe Association. This body is responsible for the specifications under which concrete pipe is manufactured.

While resident of the United States Mr. Paulin was elected to the boards of several companies, including General Plastic Inc.

He was for a number of years a director of the Concrete Pipe Company.



F. W. Paulin, M.E.I.C.

Largely responsible for organizing the Consolidated Specialties Limited, now known as John Dickinson Limited, he was also a founder of Design-Craft Limited, at Toronto. He was chairman of the board of that company which for eight successive years built the Canadian International Trade Fair.

In recent years Mr. Paulin served the City of Hamilton as chairman of the Adjustment Committee.

He joined the Institute as a Student member in 1907, transferred to Associate Member in 1913, and became a Member in 1922. He attained Life membership in 1948.

John Russell Montague, M.E.I.C., director of engineering for eight years for the Hydro-Electric Power Commission of Ontario died at Toronto on January 9, 1957. Recently retired from the above position he had remained with the commission as a consultant.

Born at Niagara Falls, Ont., on March 25, 1891, he studied engineering at the University of Toronto and obtained a B.A.Sc. degree in 1914.

Responsible in some measure for the design of almost every hydro power plant in the province, including the Sir Adam Beck No. 2 development at Niagara Falls Mr. Montague's association with the Hydro Electric Commission dates back to 1918, a period of thirty-eight years.

He received his early engineering experience with the Laurentian Power Company, Beaupre, Que., the International Waterways Commission, in the Niagara area, and the old Ontario Power Company at Niagara Falls. He also served two years as superintendent of construction for the Raymond Concrete Pile Company of Montreal and New York. He joined the Ontario Hydro as a design engineer in 1918 and worked first at Niagara, before moving to Toronto.

Besides planning and building complete power plants, Mr. Montague was responsible for investigation of numerous power and storage sites, and river diversions.

In his capacity as director of engineering Mr. Montague last year travelled to England to recruit engineers for the Hydro Electric Power Commission.

He was to have become president of W. S. Atkins and Associates, consulting engineering firm, on his retirement.

A member of the Association of Professional Engineers of Ontario he was their 1955 choice as president. Also a member of the American Institute of Electrical Engineers he was an executive officer of the Electric Club of Toronto.

Mr. Montague joined the Institute in 1918 as an Associate Member and was transferred to Membership in 1940. He attained Life membership in 1954.

Leonard H. Robinson, M.E.I.C., retired division engineer with the Canadian National Railways, died October 9, 1956, at Ganonoque, Que.

Born at Brockville, September 4, 1878, he attended the School of Practical Science, Toronto, graduating in civil engineering in 1904.

His engineering career, which was spent in railroading began in 1904 when he went into exploration and survey work for the National Transcontinental Railway in Northern Quebec, Ontario and Manitoba. Transitman for locating engineers Frank Moberly and W. H. D. Armstrong in District D, he was later in 1907 transferred to a post as resident engineer on Residency 12, east of Superior Junction, and also served at Sioux Lookout. Promoted to locating engineer in 1913, and to division engineer maintenance of way six years later, he held the post until 1926, residing at Bridgewater, N.S. and Campbellton, N.B. From 1933 to his retirement in 1940 he was division engineer with the C.N.R. at Halifax.

A man of diverse interests it is interesting to record that he rowed for the Brockville Rowing Club in a "four" that won the Canadian Championship; that he played in a symphony orchestra and was an excellent boxer, fighting with "Gentleman" Jim Corbett. Accredited as one of the finest canoe men in the North Country he shot the Drowning Rapids on the Quinzes River carrying two bodies in the canoe, rather than carry them over the portage. He was the first to master the rapids.

He is known to have discovered

Noranda mines, long before it was staked. He did not possess a license at that time.

Mr. Robinson also enjoyed writing poetry in later years. Several of these were published.

Mr. Robinson joined the Institute in 1909, transferred to member in 1927 and attained Life Membership in 1940. Active in the affairs of the Institute he was a Councillor representing the Halifax Branch in 1932 and 1933.

Kenneth George Ross, M.E.I.C., retired partner in the firm of Lang and Ross, Sault Ste. Marie, Ont., died at his home in that city on December 26, 1955.

Mr. Ross was born in Toronto on August 2, 1884, and followed his studies at Upper Canada College and at the School of Practical Science, University of Toronto. He graduated in engineering in 1906.

One of the pioneer Land Surveyors of Ontario he worked in Manitoba and Northern Ontario following graduation, and carried on the work of land surveying for a number of years. He moved to Sault Ste. Marie in 1910.

Overseas with the Canadian Army during World War 1 with the 227th battalion, he was returned to Canada in 1918 with the rank of major and resumed his work as land surveyor. About that time he also went into private practice with the late John L. Lang, M.E.I.C., and became vice-president of the firm, named Ross and Lang. They were general engineering contractors, specializing in hydro-electric developments and transmission lines. Instrumental in the building of power projects at Algoma, he also directed the building of the first dams and powerhouses to harness the Montreal and Michipicoten Rivers.

Mr. Ross became a director of the Great Lakes Power Corporation and the International Transit Company. He retired from active engineering practice in 1953. He was for many years a member of the Sault Ste. Marie town planning board.

He was also an authority on Ojibway folklore, history and habits.

He was also a member of the Newcomen Society.

Mr. Ross joined the Institute in 1919 in the status of Associate Member. He transferred to Member in 1932, and attained Life membership in 1955.

James Norman Stanley, M.E.I.C., retired Ontario engineer died at his home in Toronto on January 7, 1957.

Mr. Stanley was born at Ruselltown, Que., on February 15, 1879. He was educated at Queen's University, and obtained a Master of Arts degree in 1901, followed by B.Sc. in 1908.

Working with various companies intermittently in the years between his two degrees, he was associated with the St. Maurice Valley Railway in 1905 and the following year signed on with the C.P.R. In 1910 employed by another company he worked on a project for the Ontario Hydro Electric Commission from Ingersoll to St. Thomas. In 1911 he joined the Shawinigan Water and Power Company Limited as a divisional engineer on transmission lines.

During his career Mr. Stanley was also resident engineer and superintendent of construction at the Hydro-Electric Power Commission of Ontario's Nipigon power development. He was also superintendent of construction at Decew Falls power development.

Mr. Stanley joined the Institute as a Student member in 1908, transferred to Associate Member in 1912 and became a Member in 1940.

Samuel W. Andrews, M.E.I.C., president and director of H. G. Acres and Company Limited, Niagara Falls, Ont., died on December 31, 1956 at Niagara Falls.

Born and educated in the United States, he was a native of South Dakota. He was born at the town of Lead on September 24, 1890. Mr. Andrews graduated with a degree in mechanical engineering at Cornell University in 1912 and from that year until 1917 worked on railway electrification in the western United States. In 1917 he joined the Hydro-Electric Power Commission of Ontario. He was assistant plant engineer and then plant engineer from 1918 to 1924 during the construction of Queenston-Chippawa Development, In 1924 he joined the staff of H. G. Acres and Company as a mechanical engineer. Appointed chief engineer of the firm in 1934, he rose to the position of president in 1945.

Among his many contributions to the development of engineering works in Canada he is to be remembered for his part in the hydro-electric developments at Grand Falls, N.B.; the Outardes Development of the Ontario Paper Company; the Shipshaw Development of the Aluminum Company of Canada; the Campbell River development of the B.C. Power Commission; the Pine Falls development in Manitoba and the Beauharnois for Hydro-Quebec.

Mr. Andrews joined the Institute in 1946.

Frederick Ernest Estlin, M.E.I.C., of the Canadian General Electric Company Limited, Regina, Sask. died on December 11, 1956, in that city.

Born on the prairies, at Melita, Man., on January 7, 1903, Mr. Estlin was a 1925 graduate of the University of Manitoba in electrical engineering. He entered the Canadian General Electric Company Limited test department at Peterborough, Ont., on obtaining his degree and remained there for a year. In 1926 he returned to Winnipeg, and late that year was named industrial control specialist with C.G.E. A sales engineer for the company at Regina, Sask., in 1938, he was in 1939 appointed manager and sales engineer and held that position until the time of his death.

Ardent in his support of the Saskatchewan Branch of the Institute in all its activities, Mr. Estlin served as a member of the executive committee in 1943 and 1944; as vice-chairman in 1945 and chairman the following term.

In 1949-50 he was elected councillor of the Institute.

Mr. Estlin joined the Institute in 1926 as a Student Member, transferred to Associate Member in 1938 and became a Member in 1940.

Ralph Allison Hendry, M.E.I.C., former resident engineer with the Department of Highways, for the Province of Nova Scotia, died in Windsor, N.S., on October 12, 1956.

Born at Halifax, N.S., on January 29, 1893, he studied engineering with a private tutor and with his father, William Almon Hendry, chief engineer of the Department of Highways of Nova Scotia, in the early twenties. Grandson of W. A. Hendry, chief Crown Surveyor of Nova Scotia, he was a great grandchild of Titus Smith, who made the first survey of the province in 1801.

Mr. Hendry served overseas with the First Canadian Division in World War I, returned to Canada in 1919 and was first employed with the Department of Highways in the early twenties. He also spent some time as a Provincial Land Surveyor and worked with the Mersey Paper Company Limited in the timber estimating and surveying field for a short time at the end of the decade. From 1935 to 1941 he was associated with the Department of Highways as a resident engineer and played an important part in the reconstruction of the Nova Scotia highway system.

During World War II Mr. Hendry was associated with the Department of National Defence, Naval Services, as a civilian engineer on airport construction.

He joined the Institute in 1940.

Howard Arthur Roach, JR.E.I.C., field engineer with the St. Lawrence Seaway Authority was the victim of a drowning accident at Montreal, on January 15, 1957.

Mr. Roach was born at River Hebert, N.S., on December 17, 1922. He attended Queen's University and received a B.Sc. degree in civil engineering in 1950, following service overseas with the R.C.A.F. in World War II. He was employed with the Ontario Department of Highways, Toronto and with the Ford Motor Company of Canada Limited at Windsor, Ont., before joining the Department of Transport, Special Project Branch, in 1953, to work on the St. Lawrence Seaway project. When he met his untimely death, Mr. Roach was senior assistant engineer at Ville Jacques Cartier lock construction area near St. Lambert, Que.

He joined the Institute as a Student Member in 1950 and transferred to Junior in 1952.

Personals

News of the Personal Activities of Members of the Institute.

Prof. C. V. Christie, M.E.I.C., for many years head of the department of electrical engineering at McGill University was recently presented with an honorary membership in the Canadian Electrical Association. He is the third person to have been so honoured.

After a career with the University dating to 1906, the year of his graduation from that college, Prof. Christie retired as head of the department in 1947 but continued as professor in electrical engineering until 1952, when he became professor emeritus.

The following year he went into private practice as a consulting engineer at Westmount, Que.

He has always played an active part in the work of engineering societies and has held office in the Institute, both with the Montreal Branch and as a councillor. He was also vice-president of the American Institute of Electrical Engineers during the thirties.

W. Elwood MacDonald, M.E.I.C., Commissioner of Water Works for the City of Ottawa was recently honoured in receiving the "Citizen of the Year" award presented by the Ottawa Press Club.

In 1952 Mr. MacDonald was winner of the Fuller Award of the American Water Works Association (Canadian section) for his distinguished service in the water supply field.

Mr. MacDonald, who received the appointment he now holds with the City of Ottawa, in 1950, first entered the service of the Corporation of Ottawa in 1912 and has devoted his entire career to the water works field.

W. E. MacDonald, M.E.I.C.

Frederic Alport, M.E.I.C., consulting engineer of Orillia, Ont., won a total of 2950 votes as newly elected candidate in the Orillia, Ont., Water, Light and Power Commission election contest, recently held in that Ontario municipality.

A native of Orillia, Mr. Alport has been carrying on private practice there since 1947, after more than thirty years in engineering work across Canada. He specializes in harbour works, tunnels, foundations, water supply and sewage disposal.

Mr. Alport served on the Council of the Institute in 1954-55, representing the Huronia Branch. Largely responsible for the founding of the Branch in 1953 he was its first chairman.

In 1946 Mr. Alport was awarded the O.B.E.

In fairly recent times he has been associated with a number of very large projects. The Department of National Defence employed Mr. Alport as a consulting engineer to the Director of Naval Technical Service. He was on loan from the Public Works Department, which later stationed him in Ottawa. There he acted as representative of the Department on the Lake of the Woods Control Board, and has handled administrative work of the Northwest Territories, including the Yellowknife projects. He was a member of the special committee of three appointed by the Minister of Transport to study and report on the St. Lawrence deep water channel from Montreal to the sea.

A.V.M. A. L. James, M.E.I.C.

F. Alport, M.E.I.C.

Air Vice-Marshal A. L. James, C.B.E., C.D., M.E.I.C., has been appointed president of Bristol Aero Engines, Limited, Montreal North, and Bristol Aero Engines (Western) Limited, Vancouver. He has also been named a director of the latter company. Air Vice Marshal James joined Bristol Aero Engines Limited in 1954, becoming vice-president and general manager of the company at the time.

Long known in aviation circles, he joined the R.C.A.F. in 1924. He has held many senior appointments in the Air Force including that of Air Officer Commanding Air Defence Command. In that post he was responsible from 1952 to 1954 for the Canadian side of the planning and implementation of an arrangement by which the air defence systems of Canada and the United States operate as a team in the event of an emergency.

As Air Member for the Technical Services at R.C.A.F. headquarters between 1946 and 1951, he became well acquainted with the British and Canadian aircraft industries.

William L. Pugh, M.E.I.C., chief engineer of the Aluminum Company of Canada Limited, for the past ten years has recently relinquished this post due to ill health. He will, however, retain his connection with the company as a consulting engineer.

While employed as chief engineer Mr. Pugh was in charge of all engineering and construction work including the large aluminum plant development at Kitimat, B.C.

Mr. Pugh joined the Aluminum Company of Canada in 1937, at Arvida, Que., as a structural engineer and carried out the design for the greater part of the expansion of the Arvida works which started at that time. He became chief engineer of the Company in 1948.

He was awarded The Keefer Medal of the Institute in 1950.

F. E. Regan, M.E.I.C., was recently named president and general manager of Bepco Canada Limited.

Mr. Regan has been with Bepco since the inception of the company in 1933. He was originally Ontario manager and latterly vice-president and assistant general manager when he moved to the head office in Montreal last year.

W. B. Pennock, M.E.I.C., of Ottawa has announced that the consulting engineering practice of the Pennock Engineering Company in that city will now be conducted by Pennock Canadian-British Limited.

The new company was formed in 1956 with W. B. Pennock as president. One of the directors of this firm is T. C. Main, M.E.I.C., senior partner of Canadian British Engineering Consultants of Toronto, Halifax and Vancouver. He was well known as first general manager of 'Ducks Unlimited'.

Mr. Pennock is chairman of the Ottawa Branch of the Institute.

A. W. F. McQueen, M.E.I.C., former vice-president of the H. G. Acres Company Limited, Niagara Falls, Ont., has been appointed president of the firm.

A graduate of the University of Toronto, class of 1923, he worked as an assistant engineer with the Ontario Hydro from 1923 to 1927. He joined the Acres Company at that time and in 1938 was appointed hydraulics engineer. He became vice-president and general manager in 1953.

Mr. McQueen is a councillor representing civil engineering in the Association of Professional Engineers of Ontario and a director of the Fluor Corporation of Canada, Canadian Overseas Projects Limited, and the Niagara Falls Club.

H. E. Barnett, M.E.I.C., who formerly held the appointment of vice-president and chief engineer of H. G. Acres Company Limited has been named executive vice-president and general manager of the company.

A maritimer and graduate of the University of New Brunswick, Mr. Barnett joined the Acres organization in 1925 and has been employed with the firm since that time except for a period in the thirties when he worked with the Dominion Construction Corporation, at Toronto.

Dr. W. H. Gauvin, M.E.I.C., associate professor of chemical engineering at McGill University, and consultant to the Pulp and Paper Research Institute of Canada, has been named head of the latter organization's newly-formed chemical engineering division. Dr. Gauvin will continue to lecture and to supervise those McGill University Ph.D. candidates in chemical engineering who are at work on fundamentals of interest to the pulp and paper industry, and who are thereby identified with the Pulp and Paper Institute. This arrangement, like those of long standing in the fields of wood chemistry and the physical chemistry of fibres, will therefore represent not only additional strength to the Institute in a basic research discipline, but also additional industrial support to the University for graduate work.

Dr. Gauvin, a 1941 graduate in chemical engineering from McGill University was awarded a Ph.D. degree in physical chemistry from that university in 1944. Two years later he received the appoint-

Dr. W. H. Gauvin, M.E.I.C.

ment of associate professor of chemical engineering which he now holds.

Since 1950 he has been consultant to the Pulp and Paper Institute, and has worked chiefly as supervisor of Project RC-6, the "Recovery of Sulphur and Other Values from Sulphite Waste Liquor". and its outcome, the atomized suspension technique.

He has published some twenty papers on electrochemistry, spray drying and the technology of small particles.

Dr. Gauvin was in 1955 elected to the Council of the Engineering Institute, representing the Montreal Branch. He also serves on the Admissions Committee and is chairman of the Papers Committee of the Institute.

M. E. Stewart, M.E.I.C., of the Northwestern Utilities, Edmonton, has been named general manager of the company. He has served in the capacity of assistant general manager for the past nine months.

Mr. Stewart joined the staff of Northwestern Utilities in 1949, on completion of his studies in the field of Business Administration. He obtained a master of commerce degree in Business Administration from the University of Toronto in 1949.

He received his initial degree in civil engineering from the University of Alberta, class of 1947.

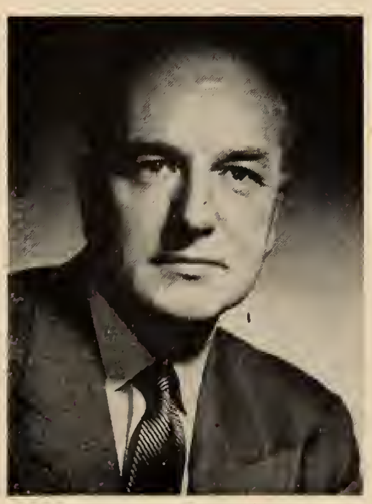
Terence J. Farrell, M.E.I.C., of Canadian Vickers Limited, has been named manager of engineering sales, Central region, with headquarters at Toronto.

Mr. Farrell, who is a graduate in engineering from Manchester College, class of 1946, began his career with Vickers-Armstrong Limited. In 1956 he was a sales engineer with Canadian Vickers Limited, at head office, Montreal.

E. T. Buchanan, M.E.I.C., formerly chief engineer of the Consolidated Paper Corporation Limited has been appointed acting division manager of the Laurentide division, at Grand'Mere, Que.

Mr. Buchanan has been assocated with the pulp and paper industry since 1935 and received his appointment as chief engineer in 1953.

Mr. Buchanan served as a Councillor



F. E. Regan, M.E.I.C.

W. B. Pennock, M.E.I.C.

Solving corrosion and impact resistance problems

The triple-vessel methane column, shown above, was designed for an unusual combination of pressure and temperature conditions. It operates at a maximum working pressure of 300 psi with temperatures from plus 300°F to minus 238°F.

This vessel, of extra low carbon type 304 stainless steel, was especially designed and fabricated to resist corrosion at high temperatures and to provide impact resistance of welds and base material at low temperatures. Vessels for this type of service demand careful design, exacting control of fabricating processes and unexcelled welding skill.

The enlarged photograph, right, shows the finished appearance of the ground and polished weld contours which resulted in complete freedom from notches.

• PERSONALS

of the Institute, representing the St. Maurice Valley Branch in 1955. He is also a past chairman of that Branch.

Viggo Jepsen, M.E.I.C., assistant to the chief engineer at the Consolidated Paper Corporation Limited, Grand'Mere, Que., has been appointed assistant chief engineer.

Mr. Jepsen joined the organization in 1936 at Grand'Mere., a number of years after coming to this country from his native Denmark where he studied engineering.

He is a past Councillor of the Institute representing the St. Maurice Valley Branch, 1947. He also served as chairman of the Branch in 1942.

Gudmund Eriksen, M.E.I.C., has accepted a position with the Toronto consulting engineering firm of R. V. Anderson Associates. He will carry out the work of project engineer.

Mr. Eriksen has been resident in Port Arthur, Ont., for a number of years and held various appointments with the City of Port Arthur.

Mr. Eriksen is a graduate of the Kristiania Technical Institute in Oslo, Norway.

J. R. Eason, M.E.I.C., was appointed secretary-treasurer of the Saguenay Branch for the 1956-57 term.

Following graduation from the University of Saskatchewan in 1949 Mr. Eason spent two years with the Water Resources division in British Columbia, working on the Columbia River drainage basin study. Later he accepted a position in Eastern Canada with the Consolidated Paper Corporation Limited at Grand 'Mere, Que.

Since 1952 Mr. Eason has been associated with the Aluminum Company of Canada Ltd., at their Arvida Works, Que.

He also holds office as secretary-treasurer of the Saguenay Chapter of the Corporation of Professional Engineers of Quebec.

H. J. Butterhill, M.E.I.C., of the Deloro Smelting and Refining Company Limited has been appointed manager of the smelting and refining division and is responsible for operations at the Deloro works.

Previously assistant manager of cobalt operations with the firm at Delora, Ont., he has also filled such positions as chief metallurgist and chief inspector of the Aluminum Company of Canada, Arvida works.

He is a graduate of the University of Toronto, class of 1940.

W. G. Mayberry, M.E.I.C., of Babcock-Wilcox and Goldie-McCulloch Limited, Galt, Ont., until recently a development engineer with the company, has been named manager of the Pump and Turbine division of the firm.

Mr. Mayberry is a 1947 graduate of the University of Toronto in mechanical engineering.

He previously gained experience with Canadian Allis-Chalmers (1951) Limited, Montreal.

D. Laschuk, M.E.I.C., a graduate of the University of Lviv in the Ukraine, class of 1943, has accepted an appointment with the C. D. Howe Company Limited at Port Arthur, Ont.

Mr. Laschuk has been for a number of years employed with the Giant Yellowknife Gold Mines Limited, and was in 1953 a layout engineer.

John H. Redding, M.E.I.C., a 1944 graduate of the University of Cambridge in mechanical sciences is at work with H. G. Acres and Company Limited, at Gujrat West Pakistan. He is employed as a project manager at the Shadiwal Canal hydro-electric project.

A. R. Moffat, M.E.I.C., who was for the past two years at work with H. G. Acres and Company Limited, in British Columbia, has been transferred to the province of Quebec. He has been employed as resident engineer with the Acres organization on the Chute-des-Passes Power Development of the Aluminum Company of Canada on the Peribonka River, Que. While at work in British Columbia

• PERSONALS

Mr. Moffat was resident engineer on the Ladore Generating Station and Upper Campbell Lake Development of the B.C. Power Commission at Campbell River, B.C.

Mr. Moffat has been with the company since 1947 and has been engaged in many important power projects.

H. B. Tafelmacher, M.E.I.C., formerly at Montreal with the Aluminum Company of Canada Limited, has been transferred to Uruguay, where he has assumed a position as an assistant general manager for the company at Monte Video.

B. W. Anderson, M.E.I.C.

Mr. Tafelmacher is a graduate of the Federal Institute of Technology at Zurich, class of 1946 in mechanical engineering.

Blair W. Anderson, M.E.I.C., has been named general manager of the British Columbia firm of Power Machinery Limited, manufacturers of PM Chain Saws.

Mr. Anderson, a graduate of McGill University, class of 1944, has recently returned from the east where he had extensive production and management experience as assistant production manager for Canada, of the St. Regis Paper Company (Canada) Limited.

L. F. Mason-Tulby, M.E.I.C., secretary-treasurer of the Sault St. Marie Branch of the Institute for the 1956-57 term is a graduate of a South African school of engineering.

Mr. Mason-Tulby graduated in 1933 from the Witwatersrand Technical College in Johannesburg.

In Canada since 1952, he has been associated with the Armco Drainage and Metal Company at Sackville, N.B., and more recently with the Algoma Steel Corporation, at Sault Ste. Marie, Ont., where he is presently employed.

Director of the South African Branch of the Armco International Corporation from 1947 to 1952, Mr. Mason-Tulby prior to that time was in private practice. He also served in the Engineer Corps in the Middle East and North Africa during World War II.

In the opening years of his career Mr. Mason-Tulby held various positions in South African mining companies, with firms handling the importation, supply and installation of mining machinery; with a large gold mining group in design and layout work; as a design engineer with a cement company, and an assistant consulting engineer with the Bailey mining group.

G. Parrott, M.E.I.C., has accepted a post with the Sudan Mercantile Company (E) Limited at Khartoum, Sudan, Africa. His work is that of senior electrical engineer.

Mr. Parrott was in 1956 associated with the Canadian General Electric Company transformer works at Guelph, Ont., as a transformer and reactor designer.

He is a graduate in electrical engineering and a member of the Institution of Electrical Engineers.

W. A. Arsenault, M.E.I.C., is resident engineer for Quebec-Hydro on the Bersimis River hydro-development project, near Labrieville, Que., the completed site of hydro development, No. 1.

Mr. Arsenault was previously associated with Fraser-Brace Engineering Company, Montreal and was also resident engineer with the Rankin Newfoundland Company, at St. Lawrence, Nfld.

He is a 1937 graduate of the Nova Scotia Technical School.

• PERSONALS

J. C. Neufeld, M.E.I.C., city engineer at Lethbridge, Alta., since 1951, has resigned from that post. He will enter private practice as a consulting engineer in conjunction with an architect.

The firm, called Lurie and Neufeld, will specialize in design of buildings, sewerage, waterworks, and town planning.

In the years since his graduation from the university of Manitoba Mr. Neufeld's career has been largely devoted to work with the City of Winnipeg in structural design work and municipal engineering; with the Department of National Defence, Air Training Command, on the construction of sewer and water systems, during World War II; and with the Central Mortgage and Housing Corporation, Vancouver, in connection with veteran housing, as well as other National Defence projects in British Columbia.

R. T. Nolan, M.E.I.C., has relinquished his affiliations with the Nova Scotia Light and Power Company in order to devote himself to private practice.

Under the firm name, Nolan Bros. and Co., he is engaged in the work of consulting civil engineer and Provincial Land Surveyor.

Mr. Nolan is a 1947 graduate of the Nova Scotia Technical College.

J. J. Donahue, M.E.I.C., the 1957 choice of the St. John Branch of the Institute as chairman, is a native of St. John, a veteran of World War II and a graduate of the University of New Brunswick, class of 1944 with a B.Sc. in electrical engineering.

Mr. Donahue joined the New Brunswick Electric Power Commission following discharge from the R.C.N.V.R. and was employed as a line construction engineer. Later he accepted a position with the Power Commission of the City of St. John as a distribution engineer. In 1952 the Commission appointed him chief engineer.

J. J. Donahue, M.E.I.C.

Mr. Donahue has served as an Institute Branch officer, and in 1956 he was general chairman of the Atlantic Provinces Professional Meeting at St. Andrews, N.B.

D. B. Sutherland, M.E.I.C., formerly superintendent of new buildings with the Protestant School Board of Greater Montreal has been living in Vancouver for some time.

Mr. Sutherland is employed as the director of construction and maintenance with the Vancouver Board of School Trustees.

Geoffrey P. Webb, M.E.I.C., is once again resident in England after a period of employment in Caracas, Venezuela. Associated with Kennedy and Donkin, a London, Eng., firm of consulting engineers, he was transferred to the South American republic as their representative in the Caroni hydro-electric scheme.

Mr. Webb has also worked in Canada. In 1952, after his graduation from the University of London, he enrolled in the General Electric course at Peterborough, Ont., and then went on to spend a year with the company in the power transformer and switchgear sales division at Toronto. Later he was employed with the Aluminum Company of Canada as an electrical engineer on the Saguenay hydro-electric system at Shipshaw, Que.

W. Tannenzapf, M.E.I.C., has terminated his employment with the Brantford, Ont., firm of Crompton Parkinson Electric Limited.

He has accepted a position with Canadian Westinghouse Company Limited, at Hamilton, Ont. as a design engineer in the switchgear engineering-power product-division.

Mr. Tannenzapf, a graduate of the University of Prague, class of 1936, has had previous professional affiliations in this country, among them the post of switchgear contract engineer with Bepco Canada Limited at Montreal.

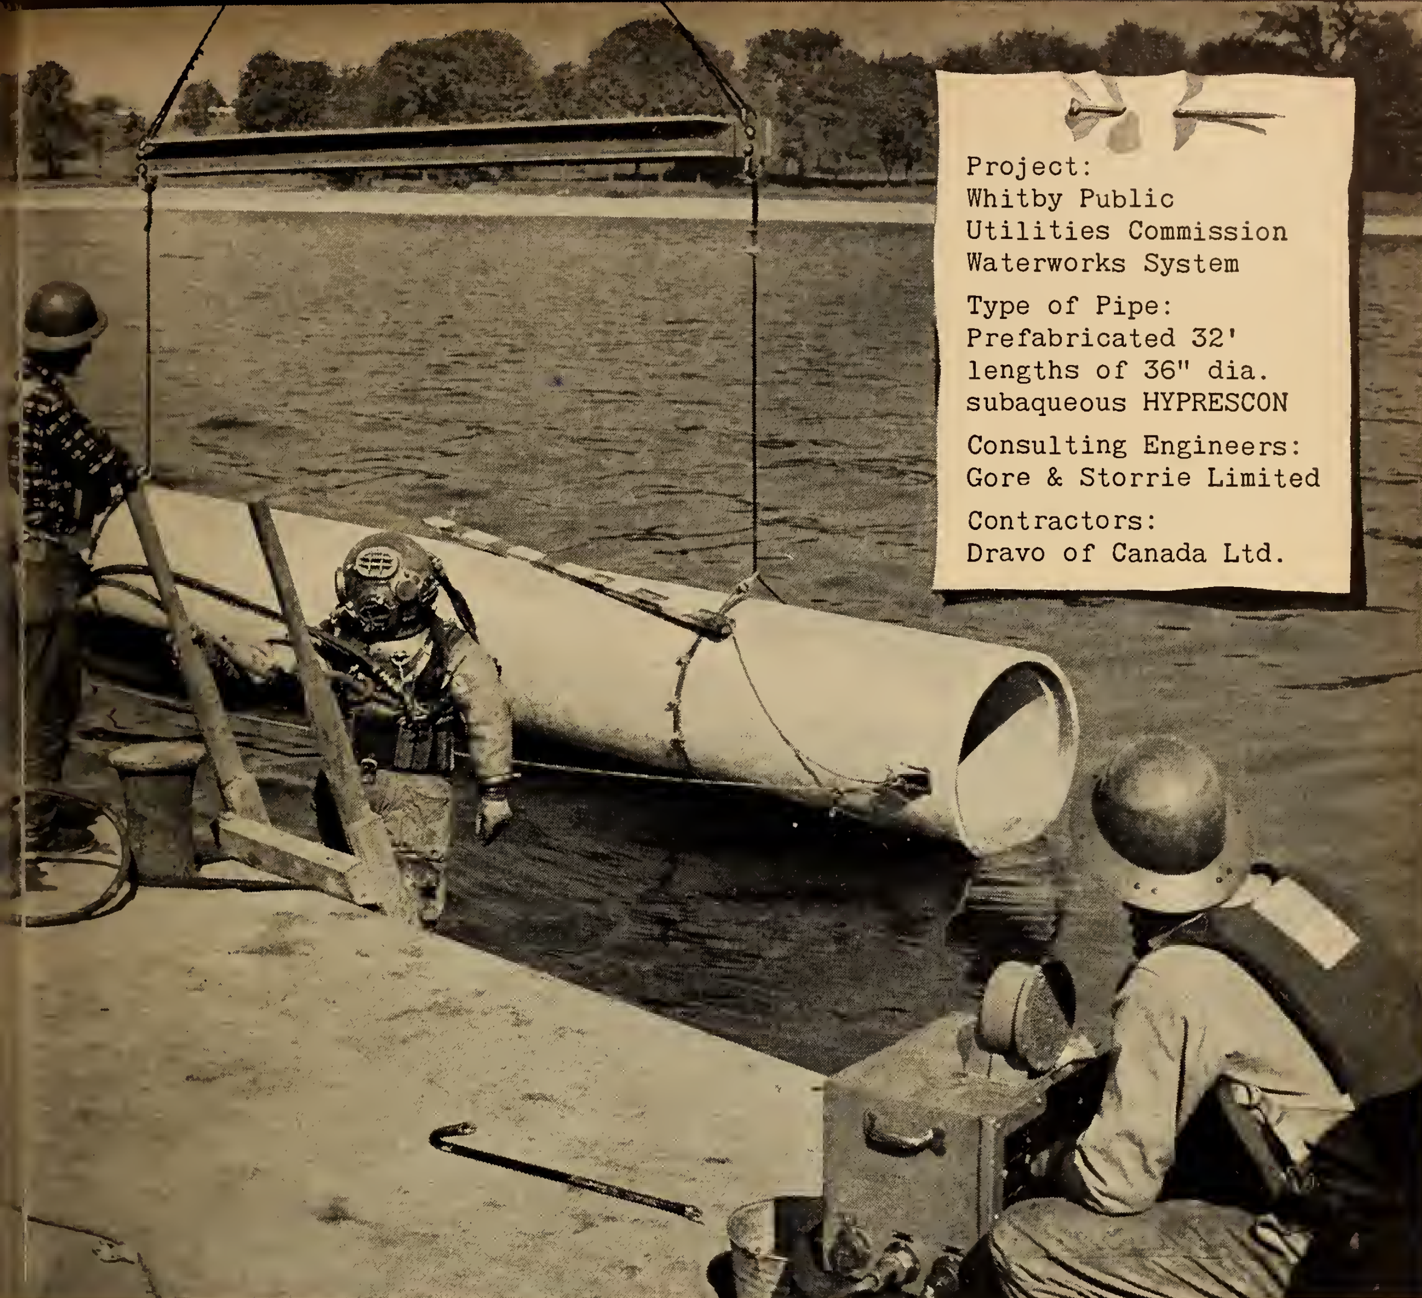
E. E. Robertson, M.E.I.C., has accepted an appointment as manager of planning and development with the Winnipeg Supply and Fuel Company Limited, Winnipeg, Man.

With the Foundation Company of Canada Limited, Montreal, for a number of years. His last position with the organization was as manager of bases.

Mr. Robertson is a University of Toronto graduate.

L. W. Swain, M.E.I.C., formerly with the firm of Babcock-Wilcox, and Goldie-McCulloch, at Galt, Ont., has accepted a position with Empire Brass, Limited at London, Ont.

Mr. Swain who came to this country from England has been engaged in design engineering at several Ontario centres, with W. C. Wood Company Limited,



IYPRESCON PROVES SIMPLE TO INSTALL
—even 17 feet under Lake Ontario

Insllation time is precious; especially on a job like hi one at Whitby where intake pipe is laid 2500 feet uinto Lake Ontario.

Prssure Pipe Company assembled HYPRESCON nt 32′ lengths to reduce the number of joints—and pi s were ready for placement on arrival at the site.

Th crane manoeuvres these 8 ton sections of pipe into po ion and the diver below lines them up.

Tw draw bolts are tightened up by the diver and the joint is complete, for HYPRESCON rubber-gasket joints are self centring and self-sealing. The subaqueous joint provides adequate flexibility necessary for bedding in the lake bottom.

Engineers make a point of specifying HYPRESCON not only for its fine field record, but for its permanently high flow factor—its rugged construction of steel and reinforced concrete—its long life and its absolute freedom from corrosion and tuberculation.

and the Cockshutt Plow Company since his arrival in 1948.

Before that time he had worked as a design engineer for a number of years and from 1946 to 1948 was a development engineer responsible for the design and development of all new products with a British firm.

R. J. Di Cicco, JR.E.I.C.

C. F. Buckingham, M.E.I.C., operating superintendent of the Maritime Electric Company Limited, Charlottetown, P.E.I., was recently appointed secretary-treasurer of the P.E.I. Branch of the Institute.

Mr. Buckingham also holds a similar office in the recently launched Association of Professional Engineers of Prince Edward Island.

A graduate of the University of New Brunswick, class of 1950 in electrical engineering, Mr. Buckingham joined his present employer at that time.

H. M. Anderson, M.E.I.C., who was previously employed with the Defence Construction (1951) Limited on the Gagetown Project has accepted a Toronto appointment with the firm of Perini Limited.

Mr. Anderson is a 1950 graduate in civil engineering from the Nova Scotia Technical College.

R. J. Di Cicco, JR.E.I.C., has been appointed chief mechanical engineer for the four mines and mills of the Asbestos Corporation Limited, at Thetford Mines, Que.

Mr. Di Cicco joined the Asbestos Corporation Limited early in 1956 as a maintenance superintendent of the King Mine and held that position until his recent appointment.

He was previously employed with Consolidated Paper Corporation Limited at Grand'Mere, Que., as Woodlands mechanical engineer. He joined the firm early in 1951 on graduation from McGill University in mechanical engineering.

George R. Durnin, JR.E.I.C., has moved from Winnipeg to Toronto in order to accept an appointment with the firm of Lescon Limited, Toronto.

With the firm of W. L. Wardrop and Associates in Winnipeg, since 1955 Mr. Durnin served as municipal engineer.

Prior to that appointment he was City engineer at Brandon, Man., for two and half years.

He is a 1948 graduate in civil engineering from the University of Manitoba.

B. C. Cameron, JR.E.I.C., of the firm of Babcock - Wilcox and Goldie-McCulloch Limited has flown to New Zealand to take up the position of assistant resident engineer for the company at the Mercer power station, near Auckland, N.Z.

He has recently been associated with the firm in England, at the Castle Donington, power station near Derby.

• PERSONALS

Mr. Cameron is a 1952 graduate of the University of Toronto in mechanical engineering.

Donald Shields, JR.E.I.C., a 1955 graduate of the University of British Columbia and winner of the Athlone Fellowship has completed his studies in Great Britain and has returned to Canada.

Mr. Shields studied at the Imperial College, London and received a post-graduate degree, (D.I.C.) in soil mechanics.

He has accepted employment with the Vancouver, B.C., firm of Ripley and Associates Limited consulting engineers in soil mechanics, foundations, asphalt mix design, wharf and harbour design.

J. Barriere, JR.E.I.C.

Gordon T. Marshall, JR.E.I.C., of the Railway and Power Engineering Corporation Limited has been named district manager of the corporation's operation in British Columbia with headquarters in Vancouver.

Mr. Marshall has served the Corporation for several years and was in 1955 employed as a sales engineer for Railway and Power Engineering Limited at Quebec city. Earlier he held an appointment at the Montreal office.

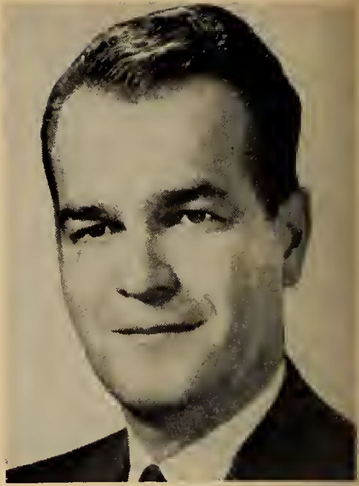
He is a 1950 graduate of McGill University, with a B.Eng. degree in mechanical engineering.

E. H. Birnie, JR.E.I.C., has accepted a position with Bristol Aircraft (Western) Limited, at Winnipeg.

He was formerly employed as a pilot with the Dorval Air Transport, Dorval, Que.

Mr. Birnie is a 1955 graduate of the University of Saskatchewan in mechanical engineering.

Jacques Barriere, JR.E.I.C, who has been appointed deputy director of the Traffic Department, City of Montreal, took post-graduate studies in traffic engineering at the Yale Bureau of Highway Traffic on an International Road Federation fellowship awarded in 1951 by the Canadian Good Roads Association.



G. T. Marshall, JR.E.I.C.

After completing a year's work at Yale University, Mr. Barriere, who is an Ecole Polytechnique graduate, class of 1950 in civil engineering, conducted a traffic study of 19 Canadian cities for the Canadian Good Roads Association.

Mr. Barriere is also secretary of C.G.R.A.'s Advisory Committee on Traffic, as well as being active in the joint project of the Canadian Good Roads As

EMCO

—need pipe, valves, fittings in a hurry?

specify EMCO

ne step ahead when time means money

Have you ever been haunted by the sight of a maintenance crew sitting around aiting for parts? It won't happen when you order replacements or spare parts from MCO. Emco has a network of fully stocked warehouses strategically located cross Canada. They're within arm's reach when you phone in your rush orders—and ll ready to make immediate delivery. There are savings in hard, cold cash as well s savings in time. EMCO is the all-Canadian company with shipping points in anada. When you want the best—and you want it in a hurry—EMCO is e name to remember.

sociation and the Canadian Section of the Institute of Traffic Engineers, to produce a manual of uniform traffic control devices for Canada, being chairman of the French language committee and assistant editor of the executive committee.

John C. Vrana, JR.E.I.C., has accepted employment at Montreal with the Canadian Pratt and Whitney Aircraft Company, as an analytical engineer.

Mr. Vrana, whose previous professional association was with the National Research Council, division of mechanical engineering at Ottawa, is a 1953 graduate in engineering physics. He received his degree at the University of Toronto.

F. J. Cameron, JR.E.I.C., a territorial design engineer with the Harbour and Rivers Engineering Branch of the Public Works of Canada, London, Ont., has resigned from that position in order to accept a position in the consulting engineering field.

Mr. Cameron has joined the firm of Manley and Plant, consulting and contracting engineers, in Jamaica, B.W.I.

Mr. Cameron is a 1952 graduate in civil engineering from McGill University.

Gordon H. Good, JR.E.I.C., has moved from Kitchener to Hamilton, Ont., where he is engaged in mechanical engineering with the National Steel Car Corporation in that city.

Mr. Good has been recently employed with the B. F. Sturtevant Company of Canada Limited, as a sales engineer. He is a 1955 graduate of the Nova Scotia Technical College with a B.Eng. in mechanical engineering.

R. A. Gyles, JR.E.I.C., has transferred his services from the Renold Chains Canada Limited, Winnipeg, Man., to the Regina, Sask., firm of Bearing and Transmission Regina Limited.

A 1948 graduate of the University of Saskatchewan in mechanical engineering, Mr. Gyles has spent a number of years with the former company. In 1951 a sales engineer with Renold Coventry Limited at Toronto, he was later a branch manager of the firm in 1953.

Claude Marion, JR.E.I.C., formerly of the Shawinigan Water and Power Company, Montreal, has accepted employment with Canadian Stebbins Engineering.

Located for a few months at Watertown, N.Y., Mr. Marion expects to be transferred to Montreal later.

He is a B.Eng. graduate in electrical engineering from McGill, 1954.

J. D. Koppernoes, S.E.I.C., a 1955 graduate of the Nova Scotia Technical College, in mechanical engineering was awarded a master of science degree at the Massachusetts Institute of Technology in September, 1956.

Once again resident in Canada, he is employed with the Aluminum Company of Canada as maintenance engineer in the aluminum fluoride plant, at Arvida.

Canada's foremost Steel Foundry

produces

bigger and better castings faster and more economically

To our customers, this means:

Complete facilities — from design office and laboratory to final inspection — to produce steel and alloy castings weighing from a few ounces to 150,000 lbs.

It means 600,000 sq. ft. of plant in 61 acres of grounds properly laid out to produce up to 36,000 tons of castings per year. It means a completely integrated and highly skilled team of 1,500 employees — engineers, technicians, machinists, foundry men, clerks, storemen.

In short, it means that Canadian Steel Foundries leads the field in production, quality, quantity and potential, in the supply of steel and alloy castings from our original designs or to customers' specifications.

Proper casting design can save you money and time. Call our Sales Engineers in the initial stage of product development.

Secretary-Treasurer

Visit to Electric Plant

The January meeting of the Belleville Branch took the form of a visit to the Northern Electric Company in this city. The actual tour was preceded by talks given by two staff members.

Gordon Thompson delivered a talk on symbolic logic indicating how this form of algebra could be employed in studying switching arrangements and relaying in telephone or electronic circuits. His talk was well interspersed with humour.

The second speaker, W. J. Flynn gave a most interesting preview of a paper on modernization of a paint finishing area. As this paper has been or will be published in the Journal, no further comments are added herewith. However, this talk was unique in as much as an actual inspection of the paint finishing area could be and was made as part of the guided tour through the N.E.C. plant which followed.

Before proceeding with the tour, Mr. Punchard, plant manager, quoted some pertinent statistics and indicated how the local plant compared in size with others operated by the Northern Electric Company. Mr. Punchard and all those members on his staff who facilitated this visit are to be commended most highly for providing such an interesting and well organized tour. (Paper is on page 275.)

CALGARY

R. G. PRICE, M.E.I.C.,
Branch News Editor

Address on Refinery

On December 6, 1956, R. G. Walford, general superintendent of Sherritt Gordon Mines Limited, chemical plant, at Fort Saskatchewan, addressed an evening meeting of the Calgary Branch on the subject of the Sherritt Gordon nickel refinery.

The talk described in some detail the work of the refinery which is currently producing 20,000,000 pounds of nickel per year, small amounts of copper and cobalt and 85,000 tons per year of ammonium sulphate fertilizer. The refinery proper, as well as the research and development division, also situated at Fort Saskatchewan, gives employment to more than 600 people and has an annual payroll of approximately $2,500,-000.

Also briefly discussed was the history of Sherritt Gordon, the development of the unique pressure leaching-reduction process, and the economic and technical factors underlying the decision to locate its refinery at Fort Saskatchewan.

The main body of the address dealt with the refinery layout, a description of the various unit operations and major items of equipment, and an outline of the refinery organization.

Hear Highway Official

Wednesday, January 16, 1957, was the date of the combined meeting of the Calgary Branch and the Alberta Services Institute at the Garrison officers mess of the Calgary armories. The group were addressed by Brigadier Meuser, who spoke on "The Northwest Highway System." Brig. Meuser is in command of the System, maintained by the Canadian Army.

The Northwest Highway System is made up of the Alaska Highway plus certain adjacent and connecting roads. Brigadier Meuser flew down to Calgary from his headquarters at Camp Takhini in Whitehorse, Yukon Territory. Illustrating his talk with colored slides he outlined the problems envolved in maintaining the Alaska highway and keeping it open twelve months of the year.

Chalk River Problems Outlined

The second monthly meeting of the Calgary Branch, for 1957, was held on February 4, in the East Room of the Palliser Hotel. R. M. Smith of Atomic Energy of Canada Limited, addressed the meeting on engineering problems in the operation of the Chalk River reactors.

Introducing the subject, Mr. Smith outlined the nature of work being carried out at Chalk River as well as the reactor program. He discussed the principles of nuclear fission as to atomic structure, fission of uranium 235, and the uses of other reactor fuels. He described nuclear reactors from the point of view of purpose, types and components. In regard to the operation of reactors he deal with the subject of control of power operating procedures, instrumentation radioisotope production and experimental assemblies. Mr. Smith mentioned the difficulties in the operations of reactors and the distortion of fuel, contamination of heavy water and damage of experimental assemblies involved.

As to the future of nuclear reactor Mr. Smith was concerned as to the development and construction of reactor for the production of electrical powe and enumerated other uses to which reactors may be put.

In summarizing, Mr. Smith stated tha Canada is now embarked on a majo research and development program fo the construction of atomic reactors tha can be used for the production of elec tric power. Two research reactors ar now operating at Chalk River, two mor are nearing completion and a pilot powe plant is being constructed at the Ontari Hydro Electric site near Chalk Rive The operation of nuclear reactors pre sents many problems to the engineer such as distortion of fuel element, ver high operating temperatures and safe guarding of component parts.

Luncheon Club

The Noon Luncheon Club of th E.I.C. continues to hold regular meet ings every Monday at 12:15 p.m. in th Al San Club in Calgary. Out of tow members are especially welcome to a tend and already this year we have ha visitors from such distant points as Hal fax, Montreal, Toronto and Vancouve

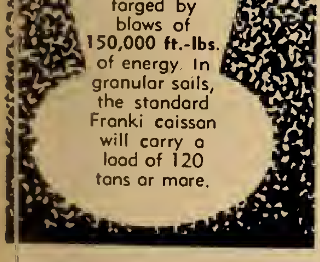
Highlights of European Trip

George M. Dick, Quebec, vice-presi dent of the E.I.C., was guest speak at the first monthly meeting of th Branch in 1957. The group met at th Club Social on Friday, January 18.

Taking the form of a "Ladies Night the meeting was under the chairmansh of Jacques Lemieux, Branch presider James C. Davidson, chairman of th program committee, introduced th speaker.

Sorel Arena, Sorel, P.Q. Consulting Engineers: Structural — Brouillet and Carmel, Montreal, P.Q.; Soil Mechanics — Foundation Engineering Co. of Canada, Montreal, P.Q. Contractor: Lucien Lachapelle, Sorel, P.Q.

Franki caissons permit erection of Sorel Arena



The Sorel arena was originally designed with foundations down to incompressible soils. However, the subsoil was found to consist of compact dark grey fine silty alluvial sand with clayey silt varves to depths greater than 80 feet. Consequently, the original foundation plans could not be considered because of cost.

The problem was solved by means of Franki pressure injected footings, concreted at a depth of 30 feet and the job was able to progress. 194 Franki caissons were used in all, 50% of them being inclined 15° with the vertical. The largest group of caissons used was 5 (4 inclined and 1 vertical).

Although a test of 90 tons produced a settlement of only 0.3", the piling was distributed to carry a working load of only 60 tons per pile. This permitted a maximum limitation of the horizontal movements of the arch abutments, since these movements were the determining factors for the whole structure.

LITERATURE on the various Franki methods of foundation and regular mailings of "Franki Facts" about job highlights, will be sent upon request. Write: Franki of Canada Ltd., 187 Graham Blvd., Montreal 16, P.Q.

• BRANCH NEWS

Mr. Dick's address, on "Highlights of a Trip to Europe" was illustrated by a number of colored slides covering a wide range of European cities and landscapes. One of the interesting items in the address was a comparison of life and habits of the people of Paris and London and several other European cities such as Frankfurt, Copenhagen, Stockholm and Helsinki. The City of London, with its relatively quiet environment, contrasted sharply with the bustle, excitement and color of the Parisian scene. The beauty of the Swiss Alps and the little chalets in the foothills were well illustrated.

Journeys to Lapland, north of Sweden, and far beyond the Arctic Circle to visit the famous iron ore mines at Kiruna, were an interesting feature of the story, as were descriptions of life in the pulp and paper industry of Finland.

Accompanied by his wife, Mr. Dick also visited his native Scotland.

Summarizing the main aspects of the trip he commented on the opportunity which such a trip affords in noting other ways of life and in appreciating more than ever the benefits of life in Canada.

FREDERICTON

G. R. W. BLISS, JR.E.I.C.,
Chairman, Public Relations Committee

O. I. LOGUE, M.E.I.C.,
Secretary-Treasurer

Joint Meeting at Officers Mess

On Monday January 14, a joint meeting of the Fredericton Branch and the Military Engineers Association was held in the officers mess at Fredericton Area Headquarters. R. D. Field, chief engineer in charge of the Passamaquoddy survey, was guest speaker.

Brigadier J. R. B. Jones, brigadier in charge of Fredericton Area opened the meeting by welcoming the members of both branches to the officers mess. He then called on J. L. Feeney, chief engineer of the New Brunswick Electric Power Commission to introduce Mr. Field.

Mr. Feeney said that he had been associated with Mr. Field on various occasions in the past and that he always enjoyed working with him. He added that Mr. Field was a member of U.S. Army Corps of Engineers and that he has worked on some of the largest earth and rock fill dams in the U.S. He also stated that Mr. Field's many years of engineering experience made him an ideal man for his present job as chief engineer in charge of the survey for the International Passamaquoddy Tidal Power Project.

Outlines Production Schemes

Mr. Field began his talk by outlining the two schemes of producing tidal hydro electric power, explaining in detail the "one-pool" scheme and the "two-pool" scheme. In the "one-pool" scheme, while water is being stored during periods of high tide, the power plant must be shut down and no power can be generated. This would mean that the power plant would be idle about five hours each day. In the "two-pool" scheme, which is the scheme under investigation, one pool is kept at a relatively high level and the other at a lower level and power is developed by releasing water from the high level pool through turbines to the lower level pool. Thus continuous generation is possible.

Investigations Under I.J.C.

He then stated that the investigations are under the jurisdiction of the International Joint Commission and that the Commission has appointed an International Passamaquoddy Engineering Board comprised of two engineer members from Canada and two from the United States. This Engineering Board has been instructed to:

(a) Determine the most desirable general project design from the viewpoint of public interest;
(b) Develop plans for dependable costs and considerations of economic feasibility;
(c) make estimate of cost;
(d) determine if power production is economically feasible;
(e) determine effects, beneficial or otherwise, on local and national economics and national defence.

Mr. Field went on to explain his subject in more detail, referring to several slides of the area, and the different schemes that have been discussed. Following his talk he answered several questions. Ira Beattie offered the thanks of the members for the interesting and informative presentation.

Following a short break a business meeting was held with chairman, Ira Beattie in the chair. Plans for the remainder of the year were discussed. After the meeting members enjoyed a buffet luncheon.

HAMILTON

W. A. H. FILER, JR.E.I.C.,
Branch News Editor and Secretary-Treasurer

Annual Meeting Held

The annual meeting of the Hamilton Branch was held at the Hamilton Golf and Country Club in Ancaster on January 17, 1957. The evening began with refreshments, and dinner at 7:00 p.m. J. J. Kelly, Branch Chairman conducted the business meeting at which the slate of officers proposed by the nominating committee was adopted. They were: Chairman — D. B. Annan; vice-chairman, R. C. Mitchell; secretary-treasurer, W. A. H. Filer; executive committee; H. E. Archibald, E. R. Bushfield, H. E.

Seely, R. H. Stevenson; ex-officio, J. J. Kelly, A. F. Barnard; councillor, L. C. Sentence; and nominating committee member to E.I.C., N. A. Eager.

The Branch was privileged to have the President of the E.I.C. attend this meeting. Mr. V. A. McKillop who brought greetings from headquarters later presented certificates to the participants in the Students and Juniors Papers Competition of last March. They were J. H. Westaway, W. A. Piecsonka, and W. A. H. Filer.

G. L. Wilcox, president, Canadian Westinghouse Co. Ltd., Hamilton, Ontario, guest speaker of the evening was introduced by N. A. Eager, who outlined the varied career and achievements of Mr. Wilcox. He has received the Order of Merit from the Westinghouse Electric Corporation, the highest award given by this company for outstanding achievement in his service to the company.

The subject of Mr. Wilcox address was "Who Caused The Engineer Shortage, and What Can We Do About It". The address will appear in the April issue of the *Journal.*

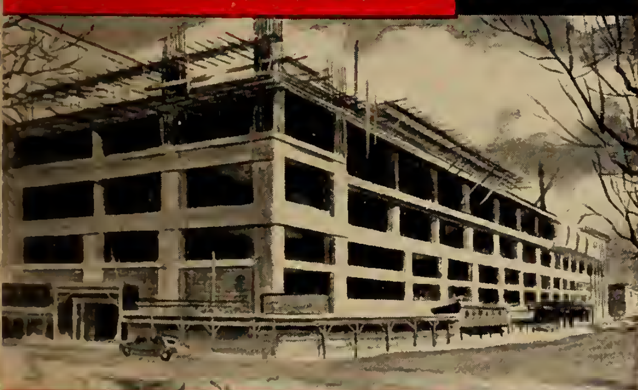
PROBLEM?

Dusty Roads?

Ice Control?



Concrete Curing?

BRUNNER MOND

Calcium Chloride

is the answer!

IMPROVE GRAVEL ROAD MAINTENANCE, at no extra cost. Use Brunner Mond Calcium Chloride with binder soil to cut down hours of work for road gangs, save road metal and provide a smooth, hard, dustless surface that stands up longer with minimum maintenance.

GET BETTER ICE CONTROL. Abrasives treated with Brunner Mond Calcium Chloride bore right in. They cannot blow away, reducing labour and material costs and providing quicker, surer stops.

SPEED UP CONCRETE CURING. Brunner Mond Calcium Chloride produces a denser, tougher, more waterproof concrete, increases workability and permits a lower water-cement ratio. Brunner Mond Calcium Chloride speeds the set, cuts down protection time and minimizes freezing.

It pays to use Brunner Mond Calcium Chloride. Our engineers will be glad to talk to you about it.

troduced the guest speaker of the evening, "Lap" Laprairie of the Explosives Department of Canadian Industries Limited.

Traced Development

Mr. Laprairie, with 39 years' experience with Canadian Industries Limited, traced the development of explosives and their applications. Of particular interest to the members were his illustrations of the uses of explosives in the construction of the Welland Canal and the Ontario Hydro Canal. A recent development, the blasting, was a feature of the construction of the Sir Adam Beck Generating Station No. 2. Mr. Laprairie also pointed out the advances his company had made in mine safety through research and tests.

SAULT STE. MARIE

L. F. MASON-TULBY, M.E.I.C.,
Secretary-Treasurer

E. A. Gilmore Guest Speaker

The Sault Ste. Marie Branch was pleased to welcome E. A. Gilmore, general superintendent of the Mannesmann Tube Company in this city, as guest speaker at the monthly meeting held January 30, 1957.

Mr. Gilmore was introduced by F. H. McKay, who explained that the speaker had spent his entire career in the highly specialized field of steel seamless tube making, including twenty years spent with the Pittsburgh Steel Corporation. This led to his later appointment as engineer in charge of hot mills at National Tube Company, and then to superintendent of the pipe and tube mills successively at Kirkland Steel Corporation and Colorado Fuel and Iron Company. Mr. McKay said that the speaker had been employed at Sault Ste. Marie for the past year, and added that the Engineering Institute was fortunate in having an address by one so well qualified in the tube making field.

Before proceeding with his talk on manufacturing techniques Mr. Gilmore explained some of the underlying reasons for the decision of the Mannesmann Company to establish a tube making operation in Sault Ste. Marie.

The meeting which concluded at about 10.30 p.m. was brought to an end by Gordon L. Brown who thanked the speaker and commented on the fine attendance and the interesting nature of the address.

Mr. Brown also accepted Mr. Gilmore's kind invitation extended to the Branch to enjoy a conducted tour of the plant at such time as it is in full operation.

NIPISSING AND UPPER OTTAWA

G. R. KARTZMARK, JR.E.I.C.,
Secretary-Treasurer

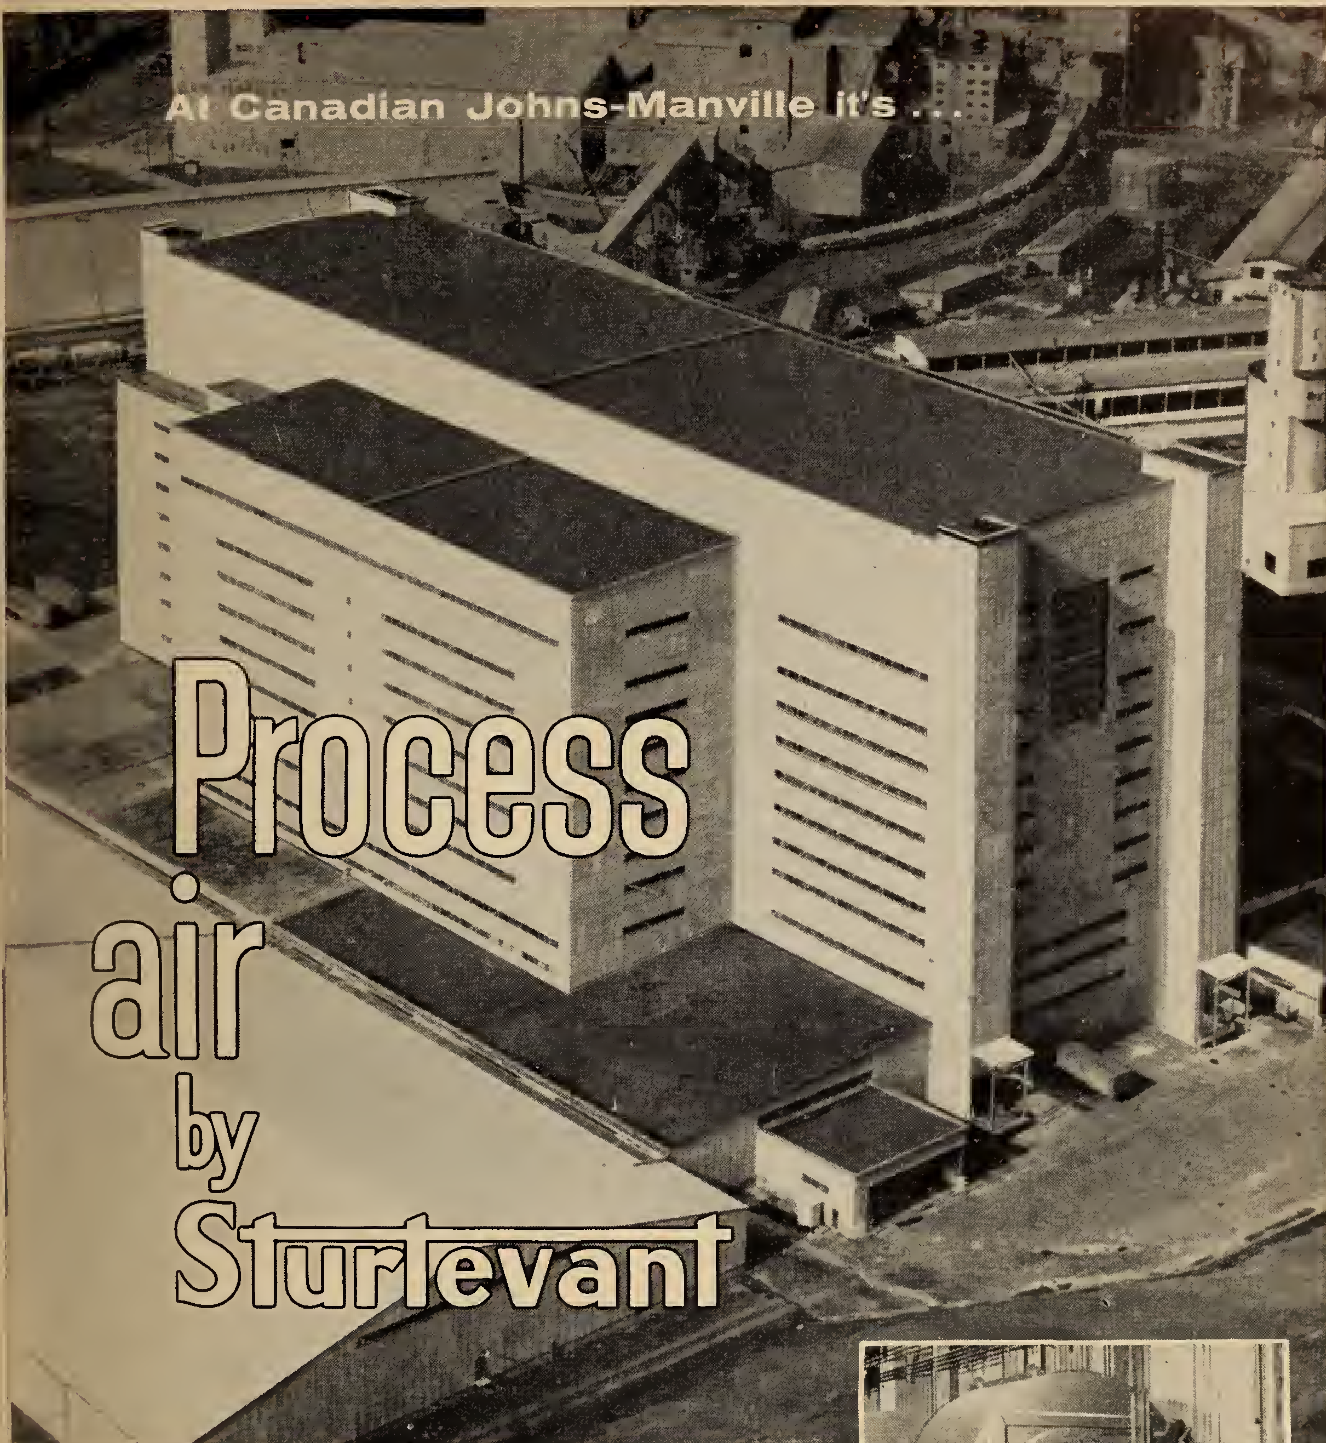
December Meeting

On December 12, 1957, the Branch played host to T. C. Macnabb, retired superintendent of the C.P.R. and father of Branch chairman, T. C. Macnabb. Mr. Macnabb Sr. spent his working years in helping build the C.P.R. in the great West. He described the many difficulties encountered in the progress of the railway and how they were overcome with available facilities.

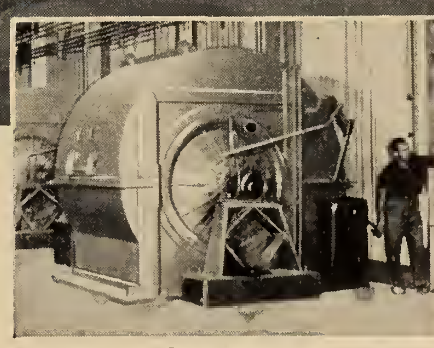
"Members Night"

The January meeting was held in North Bay, Ont., and constituted what is called "Members Night." One meeting a year is devoted to presentation of papers prepared by Branch members.

This year Mr. Snook of the Ontario



The new Jeffrey Mill of Canadian Johns-Manville Co. Ltd. is the largest producer of asbestos in the world! It processes 14,000 tons of ore daily. And for each ton of ore, 10 tons of air are needed to maintain production flow. To provide this tremendous volume of air, Johns-Manville relies on Sturtevant Airfoil Fans.



Sturtevant
AIRFOIL CENTRIFUGAL FANS

19 huge Sturtevant Airfoil Fans, each powered by a 350 HP Westinghouse Motor, supply air at the rate of 2,500,000 cfm for the Jeffrey Mill. These fans are capable of achieving a peak total efficiency of 92%. Making use of variable inlet vanes, considerable power savings are achieved over a wide range of performance requirements.

Hydro discussed the "Estimating of Peak Power Loads". Mr. Chantler of C.I.P. discussed the "Manufacture of Pulp". Both papers were well presented, and were followed by a very lively discussion period.

It is hoped that this will be a yearly event, enabling members to voice ideas.

ST. MAURICE VALLEY

J. H. A. LAVALLEE, JR.E.I.C., *Secretary*

W. A. PANGBORN, JR.E.I.C., *Publicity chairman*

Business Lectures Held

The St. Maurice Valley Branch has organized a series of five two-hour lectures for its members, on "Investment Finance and Stock Market," The lectures, held at Shawinigan Falls and Three Rivers, from February 4, to March 4, were similar to extension courses given in Canadian universities such as McGill, University of Montreal, Toronto and Laval Unversities.

At the universities these courses are given in co-operation with the Investment Dealers Association of Canada which has also agreed to undertake the project in the St. Maurice Valley, for the benefit of members of the E.I.C.

TORONTO

L. F. BRESOLIN, JR.E.I.C., *Secretary-Treasurer*

A. C. DAVIDSON, M.E.I.C., *Branch Editor*

Brigadier Quilliam, O.B.E.

At the Annual meeting, of the Toronto Branch on January 18, 1957, the regular business meeting was followed by an address delivered by Brigadier C. D. Quilliam, O.B.E. It was entitled "Events in the Middle East".

Brigadier Quilliam was introduced by D. Whitson, Toronto Branch councillor.

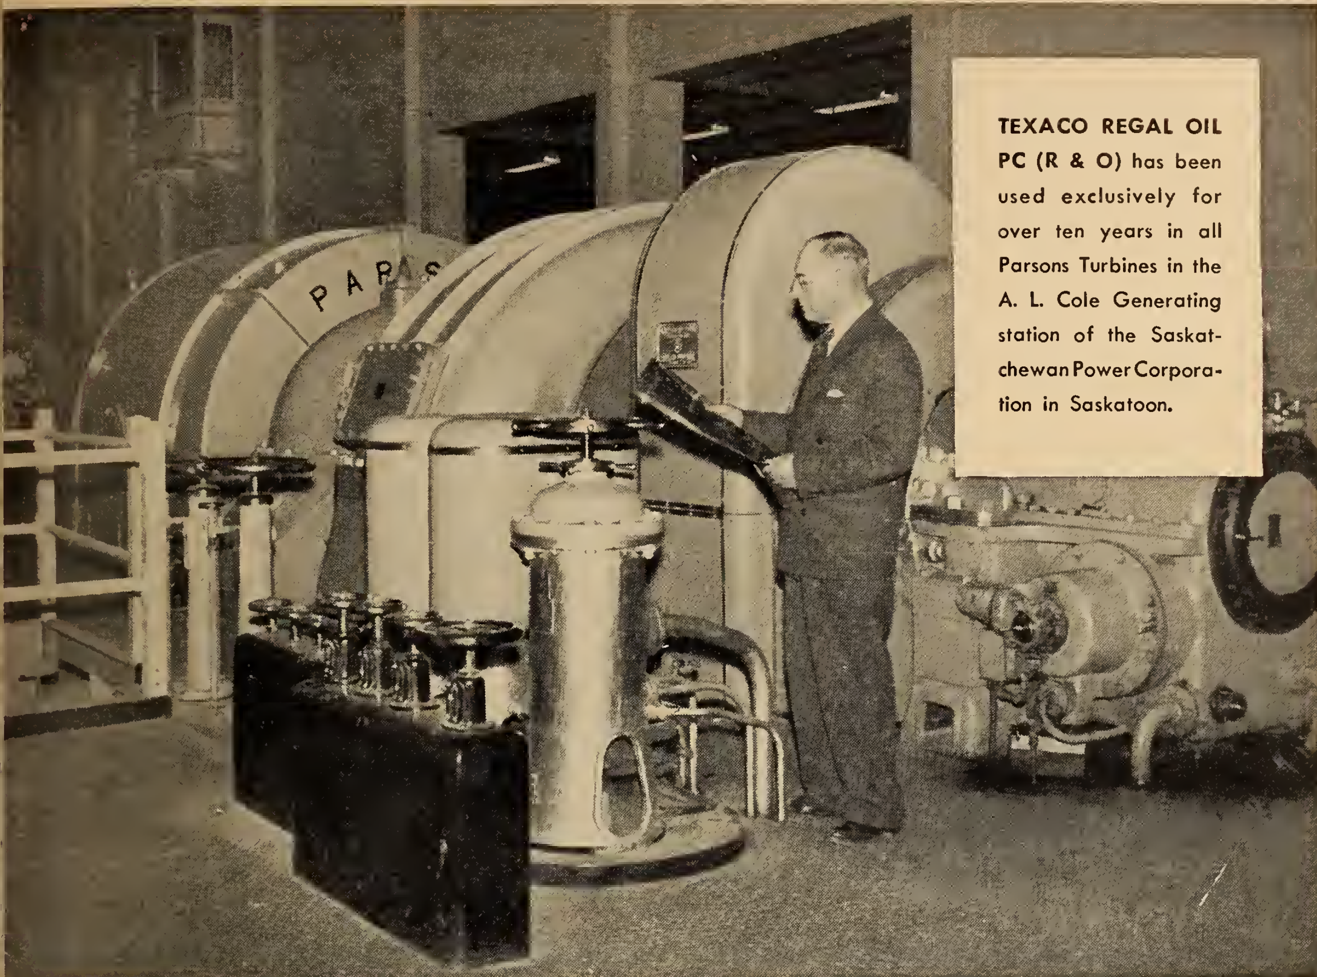
Background Situation. The speaker gave a very detailed background decription of the present situation in the Middle East making it clear at the beginning that next to Western Europe, the Middle East is the most important strategic area in the world and that it is necessary to maintain amicable relationships among the nations in the area or risk war with Russia.

The nations in the Middle East are comparatively new, coming into existence in the 1920's after the breakup of the Turkish Empire. These new countries took the British Empire as a mandatory guide, and developed under the expert supervision of the British Civil Service, whose selfless devotion to the development of the people with whom they worked is still a byward among the older generation.

Rift Created. The 1939-45 was created a rift in this harmonious relationship. The present representatives of the Western powers are not of the calibre of those who went before, and the younger generation do not remember or know what their fathers knew.

Nasser Represents Generation. Nasser is typical of this younger generation, which grew up in a frustration not of their own making, and who are endeavoring to make the Arab over into a fighting man which he is not and does not want to be. Nasser is a Moslem and believes in predestination, seeing himself as the man who will lead Islam into its rightful place in the world of politics.

Nasser's internal policy of installing reforms made the already poor people of Egypt worse off, and wrecked the economy. His external policy, the call to glory, is designed to direct attention away from this failure.



TEXACO REGAL OIL PC (R & O) has been used exclusively for over ten years in all Parsons Turbines in the A. L. Cole Generating station of the Saskatchewan Power Corporation in Saskatoon.

"TURBINE SYSTEMS completely Free of deposits, oxidation and foam"

Mr. W. R. Riddell, Superintendent of this plant, states: "Texaco Regal Oil PC (R & O) has always given dependable performance as a turbine lubricant. All systems remained free of deposits, oxidation and foaming conditions. We are also very impressed by the length of service your oil continues to give."

Texaco Regal Oil R & O has been proved by test to have *ten times the oxidation resistance* of ordinary turbine-quality oils—far greater ability to keep systems free from sludge, rust and foam. And there is a complete line of *Texaco Regal Oil R & O* approved by all leading turbine builders for all types and sizes of turbines—as well as types and sizes of hydraulic equipment.

Let a McColl-Frontenac Lubrication Engineer help you select the proper one to keep *your* turbine and hydraulic equipment trouble-free. Just call the nearest of the many McColl-Frontenac Bulk Stations across Canada, or write: McColl-Frontenac Oil Co. Ltd., 1425 Mountain Street, Montreal 25, Quebec.

McCOLL-FRONTENAC OIL COMPANY LIMITED—Manufacturers and Distributors in Canada of Texaco Petroleum Products.

• BRANCH NEWS

This external policy is threefold:

1) To prevent the development of Israel.
2) To see Egypt the leader in the Arab world.
3) To make Cairo the centre of Islam, and Egypt the leading country in Africa.

Policies Strange To Westerners. Although these policies may seem strange to a Westerner they are generated by the attitude of the West; and must firstly be countered by improving the quality of westerner going to the Middle East. The present type is not diplomatic. Secondly, Israel must be maintained as a small country. The Arab does not object to the Israeli, both are Semites, but he does feel that the West has treated the Jew veiy badly and the Western policy of creating Israel has worked hardship on fellow Arabs. Thirdly, the West must refrain from its practice of ramming its own materialism down the throat of Middle Eastern peoples. The Arab does not believe the Westerner's ideals are high; he is a mystic. The West worships success in business, sport and in pleasure. On the other hand, though the Arab might be backward in our eyes, he produced the prophets, Mohammed and Christ.

Lively Discussion The 140 members present entered into lively discussions over various aspects of the Middle East question, which proved as interesting as the talk itself.

The thanks of the meeting were tendered to Brigadier Quilliam by Don Beam, of the Canadian Institute of Steel Construction.

Inspection Trip

On January 12, the Vancouver Branch was treated to an inspection trip through the head office building of the B.C. Electric Company Limited, Vancouver, now nearing completion. About 100 members took advantage of the opportunity.

Three years were spent planning this building under the direction of Tom Ingledow, B.C. Electric vice-president and executive engineer. Many advanced features included in the design, the total cost will be about 6½ million dollars. Some of the interesting items of the project are listed below.

a) Temperature and humidity control: air conditioning and electric boilers using off-peak power to generate steam heat will maintain a constant climate, summer or winter.
b) Glareless, shadowless lighting: a new method using fluorescent lights behind a translucent plastic ceiling will bathe offices in light as the whole ceiling glows.
c) Moveable walls: partitions inside the building will be adjustable at 39-inch intervals to allow maximum flexibility and efficient use of the building's 360,000 square feet of floor space.
d) Automatic elevators: push-button operation will work with electronic control for service. Recorded voices will announce overloading or obstruction of the doors. Three of these elevators will travel to the twelfth floor, while the other three will provide service up to the twenty-first floor — the highest occupied building level in the city.
e) Automatic mail service: a conveyor system will carry mail to all floors from the mailing room.
f) A cafeteria on the main floor will serve employees with hot lunches. For summer use an open deck will be adjacent to the lunch room.
g) Two auditoriums will accommodate audiences of 200 and 100.

The inspecting group of engineers visited the below ground utility centres and were most impressed with the diagrammatic display of the heating and air conditioning system at the control centre which permits one man to control the conditions in all parts of the building while observing the exact readings telemetered to the centre. An elevator was then taken to the twenty-first floor and then a climb was made to the top of the 40 foot penthouse on the roof. This penthouse contains the water cooling towers and ventilating equipment.

Dropping down floor by floor the finishing was observed until at the third floor all was ready for the office partitions.

At the conclusion of the trip the chairman, S. S. Lefeaux, thanked Mr. R. M. Bibbs the B.C. Electric official in charge of arrangements and the engineers and contractors, John Laing and Son Limited, for a most interesting tour.

The new 6½ million dollar head office building of the B.C. Electric Company Limited at Vancouver, which Vancouver Branch members visited in January.

As the walls and interior were at that time in a state of progressive completion from the foundations up, it was possible for all stages of the construction to be observed.

News of Other Societies

C.C.A. Meets at Toronto

The annual meeting of the Canadian Construction Association was held in Toronto, January 20-23, 1957, with some 1200 delegates in attendance.

Committee Reports

The first general session on Monday morning was devoted to presentation of committee reports. Chairman R. H. Foss of the C.C.A. Apprenticeship Committee told delegates 7,400 registered apprentices for eight provinces was cause for something less than jubilation. The many new trades and skills coming into the industry should be worked into the training program. The number of journeymen being developed was quite inadequate to replace the skilled men who leave the industry, he pointed out. However, as various apprenticeship programs develop, more ex-apprentices are becoming superintendents, and are 'sold' on the benefits of training.

Chairman Bob Drummond of the Building Committee reported his committee's assignment had been completed, and "Construction House" was fulfilling its functions as Headquarters of the construction industry in the nation's capital.

H. R. Montgomery, chairman of the Construction Equipment Committee, reported the government had not yet closed the door on temporary importation of construction equipment into Canada without payment of full duties, but had referred all applications for import under special orders-in-council to the Association.

Following the major effort last year of preparing a brief concerning 'Capital Cost on Contractors' Movable Equipment,' referred to as the "Brief on depreciation rates", the Association felt the present rate of 30 per cent was unrealistic and a change to 40 per cent was appropriate. A new draft, if approved by Provincial Roadbuilders' Associations and other interested groups, would be seriously considered by the Minister, it was believed, and its recommendations would be acted upon.

R. F. Legget, chairman of the Contractor Relations Committee, referring to the question of 'bid-peddling' within the industry, stated the Committee had in September, 1956, been able to present a unanimous interim report, endorsing generally the idea of bid depositories, provided there was a local or regional demand for them. The Committee had recommended two resolutions to the Management Committee for the annual meeting in Toronto, generally endorsing the idea of bid-depositories.

Chairman J. Hastie Holden of the Legislation Committee reported that at the last annual meeting a resolution had advocated continued allowance of the option of using either the 'completion' or 'progress' method of reporting profits, if used consistently. National Revenue had ruled to this effect in 1953 with the qualification that projects lasting over two years should be subject to taxation returns based on the 'progress' method. This was allowed by the Department, which, however, ruled all unit-price contracts and all projects lasting two years would be reported on the 'progress' basis.

However, some members engaged in large-scale engineering projects were unhappy about the exceptions, and a brief was presented to the Minister in July, 1956. The association had been advised on January 3, 1957, by the deputy minister that a decision had been reached that "no change in departmental procedure should be made at the present time".

An amendment to the Export Credit Insurance Act had been promised by the Rt. Hon. C. D. Howe last year, to provide insurance coverage to contractors engaged on foreign projects. The legislation schedule had been delayed, however, and the amendment to the Act had not yet been made.

Speaking for the Sales Tax Committee, Chairman W. A. Marshall reported that practically all the Association's proposed additional exemptions to Schedule III had been included by the Department of Finance sales committee.

Chairman E. V. Gage of the Standard Practices Committee reported that the 'Suggested Guide to Bidding Procedure', advocated in 1952 at the C.C.A. convention, had been again taken up wit the R.A.I.C. during 1956 and the docu ment had been finally distributed wit the approval of both national bodies.

Following an interview last Februar with the federal cabinet, it was rule that tenders for all federal projects wit exception of Federal District Commissio jobs, 'secret' projects administered b D.C.L., and C.M.H.C., tenders at re gional offices were to be opened in pub lic. Representatives of the C.C.A. ar also permitted to be present fo C.M.H.C. tenders.

Chairman J. J. Pigott of the Labo Relations Committee announced that th association had prepared a brief to th Minister of Finance, asking for change in the treatment of board and travellin allowances paid to construction em ployees, which treated the workers ur fairly in its present form. The Depar ment of Labour had also been requeste to leave fair wage schedules include with tendering documents unchange for at least six months after these docu ments are issued, but so far the admini tration of the act remains unchanged.

Chairman V. L. Leigh of the C.C./ Housing Committee told delegates th in 1955 over half the loans under tl National Housing Act were issued those with annual incomes of $5,000 more. Only a small number obtainir loans had an income of less than $3,6(a year. Last year the number of loa

PRESIDENT, T. N. Carter, Toronto.

VICE-PRESIDENTS, H. J. Ball, Kitchener; E. Gage, Montreal; A. G. Sullivan, Halifax; A. W. Purdy, Moncton; J. E. Harrington, Montreal; F. C. Ainsworth, Toronto; J. J. Bernard, Winnipeg; J. P. Lord, Regina; E. S. Sunley, Edmonton; W. F. Foster, Vancouver.

PAST PRESIDENT: A. Turner Bone, Montreal.

HONORARY SECRETARY: R. A. Seasons, Ottawa.

HONORARY TREASURER, D. L. Donaldson, Ottawa.

had dropped, and those going to people earning more than $5,000 had increased. Provisions of the N.H.A. should be broadened, he said, otherwise the proportion of loans issued to those deserving of assistance when the act was passed would be even smaller in 1957.

President's Address

Association President Alan Turner Bone, told the meeting that in spite of a steel strike and a tight credit situation, the industry had a volume of over $6 billion for 1956. This represented some 20 per cent of Canada's gross national product, and gave direct employment to over half a million Canadians.

Barring major upsets to the economy, predicted the speaker, it appeared likely there would be a further increase of 5 per cent to 10 per cent in the volume of construction this year. This would, of course, be dependent on further increases in the supply of materials and machinery.

The leading Canadian banks were fairly unanimous in agreeing something must be done to prevent inflation, but frankly disturbed that the burden from higher interest rates and restriction in funds available for business loans was borne unevenly by different parts of the economy. "Since the federal government is concerned about the demand for credit, would it not be desirable for it to reduce the amount of credit tied up on public works contracts" asked the speaker, "such steps might include smaller security deposits, substitution of bonds, progressive release of holdbacks and faster payments." A government job took four times as much working capital as was required by a contractor for a private job of similar value, he observed.

The housing section of the industry had been the one most seriously affected by the present situation.

What concerned the average general or trade contractor most was that he must pay more now for his credit facilities than formerly, and that he could no longer count on getting credit facilities in line with his requirements.

What disturbed him most, continued the speaker, was that the credit curbs seemed to be directed principally against construction, the very industry so vital to the growth of our country and the one that should be the last to be subjected to them.

Efficiency and profits were both needed for business success, said Mr. Turner Bone. The problem was psychological, and called for leadership on the part of the big operators who had the most influence on the trend of prices.

Prime Minister the Guest Speaker

The guest speaker at the annual banquet was the Rt. Hon. Louis St. Laurent, Prime Minister, who predicted current shortages of money and materials would be greatly intensified in the coming year, with planned capital investment expected to climb to a new high of $8.7 billion. The money intended to be invested in expanding the economy by building new plants, shops, offices, houses, schools and other facilities and equipping them, he said, would rise by some 12½ per cent this year, roughly $1 billion higher than in 1955. Of the total increase, some 7 per cent would represent greater volume. The other 5 per cent would represent higher prices. The 7 per cent greater volume would greatly intensify the present shortages and something would have to yield, either the competition for funds or the competition for labour and materials.

The demand for many products was so strong that producers might be willing to pay more for loans than those borrowing to build houses. On the other hand, said the Prime Minister, he expected that over the longer term there would be a good supply of funds available for housing. He expected the present shortage of funds to relax somewhat, back towards what had been experienced during the past five years.

