Comparative data on mass transfer rates are limited. Preliminary data[6] for a liquid-solid system in which limestone particles were contacted with very dilute hydrochloric acid show that the mass transfer rates were slightly less in the spouted bed than in either the fluidized or fixed bed. This decrease is probably due to the fact that the fluid passing through the spout by-passed the bed. Thus, these heat and mass transfer data show that where a bed material will fluidize satisfactorily, there appears to be no advantage in spouting over fluidizing.

Spouting of Cellulose Acetate

The main application for spouting is, however, in the upper range of particle size where fluidizing is unsatisfactory. For example, large particles of cellulose acetate or wood chips cannot be fluidized, but can be agitated satisfactorily by the spouted bed technique. Preliminary experiments have been made with these materials with the object of developing a spouted bed type dryer. The results obtained illustrate some of the limitations as well as the possibilities in the method.

The cellulose acetate consisted of matted fibrous particles in sizes up to one inch in the largest dimension. The particle size distribution is given in Figure 5. The material as received was damp, but since it was proposed to dry it to 30% moisture (on a dry basis), it was air dried to this level of moisture in order to carry out exploratory experiments on its spouting behaviour.

The column used in these experiments was a 2-ft. dia. semi-circular column, fitted with a plexiglass front so that spouting behaviour could be observed. Figure 4 shows the unit containing cellulose acetate.

It was found that, when suitable orifice size had been selected, this

material could be spouted in bed depths up to 8 ft. The air rates required are given in Table I for two different orifice diameters at several different bed depths. These experimental values are about 1.6 times the air rate predicted from formula (1). The discrepancy is probably due to the fact that the particle size, distribution and, particularly, surface roughness are substantially outside the range of data for which formula (1) applies.

At these air rates the inlet orifice velocities were high, and consequently attrition effects were large. The result was a reduction in bed particle size, as well as an increased dust load. The change in particle size distribution is apparent from the data plotted on Figure 5 where size distribution curves are given for the initial bed, and for the bed after one hour of spouting. These data were obtained with an air flow of 268 c.f.m. through a 2-inch dia. semi-circular orifice. The material removed by the cyclone during the one hour test was about 9.5% of the initial bed weight. In this particular case the carry-over and particle disintegration were too high to warrant further drying experiments.

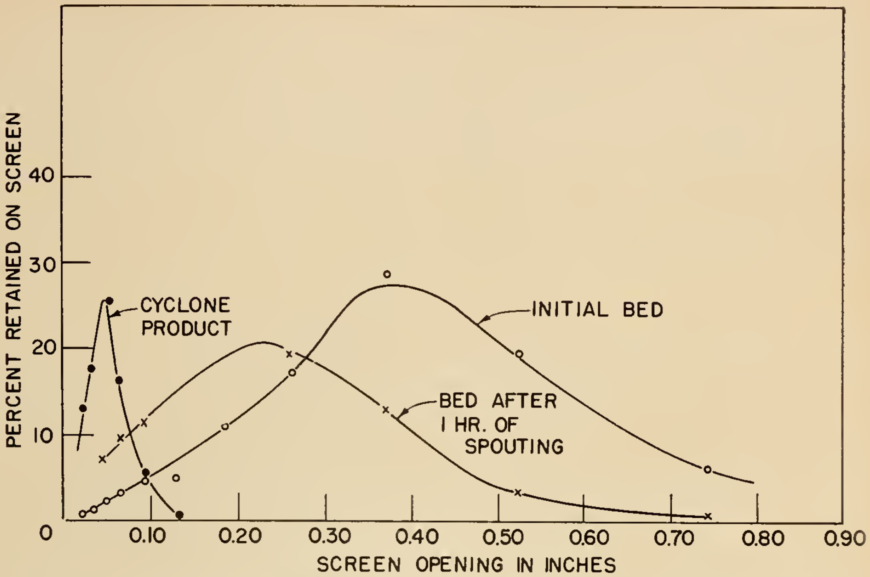

Fig. 5. Size distribution of cellulose acetate before and after one hour of spouting.

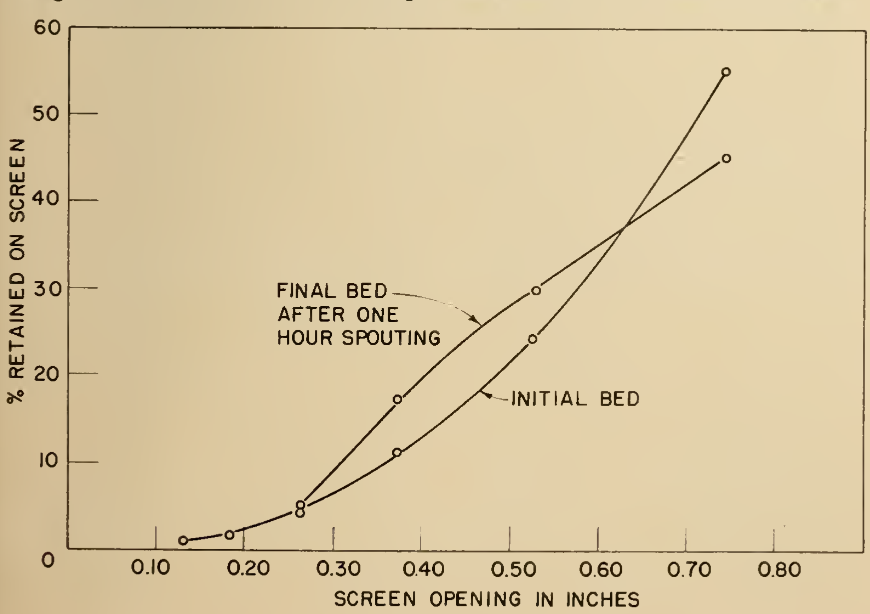
Spouting of Wood Chips

The exploratory experiments on the spouting of wood chips yielded more promising results. As in the case of cellulose acetate, the initial runs were made to establish conditions for spouting as well as the magnitude of the attrition effects. The 2-ft. dia. semi-circular column previously used for cellulose acetate was employed, though modifications in cone angle and orifice size were made in order to improve spouting behaviour. Run-of-the-mill chips were sampled by passing through a 1-in. slotted sifter. Slivers and chips longer than 4 in. were rejected. The size distribution of the initial bed is shown in Figure 6. The chips were generally flat in shape, the larger ones being about 1¼ in. x 1 in. x ¼ in. Again, after several trial runs, satisfactory spouting up to bed depths of 6 ft. were obtained in the 2-ft. semi-circular column.

The results of one attrition test are shown in Figure 6. The particle size distribution after one hour of spouting is compared with the distribution of the initial bed. Some reduction in particle size did occur. Fine material was recovered in a cyclone and at the end of one hour the net increase in minus 8 mesh material amounted to 2.3% of the bed weight. These data were obtained with an air flow of 783 c.f.m., using a 4-in. semi-circular orifice and an initial bed height of 4 ft. in the 2-ft. diam semi-circular column.

Fig. 6. Size distribution of wood chips before and after one hour of spouting.



Drying of Wood Chips

The initial experiments established that wood chips could be spouted without severe particle disintegration and so drying runs were undertaken with the object of estimating drying capacity and thermal efficiency. Details of drying runs have been described fully elsewhere[1] and, therefore, only a summary need be given here.

The drying runs were done in a one-foot diam. 7-ft. high column. The inlet air was heated by burning propane in the air stream up to a temperature of 1100°F. The feed was minus ⅜ in. screened wood chips. This size had to be used because run-of-the-mill chips could not be spouted in the one-ft. diam. column available for the drying tests. The initial water content was about 150% based on bone dry material (D.B.), and the final water content desired was 50% moisture (D.B.).

Data from a few typical runs are given in Table II. In each of these runs a few chips were charred, but the main bed was undamaged as far as a visual examination could ascertain. The charred chips were caused by lodging in the orifice, and a re-examination of the orifice indicated that this difficulty might, in fact, be fully overcome by careful design.

Examination of the data shows that the chips were dried from 150% to 50% moisture (D.B.) using retention times in the range of 2 to 5 minutes. High drying rates were obtained. The water evaporated was from 100 to 175 lb/hr/sq. ft., or on a volume basis 15 to 25 lb/hr/cu. ft. The corresponding figures for a rotary drier are given by Lapple and Clark[3] as 0.2 to 10 lb/hr/sq. ft. or 3 lb/hr/cu. ft. The fraction of the available heat which actually evaporated water, designated here as thermal efficiency, was only 52%. This is appreciably lower than the 65% figure previously obtained by Mathur and Gishler[5] in a spouted bed wheat drier. It is believed, however, that this efficiency would have been improved if much deeper beds could have been used. It has been estimated[1] that a 2-ft. diameter spouter with a 6-ft. depth of bed could be used to dry about a ton per hr. of run-of-the-mill chips from 150% moisture to 50% moisture (D.B.). Inlet and outlet air temperatures as given in run A were assumed in this calculation. These experiments terminated the work with wood chips but obviously more is required on scaling up factors before a commercial-size drier could be built.

The main attempt thus far in utilizing the spouted bed technique has been in drying of large particles which do not fluidize well. Its use in other chemical processing operations has not been investigated as yet, though it is being tried in a new clay activation process under study in our laboratories[7]. Thus, the spouted bed technique remains at the moment an interesting and potentially useful contacting method which has not yet gone beyond the laboratory level. It needs further development work in larger units before its commercial value can be reliably assessed.

The Altitude Test Facility at Orenda Engines Limited

(Continued from page 59)

separate functions and, to ensure easy communication, a suitably sound-treated common control room is provided. The room is air-conditioned to avoid the errors in instrument readings and the damage to expensive equipment that would result from fluctuating temperatures and excessive humidity.

On one side of the room, the engine monitoring and data display instrumentation surrounds the control console, a vantage point from which the operator can view the test cell through an observation window. On the opposite side of the room a large panel graphically displays the entire process air system and depicts the flow circuit in operation and the state of valves and the other equipment by the illumination of lamps at each of the control points. Consoles containing switchgear, amplifiers, and controls for all aspects of the process air system face the graphic panel, and a warning system will indicate irregular operation wherever it may occur. Safety interlocks are provided to ensure that operation cannot possibly commence without valves and controls being correctly positioned for the selected flow circuit, and so that the possibility of damage due to operators errors in other respects is minimized.

Explosion and Fire Protection

The possibility of fire or even explosion cannot be ruled out when a building of this nature is being designed. As is the case with so many test establishments in which volatile fuels are used, leaky fuel lines or engine components make possible the introduction of combustible contaminants into the air and, if present in a favourable air/fuel mixture ratio, these gases could conceivably ignite at the next engine light up. The possibility of engine or afterburner false starts or flameouts introduces another means whereby combustible fluids may become introduced into the atmosphere, and therefore to protect the facility, personnel, and test engine from hazards such as these, the following remedial measures were taken.

The first consists of a means of continually sampling the atmosphere in the explosive regions to detect a critical air-fuel ratio and the second provides for relief of the damaging pressures that would occur after an explosion has been initiated. Explosion pressures are relieved by venting the entire region to atmosphere, in a sufficiently short time, through an adequate total area of explosion ports. In such a system two factors are of fundamental importance: the condition of explosion must be detected before it reaches unmanageable proportions and the relief vents must be opened extremely rapidly. The method to be used can take one of two forms, either relief by bursting a diaphragm set to fail at a pre-determined pressure that is just in excess of the maximum to be anticipated under normal operating conditions; or the release of the vents by explosive bolts or detonators fired by an electrical signal from a detector sensing pressure level or rate of pressure rise.

The possible collection of fuel in the engine bay and the gas cooler also presents a considerable fire hazard and, although control can be exercised by the injection of CO_2, sufficient notice of the commencement of a fire cannot be guaranteed when the only means of vision is through windows in the side of the closed vessel. To overcome this difficulty, temperature sensitive co-axial cable will be laid in critical regions and a warning signal transmitted to the control room should the temperature exceed the maximum to be expected from normal operation. Further, in the engine section of the test chamber, water spraying will be installed for washing through suitable drains any collection of fuel on the lower portion of the chamber wall.

Saskatchewan River Generating Station of Saskatchewan Power Corporation

R. R. Keith M.E.I.C.

Assistant General Manager in Charge of Operations, Saskatchewan Power Corporation

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., May 1957.

Paper received 9 September 1957

CONSTRUCTION WORK is in progress on the Saskatchewan Power Corporation's new Saskatchewan River generating station. Post World War II growth of electric load in Saskatchewan has been in the order of 20% per annum and this rate of growth is continuing and is expected to continue at the same rate for the next five to ten years at least. This rapid load growth requires continually expanding generation and transmission facilities and, about five years ago, reached proportions which would economically justify an integrated generation and transmission network throughout most of the settled area of the Province.

Figure 1 is an electrical transmission map of the Province, which shows only lines of 72 kv. and up, and includes 1957 construction. The entire area is, in addition, covered by an extensive network of 25 kv. and 34.5 kv. sub-transmission lines. It will be noted that the area covered is approximately three hundred and sixty miles by three hundred and fifty miles in extent; a major portion of this area being rather thinly populated. There are two distinct load centres within this area; one with the City of Saskatoon as its hub and the other with the City of Regina as its hub. Hydro-electric development within economical reach of these two load areas is confined to development of the Saskatchewan River system. The potential sites on this system which have so far been studied have not proven to be economically justified at this time as power projects only because of the high capital cost, low winter stream flows, and the relatively low cost of thermal fuels with which hydro-electric power must compete.

There are vast deposits of lignite coal in the southeast portion of the Province, and its use for thermal generation is only limited by cooling water supplies and the high cost of long distance transmission. This thermal fuel source can, to the limits of the cooling water which can be obtained, serve the southern load area with low cost electrical energy and, at the same time, feed certain quantities of energy into the northern load area, subject to the previously mentioned limitations. The northern load area which has the City of Saskatoon as its hub, does not have local deposits of coal close by, but does have abundant cooling water facilities afforded by the South Saskatchewan River, and is quite close to the oil and gas fields of Western Saskatchewan. Even if it were economically feasible to provide power to the northern area from the low cost fuel area in the south, the matter of continuity of service cannot be ignored. In other words, it would not be advisable to attempt to feed an area as large as this from only one source. This was a factor in the selection of the location for this station.

The paper describes the factors involved in planning and design of the Saskatchewan River generating station as part of an integrated generation and transmission network. Initial plans are for four 66-Mw. turbo-generators and four steam generating units.

The new station under discussion will be connected with a station of approximately the same size which is being constructed in the lignite coalfields in south-eastern Saskatchewan by a double circuit 138 kv. link by the year 1960, making it possible to base load the most economical station within the limits of transmission line and cooling water availability and use the Saskatchewan River station as a peaking plant.

This then, in general, is the background of the problem which confronted the engineers who were given the responsibility of designing the Saskatchewan River station.

Considering the above points, a search was begun for a site with the following characteristics:

1. Close to the centre of the northern load area.
2. Adequate cooling water available.
3. Close to rail trackage.
4. Readily accessible to economical fuel sources.
5. Adequate accommodation for construction and operating personnel without the necessity of building a "Company town".

Following the usual site surveys, foundation studies, and river channel investigations, a location was chosen on the north-west bank of the South Saskatchewan River just within the southwesterly limits of the City of Saskatoon. The site selected satisfies all the conditions established above. This location is adjacent to the main trans-continental Canadian National Railway line, an important factor in that all coal fuel must be transported by rail to the site. The site location is also within one mile of the terminal station of a gas transmission loop from the Coleville-Brock area and within one mile of a large oil refinery.

After selection of the site the next step in the design of a steam electric generating station is the choice of initial steam conditions. Primarily this is merely simple arithmetic involving weighing costs of fuel against the capital cost of the plant for different steam conditions. However, one must also base these calculations on not only the present and past fuel costs but those which may be expected over the life of the station. One must also give consideration to other types of generation such as hydraulic and even atomic energy, and their probable cost in the future. Taking all these factors into consideration, steam conditions of 850 p.s.i.g. and 900°F. were chosen for the first two units of this station. The station is being constructed on the unit system, that is, each boiler turbine unit with the necessary auxiliaries are independent and not connected with any other units in the station, so far as the steam cycle is concerned. Incidentally, here is represented one of the many advantages of the unit system in that the steam conditions for future units are quite flexible and no precedence in this regard, which could influence future decisions, is set.

Present plans envisage a generating station with a capacity of 264 Mw., in which will be installed four 66-Mw. turbo-generators and four steam generating units. The present construction is for one-half of the station, the other half to be proceeded with as load conditions may dictate. Provision is made in the design to accommodate future units of at least 100 Mw. if this proves to be desirable. The first unit is scheduled for commissioning in the spring of 1958 with the second following in the spring of 1959.

Before proceeding with the detailed design work on this station, certain studies were carried out and decisions reached with regard to the station which represented what might be called "departures from designs previously used by this Utility". These were as follows:

(a) Steam conditions of 850 p.s.i.g. and 900°F. employing a straight steam cycle without re-heat was decided upon as has been previously mentioned. A regenerative feed heating cycle employing five extractions from the turbine was selected.

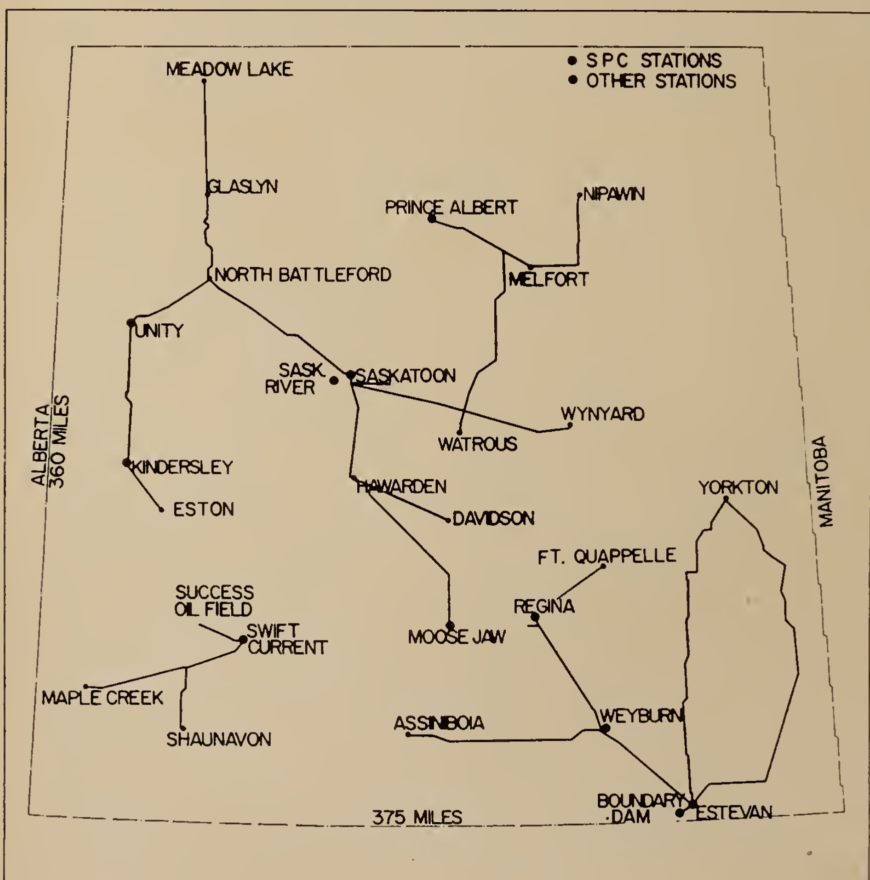
(b) In order to reduce the construction costs and arrive at what is thought to be a better operating and maintenance arrangement, it was decided to locate what is generally termed as "the basement floor elevation" at or near grade, with the operating floor 30 ft. above grade. With perhaps the exception of the turbo-alternator itself, a good deal of the heavy auxiliary equipment in a thermal station is located below the main boiler and turbine units in a basement, and the matter of access to this equipment directly from grade outside the building is important. This includes pulverizers, feed pumps, and other miscellaneous auxiliaries which are either maintained in place or, on occasion, removed from the building. All major auxiliaries such as pulverizers and feed pumps are accessible to a motor truck which can be driven into the plant on the lower floor. This type of building does have the disadvantage of adding some pumping head to the cooling water system since the condenser cannot be located near or at normal river level, but this can be overcome in part by using a syphon system.

(c) A somewhat non-conventional arrangement of the four units is planned in this station in that the four steam generating units will be arranged in a square pattern in the centre of the station with two turbine rooms each containing two units laying alongside, on each side of this square. The design provides a very compact arrangement from the standpoint of centralized control and will result in some saving in cost of the building and installation of equipment. The only increased cost of this arrangement appears to be the purchase of a second engine room crane. Figure 2 shows this arrangement in plan, and it can be noted that it results in an "H" shape building and that the draught equipment and stacks are located on each side of the plant between the two turbine room buildings protruding on each side and forming the legs of the "H". Figure 3 shows a cross section through the firing aisle facing the boilers. Figure 4 shows a cross section through the turbo-generator room looking toward the boiler room.

It will be noted that this arrangement is not expandable beyond four units. This may be considered a disadvantage, but other items such as coal-handling and cooling-water facilities normally limit any station to the expansion planned for initially. As more capacity is required in the area other plants will be constructed which will, no doubt, contain larger more efficient units.

(d) It was decided to attempt to reduce building costs by use of some form of semi-outdoor construction, and this feature has been adopted by exposing one side and the rear of each of the four boilers from engine room roof level to boiler top level. By this method, only the gaps between

Fig. 1. System map.



each boiler on all four sides of the boiler room have been closed in with insulated metal panels on building and boiler steelwork, leaving one side and the rear of each boiler exposed. A roof is added over the whole area. The boilers are designed so that an operator does not have to go outside during normal operation. All soot blowers are operated from the enclosed side of the boiler. Taking into consideration the increased cost of boiler installation, it is estimated that this method will reduce the cost of this station by five to six dollars per kilowatt of installed capacity. Figure 5 illustrates this type of construction.

(e) The matter of a centralized station and system control room required considerable study and since this location must also contain a dispatching headquarters for the northern system, it was decided to construct a separate building near the station in which all system control would be located, together with the station administrative offices. The station control room, therefore, is limited to control of boiler turbine units. Synchronizing and loading of the units is to be carried on from the system control room.

(f) In the matter of fuel handling, coal fuel, of course, requires the greatest amount of equipment and, consequently, a large expense. Facilities for handling of either natural gas or oil can readily be expanded, as the use of these fuels increases, at a minimum of expense and require relatively little space. The coal handling plant is costly and can occupy a considerable amount of space for storage and the necessary switching trackage. Since, in the foreseeable future, all three fuels, namely, natural gas, bunker oil, and coal will be available for use in the station in varying quantities at competitive prices, there appeared to be no other alternative but to design this station originally to use all three fuels.

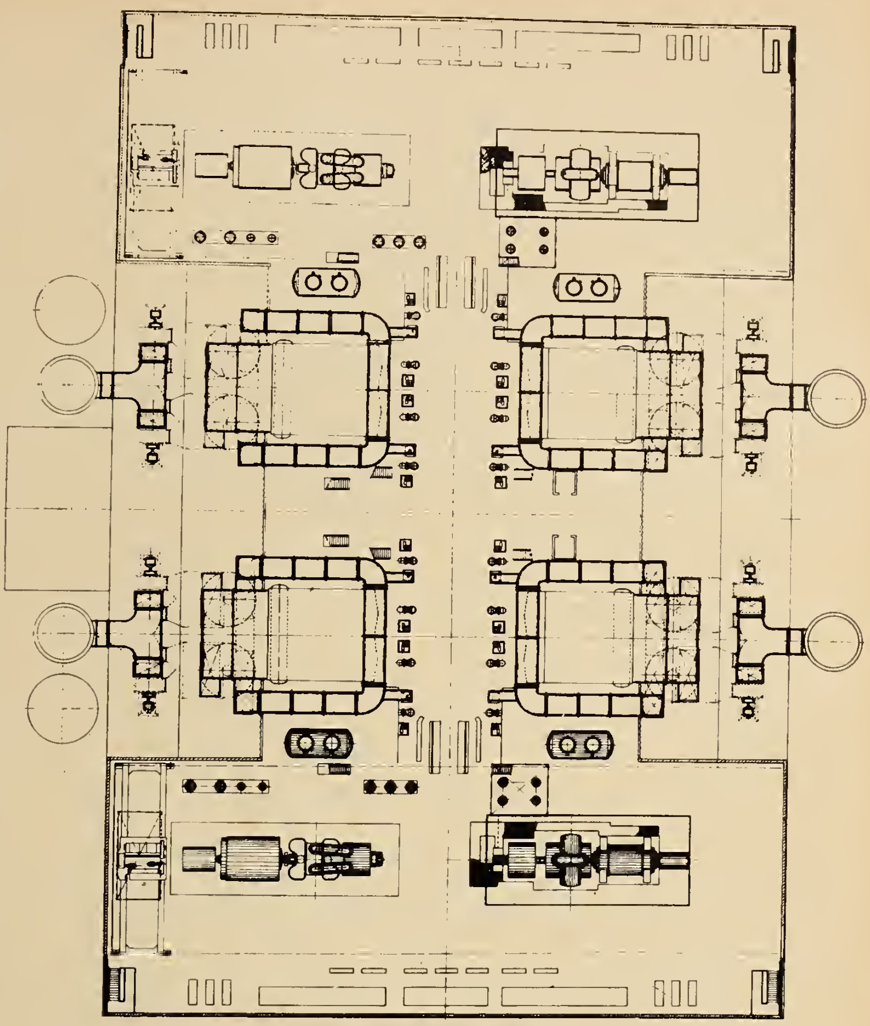


Fig. 2. Operating floor plan.

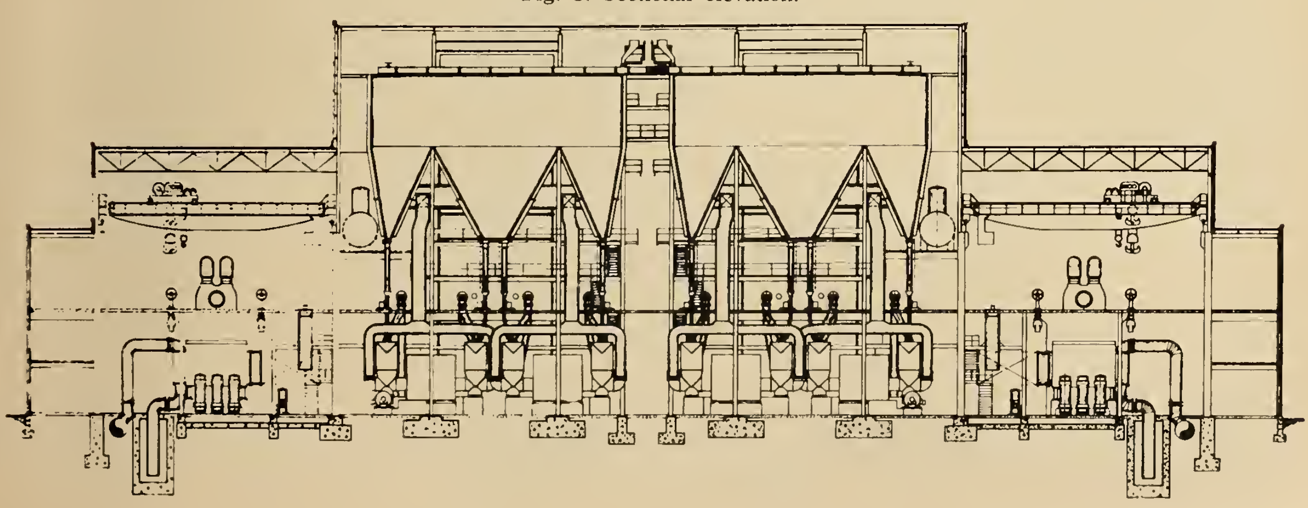
(g) In designing a unit station, the question of how far this unitization should go within the design and choosing of certain auxiliaries was given considerable study. From these studies, it was decided that the cooling water system would be unitized in two separate systems to serve a four-unit station. Each of the two cooling water systems will have three pumps to serve two units. Normally two pumps will be in service with

Fig. 3. Sectional elevation.



one standby. The coal handling system, of course, will serve all four of the station units.

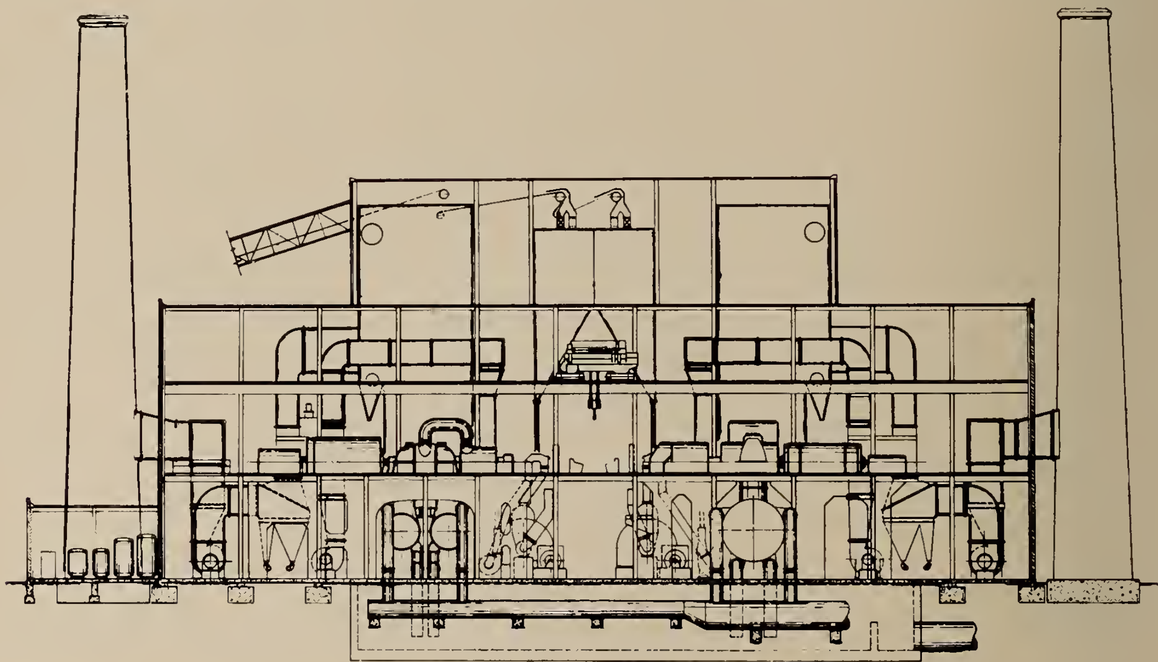
The foregoing decisions provided, in the main, the general terms of reference for the design of this station. Before going into detail as to the description of various pieces of equipment and their specifications, Figure 6, showing the general site layout, should be noted and will illustrate many of the features discussed in the foregoing.

Buildings

The power plant will be enclosed with a combination of Saskatchewan brick, which is light buff in colour, and insulated metal panels. The turbine rooms, electrical bays, and fan rooms will be of brick. The upper portion of the boiler room will have aluminum panels supported from the building and boiler steelwork. The chimneys are of buff-coloured radial brick which appeared to blend best with the Saskatchewan brick. The power plant will have ventilating fans arranged to supply filtered air to maintain the inside of the building at a slight positive pressure. The forced and induced draught fans are in an enclosed room, and air for the forced draught fans will be introduced separately so as not to interfere with ventilating boiler and turbine rooms.

The adminstration and control building contains the plant offices and system control room, as previously mentioned, and a large lecture room which can be used for training, safety meetings, conferences, and other purposes. This building is finished with a combination of brick, enamelled metal panels, and glass, and is completely air conditioned. There is an enclosed walkway connecting this building with the power plant. A tunnel under this walkway contains control and alarm circuits, and service piping. Located at the rear of the power plant are auxiliary buildings constructed of concrete block and metal panels, which serve as a diesel locomotive and tractor shed, and a stores and machine shop building.

The pumphouse building, above the concrete, will be of Saskatchewan brick to blend with the power plant.



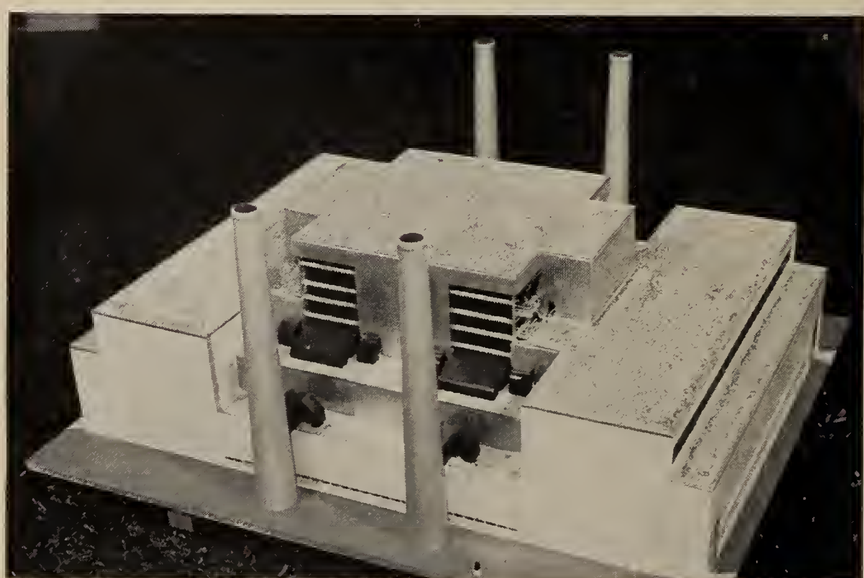


Fig. 4. Sectional elevation. Fig. 5 (below): Model of station.

Steam Generating Units

The steam generating units are designed for a continuous output of 600,000 pounds of steam per hour and 660,000 pounds per hour for four-hour peaks with steam at 870 p.s.i.g. and 910°F. total temperature at the superheater outlet. Figure 7 shows a sectional elevation of the steam generating unit. The boiler furnace is completely water cooled and has a water impounded type of ash hopper. The superheater is of the combined radiant convection type. The radiant section forms the front wall and roof of the furnace; the convection section being of the cross flow pendant type is located immediately behind a row of screen tubes in the upper part of the furnace. This type of combined radiant convection superheater has an inherently flat temperature/load curve. However, since steam temperature varies widely with the fuels to be used, additional steam temperature control equipment is required. This is provided in the form of a condenser located in the inlet header to the radiant superheater section. The final temperature is controlled by varying the quantity of boiler feed water passing through this condenser. Figure 8 is a schematic of the steam temperature control system. Each steam generating unit will have two induced draught and two forced draught fans. The ducts and dampers are arranged so that the unit may be operated at reduced load with one set of fans, one air heater, and one dust collector in service. The dust collectors are installed between the boiler and the air heater. Each unit is equipped with two pulverizers of the ball mill type suitable to handle coal crushed to ¾ in. minus. Two separately-driven exhausters per pulverizer each deliver fuel to two of the eight burners, which are suitable for burning pulverized coal, natural gas, or oil, or a combination of these fuels.

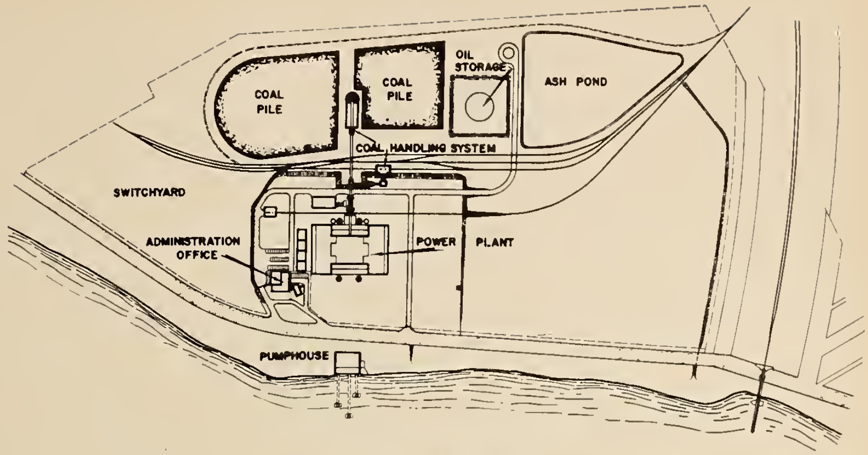

Fig. 6. Site layout.

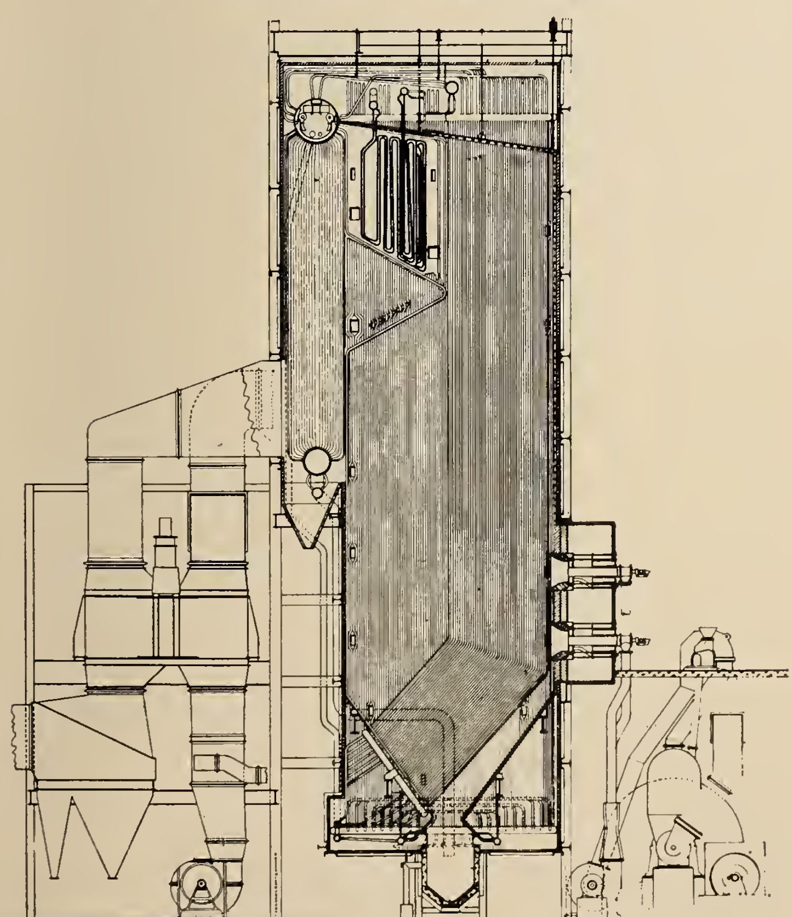
The table of Figure 9 outlines pertinent design data and the predicted performance of the units at 600,000 lb. per hr. when burning Forestburg coal.

Boiler No. 1 is to be equipped with two 100% capacity boiler feed pumps with totally enclosed water-cooled motors. In addition, a 50% capacity steam turbine driven feed pump is provided to facilitate feedwater regulation at very low loads during start up and shut down.

Boiler No. 2 is to be equipped with two 60% capacity motor driven boiler feed pumps. The turbine driven feed pump referred to above will be piped up so that it may also be used as standby for the motor driven pumps on No. 2 unit. Space has been left for the addition of a third 60% motor driven pump if this proves to be desirable.

All boiler feed pumps will be equipped with automatic thermal by-passes to prevent damage to any pump from over-heating at light loads.

Fig. 7. Sectional elevation through steam generator.



Turbo-Generators

Unit No. 1 is nominally a 66 Mw. unit but the turbine has a maximum capability of 75 Mw. The generator is capable of delivering 75 Mw. at 80% P.F. by increasing the hydrogen pressure from a normal 10 p.s.i.g. to 30 p.s.i.g. At the most economical rating of 50 Mw. the turbine water rate is 8.22 lb. per kwh. The turbine is a conventional two-cylinder single-shaft 3600-r.p.m. machine with five extraction points for feed water heating. The feed heating system consists of two low-pressure closed heaters, a deaerating heater, and two high-pressure closed heaters. The turbine blading consists of one velocity compounded impulse stage and 32 reaction stages, 20 of which are in the HP cylinder and 6 in each part of the double-flow LP cylinder. The turbine is direct-connected to the two-pole 3-phase 60-cycle, 14,400-volt generator. The exciter and pilot exciter are direct connected to the generator.

The condenser is a single shell type with two water passes and divided water boxes, which permit one-half of the condenser to be cleaned while the turbine remains in service at reduced load. It has 57,000 sq. ft. of heating surface and requires 60,000 g.p.m. of cooling water at 65°F. to maintain the design exhaust pressure of 1.2 in. Hg at 66 Mw.

Unit No. 2 is a 66 Mw. C.M.E.R. machine, that is, the most economical rating is equal to maximum continuous rating of 66 Mw. The generator is normally operated at a hydrogen pressure of 30 p.s.i.g. The turbine water rate is 8.43 lb. per kwh. at 66 Mw. Similar to No. 1, this turbine is a conventional two-cylinder single-shaft 3600-r.p.m. machine with five extraction points. However, the blading consists of one velocity compounded impulse stage and 18 pressure compounded impulse stages in the HP cylinder, and one impulse and 6 reaction stages in each part of the double-flow LP cylinder. The regenerative feed heating system consists of one closed LP heater, one open type deaerating heater, and three closed HP heaters. The turbine is direct-connected to the two-pole, 3-phase, 60-cycle, 14,400-volt generator, but the exciter and pilot exciter are geared to the generator shaft and operate at 1200 r.p.m. This unit is being designed to operate at low kw. loads and low loading power factor for power factor correction on the system.

The condenser is of the twin shell design with two water passes and a total heating surface of 48,000 sq. ft. It requires 36,000 g.p.m. of cooling water at 65°F. to maintain the design exhaust pressure of 1.5 in. Hg.

While there appears to be a vast difference in the surface and water requirements of the two condensers it should be remembered that No. 1 condenser must be capable of handling the steam flow at 75 Mw. The condenser for No. 2 machine was deliberately purchased smaller than the normal practice of this Utility in the past in the interests of economy of first cost and water pumping cost. It may be necessary to reduce load slightly when water temperature exceeds 75°F. This condition only occurs in years of abnormally high ambient air temperatures.

Instruments and Controls

Each half of the generating plant will have a control centre, located between the boiler and turbo-generator bays, on the operating floor, from which point two units will be operated. The control centre will not be totally enclosed but will have an acoustic ceiling over the area. Full automatic combustion control will be achieved on the steam generating unit when burning any one of the three fuels. When two fuels are burned simultaneously the predominant fuel will be on automatic control with the supplementary fuel on manual control. Safety interlocks are provided on fuel supply, igniters, and fans to ensure adequate purging prior to lighting off, and to limit the amount of fuel in the event of failure of any fan. Supervisory instruments will be installed at the turbo-generator for the use of the operator in starting up; these, however, will be duplicated at the control centre. The control centre panels will contain all indicating and recording meters and instruments required for plant operation and records. Control consoles will contain all switches and controls required for the operation of the plant, except for the hydrogen cooling system, which will have separate panels at each generator. An adjustable load limit control will be provided on the console so that the plant operator can limit the maximum load on the units in the event of trouble or unusual conditions. An alarm system will have the annunciator panel at the control centre. Continuous communication will be provided between the station control centre and the system control room, and a telephone intercom system will connect all parts of the station.

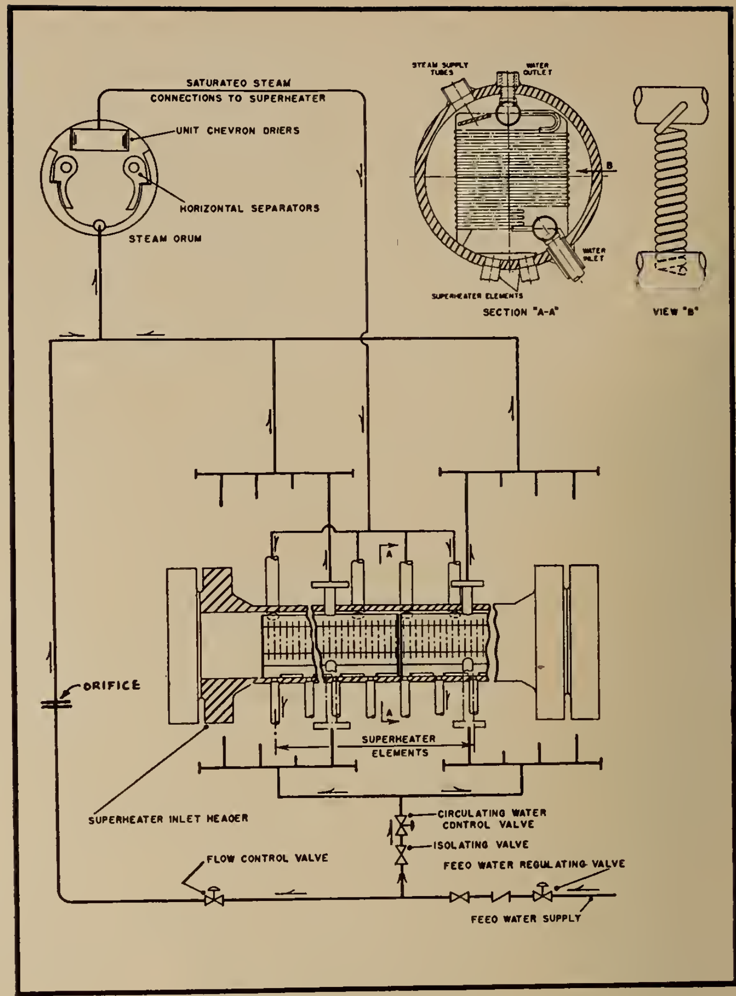


Fig. 8. Steam temperature control system.

Fuel Handling

The coal to be used will be brought by rail from the Alberta coal fields to a siding adjacent to the railway line outside the station site. The Corporation's diesel locomotive will shunt the cars to the unloading track, and will return the empties to a location adjacent to the main line. Figure 10 is a sketch of the coal handling system. Since up to fifty cars of coal per day will be handled when the station is completed, a rotary car dumper is being installed. The cars will be fed to this dumper by the diesel locomotive. Since slack coal may not always be available, primary and secondary crushers to handle run of mine, which may contain lumps up to fourteen inches, are being installed. An unusual feature of the coal handling system is that the primary crushers are located directly under the unloading hopper. This system practically eliminates any possibility of plugging or hanging up in the hopper or feeder when handling frozen or large lump coal. Apron feeders deliver the coal from the primary crushers to the first rubber belt.

The disadvantage of this system is that crushers have to be run even when handling slack coal in order to pass coal through them. However, the power consumption is very low under this condition. This layout of primary crushers was investigated at a large U.S. station and it appeared to be operating very satisfactorily.

The coal, after passing the secondary crusher, is conveyed to a transfer tower where it may be directed to any bunker in the power plant, to outside live storage or to the stocking out pile. It will be possible for the operator in the boiler room to fill the boiler house bunkers from the live storage by remote control. The provision of outside live storage permits smaller bunkers to be installed in the plant without the necessity of handling coal over weekends and holidays.

The conveyor under the live storage is extended to a reclaim hopper to receive coal from the outside storage piles and convey it to the bunkers. Crawler tractors with bulldozers will be used to handle the coal to and from the outside storage piles. The system is designed to handle 350 tons coal per hour initially and 700 tons per hour when the station is completed. All conveyors will be rubber belt except those over the bunkers which will be "Redler" conveyors.

The natural gas will be delivered to a metering and pressure regulating station, thence to a header with branches to the boilers; the piping being arranged so that only the branches are installed in the building.

The fuel oil will be delivered by tank truck initially to a main 125,000-barrel storage tank. At a later date a pipeline may be built from a nearby refinery if suficient oil is available. From the main storage tank the oil will flow through steam traced pipe lines to a 25,000-gallon oil service tank, thence to the oil heating and pumping set and to the burners.

Ash Removal and Disposal

A hydraulic ash handling system is to be used. Bottom ash will be sluiced from the ash hopper to a "Jetpulsion" pump, one for each boiler, which will pump the ash through a 10-in. discharge line approximately 1200 ft. long to the ash storage pond. Provision has been made to add clinker grinders at the ash hopper outlets if this proves to be desirable.

Fly ash from the boiler dust hoppers and the dust collectors will be transported in an air stream to a hydraulic ejector. The mixture of ash, air, and water then passes to an air separator where the air is removed. The air separator is located in the upper part of the boiler room permitting the mixture of ash and water to flow by gravity through the same discharge line as the bottom ash.

All fly ash intakes are controlled by an automatic sequential control system permitting the removal of fly ash to be a completely automatic operation once the system is put into service. It is expected that, when burning coal, bottom ash will be removed once per day and fly ash once per shift.

The ash pipeline discharges to a storage pond from which the water overflows to the river. The ash will be removed periodically from the ash pond and transferred to the ultimate disposal area by truck or rail. Since only one ash pond is being constructed initially it will be necessary to operate the station on oil or gas to allow the pond to drain and permit ashes to be removed. An alternative method of removing ashes from the pond by overhead dragline is at present being studied.

Circulating Water System

The circulating water pumphouse, located on the river bank, is being constructed initially for the ultimate four-unit station. However, pumps and equipment for the second stage will not be installed until turbogenerators 3 and 4 are installed.

The pumphouse structure is divided into seven wells. Six travelling screens will be installed (three initially), one for each of the C.W. pumps. The seventh well will receive water from the pump on either side and will be used for pumps to supply high-pressure water to the ash system, plant service water, and screen wash water.

Three diamond-shaped concrete intake structures are located on the river bottom about 150 ft. from the bank. Intake openings fitted with trash racks are located in the downstream faces of the diamonds. These structures are each connected to two intake wells by large-diameter concrete pipe lines below the river bed. This design of intake structure has given excellent service at other Corporation plants on the North and South Saskatchewan Rivers.

Initially, three vertical mixed flow pumps will be installed; two with a capacity of 60,000 g.p.m. and one of 30,000 g.p.m. at 37 ft. (total head). The small pump was selected to pro-

Boiler outlet temp. 1895°F.
Air heater gas outlet temp. 280°F.

Calculated Efficiency 85.96%

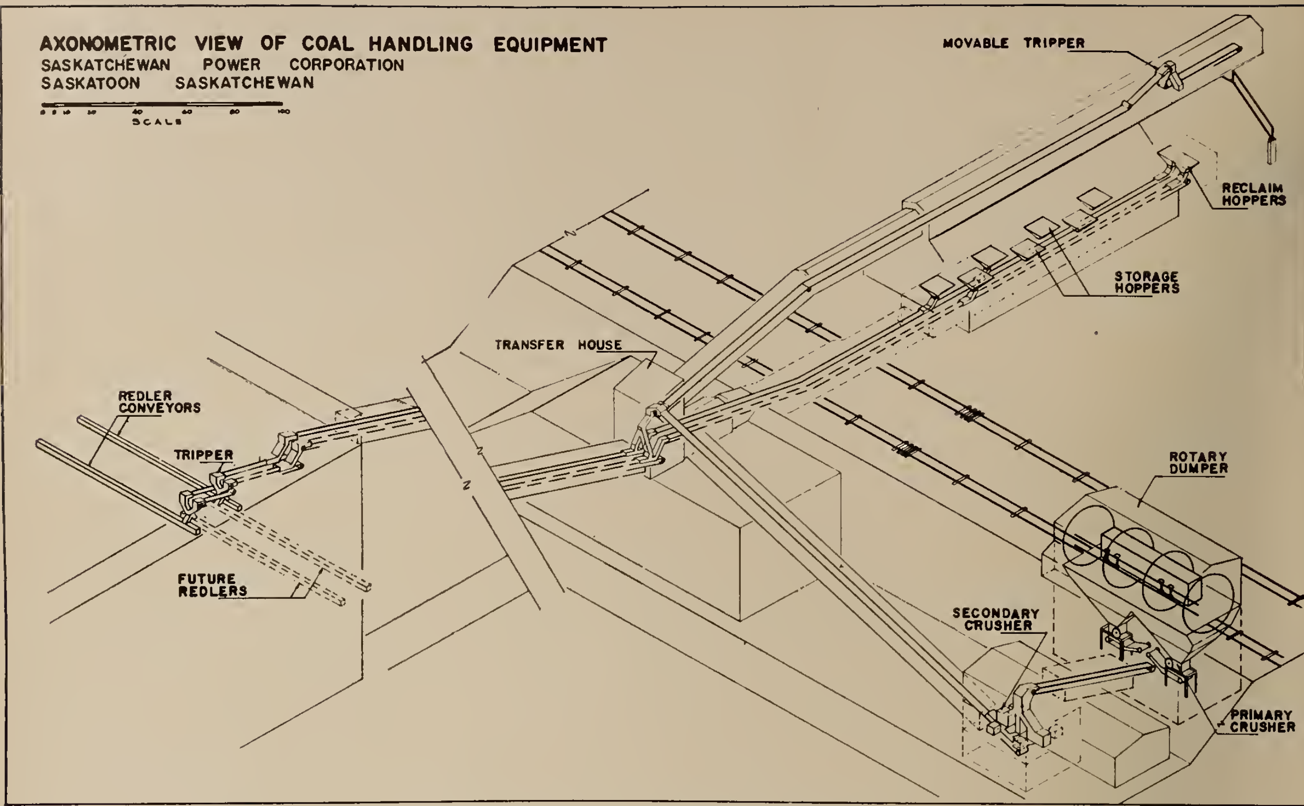

Fig. 10. View of coal handling equipment.

vide good flexibility with water temperatures fluctuating from 34°F. to 80°F. while still providing adequate standby.

An interesting feature that should be noted is the absence of check valves on the discharge of these pumps, which are connected to a common header. Butterfly valves on the discharge of each pump are interlocked electrically with the pump so that the valve cannot open until the pump is started and the valve automatically closes if the pump stops for any reason. These valves are operated from a hydraulic system, which contains a high pressure reservoir with sufficient capacity to close all valves if this is required during a failure of the electrical supply to the hydraulic pump. A similar system has operated satisfactorily at other plants in the Corporation's system, and the butterfly valves have proven to be extremely reliable. Rubber seated butterfly valves are used throughout the C.W. system.

The discharge of the three pumps is connected to an 8-ft. diameter steel pipe, which will deliver the water to the condensers of units No. 1 and 2. The pipe is coated and wrapped with a plastic tape to protect it against soil corrosion. All joints are welded, and expansion joints provide for the movement that takes place with water temperatures varying from 34°F. to 80°F. The pipeline is installed on concrete pile foundations.

The outlets from the condensers discharge into a common concrete duct, which passes under the station floor. This duct contains a weir, which controls the maximum syphon head on the discharge lines. Water flows over the weir to a 9-ft. diameter concrete pipe which discharges to an outlet structure on the downstream side of the pumphouse. Provision is made to recirculate warm discharge water to the inlet wells to prevent freezing troubles under severe winter conditions. It is not expected that chlorination of circulating water will be required. Experience on the Saskatchewan River indicates that sand and silt in the water effectively scours away any fouling or build-up that might occur.

Service Water

The pumphouse contains service water pumping, and treating facilities, as well as the necessary chemical storage. Water used for bearing and motor cooling and the like will pass through a clarifier to a clear well from where it will be pumped to the service required.

Domestic water will be taken from the clear well and will pass through gravity filters, before being chlorinated and delivered to the domestic water main.

The high-pressure ash sluice pumps will also be used as emergency fire pumps.

Feed Water Treating

The feedwater treating plant is located at the west end of the main power plant. Makeup water will be pumped from the clear well in the pumphouse to twin four-bed demineralizer units in the feedwater treating plant. Two 10,000-gallon tanks are provided for the bulk storage of sulphuric acid and caustic used for regeneration of the demineralizer. The regeneration cycle is automatically controlled by a program timer operating diaphragm valves. The conductivity and pH of the effluent from each bank is continuously recorded and either bank is automatically shut down if the conductivity reaches a pre-determined level. The product from the demineralizers will contain less than 2 p.p.m. of dissolved solids and will have a soluble silica content of less than 0.02 p.p.m. The product will be stored in two (initially one) 90,000-gallon storage tanks from where it will be pumped to the cycle as required.

Main Power Electrical System

The generators are directly connected by a 4,000 amp. isolated phase bus duct to the low-voltage terminals of the main 75 Mva., 14.4/138 kv. step-up transformers, which are located outside and adjacent to the turbine room. Overhead lines connect these transformers to the switching site which connects each unit to the 138 kv. Provincial grid system. Figure 11 is a simplified one line diagram of the main power and station auxiliary electrical systems.

Station Auxiliary Electrical System

Under normal running conditions, each unit will supply its own auxiliary power from a 6 Mva., 14.4/4.16 kv. transformer which is connected directly to the main bus duct between the generator and main step-up transformer. All motors over 150 h.p. such as pulverizers, boiler feed pumps, etc., are served directly from the 4160 volt unit bus. A 500 kva., 4160/480 volt transformer supplies smaller motors at 480 volts for each turbo-generator and a 600 kva., 4160/480 volt transformer supplies 480 volt loads for each boiler.

Auxiliaries common to more than one unit are served by a 10 Mva., 138/4.16 kv. station auxiliary transformer. Ash sluicing pumps and one standby circulating water pump are supplied directly at 4160 volts. Smaller loads are supplied from this bus through 4160/480 volt transformers located near the various load centres. These include a "station essential" bus which serves such items as the water treating plant; a "station general" bus which serves heating and ventilating equipment, cranes, etc.; a 480 volt bus to serve coal handling equipment, and a 480 volt bus to serve the circulating water pumphouse. In addition, a standby 4160/480 volt transformer is permanently installed and wired to serve any 480 volt distribution centre in the event of a transformer failure.

The 4160 volt station auxiliary bus may be connected to either or both 4160 volt unit auxiliary buses to provide start-up power or to replace the unit auxiliary transformer in the event of a transformer failure. The station auxiliary transformer is sized to carry all essential station auxiliaries plus all auxiliaries for one unit plus start-up power for a second unit.

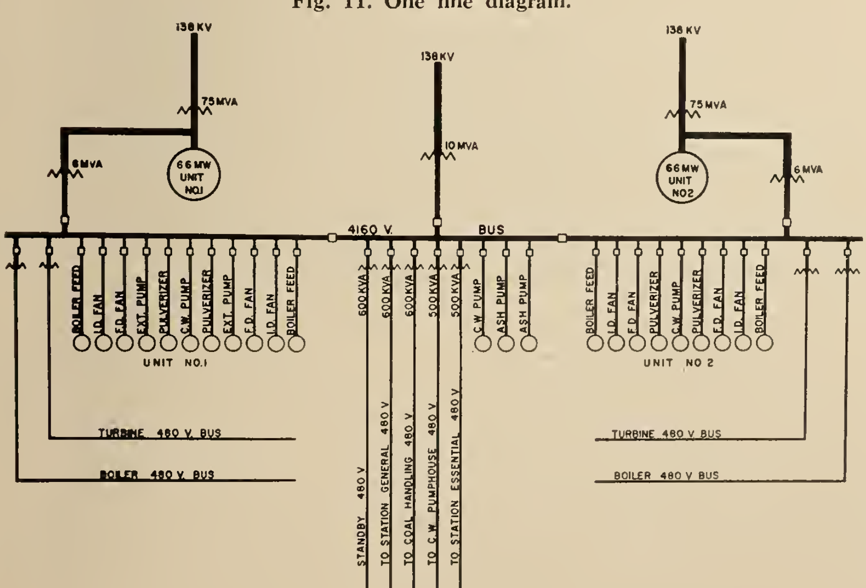
A second station auxiliary transformer of 12.5 Mva. capacity is being installed initially to provide standby for the 10 Mva. bank. When units 3 and 4 are installed, the 12.5 Mva. transformer will become the station auxiliary transformer for those units. The 12.5 Mva. capacity will allow for future 100 Mw. units if these are decided upon. In the future, standby for these transformers will be provided by an emergency tie between the 4160 volt station buses serving units 1 and 2, and units 3 and 4.

Synchronizing check relays will prevent any station service tie breaker from being closed out of synchronism.

It should be noted that there will be no oil filled electrical equipment inside the main station building. The 4160 volt circuit breakers are of the air-break type and all 480 volt and lighting transformers are air insulated and cooled. All other transformers including the main step-up transformer will be of the oil filled, natural oil circulation, forced air circulation type.

All 4160 volt cables will be of the paper-insulated lead-covered type, and lower voltage cables will be rubber-insulated, neoprene-covered, multi-conductor type. Cable dispersal will be accomplished by the use of a cable tray system routed to give an economical balance of maximum concentration and minimum cable lengths.

Fig. 11. One line diagram.



Staff Requirements

It is estimated that the staff for the first stage of the station will consist of the following: supervisory, 3; laboratory, clerical and miscellaneous, 9; operating staff, 5 shifts @ 7 men, 35; fuel handling crew, 8; maintenance crew, 12. Total, 67.

It should be explained that since the Saskatchewan Power Corporation operates on a 40-hour work week, it is necessary to maintain five complete shifts of operating staff. Since the fifth shift is normally only needed for relief 8 hours per week, advantage is taken of training junior employees in more senior positions during the periods that two shifts are on duty at the same time.

Experience in actual operation of the station will be needed to determine if this estimate of staff requirements is accurate. It will, of course, not be necessary to double this staff when units 3 and 4 are added to the station.

Capital Cost

The total cost of the first stage of this station is estimated to be $18,950,000 ($143.50 per Kw.) including all land, improvements, and the step-up substation, but not including the high voltage switching station, which is logically considered part of the transmission system.

If units 3 and 4 are also 66 Mw. units, the ultimate cost of the station is estimated to be $35,913,000 ($136.00 per Kw.) based on present day construction costs.

Ursel, M.E.I.C., electrical design engineer, Saskatchewan Power Corporation.

The AASHO Road Test

Gordon G. Campbell, JR.E.I.C.

Director of Technical Services, Canadian Good Roads Association.

Presented to the Ottawa Branch, the Engineering Institute of Canada, 7 February, 1957

Paper received 18 February 1957

NEARLY EVERYONE present today is aware of the severe limitations of the body of knowledge which we, as engineers, are forced to rely upon in the design, construction, and maintenance of roads and streets. All of us associated with highways are daily seeking answers to the numerous complex problems in our field. Such problems can only be solved through research, whether this is done by the resident engineer who incorporates some new innovation in the construction of his section of road, or whether it is done in a laboratory by a trained research specialist, using complex scientific equipment and instrumentation methods.

Research is a continuing thing in almost every country today. This is evidenced by the numerous papers and reports presented at the annual meetings of the Canadian Good Roads Association and the Highway Research Board. As practising engineers, we must endeavour to keep abreast of all such developments in our special area of interest.

I shall attempt to acquaint you briefly with the largest single highway research project in the history of road building. I refer to the $20 million AASHO road test. This project derives its name from the American Association of State Highway Officials, the agency initiating and sponsoring the experiment. The various committees of that Association spent nearly five years in planning for this test before the final prospectus was drawn up and the administration and direction of the project was turned over to the Highway Research Board in 1955. Since that time, most of the details of the design, construction, and instrumentation of the road have been worked out by the project staff, and the actual construction has begun.

The AASHO experiment will consist of the testing of both rigid and flexible pavement sections of various thicknesses and composition, and of the testing of bridges of various designs and type by means of the repeated application of both single and tandem axle loads representing a wide range of intensities. The pavement sections have been selected to be typical of good current design practice throughout the United States. They are representative of Canadian design procedures as well.

Layout of Test Loops

The test road is being constructed at Ottawa, Illinois, approximately 90 miles south-west of Chicago. It will consist of four main loops and two auxiliary loops. The principal loops, designated by the letters A through D, will each have a length of approximately 7,600 feet. They will, at the conclusion of the test, form a part of a relocation of U.S. 6, a four-lane divided limited-access highway facility. Loops E and F will be about 5,000 feet long and 2,200 feet long respectively. They are being constructed immediately adjacent and parallel to one of the main loops. All loops will thus be made up of two 24-foot roadways with 10-foot shoulders, separated by a median strip and connected at either end by turnarounds.

Loop F will not be subjected to regular test traffic, but will be used for special studies, and to evaluate the effects of weather and climate. As in the WASHO test, the inner and outer lanes of the five traffic loops will be subjected to axle loadings of different intensities. The north tangent of each loop will be provided with flexible pavement test sections, while the south tangents will contain rigid pavement test sections. The 16 test bridges of the experiment will be located in groups of four adjacent to each turnaround of two of the loops.

Experimental Design

The previous test roads proved to be valuable pilot studies for this experiment. We now know most of the characteristics of the variables to be measured, and how to go about measuring them. We have learned the value of applying mathematical statistics to the experimental design of the project. In none of the previous road tests was the experimental design established so that methods of statistical inference could be utilized in analyzing the data obtained. Therefore, it was impossible to make any probability statements as to the true influence, in all similar circumstances, of any of the variables studied.

In the AASHO road test, the methods of statistical analysis constitute the basis for the experimental design. These techniques will ensure that the maximum amount of valid information is developed from the limited test area and funds available for the project. For experimental research work of this nature, designs have been planned to allow the relationships between variables to be studied with the maximum accuracy and the minimum computation. One such class of experimental designs, the factorial design, will be used in the AASHO project. In this method, the levels chosen for each independent variable are restricted in number, but the observations are so arranged that all possible combinations of levels of the independent variables occur.

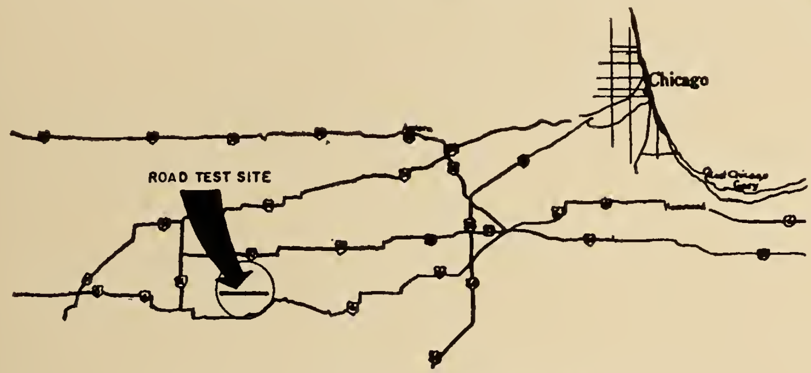
For example, in the rigid pavement

experiment, it was desired to evaluate the effects of concrete slab thickness, reinforced and non-reinforced, and sub-base thickness under various axle loadings. Thus, the design was developed with eight levels of surface thickness, each reinforced and non-reinforced, four levels of sub-base thickness and 10 axle loadings. Therefore, the primary rigid pavement experiment became an 8 x 2 x 4 x 10 factorial design. There are a possible 640 pavement sections in such an experiment. However, it was possible to reduce this design to approximately 300 sections, including some replications, by omitting sections that were obviously either too light or too heavy for specific axle loadings. The practical economical designs adopted for each phase of this study will make it possible to state with a high degree of certainty, the actual relationships existing between pavement design, axle loading and pavement performance in this test.

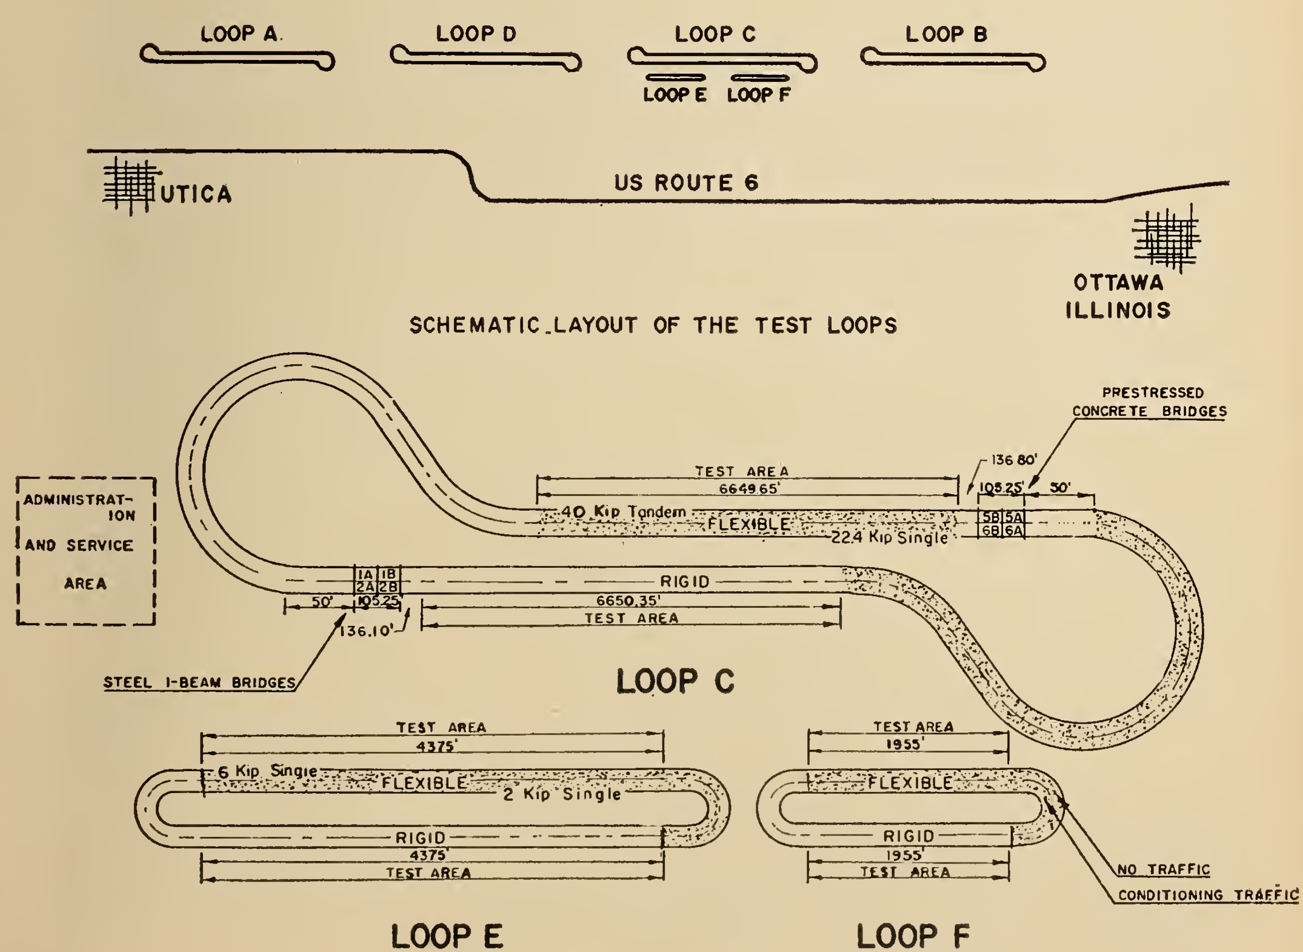
Apart from the bridge experiments, the AASHO project is primarily an evaluation of pavement performance. To compare pavements of different design, it is essential that the subgrade or basement soil be identical and in the same condition under all test sections. Therefore, the top three feet of the embankment for the entire test road was constructed with a highly uniform soil obtained from selected borrow pits. Furthermore, extreme care was taken during construction to

Fig. 1 and 2. Location of project, layout of test loops, and detail of flexible and rigid test areas.