These difficulties, said Mr. St. Laurent, were symptoms of health and economic strength, not of weakness; evidence that competition was at work, not that it was being interfered with. The Government and the Bank of Canada took the view that the quantity of money should not be increased in a manner and to a degree that would strengthen significantly the inflationary tendencies.

Sectional Meetings

At the second sectional meeting on Tuesday, R. G. Johnson, president, Defence Construction (1951) Limited, addressed the General Contractors Section on federal construction projects, while Major General H. A. Young, C.B., C.B.E., deputy minister, Department of Public Works, discussed the activities of his Department. C. E. Hipp, vice president, Canadian General Electric Co., Ltd., addressed the Trade Contractors Section on business management and profits.

On Wednesday, the Manufacturers and Suppliers Section attended a panel discussion on "Where Research is Heading in the Construction Industry". The speakers were C. O. P. Klotz, Aluminum Company of Canada, on aluminum and related metals; J. B. Armstrong of the Plywood Manufacturers Association of B.C., on plywood; and L. H. Corning, Portland Cement Association, on prestressed concrete. C. C. Pettit, Canadian Paint and Varnish Association and P. V. Johnson of Structural Clay Products Research Foundation, addressed the meeting on paint and structural clay products respectively. R. F. Legget, director, Building Research, NRC, acted as moderator.

Calendar

Welding

The annual spring meeting of the American Welding Society (12 E. 41 Street, New York 17, N.Y.) is planned for April 8-12, in Philadelphia. At the same time the annual welding show will take place.

Electrical Engineering

The Canadian Electrical Association plans the annual meeting, 1957, for June 19-21, at Murray Bay, Que.

Headquarters of CEA is at Room 714, Tramways Building, Montreal 1, Que.

Colloquium on Radiation Effects

It is announced that on March 27-29, 1957 the Office of Naval Research and the Martin Company will co-sponsor a colloquium on Radiation Effects on Materials to be held on the campus of Johns Hopkins University, Baltimore.

Information is available from Dr. J. G. Morse, Supervisor, Radiation Effects Unit, Nuclear Division, Mail No. 711, Martin Company, Baltimore 3, Maryland, U.S.A.

Chemical Engineering

The American Institute of Chemical Engineers (25 West 45th St. New York 36, N.Y.) announces 1957 meetings as follows: White Sulphur Springs, Virginia, March 3-6; Seattle, Washington, June 9-12; Baltimore, Maryland, September 15-18; Chicago, Ill.; the annual meeting, December 8-11.

Irrigation and Drainage

The third congress of the International Commission on Irrigation and Drainage will be held in San Francisco, Calif. April 29 to May 4, 1957. This is the first such congress in the United States

Information may be obtained from the United States National Committee of the Commission, P.O. Box 7826, Denver 15 Colorado.

Radio and Electronics

The fourteenth annual exhibition organized by the Radio and Electronic Component Manufacturer's Federation is to be held at Grosvenor House and Park Lane House, London, W.1, from April 8 to April 11, 1957.

Heating and Ventilation

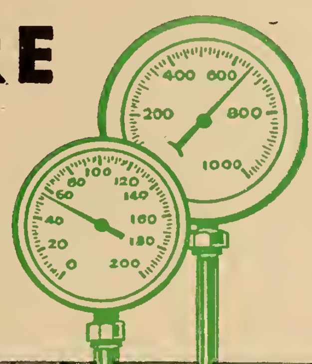
There will be International Session on Heating, Ventilation and Air Conditioning, May 27, 28, 29, 1956, in Paris

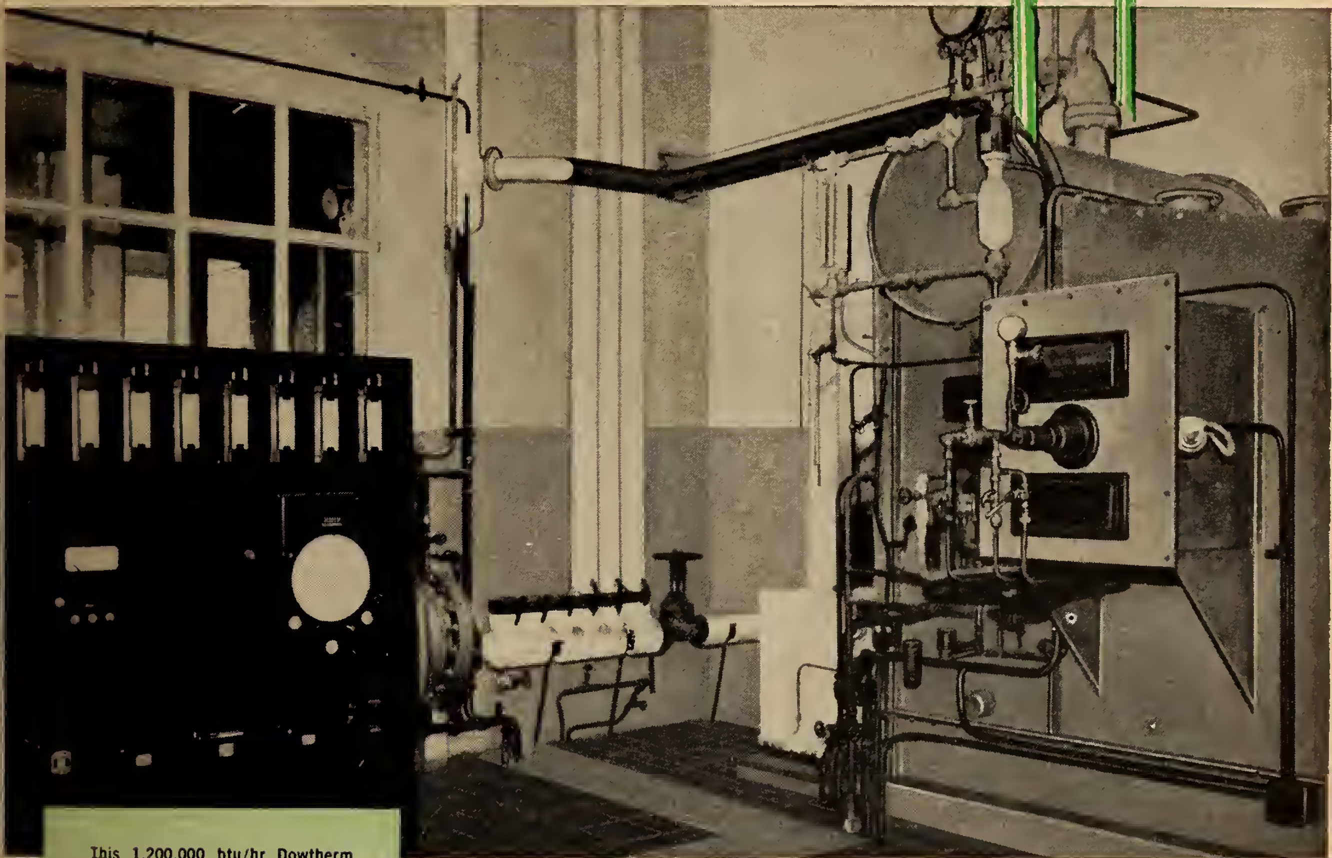
L'Institut Technique du Batiment et des Travaux Publics (6, rue Paul-Valery Paris XVI) is arranging the meetings.

HERE'S WHY YOU ARE AHEAD WITH FOSTER WHEELER

HIGH-TEMPERATURE LOW-PRESSURE

PROCESS HEATING SYSTEMS





This 1,200,000 btu/hr Dowtherm unit supplies precisely controlled process heating at 650F, 53 psi, for a fatty acid distillation plant at Compania BAO, Montevideo, Uruguay. Designed and engineered by Foster Wheeler, this plant has a rated capacity of 1500 lb per hr of crude fatty acid.

FW does the Complete Job

DESIGN
INSTALLATION
OPERATION
SERVICE

FW Dowtherm heating systems provide a vapor temperature range of 500F to 700F at vapor pressures of 15 psi to 95 psi absolute, fraction-of-a-degree temperature control, uniform temperatures throughout each processing step, fully automatic operation and low maintenance and repair costs.

Over 510 installations, in operation or on order, are proof of the acceptance and unique advantages of Foster Wheeler Dowtherm systems, for *modern processing.*

For complete information, send for your copy of 32-page Bulletin No. ID-54-5. *Foster Wheeler Limited, St. Catharines, Ontario.*

Bridging the Years

C. M. Norrie. London, Arnold, Toronto, Macmillan, 1956. 212p., illus., $4.00.

A short history of British civil engineering written primarily for the young civil engineer, this book should prove of interest to a much wider audience.

The author begins his history with brief biographies of the early engineers, Brindley, Smeaton, Rennie and Telford. He surveys the effects of the industrial revolution on the civil engineer, and recounts the engineer's contributions to the great railway building era of the nineteenth century. There are two chapters describing notable British civil engineering works of the period, and the final chapter surveys the years following 1914.

As the author points out in his introduction, today's engineers are at the beginning of a new era, as were those at the end of the eighteen century. At that time the potentialities of coal and iron were just being realized, whilst today it is nuclear energy which is occupying such a prominent position.

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

LIBRARY HOURS

Monday to Friday

9 a.m. — 5 p.m.

Saturday 9 a.m. - 12 noon.

Calculus Refresher for Technical Men

A. A. Klaf. New York, Dover, 1944. 431p., $1,95 (U.S.)

Presented in easy-to-understand question and answer form, this 'refresher' is divided into three sections. The first covers simple differential calculus; constants, variables, functions, increments, derivatives, differentiation, logarithms etc. The second covers fundamental ideas of integration; inspection, substitution, areas and volumes, mean value, etc., while section three gives illustrations of the applications of calculus to various problems encountered in the different fields of engineering and technology.

The Climate of British Columbia and the Yukon Territory

W. G. Kendrew and D. Kerr. Ottawa, Dept. of Transport, 1955. 222p., maps, tables. $1.00.

This is the second in a series of climatological reports on Canada. Part 1 covers southern British Columbia, part 2 northern British Columbia and the Yukon territory. Topics covered in each section are: regional divisions; pressure systems; air masses and frontal zones; surface winds; temperature and humidity; cloud sunshine; preciptation; visibility. Climatological tables are given throughout the book for various regions, as well as tabulated data on the subjects covered by the text, including means of temperature, pressure, etc.

The Elements of Mechanics and Mechanisms

F. J. Camm. Toronto, British Book Service, 1956. 431p., illus., $5.10.

Revised and expanded from a series of articles appearing in the periodical *Practical Mechanics*, this text provides an elementary guide to mechanics and mechanisms. The topics covered include: the laws of motion, friction, mass and momentum; force, energy and power; conduction, convection, radiation and heat; the lever; the wheel and axle; the gear; the inclined plane; hydraulics; intermittent mechanisms; and power transmission.

*Engineering Inspection, Measurement and Testing

H. C. Town and R. Colebourne. New York, Philosophical Library, 1956. 191 p., illus., $7.50 (U.S.).

The greater part of this book is devoted to descriptions of various devices and to brief indications of their applications. The devices covered include comparators, linear measuring machines, multi-dimension inspection machines, auto-collimators, etc. Also dealt with are the functions of the inspection department, principles of precision measurement, measurement during machining, inspection methods and calculations, screw-thread measurement, and the measurement of surface finish.

*The Fatigue of Metals

London, Institute of Metallurgists, 1956. 148p., illus., 17/6.

This book contains a general discussion of fundamentals and four lectures devoted to the effect on fatigue of notches, surface finishes, etc.; structural aspects of aircraft fatigue; corrosion fatigue; and the effect of temperature on fatigue properties. At the end of the book is a tabulation of fatigue data on a number of alloys.

F.B.I. Register of British Manufacturers. 29th ed.

Federation of British Industries. London, Iliffe, 1956. 1129p., 42/-.

This directory of British firms lists 7500 companies in two ways: alphabetically by name, and classified by products and services. Various means to aid in consulting the directory are given, such as French, German and Spanish glossaries, a list of brand and trade names trade marks, and trade associations.

The Grenville Problem

G. E. Thompson. Toronto University Press, 1956 119p., tables, maps. $3.95. (Royal Society of Canada special publications no. 1)

The Grenville subprovince, as part of the Precambrian shield of eastern Canada, and yet of different structure presents something of a puzzle to geologists. There has been some investigation of its rock types and mineral content, and some

industrial minerals have been developed recently. This has led to further interest in exploring the region. The contributors to this symposium represent mining companies, government surveys and universities. It is not a comprehensive survey of all that is known regarding the Grenville subprovince, but rather a number of papers on particular aspects of the problem.

Hi-Fi: from Microphone to Ear

G. Slot. Eindhoven, Philips, 1956. 169p., illus., $2.75 (U.S.)

This book explains and discusses the technique and technical problems of the recording and reproduction of sound. The apparatus and factors affecting these processes are given in order, beginning with the pressing of records. Following this the subjects covered are: the operating principles and characteristics of pickups, the needle and record, amplifiers, loudspeakers, acoustic problems, high fidelity, and magnetic tape.

The High Girders

John Prebble. Toronto, British Book Service, 1956. 219p., illus., $4.25.

There were many who believed that the North British Railway Company was attempting the impossible in erecting a bridge across the estuary of the River Tay. The bridge would be over two miles long, the longest span erected over open water up to that time. However, the bridge was completed in 1878, and Queen Victoria herself crossed some months later.

The sceptics' fears were realized in December 1879 when, during a gale, the centre span, "the high girders" collapsed while a train was crossing, drowning seventy-five people.

The High Girders is an account of the erection and collapse of the bridge, and the enquiry which followed its destruction. It makes fascinating reading, and shows how important a part the human element can play in an undertaking of this type, although it seems certain that with the technological advances of the last seventy years, a similar tragedy could not now occur for the same reasons.

*Information Theory and its Engineering Applications, 2nd ed.

D. A. Bell. Toronto, Pitman, 1956. 174p., $5.00.

This is a concise summary of the substance of recent developments, using only the mathematics ordinarily familiar to the electrical engineering or physics graduate. Chapters deal with the binary digit measure, entropy and information, signalling speed, signal-to-noise ratio, and coding. Applications such as pulse-modulated telephony, radar storage-systems, and colour television are also discussed. A new chapter on decoding has been added to this edition.

International Dictionary of Physics and Electronics

W. C. Michels, ed. Toronto, Van Nostrand, 1956. 1004p., $22.00.

Compiled by a group of distinguished scientists and educators, this dictionary has taken over five years to prepare. It includes the principle terms used in classical and modern physics, and pure and applied science.

The dictionary is intended not only for physicists, but also for those in other fields such as chemistry, biology, and engineering who frequently need information about terms used in physics. For this reason in many cases two definitions have been given for a term — a "simple" explanation, and a more detailed one.

The definitions in the volume are, wherever possible, those recommended or established by recognized groups.

For the sake of those without an extensive mathematical background, definitions of many of the mathematical terms used in physics are included.

The twelve thousand definitions cover the fields of mechanics, heat and thermodynamics; low temperature physics; the properties of gases, liquids and solids; acoustics; optics; electricity; electronics; nuclear physics; mathematical physics; and representative topics in relativity. The terms defined include laws, relationships, equations, and basic principles and concepts.

Jay-Bird feather lacing ...and the 105-ton boring machine

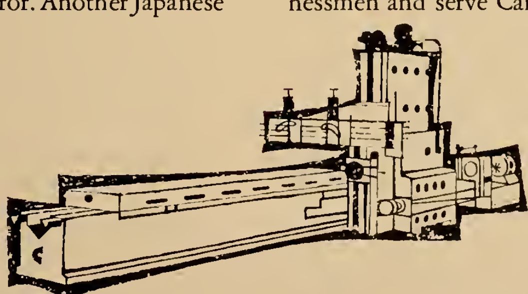
THE FEARSOME GENTLEMAN depicted on this page is *not* a Roman centurian from Cecil B. DeMille's "The Ten Commandments." He is a Japanese general, circa 1400 A.D., fashionably accoutred for a good hard equestrian bout of swordsmanship. His handsome suit was manufactured by Japanese craftsmen from the finest materials, including iron scales, black-lacquered leather, and textile braids cunningly woven to duplicate the feathers of the jay-bird.

Cuirasses with jay-bird feather lacing have been out of date in Japan—as proper dress or as a heavy production item—for several hundred years. These days, Japan's metal-working craftsmen are busy turning out 80,000-ton ships, railway rolling stock, oil casings, drilling rigs, hydraulic and thermal power generators, flour mills, earth-moving equipment, cold strip and electric plating mills, rotary kilns, pneumatic tools, and assorted machines that produce such commodities as cans, matches, textiles, pills, buttons and toothbrushes. Two years ago a Tokyo works built a gear-hobbing machine that allows only six seconds maximum pitch error, compared with the world's previous best of 12 seconds pitch error. Another Japanese firm has completed a boring machine of 105 tons net weight with a main spindle 250 mm. in diameter.

These and similar engineering achievements indicate the range of productive capacity in the New Japan, where just about anything an engineer is likely to ask for can be obtained from inventory or constructed to specification.

Japan's engineering capacity is presently at a new high—but it's no Johnny-come-lately. The Japanese industrial revolution began with the Restoration of the Meiji in 1869; today Japan (second-biggest shipbuilder in the world) builds machinery and equipment of every type for her own growing industrial plant, for Southeast Asia, the Middle East, Europe and South America.

The designers and workers who produce all this superb machinery are—literally or figuratively—descendants of the skilled craftsmen who made the general's armour. Some of them may even be descendants of the general himself. Whatever their genealogy, they are well qualified to meet the specifications of Canadian engineers, increase profits for Canadian businessmen and serve Canadian development.



F information on any type of light or heavy machinery, industrial or construction equipment, write: The Japan Trade Centre, 83 Yonge Street, Toronto, Ontario

THIS ADVERTISEMENT IS PUBLISHED BY THE JAPAN EXTERNAL TRADE RECOVERY ORGANIZATION OF TOKYO

● LIBRARY NOTES

The dictionary is carefully cross-indexed, and the units used in physics are included in the definitions and discussed in the introduction.

The dictionary is almost a library in itself, and, an important consideration, the type is particularly easy to read.

Introductory Electrical Engineering

G. F. Corcoran and H. R. Reed. New York, Wiley, 1957. 527p., diagrs., $7.95.

Intended as an introductory text in electrical engineering, the book is based on Corcoran's *Basic Electrical Engineering* published in 1949. If it is desired, the first five chapters may be used by themselves for a short course.

Revised and re-written, it covers the electric charge and current, d-c circuit analysis, magnetic field concepts, magnetic effects, ferromagnetic circuits, inductance, the electric field, capacitance and boundary-layer voltages.

Kempe's Engineers Year Book, 62nd ed.

London, Morgan, 1957. 2v. 82/6.

This standard reference work, now in its 62nd edition, needs no introduction. Each section has been brought up to date, and the two volumes cover all aspects of engineering.

Major changes in this edition include new chapters on gearing and diesel locomotives. Additional material is given on of shot and grit blasting and machinery railway brakes; electric traction; methods employed; hydraulic copying lathes; demagnetizers; new types of tipped tools, and transfer machining processes; high temperature alloys and nickel alloys; shell moulding and the carbon dioxide process; revised tables on non-ferrous metals and alloys, magnesium alloys and titanium alloys; atomic power; liquid pumps, and hydraulic transmission of power; bearing materials, slotted metal sections; the gyroscope; pump turbines and the feathering Francis turbine.

As usual, each section contains a selected bibliography.

Laboratory Administration

E. S. Hiscocks. Toronto, Macmillan, 1956. 392p., illus., $7.00.

In this book, the Secretary of the National Physical Laboratory in Great Britain examines the requirements in the organization and management of research laboratories which will provide the conditions in which scientifc work can be most productive. Concerned with both governmental and industrial laboratories employing more than 200 people, the book deals with the functions of the director and the staff, recruitment, salaries, finance, technical services, buildings, training for management, and other matters, related to the day-to-day running of a research establishment. Some data on costs are given.

Manual of Reclaimed Rubber

J. M. Ball, ed. New York, Rubber Reclaimers Association, Inc., 1956. 94p., $3.00 (U.S.).

The processing and manufacture of reclaimed rubber is an integral part of the rubber industry, since knowledge of effective methods of reclamation has kept pace with the need for more and better synthetic and natural rubber products. This manual contains data on types of reclaimed rubber; compounding of reclaimed rubber; and commercial uses of reclaimed rubber. Appendices cover laboratory test methods, chemical analysis, and a bibliography is included.

National Directory of the Canadian Pulp and Paper Industries

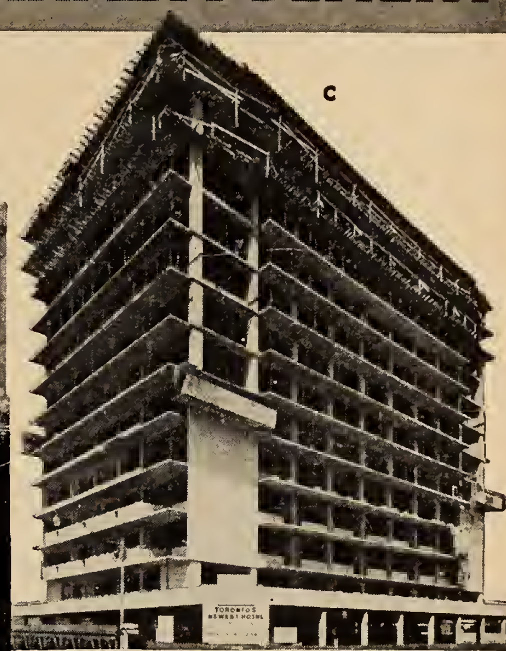
Gardenvale, Que., National Business Publications, 1956. 514p., $5.00.

In this edition, listings of pulp and paper mills, paper converters, distributors, and merchants have all been brought up to date. A classified directory is included at the end. In the geographical section listings include company ad-

CONCRETE FRAMES and FLOORS made with CANADA CEMENT

A

B



C

Competitive bids and cost analyses prove that reinforced frame and floor construction can show savings up to 25%. Building with reinforced concrete allows frame and floor construction to proceed simultaneously. Plumbers, electricians, masons and other tradesmen can do their jobs as structural work proceeds. The saving of time is considerable. Because reinforced concrete construction is durable, fire-safe, moderate in first cost and low in annual cost, it is ideal for hotels, hospitals, schools, factories, apartment and office buildings.

● LIBRARY NOTES

dresses, freight connections, officers, directors, personnel, capitalization, agents, number of employees, equipment, production, etc. Paper products manufacturers and trade associations are also listed.

The National Reference Book, 11th ed.

L. M. Durant. Montreal, Canadian newspaper service, 1956. 1499p., illus.

This reference work contains bibliographical sketches and photographs of prominent Canadian businessmen. The last section contains miscellaneous information entitled Facts and Figures on Canada. An extremely useful Business Directory is included, listing Canadian firms and giving a list of officers for each together with other pertinent information.

Pictorial Microwave Dictionary

V. J. Young and M. W. Jones. New York, Rider, 1956. 110p., diagrs. $2.95 (U.S.)

This dictionary lists the more important terms in the comparatively new field of microwave technology giving derivation, explanation, definition and illustration. It does not attempt to be comprehensive since the explanations given are encyclopaedic, as this type of definition is thought to be of greater value than a more concise entry. The dictionary is written for persons with basic technical knowledge.

The Plastic Methods of Structural Analysis

B. G. Neal. Toronto, British Book Service, 1956. 353p., $7.75

The plastic methods of structural analysis have been developed for calculating the plastic collapse loads for frames, with the idea of establishing a rational and economical design procedure. The calculations involved are simpler than those which must be made for an elastic analysis of the same structure.

The author, now chairman of the Department of Engineering at the University College of Swansea worked at Cambridge under Professor J. F. Baker who is a British authority on the subject, and at Brown University under Professor W. Prager who holds a similar position in the United States.

The plastic methods of analysis are presented in the first four chapters of the book, while the other four chapters deal with associated topics; estimates of deflections, factors affecting the fully plastic moment, minimum weight design and variable repeated loading. Included in the appendices are proofs of plastic collapse and shake-down theorems, tables showing the plastic moduli of British Standard beams and notes on plastic theory and trusses. There are useful bibliographies at the end of each chapter.

Practical Mechanics Handbook, 8th ed.

F. J. Camm. Toronto, British Book Service, 1956. 400p., illus., $2.75.

A mine of information for the Do-it-yourself enthusiast, this handbook includes information on lathe work, small tools, filing, fitting and marking out, the dividing head, hardening and tempering, electro-plating, brazing and soldering, etc.

Frequently used information is presented in tabular form, and there is a useful index. This is a valuable guide for those interested in metalworking.

Prospecting in Canada, 3d ed.

A. H. Lang. Ottawa, Dept. of Mines and Technical Surveys, 1956. 401p. illus. $2.00. (Geological survey of Canada. Economic geology series no. 7.)

Because of the importance of the discovery of new mineral deposits to Canada's mining industry, this third edition has been published to give prospectors the scientific information and modern technological knowledge necessary for successful prospecting. Subjects covered include: the geology of Canada; equipment and travel; conventional and spe-

cial methods of prospecting, geophysical, geochemical etc; exploring and appraising mineral deposits; notes on metals and minerals; placer and small-scale lode mining, and mining laws. Suggestions for additional reading are given in each section.

Radio Telemetry, 2nd ed.

M. H. Nichols and L. L. Rauch. New York, Wiley, 1956. 461p., illus., $12.00.

This is essentially the first work to gather together the basic information on radio telemetry, as the earlier edition, published in 1954, was for use by the U.S. Air Force.

The background covered includes environmental and inherent errors, frequency and time domain analysis, modulation and multiplexing, minimum signal strengths and thresholds, sampled data smoothing, and interpolation. The authors analyze current telemetry practices and compare them in terms of minimum required signal strength, cross-talk, susceptibility to environmental errors and information efficiency.

Much of the material presented is based on the authors' experience and research, and there is a useful bibliography.

°Relaxation Properties of Steels and Superstrength Alloys at Elevated Temperatures

Compiled by ASTM-ASME Joint Committee. Philadelphia, American Society for Testing Materials, 1956. 97p., $4.00 (U.S.).

Tables and graphs give relaxation strengths for low-alloyed Mo, Cr, and V-bearing steels; 12 per cent Cr type steels; a number of super strength alloys, and cast iron. Residual stresses for relaxation to 100, 500, 1,000 and 10,000 hours are used as the main measure of relaxation strength, and the temperatures covered range from 750 deg. to 1100 deg. F. with data at 1200-1500 deg. F. for super strength alloys. The tables also give chemical composition, heat treatment, mechanical properties at room temperatures, and limited creep data.

Résolution numérique des systèmes d'équations linéaires

L. Couffignal. Paris, Eyrolles, 1956. 178p., 2000 fr.

The wide use of mathematical calculations in the solution of the engineer's, architect's, and technologist's problems necessitates a working knowledge of various systems of calculation. This publication expounds the system of the numerical solution of linear equations, which is a method that may be used to solve problems that are not solvable by ordinary calculus. Contents include: definitions and notation, method of reduction to tables, formal solution of linear equations, and numerical solution of linear equations. Illustrated examples and tables are included.

°Roll Design and Mill Layout

R. E. Beynon. Pittsburgh, Association of Iron and Steel Engineers, 1956. 178p., diagrs., $5.0[illegible] (U.S.)

This book traces the development of rolling from early times to the present and deals, from the practical viewpoint of the designer, with roll pass design and mill layouts, with roll manufacture, basic principles of rolling, and for the rolling of blooms, billets, slabs, bars, rods, rails, beams, channels, and angular sections.

°The Running and Gating of Sand Castings: a Review of the Literature

R. W. Ruddle. London, Institute of Metals, 1956. 183p., diagrs., $3.75. (Monograph and report series no. 19)

A critical review and summary of research on the flow of metals in gating systems, carried out in order to determin[illegible]

how to minimize defects in castings. Types of defects, experimental methods, and elementary hydrodynamic theory are dealt with in the first three chapters. The various kinds of gating systems are discussed in detail in the next three chapters, and the last chapter presents conclusions and suggestions for future research. A mathematical treatment of relevant hydrodynamic theory is given in the appendix.

Russian-English Dictionary of Nuclear Physics and Engineering

D. I. Voskoboinik, ed. Moscow, Academy of Sciences of the USSR, Institute of Scientific Information, East Orange, N.J., Associated Technical Services, 1955. 350p., $10.00 (U.S.)

This dictionary, besides covering the fields of nuclear physics and engineering, also covers subjects pertinent to these fields when nuclear phenomena and their effects are involved: chemistry, biology, medicine, geology, electronics, and mathematics. There are 8,000 entries defined in concise and idiomatic English.

Scatter Propagation, Theory and Practice

I. Kamen and G. Doundou'akis. Indianapolis, Sams, 1956. 197p., illus., $3.00 (U.S.)

The principles and uses of scatter propagation are presented in this publication which covers ionospheric and tropospheric propagation, and the equipment and installation of microwave systems. Examples of the work done in this field by the Collins, General Electric and Marconi companies are given in illustrations and circuit diagrams. Test techniques are included and there is a chapter describing northern radar installations.

***Sewage Treatment, 2nd ed.**

K. Imhoff and G. M. Fair. New York, Wiley, 1956. 338p., illus., $7.50.

This standard text provides the sanitary engineer with the essential practical information needed for the design and operation of sewage treatment plants. Such general considerations as costs, plant location, and works equipment are briefly discussed, and the various methods of treatment common in American cities and industries are dealt with fully. New processes covered in this edition include step aeration in the activated sludge process and continuous loading and unloading of sludge digesters with thickened sludge.

Soldering Aluminium Cables

L. Roullier, comp. London, Aluminium Union Ltd., 1956. 83p., illus.

Compiled by a member of the Engineering Institute of Canada, the purpose of this book is to discuss the soldering of aluminum as applied to insulated cables.

The characteristics of aluminum stranded conductor and the nature of the soldering problem are reviewed briefly, following which the jointing techniques using organic fluxes and reaction fluxes are covered. The jointing of aluminum sheaths is discussed in the final chapter. Included in the appendix are current rating tables and factors, as well as a list of suppliers of fluxes and solders.

Statistical Tables on Aluminium, Lead, Copper, Zinc, Tin, Cadmium, Magnesium, Nickel, Mercury and Silver, 43rd issue, 1946-55

Frankfurt an Main, Metallgesellschaft Aktiengesellschaft, 1956. 219p.

This compilation contains detailed statistics on the production and consumption of the principal non-ferrous metals. Historical data covering very early years (B.C.) until 1945 are given in the preliminary section, followed by 1946-55 averages for each metal; a world survey; comparison of production and consumption by continent; statistics for each country by individual metal; and price averages. The tables are clear and comprehensive.

La Stratégie dans les actions humaines

J. D. Williams, translated by Mme. Mesnage. Paris, Dunod, Montreal, Fomac, 1956. 287p., $6.80 (Fomac)

A "primer on the theory of games and strategy" this book presents a comparatively little-known subject in non-technical form. The game theory may be applied to any situation containing a conflict of interests, from games played at home to war. The only type of mathematics used in the examples given is simple arithmetic, and the tone is humorous throughout. The English edition, entitled *The Compleat Strategyst*, is also available in the library.

Stress Corrosion Cracking and Embrittlement

W. D. Robertson, ed. New York, Wiley, 1956. 202p., illus., $7.50

The proceedings of a symposium held in 1954 under the auspices of the Corrosion Division of the Electrochemical Society, the fourteen papers cover the major developments of the last twelve years in the field of stress corrosion cracking and embrittlement. A great deal of work has been done on the problem in the years since the symposium held in 1944 by the A.S.T.M., and A.I.M.M.E., as can be gathered from the lists of references accompanying each paper.

Among the topics covered are: the structure of grain boundaries; the role of boundary absorption in stress corrosion cracking; the mechanism of chemical cracking; stress corrosion cracking in aluminum alloys, homogeneous alloys, a magnesium alloy, austenitic stainless steels, and mild steels.

The papers are indexed.

Structures

P. L. Nervi. New York, Dodge, 1956. 117p., Illus., $6.95. (U.S.)

A designer of reinforced concrete structures for over forty years, Pier Luigi Nervi is architect, engineer and builder, and also the inventor of a new construction material, Ferro-cemento. Using this material, Nervi was the first to build large prefabricated thin shells, and he also used it to make forms which revolutionized flat slab design.

In this book, Nervi presents his ideas on the art of building correctly, and discusses his approach to structural problems and the schemes and materials he has used for their solution, including Ferro-cemento. There are many photographs showing his works both in construction and completed.

The book is translated by Mario Salvadori, a professor of civil engineering at Columbia University, and his wife. He has also written an introduction.

Le Styrène et ses polymeres

H. Gibello. Paris, Dunod, Montreal, Fomac, 1956. 273p., illus., $9.15.

The chemical composition, manufacture and polymerisation of styrene are treated in this book, as well as the many characteristics and applications of polystyrenes. Methods of polymerisation are discussed and uses of the resulting products according to their characteristics; for example, injection molding, coloring and decorative uses, and industrial applications. Contents include: preparation of styrene, analysis of styrene, chemical properties, polymerisation, applications of polystyrene, injection molding, and compression molding.

Trigonometry Refresher for Technical Men

A. A. Klaf. New York, Dover, 1946. 628p., $1.95 (U.S.)

The subjects of plane and spherical trigonometry are conveniently presented in this book, designed to be of service in the solution of problems in navigation, surveying, eleasticity, architecture, and various fields of engineering. Part one covers plane trigonometry including trigonometrical functions, equations, logarithms, and the use of the slide rule; part two covers small angles, periodic functions, and vectors, while part three covers spherical trigonometry.

***VDI-Wasserdampftafeln (Steam tables), 4th ed.**

Sponsored by Verein Deutscher Ingenieure, ed by E. Schmidt. Berlin, Springer-Verlag, 1956. 109p., DM 15.

In this new edition the temperature range has been extended to 800 degree C with a pressure range to 300 atm. The three sections of the tables are as follows: state of saturation (temperature table); state of saturation (pressure table); values of volume, enthalpy, and entropy for water and superheated steam. The large, folded Mollier diagram is in a pocket at the back. The foreword and the explanatory introduction are given in three languages, German, English, and French.

Profitability

Keep pipelines profitably on stream

Valve down time often plays a large part in the profitability of gas, petroleum and products pipelines. Years of exceptional performance records and cost studies prove that Rockwell-Nordstrom valves are the best way to keep profitably on stream. Here are three reasons why you see so many Rockwell-Nordstrom valves on so many pipelines:

LEAKPROOF SAFETY: Pressurized lubricant sealing eliminates risky "forced" seating . . . prevents internal or external leakage of lightest gases or heaviest liquids.

FAST, DEPENDABLE: Quarter-turn closure . . . lubricant jacking for instant operation . . . power operation is simpler, less costly.

ECONOMICAL: First cost is no higher (often lower) than ordinary valves . . . elimination of metal-to-metal wearing friction and unexposed seats assure low maintenance and long life.

Rockwell-Nordstrom valves are available in a complete range of sizes and pressure ratings in steel, semi-steel and corrosion resisting metals. For more information, see your nearest supplier or write: *Canadian valve licensee:* Peacock Brothers Limited, Box 1040, Montreal, Que. Also, Sydney, Toronto, Sudbury, Winnipeg, Edmonton, Calgary and Vancouver.

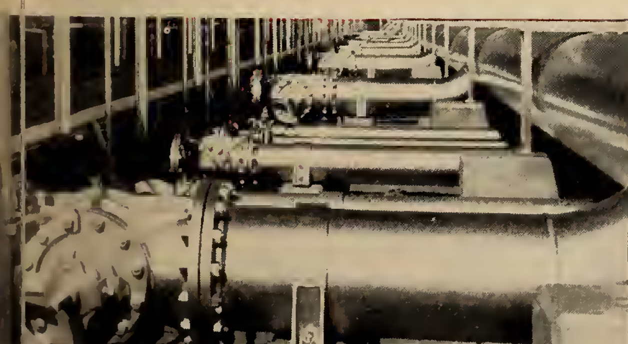
Made in Canada by

PEACOCK BROTHERS LIMITED



ENGINEERING CAREERS

Machinery and Manufacturing Industries

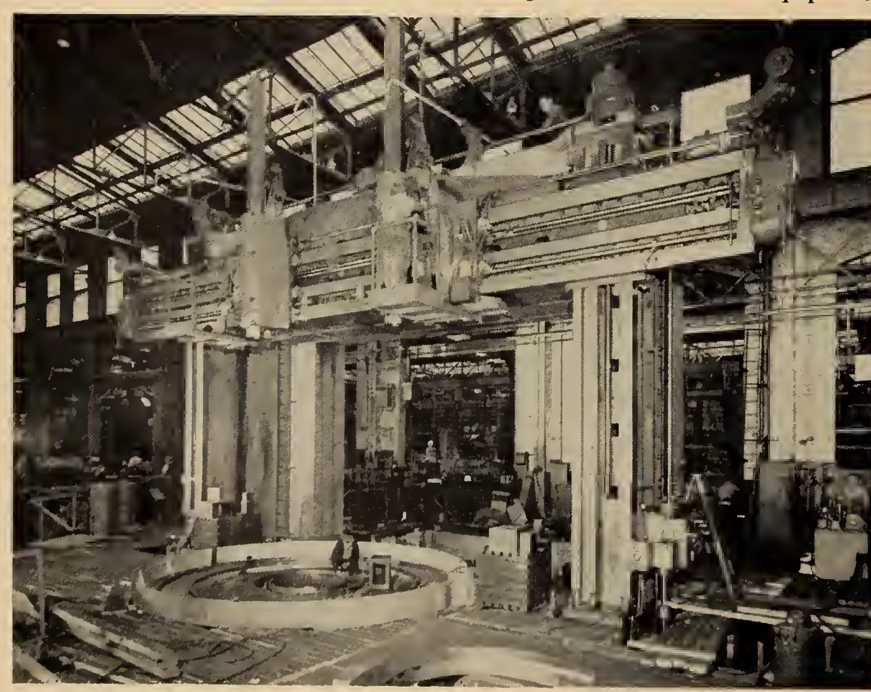
The activities covered by the title of this article are very varied. They are largely associated with the secondary industries.

Canada's primary industries include the exploitation of the country's great resources of minerals, including petroleum and natural gas; forests, pulp and paper; and the general development of transport and communications. Certain large or specialized industries, such as chemical, metallurgical, and heavy metal-working and engineering are dealt with elsewhere from the point of view of what they may hold in store for the engineer who may be planning or starting his career.

To meet the needs of other industries as well as the goods and services that are a part of everyday life, there is this secondary industry. There has been criticism that Canada has tended to neglect secondary industry by concentrating on the development of her natural resources and so having to import many manufactured goods that might just as well have been made in Canada in the first place. There is certainly plenty of room for expansion in these manufacturing fields, especially as the population grows, but there are good indications that this expansion is well under way.

For British Columbia alone, it is estimated that employment in manufacturing, other than the primary industries, will increase 90 per cent in the next ten years. At least similar rates of expansion might be expected elsewhere, particularly in the more industrialized provinces such as Ontario and Quebec. Another authority lists some eighty new industries, classed as important developments, which were established in Canada in 1956. Major developments and expansions of manufacturing industries in the same period are numbered in the hundreds. All this will mean an increased demand for engineers.

Among the larger varieties of machine tools used by the manufacturing industries is this 25-foot vertical boring and turning mill with a table capacity of 300,000 pounds. Engineers are responsible for the design and use of such equipment.



What are the Industries?

It is only possible here to give a few general examples of the types of manufacturing industry in which the professional engineer may look for a career. Of these the widest scope is covered by the heading "machinery".

Machine Tools—In this field one may start with machine tools, since these are the implements with which much of the other machinery and manufacturing equipment and products is made. The actual production of machine tools in Canada is not a very large industry, though it has shown some interesting developments. The use of machine tools by industry in general is on a very wide scale. The tool engineer has an important job in helping to develop new methods, increase rates of production from existing equipment, and adapt techniques to the processing of new materials, to give but a few examples. More specifically, productivity and perhaps quality at the same time might be increased by changing from drilling to a broaching technique in a manufacturing process. The metallurgical engineer is another who is considerably concerned with machine tool operations.

Industrial Machinery—Modern industry tends more and more to use machines rather than manual operations. The handling of materials is made easier, and high production rates made possible, by the use of cranes, lift trucks, conveyor systems and similar equipment. Automatic canning and bottling machinery is widely used in the food and drink industries. Few industries are now without some form of automatic pack ging machinery. Many parts are produced in finished form from the starting raw material, without human intervention, by automatic machinery. The manufacture of all such machinery is itself the work of several industries who may specialize in certain fields. The design of this equipment is largely done by engineers with the machinery-manufacturing companies.

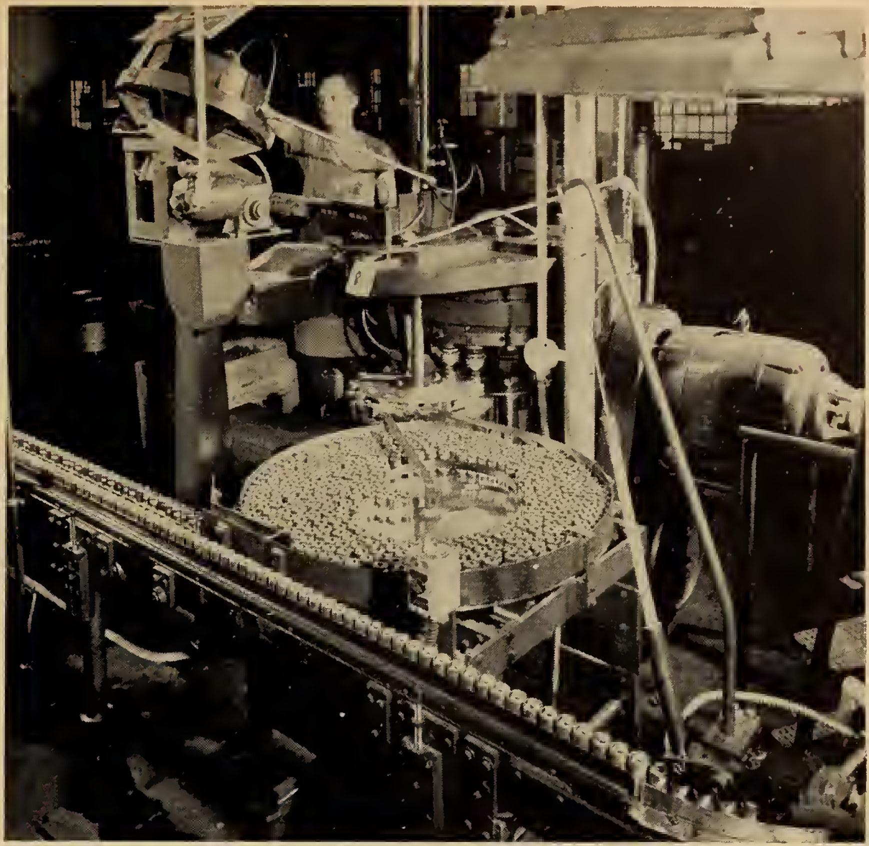
On the other hand, the industries that use this machinery in their manufacturing processes frequently have their own engineering departments who may be called upon to design, develop or improve the production equipment and methods. As a plant expands there is often need to improvise in linking existing and new facilities or it may prove economical to adapt present machinery to a different production role rather than invest in entirely new equipment.

Even in cases where a manufacturer does not normally contemplate the employment of his own staff for the engineering of plant extensions and major modifications, there is frequently the necessity for an engineering staff to maintain the efficiency of the plant. The proper use of planned maintenance engineering is of great importance, both practically and economically, to the manufacturer, especially as machinery becomes more complex and its capital cost higher. Plant and maintenance engineering are therefore both important fields in the manufacturing industries.

Mobile Equipment — Agriculture has long been a major contributor to Canadian economy. The production of agricultural machinery, such as tractors, soil tilling implements, and harvesting equipment, is a correspondingly active industry in Canada and one which makes wide use of professional engineers.

Heavy earth-moving equipment, bulldozers, graders, and so on, are very extensively used in Canada, especially in opening up new areas for development, and engineers are concerned with their design and manufacture, though this is not yet on a very large scale in this country.

Other Industries — Among other industries may be mentioned the manufacturers of plumbing, heating, refrigerating, and ventilating materials and equipment; pumps, valves, and fittings for handling a variety of materials in many different industries; hardware; stationary engines and compressors; household goods



Typical of machinery used in the mass-production of small items is this section of a production line that turns out some 60,000 flashlight batteries a day.

such as cleaners, washing machines, stoves, and even kitchen utensils, which are often made by mass-production methods and represent a large industrial investment.

The rubber industry, textile manufacture, wire and cable production, are other examples of industries that are largely dependent on efficient machinery for their activities, and all have need of engineers. The modern fishing industry is an example of a traditional activity that is turning to engineering to keep it competitive, by using new refrigeration and processing techniques. Other food processing industries are also actively concerned with engineering of plant and production facilities. It is among these industries that there are many openings for chemical engineers.

Opportunities

Among all these varied industries there are some, even those with substantial investments in plant and machinery, that do not specifically employ professional engineers. Others may have very small but specialized engineering staffs. The machinery industries may employ high proportions of engineers. In all, though the demand varies widely, there is always the opportunity for the professional engineer with the right qualifications to progress to the upper administrative and management levels of most industrial undertakings. Though there may be a preponderance of mechanical engineers in the field, engineers of all categories are in demand.

Many of the companies considered here employ sales engineers.

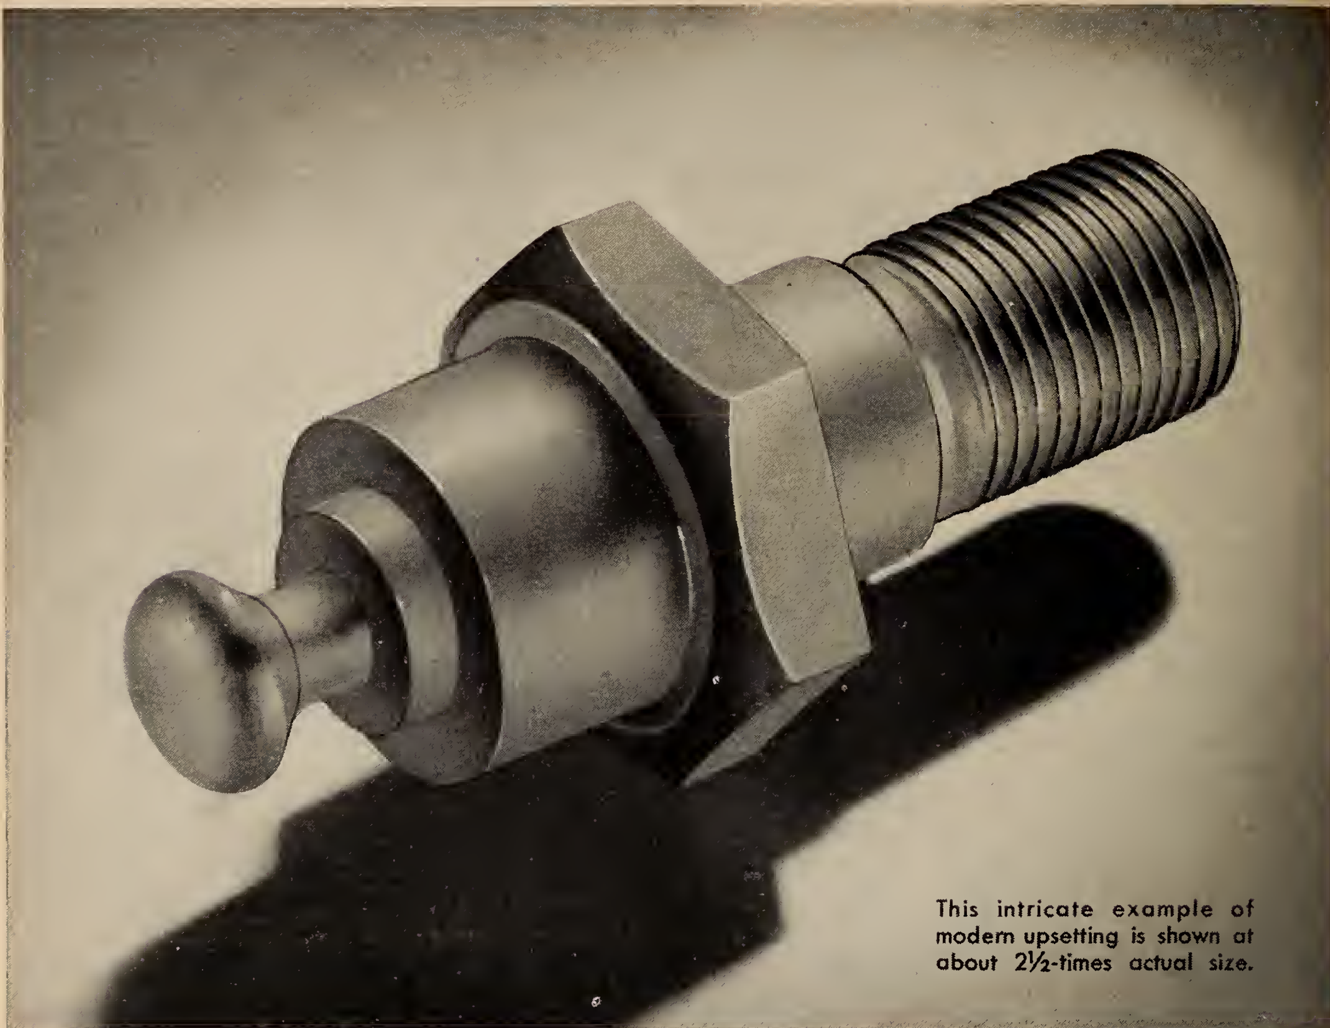
Training

The extent to which training facilities are provided also varies considerably between the different industries considered here, though adequate further training is customary to familiarize the engineer with his new work. Many companies extend these facilities, for example, to financial support of special courses.

Salaries and Benefits

Because of competition for the services of engineers, most industries tend to offer starting salaries within a comparable range. Subsequent advance depends on the individual.

The majority of Canadian industries in which engineers are employed offer the usual benefits of paid vacations, assisted pension and health schemes, and others.



How much would YOU save with a . . .

STELCO SPECIAL FASTENER ?

- *If you use a machined part . . .*
- *If you "make-do" with a standard fastener . . .*
- *If you use a forged fastener . . .*
- *If you have a fastener design problem . . .*

STELCO can probably save you money with a SPECIAL FASTENER

Where Special Fasteners are used the saving is not only in parts at a lower cost . . . but in faster, better assembly as well.

The Fastener shown above indicates the extremely wide design possibilities of Stelco Special Fasteners. The range of contoured and special shapes produced by Cold Heading is increased by threading, punching, shaving, and bending operations.

Cold Heading saves material and production time. Cold Headed parts are stronger and cheaper than similar machined pieces, cheaper than forgings and equally strong.

Stelco's Engineering Service can advise if a Special Fastener would be beneficial in *your* operation . . . if so, there is a substantial saving for *you.* Contact any Stelco Sales Office for further information.

Contents - April 1957

(18,650 copies of this issue printed)

A Message from the President

IT HAS BEEN my pleasure to meet many of you during recent months and on most occasions there has been an opportunity to discuss Confederation. I have attempted to keep the membership informed about the action of Council with respect to this very important matter and, in addition, the *Journal* of July 1956 carried a statement on Confederation.

It has come to my attention that some members seem to believe that the Institute has been stalling, holding back or otherwise discouraging the work towards Confederation. Nothing could be farther from the truth. I hope that a plain simple account of what has happened will illustrate clearly that the Institute is strong for Confederation, and has taken every step reasonably possible to push it forward, and will continue to do so.

Recently the Council of the Institute proposed that I should write to every member, in order to impress them with the Institute's policy on this important matter, in the hope that, in this way we may overcome some of the negative opinions to which I have referred.

May I reaffirm my personal conviction that Confederation is a matter of utmost importance to the engineering profession in Canada. Furthermore, I believe that the Institute will, and should, continue to press for action. I have every reason to assume that the same feeling prevails in the other organizations. So far as I am aware there is no question that cannot be resolved with benefit to the profession at large. I also believe that this project is of such importance that sufficient time should be allowed to build wisely and well for the future.

If you will read regularly the Month to Month section of the *Engineering Journal*, you will be kept informed of developments as they occur. This is the one sure means of following not only Confederation but all the business of the Institute. Your Council and the Confederation Committee have stated that they will move ahead as rapidly as possible and will not be responsible for any unnecessary delays. We hope you will be patient until a final recommendation is ready. We can assure you that as far as Council is concerned and the committee also, there will be absolutely no delays that can be avoided.

A committee was established by Council on April 30, 1954, under the chairmanship of Dr. R. E. Heartz. On his election to the presidency, Dr. I. R. Tait was made chairman on March 25, 1955. This committee has been in close touch with a similar committee set up by Dominion Council. There has been splendid accord between the two groups, which resulted in the preparation of a joint report for the consideration of the Institute and Dominion Council.

The joint report was presented to the Council of the Institute, to the Branch Officers' Conference and to the Annual Business Meeting, during the Annual Meeting in Montreal in May 1956. The report was approved unanimously on all three occasions. It was then sent to the Dominion Council for consideration at their Annual Meeting in June 1956. Dominion Council sent it to each provincial registration organization for study and report.

It is evident that the Institute can take no further steps until Dominion Council have received the reports from the provincial associations, and reported back to their own committee. It is our hope and expectation that they too will accept the joint report as a basis for further study. When that approval has been received it is expected that a joint committee will be created to prepare a detailed proposal. From then on I am confident that rapid progress will be made towards the much desired goal of Confederation.

In the meantime each of you can help by boosting for Confederation on every possible occasion.

V. A. McKillop, M.E.I.C.
President

A Brief Report on the

McGill Coal Burning Gas Turbine Project

D. L. Mordell, M.E.I.C.

Head, Department of Mechanical Engineering, McGill University

An extension of a paper read at the 70th Annual General and Professional Meeting of the Engineering Institute of Canada Montreal, May 1956

IN 1949, the writer suggested that gas turbine engines could burn coal if they operated on what is now known as the exhaust heated cycle.[1] In this cycle, compressed air is heated indirectly in a heat exchanger prior to expansion in a turbine. The hot turbine exhaust air is heated further by combustion before giving up its heat in the heat exchanger. Such a coal burning engine offered a prospect for better generation of electric power and for a locomotive which should be cheaper to operate than the Diesel engine. It was clear, however, that there was at that time insufficient knowledge for the design of any prototype power plant.

In considering the possibilities of such a design, the choice of compression ratio, turbine inlet temperature, heat exchanger pressure loss and thermal ratio presented no problems and analysis by the usual thermodynamic methods could be employed to calculate the obtainable performance, and to obtain an optimium design from a thermal and economic viewpoint. However, there were a number of problems for which solutions were lacking and the writer at that time suggested that a research unit should be built to prove the general principles of the exhaust heated cycle and to study solutions to the following problems, among others.

(*a*) Accurate metering and feeding of coal.

(*b*) Combustion of coal at elevated temperatures.

(*c*) Ash handling.

(*d*) The possibility of fouling or corrosion of the heater tubes.

(*e*) Permissible temperatures in the heater.

(*f*) Optimum mechanical design of the heater.

(*g*) The best materials to use in the heater.

(*h*) The magnitude of the heat losses.

It was clear that once information has been gained on these problems, and assuming that the solutions were practical, it would be possible to design a coal burning gas turbine with every expectation of success.

The writer suggested that the research unit should be built around an existing design of aircraft gas turbine, since this could save time and money, and for this preliminary investigation the actual thermodynamic performance of the gas turbine itself was irrelevant.

This paper is a short description of the work done from the inception in 1949 to the end of 1956 on the project to develop a gas turbine engine that could burn coal as a fuel. Operating on the exhaust heated cycle, such an engine could offer advantages for locomotives or electric power generation.

The writer was introduced to the Federal Department of Mines and Technical Surveys by the late Mr. W. A. Newman, former manager of research for the Canadian Pacific Railway, who believed in the possibilitics of a coal burning gas turbine locomotive. Mr. S. W. Fairwether, vice-president of Canadian National Railways, was also interested in this possibility, and with this support th Department entered into a contrac with McGill University, under whicl an experimental test unit would b designed and constructed under th direction of the writer.

Construction and Test Program

The original program called for u to design and construct the experi mental unit and the necessary facil ities for its testing at an estimate cost of $167,000. The Fuels Divisio of the Mines Department were t test and develop a cyclone furnace t obtain preliminary information for th furnace design. The experimental uni and test facilities were completed i November 1953, at a cost of abou $300,000. The increase over the esti mate was due to the following:

(*a*) The estimates were low.

(*b*) The inflationary effect of th Korean war.

(*c*) An extended strike at a sub contractor's works

(*d*) It was essential to build an test a furnace[2] in our own laborator to extend and supplement the test made by the Fuels Division, whicl were suspended due to unforesee circumstances before much was ac complished.

It was anticipated that about 1,00 hours testing would be necessar which would take about two yea and would cost $200,000. The pro gram called for about 300 hours test ing in the first year, after which i was expected that modification would be introduced, to be followe by 700 hours testing in the secon year. The first part of the prograr

:tually took seventeen months, the ⸱lay being due to the fact that un-:pected troubles relating to the ⸱e of an aircraft engine as a test ⸱hicle took six months to solve, due the large amount of time required strip and reassemble to test the ⸱cessary improvements. At the end the first period it was clear that a ore extensive rebuild than had ⸱en anticipated was desirable. To ⸱rmit this the contract was amended permit the test program to cover ⸱e extra time involved in the rebuild bout six months) and the extra ⸱st.

Results of First Test Program

The results of the first program hich terminated in March 1955 ⸱ve been described in considerable chnical detail in Refs. 3 & 4. They ay be summarized as follows:

(a) It has been amply and ade-⸱ately demonstrated that the ex-⸱ust heated cycle is a practical way burn coal in a gas turbine.

(b) The unit has shown itself to robust and rugged in operation. has been handled throughout by ⸱echanics and testers with no prev-⸱s experience of gas turbines or ⸱rnace equipment. It has survived, ⸱fely, accidents in operation that ⸱ould be likely, in other types of gas ⸱rbines, to cause extensive dam-⸱e.

(c) The maximum power taken ⸱m the machine was 280 horsepow-⸱ compared with a design predic-⸱n of 500. This discrepancy was ⸱e to excessive pressure losses. ⸱ese were higher than the design estimates because at the time of the design, precise information was not available (no similar heat exchanger having been constructed hitherto). Correct information has emerged from the tests.

(d) In any plant of this type experience shows that mechanical teething troubles will be encountered. Our own mechanical troubles were few; in fact, they were virtually confined to one part of the plant, and were not fundamental to this type of gas turbine. Although the troubles were few, considerable time was occupied in correcting them due to the time factor involved in making modifications.

Turning specifically to the questions raised in the introduction:

(a) The original coal feeder was a vibrating type. This was replaced in turn by a compressed air ejector, and by a screw feeder. At the end of the program the screw feeder had shown good results, although further development was needed.

(b) The cyclone furnace showed that it could burn the coal at high efficiency. It was found that a tendency to form cinders, and so cause a deterioration in performance, could result from small changes in type of coal entry. In the arrangement tested, the cooling water losses were higher than desirable.

(c) Ash handling gave much trouble. Numerous arrangements of slag drain removal systems were tried and by the end of the tests it appeared that many aspects of the problem were clear.

(d) On the whole, there appeared to be little tendency for dry fouling of the heater tubes. Serious corrosion was experienced and was shown to be due to the effects of high sulphur content of the coal upon the Nimonic alloy used in the tubes. Small scale work by the Mines Branch helped to elucidate this problem.

(e) It was found that with the particular coal used, the maximum acceptable temperature of the gas entering the tubes was about 1850° F. Attempts to run at higher temperatures led to slagging of the tubes.

(f) It was found that the mechanical design of the heater could be improved a lot. In particular, the tests showed that the gas tube heater was subject to troubles that should not occur in an air tube heater. The cooling losses were high and the pressure loss was high. Determination of the exact values and their correlation permits more accurate design in the future.

(g) It was clearly demonstrated that Nimonic was an unsuitable material to use with sulphur-bearing coal in a gas tube heater. Small scale corrosion tests of numerous alloys were made by the Mines Department and it was suggested that other and cheaper materials could better withstand the attack.

(h) The heat losses were excessively high. Careful analysis showed that losses from the furnace amounted to about 26% of the heat added, while the total losses from other sources were 14%, making a total

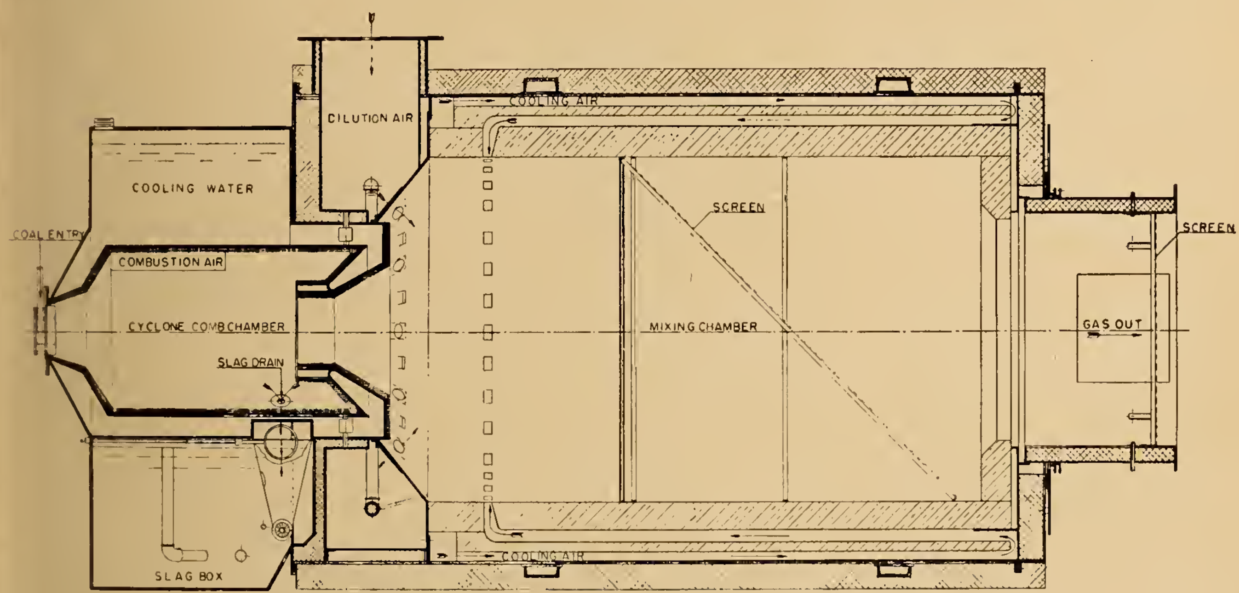

Fig. 1 Cyclone combustion chamber of exhaust-heated coal-burning gas-turbine.

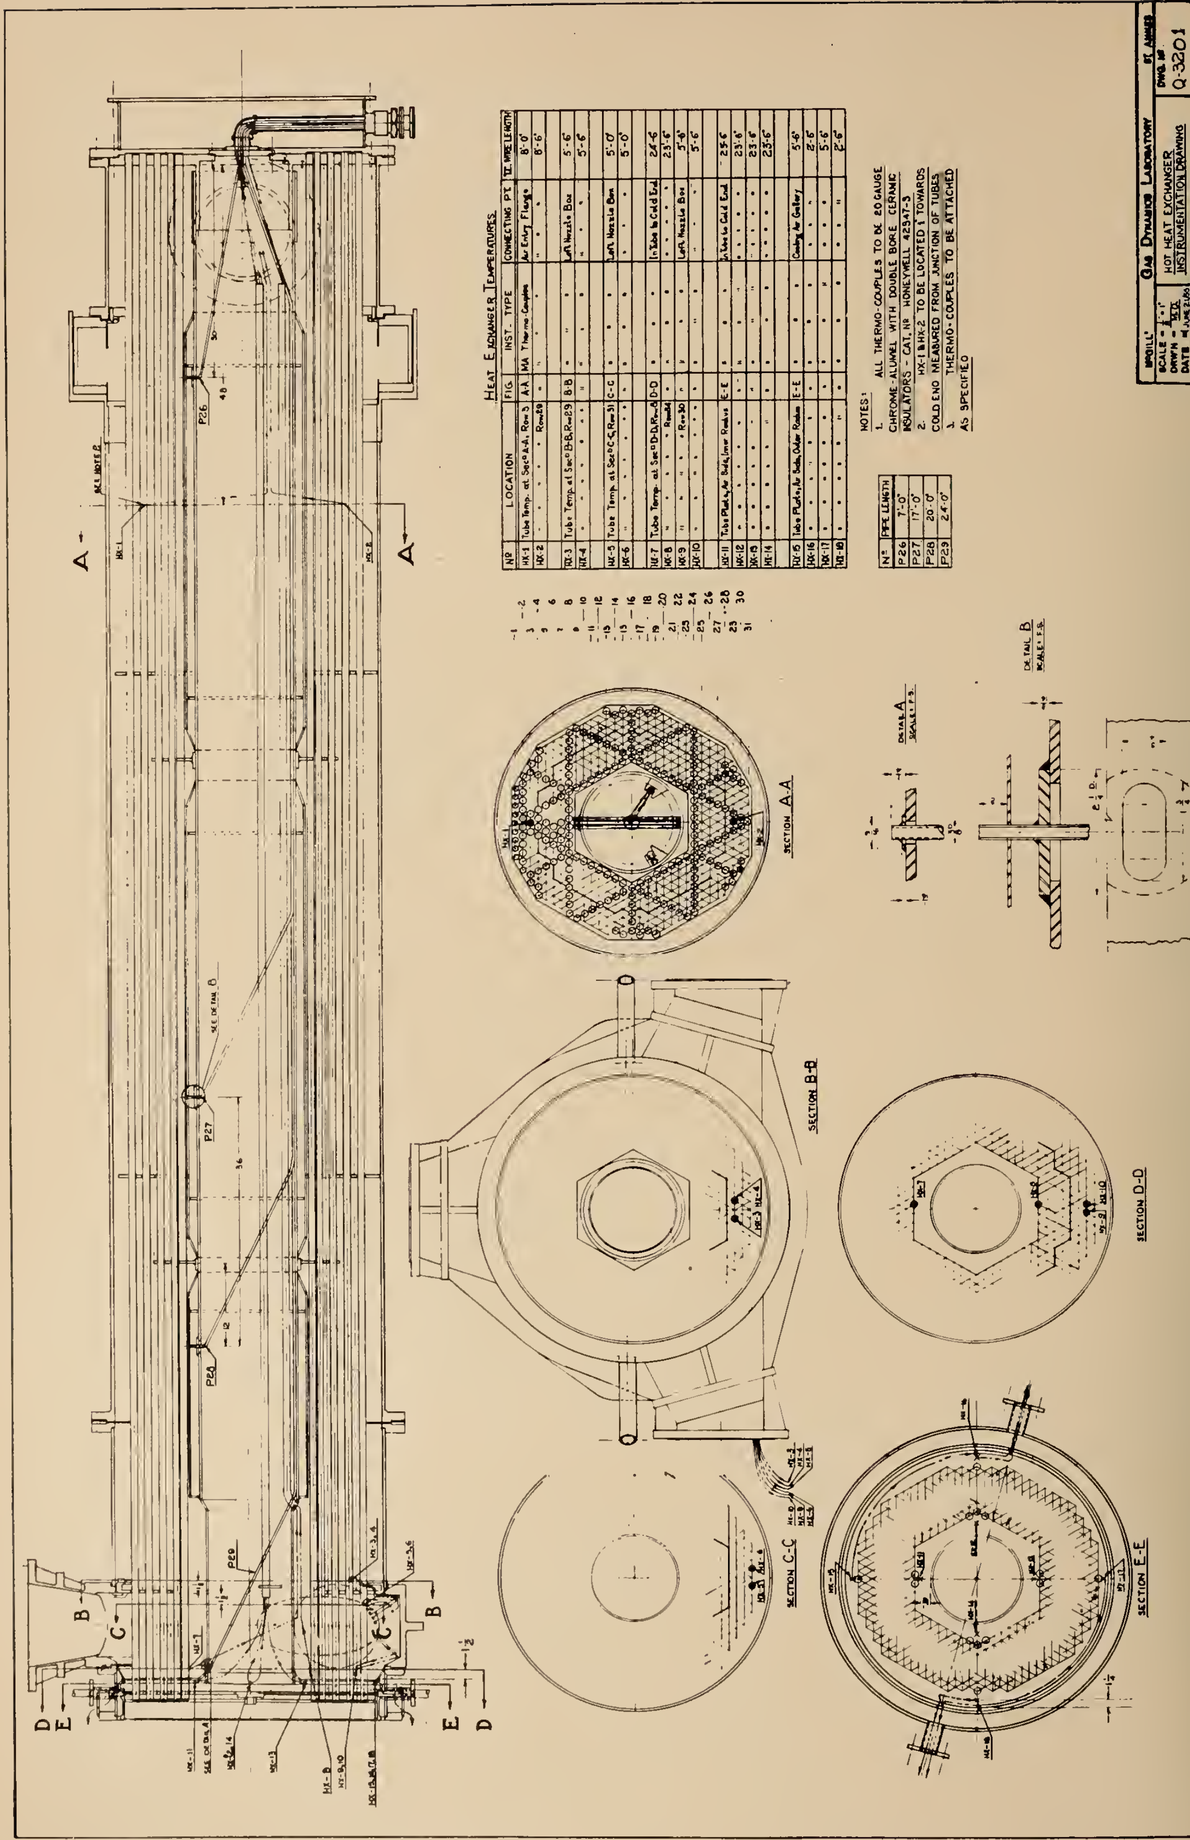

Fig. 2. Sectional views of the rebuilt heater.

loss of 40%. Study showed that in a new design it should be possible to reduce these to 10% and 2%, for a total of 12%. This is accepted as reasonable since the greater part of these losses would go to the cyclone cooling water and not, in fact, be wasted.

Modifications to the Plant

Towards the end of the first series of tests it was possible to review many of the results mentioned above and as a result the decision was taken to stop the tests and make some modifications. These were confined to the furnace and heater. A new design of furnace (Fig. 1) including all the information gained was put in hand in the expectation that heat losses would be reduced, slag removal facilitated, and carry-over reduced. The heater was rebuilt as a simple counterflow unit using as much as possible of the original material. (Fig. 2). Full advantage of the information gained could not be taken as it was not practicable to rebuild it as an air tube heater. Sets of tubes of twelve different materials were included to get direct comparative performance, and although it was expected that some purely mechanical troubles would develop owing to the difficulty of matching different expansion rates exactly, this was regarded as a small penalty to pay for the information on tube corrosion resistance that will be gained. The information gained from pressure loss and thermal measurements was employed to reduce the losses.

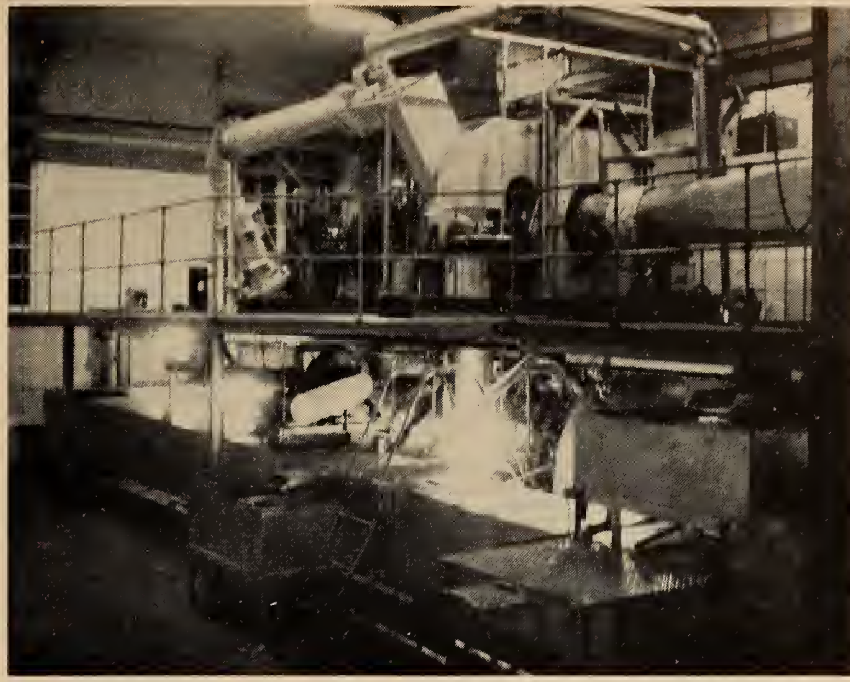

Fig. 3. General view of the rebuilt plant.

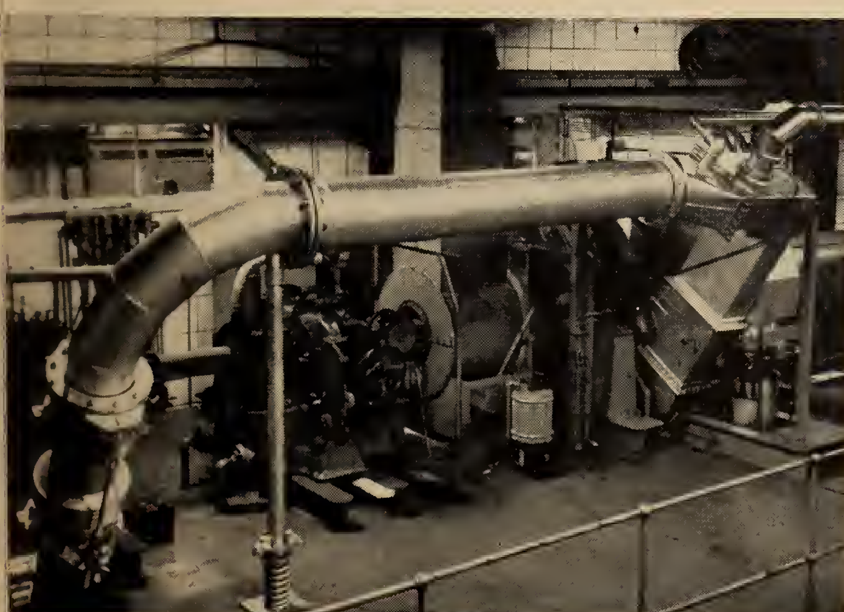
In the actual rebuild of the plant, the opportunity was taken to omit one of the original heat exchangers which converted the operating thermodynamic cycle to one which investigation shows is easier to apply in a locomotive than the original cycle. Figures 3, 4 and 5 show the plant in its present arrangement.

During the time in which the plant was being modified, extensive series of rig tests were run on coal feeding screws, slag removal systems, and model heat exchangers. In addition, a detailed estimate of the anticipated performance of the rebuilt plant was carried out.

Fig. 4. View of the machinery line of the rebuilt plant.



Results With The Rebuilt Plant

The rebuilt unit was ready for test on 8th January, 1956. After preliminary "shake down" tests the furnace was modified to give improved slag drainage. At this stage the general performance of the plant was much better than ever before. Exceedingly steady running was achieved, proving that the development of the screw feeder was well merited. The heat and combustion losses of the furnace were reduced to about 15% and the heat losses from hot casings were reduced to about 1%. We still have the loss of about 9% in the heat exchanger tube plate cooling which is inevitable with the gas tube heater. The pressure loss of the heat exchanger agreed with that predicted, and as far as we can tell so far, the performance of the plant is in close agreement with the predictions.

Further minor modifications were made to the furnace as running continued, in order to secure long periods of non-stop operation without continued attention. The initial target of 100 hours uninterrupted furnace operation has now been achieved.

A total testing period of 485 hours has been run in this series, including one run of 102 hours without any interruption or stop whatever. At the end of this period the heater was dismantled to remove tubes for metallurgical examination. Detailed results are not yet complete, but, and most important, analysis of the tubes of type 446 ferrite steel shows no signs of chemical attack, and only slight erosion due to the excessively high velocities necessitated by the plant conversion.

Conclusion

The above is necessarily a very attenuated description of the major results achieved. We believe, on the basis of the work so far done, that we have shown that the exhaust heated machine is practical. Although the cyclone furnace is not the only, nor in some applications, the best type of furnace to employ, we have had good performance from it. We feel that we now know how to design a heater, and what materials to employ, although we recognize that 750 hours of test is no substitute for 10,000 hours of operation.

Our studies of the possible applications, combined with studies of the economics, convinces us that there is indeed a niche for the exhaust heated machine, in which it will be a useful member of the family of prime movers. The only step remaining is to confirm our findings of 750 hours test experience and our studies, by submitting the prototype of an "industrial" engine to prolonged operating conditions.

High Capacity Piles

for the Support of a Large Basilica

J. C. Brodeur, JR.E.I.C.

Spencer, White & Prentis of Canada, Ltd.

The Basilica of Notre Dame du Rosaire, at Cap-de-la-Madeleine, Que., is a large octagonal structure with a 242-foot high eight-sided dome. The walls of the building and the dome are supported by high capacity pipe piles, of sixteen and twenty-inch diameter. The paper describes the installation of the foundations from soil investigations to final testing.

ONE OF THE largest and most complex foundation jobs award-d in Eastern Canada in recent ears was completed by the author's ompany. It is for La Basilique Notre)ame du Rosaire, at Cap-de-la-Made-eine, Quebec, on the bank of the t. Lawrence River; this famous hrine was developed over the years y the Oblate Fathers of Mary-Im-naculate. The basilica will rise on ne former site of the 3000-ton four-ory monastery, which was moved ngeniously on 300,000 steel ball earings some 261 feet to a new te in 1949 by the same foundation rm.

The walls of the structure will be n the shape of an octagon, 175 feet n diameter. From these walls, an ight-side dome will rise to a height f 242 feet. This massive dome will e supported by eight columns, each f which will support 1,050 tons. A luster of piles under each column ill carry the weight some 90 to 100 eet below the ground surface.

Since even a slight settlement of ne structure could mean extensive amage to the dome, the architect, wners, and consulting engineers felt nat the underground work should e handled by foundation specialists ith the experience essential to the roper installation of high-capacity iles. All soil borings, taken at ran-om over the site, clearly indicated ne soil characteristics — a 15 foot and layer underlain by a 75 to 80 oot stratum of highly plastic clay, n turn overlying 8 feet of gravel, and and clay mixture (hardpan) and 2 feet of fissured rock. Due to the existing soil conditions, the heavy loads to be supported, and the nature of the structure, the foundation was designed for twenty-inch diameter pipe piles, loaded to 206 tons, and sixteen-inch diameter steel pipe piles loaded to 150 tons to be driven open-end through the existing soil strata and finally to bedrock. The carrying capacity of the steel cylinders on rock was based on the following formula:

$$P = 0.25\, f_c \times A_c + 9000 \text{ psi} \times A_s$$

Where P = maximum load, lb.

f_c = compressive strength of concrete (28 days)

A_s = area of steel.

A_c = area of concrete

The cylinders consist of electric-welded steel pipe with wall thickness of 0.344 inch driven by a Vulcan No. 1 single acting pile-hammer (5,000 lb. ram, 36 in. stroke), delivering a blow of 15,000 ft.-lb. When the bottom end of a pipe pile had been driven to rock, a small diameter jet pipe, 100 feet long, was lowered into the pipe. With successive bursts of air at 100 pounds per square inch pressure, the contents of the pipe pile were spewed out, with clay often being ejected in fifteen-foot lengths.

As the bottom of this jet pipe approached the rock, water was poured into the pipe pile and again bursts of air through the jet pipe carried up loose rock, gravel and clay, and cleaned the inside of the 100-foot-deep cylinders. Next a churn drill was lowered into the pipe to pulverize the rock for a depth of two feet, creating a socket for the bottom of the steel pipe. In order to seat the bottom of the pipe pile firmly on a clean horizontal rock surface, a series of two or three blowing and re-driving steps was carried out. The bottom of the pile was then visually inspected by the owner's representative on the site, the resident engineer.

At this stage, in several selected locations, a fifteen-foot diamond-drill rock core was obtained from the bottom of the pile. Laboratory tests on these cores revealed compressive strengths of 4,000 pounds per square inch, well in excess of the design load to be carried. With the inspection completed, the pile was then filled to the top with 3000 p.s.i. concrete. Three standard test cylinders were taken from each pour, cured on the job, then sent to the laboratory for testing. The test results, in all cases, exceeded the requirements specified. Concrete was placed continuously and in one operation to prevent cold joints or separation of the ingredients.

Due to the character of the rock, it was not always possible to secure a dry cylinder through redriving. The flow of any material was always stopped, but water leaked into the piles. For such conditions, it was found impractical to entirely remove the water from the bottom of about 30 per cent of the piles, and in accordance with the specifications a bottom dump bucket was used to install the concrete under water.

Prior to any concreting, each pile was checked for location and plumbness. All piles were found to be within the standard practices and tolerances permitted by the specifications; i.e., plumb within two per cent of the length of the pile, and the top of the pile within a maximum of three inches of specified location.

Pipe came to the job in double-random lengths of 45 to 50 feet and sections were joined in the field. Splices were made as the pile was driven, and consisted of external cast steel plate bands or tight fitting sleeves, welded top and bottom to the two lengths of pipe after their ends had been tightly butted together. The splice bands were attached to the lower end of the pieces as the pipe lay in a horizontal position. As driving proceeded and additional pipe was necessary, it was set in the leads and welded to the section below, a skilled welder requiring only 8 to 12 minutes to attach a joint. The low percentage of damaged pipe was due largely to the use of a heavily-framed, rigid pile-driving rig whose operation was directed by experienced men. Great care was exercised to keep the hammer ram always striking exactly in line with the axis of the pile and with the blow centred directly over the pile section.

Due to the physical conditions of the material through which the piles had to be driven, a 12 inch long steel band of the same wall thickness as the pile was welded to the outside bottom of each pile to reinforce the cutting edge.

Table I gives a complete record of piles No. 163 and 118 that were load-tested.

Piles Load Tested

Before continuous pile driving began, one 16-inch and one 20-inch pile were load tested. The piles, designed for 150 and 210 tons respectively, were subjected to a test load 50

Table I. Record of Piles for Load Test

Pile:	No. 163	No. 118
Diameter of cylinder	16 in.	20 in.
Wall thickness of cylinder	0.344 in.	0.344 in.
Length of pile	91.44 ft.	93.33 ft.
Alignment of pile	¼ in. North 2 in. West	½ in. North 1⅛ in. West
Verticality of pile	0.27%	0.40%
Penetration	20 blows/¼ in.	40 blows/1 in.
Strength of concrete after 2 days	4880 psi.	3535 psi.

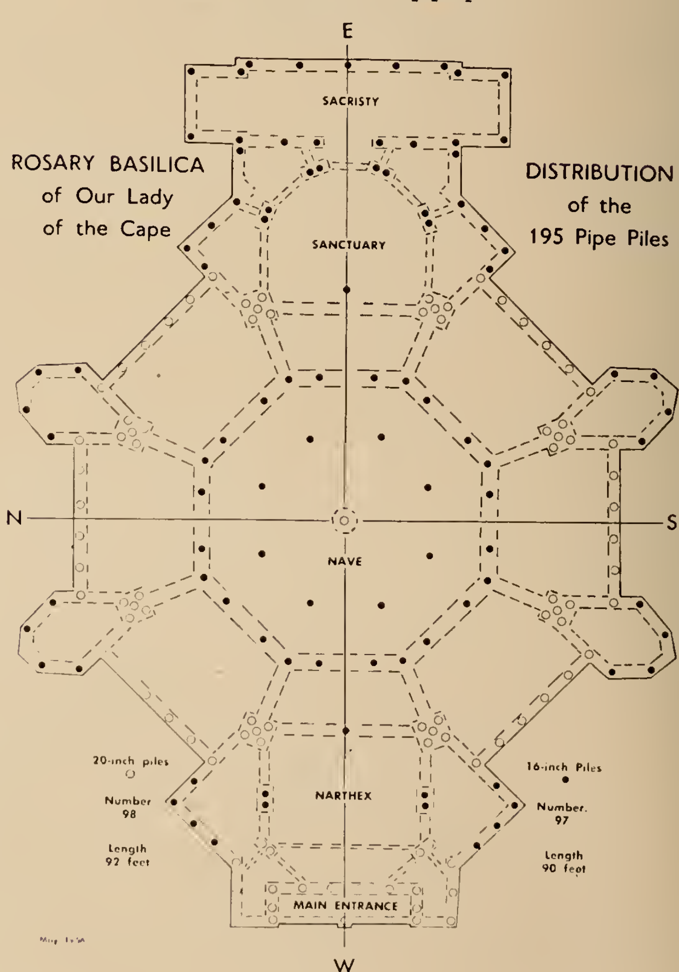
Fig. 1. Distribution of pipe piles.



er cent greater than the design ıpacity. To assure accuracy of reılts, two and three 8-inch hydraulic cks were used respectively on the 6-inch and 20-inch pile. Two presıre gauges, checked in the laboratory rior to the load tests and calibrated ı pounds per square inch, were inorporated into the system to asıre further accuracy during the sts, since the maximum permissible ttlement for each type of pile was ot to exceed 0.0017 inch per ton fter corrections for elastic deformaon. This exceeds by far the reuirements of the National Building ode of Canada.