APPENDIX I



LOCATION OF AASHO ROAD TEST PROJECT



control the placement and compaction of this material.

Despite these precautions, some variation in the subgrade condition may occur. So that such variations will not influence the correlations developed from this test, another important statistical tool was employed. The location of the loops and the location of each test section within any one loop tangent were randomized. The importance of the use of statistical methods, such as factorial designs and the randomization of tests, in any highway research investigation, no matter how small the project, cannot be overemphasized. The use of statistical design and analysis techniques will ensure that valid results are obtained with minimum cost and effort in any research undertaking. This is particularly important in a project of the magnitude of the AASHO Road Test.

Due to the complexity of the experimental design which in all contains 836 test sections, no attempt will be made here to describe its details. However, the scope of the undertaking can be realized by considering certain limits of the design variables. The 10 traffic lanes of loops A through E will each be subjected to a different axle load. These loads will range from 2,000 pounds on single axles to 48,000 pounds on tandem axles. In the rigid pavement experiment, the concrete slabs will be both reinforced and non-reinforced, and will range in thickness from 2½ inches to 12½ inches. Beneath these various slabs, sand sub-bases having depths of 0, 3, 6 or 9 inches will be used. The flexible pavement test sections will be composed of asphaltic concrete surfacing, crushed stone base course, and a sand sub-base. The surface will range in thickness from 0 to 6 inches, the base from 0 to 9 inches, and the sub-base from 0 to 16 inches. The total flexible pavement thicknesses will thus range from 0 to 31 inches. Special test sections have been included to evaluate the effect of bituminous concrete paved shoulders on the performance of both rigid and flexible pavements. Other special sections with cement treated base, bituminous treated base and gravel base have also been included in the experiment.

In addition to the pavement design studies, 16 single-lane, 50-foot-span bridges will be included in the investigation. These structures will be subjected to repeated applications of the four heaviest axle loadings used in the test, and will be loaded to destruction at the conclusion of the experiment. Eight of the bridges will be of steel I-beam design, four of prestressed concrete design, while the remaining four will be of conventional reinforced concrete design.

Measurements and Instrumentation

Two main classes of measurements will be made in the test. First are the pavement behaviour characteristics including surface roughness, cracking, and faulting of joints. These will be used to evaluate the relationship between the behaviour of the different pavement sections, and the loads that operate on them. The second type of measurements will be designed to determine why any particular pavement section failed, and in what way it failed. These measurements will include moisture contents, temperatures, deflections, stresses, and strains.

Some of the instruments to measure the indicated variables are already available. These would include thermo-couples and strain gauges. However, no device is available with which subsurface soil moisture contents can be measured in a non-destructive test with a sufficient degree of accuracy. A new device to accomplish this is currently under study by the project staff. Although the insrument shows promise, it may be necessary to resort to destructive tests in which samples are taken through the pavement, if the device does not prove satisfactory.

The project staff is also working on the development of an accelero-

AASHO TEST ROAD July 31, 1956, Revised Sept. 27, 1956

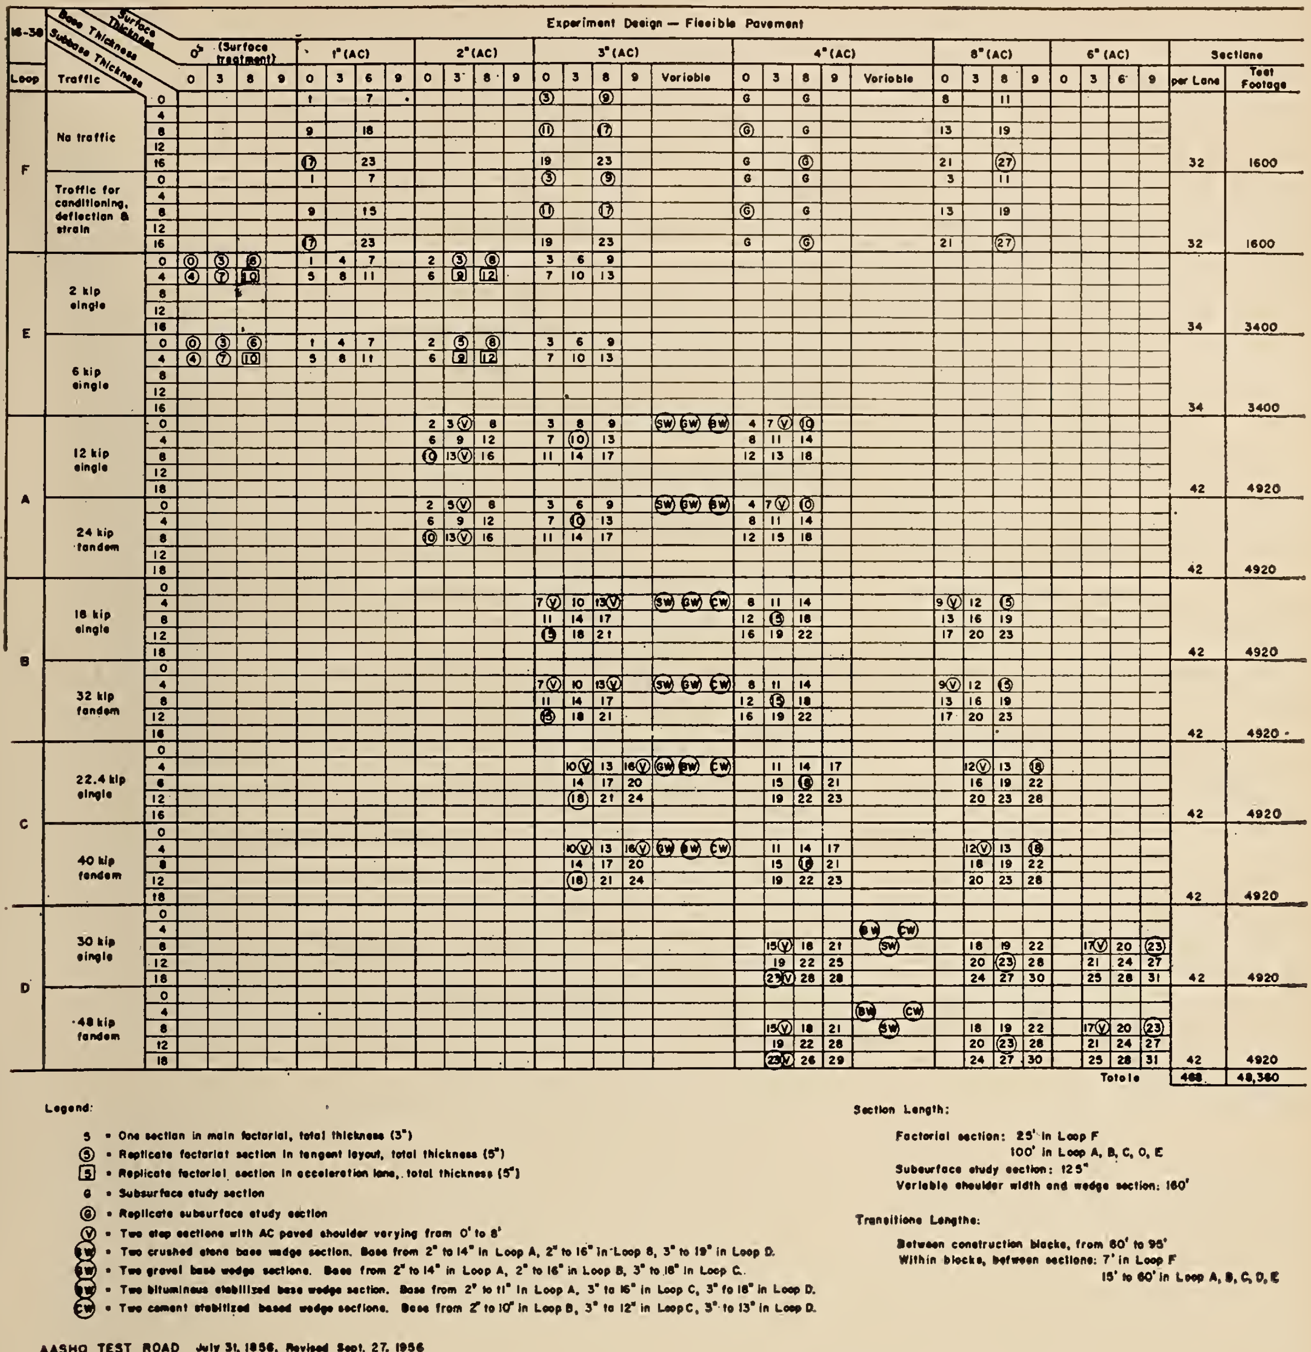

Fig. 4. Chart defining the flexible pavement test sections to be included in the AASHO test.

meter which could be installed in the pavement in order to measure dynamic pavement deflections under moving loads. This device would not require the installation of long reference rods under the pavement. Such rods partially invalidate the results of these tests by creating a serious discontinuity in the pavement structure. This was demonstrated in the WASHO test. Of course, other routine deflection measurements will be taken under slower moving loads by means of the Benkleman beam.

One of the most important measurements which will be taken in the road test will be longitudinal profiles. These, of course, are related to surface roughness and hence to riding quality. In general, riding quality determines whether a pavement is satisfactory or not. The project staff has been working on a device to record profiles quickly. If successful, this would ensure adequate coverage of all sections, and reduce test traffic delays to a minimum.

Wherever possible, instruments will be electronic rather than manually operated mechanical devices. This is almost essential if the many millions of necessary measurements are to be made during the brief two years of traffic testing. The multitudinous data from these instruments will be recorded either on IBM punch cards or digital tape. In this way, data analysis may be programmed for high speed electronic computers.

Test Road Program

After this description of the design, physical layout, and instrumentation of the AASHO road test, it would seem appropriate to mention the target dates for the completion of construction and testing as well as publication of the final report. Although the grading contract was only let in July 1956, the contractor was able to complete about 95 per cent of the subgrade construction (nearly 1½ million cubic yards of earth) before the job was closed down in November. This work will be completed in the spring. Paving contracts will be let in the spring and it is hoped that by late summer of 1957 the paving and test bridges will be complete. A permanent office and laboratory building was erected last fall. Other buildings, including a vehicle maintenance garage should be completed this summer. Hence, by the fall of 1957 traffic testing should commence. This will continue for about two years. As nearly a year will be required for data analysis and report writing after the completion of testing, the final results will probably not be available until some time in 1960.

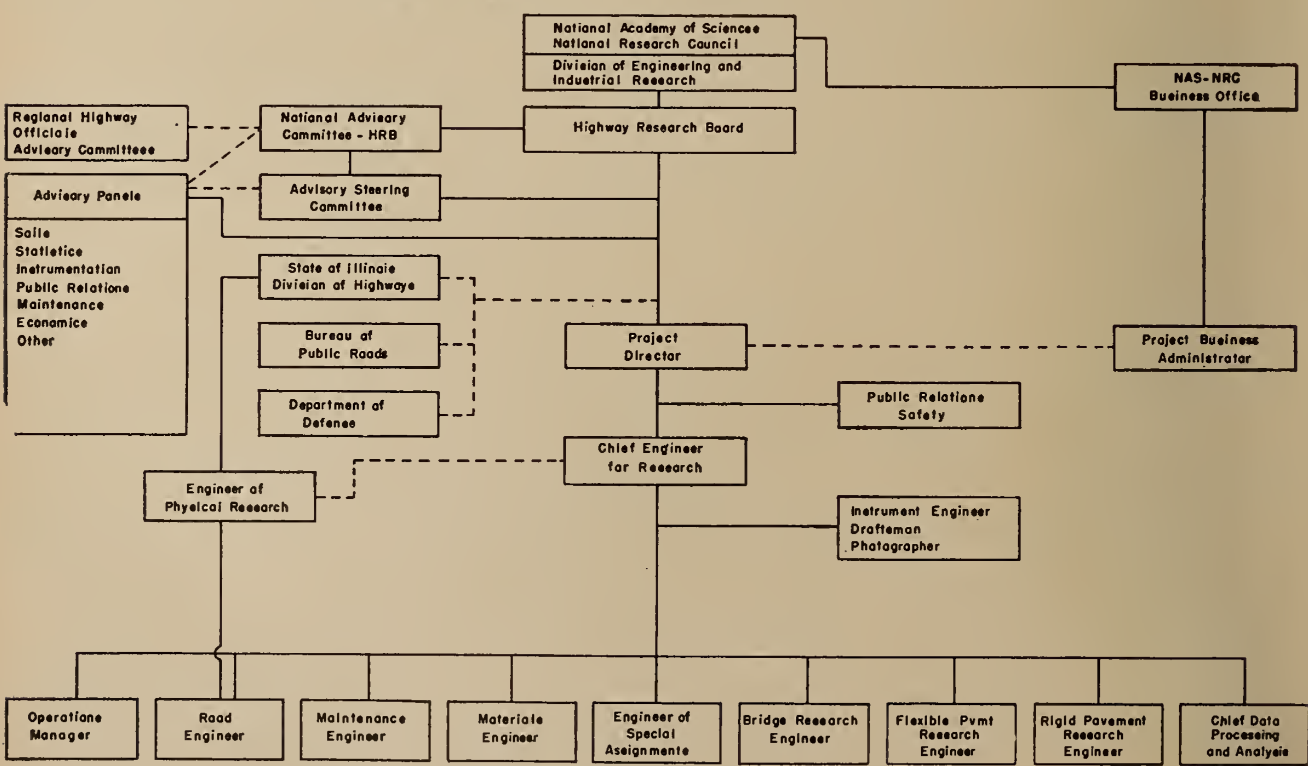
Significance of the AASHO Road Test

The AASHO project is designed to provide at least partial answers to many important questions of vital concern to all people interested in highways and highway transportation. Among these questions are the following: What is the relationship between single and tandem axle loads of various intensities? What are the relative pavement design requirements for various axle loadings? What are the relative supporting values of the various components of both flexible and rigid pavements? Would thicker bituminous surfaces, for example, provide a more economical flexible pavement design than the sections currently in common use today? To what extent, and in what way does reinforcing affect the behaviour of concrete pavements? What are the most suitable tests for pavement design and the evaluation of existing pavements? Will paved shoulders increase the load-carrying capacity of flexible or rigid pavements? Could maintenance practices be improved to prolong the life of existing pavements?

It would be entirely unrealistic and unwarranted to assume that the AASHO road test will provide all of the answers to all or any of the questions confronting highway technologists today. However, a substantial body of new and valid information should be obtained which, when combined with the results of other investigations, could produce information of very great importance. These companion investigations, which must be undertaken on a local or regional basis, are essential if full benefit is to be derived from this test. These supplementary studies, which are of equal importance to the road test itself, are necessary if we are to redefine legal load limits on an economic basis, or are to use the test road data for taxation studies. Such comprehensive studies of highway costs, vehicle operating costs, road and street use, and highway needs, are currently being conducted in the United States for the purposes indicated.

As I have said, the AASHO project is not the first major road test. Furthermore, it probably will not be the last. Many major problems will remain unsolved, and undoubtedly the results of this test will indicate significant variables which will require further research and investigation. However, for a period of years after the AASHO experiment is finished, the results of this test will be the only valid data available for use in any solution to many problems of pavement design, vehicle load limits, and road and street tax allocation. No matter how this test turns out, its results will greatly influence the thinking of all engineers, economists, and legislators. I am convinced that all highway engineers should be familiar with the design and conduct of these tests as well as the analysis of the results. Follow the articles which will appear in engineering publications from time to time. This is necessary if the data to be obtained are to be used intelligently and effectively in our efforts to create good roads.

Fig. 5. Organization of the AASHO road test project.



Evaluating Performance in an Engineering Department

H. L. Johnston, M.E.I.C.
Chief Engineer, Du Pont of Canada Limited

Paper presented to The Engineering Institute of Canada, Montreal Branch, 26 March, 1957

Revised paper received 3 October 1957

The author gives a comparative appraisal of the various systems for rating employees and describes the procedure used in the engineering department of his own company. The paper was presented to several branches of the Institute and was received with considerable interest.

BEFORE "MOSES chose able men out of all Israel", after consultation with his father-in-law Jethro, "and made them heads over the people, rulers of thousands, rulers of hundreds, rulers of fifties and rulers of tens" he had to make some sort of evaluation of the capabilities of a large number of people. As time passed he undoubtedly found that some of his appointees meted out justice much more ably than others and referred fewer of the "hard causes" to him for adjudication. We suspect that he did not use a formal rating plan to help him distinguish between the better and the poorer administrators but at least he had a method of doing so even if it consisted only of making mental comparisons.

The same thing happens today. Every administrator has to rate those who respond to him in some fashion, call it by whatever name you will. According to "Studies in Personnel Policy No. 121" by the National Industrial Conference Board about forty per cent of companies have formal rating systems. While some companies are discontinuing the use of rating plans, others are starting to use them. Some organizations that use formal plans say they could scarcely operate without them whereas some of the nearly sixty per cent of companies that do not use them say they are unnecessary, undesirable and full of potential danger. Thus, there is wide disagreement about the desirability of rating employees by formal systems.

There is also great divergence of opinion among those companies that have rating plans about the type of plan to use; and furthermore, for any one type opinions differ about how complex or how simple it should be. Sponsors of the different plans have very strong opinions about them. These varying and resolute opinions stem to some extent from the varying forms of organization that have used particular plans and from the success or lack of success they have had with them.

In selecting the type of rating plan to use or whether or not to use a formal plan one can not be guided with certainty by those whom Prime Minister Louis St. Laurent called "successive generations of thoughtful men". These thoughtful men seem not to have arrived at a unanimous conclusion. One also has to recognize that some of those who have developed rating plans started them because they were fashionable. Some of the fashion followers are probably among those who have discontinued formal rating, as their motives were not well founded.

With these preliminary remarks as a background I should like now to discuss the reasons for rating employees, the various types of rating plans, the arguments for and against each and the type that I use in assessing performance in an engineering department.

I have called this talk "Evaluating Performance". It could be said that I have needlessly introduced another expression but in defence I plead that I have done so in order to include under one heading many of the names given to rating or performance review procedures, such as Employee Rating, Merit Rating, Performance Reviews, Performance Appraisals, Progress Reports, Employee Evaluation Reports, Service Reviews and many others.

From a supervisor's point of view the most useful rating procedure is the one that will give him, without wasted effort, the information about his subordinates that he has to have to do his job efficiently.

I do not think that many organizations have established rating plans because it is a noble or splendid thing to do. I do think, however, that many plans do not yield a return commensurate with the effort expended on them and that there is such a thing as a law of diminishing returns.

The first thing to decide in setting up a rating plan is what you want it to do for you. Some of the reasons given for having rating plans are:

(1) To help sort out the better from the poorer performers.

(2) To assist in selecting employees for promotion, retention or lay off.

(3) To aid in determining equitable salary differentials.

(4) To form the basis for letting an employee know where he stands.

(5) To point up training needs.

(6) To make sure that every supervisor takes time to think about every one of his subordinates.

Having determined what you want from a rating plan or procedure your next move is to select a suitable one. If you can't find one that will fulfil your requirements you may with a little thought develop one of your own. It will probably fall within the following types of plan or be a combination of more than one type.

(1) Graphic rating scale. For each trait or characteristic the rater is required to mark on a bar, representing 0% to 100%, his assessment of the employee.

(2) Chart system. The rater, for each trait, puts a check mark in one of several blocks indicating whether the employee is average or above or below average. Sometimes the blocks or spaces above and below average (or standard) are headed average plus, high, average minus, and low; and sometimes they are headed by descriptive phrases.

(3) Check list with descriptive phrases. The rater is usually required to check Yes or No for each trait.

(4) Forced choice. In each of many blocks of four to six unrelated job performance statements the rater has to indicate the statement that is most descriptive of the employee and the statement that is least descriptive.

(5) Field review. The rater is a specialist, probably from the personnel department, who discusses with a supervisor the traits and performance of each of his subordinates. Later the specialist discusses his completed ratings with the supervisor who signs each rating sheet after it has been revised to suit him.

(6) Critical incident. A supervisor lists for each of his employees incidents, as they occur, that reflect favourable or unfavourable performance. He uses the lists later to complete the ratings of his subordinates.

(7) Self rating. The employee is asked to make a sincere appraisal of his own performance.

(8) Freely written paragraph. A supervisor is required to write a concise paragraph describing the performance of each of his subordinates.

(9) Forced written paragraph. The supervisor is required to comment on particular phases of each person's performance.

(10) Rank order. All persons in a classification are listed in order from best to poorest for each characteristic and assigned consecutive numbers commencing with number one. The ranking numbers for each person for all characteristics may be added. The person with the lowest total ranks first.

(11) Paired comparison. The supervisor compares each person in a particular classification with every other person and ranks him 1 or 2 for each trait or characteristic. The person with the lowest total rating ranks first.

(12) Forced distribution. Employees in a classification are distributed into designated percentage groups from poorest to best. Ten per cent must be designated as the poorest performers and ten per cent as the best.

Most of the twelve better known plans or systems that I have just listed have been used for rating persons at all levels of responsibility. The traits or characteristics on which persons are judged in many of the systems have to be changed for groups having widely different degrees of responsibility. Plans that are used for rating hourly paid employees may be unsuitable for rating salaried employees who occupy senior supervisory positions. Much formal rating of hourly paid persons has been discontinued as unions object not only to unilateral ratings but to any procedure that will point up differences between employees in a particular classification. All rating plans are designed to point up differences. Management wants to know these differences in order to utilize its employees in the most effective manner and in order to reward them equitably.

There is, of course, also a wide difference in responsibility among salaried employees, all the way from the office boy up. Some companies use forms for rating persons in the more responsible positions that differ from the forms used for rating persons in the more junior positions. Unless this is done, under some systems many meaningless entries may be made in rating all of the employees in the organization.

The graphic scale method and the chart method (a variation of the graphic scale) are the most commonly used. The degree of perfection has to be indicated opposite each characteristic whether or not it has a major influence on performance. The employee is pulled apart piece by piece not always by persons fully qualified to do so. The overall performance is often judged by a summation of the pieces which may not give the correct or best answer. A salesman who brings in business amounting to half a million dollars a year is doing better than the one whose orders total two hundred thousand dollars. The totals of the bits and pieces on the chart may not give the nod to the better performer. He may show up to be the poorer in the majority of the characteristics but the form does not give his outstanding trait that brings in the orders any more weight than is given to less important characteristics. The graphic scale and chart methods do reveal where training may be used to improve performance and they do make a supervisor think about the parts that go together to make the whole man.

The tendency now is to reduce the number of characteristics or traits listed on the forms used in the graphic scale and chart systems and to rate job performance rather than personal traits. Some analysts advocate limiting the number of characteristics to between six and ten and some to not more than three. They think that the less detail asked for the less tedious will be the job of sorting out the significant elements and the more useful the tool will be.

Check lists like many other systems have the virtue of making a supervisor think of each subordinate from different points of view. They tend to be cut and dried in their approach and therefore beget mechanical answers.

The forced choice system was developed by the United States Army and used by it during World War II and by some industrial organizations. Specialists are required to correlate the answers to the unrelated statements. The system is designed to make the ratings more objective. The supervisor who answers the questions about his employees has to wait for someone else to tell him the result.

It takes a long time to rate large groups using the field review system. The personnel department does most of the work and that is a good or bad thing depending on your convictions.

The critical incident system has the virtue of dealing with observed performance. It is a bit like some of the employee counselling systems that were set up during World War II. One had to watch that entries recorded were not all critical of the employee. I can remember a union deriding attempts at counselling and calling the notes that were kept "little black books". Incidents really should be discussed when they occur and not some weeks or months later.

It is reported that where self rating has been tried the rater is frequently more critical of himself than his supervisor would have been but this is not always the case. The ratings can be used only as a basis for counselling or discussing performance, preferably by one skilled in the art.

The freely written paragraph has the advantage of being simple. The rater deals with the whole man and intuitively probably gives him a truer overall rating than could be done by adding the pieces. The "halo" effect (a single outstanding characteristic dominating the rater's judgment) undoubtedly plays its part but it can quite well be a proper part. Paragraphs written by different raters will certainly lack uniformity.

The forced written paragraph gives uniformity to the paragraphs by requiring comments on specific phases of each man's performance. Comparison of one employee with another based on these specific phases may be made more readily than with the freely written paragraph.

For a single characteristic probably no system is better than the rank order system for comparing employees doing the same type of work in a particular group. Comparisons between persons in different groups are not easy unless reliable reference points can be established. Overall ratings are not too reliable if obtained by assigning numbers for each characteristic and adding the numbers to determine the overall rank order as it cannot be assumed that the different characteristics carry equal weight.

The paired comparison system is a variation of the method of arriving at rank order rating. Whether it is worthwhile is purely a matter of opinion.

The forced distribution system is something like the rank order system. Its sole advantage is that some people find it easier to divide people into a limited number of groups than to list them in order of merit.

I have used a few of these rating systems or techniques in the past and have not been satisfied with any of them whether rating hourly paid employees or staff employees. At the present time I use a combination of a few of them and do so because the combination which I call a comparative performance review gives me in a large measure the results that I want with a minimum of effort by all levels of supervision. The end result is the important thing and not the system. No supervisor has to rate his men on a particular form or on any form to find out which is his best man and which is his poorest. The form can be of assistance to him however in recording the performance of an employee in such a way that it can be compared readily with the performances of others in the same group and in other groups.

The things that I want from a performance review are:

(1) A concise paragraph written by the immediate supervisor describing the man's overall performance, his outstanding strong points, if any, and his outstanding weaknesses, if any. If the paragraph has more than eight lines it is too long and if it is shorter than two lines it is too short.

(2) The rank order of the employee in his classification in the immediate supervisor's jurisdiction. This rank order is to be determined from an assessment of the employee's immediate worth to the supervisor. If the supervisor had to drop one man from the classification the one that he could spare easiest would rank the lowest.

(3) The immediate supervisor's assessment of the overall performance of the employee compared with the performances of all others across the country in a similar classification and having a like amount of experience. This assessment may be recorded as "Top 10%" or "Top 10 to 25%", etc.

A supervisor should talk to his subordinates on the job daily, weekly, and monthly about their work. He should not fail to tell them when a job has been done well . . . and how a job could be done better.

The entire record by the immediate supervisor should occupy no more than half of an 8½ x 11-in. sheet of paper. He may use a plain sheet but it saves him a little writing to have one headed "Comparative Performance Review" and to have items 2 and 3 headed so that all he has to do is to record numbers.

That is all, except for the all important reviews by succeeding levels of supervision which are to be recorded on the remainder of the sheet. The supervisor next in line (supervisor B) holds a meeting with all of the supervisors who respond to him (referred to above as "immediate supervisor") and now designated as "supervisors A". The "supervisors A" question one another about the ratings already recorded. One may say to another: "I had Joe and Harry working for me last year and unless Harry's performance has fallen off he is a better man than Joe". Thus, "supervisors A" criticize one another's ratings and of course "supervisor B" contributes his observations. Having agreed on one another's ratings a comparative rating for each classification in "supervisor B's" group is made by discussing the relative merits of all of the employees. "Supervisor B" then records on each sheet the agreed ratings for items 2 and 3 in his jurisdiction and records any modification he cares to record of item 1, the concise paragraph. So also for succeeding supervisors including the chief engineer. Thus a comparative rating of employees in every classification is arrived at through pooled judgment.

The system works equally well for rating draughtsmen, clerks, stenographers, and engineers and any other classification of employees in an engineering department or for that matter in any other department.

The results may be readily tabulated and used for various purposes including the administration of equitable salaries. The sheets are not typed but are filed, just as prepared, in the employees' personal files where any supervisor may examine at any time the rating sheet for any employee who responds to him.

The first item on the comparative performance review sheet is a freely written paragraph, the second a rank order rating and the third a group rank order rating. (See page 84.)

When meeting with those who respond to me to agree on final comparative ratings I find it convenient to have sheets prepared ahead of time that list employees in each classification in the order of their experience. (Listing people alphabetically tells you nothing about them.) The sheets have columns for recording comparative ratings and performances. By the time we finish discussing the performances of the last group of employees to be considered we each have before us in convenient form comparative ratings for all employees in the department. I know how each employee compares with others in his classification and frequently with those in other classifications. I also know how each one's performance compares with the performances of others across the country having a like amount of experience and doing comparable work. Later, I again review in detail the written comments on each person's performance, make notes on matters that require attention and sign the sheets before they are filed.

Until now I have said nothing about post appraisal interviews. Some rating systems appear to be directed straight towards post appraisal interviews as if these interviews were the ultimate goal of all management effort. That presumably was not the intention of those who developed the systems but some few supervisors have felt it incumbent on themselves to live up to the supposed intent and to embark on a campaign of telling each employee just what is wrong with him. These campaigns include dissertations on the philosophy of behaviour and include exposing the detailed rating sheets to the view of employees and a blow by blow recitation of the ratings. An employee who has a good rating throughout may be somewhat relieved but at the same time wonder how he would have felt had his judgment or intelligence or some other characteristic been rated as poor. An employee who receives a poor rating on some traits feels resentful, but if he is wise he recognizes his position as a captive audience. If he argues about the justification of a rating, next year, opposite the proper description he will find that he is labelled "Does not take criticism well".

The write-ups of post appraisal interviews are sometimes used to judge the ability of the interviewer. Recognizing this the occasional supervisor puts his best foot forward and puts on record an exaggeration of the interview which will put him in a good light. Such practices are occasionally exposed when a transferred employee is reminded of something that was said to him by an earlier interviewer.

I have not made these comments to discredit post appraisal interviews but rather to try to put the whole matter of rating and interviews in proper perspective. I do not think that an elaborate rating form or any rating form need be made out before a supervisor talks to one of his employees about his performance. He should talk to his subordinates on the job daily, weekly, and monthly about their work. He should not fail to tell them when a job has been done well and should not fail to tell them how a job another time could be done better. He should lead them and train them and strive for their interest and co-operation by giving them responsibility. He must avoid tactless criticism of personal traits. It is dangerous to talk to an individual about his traits. You can however talk to him about performance and should do so at opportune times which may be as incidents arise or when letting him know of an increase in his salary or after making an appraisal of his performance. The supervisor, knowing the conditions, must be the sole judge of when to interview an employee and of what to discuss with him. There are of course occasions when a supervisor should talk to an employee about some characteristic that if not improved will retard his progress but the supervisor himself has to determine the opportune time and the probable effect.

Much has been said in the past about how to carry out post appraisal interviews. Certain techniques were developed some of which at times became ludicrous as a supervisor would find that the stereotyped techniques that he used were in turn used on him. Interviewers slavishly followed instructions on how to put a man at ease at the start of an interview. At no other time did a supervisor stand up and greet his subordinate when he came to his office, ask him to sit down and be comfortable, offer him a cigarette and ask him about his family. The whole interview was wrecked if the subordinate said he wanted to stand up, did not want a cigarette and had no family. This reminds me of an interview I once had with a man who had one degree, was about to receive another in engineering, and then proposed to study for a Ph.D. specializing in mathematics. He told me that he knew that he was more intelligent than other students as he always led the class and always expected to get 100% in examinations. He said that he spent all of the time that he was awake studying or solving interesting problems and did not have time to play games or go to dances and meetings. I felt very wise and ventured to suggest that associating with others at a university was part of one's education. It taught one how to get along with people and how to become a leader. I suggested that if he were some day going to be the president of a company he would at some time have to learn how to associate with and handle people. He replied that he had no desire to become the president of any company or a manager or supervisor. His sole ambition was to be a mathematician and to spend his time solving problems. He had no ambition to make a lot of money. He merely wanted to have work that interested him.

More power to him! We need more such people with singleness of purpose. He will function in a realm unknown to most of us. He will be the brains behind the design and use of the electronic computers of the future and of other devices not yet invented. There is a lesson to be learned from my encounter with him. Why should I attempt to mould him into a standard article? Who am I to set myself up as accuser and judge of his personal habits and traits? Don't I realize that he might resent my intrusion into his personal life? Might he become disturbed and frustrated and instead of becoming a genius end up like the rest of us?

To get back to the subject of this talk I should like to compare briefly the comparative performance review that I use in assessing performance with the so-called chart system having three or four legal size pages of spaces to fill in and comments to make. The advantages of the procedure used in our Engineering Department are:

(1) The review is simple and all on one small page.

(2) It is not typed as only one copy is required, thus keeping cost to a minimum.

(3) A complete review of over 250 employees can be done within two weeks instead of up to three months.

(4) Comparative information is readily available for determining salary differentials.

(5) Other comparative information is readily available for considering promotions, transfers and dismissals.

(6) Salient strengths and weaknesses stand out for consideration in undertaking training or an interview.

(7) Supervisors are encouraged to discuss performance on the job and at the time of a salary increase interview. A written record of the latter interview is put in the employee's file. Supervisors are also encouraged to file a record of any significant interview carried out at any time.

I do want to say a word about training because training courses can be used to discuss objectively traits or characteristics that would cause resentment if discussed subjectively in a private interview. In a training course unsatisfactory traits may be discussed in a two-fisted manner and sometimes a knock out blow can be administered that will have a salutary effect. A training course is also a good place to tell all employees about the rating procedure and what it is used for. It is revealing to observe the satisfaction that is expressed by persons on training courses when they hear that their performances are judged not by one person but by a group.

Comments on Forms of Ratings

I carried out a minor survey not long ago among persons who had had experience with the two types of rating that I have been talking about. Some of them are in supervisory positions and some not. Here are some of the comments.

(*a*) "I went a long time under different supervisors before anyone said anything about my performance. Interviews are worth while".

(*b*) "Anyone who discussed my performance did so when I was told about an increase in salary. As a supervisor I found the forms tedious to work with and not too effective in assessing a man's real worth. Performance should be discussed at a salary increase interview and at other appropriate times".

(*c*) "The trait type of form is educational for a person new to a supervisory position as it reminds him of traits that he might not think of. As he gains experience he does not need a list and may be better without one. A compulsory type of performance interview has its drawbacks particularly if there is little to say. I knew of a supervisor who tossed a cigarette to a subordinate whom he had previously interviewed several times and said 'Here is your cigarette Joe. We're back at it again'."

(*d*) "I was unfavourably impressed by a supervisor who read off from a rating form the ratings he had given me saying you are above average in this and not quite average in this. I felt like arguing with him, thought that some of the ratings were unreasonable and felt at a disadvantage as he had obviously got prepared for the interview. I feel that at intervals of a few months and when various assignments are being completed it would be stimulating to hear from your supervisor comments about your performance, that is, whether you had done a good job or whether some improvement could have been made".

(*e*) "I have never seen a rating form but heard that performance reviews were made. I have had my performance discussed with me on the job and when told of increases in my salary. I think these were proper times. I have been under different supervisors. If I rated them their ratings would be wide apart. I would hate to put some of the ratings on paper as I would not know what to do with them".

(*f*) "I once thought that the idea of a multi-factor rating form was quite noble but found later that it fails to give an easily understood assessment of individuals in a group. I have been told at the time of an increase in my salary that I was doing good work. I think that performance should be discussed more frequently while work is in progress".

(*g*) "I have disliked the analytical approach to interviews and have felt that the forms that were used for rating had far too many details. A man can take criticism much easier at the time he is told of an increase in his salary. At that time he does not feel that he is on the spot. If the same criticism of a personal trait is repeated the employee will probably become particularly resentful and may develop an inferiority complex. I know of a case where a performance review form was followed step by step by a supervisor in carrying out an interview. This created a most unfavourable impression on the employee".

(*h*) "I find that our present method of comparing employees helps me greatly in my day to day work. With a large number of employees I do not know what I would do without it. I was never able to get much help from the detailed sheets we used to use. I hope we don't go back to them".

(*i*) "I have had my performance discussed with me informally on a few occasions when I asked how I was doing and what I could do better. Also in the past one supervisor read out to me the answers he had recorded on a form on which I had been rated. There were many of them and it all seemed sort of senseless".

Comparative Performance Reviews

Let me now quote from some of the comparative performance reviews made in July 1956 of a hundred and thirteen draughtsmen. These are in their final rank order. You will note that the freely written paragraphs give a good idea of the change in performance as the rank order changes; that the rank order indicates an employee's immediate relative worth to the Company; and that the position-experience-performance rating directs attention to the best and poorest performers in all experience groups and helps in determining salary levels and differentials. I have substituted numbers for actual names in the following extracts from our files and, except for the first example, have omitted the ratings by intermediate supervisors. Similar reviews are made for engineers at all levels in the Engineering Department as well as for clerks and stenographers.

(1) *Draughtsman Grade IV.* Experience 28 years. He has a sound mechanical background, broad experience in machine design and is the key man in his squad. He has on occasions satisfactorily replaced his squad leader.

Rank order in immediate supervisor's jurisdiction: 1st of 2 Grade IV draughtsmen; 1st of 14 in the squad. Position - experience - performance rating: Top 25% to 50%.

Rank order in Chief Draughtsman's jurisdiction with 12 squad leaders: 4th of 20 Grade IV draughtsmen; 4th of 113 draughtsmen.

Position - experience - performance rat-

ing: Top 25 to 50%. He consistently does good work.
Review by Chief Engineer, 1 Supervising Engineer and Chief Draughtsman: As above except position-experience-performance rating changed to Top 10 to 25%.
(Note: If engineers were being rated, 5 supervising engineers and the Chief Engineer would form the final appraisal group.)

(2.) *Draughtsman Grade IV.* Experience 35 years. He is a conscientious worker with good design ability and excellent basic technical training. He can do a variety of work and is reasonably fast and neat. He would be more valuable if he had more self-confidence and did not depend so much on others.
19th of 113 draughtsmen.
Position - experience - performance rating: Top 25 to 50%.

(3) *Draughtsman Grade II.* Experience 7 years. He has been with the Company only a short while but has made a good impression. He has design ability and is a keen, aggressive worker. He has completed all but one year of an engineering course at a university.
28th of 113 draughtsmen.
Position - experience - performance rating: Top 10%.

(4) *Draughtsman Grade II.* Experience 8 years. He is a technical school graduate and shows excellent promise for arrangement and process work. He can work on his own and has shown initiative.
37th of 113 draughtsmen.
Position - experience - performance rating: Top 10 to 25%.

(5) *Draughtsman Grade III.* Experience 33 years. He is a neat draughtsman but a bit slow. He requires close supervision.
77th of 113 draughtsmen.
Position - experience - performance rating: Top 50 to 75%.

(6) *Draughtsman Grade II* Experience 7 years. He has been trained as a machinist but has changed to draughting. He has little draughting experience and is careless. At the moment his ability and future value are in doubt.
112th of 113 draughtsmen.
Position - experience - performance rating: Top 75 to 90%.

Conclusion

I have described to you a procedure for rating employees that is peculiar to the Engineering Department of Du Pont of Canada. With a minimum of effort it seems to give us most of what we need to know to sort out the better from the poorer performers; to make proper selections for promotion, retention and lay-off; to determine equitable salary differentials; to discuss performance with an employee; and to determine training needs. Not only must every supervisor take time to appraise every one of his subordinates at regular intervals but he must justify his appraisal before a group of other supervisors. Like most other works of man the procedure has its limitations and for optimum results is dependent on the efforts put forth by those who use it. It is one way of evaluating performance. Your way could quite well be a better way for your particular conditions.

COMPARATIVE PERFORMANCE REVIEW

Date: *10th June,* 1955 (*Fictitious*)

NAME *John Doe* Experience *7* years Position *Design Engineer*

PERFORMANCE

He is co-operative and possesses initiative, drive and a strong desire to do a good job. He tends to become involved in details although he tries (not always successfully) to meet schedules. He has limited experience on the type of design on which he is now employed.

A. IMMEDIATE SUPERVISOR'S JURISDICTION

Rank Order *Design Engineers* *3* out of *3*
___ out of ___
Position — Experience — Performance Rating Top *25%* to *50%*

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

APPLICATION OF GAMMA RADIOGRAPHY TO CONCRETE

J. A. Forrester, *The Engineer*, v. 205, no. 5327, Feb. 25, 1958.

The scope of industrial radiography has widened immensely in the past few years. This is due in part to the increased availability of inexpensive γ-ray sources, products of the atomic energy programme. Radiography is now being applied to an increasing extent in the production of metal castings and to the inspection of welds; but, in the field of cement products, very little use has been made of this non-destructive method of testing. The use of X-ray equipment is at a disadvantage because of high initial cost and immobility. Five γ-ray sources are commercially available for industrial radiography: cobalt-60, tantalum-182, iridium-192, thulium-170, and caesium-137. The sources are supplied as right cylinders of 2 mm., 4 mm., and 6 mm. diameter. A small aluminum alloy capsule encases the source and shields any β radiation. The main advantages compared with X-ray sets, are their small bulk, mobility, and relatively low cost.

All materials will attentuate γ-rays by an amount almost proportional to their density and thickness. The absorption co-efficient is a characteristic property of an element arising from two principal interactions of γ-rays with its atoms. In one form of interaction the rays give up all their energy to an orbital electron which is expelled. This is called the photo-electric effect. The other form of interaction called the Compton scattering effect occurs when the γ-ray photons impinge on the peripheral electrons of the atom and undergo energy losses in becoming transformed to photons of greater wavelength. These latter photons are scattered at an angle to the path of the original γ-rays. In the interaction of γ-rays of the energies generated by a cobalt-60 source with elements such as those comprising concrete the Compton effect predominates.

Assuming that the absorption by steel and concrete of γ-rays is in proportion to their respective densities, then the intensity of radiation which emerges from a 6 in. reinforced concrete slab, and which has passed transversely through an embedded ⅝ in. diameter steel bar, can be shown to be only 16 per cent of that emerging when the rays pass solely through 6 in. of concrete. Lead intensifying screens of 0.01 in. thickness placed in front of and behind the film during exposure to cobalt-60 rays will nearly double the effect of the rays. Cobalt-60 sources of the strengths which can be readily obtained will penetrate up to 18 in. of concrete and will define the presence of steel, but, due to hardness of radiation, will not show up differences in texture so well as the lower energy sources. The same applies to tantalum-182 which has the added disadvantage of a short half-life. Caesium-137 and iridium-192 have the right energy range and manageable sources can penetrate up to 10 in. of concrete. However iridium has a short half-life and caesium is expensive.

Cobalt-60 was the source used in the series of tests described. Concrete specimens suspected of being honey-combed or cracked were obtained and radiographed. Their condition was subsequently confirmed by breaking open the specimens. For example a piece of spun pipe which had an abnormal permeability to water was considered to be cracked below a coating of bitumen. The outside of the pipe was crazed and no definite crack could be seen from either side. The radiograph clearly showed a crack normal to the surface and travelling in from the edge of the specimen. Honey-combing in concrete is distinguishable as white patches in the radiograph. Movements of aggregate before and after vibration were made using pieces of artificial aggregate made from wood and lead. The location of reinforcing bars, the examination for severe pitting of the steel, and the checking of the grouting around prestressed wires can be effectively carried out by radiography.

As the prefabricated concrete member becomes more valuable there will be greater demand for it to be tested in a non-destructive way, and inspection by γ-radiography may be as important in concrete technology as it is in foundries and heavy fabricating shops.

SWEDEN TO USE NUCLEAR POWER FOR DISTRICT HEATING

John Grindrod, *Combustion*, v. 12, no. 118, March, 1958.

Sweden is decidedly lacking in indigenous sources of coal, oil and natural gas, and has to import carbonaceous fuels to cover more than 70 per cent of the total energy consumption, and a considerable part of this is used for space heating. Therefore there is great interest in the use of nuclear energy for district heating purposes. According to present plans, six reactors for central district heating will be erected within the next 10 years, the first two of which, one for Stockholm and one for Vasteras, are scheduled to be in operation by 1960.

The country's total possible production of water power is estimated at 80,000 m. kwh/year and present production is about 24,000 m. kwh/year. With the present rate of increase of electricity consumption it is estimated that Sweden will be able to continue to increase electricity generation from her water power resources for the next 20 years, but not much longer.

In 1945 the Swedish government appointed an Atomic Energy Committee to follow developments in the nuclear field. It now works as a research council supporting different kinds of fundamental research at universities and other institutions. A special organization, the Atomic Energy Company, was formed as a joint establishment between the government and private industry. The state owns four-sevenths and private industrial interests three-sevenths of the share capital. About 70 larger enterprises form the private shareholders.

During the last two years this company has begun to design industrial reactors based on the use of natural uranium and heavy water. Sweden has large deposits of uranium-bearing oil shales, but since this raw material is very low-grade, making the price of uranium comparatively high, the system of natural uranium and heavy water which requires limited quantities of uranium, seems especially attractive.

The first reactor R 3a with a 76 Mw. heat output for district heating is sufficient for a town of 30,000 inhabitants. Since a temperature of only slightly above 100°C. is required for heating water, the problems are less severe than for a power generating reactor. The reactor is so designed, however, that it can also be used later for the production of 14 Mw. of electricity by back pressure turbines. This later version is called the R 3b and if the problem of the production of fuel elements of sintered uranium oxide canned with zircaloy is solved in time the company will likely proceed with its construction directly. It will be built in collaboration with the city of Stockholm for the suburb Farsta, south of the city, and will be housed in an underground building.

This reactor is expected to provide valuable information for subsequent projects, e.g., for steam producing reactors for the pulp and paper industry, and on a reactor R 4, which is a power reactor for about 100 Mw. of electricity, also based on natural uranium and heavy water.

The present capacity of the Swedish Shale Oil Co. is only about five tons of uranium a year but it will shortly be doubled and then estimated at 20 metric tons/year in 1960, 75 metric tons/year in 1965, and roughly 200 in 1970. A new uranium plant for 100 tons/year is projected and is expected to be in operation in the early 1960s.

WIND POWER: BRITISH MACHINE IN ALGERIA

Engineering, v. 185, no. 4800, March 7, 1958.

The 100 kw. Enfield-Andreau experimental wind-driven generating plant built in 1950 for the British Electricity Authority has been under test in Algeria. Previous tests at St. Albans in the U.K. were not satisfactory due to poor wind conditions. In some 60 hours of running over a two-year period the maximum power developed was 25 kw. at 98 propeller r.p.m. with a measured depression of 16½ in. water.

The site in Algeria is 7 miles from Algiers and 850 ft. above sea-level. In November 1957 within the first seconds of operation the output rose to 130 kw. The machine has been turned over to the Algerian authorities who plan a 5 year test programme covering detailed performance measurements, including vibrational checks on the tower and the propellers to prove design assumptions.

The alternator works on the depression principle developed in France by the late M. Andreau. The blades of the wind-driven variable-pitch propeller are hollow, and as they rotate air is discharged through tip outlets by centrifugal force. The depression thus generated causes air to be drawn up into the blades, through an air turbine, near the base of the tower, which drives the alternator. There is no mechanical connection between alternator and propeller. The latter operates at a constant speed of 100 r.p.m. at wind speeds above 30 m.p.h., giving a constant volume of air flowing through the turbine (58,500 c.f.m.) The electrical output is held constant at 100 kw. between wind speeds of 30 and 65 m.p.h. Below wind speeds of 30 m.p.h. the propeller operates at constant pitch and the output of the turbine falls rapidly as speed decreases.

In the original design there was a free-wheel arrangement between the air turbine and alternator: the turbine ran free until a speed of 1,000 r.p.m. was attained when it locked with the alternator shaft. When the machine was re-erected in Algeria the free wheel was eliminated, the turbine rotor being coupled solidly to the alternator, which assists in stabilizing the alternator at synchronous speed during starting when the alternator is motoring.

It is hoped that devices such as this can be successful in supplementing hydro-electric power in the country.

REFUSE COMPOSTING PLANT

The Overseas Engineer, v. 31, no. 362, Feb., 1958.

Bangkok, capital of Thailand, is to have the largest mechanized composting plant ever built. Instead of dumping the garbage collected from the population of one million on the outskirts of the city, where land is urgently needed, the refuse will be processed and composted. A commercial company is to be established to sell to farmers and gardeners the clean granulated material, sterilized of germs and seeds, which is the product of the composting plant. This will help to improve the poor, dusty sand/clay soil which occurs in certain areas around Bangkok, reduce the need for imported fertilizers, and increase the rice crop, an important Thailand export.

The system to be used is a British method which has proved successful. The Department of Agriculture, Thailand, set up a pilot plant, which proved that the composting method produced compost of high value as a fertilizer. It is estimated that rice yields will be up 25 per cent and there are prospects that two rice crops a year will be possible; in this case the output will be up by 2½ times.

The Bangkok plant is designed to receive 1,100 cubic metres of refuse daily. Materials unsuitable for inclusion in compost will be removed from the refuse by magnetic and manual sorting, salvageable material being separated for sale. The remaining compostable garbage will be shredded mechanically and refined in ballistic separators, which will remove fragments of non-ferrous metal, ceramics, and so on, before sewage sludge is mixed with the garbage to form the raw compost. This will then be conveyed and distributed mechanically into special chambers in which the right conditions will be provided for the active development of aerobic fermentation in such a manner that temperature-duration conditions lethal to harmful organisms are created. The natural heat generated is also sufficient to sterilize weed seeds which would be a nuisance when the compost is applied to the land. The composting process can be operated with or without sewage sludge, the garbage being mixed with water if sewage sludge is not added. Present plans at Bangkok are that certain quantities of dried sludge will be brought to the site and added as required. With a suitable sewage system available, the conveying of sludge could be completely mechanized with both sewage wastes and refuse being disposed of in a combined disposal plant. The whole process is so hygienic that houses and schools can be built alongside. The plant is scheduled to come into operation in 1959. Some 80,000 tons of a safe and useful humus-forming compost will be produced annually.

Upon removal from the composting house, the compost is transported to maturing areas where it is formed into stockpiles. After six to eight weeks the matured compost will have a balanced nitrogen/carbon ratio. Most of the compost will be sold in bulk quantities. Power for the completely mechanized plant is provided by diesel-alternator sets situated in a separate power-house.

It is estimated that the sale of composted material will more than cover the costs of the plant and its operation so that profits can be set against the cost of refuse collection. The proportion of compostable material in the refuse at Bangkok is high, about 80 per cent, but even with a lower figure the system of salvage and composting is economic provided that there is a market for the composted material.

DEVELOPMENTS IN NEW ZEALAND

Civil Engineering (Britain), v. 53, no. 620, Feb., 1958.

Geothermal steam should be contributing to New Zealand's electricity generating capacity before the end of this year. This will make New Zealand the second country in the world to have harnessed steam from underground sources for the generation of power. The first country, Italy, now produces about 300,000 kw. from geothermal steam.

At the outset, a contribution of about 70,000 kw. will be fed into the North Island supply but plans are already in hand to increase the output beyond the 150,000 kw. originally envisaged.

About 50 bores have been drilled so far to an average depth of about 2,000 ft. and a maximum depth of 3,360 ft. and tests have shown that the amount of steam escaping is sufficient to produce 150,000 kw.

THE SAFE USE OF ISOTOPES IN INDUSTRY

W. A. Brobst, *Mechanical Engineering*, v. 80 no. 3, March, 1958.

The use of isotopes in industry, agriculture and medicine is already saving over $500 million annually in return for a direct outlay of about $3 million annually. By 1960 it is anticipated that these savings should increase to $5 billion.

Some examples of their use are as follows: tagging interfaces between different batches of oil flowing in a pipeline by introducing isotopes and measuring their penetrating radiation through the walls of the pipe; over 3,000 different types of isotopic thickness gauges have been licensed for use in the production of paper, rubber, plastics, glass, etc.; radiographic testing of welds and castings frequently at one-tenth the cost of X-ray radiography; radioactive tracing in studies of wear, corrosion, flow of lubricants, etc.; practical application of million-curie radiation sources about to be realized for food preservation, sterilization of drugs and medical supplies, and as catalysts for plastic reactions; cobalt-60 teletherapy sources; in agriculture the eradication of various pests, fertilization experiments and studies of soil-erosion.

Aside from possible toxic effects of the elements themselves, there are two primary hazards involved in the handling of radioisotopes. One is the external exposure a person can receive merely by being in the vicinity of a quantity of radioactive material, and the other is the intake of radioactive material into the body either by inhalation of the dusts or fumes, or by ingestion into the gastro-intestinal tract as a result of contamination of hands, food, beverages, cigarettes or other material which can carry contamination into the body. The seriousness and type of hazard for any facility using isotopes depend primarily upon the amount of the isotope present; whether it is solid, powdered, liquid or in some other form; and its biological effects. With very small tracer amounts for laboratory or field work, the external hazard is usually small, but the contamination problem might be significant. With sealed sources, as in radiographic or teletherapy units, the contamination is usually not a serious problem, and the external radiation levels are the governing factors. Each case will require special rules and regulations.

The most important practical duty of safety personnel, and of management, is to inform all individuals working in a restricted area of the presence of radioactive materials or radiation; to instruct them in the hazards of excessive exposure to such materials or radiation; and the precautions or procedures to minimize exposure and ensure that they are carried out. Instruction manuals and written procedures are necessary to make sure that all persons have the same information and handle the material in the same way.

The duties of the radiation-safety supervisor are to: (a) ensure that every worker selected to handle radioactive materials has suitable physical and mental requirements to qualify him for the work to be performed; (b) be responsible for the instruction of new personnel in safe working practices and in the nature of injuries resulting from overexposure to radiation; (c) establish and maintain operational procedures so that radiation exposure of each worker is kept as far below the maximum permissible as possible; (d) ensure that personnel-monitoring devices are properly used where indicated; (e) ensure that suitable warning signs and devices are in place and operating as required; (f) conduct radiation surveys, leakage tests, air and water sampling where required, and keep records on these surveys for future use by other groups; (g) ensure that shielding, storage containers, and handling equipment are maintained properly; and (h) maintain up-to-date operating instructions for the radiation equipment.

If the proper precautions are taken and the hazard is recognized for what it is, radioactivity can be utilized by industry with a maximum of efficiency and economy, and a minimum of danger. By the proper initial design of facilities and by the institution of safe, workable operating procedures the hazard from radioactivity should cause no more concern than other industrial hazards. The whole problem with radiation safety hinges upon education and understanding of the basic principles of safety.

CREVASSE DETECTOR BLAZES GLACIAL TRAILS

H. P. Van Eckhardt, *Electronics,* v. 31 n. 3, Jan. 17, 1958

Crevasses, hidden pitfalls often wide and deep enough to swallow men and equipment, have haunted Arctic explorers for many years. Bridged over slightly with snow, these chasms in the ice are particularly dangerous in summer Arctic white-outs and snow storms. Until recent years, the only methods used for detecting crevasses were aerial photography and hand-probing with long rods. Aerial observation proved effective only under highly favourable weather conditions and hand-probing was extremely tiring, tedious and slow.

A research program has resulted in the development of electronic techniques employing surface-electrodes for the effective detection of crevasses. The detector consists of a double system of electrodes. A wide system detects crevasses in a path around and in front of a vehicle. A long system detects crevasses with very thick snow roofs missed by the wide system, and distinguishes between large crevasses and narrow cracks.

Each system consists of four dishpan-shaped sled electrodes in contact with the ice or snow surface. The wide-system electrodes are pushed in front of the vehicle in a fanwise arrangement on wooden booms. Two pans act as current electrodes which set up an electrical field in the surrounding ice pack. The remaining two signal electrodes pick up readings from this electrical field. When the ice is solid and safe for travel, the signal is comparatively constant. As the vehicle approaches a crevasse, the flow of the electrical field is disrupted and an alarm signals danger. The long system operates simultaneously with the wide but on a separate frequency. One electrode is pushed ahead by the vehicle and the other two are towed behind at 20 ft. intervals.

As the vehicle travels over the glacial surfaces the detector reports its findings by a two-channel recorder, mounted in the vehicle. An alarm box containing a pair of special relay meters, a red light and a buzzer warns the driver of crevasses.

A source of alternating current is connected between two current electrodes, and a three-dimensional pattern of current flows through the ice. Since ice is a non-conductor, this is displacement current, like that flowing through the dielectric of a capacitor connected to an a.c. source. A potential-difference measuring device is connected between the signal electrodes. Any marked distortion of current pattern by an obstruction, such as a crevasse near the electrodes, will cause a change in the voltage reading.

PRE-CAST CONCRETE JETTY

Engineering, v. 185 n. 4792, Jan. 10, 1958.

A jetty of pre-cast prestressed concrete has recently been finished on the Thames to accommodate ocean-going colliers of 14,000 tons displacement. Three cranes each of 8 tons capacity have a maximum handling rate of 250 to 300 tons an hour. They are sufficient to ensure that a Liberty ship berthed on the flood tides can be sufficiently lightened to reduce its draught to less than 23 feet by first low-water tide. This means that some 4,000 tons of coal will have to be shifted within 8 hours. The cranes, which weigh 230 tons each, are able to lift their full load at 94 ft. radius and in the worst condition, each wheel of the three-wheel bogies could impose a 50 ton load on the jetty rails.

The jetty is L-shaped in plan. The straight approach arm consists of eight bays of 50 ft. span and the jetty head comprises 22 bays of 25 ft. span. At the connecting corner there are two lines of standard gauge railway track at radii of 150 and 160 ft. Deck slab widths are 34 ft. for the approach and 38 ft. 3 in. for the head, with an enlarged portion approximately 75 ft. by 70 ft. at one side of the junction.

The foundations for the jetty consist of 72 prestressed concrete cylinders varying in length between 35 and 65 ft. Each cylinder is built up of a number of hollow precast concrete units all of which have an outside diameter of 6 ft. and a length of approximately 5 ft. The concrete shell is 6½ in. thick and constitutes the main structural portion of the cylinder.

After vertical assembly of the cylinders in a special berth built against the wharf wall the units were post-tensioned together using the Lee-McCall system with 16 'Macalloy' bars of 1⅛ in. dia. spaced symmetrically around the shell. The bars were threaded through 2 in. dia. cored holes and, after stressing, grouted with colloidal grout.

To facilitate sinking, each cylinder was fitted with a cast-steel shoe which was filled with mortar prior to launching. The weight of the 65 ft. hollow cylinders was about 40 tons each. They were open-ended and were sunk by grabbing and loading with kentledge blocks. After each cylinder had been placed, silt and mud were removed by a diver and a concrete plug made in the bottom, then the hollow columns were pumped dry and filled with low-grade concrete.

In the approach arm the foundation cylinders, 25 ft. apart and at 50 ft. longitudinal centres, are connected by *in situ* concrete main cross beams which have a precast prestressed soffit. Stringer beams, also a pre-cast and prestressed span between the main beams and the whole structure, are integrated by a 7 in. reinforced deck slab cast *in situ.* Nearly all stringer beams are seated on pre-cast concrete plinths. They are of a modified I-section with solid end blocks and are 48 ft. 0½ in. long with a tolerance of plus zero, minus ½ in. To transmit the horizontal shear forces the top surfaces of the beams have shear connectors of ½ in. dia. bar hoops at 8 in. centres.

Few of the pre-cast units exceeded 7 tons in weight. A screed of mass concrete has been placed over the length of the jetty to produce a finished deck. Electrical services, aircraft runway lighting, and water supplies for the vessels are contained within the deck screed.

INTERNATIONAL NEWS

The Technion and the State of Israel

TEN YEARS AGO, in 1948, the Technion (the Israel Institute of Technology) had a scholastic tradition already more than two decades old, but the enrollment was still not high. There were 669 students, and a teaching staff of 48. During its entire lifetime, the Technion had created less than one thousand engineers, architects, and technologists, but these had played prime roles in the development of the young country.

At the head of the Technion was Dr. Shlomo Kaplansky, distinguished Zionist leader and economist who, until his death in 1950, guided the Institute through eighteen years of development.

The War of Independence forced the Technion to suspend its studies for a period of one and a half years and, during this crucial period, the Technion laboratories and workshops were kept working to full capacity to supply the army with essential equipment. Fifty-four students of the Technion fell during the war.

With the birth of the State of Israel, a tremendous responsibility fell to the share of the Technion. As the only institute of university rank offering undergraduate courses in engineering, architecture and technology, it had to answer the urgent needs of the young State for skilled manpower in every branch of industrial activity. The vital task of absorbing new streams of immigrants and promoting Jewish settlement in the country was one in which the Technion played a leading role. Research, pure and applied, was urgently called for, and the testing and consulting services of Technion laboratories and experts were constantly in demand by Government and industry.

In 1952, the Technion Research and Development Foundation Ltd. was founded, in order to co-ordinate and centralize research projects carried on by the Technion or sponsored by agencies in Israel and abroad. More than 120 research projects have been pursued through these channels.

In the ten years since 1948, the number of faculties and departments has grown to include practically every branch of modern engineering and technological science. In chronological order of their establishment, they are the Faculties of Civil Engineering, Architecture, Mechanical Engineering, Electrical Engineering, Chemical Technology, Science, and the Departments of Agricultural Engineering, Aeronautical Engineering, Metallurgy and Mineral Engineering.

Now known as the Technion, Israel Institute of Technology, the school has a student enrollment of over 2,000, and an academic staff of more than 500 full and part-time teachers. The number of its graduates has risen to 2,500. President of the Technion is General Yaacov Dori, himself an engineer by training.

In recent years, and particularly

At right is a group of students in front of the new Harry F. Fischbach Electrical Engineering Building at the Technion, Israel Institute of Technology. Below is the Aeronautical Engineering Building.

since the establishment of the Faculty of Science, the Technion's scientific standard have been brought into line with those of leading universities, all over the world. A wide range of higher studies are being pursued through the Graduate School, where over 200 young men and women are working for Master's and Doctor's degrees. Many of these will rise through ranks of the academic staff to become the senior teachers of later generations of students.

Built in 1912 to accommodate some 600 students, the main Technion building on Hadar Hacarmel was supplemented by 28 other structures on the eight-acre campus. However, the rapid expansion which has taken place in the ten years since the founding of the State caused serious overcrowding at the Technion, and the lack of sufficient space forced the authorities to turn away large numbers of candidates for admission each year. To enable the Technion to expand and build new laboratories, install much-needed new equipment, and accommodate larger numbers of students, the Government of Israel placed at its disposal a 300-acre tract of land on the northern slopes of the Carmel, and in 1953 the cornerstone of the first building on the new Technion City was laid.

Since then, with the active cooperation of friends in the United States, Great Britain, South Africa, Latin America, and Israel, ten new buildings have been completed on the new campus and others are under construction. More than 200 students live in the well-planned and comfortable dormitories, and over half the student body are now devoting themselves to their studies in the beautiful surroundings which have already earned Technion City fame as one of the most beautiful campuses in the world.

SWEDEN

KEEPING SHIPPING LANES OPEN WITH COMPRESSED AIR

Successful Swedish experiments have been carried out in recent years to keep shipping lanes free from ice by bubbling air up from submerged plastic pipes. During the past winter a 4-mile test installation has operated in Lake Mälar. The picture shows the ice-breaker *Thule* entering the test channel when opening Mälar port traffic on 27 March. The surrounding ice was up to three feet thick. White edges along the channel are frozen snowdrifts. The compressor for the test route is driven by a 100 h.p. electric motor, which is more than adequate for the 4-mile stretch.

BELGIUM

INTERNATIONAL FAIR

The universal and International Exhibition was opened at Brussels, Belgium, on 17 April and will continue until 19 October. It is the first exhibition of this scope to be held for twenty years.

A town of 490 acres has been built on the outskirts of Brussels, and will be the meeting place of forty-six countries and eight international organizations.

The Belgian section covers 110 acres and includes a group of 'Grand Halls' and other buildings in which are displayed the industrial activity, scientific achievements, and cultural life of the country. Another large group is devoted to the development of the Belgian Congo and Ruanda Urundi.

The dominating feature of the Exhibition is the Atomium, a 350-ft. high structure of nine spheres arranged as a body-centred cubic lattice standing on one corner. The spheres are some 59 feet in diameter and are connected by 10-ft. diameter tubes which contain elevators and escalators. The metallic structure weighs some 2300 tons and rests on a 500-ton concrete foundation.

Four lower spheres house an exhibition of the peaceful uses of nuclear energy. Two spheres, including the upper one, contain restaurants and lookout galleries. The whole interior is air-conditioned.

The foreign section, linked to the Belgian section by a bridge, 81 ft. wide, 51 ft. high, and 430 yards long, is a park of 550,000 sq. yd. in extent and contains the Halls of the participating countries.

The Canadian Hall covers some 10,000 square yards and is designed to give an impression of space. It is a steel framework, partly open and partly encased in blue glass panels. A 125-ft. long, 10-ft. tall mural depicts Canadian enterprise and industry, and there are 23 further exhibits of Canadian resources.

There are international sections for science, art, and organizations such as the United Nations, Red Cross, and so on; gardens of all ages; a Belgian town of 1900; and many facilities for conferences.

It is hoped to give further details of the many interesting structures and other features in future issues of the *Journal*.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Progress by Ontario Hydro

Weather conditions during all of February and in the early part of March were unfavourable but the latter part of the month improved greatly. The total work force at the end of March was 2,550 persons. In February it had averaged 2,775.

With four turbine runner assemblies in place, headgates in place for seven units, and all steel stoplogs installed during February, installation of the rotor for the second of the sixteen generating units in the Ontario half of the international power-house was completed during March, in unit No. 1. Earlier in March, the 225-ton rotor had been installed in unit No. 3. Work had commenced on the lower brackets for generating units two and four. Assembly of the rotors for these units also was progressing favourably.

Three transformers were installed on the downstream side of the power-house main deck. These transformers will receive power from the first four units when operations commence this summer. Construction of the switch gear and bus work was proceeding for the first unit. Station service transformer was installed and control was proceeding for the first four units. Installation of control equipment had commenced for units five and eight.

Meanwhile, concrete placing was proceeding around units ten to thirteen. All the headworks concrete was completed earlier in the month. Total concrete placed to end of March in the power-house was 935,000 cubic yards. As major placing operations neared the end, the downstream construction gantry and the gantry on the upstream side of the power-house were removed.

All preparations were completed for the breaching of C-1 cofferdam scheduled to start at month end. This work began at cell 28 at the international boundary where the cell is being unloaded and removed to flood the tailrace. The cofferdam is being removed cell by cell working backwards from both sides of the international border.

At the St. Lawrence transformer station, the control building was 90 per cent completed. Installation of the breakers was proceeding, as well as the extension of the 230 kv. area to receive power from the generating station.

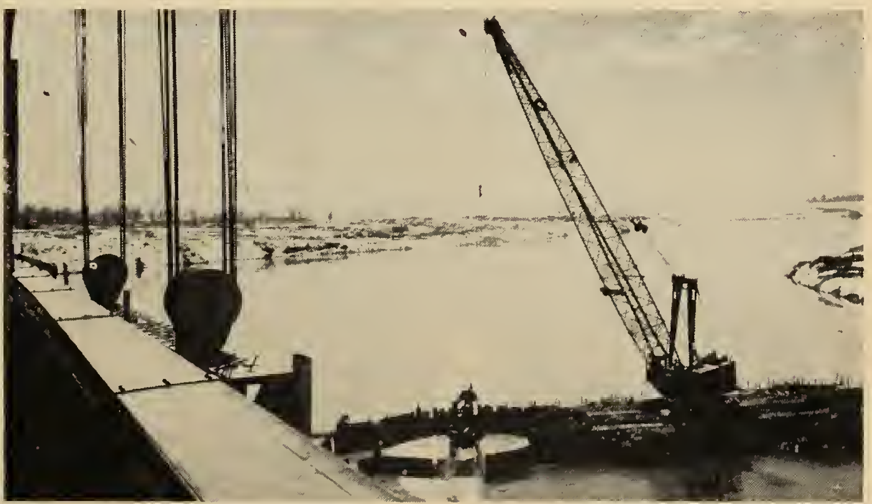
Final clean-up of the area to be flooded was being held up for improved weather conditions, but it got underway in April. Meanwhile in Morrisburg, the demolition of the former main business area was 95 per cent completed, and work now had started on shoreline improvements. The Morrisburg pumping station was completed in February.

Construction continued on the United and Anglican churches in Iroquois. The Anglican manse was ready during April. At Ingleside, construction had resumed on the Anglican Church and manse as weather moderated. All interior work was completed in the United Church ready for handing over to church authorities. All hydro and telephone lines in Osnabruck Township to be flooded, had been removed.

Progress by NYSPA

March was highlighted by transfer of the operation of the Massena intake pumping plant to Alcoa. Concrete in place at end of March for all structures totalled 1,933,000 cubic yards or 94 per cent of the estimated total. Excavation quantities had reached 49,900,000 cubic yards or 94 per cent. Employment averaged 2,260 for the month, compared with 1,830 for February.

On the American half of the power plant approximately 3,700 yards of concrete were placed during the month. The quantity placed to end



Long Sault dam. Removal of cofferdam DU was in progress in March and fill material was being excavated from cofferdam cells.

of March was 96 per cent of the total. Four generator stators and three rotors were in place and two more rotors were being assembled in the erection bay. Five runner assemblies were in position in the units. The installation of drum gates in ice sluices 5 and 6 was completed. Excavation in the unwatered tailrace area was completed.

At Long Sault dam, removal of the earth and rockfill portion of cofferdam DU was completed and the removal of cells was continuing. Cofferdam DU was breached on March 15 and removal of cells was in progress. The three caissons to be used for placing stage III concrete in the spillway diversion openings were lowered into position on the downstream side, and placement of concrete started on March 19. The river had been partially diverted through tunnels in the stage II portion of the structure.

Removal of cofferdams at Iroquois dam was completed early in February and remaining contract work was postponed until spring. Channel improvement work continued during March with two dredges completing work at Sparrowhawk Point and resuming removal of the rim dike at Toussaints Island. Removal of the causeway between Toussaints Island and Presque Isle was completed early in March. Channel work on the entire project was 94 per cent completed at month end.

Power facilities to provide the permanent power supply for the Grass River lock were completed and cutover from the temporary facilities was accomplished ahead of schedule on March 9. Construction was started on dike relief wells, dike observation wells and groundwater investigation wells within the project areas.

Some 80 per cent of the poles had been set and 8 miles of the Barnhart-Plattsburg transmission line were completed. Concrete was being placed in tower footings and erection of tower steel was started for the Plattsburg substation.

Tower steel continued to be moved to tower sites as tower erection was started for the north extension of the Barnhart-Adirondack 230-kv transmission line.

Progress by SLSA

Following severe blizzards and extremely cold weather throughout February and the first half of March, mild and clear weather obtained over the second half of the month. Employment, which averaged 3,500 persons in February, increased to some 4,000 during second half of the month as work on steel erection was speeded up.

At the St. Lambert lock, with all concrete placed and stoplogs and one spare downstream gate installed, erection was being commenced on the lower mitre gates. At the Cote St. Catherine lock preparations were underway for resumption of concrete placing and dikes were being trimmed up. Installation of gates and gate machinery started during April.

On the Upper Beauharnois lock rock excavation was continued during the winter months. Placing of concrete; discontinued during the cold weather, had been completed for the upstream gate section and on both walls of the chamber for about half its length. On the lower lock, both walls of the chamber had been poured to full height for some 80 per cent of their length as well as the lower gate section and upper entrance wall one side. Placing of concrete at both Beauharnois locks was scheduled to be resumed early in April. Piers had been poured for the Valleyfield and St. Louis bridges over the Beauharnois canal, and preparations were underway for an early start on steel erection.

At the Iroquois lock, dredging of the rock in the approach channel to a depth of 14 feet had been carried on during the winter months, but was discontinued at mid-March to permit overhaul of equipment. The lock and channel were ready for service at the opening of lake navigation on April 15.

Channel excavation had been completed at month's end for the stretch of some seven miles between the lower end at Montreal harbour and a point three miles above Victoria bridge. Channel excavation had been resumed on the Northern Construction Co. contract along the Laprairie Basin. The channel was completed for some 2 miles upstream from the C.P.R. Caughnawaga rail bridge. On the Welland Canal, winter work on the channel at Port Colborne had been completed and rock dredging and clean-up was continuing at Thorold. Dredging at Port Weller was completed.

The Canadian National Railways are engaged in constructing an alternative line for diversion of rail traffic over the upstream end of the St. Lambert lock at times when the new lift spans on Victoria bridge are raised to accommodate shipping.

Bridge Construction

Progress has continued steadily on bridge construction during February and March in spite of cold weather and heavy snowfalls. On the Jacques Cartier bridge, numbering from the south shore, piers 1 to 5 are raised to final height. Jacking at piers 6 to 13, including the new through span between piers 9 and 10 placed last October will continue throughout the summer, with completion expected in September. The new span still required to be raised a further 40 feet at end of March.

At the Victoria rail-highway bridge with road traffic diverted to a partially completed alternative crossing upstream, structural steel was in place for upstream roadway over the seaway channel and being erected for the downstream roadway. One of the towers for the double-track lift span was erected and erection of the other was proceeding at end of March, with target date for completion at end of July.

At the Honoré Mercier highway bridge, the first 11 steel girder spans were in place on the new piers at the south end and forms were being placed at end of April for the concrete bridge deck. With temporary timber falsework in place across the seaway channel, erection of the channel span was under way. Further south, steel girders were in place for the last nine spans to connect with the new rock fill which will join highway 3 leading to Laprairie, and forms for the bridge deck were being set.

On the C.P.R.-N.Y.C. rail bridge at Caughnawaga both lift spans for the double track on the new location across the seaway channel were in place and all four lift towers erected, as well as one counterweight.

Roosevelt Bridge Closed

After April 1 the south channel section of the Roosevelt international bridge ceased to be available for traffic. This section crosses the south channel of the St. Lawrence river between Cornwall Island (in Canada) and the mainland of the United States, near Rooseveltown, N.Y. Highway and pedestrian traffic between these points is now being carried by the ferry, *John J. Walsh.*

The north channel part of the Roosevelt international bridge, provides crossing between Cornwall and Cornwall Island. A new south channel bridge which will provide the requisite 120 foot overhead clearance for ships is being constructed jointly by SLSA and SLSDC.

Seaway News

First step in the development of Nun's Island and the construction of the $26 million bridge linking Verdun with the south shore of the St. Lawrence opposite Montreal was taken on March 11, when work commenced on a causeway linking the island with the Verdun shoreline. It will be used by the contractor to sink cofferdams for the piers, and by crews of the Quebec Homes and Mortgage Corporation which is developing the island. Work on the apartment buildings will begin in the spring.

Ottawa Studies Aids for Winter Shipping

Winter navigation in the lower St. Lawrence is now assumed to be only a few years away, according to Department of Transport officials. A three-man team of economists and engineers is studying existing facilities and suitability of Department of Transport harbours such as Rimouski, Riviere du Loup, Pointe au Pere and others, as winter ports.

Vital for general development of winter shipping are the services to be provided, such as icebreakers and aids to navigation. By 1961/62 at latest, the government expects to have a fleet of heavy icebreakers available for St. Lawrence service. The main navigational aid requirements are buoys and lights. Installation of automatic lights may solve the problem of keeping light keepers on duty through the winter. Marker buoys would have to be of a special type, heavier than summer buoys and requiring regular inspection service.

The Meteorological Service Division has been training men for expert work as ice observers for aerial inspection and for making ice-maps and forecasts of ice movements. Chartered aircraft are being engaged earlier than usual this year for regular observation trips. Next year it is intended to maintain regular inspection surveys throughout the winter.

Captain R. G. Edwards, port captain for Canadian International Paper Co., who completed a 2,000 mile air survey from Montreal to Newfoundland early in March, stated there was little to hamper winter shipping at that time. "Ships could easily reach the eastern docks of Montreal harbour right now", he said.

Canadian Pipeline Projects

British Columbia Electric

At the end of 1957, B.C. Electric was serving 24,000 residential heating accounts, compared with only 3,000 at the beginning of 1956 when it was serving customers with manufactured gas. The company received gas distribution franchises from 14 Fraser Valley communities during 1957. Capacity of its system is now 130 million c.f.d. At year-end the company had installed 1,400 miles of mains on the B.C. mainland and 150 miles on Vancouver Island. Its peak-day sales during the winter 1957-58 reached 36 million cubic feet. The company's gas division estimates peak-day sales will increase 300 per cent by 1962.

Alberta Gas Trunk Line

Trunk Line's construction program for 1958 includes a 55-mile westerly extension of the 34-inch mainline; a 24-inch-diameter lateral from the Pincher Creek field, 145 miles in length, to the Princess main line junction; a 26-inch lateral 24 miles long to the Cessford field; an 11-mile lateral of 6½ inch diameter from the Bindloss-Provost line to the Sibbald field; and small laterals to tie in the Atlee-Buffalo, Princess and Steveville fields. A contract has been awarded to Pigott Construction Co. for construction of the 145-mile line from Pincher field at a cost of $1.5 million. Welland Tubes Ltd. is supplying the pipe. Total cost of the line will be approximately $11 million.

The company expects to operate at a loss during the first four years of operation from September 1957. Agreement with Trans Canada calls for Trans Canada to pay four cents per M.c.f. during the first four years, effective as long as it provides the following minimum payments in 12 monthly installments: $210,480 the first year; $2,312,640 the second year; $3,326,400 the third year and $3,621,760 the fourth year.

Alberta Trunk had awarded two large contracts early in March for stringing. Campbell McLeod and Campbell was awarded the stringing for the 24 miles of 24-inch pipe to Cessford, while the 144 miles of 24-inch pipeline out of Pincher Creek will be strung by Hutchison Construction, Ltd., of Leduc. Contracts for three major river crossings over the Bow, Old Man, and Red Deer rivers have been awarded to Fulton-Bannister Ltd.

Two river-crossing jobs on the Goliad gathering system for natural gas in the Pembina Oil field were awarded to Marine Pipeline and Dredging, Ltd., of Vancouver, and both were completed in March. One involves a crossing of the Saskatchewan river 2,500 ft. long, while the other is a 4-inch crossing of the Pembina river 650 ft. long.

Trans Canada Pipelines

Winter work was in progress during March in southern and central Ontario. Pipe was being strung along most of the right-of-way for both the Trans Canada line and the 1958 section of the Crown Corporation line where weather and ground conditions permitted. Canadian Willett-Gaby, Ltd., was stringing on spreads *Y* and *Z*, Mannix Ltd. was stringing on spread *Y*; Canadian Construction Ltd. on spread *Z*. Spread *V* had been awarded to Dunn Bros. (Canada) Ltd. Canadian Parkhill Stringing Ltd. was stringing on Spread *X*.

On the Trans Canada line, spreads 8, 9, 11, 12 and 13 will be strung by Parkhill. On spread 10 Dutton-Williams Ltd. will do its own stringing and on spread 14 Oklahoma Constructors will string its own pipe. Price-Poole will double-joint most of its spread 13 as most of it can be handled off the highway. Majestic has its entire spread organization set up for spread 9 between Potter and Kirkland Lake, and pipelaying is scheduled to start early in June. Grayco Constructors will be on spread 8 from Kapuskasing to Potter. Marine Pipeline and Dredging Co. has a contract from Trans Canada for a buried crossing under the Welland Canal in south eastern Ontario.

Presently authorized gas supplies to Trans Canada will not meet demands in 1960. Contracts now add up to 520 million c.f.d., while nearly 21 trillion feet will be needed over the next 20 years.

Trans Canada's 1958 compressor station program calls for installation of 48,500 hp., or 20,800 over what was originally planned for 1958. This will enable the system to serve the midwestern United States if permits are obtained, or alternatively will provide facilities to serve expanded Canadian markets as they build up.

Canadian Western Program

The 1958 construction program of Canadian Western Natural Gas Co., Ltd. contains five items valued at a total of $1,726,000 in addition to the 55-mile 16-inch main pipeline from the Carbon gas field to Calgary. Additions and improvements to the Bow Island field will cost $298,000; transmission line replacements and improvements will cost $137,000. Largest single item is $640,000 for extensions to local distribution systems. New services and regulators are valued at $403,000. Only major extension planned for 1958 is a line from the Alberta Trunk System to serve Vauxhall. All these items will be handled by the company's own crews.

Northwestern Utilities

A record expansion program, costing an estimated $6.5 million to improve and extend its pipeline system and to service new areas, is planned for 1958. Major item is construction of a 70-mile, 16-inch line from the Pembina field to Edmonton, costing $3.8 million, on which work had already begun in March. Northwestern will buy residue gas produced with crude oil at the Pembina field. Quantities to be purchased are estimated at 65 million cubic feet per day.

The company plans to provide natural gas service to Provost and Cadogan, supplying these communities 160 miles southeast of Edmonton from the Provost gas field. There are about 365 customers who can be served in this area. Cost of this new installation is estimated at $310,000. Some 445 customers in Oyen, Consort and Monitor also will be served by connection to the Trunk Line system, at a cost of about $210,000.

Extensions to the present distribution systems will cost more than $400,000 this year. More than $700,000 is provided for installations for new customers, and for measuring and pressure-control equipment. Improvements to transmission and distribution systems will total $320,000. More than $300,000 is provided for expansion of production facilities, including the acquisition of natural gas rights.

Canadian Western Natural Gas and Northwestern Utilities Ltd. which together serve 145,000 Alberta consumers, will together require more than 260 billion cubic feet yearly within the next 30 years, or triple present needs, according to President D. K. Yorath. Peak demand by that time will rise to 1,650 million c.f.d., or three times presently authorized average daily demand of Trans Canada Pipelines.

(Continued on page 97)

The *Journal* Reports Growth in Engineering Faculties in Canada

Fifth article of a series.

The Department of Engineering Dalhousie University

Dr. H. R. Theakston, Head of the Department of Engineering, Dalhousie University, Halifax, reporting on the *Journal* for this series, gave a review of the structure of engineering education in the Atlantic Provinces. The scheme is different from that in the remainder of Canada.

Prior to 1909, Dalhousie University had, for some years, been giving bachelor of engineering degrees in civil and mining engineering. That year the Nova Scotia Technical College was opened by the Province of Nova Scotia to give the final two years of the degree course. The other Maritime universities, with one exception, were to give a three-year (from junior matriculation) general course in engineering common to all branches. Students, on successful completion of this course, would proceed to their final two years of specialization at the Nova Scotia Technical College. Most students have done so, although each year some few proceed to Queen's, McGill, M.I.T., etc.

The exception to this scheme was the University of New Brunswick, which for many years had given bachelor degrees in engineering. Latterly, however, U.N.B. has been associated with the Nova Scotia Technical College in chemical and mining engineering.

Colleges Associated with N.S.T.C.

Those colleges now associated with the Nova Scotia Technical College are Acadia, Dalhousie, Memorial of Newfoundland, Mount Allison, St. Francis Xavier, and Saint Mary's Universities.

The Department of Engineering at Dalhousie gives the courses in drawing, surveying, mechanics (including kinematics and graphical statics), strength of materials, and materials of construction. The other courses are given by other departments in the faculties of arts and science.

No great changes in courses or content are anticipated in the near future at Dalhousie, Prof. Theakston reports. The course is kept quite fluid, and the Associated Universities are in constant contact with the Nova Scotia Technical College, and minor or major changes are made frequently. Incidentally the deans or heads of Engineering Departments at the Associated Colleges are members of the Senate of the Nova Scotia Technical College.

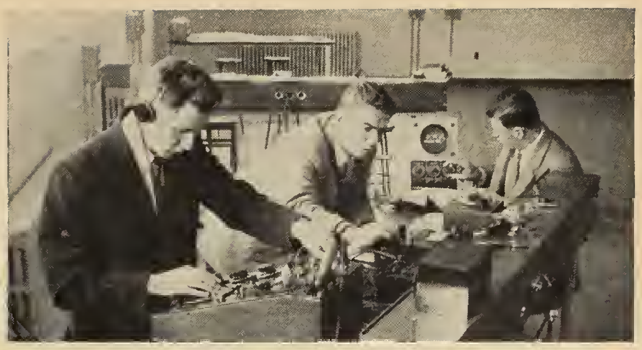
Dalhousie University has four full-time staff members in the Engineering Department, two of them also being responsible for the maintenance of the physical plant of the university.

New Science Building

There is a new building now under construction at Dalhousie, the Sir James Dunn Science Building, made possible through a gift by Lady Dunn of nearly $2 million. This building will house the Departments of Physics, Engineering and Geology, construction having been started about the middle of April, 1958. The move of the departments into the new building will be made in 1960.

The space to be vacated by Physics in the present science building will be taken over by the Chemistry Department which is now using about half of the building. The building presently occupied by Engineering and Geology will be made available to other university activities.

Electrical Engineering Building, University of Ottawa.



Students in the electronics (top) and power laboratories.

Electrical Engineering Building
University of Ottawa

The University of Ottawa has recently completed a new Electrical Engineering Building consisting of two stories and basement, the plan size being approximately 140 feet by 50 feet. The basement houses a small workshop, standards room, storage for heavy equipment not in use, and similar facilities as well as the d-c power supply and a small storage battery. The two "teaching" floors house two classrooms, a seminar room, power and electronics laboratories with their instrument rooms, research laboratories and offices. The flat roof is planned for antenna experiments.

This building was originally planned for classes of 15-20 students in the graduating year in electrical engineering and "EE service courses" of about the same size for students in chemical, civil, and mechanical engineering. The facilities are, of course, supplemented by the other buildings of the university, in which students spend the first two years of the five-year engineering courses. They will also be supplemented, in due time, by other engineering buildings where third, fourth and fifth-year electrical engineering students will receive "service courses" in mechanical engineering subjects and the like.

Modern equipment is being purchased for instruction in electrical engineering, and a number of donations have been received from manufacturing firms. Power equipment is of ratings which are sufficient to present true pictures of commercial practice and yet of economical size. Only a limited amount of such equipment is being permanently installed, the remainder being removable (by portable crane and freight elevator) to basement storage. The objects of these provisions are maximum emphasis on basic principles with minimum emphasis on trades training, and economy of teaching floor-space. The flexibility of the laboratory arrangement of both the power and electronics laboratories is intended to allow of the most modern innovations in equipment and in teaching methods being introduced whenever changes appear desirable.

Increased Enrolment in September
Sir George Williams College

Sir George Williams College, Montreal, has for many years been teaching a pre-engineering (senior matriculation) year as part of its science degree program.

In 1956 the College moved into modern quarters making it possible to add two years of engineering to its curriculum.

By September 1958 the College will be offering the first three years of a five-year course to a limited number of students in civil, mechanical, electrical, and chemical engineering.

The program is being offered in both day and evening divisions of the College making it possible for an evening student to complete the three academic years in six calendar years.

It is planned to admit forty new students into the second year in each division in September 1958.

Jack Bordon, M.E.I.C., Associate Professor of Engineering, is head of the Engineering Department.

Diamond drill exploration showed the possibility of the mining operation. In November, 1955, the contract was awarded to Northern Construction Company, J. W. Stewart Ltd., and Boyles Bros. Drilling Co. Ltd.

The shaft at Maud Island went down 570 feet. The 2,000-ft. tunnel, 6 ft. by 7 ft. high, mined out to Ripple Rock base, was a minimum of 100 feet below the channel floor. From the base, two main shafts, 15 ft. by 7 ft. were driven upward about 300 feet. Radiating from these there were sub-levels, and "coyote" tunnels into which the explosive was packed. The rock was honeycombed with Nitramex 2H, an imported explosive the use of which was technically directed by Du Pont of Canada.

Safety in the mining operation was ensured by emergency pumping equipment, and steel emergency doors designed by Vivian Diesels and Munitions Ltd. to close automatically on any abnormal flow of water.

Public safety was provided by designating as an evacuation zone an area within 3 miles radius of the centre of the blast, as determined in recent tests by the firm Racey, MacCallum and Associates.

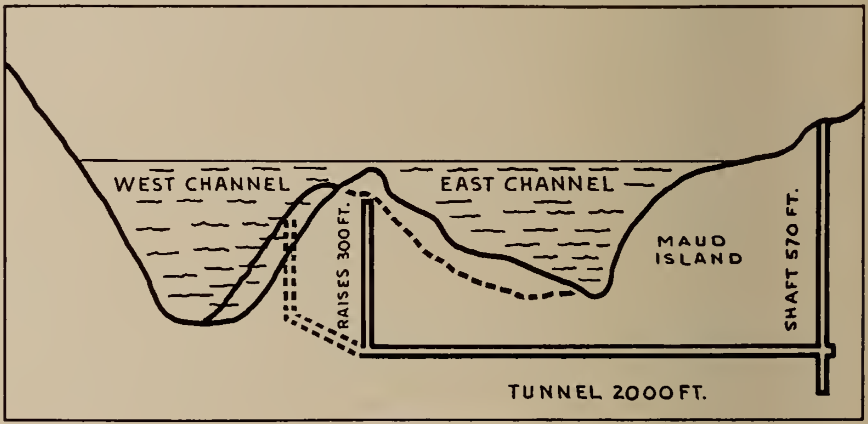
Seismographic stations in Western Canada measured the effect of the blast and their records will form part of Canada's contribution to the International Geophysical Year. Hydrographic and geophysical information about the calculated blast will be available only later, and the editors hope to be able to publish more on this aspect. The explosion was as spectacular as expected, as the climax of the $3 million project was witnessed with attention by a nationwide television audience.

End of Ripple Rock

It took two and a half million pounds of explosives to de-cap Ripple Rock, but the task was completed successfully on April 5. So the Strait of Georgia in British Columbia is rid of a navigation menace at Seymour Narrows that has withstood all earlier attempts at demolition. First surveys showed the channel to have a minimum depth of 47 feet at low tide.

The drawing shows the tunnel plan adopted by the Department of Public Works as the best method of attack on the two underwater peaks. The National Research Council was requested in 1953 to undertake research. The underground approach which they favoured was accepted by the Department. Dr. Victor Dolmage, consulting geologist and E. E. Mason, consulting mining engineer, both of Vancouver, were employed to work under the direction of the chief engineer, Harbours and Rivers Engineering Branch.

Ripple Rock stood in the Seymour Narrows, an obstacle in the shipping lane between Vancouver and Alaska via the Strait of Georgia. This is the inner passage between Vancouver Island and the B.C. mainland, and at this point it is only 2,500 feet wide. The tides became turbulent over the two peaks, 450 ft. apart, reaching to within 9 and 20 feet of low water, while the channel at either side of the rock is 325 and 400 feet deep. The cross currents have caused the loss of some 100 small vessels and the loss of or severe damage to 14 large ships. A toll of 114 lives is attributed to this hazard. Ships waited hours to navigate the passage during the 20 to 40 minutes of slack tide twice a day.



Tunnel to Ripple Rock

Canadian Pipline Projects

(Continued from page 94)

Saskatchewan Power Corporation

One of the largest programs in its history at a total cost of some $16 million, has been announced for 1958 by the S.P.C. Confirmed are major additions to the main pipeline system and a large gathering system in the Hatton field. More than 300 miles will be built as well as an undetermined amount of footage for local distribution systems. Largest job is the 90 mile 14 inch line from Hatton to join up with the line from the Success field to Moosejaw. Some 75 miles of gathering lines will be laid in the Hatton field. The Extension from Moosejaw to Regina will take 40 miles of 21-inch pipe. From Regina to Weyburn and Estevan there will be 125 miles of 10 inch line.

It is not yet announced how the work will be distributed for the purpose of awarding contracts. Pipe will be supplied by Prairie Pipe Manufacturing Co. Ltd., from its Regina mill, under a long term existing contract with S.P.C. Ultimate objective is to provide gas service for every community within economic range, regardless of size and to every community of 1,000 population or more.

Northern Ontario Natural Gas

Detailed surveying for the 88 mile Sudbury lateral was completed in February. Actual construction is scheduled to start May 1. Cost exclusive of distribution systems will be $4.7 million. Fish Service, an engineering consultants firm, is retained by Northern Ontario Natural Gas to supervise the latter's initial construction activities. This year 'Northern' will spend $15 million building distribution systems and laterals to supply communities throughout northern and northwestern Ontario.

Signing of a third large industrial gas sales contract was announced late in February. This contract provides for delivery of some 18 billion cubic ft. of gas over a 10 year period to the Spruce Falls sulphite pulp and newsprint mill at Kapuskasing at a cost of $7,750,000. Gas will fire the steam boilers. Delivery will start later this year when gas becomes available from Trans Canada and when conversion on the boilers is completed.

Twin City Gas

Twin City Gas Co., affiliated with Northern Natural Gas Co., and Dryden Paper Co. Ltd., report that the latter will convert to natural gas this year. A sales contract provides for delivery over a 10 year period of some 10 billion cubic feet to the Dryden mill. This will average 2.7 million c.f.d. over the whole contract term. The new fuel will fire the two main mill boilers, producing steam for drying paper and pulp and for other purposes. Delivery will commence in October, 1958.

Consumers Gas Co. of Toronto

Natural gas service will be extended to some 20 additional communities in Georgian Bay and Ottawa Valley areas during 1958. Construction of pipelines and distribution systems will commence early in the summer. Georgian Bay communities will receive the gas by September, while completion date for the Ottawa valley communities is set for about November 1. The construction program will employ more than 500 workers, the Company reports.

Quebec Natural Gas

The Company's proposed new rate structure was expected to be submitted to the Quebec Electricity Board during the latter part of April or early May. Preliminary findings indicate the Montreal price for the first 1,000 cubic feet per month will be 44 per cent lower than the Toronto price for the same service when natural gas was first introduced there three years ago. The Toronto price was then $4.12 per M, since reduced to $3.94. Quebec Natural estimates $30 million or more will have to be raised to implement the long-term program of building lines into communities not presently served.

Midwestern Case

The bitterly contested Midwestern Gas Transmission project took a dramatic turn early in March with withdrawal of opposition by a Chicago utility, People's Gas and Coke Co., Ltd. To get the project going, however, Midwestern must not only overcome continuing strong opposition from Northern Natural Gas and American Natural Gas, but must cope with uncertainty as to decisions of the Borden Commission. But Midwestern gets a break when opposition to the southern section of the pipeline disappears.

What Goes On

Stelco Expansion

The new blooming mill of the Steel Company of Canada at the Hamilton Works was opened in February.

The mill, representing an investment of $25 million, will allow Stelco to handle the increase in steel production expected between now and 1980. It is only part of a $70 million expansion program nearing completion.

The mill is a 3-acre building, capable of handling 2.8 million ingot tons annually. The rolling operation is adaptable to 30-ton ingots.

Production begins in Stelco's new mill at the 12 soaking pits which are 18 feet square and 11 feet 6 inches deep. In these pits, which will use a fuel mixture of blast furnace and coke oven gas, ingots will be heated to proper rolling temperatures, about 2350 degrees F.

Once an ingot has been selected, it will be placed on a cable-driven roller top ingot buggy which can operate at 1000 feet per minute.

After the ingot reaches the mill table which stretches 425 feet in length, it proceeds to the nerve centre of the operation which is the 46-in. x 100-in. mill proper with a 78-in. lift. The first dimension is the nominal diameter of the rolls, the second corresponds to the width of the mill, and the latter is the maximum opening between rolls.

This huge mill is powered by two, 5000 horsepower motors and is operated from the entry side by two men in a pulpit located above the mill table.

The steel, after being reduced to slabs, proceeds downstream to an electric shear which crops the slabs to required length. They are subsequently stamped automatically with the ingot number, heat number and whether top cut from the ingot. The slabs move along to either of two piling tables where they are stacked on a transfer car. From here the slabs are taken on railway flat cars to subsequent rolling operations.

Also slated for completion early in 1958 are the reversing cold mill, additional batch annealing furnaces, the No. 2 temper mill, and the new metallurgical and chemical laboratory.

Place Ville Marie, Montreal

Huge Urban Development

The general contract for the construction of the Place Ville-Marie project in Montreal was awarded to the Foundation Company of Canada Limited, in March by Webb & Knapp (Canada) Limited.

Place Ville-Marie Corporation, a recently formed subsidiary operating firm is entrusted with the construction and management of the development, located on property leased for 99 years from the Canadian National Railways.

Plans call for completion of the entire Place Ville-Marie development within four years at an estimated cost of $60 million. It will contain a 40-storey aluminum and glass cruciform office building, another major 15-storey office building, a wide pedestrian plaza with shopping concourse and a three-level 900-car underground parking garage.

Foundation explorations started in April. Canadian National Railways have also announced their plans to build immediately a $15 million railway administrative building south of the Queen Elizabeth Hotel in accordance with Webb and Knapp's master plan.

Toronto Harbour Improvement

Two projects currently under way in Toronto harbour are the dredging of the harbour and the building of Terminal No. 15, now nearing completion. On this page is an early progress picture of the Terminal, a steel frame and masonry building, 475 ft. by 200 ft., providing total floor area of 100,000 sq. ft. It has a monitor type roof, with 100-ft. clear span in the centre portion and 50-ft. spans on either side.

Ice-Free Construction

Dravo of Canada Limited, Toronto, used an underwater aeration process in constructing the substructure for a highway bridge in sub-zero temperatures at Vernon Lake Narrows at Huntsville, Ont.

In the aeration process, compressed air is passed through holes in a plastic pipe laid across the channel floor. Despite temperatures as low as 30 deg. below zero, floating construction equipment was able to operate in a 200-ft. wide strip of open water across the channel.

Dravo was building eight concrete piers and two abutments for the 810-ft. span, and expected to complete its phase of the work this spring.

A terrace of factories for light industry on the Annacis Industrial Estate. More than thirty companies are settled on Annacis, and a second development area is proceeding. Western Copper Mills Ltd., will occupy a new plant there in 1958.

Terminal No. 15, Toronto Harbour.

Life Members Activities

The Life Members Committee continues to be active in the affairs of the Institute and in particular in those related to students and young engineers.

Mr. E. V. Gage has been made chairman of the committee, replacing C. M. McKergow who died in 1957.

At its latest meeting, the committee appropriated approximately $1,500 of its funds to assist the Institute in several of its projects. The following is a short description of the purpose for which the funds have been given and the amounts made available in each case.

1) In order to assist in the distribution of the Institute's publication "Daylight through the Mountain" and to make certain that the universities and the branches are aware of it, 125 copies have been purchased by the committee for distribution by Headquarters.
2) In view of the extra cost of the Students Conference in 1957, the committee made $500 available to the Institute to assist in meeting the extra cost.
3) For many years the Institute has been giving to each university an E.I.C. student prize consisting of $25 in cash and an engraved certificate. The committee agreed to make an additional $25 available to apply to the prize for 1958.

There are now 809 life members in the Institute and each year through their committee they make a canvass to raise funds to assist in projects which will be helpful to the young engineers.

Secretary of the committee is John Freeland and correspondence may be addressed to him through the Institute Headquarters.

Canadian Commission for Unesco

At the first meeting of the Canadian National Commission for Unesco held in Ottawa, February 5-6, 1958, the constitution of the new Commission was presented, the roster of officers was filled, applications for membership were treated, and future work of the Commission was discussed.

The Commission has been organized by the Canada Council, at the request of the Governor General in Council (dated June 1957), in conformity with the constitution of Unesco (United Nations Educational, Scientific, and Cultural Organization).

The Canada Council provides the secretariat, and is the channel of communication between the National Commission and the Department of External Affairs. Functions of the National Commission are:

(a) to assist The Canada Council in advising the Department of External Affairs on matters relating to Unesco;
(b) to serve as an agency of liaison with organizations, institutions and individuals in Canada interested in the activities of Unesco, with Unesco Secretariat and the National Commission or other co-operating agencies of Member States;
(c) to promote an understanding of the general objectives of Unesco on the part of the people of Canada and facilitate Canadian participation in Unesco affairs;
(d) to assist The Canada Council in the execution of its program of external relations.

Members, of the Commission are three representatives of the Canada Council and one of the Department of External Affairs; the associate director of the Canada Council, and 12 members from designated agencies. Co-operating bodies supply some members of the Commission by election, 9 officers of the total of 26 being derived from this source. The E.I.C. was named a co-operating body at the first meeting, and as such will be consulted by the Commission on all matters relating to engineering in Canada insofar as the commission may be concerned.

President of the Commission is Dr. N. A. M. MacKenzie, president of the University of British Columbia who heads the executive committee. Advisory committees may be formed corresponding approximately to program sections of Unesco.

The Secretary, Eugene Bussière, reporting to the meeting on a trip to Unesco headquarters in Paris, said of the natural sciences department of the Unesco work:

"The program of this department and its methods of operation seem in all respects to meet the standards which normally can be expected from an Organization such as Unesco. Instead of spreading its funds and efforts amongst scattered projects, Unesco calls upon specific and qualified international non-governmental organizations to carry out its projects and relies on consultative committees for the formulation of its program.

"In this respect, I am glad to note that the National Research Council of Canada will be represented by its President, Dr. E. W. R. Steacie, on the Unesco International Advisory Committee on Research in the Natural Sciences at its next meeting in Moscow in 1958. Furthermore, Unesco is playing here an essential role of co-ordination in a field where international co-operation is the necessary and logical outcome to the development of science."

Southern Ontario Regional Conference

The first E.I.C. regional technical conference of its kind, was held in Hamilton, Ont., on March 15, 1958. Most noticeable and welcome evidence of success was the keen interest and enthusiasm of approximately 400 engineers and their ladies who supported the Hamilton venture.

The Hamilton Branch undertook the experiment in this new form of activity within the Institute, with the co-operation of six other branches, the Border Cities, Kitchener, London, Niagara Peninsula, Sarnia and Toronto Branches. The support and practical help of the Engineering Institute Headquarters was assured in advance.

This type of meeting was specially applicable to the Southern Ontario region, with its concentration of engineers. All engineers were invited, whether members of the E.I.C. or of the Association of Professional Engineers of Ontario.

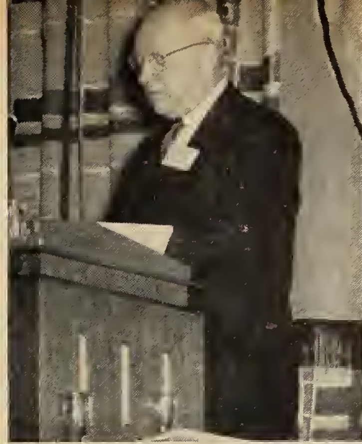
The ladies particularly enjoyed the special luncheon and afternoon fashion show arranged by the Hamilton Branch Auxiliary.

The four technical papers on the one-day program covered technical subjects of interest to all branches of engineering. Guest speakers Dr. J. A. Ouimet and Mr. J. Lance Rumble proved exceptionally interesting and found an attentive and appreciative audience.

The favourable reaction and comments received during and after the conference would encourage future endeavours of this kind, not only in Southern Ontario but in other regions of Canada.

In the small groups above and below: V. A. McKillop, past president, E.I.C., London, F. W. Roberts, Toronto, T. M. Medland, A.P.E.O., Toronto; C. Climo, D. A. Barnum and C. B. Beamer, Niagara Falls; A. F. Barnard, Hamilton, J. A. McLaren, E.I.C., Toronto, G. Norton, Toronto, H. E. Seely, Hamilton; Branch chairmen R. H. Self, Toronto, R. C. Mitchell, Hamilton, C. A. Leicht, Kitchener, E. C. Little, Niagara Peninsula.

The speakers: J. Lance Rumble (left); and N. A. Eager, H. R. Chipman, H. F. Burns, F. R. Denham. Speaker J. A. Ouimet was not photographed, regrettably.



Below: E. G. Jorgensen, Toronto, with W. A. Wheten and B. Spence of Hamilton.

Southern Ontario Regional Conference

by J. R. CURRIE, M.E.I.C., *Branch News Editor*

The first E.I.C. Southern Ontario Regional Conference was held on March 15 at the Royal Connaught Hotel in Hamilton.

Following registration and a buffet luncheon, members and guests were welcomed by Conference Chairman R. H. Stevenson who introduced the guest speaker, Dr. J. A. Ouimet, B.E., D.Sc., M.E.I.C., general manager of Canadian Broadcasting Corporation.

Dr. Ouimet, speaking on "The Impact of T.V. on Canadian Life To-day and To-morrow", described the early development of T.V. in Canada and indicated the extremely rapid growth of T.V. in this country. Results of polls taken in Canada show that T.V. viewing to-day is the third major activity of the average Canadian, exceeded only by sleep and work. The particular problems peculiar to the Canadian geography and the use of the two languages have played a dominant role in C.B.C. policy and decisions. The Canadian micro wave set-up, now nearing completion, will extend across 4,200 miles and six time zones. Dr. Ouimet concluded his address with a discussion of the need for the development of a truly Canadian pattern of T.V. productions.

Following Dr. Ouimet's address, four technical papers were presented as follows:

F. R. Denham, B.SC., PHD., M.E.I.C., of the Electro-Metallurgical Company of Canada Limited, presented a paper entitled "Heat wave". N. A. Eager, B.SC.,M.E.I.C., of Burlington Steel Company Limited, spoke on "Rail Steel as a Medium for Reinforcing Concrete". H. F. Burns, B.SC., M.E.I.C., of A. D. Margison & Associates Limited, presented a paper entitled "The Engineering Approach to Municipal Traffic Problems". H. R. Chipman, B.SC., of Naugatuck Chemicals Limited, presented a paper, "Engineering Applications of Reinforced Plastics".

During the afternoon, the Hamilton Branch E.I.C. Auxiliary and Wives of Professional Engineers entertained the ladies with a luncheon and a special Spring Revue held at the Westinghouse Auditorium.

Following the presentation of the technical papers, the Hamilton Branch entertained the delegates and their ladies at a reception held in the Sheraton Room. The reception was followed by the Conference Banquet at which the guest speaker was J. Lance Rumble, general manager of the G.M.C. Toronto Retail Truck Branch. The banquet was followed by the conference ball, with music by Chris. Lovett and his orchestra.

New Dimensions in Post-Graduate Education for the Young Engineer*

Ralph W. Rawson
Chief Engineer
Fansteel Metallurgical Corporation, North Chicago, Ill.

My remarks should be considered as four paragraphs. With my first deep breath, I will describe Fansteel Metallurgical Corporation. Next, I will discuss the nature of our engineering requirements. The topic sentence of paragraph three will be: Fansteel develops an adequate reserve of engineering manpower. Finally, I will submit for your consideration, three dimensions of engineering education as I read them.

Fansteel Metallurgical Corporation is a fifty year old company dedicated to the extraction, fabrication and sale of refractory metals. We are currently marketing tantalum, columbium, molybdenum and tungsten as oxides, carbides, powdered metal, sheet, bar, wire and fabricated parts. Our operations involve many technical fields.

Three of the twelve top Fansteel executives are Ph.D.'s, one in Chemistry, one in Metallurgy and one in Physics. The technical staff, that is, Research, Development and Engineering, consists of seventy scientists and engineers. Five have Ph.D.'s, sixteen

Ralph W. Rawson

(or about one quarter) have advanced degrees. The Fansteel technical staff includes mechanical, electrical, aeronautical, metallurgical and chemical engineers, chemists, physicists, mathematicians, theoretical metallurgists and others. In production departments we have one Ph.D., two Master degrees, thirteen Bachelor of Science degrees. Eighty percent of our salesmen have graduated from college. One conclusion, which I drew during my analysis of individual backgrounds, is that chance more than choice determines the destiny of engineers. It's a slim thread that guides us in and out of companies, causes us to specialize in sales, design, maintenance, production, industrial relations, advertising or management. If this conclusion is correct, and Fansteel is a representative population, each of you, in retrospection, will agree that your professional careers have been influenced by some of the following: your wife's choice of climate, your children's education, somebody's health, a real estate deal or a friend who misled you. All of these things happened to you after you left college. Assuming that you are forty years old, less than a third of you are working in your college specialty. If you were at Fansteel, the majority of you would have changed your specialty twice since leaving school. If you accept these findings, you will agree with me later when I say, generalize the engineering education.

As I promised, the topic sentence of paragraph three is, Fansteel develops an adequate reserve of engineering manpower. Two years ago, Mr. John Meade, our vice-president and director of industrial relations, conceived an operation known to us as the Engineering Aide Program. It has received considerable publicity in Chicago papers and may have already come to your attention. We are augmenting our engineering staff by training and utilizing technicians. A dozen young men, three of whom were already employed by us were selected from seventy applicants. Each candidate was required to be less than twenty-seven years of age and have completed his military service. The trainees were selected after an analysis of their academic records, intelligence and mechanical aptitude tests and interviews. Eight of the twelve are in their second year of chemistry, physics, mathematics, and English at Lake Forest College. Twelve more employee-students were matriculated at Lake Forest College this summer. Each man works thirty hours per week in addition to his studies. The company pays tuition, books, laboratory fees and nominal wages. The Engineering Aide Program will yield outstanding technicians at the end of two years. Further study will be allowed for those who want to continue toward a degree. Approximately *six years* will be required to complete the engineering curriculum.

Art and Science — Dr. Joseph C. Elgin, Dean, School of Engineering, Princeton University, in discussing *Trends in Engineering Education*, distinguished between *engineering art* and *engineering science*. "The engineering art", he states, deals with *know-how* and specialized techniques, with specific manufacturing processes, products, types of equipment and kinds of material and machines . . . The *art* looks to the past, and builds on past knowledge and technology, much of which may have found its way into engineering handbooks. On the other hand, the *engineering science* thinks in terms of principles and *know-why*. It attempts to generalize in order to predict the future. It deals with mechanisms by which and the reasons for, and with the principles for designing, building or operating machines, chemical processes or products of any variety. It deals with fluids or solids of any description — not restricting itself to a particular fluid such as gasoline . . ."

Our Engineering Aides at the end of two years will have *"know-how"* which constitutes *engineering art* and a considerable amount of the *"know-why"* of *engineering science*. Referring now to our development of engineers, we have arrangements with both Northwestern University and the Illinois Institute of Technology to participate in their co-operative engineering programs. The graduate engineers, whom we recruit, are selected on the basis of academic standing, extra-curricular record, motivation and

*This was Mr. Rawson's contribution to a session of the joint assembly of The Engineers' Joint Council and The Engineers' Council for Professional Development, October 25, 1957. Mr. Rawson dealt with "Development of In-Plant Training".

enthusiasm. Our recruiting is simplified by providing summer employment each year for thirty to forty engineering students who live in our locality. We prefer a man who has partially supported himself during his college career. In our opinion, the attributes of character most important in an engineer are intellectual honesty, patience, imagination, courage and perseverence. Fansteel employees who have degrees are encouraged to continue their post-graduate studies at a school of their choice. Lake Forest College, Illinois Institute of Technology, Northwestern, University of Chicago and the University of Wisconsin are available. Tuition and books are paid for by Fansteel provided a satisfactory grade is earned and the subject is related to their employment. Forty employees are taking advantage of this opportunity this year. Several men have obtained Masters degrees in this way and one Chemist is in the final stage of obtaining a Ph.D. These men are well qualified in the "know-why" of *engineering science.* Our post-graduate program also includes a curriculum at Lake Forest College known as the Industrial Management Institute. Selected employees with three years or more at Fansteel meet at the college one night each week for four years to study and discuss management problems with professors and successful executives. Several other corporations in our area participate as co-sponsors of this Institute. The Industrial Management Institute emphasizes the humanities more than the technicalities of engineering and develops leadership and managership more than professionalism. Fansteel has also sent selected supervisors to Harvard Business School and the University of Chicago for special training in management and business. Our post-graduates are combining the *"know-how"* and *"know-why"* of engineering with managerial experience and acumen.

The easiest way I could think of to cue myself for my paragraph four remarks about the Dimensions in Post-Graduate Education was to hypothesize on the length, breadth, and depth of engineering curriculums.

Concerning length: The trend toward five year courses of instruction for bachelor degrees in engineering is detrimental to the profession and not in the best interests of the individual. The engineering profession needs practical, realistic, objective, as well as intelligent young men. These characteristics are less prevalent among the "silver spoon" class who have $10,000 to invest in five years of college. The practical man won't go deeply in debt and will choose another career. The realist wonders whether or not a five year degree will increase his initial rate of compensation or merely postpone it one year. The objective man is apt also to be a utilitarian who grows impatient with unused knowledge. The intelligence level required by engineering schools insures the success of practical, realistic, objective, young engineering students in almost any other line they may choose to follow.

Concerning breadth: Continuation of this trend may lower the caliber of young engineers. The trend toward broadening the undergraduate engineering curriculum has been limited to the inclusion of humanities. Generalization of the undergraduate scientific courses is also in order. I suggest that we teach more principles of electricity, vibration and heat transfer and less induction motors, bridge construction and petroleum cracking. Since few of us are supporting our families on our college speciality, why not let industry and post-graduate schools train the engineering specialists?

Concerning depth: Depth, in terms of years of study and practical experience, is essential to individual engineers and to engineering departments. My suggestion that the undergraduate curriculum be limited to four years does not mean that the total years of scientific study should be lessened. Depth does not necessarily mean advanced degrees. By my standards, a man with a bachelor of science degree in electrical engineering and a bachelor of science degree in mechanical engineering has more depth than the man with a masters degree in either. Companies like Fansteel are making it easy for you and me to return to college for graduate work because they recognize that we are more valuable to the company after further education. As the *art* and *science* of engineering continues to grow, so will the need for post-graduate engineers. Get modern! Get more degrees!!

Canadian Conference on Education

The Engineering Institute was one of the 19 sponsoring organizations of the Canadian Conference on Education. The Institute made a considerable contribution to the conference held in Ottawa, February 17-20, 1958, which attracted great public attention.

E.I.C. delegates were Professor L. P. Bonneau, Laval University, Quebec City; Dean H. G. Conn, Queen's University, Kingston; M. J. McAuliffe; Canadian Westinghouse, Hamilton; Dean R. R. McLaughlin, University of Toronto; and Dr. Garnet T. Page, deputy general secretary, E.I.C. Unfortunately, Dean Conn was unable to attend because of illness. Two other members of the Institute, Dean H. G. Gunning, of the University of British Columbia, and Mr. P. M. Hopkins, of Aluminum Company of Canada, Kitimat, B.C., attended as delegates of other groups.

The Institute's representatives participated actively in the workshops on Higher Education, Curricula, School Buildings and Equipment, and Teachers: Quality and Quantity.

The thirty resolutions passed by the conference were all constructive and should result in useful action being taken toward solving some of Canada's most pressing problems in education.

One particular motion, recommending to the Privy Council of Canada the appointment of a national committee to examine the development of a national policy for the promotion of basic research, particularly at universities, was of special interest to the Institute. This motion developed from a suggestion originally put forward by several members of the staff of the University of British Columbia. It is understood that a number of national organizations including the E.I.C. have been asked to support the original suggestion emanating from the University of British Columbia, and the Institute will meet with representives of other national technical societies to discuss the full implications of both the original suggestion and the motion as finally passed by the Canadian Conference on Education.

The Conference appeared to have been successful in increasing public awareness of Canada's problems in education, in bringing together those concerned with these problems, in stating what some of the basic problems are, and in the establishment of a continuing organization to sponsor constructive action toward the solution of these problems.

Here are a few informal comments on the conference received from the E.I.C. participants.

"All in all I believe the Conference had a very good influence in bringing once again to the attention of the public the problem of education, and that on a national scale. It also was beneficial in bringing together a good cross-section of the Canadian educators of every level. They found out that they have many things in common and that their differences of opinion are slight in most cases."

"I attended the sessions on Organization and Curricula. The outstanding feature of the discussions in this part of the conference as I saw it, was the conclusion that we must stress the basic and traditional subjects of reading, writing and arithmetic. There has been a tendency in recent years to try to make education too easy, to think of everything as fun, and to shy away from the hard work of instilling a thorough mastery of the fundamental tools of learning in the early years of schooling."

"We must get down to first principles and recognize the primary role of the school as the academic and intellectual development of the child. If we do this properly most of the other great ideals we seek will come as a natural corollary."

"I thought the Conference a marked success. This was partly because of the 'spontaneous' gathering of so many representatives of widely different organizations and the opportunity that this afforded for interchange of views. It was good, certainly, that university people could meet with and learn to appreciate more of the problems of the public schools and their representatives. I found all these people, whether they were teachers, inspectors, representatives of labour, school boards, or industry, most friendly and co-operative and I hope they found the representatives of the universities the same way."

Correspondence

Publication of Colonel Grant's letter below was delayed for lack of space. However, a word from Col. Grant is always a pleasure, and so it is published now. Editor.

Field Secretary Retires

Dear Dr. Wright,

On leaving the position of field secretary of the Institute, which I have held for the last eight years, I feel it incumbent upon me to express my deep appreciation of the support that I have had from the eight Councils under which I have served, and for the liberality with which they have treated me.

I also wish to record my gratitude for wise direction and encouragement from yourself, for ready and efficient help from Miss McLaren and the staff at Headquarters, and for loyal and devoted service by my two assistants in Toronto, at first Mrs. Wardle, and latterly Mrs. Robertson.

Any success attained for the Institute by the field secretary's office has been due much more to those mentioned in the foregoing paragraphs than to my own efforts.

I also have to express my thanks to the chairmen, secretaries and other members of the executives of the branches of the Institute, and to many individual members who have given me help, advice and co-operation.

L. F. GRANT, HON. M.E.I.C.
Kingston, Ontario.
December, 1957.

Fourth Nuclear Congress, 1958

The 1958 Nuclear Congress concluded on March 21st, after five days of meetings in Chicago, Ill. These congresses have as their aims to (1) foster a free exchange of knowledge, information, and ideas — among engineers and scientists in all fields of technology, — among leaders in industry and management, — among management, engineers and scientists; (2) reduce the demands on the time of individuals; (3) bring into one meeting the latest information and exhibits from all fields of nuclear science, engineering and management; (4) implement the utilization of atomic energy for industrial purposes.

The Congress included the Fourth Nuclear Engineering and Science Conference, the Atomic Energy Management Conference, the 6th Hot Laboratories and Equipment Conference, and the Atomfair.

The Engineering Institute is one of the thirty societies sponsoring the Congress. Dean H. G. Conn of Queen's University, Kingston, was the Institute representative at the "All-congress Banquet". On this occasion the speaker was Vice-President Nixon of the United States. The E.I.C. was represented at these meetings, also, by the deputy general secretary, Garnet T. Page.

Sponsorship entails collaboration in the program of the Congress and in advance publicity and promotion. Through the agency of the E.I.C., three papers were presented by personnel of Atomic Energy of Canada Limited. They were: — "The Nitrate Complexes of Tetravalent Plutonium," by J. A. Brothers, R. G. Hart, and W. G. Mathers; "Kinetic Effects in the Partitioning of Uranium and Plutonium in the Processing of Irradiated Reactor Fuels by Extraction with Tributyl Phosphate," by W. W. Morgan, W. G. Mathers, and R. G. Hart; "The Behavior of Ruthenium in the Fixation of Fission Products", by W. E. Erlebach and R. W. Durham.

Space does not permit the listing here of the 214 original papers presented relating to this year's theme, "Industrializing the Atom".

Copies of many of the papers are still available in the form of preprints. A list of the preprints available is in the E.I.C. Library; or it can be obtained from the American Institute of Chemical Engineers, 25 West 45th Street, New York 36, New York.

DATES TO REMEMBER

AUGUST 11, 12, 13, 1959

NOVA SCOTIA TECHNICAL COLLEGE

50th Anniversary Reunion

For information write Box 811, Halifax, N.S.

THIRTY-FIVE YEARS AGO

Comment on the Journal of May, 1923

Three papers were published in the May 1923 issue: the first by W. Nelson Smith, M.E.I.C., consulting electrical engineer, Winnipeg Electric Co., entitled The Principles of Three Wire Distribution for Electric Railways. Though of wide interest at the time, the subject has lost much of its interest today.

The second paper, by G. F. Blair, K.C., city solicitor of Regina, dealt with important points relative to specifications for building contracts, and covered many aspects of specifications that are true today.

A third paper, entitled Electrons, Atoms and the Ether by W. B. Cartmel, M.E.I.C., of Northern Electric, was continued from the April issue.

Editorially, plans were announced for the first meeting in Montreal of the American Society of Mechanical Engineers, to be held jointly with the Engineering Institute of Canada.

A cross-section of 'News of the Branches' for the month reveals the subjects which were of interest in the twenties. The Victoria Branch reported on a visit of members to the plant of the Victoria Gas Company, a new up to date plant for producing manufactured gas. The Calgary Branch heard two papers on street railways.

The London Branch reported on two papers, one on rural roads in the Province of Ontario, the second on The Mechanical Engineer of Today. At a third meeting, General Secretary Fraser S. Keith stated that there were then twenty-three branches with a total membership of 5,300.

The Toronto Branch had a luncheon meeting on April 19 to do honor to President-Elect Walter J. Francis, with some 150 members in attendance including C. R. Young, Dr. R. A. Ross, General C. H. Mitchell, C. H. Rust, Frederick B. Brown, M. J. Butler, Willis Chipman.

The Hamilton Branch had listened to an address on Power Developments in Japan, by Stephen Q. Hayes of the Westinghouse Co. of Pittsburgh. At the Niagara Branch, members attending a dinner meeting heard an address by Hew M. Scott, M.E.I.C., on the Esquimalt Dry Dock and on the Ravages of Marine Pests on the Pacific Coast. Street Lighting was the subject treated at a meeting of the Peterborough Branch, by R. C. Flitton, M.E.I.C.

At Ottawa, W. Kynoch, F.R.S.A., of the Forest Products Laboratory addressed a meeting on Wood and its Possibilities and Commander C. P. Edwards of the Dept. Marine and Fisheries spoke on Wireless Telephony.

The Quebec Branch report covered seven addresses and papers. Julian C. Smith, M.E.I.C., had given a lecture on Recent Advances in Water Wheel Design. P. A. Galarneau, general manager, Citadel Brick Co. had presented an address on the Making of Brick Throughout the Ages.

S. L. DeCarteret, A.M.E.I.C., had spoken on The Manufacture of Wood Pulp. Avila Bedard, director of the Quebec Forestry School had reviewed the forest situation in the Province of Quebec and the extent and effect of various destructive agents.

Professor Augustin Frigon, M.E.I.C. of Ecole Polytechnique at a luncheon meeting had attempted to interest engineers in research work, both scientific and industrial. Finally, E.I.C. General Secretary, Fraser S. Keith, had reviewed the history of the profession.

The Moncton Branch heard a talk by W. B. MacKenzie, M.E.I.C. on the City of Halifax and its harbour, bringing to light some historical data and many scientific facts. The speaker felt the proper site had not been selected for the city and docks.

Three meetings were reported from the Cape Breton Branch at Sydney, N.S. John T. Farmer, M.E.I.C., chairman of the Montreal Branch, gave an address on Mechanical Stokers. K. G. Cameron, A.M.E.I.C., of the Dominion Coal Corporation was guest of honour at a special dinner meeting on the eve of his departure for Montreal. E. C. Tonge, A.M.E.I.C., addressed the regular meeting on the subject of Coke Manufacture with By-Product Recovery.

In an open letter signed by Willis Chipman, M.E.I.C., president of the Association of Professional Engineers of Ontario, members of the Engineering Institute of Canada resident in Ontario, were urged to register and apply for membership.

H. G. C.

Nuclear Congress, 1959

Canadians Invited to Present Papers in Nuclear Field

The Fifth Nuclear Congress is scheduled for April 5-10, 1959 in Cleveland, Ohio.

The Engineering Institute of Canada, as a participating society, will provide for the Nuclear Engineering and Science Conference one or more technical papers. Authors are invited to submit summaries (300-500 words) of proposed papers. Summaries should be received at Headquarters by October 1, for transmission to the Congress Manager.

Authors will be notified in October of the selection of papers for the program, and will be given specifications for the preparation of manuscripts, to be received by the E.I.C. by November 28.

Interested authors should send summaries to: Dr. Garnet T. Page, The Engineering Institute of Canada, 2050 Mansfield St., Montreal 2, Que.

MARITIME PROFESSIONAL ENGINEERS CONFERENCE

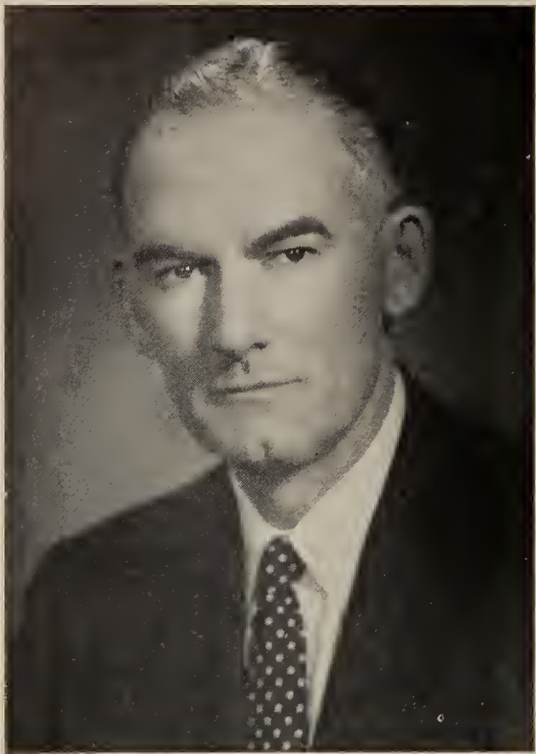
of the Engineering Institute of Canada, Atlantic Provinces Branches, and the Associations of Professional Engineers of Nova Scotia, New Brunswick, Prince Edward Island, and Newfoundland.

This important meeting will be held on

September 2-5, 1958

at

Digby Pines, Digby, N.S.



K. F. Tupper, O.B.E.

PRESIDENT

The Engineering Institute of Canada

1958 - 1959

THIS YEAR the Engineering Institute of Canada elected as its head, a man with wide experience in the field of atomic energy. He is K. F. Tupper, president of the firm of Ewbank and Partners (Canada) Limited. Located at Toronto, this is a firm of engineering consultants in the field of thermal and electrical power.

Mr. Tupper grew up in Western Canada; taking his elementary and secondary education in Saskatoon and Calgary. He went on to engineering studies at the University of Toronto where he won a B.A.Sc. degree in mechanical engineering in 1929. He subsequently studied aeronautical engineering at the University of Michigan, receiving a M.Sc. degree in 1938.

What was to develop into an eventful engineering career began at the Riverside Iron Works Limited, Calgary in 1929. Later that year he joined the National Research Council, physics department as a draughtsman. Subsequently the division of mechanical engineering was formed and the aeronautical laboratories became a part of it. He was concerned with the design and operation of wind tunnels and the ship model testing basin.

In 1943, Mr. Tupper was assigned to the Canadian aircraft jet engine project. Emerging from this project a Crown company, called Turbo Research Limited was formed in which he became chief engineer. A forerunner of the Aircraft Gas Turbine Division of A. V. Roe, Canada Limited at Malton, Ont., it subsequently became Orenda Engines Limited. In 1946 when the project passed from Turbo Research to A. V. Roe, Mr. Tupper returned to the National Research Council. He was assigned to the atomic energy project at Chalk River, Ont. In 1947, he was appointed director to take charge of the division responsible for plant operations and services.

In 1949 the University of Toronto conferred on him the office of fifth dean of the faculty of applied science and engineering. However, he retired in 1954 in order to devote his time to the firm with which he is now associated.

In recognition of his wartime services he was awarded an O.B.E

Mr. Tupper was in 1957 elected to serve a three-year term as councillor of the Institute representing the Toronto Branch.

NEWLY ELECTED OFFICERS OF THE INSTITUTE

At the Annual Meeting, three vice-presidents and twenty-five councillors will take office, and will serve with others whose terms of office continue. The complete list of Council Members will appear in the June issue.

THE MARITIME PROVINCES

John Bartlett Angel, M.E.I.C., president of the United Nail and Foundry Company Limited, St. John's Newfoundland, and charter member of the Newfoundland Branch, has been elected a vice-president of Zone D of the Institute, which encompasses the Maritime provinces.

Mr. Angel attended the Memorial University of Newfoundland and McGill University. He received a B.Eng degree in metallurgy in 1935 from the latter institution.

Mr. Angel is among those fortunate few who have travelled extensively in the Arctic. Between 1931 and 1935 he was privileged to visit Greenland several times. Together with Captain Robert A. Bartlett he went to Foxe Basin in 1933.

He joined the United Nail and Foundry Company Limited in 1935 as an engineer, became managing director in 1938 and president in 1948.

Mr. Angel is president of Wm. Noseworthy Limited, St. John's, and the Angel Manufacturing and Supply Company Limited, of North Sydney, N.S. He is chairman of Heap and Partners (Nfld) Ltd. and director of the Newfoundland Fire and General Insurance Company and Majestic Sales Limited, at St. John's. He is a past-president of the Newfoundland Board of Trade.

Michael R. Campbell, M.E.I.C., 1955 chairman of the Cape Breton Branch will serve a two-year term as councillor of the Institute. Mr. Campbell is assistant general superintendent of Dominion Iron and Steel Limited, Sydney, N.S.

A graduate of St. Francis Xavier University and the Massachusetts Institute of Technology, he gained an M.Sc. degree in chemical engineering from M.I.T. in 1927.

Joining Dosco at that time, he was almost immediately named assistant superintendent of the open hearth department.

Late in 1932 he was granted a leave of absence to become head of the chemistry department at St. Francis Xavier University, and returned to the Sydney steel plant in 1934. Appointed superintendent of the open hearth department in 1946, his promotion to assistant general superintendent of Dominion Iron and Steel Limited dates to 1953.

William S. Hosking, M.E.I.C. of the Northern New Brunswick Branch, E.I.C., steam plant superintendent of the Bathurst Power and Paper Company Limited, Bathurst, N.B., has been chosen a councillor of the Institute to serve a two-year term. Mr. Hosking held office as chairman of the Branch in 1955.

A Queen's graduate, class of 1931, in mechanical engineering, he has been continuously employed with the Bathurst Company since that time.

He is a member of the Institute of Power Engineers, and a member and former chairman of the technical section, Canadian Pulp and Paper Association, Atlantic Branch.

Robert S. Morrow, M.E.I.C., of the North Nova Scotia Branch, newly elected councillor of the Institute who will represent that Branch for a two year term, is associated with the power shovel department of the Maritime Steel and Foundries Limited, at New Glasgow, N.S. He previously served as a member of the Branch executive.

After several years service with the R.C.A.F., Mr. Morrow attended Mount Allison University, from which institution he was granted a B.Eng. degree in mechanical engineering in 1950. He joined his present employer at that time.

A. W. Purdy, M.E.I.C., of Moncton, N.B., district sales manager for the Maritime neers of Quebec, the Montreal Section Quebec section of the E.I.C., and past-Cement Company Limited has been elected a councillor of the Institute to serve a two year term of office. Mr. Purdy has been active in the affairs of the Institute as chairman of the Moncton Branch in 1955.

A 1949 graduate of the University of Queen's with a B.Sc. degree in civil engineering following a three year period of army service, he became associated with the Canada Cement Company Limited, Toronto, on graduation. Two years later named district sales manager of the Maritime Cement Company Limited at Moncton, he has held the position to the present time.

He is vice-president of the Canadian Construction Association for N.B. and P.E.I.

Gilbert F. Vail, M.E.I.C., associate professor, department of electrical engineering at the Nova Scotia Technical College, Halifax, has been elected councillor of the Halifax Branch of the Institute to serve a two-year term.

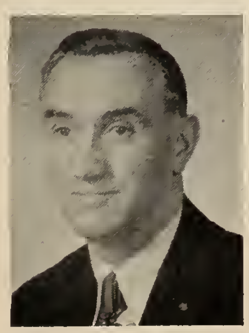
Mr. Vail graduated from Dalhousie University and the Nova Scotia Technical College 1943, with a B.Eng. degree, in electrical engineering. Immediately he joined the Royal Canadian Navy as an electrical officer in 1943.

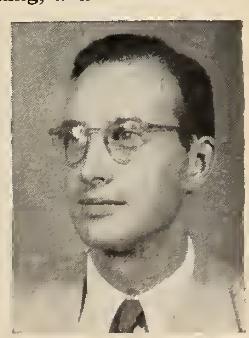
Professor Vail became a lecturer in electrical engineering at the University of Toronto in 1946. In addition to lecturing duties he carried on research and advanced studies leading to an M.Sc. degree in electrical engineering, received in 1948. He was named to an associate professorship at this point in his career at N.S.T.C. Recently he has availed himself of leave of absence for special study at the University of Michigan, 1956-57.

Recipient of two special awards, these were the Queen's Coronation Medal and the Canadian Forces' Decoration presented in 1955.

Professor Vail holds the rank of Commander in the Naval Reserves and is

Shown left to right are Maritimes vice-president J. B. Angel, and four of the five councillors elected, M. R. Campbell, A. W. Purdy, W. S. Hosking, and R. S. Morrow.





a commanding officer of the Halifax universities naval training division.

In addition to past service as an executive of the Halifax Branch he is a past chairman of the professional development committee and of the student members' committee.

QUEBEC

Edward T. Buchanan, M.E.I.C., division manager of the Laurentide division of Consolidated Paper Corporation, Grand' mere, Que., has been elected a vice-president of the Institute, representing Zone C, or the Province of Quebec. Mr. Buchanan has given former Institute service as branch chairman and as a councillor representing the St. Maurice Valley Branch of the Institute in 1955.

An electrical engineering graduate of McGill University, class of 1928, Mr. Buchanan has been associated with the pulp and paper industry since 1935. At that time associated with the Corporation in the field of accounting, he was promoted to assistant chief engineer in 1946, to chief engineer in 1953 and division manager of the Laurentide division of the organization in November 1956.

Mr. Buchanan was granted the I. H. Weldon Medal of the technical section of the Canadian Pulp and Paper Association in 1948.

Ben O. Baker, M.E.I.C., has been elected to a two year term of office as councillor of the Institute representing the Quebec Branch. Having completed terms as vice-chairman and chairman of the Branch, his new position of councillor also brings with it a chairmanship of the 1958 annual meeting committee of the Institute.

Graduating with a B.Sc., electrical, from the University of Manitoba in 1940, Mr. Baker joined the Canadian General Electric Company at that time. He completed the test course and entered the engineering department at Peterborough. With Genelco Ltd., armament manufacturing division, in 1941, he was loaned to the Government of Canada in 1943-44 and underwent armament design training in England. He joined the Canadian Armament Research and Development Establishment in 1946, which became part of the Defence Research Board upon its foundation in 1947. He became deputy superintendent, then superintendent of the design wing at C.A.R.D.E.

Mr. Baker is the Defence Research Board representative for mechanical engineering and drafting on committees of the Canadian Standards Association and the Canadian Government Specifications Board.

E. D. Gray-Donald, M.E.I.C., elected a councillor of the Institute, representing the Montreal Branch for a three year term, was previously chosen for this office in 1953. He was the 1956 choice as chairman. He served the Quebec Branch as councillor in 1942 and 1948, as chairman in 1944-45.

Mr. Gray-Donald is the vice-president, administrative services, for Shawinigan Water and Power Company, Montreal; vice-president and director, Quebec Power Company, Quebec City, and a director of the Montreal City and District Savings Bank.

With an earlier background of general engineering experience in Palestine and in London, England, he graduated from McGill University with a B.Sc. degree in 1926, an M. ès Sc. at Laval in 1934.

His career with the Shawinigan Water and Power Company dates to the time of his first degree. Transferred to the Quebec Power Company in 1927, he filled various positions until in 1937 he was appointed general superintendent of the Quebec Power Company and the Quebec Railway Light and Power Company. He was appointed chief engineer for both companies in 1942. Appointed vice-president and chief engineer of the Shawinigan Water and Power Company in 1950; vice-president, personnel and public relations in 1954; he was named to his present post in 1957.

J. E. Leo Roy, M.E.I.C., general manager of the Quebec Hydro-Electric Commission is a newly elected councillor of the Institute representing the Montreal Branch for a three year term. Mr. Roy is an immediate past-president of the Corporation of Professional Engineers of Quebec, the Montreal Branch of the Institute, former secretary of the Quebec Branch of the E.I.C., and past-president of the Montreal section of the American Institute of Electrical Engineers. He is currently Canadian representative on the Ethics Committee of the Engineers' Council for Professional Development.

Mr. Roy who holds engineering degrees from L'Ecole Polytechnique, Montreal, civil, 1930, and from McGill University, B.Eng., 1932, began his professional career with the Shawinigan Water and Power Company. In 1938 he joined the Quebec Power Company as power sales engineer, transferred his services to Hydro Quebec in 1946, and the following year was named superintendent of the transmission and distribution section of the organization. Taking charge of the auxiliary services of the Commission at an executive level in 1952, as chief engineer, he was in July 1957 named general manager.

ONTARIO

Dean Hugh Gordon Conn, M.E.I.C., O.B.E., F.R.S.A., of the faculty of applied science, and professor and head of the department of mechanical engineering at Queen's University, Kingston, Ont., has been elected vice-president of Zone B of the Institute, representing the Province of Ontario. In 1955 he served as councillor of the Institute.

An Ontario-born mechanical engineer with a background of service in industry and the army, H. G. Conn was educated at Queen's University and the University of Michigan. He received a B.Sc. degree in mechanical engineering at the former institution in 1931. The American university awarded him an M.S. degree in 1946. In 1932 he joined the firm of Procter and Gamble Company Limited, at Hamilton. He returned to Queen's University as a lecturer in mechanical engineering in 1937.

Dean Conn served with the Royal Canadian Electrical and Mechanical Engineers from 1939 until the end of the war, returning to Canada in 1945.