Jack reaction was secured through load consisting of a platform of 48 ieces of 10 in. WF @ 49 lb. beams ach 40 feet long. Next 164 pieces f reinforced concrete slabs, 10 ft. y 3.5 ft. by 0.67 ft. were placed ver the beams. The concrete slabs ad been used previously as runways or moving the monastery and the ontractor was fortunate to have them vailable. The ends of the wide flange eams rested on 12 x 12 timber locking, 15 feet long, resting on the round. Two-inch steel plates were laced on the test pile and on the ıcks. Resting on the top plate above ıe jacks and bearing on the WF eel platform were two 36 inch VF @ 182 lb. beams bolted toether and reinforced with 1 x 4-in. iffeners.

The load was applied gradually nd the settlements observed. Total oad was kept for twenty-four hours nd settlement of the piles was reorded after each hour. Permissible ettlement for the 16-inch pile was 4/64 inch, and 33/64 inch for the 0-inch pile. The total net settlements bserved were 9/64 and 15/64 inch espectively.

Table II gives the results of the oad tests on the two piles.

Grouped in Table III are the charcteristics and the results of the load ests carried out on the two piles.

After a detailed study of the load est results, and when a two-day wait

showed no further settlement, the engineers were satisfied with the method and knew that the pipe piles were adequate to carry the loads of the future basilica. Work then proceeded with the driving of the remaining piles in the same way.

Five 20-inch diameter pipe piles are located in a cluster under each of the eight main piers that will support the dome, and each of these piles supports 206 tons. Additional sections of the basilica will be supported similarly by concrete-filled pipe piles, 16-in. in diameter, each of which will support 150 tons. In all, ninety-eight of the larger and ninety-seven of the smaller pipe piles were driven.

Because of the unusual design, no columns will be visible in the basilica. The nave will accommodate some 2,000 seats, and an additional 6,000 standing can be accommodated in the rear and in the wide aisles. The altar will be clearly visible from every seat.

Acknowledgments

The foundation work carried out for the owners, the Oblate Fathers of Mary-Immaculate at Cap-de-la-Madeleine, Quebec, was under t supervision of architect Adrien D fresne, of Beauport, Quebec, ai the consulting engineers, Survey Nenniger and Chenevert, of Moı real. The resident engineer for t consultants was Jacques Clero Consulting engineers for the mecha cal installations are Tasse, Sarault Associates, of Quebec, P.Q. The e cavation work was carried out by P. Morin Ltée of Cap-de-la-Mac leine. Vincent Fahey was general s perintendent and Harold Ahlberg w in charge of pile driving for Spe cer, White & Prentis of Canada, L

The Kelowna Floating Bridge

W. Pegusch, Jr.E.I.C.
Swan, Wooster & Partners, Vancouver.

Paper to be read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June 1957.

This paper describes in some detail the design and construction of the Kelowna floating bridge, which will cross Okanagan Lake to complete the main north-south route (B.C. Highway 97) through the Okanagan Valley in the southern part of British Columbia. Pictures of the progress of construction are to be shown when the paper is presented at the 1957 annual meeting, and it is proposed to illustrate this progress in later issues of the *Engineering Journal.*

THE KELOWNA floating bridge is being constructed across Okanagan Lake, closing the last gap in B.C. highway 97, the main north-south route through the Okanagan Valley in the southern part of British Columbia. This highway runs from Osoyoos, on the U.S. border, to Salmon Arm, on the Trans Canada Highway. At present the traffic on this highway is mostly local, between the various communities on the lake, with very heavy summer tourist traffic to the Okanagan Valley and to the national parks in the Rockies. However, the highway is a direct connection between the north-western United States and the relatively undeveloped north of British Columbia. Its future importance will probably be directly connected with the growth of this large area.

The present highway, constructed to a very high standard, runs up the west side of Okanagan Lake from Penticton to Kelowna. At Kelowna the traffic crosses the lake on a car ferry and then continues north on the east side of the lake. The new bridge will replace the ferry at Kelowna.

The original report on the Kelowna Bridge, recommended the construction of a suspension bridge or a rockfill causeway rather than a floating bridge. On the basis of costs and aesthetics the design of a suspension span was started. At the same time a thorough subsurface investigation and a programme of aerodynamic stability tests were undertaken. Unfortunately the subsurface investigations, contrary to preliminary findings, indicated that it would not be possible to build a suspension bridge. The foundation material was found to be very compressible and highly susceptible to liquefaction under earthquake loading, a very unsatisfactory type of soil on which to found large piers and heavy cable anchorages. In addition, the shear strength of the material was so low that it could not support a rock fill causeway of the depth required. The final alternate was a floating bridge which derives positive support from its own buoyancy rather than the unstable material of the lake bottom. The lift span over the navigation channel is located towards the east shore where the foundation material is good enough to support the lift span piers.

The entire bridge project is over two miles long. This includes:

(1) One mile approach road, connecting the existing highway on the west side of the lake with the bridge site;

(2) 1400 ft. rock fill embankment out from the west shore;

(3) 175 ft. west transition span between the rock fill and the pontoon section;

(4) 2,100 ft. pontoon section;

(5) 175 ft. east transition span between the pontoons and the west main pier;

(6) 260 ft. lift span;

(7) 175 ft. east approach span from the east main pier to the rock fill embankment;

(8) 300 ft. of rock fill to the east shore;

(9) 500 ft. of approach road through city park in Kelowna.

Pontoon Section

The floating section consists of twelve reinforced concrete units, rigidly connected together, to form one continuous pontoon 2100 ft. long.

The six centre units each 200 ft. by 50 ft. in plan and 15 ft. high, are referred to as standard pontoons. At either end of these are two superstructure pontoons. The lower portion of these superstructure pontoons is identical with the standard type. However, to provide clearance for small boats under the transition spans, the roadway is gradually raised on these pontoons, by means of a steel superstructure.

At either end of the floating section is a smaller 50 ft. by 50 ft. pontoon, on which the draught is increased some 14 ft. to provide the additional buoyancy necessary to

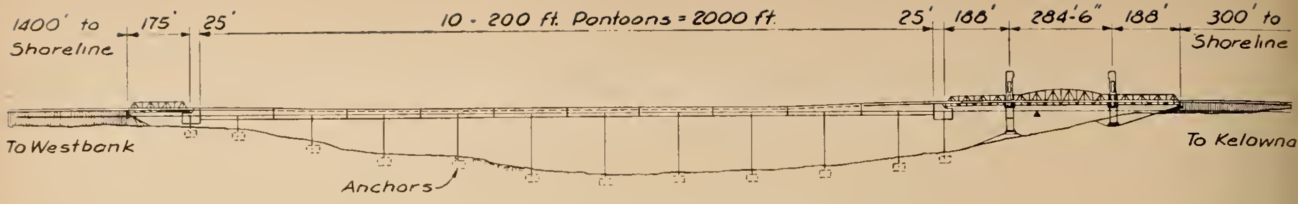

Fig. 1. General arrangement of the Kelowna Bridge showing the floating section and the steel trusses.

balance the dead load reaction of the transition spans that land at the centre of these pontoons.

The pontoons are all held in place laterally by heavy cables, running from the centre of each one to large concrete anchors embedded in the lake bottom. There is a cable and anchor on either side of each pontoon. The entire pontoon section is tied longitudinally to the west shore by a structural steel member suspended from the underside of the west transition span. This steel member is connected to a concrete anchor embedded in the approach embankment.

The top slab of the pontoon provides for a 36 ft. roadway, two 6 ft. sidewalks and two 1 ft. wide solid concrete handrails. Lamp standards, mounting mercury vapour fixtures, are set on top of the concrete handrail.

Standard Pontoons

As noted previously, the standard pontoons are 50 ft. by 200 ft. in plan and 15 ft. deep. The interiors of the pontoons are divided into quarters by three longitudinal walls and then transversely by a series of cross walls. This system of dividing walls forms a total of 56 cells approximately 13 ft. cubes. A group of four cells constitutes a watertight compartment. The four cells of each compartment are interconnected by openings, and access is gained by a ladder and a manhole in the sidewalk.

The top and bottom slabs are 8 in. thick and the sidewalls are 9 in. thick; all interior walls are 6 in. thick. Re-entrant corners are filleted 6 in., except at the intersection of the top and bottom slabs with the sidewalls, where the fillets are increased to 12 in.

The 4 ft. 6 in. solid concrete handrail is provided with a small return at its upper edge to deflect breaking waves down and away from the bridge.

The bottom slab is designed as a two-way slab subjected to hydrostatic pressure and the additional dynamic loading due to wave action. The top slab is also a two-way slab designed for AASHO H20-S16 loading. The sidewalls are designed for the hydrostatic pressure of the water and the pressure due to wave action. A longitudinal ice beam is provided at the waterline to strengthen the side walls against possible ice pressure.

Cables

The lateral loads to the pontoons governed the size and spacing of the anchor cables. Consideration of various factors, primarily possible ice movements, led to the selection of a bridge strand 3.2 sq. in. in area spaced at 200 ft. intervals. This arrangement is sufficient to withstand a wind and ice load of 1900 lb. per lineal ft.

The bridge strand is built up of 90 zinc coated wires 0.210 in. diameter and one centre wire 0.224 in. diameter. The average tensile strength of these wires is 225,000 p.s.i. and the yield strength is about 160,000 p.s.i. The ultimate strength of the completed strand is 350 tons. All completed cables will be prestretched with a load of 150 tons, marked and cut off to length when stressed to 20,000 p.s.i.

The water level in the lake is controlled between El. 1119.0 and El. 1123.0. This four foot change in elevation is accommodated by stretch in the anchor cables. Since the depth of water at the floating section varies between 20 and 160 ft., the anchor cables will vary in length causing different minimum and maximum stresses in all the cables. To make the stress variation in each cable the same, a simple equation was set up relating the cable angle to the depth of water with the particular stress variation selected. The cable stresses were set at 20,000 p.s.i. when the lake is at El. 1119.0 and 70,000 p.s.i. when the lake is at El. 1124.0. This leaves a reserve safety factor in the cables to provide for the exceptional time that the lake level goes above El. 1124.0. The calculated cable angles vary between 8 deg. to the horizontal in the shallow water to 18 deg. in the deepest water.

Cable Attachment

The cables are attached to the cross wall at the centre of each pontoon. This cable wall is divided into an upper and lower part by a slot running the full length of the wall (see Fig. 2). The upper part is 12 in. thick and the lower part 8½ in., enlarged to 12 in. immediately below the slot.

The cable enters the pontoon through the cable port where it passes over the outer saddle assembly. This outer saddle increases the slope of the cable to get it above the water line and in addition accommodates the variation in cable angles. Approximately 6 ft. inside the pontoon the cable passes through the stuffing box and over the inner saddle assembly. The stuffing box will make the cable port almost watertight. Any water that does enter will be retained in the cable well and drained at any time that it is necessary to inspect or work on any of the parts submerged in the well. The inner saddle gives the cable a more horizontal inclination and thereby increases the length of the cable track. The cable socket is then attached to the socket shoe which bears against two plates. These bearing plates are adjustable and can be attached at any point on the cable track.

Saddle Assembly

The inner and outer saddle assemblies are identical except for one cable keeper that is left off the outer saddle assembly. This is necessary since the cables are not tangent to the outer end of that assembly. When the cables are first inserted into the pontoon the cables are bedded in the saddle grooves but not fastened down. The saddles are keyed to the rockers and the cable slides in the saddle groove as the cable slack is being taken up. When the cable is in its final position the cable keepers are installed and the keys removed. Any relative movement that takes place after final positioning will be between the saddle and rocker.

Jacking Assembly

Cables on opposite sides of the same pontoon are installed simultaneously. By careful adjustment of the stress in these two cables, the pontoons are positioned on the bridge centre line.

The cables are stressed by means of the jack bearing against the rear jacking assembly. When the cable has been taken up 3 in. the bearing plates are removed from the cable track and brought up in contact with the socket shoe. The load is then transferred from the jack and rear jacking assembly to the shoe and bearing plates. The rear jacking assembly is loosened, moved up 3 in. and the jacking started again. This operation is repeated until the cable is stressed to the desired amount. The final cable stress will depend on the level of the lake at the time the stressing is done (20,000 p.s.i. at El. 1119.0).

Pontoon Connections

The detail of the pontoon connection is shown in Fig. 3. The two 3 ft. by 3 ft. shear keys, centred on the two intermediate longitudinal walls, are temporary connections to hold the adjacent pontoons in line while the permanent connections are being made. Steel shims are placed around the perimeter of each key to align the pontoons exactly. The pipe sleeves along the bottom and up the sides of the pontoons are tapped and provided with plugs to prevent water from entering while the pontoons are being floated into position.

When the pontoons have been brought together the bolts under the roadway slab are installed and the 1-in. grout space unwatered by removing the plugs from the lower pipe sleeves. The rubber strip at the bottom of Fig. 3 is continuous along the bottom and up the side of the pontoons and seals off the 1-in. grout space. Large ½-in. spacers centred on each longitudinal wall keep the pontoons 1 in. apart while the remainder of the bolts are being installed.

During this phase of the connecting operation all the bolts are just stressed enough to maintain the 1-in. grout space. A non-shrink type of grout is placed through the top of the grout space and the top 2 or 3 inches finished off with an ordinary sand cement grout.

When the grout has set up, the bolts, made from high tensile steel (ASTM A-325), are stressed to 72,000 p.s.i. There is a total of 146 1¼-in. diameter bolts per connection, and when they have all been tensioned to their specified amount we have, in effect, a very short prestressed beam.

Before making the connections with the end pontoons, they have to be ballasted with water so that the end connections will line up. The weight of this water ballast will be equal to the dead load reaction of the steel transition span.

Pontoon Analysis

When the pontoons are all positioned and connected together they will act as one continuous unit 2100 ft. long. This long pontoon, floating in the water, is a perfect example of a beam on an elastic foundation.

The usual problem of an elastic foundation involves the rather debatable and uncertain properties of a soil foundation. However, in this case we have a perfectly elastic foundation; in other words the material follows Hooke's law. A downward deflection of any part of the pontoon increases the buoyancy and produces an upward reaction, proportional with the displacement. Similarly an upward deflection decreases the buoyancy and produces a downward reaction. Of course in this case we are concerned only with displacements and reactions relative to the initial unloaded condition. Hetényi[1] has investigated this theory very extensively and has developed nu-

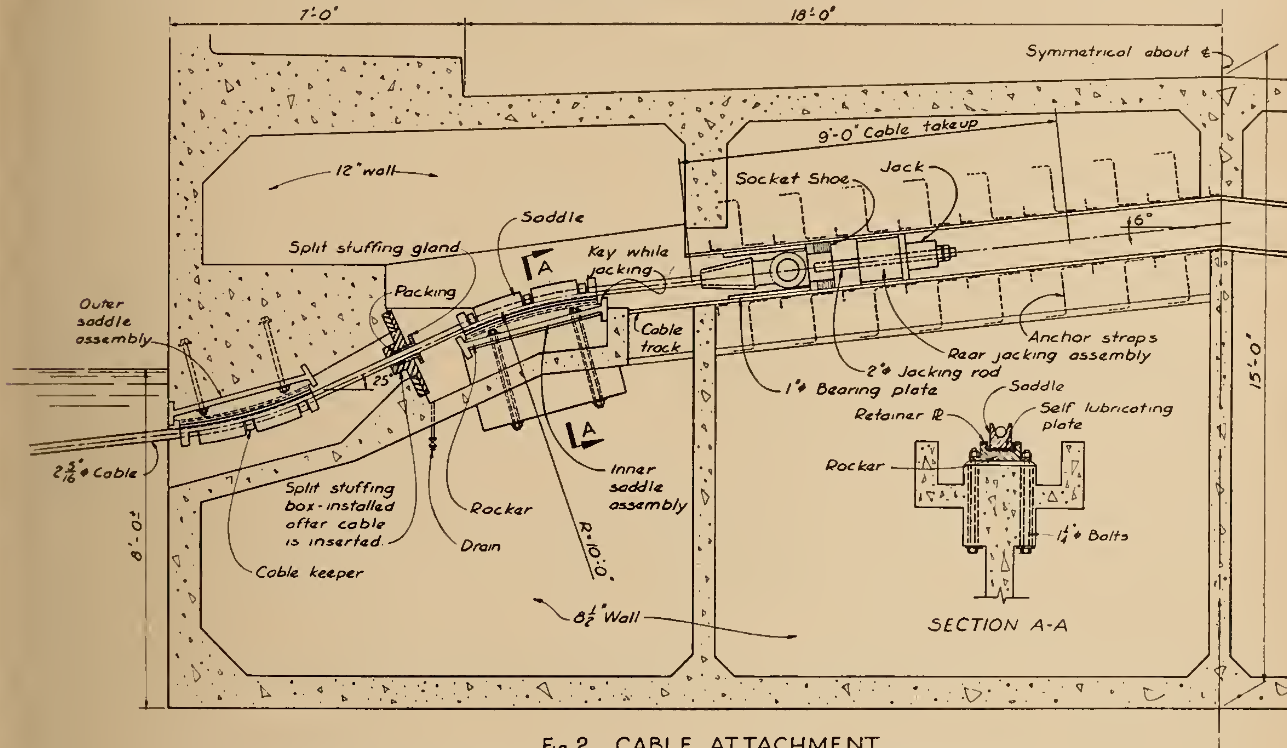

Fig. 2. Cable attachment at the centre cross-wall of each pontoon, showing the jacking assembly and cable saddles. The cable is adjusted with a 100 ton jack.

merous formulae which helped a great deal in analysing the pontoons. Using these formulae, influence lines for moment and shear were set up for 100 ft. intervals along the bridge.

Figure 4 *(a)* shows the pontoon subject to a point load at its centre. The curves *(b)*, *(c)* and *(d)* are, respectively, the deflection, moment and shear. From the examination of the curves of Fig. 4 it can be seen, that if at point 1 a force P_1, and a point 2 a force P_2 are acting, the deflection at 2 due to the load at 1 is equal to the deflection at 1 due to the load at 2, i.e. $Y_{1,2} = Y_{2,1}$. Similarly $M_{1,2} = M_{2,1}$ and $Q_{1,2} = Q_{2,1}$. In other words the curves of Fig. 4 are actually the influence lines for the point under consideration. These curves are used in the centre section of the bridge but are modified, very simply, to investigate points close to either end.

Pontoon Loading

If the weight of the pontoon were uniformly distributed along its length, the dead load would not induce any stresses. However we do have certain concentrations of dead load at the cable wall, end connections and superstructure pontoons. In addition the vertical components of the cable reactions apply a series of point loads to the pontoons. The stresses resulting from these loads were considered as dead load stresses.

Live load stresses were calculated using the AASHO H20-S16 lane loading, with appropriate reductions for loading of multiple lanes.

Because of difference in temperature between the air and water at various times of the year, it was assumed that the temperature of the upper and lower surfaces of the pontoon could differ by 25°. This temperature differential tends to bow the pontoons up or down depending on which surface is at the higher temperature. If the deformation were not restrained, no stresses would be induced in the pontoons, but since the deformation alters the buoyancy along the length of the pontoon, the bowing is restrained and temperature stresses are set up in the pontoons.

The longitudinal forces applied to the pontoon section are taken by a structural tie at the west abutment. This tie is connected about 15 ft. above the centre of the pontoons and hence applies a moment to the end of the pontoon section. We therefore have bending stresses as well as direct tension or compression due to the longitudinal forces.

The combination of ice and wind was the only horizontal loading investigated. This combination is much more critical than the loading due to wind and waves which is the only other loading possible. The ice

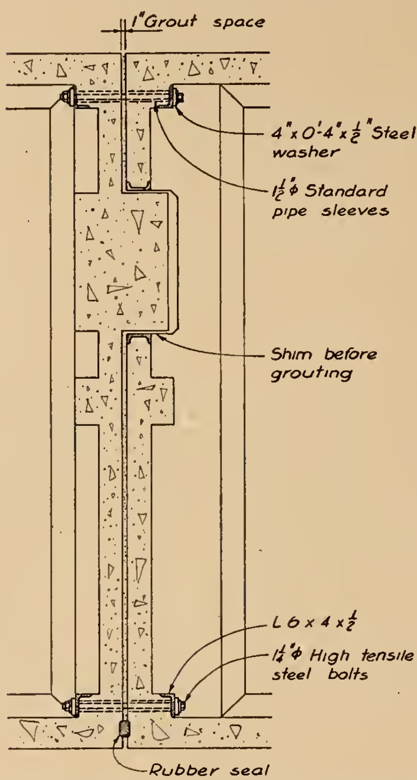

Fig. 3. Pontoon connection showing the 3 ft. square keys and the 1¼ in. diameter high tensile steel bolts.

and wind loading was assumed as a moving load of 300 lb. per lineal ft. due to the wind and 1600 lb. per ft. due to the ice.

Anchors

Each pontoon cable is fastened to a large 20 ft. by 32 ft. concrete anchor embedded in the bottom of the lake. These anchors, as shown in Fig. 6, are rectangular plates with slight folds toward either end and two tapered ribs connecting the plate to the cable fastening. The anchors weigh approximately 70 tons each and are buried 20 ft. below the bottom. Jet pipes are provided along the length of the anchor to assist in the sinking. The anchors are designed to resist the ultimate load that can be taken by the cable. As a check on this design, the first set of anchors will be tested by applying a test load of 220 tons, some 40 per cent over the working load. This test will be made by ballasting one of the end pontoons with water and then making a temporary connection to the cables. The ballast will then be removed to apply the test load to the anchors.

Construction Plant

The pontoons will be built in two graving docks specially constructed for this purpose. The graving docks are located on the east shore of the lake approximately one half mile north of the bridge site. The north graving dock is 60 ft. by 210 ft. in plan, with its bottom 17 ft. below the surrounding ground. The other graving dock is parallel and 200 ft. south. The bottom of this south graving dock is 19 ft. below the surrounding grade.

The sides of the graving dock are allowed to assume their natural slope and the working area kept unwatered with a well-point system around the perimeter of each dock.

The timber bottom of the graving dock is supported on five rows of piles centered under the longitudinal walls of the pontoons. A system of 12 by 12 caps and 4 by 12 stringers on top of the piles are decked in with 4 x 12 planks. These planks will be covered with a heavy building paper and will serve as the bottom forms to the pontoons.

Running along each side of the graving docks are two rows of piles which support a working platform and a runway for the concreting gantry that spans each graving dock. These piles will also be used to brace the outside forms of the pontoon sidewalls.

On either side of the graving dock excavations, provision is made for four 30 ft. crane runways. Mobile cranes operating from these runways will place forms, reinforcing steel and transfer concrete to the concreting gantry. The remainder of the space between the graving docks and two 60 ft. by 200 ft. areas on either side, will be used for storing wall forms.

Concrete Plant

Concrete for the project will be supplied from two 2-cu. yd. mixers. The mixers are part of the completely integrated concrete plant specially set up for this contract. The 150 ton aggregate bin on the concrete plant is charged with a 24 in. belt conveyor. This aggregate bin is divided into separate compartments to store five different sizes of aggregate. Bulk cement will be stored in a 2000 cu. ft. circular silo. Automatic batching equipment will weigh

The five aggregates and cement preparatory to charging the 2-cu. yd. tilting mixers.

The mixers will discharge the concrete into bottom dump concrete buckets, sitting on flat bed trucks, and the trucks will carry the concrete buckets from the plant, to a point opposite the concreting gantry. At that point the buckets will be picked up by a mobile crane and swung over the concreting gantry where the concrete will be deposited into a hopper on the gantry.

The concreting gantry will be of heavy steel truss construction and will travel the full length of the graving dock. Concrete will be transported in concrete buggies from the main hopper at one end of the gantry to small chutes fastened on either side of the gantry. From the chutes the concrete will be discharged through elephant trunks into the pontoon forms.

As the concreting gantry moves along the pontoon, concrete will first be placed in the wall forms to a depth of about three feet. This concrete is placed from the leading edge of the gantry and will spill out through the bottom of the wall forms to a distance of about two or three feet. From the trailing edge of the gantry the remainder of the bottom slab and the walls to the underside of the roadway fillets will be poured. The first concreting operation will precede the second by about 20 minutes. This continuous pour of bottom slab and walls will require about 800 cu. yd. of concrete.

Before the pontoon is removed from the graving dock, the roadway and sidewalk slabs will be placed. Pouring of the handrail and erection of any superstructures will be done at the outfitting wharf when the pontoon has been floated.

Pontoon Formwork

Each graving dock has its own set of prefabricated wooden forms. The formwork for each cell consists of four separate panels with removable bracing at each corner. The corner closure is made with a strip of plywood that forms the fillets at the wall intersection.

A mobile crane is used to install the forms to alternate cells, after the bottom slab steel has been placed. This checkerboard arrangement of cell forms provides support for the wall steel which is then placed.

Each wall panel when it is first installed is supported by linkage bars to two 6 by 6 posts. The forms are supported in this manner until just before the concrete pour is begun. As a final operation the forms are raised about 1 in. by means of small screw jacks attached to the forms and supported on concrete blocks.

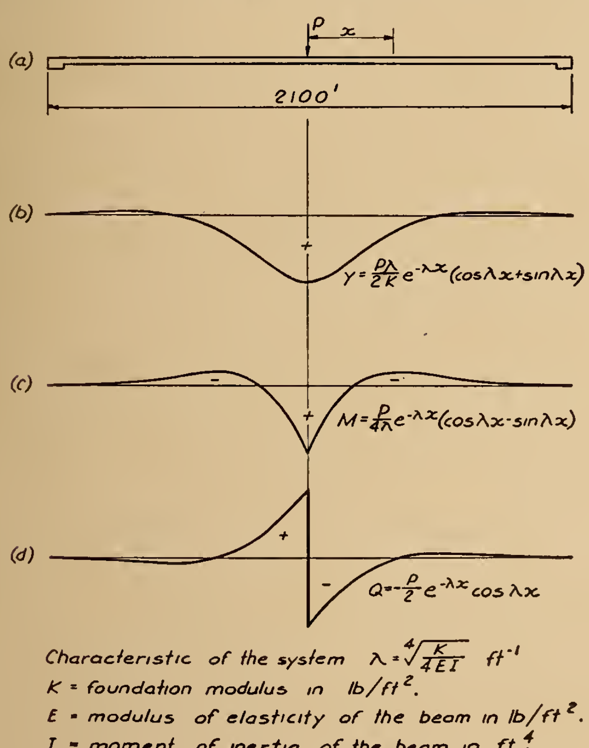

Fig. 4. Beam on an elastic foundation. These curves show the extent over which a point load exerts any influence.

As the forms are raised the linkages fall loose from the 6 by 6 posts and the posts can then be removed.

The panels of the cell forms are removed individually by the mobile crane and placed in the form storage area adjacent to the graving dock. The pressboard form for the roadway slab is supported on a light wooden grillage and four timber posts at the quarter points of the panel. This wooden grillage is collapsible and can be easily removed through the access doors and sidewalk manhole.

Main Piers

The west main pier has a 42 ft. by 93 ft. base which tapers to a 28 ft. by 80 ft. 6 in. section, 7 ft. 6 in. above the bottom. This rectangular section continues up to the second transition 48 ft. above the base. At this point, both ends of the pier are changed to a semi-circular section. This section continues to the underside of the cap. Total height of the pier is 85 ft. 6 in.

A centre longitudinal wall and six cross walls divide the inside of the pier into fourteen 10 ft. by 12 ft. cells. The bottom slab of the pier is 30 in. and all interior walls are 13 in. thick. Sidewalls are 18 in. thick for the lower 48 ft. and 15 in. for the upper section.

The pier will be carried on 390 fifteen-ton friction piles. These 80 ft. long untreated timber piles will be driven with an underwater driver and cut off within ±1 in. When the piles have been cut off, 4 ft. of gravel fill will be placed level with their tops.

The west main pier and the east main pier will be built as floating caissons. The base or launching sections will consist of the 2 ft. 6 in. bottom slab and 5 ft. of the vertical walls. Fastened to this concrete section will be 12 ft. of a 12 by 12 timber cofferdam. This timber cofferdam will provide the free-board required and also serve as the outside forms for the pier sidewalls; 2 by 4 spruce splines between adjacent 12 by 12 timbers will make the cofferdam watertight. The cofferdam is braced with one hundred and twenty-one 31.8 vertical wales in pairs and 12 by 12 timber strutting. The vertical wales run up the inside of the cofferdam and will be embedded in the pier walls.

This launching section will be constructed in the pontoon graving dock. To make this possible without additional dredging the dead weight of the pier is reduced by the installation of 1600 ft. of 14 in. diameter "Sonovoids". The addition of these "Sonovoids" reduces the draught of the launching section by about 4 ft.

The launching section will be floated from the graving dock and anchored at the pier site. Lifts of concrete and cofferdam will then be built until the freeboard of the pier is sufficient to discontinue the cofferdam. Continued construction of the pier shaft, and the admission of some water to the cells, will eventually seat the pier on its foundation. At this point water is to be admitted into the cells to the full height of the pier to preload the foundation. When a stable condition has been reached, water will be expelled from the cells and the remainder of the pier completed. During this preloading operation the piles will be subjected to a larger load than they will be required to carry when in service. When completed, the pier is kept partially buoyant by automatic controls regulating the water level inside the pier.

Except for a slight rearrangement of the interior walls; the east main pier is the same as upper portion of the west main pier. The pier is only 47 ft. high and therefore the rounded section was continued down to the top of the 87 ft. by 36 ft. base section. This pier is considerably shorter than the west main pier and as a result is supported on only 308 piles. In addition the cofferdam used during construction has to be removed since it would be exposed at low water.

A wood pile fender system extending 240 ft. north and south of the east main pier will prevent railroad car barges from grounding in the shallow water behind the pier.

Steel Superstructure

All the steelwork was designed for an H20-S16 trailer truck loading in accordance with the AASHO standard specifications for highway bridges and movable highway bridges with slight modifications for rivet or bolt spacings and thickness of cover plates on truss members. Structural carbon steel was used throughout for main members since the stresses nowhere would warrant the use of higher strength steels. The truss members and connections are designed for rivets or bolts while the main tower members are welded box sections with bolted field joints.

As the towers are the most prominent feature of the structure, they were designed as rigid frames with only one cross bracing frame at about mid-height to eliminate unsightly diagonal bracing. The lifting equipment is completely enclosed in a steel sheathed housing to enhance the tower's appearance.

Generally, the sections of the truss members were governed by the dead plus live plus impact stresses except for the end posts of the approach and transition spans where portals exist. The size of wind bracing members on the lift span and east approach span were generally governed by slenderness requirements, but the wind bracing of the two transition spans was governed by stress for reasons that will be noted later.

Lift Span and Towers

To keep the loads on the towers as low as possible the deck of the lift span was provided with a steel open grid roadway surface and lightweight concrete sidewalks. The open grid deck was supported on longitudinal stringers which are simply supported on the top flanges of the floor beams thereby providing access to the top flange of the floor beams for painting.

The trusses are 41 ft. 6 in. on centre and are of the Warren type with a depth of 38 ft. at the centre panel and 28 ft. at the end panel. The lifting beams are framed into the top joints of the end panels and connected to the counterweights by eight cables at each end of the beam. The beams are four feet deep with heavy webs well stiffened to resist the high shearing stresses. The centre portion of the beam, between lifting cables, has no web since shear is non-existent, but is trussed to support the flanges for moment resistance. The cables are connected by means of sockets to a heavy plate which bears directly on the underside of the bottom flange of the lifting beam.

The truss bearings are designed to carry the dead load only of the span as this load is greater than the live load plus impact. When the structure is in service the only loads on the bearings will be the live loads plus the small portion of the dead load which is not balanced by the counterweight. However, when the structure is not in service, such as during construction or maintenance, it will carry no live load and the bearings may then be required to carry the full dead load of the span for which they are designed.

The fixed bearing is of cast ste and is in two halves; the bearing p being fixed to the lower porti which is anchored to the pier wh the upper portion is connected truss and lifts off the pin when t truss is raised. The expansion be ing is a pin and rocker assemb the entire unit being connected the truss with only the base pl being anchored to the pier. Se lubricating bushings in the expansi bearings allow the rocker to assu a vertical position each time the sp is raised.

Four truss guides each 30 in. de are located at both ends of the sp, one at each of the upper and low joints. At the fixed end of the sp, the truss guides engage a conti ous runner which is bolted to a l extends the full length of the tow leg. The bottom guides at this e resist movement in both a late and longitudinal direction, and t top guides in only the lateral dir tion. At the expansion end of t span the truss guides will resist mo ment only in a lateral direction a will allow longitudinal movement expansion and contraction.

The clearance between the tr guide and tower runners is ¼ when the span is in the raised po tion, but as the span is lowered t clearance decreases to ⅛ in. which point the centre of the e floor beam engages a centring vice which positions the span in lateral direction for accurate se ing on the fixed pin and on the b plate at the expansion end. The tr guides are bolted to the trus through slotted holes to allow fine adjustment in the field.

To reduce impact on the lift sp towers and piers, buffers a attached to the floor beams n each bearing to decelerate the dov ward motion and allow the span settle gently on to the pier suppo. Shock absorbing bearing pads also used under the bearings to f ther reduce impact.

The towers are designed as ri frames in both directions with t legs and struts being of welded pl construction. The design of t frames perpendicular to the bri was governed by earthquake for and dead load at a 33 per cent crease in allowable working str while the frames parallel to t bridge were governed by stres due to 30 lb. wind and dead l at 50 per cent increase in work stresses. The front legs, adjacent the lift span, carry a very high axial load, about 80 per cent of the sheave reaction, but they are the same cross section as the rear legs which carry a smaller axial load but have a much higher eccentricity.

Lift Span Machinery

The vertical lift span will be raised 45 ft. to give a vertical clearance of 60 ft. above high water. The

In order to keep the span as light as possible it was decided to locate the drives in the lift span towers. These tower-drives could be described as counterweight - sheave drives. That is, the bridge is moved either up or down by suitable gearing from the electric motors to the rim of the counterweight sheaves.

The two motors on each tower are coupled to the opposite ends of shaft. The slipping coupling provided will prevent this type of overloading. The slipping coupling will also permit adjustment of the seating of opposite sides of the span. This adjustment will be necessary to compensate for unequal creep or stretch of the lifting ropes and will also be particularly useful when the bridge is being aligned during construction.

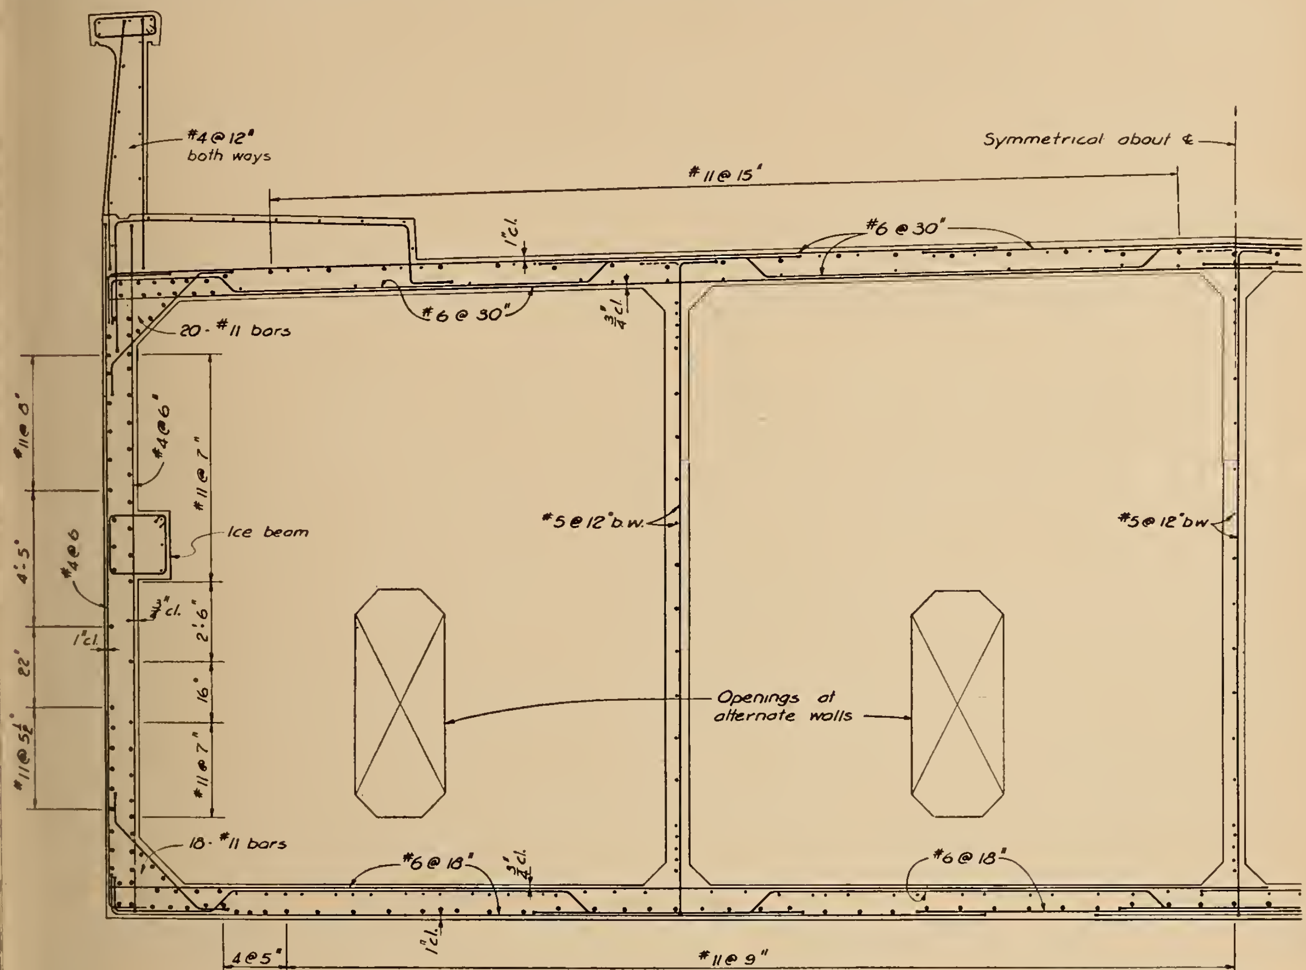

Fig. 5. Typical reinforcing of pontoon section

lift span, weighing approximately 500 tons, is suspended at each corner by eight 2-in. diameter special plough steel wire ropes that pass over sheaves 12 ft. in diameter. These ropes are connected at one end to the cross girder between the top chords of the two trusses and at the other end to the concrete counterweight. The concrete counterweight moves up and down inside the tower and to compensate for the weight of the lifting ropes, a cast iron counterweight chain is fastened to the bottom of the counterweight and to the tower. In this manner the system is balanced for all positions of the lift span.

the high speed shaft of an enclosed gear reduction unit, located at the centre of the tower. The main cross-shafts extend from each side of the gear box to an open gear reduction at their outer ends. A 7 in. diameter intermediate shaft carries the main drive pinion meshing with a ring gear integrally cast with the counterweight sheave.

The main cross shaft carries an overload slipping coupling. Under normal conditions equal power is transmitted to both cross-shafts. However, if one side of the lift span should jam, and the other remain free, all the power from both motors would be transferred to the one

The main cross shaft carries a shaft brake consisting of a 19 in. diameter cast iron brake wheel with spring set, solenoid operated jaws. This brake holds the bridge in the open position against the forces of ice and wind. The brake is normally closed and will only be released when the span is being moved.

The cast steel counterweight sheave, together with its 17 in. diameter shaft, weighs approximately 25,000 lb. The shafts rotate on spherical roller bearings. In fact, roller bearings are employed throughout the design and their use reduced the power requirements by one third.

The wires of the 2 in. diameter

ropes are of special improved plough steel. The ropes are of 6 x 19 construction with an impregnated hemp core. These ropes will be prestressed and cut to length in order to avoid extended field adjustments. Provision is made for small field adjustments to equalize the rope tensions.

The bridge operation is a completely automatic variable voltage tower drive and is controlled by the operator from his station in the east tower, just above the roadway. The opening sequence is started when the operator pushes the button that closes the traffic gate. All other necessary operations follow automatically until the span is in the raised position. The operator again pushes the button to close the bridge and when his panel indicates the bridge is locked in the closed position, he pushes another button to open the traffic gate.

Power is supplied at 440 volts to the motor generator sets in each tower. Each generator then supplies direct current at 230 volts to the two drive motors in each tower. The drive motors are of such a size that the span can be raised or lowered with only one motor at either end operating.

Sufficient indicators and warning lights are provided on the control panel to show the operator that the entire opening and closing operation is proceeding satisfactorily. In particular a selsyn control is provided to indicate and align the position of the opposite ends of the span. This control will disconnect the drives and sound an alarm if the skew becomes excessive.

Transition Spans

The transition spans and the east approach are very similar in side elevation and the main truss members actually carry the same stresses with the exception of the end posts. The similarity ends here, however, and the bracing members, connections, and bearings are quite different on these two types of spans, due entirely to the flexible supports provided by the end pontoons. These supports allow four types of motion: longitudinal, due to temperature, currents, live loads and wind; lateral, due to currents, wind and ice; vertical, due to live load and change in water level; and a torsional motion, due to lateral wind and unbalanced lane loading. The magnitude of these movements is greatest at the pontoon or free end support of the east transition span, the totals being 21 in. longitudinally, 30 in. laterally from the centre line of the bridge, 62 in. vertically, and a torsional movement of 9½ in. from the centre line of the bridge.

The transition spans are designed to allow for all these movements with the main trusses always in a vertical plane. To accomplish this it was necessary to pin the span horizontally

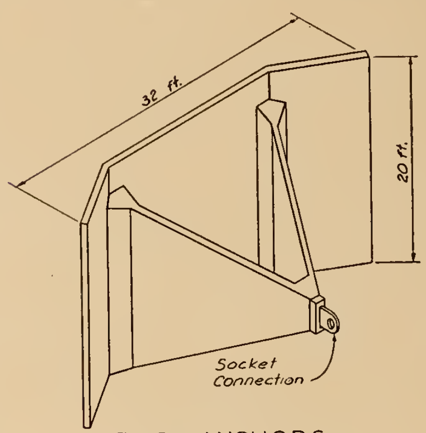

Fig. 6. Anchors embedded 20 ft. below the lake bottom provide lateral stability for the pontoon section.

and vertically by means of a universal pin on the centre line of the bridge at the pier and abutment supports (non-moving) and to allow the free ends of the spans on the pontoons to swing laterally and vertically and make all bearings of the rocker type that would allow longitudinal and torsional movements.

The bearings at the free ends of the two transition spans (pontoon ends) are composed of three steel castings that house two pins, one vertical pin and a universal pin (see Fig. 7). The lower casting is a rocker which rotates on the universal pin, the lower section of the pin being horizontal and perpendicular to the bridge length. The rocker bears on a bed plate to which is attached a toothed rack which meshes with gear plates bolted to the sides of each rocker, thereby preventing longitudinal displacement of the bearing. A cast steel shoe which bears on the upper portion of the universal pin is provided with a vertical steel pin about which rotates the upper steel casting, which is bolted to the truss. The moving contact surfaces are provided with self-lubricating bushings. These bearings thus allow movement in three directions, a longitudinal and lateral rotation about the universal pin and a horizontal rotation about the vertical pin, and therefore satisfy all requirements at the pontoon bearings.

Since these bearings will transmit only vertical loads, it was necessary to provide a special wind anchor to resist the lateral wind loads. The anchor must allow longitudinal movement of the span, horizontal rotation, and a vertical rotation due to the change in grade of the roadway, but it must resist all lateral forces. It consists of a horizontal guide on the centre line of the bridge and is located slightly below the bottom flange of the end floor beam. It is supported at one end by the reinforced concrete end wall of the pontoon and at the other end by two steel legs of a vertical "A" frame. Attached to the underside of the end floor beam is a tongue which slides within the guide, bearing on the side shoulders depending upon the direction of the wind. The sides of the tongue are curved to allow horizontal rotation of the span without interfering with the action of the wind anchor.

The bearings at the pinned ends of the spans (pier and abutment ends) are designed to accommodate only two movements, longitudinal displacement and horizontal rotation about the centre line of the end floor beam. Only one pin is, therefore, required in this bearing and the rocker rotates through a horizontal arc with its centre on the centre line of the end floor beam.

The anchorage at the pinned enc of the east transition span is on the centre line of the end floor bean and consists of steel castings housing a vertical and a horizontal pin which allow horizontal rotation, and vertical rotation due to change in wate level. This anchorage provides resistance to both lateral and longitudina forces.

Roadway Deck

The roadway deck is lightweigh reinforced concrete supported o stringers that frame into floor beam that have a built-in crown of inches. The floor beams are of necessity pinned to the truss vertica to allow for tipping of the pontoon while the sidewalk brackets are fixe to the verticals so that the sidewall always remain horizontal when th roadway is tipped.

Roadway expansion joints at bot

ends of the transition span are the interlocking finger type. At the pontoon end of the east transition span, owing to the large movements to be accommodated, the fingers on the pontoon section had to be horizontally pinned in order that they would not in some cases project above the road surface as the span changed grade. Sidewalk expansion joints are the sliding plate type and it was necessary at the pontoon joint to

span as is the usual case but had to be resisted by a horizontal force in the wind anchor on the pontoon. This introduced additional stresses in the truss members but they were insufficient to change the controlling stress grouping from dead plus live plus impact; except in the end post.

The struts of the top and bottom lateral brace systems, like the roadway floor beams, had to be pin connected to the main trusses to allow

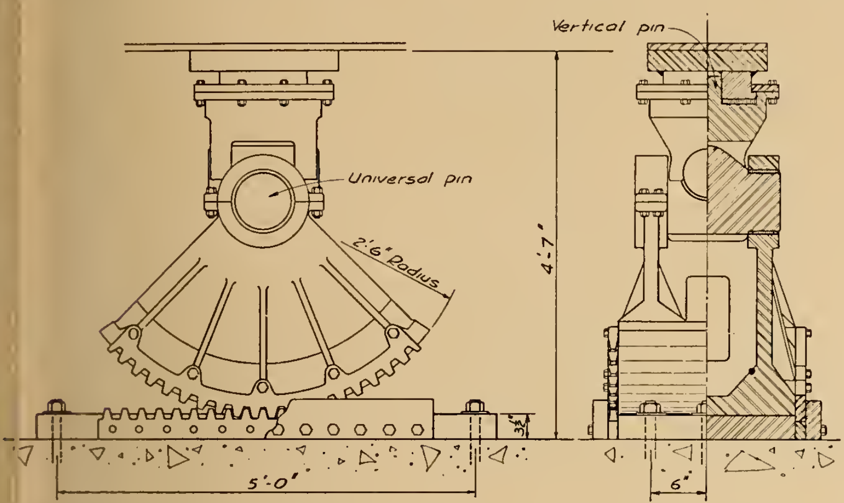

Fig. 7. Rocker bearing at the elastic support, provides for vertical, longitudinal, lateral, and torsional movement.

hinge the top plate diagonally and provide a sliding guide along one free edge to prevent the plate from projecting above the sidewalk level as the pontoon tipped.

Since the pontoon section was not provided with longitudinal anchor cables, the most westerly pontoon was tied to the west abutment by means of a heavy "H" section which was supported by, but not attached to the truss floor beams of the west transition span. The only point at which the tie and the transition span are rigidly connected is at the end floor beam at the west abutment. This tie must resist all the longitudinal forces on the pontoons and the west transition span.

Wind

Wind on the transition spans could not be dealt with in the conventional manner because of the absence of a portal frame at the pontoon end of the span. The top lateral system was designed as a cantilever truss supported at the pinned (or pier) end of the span. The couple required at the bottom end of the portal frame to balance the cantilever effect could not be offset by an equal couple at the other end of the

for the pontoon tipping. At the same time, the diagonal braces had to be connected in such a manner as to transmit to the main trusses the longitudinal component of their stresses. At a typical top lateral brace connection, the diagonal and the strut were connected with horizontal gussets to act as a unit and the strut was then pin connected with a horizontal pin to the side of the chord member. A built-up tongue, rigidly connected to the brace strut, was projected over the top of the chord member and fitted to bear between two shoulders fixed to the chord members.

Twisting of the pontoons introduced some difficulties in the connection of the lateral braces since the warping of the plane of bracing tended either to shorten or lengthen the diagonal braces varying amounts. If the members had been proportioned so they would not change length they would have been larger than any of the main truss members and would have tended to hold the low-side bearing off the pontoon when it tipped. Consequently, the diagonals of the bracing system were connected with slotted holes of varying lengths depending upon the distance of the connection from the pinned end of the span to allow the trusses to follow the rotation of the pontoons without introducing extremely high stresses in the bracing members.

Slotting of the diagonal brace connection holes to allow for warping in the plane of the brace system results in the end posts of the pontoon ends of the spans moving out of plumb not more than 1⅝ inches in a vertical distance of 28 ft., an amount that would hardly be visible to the naked eye.

Personnel

The bridge project is being constructed for the British Columbia Toll Highways and Bridges Authority and will be operated by them as a toll bridge. The contract for the approach roads and rock fill embankments was completed in August, 1956, by General Construction Company of Vancouver, B.C. The contract for the abutments, main piers and the floating section is being carried out by Kelowna Bridge Contractors, a joint venture of General Construction, of Vancouver, B.C. and the sponsors, Pacific Bridge Co. of San Francisco, California. Mr. Emerson Hail is project manager for Kelowna Bridge Contractors, Mr. Chris Andersen, general superintendent, and Mr. T. B. Coull, Jr., project engineer.

The contract for the steel superstructure will be let in April, 1957, and, subject to the availability of structural steel, the bridge should be completed in the summer of 1958.

Swan, Wooster and Partners, consulting engineers, Vancouver, are the designing and supervising engineers for the whole of the work. The assistance of Mr. C. E. Andrew of Seattle, Wash., and designer of the Lake Washington Floating Bridge, is gratefully acknowledged. Mr. D. C. Gough is resident engineer at Kelowna for Swan, Wooster and Partners.

The writer has been in charge of the design of the pontoons and the substructure for the steel work. Acknowledgment is made of the assistance given to the writer by Mr. W. V. Coventry, who was responsible for the design of the steel superstructure and Mr. H. F. Wooster, M.E.I.C. who supervised the design of the entire project.

Who Caused the Engineer Shortage?

G. L. Wilcox

President, Canadian Westinghouse Company Limited

Address to The Engineering Institute of Canada, Hamilton Branch, January, 1957

IT IS EXTREMELY important for me and for my company that in speaking to you I attempt to answer honestly the question posed in the title: "Who caused the engineer shortage and what can we do about it?"

Engineers these days are a problem of a peculiar sort to the industrial manager. On the one hand they are desperately needed — not only the engineers already in the organization, but more as well. On the other hand, there is a continuing question as to how engineers should be dealt with in the organization; how to provide them with the best possible conditions for efficient functioning.

The shortage of engineers has now reached a point where an industrial manager hardly dares send them out to recruit other engineers. One company in the U.S. recently sent seven engineers to a technical convention to see if they could recruit from among those in attendance — and five of the seven just never came back. They had been recruited by other company scouts at the same convention.

In Canada, the engineer shortage is beginning to have serious effects in many areas. In our own field the pressure seemingly is not quite so great as it was, but the shortage still exists. The enrolment of young people in engineering schools is increasing, but not as fast, by any means, as the estimated demand. There is certainly good evidence that the engineer shortage will be with us for a good while to come. In fact, it may be that there never again will be a surplus of engineers in this country.

As to the causes of the shortage, on reflection I have come to the conclusion that no single factor is to blame. A great many of us have played a part in this situation. First and foremost among the causes, of course, is the engineer himself. He has brought about the shortage by being so successful. If the engineers had not been able to show us how important and valuable they can be in industry, there would be no more shortage of engineers now than there was in the 1920's and 1930's. But the world, thanks to the scientist and the engineer, is quite a different place today than 30 or 40 years ago.

It is a world based on technology —on competitive technology between industries, between sections of the country, and between countries and vast political "spheres of influence". The key to success in almost any enterprise these days, little or large, is engineering.

The engineer has made a very large place indeed for himself in the modern world — a place so large that there just aren't enough engineers available to fill it.

For this — as a primary cause—the engineer has himself to blame.

But from there on, the difficulty has been compounded by almost every factor in our economy. The root difficulty has been failure to foresee, in recent years, where the furiously burgeoning development of technology in industry, warfare and daily life was leading us.

Among the institutions that seriously failed to foresee and prepare for the great change were o schools, colleges and universitie Though many voices were raise and many fingers pointed, the scho system in Canada as well as in tl United States continued in its tr ditional pathways, turning out gra uates of about the same kind ai with the same basic preparation f their lifework as in the previo twenty years or more. Meanwhile tl demand for engineers mounted.

Those who support the schools (should support them) including ta payers, businessmen, foundatior private donors and the like, we equally at fault. Money becan available too slowly to provide f the necessary expansion in the scho system. There is still too little mon to catch up with the demand, ev for bricks and mortar and physic school facilities.

As to teachers — their salari were allowed to fall far behind t economic procession. Many of t best of them left the school sy tem to seek better-paying jobs el where. So, when we began c manding more and better enginee we found that through our natic al and economic short-sightedness v had starved the schools of the mea of supplying our needs.

Finally, in the front row of cc tributors to the engineering shorta I put business and industry itself. F we in industry have been lagga in finding the best ways to use o engineers. If industry had been de ing with a *material* that was simil ly in short supply, you may be su the research laboratories and en neering departments would lo ice have found ways to make every pecious ounce of it do full duty, and ne of it would have been wasted applications in which its unique alities were not needed.

In the case of scarce engineers, wever, we have tended to use m in the traditional, wasteful ys inherited from the days when re were plenty of them — when gineers, in the minds of many in- strial managers, were just another m of white-collar worker.

In investigating this, we are apt to e in almost every industrial com- ny numerous cases of mis-employ- nt of engineers — that is, engi- ers doing non-engineering work; o many instances where able en- neers are being prevented from ing their best, or accomplishing as ich as they are able, for lack of itable trained technicians, general sistance or other personnel and fa- ities.

Key Positions

I am not referring, of course, to ose numerous instances where en- neers are satisfactorily filling super- ory or management positions. aduates of university professional urses will always continue to fill y positions in many fields other n those of their specialties.

Professional graduates are almost variably men of high intelligence d multiple capacities, and after aduation some of these talents de- lop faster than others, frequently anging a man's role in life radical- l Some of our best industrial man- ers are men who formerly were en- neers — and I hope I may be par- ned if I say that this is a tendency t should be encouraged, rather n otherwise.

When I speak of the mis-employ- nt of engineers, I mean those in- nces where a man, prepared for gineering, is now engaged in work a non-managerial nature that does t require, or in many instances en make use of, the special train- g that goes into engineering. Such e of engineers is often sheer waste. results too often from careless nagement, failure to appreciate special values of engineers, or glect. The net result is that both lustry and the engineer fail to get most out of professional training d talent.

In our own company we have en studying the problem of mak- g better use of engineers for some ne. Our surveys have disclosed gineers doing time study, serving as order clerks in the pricing de- partment, engaged in minor rede- sign of equipment that could just as well have been done by men of lesser training. We have found engineers as- signed to such jobs as converting drawings from the metric system, or revising stock order numbers on Kar- dex cards.

We have not been alone in com- mitting such sins. In the United States, particularly, surveys have shown similar situations.

Fabian Bachrach Photograph

G. L. Wilcox, President, Canadian Westinghouse Company Limited.

In a recent study of several var- ied industries reported in the maga- zine *Machine Design*, engineers were found to be engaged in at least 75 non-engineering jobs and occupations. These jobs ranged all the way from draughtsman to checker, estimator, plant maintenance man, core-room supervisor, traffic analyst, technical writer, and tool room foreman.

If engineers are being used to any great extent on jobs of this kind throughout the continent, no wonder there is an engineer shortage! But equally bad, I think, is the rather common industrial practice of failing to give a creative engineer adequate help.

Often a large part of his time must be used uncreatively, in making drawings, checking computing and the like — tasks that could as well be handled by technicians or others specially trained for these specific jobs. Their education and training would not need to be nearly as ex- tensive as that of an engineer.

In dealing with this aspect of the engineer shortage, industrial manag- ers could do worse than to study the ways in which our better hospitals make use of trained surgeons and doctors. In such hospitals, the high- ly trained medical man or surgeon does not use any of his time or ener- gy in making beds, tying bandages, handling bedpans or serving meals. Such tasks are well and efficiently handled by well-trained specialists, technicians and nurses, at consider- ably less cost than if the doctors were to do them, even assuming that there would be enough doctors to go around. By this intelligent dividing up of the job among several kinds of trained workers, the highly skilled medical men are released to per- form, at high efficiency, in precise- ly those areas where only they can accomplish the necessary result.

In some parts of the continent, I understand, school systems are now also experimenting with this same kind of division of labour. In many schools there is a teacher shortage, just as in industry there is an engineer shortage. In the experi- ments to which I have referred, trained technicians are being used to assemble the students, call the roll, set up educational paraphernalia such as charts, motion pictures, dia- grams, etc., and the teacher comes in only to teach. His time is thus re- lieved of non-teaching chores. The results of his efforts are thereby not only improved, but more students can be taught by fewer teachers.

What Can Be Done?

Now, what can be done about the engineer shortage?

These observations have already pointed one way in which industry can help. There is also another step that industry can, and must, take, and which we at Canadian Westing- house have been trying to implement in recent months. This is the recog- nition of engineers as a special group, a sort of *third estate*, in the indus- trial organization. The purpose is to give the engineer status; and with it, increased opportunity to perform ef- fectively.

Until quite recent years it has been natural to think of industrial or- ganization as consisting primarily of two groups or classes. On the one hand was "management", often in- cluding the owner or owners. On the other hand, there were the "employ- ees"; the people who did the manual work, tended the machines, and car- ried out the accompanying clerical tasks.

In this conceptual scheme no place was left for the engineer or other professional man. They had to be lumped off with the so-called "employees", and dealt with on the same basis. Nowadays, when everybody in a large company is, in a very real sense, an employee — including top management itself— some of the old distinctions between "management" and "employees" are melting away.

But in any effective form of industrial organization, there still must be those who make the vital decisions (the so-called "management") and those who carry out the decisions (the so-called "employees").

But engineers — and several other types of professional people such as accountants, lawyers, industrial relations men — are not really either "management" or "employees" in the usual sense. Their function is creative or advisory. They are especially prepared, for a special function, by special training and education. They are set out from others also by their special talents and creativity.

You will recall that in feudal England there were traditionally three classes, or "estates", among that part of society having political rights. These were the Lords Temporal, or the ruling class; the Lords Spiritual, representing the church; and the Commons, the latter being the great class of landowners from whom sprang so much of the strength of the English state. Without carrying the analogy too far, it seems to me we must realize that in industrial organization there are now also three estates: the management, the non-managerial employees, and the professionals.

Professional Men

As I have already implied, the term professional must not be taken here as applying only to engineers. Any major business enterprise today makes use of a small army of professional men of many kinds. In addition to engineers, they include the professional men in research, law, purchasing, accounting, industrial relations, public relations, advertising, manufacturing, sales and service. Of these, in most manufacturing industries, the engineers are probably the largest group — and, at least from some points of view, the most important.

Proper recognition and status for these professionals will not, of course, create any more of them. In that sense, it will do nothing to overcome the immediate engineer shortage. But it will, I think, make the professionals we have more effective. And, in the long run, proper status for the engineer in industrial organization will help to make engineering a more attractive and satisfying career, helping to attract to the engineering profession many young men who today might choose against it.

A path of increased recognition and status must, of course, consist of greater financial reward; greater opportunity to earn commensurate with ability and productiveness. A good engineer ought not to have to go into some other line of work, for example, management, solely for the purpose of making an adequate living. If he is a good engineer, he ought to be able to earn as much in engineering as he can in any other way.

The Right Job

At Canadian Westinghouse we believe that a person will always produce at his maximum potential when he is doing the job that he likes to do best. Therefore, we try to see to it that the question of more pay alone will not be an inducement for him to change jobs or status.

A successful professional engineer in Canadian Westinghouse can now earn a salary that approximates that of a successful manager — and he can certainly earn more than many supervisory people. Moreover, we try to see that the other forms of prestige that a professional enjoys in the company is also equal to that of a manager.

In all this, we do not believe we are unique. Many other companies are undoubtedly developing along these same lines. As this kind of thinking progresses, the engineer's estate will become more and more satisfying and more and more creative.

None of these measures by themselves will end the engineer shortages, and end or alleviate it we must, if we are to continue to enjoy our present high standard of living, and at the same time keep ahead in the international race for survival in which we find ourselves engaged.

In winning the rest of the battle we need a grand alliance, a concerted effort, among all the forces involved: industry, the schools, the government, the taxpayer and the engineers themselves.

Industry can do far more than it has been doing, I am sure, in stimulating the interest of young people in engineering careers. Last fall, as yo know, a number of industrialists an educators from all parts of Canad assembled at a "National Engineer ing Manpower Conference" sponsore by A. V. Roe Canada Ltd., to dis cuss this problem and to take actio on it. Some of the things suggeste at that conference, and some of th activities stemming from it, will un questionably have far-reaching e fect.

Industry and Schools

But in addition, industry mu give more support to the school must refrain from competing wit the schools for technical personn who are needed to teach; must co tinually press for more adequate f nancial support for the schools, s that the facilities will be adequa for training, and above all, so th the kind of salaries can be offered teachers which will attract the be of them for the vital job of teachir the nation's forthcoming crop young engineers.

Industry, the schools and govern ment must stimulate and encoura more fundamental research, as we as the training of engineers. The e gineer's function, as I see it, is tl translation of fundamental scien into practical applications. But if tl stream of new scientific knowled slows to a trickle for want of suitab support, or dries up, the engineeri achievements will ultimately slow as well.

Research of this kind can best l carried on in other types of esta lishments especially set up for tl purpose. Some types of fundamen research can be done also in ind trial laboratories; but by and lar the best fundamental research done in laboratories that are free publish their full results, and to p sue their investigations to the e regardless of commercial conside tions.

It seems to me, finally, that a la part of the cure of the engineer sh age depends on the very people w started it all in the first place — engineers themselves.

I have pointed out that if the gineers had not been so success in transforming the face of the e nomic and industrial world th would not be any engineer short today, or for that matter, any dem for engineers whatsoever in indus

But they have been successfu successful beyond any possible dre that our ancestors could have h

The present unprecedented era of widespread material wealth and prosperity can only continue so long as the engineers keep up the rate of progress, not only through new discovery and invention, but also by the continued enhancement of man's productivity. Having aided so much in increasing the productivity of all mankind in recent years, the engineers must now address themselves to increasing their own efficiency and productiveness.

As Winston Churchill has said in quite another connection, "Never have so many owed so much to so few". The human race owes much indeed to the few thousand creative engineers who have brought about the present era of productiveness and plenty. But the few will always remain relatively few — no matter what we may do. For in a very real sense, the scarcity of engineers is only a special manifestation of the general scarcity of brains.

Psychologists say that it takes an I.Q. of 125 or better to produce a good professional man, in any professional field. Only about 10 per cent of the whole population have an I.Q. of this magnitude. Upon this precious 10 per cent (about half of whom are going to devote themselves to motherhood, no matter what) the world must depend for all its professional developments of the present and future. Thus, engineers will always be precious and few. We must find ways to make every one of them count; and this is a responsibility for the engineers, as well as for the managers and the rest.

A Special Problem

In Canada, we have a special problem. Our precious engineering talent tends to leak away, most especially across the porous border to the south, where wages are high, opportunities great, and temptations mighty. We cannot close that porous barrier directly, nor would we want to, for the engineer must be free to seek his fortune wherever he can most readily find it. But we can close the border, in effect, by equalizing the conditions — as one might stop osmosis through a membrane by putting the same solution on both its sides.

We can eliminate much run-away young engineer traffic by making it more attractive for the young Canadian engineer to stay at home; by offering him better opportunities to earn, more opportunities to advance in his profession, better status in our society and in our own Canadian industrial organization. We can also make it more attractive for him here by building up the already great reputation of the Canadian engineer, so that he will feel it unnecessary to move to the south to be found among his peers.

Enhancing further the reputation of Canadian engineering is uniquely an operation that your Institute and its members can undertake; I am sure, with success.

Canadian engineering and technology already rest on a secure foundation, established by a long series of great men, some of whom made their reputation, and their fortunes, here, and some of whom moved away.

Canadian Pioneers

It was the Canadian-born, Queen's University educated Charles Fortesque who first developed the mathematical basis for dealing with polyphase circuit problems. It was Canadian-born Joseph Hobson who designed and built the St. Clair Tunnel at Sarnia, largest sub-aqueous tunnel in the world at the time; and who also built the Victoria Bridge at Montreal and the Niagara Bridge at Buffalo. It was the Canadian engineer-scientist William Logan who helped develop the basic theory of the origin of coal, and first called attention to the geological and mineralogical importance of the Canadian Shield.

Canadian engineers spanned the continent with railroads at a time when it was thought next to impossible to do so. They developed the mines and the hydro-electric systems of the country against almost insurmountable obstacles. They have become, although many of them unknown and unsung, in a very real sense the embodiment of that legendary figure Paul Bunyon.

Big as he is, strong as he is, and tough as he is, this Paul Bunyon has a problem; the more he does, the more there is to do. But this, according to the historian, Toynbee, is the right kind of problem to have. Real progress occurs, he says, when the response to a particular challenge is not only successful in itself but provokes a further challenge, which again meets with a succesful response and so on, *ad infinitum*.

It is clear that individually and collectively those in the engineering profession have been abundantly successful in meeting past challenges and are coping with present challenges, and there is no doubt in my mind that they will seize the opportunity to respond somehow but successfully to the challenges that face us today.

Engineers are Guilty

To get back to the subject of our talk, I believe it is quite clear that engineers have, because of their success, been guilty in large part of our present dilemma. But you as individuals, and as the Engineering Institute of Canada, can do a great deal toward solving it.

In considering how this is to be done, I think it will be necessary for every engineer to look at the problem individually, as well as for engineers as a group. Soul-searching and self-challenge will be necessary. Unpalatable truths will have to be faced.

For example, is it possible that engineers have been a bit too small, too petty, in their professional approach to their work? Is there a holdover from the days when engineers literally did everything? Are individual engineers persisting in undertaking tasks that are beneath professional levels, and too often resisting progress by making it difficult to introduce technicians to aid them?

Are some engineers, possibly through a vague feeling of insecurity, insisting on carrying on too much of the slide rule and meter reading phases of their work that could just as well, or better, be turned over to men with lesser training?

I know of a number of instances where this is true. Perhaps you may know of others. Possibly some of the engineers in this room are guilty of these shortcomings.

As engineers, let us all take a new look at ourselves, our daily work, our work habits, and our attitudes. The road to true professionalism involves giving up, as well as gaining. The medical profession would never have attained its present stature if doctors had insisted on being nurses as well as physicians, or if surgeons had also continued to serve as barbers, as they once did.

It is up to the engineer himself to establish his true professional status. I believe by establishing his true professional status he will have gone a long way toward a solution of the total problem. It is the necessary road to his own salvation, as well as that of industry and the economy as a whole.

Training and Orientation of the Graduate Engineer on the Job

A panel discussion held as Session 3 of the joint Conference of the American Society of Mechanical Engineers and the Engineering Institute of Canada, University of Western Ontario, October 1956

Cornelius Wandmacher

Head, Dept. of Civil Engineering, University of Cincinnati.
Moderator of the Session

To encourage the continuing professional growth of young engineers after graduation from college, the Enginners' Council for Professional Development in recent years has promoted a plan known as the "First Five Years" program.

This is a six-point program the outline of which is based on two cardinal principles:

(a) Industry and the engineering profession must provide the young engineer with a "favourable climate" in which to grow;

(b) The young engineer must be brought to realize that the final responsibility for professional advancement rests with him, the individual.

Point No. 1 in the "First Five Years" program is directed to the matter of "Orientation and training of the graduate engineer on the job." Since both EIC and ASME are participating societies of ECPD it is therefore quite appropriate that the following papers direct attention to this program and especially to this point.

Most organizations with which young engineers now take employment offer some type of orientation and training program. Some companies merely give lip service to orientation and training; others merely organize a "merry-go-round." But the majority of firms are constantly endeavouring to evaluate and improve training methods, to determine whether present programs represent the best use of time. Do graduates of the training programs make good use of what they have learned and would they have learned as much in other ways, or on their own? That is the question which is being constantly asked.

Some views on these points are offered in the following four papers, two of which are presented by management representatives responsible for the administration of training programs and two of which are presented by relatively recent graduates of well-organized training programs.

Summary

A summary of the highlights of the four papers in this panel group and related ECPD literature should certainly include the following thoughts and ideas expressed in one or more instances:

(1) The essential need of industry is a loyal, efficient, and aggressive working organization.

(2) Training is a way of operating with new people in the total work situation.

(3) Making the trainee a part of a working team is an essential part of a realistic training program.

(4) To work, not merely to observe, should be the key to any training assignment.

(5) Put responsibility into trainee jobs — make the trainee carry a burden and learn to produce.

(6) Opportunity to contribute at the earliest possible moment to the everyday productive effort of the company is the basic desire of every trainee.

(7) Selected job experiences are the foundation stones of any training program.

8) Flexibility in training assignments is necessary to serve the best interests of the individual and give him the training he really needs.

(9) Follow-up on training must go on for a period of several years. Carry-over should be provided for and checked.

(10) The development of a professional consciousness and attitude should be the paramount goal of any training program for young engineers.

L. L. Case

Chicago Blower Corporation, Detroit, Mich.

It would seem that industry, in general, agrees that the young engineer, who is freshly graduated from an accredited engineering college, has a broad theoretical knowledge about many different fields. Conversely, he does not have enough knowledge in any particular field or the practical experience in that field to immediately become a productive part of industry — hence our topic "Training and orientation of the graduate engineer on the job."

I will discuss this topic from the viewpoint of the young engineer who has quite recently completed one of the programs, somewhat similar to those discussed by other members of this panel. My comments are personal observations and do not necessarily reflect the thinking of the company's program being discussed.

The program to which I refer is the Test Engineering Program of the General Electric Company, in Schenectady, N.Y.

Initial Assignment

On reporting for work, the new test engineer had an interview with the test director and was told of his initial assignment, for which the test engineer had earlier made known his preferences from some 98 different assignments. These tests were available at Schenectady as well as at various other plants throughout the United States, and included steam turbines, induction motors, gas turbines, magnetic control, electronic control, fire control equipment, air-conditioning and refrigeration, and many others.

During the third session. From left: Prof. Cornelius Wandmacher, the moderator; M. J. McAuliffe; and John Gammell. Not shown are L. L. Case and C. A. Peachey.

Each assignment was for a duration of thirteen weeks. Since the tests varied in their scope, the exact method of conducting each test varied considerably, but the general pattern of those in which I participated was about like this:

The first week, the test engineer was given a chance to acquaint himself with the facilities for production and testing of the product involved.

The test supervisor (himself a graduate of the test program), instructed us on the construction and operation of the product. We then studied the product thoroughly with particular emphasis on the step by step analysis of the manufacture and assembly. The test engineer also had an opportunity to learn, at least generally, some of the problems of research, development, design, scheduling and production.

After the first week, we were assigned to a "test" group, consisting of three test engineers: the leader, who had been in this group for eight weeks previously; the assistant leader, who had been in the group for the four preceding weeks; and the novice. This group worked as a team doing production testing, all under the direction of the test supervisor.

After four weeks, the novice became the assistant-leader, the former assistant-leader became leader, and the former group leader, who had then completed his "test", moved on to a new test assignment. By this progression, each engineer performed all types of work, had an opportunity to understand thoroughly the test procedures and operating characteristics of the product, and to acquaint himself with the operations of the department; he had performed productive work for the Company, and had the opportunity to show his individuality and ability for leadership.

At the end of each test, the engineer had to submit a written report to the test director, covering his activities during the test assignment and outlining recommendations for changes in the test as well as his feelings about permanent assignment to that department. At the same time, the test supervisor reported to the test director about the test engineer, including all phases of the engineer's development such as technical, creative, and leadership ability, sociability, and many others. These two reports were reviewed during a personal interview with the test director, after which the engineer's next test assignment was made.

The length of the test program varied from one to two years, which included from four to eight different tests. By this time, the engineer had become familiar with the field in which he was interested, and the Company had had ample opportunity to learn the man's abilities and his limitations, thereby enabling the test director to place him in a position compatible with the best interests of both. The engineer could "go off" test at the conclusion of any test if he so desired, but it was recommended that he complete the test assignment in his chosen department before he actually joined that department.

To me, one of the most important things about this program was that the "fresh" engineer had an opportunity to work with the finished machine or product. It was no longer a mental picture absorbed from a book, and the theoretical limitations became very real. Such experiences are not soon forgotten. Furthermore, the wide diversification of test activities was an education in itself and provided a broad practical background of great value regardless of the engineer's final position.

Another important aspect of this type of training was that it taught the young engineer the value of accuracy and thoroughness, particularly relative to guarantees. A guarantee is basically a promise to pay (either material or services) if promised performance is not met. Such promises usually involve a considerable number of his company's dollars, so guarantees and warranties will usually influence an engineer's thinking. Therefore, inducing an early respect for this thinking is quite inexpensive insurance.

The value of such close association with both the supervisors of the various departments, as well as with so many other young engineers, cannot be over-estimated. The opportunity to act as test leader gives each engineer a taste of supervisory work and also of responsibility, both of which are very important.

In addition to the actual test assignments, several advanced technical courses were available to the test engineer, which emphasized the practical aspect of engineering and kept him thinking about self-improvement.

Additional Areas of Training

There you have an outline of a very well thought-out and well-organized test program, which was and is doing an excellent job of orientating and training young engineers for industry. However, I would like to present three additional areas of the young engineer's training, which cannot be completely developed by the engineer himself, nor can they be completely covered by a training program, yet are vital to the engineer in his profession.

(1) *The Language of Engineering* —That is, of drafting and blueprint reading. Every engineer should be conversant with this method of presenting ideas. I would suggest that a minimum of six months of this work is a necessity for every electrical, mechanical, civil, and architectural engineer. Verbal orders cannot be tolerated in any business, and many times the illustration of ideas in blue print form is the fastest and most accurate method of projecting one's thoughts.

(2) *Good Verbal Expression* — This is another very important attribute of a good engineer. The ability to express one's thoughts and "sell" ideas is just as important as thinking those ideas. Many engineers are poor public speakers and yet, to assume supervisory or management duties, an engineer must possess this ability. The one fast and sure way to develop this ability is through active selling, which means becoming a "salesman" for a time, preferably six months to a year. Selling is an art in itself, although it is not classed as a profession. Similar problems are encountered whether trying to persuade a customer to purchase your product over several others, or trying to persuade your supervisor or the board of directors that your idea should be followed rather than some other plan of action.

(3) *Administrative Ability* — This is probably one of the most elusive traits to develop, and can only be improved by actual supervisory work, which is not always possible in the first few years of employment. Therefore, the engineer must find other ways to develop this ability. One of the most effective is through social, civic, and technical groups outside business associations. This type of participation not only helps the engineer himself, but also his profession and his company. These activities should be encouraged and recognized by the employer.

Finally, a good engineering education might be called the "tool box" of the engineering profession; industry can provide the facilities and capital through good training programs, but the quality of the finished product, "the engineer for industry," is greatly dependent upon the raw material, which is the ability and efforts of the young engineer himself.

John Gammell

Director of Graduate Training,
Allis-Chalmers Manufacturing Company,
Milwaukee 1, Wis.

Many students when they come to us arrive in a new world. The young graduate engineer has, up to the time he comes into our companies, been at the centre of activities involving him and indeed, the reason for those activities. For instance, he has been the centre of his family's attention and the reason for its existence. He has been the centre of attention of schools for 16 years and the reason for their existence. For the first time in his life he now comes out of the relatively orderly predictable atmosphere of schools to the unpredictable and sometimes disorderly atmosphere of industry. When he starts to college he knows what courses he is going to take, and when he walks into a math class, he knows he is going to study mathematics, nothing else. If he gets all the problems right and he gets them in on time, he gets an "A". Contrast all this with industry.

In the first place, he is on the outside of the circle fighting his way in to a position of importance. The men who will train him have primary interests in quite other directions than towards his training. Their raises and their advancements in the industry depend on how well they manufacture something; how well they design it; how many they can sell, and so on, and not on the immediate success of their training activities with an employee. In the long run, of course, this training activity may be more important to their career than their present-day job; but only in the long run. They will, therefore, neglect the student and the training any time they interfere with the proper attention to an important customer or an important conference with the top brass or a vital piece of test work which has come to a head, and so on. These people are all very much interested in the student but not as directly as were his family and professors.

The realization of this for the student and the necessity for his learning how to work under these conditions is the business of industrial training. We must somehow teach the young engineer how to establish his own curriculum; how to determine the time to be allowed for study and what he is going to study; what meetings available to him he is going to attend; what magazines he is going to read. He has to learn how to ask questions without irritating a busy man. He has to learn how to be interested and show it or he will be regarded as lacking in enthusiasm. He has to learn to do his job well and still keep this enthusiasm when he finds some one else getting a promotion because they also did their job well and perhaps were older, more experienced, or simply liked better by the boss.

The young student has to learn that to carry on a successful development is not always a matter of technical competence, but is frequently a matter of selling the officials of the company on granting money, time, space, assistance, and equipment for doing the job in competition with many other demands for the same services. My own company sponsors a special sales training course of 26 half-day per week sessions in which the student is given assignments to talk about our products, their engineering, their production, their application. We feel that to be able to talk easily and effectively about the products with which he is concerned is a highly valuable asset to the young engineer.

The young trainee has to learn that keeping a department in the black may depend as much on an emotional approach to a couple of key employees as a purely factual approach to the scientific and engineering problems of the department. He will find that the selection and discrimination which he exerts in determining difficulties in industrial activities has as much to do with his progress as does his actual knowledge of the business.

He will learn that, because of lack of time to consider all the factors objectively, he must frequently make decisions based on intuitive faith in the judgment and information given him by his associates. He must be quick to change his course when he finds he has made a mistake.

Against this backdrop of requirements and many others, the industrial trainer must plan his approach to the education of the young engineer. A common method is first to have a brief period of orientation in which the student learns something about the policies and business of the company for which he is going to work. This is followed by an on-the-job training period in which he rotates to various departments. In these he serves as a helper to more experienced engineers. He does some work and he does some study during this period, and most of all he learns how to work under the varying conditions of industry. In larger companies he also uses this period to find the type of work he wants — research, development, production, sales, application, service, maintenance, etc. After finding his field he has to sell himself into it.

In addition to on-the-job training, there are a series of survey type courses where men skilled in the various activities of the company talk to him about what they do and how they do it. There is very little rigorous education in all this, as most companies leave this type of education and the theoretical aspects of engineering to the colleges, to night schools, and special arrangements. More and more, industry is encouraging its young men to continue their academical work through going to night school and sometimes through special leaves of absence to pursue particular courses. A few larger concerns have special theoretical courses designed for their problems and for developing the more academically gifted student.

A new activity is beginning to enter industrial training operations for the undergraduate engineer. It is realized that a large percentage of them will sooner or later have responsibilities that are primarily administrative. For their success, these activities will depend largely upon the man's ability to lead and motivate others. Because of this, management seminar type courses are being carried on, or at least thought about, to an increasing degree. The top brass is taking more real interest in the young men and more arrangements are being made for them to have some contact with the beginning engineer in order that these students may have a better feel of the kind of work many of them will too soon have to undertake.

Whether or not an engineer's talent can be used more effectively when partially directed toward the managing of others, or whether it should be totally used in a purely engineering field is a subject for debate. I would point out, however, that if the engineer does not manage, who will? Can a non-engineering graduate direct engineering activities as efficiently as an engineering graduate? And aren't the most challenging problems of business becoming engineering problems?

C. A. Peachey

General Manager,
Communications Equipment Division,
Northern Electric Company Limited

There are two ways of tackling this subject. The first would be to limit the discussion to the philosophy behind the necessity for training of the graduate engineer after he arrives on the job. This method would involve evaluation and appraisal of general principles. The other method, and the one which I propose to follow, is to discuss the subject as it applies to my own particular industry and company. It is reasonably obvious that this approach would differ vastly from industry to industry and, for that matter, does differ in various areas of any one particular company. On the other hand, there seems to be a general pattern.

My company is the Northern Electric, which has about 15,000 employees. The engineering staff, excluding those who have progressed to administrative positions, is about 450.

Our engineering effort is spread over a number of fields, such as product design, communication systems engineering, design and development of manufacturing facilities, and manufacturing methods engineering for improvement and cost reduction.

Now, as has been said earlier, training needs will vary even within one company so I will limit my remarks to the manufacturing plant at Montreal which manufactures telecommunication equipment. In this plant there are about 7,500 people, including about 300 engineers, science graduates and some "up from the shop" engineers. I will leave design engineers out of my discussion as they are a particular group who must be fundamentally development-minded and with a strong preference for creative work. The majority of our engineers in this plant do not work in that area but are employed in the design and development of manufacturing facilities and manufacturing methods.

With this group in mind, I can say that when an engineer arrives on the job following graduation, he has sufficient basic technical knowledge. I am one of those who strongly favour a basic undergraduate course. The further training and education which he requires is spread out into three fields.

(1) Orientation

This is immediately required for most graduates and is intended to develop the man into a useful and enthusiastic member of the industrial society in which he finds himself. This implies that he must develop in the language and "know how" of a particular industry, and must develop an awareness of how he can contribute in a productive way to the objectives of the whole organization.

For a time after the War, many graduates coming into industry were mature as a result of their wartime experiences, and today those graduates who have been employed in industry during the summer months have often become oriented so that they can proceed quickly to fit into their new assignment. A number of graduates, however, have not been exposed to an industrial atmosphere and, as a result of their university training, they tend to react technically to situations and think in the abstract to a point where they lose communication with some of their fellow employees.

The first part of the training which the engineer receives is an explanation of the organization, its purposes and the possibilities he will have to make a creative contribution to the organization. When he senses these possibilities, he will develop an interest in his work, and should be motivated to further self-discipline in the direction of hard work. He should come to affiliate himself with the organization and finally see his own job as meaningful and important.

This orientation training specifically consists of a combined shop course of about four weeks' duration, interspersed with a series of talks, followed by discussion periods. During his tour of the shops, the engineer is under the guidance of a "sponsor" engineer, and he is asked to turn in a report on his shop study. He gets a quick overall tour of the entire shop, and then makes a more detailed study of one particular product shop. He is asked to turn in another report on a more general topic at the end of the four week period. This topic may be selected from one of a number, such as material handling, accident prevention, inspection methods, etc.

The series of about 20 talks which are interspersed into the engineer's study of the shop are given by various members of different organizations, from the works manager down. They include talks on the company's history, organization, stock holdings, and its place in the telephone industry, and help both the engineer and management in that they afford some opportunity for higher levels of management to meet some of the engineers. There are always question periods after these talks.

(2) Technical

We find that the men are anxious to get to work and, after four weeks, our new engineer becomes a working engineer. Further technical studies are then required on his own on the specific problem which is assigned to him. He might be working with vacuum tubes, punches and dies, chemical processes such as electrical plating or plastic moulding, and is expected to delve into the technical aspects of the particular problem and apply the basic principles which he has learned in college, so as to become proficient technically in his immediate specialty. The detailed technical studies are left to the man himself, as he is already prepared by training to advance quickly in this regard.

During this period, all new engineers attend several other training courses.

(a) Work Simplification and Work Measurement (100 hours) — Toward the end of this course, a class is split into a number of small groups, each of which studies a particular job in the shop and works as a team analyzing the operations in detail; later the groups meet as a class again and discuss, evaluate, and compare the various proposals made by each team.

The work simplification and work measurement courses are specific tools of scientific management, but the training has also the second purpose of developing creative thinking on the part of the engineer in his daily work. This attitude is most important, as the engineer's main contribution is from his ideas. He is more highly paid, must produce more. Technical assistants may perform a lot of the leg-work and measurements, but the ideas — and the selling of them — come mostly from the engineering group.

(b) Statistical Quality Control — This is another basic tool of scientific management. This course teaches a few basic principles but mainly application techniques.

In addition, depending on the engineer's area of work, he is given a course on: (i) production machines, or (ii) wired equipment test set design, or (iii) theory and operation of communication facilities.