He completed work for an M.S. degree at the University of Michigan in 1946. That fall he was appointed head of the department of mechanical engi-

Maritime councillor, Professor G. F. Vail; vice-president for Quebec, E. T. Buchanan, and the three Quebec councillors elected, J. E. L. Roy, E. D. Gray-Donald and B. O. Baker.

Ontario vice-president Dean H. G. Conn, and left to right, four of the eleven councillors elected, W. D. Adams, E. T. W. Bailey, P. E. Buss, and Colonel W. A. Capelle.

neering, at Queen's, he became dean of the faculty of applied science in 1955.

He is chairman of the Canadian Advisory Committee of the Institution of Mechanical Engineers (London).

W. D. Adams, M.E.I.C., of Sault Ste. Marie, piling engineer with the Algoma Steel Corporation Limited until his retirement in 1957, has been elected to represent the Sault Ste. Marie Branch of the Institute as councillor for a two year term.

Mr. Adams is a graduate of the Royal Military College of Canada, 1908, in civil engineering. He gained various engineering experience before enlisting in the Victoria Rifles of Canada in 1914. He served overseas, was awarded the M.C., 1917, and demobilized as a major.

Returning to Canada he became a partner of the Adams Brothers, Toronto, later joining the Toronto Transportation Commission in 1921. Subsequently he was associated with Walter J. Francis and Company of Montreal, and with A. Bentley and Sons, Toledo, Ohio. He returned to Toronto in 1925 as resident engineer with the Toronto Waterfront Viaduct. He also spent some time in Montreal with Watson Jack Company Limited as sales engineer before becoming Toronto manager of the H. E. McKeen and Company in 1935. He joined Algoma Steel in 1944.

He was chairman of the Sault Ste. Marie Branch in 1946 and in 1955.

E. T. W. Bailey, M.E.I.C., chief combustion engineer of the Steel Company of Canada, Limited, Hamilton, Ont., has been elected to represent the Hamilton Branch of the Institute as a councillor, for a two-year term. He has chalked up previous E.I.C. service as chairman of the Branch during 1951 and 1952.

Mr. Bailey attended the University of Toronto, received a B.A.Sc., degree in 1926, and a Chem.E., degree from the same institution in 1932.

The first two years of his post-graduate career were spent with the Aluminum Company of Canada Limited, at Arvida, Que. In 1928 he joined the engineering staff of the Steel Company of Canada, Limited at Hamilton.

Mr. Bailey has served as chairman of the Hamilton Chemical Association, as a director of the Association of Iron and Steel Engineers, Pittsburg, Pa.

In 1947 he was the recipient of the Plummer Medal of the Institute.

Paul E. Buss, M.E.I.C., president of Spun Rock Wools Limited, Thorold, Ont., will serve his seventh consecutive two-year term as representative of the Niagara Peninsula Branch of the Council of the Institute, in 1958-59.

A graduate of the University of Michigan with a B.Sc. degree in electrical engineering, Mr. Buss joined the engineering staff of the Provincial Paper Limited, as a plant engineer, Thorold division, after overseas service with the United States Army Engineers in World War I. He was also associated with the Dominion Engineering Works.

During 1932 and 1933, Mr. Buss and his brothers made experiments in the development of a new process for the production of rock wool by the spinning method. A direct outcome of these was the setting up of the firm Spun Rock Wools Limited, at Thorold, of which Mr. Buss is president.

Previous to his activities as councillor of the Niagara Peninsula Branch he served as its secretary-treasurer in 1931, as its chairman in 1935.

He recently retired from the Thorold Board of Trade after twenty years service as secretary-manager.

Colonel W. A. Capelle, M.E.I.C., Commander, Canadian Base Units, Middle East, formerly director of engineer development at Ottawa, has been elected a councillor of the Institute to represent the Ottawa Branch for a three-year term. It is expected that Colonel Capelle will return to Ottawa in September.

Colonel Capelle is a graduate of the University of Manitoba, 1932. He joined the R.C.E. at that time and has since followed the career which has combined engineering and a military life.

Colonel Capelle saw extensive service in World War II, retiring as senior officer with the Royal Engineers, Airfields, at headquarters, First Canadian Army in 1945. He rejoined the regular army two years later. In 1952 he was promoted to the rank of colonel and appointed director of works, A.H.Q. He was appointed director of engineer development in 1954.

E. L. Cavana, M.E.I.C., of Orillia, Ont., has been elected to represent the Huronia Branch as a councillor of the Institute for a two-year term.

Ernest L. Cavana attended the University of Toronto and graduated with a B.A.Sc. degree in civil engineering in 1920. He became an Ontario Land Surveyor in 1922. Early in his career he was employed with the Canadian National Railways, maintenance division, with the Department of Highways, Province of Ontario in engineering and construction. In 1926 he was associated with the Hydro-Electric Power Commission, in the field of hydraulic engineering.

For the greater part of his professional life Mr. Cavana has been engaged in private practice in the field of general engineering and surveying.

E. R. Davis, M.E.I.C., Toronto, consulting engineer, in private practice, has been elected to serve the Institute as a councillor for a three year term. He has given his energies to Institute service as a member of the executive committee of the Toronto Branch since 1953. He was the 1957 choice as chairman of the group.

He is also active in the work of the American Society of Mechanical Engineers.

Mr. Davis, who holds a B.Sc. electrical, from the University of Manitoba, 1936, and a B.Eng. degree, mechanical, McGill, 1937, worked with Dominion Engineering Works, Hamilton, and Canadian Controllers Ltd., Toronto in the early part of his career. Throughout the 1940's he was with the Canadian Comstock Company Limited, in Montreal, Hamilton, Halifax, rising to the post of manager, mechanical department in 1948.

Briefly associated with Margison and Babcock, consulting engineers, Toronto in 1950-1951, he set up his present consulting practice which designs power plants, mechanical and electrical, in 1952.

A. A. Kidd, M.E.I.C., will represent the North Eastern Ontario Branch of the Institute as a councillor for a two year term of office. Mr. Kidd, who resides at Cochrane, Ont., is manager of the Cochrane Public Utilities Commission.

A B.Sc. graduate in engineering physics from Queen's University, class of 1941, Mr. Kidd enlisted as a radar officer in the Royal Canadian Navy on graduation and was for most of this time on loan to the Royal Navy.

Later his experience included seven years as a mechanical and electrical project engineer with the Spruce Falls Power and Paper Company at Kapuskasing, Ont. He has been engaged in his present work for five and a half years.

He is a member and ex-director of the Association of Municipal Electrical Utilities (of Ontario).

R. A. McGeachy, M.B.E., M.E.I.C., administrative assistant to the manager of the Sarnia refinery, Imperial Oil Limited, who served the Institute as a councillor representing the Sarnia Branch in 1956-57 has been re-elected to this office, for a two year term.

Mr. McGeachy graduated from the University of Michigan in 1923 with a B.Sc. degree in civil engineering. He gained experience in railway and general construction work until 1930. Beginning his career with Imperial Oil Limited as a draughtsman, he was later transferred to the mechanical department and was engaged in construction and maintenance. In World War II, on leave of absence, he served overseas for five years with the Royal Canadian Engineers. Discharged with the rank of major, he was later awarded the M.B.E. Returning to Imperial Oil Limited, he was named zone engineer. His present post dates to 1953.

He servel the Sarnia Branch as secretary in 1954.

L. J. R. Sanders, M.E.I.C., of Galt, Ont., has been elected councillor for the Kitchener Branch of the Institute for a two year term. One of the charter members of the Branch, he became its chairman in 1955. He is president and managing director of the L. J. R. Sanders Engineering Company, Galt, Ont. The firm designs and builds special equipment.

Mr. Sanders began his training with the later Westinghouse Company in England. He graduated from Loughborough College, England, in 1923, with a degree in mechanical engineering after serving with the Royal Navy Air Service. A post-graduate course at Cornell University preceded his move to Canada in 1926. Employed first with the Tudhope Anderson, Orillia, Ont., as chief engineer, and later with Lake Shore Mines at Kirkland Lake, Ont., for the first few years, he joined the Aluminum Company of Canada in 1929 as divisional superintendent at Toronto. Later, sent to England by the organization, he supervised construction of the subsidiary plant for Northern Aluminum at Banbury. He returned to Canada in the depression days of the mid-'thirties, after four years in England.

After interim work as a consultant in machine shop and foundry practice in the United States and Canada, he joined the Algoma Steel Corporation, Sault Ste. Marie, in 1937 as superintendent of shops. In 1940 he was one of those chosen to go to England with a group from the Otis Elevator Company to study the Bofors gun.

Joining the Wartime Merchant Shipping in 1941, he was responsible for the production of the machinery and equipment for ships. Subsequently, the Bureau of Technical Personnel transferred him to Ottawa as director of naval stores.

At war's end, Mr. Sanders purchased the C. H. Smith Machine Company in Galt and founded the organization which he now heads.

Howard E. Meadd, M.E.I.C., of Cornwall, Ont., has been elected to represent the Cornwall Branch of the Institute as a councillor for a two year term. Mr. Meadd was associated with the Howard Smith Paper Mills Limited from 1925 until his retirement in 1957, and was in charge of engineering and construction for the Cornwall division of the firm.

Mr. Meadd graduated from Queen's University in 1921 following an interruption of his studies by overseas service in World War I. He worked for the Ontario Hydro-Electric Power Commission on the Cameron Falls development of the Nipigon River. Following this he spent three years with the Fort Francis Pulp and Paper Company Limited, as a design engineer, prior to joining Howard Smith.

P. F. Peele, M.E.I.C., will serve on the council of the Institute representing the Peterborough Branch for a two year term of office. This election follows previous Institute service as Branch secretary-treasurer in 1940-1941; chairman in 1945.

He is employed with the Canadian General Electric Company Limited, apparatus department, transportation sales division at Peterborough. Mr. Peele has served his company both in Eastern and Western Canada. On graduation from the University of British Columbia with a B.A.Sc. degree in electrical engineering in 1924 he joined the Canadian General Electric Company Limited through the medium of the test course at Peterborough. Later he served as sales engineer at Vancouver, apparatus manager at Calgary, before moving to the locomotive sales office of the organization at Toronto in 1951. He moved to Peterborough in 1956 when the apparatus headquarters was transferred to that point.

WESTERN PROVINCES

W. M. Berry, M.E.I.C., of Regina, Sask., chief of the hydrology division, Prairie Farm Rehabilitation Association, at Regina, Sask., has been elected to serve a two year term as a councillor for the Saskatchewan Branch of the Institute. This follows similar service in 1953-1954.

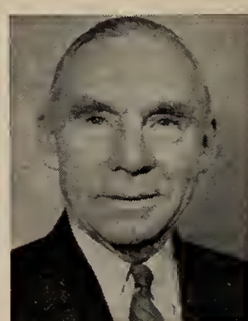
Mr. Berry is the Canadian secretary of the International Engineering Committee, set up by the International Joint Commission to study the problems of the Waterton, Belly, Souris and Red Rivers. He is also the engineering secretary of the Prairie Provinces Water Board, which duties were assigned him in 1948.

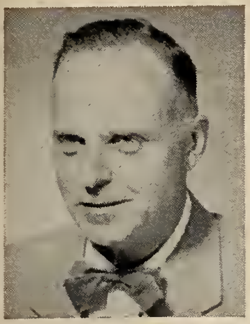
Mr. Berry holds a B.Sc. degree from the University of Manitoba, gained in 1944, an S.M. degree from the Massachusetts Institute of Technology, 1947, following studies in water resources development.

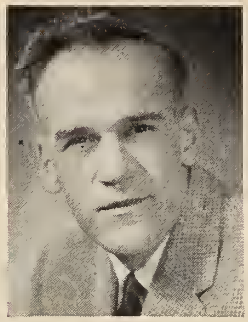
In 1947 Mr. Berry took over responsibility for hydraulic and hydrologic prob-

Five councillors representing Ontario Branches are shown: E. L. Cavana, E. R. Davis, H. E. Meadd, R. A. McGeachy and A. A. Kidd.







Two Ontario councillors appear at the left, P. F. Peele, and L. J. R. Sanders. Representing Western Canada are councillors N. M. Hall, W. M. Berry, and D. Cramer

lems in the Regina, Saskatchewan design office. His present appointment with the department of hydrology was announced in 1951.

He is a past chairman of the Regina community planning committee.

He was a councillor, 1953-1955, for the Association of Professional Engineers of Saskatchewan.

He is a member of the hydrology committee of the National Research Council.

F. M. Cazalet, M.E.I.C., of Vancouver has been elected a councillor of the Institute representing the Vancouver Branch for a two year term.

Mr. Cazalet is supervisor of mechanical engineering for the B.C. Electric Company Limited, and past chairman of the Branch, 1955.

Mr. Cazalet, whose home was originally England, received part of his education in that country and then graduated from the University of B.C. with a B.A.Sc. degree in mechanical engineering in 1937.

Joining B.C. Electric on graduation, he became supervisor of mechanical engineering following experience in the research, sales, and planning departments.

David Cramer, M.E.I.C., office engineer for the St. Mary irrigation project, Lethbridge, Alta., has been elected to serve a two-year term as councillor of the Institute. Active in the affairs of the Institute, he was secretary-treasurer of the Lethbridge Branch from 1948 to 1952, was vice-chairman for a season and in 1953 was the Branch choice for chairman. Since that time he has remained active in the Branch and has served on various committees.

Mr. Cramer is a 1944 graduate of the University of Saskatchewan in civil engineering. He joined the P.F.R.A. department of agriculture, at Regina, Sask., as a design engineer. He was transferred to Calgary in 1945 to work on the St. Mary Irrigation project, as a design engineer and the following year took part in the construction of the project, at Lethbridge. His appointment as office engineer dates to 1948.

N. M. Hall, O.B.E., M.E.I.C., has been elected a representative of the Winnipeg Branch to the Council of the Institute for a two year term. Mr. Hall is a retired professor (emeritus,) and chairman of the mechanical engineering department, University of Manitoba. He operates a consulting mechanical engineering practice in Winnipeg.

Mr. Hall attended McGill University and the London School of Economics, graduating from the former institution in 1907, with a B.Sc. degree in mechanical engineering.

Mr. Hall joined the B.E.F. during World War I and served with the Royal Engineers.

He became associated with the University of Manitoba in 1919, at which time he also set up his consulting engineering practice.

Stanley J. Hampton, M.E.I.C., 1957 chairman of the Edmonton Branch has been elected to serve a two year term as councillor of the Institute representing that branch. He is chief electrical engineer for the City of Edmonton, electric light and power distribution system.

Mr. Hampton commenced his engineering career in the electrical distribution field with the City of Edmonton in 1946 as a design engineer on the underground network system. He was promoted to chief electrical engineer in 1950.

He is a graduate of the University of Alberta and holds a B.Sc. degree in electrical engineering, class of 1946.

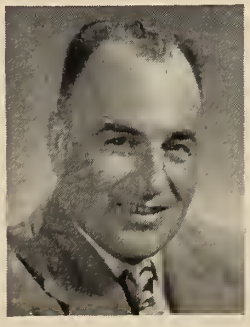
T. D. Stanley, M.E.I.C., of Calgary, production superintendent of Calgary Power Limited, Calgary, past chairman of the Calgary Branch, 1952-1953, has been elected to serve as councillor of the Institute, representing the Calgary Branch for a two year term.

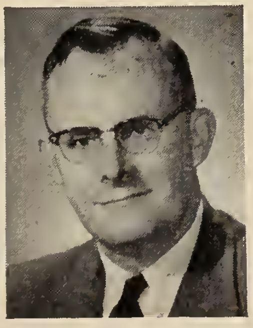
Mr. Stanley had his engineering training at the University of Alberta, graduating with a B.Sc., in arts in 1929; a B.Sc. in electrical engineering from that institution also in 1932; and a M.Eng. in electrical engineering at McGill University the following year. After following post-graduate work in electrical and civil engineering at the University of Alberta, he joined Calgary Power Limited as an apprentice engineer in 1935. Six years later he was named assistant to the production superintendent. He assumed his present responsibilities in 1942.

Mr. Stanley is a past-president of the Association of Professional Engineers of Alberta, 1955-56.

T. D. Stanley, F. M. Cazalet, and S. J. Hampton, complete the list of six Western representatives.





What Goes On

(Continued from page 98)

Investment Intentions, 1958

Plans for a total capital expenditure program in Canada in 1958 of $8.5 billions were revealed by a survey of Canadian business, institutions, governments and housebuilders, according to the Department of Trade and Commerce, Ottawa. This is close to the record $8.7 billion capital spending rate of 1957.

The Department's "Private and Public Investment in Canada — Outlook 1958" was released in March. (Queen's Printer, Ottawa.)

Within the total, construction outlays are expected to reach $5,991 millions. Outlays for acquisition of machinery and equipment are expected to total $2,530 millions.

A strong resurgence in outlays for housing and social capital largely offsets a lower level of business capital spending. Expansion is expected to continue at about the 1957 rate in secondary manufacturing, utilities, commercial building and agriculture. A lower rate of expansion is planned in resource-based industries, for mining facilities, and for plant and equipment in such manufacturing industries as paper products, iron and steel and non-ferrous metal and non-metallic mineral processing.

Substantial increases are expected in the construction of hospital and university facilities and in construction expenditures by all levels of government.

CF-105 Avro Arrow

The Avro *Arrow* flew in April at approximately 1,000 miles an hour, the R.C.A.F. reported.

In one of a series of flight tests the *Arrow* attained, in level flight, one and one-half times the speed of sound at an altitude of 50,000 feet. This significant achievement came only about a month after the first flight of the interceptor, developed by Avro Aircraft Limited, Malton, Ont.

The decision as to full production of the CF-105 for the R.C.A.F. is to come later in the year.

Road System in the North

Work has begun on a recently announced Federal Government project of roadbuilding in the Yukon and Northwest Territories. The building of 1,200 miles of roads and six major bridges will be a $31 million program.

In the Yukon a development road from the existing road system at Flat Creek, near Dawson, to Fort McPherson on the Mackenzie River is expected to be carrying traffic by 1962. This road will pass the Eagle Plain Oil Reservation, where large-scale exploration for oil is under way, and will be about 400 miles long.

The major road project in the Territories is the 550-mile Great Slave-Great Bear road. The first stage, to be completed in 1960 at a cost of $10 million, is a road going 300 miles around the west end of Great Slave Lake to join Yellowknife with the Mackenzie Highway. The second stage will be another 250 miles of road to Great Bear Lake, at an estimated cost of $5 million. Some existing roads will become part of the main development road system; the Fitzgerald-Bell Rock road will be surfaced; and a road from Peace Point to the Wood Buffalo National Park is being built. When the Province of Alberta constructs a road from North Vermilion, it will provide the first year-round communication between Fort Smith and outside points.

A $150 million plan for 50-50 federal-provincial sharing of costs of development roads in the northern areas of the four western provinces, tentatively agreed, is another prospect. The development roads will link up with the federal projects mentioned above.

Alchem Microbiological Laboratory

Alchem Limited has established at Burlington, Ont., a new Microbiological Laboratory to offer service in the control of slime and algae in the paper industry. A three point plan, the service consists of mill survey, report on basic control measures, and regular mill inspections and microbiological checks.

Lloydminster is a City

Lloydminster became a city of Saskatchewan and of Alberta in January 1958, when its status of city was established by both provinces. The city is astride the Saskatchewan-Alberta border.

Called Canada's "Black Oil Capital", Lloydminster profited by the advent of new industries following the discovery in 1943 of crude oil — asphalt companies, manufacturers of caulking compounds and wood preservatives, machine shops, as well as concrete block and pipe and welding companies. Two grain elevators have a combined capacity of 70,000 bushels.

Quebec Power Company

Substantial increases in electricity sales, in revenue and in net earnings were shown in Quebec Power Company's annual report for 1957.

Kilowatt hour sales of electricity exceeded the billion mark for the first time. The report showed total revenue up 9.7 per cent to $13,713,751.

Continuing expansion of the Company's system required capital expenditures of $2,555,622. A second 25-mile high voltage transmission line was completed from Quebec City to Beaupré; the new La Suete substation in Ste-Foy came into service; and 109.5 miles of distribution line were built in urban and rural areas.

New Blasting Technique

Canadian Industries Limited describe a new technique of submarine blasting — the Air Cushion, which is being used by McNamara Construction Co. Ltd. in the deepening of the Welland Ship Canal at Port Colborne.

The technique ends the necessity of restricting blasting operations to a distance of 14 feet from the canal wall. This restriction had resulted in a sloping berm 14 ft. wide by about 4 feet deep remaining along each side of the canal bottom.

Very satisfactory results were obtained with the C-I-L technique, which provides a "line of weakness" at the desired boundary of the excavation. The line is a row of close-drilled holes, into which are placed specially designed hermetically sealed empty cans to make them water free. In present submarine blasting operations on the canal the Air Cushion is being placed flush along the foundation line of the retaining wall, thus avoiding any berm whatsoever. The construction company by seismic recordings have established that vibration is reduced when the air cushion is in operation.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

THE CANADIAN COUNCIL

General Secretary Appointed

Leopold Maurice Nadeau, P.ENG., of Montreal, has been appointed general secretary of the 32,000-member Canadian Council of Professional Engineers, it was announced by C. N. Murray, P.Eng., of Sydney, N.S., Council president, on March 26, 1958.

Mr. Nadeau will make his headquarters in Ottawa. In his new capacity, he will co-ordinate the activities of the engineering licensing bodies of which there are 11 — one in each province and one in the Yukon. The Council deals with all matters effecting the engineering profession at the national level.

Annual meeting of the Council will be held in Vancouver this month.

The C.C.P.E. is the national body for all provincial engineering associations. Its 12-man directorate includes one representative from each association.

Mr. Nadeau is a graduate in applied science and civil engineering from L'Ecole Polytechnique, in Montreal. His early experience includes employment as assistant plant engineer for a pulp and paper company mill and as resident engineer for the Department of Highways, Province of Quebec.

Later, he served on the technical staff of the Canadian Underwriters Association as fire protection engineer. During the war years he was engaged in designing and supervising the fire protection equipment of war industries and other installations.

L. M. Nadeau, P.ENG.

In 1946, he joined the Corporation of Professional Engineers of Quebec as assistant general secretary, and became general secretary three years later. During his term of office, the Corporation membership increased from 2,000 to more than 5,000. At the same time, he also acted as joint secretary-treasurer of the Dominion Council of Professional Engineers.

In 1955, Mr. Nadeau joined the consulting engineering firm of Racey, McCallum and Associates as assistant to the present and administrative engineer. A year later, he was appointed executive engineer in charge of the firm's Montreal division, and was elected a director of the company.

Mr. Nadeau is a councillor and honorary secretary-treasurer of the Quebec Corporation.

QUEBEC

39th Annual Meeting

Close to 1,000 Quebec engineers and their wives heard Premier Maurice Duplessis laud the engineering profession at the 39th annual meeting of the Corporation of Professional Engineers of Quebec.

The annual event, the most successful in the history of the Corporation, was held Saturday March 22 at the Sheraton-Mount-Royal Hotel, Montreal.

Well over 300 members attended the business sessions in the afternoon and more than 1,100 attended the dance during the evening.

A highlight of the meeting was an exhibition of paintings and ceramics by artist-engineers. Thirty-five tableaux were hung in the Brittany Room of the hotel and earned the admiration of hundreds of visitors.

In addition, firms and individuals displayed attractive scale models and photographs of engineering projects undertaken in 1957, or on which work had been done during the year. This exhibition was in line with the theme of the annual meeting: "Quebec, The Engineering Challenge".

At the dinner meeting, Mr. Duplessis was presented with an honorary membership in the Corporation. He was awarded the honour in recognition of his contribution to the industrial development of the province and to the establishment and improvement of engineering faculties in Quebec.

G. Piette, P.ENG.

In his address delivered to the assembled engineers Mr. Duplessis said that civil engineering was the most "indispensable" profession and that at the same time, the Province of Quebec offered engineers unsurpassed opportunities.

"No other place in North America offers as many good and great opportunities," he said. He listed a number of major provincial projects undertaken by Quebec engineers.

Mr. Duplessis added that the preservation of the rights of the engineering profession is a provincial responsibility and the engineers could be sure that the province would protect these rights.

Membership in the Corporation of Professional Engineers of Quebec soared to a record 7,000 of which almost 1,000 were new members registered last year, according to the C.P.E.Q. annual report.

The report and those of the Corporation's 22 committees formed the basis of discussion at the annual meeting scheduled for 1.30 p.m. Saturday, March 22nd in the Sheraton-Mount-Royal Hotel.

"The tremendous increase in the number of new engineers reflects the continuing industrial growth of the province," C. A. Peachey, P.Eng., outgoing president of the Corporation said.

Of the 952 new members, 650 signed up during an intensive and highly successful recruiting drive held last year.

Some 302 others registered after graduating from Quebec universities.

Mr. Peachey also expressed satisfaction with the progress of the plan for unity in the engineering profession in Canada.

Election of Officers

Guillaume Piette, P.ENG., of Quebec City, was elected president of the 7,000-member Corporation of Professional Engineers of Quebec at the annual meeting Saturday afternoon in the Sheraton-Mount-Royal hotel. He succeeds C. A. Peachey, P.ENG. of Montreal.

Mr. Piette is principal in the consulting firm of Cartier Cote, Piette, with headquarters at Lachine, Que.

He has been a member of the C.P.E.Q. since 1955; is currently a representative of the organization on the Canadian Council of Professional Engineers; a member of the Canadian Council Committee on Plan for Unity, and president of the Progressive Conservative party Association, Quebec district.

Mr. Piette, who has been engaged in consulting engineering since 1947.

He is currently consultant to Hydro-Quebec for the Lachine power project. He is a lecturer in soil mechanics at Laval University.

Mr. Piette holds B.A., B.A. Sc., and M.Sc. in civil engineering degrees, from the University of Montreal, Ecole Polytechnique, and the University of Michigan, respectively.

W. J. Riley, P.ENG., Montreal was elected vice-president and A. G. Ballachey, P.ENG., Noranda, honorary secretary-treasurer.

Council members are elected to two year terms, Mr. Peachey remains on Council as immediate past president.

Other new councillors are Professional Engineers Gerald N. Martin, and J. Georges Chênevert, both of Montreal and Arthur Piché of Quebec. Oscar Gislason, P.ENG., Arvida, was re-elected by acclamation.

Outgoing members of Council are Engineers Léopold Nadeau, past honorary secretary-treasurer; Léo Roy, who was past president last year, and Yvon De Guise, Montreal, and Robert Painchaud, Quebec, councillors.

NEW BRUNSWICK

Annual Meeting

The annual meeting of the New Brunswick Association of Professional engineers was held on February 1, 1958 at Saint John.

Elected president for the 1958 term of office was D. O. Turnbull, of the firm of Turnbull and Scott Limited, consulting engineers of Saint John. Mr. Turnbull also served as president in 1952. He succeeds W. D. G. Stratton, district airways engineer, of Moncton. Other officers elected were: vice-president, S. B. Cassidy, of Fredericton; councillors, F. L. Doty, Saint John, R. S. Miles, Fredericton; and W. E. Peterson, Dalhousie; R. D. C. Clark of Saint John is the secretary-registrar.

Mr. Turnbull urged members to support the unification between their own group and The Canadian Council of Professional Engineers.

Dr. Colin B. Mackay, guest speaker and president of the University of New Brunswick stressed the increasing importance of a liberal education for today's engineers, with courses in the humanities and social sciences, supplementing their specialized technical training.

In answer to a fear prevalent among some educators that extra training would mean a congested curriculum and superficial treatment of the humanities, Dr. MacKay cited a report of the American Society for Engineering education noting the success of such a venture in more than thirty leading engineering schools in the United States.

D. O. Turnbull, P.ENG.

ONTARIO

Accrediting Committee Formed

(From the Journal of the Association of Professional Engineers of the Province of Ontario)

At the January meeting of Council it was considered that with the increasing number of engineering courses being offered in Ontario an accrediting committee should be set up. The following were appointed: Dr. G. Ross Lord, P.Eng., chairman; H. G. Conn, P.Eng., dean of the faculty of applied science, Queen's; Professor V. G. Smith, P.Eng., Toronto; Professor H. S. Pollock, P.Eng., Queen's; and Professor B. Etkin, P.Eng., Toronto. Briefly, the terms of reference are: to recommend to Council a guiding policy for accreditation and to appoint accrediting teams when applications are received for approval of new courses.

Engineering courses are being offered at nine Institutions; Queen's, Toronto, Essex, Sudbury, Lakehead, Ottawa, Carleton, Ontario Agricultural College, and Waterloo.

The committee has held its first meeting and will present for consideration to the April meeting of Council a policy for accreditation.

Engineers and the Political Arena

(Taken from the Section "President Carson Says," in the Professional Engineer)

"By the time you read this, it is probable that the results of the federal election will be history. It would be interesting to know how many of our members take an active part in provincial and federal politics but the information is not readily available. As to those who enter the field as candidates, the number appears to be negligible.

In a recent address in Pontiac Mich., former U.S. Secretary of Defense Charles E. Wilson, stated that he thought business men still have a place in government—"except on the level of politics". If we may take any comfort from it, he was referring to U.S. politics.

Speaking of engineers, Mr. Wilson, an engineer himself and president of General Motors Corporation, before joining the Eisenhower cabinet, continued: "I don't think engineers are trained for politics. They have too much respect for truth and fact to be successful politicians."

Before resigning from the cabinet this gentleman was the author of quite a number of controversial statements, often finding himself in hot water as a result. But we will not quarrel with him on the question of being truthful and factual. What is discouraging is the thought that we are unfit, because of that, to venture into the political arena. Perhaps what this country needs is more of those attributes in high places, more statemanship and less political high-jinks, more "truth and fact," and less irresponsible attacks on those who are trying to do a good job, in short, more engineers.

A report of recent studies of the potentials of the engineer states that "the engineer's mental makeup is likely to be directed toward a specialized area. Personality tests show that he normally has concentrated on his specialty at the expense of his development as a social animal. Often he is short of human relations "know-how". Many of our members have already proven this to be an unfair indictment but if it is a commonly held opinion, it is time we changed it.

I suggest, therefore, that those who have not already done so start busying themselves in public affairs. If you will do so, the community, your Association, and you, as an individual, will definitely benefit from your activity. And, notwithstanding Mr. Wilson's pronouncement, you too may someday be prime minister. Apart from its spiritual significance, the ultimate purpose of life is service to humanity."

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Colonel H. G. Thompson, M.E.I.C. The Engineering Institute is sorry to report the death of the retired executive assistant general secretary of the organization at Pickering, Ont., April 19, 1958. An obituary will appear in the June issue of the *Journal.*

Ernest R. Clarke, M.E.I.C., of Scarborough, Ont., retired consulting engineer, died on July 5, 1957.

Ernest Randolph Clarke was born at Montreal on October 11, 1875. He attended McGill University and graduated with a B.A.Sc. in mechanical engineering in 1896. His first position was that of draughtsman for the Royal Electric Company, Montreal. Within the next few years he also served as an engineer with the 'S.S. Vancouver' of the Dominion Line, and with the Superior Power Company, the Northey Company Limited, Toronto, as a mechanical engineer, and the Canada Foundry Company as a hydraulic engineer. He was named a partner in the firm of Connor, Clarke and Simonds, consulting engineers, at Toronto in 1902.

For a number of years, Mr. Clarke was engaged in general contracting in Toronto. Later he operated a consulting engineering practice in that city.

Mr. Clarke joined the Institute as an Associate Member in 1906, transferred to Member in 1940, and attained Life Membership in 1946.

H. W. Vaughan, M.E.I.C., retired superintendent, electrical division, City of Montreal, died after a long illness in that city on February 18, 1958.

Harold Wilfred Vaughan was born at Wolfville, N. S., on May 3, 1896. He studied electrical engineering at McGill University and in 1921 graduated with a B.Sc. degree in electrical engineering. Almost immediately he began what was to be a lifetime career with the City of Montreal, electrical commission as an assistant to the chief engineer. In 1923 he transferred to the post of assistant superintendent of the light department, at the city hall. He assumed the post of superintendent of the lighting department in 1938. The appointment of superintendent of the electrical division was announced in 1944.

Mr. Vaughan retired from active professional duties in 1955.

He joined the Institute as a Student Member in 1920, tranferred to Associate Member in 1926, and became a Member in 1940.

Stephen John Murphy, M.E.I.C., former head of the instruments and control systems laboratory of the division of mechanical engineering, National Research Council of Canada, died on February 2, 1958.

Mr. Murphy was born at Montreal, Que., on December 30, 1893. He graduated from McGill University in civil engineering in 1913.

He began his engineering career in 1913 as a steel designer with the Dominion Bridge Company, Montreal. The following year he joined the Structural Engineering Company of Montreal in a similar capacity.

In 1915 Mr. Murphy entered the topographical survey branch, department of the Interior, as survey physicist. In 1920 he joined the physical testing laboratory of the same department. From 1924-1931 he was also assistant supervisor of the laboratory.

In 1931 Mr. Murphy joined the division of physics and engineering of the National Research Council as leader of the aeronautical instruments group. In this capacity and until World War II, Mr. Murphy was responsible, among other things, for the maintenance and calibration of all aircraft flight instruments used by the R.C.A.F. During World War II, as head of the aircraft and allied instruments laboratory of the division of mechanical engineering, National Research Council, he collaborated with the armed services on a number of special projects and investigations. Subsequently, Mr. Murphy pioneered the design and development of a unique series of airborne mechanical optical recorders for aeronautical research application.

Mr. Murphy joined the Institute as an Associate Member in 1922, was transferred to Member in 1940 and on January 1, 1957 attained Life membership.

C. P. F. Faulkner, M.E.I.C., retired district engineer for the B.C.-Yukon district of the Department of Public Works at New Westminster, B.C., died at North Surrey, B.C., on October 4, 1957.

H. W. Vaughan, M.E.I.C.

Charles Frederick Faulkner was born at St. Alban's, Herts., England, on June 29, 1888. He had his engineering training at the Heriot-Watt College, Edinburgh, and his apprenticeship with James Milne and Son, Edinburgh. He moved to Vancouver in 1910, and the following year was articled to Alister Robertson, B.C.L.S., in Victoria. While there he became one of the original officers of the 88th Regiment of the Victoria Fusiliers.

After service during the First World War in Canada, England, and France, he joined the staff of the Canadian National Railway. He then became employed on road location and construction with the provincial government and later assistant engineer with Peter Lyall and Son on the construction of the Esquimalt Dry Dock. He joined the Nelson office of the Department of Public Works in 1925, and upon consolidation of the B.C. districts, he was transferred to New Westminster. From 1934 to 1949 he was in charge of all works on the Northern coast. A year later he was appointed district engineer. In 1952 he was named district engineer of the British Columbia and Yukon territory

Retiring in 1955, he continued for a year to give service to his profession as a consultant in connection with the Okanagan Flood Control project.

Mr. Faulkner joined the Institute as an Associate Member in 1921, transferred to Member in 1940.

Walter O. Sorby, M.E.I.C., Atlantic district manager, Canadian Westinghouse Company, Halifax, N.S., died at Guelph, Ont., on February 3, 1958.

Born on August 18, 1901 at Guelph, Mr. Sorby attended public and collegiate schools in that city. He enrolled at the University of Toronto for his engineering studies and was in 1925 awarded a B.A.Sc. degree in electrical engineering.

Mr. Sorby joined his present company in 1928 after serving with the Westinghouse Electric Corporation on its student training course and at Elmira, Pa.

W. O. Sorby, M.E.I.C.

His service with the Canadian Westinghouse Company included several years at Winnipeg and Montreal, prior to his appointment of Atlantic district manager at Halifax. His work put him in contact with people in all phases of the electrical industry, mining, pulp and paper, and the retail trade.

He served with the Canadian Artillery from 1940 to 1946 and retired with the rank of major after extensive overseas service. His final army appointment was that of technical staff officer, with the rank of major, at Canadian military headquarters, London, Eng., in charge of technical work on artillery equipment. This appointment included liaison with the British ministry of supply and the war office.

Mr. Sorby joined the Institute as a Member in 1945.

A. E. MacDonald, M.E.I.C., sales engineer with the Holden Manufacturing Company Limited, Montreal, died at Quebec City, Que., on February 12, 1958.

Arthur Lamond MacDonald was born at Glace Bay, N.S., on June 23, 1914. Educated at Acadia University and at the Nova Scotia Technical College he was awarded a B.Sc. in 1935, at the latter college and in 1938 qualified for a B. Eng. degree, electrical, at N.S.T.C. On his final graduation he became a junior engineer with the Eastern Light and Power Company, Sydney, N.S. The appointment was however, short-lived. On August 29, 1939 Mr. MacDonald enlisted in the Royal Canadian Engineers. Works officer in charge of works and construction of buildings and fortifications at that time, he was given charge of searchlight installation, with the rank of captain, on the Canadian East coast and Newfoundland. In 1942 he assumed the duties of second in command of a heavy coast battery, Royal Canadian Artillery. He continued to serve in this capacity until 1944. His final army post, was that of inspector of electrical engineering stores, for the Inspection Board of the United Kingdom and Canada. He held the rank of major.

At the close of the war he joined the firm of the Holden Manufacturing Company Limited at Montreal, and was associated with this company at the time of his death.

Mr. MacDonald joined the Institute as a Student Member in 1938, transferred to Member in 1945.

Alfred Edwin McGruer, M.E.I.C., engineer with the Canadian Pacific Railway, electrical equipment system, at Montreal, died in that city on March 1, 1958.

Born at Barrow, England, on December 13, 1900, Mr. McGruer came to Canada at an early age. He studied electrical and mechanical engineering at the Montreal Technical Institute, the University of Toronto and the Central Technical School, Toronto. He also attended special courses in the United States, with the diesel locomotive schools of the General Electric Company and the General Motors Corporation at Schenectady, N.Y. and Chicago. Early in his career Mr. McGruer was associated with Canadian Vickers Limited, at Montreal, the Montreal and Southern Counties Railway, the Hydro-Electric Power Commission of Ontario and Canadian Pacific Railway. He became permanently employed with the C.P.R. in 1928 as chief electrician, at the West Toronto shops. In 1942 promoted to supervisor of stationary power plants, Eastern region, at Toronto, he assumed the post of electrical engineer for that region in 1946. He was named to the post of general electrical engineer, systems, at Montreal, in 1953, which appointment he held at the time of his death.

Mr. McGruer joined the Institute as a Member in 1954.

Elections and Transfers

On the recommendation of the Admissions Committee the following elections and transfers were effected at the meeting of Council on April 19, 1958.

Members: P. E. Ayre, Montreal; R. P. Bourgeois, Montreal; M. M. Chmilar, Calgary; H. K. Fairbanks, New York; J. M. Ferguson, Cornwall; S. Forrester, Montreal; K. R. Fowler, Calgary; K. P. Furness, Toronto; H. F. Gautrin, Montreal; J. Greenaway, Winnipeg; D. W. Gunter, Winnipeg; L. H. B. Hatherell, Montreal; Z. Heczko, Montreal; D. J. Inglis, Montreal; G. H. Jackson, London; F. L. Johnson, Toronto; E. J. Kavanagh, Montreal; T. K. Kearney, Montreal; R. O. King, Ottawa; F. H. Knelman, Montreal; S. L. Mason, Devon, Alta.; F. G. Milligan, Toronto; A. M. Monneret de Villard, Montreal; R. Neal, Montreal; J. C. Ormond, Isle Maligne; J. J. O'Sullivan, Brampton; P. J. Parsons, London, Eng.; R. W. Pryer, Sept Iles; G. E. Reid, Temiskaming; T. J. Robertson, Edmonton; E. R. Rowbotham, Montreal; R. W. Ruthman, Montreal; E. W. Smythe, Toronto; C. L. Speiden, Shawinigan; M. J. Taylor, Montreal; P. S. Thornton, Montreal; O. van Deurs, Atikoken; G. E. Weir, Montreal; H. B. Young, Winnipeg.

Juniors: W. R. Allan, Montreal; M. V. Allinson, Calgary; J. P. A. Arsenault, Montreal; I. G. Bowie, Port Arthur; D. J. Bull, Sept Iles; G. P. Button, Three Rivers; M. H. MacLeod, Orillia; C. F. Marston, Brownsburg; C. J. Mills, Shawinigan; F. Moller, Montreal; J. Perreault, Montreal; P. M. Power, Sydney; D. G. Wood, Sudbury.

Junior to Member: D. G. Best, Montreal; G. D. Campbell, Ottawa; R. H. Darke, Windsor; B. G. Fraser, Toronto; J. Greenberg, Ottawa; A. A. Greenlees, Sarnia; J. G. Hooper, Peterborough; W. G. Ivany, Brownsburg; V. D. MacDonald, Cornwall; A. F. Morrison, Montreal; S. Oancia, Montreal; K. J. Radcliffe, Sarnia; G. H. Shaw, Sarnia; R. H. Whittaker, Toronto.

Student to Junior: M. O. Diorio, Joliette; L. R. Keddy, Windsor; R. G. Plamondon, Montreal.

STUDENTS ADMITTED

University of Toronto: D. M. Aiton; S. M. B. Bailey; M. K. Bonnycastle; D. H. M. Branion; A. A. Bruneau; D. Buchanan; A. Z. Capri; R. K. Cornbill; K. A. Craig; A. Cronin; L. A. Cummings (Miss); T. L. Easterbrook; J. H. Flett; Amy M. Forman; G. R. Frazer; R. K. Gibson; W. J. Harmer; L. S. Harrison; W. C. A. Hay; A. R. Hill; J. Hunt; R. I. Jones; D. A. Keenleyside; D. C. Mabee; R. McDermott; K. A. McLennan; W. P. Reynolds; M. R. O'Shaughnessy; J. M. Perz; R. J. Sanders; D. J. Shepley; K. N. Smith; T. S. Szekely; J. Van der Heyden; J. W. Van Loon; F. J. Wawrychuk; R. A. Williams; A. E. Wilson; J. F. Zupancic.

University of British Columbia: F. J. Brooks; M. S. Chappell; R. G. Fraser; B. A. Heskin; I. R. McAllister; H. Norrish; D. E. Park; P. J. Reader; A. Reinemo; D. J. Thomson; R. J. Van Ryswyk; R. K. Wiltse.

University of Alberta: R. R. Alton; I. J. Curry; M. Dzidrums; R. C. Howe; G. L. Kulak; A. E. McMullen; R. W. Pollock; S. Skrypiczaiko.

Nova Scotia Technical College: F. J. Bradbrook; W. A. Castell; C. N. Colwell; J. L. Cullinan; B. C. Smith; E. J. Stewart; L. V. Windsor.

McGill University: E. Bizon; S. I. K. Bojnowski; P. S. G. Campbell; J. D. Chase; T. Fancott; R. C. Nesbitt; R. P. Racicot.

St. Francis Xavier University: J. H. Bethune; L. A. Chiasson, P. J. Chiasson; C. R. S. Haslam; A. M. Laliberte; J. Rankin; G. G. Weeks.

Queen's University: E. C. Hanna; D. G. Hilliard; E. J. Jackiw; J. E. Vollmer.

Royal Military College: J. B. Franklin; P. V. Glasheen; P. P. M. Meincke; R. L. Walkington.

St. Dunstan's University: E. J. Nagy; F. Tam. **Sherbrooke University:** J. C. Gaudette. **Ontario Agricultural** College: A. B. Campbell. **Univ. of Manitoba:** E. H. Geres.

Mount Allison University: M. A. Pratt.

Rensselaer Polytechnic Institute: A. J. Muradliyan.

Graduate: R. G. Bethell, University of Saskatchewan, 1957, B.Sc. (civil).

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members: L. Boyer; D. W. McCallister; H. L. Johnston, A. C. Pitt.

Juniors: H. Karasiuk; W. B. Peacock; G. D. Morrison; N. E. Pullin.

Junior to Member: T. E. Wilson.

SASKATCHEWAN

Members: E. E. Brooks; R. K. Craig; R. W. Durie; A. Guthrie; W. H. W. Husband; W. H. Jones; J. B. Lintz; N. Ludwick; R. L. Padget; J. L. M. Scott; D. M. Shier; K. M. Stephenson; J. L. Stoik; H. J. Strain; S. Trausch; D. T. Waleski; M. P. Werner.

Juniors: P. W. McAra; A. I. Reed; L. H. Sawatsky.

Students: G. H. Anderson; J. G. Anderson; W. G. Atkinson; V. G. Beckie; R. J. Bell; G. H. Beuker; R. E. Beveridge; W. G. Bierlmeier; R. H. Billings; R. L. Blanchette; B. G. Brown; P. E. Brown; R. H. Bryce; D. L. Burke; D. C. Burr; R. G. Cameron; A. J. Cartier; D. F. Child; E. P. Chou; L. W. G. Collins; G. T. Conn; H. R. Daniel; A. Dzuba; W. D. Evans; H. P. Fahlman; M. Feldman; D. J. Ferguson; R. George; K. N. Gulstene; T. E. Hage; H. Heinmark; H. M. Hesjedal; F. A. Hlohovsky; G. F. Hutch; W. S. J. Jakubcak; P. Jmaeff; K. D. Johnson; A. L. Kipling; E. E. Kuntz; W. C. Lee; D. R. O. Lennox; R. Loch; J. E. Lovecky; M. L. Lowe; D. L. MacLeod; A. I. Massier; R. G. McCarthy; J. E. McGuire; F. B. McPherson; M. F. Main; D. G. Mathieu; V. E. Mayerle; J. R. Mayor; D. G. Mitchell; T. J. Monastyrski; D. C. Morton; G. B. K. Neely; W. A. Neff; R. W. Nordquist; L. E. Novakowski; D. G. Olafson; G. Paicu; G. A. Palichuk; B. W. Petschulat; B. G. Pryce; H. R. Ramstead; W. E. Randall; H. G. Reesor; J. W. Rittinger; C. A. Rose; A. A. Schuldt; D. E. Shemansky; D. A. Smith; W. L. Smith; N. Soloducha; L. E. Stanley; P. D. Stata; P. P. Steinhubl; D. M. Stewart; J. D. Stothers; F. L. Stromotich; D. A. Vaughan; V. G. Walls; L. S. Werboweski; G. J. Will; M. J. Yablonski; E. A. Yasinko; D. R. Yont; D. A. Young; J. E. Zuk.

Junior to Member: K. W. Domier; J. S. Dudar; J. W. Hawthorne; D. G. Matheson; K. A. Mellish; T. L. Salmon; G. L. Sladek; A. Stewart; P. van Vliet; G. J. Willmon.

Student to Junior: R. J. Clarke; G. Cox; M. J. Demetrick; S. A. Dencsak; B. H. Hamilton; M. M. Hawrysh; J. Martin; R. N. Thompson; S. S. Turek.

NOVA SCOTIA

Member: H. L. Cameron.

MANITOBA

Member: P. G. Hadrill; W. G. Salway.

Personals

News of the Personal Activities of Members of the Institute

H. G. Welsford, M.B.E., M.E.I.C., president and managing director of the Dominion Engineering Works Limited, has been elected president of Dominion Bridge Company, Montreal.

Mr. Welsford started his career with Dominion Bridge at the age of sixteen.

Transferred to Dominion Engineering in 1922, he was appointed general manager of the company four years later. He was named vice-president of the firm in 1938 and assumed responsibility as president of the organization in 1951. In that year he also became vice-president of the Dominion Bridge Company.

A. G. Lester, M.E.I.C., has been named vice-president of The Bell Telephone Company of Canada effective April 1st. With the company 36 years, his service was interrupted several times From 1942-45 he was with the Royal Canadian Corps of Signals, retiring as a major. He was on loan to the Federal Government as an industrial representative at National Defence College, Kingston, in 1949-50; and two years later was called to the Department of Defence Production, Ottawa, as associate director, electronics division.

Mr. Lester's most recent appointment has been that of assistant vice-president (engineering) and general manager of the special contract department.

He was awarded the Ross Medal of the E.I.C. in 1955.

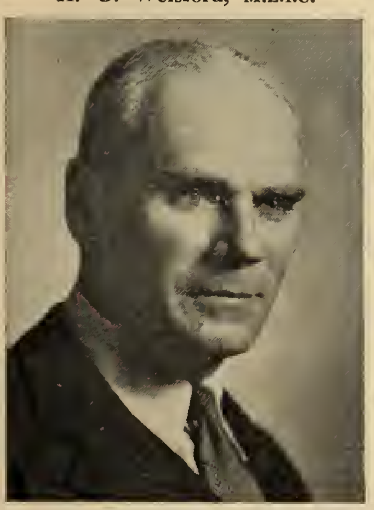
H. M. Finlayson, M.E.I.C., (B.Sc., civil, McGill, 1923), formerly manager of the hydraulic resources department of the Shawinigan Water and Power Company, Montreal, has been appointed an assistant vice-president of the Company. He will continue to be responsible for the management of the company's hydraulic resources department.

Mr. Finlayson, who joined The Shawinigan Engineering Company in 1928, was named manager of the hydraulic resources department in 1954.

H. M. Finlayson, M.E.I.C.

A. G. Lester, M.E.I.C.

H. G. Welsford, M.E.I.C.



Leo Scharry, M.E.I.C., (B.A. Sc., civil, Ecole Polytechnique, 1946), of the Leduc Electrical Company, Montreal, has been elected vice-president of the firm. Late in 1957 Mr. Scharry was appointed vice-president of the organization following a number of years experience with the Sangamo Company Limited, and the Wagner Electric Company, Montreal, as technical sales representative.

Leo Scharry, M.E.I.C.

N. F. Moodie, M.E.I.C., (B.A.Sc., mining, U.B.C., 1936), has, since November 1957, been engaged in operations as an independent consultant at Calgary. He was previously associated with Dutton-Williams Brothers Limited, Calgary, and before that with the National Defence Headquarters, R.C.N., Ottawa, for several years.

Henri A. Audet, M.E.I.C., (B.A., Ecole Polytechnique, 1938; B.Sc.A., Ecole Polytechnique, 1943), formerly Quebec regional engineer for the Canadian Broadcasting Corporation, Montreal, is president and general manager of Television St. Maurice Inc. This is a new company organized by Mr. Audet to operate station CKTM-TV in the Three-Rivers, Que., area.

W. J. Riley, M.E.I.C., of Montreal has been appointed the representative of the Corporation of Professional Engineers of Quebec on the Council of the Engineering Institute. Mr. Riley is chief engineer with Sperry Gyroscope Company of Canada Ltd.

Professor M. L. Baker, M.E.I.C., of Halifax, N.S., has been appointed representative of the Association of Professional

Engineers of Nova Scotia to the general council of the Engineering Institute of Canada. Prof. Baker, who has been active in both professional organizations for a number of years, is a member of the faculty of mechanical engineering at the Nova Scotia Technical College.

H. J. Leitch, M.E.I.C., (B.Sc., civil, McGill, 1926), has been appointed engineer-in-charge of structural steel sales for the Dominion Bridge Company Limited, which he joined in 1929.

Mr. Leitch inaugurated operations of the Sault Structural Steel Company Limited, now operating under the name of Dominion Bridge Company Limited, at Sault Ste. Marie in 1937 and for some years afterwards was its manager. During World War II, Mr. Leitch was away from Dominion Bridge for a period, first as general sales manager of Algoma Steel Corporation and then as assistant director general, naval shipbuilding branch, Department of Munitions and Supply.

J. T. Fisher, M.E.I.C., (B.A.Sc., McMaster, 1927), until recently plant personnel supervisor of the Toronto area of the Bell Telephone Company of Canada, has been named chief engineer of the area. Mr. Fisher has been with the Bell since his graduation. He was special studies engineer in the plant extension division in 1950. In 1952 he was appointed district plant superintendent, Toll area, becoming plant supervisor during the following year. He maintained this position until 1955 when he was named to his most recent appointment.

A. J. Groleau, M.E.I.C., (B.Sc., elec., McGill, 1928), until recently chief engineer of the toll area of the Bell Telephone Company of Canada with headquarters in Montreal, becomes plant manager of the area. Mr. Groleau, who joined the Bell in 1928, has held various engineering posts with the company, being successively traffic assistant, dial equipment engineer, general traffic engineer and general facilities superintendent.

W. R. Staples, M.E.I.C.

He was named chief engineer, Eastern area, in 1951, and became toll area chief engineer in March 1953.

John Austin Loy, M.E.I.C. (B.Sc. civil, McGill, 1921), plant manager of the toll area of the Bell Telephone Company of Canada, has retired from active professional life after thirty-five years service with the company. He was plant manager of the toll area in Montreal and Ottawa, a position he has held since 1953.

Mr. Loy began his career as an inspector with the Department of Public Highways of Ontario in 1922. Within a short time he became associated with the construction staff of the Bell Telephone Company, eastern division.

W. R. Staples, M.E.I.C., (B.Sc., mech., Sask., 1944), professor of mechanical engineering, at the University of Saskatchewan has been promoted to assistant dean of the college of engineering.

He joined the staff of the University of Sask. in 1946 and became assistant professor, college of engineering and then associate professor in 1947.

He was in 1955 elected president of the Association of Professional Engineers of Saskatchewan, at the same time serving as chairman of the Sask. Branch of the E.I.C.

H. J. Leitch, M.E.I.C.

G. V. Meagher, M.E.I.C., (B. Eng., mech., McGill, 1942), has joined the consulting engineering firm of Dilworth Secord and Associates Ltd., Toronto, as a third principal.

Mr. Meagher has worked with National Research Council, Ottawa, as a mechanical designer and consultant at Vancouver, with Canadian General Electric Limited, Montreal, as manager of marketing research, major appliance department, and as director, market research, for Moffats Limited and affiliated companies.

P. M. Sauder, M.E.I.C., of Edmonton, retired general manager of the western irrigation district, with the Department of Water Resources, Province of Ontario, has been re-appointed as a representative of the Association of Professional Engineers of Alberta on the Council of the Engineering Institute.

Mr. Sauder has represented the Association in this capacity since 1944.

A. Madeyski, M.E.I.C., is now employed by N. Slater Company Limited, Hamilton, Ont. as a mechanical engineer and

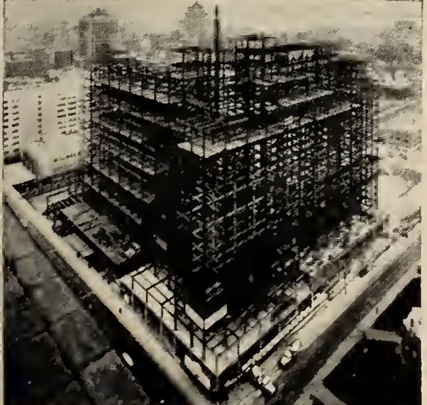
He had to be quiet...



This man is one of a team of despatchers in the C. N. R. Central Station, Montreal. The safety of thousands of passengers depends on him, and others like him, as trains are routed through the maze of C. N. R. tracks. Such responsibility calls for experience, concentration and above all *quiet.*

When the new Queen Elizabeth Hotel was being built directly above his head a special problem arose. How to erect this large steel structure without distracting noise so that railway operations could be safely continued. Dominion Bridge engineers, working closely with C. N. R. officials, met the challenge. Riveting was virtually eliminated and special field erection procedures were evolved, using welding and bolting.

Once again steel proved its versatility in the solution of a pressing construction problem.

proves ideal for drainage pump piping

Like other modern cities, Calgary, Alberta, prevents flash-flooding in highway underpasses . . . by relying on Dresser Couplings to absorb vibration, movement and other pipe-transmitted stresses in its new Fairbanks-Morse-equipped pumping stations.

No need to worry about leaky pump connections when installations are Dresser-Coupling protected! The strong resilient rubber gaskets provided by the Dresser design *flex with* and *absorb* vibration, expansion or contraction movement . . . assure bottle-tight joints for life.

In addition, Dresser Couplings are fast and foolproof to install. No caulking, threading or precise pipe fitting required. Equipped with only a wrench, any workman can make leakproof joints every time, regardless of weather or job conditions.

Save the Dresser way on your next water, sewerage or drainage project. Precision-made and factory-tested, Dresser Couplings are available for lines from 3/8″ to 72″ in diameter or larger. Call your local piping supplier for complete information or write us.

Now . . . another good reason to specify toilet compartments by WESTEEL

Here's a major improvement in door control! All working parts of the new Westeel 7700 Hinge are concealed within the door, providing permanent protection from dirt, moisture and tampering. The 7700 Hinge allows the door to swing freely, in or out, and controls its rest position. The door does not rise or fall as it swings and the entire suspended load rests on a frictionless type ball bearing assembly.

We offer a full range of Toilet Compartments with this new 7700 Hinge*. All are designed to use space economically and to facilitate cleaning and are engineered to give many years of service with minimum upkeep. A wide choice of baked-enamel finishes. For detailed information ask for Toilet Compartment Catalogue No. 56.

ONLY BY SPECIFYING "WESTEEL" CAN YOU GET THE 7700 HINGE

*Not available on "York" type.

Works Department, Dominican Republic as a road construction engineer. Promoted to senior engineer in 1956, he became acting director of works in 1957.

L. F. Giauque, M.E.I.C., (B.Sc., mech., Sask., 1942), is project engineer for the Spruce Falls Power & Paper Company Ltd., Kapuskasing, Ont. Mr. Giauque joined the company in 1945 as mechanical engineer. Further to his actual position, he also carries on the business "Giauque Enterprises".

Don A. McRae, JR.E.I.C., (B.Sc., elec., Manitoba, 1948), holds the position of chief electrical engineer in the manufacturing department of Ets-Hokin and Galvan Inc., in Wilmington, Calif. Earlier, Mr. McRae was in charge of all electrical construction of Cemco Inc., Downey, Calif.

J. P. Dagenais, JR.E.I.C., (B.A.Sc., C.E., mech. and elec., Ecole Polytechnique, 1948), sales engineer with Dominion Bridge Company Limited since 1954, has been appointed combustion sales engineer, Eastern division.

Mr. Dagenais is a former president of the junior section of the Montreal Branch of the E.I.C. He is presently serving as secretary of the Institute's program committee.

J. P. Dagenais, JR.E.I.C.

J. J. Harris, JR.E.I.C., (B.Sc., mech., Univ. of Man., 1951), has been appointed mechanical engineer (car) of the Canadian National Railways at Montreal.

Mr. Harris who has been associated with the C.N.R. since graduation, has been assistant engineer (car), mechanical engineer in the shop methods department and with the research and development department economics branch.

Gordon L. Springate, JR.E.I.C., (B.Eng., elec., McGill, 1955), until recently sales engineer for Reliance Electric and Engineering Limited in Montreal, has been transferred by the company to their Vancouver Branch to assume responsibilities as district manager.

Maurice Lauzon, JR.E.I.C., (B.Sc., geology, Laval, 1949), has joined the staff of Lake Asbestos of Quebec Ltd., as resident geologist. He was formerly geologist and field engineer for Coulee and Headway Mines Limited at Oka, Que.

A. G. Westaway, JR.E.I.C., (B.A.Sc., mech., U.B.C., 1951), has been promoted to plant superintendent with the Clayburn-Harbison Ltd. operations at Abbotsford and Kilgard, B.C. He was formerly acting plant superintendent with Clay Products Ltd. at Medicine Hat, Alta.

J. W. Bouskill, JR.E.I.C., (B.Sc., mech., Manitoba, 1954; M. Bus. Admin., Western Ontario, 1957), is following his career as department supervisor in production at Proctor and Gamble at Hamilton, Ont.

Ivan Brucky, JR.E.I.C., (B.Sc., C.E., Manitoba, 1954), has recently accepted a position as construction engineer in the design and special products branch of the Corporation of the City of Ottawa. Mr. Brucky was formerly associated with the Ontario Department of Highways as project supervisor, and with the Abitibi Power and Paper Co. in Toronto as junior structural engineer.

W. G. Woodcock, JR.E.I.C., (B.Sc., civil, Queen's, 1953), has been appointed district manager for the Toronto and Eastern Ontario division, Air Coils Manufacturing Company Limited, Oakville, Ont.

Most recently, Mr. Woodcock has been associated with Frigidaire Products of Canada Limited as supervisor of sales of commercial refrigeration and air conditioning, also in Toronto and Eastern Ontario.

A. G. Gentle, JR.E.I.C., has resigned his position as mechanical design engineer, development department, of Atomic Energy of Canada Limited in Ottawa, in order to accept an appointment as project engineer for California Pellet Mill Company, at San Francisco.

F/O M. Romanow, JR.E.I.C., (B.Sc., elec., Alta., 1956), is a stations telecommunications officer with the R.C.A.F. at Halberg, B.C. Prior to his transfer to B.C. he was located at the Radio and Communications School at Station Clinton, Ont., for a period of eight months. While there he was engaged in the instruction of communications and armament officer candidates in basic radio and radar theory.

B. S. Fulmore, S.E.I.C., (B.Eng., mech., N.S.T.C., 1957), has accepted the post of assistant plant engineer for Canadian Gypsum Company at Hillsborough, N.S.

NEWS OF THE BRANCHES

Activities of the Forty-Nine Branches of the Institute and abstracts of the papers presented at their meetings

AMHERST

G. R. Pond, JR.E.I.C., *Sec.-Treas.*

A COUNSELLING NIGHT for the Engineering Students of Mount Allison University, Sackville, was sponsored by the Branch on March 17, 1958. The event was preceded by a dinner meeting for branch members and guests. Approximately one hundred engineering students attended the meeting called to order by Merle Pratt, president of the Mount Allison Engineering Society. Mr. Pratt introduced the panel members. They were as follows: Civil—H. W. L. Doane, vice-president, E.I.C.; manager of the Standard Paving Maritimes, Ltd., Halifax, N.S.; electrical—O. M. Sweetzer, chief engineer, Canada Electric Company, Amherst, N.S.; metallurgy—J. R. Wallace, chief metallurgist, Dominion Steel and Coal Company, Sydney, N.S.; mining—E. Browne, manager, National Gypsum Company Limited, Milford, N.S.; mechanical—Lyle Renner, Public Service Commission, Halifax; sales—J. W. Wilson, maritime manager, engineering, Armco Drainage and Metal Products of Canada Limited, Sackville, N.B.

Mr. Doane acted as panel chairman and after giving a brief talk on the E.I.C., he called upon each panel member to define his particular branch of engineering, to explain the function of an engineer in that branch and to forecast what the future opportunities in that field will be. Each member spoke for five or ten minutes. A general question period followed. Such questions as the following were put forward: What is the future of the mechanical engineer in the field of automation? How could one choose the best branch of engineering to suit his particular abilities? What is the principal trend of the high specialization of electrical engineering? What new metals and alloys are needed for the future? The panel members dispersed about the auditorium to discuss with students specific questions pertaining to a particular field.

BAIE COMEAU

N. Lapierre, JR.E.I.C., *Secretary*

George W. Scott, M.E.I.C, *Branch News Editor*

THE MANICOUAGAN POWER development became the subject of a talk by Charles Miller, project manager of the Canadian British Aluminum Company, Baie Comeau, at a February 28 meeting of the Branch.

Mr. Miller gave a thorough resume of the hydro-electric potentialities of the Manicouagan River and the remainder of his talk dealt with the hydraulic, civil, and construction problems, particularly associated with stage 1, of the Manicouagan development. The value of using models to solve and study hydraulic and civil engineering problems was emphasized, the difficulties and problems of executing a project of this kind during a severe winter was stressed. A detailed description was given of the excavation of a 35 ft. diameter diversionary tunnel and the blasting of the upper and lower access plugs which involved the shifting of 9000 cubic yards of granite and rock barrier with 22 tons of dynamite. Following the talk a 16 mm Kodachrome silent film taken during the construction of stage 1 of the project was shown and commented on by the speaker.

BELLEVILLE

F. E. Moore, M.E.I.C., *Sec.-Treas.*

T. E. Flinn, M.E.I.C, *Branch News Editor*

THE REGULAR MONTHLY meeting of the Belleville Branch on March 10 took the form of a tour of the plant of Pyrotenax of Canada Limited at Trenton, Ontario.

Approximately twenty-five members of the Branch gathered at the plant at 7 p.m. and were taken on a guided tour by company officials. For the benefit of the sightseers sufficient plant staff had been called back to work in the evening to demonstrate the manufacture of a length of pyrotenax cable.

It was first explained that pyrotenax was a French invention, arrived at by French engineers in their search for an electric cable which in case of fire would continue to operate and which ordinarily would neither cause nor contribute to a fire. Pyrotenax Ltd. is a British company which built the Trenton plant in 1953. The plant now employs approximately fifty persons.

A length of cable was built by enclosing a copper rod in a 2 inch diameter seamless tube of copper and packing the tube with magnesium oxide under pressure. The tube is then drawn, after which the copper sheath, insulator, and conductor became a homogeneous mass. Each component maintains its original proportionate size and relative position throughout the remainder of the process until the required finished sheath diameter is reached. Each length of finished cable is given voltage and insulation resistance tests before being shipped.

The tour ended in the plant demonstration room with refreshments supplied by our hosts. The Company officials were suitably thanked for their hospitality by Sid Sillitoe on behalf of the Belleville Branch.

At the Branch executive meeting held on March 10 Mr. J. A. McLaren, Eastern field secretary, successor to Colonel L. F. Grant, who retired recently was welcomed. Mr. McLaren accompanied the Branch members on their tour of the Pyrotenax plant later in the evening.

Dave Pullan, papers chairman for the Belleville Branch, has recently transferred to St. Catharines, Ont. He has been succeeded by Mr. Needham Throop. Mr. Pullan is going to work for North American Cyanamid Ltd. in Niagara Falls.

CALGARY

O. O. Junker, M.E.I.C, *Secretary,*

F. L. Perry, M.E.I.C, *Publicity Committee Chairman*

A DOUBLE HEADER SESSION marked the March 13 dinner meeting of the Calgary Branch with guest speakers at 5.30 p.m. and 8.30 p.m. R. A. Huth, first to mount the platform, discussed the "Pulpwood Industry of Alberta." He is the public relations and training manager of the North Western Pulp and Power Limited, at Hinton, Alta.

"Research and Technical Problems in Highway Construction", received notice when R. H. Cronkhite addressed the group after the dinner. He is assistant chief construction engineer with the Department of Highways, Government of Alberta.

Mr. Huth's talk described the activities and relationships of his company to the economy of the Edmonton-Jasper district. He described the impact of this new industry to the economy of the community of Hinton which has mushroomed from 180 to over 3,000 residents in the past two years. Mr. Huth also made an assessment of the future of pulp and paper in Alberta. He described the plant and answered many technical questions at the end of his talk.

A questionnaire was circulated to determine if the membership would prefer a continuation of the type of programming for technical meetings practised here during recent months. It was almost unanimous that 1958-59 should see fewer general meetings — perhaps a total of four — but that the dinner meeting should be the "meat" in the sandwich of two technical papers at 5:30 p.m. and 8:30 p.m. respectively.

EASTERN TOWNSHIPS

Jean Bourassa, JR.E.I.C., *Secretary*

STUDENTS' NIGHT was a feature of the March 14 meeting and included the presentation of three papers by the University of Sherbrooke students. The first prize of $30.00 was awarded to A. Leroux for his paper entitled, "Power Factor Correction." The paper, "Evolution in Ship Construction," by Camille Blais won the second prize of $25.00. Third prize, $20.00, went to G. Hénault for his work, "Heat Treatment of Carbon Stell."

The jury was comprised of G. M. Dick, R. D. Mawhood, C. Langlois and L. G. Carignan.

Marcel Lafreniere, faculty representative who was responsible for the organization of the meeting made the introductions.

A film on the construction of the St. Lawrence Seaway was shown when the jury retired to make its choice.

The students reported that it is their practice to present two or three films each week on technical subjects.

Students' Night brought the activities of the student section to a close for that term as the time for examinations drew near.

Eastern Townships. Below are, l. to r., Jaques Lemieux, secretary of the faculty of engineering, University of Sherbrooke; Camille Blais, second prize contestant; R. D. Mawhood Branch chairman congratulating Adrien Leroux, first prize; Gilles Henault, third prize, and Marcel Lafreniere, faculty representative.

KINGSTON

D. I. Ourom, M.E.I.C., *Sec.-treas.*

AN INTERESTING EVENING was assured when presentation of five papers was planned for a February meeting of the Kingston Branch. Presented by senior Royal Military College students and Queen's science students the papers were, "Development and Design and Construction of Earth Dams", by O. M. Hodgkins; "Selection of Suitable Gas Turbines for use with Small Free Piston Gas Generators," by R. W. Warkentin; "A Study of a Cut and Fill Stoping Problem at Hardy Mines", by A. J. Patrina; "Thermionic Emission", by P. P. M. Meincke, and "Collapsible Tension Reels for Higher Productivity in Steel Rolling Mills," by D. J. Kilgour.

Vibration problems in a large utility were discussed by Aubrey Edwards, of the Hydro-Electric Power Commission of Ontario at a meeting later in the month. A specialist in vibration problems in the H.E.P.C., research department, Mr. Edwards is in his work concerned with such things as transmission line vibration and the vibrations of building structures due to motors.

H. M. Jones, works manager of the C.I.L. chemicals and agricultural chemicals plants at Hamilton, Ont., on March 18, addressed the Kingston Branch on "Air Pollution in Hamilton, Ont." The subject of air pollution and its reduction has been the subject of discussion in many groups in Hamilton. More than two years ago, the Hamilton-Brantford Branch of the Canadian Manufacturers Association decided to take definite steps toward the definition of this problem. Mr. Jones is a member of the C.M.A. committee associated with the air pollution survey.

Sixty volunteer members of the Hamilton-Brantford Branch of the C.M.A. donated $130,000 to complete an Air Pollution Survey in Hamilton. The Ontario Research Foundation was retained as the agency performing the actual survey.

Two years of the projected three-year program have now been completed and the paper which was presented is a summary of the progress to date.

LETHBRIDGE

R. D. Hall, JR.E.I.C., *Sec.-Treas.*

R. F. Smith, JR.E.I.C.,
Branch News Reporter

HYDRAULIC MODEL TESTING was the engineering subject chosen for the February meeting of the Branch. During his very interesting and informative address, C. D. Smith, of the Prairie Farm Rehabilitation Association, Regina, Sask., showed a number of short films of various hydraulic models used by P.F.R.A., and of several of the dams and structures they have built.

The importance of correct design in order to prevent cavitation and erosion of stilling basins at the entrance of spillways was stressed. Films of the model tests indicated the results of improper design, and of the changes made in the models, which practically eliminated undercutting of the spillways and erosion of the banks of the stilling basins.

The use of the hydraulic jump to dissipate energy and of the effectiveness of various weir structures was also vividly shown.

The experience gained by the use of models has proven effective in practice. Construction and maintenance problems have been greatly reduced, and appreciable financial savings made.

Telephone Industry Innovations

H. J. Childs, switching planning engineer, with the Alberta Government Telephones, at Edmonton addressed the Branch on March 15. The subject of his talk was, "A Forward Look at the Telephone Industry."

A solar powered battery radio was demonstrated and solar batteries will prove valuable for rural telephone exchanges, Mr. Childs stated. Equipment will be miniaturized, keyboard and hands off phones will replace the pres-

ent dial and handset units. A model of a television phone was shown.

Mr. Childs explained in detail the operation of the 3-4 numbering system and of additions required for direct dialing not only on this continent but eventually throughout the world.

LONDON

W. C. Sinkins, JR.E.I.C., *Sec.-Treas.*

George W. Chorley, M.E.I.C., *Branch News Editor*

Dr. A. D. Misener, head of the department of physics, University of Western Ontario, delivered an address to the Branch meeting, March 18. Subject of the talk was, "Education". Dr. Misener began by defining "training" and "education" ,and referred mainly to engineering courses at university level. It was his view that "education" was of little use unless preceded by a basic "training".

Dr. Misener labelled as "woolly thinking" the widely stated view that because the West is behind in missile development, that we should produce more engineers. He went on to develop his thoughts on this very important subject. He was politely heckled at one point by E. V. Buchanan when he was rash enough to refer to the "humanities" without first defining these subjects. Dr. Misener was not in favour of broadening the base of an engineer's education or training to include so called "cultural" subjects.

In his statement that the engineer was better qualified to talk on other subjects, than other professional men were qualified to talk on engineering, Dr. Misener raised a protest from D. Sutton, superintendent of public schools at London. There was a spirited discussion period in which Professor L. S. Lauchland of the University of Western Ontario, Mr. Sutton, Mr. D. J. Matthews and others took part. The chairman of the meeting was R. W. McMeekin.

Although not a large meeting by London standards, it was obvious that all present considered the meeting to have been rewarding.

NEWFOUNDLAND

R. L. Smyth, JR.E.I.C., *Sec.-Treas.*

R. P. Hunt, JR.E.I.C., *Branch News Editor*

THE ANNUAL STUDENTS NIGHT of the branch. was held March 10, 1958. Three engineering students from Memorial University compete for a public speaking prize awarded by the branch. Mr. Duffett discussed "The Alaskan Highway"; Mr. Moore outlined "The Proposed St. John's Harbour Development"; and Mr. G. Moores gave a talk entitled, "Bear and Bull—The Stock Market".

During the student year the engineering faculty holds a weekly seminar. The three speakers who compete at this meeting are chosen by students ballot from all those who speak at the seminars. Meeting are chosen by students ballot from all those who speak at the seminars.

At the conclusion of the three talks, Dean Carew of Memorial University introduced the three speakers and provided brief biographical sketches. A vote was taken among the members to determine the best speakers. G. Moores, declared the winner, will receive the prize at one of the engineering seminars.

The report of the nominating committee, with the slate of officers for the ensuing year, was presented.

Chairman G. Knight announced that the annual dance to take place April 18 at the Old Colony Club.

NIPISSING AND UPPER OTTAWA

R. A. Booy, JR.E.I.C., *Sec.-Treas.*

J. W. Millar, M.E.I.C, *Branch News Editor*

THE ANNUAL STUDENTS' NIGHT and monthly dinner meeting was held recently. This is the evening in which members of the Institute each sponsor a senior high school student who has expressed an interest in engineering as a career. The students were from Algonquin Composite School, Scollard Hall, Sturgeon Falls and Temiskaming High

Schools. Seventy members and guests were present. Mr. J. Chantler of Temiskaming presided.

The speaker, introduced by J. W. Millar, was K. D. Landell of Montreal, president of Adanac Supplies Ltd., and vice-president of Canadian Waugh Equipment Co. Ltd.

Basing his address on "Another Look at Engineering" Mr. Landell placed emphasis in the broader aspects of the fundamental importance of the profession of engineering.

He said that there have been three great turning points in material progress — organized agriculture on which the establishment of settled communities was founded, man's victory over fire which made man virtually independent of climate and led to the industrial era, and thirdly, the advent of atomic energy. The fourth great era is just ahead — it is the crossing of space and interplanetary travel, and may come by the year 2000.

In conclusion, Mr. Landell stated that science and engineering are among the most attractive and exciting careers open to young men and women today, the way is long and hard. An engineer must be a dedicated man and a man of extraordinary intellectual honesty.

Shown together while planning the 3rd annual Architect-Engineer dance, are, left to right, R. Silver, chairman, proceeding committee; H. Chaput, chairman, Ottawa Branch, E.I.C., and G. Pritchard, chairman, Ottawa Branch of the Architects Association.

J. Warburton of Temiskaming thanked Mr. Landell on behalf of the members of the Institute and the students.

OTTAWA

W. V. Morris, M.E.I.C., *Secretary*

A. H. Graves, M..E.I.C., *Publicity chairman*

Five years of Canadian television was the subject discussed at the February 8 meeting of the Branch. J. A. Oimet, general manager of the C.B.C. described the development of the Canadian Television network across Canada during the past five years.

A.I.E.-I.R.E.-E.I.C. Joint Meeting

Dr. R. G. Griffith, chief engineer of the Canadian Overseas Telecommunication Corporation, addressed the Branch on the subject of the "Trend of Overseas Telecommunication Development" at a meeting on February 27. Dr. Griffiths talk was published in the January 1958 issue of the *Journal*.

Computers and Engineering

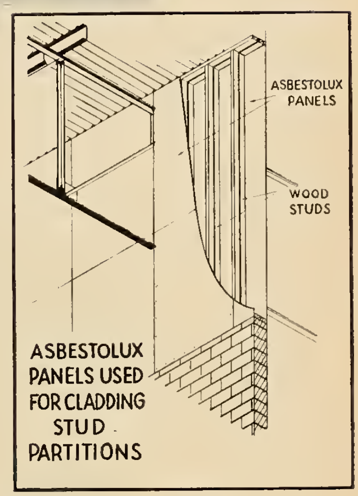
Dr. K. W. Smillie, of Computing Devices of Canada was guest speaker at a meeting held March 6 when he delivered an address on "Electronic Digital Computers and their Application to Engineering Problems." The clarity with which so complex a subject was dealt was remarkable.

CANADIAN STEEL CORPORATION,
Etobicoke, Ontario.

Architects: *Giffels and Vallet of Canada, Windsor, Ontario.*

General Contractor: *Eastern Construction Co. Ltd., Windsor and Toronto*

The partitioning illustrated consists of ASBESTOLUX nailed to wood studding above 12" cement block wall separating hazardous areas. Contractor found big savings in labour costs because of light weight and ease of handling and general application of the ASBESTOLUX board. The board was undecorated, the natural white finish providing good light reflection was considered excellent.



ASBESTOLUX PANELS USED FOR CLADDING STUD PARTITIONS

ASBESTOLUX was specified

due to its

- High fire retardancy
- Absolute stability
- Light weight, high structural strength ratio, being unaffected by moisture, steam, chemicals, moulds and corrosive atmospheres
- Workability

ASBESTOLUX

- Totally incombustible as established by Underwriters test.
- Can give fire ratings up to 4 hours as supported by independent tests fully approved under National Building Code.
- Is easily workable — can be drilled, sawed, nailed, sanded, routed without danger of spalling, cracking or breaking.

Complete specification and fire test data available from

CAPE ASBESTOS (Canada) LTD.

200 BLOOR ST. EAST • TORONTO 5 TEL. NO. WA. 1-2139

Also at: MONTREAL, QUE., OTTAWA, ONT., WINNIPEG, MAN., EDMONTON, ALTA., VANCOUVER, B.C.

Dr. Smillie spent two years on operational research with the Defence Research Board. He has been with the data producing department of Computing Devices for the past three years.

Annual Architect-Engineers Dance

One hundred and eighty persons gathered at the Assembly Hall, Lansdowne Park, for a most enjoyable evening of dancing to Clifford Trip and orchestra for the third annual architect-engineers dance. Mr. and Mrs. Gordon Pritchard and Mr. and Mrs. Hector Chaput received members and their wives.

The Forgotten Man

The regular Thursday luncheon meeting, held April 3, 1958 was marked by a talk entitled, "Casey Baldwin, first Canadian Aviator." J. B. Parkin, senior consultant to the mechanical engineering division, N.R.C. in making the address, used as his theme the idea that Casey Baldwin is the forgotten man of Canadian aviation. The flyer was associated with Alexander Graham Bell, and John McCurdy, at Baddeck, N.S. in 1907. He made his first airplane flight in March 1908, in the United States.

SAGUENAY

D. L. Aker, JR.E.I.C, *Sec.-Treas.*

BASIC PRINCIPLES OF LUBRICATION was the title of a film presented to the Saguenay Branch of the Institute and the Corporation of Professional Engineers of Quebec, Saguenay Chapter, by B. H. Miller, manager of sales engineering, Imperial Oil Company of Canada, at a meeting on February 25. After the film showing he discussed points raised in the film and considered automotive lubrication and gasoline as a motor fuel.

At a March 18 meeting of the Branch, and the C.P.E.Q., Saguenay Chapter, G. Riedl, M.E.I.C., of the Aluminum Company of Canada considered the subject of "Aluminum Finishing," Mr. Riedl is a member of the technical department of the Arvida, Que., works, of the company, and specializes on corrosion. He described and evaluated mechanical finishing, chemical and electrochemical brightening, anodizing and other types of finishes and the processes by which they are obtained.

A joint meeting of the E.I.C., the C.I.C., and the C.P.E.Q., Saguenay Chapter on March 25, heard H. McClymont and R. F. D. Collin, in a talk entitled "Get Ready for New Markets." The speakers are members of Alcan's sales development department at Montreal.

The film, "Put this in your Pipe," dealing with a pipe line installation in Alberta was shown.

Professor Kenneth R. Andrews, of the Harvard University Graduate School of Business Administration, who was in Canada for the purpose of giving a series of courses to Aluminum Company of Canada supervisory personnel, graciously consented to address the Saguenay Branch E.I.C., and the Corporation of Professional Engineers, Saguenay Chapter. His talk was entitled, "Top Management's Hope for Engineers."

SAULT STE. MARIE

R. L. Wimperis, JR.E.I.C., *Sec.-Treas.*

"EARLY OJIBWAY HISTORY and legends of the Soo Area", was the title of a talk, which, although not a technical paper brought forth much interest from the Branch meeting held March 28, 1958.

The subject was illustrated by slides and was drawn from the personal experience in the past years of C. B. Lawrence, senior draughtsman, at the Algoma Steel Corporation who visited tribes in this area and as far as the Dakotas. He has been engaged in excavations and in the compiling of Ojibway history and legends. Mr. Lawrence has been adopted into one of the local tribes in a very impressive ceremony in 1953. The Ojibways actually did not settle this area until 1525, coming from St. Lawrence area. The general westward movement of Indians at the time was mainly due to the presence of white men.

SUDBURY

W. J. Ripley, JR.E.I.C., *Sec.-Treas.*

M. D. Head, M.E.I.C., *Branch News Editor*

MEMBERS' NIGHT, held March 13, was celebrated with two speakers. The first of these was a discussion of the history, present status, and future plans of the Sudbury parking authority by Lennox Lane, of Lane, Lane, Lewis and Associates, surveyors, of Sudbury. It was felt that this subject would not command sufficient interest outside Sudbury to merit further mention in the Journal.

Second speaker of the evening, Hugh McGinn, introduced by J. Steele, is an electrical engineer at the Gordon Mines, International Nickel Company of Canada Limited. He graduated from the University of Toronto with a B.A.Sc. degree in 1956. Mr. McGinn's talk was entitled, "Ignition Rectifiers." It is explained that in 1903 Cooper Hewitt found that an electric arc in mercury vapour at a low pressure can possess the property of allowing current to pass in one direction with only a small voltage drop while practically acting as a non-conductor

in the opposite direction. By providing additional paths both half waves of an alternating current can pass to the D.C. Circuit, and all phases of a poly phase A.C. supply can separately pass to the D.C. circuit, and all phases of a polyphase A.C. supply can be utilized thus enabling D.C. output to be obtained.

Applications

Railways—high A.C. voltage line, D.C. traction motors; Magnesium and Aluminum Production—advantages, cooling; no noise, anti-corrosive.

High Energy Accelerators—used as inverters, high current or short cycles.

Efficiency Comparison

Better efficiency than M.G. set and synchronous converter—increases efficiency as D.C. voltage output increased. Discussion of design, anodes, cathodes, tank, auxiliary circuits, multi-phase versus single phase.

Counselling

Roy Switch, chairman of the education committee reported that Lively High School had requested speakers on mechanical and civil engineering for forty-two of the students. Messrs. Robinson and Neill had given the desired talks and had been very enthusiastically received. A further eleven high schools in the district are to be visited for similar talks in the near future, and Mr. Switch requested volunteers for this duty.

UNIVERSITY OF ALBERTA

Student Section

N. H. Crawford, S.E.I.C.,
Branch News Editor

The thirty-fourth annual banquet of the Engineering Students Society was held March 6, bringing to a close the activities of the group for the spring term. Guest speaker for the occasion was a Mr. Ackroyd, of the Department of Extension, University of Alberta. Mr. Ackroyd who is a lawyer, chose the subject of professionalism for his talk.

The Web Memorial award for the best technical paper presented to the Society was presented to Frank King, senior chemical engineering student for his paper, "The Utilization of Sulphuric Acid as a Catalyst in the Alkylation Process." Awards were also presented to J. N. Fry, retiring president of the Society and other executive members.

Bob Pollock, a third year petroleum engineer is president of the Engineering Society and E.I.C. representative.

UNIVERSITY OF BRITISH COLUMBIA

Student Section

Blake Tweddle, S.E.I.C,
Branch News Reporter

The student section of the Education Council at U.B.C. participated in the open house held recently at U.B.C. A booth was set up in the field house to display some of the pictures from the E.I.C. photo display. Different in design, the booth featured a canopy supported by many strings which formed the shape of an hyperbolic paraboloid. The rest of the photos were displayed in the engineering building.

Bob Noble shown attending the E.I.C. booth at University of British Columbia open house.

The booth was designed and constructed by Bill Gill. Several photos from the E.I.C. photographic display. were presented. A canopy formed by a grid of strings outlined an hyperbolic paraboloid. Approximately 80,000 people visited the campus during the two days. Most of these visited the field house where the majority of clubs on the campus had set up displays.

Several student speakers were sponsored by the student section. First year students gave talks on "One Hundred Years of Engineering in British Columbia." Third and fourth year students spoke in connection with their summer essays. The first year essays were judged by the English department.

Essay Public Speaking Contest

Gerald Gatz, a first year student, obtained very high marks in both aspects of the contest to win the first prize of $40.00. It will be published in a later issue of the Journal.

Election of Officers

At the March 14 meeting, the following officers were elected to our executive for the 1958-1959 session:

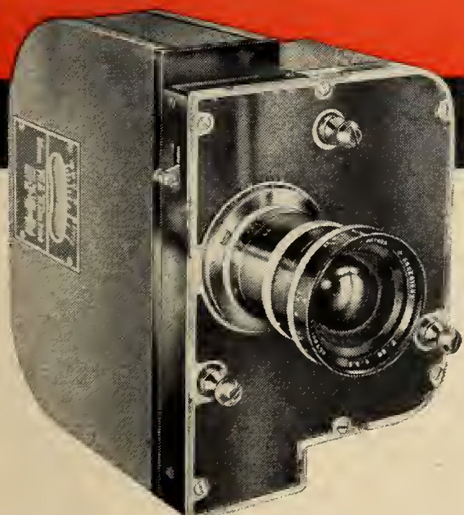
Chairman, Bill Calderwood; vice-chairman and chairman of Toastmaster's Club, Bill Gill; secretary-treasurer, Gero von Dehn; program chairman, Jack Walton; publicity chairman, Murray Brown; field trips chairman, Bill Montador.

UNIVERSITY OF SASKATCHEWAN

Student Section

Raymond L. Blanchette, S.E.I.C.,
Branch News Reporter

Organization of a student's branch was the purpose of a meeting held March 17th on the campus of the University



of Saskatchewan. The following members were elected for office. Brian MacFarlane, chairman, Raymond Blanchette, secretary-treasurer and Dave Burke, program representative. The branch gained the approval of the Saskatchewan Branch, Regina section, on March 21. Approval from E.I.C. headquarters is still awaited.

Some of the rules which the new Branch aims to follow are to interest the student in the professional activities of the Institute and association and to advance his technical knowledge.

It will sponsor and promote the following: monthly technical meetings during the academic year, noon hour showing of technical films, students' paper nights, an annual drive for membership and others.

VANCOUVER

A. D. Cronk, JR.E.I.C., *Secretary*

J. J. Kaller, M.E.I.C., *Publicity Chairman*

THE STRUCTURAL SECTION of the Vancouver Branch held a meeting February 18, during which S. A. Sanderson, M.E.I.C., of Sanderson and Company, consulting engineers delivered a paper on the Nelson bridge design and construction with particular emphasis on the main pier foundation. Numerous slides accompanied this well-attended lecture.

On March 18, the Structural Section was the host to the general membership of the Branch during which a film on the construction of the 24 mile long Pontchartrian Bridge was shown. This bridge which is the longest one in the world is constructed on prestressed cylindrical Raymond piles. Mr. R. L. Nordlund, Ph.D., M.E.I.C., manager of the Raymond Concrete Pile Company answered numerous questions amplifying some details of that structure.

Some sixty engineers and their families recently took part in a conducted tour of the Vancouver aquarium.

VANCOUVER ISLAND

J. A. Cowlin, JR.E.I.C., *Sec.-Treas.*

H. F. Coupe, E.I.C, *Branch News Editor*

THE DEAS ISLAND TUNNEL was the subject of a talk given to Vancouver Island engineers by Norman D. Lea, vice-president of the Foundation of Canada Engineering Corp. Ltd. on March 19. Mr. Lea began his talk by outlining the present and future traffic requirements in the Vancouver area which led to the decision to build a tunnel under the Fraser River at the Deas Island location. It was pointed out that this will be the first tunnel of its type on the North American continent, being of rectangular cross-section supported on sand fill jetted under the tunnel elements to form a uniform and reliable support. The speaker continued with a description of the method of constructing the concrete tunnel segments in a drydock adjacent to the site from which they were floated out into the river and sunk in position. The method used to connect the segments under water and the jetting of the sand fill under the tunnel elements was explained followed by a description of the protective measures taken to safeguard the tunnel against river scour and uplift. The talk was illustrated with slides and was followed by an interesting question period.

Twenty-two engineers travelled to the Deas Island Tunnel site near Vancouver on March 22, to be guests of the Foundation of Canada Engineering Corp. Ltd. on a tour of the project. The tour began with an inspection of the drydock where the tunnel elements were constructed which at the time was flooded and contained the last two elements, the remainder having been placed in the river bed. From here the party visited the fitting out jetty and the construction area where concrete mats for scour protection of the tunnel were being poured. The north tunnel approach, of open

TAYMAR
METAL FLOOR FORM

TAYMAR proved to be a remarkable time-saver in constructing the 17 storey addition to Toronto's Royal York Hotel.

TAYMAR panels join together quickly and conveniently, and are in immediate use to support equipment and construction crew. In the job shown here, 20 gauge TAYMAR Floor Forms served as a rugged base for pouring concrete slabs, over a 300,000 square foot area.

Strong, durable, yet lightweight and easy to handle, TAYMAR Sheet Metal Products are available in various gauges for roof and floor deck, and side wall panels.

Write today for the TAYMAR *Metal Roof Deck Catalog to:*

Following the tour light refreshments were provided at the construction office.

WINNIPEG

C. S. Landon, M.E.I.C., *Sec.-Treas.*

D. G. Curiston, *Section Reporter*

The annual meeting of the Electrical Section which was held on January 8, took the form of a dinner meeting. Attendance was increased over last year's figures.

A film produced by the The Quebec Hydro Electric Commission and available through the courtesy of Canada Wire and Cable, entitled "Beneath the Wide St. Lawrence" was shown. This film dealt with the manufacture and laying of the 69,000 volt, 3 phase power cable across the St. Lawrence River at Rimouski, Que. Its function is to supply power to the residents of the Gaspe area. The cable is now in operation.

New Executive

The new executive selected for the 1958-59 season are as follows: P. Shane, past chairman; S. Eggertson, chairman; G. Flavell, vice chairman; A. Oddleifsson, executive member; and J. Crawley, executive member.

Commissioning Brandon Plant

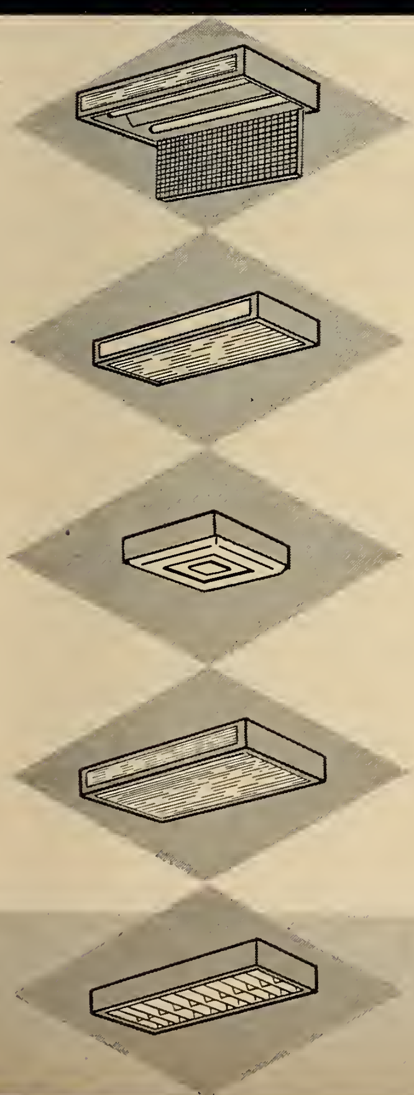
S. Irving, superintendent of the Brandon steam generating station, gave a talk on the commissioning of the Brandon plant, comparing it with one at Poole, England.

The Brandon plant consists of 4 — 325,000 lbs./hr. boilers fired at 625 p.s.i. and 825°F using No. 2 diesel fuel for starting and Souris lignite as the main fuel. The boilers are designed to burn natural gas as an alternative. There are 4-33 M.W. turbines to be installed. These are single cylinder units with hydrogen cooled alternators. The flow of the Assiniboine river is somewhat unreliable and for this reason a cooling tower has been constructed so that now the river has only to supply make-up water. The tower which is 385 feet long and 70 feet wide and is cooled by 24 cooling fans, is designed to drop the water temperature 30°F. The circulating pumps are capable of handling 4,500,000 gallons of water per hour. All water used in the plant must be treated. Coal is brought in by rail from the Souris field. Handling equipment at the plant will handle 400 tons/hr. When the station is in complete operation it will be necessary to handle between 50-60 cars a day or one car every 8-10 minutes. Dust and ash is handled on the wet system and is pumped out to a dyked area where the water drains back into the river. The first unit was put on the system on November 26/57 and the second on January 11/58. Two more units will be completed during the summer of 1958.

At a march 6 meeting the Electrical section heard J. Adamson, technical sales superintendent from Bepco Canada Limited, Montreal, present a talk on variable speed drive control.

Mr. Adamson dealt with the various means of speed control, particularly in connection with paper machines. The three methods of control are electronic, magnetic and direct drive. Down time was dealt with at great length by the speaker and there doesn't seem to be much to choose between the methods of control as far as influencing down time is concerned. Down time is more liable to be mechanical than electrical. Mr. Adamson showed several slides which demonstrated the processing of newsprint.

The annual wind-up of the seventh section was held in the form of a smorsgasbord and dance at the Vasalund in Charleswood. About 110 people attended.



ARCHITECTURAL APPEARANCE
SHALLOW ◆ VERSATILE

You can choose a model to meet most requirements. All with same shallow 3⅞″ depth, clean cut appearance and sturdy construction.

3 WIDTHS — 12 11/16″ wide for 2 lamps, 17″ and 23 9/16″ wide for 4 lamps

2 LENGTHS — 2 feet and 4 feet

News of Other Societies

Canada-U.S. Chemical Engineering Conference

One of the main achievements of the Canada-U.S. Chemical Engineering Conference held in Montreal, April 20-23, 1958, was to bring together the views and opinions of the United States, Canadian, and European leaders in the chemical engineering field—"European" including, in this event, a Russian delegation. To some extent, the Canadian participation can be seen as an extension of the frequently occurring Canadian role of "interpreter" between the United Kingdom and Commonwealth and the United States and between the greater and smaller powers.

Sponsors of the conference were the American Institute of Chemical Engineers, and the Chemical Institute of Canada, Chemical Engineering Division.

Of the total registration of 1,370, some 550 delegates were from the United States. There were eight European delegates: Dr. Paul Ferraro, Belgium, Dr. R. Holroyd, London, J. J. Desportes, Paris, Dr. Karl Winnacker, Frankfurt, West Germany; Prof. Giulio Natta, Milan, Italy; Professor Nikolai N. Melnikov of Moscow, and Dr. Valentin B. Aleskovskij of Leningrad, and Mr. Sergej F. Filipytchev of Moscow.

The European speakers gave a review of the chemical industry on that continent, dealing with such subjects as: the policy of France toward an atomic energy program; the increase in production by Britain's chemical and allied trades in the past ten years; the economic position of the West German chemical industry; the post-war strides in Italy's chemical industry; the advantages to industry of the Benelux economic pattern.

Prof. Melnikov spoke about the rapid development in the U.S.S.R. chemical industry envisaged in the coming years. Dr. Aleskovskij explained the Soviet educational system which accommodates 700,000 students in 750 schools of higher learning. The Soviet participation was the first of its kind in North America.

The American and the Canadian speakers brought up to date the development in the chemical industry on this continent. In a session on future sources of power, speakers from the Atomic Energy Commissions gave the latest data on heavy water reactors.

In discussions the main concerns of the industry were reviewed, in sessions on The Investor and Chemical Industry Management; Chemical Engineering Education in the U.S. and Canada; Career Opportunities in Chemical Engineering. Technical information was made available in symposia and papers on the subjects of mineral processing, high temperature materials for jets and rockets, fluid mechanics, noise in the industry, chemical engineering, and construction techniques, heat transfer, and others.

The Hon. J. Paul Beaulieu, Minister of Industry and Commerce of the Government of Quebec, gave the welcoming address.

W. M. V. Ash, president of Shell Oil Company of Canada, Limited, speaking at a luncheon during the conference, gave a history of the petrochemical industry, comparing Canadian and American progress in developing new products.

The Hon. Lester B. Pearson, M.P., spoke on international affairs at a luncheon on April 22, discussing the political signficance of control of nuclear power.

International Conferences, September, 1958

Fifth UPADI Convention

The fifth convention of the Union of Panamerican Engineering Associations (UPADI) will take place in Montreal, Canada, at the Queen Elizabeth Hotel, September 2-6, 1958.

The Engineering Institute of Canada (2050 Mansfield Street, Montreal) as the Canadian member of UPADI, is participating actively in the organization of the meeting.

World Power Conference, Canadian Meeting

The Canadian Sectional Meeting of the World Power Conference will be held in Montreal from September 7-11, 1958. It is being arranged by the Canadian National Committee of the World Power Conference (Room 150, 500 Wellington Street, Ottawa 4, Canada).

Theme of the Canadian Sectional Meeting will be "Economic Trends in the Production, Transportation and Utilization of Fuel and Energy."

The four-day meeting will afford delegates an opportunity to visit industrial enterprises and construction projects in the Montreal area. There will also be a number of post-conference tours.

Application forms for participation are required to be in the hands of the Canadian Secretariat not later than July 1, 1958.

Sixth International Congress on Large Dams

The Sixth International Congress on Large Dams will be held at the Hotel Statler, New York City, from September 15-20, 1958.

The United States Committee on Large Dams has invited all member countries of the International Commission on Large Dams to participate in the congress and in the study tours which will follow it.

One study tour is sponsored jointly by the Canadian National Committee of the World Power Conference and the U.S. Committee on Large Dams. This tour will leave Montreal on September 11 and will include visits to the St. Lawrence Seaway Power Project near Cornwall, to Niagara Falls, and to the Shippingport Nuclear Energy Plant near Pittsburgh, Penn.

Inquiries on the part of Canadians relating to the Sixth Congress should be addressed to the Canadian National Committee (Secretary, Dr. R. L. Hearn, Glen Nevis, Queenston, Ont.).

Canadian Building Conference

Administration of building regulations was one of the topics discussed at the Ninth Canadian Building Officials Conference held in Ottawa early in April. More than 80 delegates attended the three-day meeting sponsored by the Associate Committee on the National Building Code of the National Research Council of Canada.

Reports were given on the technical work leading to the development and improvement of the Code, an advisory document issued by the associate committee and designed for use by municipalities throughout Canada. At present 364 municipalities have either adopted the Code or are making wide use of it, indicating a large degree of success in achieving uniformity of building regulations in Canada.

Stanley H. Pickett of the Community Planning Association of Canada spoke on Rehabilitation of Buildings in the Urban Renewal Process. It was emphasized that building officials play an important part in maintaining standards in building and that by this means, urban decay could be checked, making urban renewal or slum clearance unnecessary in some cases.

The delegates visited Central Mortgage and Housing Corporation and the information office of the Federal District Commission where Walter Bowker

described the National Capital Plan and the operations of the Commission. The Conference concluded with a tour of the National Capital region.

Copies of the proceedings of the conference can be obtained by writing to the Secretary, Associate Committee on the National Building Code, National Research Council, Ottawa, Canada.

British Scientific Instruments Mission

During the month of March, members of the Scientific Instrument Manufacturers' Association of Great Britain visited Canada in response to the invitation of the Canadian Trade Mission which visited Britain late in 1957. It was the purpose of this body to explore ways that Britain could increase her exports to Canada without entering into competition with Canadian manufacturers.

The instrument field is one which fits the requirements, since 90 to 95% of the instruments used in this country are imported, and of these imports probably 90% come from the United States.

The team of representatives of British manufacturers visited university laboratories, the hydro-electric power plants at Niagara Falls, Ont., and hospitals, aircraft, electronic and chemical industries and oil refineries. They spoke to the press in Toronto, Montreal and Ottawa.

Particular instruments or types were not described, but mention was made of the British instruments used to record the natural phenomena on the Fuchs expedition in the Antarctic, and of the instrumentation of the ZETA project at Harwell.

Head of the mission was L. A. Woodhead, director of Cossor Instruments Ltd., member of council of the Scientific Instruments Manufacturers Association. Other members were: D. A. Pitman, sales director; Electronic Instruments Ltd.; V. A. Sheridan, director, British Physical Laboratories; D. R. Stanley, director, Hilger & Watts Ltd.; W. H. Storey, director, Unicam Instruments Ltd.; J. R. Waite, director, L. Oertling Ltd.; and R. H. Rybb, correspondent to the group.

Calendar

Canadian Aeronautical Institute

Annual general meeting, at Toronto, Ont., May 26-27.

The Royal Society of Canada

Conference in Edmonton, Alta., June 2-4.

Mechanical Engineering Congress

Seventh International Mechanical Engineering Congress, Scheveningen, Netherlands, June 2-7.

Metallurgical Research

International Congress on metallurgical research, Liege, Belgium, June 17-29, 1958.

Chemical Engineering

Institution of Chemical Engineers, symposium on the organization of chemical engineering projects, London, Eng., June 24-26.

Welding Assembly

The International Institute of Welding, annual assembly, Vienna, June 30-July 5, 1958.

American Institute of Chemical Engineers

Fiftieth anniversary, Golden Jubilee celebration, June 22-27, 1958. Theme, "A Look to the Future." For further details write: Joseph I. Savoca, Socony Mobil Oil Company, Paulsboro, N.J.

American Society of Civil Engineers

Convention featuring water, wood topics, Portland, Ore., June 23-27, 1958. Write: A.S.C.E., 33 West 39th St., New York 18, N.Y.

Management Training Institute

The eighth annual Management Training Institute, sponsored jointly by the School of Business Administration, University of Connecticut, and the Northwestern region Society for Advancement of Management, also Conn. U., June 20-29, 1958. Write: Dr. A. D. Joseph Emerzian, University of Connecticut, Storrs, Conn.

Canadian Electrical Association

The sixty-eighth annual convention of the Canadian Electrical Association, Banff Springs Hotel, Banff, Alta., June 30, July 2, 1958. Write: managing director, Room 320, Tramways Bldg., Montreal 1, Que.

Comite National de l'Organisation Francaise

A work report of the Eleventh International Congress of the Scientific Organisation, Paris, June 24-28, 1958, to be published by C.N.O.F., the monthly publication of the organization. A number of reports translated to English. Write: C.N.O.F., 57, rue de Babylone, Paris VIIe.

American Society of Heating and Air-Conditioning Engineers

Semi-annual meeting, Pick-Nicollet Hotel, Minneapolis, Minn., June 23-25, 1958. Write: W. M. Vidulich, 62 Worth St., New York 13, N.Y.

Canadian Institute of International Affairs

Twenty-fifth annual study conference on Canadian-American Relations, University of Alberta, Edmonton, June 7, 8, 1958. Write: Canadian Institute of International Affairs, 230 Bloor Street West, Toronto.

The Society of the Plastics Industry, Inc.

The S.P.I. Midwest section conference, French Lick-Sheraton Hotel, French Lick, Indiana, June 26-27, 1958.

American Society for Testing Materials

The 61st Annual meeting of the A.S.T.M., to be held at Hotels Statler and the Sheraton-Plaza, Boston, Mass., June 22-27, 1958. Write: Asst. Secy., 1916 Race Street, Philadelphia 3, Pa.

Society of Automotive Engineers, Inc.

S.A.E. Summer meeting, Chalfonte-Haddon Hall, Atlantic City, N.J., June 8-13. Write: S.A.E., 485 Lexington Ave., New York 17, N.Y.

Society of Naval Architects and Marine Engineers

Annual spring meeting, Chamberlin Hotel, Point Comfort, June 2-3. Chairman, P.R. Committee, S.N.A.M.E., c/o American Bureau of Shipping, 45 Broad St., New York 4, N.Y.

National Society Professional Engineers

Annual meeting, Chase-Park Plaza Hotels, St. Louis, Mo., June 11-14. Write: K. E. Trombley, 2029, K. St., N.W., Washington 6, D.C.

International Institute of Welding

Annual meeting, I.I.W., Vienna, June 20-July 6. (see Journal, Feb. issue, p. 118). List of welding displays and conferences: Welding in the Chemical Industry—Great Welding Invention of the Deutscher-Verband fur Schweiss-Technik, E.V., Mannheim, June 18-20; I.S.O. General Meeting, covering such topics as steel, cast iron, copper and copper alloys, Harrowgate, June 9-21; International Electro-Technical Commission General Meeting, Stockholm, July 8-18. Write: W. R. Stickney, exec. secy., Canadian Council International Institute of Welding, 7 Pleasant Blvd., Toronto.

Notices

Gray Iron Founders' Society

The 1958 design contest sponsored annually by the Gray Iron Founders' Society, Cleveland, Ohio, offers recognition to designers and engineers of gray and ductile iron castings, and an award of $500.00, first prize. Deadline for the contest is June 20, 1958.

Write: Gray Iron Founders' Society, Inc., National City, East Sixth Bldg., Cleveland 14, Ohio.

Jet Piercing is a development of Linde Air Products Company, Division of Union Carbide Canada Limited

BOOK REVIEW

HYDRODYNAMICS IN SHIP DESIGN

One of the most complete works of its field, this 2 volume set presents a most up-to-date theoretical and practical treatment of ship hydrodynamics. It is sponsored and endorsed by the Society of Naval Architects and Marine Engineers, as well as by the Bureau of Ships, Department of the Navy.

The authors are Captain Harold E. Saunders, U.S.N. (retired) and his staff, who devoted eight years exclusively to the preparation of the first two volumes and who are at present working on a third volume. The third volume is expected to be completed in 1961, and will deal with manoeuvring, towing, natural waves and motion in waves.

Captain Saunders is exceptionally qualified to write a ship hydrodynamics work of this magnitude, having spent a life-time engaged in all phases of ship design, construction and theory. From the time of his graduation from the U.S. Naval Academy, where his standing was the highest in the Institution's history since the graduation of his eminent predecessor, Admiral Taylor, to the present time, his career has included many outstanding accomplishments in this field. Not the least of these was the award to Captain Saunders of the David W. Taylor Gold Medal for notable accomplishments in Naval Architecture.

The two volumes are arranged in four parts. The first two parts, which appear in the first volume, describe the useful aspects of liquid flow and the phenomena associated with the motion of the simple ship and its elements in a liquid, making extensive use of a graphical representation. This is supplemented by a description, with diagrams, of the nature and results of the flow around propulsion devices, control surfaces and the like. The general concepts of flow are expanded in Part 2 and made more specific. They include the phenomena pertaining to motion of water around ships, propellers and appendages. The application of fundamental principles to the problems of flow, pressure and frictional drag about actual ship forms and their many parts is explained in the endeavour to show how the component parts of the whole, individually and collectively, affect and influence its resistance, propulsion and manoeuvring characteristics.

In Part 3 (Vol. 2) the liquid flow phenomena and ship motions are treated in a quantitative manner. Those formulas which are useful in calculations and quantitative prediction of the behavior of a ship and its parts are presented with sufficient background to give them meaning and ensure their proper use. Most formulas given are supplemented by practical examples.

Part 4 (Vol. 2) contains rules, principles and source information for data in the preliminary design stage of ships and their appendages and propulsion devices, insofar as their form, propulsion, motion and other hydrodynamic characteristics are concerned. A practical example of the design of the hull form, the propellers and the appendages of a ship is included to illustrate how the knowledge gained in the book and its references is applied.

The text concludes with an actual preliminary hydrodynamic design of a large merchant ship, including the design of its propeller and two alternative types of motorboat to be carried by the large vessel as a tender. Complete data and explanation is given of each step in the designs, and the latest methods of design procedure are used. Finally, the design of the merchant ship was tested in the David Taylor Model Basin and complete results and analysis are given for the self-propelled and towed tests.

In general, Volume 1 presents theory and description of hydrodynamic effects, while Volume 2 presents data and formulae and shows how application is made to specific design problems. In this approach, an extremely complete coverage has been obtained of almost all types of hydrodynamic effect likely to be met with in contemporary ship design. The accumulated findings of research centres and model testing basins the world over have not been ignored. The student and practising naval architect will also find a comprehensive and unusually complete bibliography for use in extending his study. (H. E. Saunders. New York, Society of Naval Architects and Marine Engineers, 1957. 2 vols., $30.00.)

J. G. German, M.E.I.C.

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m. — 5 p.m.; Saturday, 9 a.m. — 12 noon.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*AMERICAN POWER CONFERENCE PROCEEDINGS, VOLUME XIX, 1957

Papers emphasizing broad aspects of technical development. A wide variety of topics is presented including steam and gas turbines, industrial power plants, condensers and feedwater circuits, extra high voltage systems, electrical distribution, computers and network analyzers, nuclear energy, and water technology. (Chicago, Illinois Institute of Technology. 746p., $8.00.)

BASIC TELEVISION

Developed in conjunction with the New York Technical Institute, this is a text suitable for study at home or in the classroom. It presents the basic theory, operation and circuitry of black and white television in a simple form, with many illustrations and diagrams. The volumes cover: the transmitter; the receiver; antennas and transmission lines;

at last... the
BLAST

receiver circuits. (Alexander Schure. New York, Rider, 1958. 5 vols., $10.00 a set, $2.25 per vol. Also available bound in 1 vol. $11.50.)

BRIDGES AND THEIR BUILDERS, REV. ED.

This is the history of the science of bridge building from man's first crossing of a stream on a fallen log to the designing by Mr. Steinman of the Mackinac bridge.

The first section of the book describes primitive bridges, and the gradual development of the art of bridge building leading to the achievements of the Romans, the middle ages and the Renaissance.

Mr. Steinman examines the changes made in the science by the use of iron, steel and concrete, and discusses the work of such men as Rennie, Stephenson, Latrobe, Eads, the Roeblings, Baker and Fowler, and many others.

He describes the various types of bridges; arch, cantilever, suspension, tubular, bascule, vertical lift, truss, etc., and examines in detail some bridges built in this century.

Although essentially written for the layman, this is a most interesting work by an authority on the subject. In this revised edition, corrections have been made, and the text brought up to date, to include mention of European bridges destroyed during the war, and those built both in Europe and on this continent since.

One criticism. Where revisions have been made in the text, or new material incorporated, a smaller type-face has been used, and the sudden transition in the middle of a sentence is most disconcerting. (D. B. Steinman and S. R. Watson. New York, Dover, Toronto, McClelland and Stewart, 1957. 401p., pa. $2.15.)

BUILDING AND PUBLIC WORKS ADMINISTRATION, ESTIMATING AND COSTING, 5TH. ED.

The fifth edition of this book to appear in eleven years is a useful work on estimating, costing and administering large-scale building and civil engineering works, and although it is British, much of the material is applicable in this country.

The first nine sections deal with various aspects of costing and administration: head office and site charges; costing; tendering; how to use the estimating tables; site administrative staff; organizing the work; and plant and labour.

The remaining sections contain detailed information on the costs of specific items of work; bricklaying, carpentry, concreting, excavation, pile driving, etc. (Spence Geddes, rev. by E. Drury. London, Newnes, 1957. 288p., 42/-.)

°BUILDINGS FOR INDUSTRY

A selection of recent industrial building designs which are accompanied by studies on the trends and factors prevalent in current practice. The philosophy and practical needs of the company are used to explain choice of site, plan, lighting, colors, location of loading docks, rail spurs, and employer facilities. Types of buildings studied include warehouses, light industry, consumer goods, manufacturing laboratories, utilities and service industries, and heavy industry. (New York, F. W. Dodge, 1957. 309p., $9.75.)

°CONTRACTS, SPECIFICATIONS, AND LAW FOR ENGINEERS

Included is an explanation of the basic principles of the law of contracts; a discussion of the application of these principles to construction contracts in particular, with data on the preparation of specifications; a consideration of the various fields of law of special interest to the engineer. The authors attempt to state legal principles simply and clearly rather than quote extensively from involved court decisions or complicated legal documents. (C. W. Dunham and R. D. Young. Toronto, McGraw-Hill, 1958. 550p., $12.00.)

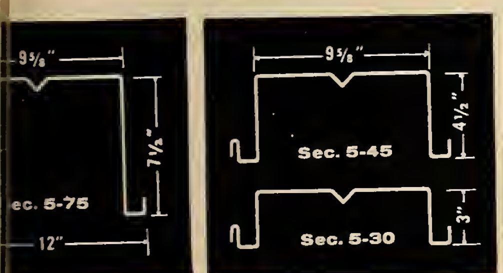
°DYNAMIC INSTABILITY

Studies the general problem of dynamic instability and in particular self-excited oscillations arising from motion. Introductory material on simple harmonic oscillations and conservative systems is followed by a description of non-

Two new Robertson

Long-Span Deck Types...

new freedom in roof design. Since its introduction two years ago, Robertson's Section 5 Long-span Q-Deck has successfully filled requirements for economical long spans in the construction of schools, supermarkets and other types of buildings. Now, two new variations are added to further increase cost-savings and add to design latitude.



cross-section of Section 5-45 and 5-30 is same as ard long-span Section 5-75. Only the vertical nsions are different.

Note drawing to left. Basic cross-section is the same—only the vertical dimensions have been changed. Underside of the decks retain the same appearance, making it practical to combine all three types for greater economy for varying load and span requirements.

Like all of Robertson's five Q-Deck types, the new Long-Span designs are weight-saving, strong, precisely made and easily erected. Lighting fixtures can be recessed, surface mounted or suspended. Any type of insulation (1" minimum) and built-up roofing can be applied.

Our experience is at your disposal ...call a Robertson man

NAME __________ TITLE __________

COMPANY __________

ADDRESS __________ CITY __________ PROV __________ conservative systems with one or several degrees of freedom. The rest of the book concerns itself with practical problems, such as the directional instability of automobiles, the instability of suspension bridges under wind, and the flutter speeds of aircraft wings. (Y. Rocard. New York, Ungar, 1957. 227p., $9.50.)

*ELEMENTS OF WATER SUPPLY AND WASTE-WATER DISPOSAL

Emphasizes the scientific principles underlying engineering applications. The first half of the book deals with the collection and distribution of water and the collection and removal of waste water, while the second half takes up the behavior of natural waters and the treatment of water and waste water. Appendices include a collection of supplementary problems and tables to simplify computations. (G. M. Fair and J. C. Geyer. New York, Wiley, 1958. 615p., $8.95.)

ENGINEERING HYDROLOGY

A concise treatment of modern hydrology, taking a primarily quantitative approach, and using runoff as its central subject. Both surface-water and ground-water runoff are considered, and their interrelation shown. Other topics are shown in relation to runoff.

The subjects covered are: precipitation and snow and snowmelt, and their analysis; subsurface water; infiltration; hydraulics of wells; stream-flow data; analysis of runoff data; net storm rain; and peak discharge and flood runoff.

Both bibliographies and problems are included in this text which is intended both for practising engineers whose main interest is not hydrology, and for students. The author is a professor of civil engineering at the University of Southern California. (S. S. Butler. Englewood Cliffs, Prentice-Hall, 1957. 356p., $7.00.)

ENGINEERING MATERIALS HANDBOOK

A detailed reference book on engineering materials for engineers, designers, students, architects and purchasing agents, with the emphasis placed on the fabricated forms of materials, their physical and mechanical properties, their adaptations, advantages, limitations, competition against each other, protection against deterioration, and the increase in their stability to withstand use and abuse.

The material was prepared by 150 specialists, and is divided into four parts, the first of which covers metals, ferrous, stainless steels, base and precious metals, speciality ones used primarily as alloys, liquid metals and paying particular attention to the uncommon metals. Also covered in this section are powder metallurgy, fusion, welding, electrical uses, dies and other tools, and coatings.

The second section deals with inorganic materials; bricks, clays, refractories, silicas, glasses, stone, concrete, etc. The organic materials are included in the next section; tars, pitches, asphalts, waxes, paints, rubbers, plastics, etc.

The final section discusses permanence and the prevention of failure; corrosion and anti-corrosives, cracking, brittle and mechanical failure, high temperature applications, etc. There is a lengthy bibliography on the sources of information on engineering materials. (Ed. by C. L. Mantell. Toronto, McGraw-Hill, 1958. Various paging, $25.80.)

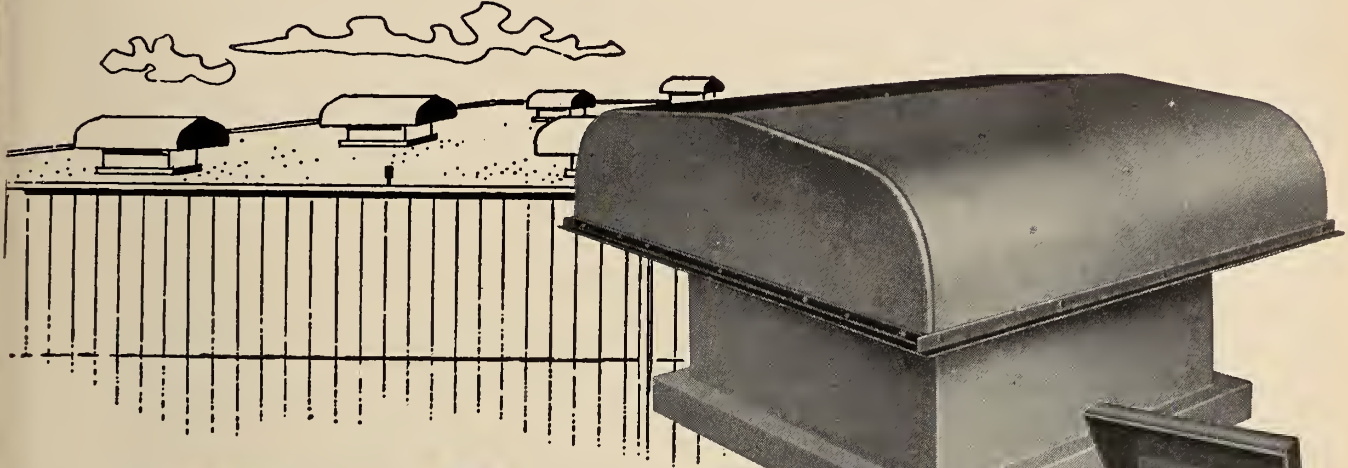
*ENGINEERING PRECISION MEASUREMENTS, 3RD ED.

This book provides a general survey of the more important methods of precision measurements employed in engineering workshops, and describes in detail some of the more widely used ones from the viewpoint of the user in the gauge room, inspection department, toolroom, and machine shop. For some cases the principles upon which the instrument is based are given, and typical examples are described. New chapters in this edition cover slip gauges, surface finish, straightness and flatness measurements, interferometive methods, and advances in automatic gauging and work sizing. (A. W. Judge. Toronto, Ryerson, 1957. 447p., $13.00.)

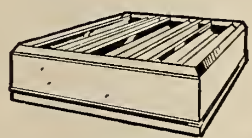
*FATIGUE OF AIRCRAFT STRUCTURES

Six papers dealing with the problems, methods of test, and latest developments in the fatigue testing of aircraft structures. The material contained is of interest to metallurgists and mechanical

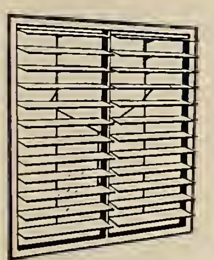
ARCHITECTS TAUGHT US A LESSON!



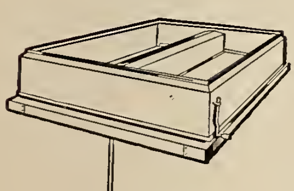
POWERED "LOW-LINE" UNIT IN OPEN POSITION



CONTOURAMIC AIRMOVER
For large scale roof ventilotion. Only 21½″ high.



SIDEWALL LOUVERS
Placed near floor level where cool oir enters.



FIRE VALVE
A large scale heat release which is weather-proof when closed.

Contemporary building and roof design means low-contour construction—and Swartwout Ventilating Equipment is meeting this trend with the new 'Low-Line' Roof Model.

All unsightly supporting stays and guys have been eliminated from 'Low-Line' ventilators. Instead, its well-proportioned hood is internally braced and anchors securely to any suitable 4″ curb by means of its integral base. Available either as a gravity unit for exhaust or powered for both intake and exhaust, 'Low-Line' is the latest word in appearance and utility.

The 'Low-Line' is specially recommended for spot ventilation. Its oversize throat—with dimensions ranging from 12″ to 60″—provides a large exhaust or intake area while the hood is hinged for easy access to damper or duct.

In addition, Eastern Steel supplies a complete line of Swartwout ventilators, including those illustrated at left. Write for further information on these ventilators and for your free copy of the booklet 'A Guide to Estimating Ventilating Requirements.'

PRESTON TORONTO MONTREAL

EASTERN STEEL ESP PRODUCTS LIMITED

engineers working with fatigue problems as well as to aircraft designers. (Philadelphia, American Society for Testing Materials, 1957. $2.75. (S.t.p. no. 203.)

*HOCHDRUCK-HEISSDAMPF

A text on high-pressure, superheated steam which reviews German, American, Russian and Czech experience in the field. Major topics covered are as follows: materials problems in a superheat installation; phenomena during the production of saturated steam; behavior of steam in the superheater; control of steam purity; the superheater, its accessories, and its production during the starting-up; effect of plant conditions on superheat temperature; and the influence of changes in temperature on the life of superheater coils. (R. Dolezal. Essen, Vulkan-Verlag, 1957. 338p., DM 48.)

*INDUSTRIEOFENBAU

A new, comprehensive treatment of the principles and construction of industrial furnaces. Although the most extensive consideration is given to metal-treating furnaces, other types are covered as well, including drying ovens, baking ovens, infrared devices, low-pressure gas burners, etc. A list of book titles is appended, and periodical literature references are included as footnotes or as chapter bibliographies. (J. H. Brunklaus. Essen, Vulkan-Verlag, 1957. 383p., DM 46.)

*JAHRBUCH DER ELEKTROWARME

The first of a proposed series of volumes summarizes current knowledge in the various fields of application of electric heating. Each of the sixteen sections has one or two long articles plus brief German abstracts of pertinent reports from the third Intl. Congress on Electric Heating, 1953. The fields covered include ferrous and nonferrous metals; wood, plastics, and other nonmetallic materials; drying and hardening processes; furnaces and auxiliary equipment; domestic and farm electric heating; power supply; special industrial uses. (Ed. H. Muller. Essen, Vulkan-Verlag, 1956. 726p., DM 64.00.)

LANDSLIDES AND ENGINEERING PRACTICE

Designed for practical use, this volume contains information for the engineer who needs to recognise, avoid, control, design for, or correct the more important types of landslide movement.

The first section of the book is entitled "Definition of the problem" and covers the economic and legal aspects of landslides, the various types of landslide, and their recognition and identification, airphoto interpretation, and field and laboratory investigations.

The second section deals with the solution of the problem, and summarizes the methods known to have been applied to the prevention and control of landslides, and the methods of making stability analyses and their use in the solution of design problems.

The book has been compiled by the members of the Committee on Landslide Investigations of the Highway Research Board, and stresses the problem in relation to highways and railroads. The information in the book is, however, applicable to landslides occurring in other situations. There are illustrations throughout of actual slides and their solution, and references for further reading are included. (Ed. by E. B. Eckel. Washington, Highway Research Board, 1958. 232p., $6.00.)

*LOGICAL DESIGN OF DIGITAL COMPUTERS

Describes methods and techniques for the design of general or special purpose computers by use of synchronous circuit components. The book discusses in detail the Veitch Diagram method of simplification of Boolean equations; the difference-equation approach to memory elements; the Huffman-Moore model of digital systems; the complete solutions to flip-flop input equations. A mathematical introduction to Boolean algebra is included. (M. Phister, Jr. New York, Wiley, 1958. 408p., $10.50.)

MANAGEMENT FOR ENGINEERS

Statistics show that eventually approximately 40 per cent of professional engineers become managers, and even those who do not themselves become managers come more and more in contact with management.

This book is an attempt to explain to engineers the workings of manage-

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Pressure Pipe Company Changes — The Pressure Pipe Company of Canada Limited announce the following executive changes: J. C. Smith, chairman of the board; P. M. Draper, president; F. E. Miller, vice-president and director.

Atlas Copco—S. H. Ekefalk and E. Ryd have been appointed deputy managing directors of Atlas Copco A.B., manufacturers of compressed air equipment.

Election to Board of Directors — The Hon. F. M. Ross, lieutenant governor of British Columbia, has been elected to the board of directors of Canada Wire and Cable Company Limited.

Bell Telephone Company — A. F. Branscombe has been appointed by the Bell Telephone Company of Canada as chief engineer of the company's toll area with headquarters in Montreal.

Senior Sales Appointment — Dominion Bridge Company Ltd., announces the promotion of K. B. Martin as engineer-in-charge plate and tank sales; he will continue to be located at eastern division headquarters in Lachine, Que.

K. B. Martin

Joy Manufacturing—D. W. M. Ross is now president of Joy Manufacturing Company (Canada) Limited, succeeding J. A. Drain, M.E.I.C., of Pittsburgh, Pa., who becomes chairman of the board of the Canadian Company.

Staff Promotions—The following promotions have been announced by the Ontario Water Resources Commission: D. S. Caverly, M.E.I.C., director of plant operations; G. M. Galimbert, director of sanitary engineering; L. Owers, JR.E.I.C., supervisor of sewage works, and K. H. Sharpe, supervisor of water works, both of the division of sanitary engineering; K. Symons, supervisor of surface waters, division of water resources.

Du Pont Plastics Division — The following appointments have been announced by the Du Pont Company of Canada (1956) Limited in connection with the formation of their plastics division: J. H. Childs, manager; J. L. Macdonald, sales manager, and F. G. Rice, market development engineer.

Canadian Westinghouse — It has been announced that Rear Admiral K. F. Adams, recently retired from the RCN, has been appointed manager, commercial development for Canadian Westinghouse Company Limited, Hamilton, Ont.

Universal Form Clamp Co. — G. W. Milligan has recently been named manager of the Universal Form Clamp Co. of Canada Ltd., located at 226 Norseman Street, Toronto.

PSC Appointment — W. A. Dymond has been made commercial manager of The Photographic Survey Corporation, Toronto.

New Branch Managers — Canadian Liquid Air Company Ltd. has announced the appointment of A. O. Raymore as manager of its Winnipeg branch, and J. A. Partridge as manager of the Edmonton branch.

D. W. M. Ross

CGE Appointment — The appointment has been announced by the Canadian General Electric Company Limited of R. J. Bridgman as sales manager, appliances, in the Toronto district office of the company's wholesale department.

F. J. Stokes Appointments — F. Y. Walters, Jr., has been appointed manager of the F. J. Stokes Company of Canada, Ltd., a subsidiary of F. J. Stokes Corporation, Philadelphia, and R. Wilson has been made a sales engineer. Headquarters of the Canadian Company are at 4198 Dundas Street West, Toronto.

Shell Oil Company — P. Gordon has been appointed by the Shell Oil Company of Canada, Limited as assistant manager of its Shellburn refinery, Vancouver; he replaces E. A. Ballman who has been named assistant superintendent of Shell's refinery at Martinez, California.

Canadian Vickers Appointment — R. R. Brooks has recently been appointed supervisor of boilers and thermal equipment sales, Canadian Vickers Limited.

Leland Electric — M. Lalonde, JR.E.I.C., B. MacRitchie and D. M. Campbell,

have been made sales engineers with Leland Electric Canada Limited. Mr. Lalonde joins the Montreal branch office and Messrs. MacRitchie and Campbell will operate in the Toronto and Southwestern Ontario areas respectively.

Norton District Representatives — The Norton Company of Canada Limited has announced the appointment of three district representatives as follows: S. Andersen, Toronto; I. H. Hall, Southwestern Ontario with headquarters in Windsor; and J. A. MacRae, Northwestern Ontario, with headquarters in Hamilton, Ontario.

Atlas Copco Expansion — Two branches of Atlas Copco Canada Ltd., Montreal Airport, Que., have moved into new and larger quarters to provide better service to customers, and more efficient operations because of expanding business. Construction of a new office, warehouse and service centre for the Toronto district branch has been completed and the branch is now located in New Toronto, Ont. This is the second move made necessary since 1951 to accommodate this growing branch. The Sudbury branch of Atlas Copco Canada Ltd., has recently opened its new office and warehouse building, which was designed by architect Cryst H. Sawchuck, of Sudbury and erected by Temiskaming Construction, of Haileybury.

News of Business and Industry

Change of Company Name — To avoid confusion and to increase their identity with the parent company, Kent-Norlantic Limited have changed their name to George Kent (Canada) Ltd., and have opened a new office at 2760 West Broadway, Vancouver 8.

Record Sales — Sales of $72,635,000 in 1957 established a new record, nine per cent over 1956, according to an announcement by Du Pont Company of Canada (1956) Limited in a preliminary review of the year's operations. Net income of $4,491,000 which is subject to audit, was equivalent to 60 cents a common share, seven cents less than the preceding year. Profits from the additional sales volume were more than offset in the second half of the year by the heavy expenses of the initial operation of new units in the diversification program. Expenditures on plant construction totalled $14,654,000 during 1957 as two large plants were completed and important expansions of existing plants were underway. Total costs were indicated to be higher than in 1956, due to increases in salary and wage rates, expenses incurred in the training of the operating and sales staffs for commercial explosives and "Orlon" acrylic fibre, and depreciation charges at relatively high rates on the new plants from the date operations commenced.

"Turnall" Pressure Pipe — Atlas Asbestos Co. Ltd. have announced that, effective May 1, 1958, "Century" asbestos-cement pressure pipe became "Turnall" asbestos-cement pressure pipe. "Turnall" pressure pipe will be manufactured to the same standards as the "Turnall" building materials and will conform to A.W.W.A. Specification C400-53T and A.S.T.M. Specifications.

New Location — Early this year, Simmonds Products of Canada Limited and their associate company, Simmonds Aerocessories of Canada Limited, conducted a transfer of their operations from Montreal to 637 Parkdale Avenue North in Hamilton, occupying the 10,000 sq. ft. building formerly operated by Grisenthwaite Construction Company.

Name Confusion — American Smelting and Refining Company have often been referred to as AS&R and, in order to avoid confusion, would like it known that their informal "name" is Asarco.

Diesel Engine Plant — A 289,000 square foot addition to the General Motors Detroit diesel engine division plant in Detroit is under construction and completion is expected next May. The new building will house all final assembly, testing, and shipping facilities for Detroit Diesel. Sales and service in Canada of engines manufactured at Detroit Diesel are handled by General Motors Diesel Limited, London, Ontario and their 45 distributor and dealer outlets, situated from coast-to-coast.

European Representation — Stadler Hurter International Ltd. announce that they will be represented in Continental Europe — with the exception of the Scandinavian countries — by the French consulting firm of Serete, 164 Rue de Rivoli, Paris. Under the new agreement Stadler Hurter will furnish process, layout and pulp and paper mill design know-how to European clients, and Serete will furnish civil and structural engineering, steam and power plant design and detailed mechanical design service for the pulp and paper industry, under the supervision of Stadler Hurter. Stadler Hurter have a similar agreement with Construcciones Industriales, S.A., Oaxaca 24, Mexico, D.F., who represent them in Mexico and Central America.

Wire Reinforcement Institute — Among new members added recently to the Wire Reinforcement Institute, trade association of welded wire fabric manufacturers, is the Steel Company of Canada, Limited. Stelco, as the Hamilton, Ontario, Company is known, is the first Canadian welded wire fabric manufacturer to join the Wire Reinforcement Institute. The Institute, which has its headquarters in Washington, D.C., founded in 1930, is a nonprofit organization for industry-wide research, education, promotion, and assistance to builders, architects, engineers, contractors, and the public.

Patent Disclosures — For the third consecutive year, engineers and scientists of the Canadian Westinghouse Company have established a new record for submitting patent disclosures. Canadian Westinghouse "Inventor Awards" program makes monetary payment for inventions to encourage engineers to put their thoughts on paper. Additional recognition is given company employees who create some particularly useful development.

Record Sales Reported — The Trane Company, manufacturing engineers of air conditioning, heating, ventilating and special heat transfer equipment, has reported record 1957 year-end figures showing total sales up 8.3 per cent and profit 8.8 per cent ahead of 1956. The company states that sales in Canada advanced by nine percent, consolidated sales increased from $74,444,000 in 1956 to $80,648,000 in 1957, and profit moved up to $6,244,000 for 1957, compared with $5,740,000 in 1956. During 1957, Trane sold 150,000 shares of common stock, providing $6,700,000 for financing expansion. The proceeds from this sale were added to the general funds of the company and are just now being used in the firm's continuing expansion program.

New Aluminum Processing Plant—Agreement has been reached to form a new company to manufacture aluminum wire and cable in Canada. The company, to be known as Phillips CBA Conductors Ltd., is a joint enterprise of Phillips Electrical Company Limited, wire and cable manufacturers, and Canadian British Aluminium Company Limited, who have a large refinery at Baie Comeau, Quebec. This is said to combine an assured source of raw materials with an established manufacturing and marketing organization. With location planned for Brockville, the new venture will have access to both railways, the Seaway, and the main highway to the major markets of Canada. When incorporated, Phillips CBA Conductors Ltd., will be managed by Phillips Electrical Co. under a management contract, and the Phillips organization will act as a marketing agency for the company's products. It is planned to manufacture aluminum rod, wire and cable, including ACSR for power transmission.

Agency for Electronic Lines — A. C. Wickman Limited, of Toronto, has announced that they have assumed the agency of Edin Company Inc., of Worcester, Massachusetts. This new line consists of oscillographs and amplifiers for industry and the medical profession.

Expansion of Equipment — Monsanto Oakville Limited, producer of commercial and industrial vinyls, has just announced the completion of a major expansion of modern processing equipment to meet the growing demand for high quality vinyl products, and the increased use by Canadian manufacturers. The new production facilities will be utilized to increase supplies of vinyl film and Monsanto's range of fabric-backed vinyls.

New Companies — Engelhard Industries, Inc., a U.S. industrial corporation, came into existence in January, 1958, as a result of a consolidation of nine U.S. companies.

Announced also was the simultaneous establishment of Engelhard Industries of Canada, Ltd., with headquarters in Toronto and a sales office in Montreal. This company will be a successor to Baker Platinum of Canada, Ltd., an affiliate of one of the companies involved in the merger.

New Address — Proctor and Redfern announce the new location of their offices at the Proctor and Redfern Building, 75 Eglinton Avenue East, Toronto 12, Ont. Tele. No. HU. 7-1171.

New Equipment and Developments

Electrorefining of Nickel — Research scientists and engineers of The International Nickel Company of Canada, Limited, have developed a new process for the electrorefining of nickel, according to a recent Inco announcement. The new method, developed after seven years of continuous study, is said to be a major achievement in chemical metallurgy. A main feature of the process is the direct electrolysis of nickel matte, an artificial sulphide. This contrasts with the usual electrorefining methods, including those employed in the nickel industry, in which a metal anode is used. The process, for which Canadian and United States patents are pending, is in commercial operation in a section of the company's Port Colborne, Ont., nickel refinery.

Evaporation Plant—A new design of evaporators for producing high-purity distilled water from sea water at a rate of hundreds of tons a day has been achieved by Richardsons, Westgarth and Company, Ltd., of Wallsend-on-Tyne, England. The whole evaporator may be arranged in a single vessel. This provides considerable saving in space and cost and dispenses with much external pipework. Operating methods have been developed so that deposits on the heat transfer surfaces are negligible, the firm states. In test runs it was shown that these deposits appeared only after prolonged running of the plant and even then were only in the form of a thin layer of powder considerably less than one thousandth of an inch (0.025 millimetre) thick.

Open Dropout Cutouts — Heavy duty cutouts with twice the interrupting capacity of the existing heavy duty units are now available from Canadian General Electric Company Limited. A new design of the fuse link holder enables the 7.8 kv. cutouts to be boosted from 5,000 to 10,000 amps., and the 15 kv. line from 4,000 to 8,000 amps. rated interrupting capacity at 60 cycles. The fuse holder, made of tough fiberglass reinforced polyester resin, has an expandable cap action. Under low fault current gases are expelled downward, and under high fault currents the gases are vented both down and up. The new fuse holders are interchangeable with previous models and can be used in many existing G-E open cutout frames.

Compact Tools — Two new, compact, portable tools, that quickly roll grooves into lightweight pipe and tubing, without removing any metal, have been developed by the Victaulic Company of Canada, Toronto. Designated "Vic-Easy" series 100 and series 200, these portable tools for use on-the-job or in-the-shop are adjustable from 1¼ in. through 12 in. diameters. The tools make it easy for anyone to groove pipe ends for leak-tight jointing of water, oil, air or other lines with Victaulic snap-joint standard or lightweight couplings, and Victaulic full-flow fittings.

Expansion Joint — B. F. Goodrich Canada Limited have announced the development of a new expansion joint designed to eliminate the rhythmic road shock which motorists often encounter on many Canadian highways. The joint section is made of man-made rubber specially compounded to absorb movement of the highway in cold or warm weather. This is important due to the variations in weather extremes encountered in Canadian seasons. Originally designed for super-highways, the new rubber expansion joint is also being designed for use on bridges and bridge approaches, as well as for highways and even airport runways.

Fluorescent Lamps — The introduction of a new line of fluorescent lamps with an increased light output has been announced by the Canadian Westinghouse Company Limited. Called the Super-Hi fluorescent lamp the new units use a mixed gas principle pioneered by Westinghouse which permits long cathode life and makes the high wattage practical in the conventional T12 bulb.

Polyethylene Film — A cheaper way has been evolved for protecting heavy equipment during rail shipment in gondola cars by using disposable covering of Visqueen polyethylene film, according to Visking Company, division of Union Carbide Canada Limited. No crane is needed and two men can handle the light covering, battening it in place with pattern strips of salvage wood. Visqueen film is said to be so inexpensive that even as a disposable covering it more than pays for itself because it eliminates having the canvas returned by the customer for credit. Visqueen film is produced by Visking Company, division of Union Carbide Canada Limited.