(3) Human Relations

This third phase of training is interspersed with phase (2) and is an attempt to give the engineer some self insight and develop his skills and ability in handling difficult situations with people and methods of motivating people. This training involves case studies along the lines of the Harvard case study approach. It is this part of the program which is usually commented on by the engineer as being the most valuable. In this program we use films and slides, as well as case studies, and an experienced moderator guides the discussions. By and large, the engineer is encouraged to work out the problems in the group. An engineer would not develop the right attitude toward feeling-people-situations by just being told that he must; he has to discover these things himself and what we think we are doing is to speed up the process. I see little gain in a university teaching this in the undergraduate period. It can be readily handled by industry.

These three basic training courses are applied to our engineers with more or less success depending on the individual. We are constantly attempting to improve the program and it changes from year to year. About 20 per cent of the first year is spent in conferences and classes. We encourage engineers to take courses at the local universities and allow them time for writing theses for higher degrees, and assist in other ways, such as use of typists, etc.

Engineers are encouraged to join professional societies, and those who show special interest usually find themselves on committees in these societies. Some of our engineers gravitate to the Junior Board of Trade and, to encourage this, we pay for a few memberships in that organization. This gets an engineer away from engineering and into community affairs, and tends to broaden his outlook.

After a few years, the engineer may expect to find himself supervisor of at least a few other engineers and requires at that time some study and knowledge of administration techniques. He begins to realize his tools are speaking, writing, listening and reading, and of course, thinking. Some engineers take courses in rapid reading and join public speaking classes which are sponsored by the company. Some of them study general semantics and learn how to think more clearly and to appreciate the importance and significance of communication and the implications behind many things which are spoken, both by themselves and others.

After an engineer becomes what we call "department chief level", i.e., if he has not become a specialist, we feed him through a more advanced course on business administration. A professor from the local university gives lectures with discussion periods; these lectures run on for about 20 weeks. This training usually develops an interest in the subject, and the man can follow up the course by reading to find out more about the subject.

In general, our training program is not too unlike the six-point program developed by the Engineering Council for Professional Development, in the United States. There are some differences, of course. We do not do much in the way of integrating a man into the community, as Montreal is such a large area. Newcomers to the city are given guidance by resident engineers, and usually the wife of one of the engineers takes the wife of the newcomer under her wing and shows her housing developments, and so on.

Perhaps some people will feel, as I do myself at times, that by too extensive training sponsored by the company we are taking the initiative from the engineer himself. This criticism is partly valid and is one of the disadvantages of the training program. I feel, however, that the exceptional man will provide himself with additional training over and above what we give him and, therefore, our program should raise the average all around. All in all, an engineer in our company may expect that his education will be a continuing one throughout his entire career.

M. J. McAuliffe
Assistant to the General Manager, Industrial Products Group, Canadian Westinghouse Company, Ltd.

My remarks are directed to one specific phase of training, the phase that I believe to be the most important, and yet is the most neglected. I refer to the training required to take a graduate engineer and produce a professional engineer — the development of a proper mental attitude on the part of the industrial engineer and industry.

I am not minimizing or overlooking the need for planned orientation and technical training, but most companies provide the training now, and other members of this panel discuss this necessary phase of training in more detail.

I wish to discuss the professional man in industry from several points of view; particularly his recent arrival in increasing numbers on the industrial scene; his place in the evolving organizational scheme of industry; and the much-discussed shortage of professional men just now —particularly the alleged shortage of engineers and the effect that training can have on these aspects.

These are problems with which my own company, as well as those represented by many of you, have been grappling for some time. I hope that what I shall have to say will prove helpful — or at least will present starting points for new thinking on these matters.

Until quite recent years, in thinking of industrial organization, it sufficed most people to consider only two classes, or groups, in the structure. On one side was "management", which often in the early days included the owners as well as those who provided planning, direction and the other attributes of managerial skill. On the other side were the "employees" — those who did the manual work, tended the machines, and carried out the accompanying clerical tasks.

There seemed to be no place in this conceptual scheme for the professional man: for the engineer, the accountant, the lawyer, and the like. Nevertheless they were necessary to the effective functioning of industrial organizations, and since they were necessary, they increased in number.

Most managers, I suspect, thought of them generally as employees — a variety of clerical worker. And most professional people in industry thought of themselves in the same terms. The professional man's place in industry seemed undefined and insecure. Many professional men sought to better their positions by forsaking the professions which they had chosen as their life work, by becoming members of "management", as a means of obtaining recognizable status in the organization.

But then after the beginning of the century, and at an accelerated pace after the first and second World Wars, the numbers of professional men in industry rapidly increased. Whole industries, such as my own, and the chemical, the automotive, and many others, came into being, industries whose very existence depended on technological ideas and developments.

Professional Group

Today, when much of the effectiveness and productivity of an industry is the result of the increasing numbers of professional people in the structure, we can no longer consider the professional man as just a special type of white collar employee, or the representative of a minority group in industry. He does not carry on in some sort of hazy limbo between the managerial group and the employee group. Professional men are a group themselves, a major one, a third force in industry. I like to think of them as representing the "third estate" in modern industrial society.

Because of the rate with which this "third estate" is growing, and because of the utter dependence of modern business and industry upon trained professional men, the professional employee today represents one of the world's scarcest and most valuable commodities. No business could be considered well managed which did not realize the importance of the professional people within its structure, or which failed to make proper provision for their effective utilization, integration, and development.

In general, I think, managements have been quicker to perceive the place and importance of professional employees in the industrial structure than have the professionals themselves. One of the ills of industry just now is the great turnover of engineers and other professional people: their leaving one company to go to another, and more especially the drive of some to forsake the professional fields for which they have been carefully trained, to become members of management.

It is as though a general restlessness and feeling of insecurity still permeates the thinking of professional people in industry, causing them to seek other places and other work; and perhaps to neglect the opportunities for professional, personal and economic satisfaction and advancement that are readily available to them where they are.

This is so, I think, because so few professional people as yet realize that they make up a large and growing army of the "third estate" in industry; that they do have position and opportunity at least equal with those of the other groups in the industrial structure; that a man does not have to give up his profession and become a manager to be important, successful and happy in the industrial scene.

Let us consider for a moment what peculiar qualities distinguish the "third estate", what special advantages, opportunities, rewards, and obligations go with membership in the professional estate in industry.

It has frequently been said that one principal difference between the position of a manager and that of a professional employee lies in the fact that the manager works with and through people, whereas the professional is an individualist who does not work with people. This, of course, is quite untrue.

In most cases, the professional man in industry must and does work with others; with other professional people, with non-professionals and with managers — in short with the whole range of people in his environment. He can hardly be successful unless he does so. For like the manager, the professional man has both individual and teamwork responsibilities.

The real difference, it seems to me, lies in this: the manager is responsible for the results of his department, and thus is accountable principally for the work of others. But the professional man is essentially responsible only for his own work, whether he works alone or as part of a group. He is thus in a creative position with regard to his work; he can take a special pride in it, because it is his own. As we all know, it is difficult — often impossible — for a manager to point to any particular piece of work that he specifically has done. To others, nearly always, must go the recognition and the credit. But this is not so in the case of the engineer or other professionals. Their work is the result of their own personal creation, insight and skill. Even when working with a group, they can usually take justifiable pride, and obtain deserved recognition, for what they have been able to accomplish.

The position of the professional in industry also differs considerably from that of the non-professional, non-managerial employee. The non-professional employee's task usually is to carry out plans and achieve objectives set by others. But the professional is responsible for setting his own goals, and developing the means to achieve them. In large part, the professional's job is to teach others how to perform tasks or produce goods which, without professional guidance, could never have existed.

Thus the professional man in industry is usually in an unparalled position to advance both himself and the interests of his company but in few companies today can he feel that his status equals his importance to the organization's success. His monetary rewards in most companies are high. But to realize his full potentialities he should also have a special kind of status; one that will set him apart from both of the other "estates".

Responsibilities

He must, of course, be willing to pay a price for this, as industry must also. For only by mutual acceptance of responsibilities and adjustment of attitudes can so major a change come about in the industrial scheme.

Today, however, we find a large percentage of engineers being misemployed; engineers doing non-engineering work; and many instances where a given engineer could accomplish considerably more in his own technical sphere if he had suitable trained assistance in the form of technicians, whose training and abilities need not be nearly so extensive as his.

In speaking of misemployment of engineers, I am not, of course, referring to those numerous instances where engineers are satisfactorily filling supervisory or management positions. It must be realized that graduates of so-called university professional courses will always continue to fill positions in many fields — something that should be encouraged, for it is the primary job of a university to teach people to think, and not merely train them for technical specialties if they have other abilities or ambitions.

In our own company, where we have been studying this problem extensively, we have found engineers doing time study, serving as order clerks in the pricing department, engaged in minor redesign of equipment that could just as well be done by men of lesser training, converting drawings from the metric system, and revising or changing stock order numbers on Kardex cards.

Nor have we been alone in commiting such sins. In a recent article in *Machine Design* on "How to Relieve the Manpower Shortage" Chester Linsky of the Pennsylvania State University quotes recent surveys that show engineers being used in at least 75 non-engineering jobs in a variety of industries. These non-engineering jobs range all the way from draughtsmen to checker, estimator, plant maintenance man, core room supervisor, traffic analyst, technical writer, and tool room foreman.

I think we will find, when steps are taken to eliminate misemployment of engineers, give them suitable status in the organization, and supply them with adequate help, a large part of the shortage will disappear.

The benefits to industry should include lower engineering costs per unit, increased engineering productivity, greater flexibility in the application of technology to products and processes, and lower turnovers of engineers and other professionals. As management begins to realize fully the importance of the professional man and the significance of his new status in the industrial organization, his misemployment will become unthinkable, and therefore less and less possible.

For the professional man, the gains will also be many. He will have a new sense of security and belonging, a new urge to create and produce, a finer sense of his own place and importance in the scheme of things. We will not then have to worry about inducing more bright, ambitious young men to enter technical or professional fields; they will begin to look upon these fields as the areas of choice for an industrial career — as indeed they are in our surging technological culture and economy.

These gains, however, will not come about without cost or effort.

In the first place, it requires determination and persistence of a high order, on the part of management, to discover and change all the instances of misemployment of professional people in large organizations. In some cases skills that have long been disused have been lost, and retraining may be necessary. In others, there are resistances to change, not only by the surrounding units of the organization, but occasionally even by the professional men themselves —though I believe the management that succeeds in establishing high respect and high estate for professional people will find that such resistances will rapidly disappear.

Finally, much has yet to be learned about applying the engineer-plus-technician team technique in industrial situations.

Rich Rewards

I am convinced that rich rewards will be gained by persistent efforts in this direction, not only for the industries that succeed, and for the professionals in those industries, but also for their customers and for the nation as a whole. As our country develops, it seems certain that there will always be more need for technical and professional skills than can readily be supplied — and every improvement in the utilization of these talents will be a gain for all.

This training must be designed to change the mental outlook of both the individual engineer and the employer. It will be a difficult and time-consuming process, requiring the support of the top man in each organization, the Universities, technical and professional societies. It is a task that none of us can afford to neglect.

A committee headed by Dr. A. C. Monteith, vice-president of the Westinghouse Electric Corporation, in their report "The First Five Years of Professional Development", stressed the need for this development during the five years following graduation. It is during this period that the individual usually decides whether he is going to be more interested in the technical or administrative side of a business enterprise. It is during this same period that the foundation is laid upon which his business career is to be eventually built. The success of our Company tomorrow will depend to a large extent upon the quality and excellence of the professional work force we build today.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

OXYGEN CUTTING TITANIUM AND TITANIUM ALLOYS

G. Coates, *The Engineer*, v. 203, no. 5270

In comparison with mild steel, titanium is characterized by a lower density, lower thermal conductivity, but a higher melting point and a much greater affinity for oxygen. The heat formed by combustion with oxygen during flame cutting is greatly in excess of the losses by conduction through the sides of the cut, and consequently titanium cuts with great rapidity. The ignition temperature is fairly high, about 1100 deg. C., but once having started the cut it can be made to progress at least five times faster than for steel of equivalent thickness. Successful cuts have been made in titanium sheet or plate from 1/16 to 3 in. thick and in a 9 in. dia. Ti 150 cylindrical billet. Sheets can be cut in stacks without tight clamping, however the mass of kerf metal removed will increase with the depth of the stack.

In commercial alloys there is the possibility of transformation hardening at the flame-cut edge owing to the rapid quench effect following flame cutting. Titanium has a very high affinity for oxygen, nitrogen, and hydrogen, and since the principle of oxy-cutting depends upon the raising of the surface to the melting point in a highly oxidizing stream, it is impossible to prevent surface oxidation and some micro-cracking. Therefore additional surface treatment by mechanical methods may be required. Examination of the surface hardness at the cut for various thicknesses of pure titanium and of alloy plates showed that the depth of hardening (0.05 in.) is virtually independent of thickness. In general the micro-cracks are at right angles to the drag lines and extend to a depth about equal to that which would need to be removed by subsequent machining to clear away the hardened zone. The affinity of titanium for oxygen is so great it is likely that alloy constituents up to a total of 10 per cent would not greatly affect the rate of cutting. A comparison of total costs including labour and salvage recovery of sawing swarf shows slight differences between sawing and flame cutting with an advantage to the latter for sections of intermediate thickness, and in every case a considerable saving in time. It is concluded that in certain circumstances oxy-cutting might have an economic future. Applications for which it can be considered are: (1) cropping of billets and trimming of thick sections in the early stages of production; (2) preparation of sections for welding; and (3) scrap cutting.

A 9 in. section which would take hours to saw may be flame cut in a few minutes, and although at present for very thick sections the cost bears unfavourable comparison to sawing this is due chiefly to the cost of the metal and the importance attached to the reclamation of sawing swarf. As the metal production rates rise in the future the metal costs can be expected to decrease. In preparation of sections for welding the major problem is the contamination of the surface layer by gaseous constituents which would cause the weld metal to be similarly contaminated even though welding is conducted in an inert atmosphere. The most serious contamination is in the surface slag and this can easily be removed by light grinding. The determination of the exact amount of material to be removed for this purpose is considered a worthwhile subject for further investigations.

EDDYSTONE PLANT EMPLOYS SUPERCRITICAL-PRESSURE CYCLE

Mechanical Engineering, v. 79, no. 2

The Philadelphia Electric Company plans to construct a steam-electric plant of 325,000 kw. capacity operating at a super-critical pressure of 5000 p.s.i.g. with a 1200 deg. F. turbine throttle temperature and two reheat stages. This marks a new high in the development of the steam plant cycle. It is being planned jointly by the Philadelphia Electric Company, Combustion Engineering Inc., and Westinghouse Electric Corporation. Among the innovations being tried are, using the lowest pressure bleed steam to heat the combustion air, and using a low-level economizer to heat the condensate thus lowering the stack temperature to about 200 deg. F. Nine stages of feed heating provide 574 deg. F. water for the boiler. The heat rate under nominal loading and with 1 in. Hg. abs. back pressure is calculated to be 8016 B.t.u./net kw.hr. The normal fuel is to be bituminous coal.

Because there is no drum to provide a steam disengagement surface, there is no water level to use for feed-water control in the once-through boiler. The temperature of the fluid at the outlet of the transition section (where water changes to steam without flashing) will be slightly superheated at 900 deg. F. and this is used to proportion water flow to firing rate. In starting a once-through boiler water is pumped through the system at the rate of about one-third maximum flow. This is the minimum flow considered adequate for ensuring sufficient circulation through all tubes. The turbine is not in operation and the flow takes place through turbine by-pass valves into a by-pass separator. After this flow is established the fire is lit. As the temperature increases, some of the water flashes in the separator and is conveyed through the reheaters to the condenser by way of a condenser injection cooler. Thus the reheaters are prevented from overheating. The hot water which does not flash drains from the separator to the condenser. When a suitable temperature is reached there is no liquid and only steam leaves the separator. The stop valves are opened and the turbine started. As the turbine comes up in load the pressures at various points in the turbine are increased and this automatically closes the turbine by-pass valves.

The boiler unit delivers steam at a rate of 2 million lb./hr. and has two identical furnaces of the dry-bottom type, each fired with tangential burners located in the four corners. Since there are two reheaters one can be controlled independently by burner tilt, thus avoiding the necessity for spray desuperheating.

The superpressure turbine is being designed and built by Westinghouse Electric Corp. for a rating of 325,000 kw. The regenerative cycle is employed with eight extraction stages from the turbine and an interposed stack gas heat exchanger. The turbine is the cross-compound type and consists of several higher pressure elements operating at 3600 r.p.m. and an 1800 r.p.m. double-flow low-pressure element.

A condenser of 150,000 sq. ft. is designed to condense 1,288,000 lb. of steam per hour and maintain a pressure of 1 in. Hg. abs. with 200,000 g.p.m. of 58 deg. F. river water passing through the tubes. The boiler feed pumps, in duplicate, are arranged in a series of three: low, intermediate, and high pressure. Each develops more than 2000 p.s.i. at full load. The first two are driven at constant speed by two-pole induction motors of 4000 h.p. and 4500 h.p. respectively. A steam turbine of variable speed drives the high pressure pump. This turbine is rated 5000 h.p. at 5190 r.p.m. when operated with steam at 1110 p.s.i.a., 790 deg. F. at inlet and 290 p.s.i.a. at exhaust.

CERAMIC INVESTMENT SHELLS GIVE HIGH-QUALITY CASTINGS

N. J. Grant and P. Manganaro, *The Tool Engineer*, v. 35, no. 2

A method of producing ceramic shell moulds for improved precision casting has been developed recently. A ceramic powder called Glascast is applied in a slurry form as a coating on a disposable wax pattern. Three to six successive coatings are applied, each followed by a period of drying. The wax is removed by heating in a furnace at 1850 deg. F. and the ceramic shell gains a high temperature sinter band before the wax melts. This enables the shell to withstand expansion pressures created by the melted pattern. After removal of the wax the mould is brought to the casting temperature for the workpiece material and the metal is cast. Usually no support is required around the outside of the shell.

Problems of cracking and spalling of the shell during firing were encountered and were found to be caused by too rapid or too slow drying in the coating operations, or by uneven coating thicknesses. A number of different binders and coating mixes were tried. Best results were obtained using Nalcoag or ethyl silicate slips for the first two coats and a phosphate bonded Glascoat mixture for the outer coats, together with foam silica stuccoing for rapid wall build-up. These moulds were found to be capable of withstanding rapid heating or cooling without cracking.

Casting tests were carried out using a large jet engine turbine blade as the workpiece. The effect of large particle size of the ceramic material was found to produce a "pebbling" of the casting surface or occasionally a fine craze cracking. A water indicator, cobalt chloride, was added to the slurry causing it to change from pink to blue on drying. With careful drying procedures using air at low humidity and controlled temperature numerous blades were produced with nearly perfect surfaces.

Castings weighing up to five pounds have been made using casting temperatures as high as 3100 deg. F. In casting plain carbon steels the metal cools more rapidly than in the case of the usual massive investment mould. This gives a finer grain structure and less decarburization. Further investigations proposed involve determination of dimensional corrections to obtain 0.005 in. per inch tolerance on castings, the size limitations of unit castings and total casting weight, and the maximum size of ceramic shell which can be used without exterior support.

ADHESION AND FRICTION

F. P. Bowden, *Endeavour*, v. 16, no. 61

Recent experimental investigations have given some knowledge of the local changes which occur when one solid slides on another under various conditions. This information on the physics of solids has great practical importance in such diverse fields as the construction and lubrication of bearings, the polishing of materials, de-icing of aircraft, and the formulation of adhesives.

It is evident that there is a close connection between friction and adhesion. Friction is essentially the shear strength, and adjesion the tensile strength of the junctions formed at the region of contact of solid materials. For most solids, whether they are plastic, brittle, or elastic, the surface adhesion can be strong. The differences in the frictional behaviour of various solids are due mainly to the difference in their mechanical properties, since it is this which determines both the area of real contact and the shear strength of the junction. Materials which give a high coefficient of friction will potentially give a strong adhesion. Whether this adhesion is observed or not depends primarily on the effect of elastic stresses released when the load is removed. If these stresses can be avoided, or if their effects can be accommodated by the ductility of the junction points, the potential adhesion will be observed. If they cannot be eliminated the observed adhesion may be very small indeed. Lubricants which reduce the friction by diminishing the amount of metallic contact produce an even greater reduction in the adhesion.

Experimental laws which govern the friction of solids sliding on one another are simple. It is usually found that the frictional resistance is directly proportional to the load and is independent of the size of the surface in contact. A detailed examination of the contour of solid surface offers a ready explanation for these laws. Even with the best modern methods it is almost impossible to make a surface which is truly flat, and to a person of atomic size an optically or electrolytically polished surface would look like a landscape of valleys and hills differing in height by a hundred atoms or more. Most of the engineer's best surfaces have irregularities greater than this and may be thousands of atoms high.

Measurements of the electrical conductivity across metal surfaces placed together confirm that the real area of contact is indeed very small. It varies with the load, but for flat steel surfaces it may be less than one ten-thousandth of the apparent area. Such experiments also show that the real area of contact is almost independent of the size of the surface. It is very little influenced by the shape and degree of roughness of the surfaces. It depends mainly on the load which is applied and is directly proportional to the load. The general behaviour is consistent with the view that the surfaces are held apart by small irregularities. This means that, even with lightly loaded surfaces, the local pressure at these small points of contact is very high and may be sufficiently great to cause the hardest metals to flow plastically. Although the stresses will cause elastic deformation of the metal in the vicinity of the points of contact, the experiments suggest that the summits of irregularities on which the bodies are supported flow plastically and are crushed down until their cross-section is sufficient to enable them to support the applied load. There is strong evidence that the friction of metals is due, in large measure, to adhesion at these contact regions and represents the force necessary to shear these small junctions. The shearing may occur at the interface, but more frequently (because of work-hardening of the contact region), it occurs a little distance beyond it. A metal fragment is thus detached from one of the surfaces and adheres to the other. The transfer can occur from a hard metal to a soft one as well as conversely.

Metal surfaces exposed to the air are always covered by a film of oxide or adsorbed gas. This may be only a few molecules thick but it has a profound effect on the adhesion and friction. If the film is removed by heating the metals and allowing them to cool in a high vacuum the friction is increased. If sliding is attempted the area of real contact increases and the friction may reach an enormous value.

Since there is strong adhesion at the local regions of contact when two metals are placed together it would

INTERNATIONAL GEOPHYSICAL YEAR

The arrangements committee of the International Union of Geodesy and Geophysics XI Assembly in Toronto, September 3-14, pose with equipment to be used this summer by University of Toronto and Canadian Research Board expeditions in British Columbia and the Canadian Arctic to study glaciers as part of the International Geophysical Year. The IUGG is a group of international scientific organizations whose interests extend over nearly all aspects of the IGY. The various projects of IGY will be the chief topic of discussion by 1500 delegates from 50 countries at the meeting. Papers will be given on such diverse subjects as the Vanguard satellite which will probe the secrets of the earth's atmosphere to others on the basic structure of the earth itself. Professor J. T. Wilson (centre), vice-president of the IUGG and chairman of the arrangements committee, holds a gravimeter for measuring gravity on Canadian IGY investigations. In front of Prof. Wilson, J. A. Jacobs, secretary of the committee (left), and R. M. Farquhar may be seen various seismic equipment.

be expected that the force required to pull the surfaces apart in a normal direction would be comparable with the force with which the surfaces were originally pressed together, but this is not generally observed. Friction is always measured while the normal load is retained, but to study adhesion the normal load must be removed before any adhesion measurements can be made. In the course of removing the normal load, the elastic stresses in the material surrounding the junctions will be released, and there will be a slight change in the shape of the interfacial contour. The junctions themselves being highly worked will be relatively brittle and very small tensile displacements will break them. Therefore as the normal load is removed the junctions are pulled apart one by one so that practically none are left when adhesion measurements are to be made. Metals which are soft and ductile do not work-harden under the test conditions and have consequently indicated coefficients of adhesion as high as 1 (i.e., the normal force required to pull the surfaces apart is as great as the original load). Tests have been made in high vacuum of hard metals such as platinum, nickel, and silver. Friction of these naked metals is very high and normal adhesion at room temperature negligibly small. However, if the temperature of the metals is raised so that annealing can occur and then allowed to fall to room temperature, the adhesion is very strong. If an attempt is made to slide the clean metals the combined tangential and normal stresses will cause plastic flow of the contact regions, so that the area of contact, and hence the adhesion, will increase. Adhesion coefficients of well over 10 have been measured at room temperature. This adhesion of clean metals forms the basis of the process of cold welding.

A study of the frictional behaviour of some polymer thermoplastics (e.g., polystyrene, nylon, polyethylene) sliding on themselves has shown that all have coefficients of friction of the same order as the metals, except PTFE (polytetrafluoroethylene; e.g., Teflon) for which μ is phenomenally low. Close examination of the surface damage shows marked adhesion, plucking, and transfer of the plastic from one surface to the other. This is also the case when plastics slide on metals and a relatively soft plastic can produce slight wear of a much harder metal. One major difference in the frictional behaviour of plastics compared to metals is the effect of load. With metals the deformation at points of contact is truly plastic and therefore the real area of contact is directly proportional to the load.

With long-chain polymers which are visco-elastic their deformation depends on the geometry of the surfaces, the load, and the length of loading time. The coefficient of friction increases as the load is reduced and can be very marked at light loads.

With most plastics adhesion is strong and shearing takes place at a little distance from the interface so that transfer and wear occur. The low μ value for PTFE is due to the fact that adhesion is small and slip can occur at the interface. This appears to be an inherent property of the material since it retains its low friction even in high vacuum. If the surface is subjected to prolonged running at high speeds the frictional heating can damage it and cause a rise in friction.

The low μ value for graphite (0.15) has previously been attributed to its lamellar structure which allows it to shear readily. However, experiments indicated that when graphite is thoroughly outgassed by heating in a vacuum, the friction rises considerably (to 0.5) and there is great increase in wear. Small amounts of oxygen or water vapour can reduce the friction of outgassed graphite to its normal atmospheric value. Measurements of graphite sliding on itself and on metals at high temperature and in a high vacuum have indicated a decreasing μ value with increasing temperature. With such metals as copper, silver or gold this behaviour continues until the melting point is reached. However with such metals as nickel, titanium, molybdenum, and iron the friction begins to rise above 1000°C. when carbides or solid solutions begin to form with the graphite. The area of contact increases and the surface layer is a metallic carbide having a high shear strength.

Observations of the adhesions of ice to metal surfaces have shown that, if metal surfaces are really free of contaminating grease films, the adhesion of ice to all metals is greater than the strength of ice, so that any break must occur in the ice itself. The fracture of ice bears a certain resemblance to that of metals in that, under different circumstances, either brittle or ductile fracture can occur. Evidence shows that in the range of zero to -6° C. the failure is ductile. It is influenced by the rate of plastic deformation and is very dependent upon temperature. Below -6°C. the failure is by brittle fracture and the strength is no longer dependent upon temperature. A small amount of contaminant, such as a fatty acid, on the surface will reduce the adhesion to a low value and the failure will occur in the layer of the contaminant. The adhesion of ice to plastics has shown a similar behaviour except in the case of PTFE where adhesion is very small and the break occurs at the interface.

Sliding friction on ice is very low ($\mu = 0.03$) and is due to the formation of a water film. At temperatures close to 0° C. the water film is formed by pressure melting, but with appreciable speed and below zero temperatures the local surface melting is caused by frictional heating. There is evidence that in skiing it is this frictional heating and melting which is the major factor responsible for the low friction. The frictional behaviour is influenced by the contact angle which the water film makes with the surface. PTFE, because of its inherently low friction and because of its high contact angle in consequence of which it is not wetted by water, should have useful applications in skiing, sledging, and aircraft landing. Tests to determine static friction at various snow temperatures of skis coated with a conventional ski lacquer, a racing ski wax, and with PTFE showed that the friction for all these surfaces falls as the snow warms up from -10° to 0° C. Below -10° C. μ is fairly constant and all three surfaces approach a minimum value of 0.04 to 0.05 at 0° C. However at -10° C. μ values were 0.43 for the lacquer, 0.20 for the racing wax, and only 0.06 for PTFE.

UNDERGROUND WAREHOUSE EXCAVATED IN GRANITE

C. D. Zernichow and H. Moyner, *Civil Engineering*, v. 27, no. 1

Lack of sufficient level ground in Norway's capital city, Oslo, has resulted in the construction of a warehouse by excavation of series of tunnel-connected chambers in a granite cliff rising from the sea. From the shore two access tunnels 28 ft. wide by 32 ft. high were driven straight into the cliff for a distance of 525 ft. Crossing these at right angles, six parallel chambers were blasted out, each 633 ft. long, 46 ft. wide and 30 ft. high. The rock cover over the outer cross chamber is about 80 ft. thick increasing to about 250 ft. over the inner chamber. About 200,000 cu. yd. of rock were excavated and dumped into the steep fjord outside the adits to form access roads and future quays for unloading ships. The quantity of explosives used varied from 1.2 to 1.4 lb. per cu. yd. and required a total working force of 0.8 to 0.9 man-hours per cu. yd.

Precast panels and arches form the walls and ceiling of the two-storey structure in each chamber and 336 cast-in-place cylindrical columns support the cast-in-place second-floor slab. A total of 13,100 cu. yd. of concrete and over 1000 tons of reinforcing steel were needed. The units making up the walls and arched ceiling in the storage chambers were pre-fabricated. Most of this concrete was treated by the vacuum curing process, as were the cast-in columns in the first storey. It was the first time this process has been used in Norway. Only two specially built vacuum steel forms were employed for pouring the columns and the form could be removed in an hour.

Ventilation is supplied by two units, one being installed in each of the two entrance tunnels. The total cost of the warehouse was 16 million Norwegian crowns. In Norway underground warehouses are slightly more expensive to build than ordinary surface types but the cost of heating and cooling is considerably lower.

CERAMIC CUTTING TOOLS FOR MACHINING

Machinery Lloyd, v. 29, no. 2 and *American Machinist*, v. 101, no. 3

Ceramic cutting tools (i.e. cutting tool tips) are at present at a crucial stage in their development. Though they are well established for the machining of abrasive non-ferrous materials such as asbestos-plastics laminates, these tips have yet to reach their true position in metal cutting. Suppliers of suitable ceramic materials are the American companies — American Lava, Stupakoff, Adamas, Diamondite, and Sintox. As an example of the properties of such materials Sintox, which was originally introduced as an insulator for high grade spark plugs, has at least twice the strength of porcelain in tension, compression, and cross-breaking. The dielectric strength is also twice that of porcelain. The electrical resistance is little affected by temperature but its most unusual property is that the thermal conductivity is about twenty times that of porcelain (more nearly comparable with steel). It is harder than glass and as a cutting tool produces a fine surface finish with no build up, also a low coefficient of friction is achieved under all circumstances.

Experience has shown that the basic essential for obtaining good results when using all types of ceramic tool tips is to provide adequate support for the tip. While success has been met in experimental work, in production operations the major problem has been excessive vibration in the cutting tool and in the toolpost holder. It is vibration which cannot be seen but usually can be felt. Efforts are being concentrated upon developing a toolpost holder which will reduce vibration sufficiently to ensure production quality and longer tool life.

Round tips, which are mainly used for heavy duty turning and facing, can be indexed as the cutting edge wears and can finally be reversed and re-used on the reverse end. Square inserts are supplied with four cutting edges at each end. Ceramic tips are relatively cheap in initial cost and are normally considered as throw-away inserts, although they can be readily reground using a diamond wheel and a vibration-free machine. Tips are mounted in various fashions. The most common method is a slotted alloy steel tool holder with a screw clamp. Some inserts have been metallized, allowing them to be brazed to a tool shank, and a plastic resin adhesive mounting is under development.

The same inserts can be used for cuts ranging from 0.001 in. deep to 0.300 in. with a similarly wide range of speeds and feeds. Square inserts are better than triangular because the 90° corner is better able to withstand overloading than the 60° corner. A 1/16 in. nose radius on the tip was found necessary. Tool life has proved to be erratic under production conditions, but in the laboratory ceramics have proved superior to carbide on hard materials.

At present no specific make of ceramic can be selected as being the most satisfactory. All grades appear to give best results at speeds considerably higher than those used with carbide. All grades require a larger nose radius than with carbide and are most satisfactory with a 15° or greater lead angle. Problems preventing more general application of ceramics in production work are found in the design of tips and holders. Also it is probable that machine tools designed for use with conventional carbides and high speed steels do not provide sufficient speed (and/or torque) necessary for successful cutting by ceramics. Milling cutters, boring tools, drills and super-finishing tools are currently under development. Despite the present unsatisfactory tool life, the productivity and surface quality resulting from ceramic cutting is outstanding and a much greater degree of success is expected in the very near future.

The titles of the articles in the two reference works are "Ceramic Cutting Tools Offer Advantages for Machining" *(Machinery Lloyd)* and "Martin Tests Ceramic Tools".

GROUND ELECTROMAGNETIC SURVEY UNIT

A new portable electromagnetometer, known as the Ronka Ground EM unit, has been developed by Vaino Ronka, an electronics engineer with Aeromagnetic Surveys Limited, of Toronto. In the illustration, part of the equipment is seen carried by Robert Parker, who did the production engineering of the unit. The device has been used operationally and experimentally for over a year, and was publicly introduced at the Prospectors and Developers convention, in Toronto, in March 1957. The equipment consists of two horizontal electromagnetic loops, one round each of two operators. One prospector carries the receiver coil and receiver compensator console, and has earphones. His companion wears the transmitter coil and is connected to the receiver by a 200-ft. cable. The working principle is in general the same as that used in airborne magnetometer surveying equipment. It is said that up to five miles of picket line can be surveyed in a day.

LONDON AIRPORT

The June 1956 issue of *The Engineering Journal* contained an article by A. R. Macrae and C. Heyes on the engineering aspects of the construction and operation of London's international airport, now among the most efficient in the world and certainly one of the most acceptable from the traveller's point of view.

Her Majesty's Stationery Office has recently published an attractive and well-illustrated booklet (64 pp.), "London Airport", for Britain's Ministry of Transport and Civil Aviation. This explains, in non-technical terms, the origin of the airport, the passenger facilities, how the airport handles its aerial traffic, and the essential background services such as maintenance, power, and communications.

The airport caters not only for passengers, but has facilities for feeding and otherwise entertaining large numbers of the general public; there were over 600,000 casual visitors to the airport in six months in 1955. (H.M.S.O. Code No. 56-20.)

DEVELOPMENTS IN SWEDEN

Bureau de Presse Suédo-International, Stockholm, February 1957.

The first permanent television relay was completed recently with the installation of a directional antenna on the L. M. Ericsson radio tower, in Stockholm. The transmitting-receiving station is some 16 miles distant. Wavelength is 6 cm., frequency is 5,000 Mc/s., and power 5 watts. The antenna, made of aluminum, is 5 m. high by 3 m. wide and weighs 600 kg. The curvature of the antenna reflector was calculated on a new electronic machine of the Saab organization. Tolerances during construction were not allowed to exceed 0.05 mm. on lengths of 2 to 3 metres; this accuracy precluded field assembly, and the complete unit was successfully installed using a helicopter.

Kaplan Turbines Ordered — The State electricity authority has recently ordered two Kaplan turbines, with a combined capacity of 160,000 kw., from Nydqvist & Holm (Nohab), of Trollhättan. These will be the most powerful of their type in the country, and will be installed at the Porsi hydro-electric station, on the Lule river, in northern Sweden, as the first stage of the planned three-turbine installation. The net head will vary between 33 and 36 metres; maximum output, at 36 m., will be 131,000 h.p., and annual power production will reach 960 million kw. The Porsi station is due to operate in 1960-61. Cost is estimated at $23.7 million.

Stockholm Airport The new international airport for Stockholm, to be situated at Skå-Edeby, 15 miles from the city centre, will involve capital investments of some $35 million; in addition, Scandinavian Airlines System is to spend some $25 million for new hangars, offices, and so on. In the first stage, to be completed in 1960, the main runway will be 2500 m. long, to be extended to 3300 m. and finally to 4000 m.

ABSTRACTS OF PAPERS PRESENTED TO THE INSTITUTION OF ELECTRICAL ENGINEERS

The remote and automatic control of semi-attended broadcasting transmitters. R. T. B. Wynn, C.B.E., and F. A. Peachey. (No. 3276)

In the chairman's address to the Radio Section in October 1949 a description was given of the steps that the BBC was taking to extend its sound broadcasting service, without a proportional increase in the number of its technical staff. This was being achieved by a process which now might be termed "automation" but which at that time meant broadcasting from unstaffed transmitters remote from the studios supplying the programme material.

This paper reviews this technique and may be regarded as confirmation that these steps were justified.

138 kv. submarine power cable interconnecting the mainland of British Columbia to Vancouver Island. T. Ingledow, M.E.I.C., R. M. Fairfield, E. L. Davey, K. S. Brazier, and J. N. Gibson. (No. 3306)

The paper describes the carrying out of the 138 kv. a.c. submarine power cable project between the mainland of British Columbia and the island of Vancouver for the British Columbia Electric Co. Ltd. (B.C.E. Co. Ltd.).

The supply system of the region involved and the requirements necessitating the installation of a submarine power cable are described. The considerations leading to the adoption of the pre-impregnated gas-filled type cable, provided with a hollow conductor, and made in continuous lengths up to 16 miles are discussed and this is followed by the engineering development, design, proving, and performance of the cable and accessories from the electrical, mechanical, pneumatic, and corrosion aspects.

The manufacture of the cable and the development, design, and installation of the special plant necessary for the continuous length manufacture of strand, lead covered, and finished cable are described in the next section. Noteworthy items are large turntables for storing strand and lead covered cable, a length storage mechanism to link up the paper lapping machine and the lead press for continuous manufacture, and the coiling down shed for the storage of 90 miles of finished cable.

The transport and installation of the cable and acessories are dealt with in the penultimate section. Descriptions are given of the transport to site, the main crossings and landing sites, the laying of the main cable lengths by cable ship, and the scow method of landing the shore-ends. The reasons for the adoption of these methods are also given and the section concludes with a brief note on the testing, gassing and commissioning of the cables.

Earth electrode systems for large electric stations. J. D. Humphries. (No. 3275)

Interconnected systems have increased considerably in recent years, and the large possible earth fault currents resulting require further thought being given to earth system design, especially in areas of high soil resistivity. The paper discusses the special practical problems of the design, construction, and testing of earth electrode systems for stations with possible maximum earth fault currents in excess of 3 kilo-amp. The basic components are reviewed in some detail, and principles of design are suggested for power station and large substation earthing installations. Several examples are considered in detail and brief notes are given of a number of other stations. The measurement of soil resistivity and of the dissipation resistance of large earth electrodes is discussed and new techniques of resistance measurement which have been specially developed for use with large installations are described.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Progress by NYSPA

During February, progress continued on all features of the project. Overall construction is on schedule as concrete placement to date exceeds 925,000 cubic yards and excavation for all features exceeds 35.5 million cubic yards. Employment averaged 2,600 for the month.

At Long Sault dam, excavation of the upstream plug was suspended one week on February 12, due to an ice jam. Rock for construction of cofferdam E continued to be stockpiled.

Concrete placement in the powerhouse at end of February exceeded 452,000 cubic yards. Erection of the 300-ton gantry crane was started and placement of concrete foundations for equipment and structures in the 115-kv, switchyard and the transmission line was progressing rapidly.

At Iroquois dam, unwatering of the stage 2 cofferdam area was completed and excavation was started within this area. Approximately 90 per cent of the upstream stage 1 dike had been removed.

At Massena intake, removal of the upstream and downstream diversion plugs progressed on a 24-hour basis. The 48-inch permanent water pipe line was placed in the gallery. Installation of the electrical and mechanical equipment inside the structure continued.

Excavation under the five channel improvement contracts had progressed to approximately 60 per cent of completion, as excavation continued under three of the five contracts. Continued progress was being made by the reservoir clearing contractors, as 3,300 acres of the required 11,000 acres had been cleared to date. Clearing of the right-of-way for the Barnhart - Plattsburgh transmission line was 85 per cent completed. The contract for fabrication of the 200-Mva auto transformer was awarded and six bids were received on February 14, for the construction of the line. Specifications were being prepared for the completion of Richards Landing dike and the bridges in the village of Waddington. Close inspection and expediting was continued on the major items of equipment being manufactured at various plants. An on-the-spot supervisory check had been completed in various European plants fabricating components to insure their delivery on schedule.

Progress by Ontario Hydro

Moderate weather conditions prevailed throughout February. The total number of workers on the Ontario Hydro section of the project at month end was 3,650 persons.

Excellent progress was made on all

The St. Lawrence power dam. Canadian construction operations are seen in the foreground.

phases of the power-house. Approximately 470,000 cubic yards of concrete had been put into the main structure by month-end. Concrete placing had been completed for the first seven draught tubes and work was in progress on the eighth.

More than half the concrete had been placed for the scroll case for No. 1 generating unit. Installation of turbine units for the generating station also was in progress. Casings for three of the turbines were in place, and work was started on the fourth turbine.

After an idle period of two months, work was resumed on Cornwall dike. Rip rap was being placed on the upstream slopes in section three and more than 1,000 feet had been completed. Excavation also was in progress on the marine clay crossings.

At the beginning of February, the plug was opened and water was let into the mile-long diversion of Cornwall canal. All the plug was removed and excavation for the turning basin at the east end had virtually been completed. Cofferdams were being constructed across the old canal west of this turning basin and immediately west of where the dike will cross the old canal.

Large scale reservoir clearing of trees had commenced. Approximately 2,400 acres in the headpond area were cleared at month-end. The section cleared represents the most densely wooded area and is about 40 per cent of the clearing.

Channel improvement work had been progressing on schedule. About 9,000,000 cubic yards of earth and some 850,000 yards of rock had been removed by month end at Galops Island. At Iroquois Point, approximately 1,000,000 cubic yards of earth had been excavated. Three contracts totalling $13,432,357 were awarded for channel improvement work in the vicinity of Cardinal and Morrisburg, Ontario.

Hydro's 1957 schedules

By the end of March, the flow down the Long Sault rapids was to be halted by a rock and earth filled temporary cofferdam. The river water in the main part of the stream then would be diverted through a wide man-made channel excavated across adjacent Long Sault Island and then into the river's south channel. This work was being done to permit the building of the second stage of the concrete Long Sault dam.

Year-End Goals

Approximately 71 per cent of the power-house is scheduled to be finished by the end of 1957. Installation of the first generator will be started in mid-summer by the Canadian General Electric Company. Canadian Westinghouse Co. Ltd., will begin erecting its first unit in the fall. These two firms are the suppliers for the sixteen generators to be installed in the Canadian half of the International power-house. Each firm has eight units to supply.

Associated electrical work, such as installation of the switchgear and heavy current-carrying conductors, is scheduled for the end of this year. Installation of transformers will commence in the spring of 1958. A new feature will be the first Hydro installation of 230-kv underground cable. The cable will carry the power from the transformers at the power-house to a terminal structure, and the power will be taken from there by overhead lines to the transformer station, two miles to the north. These cables are being made in Britain. The longest one will be 2,200 feet.

Nearly 90 per cent of the power-house headpond is scheduled to be cleared. Cornwall diversion canal and dike closure will be completed and in operation early in the year. This will enable ships to sail without interference through the power-house area during the 1957 navigation season. Likewise, trains will be running over the 40-mile stretch of relocated CNR double track that will be completed this summer. Highway No. 2 will be relocated along the 40 miles between Iroquois and Cornwall. A major part of the relocated highway will be paved and in use.

All house-moving will be essentially completed in 1957, involving a total of approximately 500 houses transported to new townsites. Work will be in progress in the three new communities and the new subdivision in Morrisburg. Clearing of abandoned townsites will be underway and should be well advanced. The new St. Lawrence transformer station will be ready early in 1958 to take power from the first four units of the new generating station. By year end area transmission lines will be about 90 per cent completed for the distribution of power into On

Iroquois dam. Excavation operations are being carried out in the Stage II construction area.

tario Hydro's grid system. At Galops Island, Chimney Island, Iroquois Point, Point Three Points, and Cardinal Channel, the excavation work will amount to a total of some 21,350,000 cubic yards and will be about 73 per cent completed.

Ontario Hydro Providing 7-day Tour Service:

Interest in Hydro's St. Lawrence power development is expected to reach record proportions this year.

As a result it has been decided to resume tour service every day in the week. Beginning in March tour guides will be on duty at Hydro's project information centre throughout the week and on Saturdays, Sundays and holidays. Mondays through Saturdays, the tour hours are 9.00 a.m. to 4.30 p.m.; on Sundays and holidays, the hours are 1.00 p.m. to 4.30 p.m.

Progress By SLSA

Progress during the month of February was mainly confined to work on the five locks and on the south shore ends of the Jacques Cartier, Honore Mercier and Caughnawaga bridges. Total employment amounted to some 3800 persons. Work on all locks was on schedule.

At the Iroquois lock the headgates were all poured and work was proceeding on the chamber section. Bases for ballards were being set and sluicegate guides were being placed. Excavation had been started at the downstream end of the lock. Four million yards of excavation had been done up to the end of February and 174,000 cubic yards of concrete poured.

At Beauharnois the tunnel under the lower lock was being poured, with 29,000 cubic yards placed by month-end. Rock excavation to date amounted to 365,000 cubic yards. At the upper lock 345,000 yards of common excavation and 430,000 yards of rock had been removed but no concrete had been placed up to the end of February.

No concrete was placed during February at the Cote St. Catherine lock. 1,500,000 yards of common excavation and 1,200,000 yards of rock had been removed to the end of the month. At the St. Lambert lock the contractor was just getting ready to resume placing of concrete, with none poured during the month of February. Over a million yards of rock had been taken out to date.

At the Jacques Cartier bridge jacking up of the superstructure was proceeding, with traffic diverted to temporary lanes in both directions. Work on the bridge piers, already nearing completion, had been suspended for the winter, while a start had been made on the new south abutment. The south end approach embankments at the Mercier bridge and the footings for the wood trestle were pretty well completed. Excavation under the Mercier and Caughnawaga bridges on the south shore to date totaled 200,000 yards of common excavation and 253,000 yards of rock.

A contract for dredging and channel improvements in both the north and south channels at Cornwall Island, near Cornwall, Ontario, was awarded January 31 to Marine Industries Limited, Montreal, at $13,411,000. Under this contract common dredging in the south channel will amount to 1,500,000 cubic yards; common dredging in the north navigation channel, 980,000 cubic yards; rock dredging, 5,000 cubic yards and common excavation, 2,860,000 cubic yards.

On the same date a contract was awarded for the superstructure of a single track railway swing bridge over the Beauharnois canal to Bridge and Tank Company of Canada, Ltd., Hamilton, Ont. This contract is valued at $508,370. Completion is called for by May 1, 1958.

As previously announced, the dredging and excavation work in the south channel has been divided between SLSA and SLSDC. The Canadian portion will extend from the present Roosevelt Bridge, downstream for three and a half miles. This navigation channel will be built in two stages. Initially, it will serve 14-foot navigation which must be diverted through the two United States locks as of July 1, 1958. The second stage will involve the deepening of this section to the required 27 feet. Under this contract a mile of dredging will also take place in the north channel.

By July 1, 1958 dredging specified for 14-foot navigation in the south channel is to be completed. By October 31, 1958 the whole of the work in the south channel is to be completed to 27 feet and by November 30, 1958, the whole of the work shall be entirely completed. The seaway is to be opened to shipping at the beginning of the navigation season of 1959.

New Victoria Bridge Span Ready by Mid-1958

The final phase of the face-lifting on Victoria bridge will begin this spring, and with completion some 18 months later will end what was for many years the "horse and buggy" tradition of the span. Final modifications at the St. Lambert end will mean multiple access for both trains and motor vehicles. Traffic on both rails and road will be continuous, as will be the movement of ocean vessels through the St. Lambert lock during the navigation season.

NYSPA Power Sale

New York State Governor Averill Harriman in mid-February agreed to approve a contract whereby NYSPA would sell 239,000 kw. of seaway power or some 25 per cent of New York's share to Reynolds Metals Co. Reynolds plans to build a 100,000 ton aluminum reduction plant costing $88 million near Massena. The Authority expects Congress will permit it to build a 1,800,000-kw. station at Niagara. If it gets the Niagara license it must borrow $566 million; thus it needs firm contracts as an inducement to bond buyers. The deal with Reynolds is just such an inducement. Tying the seaway and Niagara power systems together, as the Authority plans, would increase the firm supply of kilowatts available at each by letting them share reserve capacity needed for peak loads. Integrating both with private utility steam plants would enhance the whole States power picture.

Authority Chairman Robert Moses has defined a 150-mile radius from Barnhart Island as the boundary of an area that could be economically served by seaway power. His first deal was with Alcoa for sale of 239,000 kw, to replace Alcoa's present power facilities which will be flooded out by the seaway. Now it is proposed to dispose of 239,000 kw. to Reynolds and 143,000 kw. to Niagara Mohawk Power Corp.

The Alcoa plant employs 6000. Reynolds, though it will only employ some 1200 persons, will probably bring a fabricator into the area as well. General Motors Corp. will build an aluminum castings foundry for Chevrolet next to the Reynolds plant to employ 500. Thus manufacturing employment in New York State, which has been declining, is due for a boost.

New Lakes Diversion not serious

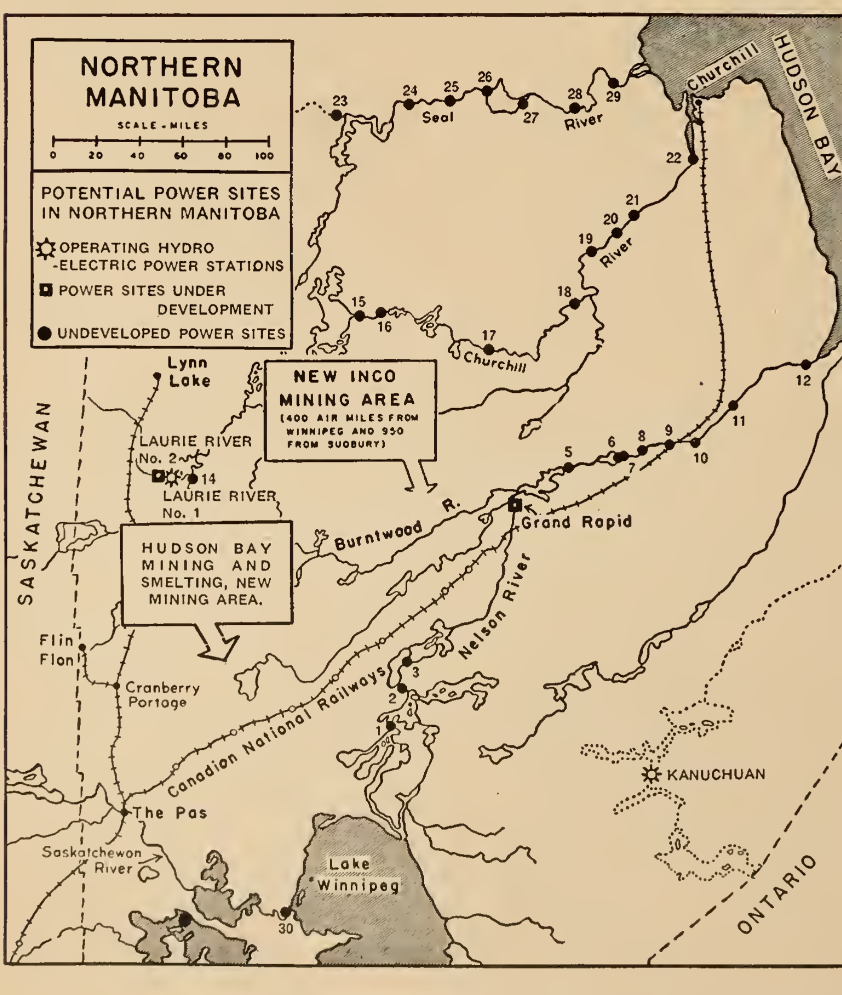
U.S. Army Engineers in charge reported in mid-February that increasing the diversion from Lake Michigan by 1000 cubic feet per second over a three year period would not greatly affect the levels of the Great Lakes. Lakes Michigan and Huron would be lowered ⅝ in. and Lakes Erie and Ontario ⅜ in. The affect would disappear in about fifteen years. Lowering of levels could be partly compensated for. Lowering levels could reduce output of power by a small fraction of one per cent. It would adversely affect navigation slightly during low lake stages, but the effect is so small and temporary that its effects could not be evaluated in monetary terms. Permanent diversion of 1000 c.f.s. would lower Lakes Michigan and Huron only one inch and Lakes Erie and Huron only ⅝ of an inch.

Northern Manitoba Resources

Great attention has been directed recently to the resources of northern Manitoba, in particular to the water powers. This was brought into focus by the recent joint announcement by the premier of the province and the president of International Nickel Company of Canada Limited concerning the establishment of an immense nickel industry in the Mystery-Moak Lake area. (Reported in the February 1957 issue of the Journal)

Eighty-five percent of the water power resources of Manitoba, or about 4½ million horse power, are located in northern Manitoba, or north of latitude 53. Less than one quarter of one percent of these resources, less than 9000 hp., have been developed, to date. Present developments comprise a hydro electric station of 7000-hp. capacity on the Laurie River, (built to serve the mining requirements of Sherritt Gordon Mines Limited at Lynn Lake) and an installation of 1,900-hp. on the Island Lake River, built some years ago.

Two sites are under development.



(1) The 7000-hp. plant at No. 2 power site on the Laurie River is meant to provide additional power for the Lynn Lake mine of Sherritt-Gordon Mines Ltd. Completion is scheduled for October 1957.

(2) The Grand Rapid power project on the Nelson River is being developed by Manitoba Hydro Electric Board. Power from this source will supply the International Nickel Company's mining operations in the Mystery-Moak Lake area. Completion is planned for 1960.

Undeveloped potential water power sites in Northern Manitoba can be listed as follows: Nelson River, 12 sites totaling 2,967,000 hp., the Churchill River, 10 sites, 1,006,300 hp.; Seal River, 7 sites, 151,460 hp.; Saskatchewan River, Grand Rapids, 150,000 hp.; other rivers, 192,000 hp.

The Saskatchewan River, Grand Rapids site represents a "probable" future source of power for southern Manitoba. This is interesting in view of the fact that harnessing of southern Manitoba water powers is virtually complete, with 762,000 hp. of generating capacity installed. Mainly, increased supplies would be met from thermal generating stations or by transmission over considerable distances.

While metals are seen first in looking at northern Manitoba's prospects, other factors take on importance, also,—eg. commercial fishing, the tourist industry, agriculture. The pulp and paper industry has received an impetus from the Grand Rapid power development on the Nelson River. This area, it is reported by the Department of Industry and Commerce of Manitoba, can offer a combination of favourable economic factors for this industry. These are listed as adequate power, existing railway facilities to the south and north, sufficient and economical wood, a long cutting season, a fair supply of labour, and acceptable townsite legislation.

Flin Flon Developments

Shaft sinking and underground development work will be started during 1957 in the Snow Lake area of Manitoba.

The Hudson Bay Mining and Smelting Co. Ltd., continued its active prospecting in the general vicinity of Flin Flon in 1956. There were discoveries of two new mineral deposits of major significance near the town of Snow Lake, Man., one of which is at Chisel Lake 5 miles to the southwest, and the other at Stall (Miller) Lake, 4 miles southeast of the town.

The Chisel Lake property has predominant zinc values with lesser amounts of gold, silver, copper and lead, while the Stall Lake property has predominant copper with lesser amounts of other metals. The company also owns another copper mine property at Osbourne Lake, 12 miles northeast of Stall Lake. This has been developed by diamond drilling.

Production from this new area will be treated in the metallurgical plants of Hudson Bay Company at Flin Flon, so that known ore reserves will extend operations there for many years. In addition to the discoveries already made in the Snow Lake area, the company has a further intensive program of exploration work under way, and is searching by geophysical methods and diamond drilling, over large areas, under option or claimed, for additional ore deposits. The recent discovery of sizable base metal ore deposits in this new district represents one of the major mining discoveries of recent years in Manitoba.

Canadian Pipeline Projects

Trans Canada Pipelines

Throughout February crews were clearing and levelling right of way between Pense, 15 miles west of Regina, and Winnipeg. Other construction operations, practically shut down from mid-December to the end of January, were resumed in part during February. Price-Poole had set up headquarters at Crandall, Manitoba, and was setting up a new type of semi-automatic jointing yard there. Welding was started at the end of January and the current rate during February was about 50 joints daily.

Pipe deliveries had been almost competed for the 34-inch line to the Red River by the end of February, and stringing was completed on sections 3 and 4. Clearing and brushing on these two sections were completed, as well as on most of section 5 and a third of section 6. Pipe was being strung out of the Price-Poole jointing yard as fast as it was stockpiled from the machine. The double jointing yard on section 6 will be reopened by early March.

Work on river crossings was resumed in mid February. No start was planned on the crossing over the Red River at St. Norbert near the end of the 34-inch line until Miniota and Portage La Prairie crossing were in.

Trans Canada officials predict almost 60 per cent of the entire pipeline will be completed this year. Work on the 34-inch western leg will resume as soon as weather permits, with natural gas due in Winnipeg September 1. Eighty-five miles will be laid this year from there to the Ontario boundary, while Trans Canada will supervise construction by the Crown Corporation of 310 miles of 30-inch pipe to Port Arthur. Trans Canada will also lay 308 miles of 20-inch pipe this year from Toronto to the west end of the Island of Montreal. Welland tubes have commenced manufacture of the 20-inch pipe for this stretch.

Alberta Gas Trunk Line Co.

Alberta Gas Trunk Line Co. plans to lay 100 miles of 18-inch line and 18 miles of 34-inch line during the current year, to connect up the Provost, Bindloss and Sibbald fields with Trans Canada's main line. They completed financing for some $13 million during February. Work on this gathering system is already under way. By 1960 the company expects to have a 500-mile gathering system costing some $54 million, capable of moving 620 million cubic feet daily. Addition of compressor stations would boost capacity to 800 million cubic feet daily.

Northern Ontario Pipeline Crown Corporation

Trans Canada Pipeline officials are not fully satisfied with the Crown Pipeline Corporation's arrangements for building the 30-inch section of the project over the Northern Ontario section from the Manitoba boundary to Kapuskasing, and want to do the engineering themselves. Tenders closed on March 1 for clearing over this section. As of February 22 no deliveries of the 30-inch pipe for this stretch had been made.

The Crown Company was reimbursed at the end of February by Trans Canada for the $50.7 million advanced to Trans Canada at various times last year. Effective March 1, 1957, J. C. Lessard of Montreal, and J. W. McKee and Dr. G. S. Walters of Toronto replaced Marc Boyer, R. G. Johnson and M. W. Sharp of Ottawa on The Board of Directors, of which D. A. Golden, Deputy Minister of Defence Production, is President.

Sale of Montreal Gas System

An option to purchase the gas distribution system and related facilities of Hydro-Québec in the Montreal area for some $35 million is held by Quebec Natural Gas Corporation. A Trans Canada contract with this company calls for initial deliveries of 30 million cubic feet per day (whether from Tennessee Gas Transmission or Trans Canada) and progressive increases in this volume to 102 million cubic feet daily by October 1963, and to 112 million thereafter. Peak sale of manufactured gas in the Montreal area at present runs about 35 million feet daily. The Quebec Legislative Assembly gave final approval on February 21 to a government bill authorizing the sale.

$200 Million Financing

Besides the $25 million initial financing for Quebec Natural Gas to be marketed early in April, there are many other offerings totalling about $90 million pending within the next three months. Largest of them is for Union Gas Co., which expects to raise some $35 million. This company faces the biggest expansion move in its history, which will triple its operations over a few years. Delivery of 140 miles of 26-inch pipe is assured by August to be laid from the Dawn Township storage field to Hamilton, at a cost of between $22 and $25 million.

Next in size is the Northern Ontario Natural Gas Company's $25 million offering, expected about the end of March. This company's various distribution systems will cost them some $32 million. Construction of systems for Kenora, Dryden, and Lakehead cities will be started early during the coming summer, while next year the company will lay distribution systems for communities from Kapuskasing to Orillia, including those for Bracebridge and Gravenhurst, as well as the 82-mile lateral from North Bay to Sudbury.

Consumers' Gas Co. of Toronto have a $50 million expansion program under way, on which they have already spent $25 million and plan to finance $5 or $6 million this year of the remaining $25 million. The Public Utilities Commission of Kingston is considering an offer by Consumers' Gas Co. to spend $5 million in developing a natural gas distribution system, which would take five years

Cobweb of wire rope carries the 30-in. tube of Westcoast Transmission Company's gas pipeline over the Fraser River at Shelley, B.C.

to complete. Consumers' would be awarded the franchise.

Lakeland Natural Gas, which holds franchises in 18 central Ontario municipalities, plans a 3 year expansion program costing $13 to $18 million, and will finance sometime this year.

Winnipeg and Central Gas Co. is already well embarked on its $20 million expansion program.

Westcoast Transmission

Work on the Westcoast Transmission pipeline was continued during the winter months, and pipe laying, construction of compressor stations, aerial crossings and other installations were well ahead of schedule in mid-March, with more than 600 men at work. Pipe laying on sections 3 and 4 in central and southern B.C. was carried out during the winter, and full-scale laying was scheduled to start shortly after the first of April.

Work was underway on the four compressor stations planned for this year. The first three were more than one-third complete, and foundation work was proceeding on the fourth. All engines and compressors for Station No. 1, located at Taylor, were delivered and were on their foundations, while the engines for Station 3, near Fort McLeod, and Station 5, near Quesnel, had been delivered. The major aerial river crossings over the Peace and Fraser Rivers at Shelley and at Quesnel, were completed.

Main line pipe installation was more than 71% complete. Nearly 90% of the main line pipe had been received. The northern 120 miles of the line had been completed in December, and plans were underway to test this section with natural gas from wells in the nearby Kiskatinaw gas field. Four-inch pipe was being laid from this field to the mainline. The double-jointing plant had been established near Prince George, and would resume its operations in March.

The Company foresaw no delays in construction during the coming season, and expected gas to be flowing through the line before the Fall of this year. Initially the pipeline will carry 400 million cubic feet of gas a day. By the addition of further compressor stations, the capacity can be increased to 660 million cubic feet a day. Total cost of the present project is $170 million.

Westcoast is establishing its operating headquarters in Vancouver. Divisional operations will be centered at Fort St. John, Prince George, and Savona, B.C., with maintenance sections located at intervening points along the line.

Saskatchewan Developments

Two power stations are under construction by the Saskatchewan Power Corporation, one at Estevan and one at Saskatoon, each to produce 264,000 kw. when completed. Each station will cost approximately $40,000,000, and when in operation they will establish complete integration of the provincial power system.

The Saskatoon plant is being built on the southwest corner of the city on the bank of the South Saskatchewan River, and will cover 85 acres of land. It will house four 66,000-kw. steam turbine generators, the first to be commissioned in the spring of 1958. The first two generators are on order from the Brown Boveri Company and the English Electric Company.

Coal and oil will be the main fuels, with natural gas from the nearby gas pipeline being utilized for off-peak generating purposes.

Two steam boilers are now on order from Foster-Wheeler Co. Ltd., in St. Catharines, Ont. They are designed to produce 600,000 pounds of steam per hour each, and are the largest boilers ever installed in Saskatchewan. In the water pumping plant there will be an initial installation of two pumps, each with a capacity of 66,000 gallons per minute.

At Estevan it was necessary to design a dam at Long Creek in order to provide a reservoir of cooling water for the new station, to be constructed on the bank of the creek. The dam will be an earth-fill type, one of the largest constructed in the province and the first of its kind built by the SPC for use in conjunction with thermal power production.

When completed, the reservoir will contain some 50,000 acre-feet of water with a surface area of approximately 2,000 acres. The maximum water level of the reservoir under these conditions will be reached at a height of 1,840 feet above sea level.

This level ensures that there will be no unwarranted increase in the water level of Long Creek across the international boundary.

Power produced by the Saskatchewan Power Corporation in 1956 is reported as 622,676,923 kwh.

The commission's new $1,500,000 gas engine generating plant at Kindersley was officially commissioned in November adding a total of 9,000 kw. to the northern integrated system. The largest internal combustion engine generating station in the province, it uses natural gas from the Brock-Coleville fields.

Work has already started on an $1,800,000 extension, to be in operation by the end of 1957. It will house two Brown-Boveri gas turbine units, each with a capacity of 8,000 kw., bringing the total capacity of the plant to 25,000 kw.

At the A.L. Cole plant in Saskatoon, in 1956, a 33,000-kw. steam generating unit was supplied by C. E. Parsons of England. This addition raises the capacity of the plant to 105,000 kw.

Mining

Production from all the uranium producers in Saskatchewan is expected to reach a value of $54,000,000 during 1957.

In the Beaverlodge area, April 1957 will mark a large increase in milling facilities. Eldorado Mining and Refining Limited will have increased their milling capacity to 2,000 tons per day. Lorado Uranium Mines Limited, having made progress with mill construction, expected to be in production this month, with a capacity of 700 tons per day. Gunnar Mines Limited had increased their rated capacity to 1,650 tons per day by the end of 1956.

The Hudson Bay Mining and Smelting Company Limited, Flin Flon, continued to be the only producer of base metals. This company produces from both the Manitoba and Saskatchewan sides of the border, with the bulk of its production coming from Saskatchewan.

Exploration for potash in the province continued at an increased pace during the year. The Potash Company of America announced plans for the beginning of construction in 1957 on their $20 million surface plant. Production is expected to commence by the fall of 1958 at the rate of about 4,500 tons of ore per day. There are a total of 18 companies and five individuals holding Crown rights in the province. Represented are all the major potash producers from New Mexico as well as German and French interests. By the end of 1956, 3,500,000 acres of Crown owned mineral rights were under exploratory disposition for potash.

There was an increase in the quantity of sodium sulphate produced in 1956 to approximately 180,000 tons. Western Clay Products Limited began construction in 1956 on a vitrified clay products plant at Regina to utilize clay from Eastend. Salt production at Unity was more than 40,000 tons in 1956.

Saskatchewan lignite coal production from the Estevan-Bienfait area set a record year in 1956, with coal production amounting to 2,343,000 tons. The plans for the Estevan thermal power plant to use 2 million tons of coal per year, will greatly increase the coal production in this area.

What Goes On

Canadian Pacific Railway Company

Canadian Pacific Railway has instituted an integrated data processing program with the establishment of a Trans-Canada network of data centres and a computer centre in Montreal. Each data centre receives information by teletype from local points in its area. This is fed into a transceiver for transmission to the computer centre for processing.

Canadian Pacific Communications have provided the necessary telephone channels for transceiver operation and the telegraph channels for the extensive teletype network which also supplements transceiver transmission to and from the computer centre.

Canadian Industries Limited

C-I-L reports the ammonia plant at Millhaven, Ont., is in the final stages of construction. Production capacity of the $9 million plant will be 200 tons per day.

Construction began in early 1957 on the sulphuric acid plant at Copper Cliff, Ont., with completion expected in 1958. The investment was $3 million. Three hundred tons per day will be produced, using smelter fumes from International Nickel Company's iron recovery plant.

A plastics research laboratory is to be completed early in 1957 at New Toronto; later in 1957 a hydrogen peroxide plant at Hamilton will be finished.

An aerial view of Lorado Uranium Mill, under construction in the Beaverlodge area of northern Saskatchewan.

Shell Oil Company of Canada, Limited

A tanker of 40,000 tons deadweight will be built in Canada at an estimated cost of nearly $11 million and will join the Shell Canadian Tankers fleet in 1960.

Davie Shipbuilding Company of Lauzon, Quebec, will build the 710-ft.-long tanker for Papachristidis Tankers Limited, a Montreal corporation.

On completion the tanker, to be named "Canada Shell", will be turned over to Shell Canadian Tankers on a 20-year bareboat charter. Shell will man, manage and maintain the vessel.

Ontario Hydro

Response to the largest bond issue, $100 million, ever floated by Ontario Hydro was reported in March as gratifying.

Proceeds from the bonds will cover expenditures by the Commission during the coming extensive summer construction period. Altogether 10 separate projects are newly authorized.

The Commission will have, in the spring of 1958, a large scale electronic Univac II computer installed in the head office building in Toronto. The transition from the present to new methods will be gradual. The computer will be engaged primarily in commercial data processing and will also handle certain scientific and engineering computations.

Employees are following classes in electronic data processing. The first of several classes will comprise fifty planning personnel who will help to integrate the new "office automation" system on a step-by-step basis.

Dominion Bridge Company

Dominion Bridge Co. Ltd., was confirmed as general contractor, at $11,099,672, for Contract No. 2, for the Second Narrows Bridge, at Burrard Inlet crossing, calling for superstructure of main and approach spans and reinforced concrete bridge deck.

Owner is British Columbia Toll Highways and Bridges Authority. Consulting engineers are Swan, Rhodes and Wooster, Vancouver.

English Electric Company of Canada

Contract for construction and installation of five 200,000-hp. turbines was awarded to English Electric Company in February.

The turbines are for the 1,000,000-hp. underground hydro electric project of Aluminum Company of Canada Limited at Chute des Passes on the Peribonka River in Northern Quebec.

The general contractor is Perini, McNamara, Quemont Construction Companies. The engineering on the project is done by H. G. Acres Company of Niagara Falls, Ont.

E.G.M. Cape & Co. Ltd.

E. G. M. Cape will be the general contractor, at $4,898,000, for the superstructure of the combined customs and immigration building at Wolfe's Cove, Que., for the Department of Public Works, Ottawa.

Consulting engineers are Leblanc, Montpetit and Dorval; and D. D. Clark, both of Quebec City.

New Schools of Engineering

Two new engineering courses will be in effect this year with the opening of classes in September. The universities offering, for the first time, engineering courses leading to the degree of bachelor of engineering, are McMaster and Carleton, both in Ontario.

Carleton, Ottawa

Professor Donald F. Coates, M.A. (Oxon), M.ENG. (McGill), M.E.I.C., assistant professor of engineering at McGill and consulting engineer, has been appointed director of the school of engineering at Carleton. Dr. C. T. Bissell, president and vice-chancellor, released this information recently.

Students entering Carleton next September in the first year of engineering will begin the new program.

The new Carleton course will be one suitable for those students interested in careers in design, development, construction, production and operation in the fields of civil, mechanical and electrical engineering.

Professor Coates said that Carleton is fortunate in having already a well established two-year certificate course, which it can expand into a four-year degree program.

Carleton's undergraduate curriculum, details of which will be announced later, will emphasize the engineering sciences but will include a sufficient amount of work in engineering design to illustrate the application of knowledge to practical problems. Students in the fourth year of the program will have the option of doing their design work in either electrical, mechanical or structural engineering. Eventually, this undergraduate program will be supplemented by a specialized graduate program in selected subjects.

While a member of the McGill faculty, besides obtaining his master of engineering, specializing in foundation engineering, Prof. Coates was active as consultant on seaway, power and building projects. He has published the results of some research and investigation work in several engineering journals.

McMaster, Hamilton

Dr. George P. Gilmour, president of McMaster University, made the announcement of the program offering four year courses in chemical, electrical, or mechanical engineering, engineering physics, and metallurgy. It is planned to enrol fifty first year students in September, 1957.

"The addition of engineering studies is a natural expansion of the scientific activities of Hamilton College", Dr. Gilmour said.

Dr. John W. Hodgins, B.A.SC., PH.D., F.C.I.C., is director of engineering studies and professor of chemical engineering. Formerly professor of chemical engineering at the Royal Military College, Kingston, Dr. Hodgins has been planning the courses and facilities for the new school.

Dr. Hodgins reported that engineering research is being planned as an integral part of the program, since a research atmosphere is necessary to staff and students alike. "The activities of engineers are having an ever increasing impact upon society," he said, "and since the current shortage of engineers has the effect of allowing recent graduates to move rather quickly into positions of responsibility, it is appropriate that about one-fifth of the course will consist of humanities and social studies".

The present first year engineering course will be discontinued in the spring of 1957. For the first year of the new courses, lectures and laboratory work will mainly be given in the new Physical Sciences Building. Nuclear engineering will be added to the curriculum as a graduate course as soon as construction of the nuclear reactor and the engineering buildings on the McMaster campus is completed. Several industries have already made generous contributions, and a special fund raising campaign is being planned to assist in the costly construction of engineering facilities.

News of the Institute and the Profession

COMMENT AND CORRESPONDENCE
ELECTIONS AND TRANSFERS

Recognition For The *Journal*

Recently it has come to the *Jour-* *l's* attention that a readership sur- y made by one of the well known nerican periodicals with a so called ınadian edition pointed up, ironic- ly enough, that *The Engineering urnal* is the most read technical iblication in Canada and also that om the advertiser's point of view e *Journal* gives a better value per ader than does the publication hich made the survey.

Naturally in a story of this kind l names will have to be omitted it suffice it to say that one of the g Canadian industries was solicited the American publication for ad- rtising and in order to prove what superior medium the American iblication was they made a reader- ip survey of twenty-five publications ostly published in Canada. They proached almost five hundred engineers to have them indicate on a questionnaire the order of their preference for the twenty-five publications.

The resulting figures are shown on a percentage basis representing the first and second choice of the engineers who responded.

From the Institute's point of view the most interesting fact is that the *Journal's* percentage was thirteen and its nearest competitor in the technical field had only four per cent. *The Engineering Journal's* showing was within two per cent of that of the two largest Canadian non-technical periodical publications in the country.

It is comforting to have this further assurance that among Canadian engineers *The Engineering Journal* is still their first choice in reading matter.

Consultants

This message is addressed in par- ular to the consulting engineers of ınada.

In the *October 1956* issue of the *urnal* it was announced that the stitute was endeavouring to bring e information on its register of con- lting engineers up to date. Over 50 engineers were contacted at that me and the information already on le was returned to them for revi- on. Most engineers have replied but ere are still some outstanding, in ldition to which we believe there ay be some additional firms in Can- da who have not yet registered with e Institute at all.

It is important that we have on ur register the names of all the con- lting engineers with some account f the work which they have done and the fields in which they are now interested. There are many instances of substantial contracts being given to persons whose names were submitted by the Institute to prospective clients. We believe the service is a valuable one to Canadian engineers and we would like to have our records absolutely complete.

If any consulting engineers who read this notice have not yet sent in the information which is required, it would be appreciated if they would do so promptly. If the standard form for information has not been received, please advise this office and one will be sent to you immediately.

This service is rendered in an attempt to show prospective clients that Canadian engineers are competent to do any class of work which may be required in Canada.

The service is absolutely free both to the client and to the consultant.

Nuclear Congress

The Engineering Institute of Canada was one of the organizations sponsoring the Nuclear Congress, held in Philadelphia in March.

The Congress was sponsored by several organizations with which the Institute has been in cooperation for many years. The list includes the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Institute of Mining and Metallurgical and Petroleum Engineers, the American Society of Civil Engineers, the American Institute of Chemical Engineers, the American Chemical Society and others.

The Congress was made up of sev-

Colour plates courtesy Canadian Pacific Railway eral parts, and brought together the different organizations that have been interested in the nuclear engineering field over recent years.

One portion of the Congress was the Second Nuclear Engineering and Science Conference, another portion was the Fifth Atomic Energy in Industry Conference and the third was the Fifth Hot Laboratory and Equipment Conference. In addition, the occasion marked the third International Atomic Exposition.

It is proposed to publish a report on the Congress in a later issue of the *Journal.*

Columbia River

This editorial, from the Daily Journal of Commerce, Portland, Oregon, *is reprinted as a further expression of opinion on the Columbia River Discussions. Editor.*

"Canada and the Upper Columbia"

The September 29 issue of *Maclean's Magazine,* one of Canada's most widely read magazines, contains an article entitled "The Coming Battle for the Columbia", Bruce Hutchison, author of the article, sets forth the Canadian viewpoint and a great deal of background and history leading to present negotiations over use of the water in the upper Columbia river.

Unfortunately for the United States, the history goes back to the days when this nation was a lusty, rapidly growing group of states with little thought of our future resources and little regard for anything that stood in the way of our growth.

The article points out one of our great blunders in the past, going back to the days when we coveted gold in Alaska. Along with the gold we desired Alaska's panhandle, which controls such rivers as the Yukon, even though nearly all of that river lies in Canada.

The common law of England had developed from the theory that no man has the right to diminish or damage the flow of that river to the detriment of another man downstream. The United States rejected any such theories, and bulled through its own concept of the time — that a nation has the right to do as it pleases with any water in its borders.

That is the way the matter now stands, and we cannot question the legality of any move Canada may make with the waters of the Columbia or any other river within her borders. We can only hope that Canada will be generous for other reasons, but to be realistic we must realize that she is well aware of the value of her hydroelectric power potentials and is not preparing to negotiate them away without some real inducement."

Institute Represented on C.E.S.S.

THE SECRETARIES MEET: This photo shows less than half the delegates who attended the annual meeting of the Council of Engineering Society Secretaries, held in New York in January 1957. In the second row from the front are some of the officers, right to left, Charles S. Doerr, executive secretary, The Engineers Club of Philadelphia, a director; Allan Putnam, assistant executive secretary, American Society of Tool Engineers, vice-president; Nelson S. Hibshman, secretary, American Institute of Electrical Engineers, secretary; T. J. Ess, managing director, Association of Iron and Steel Engineers, retiring president; L. Austin Wright, general secretary, The Engineering Institute of Canada, newly elected president; William P. Youngclaus, executive secretary, American Society of Quality Control, treasurer. The ladies represent the Women's Engineering Society.

BANQUET ADDRESS

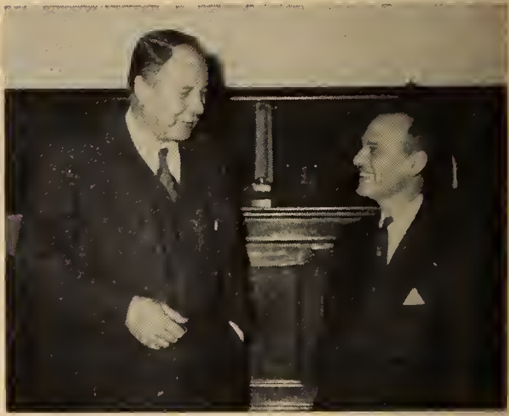
Mr. Justice S. Freedman, Winnipeg

- 34 Technical papers
- Unveiling of the Cambie Memorial Plaque
- Scenic bus excursion to Mount Norquay Lodge.
- Branch Officers' and Students' Conferences.
- Hospitality of Muriel's Room.
- Calgary Branch stage show—"Pipe Line Musical Review".
- Golf Tournament.

Athlone Fellowships. The Institute entertained Dr. H. H. Burness of the Ministry of Education, Great Britain, when he was here selecting candidates. Left to right, Dean R. E. Jamieson, Dr. Burness, Past-president R. E. Heartz, Dean Henri Gaudefroy, and Dean Emeritus J. J. O'Neill, of McGill.

Branch Events

Belleville Branch. Head table (left), including Councillor S. Sillitoe, President and Mrs. McKillop, and Vice-President and Mrs. H. R. Sills of Peterborough.



Montreal Branch (above). The retiring chairman E. D. Gray-Donald (left) hands over the chairmanship of the Branch to Leo Roy.

The Kingston meeting (above). "A good time was had by all". The head table (right) at Kingston. Left to right, His Worship Mayor F. P. Boyce, Mrs. McKillop, Col. C. W. Jones, Commandant, RCEME School, The President, Mrs. Jones, Air Commodore D. A. R. Bradshaw, Commandant, Royal Military College, Mrs. L. F. Grant, and Mrs. Boyce.

THIRTY-FIVE YEARS AGO

Comment on the Journal of April, 1922

Advertising has changed a lot in thirty-five years. By modern standards, that in the *Journal* for April, 1922, seems pretty dull and one wonders why anybody would read it. There was a total lack of colour and few illustrations; advertisers depended upon using as many varieties of type as they dared for pulling power, but the pull seems to have been there nevertheless, because most of the names I notice in 1922 are those of our advertisers of today, with the exception, of course, of the fairly numerous firms which have gone out of business in the meantime. Perhaps the modern advertiser pulls the long bow in praise of his wares as often and as far as the old timers, but he is more subtle and artistic about it.

Technical Papers

Of late years the *Journal* has not published prize-winning student papers; in 1922 it did. The position of honour at the front of the April issue for that year is occupied by E. R. Woodward's (JR.E.I.C.) paper on "The Lignite Briquetting Plant at Bienfait, Sask". This plant was built as a joint effort of the provinces of Manitoba and Saskatchewan and the Federal Government as part of an attempt to find better ways of utilizing the vast deposits of low-grade coal in the southern parts of the two provinces. Containing about thirty per cent moisture, the raw lignite quickly slaked to dust on exposure to the air and had a lamentable propensity for spontaneous combustion.

At the Bienfait plant the lignite was subjected to low-temperature carbonization and the char briquetted, producing a high grade, smokeless fuel. The yield of gas was expected to be great enough to operate the carbonizers and it was thought that valuable by-products could be recovered from the tar.

Although much experimental work had been done and a semi-commercial plant had given encouraging results, the Bienfait plant was not a success. It never got into satisfactory production. The jump from pilot plant to full scale operation was too great and made too quickly and with too many guesses and too little reliable information. Perhaps for political reasons, operation was begun too soon; there should have been more time to "get the bugs out of the process".

The failure of this scheme was a disappointment to all connected with it, especially as most of them felt that better results could have been attained had circumstances permitted. Oil and gas fuels and improved methods of burning lignite have reduced the appeal of any process of the benefication of the raw coal.

The second paper in this *Journal*, "Actuarial Factors in the Design of Irrigation Structures", by H. B. Muckleston, M.E.I.C., contained a lot of good sense and might be read to advantage by many engineers today. The author set himself the task of discussing the value of storage, its relation to runoff, capacity and unit cost curves and economic storage capacity. Some of these matters were approached from the angle of probability, and early use of that theory. This paper is worthy of permanent preservation, type of which, unfortunately, we get too few. No matter how useful and interesting at the time of publication, the value of most of our papers naturally and gradually fades as time passes.

In 1922 Winnipeg had just finished the Maryland Street bridge across the Assiniboine river, a two-span concrete arch of conventional design. This paragraph may be quoted from the paper describing it: ". . .A concrete bridge presents all exposed faces of one colour . . . These faces . . . disclose . . . irregularities; each . . . day's run of concrete . . . is . . . outlined in any exposed . . . surface; board marks have . . . different shades of grey; . . . any yielding of forms . . . results in offsets and waves; occasionally, rock pockets appear which must be covered by . . . patches". These words might be borne in mind by those who wish to turn out a good looking, as well as structurally sound, concrete job.

It is an odd fact that the author of this paper, J. F. Greene, M.E.I.C., nowhere in his paper gives any clue to the size of the bridge, beyond saying that it had a fifty-foot roadway and two seven-foot sidewalks, nor were there any illustrations from which dimensions could be obtained. The finished bridge is shown to be a graceful structure.

Leonard Medals Awarded

Among the editorials in this *Journal* is an account of the Leonard Medals for 1919, 1920 and 1921. These were the first awards of these medals, all made to members of the Canadian Institute of Mining and Metallurgy. The gold in the medals came from the Coniagas mine, 24.5 ounces having been recovered in the electrolytic refining of 41 million ounces of silver, truly only a "trace".

There was also a brief account of a series of "special water power lectures" at the University of Toronto. These had been arranged by Professor R. W. Angus, M.E.I.C., of the department of mechanical engineering. Three of the five speakers were Max V. Sauer, M.E.I.C., and T. H. Hogg, M.E.I.C., both of the Hydro-Electric Power Commission of Ontario, and Norman R. Gibson, M.E.I.C., of the Niagara Falls Power Company.

The Branches

The Vancouver Branch decided it could get along without any dues for the current year, though it didn't say how this eminently satisfactory state of affairs was to be attained. Was the Branch to live on its surplus or had it discovered a fairy godmother or perhaps a gold mine? The Branch also decided that the provincial Association of Professional Engineers might be gently requested to confine its activities to those connected with the administration of the British Columbia Engineers' Act and cease to trespass on the field of technical meetings and the like, which the Branch felt was its own preserve.

The Calgary Branch reported 101 members of all kinds. The Edmonton Branch was listening to another chapter in the perennial discussion of Alberta's tar sands. The thirteen other branches reporting in this *Journal* had little to say beyond noting the results of their elections, offering summaries of papers presented to them and retailing items of branch gossip.

R.DE L.F.

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

Salary Survey

The response to the December, 1956 Salary Survey was a little better this year with a 45 per cent return of 2782 replies compared to 39 per cent last year. The remuneration committee which has been sponsoring the survey ever since its inception in 1952 was quite pleased with the return although the results would have been more significant had the response been larger.

The statistics reflect that considerable movement was evident in engineering salaries last year. As a reasonable approximation it may be said that the increase during 1956 was about equivalent to that of the two previous years combined.