New Rock Drill — Atlas Copco Canada Ltd. has announced the introduction of a new rock drill for drilling holes up to 18 feet. The new machine, numbered BBD-50W and known as the Tiger, has many new features of importance to the mining and construction industry. Of particular significance is the fact that most of the parts on the Tiger are interchangeable with those of the BBD-46 stoper. This factor is of economic importance to operators since it reduces the requirements for spare parts in inventories.

Silicone Oil — Union Carbide L-45 silicone oil, electrical grade, is a clear dimethyl silicone polymer. It is said to possess all the advantages normally associated with silicone oil, such as excellent thermal and oxidative stability, high flash point, and small changes in viscosity with changes in temperature. The electrical grade liquids are specially dried, packaged, and control-tested to insure maximum dielectric strength and volume resistivity.

Delpark Filter Distributors — Joy Manufacturing Company (Canada) Limited becomes the exclusive distributor for the Delpark filter to the mining industry in Canada, and also has the exclusive franchise to sell the filter to any other industry when sold as a component part of the Joy Microdyne dust collector. The Delpark filter is manufactured by Industrial Filtration Company. It provides a dependable source of clear water for locations having only a dirty water supply. Dirt is removed in the form of a damp, clay-like slurry. At the special request of Joy, the Delpark unit was modified specifically for mine use and the handling of low-gravity solids.

Publications

Asbestos—On the occasion of its 100th anniversary, Canadian Johns-Manville Co. Limited has published a 32-page illustrated booklet entitled "Asbestos, the Magic Mineral'.

Wood Tank Data Book—An up-to-date reference source on wood tanks, the "Wood Tank Reference and Data Handbook", has been published by the National Wood Tank Institute, Chicago. The volume includes such subjects as: the uses of wood tanks; capacities; physical and chemical properties of wood and their relation to expected service of wood tanks, etc. This manual projects the use of wood to cover the most severe conditions found in chemical processing by the use of selected polymer linings.

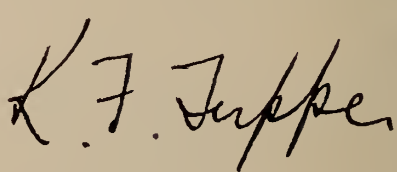
Message from the President

THE ADVENT of earth satellites, electronic computers, nuclear power plants and nuclear weapons has focussed the public's attention on the works of the scientist and the engineer. There has been a clamour for the training of more scientists and engineers.

If engineering is to become and continue a profession I think we engineers must be willing to take a larger share of responsibility for the social consequences of our work. It seems there is a real danger that instead of becoming leading citizens as they well might be, engineers may tend to become technological mercenaries. I fear that too often the men who have the training and talent to design and develop an unlimited variety of new devices can be hired by any employer who offers attractive working conditions, good pay, and a task with a technical challenge; that these men do not regard it as any of their business to enquire into the impact of their work on the society in which they live. "A technologist is a man who knows everything there is to know about his job except its place in the scheme of things".

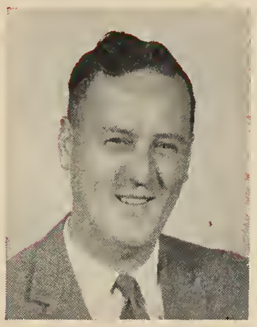
Of course we cannot all enter political life. Our society has a place for many honest men, those who bake bread and cut hair as well as those who design or build bridges. But we can take an interest in public affairs particularly those which relate to our work, the use of expendable resources in particular.

During the next twelve months I hope I shall be able to visit most of our fifty branches, and meet a great many of the Institute members. I am deeply appreciative of the privilege which you have conferred upon me in letting me serve you as your President. I undertake to bring to this task all the energy I can muster and all the wisdom I may possess.



K. F. TUPPER, M.E.I.C.
President

MEET THE AUTHORS



J. F. Whiting, Aluminium Laboratories Limited, Kingston, Ont. *(The Corrosion Behaviour of Aluminum in the Construction Industry.)* Mr. Whiting graduated from Queen's University, Kingston, Ont. in 1941 (B.Sc., metallurgical engineering). From 1941 to 1948 he was a member of the technical staff of the Aluminum Company of Canada, Limited, Kingston Works, and in 1948 was transfered to the Publications Division of Aluminium Laboratories Limited, Kingston. He is a past president of the Eastern Ontario Chapter of the Society of Technical Writers and Editors, and a member of the National Warm Air Heating and Air Conditioning Association of Canada.

H. P. Godard, Aluminium Laboratories Limited, Kingston, Ont. *(The Corrosion Behaviour of Aluminum in the Construction Industry.)* Dr. Godard holds a master's degree in chemical engineering from the University of British Columbia, and a Ph.D. in industrial and cellulose chemistry from McGill University. An industrial chemist, he worked in B.C., Ontario and Quebec before joining Aluminium Laboratories Limited in 1945. He is a member of the N.R.C. Associate Committee on Corrosion Research and Prevention, has served on the Board of Directors of the Chemical Institute of Canada and is vice-president elect of the National Association of Corrosion Engineers.

J. C. Langford, Production Manager, Canadian Chemical Company Limited, Edmonton, Alta. *(Design and Operation of an Effluent Disposal System.)* A graduate of the University of Toronto (B.A.Sc. chemical engineering, 1938), Mr. Langford obtained an M.Sc., chemical engineering, from the University of Michigan in 1939. From 1939 until 1946 he was associated with C-I-L and Defence Industries Limited in the Province of Quebec; he spent a year in Montreal as a consulting engineer before joining the Dominion Tar and Chemical Co. Ltd., development department, in 1947 where he held several senior positions. He joined his present company in 1955.

J. P. Hague, Senior Location Engineer, Department of Highways, Province of British Columbia. *(Selection of the Trans-Canada Highway Route Through the Selkirk Mountains.)* Mr. Hague has been associated with the engineering industry since 1923; he was resident engineer on railway construction with the Canadian Pacific Railway Company for eight years, and spent seven years with the Manitoba Department of Public Works where he was resident engineer on highway construction. He is a member of the Association of Professional Engineers, and served in the Royal Canadian Engineers from 1940 to 1947, lieutenant to major. Mr. Hague joined the B.C. Department of Highways in 1947, and is now in charge of highway location and design.

W. H. Hoyle, Radio and Electrical Engineering Division, National Research Council, Ottawa, Ont. *(Marginal Punched Cards for a Reference File in the Field of Electronics.)* An electrical engineering graduate of the University of Alberta (B.Sc.) and McGill University (M.Eng.), Mr. Hoyle served in the Royal Canadian Navy during World War II. On demobilization he joined the National Research Council and worked on transmission line fault location, but was transferred to military work on the outbreak of the Korean War; he is now engaged mostly on military work. Mr. Hoyle takes a deep interest in the work of the Canadian Standards Association, particularly in their electrical safety codes; he is a member of the A.I.E.E.

C. Jaeger, Consulting Engineer, The English Electric Company Limited, England. *(Economics of Pumped Storage.)* Dr. Jaeger graduated from the Federal Institute of Technology, Zurich, Switzerland, in 1923, and subsequently became senior lecturer in civil engineering there; simultaneously, he was engaged on scientific research at the Federal Hydraulic Research Station, Zurich. He became a lecturer on engineering fluid mechanics at the Federal Institute of Technology, Zurich, in 1943, and since 1946 has been consultant to The English Electric Company Limited, and also special lecturer in hydro power at the Imperial College, London, England. Dr. Jaeger is the author of numerous publications on engineering fluid mechanics, arch dams, underground power stations, and economics of power production.

COVER PICTURE

The 72nd Annual General Meeting of The Engineering Institute of Canada is reported on pages 85 to 87. The cover picture shows (l. to r.) C. M. Anson, M.E.I.C., the retiring President of the Institute; L. Austin Wright, Hon. M.E.I.C., whose retirement as General Secretary was announced at the meeting; and K. F. Tupper, M.E.I.C., the newly-elected President of the Institute.

The Corrosion Behaviour of Aluminum in the Construction Industry

J. F. Whiting and H. P. Godard
Aluminium Laboratories Limited, Kingston, Ontario

Paper received 11 April 1957. Originally read at a meeting of the National Association of Corrosion Engineers, Detroit, Mich., 1956.

The general corrosion behaviour of aluminum alloys used in the construction industry and the influence of environmental factors on their performance are discussed. It is shown that aluminum is a preferred metal for many applications, is suitable for most applications, and is unsuitable for a few applications. With good design, correct choice of alloys, and normal care during installation, aluminum will give excellent service for a wide range of applications in the construction industry.

ALUMINUM AND its alloys have good corrosion resistance and are suitable for most architectural and structural uses in the construction industry. This is borne out by the fact that about one-third of all aluminum fabricated forms produced in Canada and the United States are used in building and the tonnage is increasing rapidly. Industrial and agricultural roofing and siding are well established as one of the main uses of aluminum. Aluminum curtain-walls, windows, store fronts, doors, railings, trim and hardware are also very important uses of this light metal. Additional large quantities of aluminum are used for finned radiators, radiant heating and cooling panels, ductwork, flashings and general sheet metal work. Bus bar, electrical conduit, scaffolding and ladders are other items fabricated in aluminum.

Aluminum has many desirable properties, one or more of which may warrant its use over competitive construction materials. These important properties are:

Good durability; colourless corrosion products; light weight; pleasing appearance; ease of fabrication, transportation, and erection; good electrical conductivity; good heat-reflecting qualities; availability in many forms—plate, sheet, extrusions, tubing, wire, bus bar, foil, castings and forgings; and reasonable cost.

While all the above properties are important and much could be said about them, this paper will deal mainly with the corrosion resistance of aluminum in the construction industry.

Definitions

Corrosion is defined as the destruction of a metal by reaction with its environment. To the layman corrosion is simply the deterioration of the metal, but to the specialist it may occur in several forms or types. These types are defined briefly here to avoid confusion when they are mentioned later in the text.

General Corrosion — General corrosion is uniform attack that leads to the gradual thinning of a piece of metal with time. This is the type of corrosion met with most frequently in the construction industry and, in the case of steel, due allowance is made for it in design. No such allowance is usually necessary for aluminum.

Galvanic Corrosion — Galvanic corrosion is that type of action produced when one metal is in contact with another in the presence of an electrolyte. Galvanic action usually results in the accelerated corrosion of one metal of the pair and the protection of the other. An example of a galvanic couple is the zinc-steel combination of galvanized steel. The zinc coating is placed there deliberately to protect the steel from rusting.

Crevice Corrosion — Crevice corrosion is encountered most commonly when water is trapped in the crevice between the faying surfaces of a joint. Pitting develops just inside the crevice where the metal is in contact with water depleted of oxygen. An anodic condition exists here relative to the mouth of the crevice where the water is saturated with oxygen.

Poultice Action — Poultice action of wet absorbent materials such as paper, cardboard, cork, felt, asbestos, etc., over prolonged periods may lead to corrosion by the oxygen concentration cell mechanism. Poultice action is simply a special type of crevice corrosion. It may be aggravated by corrosive agents leached from the absorbent materials.

Pitting Corrosion — Pitting corrosion occurs on a film-protected metal when the film is almost, but not completely, protective. It may cause perforation of a roof or pipe although only a very small amount of a metal is corroded.

Deposition Corrosion — Deposition corrosion is a special case of galvanic corrosion and results from the deposition of particles of a more noble metal on the surface of another metal. This may be caused by settling or be the result of electrochemical action. The particles set up local cells and lead to pitting of the metal surface.

Intergranular Corrosion — Intergranular corrosion is a form of localized sub-surface attack in which a preferential path of small dimensions is corroded out along the grain boundaries of the metal. This type of corrosion is seldom encountered in the construction industry.

Corrosion Rate Curves and Their Importance

There is no uniform criterion or "yardstick" to measure corrosion resistance, because the seriousness of a given amount of corrosion depends on the use to which a metal is put. A corrosion rate that can be tolerated in one application may be completely unacceptable for another. The most common criteria for the evaluation of corrosion resistance are:

1. Time to perforation
2. Loss of strength
3. Impairment of appearance
4. Contamination of a product

For roofing, flashings and hot water tanks, resistance to perforation is most important. On the other hand a structural member can perforate without serious loss of strength and, in this case, resistance to mechanical failure is most important. With metal curtain-walls, windows, store fronts and other architectural items, resistance to impairment of appearance is the important and desirable property. Contamination of a product by metal pickup is not usually a problem in the construction industry although it is often critical in chemical and food processing equipment.

It is important to choose the right criterion for evaluating corrosion. If the criterion is made too restrictive, a metal that is suitable may be excluded. The layman accepts the fact that steel rusts and that copper roofs turn green and rarely gives the matter a second thought. However, he is apt to view with alarm the natural greying which accompanies the weathering of aluminum, even though it is of no practical significance to durability.

The rate of corrosion of a metal is rarely constant and may take one of the three general forms shown in Fig. 4. Of the three types the decreasing rate curve is the most common and is typical for metals exposed to the atmosphere.

Figure 5 shows the corrosion rate curves for three aluminum alloys at several atmospheric exposure stations,[1] From Fig. 5 it can be seen that if the first initial rate of attack can be tolerated, the long term rate is usually low enough to be acceptable for most purposes. Also, it can be seen that by doubling the thickness of the material, its life will be extended much more than twice.

The surface to volume ratio of a metal object will have a marked influence on its corrosion life. If the ratio is high the part will deteriorate more rapidly than if the ratio is low. For example, the rate of deterioration of fine wires increases as the diameter of the wire is reduced; this is because the loss of a given thickness of metal is a larger percentage of the original for thin than for thick wires. A 1-inch diameter aluminum lightning rod on the mouth of an industrial smoke stack lost 12 per cent of its cross section due to corrosion in 28 years, yet remained an effective air terminal. On the other hand the stranded aluminum grounding cable (wires 0.140 inch diameter) corroded away completely at the mouth of the stack. An aluminum insect screen (wire diameter 0.012 inch) on a seashore cottage may deteriorate in a period that would not measurably affect an aluminum roof on the same cottage.

The heat capacity of a metal part can affect the corrosion rate. This may be due to the thickness of the metal itself or to the heat capacity of other objects to which the metal is affixed. This effect has been demonstrated by exposing two panels of aluminum sheet in a horizontal position in the atmosphere, one with a large block of aluminum on top, and one exposed by itself. After about a year, pitting was more severe on the under surface of the sheet beneath the block than on the single sheet even though the surfaces were side by side. The mass effect of the large block of aluminum prevented the panel beneath it from coming up to atmospheric temperature as quickly as the panel exposed by itself and thus, moisture condensed on its under surface remained there for a longer period of time. It has been demonstrated also that thick metal specimens corrode in the atmosphere at a slightly higher rate than thin ones.

Function of the Oxide Film on Aluminum

Aluminum has excellent resistance to weathering and chemical attack owing to a thin oxide film which covers it at all times. This film forms naturally and instantaneously whenever aluminum is exposed to the air and it slowly increases in thickness as the exposure time increases. If corrosion occurs it is the result of circumstances which damage the oxide film and prevent it from reforming. The ability of the oxide film to protect the aluminum depends greatly on the environment and conditions of service. Therefore, a knowledge

Fig. 1. The Laurentien Hotel, Montreal, Que., erected in 1946/47, was the first multi-story building on this continent to be faced with aluminum.

of the behaviour of aluminum in natural environments and in contact with the common construction materials is necessary to promote proper design and methods of installation.

Behaviour of Aluminum in Natural Environments

Atmosphere

In rural atmospheres the corrosion of aluminum is barely detectable (less than 0.003 mpy). In industrial and marine atmospheres aluminum tends to corrode somewhat more rapidly; the rate stays between 1-4 mpy for the first six months to two years, depending on locality and alloy, and then slows markedly to rates in the order of 0.1 mpy. The Church of St. James in Rome was covered with aluminum in 1897 and an inspection in 1949 showed the roof to be in excellent condition with a corrosion rate of approximately 0.06 mpy. The corrosion rate on a fifty-two year old aluminum cornice on a building in down-town Montreal which has a heavy industrial atmosphere, was 0.12 mpy. A recent publication by the ASTM[2] gives the average corrosion rate and maximum depth of attack for several aluminum alloys exposed at various locations in the United States (see Table I).

Fig. 2. Aluminum curtain-wall construction used on the Commonwealth Building, Ottawa, Ont. (Built in 1955.)

Behaviour of Alloys — Aluminum of very high or super purity (99.99% minimum aluminum) has exceptionally good corrosion resistance and is used for special purposes. Commercially pure aluminum varies in purity from Alcan 1S (99.5% minimum aluminum) to 99.8% and, in general, the higher the purity the better the corrosion resistance. However, for most uses there is little difference in performance and they may all be rated as excellent. Alcan 2S (US 1100) and 3S (US 3003) have very good corrosion resistance although Alcan 3S alloy is somewhat superior to Alcan 2S in resistance to pitting and has higher strength. The aluminum-magnesium alloys, such as Alcan 57S (US 5052) B54S (US 5154) and A56S (US 5056), have excellent resistance to attack by marine environments and in other environments are in a class with Alcan 1S. If the application involves prolonged exposure to temperature above 60°C. (140°F.), the corrosion resistance of alloys containing more than 2.5% magnesium may be adversely affected and the aluminum supplier should be consulted. Alcan 50S (US 6063) has good resistance to weathering and chemical attack and is rated with Alcan 3S. Alcan 65S (US 6061) is a general-purpose, medium-strength alloy that weathers well and has good corrosion resistance, although its surface appearance may deteriorate more rapidly than Alcan 50S in some severe industrial environments. Alcan 17S (US 2017), 24S (US 2024), 26S (US 2014) and 75S (US 7075) alloys have somewhat lower corrosion resistance and are not used in a corrosive environment without a protective coating such as Alclad or paint or both. Following World War II several aluminum producers in various parts of the world marketed a general purpose corrugated roofing sheet made from scrap aircraft alloys. The composition of this sheet varied widely but usually it contained several per cent copper. It was clad with pure aluminum to give improved corrosion resistance but owing to improper fabrication and heat treatment the copper diffused into the cladding, and early failure was frequent in marine and industrial environments. Failure was by intergranular corrosion with exfoliation at the edges of the holes. It is unfortunate that this material was used since aluminum has unjustifiably been given a bad name in the countries where trouble occurred.

TABLE I—Corrosion of Aluminum Alloys Exposed About 20 Years to Different Atmospheres

Location	Type of Atmosphere	*2S alloy (1100—H14)* Av. penetration based on loss of weight mpy.	Max. measured depths of attack mils	*3S alloy (3003—H14)* Av. penetration based on loss of weight mpy.	Max. measured depths of attack mils
Phoenix, Ariz.	Rural	0.003	0.7	0.0005	0.4
State College, Pa.	Rural	0.003	3.5	0.003	2.2
New York, N.Y.	Industrial	0.029	8.4	0.037	6.4
Altoona, Pa.	Industrial		11.0		7.5
Key West, Fla.	Marine		4.9		4.6
Sandy Hook, N.I.	Marine	0.011	9.1	0.014	3.3
LaJolla, Calif.	Severe Marine	0.025	14.0	0.026	10.2

Corrosion of casting alloys is usually less of a problem than with wrought alloys since, in general, the cross section is thicker, and more surface corrosion can be tolerated. The aluminum-magnesium alloys, such as Alcan A320 (US 214), 340 (US best corrosion resistance particularly in marine environments. The aluminum-silicon alloys, such as Alcan 123 (US 43), 135 (US 356) and 160 (US 13), have very good resistance to weathering and chemical attack and are used widel yin aggressive locations. The aluminum-copper alloys, such as Alcan 125 (US 355), 225 (US 195) and 250 (US 122) have somewhat lower corrosion resistance than the above alloys and are not used in corrosive locations without protection.

The aluminum alloys used most widely in the construction industry are Alcan 3S, 50S and 65S for wrought products and Alcan 123, 135, and A320 for cast products. From the discussion above it can be seen that all these alloys have excellent resistance to weathering even in severe environments.

Water

Water, containing air or oxygen, is responsible for most of the corrosion of metals in service. If the air or oxygen are removed corrosion will cease. On the other hand, water may decrease the corrosion rate. For example, it is well known that aluminum exposed to an aggressive atmosphere corrodes more slowly if rained on frequently, because the water dissolves and washes away corrosive residues such as soot or salts.

Pure rain water is not corrosive toward aluminum but it may become so if contaminated with traces of impurities such as soot, alkalis, acids, and salts of copper and iron. Water running off a copper roof on to aluminum may deposit copper salts on the aluminum which may eventually lead to pitting. Water contaminated by extracts from mortar and concrete may stain aluminum and under severe conditions corrode it, though at a slow rate.

Only limited information is available on the corrosion of aluminum in natural waters. Papers by Sawyer and Brown, ([3]) as well as Porter and Hadden, ([4]) contain valuable information on this subject. If corrosion does occur it is in the form of pitting.

In 1948, a 50,000 gallon elevated water storage tank was erected at the Shawinigan Falls Works of the Aluminum Company of Canada, Limited. It is an all welded tank made from 3S (US 3003) plate: the floor plates are ½ inch thick, wall

Fig. 3. Extruded aluminum rail at the new Woodbine race track, Toronto, Ont. Installed in 1956.

plates ¼ inch thick and the roof plates 3/16 inch thick. Inspection in the fall of 1956 revealed that pitting of the wall and floor plates had occurred to an average depth of 1/32 inch and a maximum depth of 1/16 inch. This pitting represents about 20 per cent of the thickness of the wall plates and should not affect appreciably the service life of the tank. The water stored in this tank has an approximate total solids contents of 47 ppm and the pH of 5.5 to 7.0

Another use of aluminum for handling waters that has been very successful is portable-pipe irrigation systems. Despite the very thin wall (about 0.050 inch), few pitting troubles have been reported. This is attributed to two facts: (1) when full, the water is moving; and (2) during moving of the system, the interior wall dries.

Still another use of aluminum that promises to be successful is for domestic hot water tanks. In very aggressive waters corrosion may be encountered, but these locations are also corrosive to other metals. In this case, the reduction in pitting rate with temperature is probably a factor; experience indicates that the best performance is obtained when water is hot (in the range 150-190°F.)

It is not possible, as yet, to predict the behaviour of aluminum with certainty from a conventional table of water composition; a field trial must be made (which can be completed within a year). However, some general conclusions can be drawn from experience thus far. Very soft waters, such as those at Arvida, Quebec (total solids 45 ppm and pH 8.4) and Ottawa, Ontario (total solids 75 ppm and pH 7.6), are least likely to corrode aluminum and its use for water piping in these locations is feasible. A recent inspection of aluminum piping in some government financed houses in Ottawa after nine years showed them to be completely free of corrosion. Fairly hard water such as that at Kingston, Ontario (total solids 185 ppm and pH 7.5) and hard water such as that at London, Ontario (total solids 335 ppm and pH 7.9) tend to pit aluminum, and its use for water piping in these locations would not be feasible. Traces of copper will cause pitting in either hard or soft waters. In general, high-solids soft alkaline well waters, such as are found in Central Alberta, tend to be corrosive to aluminum.

Usually movement of a corrosive liquid accelerates the rate of corrosion. However, when aluminum pits in an aggressive water, movement will slow down the amount and rate of pitting and may even prevent it entirely. At very high velocities (about 20 fps), which may cause turbulence at bends or fittings, localized corrosion of aluminum may develop. The presence of solids in the moving liquid may accelerate corrosion by eroding away the protective oxide film. Stagnant pools of water should be avoided by proper design.

Seawater and Marine Atmospheres

Aluminum is being used on an ever increasing scale for ship-building and for buildings in coastal areas where experience has shown it to have good durability in comparison with other metals. Case histories ([5]) of aluminum windows installed in coastal areas prior to 1940 prove that aluminum has good resistance to corrosion in this aggressive environment. A corrosion rate of about 0.4 mpy or one-tenth the rate for steel was found for Alcan 57S (US 5052) immersed in the ocean at Harbour Island, North Carolina. A few years ago, the author's company exposed foot square plates of quarter-inch thick mild steel and aluminum alloy (Alcan 65S-T6: US 6061-T6) on a rack facing the open Pacific Ocean near Port Alberni, B.C., which is about half way up Vancouver Island. Two years later the plates were examined after the removal of corrosion products and it was found that the steel plate had lost 940 grams (about 20 per cent of its thickness) while the aluminum plate had lost only 1 gram. Allowing for the difference in density the penetration ratio was about 300 to 1.

Soils

Little has been published on the corrosion behaviour of aluminum in various soils, but test programs are now underway which should provide considerably more information in the next few years. In general, the corrosiveness of soils to aluminum varies greatly from one type to another with moisture content being an important factor; poorly drained wet soils are generally more corrosive. If corrosion does occur it usually takes the form of pitting or etched patches with small weight loss, so that the rate of penetration is the most important criterion.

In the US Bureau of Standards soil corrosion program, (6) specimens of 2S, 3S, and Al-4.1 per cent Cu alloy were buried in five soils which are listed in decreasing order of corrosivity:

	pH
muck	4.2
sandy loam	9.5
Susquehanna clay	4.7
alkaline soil	7.4
tidal marsh	3.1

After ten years the Al-Cu alloy had completely disintegrated in the first two soils and had perforated in the other three. The other two alloys had pitted severely in all but the tidal marsh, where corrosion was slight (maximum penetration 13 mils).

In an English test program,[7] commercially pure aluminum sheet and tubing were buried for five years in five soils which are listed in order of corrosivity:

(1) Cinders. (2) Salt marsh. (3) Keuper marl. (4) London clay. (5) Moist neutral clay. These soils were all slightly alkaline in the pH range 7-8 and produced severe pitting except for the neutral clay in which aluminum was virtually unaffected.

Several short buried aluminum pipe lines carrying oil and gas are now in service in the United States with uncoated test sections. One test shows that a Louisiana salt marsh is relatively non-corrosive to aluminum. (8)

In a small test program we have found Al-Mg alloys such as 57S (US 5052) to be the most resistant to soil corrosion in several locations.

Underground in Mines

Aluminum equipment is used extensively in mining for such purposes as skips, cages, hopper cars, pit props, and tools. Performance varies with the nature of the ore body which influences the composition of the mine water. Aluminum is giving good service in the gold mines of Northern Ontario since 1931, (9) and in South Africa. It has been used extensively in English, German and Canadian coal mines as well as Canadian asbestos mines.

Behaviour of Aluminum in Contact with Building Materials

Wood Sheathing and Building Board

Frequently, aluminum roofs and flashings are laid over wood. The lumber should be of good quality, and well-seasoned. Green lumber should not be used. To prevent mechanical damage to aluminum, the wood sheathing should be laid carefully and firmly attached with all nail heads driven home.

Kiln-dried lumber, impregnated against decay, makes ideal sheathing where the cost is justified. It is recommended for cant strips, coping blocks, and facia boards to be covered with aluminum. Creosote and pentachlorophenol preservatives are satisfactory as they are non-corrosive to aluminum. Other preservatives may be used but assurance should be obtained from the manufacturer that they are not harmful to aluminum. Aluminum paint is an excellent primer for wood as it reduces the tendency for moisture absorption and eventual rot.

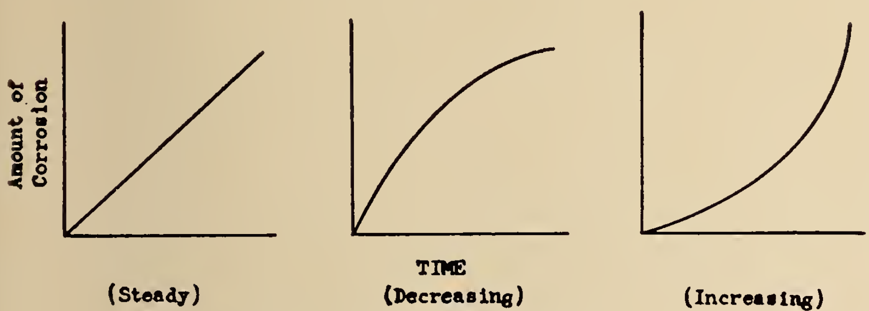

Fig. 4. Typical corrosion rate curves.

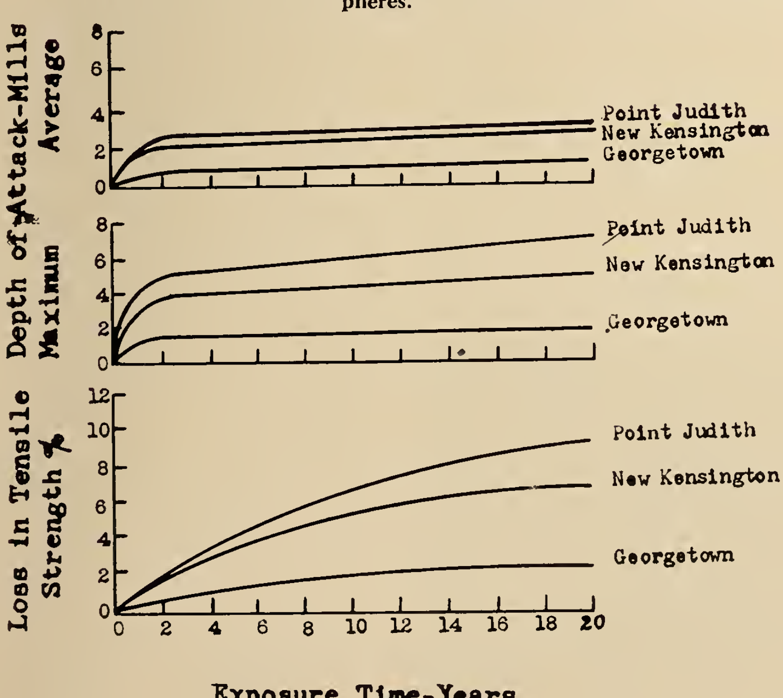
Fig. 5. Average rate of weathering of wrought aluminum alloys in various atmospheres.



All wood surfaces to be covered with aluminum should first be covered with an underlay of asphalt-saturated and coated building paper or felt. If the wood has been impregnated or painted, a satisfactory alternative is to back-paint the aluminum with bituminous paint.

Building board also provides a good surface upon which to place aluminum. In dry locations where condensation is not likely to occur, any type of building board should be satisfactory. Under moist conditions or where condensation may occur asphalt-impregnated building board is recommended. When impregnated building board is used, the aluminum should be back-painted before installation. When other types of building board are used under moist conditions, they should be covered with an underlay of asphalt-saturated and coated building paper or felt, before the aluminum is applied.

Fig. 6. Aluminum roof on the church of St. James, Rome, Italy, installed in 1897.

Fig. 7. Aluminum cornice installed in 1896 on the Canada Life building, Montreal, Que.

Concrete, Masonry, and Other Alkaline Building Materials

Concrete and mortar materials, such as Portland cement and lime, are alkaline and under some conditions may affect aluminum in contact with them. Experiments ([10]) and experience indicate that the action of concrete and mortar on aluminum is not rapid and if the concrete or mortar dries and stays dry the action comes to an end quickly without damage to the aluminum other than some mild etching. However, under wet or intermittently wet and dry conditions the rate of attack is higher and the aluminum should be protected by an underlay of asphalt-saturated and coated building paper or felt or by back-painting it with bituminous paint. The bituminous paint should be of the cut-back type.

Where aluminum is to be caulked into slots or reglets in masonry, brickwork or concrete, the slot or reglet should be cleaned out thoroughly and filled with caulking compound and not mortar or plaster. In effect, the aluminum should be "floated" in the caulking compound.

A few years ago a hospital was erected in which aluminum conduit ([11]) was embedded in reinforced concrete floors. The concrete was poured in the winter time and contained a fairly high percentage of calcium chloride. A few years later it was found that some of the aluminum conduit was badly corroded. An extensive laboratory investigation showed that aluminum embedded in concrete will be corroded by galvanic action only if three conditions are all met.

(1) Reinforcing steel must be present.

(2) There must be electrical contact between the aluminum and steel

(3) Calcium chloride must be present.

In the laboratory tests it was possible to duplicate exactly the type of corrosion found in the hospital. In the absence of calcium chloride in the concrete there is nothing to fear from aluminum-steel couples.

Pure gypsum plaster has little or no effect on aluminum. Stone, brick, stucco, terra cotta, etc., are often encountered in flashing work and these should be treated in a similar manner to concrete.

Several months ago we were asked to investigate a corroded aluminum coping on a large office building in Hamilton, Ontario. Numerous holes had appeared in the aluminum after about two years' service. These are illustrated in Fig. 11. Upon investigation it was found that the aluminum flashing had been installed in direct contact with the structural clay tile of the parapet wall. Figure 12 shows the inside surface of a flashing sheet and it can be seen that corrosion occurred mainly where the aluminum was in contact with the ribs of the clay tile or the mortar joint. It is well known that moisture in a crevice between mating aluminum surfaces or between aluminum and other building materials can cause corrosion of aluminum. The alkaline materials leached from the mortar may have contributed somewhat to the corrosion but were not the main cause of trouble. Back-painting of the aluminum sheet or the covering of the parapet with asphalt-saturated and coated building paper would have prevented the trouble. It was interesting to note that where the aluminum sheet was in contact with the wooden cap on top of the coping, no trouble was encountered.

Where aluminum in its "natural finish" is to be installed adjacent to concrete, masonry, or plaster work, as in the case of ornamental sheet-metal work, windows, spandrels, mullions, panelling, ducts, etc., it is wise to prevent stains resulting from careless splashes of mortar or plaster by giving the aluminum a thin coat of alkali-resistant lacquer. The methacrylate type is made by several paint firms and gives good results. If the film is sufficiently thin (i.e. 1 part lacquer to 3 parts thinner) it will gradually wear away without disfigurement. There are also several "peel off" types of coatings available, but care should be taken not to leave these on too long, since they sometimes become hard and difficult to remove.

Steel, Copper, and Other Metals

Aluminum may be used in contact with steel, copper, and other metals but with some combinations and under some conditions, galvanic corrosion may occur. An understanding of galvanic corrosion and its prevention is desirable and relatively simple.

Galvanic action cannot occur in the absence of moisture. In the presence of moisture galvanic action will only occur if the water solution will conduct an electric current; the better the conductivity of the electrolyte the stronger will be the galvanic action. Distilled water and pure rain water will not conduct electricity but when contaminated by smoke, soot or dust, they become electrolytes through the formation of weak acids. Also salty water is a very good electrolyte.

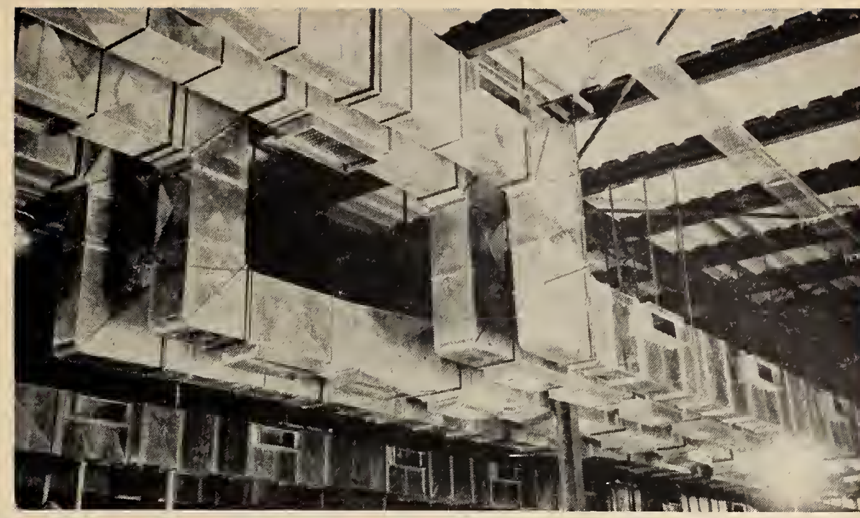


Fig. 8. Aluminum ductwork installed during 1954 in the Terylene plant of Canadian Industries Limited, Millhaven, Ont.

In most cases, the two metals are in direct contact but galvanic action may also occur when they are separated provided they are joined by a connection through which an electric current will flow. One of the simplest ways to stop the flow of current is to separate the two metals from one another by insulating gaskets of fibre, waterproof papers, rubber, bituminous paint, or plastic coatings. Care should be taken to avoid moisture absorbent papers or membranes.

Experience has indicated that the following holds true. Indoors, under dry conditions, any combination of metals may be used. Outside or inside, where moisture or condensation is present, the action between aluminum and iron or steel is extremely slow and can be eliminated readily by painting the iron or steel. Lead washers are satisfactory on aluminum nails used to secure aluminum roofing and siding, except in marine locations. Zinc, galvanized steel and stainless steel may be used in contact with aluminum under most conditions. However, in marine locations the zinc coating on galvanized steel soon disappears and an iron-aluminum couple is left. Direct contact with copper, brass, or monel should be avoided except under dry conditions, or if the thickness of the aluminum section is sufficient to tolerate some corrosion. In roofing and flashing work, in particular, copper should not be used above aluminum, even though the two may be separated by a considerable distance, since water running down over the copper will carry copper salts on to the aluminum and deposit them there, and this will lead to pitting of the aluminum. Aluminum may be used above copper provided that direct contact between them is prevented by an insulating gasket.

Insulating Materials

The insulating materials in general use today are composed of relatively inert substances which have no harmful effect on aluminum. However, high-soda glass wool and magnesia insulation may cause corrosion of aluminum by poultice action. This only occurs if these absorbent materials are wet and in prolonged contact with the aluminum. Coating of the aluminum with bituminous paint is an effective preventative against this type of attack. The suppliers of insulating materials should be asked whether or not their materials are satisfactory for use in contact with aluminum. Wood shavings and sawdust are used occasionally as insulating materials and for this purpose are usually treated to render them fire and vermin resistant. The effect of these substances on aluminum should be checked with the manufacturer before they are used.

Aluminum foil is increasing in popularity as an insulating material, and it may be used safely in contact with aluminum employed for other purposes. Aluminum foil is an excellent vapour barrier and it is frequently used for this purpose with other insulating materials.

Joint-Caulking Materials

Joint-caulking materials are widely used today to ensure the weather tightness of building components and assemblies. They must seal the joints effectively against moisture and yet retain sufficient plasticity to allow for slight movements.

Fig. 9. Welded aluminum water storage tank (50,000 gallons) erected in 1948 at Shawinigan Falls, Que.

A large number of caulking materials and compounds are available, some of which have been developed specifically for use on aluminum. The caulking compounds generally used with other metals, may in some cases be used with aluminum. Caulking compounds should be non-drying and those that show the least variation in plasticity with variations in temperature are preferred. Caulking compounds embodying zinc or barium chromate are effective for sealing joints in aluminum because both these chemicals inhibit corrosion of aluminum. To assist in the selection of the proper caulking compounds, some of the more common types of caulking materials and compounds are discussed below.

Fig. 10. Aluminum corrugated roofing and siding installed in 1952 on loading tower and conveyor at Kassa Island, French Guinea.

Mastic Compounds — Mastic compounds, as a rule, are very suitable for caulking joints in aluminum. Various compounds, using an asphalt, resin, or oil base, have been especially developed for use on aluminum. Aluminum pigment and zinc chromate are usually added to give additional protection and colour. Mastic compounds are usually fibred with asbestos and filled with marble dust or other similar materials. They are available in several consistencies to suit the various methods of application.

Thiokol-rubber type caulking compounds, which have many desirable properties, are being used widely by the aircraft and building industry. Available evidence indicates that this type of caulking compound is compatible with aluminum.

Zinc White in Oil — Zinc white (zinc oxide) in oil (usually fish oil) is a simple and effective caulking compound suitable for many types of joints. The oil base should be non-drying and its fluidity should suit the temperature range to which the work will be subjected. A typical mix consists approximately of two to three parts zinc oxide and one part oil.

White Lead — Caulking compounds consisting of white lead in oil have been widely used for many years on wood and metal, but are not recommended for aluminum.

Lead Wool — Lead wool should not be used to caulk joints in aluminum.

Atmospheric Performance of Anodized, Coloured and Porcelain Enamelled Aluminum

Anodized aluminum exposed in a rural atmosphere will maintain its pleasing initial appearance for an indefinite period of time. In severe urban and industrial atmospheres the coating will become covered with dust and soot particles and if regular maintenance is not carried out, pitting will occur. The simplest explanation is that moisture condenses on the particles and sulphur oxide gases are absorbed from the atmosphere to form sulphur acids. Thus, over a period of time, pitting of the anodic coating may take place at or under the particles of dust or soot. The length of time before pitting commences depends on the severity of the environment and the thickness of the anodic film. The pitting which occurs will not be serious from a structural point of view, but it will mar the appearance of the surface. Corrosive attack is less in a boldly exposed than in a sheltered location owing to the washing action of the rain. Thick anodic films (in the order of 1 mil) are more resistant to pitting than are thin films.

The necessity for periodic cleaning of anodized aluminum curtain walls, store fronts, doors, windows, and other architectural items, which can be examined closely by the public, exposed in urban, industrial, and marine atmospheres is sometimes over-looked. There is no alternative if the very attractive initial appearance is to be retained, and this is true of all building materials. The

TABLE II—Capitalized Costs[1] of Several Metal Roofing Materials in Various Environments

Metal	Approx. Thickness inches	Weight	Cost[2] of 5000 sq. ft.		Corrosion Rates			Capitalized Costs[8] in dollars			
			Metal	Total[3]	Rural	Marine	Industrial	Based on Depreciation Period of 50 years[9]	Rural	Marine	Industrial
		lb/sq. ft.	dollars	dollars							
Aluminum	0.032	0.451	800	1880	0.047 mpy[4]	0.110 mpy[4]	0.123 mpy[4]	2060			
Copper	0.0216 (16 oz.)	1.00	2500	3500	0.011 mpy[5]	0.036 mpy[5]	0.054 mpy[5]	3840			
Lead	0.625 (4 lb.)	4.00	4300	5300	0.008 mpy[5]	0.021 mpy[5]	0.015 mpy[5]	5810			
Galvanized Steel (1.5 oz. per sq. ft.)	0.022	0.91	580	1580	27 years to 50% Rust[6]	13 years to 50% Rust[7]	6 years to 50% Rust[7]		2150	3365	6230

Aluminum, copper and lead all last longer than 50 years but the normal depreciation period for most buildings is 50 years.

work required to maintain the appearance indefinitely is only nominal in extent, particularly if started as soon as the material is placed in service and continued regularly. Numerous cleaning and protective treatments can be applied, but one of the simplest is to use a "lacquer wipe". The cloth, wet with the solution of a good lacquer diluted one part to three parts with the correct thinner, is wiped over the surface. This treatment not only loosens and removes the dirt particles, but leaves a thin, clear, protective, non-oily film. A thicker and more protective film can be obtained by wiping the surface with another rag dipped in the same solution. The frequency of this treatment will vary with the exposure conditions but generally should be done about every four months in an urban atmosphere.

Anodic coatings may be coloured with organic dyes, inorganic pigments or by means of alloying additions. A wide range of attractive colours can be produced, many of which are suitable for outdoor exposure. The use of proper dyes, thick anodic coatings, and the application of lacquer, particularly of the methacrylate type, will enhance the service life of coloured anodic coatings exposed to the weather. There has been much discussion about the outdoor use of coloured anodic coatings on aluminum alloys and claims have been made about the "life-time" retention of the original colour. The following facts are pertinent to this application:

(1) All commercial coatings weather to some degree when exposed outdoors for prolonged periods.

(2) Weathering of the anodic coating will effect the colouring material regardless of its composition.

(3) All organic dye-stuffs fade to some extent on exposure to light.

(4) Outdoor exposure in an urban environment will soon produce an adhering layer of oily soot and dust which will affect the visible colour. Unless this material is removed periodically, pitting attack will initiate.

The use of porcelain-enamelled aluminum in the construction industry is expanding rapidly. There is a good range of colours available which have excellent resistance to fading and weathering. The coatings are very adherent and the metal may be bent and cut without impairing the coating. Much work is being done, principally by the supplier of the enamelled frits, on the porcelain enamelling of aluminum.

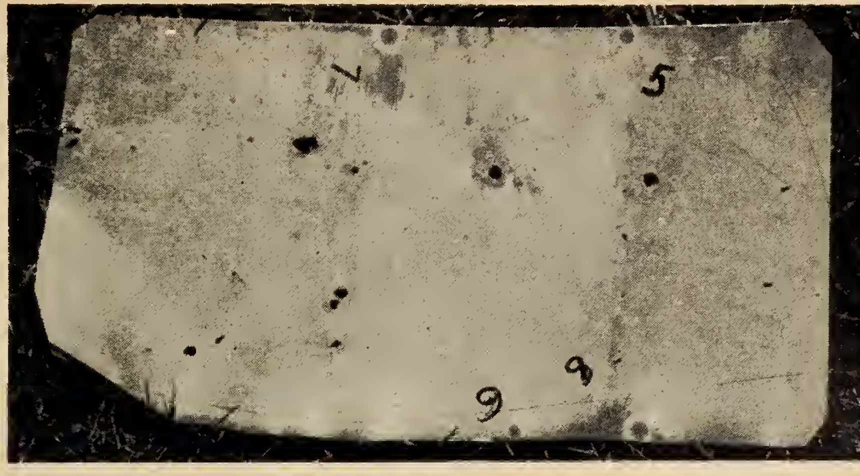

Fig. 11. Close-up view of corroded parapet flashing.

Fig. 12. Close-up view of reverse side of parapet flashing. Note ghosts of tile ribs and mortar joints. Sheet was not back-painted.

Cost of Corrosion

Corrosion and measures to combat it cost billions of dollars a year in Canada and the United States. In considering the cost of corrosion, the following factors are important:

(1) Initial cost.
(2) Cost of maintenance.
(3) Cost of replacement.
(4) Loss of production or revenue during repair or replacement.
(5) Inconvenience to occupants during repair or replacement.

The relative capital costs of metal roofing in various environments is given in Table II. The term "capital cost" means the money that must be available now to put on the roof, and to provide a sufficient sum to replace the roof at the end of its service life. From Table II it can be seen that the cost of aluminum is very much lower than that for copper or lead in all types of environments. The cost of galvanized steel used in rural atmospheres is close to that of aluminum while in marine and industrial atmospheres the capitalized costs of galvanized steel are much higher. The figures used in Table II do not include freight allowance, and assume that the installation costs are the same for the heavier metals as they are for aluminum. While the above example deals with metal roofing the same may be applied to other applications in the construction industry.

Prevention of Corrosion

Corrosion can be prevented by following good practices which have long been accepted by the building industry. These practices are the result of applying common sense in the use of the various building materials so that each material is used to its best advantage. With aluminum the following factors are the most important.

Selection of the proper alloy for a given application is important. The alloys offered for architectural uses by the manufacturers all have good corrosion resistance for normal purposes. When special conditions are to be encountered in service the advice of the metal supplier should be sought. Good design will eliminate direct contact of unpainted metal with masonry, wood, and metal surfaces. Where aluminum must be used with these materials, it should be separated from them by an underlay of asphalt-saturated and coated building paper or felt or by back-painting the aluminum with bituminous paint. Aluminum should not be used in contact with copper or copper alloys or where water can run from them on to the aluminum. Crevices can be eliminated or if this is not possible they can be filled with mastic sealing compound. Good drainage will eliminate stagnant pools of water. During construction it is important to follow the instructions of the designer. Also, many of the suggestions contained in this paper will be of use during the construction stage.

Regular maintenance will help aluminum retain its original appearance, when this is desirable. The type and amount of maintenance will vary with the environment and the location of the aluminum. Aluminum can be cleaned using water, a detergent, and mild abrasive, such as pumice. If necessary, the clean surface can then be covered with wax or lacquer as mentioned earlier. Thicker coatings of lacquer can be applied, but can not be expected to last more than about two to four years.

When aluminum is painted it is usually for aesthetic reasons, rather than for corrosion prevention. In general, a paint system on aluminum will last longer than a similar system on steel, because, if moisture permeates the paint film, it has less action on aluminum than on steel. The painting of aluminum is simple and satisfactory since suitable techniques and paints exist. It is essential that the surface be clean prior to painting, and proprietary cleaning agents containing phosphoric acid aid paint adherence. The recently developed wash primers provided an excellent base for subsequent paint systems. A general review of the subject has been published. [12]

Design and Operation of an Effluent Disposal System

J. C. Langford,
Production Manager, Canadian Chemical Company Limited, Edmonton, Alta.

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June, 1957.

The disposal of industrial wastes is becoming a problem of increasing importance in the location and operation of chemical and other industries. The solution to this problem requires careful analysis for each individual situation.

The design, construction, and operation of a high odour effluent disposal system comprising holding tanks for evaluation and a disposal furnace are described.

THE CHOICE of an economic location for a plant depends on a great number of factors. Most of the recognized authors on the subject attach some degree of importance, however minor, to the economic effect of the problems of waste disposal. It is becoming evident that this factor is far too often treated too lightly or even ignored. The costs involved in properly controlling effluent to avoid contamination of ground waters and air pollution make it an economic factor which may affect seriously the choice of a plant location and influence process design.

Over the years municipal engineers have developed processes and equipment for treating the domestic effluents from our large urban centres to render them harmless to the surface waters into which they are usually discharged. Only in relatively recent years has it been necessary for engineers in industry to devote a considerable amount of study to the problem of the effect of effluent and waste disposal on the economics of a proposed or existing plant. The stage has now been reached where not only is plant location strongly affected but also the actual design, or choice of the process to be used.

In the chemical industry the problem is particularly difficult. The majority of chemical processes are designed to return a high percentage of the water required for their process needs to the waste effluent streams, but in so doing many undesirable components are included which may cause an extreme contamination problem.

It has been estimated that the contamination due to industrial sewage is roughly equivalent to the total discharge as a result of the human population, in the United States. Canada, because of its smaller industrialization, might be considered in a better position, but since our primary raw material processing industries are a proportionately higher percentage of our total industrial effort, this figure may well be true for our country as well. The methods used, to render innocuous domestic sewage, are not usually effective with industrial wastes and new methods must be devised to handle them, the development of which tax the total range of available technical skills.

Governmental agencies, municipal, provincial and federal have not as yet established fully criteria for control of industrial disposal in all locations and it is an essential responsibility of industry itself to take a leading part in eliminating and controlling pollution in an effective manner.

Each industrial disposal problem is unique, not only from the standpoint of the process differences, but also from the natural facilities available for disposal. In spite of this great variability of conditions, the problem usually can be broken down for solution into four main components. They are:

(1) Separation
(2) Collection.
(3) Storage.
(4) Disposal.

To point out the magnitude of the job of industrial disposal of effluent, the solution to the problems involved in the Edmonton Plant of Canadian Chemical Co. Ltd. will be discussed as an example.

Separation

The plant in Edmonton consists of three distinctly different types of processing units as well as a completely self-contained utilities facility. Operating are, a large and highly integrated petro-chemical plant, a plant for the production of cellulose acetate, and a yarn plant in which textile fibres are produced. The first named unit presents the most difficult waste problem in that it produces a wide variety of chemicals which are separated and purified from aqueous solution by more or less conventional techniques of distillation, extraction, filtration, etc. The difficulties here lie in the fact that trace impurities in the form of complex organic chemicals appear in almost all waste streams from the process. They are of such a variety and of such complexity that it is an almost hopeless task to attempt their ultimate removal from the aqueous waste by distillation, extraction, etc., or by chemical destruction or conversion.

It is necessary to take a very empirical approach to the problem and to segregate as rigidly as possible the waste streams at their source. In this manner, the volumes of undesirable wastes are kept to a minimum and can be dealt with. In actual practice, installations have been made which segregate, by means of sumps, pump gland drip pans, etc., extremely small amounts of contaminated waste at the source, in order that the material will not mix with larger volumes of "clean" wastes and thus increase the total volume of contaminated material for ultimate disposal.

Wastes of a contaminating nature are of two general categories, those which have a high odour and those which have a high bacteriological oxygen demand.

Collection

The plant as it is now constituted contains the following eight types of separate sewage collection systems; in some cases more than one piping system exists for each type.

(1) A storm sewer system for all surface run-off.

(2) A sanitary sewer system with septic tank for sanitary sewage.

(3) Complete process sewer systems carrying material from floor drains in clean areas or from clean process waste streams.

(4) A separate sewer system carrying process waste streams which may by their nature, be contaminated by high odour materials from time to time.

(5) A separate sewer system into which is discharged process waste material or drainage which usually contains high odour contamination.

(6) A separate sewer system containing process waste material which has a high bacterialogical oxygen demand. B.O.D.)

(7) A separate sewer system used to convey material which is rich enough in hydrocarbons to be flammable.

(8) Provision of truck transported liquid collection containers at certain locations where piping is not economical.

Storage and Disposal

The storm sewage system is conventional except that all drop inlets in areas draining tank farms, pipe racks, etc. are provided with a retaining ring with a normally closed control gate. With this modification protection is achieved from inadvertent spills or line breaks while normal surface drainage can be disposed of through manual operation of the gate. All storm sewage is discharged into the North Saskatchewan River.

The sanitary sewage after treatment and clean process sewers are allowed to discharge directly into the river, although a rigid sampling and evaluation procedure is followed to assure these streams remain low in both odour and B.O.D.

The possibly contaminated process waste stream is pumped into large tanks of sufficient capacity to hold over 24 hours total effluent. It is held in these tanks until it can be sampled and odour determinations made. If the results of these tests are satisfactory, it is released under control to the river, if not, it is pumped to one of the two so called high-odour ponds on the property, where it is impounded.

The fifth type of effluent disposal, that of process high-odour material is made to one of the above mentioned impounding basins. The sixth form of sewer system which contains high B.O.D. material is piped to discharge into a completely separate impounding basin. Disposal from these impounding basins is described later.

The seventh sewer system, that for combustible wastes, discharges alternatively into storage tanks or to a burning pit where it is burned as it is produced.

Material collected in the containers referred to in (8) above is carried by trucks to burning pits or impounding basins, depending on the composition, for disposal.

During the winter periods of low river flow, when the plant usage of water and hence the total effluent may be of the order of 1% of the total river flow, only clean streams are discharged to the river. Composite samples are taken and evaluated daily from these streams and all their contributary branches to enable the closest control.

A new installation has recently been made in the form of an effluent furnace in which the combustible effluent mentioned above is burned and into which is atomized the impounded high-odour material. The furnace is so operated that the material is not only vaporized but the vapour raised to a temperature at which the true organic material present is oxidized or otherwise broken down to odourless material. It has been found that, under the conditions at Edmonton, a stack temperature of 750°F. is sufficient to accomplish this destruction and prevent air pollution. This type of furnace is relatively new and it was necessary to build a pilot unit and conduct extensive development work before the full scale design could be made and the furnace constructed. A view of the furnace in operation is shown in Fig. 1. It is designed for a heat release of over 15,000,000 Btu/hr.

The impounded high-odour material is disposed of by three methods:

(continued on page 60)

Fig. 1. View of effluent disposal furnace in operation.

Selection of the Trans-Canada Highway Route Through the Selkirk Mountains

J. P. Hague

Senior Location Engineer, Department of Highways, Province of British Columbia

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June, 1957.

SOME SEVENTY-five years have passed since Major Rogers and his associates explored unknown passes through the Selkirk Mountains for a transcontinental railway route. Adventure such as this is a thing of the past. Nowadays we benefit from the experience and knowledge accumulated by those who have passed before. Access problems are now relatively easy. We have the use of air reconnaissance, aerial photography, aerial mapping, and such facilities as the helicopter, motor vehicle, swamp buggy, snowmobile, tractor, outboard motor, etc. However, even with all these modern day aids, the choice of a single all-weather route through one of our most rugged mountain ranges, was a major engineering undertaking.

Before analysing the various passes through the Selkirk Mountains, we will first consider the existing route of the Trans-Canada Highway. This highway, commonly known as the Big Bend, follows the Columbia River Valley for its entire length from Golden to Revelstoke. It was completed in 1939 and has been subsequently improved to its present condition as a second class gravel-surfaced road.

Advantages in favour of this route are: it circumvents the Selkirk Mountains along a water level route; it can readily be constructed to Trans Canada Highway standards for a lower average cost per mile than any alternate route; it can provide superior alignment gradients and geometric design to any alternate route; snowfall is no more serious, and in most winter seasons somewhat less than any high level route, while avalanche or snowslide conditions are practically negligible, resulting in lower average per mile winter maintenance costs; temporary closure of the highway due to hazardous conditions are practically non-existent.

The main disadvantages of this route are: the total distance from Golden to Revelstoke along the Big Bend Highway is 196 miles, as compared to a distance of 88 miles via the Canadian Pacific Railway and Rogers Pass; only a very small portion of the existing highway could be utilized in the relocation of this route to Trans Canada standards; there is no doubt that a high level storage dam will eventually be constructed at Mica Creek which would make the relocation of the highway above the flood level extremely difficult and costly. The Department's estimate for reconstruction of the Big Bend route to Trans Canada standards, not considering the proposed dam, amounts to approximately $31,000,000. This estimate is based on 60 miles of final location and a thorough knowledge of the terrain over the entire route.

Even with the aid of modern engineering methods and equipment, the selection of an all-weather route through one of Canada's most rugged mountain ranges was a major undertaking.

Factors instigating the investigation of alternate routes were:

(1) whether a shorter route with its resultant economy in maintenance and vehicle operation, although more costly per mile to construct, could be constructed for a similar overall cost, due to reduced distance;

(2) the consideration of Mica Dam.

In 1952 the Provincial Department of Highways undertook preliminary investigations of all possible highway routes through the Selkirks in the area bounded by the Big Bend on the north and the Canadian Pacific Railway on the south. A study of aerial photography and a reconnaissance by air eliminated further consideration of a route via Downie Creek, Sorcerer Creek, Bachelor Creek, and Gold River, and also a route via Goldstream Creek, Moberley Pass (elev. 5825 ft.), and Gold River. A route via the Illecillewaet River, Tangier Creek, and Mountain Creek to Beavermouth appeared feasible and worthy of ground investigation. A reconnaissance was therefore undertaken by Mr. Norman Zapf, Assistant Location Engineer, Department of Highways, Victoria, assisted by Mr. Scarborough of our Location Branch, accompanied by a guide and packers. The route was thoroughly examined on the west side of the range to the summit. Most significant was the fact that no water course or valley led directly to the summit, forcing any proposed location to traverse the mountain side on steep rock slopes of 50°-60° and using maximum grades of 7% to 8% for approximately seven miles to reach the high levels. In addition, some extremely heavy work would also be encountered in the lower Tangier Valley. These features, coupled with the existence of many large slide areas on both sides of Tangier Creek, proved the route to be economically impractical to construct, or maintain a safe all-weather highway. Final conclusions were that there are no feasible highway routes through the passes of the Selkirks north of the Canadian Pacific Railway.

Preliminary Investigations

The Department had also carried out a very preliminary investigation of the Rogers Pass route without reaching any definite conclusions. As a decision on the route for the Trans Canada Highway was becoming vital, a reconnaissance of the entire Rogers Pass route was undertaken by the Federal Government. Messrs. W. J. Bishop and G. N. Brittain, of the Trans Canada Highway Division, carried out the reconnaissance survey during the summer of 1953. Their report revealed that a route from Golden to Revelstoke, via Rogers Pass, was entirely feasible. It indicated reasonable construction costs, availability of good construction materials, the possibility of standard geometric design, and the feasibility of combating snow conditions. It was therefore concluded that this route, with a total length of 88 miles, and an estimated cost of $28,000,000 would be superior to the Big Bend route.

At about the same time representatives were received from Boards of Trade, and other organizations, in the West Kootenays and the Lake Windermere area, to consider a route via Jumbo Pass, some 80 miles south of Rogers Pass and through the Purcell Mountains. This route contemplated leaving the present Trans Canada Highway at Eisenhower Junction, following the existing park road through Kootenay National Park to Radium Hot Springs and Invermere, westerly through the range via Jumbo Pass to the south end of Duncan Lake, and northwesterly along the Lardeau River, Trout Lake and Columbia River to Revelstoke. Consequently, in the summer of 1954, Mr. Zapf, accompanied by Mr. Scarborough and Mr. F. Feuz, of Golden, undertook a reconnaissance on foot from Invermere, via Toby Creek and Jumbo Creek to Jumbo Pass, thence down Glacier Creek to Howser at the south end of Duncan Lake. Results of the survey showed Toby Creek and Jumbo Creek to be reasonably wide "U" shaped valleys, and while they presented some minor difficulties, a high standard highway could readily be constructed to the base of Jumbo Pass. On the other hand, Glacier Creek valley is a typical Selkirk "V" trench with steep rock slopes, and an average gradient of 4%, leaving little flexibility to avoid difficult sections.

The most difficult obstruction, however, is encountered in the area of the pass itself. Jumbo Pass, which could be more correctly named Jumbo Ridge, is actually a narrow hogsback, 7500 ft. high, between two flanking mountains, Jumbo to the north and Earl Grey to the south. Both water courses, Jumbo Creek on the east side and Glacier Creek on the west, fork to the north and south at the base of the ridge. The elevations of the forks are 5000 ft. and 4500 ft. respectively. A highway over the summit would have to overcome 2500 ft. in elevation on the east approach by looping up the North Fork of Jumbo Creek through large slide areas, snow cols and a glacier. The west approach presents an even more dismal picture, in that the lack of distance, the tremendous slide area on the west slopes of the South Fork of Glacier Creek, and the close proximity of the glacier, discourages any notion to climb to the summit at all. The only plausible solution, then, was to use what distance was available from the forks of the creek to rise as high as possible and tunnel through the ridges. It was possible to reach a maximum elevation of 5300 ft. on the west side and 5500 ft. on the east side, resulting in a tunnel on a 2% grade at least two miles in length which would require lighting and a ventilation system. As a result a decision was reached that Jumbo Pass should not be considered as part of the Trans Canada route, but that providing a tunnel was acceptable, the route was feasible and might be worthy of further consideration at some future time if development of the Province indicated the necessity of another highway connection from the Columbia Valley to Kootenay Lake.

Apart from a comparison of costs and topographic features of Jumbo Pass and Rogers Pass routes, other factors such as traffic origination and destination, distance, and vehicle operation costs, must be considered. There is no doubt that a highway through Jumbo Pass would benefit the residents of the West Kootenays. Unfortunately, however, only one route through the Selkirk Mountains can be justified or financed at the present time. With early completion of two existing bottlenecks on the Southern Trans Provincial Highway, namely, Cascade-Trail and Salmo-Creston, the West Kootenays will have direct access west to the Coast and east to the Province of Alberta. Admittedly, the route from Salmo to Calgary, via Crows Nest Pass, is some 50 miles longer than route via Jumbo Pass, but this extra distance is more than offset by superior gradients and alignment.

A study of traffic patterns indicates that, for traffic originating on Vancouver Island, Lower Mainland, the Okanagan, Fraser Canyon, Cariboo, Northern B.C., the North Thompson and Kamloops regions, with destination Banff or Calgary, the shortest and most logical route is via the Trans Canada Highway.

In considering distance, the Rogers Pass and Jumbo Pass routes have two common points, namely, Revelstoke and Eisenhower Junction. The length of route between these points is 158 miles via Rogers Pass, and some 234 miles via Jumbo Pass. Rogers Pass was chosen because of the economics involved in a reduction of some 76 miles in distance, resulting in greatly decreased estimates for cost of construction, maintenance, and vehicle operations.

Savings in Costs

As a rough example of savings in vehicle operation costs, a reduced distance of some 76 miles results in a saving of 1½ to 2 hours or more in the operating time of every vehicle passing over the highway. In operating costs, a reduction of 76 miles at some 8c per passenger vehicle mile results in a saving of $6.00 for every passenger car passing over the highway. Assuming an ultimate average daily traffic volume of 1,000 cars per day in each direction, the saving in operating costs to passenger vehicles could exceed four million dollars annually. Although we have no data at the present time on the ultimate volume of freight to be hauled over this highway, a reduction of 76 miles in distance would greatly reflect on the cost of freight carried.

Although the reduction in highway mileage via Rogers Pass is some 76 miles, the reduction in mileage of Provincial highway via this route is some 99 miles. This is because there is 23 miles more highway within National Parks on the Rogers Pass route. This reduction of 99 miles of Provincial highway means a saving of from $300,000 to half a million dollars, annually, to the Province in maintenance and snow removal costs.

Comparing the mileage of highway to be constructed or reconstructed via either route, we have the following comparison.

Rogers Pass Route

The section from Golden to Eisenhower Junction is already reconstructed to Trans Canada standards or work is committed. This leaves a distance of 90 miles to complete or reconstruct, including the 16 miles of existing road from Golden to Donald.

Of the 90 miles total distance, 27 miles lie within the Glacier National Park and 8 miles within Revelstoke National Park, which the Federal Government is committed to build. This leaves a distance of 55 miles to be constructed and maintained by the Provincial Government, with contributions by the Federal Government of from 50% to 90% of the cost.

Jumbo Pass Route

Jumbo Pass route from Eisenhower Junction to Revelstoke is a distance of some 234 miles, of which 68 miles lie in the Kootenay National Park. This 68 miles would have to be reconstructed by the Federal Government to Trans Canada Highway standards. The remaining 166 miles of this route would have to be constructed and maintained by the Provincial Government.

Throughout the provincial section almost none of the existing local mining roads and trails, etc., could be incorporated into a Trans Canada highway design. They would only prove useful as access to construction.

The section of the route along Toby Creek and Jumbo Creek is certainly feasible, and compares favorably with our sections of the Rogers Pass route. However, as previously mentioned, at an elevation of 5500 ft. it is necessary to tunnel through Jumbo Ridge for a distance of two miles in order to overcome gradients not acceptable to major highway standards. The tunnel, complete with ventilation equipment and lighting, could cost up to ten million dollars.

From the west portal of the tunnel the highway would have to traverse the Glacier Creek Valley for some 20 miles to Howser, at the bottom of the Duncan Lake. Because of the steep nature of the valley, it would be difficult and very costly to construct a highway to Trans Canada standards for gradient and alignment through this section, and maintenance costs would be heavy.

The remainder of the route from Howser to Revelstoke is entirely feasible, with normal construction, with the exception of a heavy section along Trout Lake and a most difficult section between Beaton and Arrowhead.

It is therefore considered that initial capital expenditures, future maintenance costs and future vehicle operation costs for the Province as a whole, justify the decision to adopt the Rogers Pass route.

Field Location of Rogers Pass Route

For the purpose of discussion, the Rogers Pass route can be divided into three sections, namely: Revelstoke to the west boundary of Glacier National Park, a distance of 28 miles; Glacier National Park which includes Rogers Pass proper, a distance of 27 miles; and the east boundary of Glacier National Park to Golden, a distance of 35 miles.

During 1955 and 1956 the Federal Government carried out the location survey through Glacier National Park and this is nearing completion. Contracts for right-of-way clearing are already under way. The Provincial Department of Highways commenced the location survey in the Illecillewaet Valley in the late fall of 1955 and again in May of 1956. The section from Revelstoke to the West Boundary of Glacier Park was completed in 1956, with exception of four miles which has been finalized this spring. The design, specifications, and estimates of cost for three sections, each approximately six miles in length, have been completed and awarded to contract. The remaining section will be finalized and advertised for tenders next month. The centre section, some seven miles in length, which is in Revelstoke National Park, will be handed over to the Federal Government for contract. On the easterly section contracts have been awarded for approximately 15 miles from Golden to Donald and location parties are presently on the ground to complete the gap from Donald to the East Boundary of Glacier National Park for construction in 1958.

To facilitate the surveys, aerial mapping at a scale of 1,000 feet to the inch with 25 foot contour interval was obtained. All feasible highway alignments were projected on this mapping along both sides of the Illecillewaet valley, including feasible crossovers from one side of the valley to the other. These various projections were then investigated from the air by helicopter, giving careful attention to control points, the number of slide areas, bridge sites, major drainage features, degree of side slopes, and types of materials. Following this a detailed ground investigation of these various control features, classification of materials, drainage, etc., was carried out by Mr. Zapf, Mr. Scarborough, the author, and Mr. Perkins, who was to be in charge of the field surveys. A review of all the features investigated by these individuals enabled us to determine the best general alignment for the survey, it being unanimously agreed that the route along the north side of the valley throughout was the best and most economical location.

The main features governing the selection of the north side of the valley were:—to avoid the construction of two tunnels which would be required on the south side, one to achieve good alignment and the other above the Laurier Tunnels where some 3,000 feet of tunnel could be the only means of crossing the slide area; to avoid close proximity with the Canadian Pacific Railway and its resulting construction, maintenance, and snow removal problems; to avoid areas of wet sidehill which is much more prevalent on the south side of the valley; to utilize the definite advantage of a southern exposure; to achieve generally better alignment. The above mentioned features favouring the north side of the valley are offset somewhat by the fact that the selected route must cross three important slide areas between Illecillewaet Station and the west boundary of the Park, where it appears certain that several hundred feet of permanent snow sheds will be necessary.

The only section where some doubt existed in the initial studies was between Greely and Twin Butte. Some preliminary surveys indicated the alignment was somewhat easier on the south side of the valley through this area. However, as this proved to be a wet sidehill and as the location would be directly above the Canadian Pacific Railway, we could foresee difficulties during construction, and future maintenance problems resulting from an unstable roadbed. Therefore, as the north side had definitely been selected from Twin Butte easterly, and from Revelstoke to Greely, it was decided to utilize the north side between Greely and Twin Butte. Any additional costs resulting from heavier grading would be more than offset by the elimination of two grade separations with the railway, and two major river crossings, and a more stable roadbed with better exposure would be achieved.