For the combination field of employment against year of graduation, consulting engineering, which combines the earnings of consultants and their employee engineers, is on top and slightly ahead of industrial engineering for the first ten years or so; the results for the consulting field are too erratic to permit continuation of the curve after that time. Utilities and Civil Service trail behind industrial engneering and the differential increases with time.

For the combination type of work against year of graduation, the executive curve is on top and points sharply upward. The supervisory curve slopes moderately upward and flattens at year 1930 or so. The non-supervisory technical curve moves upward only moderately and heads downward after year 1944.

The non-supervisory sales curve is close on the heels of the supervisory curve for the first 10 years; the results are too erratic to permit continuation of the curve after that time.

Membership

The membership committee is presently conducting campaigns in several different fields in its quest for new members. One of these areas of operations is the large employer of engineers. Our records show that approximately 30 per cent of the province's engineers are employed by only twenty large firms.

Over the years many representations have been made by the Corporation to management and engineering groups in various large concerns with varying degrees of success. With this experience as a guide, the committee set about to plan a campaign which with slight modifications, could be employed as standard procedure for each company.

Very briefly, a program has been devised which, to be successful, depends upon the co-operation and support of the three interested groups, namely management, Corporation members and prospective members.

The committee initially presents its case to the management for approval, and a list of all eligible individuals is requested. Contact is made with several Corporation members employed by the firm, and the membership sub-committee is formed. This sub-committee is invited to attend one or more regular meetings of the Membership Committee to equip them with sufficient information and literature for recruiting.

Liaison is maintained during the recruiting period between the main committee and the sub-committee, and a record is kept of the outcome of each individual case.

ONTARIO

Technician Registration

Guided by Dr. George B. Langford, head of the Department of Geological Sciences of the University of Toronto, the rapidly-growing force of engineering technicians in Ontario, currently estimated at some 30,000, are now being certified as such under a voluntary program initiated by the Association.

The first of its kind to be established in Canada, the program requires engineering technicians who apply for certification to be examined by a special panel of examiners and classified in five grades, determined by educational qualifications and technical experience.

Opportunity to Advance. In this method of certification, engineering technicians will be given an opportunity to advance through the various grades to Grade five, and could by further self-improvement, education and experience, become eligible for registration as a professional engineer. Such certification would tend to instill pride of accomplishment among technicians, and act as a form of recognition, encouraging more young men to train as technicians. It would also serve industry as a method of defining the upgrading of their technical employees, employment requirements and salary structure.

The Association is receiving an increasing number of applications for registration from persons who are not graduates of recognized engineering schools. Each of the applicants is given an examination program. At present there are more than 1,500 of these applicants on file. The program will be carried out by a special Certification Board and a panel of examiners appointed by the Ontario Association executive council.

A certificate will be issued stating that the person has been examined and granted a certificate as "Engineering Technician Grade . . .", and that this fact is recorded at the Association offices.

Not Affiliated with Association. It is pointed out that the technician will have no connection as a member of the Association, and that the application for certification specifically states that the applicant understands that the granting of the certificate does not hold with it any right to practise professional engineering.

In its experimental stages, certification will not be compulsory and the program will operate without legislation.

It is expected that a report on the progress and success of the certification plan will be given at the next meeting of the Dominion Council of Professional Engineers.

Classification of Technicians

I. *Engineering Technician (Grade 1)*

(a) Minimum educational qualifications:
The Ontario Secondary School Graduation Diploma (obtained at the end of Grade XII) or equivalent provided the applicant has taken the science and mathematical subjects of Grade XI and XII, and

(b) Practical experience
One year's experience in an approved engineering office.

II. *Engineering Technician (Grade 2)*

(a) Minimum educational requirement:
Grade XIII Technical, or
Grade XIII General Course, (English composition, English literature, algebra, geometry, trigonometry, physics and chemistry), or
The Advanced Technical Evening Class Certificate, or
The Ordinary National Certificate, and

(b) Practical Experience

Three years' experience for applicants who possess a Grade XIII Technical standing, or standing in the seven subjects of the Grade XIII General Course referred to above.

Five years' experience for holders of the Advanced Technical Evening Class Certificate, or for holders of the Ordinary National Certificate.

III. *Engineering Technician (Grade 3)*

(a) Minimum educational requirement:

Completion of one year of an engineering course in a recognized university, or

Completion of a two year Technical Institute Course, the admission requirement to which is complete Grade XII standing or equivalent, or

Higher National Certificate (without endorsements), or

Engineering Technician (Grade 2) qualifications plus further evening school or part-time instruction to the level of the two year Technical Institute Course referred to above, and

(b) *Practical Experience*

Three years' experience (one of which shall be in Canada) for holders of the Higher National Certificate (without endorsements)

Three years' experience for applicants who have completed one year of an engineering course in a recognized university or a two year Technical Institute course

Three years' further experience for persons who previously had been classified as an Engineering Technician (Grade 2).

IV. *Engineering Technician (Grade 4)*

(a) Minimum educational requirement:

Completion of the first two years of an engineering course in a recognized university, or

Diploma from the Ryerson Institute of Technology, or

Other Institutions with an equivalent standing, or

Higher National Certificate with satisfactory endorsements, or

Examination established by the Certification Board.

(b) *Practical Experience*

Three years' further experience for applicants who have completed the first two years of an engineering course in a recognized university, or for holders of the Ryerson Diploma (or equivalent)

Two years' experience (one of which shall be in Canada) for applicants who hold a Higher National Certificate (with endorsements)

Two years further experience for persons who had previously been classified as an Engineering Technician (Grade 3)

V. *Engineering Technician (Grade 5)*

(a) Minimum educational requirement

Intermediate examinations of the Association of Professional Engineers of Ontario, or

Completion of examinations prescribed by the Certification Board.

(b) *Practical Experience*

Two years' further experience beyond Grade 4, or equivalent.

NOTE: Experience in all grades must be of a type that is satisfactory to the Certification Board.

Engineers in the News

Geoffrey T. Gambling is now residing in Toronto and is employed by the Hydro-Electric Power Commission of Ontario as plant engineer in the fuel electric generation department.

Peter Munk has recently formed Peter Munk Associates Ltd., 781 Warden Ave., Toronto, for the purpose of designing audio-electronic installations for industry and the home.

Mr. Munk was earlier associated with Atlas Radio Corporation Ltd., Toronto.

J. T. Dew has been appointed general manager of Kilborn Engineering (1954) Ltd., Toronto. This was recently announced by R. K. Kilborn, president of the Company.

Mr. Dew graduated in mechanical engineering from the University of Toronto in 1949 and has been with the organization for the past seven years.

J. Owen Dibbs of Toronto is vice-president of Executive Services Limited, management consultants, of 200 Bay Street, Toronto, Ont.

J. G. Beresford is assistant manager of the project engineering department of Union Carbide Canada Limited, 2221 Yonge Street, Toronto 7, Ont.

John B. Moore is partner in the firm of Dawes-Moore-Associates, Architects and Engineers, 216 Queen Street, Chatham, Ont. The firm name was changed at the beginning of the year from Dunlop-Moore-Associates.

Mervyn C. Jerrard has moved to Minneapolis, Minn., where he is employed in the engineering test department of Minneapolis-Honeywell Regulator Company in that city.

L. C. Ruby is manager of Weymouth Industries Ltd., Weymouth, N.S.

D. S. McCann who was recently appointed assistant general sales manager of Peacock Bros. Limited, continues as manager of the Company's Toronto office.

Donald F. Martin general sales manager of Packard Electric Co. Ltd., has been elected as a vice-president and a director of the company. **W. L. Hetherington** has also been elected a vice-president of the company.

Mr. Martin fills the vacancy created by the resignation of C. W. Spratt who has been with the company for 46 years.

Herbert A. Skelton has been appointed to the staff of the Canadian development and research division of the International Nickel Company of Canada, Ltd., Toronto. He will be directly concerned with the mechanical and metallurgical problems in welding, fabrication and general manufacturing fields.

Mr. Skelton graduated in metallurgical engineering from Toronto in 1940 and following graduation joined the John Inglis Company in Toronto as assistant chief metallurgist. From 1943 until the end of World War II he served with the Royal Canadian Navy as an engineer officer.

Following the war he was appointed chief metallurgist of the consumers product division of John Inglis Company succeeding to the position of chief metallurgist of all divisions in 1948. He held this position until joining the International Nickel Company.

NOVA SCOTIA

1957 Council Announced

Elected president of the Association of Professional Engineers of Nova Scotia is E. D. Brown, vice-president and general manager, National Gypsum, Canada Limited, Burnside, Dartmouth, replacing C. N. Murray, general superintendent of the Dominion Iron and Steel Ltd., Sydney. L. D. Wickwire was chosen to fill the office of vice-president.

In the election of councillors the following were named for a one year term: L. J. Archibald, mechanical superintendent of the Halifax Refinery, Imperial Oil Ltd., Dartmouth; A. A. Ferguson, president of the Pictou Foundry and Machine Company at Pictou; W. D. Hagen, manager, Robb Engineering Works Limited, Amherst; G. F. Vail, associate professor of electrical engineering, Nova Scotia Technical College, Halifax.

Councillors for a two year term of office are; B. N. Cain, dean of applied science are; B. N. Cain, dean of applied science, Acadia University, Wolfville; J. D. Kline, assistant manager and chief engineer, Public Service Commission Halifax; A. B. Rossetti, president and general manager, Sydney Engineering and Dry Dock Company Ltd., Sydney and J. B. Ternan, registrar of the Nova Scotia Technical College, Halifax.

Secretary-treasurer and registrar of the organization is E. Lee Cameron, assoiate professor of mineral engineering, Nova Scotia Technical College.

On the Standing Committees, E. D. Brown, of Halifax, L. D. Wickwire, Liverpool, C. N. Murray, Sydney, L. J. Archibald, Dartmouth, and J. D. Kline, of Halifax, were elected to the executive Committee.

On the Board of Examiners are: G. F. Vail, chairman, of Halifax; G. F. Bennett; G. H. Burchill; M. F. Dean; W. A. Devereaux; J. B. Ternan; and D. E. Whitman, all of Halifax.

Comprising the Professional Relations Committee are F. C. Morrison, chairman, of New Glasgow; A. E. Cameron, vice-chairman, of Halifax; W. A. Macdonald of Sydney; E. T. Cosgrove of Halifax; and J. J. Kinley of Lunenburg.

On the nominating committee are E. D. Brown of Halifax, chairman; C. N. Murray, Sydney; M. L. Baker, J. L. Wickwire, and E. L. Cameron, all of Halifax.

G. L. Renner, J. E. Reardon, and E. R. Richard of Halifax will form the Scrutineers Committee. Mr. Renner was elected chairman.

Representatives for 1957

C. N. Murray of Sydney will serve as representative on the Dominion Council. E. D. Brown and E. Lee Cameron of Halifax have been chosen as Observers.

Representative on the E.I.C. General Council is Professor M. L. Baker, Halifax; while L. J. Archibald, Dartmouth and Dr. B. N. Cain of Wolfville will carry out these duties on the A.P.E.N.S. and I.E.C. Joint Finance Committee.

BRITISH COLUMBIA

Engineers in the News

D. A. Whelan has become a partner in the firm of Associated Engineering Services Limited. The firm now offers a broad service in general municipal engineering.

Mr. Whelan has spent more than ten years in the municipal engineering field and during the past six years has been municipal engineer for the District of Burnaby.

R. L. Walker is leaving his position as executive assistant, Fraser River Board, to take up a post with Photographic Surveys Corporation and will be stationed in Ceylon.

E. M. Silver has moved from his position at Grant's Brewery Limited, Winnipeg, to Western Canada Breweries Limited, Vancouver.

A. J. Routley of New Zealand has joined the staff of Crippen Wright Engineering Limited.

F. W. Clark has joined Imperial Oil (Alberta) Limited in an engineering position at Calgary.

A. T. Vaughan, recently arrived from the United Kingdom via Ontario, has joined the firm of Jones, Read and Christoffersen.

Allan Drab, a 1956 U.B.C. graduate has also joined this firm.

J. L. R. Hughes has taken up an appointment with Wiesser Lock Company of Canada Limited.

H. P. Burden is now a flying officer, engineering division, R.C.A.F., Cold Lake, Alta. Mr. Burden was for three years with his father, F. P. Burden, surveyor and civil engineer at Prince George.

J. R. M. Palmer, who recently arrived from the United Kingdom has joined the Powell River Pulp and Paper Company at Powell River.

J. S. C. Frost is now a design engineer with the P.G.E. Railway. He was formerly divisional engineer at Squamish.

J. Guthrie has been appointed to the position of manager, Columbia Cellulose Company Limited. He was formerly at Port Alice, B.C.

R. C. B. Henderson is with the International Engineering Company Inc., and is working on a dam and spillway project in Kaptai, East Pakistan.

ALBERTA

Abstracted from the Alberta Professional Engineer, January, 1957

It is interesting to reflect upon what may take place in the next eighteen years and also to ask, what will be the nature of engineering at the third quarter century mark?

During the second quarter of the twentieth century there were many changes. This was the period of engineering's great contribution to making man's labor more effective. The use of powered machines made it possible for each worker, in 1950, to produce twice as much as he did in 1925.

In this same period there were changes in engineering. This quarter century saw the development of many new specialized engineers; the aeronautical, petroleum, electronics, the reservoir, sanitary, industrial and many other types of engineer, as well as geophysicists, nuclear physcists, and petro-chemists.

Multiplying Manpower — Brainpower. As we approached the beginning of the third quarter the engineer and the scientist had turned their efforts to developing tools to make their work easier. In the second quarter the emphasis had been on multiplying manpower. Some of the emphasis has now shifted to multiplying brainpower. The engineer now finds it is not necessary to engage in days and months of brain-breaking mathematical calculations; he can now call upon an electronic machine to do this tedious work for him.

Aided by these and other machines in his search for new ideas, methods and machines, he will, before 1975 have found hundreds of new materials. This demand for new materials arises through the need to conserve present material resources and through the necessity to develop materials to meet new requirements of strength, corrosion and temperature resistance, chemical and electrical properties. The last ten years has seen the new names: epoxies, acrylics, polyethylene, polyesters and many others.

Conservation a Factor. The need for the conservation of materials and manpower will see its effect in the design of machines and structures. The development of lighter and stronger materials will help. In the steel industry pilot continuous casting plants are now in use. Full-scale units will eliminate the use of much massive equipment and manpower. In buildings the search will be for lighter, lower material content structures, smaller air conditioning and electrical distribution systems and new all-purpose materials. In product design the engineer will search for ways of reducing material and labor content.

One of the major problems facing engineers today and a problem that will become more difficult is that of waste disposal. In the second quarter of the century progress was made in the effective use of wastes in many industries. By 1975 great strides will have been made, possibly to the extent that atomic reactor wastes will then be useful by-products.

To run the ever increasing number of machines will require the development of more sources of power. The development of new fuels, new power sources, and the more efficient use of present power supplies will challenge the engineer. The use of solar, tidal and other potential sources of large quantities of power will be studied. New fuels to power air-borne transport will be developed. Above all the engineer will be called upon to use available power more efficiently.

Co-ordination. The engineer will find, too, in the next eighteen years, that he must search for a better understanding of men. In research, design, production and practically all aspects of engineering he will depend to a greater extent upon the work of others.

The use of technicians to assist the engineer directly and the demand for engineering experience in management, sales, and other aspects of business requires a greater knowledge of human behavior. This will lead to his study of more of the basic sciences, especially of psychology and physiology. He will apply statistical and scientific methods to the study of man, his motivations, his habits and his welfare.

To accomplish the great advances which will be his opportunity will require ascending standards of professional responsibility and technical ability. Just as he must improve his use of men and materials so must he strive for self-improvement. The engineer will not fail in his responsibility in what may well be known as the Engineering Age.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

James Shearer Costigan, M.E.I.C., president of T. Pringle and Son Limited, industrial engineers of Montreal, died at his home at Westmount, Que., on February 11, 1957.

A native of Montreal, Mr. Costigan was born on September 21, 1873. His engineering studies undertaken at McGill University, he graduated with a B.A.Sc. degree in mechanical engineering in 1894. He gained his early experience with the Dauville Asbestos and Slate Company as assistant superintendent of an asbestos fibrizing mill and with the Glasgow and Montreal Asbestos Company as manager of the Black Lakes Mines.

Mr. Costigan became associated with the firm of T. Pringle and Son, as a mechanical engineer on the original Shawinigan Water and Power Company development at Shawinigan Falls in 1898. In 1902 he gained the appointment of chief engineer in charge of the design of water and steam plants and many other industrial works. On the incorporation of the company in 1907 he was elected vice-president of the firm and assumed charge of the general management of the business of the company. In 1928 Mr. Costigan became president of the firm in which he remained active until his eightieth year.

He joined the Institute as a Student member in 1889, and transferred to Member in 1908. He attained Life membership in 1947.

Major A. R. Ketterson, M.E.I.C., former engineer of bridges for the Canadian Pacific Railways, died in Montreal on February 11, 1957.

Major Ketterson was born in Scotland on June 24, 1881, at Greenock. He attended public and private schools in Scotland and later became a student of the Royal Technical College, Glasgow. He graduated in 1902 with the degree of Associate of the Royal Technical College, later carrying out post-graduate work in advanced structures at that College. He also served with the Argyll and Sutherland Highlanders for three years during an early period of his career and held various appointments in Scotland before moving to Canada. These included the firm of A. Findlay and Company Limited, bridge builders, at Motherwell, Scotland, and Babtie and Brown, consulting engineers at Glasgow.

First employed as a bridge builder with the Canadian Pacific Railway in 1907 he was also employed as a draughtsman and became an assistant engineer at Winnipeg. In World War I he served with the First Canadian Construction Battalion and became second in command of the battalion. He was retired from the army with the rank of major and was awarded the D.S.O.

In 1928 appointed assistant engineer of bridges, he was in 1937 named engineer of bridges at Montreal and continued to hold the post until his retirement in 1946.

Major Ketterson joined the Institute in 1908 as an Associate Member. He was transferred to Member in 1938 and attained Life Membership in 1947.

William Norman McGuiness, M.E.I.C., of the Northern Electric Company, Montreal, died at Ciudad Trujillo, in the Dominican Republic on August 28, 1956, while on holiday.

W. N. McGuiness, M.E.I.C.

Born at Montreal on October 2, 1896, Mr. McGuiness had his schooling in Montreal. He enrolled at the Montreal Technical School graduating in 1915.

Beginning his career with Northern Electric at that time he worked first as a maintenance electrician and a telephone equipment draftsman. During World War I he served with the Fifth Canadian Division Column in Europe. On his return to Canada in 1919 he was appointed supervisor of the power equipment department of the firm. In 1920 he was transferred to the duties of power equipment engineer.

Mr. McGuiness served in various capacities with the equipment engineering department until early in the Second World War when he was loaned to the Crown company named Communications Limited. He was assigned the duties of power equipment engineer to assist in the design of power equipment for an East Coast carrier system. On his return to the company he was transferred to the dial equipment engineering division of the firm and was in 1948 named assistant superintendent of instal-lation engineering.

On loan to the Bell Telephone Com pany of Canada, special contract de partment in 1955, he supervised the en gineering of power equipment for al doppler stations on the Mid-Canad Line.

He joined the Institute in 1929 as a Associate Member, and transferred t Member in 1940.

Harry E. McCrudden, M.E.I.C., forme Bell Telephone official, at Montrea died there on December 24, 1956.

Mr. McCrudden was born in Buenc Aires in 1892. He had his early schoo ing at Montreal and attended McGi University. Interrupted in his studies b World War I, he enlisted in the Can dian Field Artillery, serving in Englan France and Belgium with the 43rd Arti lery Battery. On his return to Canad he worked with the Department of So dier's Civil Re-Establishment at Mon real until 1923 when he first becam associated with the Bell Telephone Con pany of Canada, working as a metho clerk with the firm. In 1927 employe as a plant inventory and cost engine with the engineering department of tl Company, he was in 1930 promoted staff engineer. Mr. McCrudden devot his entire career to the Bell Telephor Company of Canada and retired 1952, after thirty years' service.

During World War II, he was grant leave of absence in order to serve wi the Canadian Air Ministry in Ottawa.

He joined the Institute as a Stude Member in 1913, was transferred Junior in 1919. He became an Associa Member in 1927 and a Member in 194

Carlo Antonio Carniel, M.E.I.C., pre dent of the contracting firm of C. Carniel Limited, Ste. Therese, Qu died there on January 4, 1957.

Born at Vedelago, Italy on Septemb 24, 1885, he was educated at Veni and came to Canada early in the centu

Throughout his engineering career e ployed in the fields of railroad, wh construction and highway building, was in 1906 engaged as engineer a superintendent for the firm of Cavic and Pagano on the National Transco tinental Railway. In 1910 he worked the construction of the Algoma Cent Railway. Superintendent of the Bedfo Construction Company during the cle ing of the Halifax disaster of 1917 worked with that firm on the buildi of the Halifax Shipyard in 1918, a held the post of manager of constr tion in the erection of the St. John D Dock and shipyard. Engaged in ma large projects, he has been in rec times employed in the building of hi ways for the province of Quebec.

Mr. Carniel joined the Institute as Associate member in 1920, transferr to Member in 1940. He attained t status of Life member in 1955.

Personals

News of the Personal Activities of Members of the Institute

J. T. Dyment, M.E.I.C., director of engineering for Trans-Canada Air Lines, has been named chairman of a new Turbines Operations Panel of the International Air Transport Association. The panel will consist of seven experts of Canadian, American, British, Dutch and French airlines. It will co-ordinate the joint effort of the world's airlines to develop the most efficient flight procedures and requirements for the new age of jet and turbojet aircraft. Mr. Dyment was chairman of the I.A.T.A. Jet Symposium in 1950 and has since headed its jet fuel study.

Dean R. E. Jamieson, M.E.I.C., dean of the faculty of engineering at McGill University will retire from this position on June 1, 1957.

He will then become director of planning for the Brace bequest. Totalling $2,000,000, the bequest provides for the founding of a practical method of providing water in economic quantities for parched areas of the globe.

Dean Jamieson has had a very long history with the University. He began his studies there, gaining a B.Sc. degree in 1914 and an M.Sc. degree in 1920. Around this period he served overseas with the Army in World War I and had experience on railway location, construction work and structural design before commencing his teaching career at McGill in 1920. A lecturer in mathematics and civil engineering in the first years, he became a full professor and chairman of the department in 1932. His appointment as dean of the faculty dates to 1952.

Dean R. E. Jamieson, M.E.I.C

During the Second World War Dean Jamieson served as director general of the Army Engineering Design Branch of the Department of Munitions and Supply in Ottawa. After his resignation from this position in 1945 he remained a member of the Army technical development board, and was at that time awarded the O.B.E.

President of the Canadian Standards Association in 1953 he had previously served as vice-chairman of the executive committee of the organization.

Dean Jamieson was president of the Corporation of Professional Engineers of Quebec in 1939. He has served on many committees of the E.I.C. and was in 1952 elected to fill the office of treasurer of the Institute.

Professor Donald Mordell, M.E.I.C., will take over the appointment of dean of the faculty of engineering at McGill University on June 1, 1957, following the retirement of Dean R. E. Jamieson.

Professor Mordell followed his engineering studies in England, the country of his birth. He attended Cambridge University and was granted a B.A. in mechanical sciences in 1942. Four years later he was awarded an M.A. in mechanical sciences. During the war years he was also associated with Rolls Royce Limited, England. He became engineer in charge of combustion research and development and worked on gas turbine development.

Coming to Canada shortly afterwards he accepted the post of associate professor of mechanical engineering at McGill University in 1947. Promoted to full professorship in 1955 he was also made chairman of the department at that time.

Professor D. Mordell, M.E.I.C.

R. F. Leggett, M.E.I.C.

As well as his usual duties, he has recently served as director of research in the Gas Dynamics Laboratory at Ste. Anne de Bellevue, Que. Work has been proceeding there under grants from the Department of Mines and other Federal agencies on the development of a coal-burning gas turbine.

Professor Mordell is an associate member of the Institution of Mechanical Engineers and the Royal Aeronautical Society.

Kenneth I. Shone, M.E.I.C., holds the appointment of visiting professor of industrial administration for the Carnegie Institute of Technology, graduate school of industrial administration, at Pittsburgh, Pa.

Professor Shone was in 1948 an assistant professor of mechanical engineering at McGill University. In 1952-53 he was sent on loan from the Royal Technical College, where he held his next appointment, on a mission to India with the International Labour Office.

Lately he has been in charge of the residential centre for management studies with the Royal Technical College.

Professor Shone is a graduate of Cambridge University.

R. F. Legget, M.E.I.C., director of the Division of Building Research of the National Research Council of Canada was

• PERSONALS

admitted to honourary membership in the Ontario Association of Architects at the annual meeting of that organization held recently in Toronto.

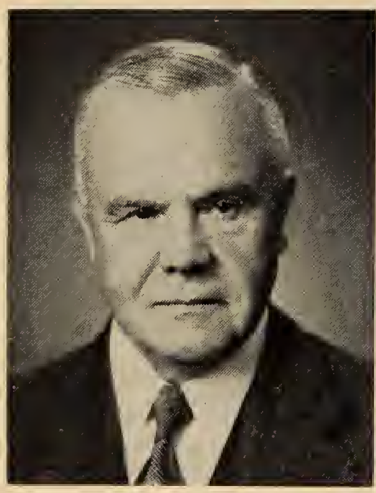
Mr. Legget was elected an Honourary Fellow of the Royal Architectural Institute of Canada in 1953. He is also a Fellow and Councillor of the Geological Society of America, a Member of the Institution of Civil Engineers and the American Society of Civil Engineers.

Mr. Legget was in 1947 invited by the National Research Council to start the new Division of Building Research and has been director since that time.

Mr. Legget was previously employed as an associate professor and consultant on soil and foundation problems at the University of Toronto.

Mr. Legget is a past-chairman of the Toronto and Ottawa Branches of the Institute. He is also serving on the Council representing the Ottawa Branch during the current season, 1956-57.

J. B. Woodyatt, M.E.I.C., has been appointed to the board of directors of the Shawinigan Water and Power Company. Chairman of the board of Southern Canada Power Company and Power Corporation of Canada, he is also a director of Bathurst Power and Paper Company Limited, the British Columbia Power Corporation and other companies.



J. B. Woodyatt, M.E.I.C.

W. R. Way, M.E.I.C.

Mr. Woodyatt became president of the Southern Canada Power Company in 1926.

W. R. Way, M.E.I.C., has been appointed to the board of directors of the Shawinigan Water and Power Company. Mr. Way is vice-president and chief engineer of the Shawinigan Water and Power Company and a director of the St. Maurice Power Corporation and the Shawinigan Engineering Company, Limited.

Mr. Way has been with the Shawinigan Water and Power Company for over thirty-eight years.

David S. Lloyd, M.E.I.C., of Toronto has been appointed a vice-president and director of Pyrofax Gas Limited, Toronto, a subsidiary of Pyrofax Gas Corporation, a unit of Union Carbide and Carbon Corporation.

Mr. Lloyd is president of the Linde Air Products Company, division of Union Carbide Canada Limted. First associated with the Pyrofax Corporation twenty-five years ago in the introduction of propane gas in cylinders into Canada, he was in 1939 concerned in the building of the original Montreal Pyrofax plant, first plant in Eastern Canada where propane was filled into cylinders for general distribution. His experience in the compressed gas business dates to 1925 when he joined the staff of Dominion Oxygen Company Limited, forerunner of the present Linde Air Products Company as a service engineer.

Mr. Lloyd received the degree of bachelor of applied science in electrical engineering from the University of Toronto in 1925. Prior to joining the Union Carbide organization he worked for Algoma Steel Corporation Limited, the Great Lakes Power Company Limited, the Department of Northern Development of the Province of Ontario and the Robert D. Hunt Company Limited.

D. D. Morris, M.E.I.C.

D. S. Lloyd, M.E.I.C.

He was a member of the administrative board of the Canadian Welding Bureau at its inception and is a past-chairman of this administrative board. He is a past-director of the Canadian Standards Association.

D. D. Morris, M.E.I.C., formerly administrative assistant with the Consolidated Mining and Smelting Company Limited has been named assistant general manager of the company.

He has served in numerous capacities in Cominco's chemical fertilizer and research divisions. He was appointed manager of the research and development division in 1951, administrative assistant in 1954 and assistant to the general manager in 1955.

First associated with the company in 1928, he began his work in the fertilizer research field in the mid-thirties and in 1940 was named assistant general foreman of ammonia operations at Trail, B.C. During the second World War, Mr. Morris served as superintendent of the government's ammonia plant at Calgary, becoming in 1943 general superintendent of operations in that area. Named head of the Cominco research and development division in 1949 he was transferred to Trail at that time.

Born at Edmonton Mr. Morris graduated from the University of Alberta in 1928.

He is a fellow of the Chemical Institute of Canada.

Dean E. O. Turner, M.E.I.C., of the faculty of engineering and professor of civil engineering at the University of New Brunswick will retire at the end of the current academic year.

Born at Harvard, Mass., he studied engineering at the Massachusetts Institute of Technology and graduated in civil engineering in 1914. He served with the

• PERSONALS

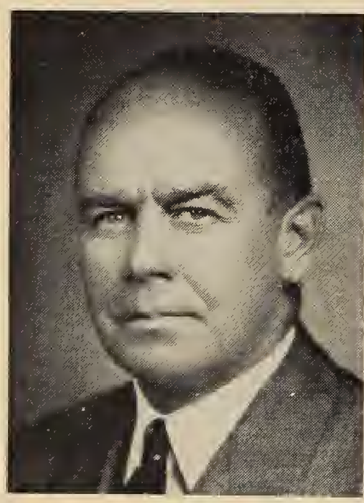
United States Army Air Force for two years and then had experience with the Boston and Maine Railway, the Massachusetts Highway Commission and the Polytechnic Institute of Brooklyn as an instructor before accepting the appointment which was to become his life work. Named professor of engineering and department head at the University in 1919 he carried out these duties until his promotion to deanship in 1946.

In 1941 the University awarded him the honorary degree of Doctor of Science.

Among the scientific societies in which Dean Turner has membership are the American Society for Engineering Education and the North American Branch of the Newcomen Society of England.

Vice-president of the Institute representing the Maritime provinces for the 1950-51 term, he has also served as one of its active supporters in the position of councillor.

D. O. Turnbull, M.E.I.C., consulting engineer of Saint John, N.B. has extended his firm in order to form a partnership with J. W. G. Scott, M.E.I.C. The practice will be carried on under the new name of Turnbull and Scott Limited.



D. O. Turnbull, M.E.I.C.

J. W. G. Scott, M.E.I.C.

A graduate of the University of New Brunswick in civil engineering, class of 1949, Mr. Scott began his career with the Department of Public Works (Canada), and has since 1952 been associated with Mr. Turnbull. He is a past-secretary of the Saint John Branch of the Institute.

Mr. Turnbull has been in private practice in Saint John since 1945. His early years in the profession were spent with the Foundation Company of Canada.

Active in the affairs of the Institute Mr. Turnbull is a past-chairman of the Saint John Branch, 1950, and was the following year elected to the Council of the Institute. He is also a past-president of the Association of Professional Engineers of New Brunswick.

V. C. Hamilton, M.E.I.C., general manager of operations with the Canada Cement Company Limited has been named a director in the organization.

Formerly general superintendent of the company, he has had many years' experience in the cement industry and was first employed with Canada Cement in 1927. At that time he was engaged in construction work for the firm at Lakefield, Ont. During the next few years he became plant superintendent for the firm at Exshaw, Alta., and at Winnipeg, Man.

He is a graduate of the Royal Military College, and a veteran of six years overseas service in World War II.

V. K. Mason, M.E.I.C., has been appointed vice-president of Perini Limited, formerly known as B. Perini and Sons Canada Limited.

Chief engineer in 1954, Mr. Mason has been associated with the organization for a number of years. A 1942 graduate from McGill University with a B. Eng. degree in civil engineering, he spent the following three years of World War II with the Royal Canadian Naval Volunteer Reserve at Halifax and Esquimalt, B.C. Later he worked with Ward McKee Engineering, and Hardy Limited, construction division, at Toronto.

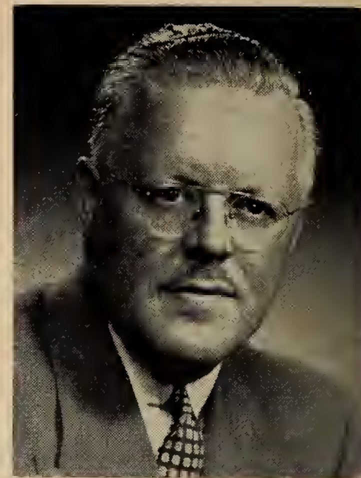
F. S. Maconachie, M.E.I.C., has been appointed chief engineer and is in charge of Canadian operations of Coode, Binnie and Preece, consulting civil, electrical and mechanical engineers.

Mr. Maconachie has established an office for the firm in Ottawa and is located in the Roxborough Apartments, on Laurier Avenue.

One of the Canadian organization's consultants is **Dr. P. L. Pratley,** M.E.I.C.

K. W. Fraser, M.E.I.C., has been appointed manager of the Canadian Westinghouse Company, Pacific district, with headquarters at Vancouver. He will be directly responsible for all sales of Westinghouse apparatus products throughout the Pacific district.

Mr. Fraser was formerly with the firm



K. W. Fraser, M.E.I.C.

F. S. Maconachie, M.E.I.C.

of B. F. Sturtevant Company of Canada Limited, and was general manager of the subsidiary since 1951. He previously held important posts in sales in Montreal and at Hamilton headquarters.

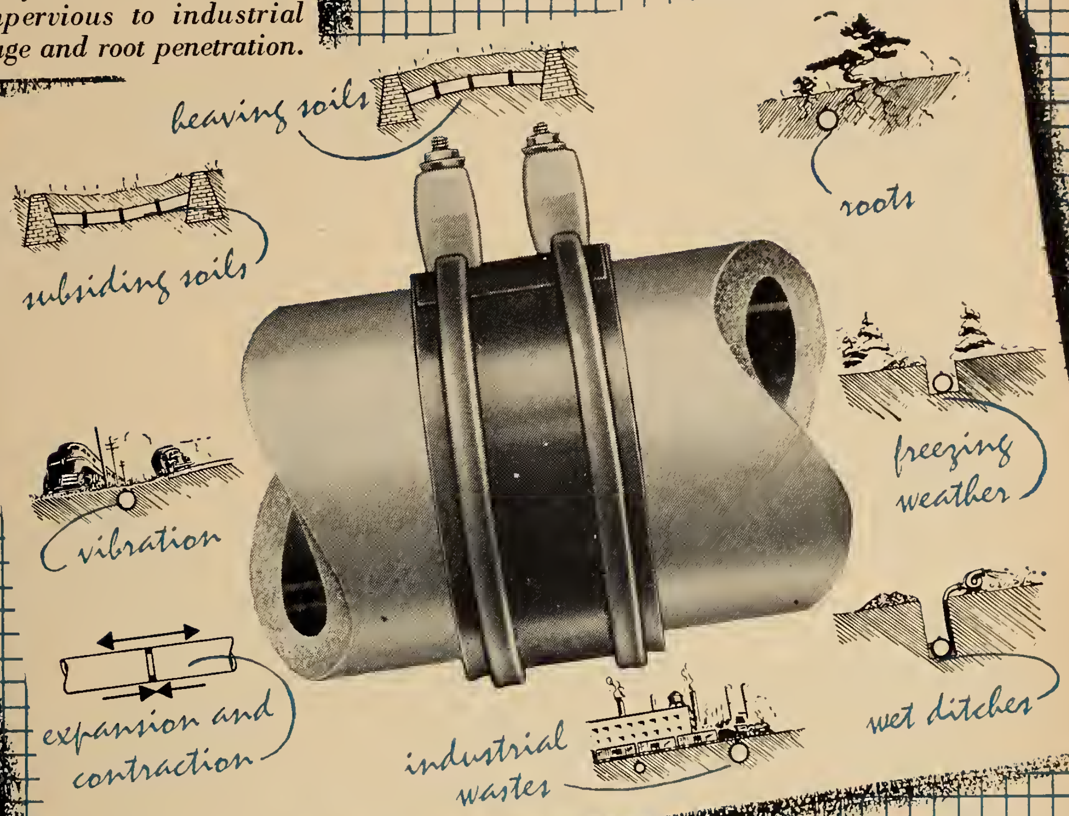
Mr. Fraser assumed the duties of sales engineer with the firm in 1930 and was appointed Quebec district manager shortly afterwards. During the following twelve years he was closely linked with the Westinghouse participation in many industrial and utility developments throughout the province of Quebec, particularly in the aluminum and pulp and paper industries.

Lieut.-Col. M. Barry Watson, M.E.I.C., professional engineer and land surveyor has been appointed Suburban Roads Commissioner for the City of Niagara Falls, Ont. He has also been elected chairman of the Public Library Board in that city.

Long established in the field of consulting engineering Lieut. Col. Watson is a graduate of the University of Toronto and a veteran of World War I. He was for many years a resident of Toronto and along with his private practice carried out the duties of director of the department of Military Studies at the University of Toronto.

Problem

National Sewer Pipe Limited needed a flexible sewer coupling that could be laid in any kind of weather and remain impervious to industrial waste seepage and root penetration.



Solution

They chose Polysar Butyl 301. This special type of Polysar has high resistance to ozone, water, heat and cold—remains constantly flexible—and gives a pressure-tight fit unaffected by either sewage or soil attack.

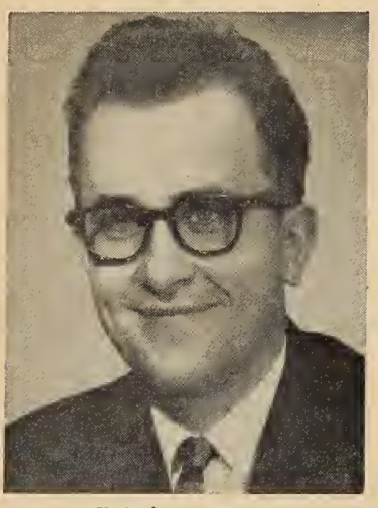
NOTHING PERFORMS LIKE RUBBER — *The best buy for your money*

• PERSONALS

He also served as registrar of the Association of Professional Engineers of Ontario earlier in his career and is as well a past member of the executive of the Toronto Branch of the Institute.

Zane Bakun, M.E.I.C., has been appointed director of community planning with the Department of Municipal Affairs of the Province of Saskatchewan.



Z. Bakun, M.E.I.C.

Mr. Bakun received a Bachelor of Science degree in civil engineering from the University of Manitoba in 1952. On receiving a Central Mortgage and Housing Fellowship in community planning, he completed post-graduate studies at the University of Manitoba and in 1953 gained an M.Sc. degree in that field.

Upon graduation employed by the Community Planning Branch of the Saskatchewan Department of Municipal Affairs as a community planning adviser he held this position until his present appointment.

J. T. Dokken, M.E.I.C., has joined the Inland Cement Company Limited of Edmonton, Alta, as district sales engineer for the Province of Saskatchewan with headquarters at Saskatoon.

A graduate of the University of Saskatchewan in civil engineering Mr. Dokken has had previous engineering experience with P.F.R.A., at Regina.

A. E. Stewart, M.E.I.C., for many years associated with the Canadian Pacific Railway in British Columbia has retired and is living in Vancouver. Mr. Stewart was divisional engineer at Revelstoke B.C., at the time of his retirement.

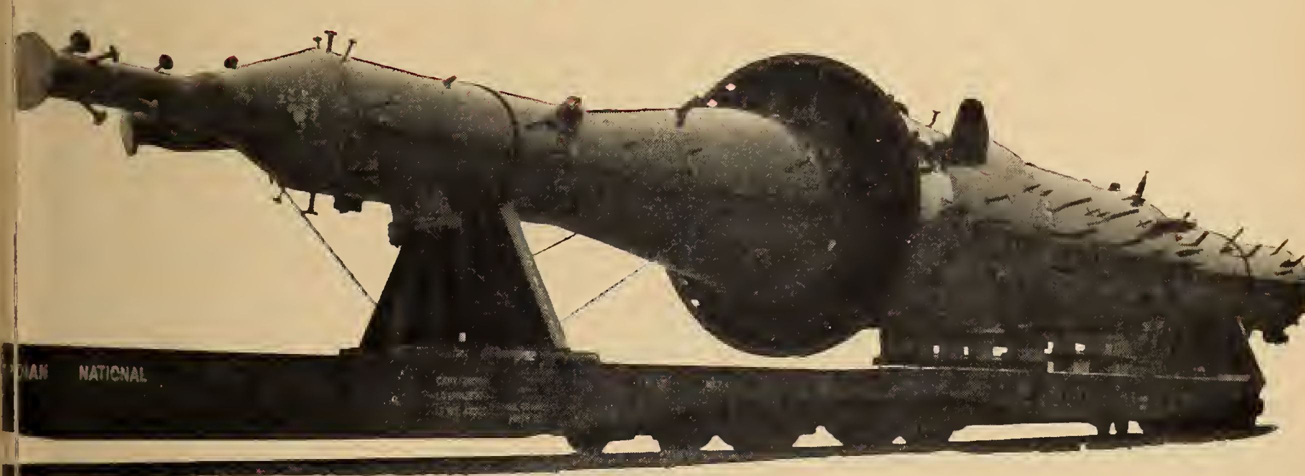
His engineering career with the Railway dating to 1909, he graduated from the University of Saskatchewan in civil engineering in 1922, after several years overseas service in World War I. With the Canadian Engineers in France, and the Royal Engineers in India, he also took part in the Third Afghan War at Baluehistan in 1919.

Assistant to the divisional engineer at Glacier, B.C. in 1922 he also held appointments at Lethbridge and Bassano, Alta. during the nineteen twenties. In 1931 he became division engineer of terminals at Winnipeg, Man., and the following year was posted to Regina, Sask. Later, in 1939 he was located at Cranbrook, B.C.

T. H. Dobbin, M.E.I.C., commissioner of works for the City of Sarnia, Ont, since 1952, has been named to a senior engineering post with the City of Ottawa. His duties are those of engineer in charge of design and special projects with the department of planning and works.

Mr. Dobbin is a 1949 graduate of the University of New Brunswick in civil engineering who undertook professional engineering studies after a number of years previous experience in building construction and land surveying and a six years period with the Royal Canadian Engineers in World War II.

WHAT IN THE WORLD IS IT?



It weighs 78,000 lbs. and it took three flat cars to ship it. You might think it was a tough job but we've specialized in steel plate fabrication for fifty years so just took it in our stride. You are wrong if you thought it was an atomic weapon. It's a Reactor Scrubber used in the refining of oil.

Specialization in the design, fabrication and erection of steel plate, stainless steel, Monel, nickel, aluminum and alloys have brought us, an all-Canadian company, leadership in this field. Send us your blueprints or problems for designs or quotations.

Since then he has held appointments with the City of Fredericton, N.S., the City of Saint John, N.B., as assistant director of works, and with the H. G. Acres Company at Niagara Falls, and Pine Falls, Ont.

In 1956 Mr. Dobbin was elected secretary-treasurer of the Sarnia Branch of the Institute.

J. A. Clement, M.E.I.C., of Montreal has recently been named superintendent of bridges with the National Harbours Board at the Montreal harbour.

A 1944 graduate of Ecole Polytechnique he has spent a number of years with Victoriaville Furniture Limited, Victoriaville, Que., and served as director of production control.

Earlier in his career he was an industrial engineer for the British Rubber Company of Canada Ltd., Lachine, Que.

Russell E. Potter, M.E.I.C., of Victoria, B.C., has gone into private practice in that city, specializing in the fields of municipal engineering, public utility regulation and hydro-power. He formerly held the appointment of Public Utilities Commissioner at Victoria.

Mr. Potter has, for the last fifteen years been employed as chief engineer of the City of New Westminster, B.C., and as executive assistant to the Dominion-Provincial Board, Fraser River Basin, at Victoria before embarking on his duties as Public Utilities Commissioner.

He is a graduate of the University of Saskatchewan in civil engineering.

A. K. Bunnell, M.E.I.C., formerly assistant to the vice-president, engineering department for Canadian Breweries Limited, Toronto has become superintendent, mechanical engineering department with Carling Breweries Limited, also of Toronto.

Mr. Bunnell graduated from the University of Toronto in mechanical engineering in 1947 and joined Canadian Breweries, working as an assistant superintendent of mechanical engineering.

A. H. Ashworth, M.E.I.C., consulting engineer of North Vancouver has formed his practice into the limited company of A. H. Ashworth and Associates Limited, with the inclusion of J. E. Dew-Jones, A.M.I.C.E., as an engineering director.

Like Mr. Ashworth, Mr. Dew-Jones, came to this country from Great Britain. He has since 1954, worked in the engineering department of the District of North Vancouver, with John Laing and Son (Canada) Limited, and with the Annacis Island Industrial Estate.

Mr. Ashworth assumed the duties of municipal engineer for the North Vancouver district in 1952 and was concerned in the water works modernization and expansion program on the North Shore linking up with Vancouver's new Cleveland Dam in Capilano Canyon.

In 1954 he took part as a member of the special committee set up by surrounding municipalities in the preparation of a report on Burrard Inlet Crossings to consider future bridges and other facilities to cross Vancouver Harbour.

Mr. Ashworth has had experience in civil engineering projects in Great Britain, South Africa, Rhodesia, New Zealand and Canada. Several professional engineers associated with him in each location formed the group in which he became an associate, known as the North Western Associated Engineering Consultants and covering a wide field of engineering service.

C. Newton Hopkins, M.E.I.C., has moved from Shawinigan Falls, Que., to Vancouver. Formerly with Canadian Industries Limited in a supervisory capacity, he is now associated with Hook-

"CATALYTIC'S ON-TIME AND ON-BUDGET CLAIM IS NO IDLE BOAST"

ST. LAWRENCE CEMENT CO.

February 8, 1957

Mr. George E. Temple
Vice-President & General Manager
Catalytic Construction of Canada, Ltd.
600 Vidal Street South
SARNIA, Ontario

Dear Mr. Temple:

I should like to express my personal congratulations to the Catalytic organization for the vital part it played in the construction of our $28,000,000 cement plant at Clarkson, Ont.

Your traditional claim of completing contracts "On-Time and On-Budget" is certainly no idle boast. It is a fact that your work, although involved and complicated, was finished well in advance of schedule and within the prescribed budget.

This is all the more remarkable because of the fact that this was your first venture as mechanical erector of a cement plant. This speaks volumes for the ingenuity, adaptability and efficiency of the Catalytic organization.

It can truly be said that Catalytic's proven knowledge and experience excellently equips them to carry out any construction project "On-Time and On-Budget" regardless of its scope and magnitude.

Wishing you continued success, I am

Yours very truly,

ST. LAWRENCE CEMENT CO.

B. Ulrich
Executive Vice-President
and General Manager

er Chemicals Limited as a chemical engineer.

Mr. Hopkins is a 1949 graduate of the University of British Columbia.

W. O. Horwood, M.E.I.C., has been appointed Eastern sales manager with International Equipment Company Limited and its subsidiary, Industrial Equipment Company Limited.

Mr. Horwood was named assistant to the president of International Equipment Company, at Montreal a little over a year ago.

He was earlier in his career associated with the Lyman Tube and Bearings Limited.

D. Zavitzianos, M.E.I.C., senior structural designer with the Toronto architectural firm of Shore and Moffat, has charge of the structural design of a new Federal Public building in downtown Toronto's Adelaide Street.

Mr. Zavitzianos is a graduate of the University of Athens National Technical University at Athens, class of 1948.

L. A. Bateman, M.E.I.C., formerly general superintendent in charge of power production with the Winnipeg Hydro-Electric System now holds an appointment with the Manitoba Hydro-Electric Board. He is senior engineer of the system planning department.

A native of Winnipeg Mr. Bateman joined Winnipeg Hydro in 1942.

He is a graduate of the University of Manitoba, class of 1942, and also holds an M.Sc. degree from that university.

J. M. Bennet, M.E.I.C., formerly of Calgary, Alta, has gone to Central America where he is employed with the Cuban Gulf Oil Company. In Canada Mr. Bennet was associated with the Canadian Gulf Oil Company as a civil engineer and geologist.

He is a graduate of the University of Dublin, class of 1950.

A. L. Adams, JR.E.I.C., who formerly held the appointment of resident electrical engineer with the C. D. Howe Company Limited, Atomic Energy Project at Chalk River, Ont., has moved to Sault Ste. Marie, Ont. He is now employed as an electrical maintenance engineer with the Mannesmann Tube Company Limited in that city.

He is a graduate of McGill University class of 1951.

C. A. Geddes, JR.E.I.C., has been appointed chief engineer with the firm of Bawden Industries Limited, special machinery manufacturers at Toronto.

Mr. Geddes graduated in mechanical engineering from Queen's University following service in the R.C.A.F. Before joining Bawden Industries he was associated with Canadian Westinghouse Company Limited, electronics division.

Corrosion Resistance:

Acid, alkali, and salt handling problems have been solved by Ductile Ni-Resist.

Weldability:

No difficulty in welding in shop or field.

Erosion Resistance:

The Ductile Ni-Resist series of irons show economical service under many erosive conditions; and resistance to erosion as in a pump impeller is outstanding.

Toughness:

Impact resistance of Ductile Ni-Resist is comparable to that of steel at ordinary temperatures; an important plus is that it suffers no appreciable embrittlement at sub-zero temperatures.

Castability:

Good flowing quality of Ductile Ni-Resist permits the casting of intricate designs, which are difficult to produce in some other cast corrosion-resistant metals.

Ductility:

Ductile Ni-Resist irons possess 10 to 40% elongation in a tensile test, ample for all normal service applications.

Machinability:

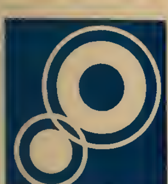
Machinability rates of Ductile Ni-Resist are of the same order as those of conventional pressure type gray iron.

Heat Resistance:

A high order of heat resistance is available with Ductile Ni-Resist up to 1300 deg. F. Certain types are recommended for service up to 1500 deg. F. Ductile Ni-Resist irons not only reduce the rate of oxidization, but also the oxidization products adhere tenaciously to the base metal.

Controlled Expansion:

Expansivities from 4.5 to 10.4 millionths per deg. F. are available with the different types of Ductile Ni-Resist.



Wear Resistance:

Metal to metal rubbing parts last much longer and perform better, especially under corrosive conditions, when made of Ductile Ni-Resist.

Non-Magnetic:

Some types of Ductile Ni-Resist irons are non-magnetic, and are therefore useful in many applications in the electric and allied fields where this quality, and the many others that this alloy has to offer, are required.

• PERSONALS

He also worked for the Brantford Engineering and Manufacturing Company at Hamilton earlier in his career.

J. E. Anderton, JR.E.I.C., a 1953 graduate of the University of British Columbia has accepted an appointment in Toronto with the hydraulic department of the John Inglis Company Limited.

In Great Britain for the past three years Mr. Anderton has been engaged in special training in the field of hydro-power with the English Electric Company.

Mervyn C. Jerrard, JR.E.I.C., has moved from Windsor to Minneapolis where he is employed with the Minneapolis-Honeywell Regulator Company in the engineering test department.

Mr. Jerrard was formerly affiliated with the Ford Motor Company of Canada Limited.

He is a University of Manitoba graduate, class of 1950 in mechanical engineering.

E. Stanley Bengston, JR.E.I.C., is employed by the Powell River Company as a design engineer in the Pulp and Paper Mill at Powell River, B.C. He was formerly employed by H. A. Simons Limited as a field engineer on the new pulp and paper mill construction at Port Alberni, B.C.

Mr. Bengston is a 1952 graduate of the University of British Columbia.

Captain R. I. Crouse, JR.E.I.C., has recently been posted to the Northwest Highway Maintenance Establishment as a roads engineer.

Awarded a B. Eng. degree in civil engineering at the Nova Scotia Technical College in 1951 he was previously posted at Montreal.

Roy A. Downing, JR.E.I.C., has been appointed chief engineer and assistant general manager with the firm of Engineered Timber Products, a division of A. S. Nicholson and Son Limited, Burlington, Ont.

R. A. Downing, JR.E.I.C.

A graduate of the University of Toronto, class of 1952, Mr. Downing has been associated with the company for several years. Earlier in his career he was employed with Timber Structures of Canada Limited, Toronto.

H. M. Curry, JR.E.I.C., a 1955 graduate of the University of Manitoba in civil engineering is employed as a field engineer at Crofton, B.C. He is engaged on the construction of a pulp plant for British Columbia Forest Products Limited.

Mr. Curry was formerly associated with the Foundation Company of Canada as a field engineer, and with the firm of H. A. Simons Limited, at Vancouver.

H. N. Dixon, JR.E.I.C., formerly of the New Brunswick Telephone Company, engineering department at Saint John, N.B., has joined the Canadian National Railways at Moncton, N.B.

In his new position Mr. Dixon is a training engineer in the motive power and car equipment department of the company.

Mr. Dixon is a 1955 graduate of the University of New Brunswick in electrical engineering.

W. L. Cary, JR.E.I.C., is associated with the research and development department of the Canadian Chemical Company Limited, Edmonton. A 1948 graduate in chemical engineering from the University of Alberta, Mr. Cary was for a number of years employed with the Aluminum Company of Canada at Arvida, Que., and also worked for the company in Jamaica, B.W.I., as a development supervisor.

M. J. M. Maughan, JR.E.I.C., a 1955 graduate of the University of Toronto in civil engineering is at work as a field engineer with the Township of Toronto at Cooksville, Ont.

He was previously employed with the Toronto firm of Marshall, Macklin and Monaghan.

Ronald W. E. McDonald, JR.E.I.C., has severed his connections with the Canadian Westinghouse Company Limited, Hamilton, Ont., and has joined the staff of the Canadian Utilities Limited at Edmonton.

Mr. McDonald graduated from the University of Alberta in 1955 in electrical engineering and enrolled in the Canadian Westinghouse Company Limited graduate training program a short time later.

Graham P. Kemp, JR.E.I.C., formerly of William Kennedy and Sons Limited, Owen Sound, Ont., has joined the staff of Dilworth Ewbank, consulting mechanical engineers of Toronto.

Mr. Kemp is a 1949 graduate of the University of Toronto in mechanical engineering and at the outset of his career was associated with the Smart-Turner Machine Company Limited at Hamilton.

Joint Meeting

A joint meeting of the Border Cities ranch of the Institute and the local membership of the Association of Professional Engineers of Ontario was held Marios Tavern on January 17, 1957. A reception at 6.30 p.m. followed by inner at 7 p.m. preceded the general meeting. One hundred and fifteen turned it for the event.

Those at the head table were: W. G. Mitchell, past-president of the Border Cities Branch; W. R. Mitchell, councillor or the Branch; C. T. Carson, first vice-resident of the A.P.E.O.; P. N. Brown, ranch chairman; J H. Fox, president f the A.P.E.O.; J. M. Reid, Branch treasurer, and B. Goodings, field-secretary the Association.

Mr. Fox addressed the gathering, dealing with the profession in general. A short discussion period followed.

ROCKVILLE

F. TREWARTHA, M.E.I.C.,

Du Pont Executive Speaks

J. A. Hornibrook, manager, textile bres division of Dupont of Canada addressed the Branch on January 15 on he subject of the Duke of Edinburgh's onference, which was held in the United ingdom, July 1956.

The main theme of the conference, Study of Human Problems in an Industrial Community" was sparked by the informal and personal interest of H. R. . The Duke of Edinburgh. One of 28 Canadians selected to go to the conference, Mr. Hornibrook found it a fascinating experience. The exchange of information between management and labour roups from all parts of the world enabled the conference groups to find a common approach to the impact of industrialization on the community.

Tours to study industrial communities were arranged and an opportunity was afforded to talk to people at all levels with complete freedom. Mr. Hornibrook was most impressed with the progress which had been made in planning community development. The formation of "satellite" communities around larger cities was well advanced. Excellent strides have been made with the diversification of industry, particularly in the Glasgow area.

Acute Problem. Mr. Hornibrook stated that the training and education of scientists and engineers was considered an acute problem in the United Kingdom. Due to the geographical nearness of Russia, British educators were ahead of their U.S. colleagues so far as providing advanced training for all qualified children, with government financial support. The speaker felt that British unions and management were well ahead of Canadians in studying the effect of "automation" on the worker.

Mr. Hornibrook concluded that the fruits of industrialization could be bitter or sweet, but that diversified industrialization must be fostered as the only way to raise the standard of living. He felt that the fruits of industrialization in Canada have been sweet and Canadians should consider themselves fortunate in living in a vigorous and expanding economy.

Chairman of the meeting was J. G. Kerfoot. The speaker was introduced by R. H. Wallace and thanked by R. M. Powell.

Forty seven members and guests attended the dinner for the first presidential visit to the Branch since its inauguration five or six years ago.

• BRANCH NEWS

man Ira Beattie, several interesting films were shown. These included an Italian film on the "Maccaferri Type of Construction" and a recent film on the St. Lawrence Seaway development. Briefly the "Maccaferri Type of Construction" consists of filling wire cages, about 3′ wide, 4′ deep and 5′ long with rocks, and laying the cages up in the form of a retaining wall to prevent erosion caused by mountains and rivers and also to keep the latter from eroding their banks away. About forty members were present for the showing.

On Friday, Feb. 15, the annual Engineering Ball sponsored jointly by the engineering students at the University of New Brunswick and the Fredericton Branch was held in the ballroom of the Lord Beaverbrook Hotel. About 150 couples enjoyed the music of the university orchestra directed by Paul Stewart and the refreshments available in the mezzanine. This dance is fast becoming one of the most popular social events of the year. Highlight of the ball was the crowning of the 'Engineering Queen', Miss Janet Hunter of Halifax, N.S., a first year student at U.N.B.

G. H. DUNPHY, M.E.I.C.,
Branch News Editor

"The Evolution of Television"

On February 20 a meeting was held at the Nova Scotian Hotel to hear H. M. Smith, Maritime regional engineer of the Canadian Broadcasting Corporation, Sackville, N.B. who presented a talk on "The Evolution of Television". This was well received by the largest attendance this winter. Over ninety people were present.

Mr. Smith began his talk by describing the first concept of picture transmission. He pointed out that the characteristics of selenium with its variable resistance when subjected to different degrees of light intensity, lent itself to the concept of picture transmission. However, this was a bulky piece of equipment consisting of thousands of selenium cells connected by conductors to individual light sources at another location. The intensity of the light source was varied relative to the amount of light falling on the selenium cells. This experiment was undertaken as far back as 1870.

Present day sets have been developed from the cathode ray tube, which was conceived at the turn of the century and actual pictures were transmitted by this medium at that time. In 1911 an Englishman presented the theory of electron scanning and co-ordination between transmitter and receiver. This was the first concept of the present day television. However, the development of material and tools to accomplish this took several years, and it was not until early in the 1920's that they were able to use this method. Mechanical scanning was finally given up in the 1930's when they were able to improve on the camera pick-up tube or iconoscope.

After a question and answer period, H. R. Doane moved a vote of thanks for the speaker.

The group were conducted through all the technical departments of the Television Studios.

KINGSTON

D. I. OUROM, JR.E.I.C.,
Secretary-treasurer

Joint Highway Research Program

A meeting of the Civil Engineering Section of the Kingston branch was held on December 11, 1956 in Queen's University Memorial Union. Short addresses were read by four staff members of Queen's who are performing research work in the field of highway and traffic engineering.

Dr. S. D. Lash. The history and the terms of reference of the program were described by Dr. S. D. Lash, head of the civil engineering department and director of the newly formed Ontario Joint Highway Research Program. It was pointed out that active work will commence at Queen's in May, 1957. The program is financed by a grant from the Ontario Department of Highways. The University is to provide the staff to direct and perform various highway research projects in the area of materials, soils, pavement design and construction, maintenance, traffic and economics and administration. Queen's will also encourage work in highway engineering by developing course work in this field at the undergraduate level, and by establishing advanced courses for graduate students. It was explained that a similar arrangement has been made with the University of Toronto.

The program is administered by an advisory committee consisting of a total of ten members representing the Department of Highways, the University of Toronto, Queen's University, the Ontario County Engineers, and the Ontario Research Foundation. It is the function of this committee to approve budgets, assess proposed research projects and generally administer the entire program.

Dr. O. Martin. Two research projects which are being performed under his direction were briefly outlined by Dr. O. Martin, associate professor of civil engineering. One project involves the development of apparatus for the purpose of measuring the capillarity of soils in the field. It is believed that the development of such equipment will enable field engineers to exercise close con-

Here is the Goodyear H.D. Glass Cord Steam Hose coupled to the head of the high-speed steam hammer.

DRIVING TO BEDROCK

with Glass Harness!

Shown above is a general view of the bridge building activity. Work is progressing on schedule.

Goodyear H.D. Glass Cord Steam Hose carries the steam to sink heavy steel pilings.

At Toronto, Ontario, McNamara Construction Co., Ltd. are building a new Humber Bridge to link an expressway of the near future.

On the job is Goodyear H.D. Glass Cord Steam Hose carrying steam pressure of 125 pounds at 353°F. to the operating head of the pile driver to sink heavy steel piling thru' clay to solid bedrock at a relentless clip.

Goodyear H.D. Glass Cord Steam Hose is economical in ultimate cost - - - lasts longer, can't be cooked to bursting point by heat. It is safe - - - cuts accident rates and saves valuable working time. It is the lightest, most supple, easiest handled hose ever built to carry 200 pounds of saturated steam of 388°F.

There are more than 800 different types of hose especially designed by Goodyear. Every inch of Goodyear Hose is backed by 50 years of experience in producing industrial rubber products.

GOODYEAR

INDUSTRIAL RUBBER PRODUCTS ENGINEERED FOR THE JOB

For complete information write or call your nearest Goodyear office at—Moncton, St. John, Quebec City, Montreal, Toronto, London, Windsor, Winnipeg, Regina, Saskatoon, Calgary, Edmonton, Vancouver or Head Office, New Toronto.

trol over sub-base material, particularly in respect to the frost susceptibility of the material. The other project under investigation concerns the plant control of bituminious mixtures. In this project Dr. Martin is constructing apparatus to measure the permeability of the mixture. It is believed that such measurements can be correlated with such mix characteristics as density and voids content, and thus will permit an assessment of pavement quality in the field.

Professor D. L. Townsend. A research project dealing with the compaction of soils was described by Professor D. L. Townsend. The purpose of this project is to attempt to evaluate the accuracy of soil density measurement as obtained with various types of apparatus currently in use. Of great interest is the new Washington State Densometer which, it is claimed, will provide more accurate density measurements in granular materials than any other testing device. Studies were undertaken to test this equipment during the summer of 1956. The studies were also extended to obtain preliminary data concerning the effectiveness of various types of compacting equipment such as sheep's foot rollers, hyster grid rollers, wobble-wheel rollers etc. It is hoped this project will develop improved specifications regarding the use of the various type of equipment on different soils and also will lead to more realistic density requirements in pavement construction practices.

Dr. D. T. Wright. Research projects relating to highway bridges were described by Dr. D. T. Wright. A project concerning the evaluation of bridges with particular emphasis on load limits has been completed by Dr. Wright, and a report has been prepared and published. In addition, a tentative specification has been prepared based on the analysis of current practices in posting bridge load limits. These two reports represent the first completed project at Queen's. Work on this project was started in May 1955, in anticipation of the research program, and was completed under the terms of the research program in 1956.

A study of bridge vibrations is being undertaken by a graduate student under the direction of Dr. Wright. The field work for this project was started in the fall of 1956 and consisted of the measurement of the vibration of various bridges. These data are to be analyzed in order to develop what may be considered to be a limiting acceptable vibration for highway bridge structures.

An additional investigation has been started to develop equipment and procedures for the field testing of bridges. This project will involve the testing to failure of certain abandoned highway bridges in order to obtain information on bridge failure characteristics.

Traffic Engineering. Professor H. M. Edwards, associate director of the pro-

THE RED SQUARES INDICATE STRUCTURES BUILT ON RAYMOND FOUNDATIONS gram outlined the research activity in the field of traffic engineering. One of these projects involves the investigation of sample sizes to be used in the collection of origin-destination data. Present data collection procedures require relatively large samples which result in high survey costs. It is hoped that the savings in survey costs which would result if sample size reduction proves feasible, would be of sufficient magnitude to enable more municipalities to undertake these important traffic planning studies.

A study of highway speeds was undertaken in the summer of 1956. The purpose of this study was to establish driver speed characteristics on Ontario highways. It is believed that the data from this study will be of value to the designer in developing future design criteria and also will provide the facts necessary to improve existing legislation relative to speeds. Subsequently it is intended to statistically analyze the data in order to determine the effect on speeds of such variables as pavement type, pavement width, vehicle type etc. This study is to be performed annually in order that speed trends can be studied.

Annual Meeting

The Kootenay Branch held their annual meeting in the Kootenay Hotel on February 19, 1957. Preceded by dinner, the meeting settled down to hear the chairman's annual report by T. W. Lazenby. Highlights of this report included the awarding of the Kootenay Branch Scholarship of $50.00 to Wayne Wharton. A student of Nelson High School he is attending Royal Roads College in Victoria.

The Branch also donated $25.00 to the Colonel By Memorial, and had forwarded $50.00 to the Institute from the proceeds of the showing of the Leonardo da Vinci film. The chairman reported that the past year had been an active one. Thirteen Branch meetings had been held and the visit of the general secretary had been much appreciated by all members.

Officers elected for 1957 were announced and W. G. Small, incoming chairman took the chair.

Guest Speaker. Dr. Colbert traced the early development of surgery from the year 1500 B.C. in India to the present time. He said that plastic surgery should be thought of as reconstructive surgery where defects in the human body were reconstructed to appear as normal. He described in detail the operations for reconstructiong the human hand to make it functional and also the treatment of badly burned patients.

Dr. Colbert illustrated his talks with slides showing various deformities of the body before and after treatment. He described the use of various methods and their limitations in reconstructing damaged parts of the body.

The thanks of the meeting were accorded to Dr. Colbert for his interesting talk.

Joint Dinner Meeting

The Lethbridge Branch of the Institute held a joint dinner meeting with the Association of Professional Engineers of Alberta on January 26. Close to sixty members and guests were present. Chairman of the program was J. G. Dale, of Edmonton, president of the Association of Professional Engineers of Alberta. According to Mr. Dale, the Profes

sional Engineers' membership in Alberta is in excess of 2,000. Bruce Porter, of Lethbridge and recently of Calgary, an engineer with the Lethbridge branch of Calgary Power, was presented with a certificate of membership by the chairman. Mayor T. R. Haig of Lethbridge, extended greetings to the engineers on behalf of the City of Lethbridge.

Six hundred people attended the annual dinner-dance of the Montreal Branch in February. The above picture shows part of the head-table. Left to right are: Dean H. Gaudefroy, of the Ecole Polytechnique; Mrs. Leo Roy; E. D. Gray-Donald, past-chairman of the Branch; Leo Roy, Branch chairman; and Mrs. E. D. Gray-Donald.

Dr. T. A. Link Guest Speaker

A pioneer geologist in Canada, Dr. T. A. Link, of Calgary, was guest speaker. He discussed "Some Highlights of Early Geology in Canada", which dated back to 1919 when he was employed by Imperial Oil to begin exploration for oil in the North West Territories. Dr. Link described the excitement of shooting Smith Rapids, 16 miles of roaring water on the Slave River, in a river scow. The year 1921 saw Dr. Link aboard the first plane, a four-passenger CL-6, ever to fly into the Mackenzie River region. When the pilot landed at Hay River natives were found plowing with a dog team. The men had a great deal of explaining to do before the natives would believe the plane was not a bird or an ill omen. The first oil well in the Norman Wells Oil Field was brought in under Dr. Link's supervision. Twenty years later he returned and worked on the Canol Project which developed this oil field, the only one in the N.W. Territories. In 1947 the famous geologist played a major part in opening up the Leduc Field, which led to the oil boom in Alberta. Graphic as well as coloured slides added considerably to this interesting address.

Engaged in private practice, Dr. Link is a fellow of the Geological Society of America, the Geological Society of Canada, and a charter member and past president of the Alberta Society of Petroleum Geologists.

Musical entertainment was provided by Art Hunt who sang two numbers and by J. Horhozer who presented accordion selections. Brown's orchestra accompanied the guest artists and provided dinner music.

R. Peterson Addresses Meeting

R. Peterson, M.E.I.C., soil mechanics engineer of P. F. R. A., Saskatoon, addressed the Branch at their regular meeting February 16, 1957. Mr. Peterson stated that the Lethbridge district has more and larger earth dams than any other locality. The two largest earth dams in Canada are the St. Mary's

TRIDENT METERS

EARN MORE

...COST LESS

It takes money to maintain the water supply your community expects. It's vitally important to make sure all the water pumped is paid for . . . by using accurate meters . . . and by keeping these meters in good repair.

Trident meters are built to hold accuracy longer, so you receive all the revenue you should. They're built to be easier to repair, so your shop time and expenses are cut down. They're designed so that the newest parts fit the oldest meters . . . simplifying your repair parts problem, helping you to get accurate, thoroughly modern performance from your oldest meters.

For more than 50 years, Neptune has built fine meters designed to earn more and cost less. Many 50-year-old Tridents are still in service . . . perhaps in your own community . . . living proof that the Tridents you buy today will be a credit to your water system for many long years to come.

neptune

Dam, south west of Lethbridge and the Travers Dam, north east of the city.

Mr. Peterson showed slides of various earth dams and of the methods and calculations used in their design. The three main problems in earth dam construction are seepage, slides and cracks. Construction is extremely important as even a well designed dam may fail if it is not properly constructed. Slides were shown taken at invervals of fifteen, thirty and forty-five minutes indicating the progression in the failure of a small dam. The dam failed completely two hours after the first sign of failure was noticed.

P. F. R. A. are now installing test apparatus in earth dams such as piezometers, settlement gauges, and inclinometers to record the actual performance of dams.

In conclusion Mr. Peterson stated that soil theories have many limitations since soil is extremely complex, and the approach using test apparatus appears to be the most practical.

Mr. Peterson's paper "Design and Construction of Earth Dams in Western Canada" appeared in the February 1957 issue of the Engineering Journal.

A gay after-dinner scene at 'Festa Italiano', the eight-course dinner-dance arranged by the Peterborough Branch in January.

PETERBOROUGH

D. B. CHASE, JR.E.I.C.,
Secretary-treasurer

Annual Ladies' Night

"Festa Italiano" was the theme of the dinner dance which marked the annual meeting of Peterborough Branch held 18 January at the Kawartha Golf and Country Club. With tickets sold out one week in advance, attendance was limited due to seating capacity. About fifty members with ladies and special guests attended "The Party of the Year".

Being carried on in the true Italian atmosphere the party lasted from eight o'clock to about 2 a.m. An excellent eight-course Italian dinner, including such delicacies as roasted sucking-pigs and Artichaut alla Castiglione e Grano Turco e Pomodore was served. The atmosphere of an Italian restaurant was achieved with well chosen decorations and tables set for eight. Well-known Italian songs were sung by a soloist during the dance pauses.

The party was under the patronage of H. R. Sills, vice-president of the E.I.C. and Mrs. Sills, and Ross Dobbin, past-president of the E.I.C. Special guests

• BRANCH NEWS

were the Honorable J. A. Dewart, mayor of the city of Peterborough and Mrs. Dewart.

Chaperones were R. T. Bogle and Mrs. Bogle, I. F. McRae and Mrs. McRae and J. H. Smith and Mrs. Smith.

The idea for this evening, so full of good fellowship, dining and dancing, came from M. M. Uloth, past chairman of the Branch and was carried out with the help of Bill Ackhurst, present Branch chairman, and other members of the dance committee.

NIPISSING AND UPPER OTTAWA

G. R. KARTZMARK, JR.E.I.C.,
Secretary

J. W. MILLAR, M.E.I.C.,
Branch News Editor

Municipal Law—Engineering

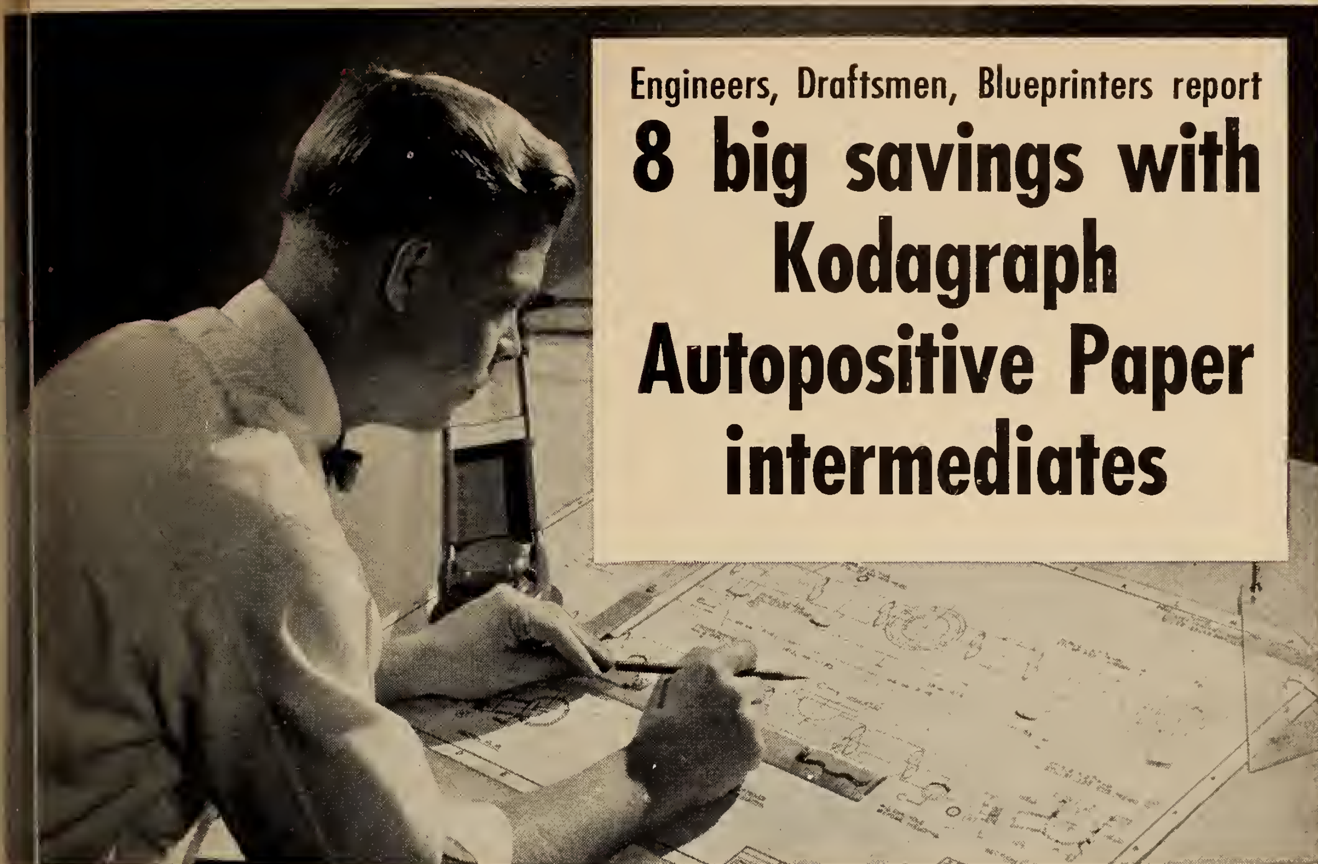
The regular monthly dinner meeting of the Nipissing and Upper Ottawa Branch of the Institute was held on February 6, in the Windsor Hotel at Sturgeon Falls, Ont. About twenty-five members and guests attended.

J. S. Cooper, councillor, reported on council meetings attended, with particular reference to progress on the matter of confederation of the Institute and the Associations of Professional Engineers. Mr. Cooper also reported that council was actively participating in an effort to supply travelling speakers and furnish educational pamphlets for prospective engineers. It was also indicated that due to the shortage now existing, a survey of engineering personnel is to be made on an international basis to obtain the best utilization of engineers.

Guest speaker was Thos. G. Farmer of the legal firm of Reynolds, Klein and Farmer at North Bay. Introduced by Mr. Macnabb, Mr. Farmer dealt with municipal law as related to municipal engineering, particularly referring to legal action by and against municipal authorities. He pointed out that municipal councils might be held responsible for wrongful acts of municipal employees. Boards and commissions are not necessarily responsible but the governing body would be.

Mr. Farmer explained that when action is to be taken against city management, notice of claim must be filed in seven days and action started in three months. Different degrees of liability with regard to sidewalks, cross walks and roadways was explained and the extent to which snow and ice create a liability.

New subdivisions came up for discussion and Mr. Farmer said that the financial burden imposed on municipalities, due to rapid expansion, had made it necessary for municipalities to make



Engineers, Draftsmen, Blueprinters report

8 big savings with Kodagraph Autopositive Paper intermediates

Revolutionary Kodagraph Autopositive Paper, which produces positive photographic intermediates *without a negative step or dark room handling,* brings these savings to drafting rooms large and small.

1. **Protects original drawings.** Low-cost Autopositive Paper intermediates are used instead of valuable originals in printmaking, reference, mailing, and making revisions.

2. **Reclaims drawings which are old, worn, or soiled.** Reproducing them on Autopositive Paper cleans up backgrounds, strengthens line detail . . . eliminates redrafting.

3. **Improves legibility of prints.** Blueprints or direct-process prints made from Autopositive Paper intermediates are consistently easier to read than prints made from original drawings.

4. **Reproduces "unprintable" originals.** When extra copies are needed of blueprints, drawings on opaque stock, two-sided originals, and other "unprintables," just reproduce them on Autopositive Paper *and you have your printmaking masters.*

5. **Speeds revisions of drawings.** A popular short cut is to cut out or eradicate detail on an Autopositive Paper intermediate . . . and then add the new detail to this print or one made from it.

6. **Eliminates redrafting standard component designs.** From a file of standard component designs made on Kodagraph Autopositive Film, select the ones needed and attach to drawing form with translucent tape. Then reproduce on Autopositive Paper, add new detail and the job is done.

7. **Simplifies print distribution.** Instead of shipping bundles of production prints, send Autopositive Paper intermediates. Mailing costs are saved. Required number of prints can be made at other end. No overstocking this way . . . or running short of prints.

8. **Provides photo-lasting copies.** Autopositive Paper intermediates, with dense black photographic lines on a translucent white paper base, will not turn yellow or become brittle in the files; will produce sharp, legible prints whenever needed.

Kodagraph Reproduction Materials

"The big NEW PLUS in engineering drawing reproduction"

- **Kodagraph Autopositive Paper Extra Thin** for high-quality photographic intermediates at lowest cost.
- **Kodagraph Autopositive Film** for very fast printing intermediates of highest quality.
- **Kodagraph Autopositive Paper Translucent** for faster printing, more durable easier-to-revise intermediates.
- **Kodagraph Contact Paper Translucent** for fast-printing durable, very high-quality intermediates.
- **Kodagraph Repro-Negative Paper** for black-line intermediates from negative-type originals.

Students' Night Quizz

The annual students' night was held at Hart House on January 30. The event, directed by Dick Muller took the form of a quiz program modelled on the "$64,000 Question", with prizes of more modest dimensions. Seven teams representing the various clubs in the faculty of applied science and engineering were entered. With about 200 students present, it was one of the best turnouts to a students' night ever recorded in these parts. Thanks for helping to bring the students out through well planned publicity goes to Keith McIntyre, one of our recent student members.

H. L. Hinchcliffe kept things moving smartly during the questioning of the various teams. Four charming young undergraduates in the faculty, Jane Kerr, Dagny Vidinsh, Maire Keskula and Marlene Metzger acted as usherettes, leading the teams into the spotlight.

The Aeronautical and Engineering Physics Club took first place, winning $64.00 and four student memberships in the Institute. The Electrical Club won second place, getting $16.00 and four student memberships. All those who entered were awarded something, the last team being donated the price of that beverage popular among engineers, as a consolation prize.

Clips Presented to Student Members. Professor A. C. Davidson gave out tie clips to the student members who had recently joined the Institute. Coffee and doughnuts followed.

The President's Visit

On February 14, the Toronto Branch was honoured by a visit from President and Mrs. Vernon A. McKillop, accompanied by General Secretary, Dr. L. Austin Wright.

Arrangements were made by Keith L. McIntyre, S.E.I.C., for President McKillop to address the student body of the faculty of applied science at the University during the lunch hour.

Otto Renelt, third year class president introduced President McKillop, who complimented the engineering students on their contribution to the welfare of the community in physical labour and financially. The President had heard with pride that the engineer freshmen at Toronto had helped improve one of the city parks, and had aided the Community Chest last fall. The President discussed the increasingly important place of the engineer in Canada's expanding economy. The student might give more attention to the impact of his work on society. As a reward for his labours, the engineer would do well to take Wren's famous epitaph for his motto: "If you would see my monument look about you."

Discusses Institute-Student Relationship Dr. Wright spoke briefly about the Institute and its relationship to the stu dent at the university. Opportunities fo engineers are at their greatest at th present time. Employers come to the In stitute Employment Service looking fo engineers. If the salary offered does no meet the going rate, the prospective em ployer is told. In one such case, an ad vertisement was refused for the Journa because it would draw no replies, th salary offered being too small. The pros pective employer then looked into th present salary scales of his own enginee employees, and revised them upward

'wo NEW Gardner-Denver All-Weather rotary ompressors feature the G-D water-oil cooling system

Flow chart shows how ardner-Denver water-oil cooling system operates

1 Water circulating system automatically provides constant operating temperature for both compressor and engine under all weather conditions—hot or cold.

2 Clutch eliminates cold-weather "dry-starts."

3 Effective oil separator minimizes oil consumption.

4 Circulating water cools compressor oil.

5 Oil pump provides positive flow of compressor oil.

6 Warm water from engine warms up compressor oil before clutch is engaged.

Dr. Wright also dwelt on the service performed by the nstitute for the profession. A vital need in the life of any young graduate, he can obtain advice and help from members, technical advice may be obtained through the library and a suitable position may be acquired through it. The Institute is a coast to coast and international organization, in which the young engineer can feel at home.

Hungarian Students Introduced. One of the highlights of the meeting was the introduction of a number of Hungarian engineering students from the University of Sopron. One of the group, in Canada for only two and a half weeks, made a short speech in English, illustrating the determination of these young men to become good citizens as well as good engineers. The event was impressive.

Executive Meeting and Dinner. The president sat in the Branch executive meeting and commented on Institute affairs from his standpoint. Dinner at Hart House preceded a meeting at which the president discussed the impressions gathered during his term of office. There was a fast moving impression of activity, of things going on over the horizon, with an occasional close look, during his tour of the various branches. His most important recollection was of what constitutes the engineer's place in Canada. As for the economic picture of the country, the President felt almost optimistic. The gross national product was rising principally due to the efforts of the engineer. If the engineer were to fulfill his destiny and accomplish the things he must in the social picture in Canada, he felt that confederation of the Institute and the professional engineering associations was a vital necessity. Although dealings with other organizations of national and international importance, such as the Chamber of Commerce, and the Canadian Electrical Association were necessary, the relationship with the professional associations is of greater concern.

Discusses Confederation. There were many advocates of confederation. The picture was analogous to the political confederation of the Canadian provinces in 1867. It will take a strong leader to bring about confederation. It will require an act of faith and in spite of misgivings and unasked questions, good will come of it. The American picture is the only alternative. President Barker of the American Society of Mechanical Engineers has urged members of the Engineering Institute of Canada to make sure that confederation takes place; to take time and to do the job well. In the United States there are many organizations working at cross purposes, however some of this duplication has been corrected. Whatever comes, the same errors should not be committed in Canada. We must nourish, sustain, keep,

for industrial trucks
of every kind!

BATTERIES
HART BATTERY GENERAL SALES OFFICES AND FACTORY, ST-JOHNS, P. Q., CANADA

• BRANCH NEWS

and build. As Francis Bacon said: "That which man altereth not for the better, time, the great innovator altereth for the worse."

Dr. Wright Discusses Spotlight Topics. Dr. Wright, the general-secretary of the Institute dealt with several important topics which presently hold the spotlight in Institute affairs. How to convey the meaning of the Institute to members is an urgent question. The average member has no understanding of the operation of the Institute. There is though, an upsurge of activity and a rebirth in all the branches. Three important undertakings have been made: the publication of Transactions; the development of Sectional Committees for technical meetings in the various branches; and a greater emphasis on the Professional Development courses.

Representatives in the engineering faculties have been appointed to foster Institute-undergraduate relations.

Dr. Wright also produced some novel forms of statistics to show how the "enemy within" apathy can be combatted. There were some 20,000 man-meetings in the branches across Canada last year. Dr. Wright gave statistics of the activities of the Institute library, the membership of branch committees, and the work of the Engineering Journal.