In order to complete the survey of the Illecillewaet in one year, three survey crews were employed under the direction of a location engineer. One of these crews worked from Revelstoke and established the location from the west side of Revelstoke easterly to Greely and beyond as far as road access was available. The other crews located the remaining section to the Glacier Park boundary where access to the survey line was difficult. Both these crews operated from tent camps at sidings along the railway and were each equipped with a cookhouse and an office erected on flat cars.

Results of this survey indicate that construction costs through the Illecillewaet section of this highway will be generally less than Trans Canada Highway reconstruction through the Fraser Canyon.

Survey of Snow Conditions and Avalanche Activity

Snow surveys were commenced during the winter of 1953/54 and the work accelerated during the past winters. The survey is under the personal direction of Mr. Noel Gardner, who is an authority on snow conditions, having been employed as a Park Warden in Banff and Glacier Parks for some twenty years. Mr. Gardner has studied snow conditions and control of avalanches for a number of years and has attended courses conducted at the University of Utah.

Prior to last winter (1956-57) these surveys consisted of frequent visits to the slide areas to record the incidence, types, depths and extent of the slides. Last winter a permanent base was established at Glacier with observation posts located on the Bear River in Rogers Pass and on Mount Abbot at an elevation of 7000 feet.

Several experienced mountain climbers and skiers are employed on Mr. Gardner's crew, and the necessary equipment has been provided to accurately record temperatures, relative humidity, wind velocity and direction, snowfall, depth and density of snow, and a careful continuous record is kept of the condition of the snow in the trigger zones of the slides. Data is also recorded on the occurrence of avalanches, such as time of day, location, width and depth of slide, type of avalanche, and cause.

These studies already indicate that an experienced crew attached to the maintenance group after completion of the highway will be able to very closely predict the periods when hazards exist so the road may be closed for a short period until conditions change or the slides are brought down by explosives or mortar fire.

Mr. Gardner has also conducted some experiments in stabilization of slide areas, and construction of terraces with bulldozers across the slide area has been tried with success in some places. These experiments and surveys will be continued until the most economical method to protect the highway public at each particular slide can be determined. The use of terracing where feasible, snow stabilization, and short closures of the highway may greatly reduce the amount of snow sheds to be constructed. As permanent concrete structures cost some $3,000,000 per mile, this is a most important consideration. It is therefore not intended that any snow sheds will be designed until the grading work is completed.

EFFLUENT DISPOSAL SYSTEM

(continued from p. 56)

(1) by destruction in the high-odour effluent furnace described above;

(2) by solar evaporation from the ponds. (In Edmonton we lose up to 2 in. per week for the summer months with a yearly total of approximately 20 in.);

(3) by carefully controlled discharge to the river during summer high river flow periods when adequate dilution of odour values can be maintained.

The impounded high B.O.D. material is also released under careful control during the ice-free and high-flow months when there is adequate oxygen in the river to accommodate the effluent.

In design of any new facilities or alterations at the plant, one of the prime criteria has become the necessity of choosing designs and processes which produce, if possible, no contaminated effluent. If this is not possible, every effort is made to provide, from the beginning, facilities for isolation of any contamination from clean streams, economic collection, storage, and disposal.

An expenditure in the order of $500,000 has been made in providing for the elaborate precautions described above, however the type of facilities involved permit operation at full and expanded scale while enabling the plant to meet not only present restrictions on effluent disposal to the river but also any future conditions which are felt may arise. Facilities of this nature are definitely a factor in the economics of the operation, not only of this plant, but of any plant which faces similar problems. The most serious consideration and skillful design must be applied to this facet of industrial operation to avoid the inevitable results of indiscriminate effluent contamination. The time is already past in Canada when industrial pollution is someone else's problem.

Marginal Punched Cards for a Reference File in the Field of Electronics

W. G. Hoyle

Radio and Electrical Engineering Division, National Research Council, Ottawa, Ont.

As an improvement on the card reference information file commonly used by engineers, a modified system using marginal punched cards is described. This punched card system enables information to be retrieved from a file on the basis of several classifications. Specifically, the system described uses date, authors, subject matter, source, and miscellaneous. Combined selections using any of the above bases are both possible and extremely useful. Rapid collation of the cards, either chronologically by date, or alphabetically by author, is possible. Normally the cards are not kept in any particular order. Only one card is used per reference and costs are similar to those of the more common card file systems.

MOST ENGINEERS, or groups of engineers, in today's rapidly expanding electronics field find it desirable to maintain some sort of card index file of information which they require to be at their finger tips. Such files eventually develop, in most cases, into one of two basic types. First and simplest is a reference file with cards arranged alphabetically by the name of the author (first author, if more than one); the second type has a card for each author and additional cards for subject headings.

Chief merit of the first type is that cards are added with little effort; its disadvantage — with the passage of time the file becomes larger and authors' names are forgotten so that eventually a card cannot be located when wanted. The second type, with multiple cards, requires much work each time a reference is added to the file, for since multi-author papers are common, and since papers are seldom limited to a single clear-cut subject, as many as seven cards may be needed for one reference. In addition, preparation of a subject index requires considerable time and skill, so that even this second system does not always function well.

The system to be described has all of the advantages and none of the disadvantages of the above systems. In addition, it has some merits possessed by neither.

1. Only one card is needed for any reference or abstract.
2. This card can be selected from the file in a multiplicity of ways, specifically by:
   - (*a*) name of first or second author,
   - (*b*) any one of several subject headings,
   - (*c*) date,
   - (*d*) source, i.e., origin or name of publication,
   - (*e*) several miscellaneous items, such as being in a foreign language, or being confidential information.
   - (*f*) combinations of items (*a*) to (*e*) above. For example, (*c*) and (*d*) could be used to select all cards from a given publication for some particular year.
3. Cards need not be kept in order. Obviously, therefore, they cannot be misplaced or lost (at least not in the file!). Cards can be put in order, when desired, at a rate of several hundred per minute. They can be arranged chronologically by date, or alphabetically by first or second author.
4. The subject index is prepared using the accumulating cards as a guide. That is, the selection of subject headings can *follow* the acquisition of the cards. When the cards in some category become too numerous for convenience they are examined for ideas by which to classify them. It is far easier to choose suitable categories for existing items than to create categories in advance. Theoretically suitable headings never seem so suitable when actually put to use.
5. No dependence is placed on memory, and no separate subject lists or subject guides are used.
6. The system is so simple that trained clerical services are not necessary, and no "operator" need intrude between the user and his cards. On the other hand, the work can be done altogether by clerical help (other than the actual abstracting of material, of course), if such help is available.
7. Cost is intermediate between that of the two basic conventional systems described in the introductory paragraph. Cards and cabinets are practically the total cost.

This improved performance is obtained by the use of punched cards; in our case by the use of marginal punched cards.

Mechanics of the Marginal Punched Card

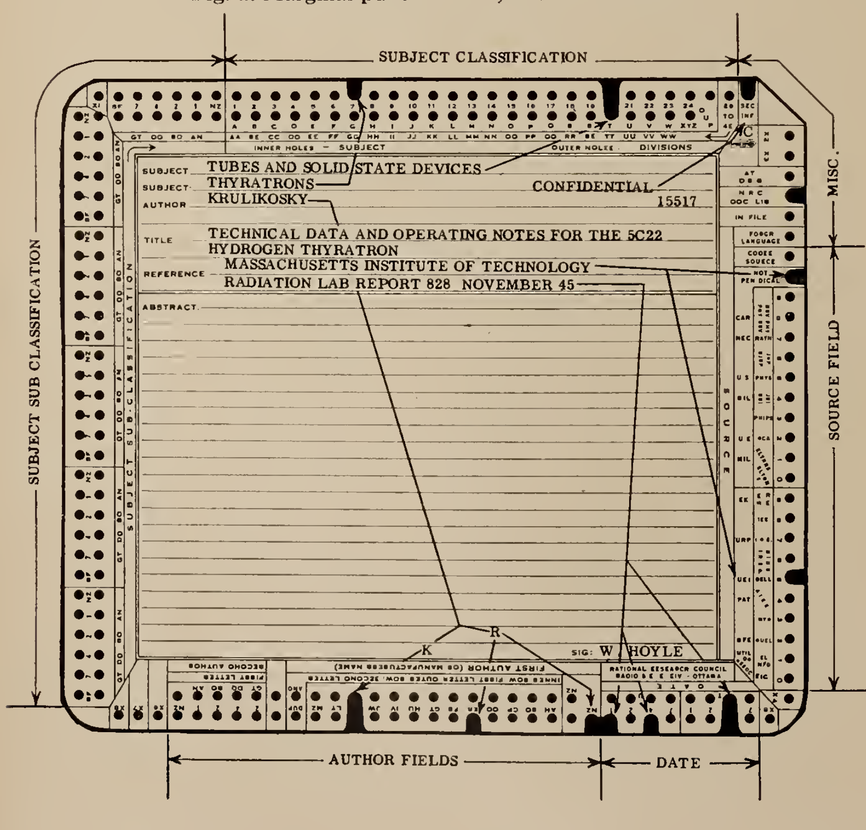
A marginal punched card is basically a common reference card in which one or two rows of holes have been punched around the edges by the manufacturer; normally there are about four or five holes to the inch. Usually there is some printed information adjacent to the holes to facilitate their use. The central area of the card is blank and is used in the same manner as is a plain unpunched card. The card in Fig. 1 is practically self-explanatory. Figure 2 shows another card as received from the manufacturer.

There is no need to use a particular size, and in fact the 5 by 8 card shown in Fig. 2 was seriously considered as an alternative. The 5 by 8 card has the advantage of being the same size as cards found in many existing card index systems using plain cards. Its use makes changeover easier since plain and punched cards could be filed together during the transition period, and existing filing cabinets could be used. The 6½ by 7½ card is somewhat easier to handle and has somewhat more holes. Two sizes are shown to illustrate the flexibility possible. Cards are available ranging from about 1½ by 3 to 8½ by 11.

On the card in Fig. 1, holes are assigned to indicate the date, the author's name, the source of the information, and the subject and its sub-categories, and so on. In use, the card material between the appropriate hole and the edge of the card is removed with a punch, much like a train conductor's punch, thus leaving a notch or slot. (Gummed patches, called "cardsavers" are available for mistakes or changes.) When a sorting needle is inserted through a hole position in a group of cards, and lifted, as shown in Fig. 3, the cards which have that hole slotted, will drop. This simple sorting method (there are more elaborate ones[1]) is well suited to files of not more than a few thousand cards. Speeds of at least 50,000 sorts per hour are customary so that for our application sorting time is trivial. The holes, then, are primarily a mechanism for selecting certain cards from a pack in accordance with a punching plan which is related to the data on the card. Cards can also be put into alphabetical or numerical order by using the punching.

Some details of the actual assignment and punching (i.e., slotting) of holes are perhaps needed. To indicate a digit we could assign ten hole positions, one to each of the digits 0 to 9, and then punch the appropriate one. Such a group (called a field) is shown in Fig. 4(a). Digits punched as described are said to have "direct" punching. Actually too many holes are required in such a system and recourse is usually made to one of the schemes of Fig. 4(b) and 4(c). Only the first five digits are shown, the extension is obvious. Systems such as those in Fig. 4 are called "coded" systems.

Fig. 1. Marginal punched card, 6½ x 7½ inches.



Sorting and Collating by Date or Author

Referring to Fig. 1, the date field consists of two digital fields of the type shown in Fig. 4(c), one field for the years, the other for the decades. (There seems little point in indicating the centuries). Only eight hole positions are used along the margin of the card whereas twenty would have been needed for the direct scheme of Fig. 4(a). As a penalty it now requires an average of three sorts to obtain a card by date, rather than the two sorts of the direct method. Besides saving holes, coded date punching has another advantage which will be seen in the following paragraph.

The date field is used not only for selecting cards of a given date, but also for arranging the cards in chronological order. Such arranging may be required in preparing bibliographies, or when considering the history of a subject. Sorting is started at the "ones" digit of the years field, and continued across hole by hole (outer holes only) to the "sevens" digit of the decade field (8 sorts altogether), the dropped cards each time being placed at the back of the pack before proceeding. The cards will now be in chronological order. There is one exception. Since 7 and 4 are punched for zero, the year 1920 for example will follow 1929 rather than 1919; the year 1930 will follow 1939 not 1929, and so on. These groups must be shifted by hand. If objection is taken to this procedure, then the card could be redesigned to include a zero hole, instead of using 7 and 4. Note that the coded scheme, using only 8 holes for the date, allows us to arrange the cards in order in 8 sorts, whereas with the direct method 20 sorts would be required.

When sorting for a card by date, it is in theory immaterial whether the year or decade hole is sorted first. For example, a card date 1948 could be sorted first for the year 8, dropping all cards 1908, '18, '28, '38, '48, and then for decade 4, thus dropping out the year 1948. Alternatively, the sort could be first for decade 4, dropping the years 1940 to 1949 inclusive, then for the year 8, giving again the 1948 group. Practically, however, the first method is much to be preferred, for the number of cards to be re-handled after the first sort is much smaller. That is, the group 1908, '18, '28, etc., is much smaller than the group 1940 to 1949. With experience many such reductions in effort can be made.

Besides the number fields so far holes, but also because occasionally it is desired to arrange cards alphabetically by author, in preparing reference lists for papers or reports. The cards are put in alphabetical order by starting at the left end of the field at letter A and sorting across hole by hole (inner holes only), the dropped cards being placed each time at the back of the pack. A final sort through the NZ hole completes the sorting. Note that only 14 sorts are required. With a direct alphabet code, 26 sorts would have been needed. If the above sorting is done

"Source" Field; Miscellaneous Items

A source classification, as shown on the right edge of the card in Fig. 1, is a most useful means of reducing the work needed to locate a card. In use, a sort through any hole position drops the cards from the sources printed opposite the hole. A second sort through the hole marked "not periodical" then separates the sources in the left column (non-periodical) from those in the right (periodical). The order of sorting can be reversed but the work is greater as a larger number of cards must be rehandled

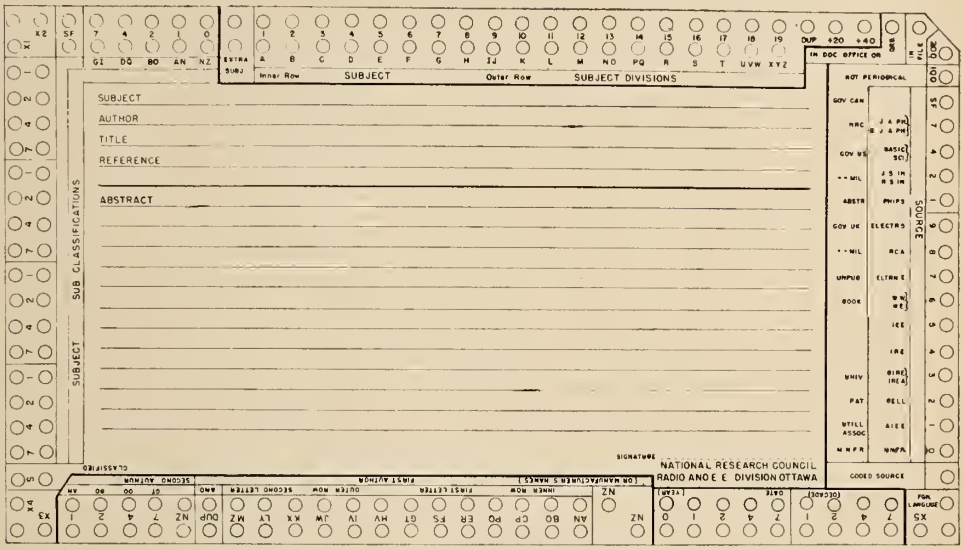


Fig. 2. Marginal punched card, 5 x 8 inches.

described, alphabetical fields are required for the author's name, etc. We sometimes use the direct method and assign a hole position to each of the 26 letters, as is done for the subject field on the card in Fig. 1. Another method which requires fewer holes, is the coded scheme shown on the card of Fig. 1 in the "second author" field. There are other five hole schemes.

Now, though with the direct scheme we use 26 holes for the alphabet, only one sort is necessary for each letter; with the 5 hole scheme, while only 5 holes are required, up to 4 sorts may be needed for one letter. For selection by author, since two letters of the name are used, 8 sorts might be required. As selection by author is frequent this number of sorts is excessive and the compromise scheme in Fig. 5(a) is preferable. Fourteen holes are needed with a maximum of two sorts per letter; the first sort selects a two letter group and this group is then divided using the "NZ" hole. This compromise alphabetical scheme is used for the first author field not only to save first with the outer holes, then with the inner holes, the cards will be alphabetically arranged by the first two letters, i.e., aa, ab, --az, ba, bb, --zz.

The author field has two rows of holes, and these inner and outer rows are used for first and second letter, respectively. Obviously interference between inner and outer rows can occur. To overcome the difficulty, the hole at the extreme right of the author field, marked "dup" (for duplicate) is punched when the second letter of the author's name has the same hole position as the first. For example, if in Fig. 5(b) the name had been Borden, then since B and O occupy the same hole position, both inner and outer hole would be punched simultaneously by the punching of the first letter. Note that the NZ hole is still punched to indicate that the duplication is for BO and not BB. The hole "ano" below that marked "dup" is for the anonymous group. When it is used, of course, the "dup" hole too is unavoidably punched but has no significance.

for the second sort. A few stray cards may be found which do not belong to the sources shown in either column; if numerous enough to be a nuisance they can be removed by a sort through the "coded source" hole. An explanation of this follows.

The number of cards from sources not shown on the card is normally small, and the hole marked "coded source", which is punched in all such cards, is generally interpreted to mean "miscellaneous sources". Such cards are normally given no further source punching. If, however, selection of cards by coded source is used, the cards from coded sources are prepared as follows; two digits, one from each of the two digital groups 0 - 9, adjacent to the source holes, are assigned to the source (in effect the sources are numbered from 10 - 99), and two sorts made through these assigned holes when the card is required. Eighty-nine sources can be coded in this fashion. The hole "coded source" need not be sorted. A list of coded sources must, of course, be kept. The list is kept on a card which has the "coded source" hole and inner "XYZ" of the subject field punched. An explanation is given later. There are some blanks left in the source field printing, so that future important sources can be added directly on card, rather than having them coded.

The source abbreviations shown have the meanings given in Table A.

In the miscellaneous field, immediately above the source field (Fig. 1), "foreign language" is self-explanatory; a third column with titles could have been added for such periodicals but it was deemed not necessary. "In file" means that a photostat, reprint, or copy of the material abstracted has been obtained and is directly available. "NRC Doc. Lib" and "at DRB" refer to the National Research Council, Radio Division Document Section, and to the Defence Research Board Library, respectively. The identification call numbers assigned at these sources are usually written in opposite the hole. In Fig. 1, for example, the number 15517 appears opposite "NRC Doc. Lib". This number, written in by the abstracter, also indicates that that hole is to be punched. The upper two holes "X2" and "X3" are extra holes to which any desired significance can be assigned, not necessarily sources.

The hole "sec inf" means that the card contains security information within the meaning of the Official Secrets Act. It is also our practice to order some cards printed in red (black is normal) and these red cards are used for all security information as a double precaution. Grade of security is indicated on the card adjacent to the hole. Included in the category could be patentable material or material confidential from a business standpoint. The word "confidential" which appears in Fig. 1 is for explanation only. Normally only the letter "C" appears, as shown immediately below the how (or else "S" for secret). This letter, written in by the abstracter, also indicates the punching.

Subject Matter Classification

The remaining marginal space on the card, amounting to almost half the total, is devoted to subject classification. The main subject headings are assigned to the inner row of 24 holes of the subject field. (Should it be necessary, these 24 subjects can be increased to 48 by using holes 25 to 48). Each individual subject heading can be divided into 24, the divisions being punched in the outer row of holes of the subject field. In turn these 24 divisions are each subdivided, using the fields on the card left edge marked "subject subclassification."

Lest it be felt that the growing subject index will eventually become unmanageable, it must hastily be stated that no effort need be made to remember the various headings of the growing index. The punched cards

supply their own memory and instructions with little effort on the part of the user. How this is done will be explained later.

It is best initially to defer subject punching until a substantial number of cards have accumulated. These cards are then consulted to determine suitable subject headings. A partial description of the subject index will clarify its use. Assigned subjects to date in the inner row of 24 holes are shown in Table I.

To see how these subjects are divided, assume a sort is made, say through the seventh *inner* hole "G". The cards for "Wave Generating and Shaping Circuits" are thereby separated from the others. To date the divisions of this subject (outer 24 holes) are as shown in Table II.

"G" of Table I did not appear to fit any division in Table II, it is simply left unpunched in the division field. Such cards automatically form a "Miscellaneous" category, and ultimately they provide information for new headings for Table II. Admittedly these "miscellaneous" groups require a somewhat lengthy sort.

It occasionally happens that a reference relates to more than one subject division, in which case all relevant division holes are punched. Since, however, subsequent classification will usually be different for these different divisions, means must be provided to separate cards with multiple punching. The hole position marked "dup" (for duplicate) is therefore punched on cards with multiple subject-divisions to make possible

Table II. Divisions of Subject Heading "G"

A — R-C Sinusoidal Oscs. and others (except B or C)	L — Linear passive circuits (classical filters, etc.)
B — L-C Sinusoidal Oscs.	M — Multivibrators and blocking oscillators, triggers, relaxation oscillators.
C — Xtal controlled or stabilized Oscs.	N —
D — Diode detectors, clippers, clamps, d-c restorers, discriminators, mixers, converters, modulators, correlators.	O —

F —	S — Scaling, dividing, and multiplying
G —	V — Specs. and standards
H —	W — Historical and Biographical
I —	XYZ — Card index system
J —	
K —	

If a sort is now made say through *outer* hole "M", we obtain the cards "Multivibrators and Blocking Oscillators, Triggers" as a division of the subject "Wave Generating and Shaping Circuits". If at the time a card is made, it does not fit any of the available categories, punching is discontinued at the point of difficulty. For example, if a card punched under their separation and subsequent correct sorting. It is not *necessary* to do multiple punching, and if it is omitted, no cards in the proper category will be missed. However, cards in related categories which might be useful will no longer appear. If the multiple punching is done, but the "dup" hole not sorted, no harm, other than the bypassing of cards in related categories, will occur. The odd stray card may appear here and there but can be ignored. Mulitple punching is equivalent to the "see also" headings, commonly used in cataloguing, with the advantage that only selected cards from the "see also" headings are dropped.

The subject divisions, such as the sample "Multivibrators and Blocking Oscillators, Triggers", are now further subdivided using the subclassification fields on the card left margin. The scheme used is the same as that for the subject field. The inner row of holes comprise the subject subdivisions, and these subdivisions in turn are each further divided using the outer row of holes. For this discussion the six fields are assumed numbered one to six, from left to

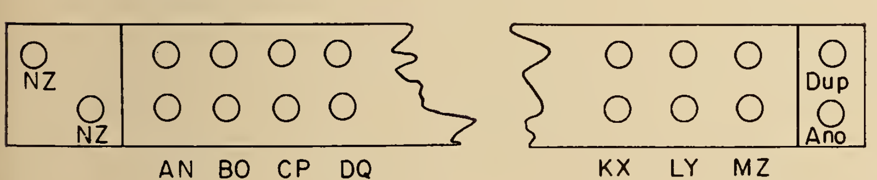

Fig. 5. (a) Author code (above). (b) Example: Copeland.

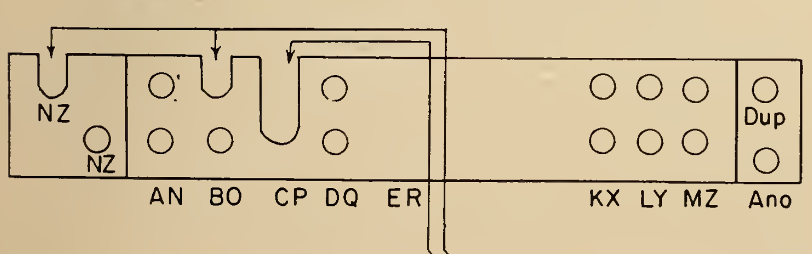

right (field six being thus the one on the same card edge as the main field). Subdivision is normally started at field five, hole 2, and proceeds left. Hole 1 of field five is reserved for the card index system. It is intended that field six be not used as are the other five. It is reserved; its inner row of holes could be used to subdivide any outer holes of the fields 1-5, and the outer row, as usual, to subdivide each inner hole topic further. We have not yet found it necessary to go this far. Hole NZ of field six again would be reserved for the functioning of the card index system, and not used in the subject breakdown. Summarizing, the scheme is this:

46 subjects	(Main field, inner row)
x 23 divisions	(Main field, outer row)
x 30 subdivisions	(Sub-Class. Fields 1–5 inner row)
x 30 branches	(Sub-Class. Fields 1–5 outer row)
x 5 sub-branches	(Field six, inner row)
x 5 final groups	(Field six, outer row).

There are thus about 20 million possible categories. Obviously, no one will use them all, but this large excess makes the scheme exceedingly flexible. It is even possible to abandon a scheme and start over with a new subject breakdown on a different part of the same card. The subdivision scheme shown is only one of many possibilities. A sample alternative would be to have on this edge two alphabetical fields (like the author field) which would allow four letters to be punched for word or title coding.

Now it is clear that such a large scheme cannot possibly be memorized. In fact even to prepare a skeleton outline of headings would be a formidable task. With punched cards neither is necessary. One of the outstanding features of the system is the facility with which a subject index can be prepared and consulted, with the cards alone as the only aid. The method of accomplishing this is described in the following paragraphs.

Operating Information and Instructions

The last hole position (XYZ) of the main subject field, like the last hole on a telephone dial, is reserved for information about the system. A sort through this position (inner XYZ hole) drops a card bearing a list of the main subject headings given in Table I. (Another card or two may drop, but ignore them for the moment). On the card also are the instructions for obtaining the list of the divisions of any subject on the card: "To obtain a list of the divisions of any subject (and their assigned holes) sort through the hole position of that subject, then through the outer XYZ hole position. On the card also will be found instructions for the next step."

Assuming that the procedure of the preceding paragraph has been followed, we now have a card with the list of subject divisions. The instructions on this card are as follows: "Sort through the subject division hole, then through inner hole 1 of field 5 of the sub-classification field to obtain the subdivision headings." The card obtained by following these instructions has, besides the subdivision headings (Table II), instructions for the next step. "Sort once through outer hole 1 of field 5 to obtain a list of the subdivision branches." This card again has instructions, and the process is repeated as above using inner and outer hole NZ of field 6 to obtain sub-branches, and ultimately, final group headings.

It is unlikely that the above scheme would be carried to completion for any subject. Normally, a stop is made at some intermediate point in the subject breakdown, the actual point depending on the number of cards in a category. Even some main subject headings may not be divided at all if interest (by that particular user) is limited.

To prevent confusion when several people share a file, it is wise to prepare a blank card for the next subject index step beyond that in use. Thus a person sorting for, say, the list of divisions of a main subject, when no division list had been prepared, would obtain a blank card to inform him of this fact. The blank card is later used for the list of divisions when it is eventually made. At that time also new blanks are prepared for each sub-division list (one blank per heading) to inform the user of this new terminal point. These blanks provide assurance that a sought-for list of category headings actually does not exist, and is not merely being overlooked through faulty sorting or through someone having removed it from the file for consultation.

Note that three (outer hole) sorts as follows: hole XYZ of subject field, hole 1 of field 5 and hole NZ of field 6 of the subclass field, will drop all cards relating to the subject index.

When the information hole (inner XYZ) was sorted and the list of main subject headings obtained, it was stated that a few other cards might also drop. One of these cards gives the list of coded sources, if one is used. This card was mentioned earlier in the description of the source field punching. It has the "coded source" position punched in addition to inner XYZ. Thus the "information" position serves both subject and source fields. It is also used when any of the "extra" holes X2, X3, X6, X7, X8 are used, the "extra" hole and the "information" hole being punched on a card which carries an explanation of the function. The information position is also used where anomalies in the system need explanation. As an example, one such card of ours explains that the coded source number 45 is not to be used. The reason is that 4 and 5 ("U.S. Military" and "University" sources, respectively) are *both* punched on many cards because they refer to work done at a University, but supported by the U.S. Military, and normally reports are available through Military channels. The anomaly of two sources results in double punching (4 and 5) which could be confused with a coded source (45) if used. As a matter of fact, it is always wise to sort a proposed punching code before adopting it, as the unexpected dropping of some cards will indicate it is already in use, if perhaps unknowingly.

Conclusion

The system described is not a panacea but, properly used, it can be a very great help. Some thought and care are necessary. The classifying of information is difficult. The equipment described will not do it for us, but it will facilitate the use of information that has been well classified. Its use should also give an understanding of the capabilities and limitations of the large machine-operated card systems which now are entering our everyday life. The cards shown in Figs. 1 and 2 are made by the McBee Co. and Copeland-Chatterson Ltd., respectively.

Economics of Pumped Storage

C. Jaeger

Consulting Engineer, The English Electric Company Limited, England

Condensation of a paper read at the 72nd Annual General and Professional Meeting of the Engineering Institute of Canada, Quebec City, May 1958

IN RECENT YEARS, renewed attention has been given to pumped storage and the eeonomics of eombined methods of power production together with pumping.

The analysis of this problem of economies can be dealt with from two different angles.

A. From the angle of general power requirements and demand: This leads to a mathematieal analysis of power systems whieh is the subjeet of a paper submitted to the Engineering Institute of Canada.

B. From the angle of actual power produetion. The best approach would be a systematic study of existing designs of pumped storage.

A. Economics of Pumped Storage from the Angle of Power Demand

This investigation on the economies of pumped storage started eonsidering an eleetrie system similar to the British system, which is rather compaet, and where addition of nuclear power is an urgent problem. The Canadian system, extending over immense areas, with still considerable hydro power potential in reserve and the possibility of additional seasonal and yearly storage of water, offers eonditions which are at the opposite of what the British system is to-day.

Can a method devised to analyse eonditions in the former system be adapted to eonditions in the latter?

The answer must lie in the method itself.

The paper deals with the economics of combined methods of power production and pumped storage, with a mathematical analysis of power systems. The full text will appear in *Water Power* (England) vol. 10, no. 6, 7, 8, 1958.

Planning of new sourees of eleetric energy is based on extrapolating the load demand eurves many years ahead.

Any suitable method of investigation must tend to reduee the number of free parameters to a minimum. The method submitted here is entirely based on the analysis of the load factors of the system and its eomponents.

It can also be shown that the balanee sheet of power and energy production by a group of stations depends entirely on these load factors too, as do the prices and eosts.

The system load faetor is a quantity which varies slowly with time and its trend ean be predicted several years ahead. A method of priee analysis entirely based on these load factors makes economie predietions fairly reliable and the method ean be adapted to a wide range of alternative eases.

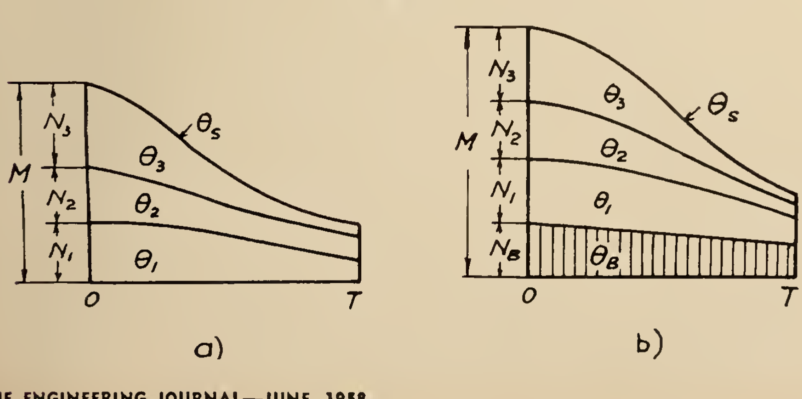
Let us look into the details of this method of analysis:

Any electric power system with a total installed eapacity M and a system load faetor θ_s can be broken down into system eomponents characterized by their installed eapacity $N_1, N_2 \ldots N_i \ldots$ and their load factors $\theta_1, \theta_2 \ldots \theta_i$ taken over a period T. (Fig. 1.)

The following general theorems can be demonstrated*

1. There is a linear relation between θ_s and $\theta_1, \theta_2 \ldots \theta_i \ldots$ depending only on $N_1/M \ldots N_2/M \ldots N_i/M$. This linear relation does not depend on the shape of the duration eurve derived from the load/time eurves of the system. (Fig. 2, below.)

Fig. 1.



Basic equations

$$\theta_s M = \theta_1 N_1 + \theta_2 N_2 + \ldots + \theta_i N_i + \ldots$$

$$\theta_s (M + N_m) = \theta_1 N_1 + \theta_2 N_2 + \ldots + \theta_i N_i + \ldots + \theta_m N_m$$

Condition of no change in existing system $\theta_s M$ is:

$$\theta_m = \theta_s$$

Condition for change of load factor θ_i to $\theta_i' = \theta_i + \Delta\theta_i$

$$\theta_m = \theta_s - \frac{N_i}{N_m} \Delta\theta_i$$

*These theorems are demonstrated at full length in the original manuscript submitted to the E.I.C. and to be published in June, July, August by "Water Power", London.

2. Any new source of power with capacity N_m and load factor θ_m added to an existing system $(M\theta_s)$ may change the load conditions in the system components $(N_i\theta_i)$. The condition for no change to occur in the existing system is $\theta_m = \theta_s$.

In the more general case

$$\theta_m = \theta_s - \frac{N_i}{N_m}\Delta\theta_i$$

where $\Delta\theta_i$ is the change occurring in the system $(N_i\theta_i)$ owing to the addition of a new source of energy $(N_m\theta_m)$. This fundamental relation will allow us to relate the price analysis of the new system to price changes occurring in the component "i".

3. More detailed investigations, especially investigations concerning pumped storage, require the exact knowledge of the true duration curve of the system. For the sake of theoretical system analysis, the true duration curve can be replaced by a convenient mathematical curve which can be integrated.

The choice was for the so called Soschinski function, which is found to match actual duration curves in a great number of cases, particularly those for large systems. This function shows the load N at the time t $(0 < t < T)$ to depend only on θ and $\theta_0 = m/M$ where

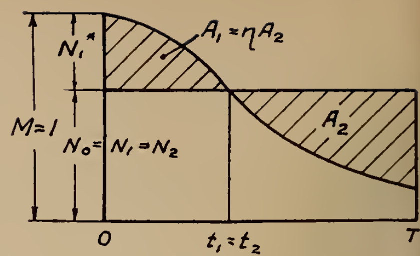


Fig. 4.

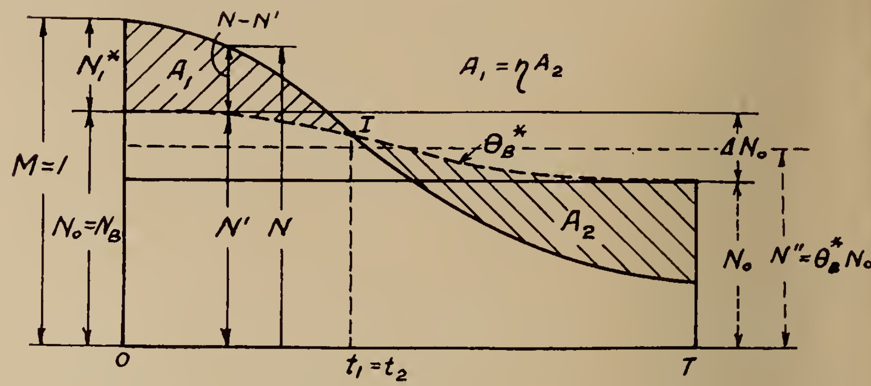

Fig. 5.

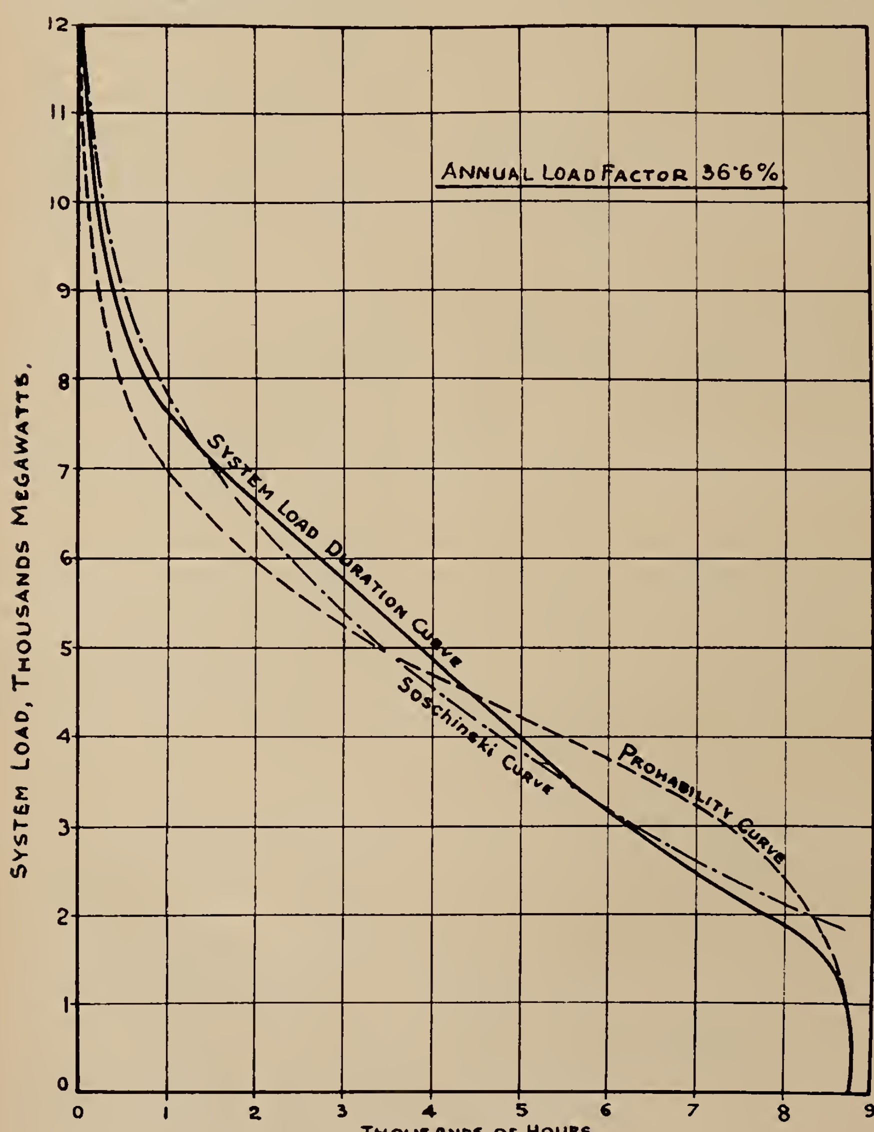
Fig. 3. 1957 load duration curve for England areas.



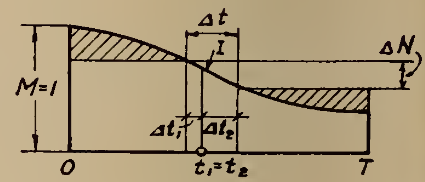


Fig. 6.

M is the maximum (installed) capacity; m the minimum required load. (Fig. 3.)

The Soschinski function is

$$N = M[1 - (1 - \theta_0)t^{(\theta-\theta_0)/(1-\theta)}]$$

Both θ and θ_0 can be predicted from a number of real load duration curves.

The basic problem for which the Soschinski curve will be used is to find out the best possible utilization of a given pumped storage or the theoretically best design and suitable capacity for a pumped storage to match a given base load station. If A_2 is the energy required by the pumps and A_1 the energy generated by the generating sets in the pumping scheme, then $A_1 = \eta A_2$ where η is the overall efficiency of the pumping scheme including transmission losses. (Fig. 4.)

The basic problem corresponds to an ideal case of full utilization of the base load $(\theta_B = 1)$. For practical purposes the following additional research will be required:

Comparative estimates will be carried out for a base load characterized by $\theta_B = 1$ and by $\theta_B < 1$. (Fig. 5.)

When there is a time lag Δt between

Basic equations

Soschinski Curve

$$N = M\left[1-(1-\theta_0)t^{\frac{\theta-\theta_0}{1-\theta}}\right]$$

Energy equation for pumping:

$$A_1 = \eta A_2$$

Effect of time gap Δt: $\Delta N = \left(\frac{dN}{dt}\right)_{t_0}\Delta t$; $\Delta E = \Delta N . T$

Variation of efficiency: $\Delta N_2 = \Delta N_1 + \frac{\eta_1 - \eta_2}{T} A_2$; $\Delta\Delta A = (\Delta N_2 - \Delta N_1)T$

Price equation

$$k = nN + mE$$

Fig. 7.

the stopping of the pumping and the beginning of generation, there is a loss of power ΔN and energy ΔE given by

$$\Delta N = \left(\frac{dN}{dt}\right)_{t_0} \Delta t, \quad \Delta E = T \,.\, \Delta N$$

(Fig. 6, 7.)

The overall efficiency of a system combining pumping and generating depends widely on the transmission distance between the primary base load station and the pumping station. When two alternatives corresponding to efficiency factors η_1 and η_2 have to be compared, the loss of power for both alternatives is given by

$$\Delta N_2 = \Delta N_1 + \frac{\eta_1 - \eta_2}{T} A_2$$

4. A detailed balance sheet has to be established for all energies generated, transformed and lost. (Fig. 8.)

It can be shown that such a balance sheet can be traced graphically and that the only variables to be considered are θ (the load factor of the demand curve), θ_B (the load factor of the base load station) and the overall efficiency η for pumping.

5. Most of the problems of cost and prices can be represented by fairly simple mathematical functions. So can the problem of the price of electrical energy, which is of the form

$$k = nN + mE$$

where N = installed capacity; E generated energy, n and m constant factors which can be shown to depend mainly on θ.

Summarizing this, it can be shown how the whole problem of costs and prices—analysed from the point of view of the demand for more power—depends mainly on the load factor analysis, the main free parameters being θ_s the system load factor and θ_B the base load factor.

Figure 9, referring to hydro power combined with pumped storage, is most instructive: k_w is the price of 1 kwh. produced in a hydro power plant working alone (capacity N_w); k_p is the price of 1 kwh. of energy generated in the pumping plant with capacity N_p and k_{w+p} is the cost of the unit energy generated in a combined system of water power supplemented with pumped storage. The system load factor θ_s is the main variable and the ratio k_p/k_w the main free parameter. The condition $k_{w+p} \leq k_w$ for the combined system to be economical is obtained for a wide range of values k_p/k_w as shown on this Fig. 9. It is possible with such a diagram to estimate a limit for which the

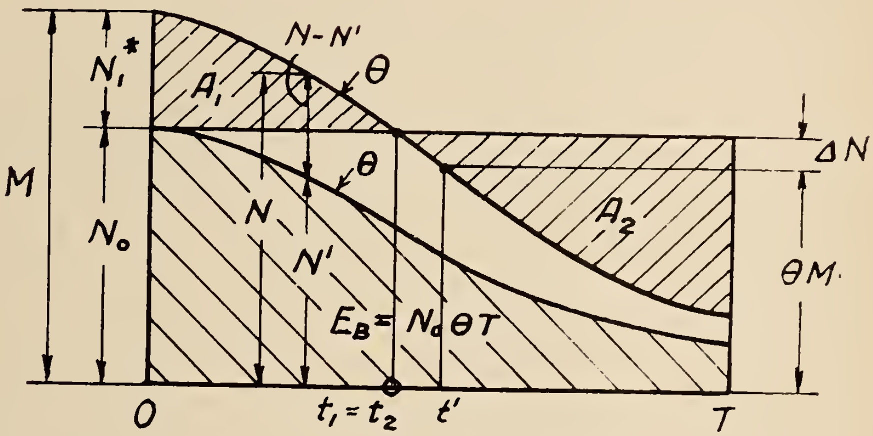

Fig. 8. (above). Fig. 9. (below).

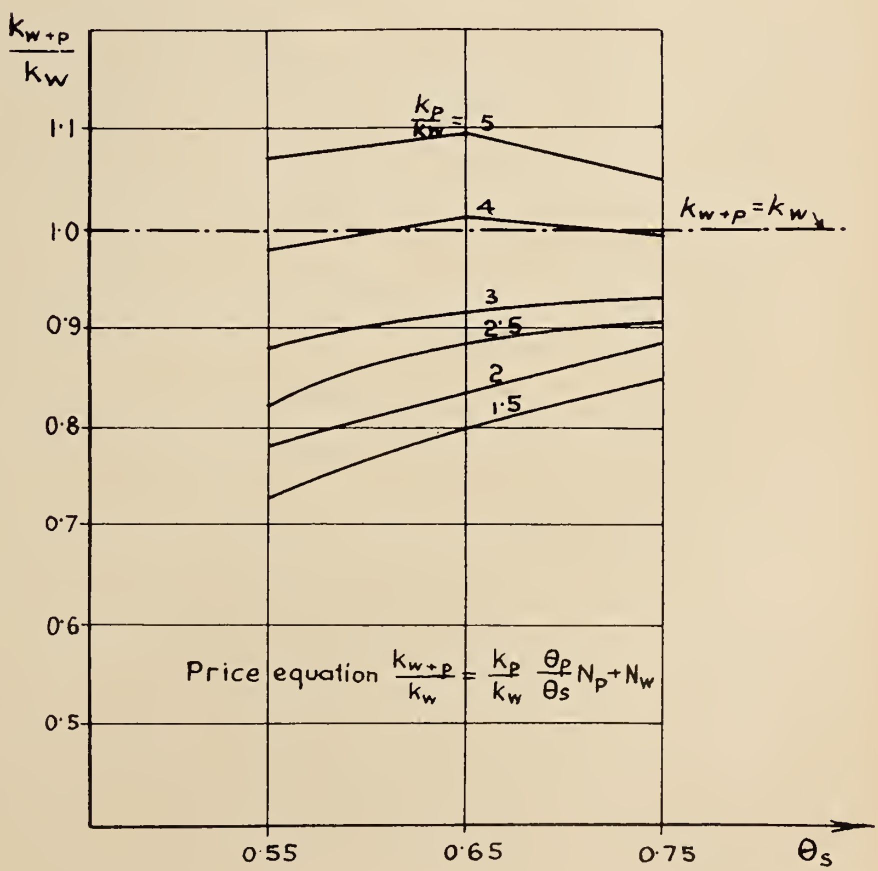

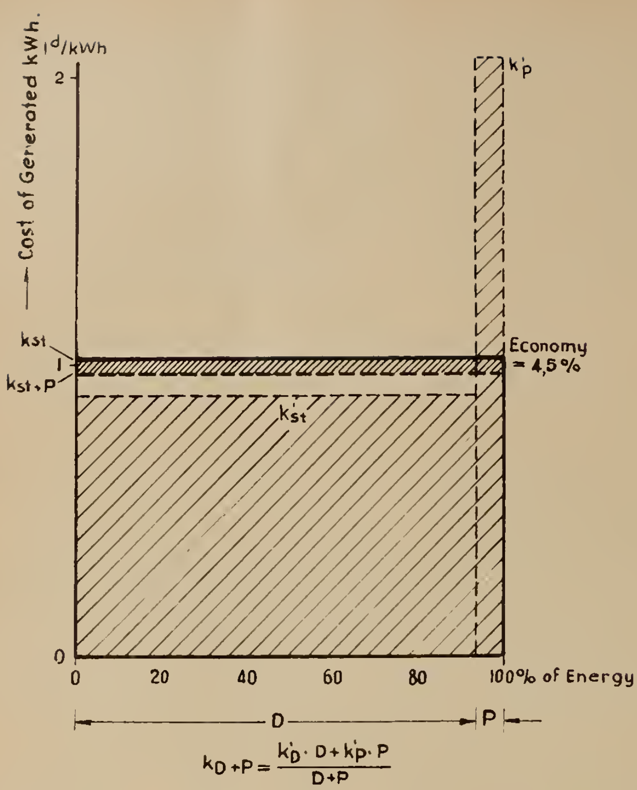

Fig. 10. Compared cost of power generation for steam and for steam plus pumped energy.

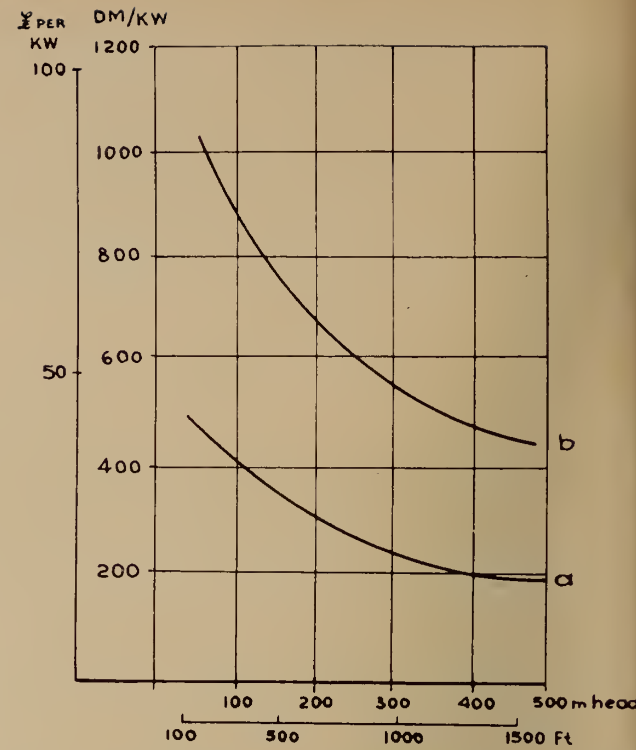

Fig. 11. Cost of German pumped storage stations in DM. or £ per kw. for head from 100 to 1500 ft. (a) Costs in 1926-1930; (b) costs in 1956 average.

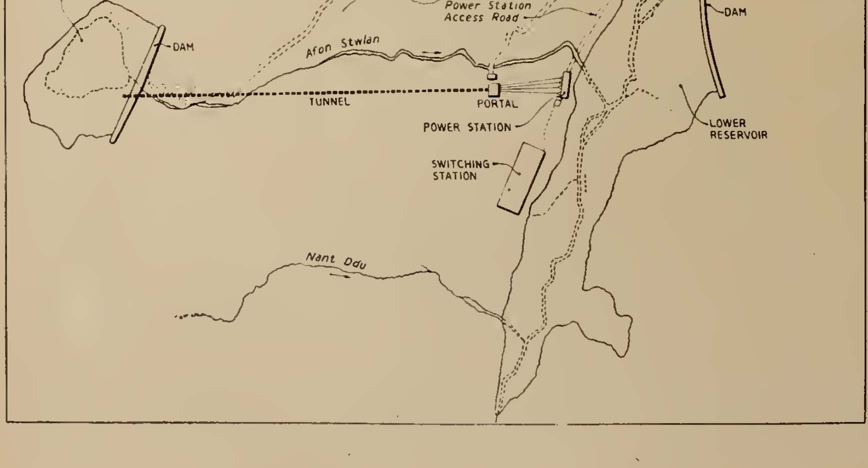
ratio of costs per kw. or prices per kwh. is in favour of hydro alone or of combined hydro power and pumped storage.

An equivalent diagram is easy to trace for combined nuclear power and pumped storage. Both diagrams show that it is economical to add large pumping stations to a system basically fed by run-of-river stations or by nuclear power. Substantial savings are possible, up to 20 per cent. on the price of the kwh. generated.*

The combination of steam power and pumped storage leads to more intricate calculations, because the cost of coal must be included as a main variable of the problem. The diagram Fig. 10, above, of the Energie Versorgung Ost Bayern in Bavaria shows such a combination to be economical. But data from other countries (U.S.A.) show that this combination is often a marginal case. For practical purposes a combination of run-of-river power, thermal energy, and pumped storage will often have to be considered.

Fig. 12. Sketch map of the Ffestiniog scheme in North Wales (according to V. G. Newman, BEAMA Journal).



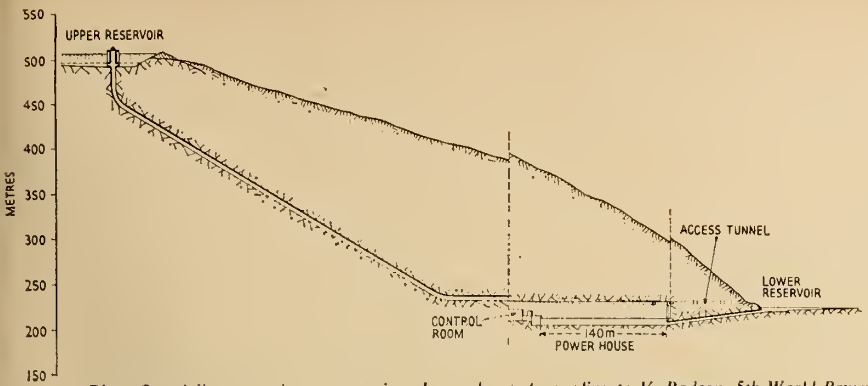
B. Research for Suitable Practical Solutions (from the Production Angle)

The second point to be discussed concerns practical pumped storage designs which can be commended as being economical proposals. The best approach is to review typical schemes and to comment on them from the angle of their economical advantages.

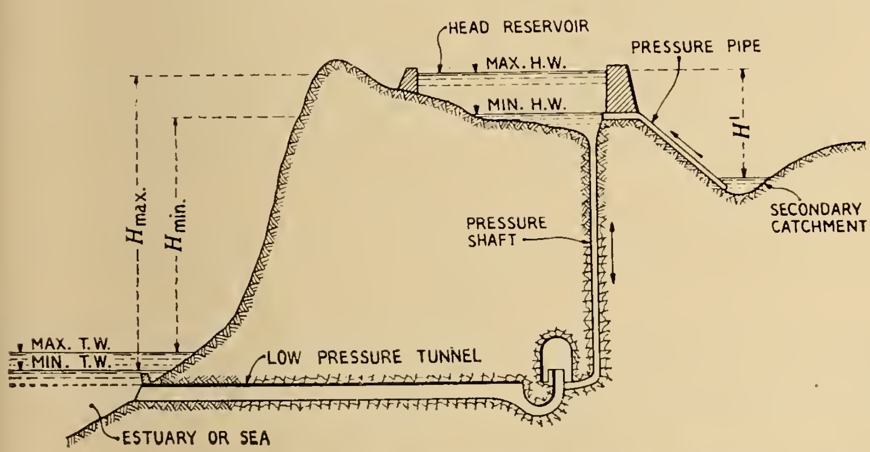
1. *Pure and Mixed Pumped Storage*

Pumped storage is said to be pure pumped storage when the total discharge and the head are the same for the pumps and the turbines, or mixed pumped storage when there is more water passing through the turbines than through the pumps and/or when the head available for power generation is

*Full details will be given in the August issue of "Water Power".



River Our daily pumped-storage station, Luxembourg (according to V. Bodson, 5th World Power Conference)



greater than the head against which the pumps have to work. Typical example of the first arrangement are *Ffestiniog* (300,000 kw.) (Fig. 12) in Wales or *Our* (320,000 kw.) in Luxemburg (Fig. 13).

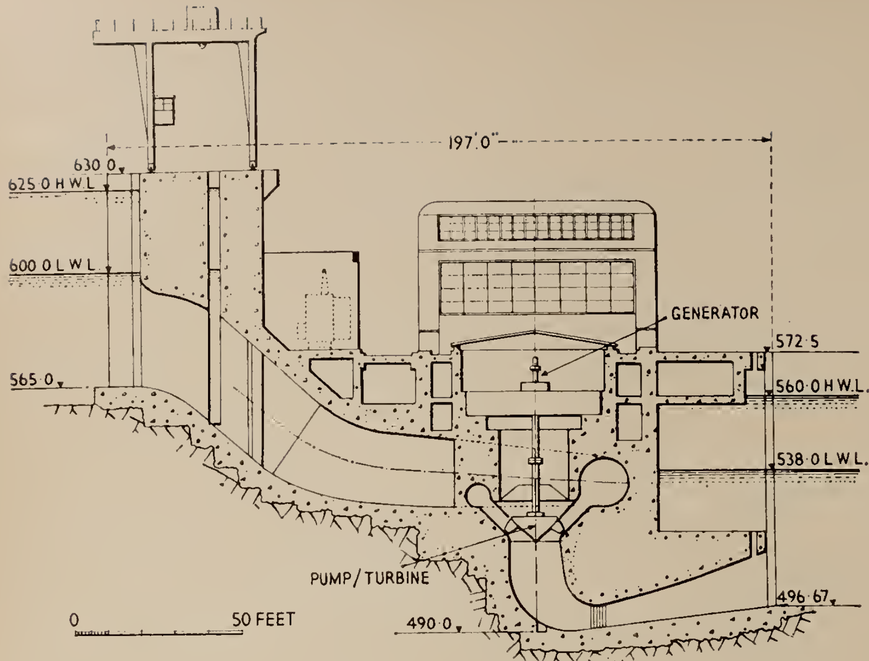
The first station uses conventional pressure tunnel, surge tank and pipe lines, the second, built in the centre of the West-European coal industry, is underground with an inclined shaft. It has also been suggested to use cliffs near the sea for installing pumping stations of this type (Fig. 14). The Sir Adam Beck Niagara pumping station in Ontario (20,700 kw.) is a well-known example of conditions where the total head available for power generation is larger than the pumping head. (Fig. 15 and 16.)

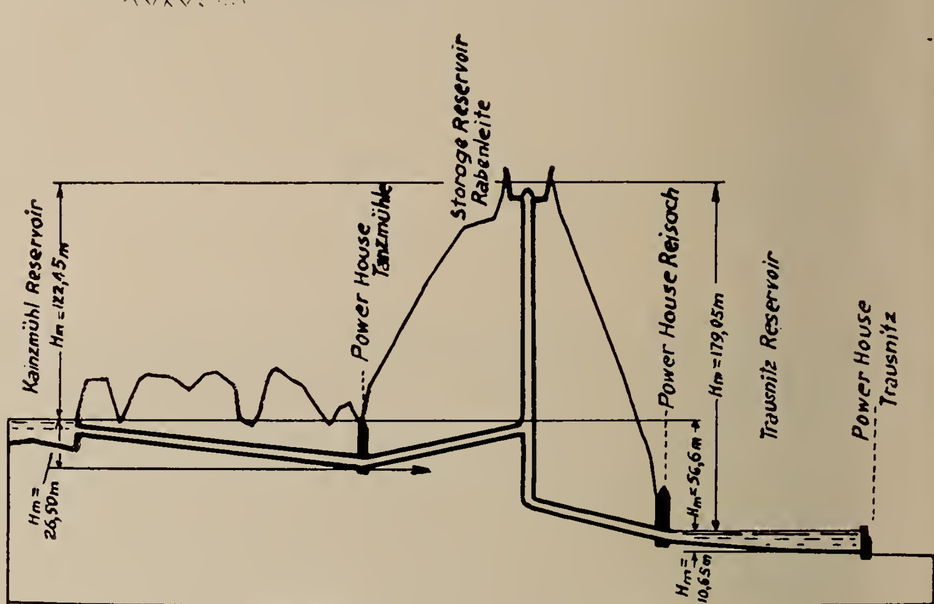
Reisach in Bavaria is a more complicated design: there are two low level reservoirs with two stations equipped with pumps and turbines but only one common high level storage reservoir. By skilfully combining these three reservoirs it is possible either to produce a maximum of kwh. or to have the highest possible capacity in kw. (Fig. 17.)

Fig. 13 (top left).

Fig. 14 (left).

Fig. 15 (below). An aerial view of the Sir Adam Beck-Niagara generating stations (E, F) with the reservoir for pumped storage (L).





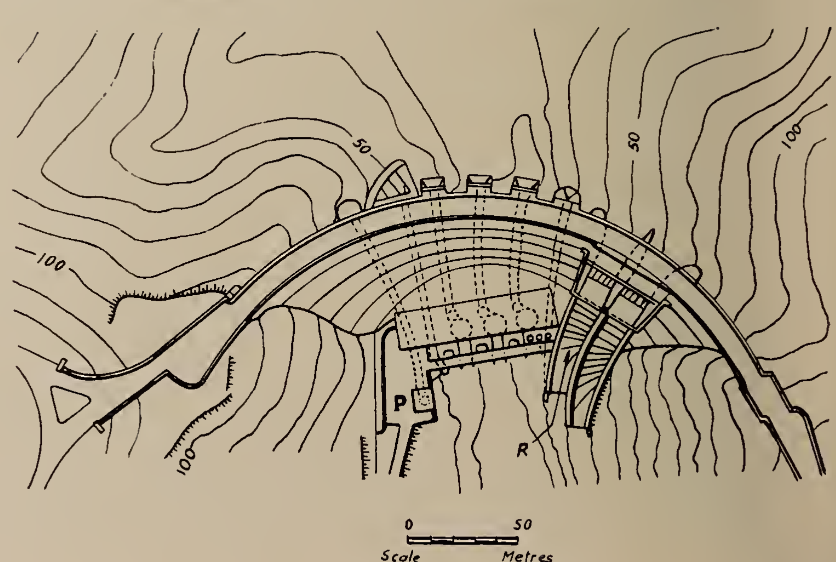


Fig. 16 (top). Section through the Niagara pumped-storage station showing the extremely compact layout obtained with a reversible Dériaz pump-turbine.

Fig. 17. Reisach pumping scheme (Bavaria).

Fig. 19. (below, r.). Diagram of English Electric Company arrangement to improve an existing low head scheme. (Fig. 18 is on p. 73.)

2. *Effect of Head on Price of Pumped Storage*

Another remark concerns the total head of a pumping station. Comparative price studies based on German pumping stations show the price per installed kw. to decrease with the pumping head. This is easy to visualize. (Fig. 11.)

3. *Availability of Excess Energy*

An even more striking difference exists between daily storage, weekly storage and yearly storage, with rapidly increasing unit prices when passing from one type to the next. This last problem is linked with the availability of excess power. In the past the market analysis for excess power has received possibly too little attention. From the point of view of pumped storage economics it is of great importance. Cheap generation of pumped energy is possible only if excess power is available in convenient quantities for convenient periods of time. In favourable cases, daily or weekly storage may be possible. If not, yearly storage may have to be considered which is a quite different proposal.

(*a*) *Cheap night power always available.* Let us suppose a base load nuclear station running at a very high load factor θ_B. Excess power will be available every night, all over the year, and combination with a daily or weekly storage is attractive. It can be shown to be economical and the economy on the generation of 1 kwh. can be as much as 20 per cent. or more.

It is estimated that in Canada nuclear energy compared with conventional steam energy may become economical about the year 1980. If pumped storage is considered in combination with the production of base load, then the point of equal production costs may come several years earlier.

Another most interesting solution concerns the case of a large run-of-river station capable of producing constant yearly power. The station may be assumed to be located at a great distance from the centre of load consumption. Only base load is to be transmitted over such a distance. A pumped storage scheme located near this centre produces the corresponding daily peak load and considerably improves the conditions for overall cheap power production. Such conditions are likely to occur in Canada, where vast resources of potential energy are available in the far north of the country.

In both cases mentioned, the basic fact is that cheap constant base load power is available over long periods when the pumps can work to make daily generation possible at a convenient load factor.

(*b*) *Excess night power available only over limited periods.* The opposite example concerns run-of-river plants where excess power is abundant during the rainy period but scarce during the dry season. Such conditions are characteristic of the European Alps: power is scarce when most required and yearly storage has to be considered. *Wäggital* and *Etzel* in Switzerland are well-known examples of yearly storage, where additional pumping of water during the wet season is used to fill existing conventional water power reservoirs for generation during the dry season. The two schemes are mixed pumping schemes, and the large reservoirs were first built for conventional production of hydro-power only.

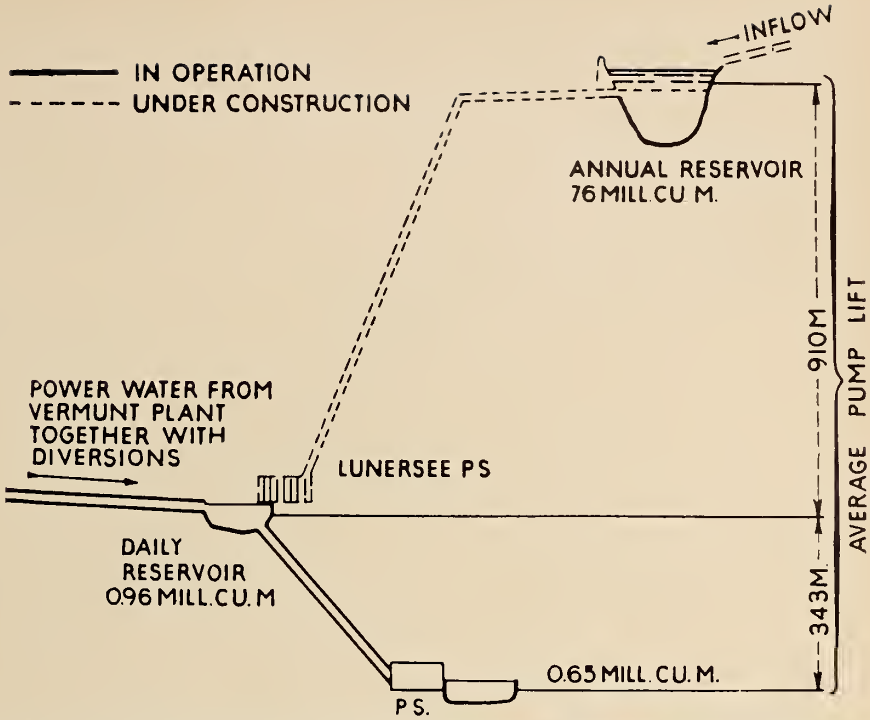

Fig. 18. The Rodund and the Lünersee pumped-storage schemes of the Vorarlberger Illwerke (according to A. Ammann, 5th World Power Conference).

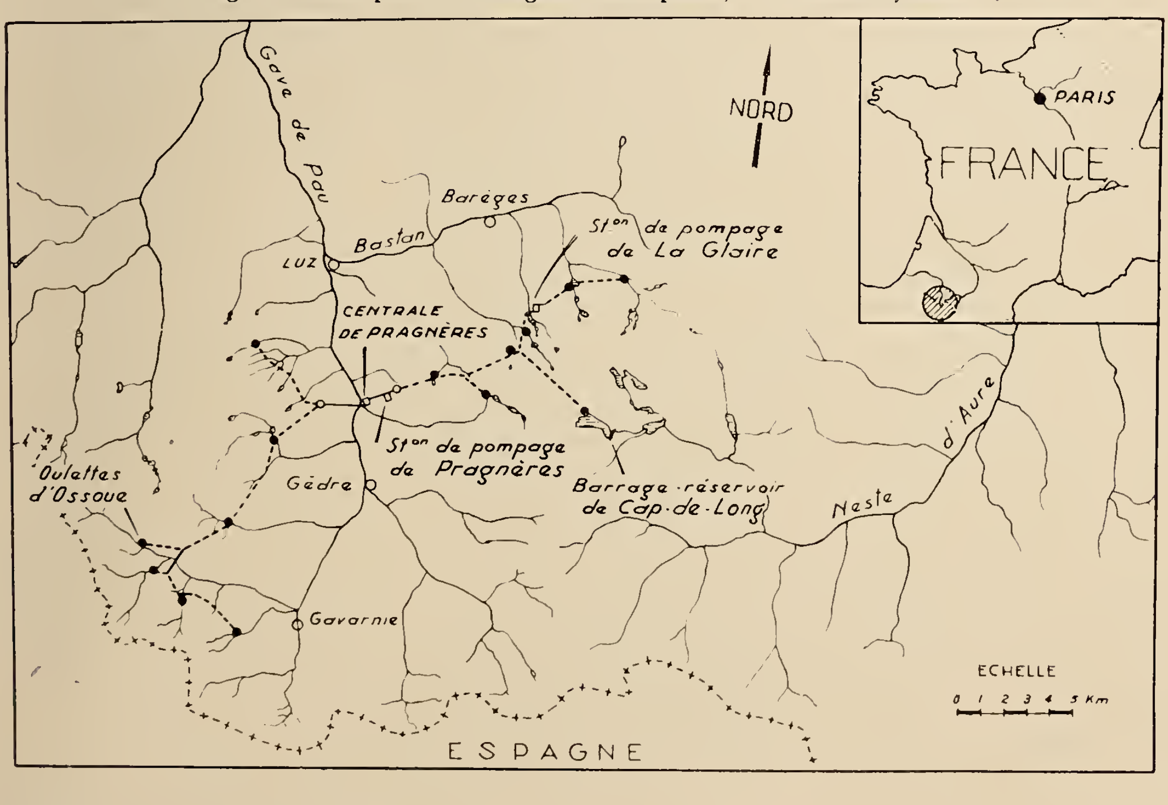
An alternative solution to this arrangement is shown by the *Illwerke* in Austria, where a daily storage (170,000 kw.) and a yearly storage reservoir (217,000 kw.), with its own catchment area, are used simultaneously. The

Fig. 20. General plan of the Pragnères development, in the French Pyrenees.