Having discussed confederation, the matter of refugee-engineers, and the shortage of engineers, the secretary closed his remarks with a hearty invitation to all those present to come to the next annual meeting which is to be held in Banff next June.

Joint Committees

The latest development in outdoor lighting were discussed by A. D. Harrington of the General Electric Company on February 5 at a meeting of the Toronto Branch of the Institute and the Institution of Electrical Engineers.

Mr. Harrington is the manager of the marketing development, outdoor lighting department of the company at Hendersonville, N.C. In this capacity he is well qualified to discuss the latest developments in ornamental and functional lighting.

A meeting of the Toronto Area committee of the E.I.C., the I.C.E., and the A.S.C.E, was held at the University of Toronto on February 7.

W. J. Fulton, deputy minister, designate, of the Department of Highways of Ontario addressed the group on "Planning for Future Highways in Ontario".

Mr. Fulton's paper dealt with the compilation of a report on the highway needs in Ontario for the next twenty year period. Outlining the problem briefly, it forecast the increase in traffic over the next twenty years, classified the highway system according to its service to traffic, and made an engineering study of the existing highway plant. The study is designed to expose highway deficiencies and point out improvement needed for adequate service to Ontario's burgeoning traffic. Having measured the lag, the report recommended the accelerated and continuing programs necessary to overcome it.

WINNIPEG

C. S. LANDON, M.E.I.C.,
Secretary-treasurer

Electrical Section Meets

On February 7 the Electrical Section of the Winnipeg Branch was addressed by A. Tallman, chief engineer of Pioneer Electric Limited, Winnipeg on the subject "Recent Developments in Large Air Cooled Transformers".

Discuss Air-Cooled Transformers. Mr. Tallman discussed air cooled transformers in general, giving details of the various insulation classes with their temperature limits. He then went on to discuss the design of a number of 5000 KVA air cooled transformers, designed and built by Pioneer Electric and recently installed in a large paper mill. These transformers incorporated forced air cooling.

Mr. Tallman gave complete details of losses, temperature rises, etc., at various loads with and without forced air circulation. He described in some detail the various steps which were taken to ensure that every part of the windings were adequately cooled. He also discussed the economics of forced air cooling and concluded that forced air cooling was a very desirable practice particularly in the larger sizes of transformer.

The question period which followed was particularly rewarding. Mr. Tallman is to be congratulated on producing a paper of a nature which promoted general discussion.

Conductor Aspects of High Voltage Transmission. On February 21, 1957 the Electrical Section of the Winnipeg Branch was addressed by Peter Malburg of the Aluminum Company of Canada. Mr. Malburg is a specialist in design problems of electrical conductors and spoke on the subject "Conductor Aspects of High Voltage Transmission". Mr. Malburg approached the problem of the design of a transmission line from the conductor point of view. The engineering and economic problems associated with the design of a high voltage transmission line are extremely complex but Mr. Malburg presented the problem very clearly and concisely and showed how all aspects of the design interlocked, the size of the conductors affecting the design of the tower and span etc.

In conclusion Mr. Malburg showed a film which had been produced in Finland, showing the construction of a high voltage transmission line in the Northern part of that country. The country through which the line was built was strikingly similar to that encountered in the Northern parts of our own province and was of particular interest for that reason.

A. D. CRONK, JR.E.I.C.,
Secretary

T. F. HADWIN, M.E.I.C.,
Branch News Editor

Inspection Trip

At noon on January 23, a field trip was made to the Pacific Coast Pipe Company Ltd. plant. The trip was arranyed with D. D. Reeve, M.E.I.C., chief engineer of the pipe company. About 50 members and students attended.

The visitors were shown all phases of wood stave pipe and tank manufacture from the receipt of the selected rough timber to the finished product. Large quantities of rough wood are stocked for air-drying and to provide the variety of sizes and lengths for pipe and tanks. Two items of particular interest were being manufactured at the time of the inspection. The first was large tanks being made out of staves of six inch square timbers of yellow cedar. The second was the largest continuous wood stave pipe in the world.

This latter pipe will be shipped to a point near Montreal where it will be assembled to deliver water at a maximum head of 90 feet, to produce 80,000 horse power. The diameter of this pipe will be 18 feet and its total length 5,600 feet in order to carry 2500 cubic feet of water per second. Two million board feet of lumber will be used which will require 150 railway cars to transport the lumber, steel cradles and metal fittings to the East. The lumber alone would build 200 average homes. A short section of the pipe was assembled in the Vancouver yard.

Lunch followed the tour and the thanks of the Branch was extended to the manager, T. A. Kennedy and staff.

Guest Speaker

On the evening of January 23, the regular meeting of the Vancouver Branch was held to view a film on Britain's "Calder Hall" atomic energy plant. Nuclear aspects were explained by Dr. G. M. Volkoff and heat transfer problems reviewed by Professor Wolfe, both of the University of British Columbia. Seventy-five members attended.

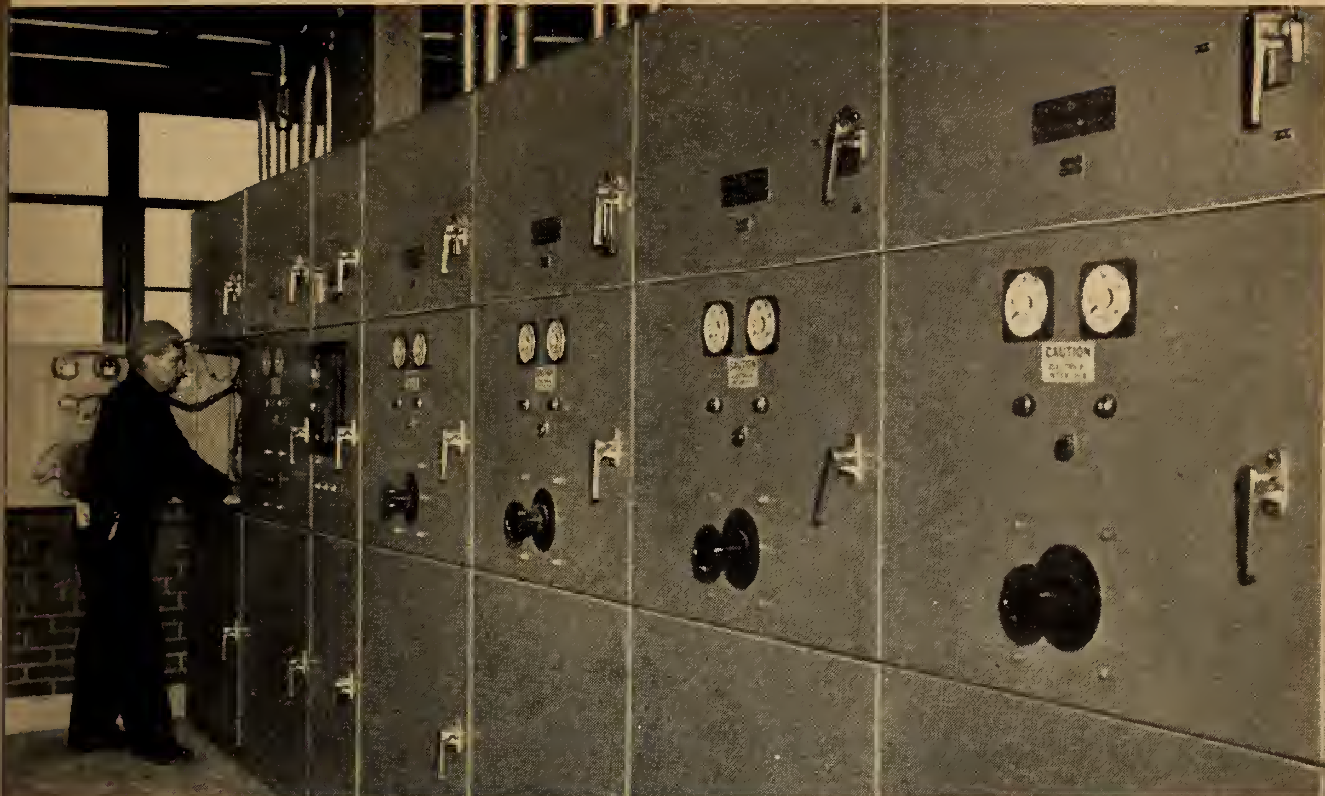
Dr. Volkoff stated that the prime purpose of the Calder Hall plant was to produce plutonium. Rather than waste the heat it was converted into electrical energy. The plant used natural uranium as would nearly all similar ventures outside the United States since this latter country was the only one with adequate facilities for producing enriched uranium.

Thermal Reactor Type. Since the plant is of the thermal reactor type and heavy water not readily available, graphite is used to slow the neutrons. Carbon dioxide at 100 lbs per square inch extracts the heat from the reactor and by means of heat exchangers supplies steam to the turbo-generators. Some idea of the magnitude of the reaction and associated equipment is indicated by the following illustration: the reactor enclosing concrete walls are seven feet thick, 1200 tons of graphite are required to moderate 130 tons of uranium, the uranium rods are in sections 1 inch in diameter and three feet long encased in magnesium cans and the cooling tower is equal in height to a thirty story building.

The film was of great interest but would not have been appreciated without the excellent background and comments given by Mr. Volkoff and Professor Wolfe. Vancouver is fortunate in having them in the area.

Professional Development

A standing committee of the Vancouver Branch of the Institute is that of Professional Development, chaired in 1956-57 by Commodore A.C.M. Davy, R.C.N. (retired). This committee, in cooperation with the Association of Professional Engineers of B.C. endeavours each spring to sponsor a course in Professional Development. This year a course on "The Engineer and the Law" commenced on January 30 and continued for a ten week period. A total of 210 registered and attendance taxed available space indicating that engineers still have a thirst for broadening their education.



Easy-to-service G-E Limitamp controls six 2300-volt synchronous motors —a total of 3800 horsepower installed at the Sarnia plant of Dow Chemical of Canada Ltd.

G-E LIMITAMP CONTROL SAVES 50% IN SPACE REQUIREMENTS IN LARGE CHEMICAL PLANT

In one of Canada's largest chemical plants space was a major consideration in the selection of G-E Limitamp High Voltage Motor Control. With the new G-E equipment, space requirements were cut in half—just over 50 square feet were required for the complete installation. Serviced and operated from the front, this G-E Motor Control requires no rear aisle, thus saving an additional 54 square feet of valuable floor space.

You enjoy safety too . . . gang-operated isolating switch, steel barriers separating high and low voltage compartments, enclosed bus compartment and reliable coordination of starter. For motors rated 2300 to 4600 volts G-E Limitamp Control also assures you of running overload protection and maximum safe-guard against short-circuit damage to starter and equipment. Back-to-back centre of room, back-to-wall, or mounting as free standing enclosure is possible with these units.

For complete application engineering service contact your nearest C-G-E Apparatus Sales office. Write for Bulletin No. GEA-6331, Apparatus Department, Canadian General Electric, 107 Park St. North, Peterborough, Ontario.

Commonwealth Mining and Metallurgical Congress

The Sixth Congress is being held in Canada this year, with major meetings scheduled as follows:

Vancouver, B.C., Sept. 8, 9, 10.
Edmonton, Alta., Sept. 16, 17.
Winnipeg, Man., Sept. 19, 20.
Toronto, Ont., Sept. 27, 28.
Ottawa, Ont., Sept. 30, Oct. 1.
Montreal, Que., Oct. 2.
Quebec, Que., Oct. 3, 4.
Halifax, N.S., Oct. 8, 9.

Communications about the congress should be addressed to: The Executive Secretary, 507-837 W. Hastings St., Vancouver 1.

Since the distribution by the Canadian executive office of the Congress of the first brochure, 3,150 inquiries from 75 countries were received, expressing interest. A second brochure giving detailed information, was circulated to interested persons.

Good progress has been reported in preparation of the Sixth Congress technical volumes: Mining in Canada; Structural Geology of Canadian Ore Deposits, Vol. II; The Milling of Canadian Ores; Case Histories in Geophysics; and Canadian Non-Metallics. The technical volumes, being prepared by the technical divisions of the Canadian Institute of Mining and Metallurgy, will be a most important feature of the Sixth Congress.

The general program and local programs are being developed. Meetings with local committees at almost all of the places in Canada to be visited by the Congress, indicate that every effort is being made to ensure a most successful and enjoyable Congress. Excellent co-operation is being extended to the Congress organization by the federal, provincial and municipal governments, by the mining, petroleum and other companies whose operations will be visited and by the entire Canadian mining industry.

Canadian Pulp and Paper Association

The Technical Section of the Canadian Pulp and Paper Association held the forty-third annual meeting at Montreal, January 23, 24, 25, 1957.

An extensive program of papers covered recent technical developments and scientific investigations of techniques being developed in Canada's leading industry. Management, fundamental and applied research were subjects of discussion, as well as training of personnel, and many other topics of importance.

Benjamin F. Avery, president and general manager of The KVP Company Limited, Espanola, Ontario, was elected chairman of the Executive Board, Canadian Pulp and Paper Asssociation.

John W. Wing, vice-president and general manager, Gaspesia Sulphite Co. Ltd., Quebec City, was elected chairman of the Technical Section.

The annual report of the Association, distributed during the meeting, stated that "In 1956, the pulp and paper industry broke many records. The over-all output of the mills of 11 million tons was greater than ever before and was nearly 6 per cent higher than in 1955. Production of pulp, newsprint, paperboard, fine paper, and wrapping paper reached new high record levels. And the value of the exports of the industry for the first time broke through the billion dollar level. Accounting thus for some 22 per cent of all exports pulp and paper continues to be the most dominant element in the foreign trade of the nation and a basic and essential source of the foreign exchange required for the imports upon which the progress of Canada depends."

Calendar

Welding

The Canadian Council of the International Institute of Welding (7 Pleasant Blvd., Toronto) has available programs for the annual assembly of I.I.W. to be held in Essen, Germany, from July 1 to July 6, 1957.

The official Canadian delegates, appointed by the Canadian Council are: R. A. Dunn, general sales manager, Canadian Liquid Air Company Limited; R. M. Gooderham, director, Canadian Welding Bureau; and H. Thomasson, manager, Metallurgical-Mechanical Section, Canadian Westinghouse Company, Limited. Mr. Thomasson is the chief Canadian delegate.

Chemical Engineering

There are three meetings of the Chemical Institute of Canada (18 Rideau Street, Ottawa 2, Ont.) scheduled as follows: May 15-17, joint conference, ACS Rubber Division and CIC Rubber Subject Division, Sheraton-Mount Royal Hotel, Montreal; June 3-5 the annual conference at Vancouver, B.C. October 9-10, divisional conference, Biochemistry Subject Division, Ottawa, Ontario.

Highways

The Canadian Highway Safety Conference, will be held April 23-25, 1957, at the Chateau Frontenac, Quebec.

The meeting will discuss highway safety problems related to engineering, laws and enforcement, education, motor vehicle administration anl public action. It will formulate plans for action acceptable to the federal government, provincial governments, provincial and community organizations for the reduction of traffic accidents.

Design Engineering

The second Design Engineering Conference and the second Design Engineering Show will be held in New York, May 20 to 23, 1957. The conference is sponsored by the American Society of Mechanical Engineers.

Industrial Engineering

The American Institute of Industrial Engineering will hold the eighth annual conference, in New York City, May 16-17, 1957.

Information can be obtained from the office of A.I.I.E. at 145 North High Street, Columbus 15, Ohio.

o other cast metal provides
seful engineering properties

Corrosion Resistance: Countless problems involving the handling of acids, alkalies and salts have been satisfactorily solved by ductile Ni-Resist austenitic irons.

Toughness: The impact resistance of ductile Ni-Resist irons is comparable to that of steel at ordinary temperatures. Also like other nickel-containing austenitic alloys, it suffers no appreciable embrittlement at sub-zero temperatures.

Ductility: Ductile Ni-Resist irons provide appreciable elongation in the tensile test (4 to 40%), and can be bent and twisted like mild steel.

Heat Resistance: Up to 1300°F., with some types as high as 1500°F. Ductile Ni-Resist Irons greatly reduce the oxidation rate but enable the oxidation products to adhere to base metals, making them especially useful in engine manifolds and superchargers.

Wear Resistance: Engine and pump liners, pistons, bearings, glands and other metal-to-metal rubbing parts last longer and perform better, especially under corrosion conditions, when made of ductile Ni-Resist irons.

Erosion Resistance: Corrosive slurries, wet steam, etc., are extremely erosive on most metals. The ductile Ni-Resist series of alloys shows economical service under many erosion conditions.

Fluidity (Castability): The good flowing quality of ductile Ni-Resist irons in the molten state permits making intricate designs which are difficult to provide in some other cast metals.

Machinability: The machinability rates of ductile Ni-Resist irons are of the same order as those of conventional pressure type gray iron. Both of these factors aid materially in producing finished parts economically.

Controlled Expansion: Expansivities from 4.5 to 10.4 millionths per °F are available with various types of ductile Ni-Resist Irons. Metals of different expansivities can be matched with selected Ni-Resist types.

Non-Magnetic: Some types of ductile Ni-Resist irons are non-magnetic and therefore are useful in many applications in the electrical and allied fields where this quality, plus machinability, heat resistance, etc., are required.

BOOK REVIEW

Samuel Smiles and his Surroundings.
Aileen Smiles. Hale, London, 1956. 206 p., 18/-.

This timely book, the family life of Samuel Smiles, 1812 - 1904, the Scottish author of "Self Help", is written by his granddaughter, Aileen Smiles, the niece of Mrs. Isabella Beeton.

To one brought up on "Self Help", in the day of mutual improvement clubs, mechanics institutes, board schools and parish councils, the memory of the "Sheffield Reformers", among the coal pits and their frequent explosions, the calico-bleaching fields of the West Riding of South Yorkshire, Miss Smiles' book is a carry back to early adolescence. And it is a most happy reminder that the life of the working man has improved almost beyond recognition, but "the fathers have eaten a sour grape and the children's teeth are set on edge."

Samuel Smiles, then a medical doctor, with degrees from Edinburgh and Leyden, visited Sheffield looking for work. The "Sheffield Reformers" included James Montgomery, editor and hymn-writer, and Ebenezer Elliot, the Corn Laws Rhymer. Smiles described Montgomery as a "pale, thin old man" Miss Smiles' quality of kindly reminiscence shows in her comment: "No wonder he looked pale and thin. He was accustomed to jail and had been there twice for publishing articles denouncing ordinary customs of the day — slave labour, state lotteries, employment of child chimney-sweeps."

We sing today in our churches—"Hail to the Lord's annointed" but do not know what social conditions were less than a hundred years ago when Montgomery wrote this as a Sheffield Editor, among the heavy industries of steel and coal.

Samuel Smiles was a worker. All his heroes were workers, some of them county aristocrats, like Dud Dudley, who first used coal to smelt iron instead of charcoal; Benjamin Huntsman, the Sheffield watchmaker, the inventor of cast-steel; Henry Bessemer, James Nasmyth, and others of the illustrious engineers, who succeeded against great difficulties through hard work. In later years it was the fashion to sneer at Smiles as an example of the *bourgeois* element of the Victorian population, the middle classes who worked for a living. He did and was proud of it. His strong appeal to the Englishman was his advocacy of common-sense, honesty and thrift.

Smiles led no narrow life, being in turn a doctor, a newspaper editor, a railway secretary, an insurance executive, and one of the most widely read biographers of Victorian times. But chiefly the men whose lives he wrote and in whose behalf he used his journalistic talents and great influence with learned societies and governments, were poor toil-worn geniuses.

Thomas Edward, the naturalist, of Banff, kept his wife and family by cobbling—"Puir Tam the cobbler", whose magnificent head made a sensation hung on the line at the Scottish Academy. Robert Dick, a baker, but also a poet and geologist, scattered spores about Caithness, so that it would be becoming beautiful "long after he was singing allelulias with the angels". Sir Roderick Murchison, director general of the Geological Survey, told the meeting of the British Association of this remarkable baker whom he described as "earning his daily bread by hard work, obliged to read and study by night, and yet able to instruct the head of the Geological Survey . . . and a profound botanist. I found to my humiliation that he knew infinitely more of botanical science than I did".

Smiles delighted to tell of pioneers, men of the mettle of the Stephensons, Watt, Davey, Trevithick, Smeaton, Nasmyth, Bramah, Fourdrinier, Babbage, Brunel, the Rennies and the Telfords.

"Lives of the Engineers" 1861 was — apart from the uniqueness of "Self Help", translated in his own lifetime into seventeen languages — the work for which Smiles became known to fame. It is best remembered among English-speaking peoples and the many nations they have now become, whose literature, art and science is native and yet inherited. The heroes of this book built ships, ports and docks, lighthouses, bridges, railways, highways, the world over and around. How many eager, bright-eyed boys and girls, of how many races, in how many lands, from tropic to arctic and antarctic zones, have been inspired by engineering ambition since our Roman legacy culminated in the year of the Diamond Jubilee, which Samuel Smiles then 75 years old, attended by special invitation. His granddaughter quotes from his letter of description of the ceremonies, written in what she affectionately, and very pardonably terms "Victorian Ecstasy" . . . "placed behind Sir Frederick Leighton and alongside Whistler with a splendid view of the Queen on her Coronation Throne, in the midst of her blooming family".

Granddaughter Aileen concludes her story of "granpa": "He is buried in Brompton Cemetery. I went there to find his grave, and to my astonishment found it. The grass was long, but there was a big plain stone:

'Samuel Smiles, Author of "Self Help"' still perfectly readable.

F. W. Gray, HON. M.E.I.C.

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of The Engineering Societies Library in New York.

Alliages magnétiques et ferrites

M. G. Say, ed. Montreal, Fomac, 1956. 247 p., $9.20.

Translated from the English edition published in 1955, this book deals with the properties and applications in electrical engineering of magnetic materials, permanent magnet steels and alloys, permanent magnet ferrites, and magnetic powder cores. The related subjects of materials for magnetic recording and magnetostriction, and non-magnetic ferrous and magnetic compensating alloys are also treated, and an introductory chapter briefly reviews modern ferromagnetic theory.

***Appraisal and Valuation Manual of the American Society of Appraisers, 1956-1957, 2nd ed.**

New York, American Society of Appraisers, Manual Division, 1956. 516p., $15.00 (U.S.)

A large part of this manual consists of technical papers covering a wide range of subjects of interest to appraisers and valuation engineers: procedures, franchises, real estate, machinery and equipment, depreciation, rate of return, oil works, etc. A group of six papers is devoted to rate making for public utilities, and one paper deals with the valuation of an industrial atomic energy enterprise. The remainder of the volume is a directory of the Society.

***Arcs in Inert Atmospheres and Vacuum**

Electrochemical Society Symposium, San Francisco, May 1956. W. E. Kuhn, ed. New York, Wiley, 1956. 188 p., illus., $7.50.

Fundamentals, design and operation of furnaces, and chemical applications are the major phases of arc technology covered. Papers on furnaces deal with vacuum arc melting of refractory metals; a pilot-model, three-phase consumable-electrode arc furnace; electrode control systems; vacuum remelting of superalloys and steels; and German developments in vacuum arc melting of titanium and zirconium. Papers on applications deal with applications of the high intensity arc in metallurgy and in process chemistry, and with energy transfer in the high intensity arc.

***Bran's Equivalent Radio Tubes Vade-Mecum, 13th ed.**

Edited by J. A. Gijsen. Antwerp, Brans, 1957. 342 p., price not given.

A listing of available tubes by type and serial designation, with equivalent or near-equivalent replacement types given in parallel columns. Differences, internal construction, and characteristics of the equivalent tubes are indicated. Thirty-seven types of tubes from the principal makers in Europe and America are represented.

Cost Data for the Management of Railroad Passenger Service

D. R. Ladd. Boston, Harvard Business School, 1957. 345 p., $4.50 (U.S.)

The changes in transportation habits in America in the last few decades have resulted in severe losses for the railroads, both in passenger traffic and in revenue. This volume, by the associate professor of business administration at the University of Western Ontario, is based on research carried out at Harvard Business School on the subject of determination and control of costs.

Professor Ladd presents the types of cost data and cost concepts which management might use to control the deficit. He discusses the measures used to find the actual cost of running individual trains, of service between various places, and of related services, and suggests alternative methods which might present the data in a more usable form.

The book is based on information obtained from various railroads in the United States, and the Canadian National Railway.

• LIBRARY NOTES

Cours de mathématiques

J. Bass. Paris, Masson, 1956. 916p., 8500 fr.

The material in this book is that given in the mathematics course given at the Ecole Nationale Supérieure de l'Aéronautique and at the Ecole Nationale Supérieure des Mines in Paris. It presupposes a knowledge of elementry analysis and analytical geometry, and although it is not a treatise on applied mathematics, the author does point out the use of mathematics in solving problems.

Some of the topics covered include linear algebra, simple and multiple integrals, the Fourier integral, analytical functions and differential equations.

***Elasticity, Fracture and Flow; with Engineering and Geological Applications**

J. C. Jaeger. Toronto, Ryerson, 1956. 152 p., $2.25.

This is a concise exposition, for engineers and geologists, of the basic mathematics of the theories of elasticity, plasticity, viscosity, and rheology. The book is comprised of three chapters devoted to the detailed analysis of stress and strain; the behavior of materials (including criteria for fracture and yield); and the equations of motion and equilibrium.

The Electrical Year Book, 1957

Manchester, Emmott, 1957. 359p., 3/6.

Besides containing basic information on various types of electrical equipment, this edition contains revised material on thermal storage heaters, the regulation of the electrical equipment of buildings, electric cables, and tests useful in the installation and maintenance of industrial equipment. A number of tables are included.

Electronic Computers; Principles and Applications

T. E. Ivall, ed. Toronto, British Book Service, 1956. 167p., illus., $4.25.

An introduction to the subject of electronic computers, this book gives a general picture of the subject, and assumes only a basic knowledge of electronics and radio techniques, although several chapters require no technical knowledge to understand them.

Both analogue and digital computers are discussed, and the difference between the two demonstrated. The circuitry and construction of computers are described, and their applications considered. Reference is made throughout to computers actually in operation, mostly in the United Kingdom.

Elements of Engineering Materials

C. P. Bacha and others. New York, Harper, 1957. 494p., $6.50 (U.S.)

Intended for students in all branches of engineering, this introductory text discusses the elements and applications of all types of engineering materials.

The first four chapters cover such general topics as the properties and strength of materials and the structure of metallic materials. The metallic materials covered include iron and steel, alloy steels, copper, and aluminum and their deterioration and protection. Non-metallic materials include wood, cements, concrete, soil, stone, glass, plastics, rubber and fuels.

The scope of the work is so great that treatment of each material is necessarily brief, but the authors have included a bibliography of further reading.

***Engineering Uses of Rubber**

A. T. McPherson and A. Klemin, eds. New York Reinhold, 1956. 490p., $12.50 (U.S.)

A text and reference work for engineers outside the rubber industry who use rubber for applications in other fields. Consisting of sixteen chapters by eighteen rubber technologists, the book deals with methods of manufacturing rubber goods; properties; means of obtaining rubber products through purchase by specification or by special construction; and uses in electrical, civil and chemical engineering. Also treated are the design of mountings, tires, belt conveyors, rubber in automobiles, and rubber in aviation. The book concludes with a brief discussion of the molecular structure and mechanical properties of rubber.

• LIBRARY NOTES

°Handbook of Standard Structural Details for Buildings

M. S. Ketchum. New York, Prentice Hall, 1956. 120p., $4.65 (U.S.)

This is an illustrated guide to the preparation of working drawings for six types of buildings: a small house, a small masonry building, a reinforced concrete building, a steel frame building, an industrial building, and a timber building. Scale drawings of details of design are accompanied by descriptions explaining the reasons for including the details given and suggesting alternative methods of presentation.

°High Temperature—A Tool for the Future

Proceedings of a Symposium, Berkeley, California, June 1956. Menlo Park, Stanford Research Institute, 1956. 218p., $5.00 (U.S.)

The thirty-six papers included are about evenly divided among three major subjects: methods for obtaining high temperatures, materials for containing high temperatures, and processes occurring at high temperatures. The methods treated include solar furnaces, the carbon-arc image furnace, the short time electrical discharges, induction and resistance heating, chemical methods and nuclear methods. Papers devoted to materials deal with ductile ceramics, refractory coatings, selection of materials, and the interactions of materials with high temperature environments. Gas and condensed state reactions, and the interactions between gases and condensed phases are the chief processes discussed.

°Instrument Technology. Volume 2, Analysis Instruments

E. B. Jones, Toronto, Butterworths, 1956. 208p., $8.00.

A practical treatment of the basic principles, construction, installation, use, and maintenance of instruments for measuring the density, humidity, chemical composition, and viscosity of process materials. The aim has been to give as complete a coverage of available instruments as possible while emphasizing the more important and more common types. The instruments described are exclusively those of British makers.

The first volume, published in 1953, covered instruments for the measurement of pressure, level, flow and temperature, and included a bibliography.

Landslides in Clays

A. Collin (1846) trans. by W. R. Schriever. Toronto, University Press, 1956. 160p., $6.50.

This interesting text is perhaps one of the first books written on the subject of soil mechanics. Published in Paris in 1846 it seems to have been forgotten for nearly a century, until, through the efforts of Mr. R. F. Legget of the National Research Council, and a member of the Engineering Institute of Canada, this translation was made.

Collin presented theories of landslides; valuable field data, including surveys of shear surfaces, on about fifteen slips. He noted that they were deep rotational movements with a cycloidal slip surface and concluded that the cause was inadequate shear strength.

This book is a valuable addition to the history of soil engineering.

Leçons d'anglais scientifique et technique

P. Naslin. Montreal, Fomac, 1956. 391p., $9.20.

This publication is intended to familiarize French speaking engineers with scientific and technical terms in English. There are thirty-two chapters or 'leçons', each containing: a number of English sentences on a technical subject, with a corresponding translation in French, lists of the new words used in each lesson, giving the pronounciation, and idiomatic usage and variations. A simplified form of phonetic spelling is indicated throughout. The presentation is lucid and convenient.

°Lubrication of Bearings

F. T. Barwell. Toronto, Butterworth, 1956. 292p., $10.00.

A compact presentation of data drawn from significant work published in the last fifty years. Intended to aid the practicing engineer in the design of bearings, the book covers the nature of surfaces,

f you needed a transmission belt

o make the world go round . . .

. . . you would certainly want to know about

DU PONT NEOPRENE

A stretch of the imagination to be sure, but since 1932 when Du Pont developed neoprene, a growing number of manufacturers the world over have asked for this versatile chemical rubber. It has proven ideal for use in rubber products which must perform under adverse conditions involving high temperatures, abrasion, chemicals, oils and fire hazards.

Products made with Du Pont neoprene outlast ordinary rubber goods many times over. Just look at these records: a neoprene conveyor belt is still on the job after 8 years of continuous service in a coal mine . . . a neoprene gasoline pump hose is in its 12th year of service—with no sign of softening or cracking!

Recently, a new chemical rubber, "Hypalon," has been brought forth by Du Pont research. "Hypalon" is ideal for those special-purpose applications where there is a high exposure to ozone, oxidizing acids, and heat. Its outstanding colour stability makes Du Pont "Hypalon" particularly useful for coloured rubber products that must age well under weathering.

Du Pont makes raw neoprene and "Hypalon" for sale to rubber manufacturers. These chemical rubbers are used by industry in a great variety of mechanical goods—conveyor belts, hose, cables—and other items. Du Pont neoprene and "Hypalon" also find their way into the component parts of consumer and durable goods of high quality.

FOR FURTHER INFORMATION *about locally manufactured products made of these wo chemical rubbers write:*

DU PONT

NAME________ POSITION________

FIRM________

ADDRESS________

CITY________ PROV.________

wear, viscosity, and other fundamentals, outlines the principles of hydrodynamic lubrication, and presents a tentative approach to design. Thrust bearings, concentrated contact bearings, externally pressurized bearings, and oscillating bearings are covered.

Mechanical World Year Book, 1957

Manchester, Emmott, 1957. 360p., 4/6.

This 70th edition of the year book contains a review of progress in the development of the steam turbine power plant. Its importance is emphasized because it is now the most important means of turning the heat of nuclear fission into electrical energy. The section on presswork is completely revised, as is the section on boiler mountings. Other topics covered include engineering materials, machine tools, etc. Mathematical and other tables are included.

Mechanisms and Dynamics of Machinery

H. H. Mabie and F. W. Ocvirk. New York, Wiley, 1957. 442p., $8.50.

Growing from a course given originally at Cornell University, this new text features a streamlined coverage of the elementary work, and devotes more attention to advanced topics.

The first section, on mechanisms, covers linkages, cams, gears, and provides an introduction to computing mechanisms and synthesis. Section two, on the dynamics of machinery, discusses the kinematics and balance of machinery, force analysis and vibration in machines. The text is illustrated by many examples, and problems are included.

A knowledge of physics, calculus, statics and dynamics is assumed in the reader.

Metallic Rectifiers; Principles and Applications

L. R. Crow. Indianapolis, Sams, 1957. 286p., $3.00 (U.S.)

The metallic or semiconductor rectifier is an important circuit component, for the purposes of rectification, instrumentation and control, and the conversion of alternating to direct current. Types of rectifiers discussed and compared in this publication are: copper-oxide, selenium, and magnesium-copper sulfide. Contents also include: rectifier circuits; applications of power and small current rectifiers; rectifiers as electrical valves.

The book is intended for those interested in the practical uses of metallic rectifiers. A bibliography is included.

*Methods for Chemical Analysis of Metals

American Society for Testing Materials, 1956. Philadelphia. 627p., $8.00 (U.S.)

This publication is a part of the Book of ASTM Standards and Complements Parts 1 and 2 which cover the metals. It contains all ASTM methods for chemical analysis of ferrous and non-ferrous metals and alloys, including spectrochemical analysis. There are ten completely new methods and recommended procedures including chemical analyses for electronic nickel and titanium. In addition, ten standards have been substantially revised. Diagrams of the apparatus and pertinent charts have been included in some cases.

Production Forecasting, Planning, and Control, 2nd ed.

E. H. MacNiece. New York, Wiley, 1957. 374p., $8.25.

The author's aim in writing this book has been to explain the engineering principles of production management, and has illustrated his text with actual examples.

New in this edition are chapters on automation, specialization, standardization and simplification, material on operations research and ratio-delay analysis, and on level production. Other topics covered include manufacturing planning, factory planning, sales forecasting, loading, scheduling production, etc. The final two chapters present a problem involving the complete forecasting, planning and control of a business, and its solution.

The book is based on the author's experiences in both the United States

and Europe. There is a useful bibliography of books on the topics covered in the text.

The Prospector's Handbook, 4th ed.

W. L. Goodwin. Gardenvale, Que., National Business Publications, 1956. 381p., $5.00.

This non-technical introduction to the science of prospecting is a useful quick-reference book for the prospector and others in related fields. The information it contains is especially applicable to Canada. Contents include: descriptions of minerals; mineral groups; rocks and rock structures; mineral deposits; and practical prospecting. This new edition has been brought up to date to include the new base metals and other minerals which have recently come into demand because of new industrial processes.

*Reference Data for Radio Engineers, 4th ed.

New York, International Telephone and Telegraph Corporation, 1956. 1121p., $6.00 (U.S.)

An extensive compilation of data most frequently used by radio and electronics engineers. Prepared by specialists, it covers properties of materials, design and operation of components and major items of equipment, control systems, antennas and propagation, and such special topics as electroacoustics, digital computers, nuclear physics, and Fourier waveform analysis. Numerous charts, tables and diagrams are scattered throughout the book, and glossaries and detailed explanations are included wherever it seemed advisable.

*Scientific Uses of Earth Satellites

J. A. Van Allen, ed. Ann Arbor, University of Michigan Press, 1956. 316p., $10.00 (U.S.)

This compilation of thirty-three papers represents current thought on the utilization of artificial satellites for scientific purposes. Among the subjects dealt with are the optical and visual tracking of a satellite; satellite instrumentation; meteorological observations from a satellite; cosmic ray observations; measurements of the earth's magnetic field; plotting out of the auroral zone; studies of ionospheric structure, and detection of meteoric particles. All the papers were presented at the tenth anniversary meeting of the Upper Atmosphere Research Panel, in January 1956.

Techniques de résolution des équations aux derivées partielles

J. Legras. Montreal, Fomac, 1956. 180p., $6.80.

The equations considered in this book, those of the second order with constant coefficients, can, as the author points out, be solved by either algebraic, numerical or graphic methods.

The author presents the different techniques used in solving the various types of problem, and the easiest method of calculation. The book should be particularly useful to students.

Theory of Land Locomotion; the Mechanics of Vehicle Mobility

M. G. Bekker. Ann Arbor, University of Michigan Press, 1956. 520p., diagrs., $12.50 (U.S.)

The author of this book was a Lieutenant Colonel in the Canadian Army until his retirement, and much of the work covered by the book was done from 1943 to 1946 under the auspices of the Canadian Department of National Defense, the National Research Council, and the U.S. Army Ordnance Corps. The book is based on a course given by the author at the Stevens Institute of Technology, 1950-52.

The author's aim in writing the book is to present the information available on the physical relationship between a motor vehicle and the environment of its operation, with particular reference to vehicles operating off the roads.

Some of the topics covered include: locomotion in nature and on wheels; morphology and mechanics of motor vehicles; problems of soil and snow mechanics; mechanics of a wheel; skis, sleighs and toboggans; dimensional analysis, testing and over-all economy.

There is a list of over three hundred references covering the work done on the subject, and although much progress has been made since the book was orig-

inally completed, it is still a very useful and comprehensive survey.

Thermodynamic Functions of Gases

F. Din, ed. Toronto, Butterworth, 1956. 2 vols., $12.50 per vol.

The surveys of the thermodynamic properties of gases found in these volumes were undertaken in connection with a scheme sponsored by the British Department of Scientific and Industrial Research. The work was done by various academic and industrial organizations.

There is an introductory chapter by the editor on thermodynamic diagrams and functions and their preparation.

Also a survey of information existing on each gas, and thermodynamic diagrams and sets of tables constructed from this information. Bibliographical references are given for each gas. The gases covered are; ammonia, carbon dioxide, carbon monoxide, air, acetylene, ethylene, propane and argon.

Further surveys will be published later.

Transistor Engineering Reference Handbook

H. E. Marrows. New York, Rider, 1956. 288p., $9.95 (U.S.)

There have been increasing transistor applications in power control, communications, manufacturing, consumer use, and various branches of engineering and scientific research. This book is intended to fill the need for a publication on transistors and the components of transistorized equipment for commercial use.

Data sheets are included covering: 200 types of transistors, 450 capacitors, 100 cells and batteries, thermistors and other miscellaneous components. Further contents are: a short general survey of transistors, including a useful bibliography; data on transistors; data on components and test sets; data on commercial applications. The information given is arranged according to the manufacturing company for the various transistor types.

The World Almanac 1957, 72nd ed.

New York, New York World Telegram, 1957. 896p. $1.25 (U.S.)

This new annual addition contains the usual collection of miscellaneous facts in the fields of biography, history, geography, economics, law and sports. Information is easy to find, and often in tabulated form. A summary of notable events of 1956 is included, the majority pertaining to the United States.

*World Symposium on Applied Solar Energy, Proceedings

Phoenix, Stanford Research Institute, (Association for Applied Solar Energy) 304p., illus,. $5.00 (U.S.)

The nineteen technical papers included in these proceedings deal with such subjects as solar machines and stills, high temperature furnaces, the heat pump, water heaters, cooling with solar energy, algae culture, electricity from the sun, and residential uses of solar energy. The proceedings also include a panel discussion on solar house heating and two round table discussions devoted to the architectural problem of solar collutors and the future of applied solar energy.

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Atomic Energy

A review of applications of radioisotopes to engineering. J. L. Putman. (I. Mech. E. Advance copy)

Some safety considerations of nuclear power reactors. C. D. Boadle. (NECIES. Advance copy)

Symposium on applications of radioactivity in petroleum research and refinery operations (Tracerlab inc.)

Civil Engineering

British contributions to civil engineering. (Gr. Brit. Central office of information. Reference Division)

Concrete

Concrete control and construction. (Bul. 132)

Curing of concrete 1925-1955. (Bibliog. 18)

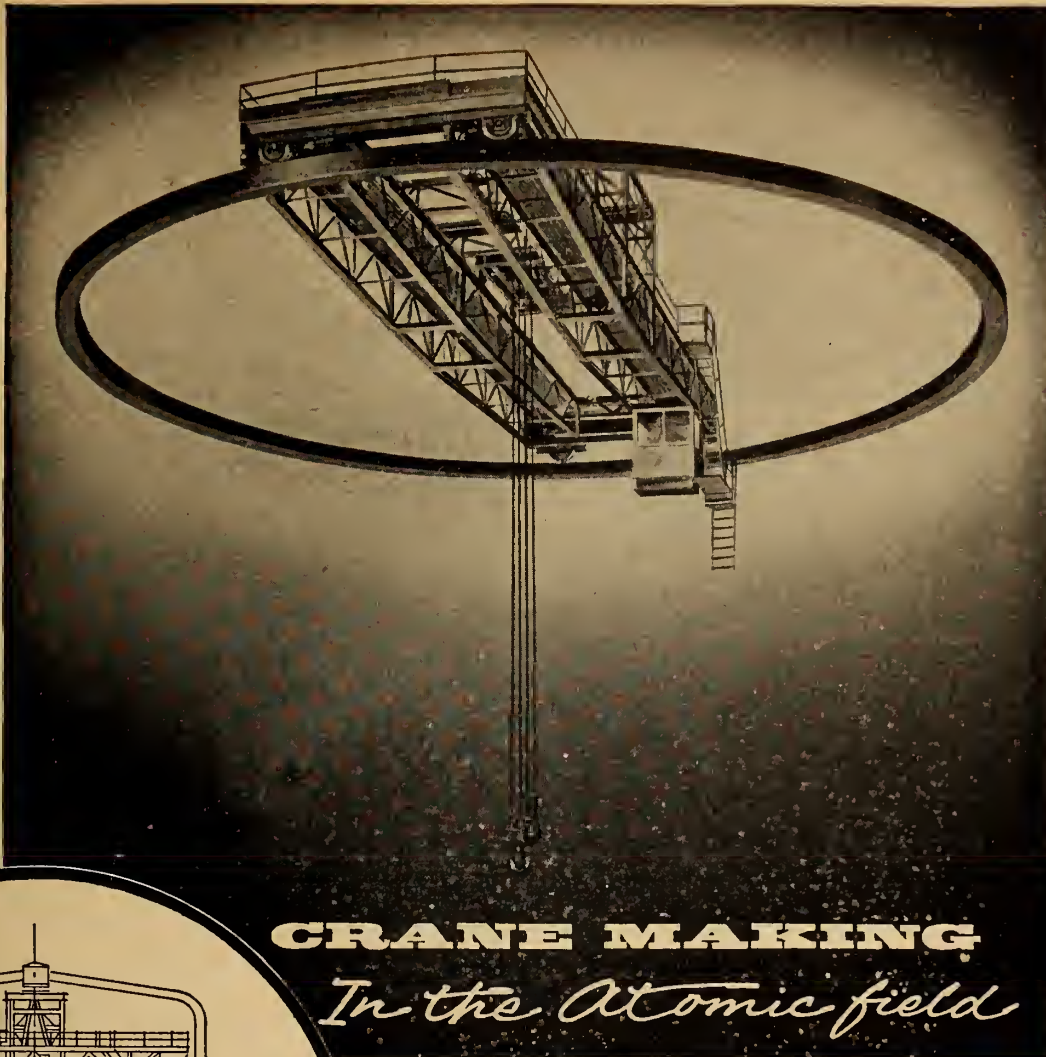
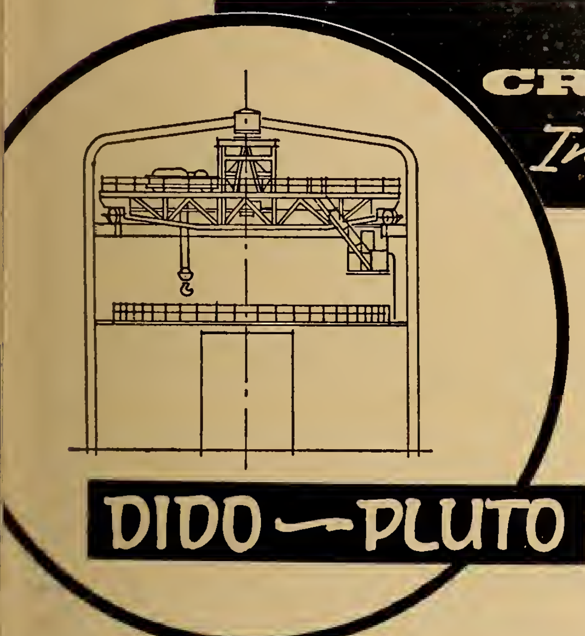
A report on income tax incentives for Canadian mineral development. J. G. McDonald. (Saskatchewan. Dept. of Mineral Resources)

Roads and Streets

Flexible pavement design correlation study. (U.S. Highway Research Board Bul. 133)





In collaboration with the Ministry of Works Engineering Staff we designed and installed a special form of circular motion Overhead Electric Travelling Crane, for operation in Britain's first experimental Reactor at Harwell.

We will shortly complete the installation of further circular motion units at both Harwell and Dounreay, the latter on instructions from the United Kingdom Atomic Energy Authority.

During the early part of 1957 we will commission a similar crane for the Australian Atomic Energy Commission.

The cranes are designed for a lift of 25 tons on a span of approximately 67 ft.

We are currently engaged in the installation of Main Turbine House and Blower House Cranes for Calder "B" and Chapel Cross Atomic Power Stations.

CORRECTION

The price of the Encyclopedia of Instrumentation for Industrial Hygiene published by the University of Michigan was incorrectly quoted in the review published in the February issue of the Engineering Journal. It should be $30.00 (U.S.)

ENGINEERING CAREERS

The Construction Industries

THIS ARTICLE HAS been called The Construction Industries because there is no simply definable single industry that covers all the many kinds of construction work that are carried on today, especially in the more industrialized countries and those, such as Canada, that are expanding their resources rapidly and to a great extent.

The building of almost any structure or series of structures, from a farmer's barn to the St. Lawrence seaway and power development, could logically be included in an all-embracing "construction industry". In practice, there is a tendency for companies to specialize in particular fields of construction work, such as housing or commercial buildings, industrial plant construction, foundations and concrete structures, and so on. There are also many companies prepared to design and build for a great variety of industrial fields.

Large Employers

The construction industries in Canada are major employers of labour; in fact, the largest of the industrial groups (outside farming and commerce), with a peak total of some 650,000 employed in 1956. They are also large employers of engineers (a 1952 census of 4,040 civil engineers showed that considerably the largest group, of 700, were engaged in construction work—the total figure for the construction industries is, of course, much higher).

On-site consultations are frequent during the construction of industrial plants and other installations. Here, a group of designing and construction engineers discusses problems at the site of a new blooming mill for the Steel Company of Canada. In the background is the soaking pit area superstructure, seen nearing completion.

Fields of Work

The construction field is a wide one, as has been stated already. Among the facilities built, most of which will be familiar, are roads and railroads, airports and docks, tunnels and bridges, dams for hydro-electric power developments or flood control, and all the buildings (houses, offices, hospitals, etc.) that make up a residential community. In addition, there is the vast field of industrial construction, including mine facilities, powerhouses, and many different industrial plants for the manufacturing, chemical, petroleum, pulp and paper, and other industries.

Engineers in Construction

The activities of engineers in the construction industries may be divided roughly into two sides. On the one hand there is the design of the permanent structure, such as a building or a bridge, and on the other is the actual erection of the structure.

The design engineer is responsible for applying the theory of structures and his knowledge of building materials and their physical properties to produce a suitably practical, stable, and reasonably economical structure. In this task he may work in close collaboration with the architect.

The construction engineer is responsible for the work in the field, from initial surveying of a route or a building site to the completion of the structure—in other words, *how* the job is done. This may involve the design and erection of temporary structures, scaffolding, formwork, materials handling plant and equipment, and so on.

Types of Engineer

The construction industries employ more civil engineers than any other category, but mining engineering is also considered a valuable training for engineers wishing to enter the construction side of the industries (rather than the design side). In addition, however, there is scope for a considerable number of chemical, electrical, and mechanical engineers in the design and construction of industrial plants.

Progress and Opportunities

On the design side of the industries, an engineering graduate may start as a junior engineer in the drawing office of a company and progress through various stages to chief engineer and to management levels.

On the construction side, the graduate may start as a field engineer, working with survey parties or at construction sites, and then proceed to resident engineer, construction engineer and estimator, project superintendent, and supervisory grades to management.

Many of the top positions in companies engaged in the construction industries are occupied by professional engineers.

Widespread Activity

The activities of Canadian construction companies are mainly confined within Canadian territories, but the vastness of the country and its current rapid expansion mean that the construction engineer may find that his job involves covering a great deal of ground. The development of the mineral resources in the north involves the construction of whole townsites as well as the necessary mining and industrial facilities and the roads, railways, and airfields to make them accessible. The aluminum smelter at Kitimat, in northern British Columbia, is a well-known example of such a complete community in an area that is at present rather remote from main settlements. Similarly, the pulp and paper industry and, frequently associated with it, the hydro-electric power-producing centres undertake major construction projects in hitherto undeveloped areas.

The radar defence chains across the continent are further examples of widespread work for the engineer. Though Canadian engineers did not take part in the actual design of the Distant Early Warning Line (DEW-Line) in the far north, this part being done in the United States, they did play a large part in the construction work and were more widely concerned with the Mid-Canada radar line.

Canada is a major supporter of the Colombo Plan for financial and technical assistance to countries in the Far East. Several Canadian engineering firms are engaged in development and construction work in these areas.

Research

There is little pure research work carried out within the practical construction industries, but a considerable amount of such work is done at the universities and research establishments, in particular the National Research Council.

Training

The construction industries generally encourage the summer employment of engineering students.

The graduate engineer is given ample opportunity for practical on-the-job training and experience under the guidance of senior engineers. In addition, some companies offer assistance in the form of scholarships and facilities for further study, either externally or within the company.

Salaries and Benefits

General starting salary scales are comparable with other industries and are based on the recommended practice of the general body of professional engineers. The industry is a very active one, and the opportunities for advancement are currently very favourable for the right man. The upper limits of salary are related to the responsibilities of the higher levels of management to which the professional engineer may progress in the construction industries.

In common with general industrial practice today, additional benefits such as pension and health plans are customarily offered by the construction industries. Bonus and profit sharing schemes are also frequently incorporated, according to circumstances.

Construction of routes to open up new territories and to improve communications between existing communities is a continuing task. Shown here are two engineering undergraduates working with a construction survey party on a new trackbed for Canadian National Railways, typical of such construction work in various fields.

n:n who make a "science of service"

In every corner of the nation, Canada Wire engineers demonstrate their renowned ability to combine the exacting principles of product engineering with the practical applications on the job.

Frank Ashworth,
Manager,
Product Control

v:ien the sun goes down

'ìis is Canada at night. Seen from te air, the twinkling lights of cities, t.wns, villages and farms virtually in-t·connect the oceans. If we could ·ew it all at once, this panorama ›uld still prove to be one of science's ;eatest achievements.

'ansmission of power from generator t population centre is a formidable ‹ough problem.

]it distribution of that same power to light up evergrowing communities is a science in itself.

Canada Wire Electrical Engineers are well experienced in the cable problems involved in utility planning. This experience and technical knowledge of the economics of power distribution, plus a constant program of product research, have built and maintained Canada Wire's reputation in the field of electrical conductors.

B.C. Welcomes Hungarians

The Journal *reprints this article from* U.B.C. Reports *because it agrees heartily with the ideas expressed. The Institute members and council have a warm interest in the welfare of these new Canadians and there is much pleasure in knowing that the University of British Columbia is doing so much for them.*

"Welcome Hungarians"

We are indeed fortunate in having the faculty and students of Hungary's only school of forestry come to Canada. We welcome them with open arms.

These are the people who jokingly claim that Hungary should have been awarded ten, not nine, gold medals in the Olympic Games "because we threw the hammer and sickle the farthest." These are the people who set up a free government in Sopron and ran the affairs of their city (nicknamed "The Faithful City") during the Hungarian revolution. They dug in to defensive positions around their city and retreated across the Austrian border five miles away only after the onslaught of hordes of Russian tanks made their cause completely hopeless.

They are a school with perhaps more "school spirit" than we have ever seen. They were originally an independent forestry school in northern Hungary until the border changes after the First World War moved them into Czechoslovakia. So they packed up and moved to Sopron. When the Treaty of Versailles ceded Sopron to Austria they were the prime movers behind a local plebiscite which got them back into Hungary.

They are proud people with a rich heritage and with an intense desire to learn the way of their new homeland. They bring with them a student orchestra (minus instruments), a soccer team, tennis champions, fencers, skiers. In fact, all that one might expect of an active student group anywhere.

They come at a time when Canada's forest industry badly needs talent such as they can offer or will be able to offer after they learn English and complete their training in forestry. The shortage of trained foresters is so acute in Canada that even with their arrival we must not let up in our efforts to recruit more and more young people for careers in forestry.

Once they learn the ways of our forests and the problems created by vast sizes and distances, they, with their different background and earlier training may make valuable contributions that no one else could make. Their approach to conservation problems alone, could in ten or twenty years' time make us extremely grateful for their presence.

Yes, we welcome them with open arms, and hearts. Let us try as hard to understand them and help them with their problems of adjustment to a completely foreign way of life as they are trying to understand us and learn to take their places as valuable citizens in our midst.

Election and Transfers

At the meeting of council held at Montreal, March 2, 1957, a number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected:

MEMBERS: V. Aare, Peterborough; S. Andrews, Vancouver; H. B. Ashenhurst, Burlington, Ont.; H. R. Bell, Vancouver; W. G. Brown, Montreal; K. C. Cox, Toronto; P. W. Doddridge, Peterborough; C. S. Elliott, Hamilton; J. P. Genge, Niagara Falls; L. Gill, Sudbury; R. F. Goodsman, Montreal; P. Heggs, Hamilton; I. C. Herd, Peterborough; E. C. Hurd, Vancouver, H. W. Jewell, Toronto; S. L. Lipson, Vancouver; A. B. Patterson, Toronto; R. H. Pinault, Arvida; R. A. Pope, Vancouver; S. Rolko, Hull; R. C. Steele, Montreal; F. X. Tremblay, Montreal; Z. C. Van Schwartz, Hamilton, Ohio; W. Villain, Dryden; J. D. Willis, Peterborough; H. R. Wright, Vancouver.

JUNIORS: G. R. Bowes, Prescott; R. M. Hanna, Grand'Mere; J. W. Smail, Ottawa; V. Tamm, Vancouver; J. C. R. Warren, Niagara Falls; K. M. Williams, North Bay.

JUNIOR TO MEMBER: J. E. Butler, Toronto; R. E. Dyson, Esquimalt; J. P. Ofrenchuk, Toronto; C. Senneville, Montreal; M. M. Smith, Toronto; H. D. Walford, Montreal.

AFFILIATE TO MEMBER: P. A. O'Connor, Col., Ottawa.

JUNIOR WITH EXAM: D. R. Morrison, Lively, Ont.

STUDENTS ADMITTED:

Queen's University: J. C. Aitken, D. H. Annala, R. W. Ansley, P. R. Barnard, J. J. Bawden, R. A. Bird, M. A. Bohn, H. J. Brooks, R. A. Brown, W. D. Budworth, J. R. Burton, R. A. C. Calder, E. Cappellani, W. Cencich, R. E. Chambers, N. J. Cowan, J. R. Eickmeier, O. K. Ellis, D. G. Foley, J. L. Gassenbeck, T. J. R. Godfrey, J. A. U. Gregg, J. V. Harvey, G. A. Hawley, B. L. Hodgins, R. F. O. Hurrle, A. A. Jackson, H. R. Johnson, W. H. Kerr, D. J. Kilgour, E. Koczkur, L. E. W. Laviolette, O. Legein, G. O. Leonard, D. C. Loucks, J. P. MacGowan, L. R. McCartney, A. McConnell, R. M. McDerment, R. J. McKelvey, A. M. McMahon, N. Moffat, E. A. Robertson, R. J. Rodger, P. M. G. St. Rose, O. J. Salari, D. S. Scott, W. R. Sexsmith, D. A. Sharp, J. C. Simons, J. D. Smith, J. F. Smith, A. M. Spriet, D. E. Staveley, D. Suzuki, R. K. Thom, J. M. R. Thomson, K. D. Trebilcock, A. G. Tucker, L. R. Tucker, W. P. Tuisku, C. J. Turkstra, N. Van Den Assem, M. R. Vanderburgh, E. C. Walker, J. E. C. White, M. M. Yovanovich.

McGill University: G. W. K. Adanuvo, J. F. Annesley, R. Borland, S. Broccolini, G. J. P. Comtois, M. J. Green, R. D. Hatfield, A. A. Lawless, F. Libera, R. Latham, A. R. McKim, W. Maslowski, B. Methoti, P. Moller, J. C. Noel, F. M. O'Shaughnessy, T. D. Owusu, R. M. Patterson, G. M. Roger, K. Takahashi, H. G. Walsh.

University of Toronto: J. M. Agnew, M. R. Binkley, J. J. Boase, A. Budra, G. S. Cohen, J. M. Corbett, D. J. Douglas, W. H. Eatock, R. L. Heise, P. Jelaffke, M. A. Krebs, C. A. Laferriere, D. A. Oakes, B. Ovenell, K. E. Plumb, E. J. Rohacek, F. C. Schwenger, V. Spring, W. C. Tripp, L. J. Westwood.

University of Manitoba: K. J. R. Blowatt, D. A. Campbell, R. M. Gordon, W. Hanuschuk, C. L. Hardy, D. J. Palanuk, C. J. Shirtliffe, F. F. Van Humbeck.

Nova Scotia Technical College: J. H. Arkwright, C. R. Baird, W. D. Blue, L. J. Cole, A. E. Keddy, W. H. Waring.

University of New Brunswick: J. R. Carmichael, J. D. Coletsos, C. H. Laurence, W. J. Starr, T. V. Stephens, T. A. Wilson.

Mount Allison University: D. A. Darby, M. G. Meacher, W. Szeto, W. A. Winsor.

Memorial University: R. I. Avery, L. D. Baikie, L. S. Cooke, A. R. Knight.

University of Alberta: J. K. Burrell, G. R. McAtney.

University of British Columbia: K. M. Johnson, T. D. Peters, J. R. Carmichael.

University of Sherbrooke: J. R. G. Chaperon.

Laval University: J. M. Levesque.

Royal Military College: R. G. Blakely.

Graduates: C. L. Hickson, B.A.Sc. (Mech.), Toronto 1956, F. E. Lucas, B.A.Sc. (Elec.), Toronto 1956, S. M. Uzumeri, B.A.Sc. (Civ.) Toronto 1956, C. L. Pelton, B.Sc. (Elec.), Queen's 1956, J. H. Simpson, B.Eng. (Elec.), N.S.T.C. 1956.

Applications through Associations:

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Junior to Member: P. A. Brett, J. D. Harper, J. E. Maybin, C. H. Weir.

SASKATCHEWAN

Members: R. G. Campbell, J. B. Dickey, B. B. Grant, H. R. Holland, J. A. Kelly, K. C. Reeves, P. E. Reimer, H. D. Ramsay.

Juniors: N. E. Parsons.

Students: H. G. Gilchrist, H. J. Girgulis, W. A. Maki, D. P. Mitchell, D. J. McGuire, R. D. McLeod, B. J. Pfeffer, E. W. Reinhardt, I. B. Wilson.

Junior to Member: D. Bing-Wo, J. C. Browning, S. S. Gray, R. A. Gyles, J. C. MacKay, D. E. McGrath, N. Peters, M. Shayna, C. L. Slegel.

Student to Member: B. I. Jamieson.

Student to Junior: T. P. Gilchrist, E. S. Jonasson, H. G. Kindred, A. Schuster, J. Stoffel.

NOVA SCOTIA

Members: J. Apinis, J. H. Walker.

Junior to Member: F. L. Mason, D. C. Tibbetts

THE ENGINEERING INSTITUTE OF CANADA

1956

REPORT of COUNCIL

and

Reports of Committees and Branches

Published as a supplement to the issue of *The Engineering Journal* for April 1957

APRIL 1957

CONTENTS

Report of Council, 1956

TO PARAPHRASE an old political cliche from south of the border—"As the nation goes, so goes the Institute", meaning simply that when Canada has a good year, so do its engineers. 1956 has again strengthened that view. The Institute has behind it another satisfactory year.

However, to say that the twelve months since the last report had been good in all respects would be evading the truth. Consider the matter of membership. The details in this report show that 1800 persons applied for admission to the Institute in the year. This in itself is very good, and stands 17 per cent higher than the corresponding number for the previous year.

At the same time, the net gain in overall enrolment was 510. This results, of course, from the application of casualties which occur through deaths, resignations, and removals. Details will be found later in the report. To understand properly what might be considered a high level of removals in 1956, one must be realistic about present conditions. Hundreds of engineers, particularly the younger ones, are on the move, often without leaving any forwarding address. The Institute loses contact, the mail is returned, and eventually a removal must be put through. Branches are urged to do all they can to keep tracing these members, and to send in new addresses as they become known.

As seen through financial eyes, 1956 again showed a sound and progressive position. The figures will be found elsewhere in this report, for those who wish to study them. It will suffice to say here that all expenses have been met from current revenues, satisfactory allocations have been made to reserves, and a small surplus remained.

The activities of the Institute have continued to expand, in several interesting directions, as this report will show.

CONFEDERATION

Confederation remained one of those subjects foremost in members' minds during 1956. The year saw the presentation of the joint report, to the Institute Council and to the Dominion Council, at their respective annual meetings, both in the early summer. The report was promptly adopted by the E.I.C. Council. Dominion Council decided that it would be essential to have the opinions of each one of its constituent provincial associations. As a consequence, the report was referred to all provinces for study and recommendation, and that is where the proposal now stands. The next move must come from Dominion Council, after receiving the reports of the provincial associations.

THE PRESIDENT'S ACTIVITIES

In addition to giving his personal attention to a host of Institute affairs from his own desk, Mr. McKillop, accompanied by Mrs. McKillop, undertook the president's annual travel schedule. In the early Fall, he attended the Maritime meeting at St. Andrews, New Brunswick, and combined with this his visits to many of the branches in that area, including Newfoundland.

The president's party was nicely on the Wester tour when the trip was suddenly interrupted by tl necessity of the president returning to his office b cause of the death of his senior assistant. The balan of the tour was continued by the general secretar with vice-president R. M. Hardy, from Edmonton.

Not less important were Mr. McKillop's several tri to represent the Institute and participate in the mee ings of other societies abroad. This is a phase activity which is increasing in scope, and which steadily raising the stature of the E.I.C., and of Canac in the technical eyes of the free world. These vis included several to the United States, and one to t conference of U.P.A.D.I. (Pan American Federation Engineering Societies) in Mexico City, as a result which the Institute will be hosts to that organizati for its 1958 conference, in Montreal.

COUNCIL MEETINGS

Council of the Institute met ten times during t year, at Peterborough, Ottawa, St. Andrews, Victor and Montreal. The average attendance was 29.

THE BRANCHES

In making any report of an Institute year, Coun remains conscious of the fact that the branches the Institute. It is on the vigour of their local activit that the health of the organization depends.

It is not the purpose of this part of the report discuss these branch activities, and it will merely stated that branch programs for 1956 reflected a h level of interest and a wide variety of ideas, b technical and social. In later pages members will f the details in the individual branch programs.

The number of branches during the year remai unchanged at 47, with seven branch sections.

PUBLICATIONS

Some interesting developments took place du the year in this field. First, the decision was taker make a change of printer for *The Engineering Jour* As the result, commencing with the July issue, *Journal* has been printed, bound, and mailed by H C. MacLean Publications Ltd., of Toronto. This course includes the report you are now reading. change has been a satisfactory one, from the Instit point of view, and the cost of publishing was stantially lower for the last six months of the y At the same time, advantage was taken of the cha over to re-vamp and improve the format and cont arrangement of the *Journal*. Comments have been vourable.

Two new publications were brought forth du 1956. The long sought pamphlet on the theme of "W should I belong to the Institute?" was compl printed, and distributed. It is now in steady den from the branches. The other item, also long awa was the compilation of an E.I.C. film catalogue. experienced man was given this task during the Sun and the book was finished and distributed in the Fall. The catalogue is one of the most comprehe its kind ever attempted in Canada. It will be useful branches, at universities, and to anyone concerned th the selection of films for engineers.

TECHNICAL ACTIVITIES

The year saw the gradual advancement of the w ideas on the technical activities of the Institute hich were explained in the annual report of a year o. A report of the special Committee on Technical perations was adopted, after prolonged study and dis ission by Council, and the proposals have now been omulgated to branches for review. In this connection l members are urged to read, if they have not ready done so, the explanation of this matter which as published in the February 1957 issue of the *Journal.*

As a further step, approval was given by Council the employment of an assistant secretary for promo- n of branch technical development, and his assistance ill be available as soon as a suitably qualified person n be found. Negotiations toward this end are now ogressing.

I.A.E.S.T.E.

In 1956 the Institute again acted as the Canadian gency for the administration of the International As- ciation for the Exchange of Students for Technical xperience. This marked the fourth year of Canadian rticipation in the plan, and the numbers of students ndled has been growing, not spectacularly but stead- . It is for the benefit of undergraduate engineering udents, to help them obtain technical employment broad during the summer vacation preceding their nal year. This past year 91 European students were aced in industry in Canada, and 9 Canadians travelled jobs on the other side of the Atlantic.

As the result of some promotional work, Canadian dustry agreed to contribute to a fund to assist Cana- an students with their travelling expenses, while par- cipating in this exchange plan. As a result the number Canadian students taking part in 1957 should be nsiderably larger. It does not require much imagina- on to see the far-reaching beneficial effects of these change visits.

FILMS

The Institute is continuing in its policy of adding owly to its library of films, concentrating on quality ther than quantity. During the year purchase was ade, to good advantage, of a copy of an excellent w mechanical engineering film on automation from e series called "The Search". This picture was first own to an E.I.C. audience during the 1956 Annual eeting in Montreal. It received an enthusiastic re- ponse then, and many times later.

Demand for the use of the Leonardo Da Vinci lm continued throughout the year, and comments on s excellence are still being received from first time ewers.

ANNUAL MEETING

Mention should be made of the fact that the 1956 nnual Meeting, in Montreal, was the largest in In- titute history. Some of those present, including a num- er of the old-timers with many meetings in their ex- erience, also ventured the opinion that it was the ost successful. The technical program, of high calibre roughout, consisted of 33 papers and 2 panel dis- ssions. A total registration of around 1700 gave the eeting an undisputed claim to the greatest in size, and the rest must be left to the appraisal of those who were there.

A new feature of the meeting was the introduction of an exhibition of engineering photographs. Industrial firms across Canada, and others such as consulting engineers, were invited to submit photos of engineering work and development of all kinds with which they had been associated in the previous year. The response was excellent. The collection of mounted prints so obtained, having become the Institute's property, is being shown elsewhere now, to university engineering societies and to other interested groups. It is planned to continue this project on an annual basis.

LIFE MEMBERS

The growing fraternity of Life Members of the Institute continued to maintain a lively interest in its affairs throughout the year. One regular and several informal meetings of their own were held, out of which came the decision to collect and donate sufficient funds to purchase another film for Institute use. The life members are now the principal support of our film activity.

More detailed information concerning this senior group of members will be found in a following section of this report, as submitted by their secretary.

INSTITUTE INSIGNIA

Another item of interest during the year, which reached quite unexpected proportions, was the introduction of the new Institute slide-rule tie clip. It was devised in the shape and appearance of a tiny slide-rule, with an "E.I.C." monogram taking the place of the cursor. Council ruled that it be given free to all new student members, sold to Members and Juniors at $2.00, and to existing Students at $1.00. The results have been beyond the most enthusiastic expectations. The clip was an instant success, and at time of writing the distribution is in its third thousand. If you want one, consult your branch secretary, or write Headquarters.

THE OTHER REPORTS

This portion of the annual report is supplemented, as usual, by those of the various committees and departments of Headquarters. They have been prepared for your information, and members are urged to read them as they continue their examination of this overall report. Only in this way can a real knowledge of the year's accomplishments be obtained.

ROLL OF THE INSTITUTE

The membership of all classifications now totals 16,580. New names added for the year amount to 1,684, but deaths, resignations and removals amounted to 1,174, making a net gain of 510.

During the year 1,610 candidates were elected. These were classified as follows: Members 276, Juniors 73, Students 1,260, Affiliate 1. Seventy-four reinstatements were effected. Life Membership was conferred on seventy-eight members under by-law 26.

Transfers from one grade to another were as follows: Junior to Member 140, Student to Junior 601, a total of 741.

Removals From The Roll

There have been removed from the roll during the year by resignation and for non-payment of fees: Mem-been little, if any, activity on this matter in Canada, but it has been noted that there is a gradual increase in the number of engineers joining unions in the United States. A recent report entitled "Unionization Among American Engineers", published by the National Industrial Conference Board, gives very complete data on this subject.

Late in the year, this Committee was requested to prepare for the development of a co-operative agreement with the professional engineers of Prince Edward Island. This matter is now in the preliminary stages and will be carried on with during the coming year.

E. B. Jubien, M.E.I.C.
Chairman

CANADIAN CHAMBER OF COMMERCE

As the representative of The Engineering Institute of Canada on the Executive Council of The Canadian Chamber of Commerce, I would like to report as follows.

As Canada's national business organization, representative of all types and sizes of business, The Canadian Chamber of Commerce develops policies on national economic matters which are presented to the Federal Government each year following the Chamber's annual meeting. Support of the system of freedom of enterprise is, of course, the central core of the Canadian Chamber's policies, and I thought you might be interested in having the Chamber's official views on subjects which are of particular interest to the engineering profession.

On trade, the Chamber, among other things, recognizes that certain segments of the Canadian economy are seriously affected by competition from foreign sources and asks the government "without deviating from the principles of GATT": *(a)* to exercise closer control over tariff classifications of imports *(b)* to investigate promptly imports suspected of evading dumping duty and *(c)* to strengthen regulations to prevent imports at dump prices.

On immigration, the Chamber reiterates its long-standing policy that Canada should aim for a population of 30 million by 1975, and warns that unless there is a marked increase in the number of immigrants, Canada is likely to fall far short of this goal. To increase the flow of newcomers, the Chamber recommends, among other things, a more active program of publicity to ensure that a true picture of Canada and Canadian opportunities is kept at all times before source countries and immediate steps taken to establish an organized program to encourage more immigration from the United States.

On public finance and taxation, the Chamber expresses the belief that both personal and corporate income tax rates are still too high for a developing country. It also asks the government to scrutinize ordinary peace-time expenditures carefully with a view to keeping them to a minimum consistent with meeting recognized public objectives and to ensuring value for the money expended and also examine with care the costs of our continuing defence establishment.

On national defence, the government is urged not to relax Canada's defence program, and to formulate and publicize as widely as possible a clear policy with respect to the Canadian militia and the reserves of the navy and air force.

On a national highway program, the Chamber urges federal appropriations be made available on an equitable basis to the various provinces for use in the improvement of Canada's main highway network. Authority over administration of road projects should remain under provincial highway departments.

On national harbours, the Chamber urges the government to take under control and assume responsibility for the necessary capital outlay of key ports in order to develop those ports scientifically to the ultimate advantage of the whole nation.

On Trans-Continental Airline Services, the Chambe asks the government to permit establishment of othe trans-continental airline services within Canada.

On radio and television, the Chamber asks th government to establish a separate regulatory bod having minimum essential regulatory powers over radi and TV broadcasting in Canada. The Chamber als asks that TV licenses be granted to citizens who desi to establish additional stations in centres at prese served by the C.B.C. or private stations, provided alte native channels are available, and that the C.B.C. b required to seek an annual grant from Parliament f any public funds requested to operate C.B.C.

On natural resources, the Chamber urges upon i members the promotion of Federal, Provincial ar business policies which will lead to the properly i tegrated development of Canada's natural resources the interest of the nation as a whole. The Chamb stresses the importance of government policies in r source management which will ensure maintenanc and, where possible, expansion of all renewable r sources, and calls upon its members to advocate a support such policies.

F. G. Rutley, M.E.I.C.
Institute Representative

CANADIAN STANDARDS ASSOCIATION

Late in the calendar year the headquarters office w moved from the National Research Council Buildi to 235 Montreal Road, Ottawa 2. Also during the ye the name by which the Approvals Division Labo tories outside Toronto have been known was chang to C.S.A. Testing Laboratories, and the service p vided has now been styled "certification service", wh replaces the earlier name "approvals service".

The Welding Bureau continues to operate succe fully and is extending its field to cover various n activities in the welding world. Considerable progr has been made in the preparation of a code for mar welding, and a new standard specification is under v for "resistance or flash-butt" welding.

The educational services of the Bureau are be particularly well-received throughout the industry a new courses are continually being developed a offered to those interested. The fundamental cou has met with very favourable comment in the Uni States and arrangements for the sale of copyrights legalize publication and use in that country are alre effective and are likely to be extended.

The general manager of the Bureau is schedu to deliver a technical paper describing this edu tional work at the Congress of the International Insti of Welding in Germany, and at the Commonwealth Welding Conference in England during next summer.

Certification of plants in Canada is constantly growing, and at the C.S.A. directors' meeting in December, the number of firms so certified was recorded as 201.

The Approvals Division have maintained a high rate of progress and are financially able to reduce their indebtedness, which was incurred at the building of their new Etobicoke laboratories. The question of licences and standard marks has been much in evidence in recent months and new procedures are now being established.

Many meetings of technical committees have been held during the year, at least 45 being recorded, while the directors have assembled five times as a board, apart from sessions of the executive and special sub-committee.

New standard specifications, to the number of 35, have been issued: 15 in the electrical field, several for car iron parts and practices, and others for such diverse matters as masonry cement, binding head screws, fire fighting apparatus, pole line hardware, copper tubing, wooden sash frames, pest control chemicals (names).

Further, standard specifications in varying stages of development number 121, and completely new projects have been authorized on construction plywood, rubber tiles, radiation danger markers, etc.

Internationally, C.S.A. has increased somewhat its participation in I.S.O. Committee work, and has enlarged its responsibilities within the I.E.C., which it represents in Canada.

P. L. Pratley, M.E.I.C.
Institute Representative

LEGISLATION COMMITTEE

No matters have been brought before your committee, but inasmuch as the "Terms of Reference" are not altogether clear, your committee has formally requested clarification.

At the Council meeting in Montreal on December 8th the president suggested that your committee submit suggestions to council as to what the terms of reference should be. Your committee will study this matter and report at a later date.

C. G. Kingsmill, M.E.I.C.
Chairman

COMMITTEE ON PRAIRIE WATER PROBLEMS

Although water still remains a very active subject on the prairies, and your Committee has been watching the problems associated with its utilization, there seemed no vital matters under discussion this year to warrant a meeting of the Committee.

The most interesting progress made this year was the decision of the P.F.R.A. to let contracts and proceed with the construction of the diversions of the Belly and Waterton Rivers into the St. Mary's reservoir. This work is now proceeding after many years of discussion with the United States and the International Joint Commission, as a fair percentage of the water being diverted is of United States origin.

No new irrigation developments are in prospect but the further development of the St. Mary's—Milk River system bought additional acres under irrigation. P.F.R.A. have continued their program of reconstruction, rehabilitation and extension of the Bow River system (formerly the Canada Land and Irrigation) with the object of bringing more acres under irrigation.

G. A. Gaherty, M.E.I.C.
Chairman

PAPERS COMMITTEE

Continuing in the pattern established over the last several years, the committee worked in co-operation with headquarters staff arranging for suitable papers for presentation at the 71st annual general and professional meeting of the Institute to be held at Banff, Alberta, in June of this year.

Suggestions for papers and offers to write them came in from several sources, i.e. directly from members of the Institute, from the various members of the Papers Committee, from branches, and from headquarters staff. In all, about 50 items were screened and considered.

Because the 1957 annual meeting is scheduled to take place in Banff, the committee followed the usual rule of selecting a fair proportion of papers of western origin and of particular interest to members from that part of Canada. In this connection the program will include a total of nine papers on subjects associated with the petroleum industry and this will accent the technical part of the meeting. In commenting on the work of the committee special mention should be made of the help provided by several out-of-town members, in particular G. W. Govier, M.E.I.C. of Edmonton, T. F. Hadwin, M.E.I.C. of Vancouver, W. B. Pennock, M.E.I.C. of Ottawa, and Fred L. Perry, M.E.I.C. of Calgary.

The committee met five times between October 22, 1956, and January 10, 1957, making its report to Council on January 22, 1957. In this report a program of 33 papers and one panel discussion was recommended. This recommendation was approved by Council at its Quebec meeting on January 26, 1957.

In addition to the foregoing work the committee was given another task by Council. They were asked to study and report upon the feasibility of establishing a panel of travelling speakers to assist in branch meetings. The survey of branches and the resulting report were undertaken by the Papers Committee chairman and, with the consent of the committee, he presented this report to Council also at its meeting on January 26, 1957.

W. H. Gauvin, M.E.I.C.
Chairman

PUBLICATION COMMITTEE

Production of *The Engineering Journal* in 1956, the thirty-eighth year of its publication, showed the highest figures so far. Some 207,000 copies were printed, and the average monthly circulation was 16,909. Reading material averaged 100 pages a month, of which 34 per cent represented technical papers. As in previous years there was more reading material than advertising space, in the ratio 51:49. (In Canadian trade journals, generally, there is a much greater volume of advertising than of reading material.)

The 60 papers published in the technical section covered a wide range of some 39 different subjects or industries. Some papers dealt with more than one engineering field and are not readily classified, but a more detailed analysis is given here.

Category	% total papers	% total pages
Civil	33.9	35.8
Mechanical	23.7	26.1
Electrical	18.7	18.2
Other branches*	23.7	19.9

*Including chemical, petroleum, pulp and paper, etc.

The committee wishes to record their thanks and appreciation to all authors, correspondents, and advertisers.

Continued and growing interest in the technical papers is shown by more extensive written discussion of papers and the total of 20,350 reprints ordered during the year.

Apart from papers from the annual meeting and direct contributions from members and other authors, over fifty requests were made to industry and other organizations for technical articles on specific subjects covering many fields of interest to the engineering profession. This policy is being carried on, and it is anticipated that further good material will continue to be received as a result.

Starting with the July issue, printing of the *Journal* was transferred to Hugh C. MacLean Publications Limited, in Toronto, for economic reasons. Good working liaison was quickly established and the new printer is now, in general, giving very good service.

The opportunity was also taken to revise the style and content of the *Journal* to the extent of improving the clarity of the typography and re-arranging the editorial content. This included the introduction of a new section, Canadian Developments, to give news and reports on major engineering developments in Canada, including the progress of the St. Lawrence seaway and power project. The Abstracts section was extended to cover news of engineering interest as well as material from engineering literature; some 96 items were published in the year.

A new series of articles on engineering careers in Canada, intended particularly for the guidance of the young engineer, was started in January and will continue into 1957.

The readership survey was re-introduced in October and is to be extended over a twelve-month period. Initial returns were around 40 per cent.

The gross average cost of production was $15,410 per issue, which represents 88c per copy printed or $10.56 per year per subscriber.

The committee submitted a report to Council recommending the publication of separate issues of *Transactions*, to include papers of technical interest. Although this was considered in January 1957, the committee is pleased to report that Council has approved such publication and action has been taken for the preparation of the first issue of *Transactions*.

The five meetings held during the year were well attended by committee members and by headquarters staff.

G. N. Martin, M.E.I.C.
Chairman

LIBRARY REPORT 1956

Commencing January 1, members were no longer r quired to make a deposit before borrowing books fro the library. Letters were sent to the nine hundr members having deposits informing them of the chan in this regulation which had been in effect since t opening of the library. One hundred and sixty-t members requested the return of their deposits, o hundred and twenty-two communicated with the libra agreeing to donate their deposits in recognition of s vices rendered, and no word was received from t remainder, who thus indicated their willingness to lea their deposits. The generosity of these members greatly appreciated. The three thousand eight hundr dollars remaining are to be used for the purchase books and other equipment. There are now five h dred active borrowers registered, whereas many of t nine hundred previously listed had not used the libr for several years.

Another change in the regulations affected memb living out of town who are no longer asked to p postage as the Institute has obtained permission fr the postal authorities to use the special book r available to libraries.

Equipment purchased during the year include book truck, new lights in the reading room stacks new card system for recording the receipt of periodic and a photostat machine. This latter is proving use especially for copying articles in bound periodic Members are sold copies at cost.

During the year the library staff handled s twenty-five enquiries a day many of which were ceived over the telephone and by mail. A pampl was mailed to all members outlining the services p vided by the library.

Five hundred books were added to the collect four hundred of which, valued at $3000, were review in *The Engineering Journal*.

During the summer the books in the reading r were re-shelved and much obsolete material discar Re-organization of the periodical stacks in the lo floor was commenced, and duplicate and unwa material sold. It is expected that this task will completed during 1957.

The increased use made of the library throug the year is encouraging, and it is hoped that in 1 the staff will be able to provide even better ser

EMPLOYMENT SERVICE

It can be stated truly that the employment de ment of The Engineering Institute has become al an international contact for those seeking inform about Canada. Letters acknowledged by the de ment numbered approximately 2,000. They cover variety of subjects, ranging from job listings, co living, and the housing situation, to the validit educational certificates and other qualifications. marks bore such names as Turkey, China, Africa, S America, countries in Europe, and all parts of United Kingdom. During the later months of the enquiries from the U.K. increased, and it is antici that Canadian employers can rely on this sour engineer manpower, at least for the near future, to an even larger extent than was experienced during the past year.

A drastic shortage of engineering personnel was noted during 1956. Approximately 500 jobs were advertised through the employment pages of *The Engineering Journal* and the employment bulletin. As was previously reported, the department was forced to rely on its advertising facilities to bring the right contact to the employer seeking personnel with specialized technical experience.

A number of large American employers approached the department. In accordance with the Institute policy, it was necessary to restrict the services to Canadian employers, or to those others seeking engineers for work in Canada.

Contrary to previous years, the department accepted a number of advertisements from U.K. personnel seeking contacts in Canada. Most applicants had made definite plans for emigration and had acceptable qualifications for eventual membership in the Institute. The response from employers was gratifying and this service will be extended during the coming year.

During the month of February employers were contacted, suggesting that they list their needs for undergraduates. Many successful placements were made. However, it was most evident that more positions were available than possible candidates. This part of the department's work is now well established and is known to many young men across Canada. The fact still remains, however, that it is difficult to arouse the interest of an employer when the applicant is not easily available for interview.

The employment service was represented for the first time at the annual meeting in Montreal. The office in the Mount Royal Hotel was visited by 41 employers and many engineers.

The employment service is anxious to extend its usefulness to the membership. Enquiries are therefore invited, in an endeavour to enlarge and improve this service.

(Miss) A. Summers
Employment Service

FINANCE COMMITTEE

The Finance Committee met eight times during the year. At these meetings the financial affairs of the Institute were reviewed and appropriate action taken. The final results are evident in the financial statement and the Treasurer's report.

It is also the function of this Committee to review all resignations, removals from the list of members, requests for special consideration and reinstatement of membership. In so doing over 1100 cases were considered.

In 1956 operating budget was received and approved early in the year, and re-studied at the half year.

Consideration was also given to proposals for expenditures outside of the budget, and recommendation made to Council.

Some of such proposals were the publication of biographies of prominent Canadian engineers, grants for professional development courses at Branches, allocation of funds for the maintenance of representatives at engineering degree-granting universities and the recommendation that funds be made available for the publication of *Transactions* to the extent of $2,500.

The investment portfolio was currently under review; reserve funds were invested as they became available.

During the year the chairman convened an unofficial gathering of available current and past presidents and vice-presidents to consider Institute development. From this meeting there has resulted the approval by Council for the formation of a policy committee.

Appreciation is expressed by this committee to the general secretary and his staff who have given every cooperation and assistance in carrying out this phase of the Institute's activities.

R. L. Dunsmore, M.E.I.C.
Chairman

The annual comparative statements of revenue and expenditure, and of assets and liabilities, are presented on pages 10 and 11.

TREASURER'S REPORT

Your Treasurer is happy to report that at the close of another fiscal year the finances of the Institute are again in a very satisfactory condition.

In the year 1956, revenues exceeded $535,000 and were the highest in our history. Expenditures on ordinary account were less than anticipated; consequently it was possible to increase the allocation to reserve funds and still show a surplus of more than $7500 in the overall results of the year, which is comparable to the surplus for the preceding year.

Your attention is drawn to the fact that income from investments for 1956 amounted to nearly $8000, approximately twice the sum realized from this source in 1955.

This result reflects the wisdom of the decision taken in 1955 to increase the portfolio of investments held by the Institute.

R. A. Emerson, M.E.I.C.
Treasurer

LIBRARY AND HOUSE COMMITTEE

Considerable work was carried out during the year 1955 in preparation for the annual general meeting. Consequently, this committee was relatively inactive during the year 1956.

The Montreal Branch elicited interest in making a contribution towards the improvement of the Headquarters auditorium facilities. Discussions were held with members of the Library and House Committee. A number of needed improvements were identified. The Montreal Branch elected to contribute a slide projector.

AUDITOR'S CERTIFICATE

We have examined the statement of assets and liabilities of the Engineering Institute of Canada as of December 31, 1956 and the atement of revenue and expenditure for the year ended on that date and have obtained all the information and explanations we ive required. Our examination included a general review of the accounting procedures and such tests of accounting records and other ipporting evidence as we considered necessary in the circumstances.

In our opinion the above statement of assets and liabilities and accompanying statement of revenue and expenditure are properly rawn up so as to exhibit a true and correct view of the state of the affairs of the Institute at December 31, 1956 and the results of its perations for the year ended on that date, according to the best of our information and the explanations given to us and as shown by he books of the Institute.

PEAT, MARWICK, MITCHELL & CO.,
Chartered Accountants.

Iontreal, Quebec, February 11, 1957.

This very handsome addition to the auditorium facilities has now been in service for some weeks and is indeed appreciated.

C. E. Frost, M.E.I.C.
Chairman

Ontario Division

A statutory meeting of the Ontario Division was held at the Royal York Hotel, Toronto, on January 28th, 1956; five branches were represented by the fifteen members who attended this meeting. Present: Chairman, Dr. A. E. Berry, Toronto; J. A. Vance, Woodstock; L. F. Grant, H. G. Conn, Kingston; D. D. C. McGeachy, D. J. Bird, London; R. A. McGeachy, G. R. Henderson, Sarnia; E. A. Cross, L. F. Bresolin, M. McMurray, W. H. Peterson, C. D. Carruthers, D. D. Whitson, G. H. Rogers, Toronto.

Discussion at this meeting stressed the earnest desire of the Ontario Branches to advance confederation and it was the general opinion of the members present that it offers definite advantages to all members of the profession in Ontario.

The following three members were nominated and duly elected to the board of management for 1956: P. E. Buss, Thorold; H. G. Conn, Kingston; M. A. Montgomery, Kitchener.

The Chairman appointed C. Carruthers, E. A. Cross and J. F. MacLaren as a nominating committee to prepare, a slate of officers for distribution of ballot.

The following change was proposed in By-Laws: Amend Sec. 4 (a) to read "The Chairman and Secretary, or duly appointed alternate, of each Ontario Branch". The proposed change was left in the hands of the Chairman and Secretary for circulation to the Branches for consideration and approval.

It will be of interest to note that the name of the Division's chairman, Dr. A. E. Berry, was included on the recently published list of Life Members, and the members expressed appreciation of his valuable services to the E.I.C. in many activities during his membership.

G. H. Rogers, M.E.I.C.
Secretary

Reports from the Branches

FOLLOWING ARE the reports received from the Branches of the Institute on their activities during the year 1956. Membership and financial statements on page 28.

Amherst

Six meetings were held during the year 1956.

In February a supper meeting was held and general business was discussed.

At the March meeting Mr. R. Alexander gave a very informative talk on the effects of the January sleet storm on his company's electrical equipment.

At the April meeting Mr. J. Wilson showed a very interesting film on the Quebec North Shore Railway from Sept Isles to Knob Lake and spoke on drainage problems involved.

Mr. J. W. Byers also showed an interesting film on the Shepody Dam.

On June 1, the Branch held its annual meeting at the Amherst Hotel and the new executive was appointed with R. Alexander as chairman; J. Wilson, vice-chairman; W. G. Miller, secretary-treasurer; and G. C. L. McEnery, R. Miner, and J. W. Byers as the executive committee.

In September, Amherst was honoured by a visit from the president, Mr. V. A. McKillop, and Dr. L. Austin Wright, general secretary.

In October five carloads of members and their wives motored to visit Shepody Dam and enjoyed dinner in Moncton on the return trip.

Belleville

During 1956 seven meetings were held by the Belleville Branch. Among the topics covered and papers read were such subjects as "The St. Lawrence Power Development", "Digital Computers", "Silicones", and "Controlled Volume Pumping".

The February meeting was one sponsored jointly with the Bay of Quinte Section of the Institute of Radio Engineers at which a paper on transistors was read.

One plant visit was made during the year, to the Bethlehem Steel Company's Marmoraton Mine, near Marmora.

The second half of a Professional Development Course in business administration, started in the fall of 1955, was concluded during the early part of 1956. This course was under the direction of Queen's University. The second half, referred to herewith, consisted of approximately 20 lectures. An average of 50 people were enrolled with the attendance running above 90 per cent.

The Belleville Branch has agreed to assist the local high schools in screening applicants for University of Toronto bursaries in connection with students planning to enter an engineering course there. Also, along this line it should be mentioned that the Branch again sponsored a $25 prize to be given to the Grade XIII student in both of the two local high schools who plans to take an engineering course and who attains the highest standing in English, algebra, trigonometry, geometry, physics and chemistry. This year the prize was won by Kurt Pieper.

Border Cities

During the year the Branch has met nine times and eight executive meetings have been held.

The regular meetings of the Branch were as follows: January 19. "Problems in the design of nuclear power reactors", by R. C. Johnston, of the Canadian General Electric Company. February 23. Dinner meeting: "Traffic Problems" by Eric Wiley, traffic co-ordinator for the City of Windsor. March 22. Tour of Great Lakes steel plant, Ecorse, Michigan, arranged by H. Lewis, public relations director. April 19. "The Investment Industry" by Jack Stodgell of S. J. Stodgell and Company. May 17. Tour of Chrysler Corporation, plant 3; address by Jarman Craig, vice-president, personnel. Sept. 13. Tour of H. J. Heinz Company of Canada Ltd., Leamington, Ont. October 26. Annual Engineers' Dinner Dance, Prince Edward Hotel Ballroom. November 15. Dinner meeting and film night; film: Job 99—Pluto. December 6. Annual meeting; film night at Prince Edward Hotel; election of officers.

Executive meetings were held in the offices of the Canadian Bridge Company on eight occasions.

The Ladies' Auxiliary has had a successful year in promoting friendship among the members. Their activities included weekly bowling, two bridge groups, one meeting every second week in the evening and the other once a month in the afternoon. A public speaking class was also held twice a month. The ladies also accompanied the Branch members on plant tours during May and September, and joined us for the annual engineers' dinner dance in October.

Calgary

During 1956, ten general meetings were held, including a tour through Imperial Oil producing department's technical service laboratories.

The annual "slide rule soiree" was held in February and once again was an outstanding success, with about 340 in attendance. The floor show put on by the members and their wives was one of the best yet.

The regular Monday luncheon meetings have remained very popular, having an attendance of from 50 to 60 members.

In the spring, a students' night was held at Western

Canada High School. A panel of six members representing the various branches of engineering addressed the students, after which a question and answer period followed. The students were keenly interested and the executive felt that this was a most successful evening.

No professional development courses were undertaken in 1956 but a series of meetings along these lines have been arranged for 1957.

Engineers' Wives' Association: As a prelude to the opening of the season, the executive was entertained at luncheon by our president, Mrs. K. W. Mitchell. Plans for the coming year's activities were discussed. All our groups, "ladies and mixed bridge" "handicraft" and "bowling" function well and enthusiasm is high.

Before our own activities got under way the E.I.C. invited us to an outdoor barbecue, which was most successful—and we hope will become an annual affair. Some of our members worked with the executive of the Men's Club and assisted in many ways.

Our annual membership tea, held this year at the Palliser Hotel on September 12th was an outstanding success, there being 149 members and 11 guests.

We entertained our husbands at a "Pot Luck" supper on October 25th in the Rosedale Community Hall. Delicious food, dancing and a bit of a floor show put on by some of our local talents, with that indispensable aid of the men, completed the evening's entertainment.

Cape Breton

There were ten gatherings in 1956, seven of which were regular dinner meetings held in the Isle Royale Hotel in Sydney, two were business meetings held in the Reserve Army Engineers Corps headquarters in Sydney and one was an informal dance held in the ballroom of the Isle Royale Hotel.

We regretted that President McKillop's visit to our Branch, early in September, was not as well attended as we would have wished. A majority of our members were away on vacation and others found the visit to be somewhat early in the season. Those who attended certainly enjoyed hearing Mr. McKillop and were only sorry that others of our membership were not present to hear him speak.

In January, Mr. M. R. Campbell, our immediate past Branch Chairman, spoke commendably on a recent trip he made to Germany in connection with their steelmaking practice. In February, we took time off from business and entertained the ladies at an informal dance at the Isle Royale Hotel. Comments on the Leonardo Da Vinci film shown in March were most laudatory. Again in March, the Branch met at the Reserve Army Engineers Corps quarters in Sydney and held a business meeting, which resulted in the drafting of a set of Branch by-laws. In April, Captain Mahar of Army Intelligence spoke on Middle Eastern affairs. In the light of present developments in Egypt and Israel, this was indeed a most informative topic. Oxygen in the steelmaking industry was the topic for our meeting in May. Our lobster party in June was by far the best to date. Good weather, a plentiful supply of lobsters and hearty appetites were all contributing factors to a very enjoyable evening. We are indebted to Mr. M. R. Campbell for the use of his summer home as the locale for our party.

For our November meeting, we had a speaker from Canadian General Electric on recent developments in gas and steam turbines.

At our annual business meeting in December, the members felt that 1956 was a very successful year in the Branch. Hopes were expressed that 1957 would be as active and enjoyable.

Corner Brook *(see page 27)*

Cornwall

Programme Committee: We have tried to maintain the varied programme of the previous year, and have, to a certain extent, succeeded. We had speakers on foundry practice, atomic power generation, town planning, plastics in industry, Duke of Edinburgh's conference, and a plant visit. In addition to these we had a very successful president's visit in February and another visit from the president to present our bursary in December.

We are, this year for the first time, running our programme from September to June. We find this attains far more continuity from executive to executive.

Average attendance for the year was thirty.

Membership Committee: The membership of the Cornwall Branch increased by eleven, from sixty-seven to seventy-eight, mainly due to an influx of engineers for the Hydro development in the Cornwall area. The Cornwall Branch is pleased to record that the Hydro engineers take an active part in Branch affairs and have arranged and conducted a number of tours for visitors to the Branch, such as the president of the Engineering Institute.

Bursary Committee: In 1956, the Magwood bursar[y] was established, and the first recipients chosen. Th[e] funds for this bursary are provided by local industrie[s] The first two recipients are brothers, Kent and Donal[d] Plumley, who are now attending Queen's Universit[y] This bursary is for $1200, and it is hoped to provid[e] these funds annually.

Eastern Townships

Branch activities for the year 1956 may be summariz[ed] as follows: January 15. Mr. H. T. Immerman, vic[e] president and chief engineer of Spencer, White [&] Prentis, engineering consultants, of New York City, [on] "The Practical Design of Foundations"; approximate[ly] 65 persons present, for the dinner meeting. Februa[ry] 10. Messrs. H. Little and L. S. Merrill, of R. & [M.] Bearings, presented two films on bearings "Engineeri[ng] to the *n*th Degree" and "Engineering on the Bal[l]" 30 persons present at the dinner meeting. March [..] Mr. J. O. Eby, mine manager, Canadian Johns-Manvil[le] on "Some Methods of Mining"; some 40 persons w[ere] present. April 12. Dr. B. G. Ballard, director of Ra[dio] and Electronics Division, National Research Council, [on] "Research and the Engineer"; close to 70 pers[ons] attended this dinner meeting. June 2. Annual elect[ion] meeting at the Hillcrest Lodge. This was at the sa[me] time a joint meeting with the members of the Corp[ora]tion of Professional Engineers of the Province of Queb[ec] at which ladies were present; some 110 persons atte[nd]ed. October 6. Inaugural meeting; golf tournam[ent] held at the Sherbrooke Country Club; some 42 pers[ons] attended the ensuing dinner and dance. November [..]

oint meeting of the E.I.C. and of the CPEQ where he present president of the Corporation, Mr. Leo oy, talked on the role of the Corporation; some 70 ersons attended the dinner meeting. December 14. Ir. R. D. Mawhood, of C.G.E., presented two films: Power and Passage" about the St. Lawrence Seaway; ome 35 persons attended the film showing.

Edmonton

This Branch held eight dinner meetings during 1956 with an average attendance of 66. The two highlights f the year were the annual picnic and the annual anquet and dance. Both of these functions had an ttendance of over 300.

This Branch did not have a professional developent course and did not carry out counselling in High chool during 1956.

The Engineers' Wives' Club was very active during 956.

Engineers' Wives' Club: The membership at the end f 1955-56 season was 215. The new season to date hows a membership of 205. Included in the club ctivities are six different groups, the handicraft group, fternoon bridge, evening mixed bridge, junior mixed ridge, book reviews and bowling, all of which are oing very well.

During the year the social activities have been as ollows: January. The annual cocktail party, husbands ncluded. February. An oriental dinner; Prof. L. E. Gads, of the Engineering College of the University of Alberta, gave a very humorous talk on "European Observations". March. An Italian dinner, entertainment provided by a musical variety show and an art display y Janet Churchill. April. A dinner and the annual usiness meeting. September. The membership tea. November. A dinner honouring Mrs. McKillop, wife of he E.I.C. president; "Women and the History of Edmonton" was the subject of a talk given by Elsie Park Gowan. December. A general meeting; Peggi Adams poke on "Grooming and your Personality". Refreshments were served at the conclusion of the meeting.

Fredericton

A total of nine general meetings were held, with attendance varying between 30 and 125.

Two of the meetings had special significance for the student members at the University of New Brunswick. One of these was a joint dance held in the Lord Beaverbrook Hotel ballroom and the other was a smoker or the graduates in May.

A joint meeting was held with the local section of he Military Engineers' Association of Canada in the Headquarters Officers' Mess, at which time Mr. Lorne Wiggs, of Wiggs, Walford, Frost and Lindsay, addressed the gathering on the heating plant and distribution system at Camp Gagetown.

The annual meeting held "up-river" to afford the non resident members a better chance to join in activities, took place at the Beechwood power development on the Saint John River. Other guests at this meeting included the Maine section of the American Society of Civil Engineers and the Engineer officers rom Loring Air Force Base, Limestone, Maine.

Much effort was expended in regard to the showing of the Leonardo Da Vinci film, with a private showing for members, influential and well known citizens and teachers. However, the film was released to television in this area less than a week before our public showing which resulted in very poor attendance and a net loss on operations.

The Professional Development section was dropped this year as it was found that the usual type of meeting in a relatively small centre would not sustain attendance and ideas to instill new blood and vigour found to be impracticable or beyond our scope.

Halifax

The past year has been a very successful one for the Halifax Branch. We have held some very interesting meetings, such as with the Military Engineers and the one at Stadacona. We have also held some very interesting and informative visits, one to the National Research Establishment and another to the Imperial Oil Refinery.

The presidential visit was a great pleasure to us and we hope the visitors enjoyed their stay in our city.

Looking to the coming year, we have quite a number of proposed meetings and visits lined up.

Last May the Branch was very well represented at the annual meeting of the Institute, held in Montreal.

The panel discussion held in conjunction with the student meeting last year was very well received and it is suggested that this type of meeting be held again this year.

Hamilton

During 1956 membership has increased from 474 at December 31, 1955, to 517 at December 31, 1956. There was an increase in all member classifications.

Seven meetings and a plant tour were held during the year and were well attended, with the exception of the Students and Juniors papers' night, and the November and December dinner meetings. It appears that Hamilton Branch dinner meetings, other than the annual dinner meeting, will not be successful either technically or socially, because of small attendance. The future of the Students and Juniors papers' night is under discussion now.

The engineer's ball held in October was again well attended and financially successful, showing a surplus of $155.65.

The executive committee learned of the J. B. Nickersons' need for an outdoor railing to aid Nick in moving about, and approved the expenditure of Branch funds to provide the equipment. A railing, repairs to front walk, and new back steps were provided at a cost of $110.

Eight committees deserve special mention this year.

Students' and Juniors' papers competition committee were successful in providing an interesting Students and Juniors night, with three contestants.

The ball committee is to be congratulated for a very successful social function, enjoyed by 215 couples.

The budget committee produced a forecast which regulated our spending and produced a surplus for the year's activities.

The professional development program committee produced a very successful program attended by many students, juniors, and members, as well as by A.P.E.O. members.

The program committee arranged a very interesting and varied program of meetings and field trip and are to be congratulated for their work.

The technical sections committee are to be congratulated for their work in setting up the atomic energy lecture series with a large number of members and non-members attending.

The attendance committee are to be congratulated for operating the telephone squad and obtaining attendance estimates for meetings.

Branch news editor is to be congratulated for the excellent press, radio, and T.V. coverage, he has been successful in providing for our meetings.

We record with regret the passing of H. G. Bertram, N. L. Crosby, and E. G. Wyckoff.

Huronia

The past year proved to be very interesting, mainly due to the wide variety of subjects covered by our meetings. Two of the most interesting meetings of the year were those at which papers were presented by our own members.

The first of these was presented by B. C. Lamble M.E.I.C. on the subject of Canada's mineral resources. This talk was supported by Mr. Lamble's personal collection of minerals which attracted a great deal of attention.

The second paper was one presented by a former councillor of our Branch, Frederic Alport, on the subject of sanitation. This was of unusual interest as it covered the engineer's responsibility for the protection of the public against the many disease-producing organisms.

During the year considerable energy was directed toward the counselling of high school students. In order to make this service more widely known, all the schools in the district were again visited and plans are being made to note this service in local newspapers. This work in our Branch was headed by our chairman, R. MacKay, and assisted by H. C. Bates, F. Alport, C. Campbell, and B. C. Lamble.

To date some thought has been given to a professional development course, but since the members of this Branch are very widely spread, no concrete steps have been taken in this direction.

Kingston

The activities for the year consisted of lectures, dinners and meetings as follows: January 24, lecture at Queen's University on "Atomic Energy"; February 23, president's visit and dinner; March 13, lecture at Queen's University on "Design in welding of aluminum"; March 20, students' papers night at Queen's University; March 23, joint Kingston Metallurgical Society, Chemical Institute of Canada, and Engineering Institute supper dance; April, lecture at RCEME Officer's Mess, on "Camp Gagetown"; June 8, annual meeting, dinner and dance.

The students' papers night, in particular, turned out to be a very successful meeting. Four papers were given on this occasion on the following topics: (a) Pitting of hydraulic turbines; (b) Alcoa direct casting process of aluminum and its alloys; (c) residual stresses; and (d) free piston engines.

Kitchener

As indicated in our financial report for 1955 our activities have been rather general and we have not attempted to conduct in the Kitchener Branch professional development courses. Careful consideration has been given to such a program and our branch directors have decided against it for the time being. Contact with the high schools has been limited to speakers outlining the course of study that a student interested in engineering might take in a recognized university in Canada. With the shortage of engineers, we feel this work is becoming increasingly important.

As far as our general meetings are concerned, we have found that plant and field trips create the most interest along with good technical papers on current engineering topics such as the atomic energy plant at Chalk River, The Ontario Water Resources Commission etc. The Branch has established a pattern of meetings and it is felt that this pattern will be adhered to for some time to come. Our social functions have been most successful and our joint meetings with other technical groups in the area have been well attended. Financially speaking, the branch has been fortunate in obtaining services from industrial concerns in the area.

Kootenay

The Kootenay Branch held eight executive meeting during the year, and 13 branch meetings, which we as follows: January. Smoker, and showing of enginee ing films; guests: members of Joint Technical Societie February. Annual meeting (dinner); election of exec tive; Branch business; speaker: Mr. Stewart Graha Inspector, School District No. 11, on "Education Toda March. Junior and Affiliate Night Dinner; talks engineering topics by our Junior and Affiliate membe April. Annual business meeting dinner; discussion branch business to help brief delegates to annual me ing of E.I.C.

May. Dinner meeting; speaker: J. H. Rees, of Tri Equipment Ltd., on "Industrial Hydraulics". June. Lu cheon; speaker: Professor H. G. Conn, of Quee University, on "Engineering at Queen's Universit guests: members of Joint Technical Societies. Ju Smoker; speaker: R. R. Pierce, general manager of Corrosion Div., Pennsylvania Salt Company, on "A Proof Construction". Guests: members of Joint Techn Societies. July. Luncheon; speaker: D. L. Mord McGill University, on "The Gas Turbine".

September. Luncheon; speaker: Dean A. E. M Donald, University of Manitoba, on "Engineering the University of Manitoba"; also in September, dir meeting; speaker: R. F. Mitchell, superintendent maintenance, C & F Division, Cominco, on "Life Formosa, Hong Kong and Tokyo". October. Di meeting; speaker: E. Benson, Cominco Administra Division, on "Duke of Edinburgh Conference". Nov ber. Headquarters' visit dinner; Dr. L. Austin Wr general secretary. December. Smoker; showing of gineering films.

Our Branch meetings this year have been received by the membership and we have endeavo to keep the members informed of the business of the Institute. All our dinner meetings contained a business meeting in which we discussed Institute and Branch business.

Our annual business meeting held in April this year concentrated on Branch business in order to brief our delegates to the annual meeting held in Montreal. Councillor H. P. Hamilton, Chairman T. W. Lazenby and Mr. E. Mason attended the annual meeting.

This year, we initiated a scholarship of $50 to be presented to the student of Grade 13 who received the highest total marks in physics, chemistry and mathematics in our area, and who is continuing his studies at a recognized university. We plan to make this an annual award and to increase its value if we can manage it financially.

Our Branch was very pleased to be able to help the Institute financially this year by donating $25 to the Colonel By memorial and by forwarding $50 from the proceeds of our showing of the Leonardo Da Vinci film.

We regret to report that we did not sponsor a Professional Development course this year, but our policy has been to sponsor such a course every second year.

Through the Joint Technical Societies in our area, our branch assisted in vocational guidance to high school students and lectures to university students during the summer.

We were disappointed this year in not having the president with us, but feel that our meeting with Dr. I. Austin Wright was beneficial to us all and was a fitting event to end a successful year.

Lakehead

During the past year, there were eight regular meetings held, and one dance. To review briefly, the meetings were as follows: January. Brigadier H. W. Love, M.E.I.C., Commander, Sask. Area, gave a very interesting talk on the Alcan Road illustrated by motion pictures. February. The Engineers' Ball was held, and for the first time since the Second World War it was formal. A tremendous success and is to be repeated. March. This was the members' night and two members gave talks. Mr. W. D. Beckett spoke on professional development and Mr. John E. Rymes spoke on the new type of diesel injection pumps now entering the automotive market. April. In lieu of the president's visit, we held a ladies' night and again we had a tremendous evening. This is to become an annual affair on the years when the president does not call on us at the Lakehead. May. This was the sister profession evening, and Mr. A. W. Maloney, a well-known Lakehead lawyer, talked on automobile insurance. An excellent evening. June. Our regular and annual meeting. September. First of the year; we heard fine talks on the Ontario part of the St. Lawrence Seaway. October. A regular meeting with a very informative address on how the men who know predict the weather. As can be imagined, this was a very humorous meeting. The local Met. man for Dept. Trans. was our guest speaker. November. Change in the chairman for meetings and did not have one this month. December. This was a luncheon meeting and was a joint effort with the E.I.C. and P.Eng. A very successful meeting, and Mr. Hotchkin and Mr. Medland of the P.Eng. were our guests.

To sum up, 1956 saw many and varied meetings for all engineers here in the Lakehead and we had a good turnout. A continued good year is expected.

Lethbridge

The following is a summary of Branch activities during 1956 (figures in parentheses are average attendances). Regular meetings, three (38); special meetings, three (97); field tours, two (46); executive meetings, eight (6).

The branch did not operate a professional development course during 1956.

Highlights of 1956 were a joint meeting with the ASCE and field tour of the Malmstrom Air Force Base at Great Falls Montana; a field trip to the P.F.R.A. Bow River project and meeting at Vauxhall, Alberta, in September and a visit by Dr. Wright in November, during which he addressed a meeting of the branch.

In April some 40 members of the branch and their wives visited Great Falls, Montana. After registering, a field trip was made to the Malmstrom Air Force Base, and to the multimillion dollar storm sewer projects under construction in the city. Following the field trips members attended a joint dinner meeting with the ASCE Montana Section, North Central Branch, followed by a dance at the Meadowlark Country Club.

In September, 52 members and their wives toured the P.F.R.A. Bow River project, including the Travers Dam, and ended the tour at Vauxhall. A brief visit was made to the Vauxhall Laboratories operated jointly by the P.F.R.A. and Dominion Experimental Station, Department of Agriculture, who are carrying on extensive research concerning soils, drainage and field crops and their suitability for use under irrigation. The party then enjoyed a dinner and an address by the late Dr. L. B. Thomson, director of the P.F.R.A., Regina.

Unfortunately, the president's visit was cancelled due to the sudden death of his assistant. Plans for the meeting in November, however, were not changed as Dr. Wright was able to visit the branch and give a very informative talk concerning the Institute. Ladies were present and a social hour and dinner were held in conjunction with the meeting.

In December the excellent film "Leonardo Da Vinci" was shown, to some 83 members and their wives, following a social hour and dinner.

The annual meeting of the Professional Engineers of Alberta was held in Lethbridge in March, and E.I.C. members were invited to the noon luncheon and dinner, hence no regular meeting was held during that month.

Branch meetings were all dinner meetings, and community singing and special musical entertainment was enjoyed at each in addition to the main program. Mr. and Mrs. George Brown who have been providing dinner music and accompaniment for our meetings for over 30 years, were again able to favour the branch during 1956.

Ladies' Auxiliary—The ladies' auxiliary completed another active and interesting year. Regular monthly meetings were held, with bridge parties alternate months. Guest speakers covered a variety of interesting and educational subjects every second month.

Highlight of the year was the year-end banquet held at the Lethbridge Flying Club in May.

Once again the ladies organized the engineers' mixed bridge club, with monthly bridge parties held October to March.

London

The following meetings were held during 1956. January, annual ladies' night and dance; February, a film presentation entitled "Mining for nickel"; March, a forum type meeting: "Water resources of Western Ontario". On the panel were Dr. A. E. Berry, Mr. MacManamna, Mr. J. Vance and Mr. V. A. McKillop; April, "Oil well exploration and drilling in Canada" presented by Mr. C. Drabble; May, "The engineer's responsibility to the community", Prof. S. Lauchland; June, a dinner meeting at which Mr. V. A. McKillop was the formal after-dinner speaker.

In September, a dinner meeting at which Mr. G. E. Humphries was the informal after-dinner speaker; October, "The Provincial Parliament and its functions", E. Jackson, M.L.A.; November, "Questions on Law", C. Calder. Q.C.; December, annual feather party (turkey raffle, etc.)

There was no professional development course in London in 1956 but a short course is being prepared for early 1957.

This Branch did not carry out any counselling in schools in 1956.

Lower St. Lawrence

The branch executive held three meetings, and two other meetings were held, attended by an average of 20 engineers.

On January 23rd, 1956, a presentation of a film in full colour, which depicted the works of Leonardo de Vinci was attended by some 20 engineers and their wives. Many friends and students of the local technical school attended this showing.

On September 1st the president of the Institute and Mrs. McKillop, and the general secretary visited the members of the Institute residing in Seven-Islands. Mr. Mike Monaghan, chief engineer of the Quebec North Shore and Labrador Railway, organized the meetings and took the party in a tour of the premises, such as ore loading equipment, railway terminal, docks facilities, and so on.

Moncton

During 1956, five technical meetings of the branch were held. All of these were dinner meetings and were well attended.

Films relating to water contamination were shown on January 9th. The design and construction of the outside plant of the New Brunswick Telephone Co., was the subject of an address by Harry S. McCleave on February 27th. D. W. Blair spoke on mechanization of railway maintenance, on April 3rd. At this meeting, nominations for branch officers for 1956-57 were made. A very successful ladies' night was held on April 27th. The annual meeting of the branch was held on May 31st.

Through the courtesy of Lloyd Parsons, who loaned his motor yacht for the occasion, an afternoon cruise on Shediac Bay was enjoyed by branch members and their wives, on August 18th. On the occasion of a brief visit to Moncton, on September 20th, president and Mrs. McKillop, and general secretary, L. Austin Wright, were entertained informally by the branch executive and their wives. Experiences in Pakistan was the subject of an illustrated address by J. E. Isbester, on November 19th. The final meeting of the year, was held on December 10th, when G. L. Radcliffe spoke on the application of electronic equipment to modern accounting.

Late in the fall, an Engineers' Wives Association was formed. On November 7th, an enthusiastic organization meeting was attended by thirty-four wives of branch members. Mrs. M. F. K. Leighton was elected president, Mrs. G. A. Peck, vice-president, and Mrs. V. C. Blackett secretary-treasurer. Plans for a meeting in January, were discussed.

Moncton branch does not operate a professional development course, nor does it carry out counselling for high school boys. However, it is customary, once a year, for a member of the branch to address the students on the subject of engineering.

Montreal

The main activities of the Branch have been, as in the past, the provision of a programme of papers of wide variety and great interest. The technical sections have functioned well and we have had papers of excellent quality. Under the aegis of the technical sections, the following numbers of papers were presented: Chemical, 4 papers and 1 symposium; Transportation, 4 papers; Special, 3 papers; Management, 8 papers and 1 symposium; Civil, 11 papers and 1 symposium; Mechanical 5 papers and 1 symposium; Electrical, 8 papers and 1 symposium.

Together with these 43 papers and 5 symposiums eight plant tours were arranged.

The annual general meeting of the Institute was held in Montreal and the general chairman was Mr C. G. Kingsmill. Many of the Branch members were active in the meeting arrangements and we feel a good part of the success of the meeting was due to their efforts.

The total membership of the Branch now stand at 4,268. During the year there have been new ad missions, exclusive of students, of 79, which is a marke decrease as compared with the two previous years

There have been a number of resignations and large number of members struck off the list for non payment of fees. Whereas it is stated that this situatio exists to an equal or greater extent in other societies the Committee is, nevertheless, very disturbed by th situation. Arrangements have been made with Head quarters for the Branch to be notified of all person who are one year in arrears, and the membership com mittee will try to have some of these fees paid u and the members retained in the Institute. It is als hoped that in cases where the member has definitel decided to let his membership lapse, we will be abl to find the reasons and possibly in that way foresta such losses of membership.

The report of the reception and attendance com nittee shows that there has been, as compared with 1954, (1955 figures not being available) a very pronounced drop in average attendance at our meetings. This is no doubt the most serious problem facing the Branch, and a special committee has been set up to study the matter and make suggestions as to how the situation can be improved. One step that has already been taken has been to change the regular meeting night from Thursday to Wednesday, as it was found hat there were competing functions on Thursdays.

In the field of publicity, excellent results have been obtained by having a committee of our own members carry out this work without the help of a paid publicity man. We have not only obtained very much better press coverage during the past year than in previous years, but this has been done at practically no cost.

inancial Results

Although the financial results of the year's operation how a loss, this deficit was incurred deliberately as ve felt that we could safely use some of our reserves 1 order better to serve our members. However, this olicy would not be continued for very long, and every ffort will have to be made to balance the budget. n all fairness, it should be pointed out that this year he Branch incurred some unusually heavy expenses ue to the fact that the general meeting of the Institute was held in Montreal and such expenses will ot recur for some years.

The Branch has studied the advisability of using ome of its reserves to improve facilities in the meeting oom at Headquarters, and as a result has undertaken purchase immediately a new slide projector. This urchase will only be reflected in the accounts for ext year, as delivery and payment will only be made 1957.

The Branch contributed a sum of $150 towards the ost of the Colonal By memorial.

There has been a considerable amount of interest the Institute shown by members in the Brownsburg-achute-Hawkesbury area, and meetings have been eld with a view to organizing a branch. At present. rt of the area is attached to the Ottawa Branch, d part to the Montreal Branch, but neither branch n be of much help to members in that area. The ontreal Branch contributed $75 to this group to further their activities.

unior Section

Junior Section by-laws, which had been under discussion for a long time, were drawn up in final form d approved by the Branch executive. At the same ne, the Branch by-laws were amended to make the airman of the Junior Section an ex-officio member the Branch executive. This will result in closer ordination between the Junior and Senior Sections' tivities. Members of the Junior Section are also inted to work on Branch committees.

A special committee of the Branch has been set to study the matter of evening courses at local stitutions to enable young men who cannot go to a iversity to obtain full professional qualifications. It is lieved that if this were done quite a few young en would be attracted to the profession.

The entertainment committee, under the chairmanship of Leo Scharry, made arrangements for food and refreshments on 17 separate occasions. In co-operation with the technical sections of the programme committee, refreshments were provided after the presentation of 5 technical papers. Five buffet luncheons and 2 evening buffets were provided and refreshments were served on the occasions of 2 ladies' film nights. Some 214 attended the dinner held in conjunction with the Branch annual dinner dance at the Windsor Hotel. At the dance following, 318 additional guests attended. The entertainment committee was responsible also for the organization of the annual joint senior-junior oyster party and the special reception for the members of the many committees of the Montreal Branch.

The student guidance committee organized 3 forums during the year for graduating high school students; 166 students attended the English-speaking forum and a total of 250 students attended the two French-speaking forums.

A list of practising engineers who are willing to grant personal interviews to undergraduate students was sent to the Deans of the local universities for their attention. In addition, considerable progress has been made in the work of a sub-committee to draw up a list of the most frequent questions asked by students and suggested answers. This work is part of a long-range plan to provide a pamphlet on student guidance for use by the other Branches of The Engineering Institute of Canada.

Nipissing and Upper Ottawa

During the year 1956 the Nipissing and Upper Ottawa Branch held seven business meetings and one field trip.

In October the Branch made a field trip to Falconbridge and were entertained royally by the Falconbridge Mines. Most of the members had never visited a nickel mine and thus the trip was very instructional.

Among our business meetings two stand out very clearly. One in January was held in Sturgeon Falls. There we asked four members of the Branch to talk on subjects of their own choosing. It was amazing to find that our Branch contained so many talented speakers who could talk on subjects of interest to all. The other meeting was our student's night, with twenty-eight students in attendance. Two members of the Branch gave short talks on engineering and the E.I.C. This was followed by the film "Leonardo da Vinci", which was enthusiastically received. The students showed considerable interest in our profession.

Our membership has increased slightly and all members are taking a more active part, with the result that we have approximately fifty per cent attendance.

Due to distances involved, no professional development courses were started.

Newfoundland

The Branch has had another successful year. Membership has increased somewhat and financing has not been such a problem as in some previous years.

The Branch was active from September to May and nine meetings were held. Of these, three were business meetings and the remainder programs. The executive was very active, holding ten special meetings.

The programs covered a wide range of subjects.

Mr. J. W. Bateman, Canadian General Electric Lighting Institute, addressed the October meeting on the subject of "Developments in Light Sources". One of the most interesting meetings was an address by Mr. D. W. K. Dawe, prominent St. John's lawyer, on "Some Legal Aspects of Engineering". Mr. Dawe's address was followed by a very lively question and discussion period.

The annual Students' Night, at which three engineering students from Memorial University presented papers on the subject of their choice, was held in March. The papers were very well prepared and presented. Mr. R. Andrews was awarded the prize of fifty dollars for his paper, "Breaking the Sound Barrier".

The high-light of the year was as usual, the annual dance held at the Old Colony Club. About ninety couples attended and the evening was a tremendous success.

The Branch looks forward to even greater success during the year to come.

North Nova Scotia

Only one meeting was held last year by the North Nova Scotia Branch, at which officers were elected. The guest speaker was Mr. H. S. Haslam, who outlined the various troubles being experienced in the McGregor Mine in Stellarton which later forced the abandonment of the mine.

Northern New Brunswick

A total of seven meetings were held for the Branch in the year of 1956, four general, one annual, and two executive. The attendance at the general meetings has been about 40%, and about 90% for the annual meeting. Membership has dropped from 64 to 60 and can be attributed to several transfers from the district. Contrary to what has been stated in the past there are several engineers in all districts of this Branch who are not members of the E.I.C. We have invited several of these to our meetings and delivered pep talks in an endeavour to obtain their support by membership with the Branch. The usual answer has been "We're waiting for amalgamation of the Institute and the Association.

The first general meeting of the year was held on March 10th in Campbellton, N.B. The speaker of the evening was Mr. B. Beaton, JR.E.I.C. of the Campbellton Division of the C.N.R. Mr. Beaton spoke on "The Economic Aspects of Railway Dieselization".

The second general meeting was held in Dalhousie on April 9th. The speaker of the evening was Mr. G. B. Lawson, JR.E.I.C., steam process engineer at Restigouche Company Ltd., Atholville, and also member of the New Brunswick Bar Association. Mr. Lawson's paper was entitled "Some Aspects of the Law of Contracts".

The next gathering of the Branch members was the annual dinner meeting held at the Kent Lodge, Bathurst, N.B., on the evening of June 9th with the ladies in attendance. A brief business session was held to provide for the installation of new officers. The guest speaker was Mr. R. L. Weldon, president of the Bathurst Power & Paper Company Ltd., who had for his topic of discussion that evening "A Review of Controversial Engineering—Economic Problems Facing Canada". A dance followed the dinner meeting.

The third general meeting of the Branch for 1956 was held at the Miramichi Golf Club, Newcastle, N.B., on November 3rd. The speaker for the meeting was Mr. Reginald Tweedale, asst. chief engineer of the New Brunswick Electric Power Commission; the title of his talk was "Power for New Brunswick". He used a physical cardex-graph system of the power growth of the Province, power distribution maps and a colour film to illustrate his talk. This was an exceptionally fine presentation and deeply appreciated by the Branch members.

The fourth and concluding meeting of the year was held in Campbellton on December 8th. The speaker for that meeting was Mr. F. M. Ross, chemist for the Fraser Companies' Research Department, and supervisor of the department's pilot plant. Mr. Ross spoke on "Pilot Plant Operation" and also discussed several experiments carried out there.

In conclusion, on behalf of the Branch, I would like to say that we have been most fortunate in our acquisition of speakers who have given most interesting and informative papers. Although we of this Branch are widely scattered geographically and have considerable travelling difficulties during the winter season, we have enjoyed our meetings and hope to continue into an even better season for 1957.

Ottawa

The Branch has had another active year. The membership continues to increase; there being now over one thousand members, of which over five hundred are juniors and students. The large membership, the increase in number of student members, and the continual expansion of Ottawa, all complicate the problem of operating the Branch to the satisfaction of the greatest number.

The management committee held nine regular business meetings during the year; all were well attended.

The president of the Institute, Mr. V. A. McKillop, general manager of the Public Utilities Commission of London, Ontario and his wife together with the general secretary, Dr. L. A. Wright, visited the branch on December 8th.

Mrs. McKillop was entertained at lunch by the wives of the chairman and two Ottawa councillors and a tea for Mrs. McKillop was held by the Engineers' Wives Association of Ottawa.

A regional meeting of the Council of the Institute was held at the Chateau Laurier, Ottawa, on Saturday March 24th. It is suggested that a regional council meeting might be made an annual event with the noon luncheon open to all members of the Branch with an address by the president or one of the vice presidents.

Plans are being made by a special committee, under the chairmanship of Mr. R. F. Legget, to celebrate the 50th anniversary of the Branch in 1959. The plans include holding a regional meeting of the Institute in Ottawa, probably in October 1959.

The Branch has continued to be represented on the National Capital Regional Branch of the Communi lanning Association of Canada; the representative for 956 being Mr. W. V. Morris.

The Branch is fortunate in that the secretary W. ictor Morris has agreed to carry on for another year.

The report would not be complete without again ferring to the excellent work of the Junior Section. is hoped they will broaden their activities in 1957.

Proceedings Committee—The proceedings committe reported that there were a total of eighteen meetgs including eight luncheons, four dinners, two field ps, two dances and, of course, the president's evening ception and the Spring golf tournament. Ladies were vited to attend both field trips as well as one of e dinner meetings.

Attendance at regular meetings during 1956 ranged om about 75 to a high of approximately 130. Hower, great interest was shown in the field trips to the away; 140 to 150 persons took part on each trip.

Junior Section—In February a visit was arranged r juniors and their wives to hear the "National Capital lan" described by Mr. Allan Hay and Mr. Walter bwker of the Federal District Commission. The famous 'lan model" was on display and discussed in detail. arch event was a visit to the Gatineau Power Comny control centre at Val Tetreau, and also to the nerating station at Farmer's Rapids. In spite of a d sleet storm, approximately 30 juniors and their lies turned out. In April the Bell Telephone Comny sponsored a talk and demonstration entitled "Talki; Box to Transistor". Again the ladies were invited ad turned out in force. The spring half of the year's aivities was terminated with a visit to the E. B. Eddy Cmpany. The tour was preceded by an illustrated dscription of the process machinery to be seen later. Frty members enjoyed the details of the tour.

The fall session opened with an excellent visit to tl new plant of Computing Devices of Canada, at Bl's Corners. A very obliging staff worked overtime to show us everything in detail from a wrist radio to the intricacies of a digital computer.

At the annual luncheon meeting, chaired by the Jior section chairman, Herb Gladish, the guest speaker was Mr. MacCallum of Racey-MacCallum and Assciates.

The annual Papers Night meeting was held March 1. Senior members kindly acting as judges were Brigier Carriere, Mr. R. E. Hayes, and Capt. H. Chaput. Wrthwhile papers were presented by student and scior members. The year's activities were concluded wh an engineering forum meeting. The panel consied of Col. W. A. Capelle, Mr. R. E. Hayes, Mr. Mrris Price, and Mr. Stewart Frost. Chairman Herb Gdish very aptly conducted the discussion along such tcical subjects as "Confederation, Why a Junior Secti", "Engineer or Technician", and "Salaries Don't Mke Sense".

Pterborough

Dring 1956 the Peterborough Branch held six reasonab well attended technical meetings. These covered a ariety of interesting subjects and we were fortunate in btaining excellent speakers.

The social highlight of the season was the annual meting and visit by the presidential party. This event, which honoured the ladies of the Branch, took the form of a dinner dance.

The annual picnic was held in June and the members enjoyed a guided tour of the Faraday Uranium Mines at Bancroft. The afternoon also included a variety of sports activities and the members tried their hand at horse shoes, and so on.

Merit awards in the form of a cash prize were extended to students in each of the three city collegiates.

Port Hope

The Branch held three regular meetings, two field trips and two executive meetings during the year.

The February meeting was highlighted by a very fine address from Dr. Tupper as he outlined his views on the future of the engineering profession. It was also our annual meeting for the purpose of electing our new executive.

Our April meeting was treated to a very interesting and informative paper "The History of Land Surveying around Port Hope" by Mr. Jack Sylvester, one of our own members.

In May the Canadian General Electric Plastics Plant in Cobourg conducted a most enjoyable plant visit for the members and their wives, which was followed by a film "Power and Passage".

Our second field trip consisted of an all-day bus tour to visit the St. Lawrence power and seaway development at Cornwall, in September. This outstanding tour will long be remembered by the 38 members and guests who started at 7 a.m. and finished back home at 4.15 a.m. the next morning.

In November we held the second executive meeting at which we decided to offer a semi-professional development course to our members during the coming winter.

Mr. Parsons, of Burns Bros. & Co., gave us an outstanding lecture on present day investment problems, as the first in our professional development series. He explained the background for our gradual creeping inflationary spiral and suggested ways to keep our investment dollars abreast of the diminishing purchasing power of our dollar.

Prince Edward Island

Eight regular meetings were held during the year 1956, of which six were dinner meetings. Attendance at all meetings was fair to good; two meetings were held at Summerside, five at Charlottetown, and one near Cavendish on the north shore.

During the year much more preliminary work was done toward the formation of the Association of Professional Engineers of the Province of Prince Edward Island, and the last several meetings of the year were held as joint meetings. The following results of our annual election were announced at the regular meeting held on September 19th at Charlottetown: N. F. Stewart, chairman; Clive W. Currie, vice-chairman; L. A. Coles, John D. M. MacDonald, R. D. Donnelly, G. H. Milligan, committee; and W. S. Veale, councillor. C. F. Buckingham was appointed secretary-treasurer. An interesting point that might be mentioned is that the above members were elected and appointed to similar positions in the newly-formed Professional Association at a joint meeting held on October 25th at Charlottetown.

The annual picnic was held August 4th, in the National Park area on the north shore near Cavendish and was enjoyed as usual by both children and adults.

The occasion of the annual visit to this Branch of the presidential party was again the highlight of our year. We were greatly honored by the visit of the president of the Institute, Mr. V. A. McKillop, Mrs. McKillop, and Dr. L. Austin Wright, general secretary on September 19th. A very enjoyable dinner meeting was held at the Charlottetown Hotel, on which occasion we were favoured with a very interesting talk by President McKillop. The meeting was very well attended by members and their ladies.

At our meeting on October 25th we were given a very interesting talk by two representatives of the Plywood Manufacturers' Association of British Columbia and this was much enjoyed by all. At another fall meeting, held at Summerside on November 19th, we were shown a very interesting film.

Québec

Le Comité exécutif a tenu cinq séances au cours de l'année avec une assistance moyenne de huit pour disposer des affaires régulières de la section et étudier les questions d'interêt local ou national pour l'Institut.

Le Comité exécutif a continué l'organisation d'un bal annuel et celui-ci a eu lieu le 20 janvier 1956, au Château Frontenac. L'assistance dépassait légèrement deux cents. Ce bal est très apprécié de tous ceux qui y participent et votre comité éspère que celui de 1957 remportera un grand succès.

En janvier, le comité exécutif a reçu officiellement les délégués de la Fondation Athlone d'Angleterre venus au Canada pour présider au choix des boursiers Athlone à Laval.

Il fait plaisir au comité exécutif de souligner particulièrement que la Convention de l'Institut pour 1958 se tiendra à Québec, les 21, 22, et 23 mai. La ville de Québec s'est méritée une réputation enviable sur la tenue des conventions de l'Institut ici et le comité exécutif espère de tour coeur que la section de Québec saura maintenir sa renommée sur ce point.

Le comité exécutif se plaît à signaler que, grâce aux efforts de plusieurs de ses membres, un camp du "Ritual for the Calling of an Engineer" a été établi à Québec. Les étudiants de la Faculté des Sciences ont grandement apprécié cette initiative.

De nouveau, cette année, le comité exécutif a obtenu un octroi de $1000 du ministère provincial du Bien-Etre Social et de la Jeunesse afin de permettre la poursuite des cours avancés ou de perfectionnement en structure. Le comité se doit de souligner l'empressement avec lequel le ministre, l'honorable Jean-Paul Sauvé, a accueilli notre demande.

Au cours de l'année écoulée, le Comité de Jeune Ingenieur a inauguré une série de conférences sur l'orientation professionnelle. Des ingénieurs distingués de notre section ont été invités à adresser la parole aux étudiants finissants de la Faculté des Sciences relativement aux problèmes professionnels qu'ils auront à envisager. En chaque circonstance, les étudiants recevaient des réponses adéquates aux questions qu'ils posaient au conférencier invité.

Réunions générales—Le programme des réunions générales, durant l'annee 1956, fut le suivant: janvier 20, assemblée annuelle de la section (28), bal annuel de la section (202); février 28, film "Léonard de Vinci" (175); avril 20, tournoi de curling, Architectes vs Ingénieurs (77); avril 21, cérémonie anneau de fer (115); mai 11, conférénce et démonstration sur "high fidelity" par des spécialistes de Northern Electric et RCA Victor. Sommes invités de l'Institute of Radio Engineers, section de Québec, (50); mai 16, visite industrielle à "Les Ciments du St-Laurent", Villeneuve (30); mai 17, forum et films sur l'automation, invités du Québec Power.

Juin 14, visite industrielle à l'usine Canadian General Electric, centre industriel no. 5, St. Malo (15) août 8, tournoi de golf de la construction environ (1950) septembre 17, tournois annuel de golf de la section de Québec (92); octobre 9, conférence par les spécialistes de Fiberglas Canada Ltd. (30); octobre 19 début des cours de structure à la Faculté des Sciences octobre 22, conférence, "calculateurs binaires" par un spécialiste de l'International Business Machine Co. Ltd. Les membres de la section de Québec de l'Institut of Radio Engineers sont nos invités (80); novembr 20, conférence, "calculateurs par analogie" par un spécialiste de Computing Devices of Canada. Les membre des sections de Québec de l'Institute of Radio Eng neers et de l'American Institute of Electrical Eng neers sont nos invités (75); décembre 4, soirée de film sur l'automation et la canalisation du St-Laurent (65 décembre 19, conférence et films sur "Internation Geophysical Year Program at Churchill". Invités c l'Institute of Radio Engineers, section de Québec.

Le comité exécutif déplore la perte d'un memb affilié en la personne de M. J. A. Hamel, de Siller Plusieurs de nos membres ont eu la douleur de perd leur père, leur mère ou un proche parent au cours (l'année. A ceux-la, le comité réitère ses plus sincèr condoléances.

Le comité exécutif souligne tout particulièreme des honneurs insignes décernés par l'Institut à d membres fort méritants de notre section. Dr. A. Decary: choisi membre honoraire de l'Institut. C'e le plus haut honneur auquel peut aspirer un memb de l'Institut. Dr. Adrien Pouliot: récipiendiaire de Médaille Julian C. Smith. Ces deux membres éminer ont beaucoup merité de la profession et les honne qui leur ont été conférés réjouissent profondément le confrères.

Il importe de souligner également la nomination certains de nos membres à des charges importan dans des organisations professionnelles, universitai publiques ou charitables. M. G. E. Sarault, présid général de la Campagne 1956 de la Federation Oeuvres de Québec. Cette campagne a remporté succès considérable. M. L. P. Bonneau, à qui on confié la charge de vice-doyen de la Faculté Sciences de Laval. Il s'occupera tout particulièrem de la partie Génie. M. Y. R. Tassé, nommé directe gérant du bureau métropolitain de Québec. M. Ta est toujours un membre très en vue de la Cham de Commerce de Québec et il fait partie de l'admi tration de la Chambre de Commerce du Canada.

Un nombre important de membres ont encore, cette année, apporté une contribution active dans la campagne 1956 de la Fédération des Oeuvres de Québec au niveau des paroisses. Plusieurs contribuent également à l'organisation du Carnaval d'Hiver de Québec. D'autres occupent des postes dans des organisations et clubs charitables.

A ceux des membres qui ont obtenu des promotions et assumé de nouvelles charges, nos plus sincères félicitations et voeux de succés.

Le comité exécutif doit souligner qu'il a appris avec joie l'élection de M. Leo Roy à la prèsidence de la Corporation des Ingénieurs Professionnels de Québec. M. Roy est un ancien secrétaire de la section de Québec (1945). Egalement il faut mentionner l'élection de M. E.D. Gray-Donald à la prèsidence de la section de Montréal de l'Institut pour 1956. M. Gray Donald est un ancient président de la section de Québec.

Les membres de la section de Québec doivent être chaleureusement félicités pour leurs activités professionnelles et extra-professionnelles. Une profession acquiert de la solidarité et une reputation enviable seulement si ses membres se produisent dans les différentes sphères de l'activité humaine.

Saguenay

Once again the Saguenay Branch and the Saguenay Chapter of the Corporation of Professional Engineers of Quebec continued close co-operative activities under an elected joint executive.

Eight executive meetings were held during the year as well as the annual meeting, a presidential visit, three technical meetings, two field trips, and two dances. These were well attended.

One film night was held at which the "Leonardo da Vinci" film was shown to an overflowing audience. This film was also shown to some of the students in high schools locally to increase their interest in engineering and science.

1956 has been one of the most active years the Branch has enjoyed. Interest is very high.

Saint John

A total of six dinner meetings, three professional development meetings, and one plant visit were held during the year.

The joint dinner with the Association of Professional Engineers of the Province of New Brunswick was held on January 26th, at which time the Hon. Edgar Fournier, chairman of the New Brunswick Electric Power Commission spoke on "The History of the N.B.E.P.C."

Three of the dinner meetings were "ladies' nights" and these proved to be most popular. The first was held on April 12th and featured an interesting demonstration of miniature towers actually transmitting on microwave frequencies. The accompanying talk, entitled "The Microwave Story" was given by H. N. D., of the N.B. Telephone Co. The second was held on May 31st when C. Gordon Clark of the Atlantic Sugar Refineries Ltd. presented a showing of slides in connection with his recent trip to England. The third ladies' night was held October 11th, at which time Mr. H. Watson Jamer, past-president of the Maritime Provinces Board of Trade, spoke on the work being done by the Atlantic Provinces Economic Council to improve economic conditions in the area.

At a dinner meeting held on November 8th, Mr. Bob DeGrace, of the Canadian Institute of Timber Construction, spoke on the use of timber in construction and methods of treatment for its preservation. A film entitled "Wood at Work" was shown at this meeting. The annual meeting and election of officers took place December 11th and at the close of the meeting two films on wiring were shown.

Professional development meetings were held March 15th, October 25th, and November 22nd, the subject being "Leonardo the Inventor", "Saint John—Its Traffic Problem", and "Civil Defence". There was no definite enrollment for the P.D. Course but the average attendance was 24.

An interesting visit to the Saint John dry dock was made on May 3rd.

Five executive meetings with an average attendance of seven members were held during the year.

Arrangements for the biennial meeting held in St. Andrews in September were under the general chairmanship of J. J. Donahue, vice-chairman of the Branch, and several other members of the Saint John Branch served on various committees in connection with this most successful meeting.

St. Maurice Valley

Again during 1956, the various committees of the St. Maurice Valley Branch have made a considerable effort to provide an active year of operation and promote the good name of the Institute in the region.

The response of the membership on all activities was most comforting; the interest was high and attendance good throughout the year. With a membership concentrated in two different centres many miles apart and meetings alternating from one to the other it becomes a tricky problem in organizing activities that will be successfully attended by both groups. It was gratifying to note that meetings in Shawinigan were well attended by people from Trois-Rivières and vice versa. A number of distinguished local and outside speakers delivered talks on technical subjects of actuality and engineering achievement which were appreciated by engineers from all spheres of endeavour.

There were, altogether, 10 executive meetings and eight general meetings in 1956. Ladies attended on three occasions, which were: Showing of the "Leonardo Da Vinci" film; a talk and demonstration of a new musical instrument; and a plant tour of the Wabasso Cotton Mill in Trois-Rivières. The other general meetings were featured by the following talks: "Automation, Machines and Men" by Dr. J. J. Brown, "Automation in the Industry" by E. R. Lehmans, "Hunting and Ammunition" by Jacques Faille, of the C.I.L., and the "Beaumont Project" by John R. Ross, resident engineer, Shawinigan Engineering Company.

The highlight events of the year were the annual dinner and dance held at the Cascade Inn, Shawinigan Falls, and the golf tournament which took place at the Ki-8-Eb Golf Club near Trois-Rivières. Both events, sponsored jointly by the St. Maurice Valley Engineering Societies joint committee comprising E.I.C., E.P.E.Q., and A.I.E.E., were a huge success. Congratulations are extended to the officers of the sister societies who largely contributed to organize these functions.

On March 1st, 1956, it was a great honour for the Branch to welcome Dr. R. E. Heartz on his presidential tour. The occasion was a double pleasure for the Branch since Dr. Heartz is also an ex-resident of Shawinigan Falls, having spent some 15 years here with the Shawinigan Engineering Company. The president was accompanied by his wife, Dr. and Mrs. Tait, and Mr. Dunsmore, vice-president. They had lunch with Messrs. Edgeworth, Copping, Buchanan, and their wives. Later in the afternoon the president and his colleagues had a meeting with the Branch executive and in the evening a dinner meeting was held at which the president addressed the membership. He was greeted by over 100 members who attended the meeting. Mrs. Heartz was entertained in the afternoon at tea by Mrs. McMullen, and in the evening at The Cascade Inn by the wives of members of the executive.

The annual dinner was held on April 27, 1956, at Hotel Chateau de Blois, Trois-Rivières. Our guest speaker was Leon Balcer, M.P., who spoke on "Parliament at Work". The meeting was well attended and the subject found most interesting by all.

A course will be started in February 1957 under the professional development scheme. The chairman is now making final arrangements with the Investment Dealers' Association, in Montreal, who will be giving five lectures of two hours each on the subject of investment and stock market. This decision was reached following an opinion survey which indicated interest in many subjects but a marked preference for investment and stock market.

Branch membership is now 232 with a peak of 238 registered during the summer.

Saskatchewan

Eight executive meetings and the annual meeting were held during the year for the transaction of Branch business.

Mr. Allan Tubby, M.E.I.C., of Saskatoon, was appointed to the nominating committee of the Institute for 1956.

The Branch distributed about 130 copies of Wickenden's "A Professional Guide for Junior Engineers" to the 1956 graduating class in engineering at the University of Saskatchewan. It was accompanied by a letter from the Branch chairman, Mr. E. J. Durnin, M.E.I.C.

A donation was made towards the erection of a memorial to Col. John By, an engineer and founder of the City of Ottawa. Complete details of this undertaking may be found in various issues of *The Engineering Journal.*

The 1956 Annual Student's Conference was held in Montreal on May 22nd. Mr. Lee G. Morrison, S.E.I.C., represented the University of Saskatchewan.

Prof. J. B. Mantle, M.E.I.C., attended the 1956 annual meeting of the Institute held in Montreal, in May, as representative of the Saskatchewan Branch.

Mr. W. L. Sharpe, M.E.I.C., city engineer of Weyburn, and a past member of the executive was proposed as candidate for the office of Saskatchewan councillor.

President V. A. McKillop visited the Saskatchewan Branch at Saskatoon on November 6th. He addressed the engineering students at the University in the morning, met with the executive in the afternoon, and attended a general meeting in the evening. This was a very successful meeting, and the Saskatoon Section are to be congratulated on a fine effort.

Another item of interest to Saskatchewan members is the appointment of a former branch member, Mr. H. P. Gatin, M.E.I.C., to the office of assistant general secretary at headquarters in Montreal.

A regional meeting of Council was held in Victoria, B.C. on November 10th, and Prof. J. B. Mantle, M.E.I.C., Saskatchewan councillor, and Mr. K. C. Graham, M.E.I.C., councillor representing the Association of Professional Engineers of Saskatchewan, were in attendance.

Sault Ste. Marie

The Sault Ste. Marie Branch of the E.I.C. had a fairly active season, holding eight general attendance meetings and three executive meetings.

The first general meeting was held on January 13th, 1956, and after a short business meeting, the speaker of the evening, Mr. D. J. Rudack, was introduced. Mr. Rudack gave a very interesting talk on his experiences in the Arctic while working on radar station installation.

Dr. R. E. Heartz, president, visited the Sault Ste. Marie Branch on February 8th, and held a luncheon meeting with the local executive. A dinner meeting was held at the Sault Ste. Marie Golf Club that evening, attended by the president's party, the local members and their ladies.

The speaker for the dinner meeting of April 20th was Mr. K. H. Snell, who gave a talk on "Industria Lubrication". Mr. Snell is the senior mechanical enginee for Algoma Steel and his speech was especially interest ing to all the local members.

A social evening was held on May 25th, and thi meeting was a great disappointment to all of the execu tive. It was very poorly attended but the couples wh did put in an appearance had a lot of fun with "round robin-bridge", and so on.

The Branch Executive held a meeting on Augus 27th. This meeting was held primarily to submit a lis of names to headquarters of heads of local industry who might be sent invitations to attend an educatio conference to be held in London, Ontario.

The next general meeting of the Branch was hel on September 21st. The nominating committee for th 1957 slate of officers was appointed. A short busine meeting followed, after which three movies were show which were of general interest.

The October meeting of the Branch was held the 9th of the month. The nominating committee ga the results of its selection. Further nominations we called from the floor and, as no more were forthcomin the slate was accepted as presented by the nominati committee. Following the business meeting, Dr. M. Yan, project supervisor of the Central Research a Development Division of the Abitibi Power & Pap Company, gave an excellent paper on the developme of platewood.

The November general meeting, held Novemb

5th, was quite well attended. A short business meeting [w]as held. Afterwards, Mr. J. W. Kinney, resident en[gi]neer for the Mackinac Bridge Authority, assisted by [M]r. W. Bell, gave a speech on the progress of the [M]ackinac Straits bridge to date. The talk was well [ill]ustrated by slides.

The annual meeting of the Sault Ste. Marie Branch [w]as held on December 12th. The business meeting [w]as held to appoint auditors and make a final resume [of] the 1956 business affairs. The chairman for the 1956 [te]rm turned the chair over to the incoming chairman, [M]r. K. H. Snell, who gave a brief rundown of the [pr]oposed activities for 1957.

[S]udbury

[Br]anch activities during 1956 were as follows: January [1]2. Mr. Donald Black, of the public relations dept. of [th]e Bell Telephone Company spoke on "Your Tele[ph]one Company and Television". March 8. Mr. J. E. [M]atthew, of the nuclear energy division of the Cana[di]an General Electric Co., spoke on "The Application [of] Nuclear Energy", and Mr. J. Monaghan of the [Al]uminum Company of Canada showed a film entitled "[T]he Kitimat Story". April 5 (member's night). Mr. [M]elvin Sproule, of the research department of the [In]ternational Nickel Company, spoke on "Atomic Energy [A]BC", and Mr. G. Charlap, of the Falconbridge [Ni]ckel Company, spoke on "Some Problems Encountered i[n] Starting a New Mine". May 3. Annual meeting [an]d ladies' night. Included were reports by the com[m]ittee chairman, election of officers for 1956-57, and a [ve]ry successful dance for the remainder of the eve[ni]ng. October 13. "A tour of the RCAF (Radar) station a[t] Falconbridge." November 15. Mr. Donald Hamilton, [ma]nager of Electrical and Silastic Sales for the Dow-C[o]rning Co., spoke on "What is a Silicone", and also s[ho]wed a film on the silicone products. December 6. [Mr]. R. W. Bowcott, local equipment engineer of the [we]stern area for the Bell Telephone Company, spoke o[n] "What is Coming in Dialing".

Seven executive meetings were held during 1956. T[h]e average attendance for the seven regular meetings [wa]s approximately 40 per cent of the branch mem[be]rship.

The average attendance for the three education [me]etings (P.D.) was approximately 42 per cent of the r[es]ident membership. It was estimated that approxi[ma]tely 2700 students, and nearly 800 adults saw the fi[lm] on "The Life of Leonardo Da Vinci".

T[o]ronto

T[he] past year has been a very satisfying one for the T[or]onto Branch. All meetings were well attended. C[re]dit for this must go to each of those who made it t[he]ir responsibility to see that each meeting was "[pi]cked up".

The field trips arranged by the junior activities co[m]mittee were well done and very successful. There w[as] excellent hospitality shown by both Ontario Hydro w[he]n the branch visited the R. L. Hearn steam gen[er]ating station in Toronto in April, and by the S.K.F. C[o]mpany during the visit to their plant in September.

The general meetings were varied from a "History of Engineering in Canada", an address given by Dr. C. R. Young at the annual meeting of the branch in January 1956, to "Seaway Progress" by Mr. D. M. Ripley, JR.E.I.C. The "quiz program" was used again for the annual Students' night in February. Mr. John G. Hall, M.E.I.C., of Combustion Engineering Corp. Ltd., acted as quiz master.

The president of the Institute visited the branch on February 16th, spoke to the students at the university, met the Branch executive later and provided an occasion for members and their wives to meet Dr. and Mrs. Heartz at a social evening in Hart House.

A joint meeting with the A.I.E.E., Toronto Section, was held on March 1st, and took the form of a panel discussion on power and energy resources. Dr. Otto Holden, M.E.I.C., chief engineer, H.E.P.C. was chairman of the panel. Panel Members were Dr. W. P. Dobson, M.E.I.C., retired chief of research H.E.P.C.; Mr. George D. Floyd, M.E.I.C., assistant general manager of engineering, H.E.P.C.; Professor A. E. Allcutt, M.E.I.C., retired head of department of mechanical engineering, University of Toronto; and Mr. W. L. Thompson, M.E.I.C., district manager, Bailey Meter Company Ltd., Toronto.

Also in March, Mr. George Cowper, of Atomic Energy of Canada Limited, Chalk River, spoke to the branch on "The Detection of Nuclear Radiation".

In April, Dr. G. Ross Lord, M.E.I.C., spoke to the branch on "Humber Valley Flood Control". The attendance and questions were an excellent indication of the interest in this subject in the Toronto area. Perhaps the branch should thank hurricane Hazel for stirring up such interest.

In October Professor H. L. Macklin spoke to the branch on modern mapping methods. This was followed at the end of October by a panel discussion on "The Engineering Manpower Shortage" with Dr. R. R. McLaughlin, Dean of Engineering, U. of T., as the chairman. The panelists were Mr. D. R. Abbey, M.E.I.C., standards engineer, Underwriters' Laboratories of Canada; Colonel J. K. Bradford, O.B.E., director of university placement, U. of T.; Mr. W. F. McMullen, manager of technical personnel, Canadian General Electric Company, Peterborough; Mr. Ira J. Needles, president, B. F. Goodrich Canada Limited, Kitchener and Mr. S. H. Deekes, special assistant, A. V. Roe Canada Limited.

Ladies' night was a great success. The branch lost less money this year on this function than it had for some years. The membership is to be congratulated for turning out so well and giving this function their best support by their presence.

On the 13th of November, Dr. Richard L. Hearn, immediate past chairman of the Hydro-Electric Power Commission of Ontario, presented a paper on "The Sir Adam Beck Generating Station No. 2". This was the paper Dr. Hearn had delivered to the Institution of Electrical Engineers, in London, England, just previously, and was very well received.

Mr. D. M. Ripley's paper on "Seaway Progress", with many fine coloured slides, was an excellent presentation and served admirably to cap off the year.

It is recognized that such a program could not have been carried off without the excellent cooperation of all members of the branch executive and the generous assistance of the membership at large. The support and assistance of the membership is reflected too in the good financial standing of the branch, which showed a surplus for the first time in some years.

The branch is pleased to note that the professional development program carried on in two groups. Group I carried out the usual general series of subjects to help the members fill in their background of general knowledge, while Group II carried on a more concentrated study of six main topics with emphasis on human relations and business problems. The branch takes this opportunity to thank the officers and members of the professional development program for their excellent handling of this activity. Some who have taken the course have chosen to join the branch executive and these have made a valuable contribution to the branch activities with their experience and enthusiasm.

Vancouver

During the past year there were ten meetings of the executive and seven Branch meetings. The spring meetings were held jointly with the Association of Professional Engineers but this practice was discontinued in the fall.

Unfortunately the president was unable to meet the Branch but Dr. Wright addressed the scheduled meeting.

In May, members of the Branch and their wives journeyed to Seattle and were entertained by the Seattle Branch of the A.S.C.E. A bascule bridge was inspected and a discussion on the Boeing wind tunnel was held, followed by a social evening.

A very successful part of the program was supplied by field trips to the Crown Zellerbach paper converting plant, Boyles Bros. Drilling Co., British Ropes factory, and the Capilano Brewing Co.

A well-attended ladies' night was featured by dancing and bingo.

The Student's night dinner was held very successfully, with three students presenting papers which were judged and for which prizes were awarded.

A structural section of the Branch was formed during the summer. Four dinner meetings were held in the fall at which local members presented papers on structural topics. Dr. R. F. Hooley was elected chairman of this section.

The Vancouver Branch ended the year with a schedule of regularly held Branch meetings and a policy of holding as many field trips as possible, and looks forward to an even more active year in 1957.

Professional Development Course. The Vancouver Branch operated a professional development course in 1955-56, and is now organizing one for this season. Last year the average attendance was 34 and 12 meetings were held. Total enrolment was 38, which indicated an attendance percentage of 90 per cent. When organizing this course, the main recommendation was that the course begin towards the end of January and end in April. The Vancouver Branch has found this period to be the best time for maximum attendance.

Counselling in Schools. The Association of Professional Engineers does some counselling here, but the Engineering Institute has not considered this step to date.

Engineers' Wives' Association. An Engineers' Wives' Association is organized in Vancouver, but not necessarily in connection with the Vancouver Branch.

Vancouver Island

During 1956, the Vancouver Island Branch held, conjointly with the Victoria Branch of the Association of Professional Engineers of B.C., seven technical meetings on the subjects: earth slides, mineral resources, bridge design, ship design, astronomy, and highway design.

Since the annual meeting for 1955 was held in January, 1956, the branch held two annual meetings in 1956; the first in the form of a dinner meeting with the ladies, followed by a showing of the film "Leonardo da Vinci", and the second in the form of a smoker.

One of the most successful meetings was arranged as a dinner and dance in the Oak Bay Golf Clubhouse on November 10. Unfortunately president and Mrs. McKillop were unable to visit Victoria this year because of the sudden death of Mr. McKillop's assistant. However the meeting was attended by the general secretary, Dr. L. Austin Wright, vice-president Hardy, and several councillors of the western region who had earlier on the same date attended the Council meeting of the western region in Victoria.

Seven branch executive meetings were held during the year.

The Vancouver Island Branch scholarship of $100 was presented to Gary J. Whitten. Mr. Whitten expressed his gratitude in the form of an excellent letter as well as personally at the October 19th joint meeting.

Winnipeg

The Winnipeg Branch enjoyed a most successful yea[r] of operation in 1956. It had the privilege of welcomin[g] and entertaining Dr. McKillop, the E.I.C. president and Dr. Austin Wright, the general secretary.

The Branch extended an invitation to headquarte[rs] to hold the annual general meeting of the Institut[e] in Winnipeg in 1960. Headquarters accepted and ar[r]angements have been made for space required and [a] committee has been set up to study arrangement[s] which will have to be made.

There were five meetings held, at which papers o[f] general application and of timely interest were give[n] and some very fine films were shown. The averag[e] attendance was 73.

Civil Section. Six meetings were held and one pla[nt] visit and the average attendance was 40. The tot[al] membership of the Section is 224 and among this num[-]ber is listed members, juniors, students and branc[h] affiliates.

Electrical Section. This Section has an enrollme[nt] of 191, which is an increase of 10 over that of th[e] year 1955. At present the membership is made up [of] the E.I.C. grades as follows: Members 120; Junio[rs] 44; Students 10; Branch affiliates 17. The section hel[d] the following listed meetings. Six Section meetings wi[th] an average attendance of 38; one joint meeting wi[th] the A.I.E.E., attendance 65; and one plant visit, atten[d]ance 60.

In addition to these the Section sponsored two soci[al] functions: a Spring wind-up at the conclusion of th[e] winter sessions and the annual dinner-dance. Both of these were well attended, there being 88 persons in attendance at the wind-up and 215 at the dinner-dance.

Brandon Section. This Section has a membership of 40 and its members display considerable initiative both in the matter of Section management and in the securing of speakers and interesting films for the regular meetings.

Seven regular meetings, which are always preceded by a dinner gathering, were conducted by the Section executive during the year, with an average attendance of 19 present. A family picnic was arranged to take the place of the June meeting. This was held at the International Peace Garden, south of Boissevain, Manitoba; 35 members and their families attended.

The Section had a guest speaker at each of its meetings and in addition special films on forestry and mining were shown.

Student Section. This Section had a most successful year and increased its membership from 172 in 1955 to 215 in 1956. The membership drive got under way early in October and prospective members were each presented with an application form, together with S.E.I.C. brochures and copies of an address given by Dr. Sidney Smith, president of the University of Toronto.

The Section held six regular meetings, at each of which a guest speaker discussed some branch of engineering, and an appropriate film was shown.

On November 5th, the Section was honoured by a visit from Dr. McKillop, the president of the E.I.C., who was accompanied by Dr. L. Austin Wright, the general secretary, and several members of the Winnipeg Branch.

This meeting was the best attended of the year and 250 undergraduates were on hand. The general attendance of all of the meetings was exceptionally good, as an average of at least 50 per cent of the total membership was registered.

Yukon

The final step in the creation of the Association of Professional Engineers of the Yukon Territory was taken when many members of the Yukon Branch E.I.C. were gazetted in January 1956 as P. Eng. in the Association of Professional Engineers of the Yukon Territory. This is the culmination of an idea that was sponsored by the Yukon Branch E.I.C.

Another major step in the solidifying of the Yukon Branch was the drawing up of a set of Branch by-laws. These were submitted and approved by E.I.C. Headquarters in December 1956. They will be presented to the members of the Yukon Branch early in 1957. During the year, five dinner meetings were held and two field trips were organized. The members, Branch affiliates and wives attended a dinner meeting after which they saw the film on the life of Leonardo Da Vinci. At the meeting in May, a paper was presented entitled "The Mechanics of Frost Action". At the October meeting, several films of engineering interest were shown. In early December, the assistant resident engineer of the project spoke on the "Whitehorse Rapids Power Development". This speech was of great interest due to its very local nature. Also in early December, a special meeting was held t

THE ENGINEERING JOURNAL

Vol. 40 No. 5

Published Monthly by
THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

Contents - May 1957

(18,600 copies of this issue printed)

The Institute as a body is not responsible either for the statements made or for the opinions expressed in this publication.

Reproduced here is a letter from the Prime Minister, the Rt. Hon. Louis St. Laurent, to mark the seventieth anniversary of The Engineering Institute of Canada.

OFFICE OF THE PRIME MINISTER · CABINET DU PREMIER MINISTRE · CANADA

This summer The Engineering Institute of Canada is marking the seventieth anniversary of its service to this country, although the fine record of contribution of our engineers extends many years further into the pages of our history.

The engineering profession is of vital importance to Canada, particularly during this period of rapid national development. Many of the projects which are being carried out at the present time constitute important stepping-stones in this development process and will be of lasting benefit to the Canadian people.

To all the members of the engineering profession in Canada I extend my warm congratulations on the seventieth anniversary of their organization and my best wishes for further notable successes in the future.

Prime Minister.

Ottawa,
1957.

This scene might seem less suited to a review of Canadian engineering and industry than to a travel prospectus. Yet this is the site of one of the country's foremost developments during 1956 — the Mystery/Moak Lake mining project. It is possible that the pulp and paper industry may also develop in this hitherto remote part of northern Manitoba. (*Photo: Manitoba Government.*)

FOREWORD

THIS ISSUE of *The Engineering Journal* is devoted to a review of Canadian industry during 1956, including all the segments of direct interest to members of the engineering profession. The reviews are mainly based on annual Bureau of Statistics reports, and on news items from trade journals and financial statements. They have been augmented by information supplied by leaders of industry. For some industries, complete DBS reports are not available beyond 1954 or 1955, but the value of factory shipments only are quoted for 1955 or 1956.

The *Journal* is grateful to many government departments at all levels, and to many firms and associations who have generously responded to requests for information and photographs. Limitation of space has made inclusion of much of this data impossible, though it has been helpful as a supplement to data provided from elsewhere.

This is a first attempt at such a review of industry which it is hoped to make an annual feature in years to come. Those to follow will be easier and, it is hoped, improved. Comments and suggestions for improvement will be helpful and are invited.

THE EDITOR

CANADA IN 1956

THE YEAR 1956, with the gross national product at $29,550 million, posted a new record for Canada in a series of record-breaking post-war years. Most to be remarked about the current boom is that it has spread to practically all economic sectors — primary, secondary, and service industries — and has been shared in varying degrees by all regions from coast to coast. Even the relatively depressed Maritime provinces have been enjoying a higher level of prosperity.

The ten per cent gain over 1955 in the gross national product may be divided roughly into a two per cent gain due to price increases and an eight per cent 'real' gain in production. The main reason for this prosperity was the high rate of gross domestic investment, which reached a total of some $7,500 million for the full year, or some 26 per cent above 1955.

When the Department of Trade and Commerce annual forecast of investment intentions was published a year ago, it was fairly evident that the ambitious plans could not be implemented without serious penalties. Shortages of manpower, materials, and plant, and the monetary limitations which developed later, caused a substantial carry-over into 1957. Nevertheless, gross domestic investments showed a gain of some 25 per cent over 1955.

Other economic indicators showed percentage increases over 1955 as follows: personal disposable income, 9%; personal expenditures, 7%; government expenditures, 7%; salaries, wages, etc., 11%; corporate profits (manufacturing), 23%; net farm income, 15%; savings, 35%; inventories (manufacturing), 8%; exports, 12%; and imports, 18%. Employment at year-end was up 6½ per cent, and unemployment down to 1.7 per cent of the labour force.

On the unfavourable side, commercial failures were up 14 per cent and both wholesale and consumer price indices up 3 per cent. Railroads had shown good gains in traffic and gross revenue but net revenue was discouraging. Urban transit services continued to show a decline in traffic, and even with rate increases barely held their own in earnings. There was a sharp drop in the number of housing starts during the fourth quarter.

Employment Covered in Review

Canada's total civilian labour force in 1956 varied from an average low of 5,642,000 in the first quarter, to 5,806,000 in the fourth quarter. Totals for non-farm labour only, varied between 4,860,000 in the first quarter and 5,036,000 in the fourth, or an average of some 4,929,000 for the year.

Employment at 1,891,000 in mining, power, petroleum, transportation, and the other heavy industries that are covered in the following review (shown in round figures for each industry in the table), thus represents the production effort of some 38 per cent of Canada's non-farm labour force. The remaining 62 per cent are employed in such industries as clothing, textiles, food, beverage, retail trade, printing and publishing, tobacco, rubber and leather footwear, and service industries.

1956 Employment in Canadian Heavy Industries (in round figures)

Outlook for 1957

Taking a look at the coming year, economists saw a more modest increase ahead in gross domestic investment for 1957 than in the year just past, with a rise of some five per cent, of which half would be a 'real' increase and half would be due to higher prices. They predicted a come-back for housing due to continuing population growth from immigration and the current high rate of natural increase. Government expenditure would be higher, except, perhaps, for defence.

Though disposable income and personal expenditures would be moderately higher than in 1956, it was anticipated that savings would again increase by 12 per cent. Imports would continue strong. Labour would still be scarce, and unemployment be maintained at less than 3 per cent of the labour force, but the gain in labour income would be less than in the previous year.

Inventories were predicted to show only a 2 per cent gain over 1956, compared with an 8 per cent gain in 1955/56. Net farm income was likely to have a modest 3 per cent gain. Price levels would be up 3 per cent at wholesale, and 2½ per cent at consumer level.

All these predictions added up to a 1957 forecast of gross national product at $32,000 million, or an increase of about 8 per cent over 1956 of which 6 per cent should represent a real increase, and 2 per cent be due to price changes.

The Canadian mining industry is continually seeking new methods to improve efficiency. Such mechanized equipment as the Joy loader, right, is now common. The scene below is a usual one when a new oil well is brought-in for the first time. *(Photos: Dominion Steel and Coal; Imperial Oil Limited.)*

MINERAL RESOURCES

METALLIC ORES

NON - METALLICS

SOLID FUELS

PETROLEUM

NATURAL GAS

CANADA'S MINERAL output has been climbing steadily since World War II and setting new records year after year. The trend continued in 1956 and no slackening is indicated in the foreseeable future. All the major minerals excepting lead and gold have shared in the advance, and are slated for further significant increases in the years ahead. Substantial gains are predicted for the coming year for copper, nickel, iron ore, uranium, zinc, asbestos and petroleum.

The overall value of Canada's mineral output for 1956 exceeded $2 billion, only six years after it reached the billion dollar mark. This compares with a value of $1.8 billion for 1955 and just under $1.5 billion in 1954. Best progress in 1956 was seen in production of copper, iron ore and uranium.

Copper, Uranium, Iron Ore the Leaders

Apart from production of petroleum, valued at $402 million (dealt with in another section), copper led all Canadian minerals in production value with 1956 output estimated at $291 million. Nickel ranks second with production worth $223 million. Part of the gain in copper has been due to the sharply higher prices for the metal, and part to increased tonnage. Sharpest gainers have been Opemiska, Gaspé copper and the nickel-copper companies. Promising newcomers include coming producers in the Chibougamau, Sudbury and Manitouwadge areas and in Newfoundland, which will swell the total in the years immediately ahead.

Uranium increased its production in 1956 to an estimated value of $40 million, 50% above that of the previous year. The many new mines soon to come into production will give Canada a place among the world's top uranium producing nations. Within the next few years output of Canadian uranium may well increase five or six-fold.

Iron ore ranks high among the star performers of the mining industry. Canadian mines produced some 23 million long tons of ore worth $156 million, half as much again as was produced in 1955, and more than triple the amount produced in 1954. Within another half decade the total will be seen moving up to around 50 million tons.

Three Exceptions

Coal, with its outlook clouded by the competition from the oil and gas which are rapidly replacing it as energy sources, barely maintained its upward output trend, with production at $95 million, and with little hope for any improvement in view. Though the program of mechanization in the Maritime mines has been accelerated, the slight increase in domestic output for 1956 was not sufficient to meet growing Canadian demand due to the upsurge in business activity, and imports of coal for the year were sharply higher.

Gold, one of the two minerals failing to establish new gains, in spite of cost-aid just about held its own in the struggle against rising costs, with production worth $151 million. The upsurge in copper mining activity brought about an increase in gold production from base metal operations in 1956. This, however, was more than offset by a decrease in output from lode gold mines, resulting in an overall decline in output from the previous year. Lead output also continued to decline, with production down 8% from 1955.

Every mining province received its share of the mining industry's spectacular growth. Many new mines were brought into production and many more are in prospect across the length of the nation from the International Boundary to the Arctic. Within a few years the record production of 1956 promises to be far outdistanced.

Manpower Shortages a Threat

Continuing expansion depends on many factors, of which three are of major importance: money, markets and manpower. Under the tight money market policy now in force, investment capital was more difficult to come by than in previous years. Though no real difficulties were encountered in 1956 in selling our exportable surplus of mineral products, non-dollar countries are still unable to purchase in the volume they require, while threats of increased tariff duties in the United States, though presently dormant, are still much alive below the surface.

A more immediate threat to progress is lack of sufficient manpower. A shortage of underground labor is shaping up similar to the one experienced during the late 'forties'. A survey a year ago disclosed an impending shortage of some 800 men. Actually the industry could have easily absorbed a further 1000 trained miners in 1956. To meet this situation the Canadian Metal Mining Association has a mission working overseas. Britain, Ireland and Italy offer the most promising sources for further supplies of underground labour.

Of equal importance is maintenance of a supply of trained mechanics and technicians of all kinds. In this respect Britain is an obvious recruiting ground. The shortage of engineers, geologists and metallurgists continues to be serious. A great strain will be imposed on our universities in providing adequate facilities in staff and equipment to train the

flood of undergraduates enrolling during the next few years.

There is the keenest competition for youthful talent, whether mechanical, professional or administrative. Only by well conceived and well executed plans will the mining industry succeed in getting its fair share, so it may maintain the momentum of its remarkable current growth.

More Domestic Consumption Means More Processing

Much of Canada's mineral production is exported as ores or concentrates, or in primary metallic forms. As we become more and more industrialized, however, more of the basic raw materials from mines and mills are being processed and consumed at home. Twenty years ago, total, value of Canada's manufactures was some $3.3 billion. In 1956 the value had risen to nearly $20 billion.

This expansion has increased consumption of primary metals and minerals. The great expansion in construction volume over the same period, amounting to almost an eightfold gain, has created a demand for large quantities of basic raw materials in the form of building products.

Canadian dependence on the United States and Western Europe for mill products and fully finished articles has been decreasing yearly, particularly in the past 11 years. This was due to greater per capita fabrication in Canada of the major ferrous and non-ferrous metals, with the resulting decreased importation of completely fabricated materials.

METALLICS

Iron Ore

Twenty-two and a half million long tons of iron ore were shipped during 1956 from Canada's iron mines a 40% increase over the 16¼ million tons shipped in 1955. This puts Canada in 7th place among the world's producers, with an output amounting to some 4½% of global output.

Though the United States is spending vast sums on research work to upgrade or beneficiate low grade deposits, the percentage of iron ore it will have to import in years ahead should climb, and much of it will come from Canada. There is, however, a pronounced trend to beneficiated or 'tailored' ores. Steel makers find a furnace charged with 'pellets' saves as much as 25% of heating time. Thus low grade iron deposits are much in demand today.

There is no real iron ore shortage. Temporary ore surpluses may appear. But despite the growing ore output the price trend still points upward. Quotations for 1957 are almost certain to be raised in view of the round of wage increases last summer. Steel has already been marked up.

1956 production was divided approximately as follows among the principal producers, in millions of long tons: Iron Ore Co. of Canada, 12; Steep Rock, 3¼; Dominion Wa-

General view of the Steep Rock Iron Mines development. In the foreground is the Errington underground plant and loading terminal on the C.N.R. spur line. Centre: the "G" ore body, showing electric dredges removing silt overburden. Background: the Hogarth open pit and Hogarth shaft, under construction. ***(Photo: Photographic Survey Corporation.)***

bana, 2½; Algoma, 1½; Bethlehem (Marmora), 0.5; Argonaut, 0.35; Texada, 0.35; Inco, 0.33; Quebec Iron and Titanium, 0.15 and Noranda, 0.07.

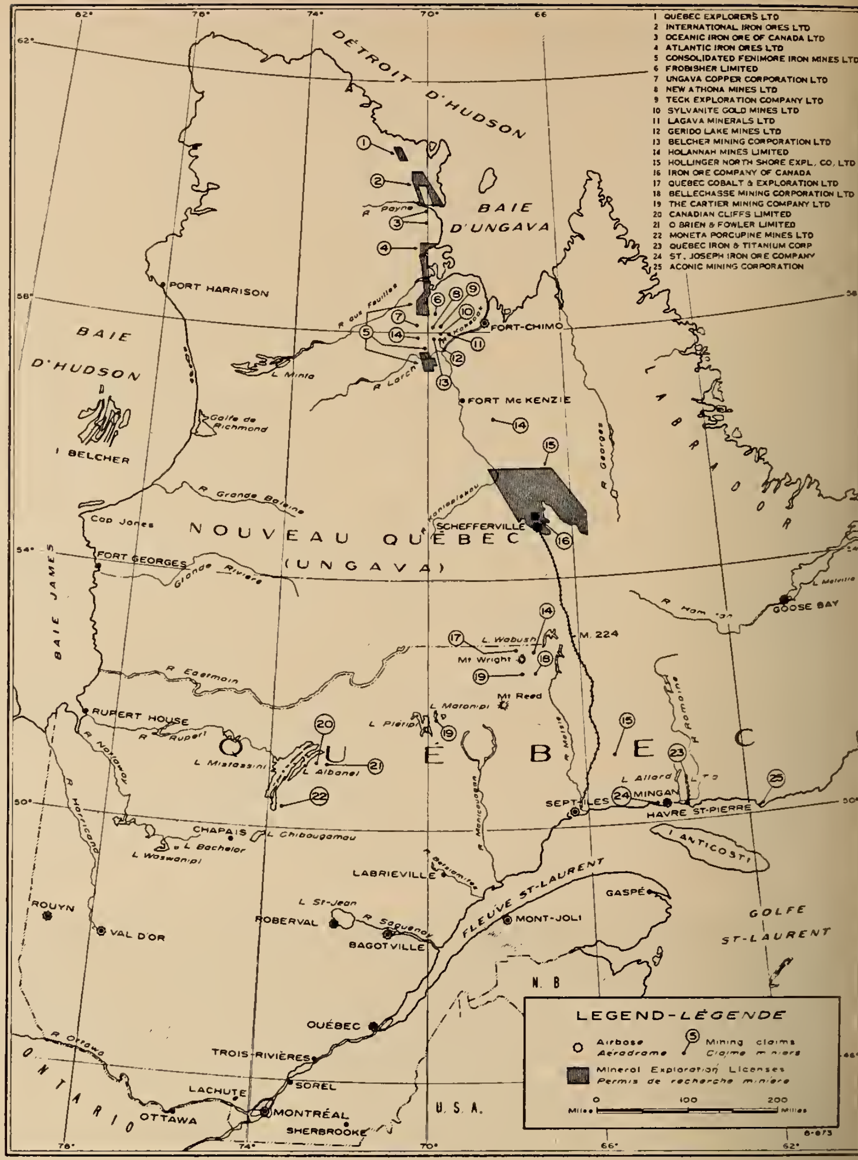
New producers soon to swell the Canadian output include Caland Ore Co. near Steeprock, with 1 million tons of reserves in 1959; Hilton Mines and Bristol-Quebec Mining Co. in Quebec with 600,000 tons of low grade ore; International Iron Ore Co. and Atlantic Iron Ores in the Ungava area, controlled by Cyrus Eaton interests; Oceanic Iron Ore of Canada and Consolidated Fenimore Iron Mines further south in the same area; and Canadian Javelin Co. in the Wabush Lake area of Northern Quebec. Other companies still in the exploration stage include Quebec Cobalt and Exploration Co., Cartier Mining Co., Mattagami Mining Co.

Copper

Canadian mines produced copper during 1956 at near record levels, only exceeded in 1940. They could have sold more if they could have produced it. 1956 production at over 353,000 tons, worth $291 million, smashed the prewar record of 327,800 tons, and compared with the 326,000 tons produced in 1955. Canada ranks fourth among free world copper-producing nations after United States (841,071 tons in 1954), Rhodesia (438,711 tons), and Chile (400,857 tons).

Refined copper output in Canada for 1956 will probably approach 275,000 tons, compared with 252,643 tons in 1954. Canadian consumption of refined copper in 1954 amounted to 102,536 tons in 1954 and exports of primary copper the same year to 47,411 tons and of refined copper 156,130 tons. For 1956 all of these totals are likely to show increases of some 8 or 9 per cent when final reports are compiled. Copper price stood at 36.62 cents per pound in January, peaked at 49.125 cents in late August, and dropped again to 36 cents at the end of 1956.

Two new copper mines were brought into production during the year, Gaspé Copper Mines and



Mining properties in the Ungava (New Quebec) region. *(Quebec, Dept. of Mines.)*

One of the new copper mines that came into production during 1956 was the Campbell Chibougamau Mines development, in the Chibougamau region of Quebec, of which the site is shown here.

Campbell Chibougamau Mines, both of them in Quebec. The former was running at half its 6,500-ton capacity at year-end, awaiting more power; the latter was producing at a rate of 1,500 tons per month.

Nickel Production

With 1956 production of nickel at 356 million lb., up some 1% from the previous year, the search for new supplies is accelerating. Several companies are now beyond the prospect stage and are planning for production over the next two years. North Rankin Inlet west of Hudson's Bay plan a 250-ton concentrator and will produce after 1958; Arcadia Nickel in the Sudbury district contemplate a 1,000-ton mill.

Consolidated Regcourt in Quebec is planning a 2,000-ton mill; Norpax Oil and Mines' shaft is down 350 feet; Eastern Mining and Smelting in the Werner Lake district have their shaft down 1,000 feet; Eastern Metals Corp. in Quebec plan a 500-ton mill for 1958; New Manitou Gold Mines plan a 1,000-ton concentrator and Temagami Mining Co. plan a 2,000-ton mill. Several more companies have blocked out substantial reserves.

Outstanding event for 1956 was International Nickel's decision, announced late in 1956, to proceed with development of the company's Mystery-Moak Lake property in Northern Manitoba.

The framework of the Geco Mine mill buildings, at Manitouwadge, Ontario, where large copper and zinc deposits have been discovered and are now being developed, thus opening up another new area. ***(Photo: Ontario Department of Mines.)***

Lead

Canadian lead production for 1956 at 186,675 tons was lower than for 1955, when output totalled 202,763 tons. Refined lead output was also lower than in 1955. Exports for the first nine months were below the same period of 1955. Canada ranks as the fourth largest lead producer. Principal source continued to be Consolidated Mining and Smelting Company's Sullivan Mine at Kimberley, B.C.

Secondary lead production accounts for about a third of the total. Demand has been steady. The current U.S. stockpiling program, which has been draining off surplus supplies, is nearing completion with no announcement of extension, though U.S. Department of Agriculture barter deals will partly replace it.

Zinc

Canada's production of zinc in 1956 at 847.2 million lb. was 2½% lower than in 1955. The value of 1956 production at $125½ million was 6% higher than in 1955.

Though zinc exports decreased over the first nine months, Canada ranks third among world producers,

Exploration shaft at International Nickel's Moak Lake development, which will be used as the main entrance to the nickel mine when operations begin. ***(Photo: Manitoba, Dept. of Industry and Commerce.)***

after the United States and Europe, with some 16½% of total production.

Consolidated Smelters' Sullivan Mine in B.C. is the largest producer. From this mine and from other B.C. zinc properties about half of the Canadian production of refined zinc is produced. Another 30% is refined by the Hudson's Bay Mining and Smelting Co. at Flin Flon, Manitoba. Quebec produces most of the remaining 25%. Smaller quantities are also produced in Newfoundland and the Yukon. Several promising potential producers are developing in Ontario, New Brunswick, Nova Scotia and the N.W.T.

Cobalt

1956 was a year of consolidation for the cobalt industry. Free world production was substantially the same as for 1955. The five-year upward trend was halted in 1955 when some 14,000 short tons was produced. Civilian consumption has been held back by the U.S. stockpiling program.

Canada will rank as second or third largest producer in 1956.

Canadian 1956 production as represented by shipments of metal, oxides and matte derived from ores of Canadian origin increased to 3.68 million lb. from 3.3 million lb. in 1954. Value increased in 1956 by 9% to an all-time high of $9,372,760.

International Nickel Co. of Canada is by far the largest Canadian producer, followed by Falconbridge Nickel Mines. Newest source of the metal is Sherritt Gordon Mines in Manitoba. Eastern Mining and Smelting Co. is carrying out pilot-plant work for a new nickel copper smelter at Chicoutimi, Quebec, which will also produce cobalt. Canada's only producers of cobalt ores are in Northern Ontario.

Platinum

Canada led the world in production of platinum metals in 1955, producing some 381,600 ounces valued at $22½ million, but may have yielded its place to South Africa in 1956 when Canadian production was 311,600 oz. Total world output of the platinoid metals amounts to only 28 tons yearly. Some 60 per cent of this is platinum, 40 per cent is palladium with the other four metals, iridium, osmium, rhodium, and ruthenium making up the balance.

Most of Canada's output comes from nickel copper ores of the Sudbury area. Increased demand for both these major metals indicates platinum production in 1956 may have surpassed all records. Outlook for 1957 is for a slight increase in world output.

Gold

Gold mining experienced a difficult year in 1956. After South Africa, Canada ranked second in 1955 Free World gold production at $U.S. 159 million. For 1956 the free world total will be up, thanks to South Africa. U.S. and Canadian production will be somewhat lower than for 1955, with Canada producing a value of $150.8 million.

For 1957 no factors can be foreseen to change the existing trend, though South Africa's increase will not be so marked. No new fields of major importance have been reported anywhere in recent years. One Canadian producer, a copper-gold mine, has been added, but four longtime producers closed down.

Cost-aid was extended last year for another two-year period, or to the end of 1958. The free market for gold bars, however, has induced some gold mines to give up cost-aid. Only three new properties are under development. No new gold mills are being constructed and very little prospecting is being done for gold. The bringing into production of several new gold-copper properties, however, has increased gold production from base metal operations.

Uranium

Canada has a uranium productior potential equivalent to at least hall of the anticipated Free World output of 30,000 tons. The country's three principal uranium producing areas are Beaverlodge in the northwest corner of Saskatchewan, Blinc River in Ontario near the north shore of Lake Huron and Bancroft abou 150 miles east of Toronto. Total refinery production for 1956 was valuec at $39,577,000.

At Beaverlodge, Eldorado Mining and Refining has expanded its mil to 2,000-ton daily capacity and wil be ready to operate this Spring. Gunnar Mines produced ore in 195 valued at $13½ to $14 million an the Beaverlodge Camp had a $24. million production. Present mill capacity is being increased from 1,30 to 1,750 tons daily. Lorado's 500-to custom mill will produce this sprin with custom ore from half a doze nearby mines.

Blind River is the world's larges uranium camp. Mines there hold con tracts totalling more than $1.1 billio and its eleven mills can handl 35,000 tons of ore daily. Pronto afte a full year's operation has overcom its difficulties and is expanding ca pacity to 1,500 tons daily. Algom Quirke Lake property started pro ducing last October and the Nordi was ready for a start at year enc Eight more mills are under construc tion.

In the Bancroft area Bicroft com menced production early in Decem ber with its 1,000-ton mill, whil

Due to go into production early in 1957 was Heath Steele's 1500-ton mill at the lead-zinc-copper operation at Little River, near Newcastle, N.B. *(Photo: New Brunswick, Dept. of Lands and Mines.)*

Faraday will follow it this spring with a 750-ton unit. The area's third mill has been started by Dyno Mines which is presently trying to complete its financing. Elsewhere, Eldorado's original mine at Great Bear Lake continued operations.

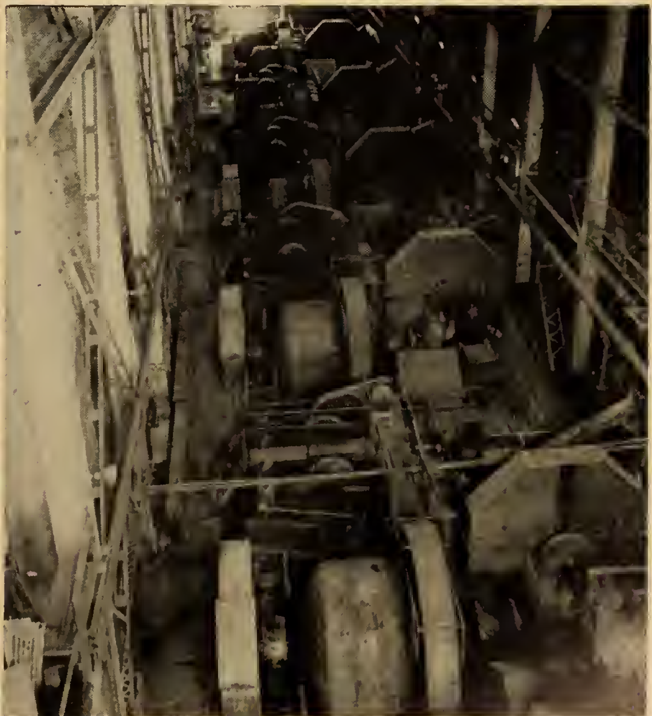
Eldorado, the government's procurement agency, has contracted for the purchase of all presently known uranium production up to 1962/63. These contracts were negotiated under arrangement with the U.S. Atomic Energy Commission except for Canadian requirements. The post 1962/63 market is still obscure, but some production may be diverted to Britain.

A total of 18 Canadian companies have received contracts or letters of intent from Eldorado covering the purchase of $1½ billion worth of uranium. Within two years production should reach $300 million value yearly or more. 1957 output should reach a value of between $50 and $60 million.

Titanium

Canada is the world's largest producer of titanium slag (72% TiO_2 plus desulphurized iron), all of which comes from Quebec Iron and Titanium Corporations' smelter at Sorel, Quebec. 1955 production was 162,784 tons, containing about 117,000

The Flin Flon mine, in Manitoba, is the second largest Canadian producer of zinc. The general view of the crushing plant (left) shows the main belt conveyors; ball mills and classifiers for secondary grinding are seen (right) in the concentrator plant. *(Photo: Hudson Bay Mining and Smelting Co. Ltd.)*



tons of titanium dioxide. Ilmenite shipments from the Allard Lake deposits totalled 444,235 tons in 1955. Titanic Iron Co. also shipped 1,400 tons of Ilmenite from the St. Urbain area of Quebec. Canada's 1956 production totalled 4,443 tons of ore valued at $37,100.

Canadian metal production is limited to pilot plant operations at Shawinigan Water and Power Co.'s Shawinigan Falls plant, and at the Dominion Magnesium plant at Haley, Ont. The Mines Branch in Ottawa is continuing research work on all phases from ore to metal.

Lithium

Lithium is a relative newcomer to Canadian mining. So far there is only one producer, Quebec Lithium. This company and several others have discovered the largest and richest lithium deposits in the world. In anticipation of increased demand, this company is expected to increase capacity from 1,000 tons to 1,500 tons daily by mid 1957. It has a 5-year contract with Lithium Corp. of America to supply 165 tons of concentrates daily, while deliveries are being stepped up beyond the minimum called for in the contract. Reserves exceed 15 million tons of 1.2% lithium oxide, 9 million tons of which are above the 400-ft. horizon. All 1956 production, at 2,400 tons valued at $4.8 million, came from Quebec.

Other companies in various stages of development include Canadian Scotia, Montgary Explorations, Lithia Mines and Chemicals in Manitoba, Nama Creek Mines in the Beardmore area of N.W. Ontario, Aumacho River Mines and Geolex Development and Exploration Co., in the North West Territories.

Manganese

Canada imports all its requirements of manganese ore. Consumption in 1956 surpassed the 113,000 tons used in 1955. Canada has developed rapidly in the production of ferro-manganese ore, and in 1955 exported 29,400 tons valued at $5.2 million. Producers of manganese alloys include Union Carbide at Welland, Ont., Chromium Mining and Smelting Corp. at Sault St. Marie, and Canada Furnace Co. at Port Colborne. Recently additional sources of low grade manganese ore have been found in New Brunswick. Other potential sources of manganese are the huge reserves of manganiferous ores in the Labrador and New Quebec districts and in the iron ranges west of Port Arthur near Steep Rock.

Magnesium

Canada, which until last year held second spot as a magnesium producer after the United States, is now being challenged by Norway, which is reported to be already producing 9,000 tons yearly and planning an increase to 12,000 tons. Germany and Japan with plans for 5,000/6,000 tons yearly each, are runners up.

In Canada, magnesium is produced by two companies, Dominion Magnesium Ltd., and Magnesium Co. of Canada, Ltd., a subsidiary of Aluminum Co. of Canada. Their combined production including calcium was valued at $5,617,826 in 1956, and would have been higher but for the power shortage in the Saguenay district. Canadian exports account for 80% of the sales, with Britain, France, and Japan the best customers. The Canadian price was increased in March 1956 to 31½ cents per pound of pure metal.

An aerial view of the Eldorado uranium mine, in the Beaverlodge area of northern Saskatchewan; where mill capacity has been increased. ***(Photo: Sask. Govt.)***

Molybdenum

Canadian production of molybdenite comes only from Molybdenite Corp. of Canada, operating some 25 miles northwest of Val d'Or, Quebec. Shipments of 90% molybdenite concentrates and crude bismuth metal in 1955 were valued at $1,068,673 and totalled 689 tons and were shipped to Europe. 1956 shipments went to Western Europe and Japan, and were slightly higher than 1955 at 756 tons valued at $967,461.

There are no facilities for treatment of concentrates in Canada but from December 1956 the company will begin production of molybdic oxide and various molybdates. Mill capacity was increased last year from 400 to 540 tons daily. At a new property in which an interest was acquired last year 25 miles away, a 1,000-ton mill will be erected. Owner is Prissac Molybdenite Mines. Quebec Metallurgical Industries also has a property 9 miles north of Shawville, Quebec, where an adit has been opened.

Other Production

1956 production value for other "metallics" includes: silver, $25.8 million; selenium, $6.86 million; tungsten, $6.06 million; and cadmium $3.8 million; all higher than in 1955.

1956 production value for nonmetallics, fuels, and structural materials includes: peat moss, $3.7 million; sodium sulphate, $2.85 million; quartz, $2.78 million; nepheline syenite, $2.5 million; dolomite, $2.4 million; and stone, $43.3 million.

NON-METALLICS

Coal

In spite of increasing competition from oil and gas developments, Canadian coal production for 1956 showed a modest gain at some 14,915,000 tons compared with 14,819,000 the previous year. Employmen

This large electrically-powered shovel is used in the coal fields of Estevan, Sask. The size may be judged by comparison with the tractor in the foreground. *(Photo: Saskatchewan Government.)*

in the industry remained stable, indicating progress toward the goal of increased productivity, so important to the future soundness of the industry. The extensive mechanization program in the Maritime coal mines was continued at an accelerated rate. Domestic output has not kept pace with the rise in consumption due to the upsurge in business activity and imports were sharply higher. On a longer term basis there is still the implied threat of increasing competition as the dieselization program continues, and the only answers are improved productivity and reduction in mining costs. Nova Scotia, Alberta, and Saskatchewan, in that order are the major producers with 5.8, 4.4, and 2.3 million tons, respectively. New Brunswick, British Columbia, and the Yukon are also producers.

Fluorspar

Canadian production of fluorspar in 1956 broke all records. Despite a

Completed during 1956 was the Algom Quirke mine of Algom Uranium Mines Limited, in Algoma, northern Ontario. A similar development was also completed at the Algom Nordic site. The projects were financed to a large extent by the Rio Tinto Group.

shipping strike, total production at 151,738 tons valued at $3.83 million was well ahead of the record 128,114 tons shipped in 1955. Two-thirds of Canada's output is consumed at home with the rest going to United States, which took 58,390 tons in 1955 and probably imported about 65,000 tons for 1956. Largest Canadian consumer is the aluminum industry, while the second is the steel trade.

Practically all of Canada's fluorspar comes from Newfoundland with a small quantity from Ontario. St. Lawrence Corp. of Newfoundland, Ltd., and Newfoundland Fluorspar, Ltd., are known to have ore reserves adequate for many years' production.

Asbestos

Canada accounts for about two-thirds of world production of asbestos. 1956 production was slightly less than in 1955, when it topped the one million ton mark for the first time at 1,063,802 tons worth $96.2 million. Due to a rise in prices the 1956 value of production exceeded the 1955 value by 14%, at just below $110 million.

The main source of Canadian asbestos is in the Eastern Townships district of Quebec, where eleven producing mines are operated by seven companies. Canadian Johns-Manville Co. at Asbestos, Quebec, is by far the largest producer, accounting for 60% of Canada's output. The Asbestos Corporation is largest producer in the Thetford Mines area, followed by Johnson's Co. and Bell Asbestos Mines. The Johnson Co. located at Black Lake is also the oldest producer. Lake Asbestos Co. of Quebec has just completed its first full year of production in the Thetford Mines area. Two potential producers are developing in Newfoundland and the Yukon.

Barite

Canada is an important producer of barite, and easily takes third place after the 1,000,000-ton output of United States, and the 400,000-ton output of Germany in 1954. Production has risen more than four-fold since 1949, and will probably increase in 1957, as consumption has been rising steadily over the past decade. 1955 production reached an all-time high of 307,808 tonr valued at $2,509,200.

Magnet Cove Barium Corp. at Walton, N.S. accounts for more than 90% of Canadian output. Reserves were last estimated at over 2.7 million long tons, one of the largest high grade barite ore bodies in the world. Most of the production has been from open pits. A new shaft is now being sunk to 1,000-ft. depth, and some production is expected from underground late in 1957 or 1958.

Other deposits occur in Ontario, Nova Scotia, British Columbia, Quebec and Manitoba, none of which are yet under development.

Canadian consumption is small, with some 75% of production used as a weighting agent in oilwell drilling muds. The mineral is also used as a filler and pigment in paints, rubber, linoleum and papers, in making barium chemicals, glass batches, as a concrete additive and where shielding is required against radiation in atomic energy plants.

Largest output of asbestos in Canada is from the Canadian Johns-Manville mine and mill at Asbestos, Que., seen here. ***(Photo: Photographic Surveys (Quebec Limited).)***

Gypsum

The gypsum industry experienced another record-breaking year in 1956, with 5,193,000 tons produced, valued at $8.3 million, or 11% more than in 1955. National Gypsum Ltd.'s new quarry at Millford, N.S. reached full production and for a time attained a daily rate of 8,000 tons on single shift, though this was reduced to 5,000 tons daily following the steel strike. The Millford deposit is one of the world's largest.

Three quarries at Windsor, N.S. operated by Canadian Gypsum Co. will have a combined capacity of 11,000 tons daily on single shift in 1956. Gypsum Lime and Alabastine Ltd. have purchased the Windsor Plaster Co., and are spending $100,-000 in modernizing the gypsum mill. Bestwell Gypsum Co. is developing two large properties in Hants County and on Cape Breton Island.

Cement

Canadian cement production has reached a new high in 1956 of close to 30 million barrels, valued at $77.9 million, compared with 25,168,000 barrels in 1955. By the end of the year 1956, productive capacity stood at some 37 million barrels, which, it is hoped, will do away with the need for imports. By early 1958 capacity of the industry will have risen by another 5 million barrels to some 42 million barrels yearly, which on a per capita basis probably exceed that of any country.

Salt

Production of rock salt increased greatly in 1956 with the coming into full production of Canadian Rock Salt Co. mine at Ojibway, Ont., in August, 1956. The mine's capacity is designed for production of 500 tons per hour. This makes possible large exports to the United States, valued at nearly $1 million in 1955. Canada's 1956 production was 1.6 million tons valued at $13.9 million. Only other producer, Malagash Salt Co. in Nova Scotia will bring a high grade rock salt mine near Pugwash, N.S. this year with capacity of 1,000 tons per shift. Sifto Salt and Midrim Mining Co. have new properties in Ontario which are due for development soon.

These developments mean a majo

·hange in the character of the salt ndustry. Instead of most salt being ıbtained by pumping brine and ·vaporating it, with the increase in ıroduction of much cheaper rock salt Canada will be supplied with this nportant raw material at considerbly lower cost.

ulphur

Canadian sulphur production from ll sources, 1956, was some 763,736 ons valued at $7.44 million; up from record 628,443 tons in 1955. Production by 1960 may well reach a otal of over 1,200,000 tons. Imports nd exports are gaining. 1955 imports otalled 373,373 tons. Exports the ame year were valued at just over 2 million and for 1956 will likely ıow a value of some $2.3 million. his means that Canada is still a et importer.

Main producers of pyrite include oranda, Waite Amulet, Quemont, 'est McDonald, East Sullivan, Noretal and Weldon in Quebec, and ritannia Mine in B.C. Geco Mines Ontario and Brunswick Mining and nelting in N.B. produce in 1957.

Sulphur also is produced from ock gases by International Nickel Copper Cliff, Ont. and by Conlidated Mining and Smelting Co. Trail and Kimberley, B.C. This is rgely used by the fertilizer indus- and by pulp and paper mills. atural gas production accounts for rapidly growing service. A sharp crease will be effected when Westast Transmission's Taylor Flats reuction plant in Northern B.C. and A. Oil's recycling plant at Pincher eek commence extraction of sulur from the gas.

l ne

Lime production in 1956 (1,304,-0 tons; $72.6 million) was slightly ls than in 1955. Most came from ntario and Quebec, with small antities from New Brunswick, anitoba, Alberta, and B.C.

G vel and Sand

The demand for building aggreges has been tremendous in recent nths. Canadian production of sand al gravel in 1956 rose to an all-time hh of close to 129 million tons, shtly above the previous year.

C Products (Brick, Tile, etc.)

Total 1956 production was valued a some $38 million, 8% higher than in 1955. Half the production comes from Ontario, a quarter from Quebec, with Alberta, B.C., Nova Scotia, Manitoba, and New Brunswick following, in that order.

Potash

Saskatchewan is the source of all current development for potash in Canada. Potash Co. of America is sinking a shaft at Patience Lake 15 miles east of Saskatoon. International Minerals and Chemicals Corp. (Canada) Ltd. is planning a shaft on its property on the east side of the province. Continental Potash Corp. has sunk a shaft to some 1,200 ft. depth near Unity, Sask. A Canadian company has applied to the Manitoba government for rights to prospect for potash in that province close to the Saskatchewan boundary.

Typifying the development of the petroleum refining industry is this second vacuum flasher installed at the Montreal East refinery of the Shell Oil Company of Canada, Limited.

Petroleum and Natural Gas

Canadian Oil posted another record in 1956, when production at 170.6 million barrels racked up a 32 per cent gain over 1955, a similar growth to that shown in 1955 over 1954. Domestic demand for oil rose 12 per cent and crude oil exports recorded a threefold increase. Measured against a favourable 10 per cent increase in the value of the gross national product these indicators emphasized the importance of the oil industry to the Canadian economy.

Alberta supplied 85 per cent of the total, while Saskatchewan and Manitoba furnished 11 and 3 per cent respectively. Last year British Columbia also became a commercial oil producer. Saskatchewan's percentage gain in production over 1955 was 66 per cent, while Manitoba's gain was 37 per cent, compared with a percentage gain in Alberta production over the previous year of only 26 per cent. This shows the extent to which these two eastern prairie provinces are catching up on Alberta.

Crude petroleum, with production value estimated at $400 million, has thus ranked as Canada's leading mineral for the fourth year in succession. Production reached a monthly high of 520,000 barrels daily compared with the best monthly average of 411,000 barrels daily in 1955. At year's end maximum potential production, at almost double the actual oilfield output, meant that Canada would be fully self-sufficient in oil if adequate transportation facilities were available to reach all economic market areas.

Capital expenditures on some 17 refinery projects added some 112,-000 barrels capacity daily, bringing total refinery capacity at year end to 708,000 barrels per day, 15 per cent higher than the 618,450 barrel capacity at the end of 1955, and triple what it was 10 years ago.

Some $200 million was spent during 1956 for the industry's plant and equipment. Large as it was, this expansion was overshadowed by the amounts spent for the acquisition of mineral leases and in the search for and development of oil and gas fields, which aggregated more than $500 million.

Drilling continued active at about 10 per cent above the footage rate for the previous year, with close to

3,300 wells completed. On the average some 250 rigs were at work throughout the year, with 276 active at year's end. Alberta led with 162 rigs at year's end, half of them on exploration. The Pembina field, one of the largest pools on the continent, now has 1,600 completed wells, double the number a year ago.

Most of the drilling in Saskatchewan which took second place, was in the southeast part of the province, with 72 rigs active in December. 21 of the total were on exploration drilling in the central west areas. Development drilling accounted for about two thirds of the total. The discovery rate on wildcat drilling was exceptionally high.

British Columbia ranked third in drilling progress for the year, finishing with 27 rigs operating in December, 18 of them on exploration in the northeast corner of the province. This is where Pacific Petroleums and other companies were hard at work developing gas fields in preparation for the opening of the Westcoast gas pipeline next September. Several promising oil discoveries in the northern part of the province during the year made B.C. a potential producer of oil in commercial quantities.

Drilling in Manitoba stepped up its drilling activity following a less active year in 1955. Wildcat drilling accounted for about a third of the drilling last year. While there was no wildcat drilling last year in the Northwest Territories, possibilities are not being overlooked.

These drilling programs have now brought proven reserves in all four western provinces to well over 3 billion barrels, compared with 2.4 billion barrels a year ago. Total number of producing wells now stands at over 10,000.

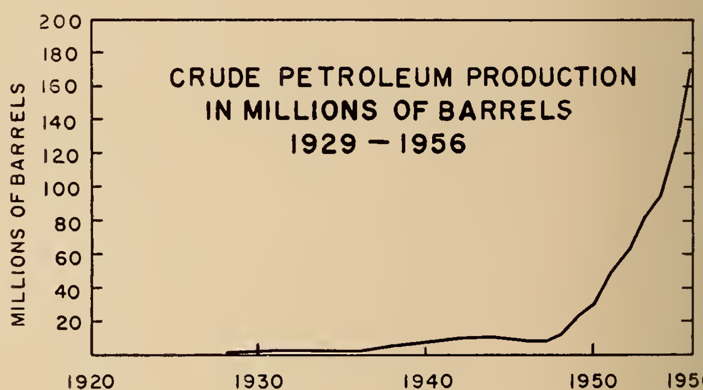
Big Year for Pipelaying

1956 was also a big year in oil and gas pipeline construction, with some 740 miles of main completed, and a total of 3,100 miles including gathering and distribution lines. This included Westspur's 109 mile line linking southeastern Saskatchewan oilfields with the Interprovincial Pipeline at Cromer, which was the year's major addition to oil pipeline facilities. Completed last summer, it was carrying 30,000 barrels daily at year-end, and capacity will be doubled in 1957. Completion of Cremona Pipeline Ltd.'s 60 mile line to Calgary and of the Peace River Oil Pipeline Co.'s system to transport oil from Peace River fields were other leading developments. Additional looping was also carried out on the Interprovincial pipeline.

For the future, Interprovincial Pipeline Co. has announced its 1,770 mile pipe between Edmonton and Sarnia will be extended to Toronto in 1957. Transmountain Pipeline Co. has announced it will boost capacity sharply from December's 184,000 b/d capacity to a possible peak of 300,000 b/d in 1958, and is considering an ultimate capacity of half a million barrels daily.

Grains From Suez

Closure of the Suez Canal last November, with the resulting shortage of a million barrels daily for Western Europe, brought new prospects for Canadian oil. A good deal more of it will likely go to the big California market, releasing extra tanker space and extra Venezuelan oil for Europe.



The pickup started last December with requests for a 36,000 barrel per day delivery.

Pressure has also increased, mainly from a group of independent western oil producers, for an early start on extension of the Interprovincial pipeline to Montreal with its huge 225,000 barrel per day refinery market, presently served entirely with imported crude.

Unfortunately, entry of Western Canadian oil into the Montreal market would put it immediately into direct competition with imported oil, which would mean an overall wellhead price cut in the west. Moreover, Montreal refiners are hardly ready yet to negotiate the guaranteed oil throughputs necessary to finance the 350 mile extension beyond Toronto. Permanent disruption of Middle East oil or a major world hoist in crude prices could, of course, change the outlook. But many oil men believe it is wishful thinking to expect much permanent gain out of the present emergency. The Middle East is still the logical supply for Western Europe, and Western Europe is the best market for its oil.

Exports now a Third of Total Demand

The solid foundation for Western Canada's rapid growth in oil production over the past decade has been the steadily expanding market outlets provided by the record pace of Canada's industrial expansion and the sharply rising trend in the standard of living. Nevertheless the volume of exports has been mounting substantially over the past year. Transmountain pipeline started the year with a throughput of 100,000 barrels daily. By October throughput had gradually risen to 158,000 barrels a day. Plans were hastily made to install two new pumping stations. Either by adding further pumping stations or by looping, capacity will be raised t around 300,000 by the end of 1957

Exports of Canadian oil at the en of the year had reached to abou the 44 million barrel per year level The remarkable gain over the 195 total of 14.8 million barrels was du to the opening up of a new marke in California and to the expansion o existing markets in the State o Washington and in the Lakehead St. Paul area. These exports enable Canada to reach a position of two thirds self-sufficiency, on trade bal ances. Canada's dependence o foreign oil imports is equivalent t about one third of total demand.

Increase in Refinery Capacity

Self-sufficiency in crude supply fo practically all refineries within ec nomic range was a notable featur of 1956 operations. Completion of th lube manufacturing plant, which can supply nearly all the specialty demands formerly served by imports, and the opening of a domestic plant for production of tetra ethyl lead in October, were added steps towards placing the industry on a balanced footing.

Tar Sands

For thirty years the Federal and the Alberta governments and various oil companies have been carrying out research and testing methods of extracting oil economically from Alberta's enormous tar sand deposits in the Athabaska and Fort McMurray areas north of Edmonton. Had a natural supply of free flowing oil in Canada not been discovered, the tar sands would doubtless be in production now.

Announcement was made at the turn of the year that Royalite Oil Co. would develop the tar sands, variously estimated to contain oil reserves of 100 to 250 billion barrels of oil or from 25 to 60 times the proven reserves of free flowing oil in Canada today. Years of research had at last paid off.

Royalite will commence building a plant this coming spring to separate 20,000 barrels of oil daily from the sticky sands by a new centrifuge process. Later they will add a processing plant, a townsite for 1,400 people and a 350 mile pipeline to Edmonton. The initial cost is estimated at $50 million to be spent over four years.

In summary, the new year finds the oil industry in as healthy a condition as it has ever been since the big expansion following the Leduc discovery ten years ago. Great changes have occurred in the geographical distribution of oil production and marketing within the past year, with Manitoba and Saskatchewan taking a larger share of the market and showing a big share of the increase in production over 1955. The export market also showed a suddenly accelerated growth during 1956.

These factors promise to be even more influential in 1957 because of impending limitations on domestic growth, and because of the outlets created for production in southern Saskatchewan. There will be a redistribution of refining facilities in eastern provinces, due to a trend last year towards more growth in Ontario and less in Quebec. This is going to be felt towards the end of 1957 in the form of a small increase in the basic market for Canadian crude once the Interprovincial pipeline reaches the Toronto area.

All these developments and trends give promise of another record year of achievement in 1957, with good prospects of an attainment of a 6½ million barrel reserve and a producibility of 1½ million barrels daily by the year 1960.

NATURAL GAS

Production of natural gas in Canada has grown almost 3 times during the last 12 years to nearly 173.3 billion cubic feet in 1956. The total produced last year showed an increase of over 11½ per cent above 1955. The amount consumed in Canada, about 151 billion cubic feet, had shown a corresponding growth. Last year about 87 per cent was produced in Alberta, 7½ per cent from Ontario fields, 5 per cent in Saskatchewan, 1 per cent in New Brunswick, and a trace from the Northwest Territories.

At the end of 1955 there were some 450 Canadian municipalities or communities served with gas by some 47 distributing utilities, 385 of them were served with natural gas and the remainder with manufactured gas. Seven per cent of Canadian homes, or 27,000, were heated with gas, 63 per cent of them in the four western provinces and most of the balance in Ontario and Quebec. There were some 878,000 gas customers of all classes, 469,000 of whom or 53 per cent used natural gas.

Pipeline Battles Finally Resolved

Following the discovery of the huge Pincher Creek gas field in southwestern Alberta in 1947, many pipeline companies had sought incorporation and competed for the right to build pipelines to serve the most promising untapped markets in Pacific Northwest States and Canada's central provinces. Government indecision as to export policy at Ottawa, Edmonton and Washington tied the matter up for more than seven

Laying the Trans Canada natural gas line through the Great Sand Hills of western Saskatchewan. The 34-inch line is coated, against corrosion, and wrapped with fibreglass and kraft paper. In the background, the trench has already been back-filled. *(Photo: Trans-Canada Pipe Lines Limited.)*

years, during which little incentive to exploration for gas as such was carried out.

Finally in October, 1955, Federal Power Commission approval for the import of northern British Columbia natural gas to Pacific States was given, and a start was made on the 650 mile Westcoast Transmission pipeline to bring Peace River gas to Vancouver and inland British Columbia, and to connect up at the boundary with the Pacific Northwest Pipeline.

Then in June, 1956, following long and acrimonious debates in the House of Commons at Ottawa, approval was given Trans Canada Pipelines to build the western leg of its giant pipeline from the Alberta Saskatchewan border as far as Winnipeg. By the end of 1958, it will be serving Toronto, Montreal and cities and towns along the route, with Federal and Ontario governments building the 675 mile gap across Northern Ontario.

Meanwhile Trans Canada in 1954 had built an 80 mile pipeline from Niagara to Toronto and leased it to Consumers Gas Co. of Toronto to build up its gas market pending arrival of Alberta gas. Union Gas Co. of Chatham, Ont., obtained F.P.C. approval for import of an additional 15 billion cubic feet per year of U.S. gas to augment its supply and to build up its southwestern Ontario market until Trans Canada pipeline was completed.

Three- or Four-Fold Increase by 1965?

Completion of the Westcoast pipeline in the fall of 1957 and the expected completion of the Trans Canada project as far as Montreal by the late 1958 or early 1959 will release additional huge volumes of natural gas to thousands of eager Canadian customers, and to the rich untapped markets in Washington, Oregon and California. Export of Alberta gas to Minnesota and other mid-western States by Trans Canada via Emerson, Manitoba, is held up awaiting approval by the Federal Power Commission, pending the result of lengthy hearings in Washington.

Sales contracts in Canada by these two huge pipeline systems, added to the normal expected growth of consumption in Alberta and Saskatchewan in areas not dependent on the new pipelines for supply, may well double 1956 Canadian consumption by 1960 and increase it three- or four-fold by 1965.

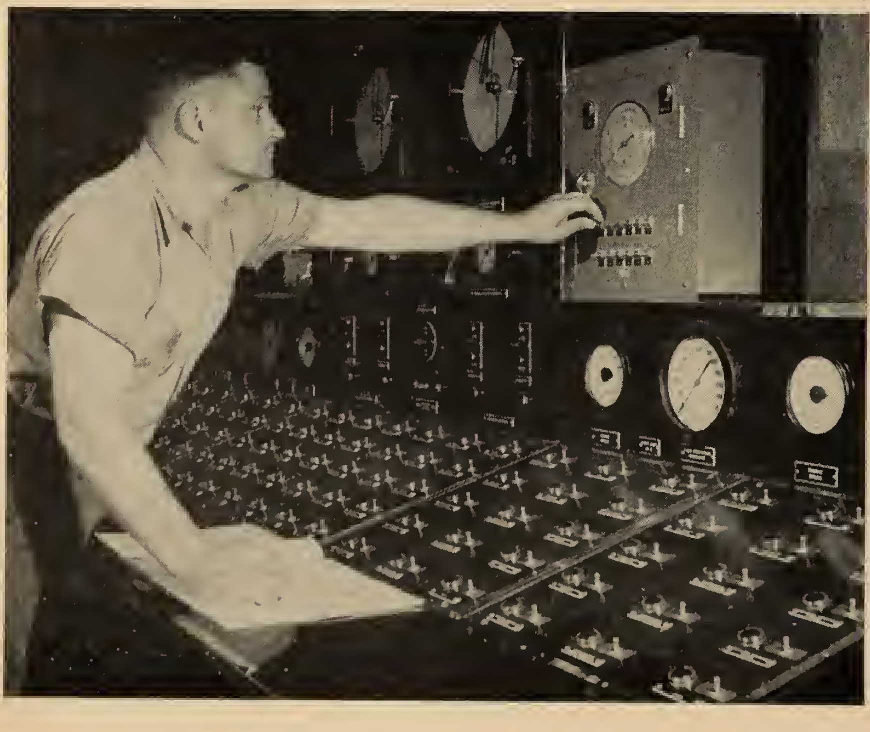
Where the Gas Will Go

Canadian sales contracts already signed with distributing companies and utilities by the two major pipelines now stand as follows: Westcoast Transmission will supply some 18 billion cubic feet yearly to Inland Natural gas in 1958, rising ultimately to some 29 billion cubic feet; British Columbia Electric will take some 19 billion cubic feet the first year, rising ultimately to 32 billion cubic feet.

Trans Canada will deliver a total of 103 billion cu. ft. to Canadian customers the first full year of operation, increasing to some 200 billion cu. ft. the fifth year. Broken down by areas, expected deliveries the first and fifth full years of operation respectively are estimated as follows: Moosomin to Swift Current, 4 and 4; Brandon to Portage, 3 and 5½; Winnipeg, 7 and 14; Keewatin to Port Arthur, 7 and 10; Port Arthur to Toronto, 13 and 26; Toronto, 24 and 48; Southwestern Ontario, 16½ and 28; Ottawa-Hull, 10 and 12; Toronto to Montreal, 4 and 7; Metropolitan Montreal, 15 and 42 (billion cu. ft.)

About 83 per cent of the gas from the Peace River fields will be exported to Pacific Northwest Pipeline Corporation; 9 per cent will go to the B.C. Electric Co. to supply the Vancouver area, while 8 per cent will go to Inland Natural Gas Co. which has franchises in practically all the communities in the southern British Columbia mainland. Initially, Vancouver is already receiving American gas from the San Juan Basin in New Mexico via Pacific Northwest pipeline. Ultimately the flow will be reversed and Canadian gas will flow southward as far as California.

At one of the sixteen stations that pump crude oil through the 1772 miles of the Interprovincial pipe line between Edmonton and Sarnia, an engineer checks the contents of a storage tank on an automatic tank gauge. (*Photo: Imperial Oil Limited*)



Impetus Given for Drilling

With construction of these pipelines under way a fresh impetus has been given for gas exploration and development. Though it is difficult to break down footage or completion figures accurately between oil and gas, drilling for gas was much more active last year by companies with acreage in Alberta gas fields earmarked to supply Trans Canada, such as Pincher Creek, Sibbald, Bindloss, Provost, Holmglen and others, owned largely by companies such as Canadian Delhi and B.A. Oil.

Activities of Pacific Petroleums in the past few years have chiefly been centred on search for gas in the Peace River district of northern B.C. and northwestern Alberta. A number of prolific fields have been discovered by Pacific Pet. and its associates in the region, most important of which is the Fort St. John field, where gas has been found in eight separate zones at potentials of up to 71 million cubic feet daily per well.

Ample Supply for Pacific States

Pacific's land holdings total over eight million acres, equal to 3½ million acres net to the company. Pacific's proven gas reserves alone total more than one trillion cubic feet of gas, though total reserves in the broad Peace River area have been placed at between 3½ and 5 trillion cubic feet. Westcoast's gas purchase contracts given it control over 2.35 trillion feet. They have also contracted for the output of the Savanna Creek field in the southwest corner of Alberta, owned by Phillips Petroleum Co.

Established Gas Utilities in Prairie Provinces

Apart from the Alberta gas fields whose production is earmarked for Trans Canada, Canadian Western Natural Gas and Northwestern Utilities, oldest established gas distributors in the west, have their own fields. Canadian Western, serving Calgary, Lethbridge and surrounding areas as far north as Red Deer, draws its gas supplies from its 775 billion feet of reserves in the Turner Valley; Jumping Pound and Nevis fields. It has storage capacity for 22 billion cubic feet in the depleted Bow Island field.

Northwestern Utilities, serving Edmonton, Jasper, Camrose, Ponoka, Lacombe and surrounding areas, draws from its 2 trillion feet of reserves in the Viking-Kinsella field. Late in 1956 the city of Medicine Hat commenced drawing gas from the newly opened Ezikom field.

In Saskatchewan, the Saskatchewan Power Commission supplies Biggar, Saskatoon and Prince Albert with gas from the Brock and Colville fields near the Alberta border. Moose Jaw is getting its supply from the Success field 120 miles west, built last year. The Saskatchewan Power Commission is seeking to import further gas from the Many Islands field astride the Alberta Saskatchewan border.

Texas Gas Building up Ontario Markets

In Ontario, two old established gas utilities are serving natural gas to their customers, namely Union Gas Co. of Chatham and Consumers' Gas Co. of Toronto. Union in addition to its own reserves in ten small fields in southwestern Ontario, purchases some seven billion feet yearly from

The Trans Canada natural gas line has 6000-lb. concrete weights attached to the 260-ft. section that crosses the Assiniboine river at Miniota, Man. ***(Photo: Trans-Canada Pipe Lines Limited.)***

other Ontario producers and imports some 16 billion cubic feet of U.S. gas from the Panhandle Eastern Pipeline Corporation. It serves 73 municipalities including London, Windsor, Chatham, and will, through a subsidiary, United Fuel Investments, serve the city of Hamilton.

Consumers' Gas of Toronto, up to February 1955 a distributor of manufactured gas, has now converted to distribution of natural gas imported from Texas and Louisiana through Trans Canada's 80 mile pipeline from Niagara. Its franchise area has been broadened to include metropolitan Toronto as well as communities east to Bowmanville, west to Clarkson and north to Newmarket. The company has a contract to take Alberta gas as soon as it becomes available.

Offshore Drilling in Great Lakes

A wave of interest in offshore drilling for natural gas commenced in a small way 14 years ago, culminated in great activity the past two years in the waters of Lake Erie, Lake St. Clair and Lake Huron. Here some 20 companies have exploration permits covering about 425,000 acres, most of it in Lake Erie. Some 50 or more wells, some of them as much as ¾ of a mile from shore, have been drilled and capped.

Consolidated West Petroleums, leading explorer in the field, has completed its 13th well. The field's reserves have not been made public by the company, but they are termed "sufficient to meet requirements of the contract with Union Gas Co., calling for 1.8 billion cubic feet in 1957".

Reserves Up

Total Canadian proven and probable reserves of natural gas rose from 21 trillion cubic feet a year to about 23 trillion cubic feet at the end of 1956. This resulted partly from continued search and development of oil fields and partly from an intensive and successful search for gas stimulated by the start of construction on the two major natural gas pipelines eastward and westward. Reserves are growing at an average rate of two trillion cubic feet yearly.

Petrochemical Industry Needs Gas (and vice versa)

The Canadian petrochemical industry is one of the fastest growing offspring of the boom in crude oil and natural gas production. With a history of two decades behind it and with production valued at $127 million for 1955, annual value of production is expected to double again within the next five years. So far, the bulk of petrochemical manufacturing has been done with oil products and their derivatives. In the United States, however, natural gas is the raw material base for about half of the entire petrochemical industry. Gas is already an important

Considerable additions were due at the Sarnia refinery of Imperial Oil Company, of which a view is shown here. These include a $25 million petrochemical plant and a detergent alkylate plant. A $30 million program was completed at the company's Halifax refinery during 1956. *(Photo: Imperial Oil Limited.)*

element in petrochemical plant operation in Alberta, the only prairie province where this type of manufacturing is done.

The versatility of crude oil as a raw material gives it a wide margin of preference over natural gas in petrochemical manufacture. Thus utilization of large supplies of oil products available at Sarnia and Montreal has made location of petrochemical plants most logical in those areas. Western natural gas is at present too distant to provide a supply at a competitive price.

Fertilizer plants at Calgary and Medicine Hat; a C.I.L. plastics plant, Canadian Chemical Co. Ltd.'s cellulose acetate plant; Polychemical Industries Ltd.'s plant, and Sherritt Gordon's nickel refinery, all at Edmonton; gas scrubbing and sulphur production plants operated by Shell Oil at Jumping Pound, by Royalite Oil at Turner Valley, and two more now under construction, by B.A. Oil at Pincher Creek and by Westcoast Transmission at Taylor Flats, B.C., as well as another projected by Inland Natural Gas in the Crow's Nest area; all these use vast quantities of natural gas from the western provinces.

The importance of these applications on the prairies is the availability of natural gas in the area where the markets exist. The major growth of markets, and of the manufacturing facilities to serve them, is bound to take place in the eastern provinces where the bulk of the population lives.

The place of oil as a sole source of fuel supply in eastern Canada will be partially displaced in future as gas becomes widely available there in 1959 or later in the large manufacturing centres.

REFINED PRODUCTS

With the addition of 112,000 barrels of refining capacity during 1956, Canada's total refining capacity for petroleum products at year's end totalled 708,000 barrels per day. During the first 9 months of 1956, total runs to stills of all types of refinery products showed an increase of some 18 per cent over production during the same period of 1955.

In 1955, the most recent year for which full statistics are published these refineries received 191.8 million barrels of crude oil, 55 per cent of it from Canadian sources and 45 per cent of it imported. Refineries in British Columbia used 17.3 million barrels; Alberta and N.W.T., 22.7 million; Saskatchewan, 18.7 million; Manitoba 7.5 million; Ontario 48.8; and Quebec and Maritime provinces 76.8 million barrels.

Of the Canadian crude supplies, 93.5 million barrels came from the Alberta fields, 5.9 million from Saskatchewan, 4.6 million from Manitoba, 0.56 from Ontario, and 0.4 from Northwest Territories. Of the 86.75 million barrels imported, 7.1 million barrels or 8.2% came from the United States, mostly from Texas and mid-continental fields, while 79.6 million barrels or 91.8% was oil from other foreign sources, 85% of it from Venezuela.

For the year 1955 sales of finished petroleum products by all Canadian refineries, in millions of barrels of 35 imperial gallon capacity, were as follows; aviation gasoline, 3.55; motor gasoline, 75.65; tractor fuel, 0.2; aviation turbo-fuel, 2.34; kerosene and stove oil, 13.26; diesel fuel oil, 15.56; light furnace oil, No. 2, 38.37; light fuel oil, No. 3, 1.59; heavy fuel oil, 43.19; asphalt, 7.22; coke, 2.16; lubricating oil and grease, 0.24; wax, 0.128; still gas, 0.19; other products, 0.39; liquefied petroleum gas, 2.87; feed stocks, 2.02; naphtha specialties, 1.3. Refinery losses amounted to 0.35 million, while unfinished products at year end stood at 5.2 million barrels.

POWER

PRODUCTION AND DISTRIBUTION

The Desroches and Bersimis dams of the Bersimis power development, in Quebec. The No. 1 plant was producing power in 1956, and construction had started on No. 2 plant.

THE YEAR 1956 was another busy one for Canadian power producers. More than a million additional horsepower, most of it hydro power, was added to the nation's installed capacity, which at the end of 1955 stood at some 19.4 million horsepower, both hydro and thermal in central stations, and for paper mills, mines, and other industries. Construction was also proceeding actively on other projects comprising over 1½ million horsepower to come into operation during 1957, and probably a further 2½ million or more during 1958.

As shown in Table I, Quebec was the leading province with more than half a million horsepower added, most of it due to the addition of the first three 150,000 h.p. units at Bersimis No. 1, followed by British Columbia with installations on several hydro projects totalling a quarter of a million horsepower. Hydro and thermal installations in Alberta, Ontario and Saskatchewan, in that order, were next in installed capacity added, while smaller additions

were recorded for New Brunswick, Newfoundland and Nova Scotia.

Total installed capacity of water power plants in Canada is now listed by the Water Resources Branch of the Dept. of Northern Affairs and Natural Resources at 18,356,148 h.p., while if thermal capacity is added, the grand total exceeds 20 million h.p. There are also several sites of high capacity presently under investigation on which development will be undertaken within a few years.

Capacity Due to Double in Another Decade

The demand for power in some parts of Canada is such that it indicates a doubling in less than 8 years. It is therefore safe to predict that the industry, if the present rate of growth continues, will add more generating capacity in the next ten or fifteen years than it has since the beginning of the twentieth century.

Although installed horsepower is generally accepted as the principal measure of the industry's accomplishments year by year, the building of main transmission lines, rural distribution lines and substation capacity also represent a large annual outlay, and construction on all of these proceeded at a vigorous rate during the past year. Central Electric Station expenditure for 1956 was forecast a year ago at $580 millions for capital plant and $55 million for repair, and these figures should be greatly exceeded during each of the years 1957 and 1958.

The Department of Northern Affairs and Natural Resources estimates the presently recorded water power resources of Canada are more than 29 million h.p. under conditions of low stream flow, and nearly 51 million h.p. at average flow. The latter figure permits a feasible installation of some 66 million h.p. Turbine installation at the end of 1956 totalled 18.36 million h.p., indicating that only some 28 per cent of available resources are developed to date.

Output of Energy

Another measure of progress for the electrical power industry is the kilowatt hours of energy produced yearly, as shown in the accompanying graph. Energy produced in 1956 amounted to some 81.7 billion kilowatt hours, 7.1% higher than the 76.3 billions produced in 1955, and almost a threefold increase over the 32 billion kwh. produced ten years ago.

In total, some 4,600,000 customers are at present receiving electric service, almost three times as many as there were prior to World War II. Approximately three quarters of the estimated 630,000 occupied farm dwellings were receiving electric service in 1956. Some 92% of Canadian households use electric power. Average annual consumption per residential customer in 1955 was about 3,300 kilowatt hours as compared with 1423 kwh. in 1939; or two and one half times per customer.

Supply and Demand by Regions

In British Columbia, Canada's fastest growing province, power companies are benefiting from the spectacular industrial expansion taking place there. Traversed by three mountain ranges and with a relatively heavy rainfall, the province looks to hydro to meet future demands for a long time to come. Some 850,000 h.p. is under construction and due for operation over the next two years, with close to another million h.p. planned for the near future.

On the prairies, Alberta is barely keeping pace with demand. Needs for power will double within the next five years. Saskatchewan depends entirely on thermal power, and by 1975 expects half its needs will be met with atomic power. Manitoba is placing its bets for the southern regions on steam stations, while planning to develop its vast hydro resources in the northern areas for extractive industries.

Ontario has almost reached the end of its major economic hydro reserves. By 1968, output of energy from thermal stations will almost equal output from hydro electric plants. By 1970 all the province's hydro resources will be developed.

Quebec can meet all its growth needs until 1978 without thermal power. The province's huge hydro development program is keeping it well in front of all the others in total generating capacity.

In the Atlantic provinces, require-

ments are increasing steadily, if more slowly, than elsewhere in Canada. Nova Scotia's hydro sites of any consequence are all harnessed and future additions will be thermal. New Brunswick has the Saint John river while potential of Fundy tides totals 3 million h.p. Prince Edward Island must depend on steam power. Newfoundland's hydro resources are large but remote and their development depends on attracting large extractive industries.

1956 Installation by Provinces

British Columbia — Major British Columbia developments in 1956 included a fourth 150,000 h.p. unit at Alcan's Kemano plant, with a fifth unit scheduled for operation in 1957. The British Columbia Power Commission installed a 35,000 h.p. unit at Campbell River, with a second unit due for 1957 operation. A 42,000 h.p. unit will come into production this year at the outlet of Upper Campbell Lake. A 35,000 h.p. development near Alberni is scheduled for completion in 1959. A third 16,500 h.p. turbine will be installed at Whatshan this year. Thirteen 3,000 kw. gas-diesel generating units will be installed this year at Quesnel, Dawson Creek and Prince George, as well as two 19,750 kw. units for a 100,000 h.p. gas turbine generating station at Chemainus.

The British Columbia Electric Co. completed its Seton Creek plant with installation of a 58,500 h.p. unit. At Lajoie dam a 30,000 h.p. unit will be completed in 1957. On the Bridge River No. 2 development four 80,000 h.p. units will be installed, the first three in 1959 and the fourth in 1960. On the Cheakamus development two 95,000 h.p. units are scheduled for service this year. At Clowhom Falls a single 40,000 h.p. unit is scheduled for operation late this year; a gas turbine plant with four 33,500 h.p. turbines will be added to the system in 1958. Other current developments in B.C. and the Yukon included completion by the Powell River Co. of its project on the Upper Theodosia river, which increased firm power output by 2,000 kw. Two 7,500 h.p. units are scheduled for 1958 installation at Whitehorse Rapids 1½ miles upstream from Whitehorse on the Yukon river, by the Northern Canada Power Commission. Northwest Power Industries had nearly completed surveys for design of an initial 800,000 h.p. development on the proposed Yukon-

The 88,000 h.p. impulse type steam-turbine and generator of the Calgary Power Limited plant at Wabamun, Alta., uses natural gas as fuel.

Calgary Power Limited also started expansion to double output of the Cascade hydro-electric plant, near Banff. A 1845-ft. wood stave pipeline leads to the surge tank.

Atlin-Taku project, while surveys continued on the Nass river with a view to reaching the design stage late in 1956.

Alberta — Calgary Power Limited brought into operation its 66,000 kw. steam turbine plant at Wabamun, west of Edmonton, in 1956. A second unit will be in operation in 1958. At present fuelled by waste natural gas the plant is convertible to use of coal. The company is adding a second 23,000 h.p. unit to its Cascades plant, for completion this year. Investigations are also under way for adding 85,000 h.p. to its Spray and Rundle plants, doubling their present capacity.

Northland Utilities installed a 1,000 h.p. turbine at Jasper, while at the Fairview steam turbine plant another 3,000 kw. unit will come into operation in 1957. Canadian Utilities Ltd. brought into operation their Forestburg steam turbine plant with one 30,000 kw. turbine fuelled by strip-mine coal. The city of Edmonton will bring into operation two 30,000 kw. gas turbine units, one each in 1958 and 1959. City of Lethbridge will have another 10,000 kw. gas turbine in operation in 1957.

Saskatchewan — Saskatchewan depends entirely on thermal engines for power production. During the year a 33,000 kw. unit was added to its Saskatoon plant, a 6,000 kw. unit to its Swift Current plant and a 3,000 kw. unit to its plant at Kindersley. The Churchill River Power Co. is actively considering addition of a 19,000 h.p. turbine as a standby unit for its Island Falls hydro electric plant. The project is now in the design stage.

Manitoba — The Manitoba Hydro-Electric Board is building a steam turbine generating station at Brandon and will bring the first two 30,000 kw. generator units into operation late in 1957. A site at East Selkirk has been acquired for a new steam generating station with initial operation of two 66,000 kw. units by the fall of 1959. Interconnection of the southern Manitoba and northwestern Ontario distribution systems was effected in October 1956 to permit transfer of power.

The Board is planning a $30 million hydro development on the Nelson River at Grand Rapid to supply power for International Nickel's Moak and Mystery Lakes mining development located some 50 miles west of the power site. The plant will contain four or five 37,500 h.p. units with provision for three additional units. An early start on construction is contemplated.

The City of Winnipeg is continuing with renovation of its Pointe du Bois hydro electric station on the Winnipeg River.

Sherritt Gordon Mines, Ltd. is at present constructing its No. 2 development on the Laurie River, with one 7,000 h.p. unit to go into operation in October, 1957.

Grand Rapid, on the Nelson River in northern Manitoba, is the site of a new power plant for Manitoba Hydro-Electric Board which will supply power for International Nickel Company's Moak Lake development. (*Manitoba Govt. Photo*)

Ontario — The Ontario Hydro-Electric Power Commission, as responsible agent for developing the Canadian half of the 1,200,000 h.p. to be made available from the International Rapids section of the St. Lawrence seaway and power project, had made good progress and work was reported to be "on schedule" at the end of the year. Initial operation is scheduled for 1958, with all units to be in operation by 1960.

The addition of the final four units in the main plant of the Sir Adam Beck-Niagara Generating Station No. 2 was actively under way. At the pumped-storage generating station half a mile up the power canal six reversible pump turbines are being installed. When acting as turbines each unit will have a capacity of 47,000 h.p.

Ontario Hydro also has four projects in northwestern Ontario. At Manitou Falls on the English river four 18,500 h.p. units were brought into operation in July 1956. At Caribou Falls on the same river construction was commenced on a 102,00[illegible] h.p. development to contain three 34,000 h.p. units for operation in 1958.

At Whitedog Falls on the Winnipeg River 30 miles northwest of Kenora, preliminary work was started on an 81,000 h.p. development in three units, with initial operation scheduled for late 1957. In addition to these three projects, it is planned to add for 1958 operation a new 19,000 h.p. unit at Alexander Fall[illegible] and one of 25,000 h.p. at Cameron Falls, both plants being on the Nipigon river.

The Great Lakes Power Co., Ltd. is installing for early 1957 operation a new 30,000 h.p. unit in its Upp[illegible] Falls plant. Raising of the dam a[illegible] the site in 1956 had added 1,90[illegible] h.p. for two existing units. Activ[illegible] work will also be under way thi[illegible] year on a new plant at Centre Fall[illegible] where a 28,000 h.p. unit is sched[illegible]uled for 1958 operation. In easter[illegible] Ontario, the Gananoque Electri[illegible] Light and Water Supply Co. is in[illegible]stalling an additional 1,500 h.p. un[illegible] at its Jones Falls plant on the Ridea[illegible] Canal, for completion this year.

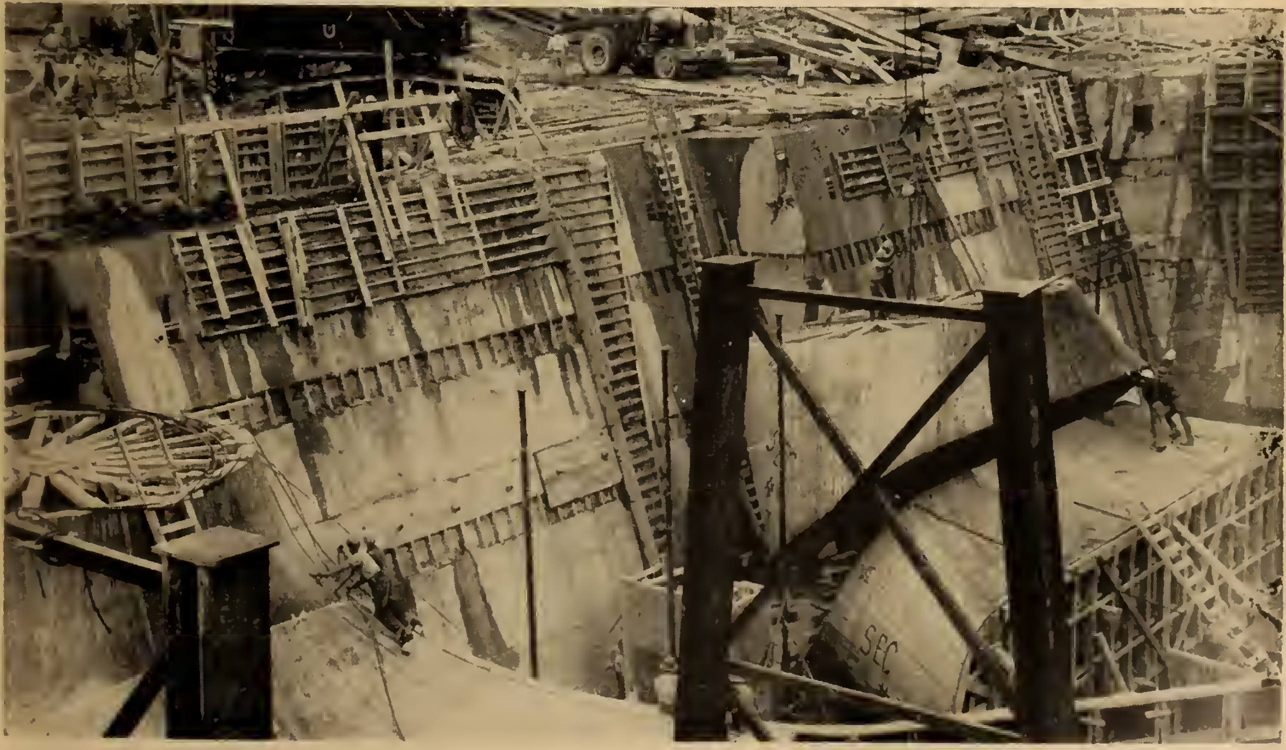
Thermal Stations — In collabor[illegible]tion with Atomic Energy of Canad[illegible] Limited, and the Canadian Gener[illegible] Electric Co., Limited, the Commi[illegible]sion is proceeding with constructi[illegible]

HYDRO ELECTRIC POWER

The underground tailrace chamber of the Bersimis power development is shown at the right. *(Photo: Hydro-Québec)*

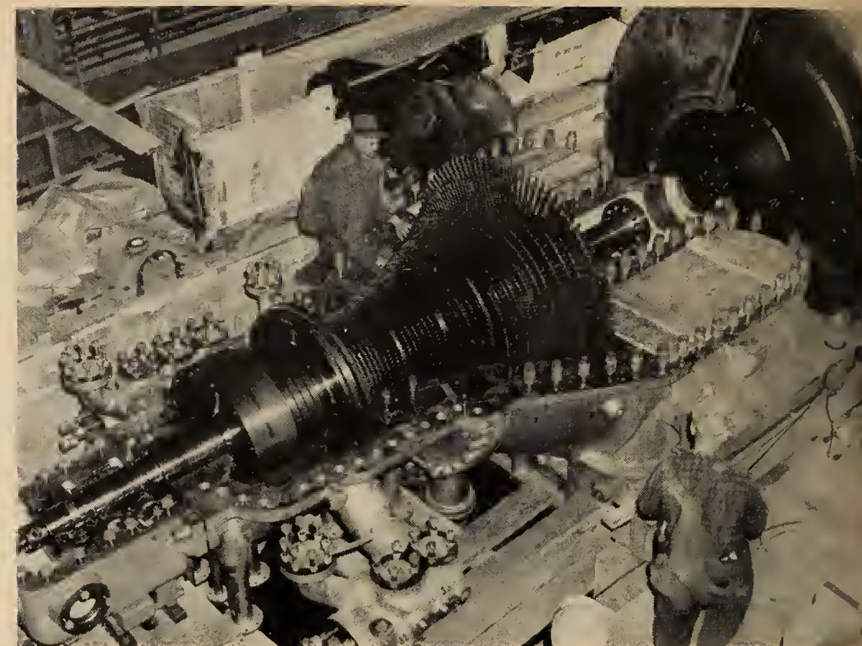
Excavation for the 1300-ft. by-pass channel at the Rapide Beaumont development of Shawinigan Water and Power Company (centre, left). Upstream from the powerhouse site, work proceeds on a new railway bridge, part of a nine-mile diversion of the main C.N.R. line (centre, right).

Lowering a section of the draught tube frames at the New Brunswick Electric Power Commission's Beechwood hydro-electric power development on the St. John River, 100 miles N. of Fredericton.



of a 20,000 kw. nuclear power experimental plant at a site adjacent to its Des Joachims' generating station on the Ottawa River. Initial generation of electrical energy is scheduled for 1959.

At the Richard L. Hearn generating station at Toronto, addition of a 200,000 kw. unit has been authorized for 1958 operation. Present expectations are that two similar additional units will be required during the next five or six years, bringing total station capacity to 1 million kw. Establishment of other thermal electric stations at centres of heavy loads elsewhere in the province is also being considered.



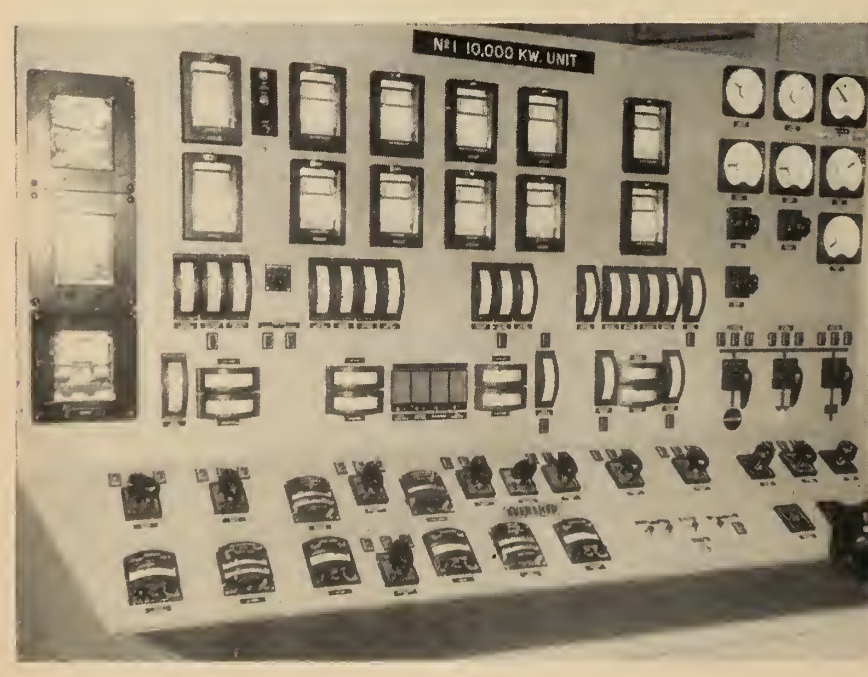
Quebec — Hydro-Québec brought the first three 150,000 h.p. units into production at its Bersimis No. 1 plant late in 1956. At Bersimis No. 2, some 23 miles downstream, preliminary construction was well under way at year end. This station will develop 835,000 h.p. in five units, bringing total installed capacity of the two Bersimis projects to 1,250,000 h.p.

At Beauharnois, enlargement of the intake canal by dredging was continued, and preliminary construction was commenced on the third and final section of the powerhouse comprising 11 units each of 65,000 h.p. It is expected initial operation will begin late in 1958, with completion of the plant scheduled for 1960 bringing the whole development to a total installed capacity of 2,150,000 h.p.

At its Rapide II plant on the Ottawa river a third 16,000 h.p. unit was added in 1956, with provision made for a fourth unit. Studies and surveys are proceeding towards development of the Lachine Rapids, while work is well advanced on a storage dam on a tributary of the Manicouagan river to allow a higher firm output from the plant of the Manicouagan Power Co.

The Gatineau Power Co. added another 47,000 h.p. unit to its Paugan Falls plant in 1956. Manicouagan Power Co. commenced work on its McCormick Dam Project No. 2, where three 60,000 h.p. units will be installed, one of them in 1957 and the other two early in 1958. The town of Parent, Que. installed a 1,300 h.p. unit in the first stage of a development on the Bazin river.

Other developments underway include Shawinigan Water and Power Co.'s 330,000 h.p. development at Rapide Beaumont with six 55,000 h.p. units, where initial development is scheduled for late 1958; Aluminum Company of Canada's 292,000 h.p. Chute des Passes project on the Peribonka river, where the first unit will operate late in 1957 and the balance in 1958; Price Brothers Co.'s 78,000 h.p. Shipshaw River plant, due for operation in October 1957; and Eastern Smelting and Refining Co.'s 42,000 h.p. plant on the Chicoutimi river which will be producing energy in June 1957.



Maritime Provinces — The New Brunswick Power Commission added a new 22,500 kw. unit to its Chatham steam station. Work continued at its Beechwood project on the Saint John river, where the first two 45,000 h.p. units will go into operation late in 1957 with provision for a third similar unit.

The Nova Scotia Light and Power Co. is expanding its Halifax steam plant, with one 45,000 kw. unit scheduled for operation this year and another similar unit to be added in 1959. The company is considering adding 5,000 h.p. to its Hemlock Falls plant for operation late in 1958. Replacements at this site last year added 2,250 h.p. Also under study is development of 4,000 h.p. on the Nictaux at Alpena.

In Newfoundland, Union Electric Light and Power Co. brought a

2,000 h.p. unit into production on the Trinity river last year. A second similar unit is under active prospect. United Towns Electric completed installation of a 5,600 h.p. unit at its New Chelsea development. The Maritime Mining Corporation will install 500 h.p. at its new Green Bay plant this year. Another 850 h.p. plant at Snook's Arm is under construction.

Bowater Power Co. Ltd. is constructing for operation in 1957, a plant on the Cornerbrook river with two 6,000 h.p. units. The company is also building a 6,600 kw. 50-cycle steam plant at Cornerbrook as a standby. The Newfoundland Light and Power Company Ltd. completed in 1956 the installation of an additional 10,000 kw. unit in its steam plant at St. John's. This company has under active prospect the construction of two plants at Rattling Brook near Norris Arm; the first rated at 13,000 h.p. and the second rated at 3,100 h.p.

In Labrador, the British Newfoundland Corporation completed investigations on the Hamilton river, which proved development of the power site at Grand Falls, one of the largest undeveloped sources of power in the world, is feasible.

Many Large Undertakings Under Way

Though space does not permit a detailed account of work carried out during 1956 on all of the many hydroelectric plants under construction, progress to date on some of the largest projects at present under construction is typical.

Beechwood — Construction of the New Brunswick Electric Power Commission's 90,000 h.p. development on the Saint John river got under way in the spring of 1955 following a two-year study of the power potential of the river basin by the International Joint Commission. By March last year eight of the dam's 11 piers had been completed with cofferdams removed to pass the spring floods. At year's end work on the main dam, powerhouse and other phases, was well ahead of schedule. Operation of the first two 45,000 h.p. units is scheduled for December this year, with provision for a third similar unit. The work is being done by contract, at an estimated cost of some $30 million.

Bersimis — On 16 Oct., 1956, the first commercial load of 50,000 kw. from Hydro-Québec Bersimis No. 1 plant at Labrieville, Quebec, was transmitted over the Commission's 300,000-volt power line to Charlesbourg, Quebec. By year end, three of the 150,000 h.p. units were in

THERMAL POWER

Installing the rotor in the New Brunswick Electric Power Commission's new 22,000 kw. unit at the Chatham generating station. (Top of p. 580.)

The first steam generating plant of the Newfoundland Light and Power Company Limited was a 10,000 kw. unit installed in 1956 at St. John's. An unusual feature is a new electronic system of boiler control, for which the control panel is shown (bottom, p. 580).

Steam plant of the Nova Scotia Power Commission at Trenton, in Pictou County, N.S., for which a new 20,000 kw. turbo-generator unit has been authorized. (Right, above.)

The Richard L. Hearn station of the Hydro-Electric Power Commission of Ontario (right) is the largest thermal station in the country, at present.

service. Commencing with preliminary construction in June 1952, Hydro-Québec had thus brought into operation one of the largest power plants in Canada within four years and four months.

The work involved a main dam half a mile long and 200 ft. high; another dam quarter of a mile in length; a diversion tunnel 1,000 ft. long, 39 ft. high and 36 ft. wide through rock; a concrete-lined main tunnel 32 ft. wide and 26 ft. high, 7½ miles in length; a surge tank 84 ft. in diameter, 680 ft. in height; eight 10 ft. diameter lined penstocks 385 ft. long; and an underground powerhouse cut out of solid rock, 565 ft. long, 65 ft. wide and 80 ft. high to contain eight 150,000 h.p. units.

In addition, a 300,000 volt transmission line comprising two double circuits to Charlesbourg and one double circuit from there to Montreal, and 400 miles long, was built to connect with the huge eastern interconnecting power pool at these points.

Three of the largest transformers yet installed in Canada, each weighing over 4 tons with oil, were placed in service at the Charlesbourg end. Electrical equipment also included the world's largest installation of 330 kv. disconnect switches, and the longest private commercial microwave communication system in Canada, linking Bersimis plants numbers 1 and 2, Forestville, Charlesbourg, and Montreal. Of the remaining five units, three will probably go into service this year with two to follow in 1958.

Manicouagan — Last November the Canadian British Aluminium Company Limited commenced construction of an aluminum smelter development at Baie Comeau, Que. The first stage of this four-stage $200 million project will be completed late in 1957, with the second stage going into operation by the end of 1958. The company is 60% owned by British Aluminum Co. and 40% owned by Quebec North Shore Paper Co. The new company also has a 40% interest in the Manicouagan Power Co., which will supply most of the hydro electric power to operate the smelter.

Manicouagan Power Company's output will be increased from its present 100,000 h.p. capacity to 250,000 h.p. at a cost of some $14 million. This involves an extension to its existing station at First Falls, the new undertaking being designated McCormick Dam Project No. 2. Plans call for installation of three additional units of 60,000 h.p. each. The present 69 kv. switching station is being extended and a new 161 kv. transmission line 10 miles long will be built to the smelter site.

Chute des Passes — The Aluminum Company of Canada began preliminary construction early last fall of a new hydro-electric development on the upper Peribonka river at Chute des Passes, about six miles downstream from the Passe Dangereuse Dam. The plant will take water frim the Passe Dangereuse reservoir through a tunnel about seven miles long, developing a gross head of 636 feet. Here an underground generating station will contain five 200,000 h.p. units, operating under a 625-foot head, the largest turbines yet installed in Canada.

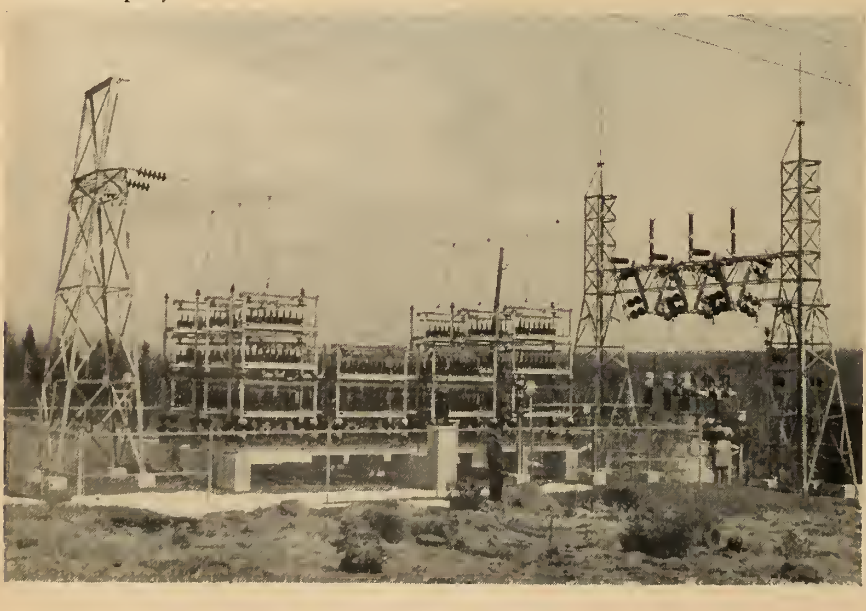
This project will add 700,000 firm h.p. to the Saguenay system as a whole, and will reduce chances of recurring power shortages. Initial operation is scheduled for 1959, with completion of the 1,000,000 h.p. development in 1960. A contract has been awarded to a joint venture group of contractors at a price of $135 million.

Beaumont-Shawinigan Water and Power Company made good progress at year end on construction of their Beaumont generating station upstream from La Tuque. Construction of camps, offices and living quarters was completed and some 450 families were living at the site, out of a total on-site force of some 1,200-1,400 men. All construction plant, including mining plant had been installed.

Work was proceeding on excavation of half a million yards of rock for the by-pass channel, and on cofferdams. Temporary diversion of the river flow will be undertaken early in the spring. The powerhouse will be of the semi-outdoor type, and will contain six 55,000 h.p. turbines operating under a 125-ft. head and driving 45,000 kva. generators. Initial operation is planned for the fall of 1958. An 87-mile 220-volt power line will be built to the Trois Rivières terminal station. Cost of the project including the transmission line is estimated at $56 million.

A 10-mile access road had been built from a new siding at Fitzpatrick.

A 9,000 k.var. 60,000 v. capacitor at Disraeli substation of Shawinigan Water and Power Company.



St. Lawrence Power Project — At year's end, work on the International Powerhouse had reached between 40 and 50% of completion. Progress on the two halves had been about equal at midsummer, but by year end the American half had forged ahead, reaching about 50% of completion with 450,000 yards of concrete placed, while the Canadian half stood at 38/40 per cent of completion. The Canadian half will catch up during the winter months while work on the American half is closed down. Installation of bedded parts for the turbines was under way on the Canadian half.

The first stage of the Long Sault dam was completed except for rollways and the entire flow of the river was gradually being diverted through the openings in the dam

)VER AND UNDER

'wo of the transmission lines of the ;ritish Columbia Electric Company Limi- ed span water by different means. \bove, the line to the Powell River de- elopment crosses Jervis Inlet, a span of 0,100 feet. Barges are carrying the able over to Nelson Island, up which an be seen the right-of-way for the line. 'he lower view shows a scow bringing a 32,000-volt cable from the cable ship)*cean Layer* to the shore of Galiano sland in the Strait of Georgia, part of he link between Vancouver Island and he B.C. mainland.

\hile the earth plug across Cut F ıpstream, already loosened by blast- ıg, became eroded as the rock fill cross the head of Long Sault rapids vas built up, diverting the flow and lrying the rapids.

The first stage of the Iroquois)am 25 miles upstream was com- ›leted except for rollways and al- ıost the entire river flow was pass- ıg through it as cofferdam cells ·ere rapidly closing off the Cana- ian half of the river.

Dredging for channel improvement ı the International Rapids and Thou- and Islands sections had been pro- eeding steadily and work on con- racts had passed the halfway mark nd were mostly on schedule. Clear- ıg on the islands was about 25% one. Tracklaying on the 40-mile NR main line diversion was com- lete and 75% of the ballasting done. ehabilitation of the Canadian area › be flooded was progressing rapid- / at the two new town sites.

Completion of all the heavy work \ the end of this year is forecast, ith flooding of the headpond heduled for midsummer of 1958 nd delivery of the first power ex- ected by September of the same ear. The channels and locks will be pen for the passage of ships in me for the opening of the 1959 avigation season.

Sir Adam Beck Generating Station o. 2 — This $344 million project, econd largest ever undertaken by)ntario Hydro and one of the orld's greatest, is now in the final ages. Currently in progress are the ddition of the final four 105,000 p. units, one scheduled for service te 1957, the other three in 1958.

At the pumped-storage generating ation, associated with the No. 2 ation and located half a mile up- ream on the power canal, six re- ersible pump-turbines are being in- alled. It is to make full use of the additional water provided by the pumped storage scheme that the aforementioned four units are being added in the No. 2 station.

An artificial lake or reservoir about two miles long and a mile wide will fill up during the night and off peak periods. In daytime when flow over the falls has to be increased, the compounded water is reversed through the pump turbine plant. Work was started in 1955.

At year end the reservoir dyke had been completed and concrete work was finished in the headworks and tailrace areas and for the first two units. When acting as turbines each unit will have a capacity of 47,000 h.p. under full reservoir head of 85 feet. Unit No. 1 will be in operation early this year and the other five each at intervals of about two months. The station is of the semi-outdoor type.

B.C. Electric's Bridge River System — The Seton Creek plant near Lilloet was completed last year with installation of one 58,500 h.p. unit under a 147-ft. head. At the La Joie Dam, construction is under way with one 30,000 h.p. unit scheduled to operate late in 1957. Work has commenced on the Bridge River No. 2 development involving a storage dam on the Bridge River, a second tunnel through Mission Mountain and a new powerhouse on Seton Lake about half a mile upstream from the existing plant. Here four units of 80,000 h.p. each will be installed for operation in 1959/1960.

Water for the La Joie reservoir will generate power at three different sites within the Bridge River system; at the La Joie plant, then at the Bridge River No. 1 or No. 2 plants and finally at the Seton Creek plant.

ATOMIC ENERGY

Any consideration of current developments in power production would be incomplete without noting briefly the important advances being made in the field of atomic energy. Its future use has been the subject of a vast amount of research by Canadian scientists, principally through the use of reactors at Chalk River.

This research is now taking concrete form for the first time in Canada on the upper Ottawa river where construction of a 20,000 kw. atomic power plant is under way by the Ontario Hydro, Atomic Energy of Canada Ltd., and Canadian General Electric Co. By means of this experimental undertaking known as N.P.D. (Nuclear Power Demonstration) it is hoped to prove the economic feasibility of nuclear plants, to obtain data on the economics of nuclear power production and to gain experience and train personnel for larger units in the future.

With the threefold increase in the demand for electrical energy predicted by 1975, inevitably a considerable number of additional installations will be in the form of thermal power and a growing proportion of these will be atomic.