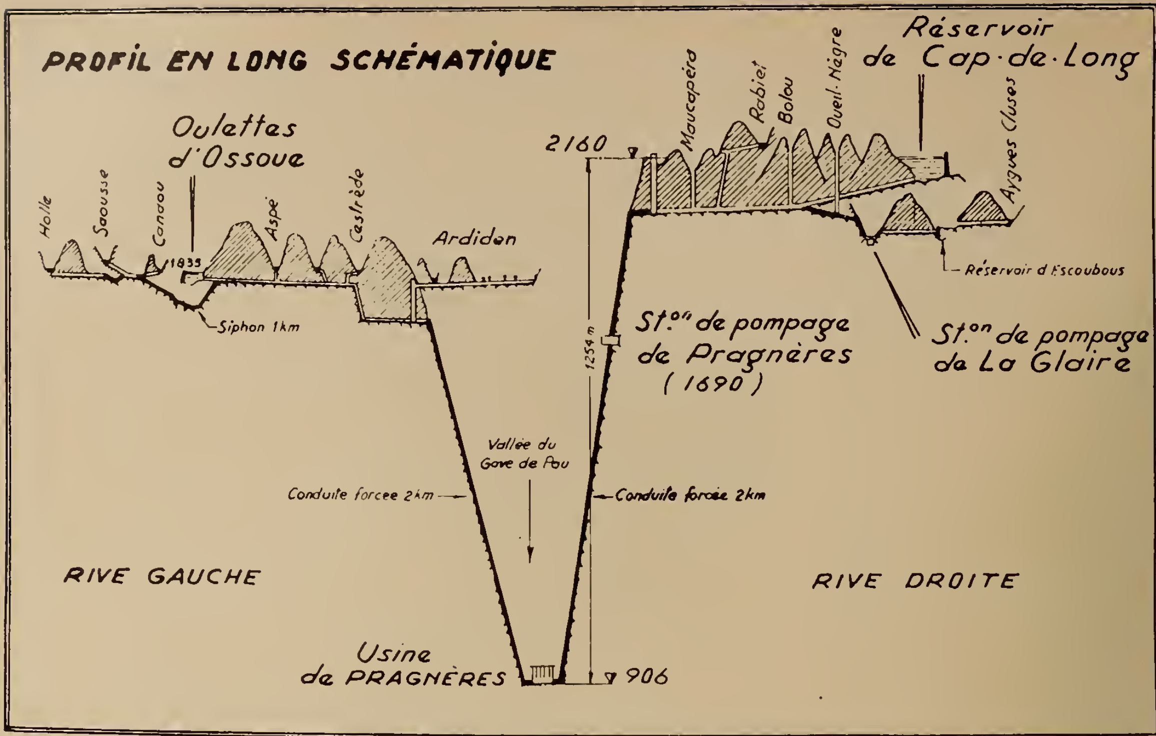


Fig. 21. Schematic profile of the Pragnères development.

Illwerke are designed to be the main regulator for power generation and frequency regulation on the central European system. (Fig. 18.)

4. *Extension of Existing Conventional Hydro Power Schemes*

Reverting to mixed storage schemes, the introduction of pumped storage to existing conventional hydro-power schemes may be a rewarding solution.

The diagram Fig. 19 shows an arrangement the English Electric Company submitted to one of their customers to improve an existing low head scheme. The existing plant is equipped with three Francis turbines. An additional Dériaz pump-turbine "P" could be added. Pumping water during the night, whenever excess power is available in the system, increases the available peak load during the next day. It also maintains high water levels in the reservoir over a longer period, compared with conventional running conditions and improves conditions for power generation during the dry period.

Enlarging existing high head schemes by adding a pumping set is another solution worth considering. To some extent it may be possible to extend the scheme without increasing the physical dimensions of the existing dam, tunnel and galleries or shafts. It has been shown that there is a limit to such improvements, owing to additional friction losses in the conduits.**

Far larger extensions of existing schemes may be considered. The extension scheme for the *Loch Sloy* hydro-power station near the city of Glasgow in central Scotland forsees a series of entirely new powerful pumping-generating stations, located underground, added to the existing conventional hydro-power station. The existing dam would be the only item not to be duplicated for the pumping station, which capacity (up to 1 or 2,000,000 h.p.) would by far exceed the capacity of the existing hydro-power station (200,000 h.p.). The capital cost for the new pumping capacity would include only the galleries and shafts and the machinery. Base load power would be mainly excess nuclear power generated during the night.

5. *Pumping Used to Increase the Potential Energy of Stored Water* (Fig. 20, 21.)

The last example to be referred to is the *Pragnère* development in the French Pyrenees: water is pumped up 325 m. into a reservoir and is then used for generation with a total head of 1,254 m. The economics of such a system, of which there are many examples in the Alps, is based on the increase of potential energy.

DISCUSSION

Discussion of technical papers and other articles in *The Engineering Journal* is welcomed.

Written contributions should be sent to the Editor, at 2050 Mansfield Street, Montreal 2, Que.

INTERNATIONAL NEWS

Research in Switzerland

COMMUNICATIONS from Dr. Edward Fueter, of Zurich, describe the organization and progress of nuclear research, and the work of the industrial research centres in Switzerland.

Nuclear Research

With a long tradition of scientific research, Switzerland has advanced considerably in the field of nuclear studies. Professor Albert Einstein, a citizen of Zurich in 1910, here developed his theory of relativity. In the 1930's a huge magnet was installed on the Jungfraujoch at the International Scientific Station, where studies of cosmic rays are made at a height of nearly 10,000 feet. Professor Wolfgang Pauli, Nobel Prizewinner for Physics, established the Pauli principle of exclusion from his work at the Federal Institute of Technology, Zurich.

Professor Paul Scherrer, of the same Institute, built one of the first cyclotron and cascade generators for laboratory use, and became the first president, in 1946, of the Swiss Committee for the Study of Atomic Energy. In each of the seven Swiss universities work has proceeded on the new science. Contributions have been made to the theory of mesons, and work has been done at Neuchâtel on applying atomic physics in the watchmaking industry.

Industrial developments include the world's first prototype of a Betatron (an induction accelerator) capable of producing 31 million electron-volts for therapeutic use, installed in 1951 at the Cantonal Hospital at Zurich, followed by further such installations in Europe.

In 1956 a Swiss firm produced a nuclear-energy/gas-turbine combination for small and medium sized power stations, and at the end of 1956 a group of industrialists offered to supply 'ready for use' nuclear power plants of various sizes.

Switzerland is admittedly behind the leaders in nuclear energy applications, but looks forward to developing a flourishing export industry of instruments and machines for the exploitation of nuclear energy. Laboratories must be created, staffs trained, and finances found. The Federal Government has drawn up a general program, headed by Director O. Zipfel, by which nuclear power stations in Switzerland should produce about 6,000 million kw. annually by 1975. This will provide the necessary power after harnessing all available hydraulic resources. The experience gained will be channelled to helping other countries.

Projects costing about 100- to 200-million Swiss francs are being prepared for the next five years. An organization 'L'énergie nucléaire' will concentrate the efforts of the four French-speaking universities and of Ecole Polytechnique, at Lausanne, to build a powerful reactor.

At Meyrin, near Geneva, a European Nuclear Physical Laboratory is being built by the Conseil Européen de la Reserche Nucléaire (CERN), at a cost of 220 million Swiss francs (about $50 million). This is the result of the united efforts of 12 European countries: Belgium, Denmark, France, the German Federal Republic, Great Britain, Greece, Italy, Yugoslavia, Norway, the Netherlands, Sweden, and Switzerland. Two-thirds of the cost will be borne by France, Great Britain, and Western Germany. Non-European scientists will also be admitted, and the Ford Foundation has recently made a donation of $400,000 for this purpose. A 600 Mev. synchro-cyclotron has been built, and a 920-ft. diameter proton-synchroton will be ready by 1960.

The CERN Institute has had help from the work of international teams of scientists working at the Alpine Research Station, where fundamentally important discoveries of the disintegration of mesons disclose a new chain of relations between the smallest elementary particles.

The proceedings of a 1956 meeting sponsored by CERN include such considerations as the acceleration of protons up to 1.25 x 10^{13} electron-volts at the plasma stage, in a circuit of about 10 ft. using magnetic fields of the order of 10^6 Gauss.

To build expensive installations, including reactors now under development, and to expand its activities, Switzerland has the assistance of the United States, as covered by an agreement made in 1956, which will assure the supply of concentrated uranium ore and supplementary materials, while respecting the independence and neutrality of Switzerland. Recently another agreement was concluded with France for collaboration in the field of nuclear energy and exchange of experience and personnel.

Work is now under way to amend the Federal Constitution and to authorize the Confederation to pass legislation for the protection of the public and for the prevention of accidents due to radioactivity.

The second international conference on the peaceful uses of atomic energy will be held in Geneva, 1-14 September, 1958.

Literature

A list of publications dealing with nuclear energy developments in Switzerland may be obtained from the Editor of the *Journal.*

Industrial Research Centres

As in all highly industrialized countries, research centres of private enterprise in Switzerland have assumed great importance in the 20th century. Together with the laboratories and testing plants of the universities and public institutions, they are an important factor in the competition for international markets.

Since the economic crisis of the 'thirties, private research centres have developed rapidly. From small staffs of a few scientists at the turn of the century, large enterprises may now permanently employ a hundred or more scientists or engineers. This is particularly so in chemical and engineering industries. One Swiss combine producing pharmaceuticals, dyestuffs, and synthetic materials spent 19 million francs on research in 1947 and 36 millions in 1955; corresponding turnovers were 478 and 783 millions. This expenditure of about 5 per cent is in line with allocations made in other countries. In some pharmaceutical and engineering firms the percentage is higher.

Facilities naturally vary, but one mechanical and electrical engineering organization has high-tension laboratories, a high-power testing plant, an electrical apparatus laboratory, a testing plant for lightning arrestors, testing plants for steam turbines, laboratories for combustion and flow research, three separate centrifugally stable remote-controlled testing beds for horizontal-axis machines, and so on.

In general, basic research is the concern of the scientific institutions, and applied research and development that of industry.

In addition to libraries for use by individual companies, some facilities are available to a wider field; for example, the Iron Library of Messrs. Georg Fischer, at Schaffhausen, and the Drug Collection of Messrs. Siegfried & Co., at Zofingen.

Only recently has contract research become commonplace in Switzerland. Substantial orders have been placed with the Federal Institute of Technology, particularly with the department for industrial research, and with such annexes as the 'International Division' of the Batelle Institute, in Geneva. In principle, however, Swiss industrialists tend to finance and carry out their own applied research, though they have made several generous contributions towards basic research at universities.

To make industrial research financially self-supporting, licence agreements are often made, which transfer results of research, patents, and inventions to foreign undertakings. This 'intellectual export' is considered a necessary and logical way of keeping self-supporting a country which is notably short of raw materials.

Branches of industry which have modern research laboratories have steadily increased their exports for at least a decade, underlining the importance of industrial research. However, overall success is based on the interaction of many factors, and without an excellent standard in general and technical education there would be no trained recruits for industry. A will to work, an ordered State, a sense of responsibility in leading personalities, and a pioneering spirit are all essential to the organization of the full value of industrial research centres and the justification of the large sums of money invested in them.

NOTED SWISS SCIENTIST

Tribute was paid to Prof. Jakob Ackeret, professor for aerodynamics at the Federal Institute of Technology (ETH), on the occasion of his 60th birthday in March 1958.

At Prof. Dr. Ludwig Prandtl's Aerodynamic Experimental Institute, in Göttingen, Germany, he wrote treatises on aerodynamic conditions on rotating cylinders (the Flettner rotor, used for the propulsion of ships) and other subjects. Returning to Switzerland in 1927, Prof. Ackeret extended and modernized the fluid dynamics laboratory of Escher Wyss Ltd., of Zurich, and organized a team which produced outstanding results in the field of turbine, pump, and propeller design.

In 1928 he established the linearized supersonic theory named after him, at the same time introducing the now well-known term of 'Mach number' for the ratio of the speed of flight to that of sound.

His work on the problem of cavitation was published as a chapter in the Textbook of Experimental Physics.

United States

MODERN SURVEY METHODS

Highway Information Services, of Washington, D.C., tell of the latest methods being used on surveys of routes for the construction of the new 41,000-mile National Interstate System of superhighways.

To establish the numerous ground control points, use is made of the tellurometer, basically a system that measures distances between a transmitter and a receiver of microwaves from the transmission and return interval. Weather conditions do not affect the measurements, and there is no need for the operators at the two points to be within sight of each other. The net result is an immense saving in time and cost.

The method is accurate to about one part in 300,000 on long stretches, or about 11 inches in 40 miles.

Each unit, transmitter and receiver, can be packed by two men, and the procedure is for the transmitter team to set up at a base line while the other team goes ahead to the 'unknown' point previously set by a reconnaissance crew. Contact is established by swinging the transmitter until a maximum signal is returned, as indicated on an oscilloscope. Both teams can talk to each other by radiophone. (See cut)

The transmitter then sends out signals and measures the return interval, using five to ten coarse and fine readings from a band of 20 frequencies to ensure accuracy.

A refinement of the technique has been used in Virginia to establish second order traverse stations every few miles along the centreline, running them in from Coast and Geodetic Survey stations about 15-20 miles apart and several miles off the proposed route.

This refinement involved the use of a chartered helicopter to ferry crew members with their instruments from one hill top to the next. In average weather it was found that the four-man crew could establish points at the rate of one an hour, including reconnaissance and turning angles.

The helicopter averaged 50 short flights a day, many of which took only a few minutes compared with an hour of hard climbing with all the equipment.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Progress by Ontario Hydro

Weather conditions generally throughout the month of April were favourable for construction work. The project work staff was increased slightly and at month end there was a total of 2,730 workers.

The No. 5 turbine runner assembly was put into position in the unit during April. All the head gates were in place and work on the hoists was well underway. Seven sump installations had been completed. During the month, the compression room work advanced favourably and was about 75 per cent completed.

Stator frames were installed in units number five and seven and the windings were started on these sections of the generators in the Canadian half of the power-house during the month. Lower bracket was installed in number four unit. Assembly of the rotor for number four unit was about 90 per cent completed, while the work of assembling the rotor for number two unit was about 70 per cent finished. Both of these rotors will be ready for installation early in May.

All the control equipment had been installed for the first four generator units and approximately 50 per cent of the installation of control cables had been completed. Installation of 230-kv. power cables through the tunnel from the power-house to the terminal structure had been started. The switch gear building for units five to eight was nearly complete and installation of electrical equipment had commenced. Meanwhile, wiring was progressing favourably in the control room.

The 1958 program in the 230-kv. section of the St. Lawrence transformer station was approximately 70 per cent completed. At the month end, work had progressed on the control building so installation of equipment could be started. Installation of circuit breakers at the transformer station was well advanced.

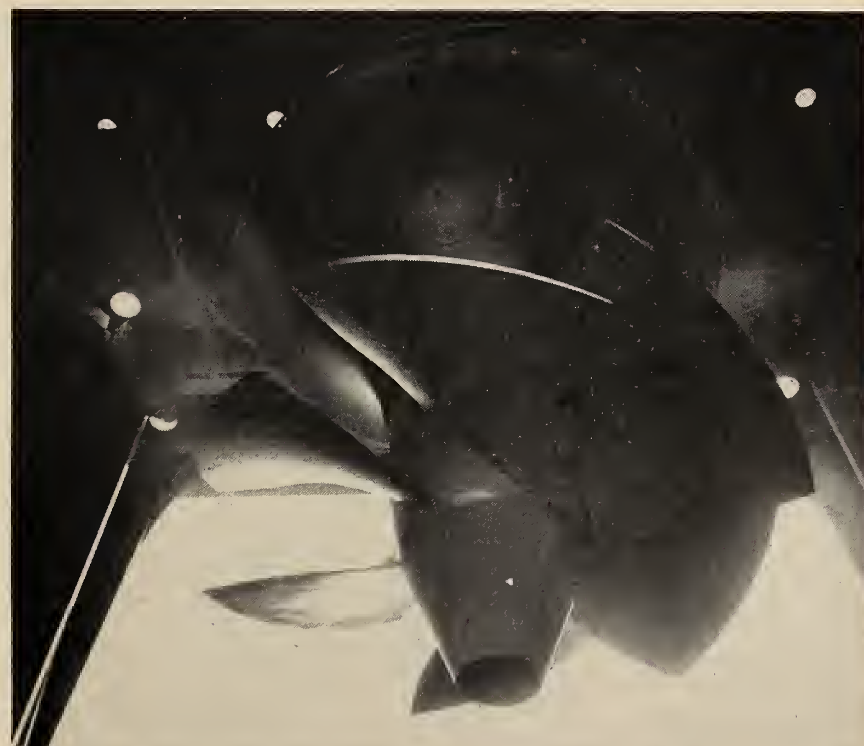
Rail connections to the power-house from CNR were removed. Work was resumed on the railway overpasses. At all four dredging contracts to improve the channel, the equipment was at work. Dragline operations were proceeding to remove the upstream half of the cofferdam at Point Three Points.

Final clean-up work was underway from Iroquois east and from Cornwall west to clear the north shore of the St. Lawrence in preparation for flooding.

It was later made known that the 34,000 acre headpond would be flooded early in July. Control will be established, in a 4-day process, by the Iroquois dam, the Massena intake, and the Long Sault dam, and the headpond for the international power-house will be brought to a predetermined operating level. Shortly afterwards, the power turbines will go through their first test run under operating conditions.

Progress by NYSPA

April was highlighted by the flooding of the area between the downstream side of the power plant and



St. Lawrence Power dam. The runner assembly for Unit 28 is suspended by gantry crane before lowering into place in unit.

cofferdam C1. Concrete in place for all structures totalled 1,976,000 cubic yards or 96 per cent of the estimated total. Excavation quantities had reached 50 million cubic yards or 94 per cent of the estimated total. Employment averaged 3,200 for the month.

At the American half of the power plant some 16,000 cubic yards of concrete were placed, bringing the total placed to 964,000 cubic yards. Cofferdam C1 was breached on April 1, and the tailrace area was filled to the level of the river on April 6. Steel piling is being extracted from the cofferdam cells adjacent to the international boundary. Five motor control centers were energized in the power plant. Aluminum conductors were being strung on the Reynolds Nos. 1 and 2 and Alcoa No. 6 transmission lines.

At Long Sault dam, removal of cofferdams "DU" and "DD" was completed except for one cell which will be removed when the construction bridge is removed. The entire flow of the river was being diverted through the diversion tunnels. Approximately 91 per cent of the required concrete had been placed.

Channel improvement work continued in the upstream and downstream areas of Toussaints Island. At Point Three Points sweeping of the upstream spoil area to elevation 211 with a drag beam was completed. Channel work on the entire project was now 94 per cent completed.

On the Barnhart Plattsburgh transmission project, all phases of transmission line construction continued despite soft ground conditions. Steel tower erection was started for the north extension of the Adirondack transmission line.

Progress by SLSDC

Employment during April increased slightly over the previous month to about 700 persons, due mainly to resumption of dredging. At the month-end excavation on the Long Sault canal was practically completed but considerable excavation remained on the approach to the Grass River lock, where a dredge and dragline resumed work late in April. Completion to 14-ft. depth is assured by July 1st and to 27 ft. depth by year end. Machinery installation on both American locks was practically completed, but no water was yet available for testing the locks.

On the dredging for the south Cornwall channel, two out of six contracts were completed but the remainder will continue throughout the summer. The channel will be open for 14 ft. navigation by July 1, 1958.

Erection of steel for the superstructure on the new high-level bridge to span the south channel between Cornwall Island and the U.S. mainland, commenced early in April, had been completed on several spans at both ends. Completion of the repair work on piers by SLSA will permit erection of the main span to be started in May. It is expected the bridge will be available for highway traffic by the end of November. Preparations were being made for removal of the south span of the old Roosevelt bridge at month-end. Falsework erected on barges will support the span, which will be floated out early in May.

Progress by SLSA

With good construction weather in April and with the ice moving out, resumption of some dredging operations increased employment to some 5,700 persons. Excavation of the channel from the Montreal harbour right through to the Caughnawaga bridge opposite Lachine was well in hand.

At the St. Lambert lock, with placing of concrete completed, regulating channel finished and gates for it installed, the only work remaining apart from gate installation was control houses and backfill. Installation of upstream mitre gates was complete, with machinery being installed, though no progress was reported on the lower leaves. All four taintor valves were in place and operating machinery was going in. Fenders were all in place.

At the Côte St. Catherine lock, installation was progressing on both the sector gates and the rolling lift bridge. Though excavation was being cleaned up around the lock itself there remained considerable material to remove at the turning basin.

At the lower Beauharnois lock, with rock excavation continuing throughout April and 236,000 cubic yards of concrete placed, the lock chamber was completed except for part of the west wall and part of the upper gate section. A start had been made on placing the gate hinges but installation of both mitre and sector gates had not been commenced.

On the upper Beauharnois lock, with excavation still continuing, 33,000 cubic yards of concrete were placed during April, leaving a part of the upper gate section still to be poured. Preparations were under way for installing the gates. With 80 per cent of the steel erected for the New York Central swing bridge at the upper end, completion of the bridge is scheduled for late in May. This section of the navigation channel, including the two Beauharnois locks, is said to be the most expensive mile on the entire seaway.

Some 2 million yards out of a total of 3 million had been removed by Canada from the tip of Cornwall Island at the international bridge. A further 700,000 yards must be removed before July 1. Work of dredging on the north channel is in progress and it appears probable enough material will be removed by the same date.

Bridge Construction

Work was progressing rapidly on bridges. Jacking up was continued on piers 1 to 13 of the Jacques Cartier bridge and work had commenced on filling at the south abutment. At the Victoria bridge the first pier north of the dike to carry the diversion of the CNR track on the upstream side had been poured and a second one was formed.

On the CPR-NYCR railway bridge at Caughnawaga, concrete was being placed in the counterweights on the lift-towers, and derrick was being dismantled in preparation for opening the bridge to rail traffic by June 1st.

On the Honore Mercier bridge, erection of steel for the span over the seaway channel was nearing completion. Two girder spans north of the channel and four south of it remained to be erected. Forms were placed for the roadway deck on several of these girder spans but no concrete had yet been placed.

On the Honore Mercier bridge, erection of steel for the span over the seaway channel was nearing completion. Two girder spans north of the channel and four south of it remained to be erected. Forms were placed for the roadway deck on several of these girder spans but no concrete had yet been placed.

Following an inspection of work in progress and the results of tests, a board of consulting engineers appointed jointly by SLSDC and SLSA approved on April 14 the remedial work being carried out by SLSA on the main piers of the south channel high-level highway bridge at Cornwall. This will permit erection of the steel for the main span about the middle of May.

Seaway News

Opening of the Welland canal for navigation took place on April 1 this year, while the Soulanges and Lachine canals were opened for 14 ft. shipping on April 17. The Great Lakes ore shipping season, however, did not get under way until late in April.

Winter Navigation of St. Lawrence

Shipping authorities are showing optimism concerning year round navigation, but maritime communities fear it would take business away from Atlantic ports. Year round navigation is expected as far west as Quebec within a few years and an open river to Montreal is considered possible, though cost of keeping harbours open and higher insurance rates are seen as limiting the advantages. So far as the seaway is concerned there is considerable caution expressed.

Cost of Widening Welland

In a memorandum to the New York State Power Authority, Major-General T. F. Farrell said there will be no need in the future for a second Welland canal. When tonnage exceeds Welland capacity, he states, additional locks and more widening can be provided. To double existing locks and to do more deepening would cost about $175 million, he estimates. A parallel canal on Canadian soil would cost about $540 million, he says.

To build an all-American canal between lakes Ontario and Erie would be possible on two routes. The Lasalle-Lewiston route would cost some $600 million. To build one along a route between Olcott via Lockport to Tonawanda, N.Y., would probably cost more. While dismissing the possibility of an all-American canal, General Farrell admits a large Welland may be needed some time in the future, nearly equal to the capacity of the new seaway.

Shipbuilding Association Issues Warning

A newsletter circulated on April 1st by the Canadian Shipbuilding and Repairing Association warns that unless appropriate action is taken, Canadian industries could become more dependent on foreign agencies for essential services. If the seaway is to be open for United Kingdom vessels to engage in the Canadian coastal trade, Canadian ships may be driven out of business and Canada's shipyards may either close down or be reduced to repair yards. U.K. ships are built and repaired in yards which pay lower wages while U.K. seamen get lower rates than Canadian. The imminence of the seaway, the Association claims, is a potent argument for reserving our coastal shipping trade for Canadian built and registered vessels.

The *Journal* Reports Growth in Engineering Faculties in Canada

Sixth article of a series

The Faculty of Applied Science, Queen's University

Queen's University, in the process of adding new specialized space, both in new buildings, and in the reconditioning of old buildings, is making provision, though not definite plans, for larger numbers of students in the Faculty of Engineering.

In the actual building program there is an engineering building, intended primarily for civil engineering. This building, now being constructed, should be open for classes in the fall of 1958.

The cost of the building and equipment is estimated at $1.8 million, and the total floor area, 100,000 sq. ft.

The plans for the future are indefinite in detail, but it is known that considerable expansion will be required in Physics and Chemistry, and later in the other engineering departments.

Engineering courses at Queen's are under continual revision, Dean of Engineering H. G. Conn reports. A good deal of the initiative for this comes from the Advisory Committee on Engineering, which is composed of approximately thirty-five engineers from industry.

At the graduate level a fifth year of course work is being offered in the fall of 1958, leading to a Diploma in Engineering. For the first few years this fifth year will deal mainly with reactor theory and design.

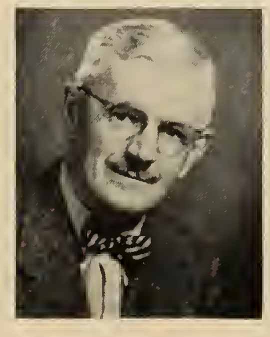
At the undergraduate level an option in petroleum geology and in geology as applied to civil engineering is being offered.

College of Engineering University of Saskatchewan

The College of Engineering at the University of Saskatchewan has expanded in enrolment in the past five years from 585 students to 1,103. The University as a whole has experienced a similar increase, the student body now numbering about 4,100, as compared to the 2,500 of five years ago.

A special course in Mechanical Engineering was provided during the past year, which includes more mathematics than the regular course. Students in this course take as much mathematics as is given in engineer-

Dean I. M. Fraser



Dr. Arthur Porter

Prof. J. B. Mantle

ing physics.

While there have been no additions to the Engineering Building, the problem of space will be eased. A new service building for the department of the Superintendent of Buildings is being erected. This will give considerably more space to the engineering faculty, when workshops are moved out of the engineering building. A new Arts Building and a new Biology Building are planned for early construction, and they will also release space in the engineering building for engineering classes. The P.F.R.A. service has moved to a new Science Services building on the campus completed last year by the Dominion Department of Agriculture.

Dean I. M. Fraser Retiring

There will be personnel changes in the College of Engineering, necessitated by the retirement in September, 1958, of Dean I. M. Fraser, dean of the College and head of the Mechanicial Engineering Department.

Dean Fraser came to the University of Saskatchewan in 1921 as assistant professor of mechanical engineering. He was appointed head of the Department in 1937, and dean of the College in 1953.

Originally from Pictou, Nova Scotia, he is a graduate of McGill University, receiving a B.A.Sc. degree in 1919.

The professional associations have benefited from his participation. A member of The Engineering Institute of Canada since 1920, he was vice-president in 1953-54. He is also a member and past president of the Association of Professional Engineers of Saskatchewan.

Dr. Arthur Porter Appointed Dean

Dr. Arthur Porter will succeed Dean Fraser as dean of the College of Engineering. Dr. Porter is professor and head of the department of electrical engineering at the Imperial College of Science and Technology at the University of London, England.

Dr. Porter is a recognized authority on automatic control systems in industry and on the development of large scale computors. He is the author of numerous research articles and of a book entitled "Introduction to Servomechanisms".

A graduate of the University of Manchester, with first class honours in physics, he received the degrees of master of science and doctor of philosophy from the same university. He was later a Commonwealth fellow in electrical engineering at the Massachusetts Institute of Technology.

During World War II Dr. Porter was senior scientific officer in the British Admiralty. In 1946 he was appointed head of the Department of Technology in the Royal Military College of Science. From 1950 to 1955 he was head of the research division of the Ferranti Electrical Company, engaged in the development of large scale computors.

J. B. Mantle to head Department

Professor J. B. Mantle, professor of engineering, has been appointed head of the Department of Mechanical Engineering, to succeed the retiring Dean Fraser in this post.

Professor Mantle is a former student of the department he will now direct, for he graduated in 1941 from the University of Saskatchewan with the degree of B.E. (mechanical). He received the degree of master of science from the University of Illinois in 1947.

During 1941 and 1942 he was employed by Canadian General Electric, and from 1942 to 1945 was an aeronautical engineering officer with the R.C.A.F.

His first appointment at the University was in 1945, as instructor of engineering; later appointments were these of assistant professor, in 1947, and professor of engineering, 1957.

In recent years he has done special research projects during the summers, having research associateships with the National Research Council. Since 1948 he has published four technical papers on experimental stress analysis.

Prof. Mantle is a wing commander with the R.C.A.F. reserve.

New Appointments

W. R. Staples, professor of engineering, will hold a newly created part time position, assistant to the dean of engineering, while continuing his present duties.

Prof. Staples will assist Dr. Arthur Porter with the routine involved in dealing with individual students.

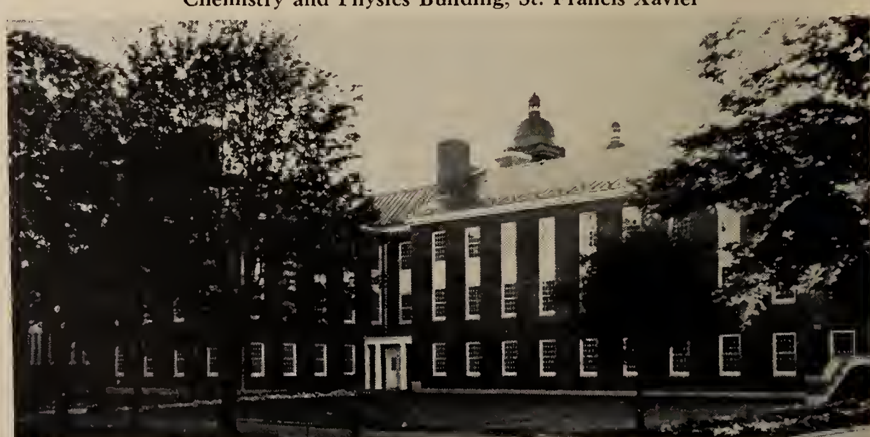
Dr. R. B. Shearn, professor of petroleum engineering, has resigned to accept an industrial position in England. His place is being taken by T. E. W. Nind (Cambridge and Royal School of Mines) who has since 1950 been with the Royal Dutch Shell Group in Venezuela, Borneo and Holland.

Chemistry and Physics Building
St. Francis Xavier University

The biggest single step in expansion of facilities at St. Francis Xavier University culminated on August 29, 1957, with the opening of the new Chemistry and Physics Building, at an approximate cost of $1 million. The building is a T-shaped structure designed by Jens Frederick Larson, noted United States university architect. It is the fifth building designed by him for St. Francis Xavier and the sixteenth building on the campus. It provides 17,000 sq. ft. of work and study space and has a cubical content of 600,000 cu. ft.

Chemistry facilities provide for eighteen laboratories plus facilities for eighteen students and professors to engage in research. The chemistry section can handle comfortably three hundred students at a time. In addition to a main supply room each laboratory has its own storeroom and preparation room, and there is a

Chemistry and Physics Building, St. Francis Xavier



Engineers at work in new drafting room, St. Francis Xavier

radio-chemistry laboratory equipped to handle radio-active materials and the disposal of radio-active waste.

Physics facilities provide for ten laboratories which can accomodate 260 students. Besides the regular laboratories there are a spectrometry laboratory and two research laboratories, and a room for advanced optics.

The building also includes a common library, 20 by 50 feet, and seventeen offices which are provided for the staff. Services to the laboratories, all concealed in service ledges, include hot, cold and distilled water; a-c and regulated a-c power, as well as d-c power from storage batteries; a 20 kilowatt generator, gas and compressed air. Six balance rooms provide fifty balances, and there are also a woodworking shop, a machine shop and an instrument repair shop.

The building is of red brick with a roof of concrete sheathed in copper. It is heated and ventilated by an intricate system of fans which feed into decorative chimneys.

In line with current expansion, the MacNeil Science Hall has been renovated, providing two new drafting rooms, each accommodating a total of 65 students, and the rest of the structure has been renovated to provide five new classrooms and offices for the engineering staff.

Experimental Program

A new experimental program which isolates the top quarter of the class for special work in English, mathematics and physics has already been put into effect in the freshman year. Freshman year currently stresses more intensive work in English; concentration in second year will be in mathematics, and in the third year in physics.

Canadian Pipeline Projects

Trans-Canada Pipelines

Some 3,000 men will be working this year in the field on building the final 853 mile link between Lakehead and Toronto. At the end of April, some 480 miles of right of way had been cleared, 104 miles graded, while pipe had been strung or stock-piled along the route for 725 miles of line. In addition to actual pipeline construction, six compressor stations will be built with a total of 48,500 h.p. Cost of the 1958 construction program will be approximately $165 million.

Threat to Trans Canada's Export

Canadian gas will not be exported to Midwestern Gas Transmission if a proposal by F.P.C. counsel in Washington is acted upon by the Commission. Counsel recommended Midwestern's application be dismissed in favour of Northern Natural Gas for extending its service. If the case is rejected by F.P.C. the whole position of Trans Canada will be changed. Two courses are open to Trans Canada, — it can drop the entire contract with Midwestern and look for another export contract, or it can await the possibility of a later revival of the Midwestern project under different conditions. Obviously the American gas companies, having disposed of their interests in Trans Canada, are not prepared to wait indefinitely for a decision from Ottawa on an application for permission to export.

Inland Natural Gas

Nearly 10,000 homes and businesses have applied to Inland for gas service, and sales of appliances from company showrooms have skyrocketed, a recent progress report indicates. The company's construction program is completed.

Saskatchewan Power Corporation

Contracts for the 1958 main S.P.C. gas pipeline extension program including gathering systems in Hatton and Many Island fields were awarded in April. The estimated cost of materials is $7 million. Pipe will be supplied by Prairie Pipe Manufacturing Company of Regina, with a small quantity from Alberta mills for the Alberta lines. Largest unit, 124 miles of 10-in. and 38 miles of 12-in., from Steelman via Regina to Moose Jaw was awarded to Fulton-Bannister Ltd. at $768,500. Engleking and James Ltd. of Edmonton were awarded 88 miles of 14-in. and 3½ miles of 16-in. main between Hatton field and Success, as well as the 22 miles of the Many Island gathering system on the Alberta side, at a price of $809,000. Swift Current Construction Ltd. was awarded the Many Islands gathering system and wellhead hook-ups consisting of 18 miles of smaller pipe, at $110,000, while Robb Construction Ltd. will build the 25 mile Hatton gathering system for $96,500.

Intercity Gas

This Winnipeg company serves Portage La Prairie, Neepawa, Rivers, Hamiota, and Steinbach, containing some 4,300 available customers. Company commenced its first sales of natural gas last October. Besides a 70 million feet per year industrial customer in Portage the company will supply 110 million cubic feet per year to the Joint Air Training Centre at Rivers.

Winnipeg and Central Gas

Manitoba Royal Commission on Natural Gas headed by J. J. Deutsch, Professor of Economics at U.B.C., opened hearings in Winnipeg suburbs in mid-April. Before it was an application by the suburb of St. James asking approval of a deal with Great Northern Gas Utilities Ltd. at an average rate of 81 cents per 1,000 cubic feet compared with Winnipeg and Central's $1.03 rate. Winnipeg and Central, now sole distributor in Winnipeg, is applying for a rate reduction. Its rates have been attacked by two other companies hoping to break into the Greater Winnipeg market. Main saving under the proposed new rate, which must be ratified by the Municipal and Public Utility Board, will be on water heaters and would be about $100 per month.

Northern Ontario Natural Gas

The company's expansion plans under study involve extension of laterals to the Blind River-Elliot Lake uranium field, the iron ore centre of Steep Rock at Atikokan, the Manitouwadge base metal camp and pulp and paper operations at Marathon, Terrace Bay and Sioux Lookout. The 34 communities to be served by the company and its affiliate, Twin City Natural Gas, have an estimated population of 306,000. Estimated total construction cost in this area is $30 million, with a further $15 million for additional expansion. Delivery of gas by Twin City to customers in Port Arthur, Fort William and Dryden commenced on May 1st. Communities of Red Rock, Nipigon and Geraldton, with 93,000 customers, will receive gas late in the summer of 1958.

Union Gas Company

Union acquired last year a third gas field suitable for storage. Its three storage fields now have a combined capacity of 33.7 billion cubic feet. Natural gas service for Guelph and Stratford began last December. Through acquisition of Dominion Natural Gas Company of Brantford, the company will serve a large number of communities in the south western portion of the province along the shore of Lake Erie and in the Niagara Peninsula.

Consumers' Gas Company

Consumers' Gas plans to carry out a vigorous expansion program over the next five years involving the expenditure of some $75 million. Capital outlay in 1958 alone is expected to reach $24 million. Early this summer construction will be started on transmission lines and distribution systems that will provide service to about 20 Georgian Bay and Ottawa valley communities this year. The main 8 inch pipeline will start from its connection with Trans Canada north of Barrie to serve Owen Sound, Stayner, Collingwood, Meaford, Midland and Penetanguishene. In eastern Ontario the main from Brockville will serve South Falls, Carleton Place, Almonte, Arnprior, Pembroke and Renfrew.

Lakeland Natural Gas

Lakeland Natural Gas Ltd. has launched a $2.75 million program to distribute and extend gas service to Port Hope, Cobourg, Trenton, Belleville, Napanee, Ganonoque, Prescott and Cornwall. Contract has been awarded to Donovan Construction Company of Canada. The project will employ close to 200 men. A special contract awarded to A. F. Simpson, marine pipeline contractor, involves laying of pipe across the Trent River at Trenton.

Quebec Natural Gas

Conversion to natural gas for 38 distributing districts covering 250,000 customers, commenced last January, will be completed by the end of May when gas is supplied from Alberta at the end of this year, the company estimates the cost will range between 41 and 48 cents per Mc.f. of 1000 B.t.u. gas. Hydro-Quebec's average cost of manufactured gas for the year 1956 was approximately 58 cents per Mc.t. of 465 B.t.u. gas or $1.25 per Mc.t. of 1000 B.t.u. equivalent. While new rates are not yet set, indications are that the rate in Montreal for 2500 c.f. monthly will be as much as 25 per cent lower than the Toronto price.

Federal Control A Threat

Federal jurisdiction over natural gas and other pipelines connecting with lines that cross provincial boundaries was again criticized by the Saskatchewan government in a brief to the Borden Commission at Regina on April 14. The brief warned it may be argued that federal jurisdiction respecting permission to build a pipeline extends back from a main trunk line crossing a provincial boundary, to a connecting trunk line built wholly within a province, and eventually might extend back to wellhead itself, making a mockery of provincial jurisdiction over natural resources. Saskatchewan is presently fronting for the whole petroleum industry in the contest to keep federal authority within legal bounds.

Canadian Gas Consumption

Gas consumption in Canada for the full year 1957 amounted to 16 billion cubic feet of manufactured gas and 168.9 billion cubic feet of natural gas, — total of 184.9 billion cubic feet compared with 163.7 billion feet in 1956. The percentage of total natural gas production showed a rise from 87.8 per cent in 1956 to 91.3 per cent in 1957, while the percentage supplied by manufactured gas fell from 12.2 per cent in 1956 to 8.7 per cent in 1957.

What Goes On

Economic Survey of Alberta

The first copy of an economic survey entitled, "Alberta, Province of Opportunity," was presented to a representative of the provincial government by G. A. Gaherty, president of Calgary Power Ltd., on May 16, 1958.

The survey forecasts a dramatic growth for primary industry in the Province, and a further growth of secondary industry whose factory shipments in 1957 were seven times those in 1939. Between now and 1975 the net value of production of secondary industries will increase nearly four times, reaching $800 million. A growing population will encourage this development.

These are some of the predictions brought out by the survey: Construction should triple, reaching $1 billion. Mining will be five times its present net value, becoming $1,600 million. Electric power will increase nearly five times and forestry three and a half times. The province's net value of production will increase three and a half times.

The survey points to a prosperous future and the capacity for continued expansion. It analyzes the history of the economy, studies the resources, the electric power and the primary industries. It details the growth of manufacturing and service industries, and analyzes the conditions necessary for such growth. The survey recommends a number of industries that might be established in Alberta.

Medical Research Advanced

A simple mechanical device enabling surgeons to quickly interconnect the ends of a severed blood vessel has been developed. Apart from its obvious use in accident cases, the new technique will greatly facilitate the implanting of grafts used to replace diseased sections of blood vessels. The group of specialists responsible for this achievement are Dr. I. J. Vogelfanger, Dr. W. G. Beattie, of the Ottawa Civic Hospital, and G. J. Klein, A. J. Smialowski and C. L. Fisher, of the National Research Council.

For physiological reasons, the vessel ends that are to be connected must be flared outward while the suture is being made in order to obtain contact between the inner surfaces, and the finished connection must be substantially free from internal protuberances.

The new device forms the suture by driving a set of small U-shaped tantalum clips in a single squeezing action. The clips are held in an assembly resembling a split bushing and are clinched by being driven axially into a set of anvil recesses in the end of a second split bushing. A number of sizes of bushings are used to cover a fairly wide range of vessel sizes.

In use, a clip-driving bushing and an anvil bushing of the appropriate size are mounted in separate clamps. One end of the vessel is threaded through one of the bushings and is turned inside out over the end of the bushing. The other end of the vessel is prepared in the same manner on the second bushing. The two bushing clamps are then coupled together in accurate alignment and the clips are driven home. The bushing clamps are released and withdrawn, the half sections of the bushings are removed and the operation is completed by turning one of the vessel-ends right side out over the other end which is left everted.

The device has been used with outstanding success in a number of experimental operations on the aorta of live animals. It greatly reduces the time required to perform the anastomosis and reliably produces perfect sutures even in quite small vessels. In the case of small vessels, it may open a door to a field of surgery which heretofore has been regarded as involving too great a risk.

Commercial production of the device has not been undertaken up to the present time.

Businessmen Visit U.S.S.R.

In May a group of thirty Canadian businessmen visited the U.S.S.R., where they had the opportunity to meet representatives of different Soviet organizations, depending on their interests.

Among the participants were the following members of the Engineering Institute: Dr. Otto Holden, chief engineer, Hydro Electric Power Commission of Ontario; T. G. Irving, managing director, Robert McAlpine Limited; J. W. Kerr, vice-president and general manager, Canadian Westinghouse; A. D. Margison, president, A. D. Margison Associates Ltd.

Spiral tunnels of C.P.R. line are being relined.

Spiral Tunnels of CPR

The spiral tunnels on the C.P.R. line between Hector and Field, B.C., are being relined, in a 10-year operation planned so that traffic is uninterrupted.

Due to various rock formation in the original tunnel excavation, reinforced concrete was chosen as the best lining material to meet varying conditions. Where sidewalls and ceiling are relatively stable, it was possible to remove the timber lining and apply a thin layer of gunite over the exposed rock in the roof. A simple system of small reinforced arch ribs, at about 5 to 6-ft. centres, was then placed by the gunite process with a mesh reinforcing gunite layer over the intervening areas of the roof.

Tunnel lining through loose and unstable rock is more substantial. Forms are constructed between existing posts, reinforcing installed and concrete poured up to the arch springing. Arch reinforcing is then placed and ribs gunited. Timber sets are subsequently removed, wire mesh installed across the space, and approximately 4 inches of gunite added to seal the openings. Struts near the base and at the springing are concreted later to complete the lining. The completed section is then pressure grouted to fill any voids between the lining and the rock walls and roof.

The project has been in progress for four years; 1865 feet of lining (of a total of 6,176 feet) have been completed. The work, employing 29 to 32 men from May to October, has been carried out by Creaghan and Archibald, Montreal, and supervised by the Railway's division engineer, M. S. Wakely.

Shawinigan Anniversary

The Shawinigan Water and Power Company, marking its 60th anniversary in 1958, reports a revenue for 1957 of $63 million, and a generating capacity of 1,284,000 kw.

At the end of 1958, when the Beaumont station will be in operation, the company will have seven generating stations on the St. Maurice River in Quebec. All these stations were designed and built by a wholly-owned subsidiary, The Shawinigan Engineering Company Limited. In 1957 the company acquired control of Southern Canada Power Company Limited. Including Southern Canada and the subsidiary, Quebec Power Company, customers served now total 444,000. Total assets, including holdings in Shawinigan Chemicals, total $335 million.

The Beaumont development should, together with present resources, provide adequate power supply till the fall of 1962. The company expects to spend some $95 million over the five years 1958-1962 for completion of Beaumont and for additions and improvements to the transmission and distribution systems.

HELP WANTED

Engineer Required for Institute Headquarters Staff

There is a vacancy in a full time position at E.I.C. Headquarters in Montreal for a well qualified engineer, to administer the Institute's increasing program of Technical Services. Responsible to the General Secretary, he will assume the direction of publications, all technical operations, branch technical development, and other associated work. The successful applicant will be expected to have the necessary technical background, plus administrative ability and some proven editorial aptitude.

This is an interesting opening, with ample scope for the right person. While age will not be a determining factor, it is probable that the man with the necessary qualifications will not be less than about 40 years old. Some preference will be given to members of the Institute. Address written applications with full particulars, to

The General Secretary,
Engineering Institute of Canada,
2050 Mansfield St.,
Montreal 2, Que.

All letters will be treated confidentially, and should be so marked.

Power in New Brunswick

Up to March 31, 1958, Unit No. 1 at the Beechwood hydro electric plant on the St. John River had produced close to 93 million kwh of electrical energy in 147 days, while Unit No. 2 had produced 27.5 million kwh in 63 days. The units went into production on November 4, and January 27 last.

This project of the New Brunswick Electric Power Commission was described by The Honourable Edgar Fournier, chairman of the Commission, in a report to the provincial legislature, late in April.

Foundation Maritime Limited had been the contractor on the project from 1955. In 1957 the major work consisted of construction of the power house superstructure, erection of the two turbines to the satisfaction of Dominion Engineering Works Limited, installation of all piping and mechanical and electrical equipment, erection of the outdoor switching station. Other major work carried on at Beechwood during 1957 consisted of erection of the two 40,000-kva. generators by Canadian General Electric Co. Ltd., erection of the sluice and regulating gates and hoisting apparatus, as well as of indoor and outdoor cranes by Dominion Bridge Co. Ltd. Six miles of railway were diverted or raised at five different locations. Highway works consisted of six diversions and one highway lift, a total of 6.8 miles being relocated or raised.

Interior of Beechwood power house, New Brunswick.

Expansion in Operation

During 1957 the New Brunswick Power Commission, Mr. Fournier reported, experienced the greatest growth in its history.

Among the plans being worked out is the interconnection of the electric systems of New Brunswick and Nova Scotia. Under this plan, one province will be able to draw from the other for capacity at any time, the result being increased reliability of power. The line will have a normal capability of 50,000 kilowatts, but an emergency capacity of 75,000 kilowatts.

The total production by all generating stations during the year ending March 31, 1958, reached 611 million kwh., an increase of 8.6 per cent. The proportion produced by hydro power was 40.6 per cent, the remainder generated by steam.

A good portion of the increased production resulted from sale of at-will power to pulp and paper companies. Beechwood was tied in with the Grand Falls plant of Gatineau Power Company. Beechwood also made possible the sale since November of 150,000 kw. daily to Maine Public Service.

Water-Power Resources of Canada

The currently recorded water-power resources of Canada are shown as totalling more than 46 million horse-power under conditions of low stream flow, and over 66 million horse-power at average flow. This information is given in Bulletin No. 2602 of the Department of Northern Affairs, titled "Water-Power Resources of Canada".

The statistics would indicate that less than 25 per cent of available resources has been developed. During 1957, new capacity to the extent of 1.5 million hp. was brought into operation.

Copies of this review may be obtained free of charge from the Director, Water Resources Branch, Department of Northern Affairs and National Resources, Ottawa.

The Seventy-Second Annual General Meeting

Nearly a thousand members, wives, and guests came to Quebec City, May 21-23, for the seventy-second annual meeting of The Engineering Institute of Canada.

Their response augured well for the success of the meeting, and their confidence was not misplaced. The smooth course of the events at the Chateau Frontenac was a credit to the splendid preparation of the Quebec Committee, and to the hospitality of the Quebec Branch, its chairman, Roger Desjardins, its officers, and its members. The Quebec Committee was composed of Ben O. Baker, chairman, Roger Desjardins, Pierre Duchastel, L. P. Bonneau, Louis Joncas, Jacques Roy, Paul Begin, Jean B. Delage, Marc Bergeron, Mme Roger Desjardins and Mrs. Ben O. Baker.

Many ladies came to the meeting with their husbands, and enjoyed the special program that had been arranged for them. A coffee get-together every morning was a pleasant event. Tours of Quebec and a fashion show were available when the ladies were not participating in the general program.

This was a memorable meeting. It marked the retirement from the office of general secretary of Dr. L. Austin Wright after twenty years of distinguished service, and gave the members present the opportunity to express for themselves and for the branches they represented, appreciation of his service. The following pages give a full account of his career.

Dr. Wright's successor as general secretary, and editor of *The Engineering Journal*, is Dr. Garnet T. Page, M.E.I.C., who has been deputy general secretary since January of this year. Dr. Page is the former general manager of The Chemical Institute of Canada (See The Engineering Journal, October, 1957, Page 1490).

The office of president of the Institute for 1958-59 was given into the hands of Kenneth F. Tupper, president of Ewbank and Partners, Toronto, by the retiring president C. M. Anson, of Sydney, N.S. Mr. Anson gave his review of the accomplishments of the Institute in 1957-58 at dinner on May 21. Reporting a particularly healthy condition of the Institute, it is well worth reading, and will be published in the next issue of the *Journal*.

As always the welcome support and collaboration of other societies was apparent from the presence of their members and official delegates.

The Program

The program started on Tuesday, May 20 with the Student Conference and the Education Conference.

Institute business was taken up on Tuesday morning. The Branch Officers Conference brought together delegates from the Branches for discussions of cooperation with and service to the Branches, which now number 50 across the country.

The Annual Meeting of Council was held on Tuesday morning, and the Annual General Meeting on Wednesday morning. The new Council of the Institute met for the first time during the meeting. The minutes of the Annual General Meeting will be published in an early issue.

The authors of the technical papers met each day at breakfast with the members who were to preside at their sessions. The technical sessions were well attended, and considerable interest was aroused by the thirty-two papers presented. Discussion had been invited in advance and a number of significant contributions were made.

Laval University, in a special convocation on Wednesday evening, bestowed on President Elect Kenneth F. Tupper the honorary degree of Doctor of Science, before a large audience.

Thursday afternoon and evening provided a recess from technical and business affairs, with the Quebec Branch arranging an afternoon cruise on the St. Lawrence River. This was a great opportunity to sample the famous scenic beauty of Quebec in the best of company.

The evening program was an innovation, starting with a session in Muriel's Room, and a fine buffet supper. Later, well warned to dress informally, the members more than willingly took part in a Habitant Frolic featuring folk dancing and singing. The scene was set by a French Canadian troupe of singers and dancers in costume.

The Association of Consulting Engineers of Canada held their annual dinner on Thursday evening, continuing their custom of associating their meeting with that of the Institute.

At luncheon on Friday, honours and awards of the Institute were presented by President C. M. Anson, Chairman of this luncheon was Vice-President Albert Deschamps.

Friday evening was the highlight of the meeting, the annual banquet and dance. The speaker, R. G. Gustafson, president and executive director, Resources for the Future, Inc., Washington, had a large audience for his very interesting address.

The introduction of the new president, vice-presidents and councillors of the Institute was a feature of the annual dinner, with C. M. Anson presiding.

Guests of the Institute at dinner were representatives of the Canadian Services, and of thirteen sister societies, Canadian, American and British.

E.I.C. Honours and Awards, 1958

These awards were presented during the annual meeting to those recipients who could be present.

HONORARY MEMBERSHIPS

Armand Charles Crepeau, Sherbrooke,
Sir Claude Dixon Gibb, Newcastle-upon-tyne, England.
Philip Louis Pratley, Montreal, Que.
Irving Richard Tait, Montreal, Que.
Earle Oliver Turner, Fredericton, N.B.
Leslie Austin Wright, Montreal, Que.

JULIAN C. SMITH MEDALS

Richard Edgar Heartz, M.E.I.C., Montreal, Que.
Robert Edwards Jamieson, M.E.I.C., Montreal, Que.

ROBERT W. ANGUS MEDAL

Russell J. Kennedy, M.E.I.C., Kingston, Ont.

DUGGAN MEDAL AND PRIZE

Robert David, M.E.I.C., Montreal, Que.
G. G. Meyerhof, M.E.I.C., Halifax, N.S.

LEONARD MEDAL

E. O. Lilge, M.C.I.M., Edmonton, Alta.

PLUMMER MEDAL

H. R. L. Streight, F.C.I.C., Montreal, Que.

ROSS MEDAL

Ronald George Griffith, M.E.I.C., Montreal, Que.

H. N. RUTTAN PRIZE

Wilfred Pegusch, JR.E.I.C., Vancouver, B.C.

PHELPS JOHNSON PRIZE

Donald Andrew Chamberlain, JR.E.I.C., Montreal, Que.

ERNEST MARCEAU PRIZE

Gilles Gagnon, JR.E.I.C., Montreal, Que.

JOHN GALBRAITH PRIZE

Charles Murray Stewart, JR.E.I.C., Sarnia, Ont.

MARTIN MURPHY PRIZE

Robert Donald Neill, JR.E.I.C., Fredericton, N.B.

Annual Meeting Quebec, 1958

Annual meeting views on the opposite page: show, top to bottom, first column:

Mrs. M. Armstrong, Windsor; Mrs. Ben O. Baker, head of the Quebec Ladies' Committee; and Mrs. A. C. M. Davy, Vancouver, at morning coffee get-together.

President Anson, (right) made a presentation to J. F. Grenon for the Quebec Branch, marking his more than 50 years of membership. Chairman Roger Desjardins (left) introduced Mr. Grenon.

Dr. Garnet T. Page, whose appointment as general secretary to succeed Dr. L. Austin Wright, was approved by Council during the meeting.

The Branch Officers Conference (top right) and the Council Meeting.

Dr. Lillian Gilbreth was present at the meeting. The group (above) conversing with her includes Chairman Roger Desjardins (right), Louis Joncas (left) and Jacques Roy.

President C. M. Anson received the honorary degree of doctor of engineering at the convocation of Nova Scotia Technical College, before he went to the annual meeting in Quebec.

President-elect Kenneth F. Tupper was awarded the honorary degree of doctor of science at a special convocation of Laval University. He is shown (above) signing the register of the University in the presence of (left) Monseigneur A. M. Parent, rector, and M. l'Abbé Jacques Garneau, secretary-general of the University.

Five newly named honorary members of the Institute are shown in the next group: left to right, L. Austin Wright, I. R. Tait, E. O. Turner, P. L. Pratley and Sir Claude Gibb. A. C. Crepeau, Hon. M.E.I.C., was not present.

Below: Delegates to the E.I.C. Education Conference.

Leslie Austin Wright, HON. M.E.I.C.

A Tribute to Leslie Austin Wright

THE OCCASION of the retirement of Leslie Austin Wright from the post of general secretary of The Engineering Institute of Canada, cannot be otherwise than an occasion bringing forth feelings of sadness and regret. Regret that no matter what the capabilities of a man, time ultimately catches up; and sadness that such has happened to a man of such sterling qualities as Austin Wright.

That the Institute today enjoys such a high standing not only in our own national field, but of equal consequence in the international field, and further that the profession of engineering in Canada has reached such high standards and enjoys the respect with which it is regarded, is in no small measure due to the contribution and the twenty years of devoted service of Austin Wright.

Not only has he contributed so largely towards his profession and to the Institute representing that profession, he has at all times been a Canadian.

During World War II in addition to looking after the interests of the Institute, he contributed to the national activities by being assistant director of the Wartime Bureau of Technical Personnel and subsequently assistant director for National Selective Service of the Dominion.

Shortly after the outbreak of war, he organized the members of Canadian engineering societies to take care of children of British engineers sent to Canada for protection against bombing.

At the request of the government he organized an intensive search among Canadian engineers to develop a countermeasure against enemy explosive machinery which was at that time holding up the invasion of Italy. The result was the production of a completely new device, a device which is still on the secret list.

During the twenty years that Austin Wright has held the office of general secretary, the Institute has grown from twenty-five branches to the fifty branches and from 4,500 members to its present membership of some 18,000.

Of far greater importance is that the Institute has greatly expanded the services which it renders, not only to its members, but to the well being of our country as a whole and beyond that to the service of humanity generally.

Dr. Wright has initiated many of these new services. It is no exaggeration whatsoever to state that the results achieved are in very large measure due to his initiative, persistance and foresight.

I have been privileged to attend international gatherings and to note the high regard with which the bodies comprising those gatherings look upon Dr. Wright. He has the distinction of being the first Canadian to become president of the Council of Engineering Society Secretaries, an organization of some sixty member societies whose overall membership exceeds 600,000.

Should Confederation on a sound basis become an accomplished fact, the engineering profession in Canada will owe a debt in this regard to Dr. Wright. He was the man who envisaged the co-operative agreements that presently work so well between the associations of some seven provinces and the Institute.

His contribution towards bringing *The Engineering Journal* to the high standard that it enjoys today has been extensive. He has been its editor throughout a period of its best growth. He has contributed largely to the other publication efforts of the Institute.

As general secretary he has at all times been a loyal friend and devoted helper to all the incumbents in bringing about such success as has attended the office of President of the Institute.

It is with pride that I exercise this privilege, almost the last official act of my years as President, to record herewith my personal debt to Austin Wright, and of far greater consequence the debt which the Institute owes to a most capable engineer, a true and loyal friend and an outstanding Canadian.

C. M. Anson

L'envoie

Twenty Years Later

IN THE MAY 1938 ISSUE of *The Engineering Journal* the leading editorial entitled "Greetings" opened with these words —

> "This is a new editor speaking. The timorous voice and quaking knees may not immediately be apparent to the audience, but to the editor himself they are painfully in evidence. After some weeks of contemplation, and a few days of experience, the magnitude of the undertaking has more fully dawned upon him, and with this appreciation comes some realization of the obligations and opportunities of the position. Who would not be nervous under such conditions?
>
> "The new editor, and general secretary, has much to learn to be equal to his task. He has great need of the patience, tolerance and kindly assistance of the membership. With these, he hopes to realize his ambitions and to make the most of the opportunities which are now his. There is a great chance in this position to render a real service to the engineers of Canada. It is his sincere wish, and his determination, to be equal to this opportunity. To this end he asks your patient indulgence during his initiatory period, and your kindly assistance throughout his entire term of office."

Looking back over the twenty years it is clearly evident that the members gave abundantly of their "patient indulgence" and "kindly assistance", and that because of it the general secretary was able to share in rendering "a real service to the engineers of Canada".

It was my good fortune to come into office just as the curve of economic prosperity was beginning to climb. It has remained on an upward grade for the entire period. Under these circumstances it was logical that the Institute should prosper. Nevertheless it was a privilege and a thrill to be the executive officer of the organization at that time and to see the great expansion in size and usefulness, with increasing prestige within the profession and in the eyes of the public as well.

In the twenty years I have seen the membership grow from 4,000 to 18,000, the branches from 25 to 50, the *Journal* from an average of 80 pages to 220 pages, the income rise from $75,000.00 to $600,000.00, and the assets from $126,000.00 to $463,000.00, the number of members on committees from 365 to 850. It has been a thrilling experience.

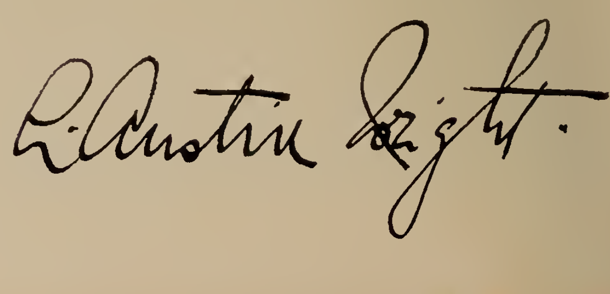
The satisfaction that comes from association with material successes should not be underestimated, but neither should the satisfaction that comes from having made a host of friends in the process. These friendships mean more than all the material gains put together. They are the real reward for the effort made.

To retire from the general secretaryship and the editorship of the *Journal*, to retire from the front rank of Institute activities, is not an easy thing to do, and yet the time has come for it to be done. The pace of engineering affairs is still quickening, the work of the Institute continues to expand, the duties and opportunities of the general secretary are growing beyond all expectations.

The Institute has been so close to me in all these years that its life has become my life, its success becomes the one great thing that matters. It is my belief that to meet the continuing challenge, younger shoulders should now take on the burden. With this in mind we have been building up the secretarial staff with industrious, intelligent and competent younger men. Only under such conditions could I ever leave office without misgivings and concern for the future.

The Institute will go on to greater and greater things, measuring up constantly to the demands of the profession and of Canada. It will be my pleasure now to watch from the sidelines and to applaud as success follows success in all endeavours.

To each of the thousands of members with whom I have had the privilege of working, may I say how gratifying it has all been — the serious discussions, the arguments ending in agreement, the joint efforts to advance the profession, the social affairs, the frequent laughs and the good fellowship. The recollection of these things will sustain me always.



Honours to the Retiring General Secretary

The great service of the retiring general secretary was acknowledged in many ways during the meeting, and a few of the ceremonies were photographed.

Dr. Wright was presented with a silver salver engraved with the signatures of presidents of the Institute under whom he has served. Present at the President's Dinner during which the presentation was made were, left to right: R. E. Heartz, Montreal, J. B. Stirling, Montreal, A. R. Decary, Quebec, De Gaspe Beaubien, Montreal, I. P. Macnab, Halifax, C. M. Anson, Sydney, Dr. Wright, J. B. Challies, Montreal, C. J. Mackenzie, Ottawa, L. F. Grant, Kingston, J. A. Vance, V. A. McKillop, London.

Above, standing with President Anson. Dr. Wright received a complete 35-mm. camera with equipment, and purse, the retirement gift of the members of the Institute.

Above, left. A. M. Purdy and M. F. K. Leighton (right) made a presentation to Dr. Wright of an engraved lighter, a tribute from the members of the Moncton, N.B. Branch of the Institute.

Above, centre, Dr. Wright is shown with his son Meade Wright, M.E.I.C., and daughter-in-law.

Above, right. Retiring President Anson (left), Dr. Wright, and J. B. Challies, who was president in 1938 when Dr. Wright's service began.

At right. Co-workers during the entire twenty years, Miss May McLaren of Headquarters, and Dr. Wright.

General Secretary
Garnet T. Page, Montreal

Treasurer
T. W. Eadie, Montreal

Assistant General Secretary
E. C. Luke, Montreal

Western Field Secretary
A. C. M. Davy, 1370 Minto Crescent, Vancouver

Assistant General Secretary
H. P. Gatin, Montreal

Eastern Field Secretary
J. A. McLaren, 160 Eglinton Ave. E., Toronto 12

COMMITTEES

Admissions
Roger Brais, chairman; W. H. Gauvin, D. H. Hobbs, J. H. R. Dansereau, R. J. Harvey.

Board of Examiners
J. L. deStein, chairman; John M. Cape, J. Hurtubise.

Canadian Standards Association (Technical Council)
P. L. Pratley—Institute Representative.

Finance
A. Deschamps, chairman; R. L. Dunsmore, R. A. Emerson, R. G. Ferrabee, J. M. Breen, O. M. Solandt, R. L. Weldon.

Canadian Chamber of Commerce
F. G. Rutley—Institute representative on National Board of Directors.

Legislation
C. G. Kingsmill, chairman; D. C. MacCallum, J. B. Stirling.

Library and House
C. E. Frost, chairman; L. A. Duchastel, W. D. Kirk, E. D. Gray-Donald, W. C. M. Luscombe.

Membership
R. H. Self, chairman.

Publication
H. A. Mullins, chairman; J. A. Audet, William Bruce, W. H. Gauvin, B. D. McDermott, D. W. R. McKinley.

Papers
J. H. Budden, chairman; D. H. Hobbs, H. L. Johnston, M. McMurray, W. B. Pennock, E. R. Smallhorn, H. S. Van Patter, L. P. Bonneau, R. Boucher.

Prairie Water Problems
G. A. Gaherty, chairman; P. M. Sauder, vice-chairman; T. D. Stanley, secretary; C. S. Clendening, D. W. Hays, B. Russell, T. H. Hogg, G. L. MacKenzie, J. H. McLean, J. M. Wardle.

Policy
R. L. Dunsmore, chairman; B. G. Ballard, A. Deschamps, I. P. Macnab, D. M. Stephens, R. L. Hearn, R. E. Heartz, J. B. Stirling, W. G. Swan, I. R. Tait.

Professional Interests
E. B. Jubien, chairman; G. A. Gaherty, vice-chairman; W. E. Brown, G. J. Currie, W. G. Swan, H. L. Branchaud, E. K. Phillips, I. R. Tait.

Property
F. G. Rutley, chairman; A. Deschamps, V. B. King, C. N. Murray, R. C. Pybus.

Student Policy
C. G. Southmayd, chairman; R. E. Jamieson, J. Dubuc, E. J. Muszinski, J. F. Riel, A. Pakalnins.

Technical Operations
F. L. Lawton, chairman; B. G. Ballard, W. H. Paterson, C. E. Frost, D. L. Rigsby, R. M. Hardy, S. Sillitoe, A. R. Harrington, E. R. Smallhorn.

OFFICERS OF THE BRANCHES

AMHERST
Chairman, J. W. Wilson; *Vice-Chair.,* D. J. Rockwell; *Executive,* F. C. Wightman, L. E. Burrill, R. G. Baxter.
Sec.-Treas., G. R. Pond, 7 Victoria Street West, Amherst, N.S.

BAIE COMEAU
Chairman, V. M. Wallingford; *Executive,* Peter Suttie, G. Scott, J. M. Pope; *Treasurer,* T. G. Rust.
Secretary, Norman Lapierre, P.O. Box 1073, Baie Comeau.

BELLEVILLE
Chairman, T. E. Flinn; *Vice-Chair.,* W. Benger; *Exec.,* V. L. Lewis, E. Hilbig, W. Canniff, N. Throop, D. Law.
Sec.-Treas., F. E. Moore, 71 Golfdale Blvd., Belleville, Ont.

BORDER CITIES
Chairman, C. Maurice Armstrong; *Vice-Chair.,* J. E. Dykeman; *Executive,* R. H. Darke F. P. Mascarin, A. W. Malmberg; *Treasurer,* E. R. Carpenter.
Secretary, J. M. Reid, 1511 York Street, Windsor, Ont.

BROCKVILLE
Chairman, W. N. Simmons; *Vice-chair.,* D. C. Turner; *Executive,* R. B. McRuer, W. E. Morden, F. E. Trewartha, K. R. Bullock, J. F. Preston.
Sec.-Treas., G. R. Bowes, 152 King Street East, Brockville, Ont.

CALGARY
Chairman, F. L. Perry; *Executive,* D. F. Kobylnyk, P. S. Grant, G. A. Hutton, T. Covello; *Treasurer,* R. G. Price.
Secretary, O. O. Junker, c/o Cumming Galbraith Ltd., 1510a - 1st St. S.W., Calgary, Alta.

CAPE BRETON
Chairman, J. V. Palmer; *Vice-Chair.,* W. L. Dodson; *Executive,* G. Ross, J. R. Wallace, H. Maitland, R. Bradley, P. Terry, J. Stevens; *Treasurer,* C. A. Campbell.
Secretary, H. M. Aspinall, P.O. Box 485, Sydney, N.S.

CENTRAL BRITISH COLUMBIA
Chairman, E. R. Gayfer; *Vice-Chair.,* P. Tassie; *Executive,* R. G. Harris, D. G. Hepburn, D. Wales.
Sec.-Treas., W. J. M. Owen, 634 Eckhardt Avenue West, Penticton, B.C.

CHALK RIVER
Chairman, C. A. Crawford; *Exec.,* J. G. Melvin, C. E. L. Hunt, J. S. Flavelle.
Sec.-Treas., W. O. Findlay, P.O. Box 339, Deep River, Ont.

CORNER BROOK
Chairman, Milton G. Green; *Vice-Chair.,* E. J. Leja; *Treasurer,* W. S. Read.
Secretary, Eric R. Skanes, c/o Bowater's Engineering Dept., Corner Brook, Nfld.

CORNWALL
Chairman, W. Rothwell; *Executive,* L. H. Snelgrove, J. Moriarity, J. Pescod, M. Broadbent, M. S. Thompson, F. J. Willis.
Sec.-Treas., D. W. C. McEwan, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.

EASTERN TOWNSHIPS
Hon. Chair., A. C. Crepeau; *Chairman,* R. D. Mawhood; *Vice-Chair.,* G. P. Cote; *Executive,* J. P. Champagne, J. E. Freeman, C. D. McKinney, E. T. Harbert, M. Lafreniere, G. B. Moffat; *Treas.,* A. S. Mitchell.
Secretary, Jean Bourassa, 450 Belvedere St., S., Sherbrooke.

EDMONTON
Chairman, S. J. Hampton; *Vice-Chair.,* T. H. Newton; *Executive,* R. H. Cronkhite, D. H. Sands, G. Ross, S. R. Sinclair, H. Hole, R. H. Gardener, R. H. Nicolson, J. Longworth.
Sec.-Treas., G. Hodge, 10615-146th St., Edmonton, Alta.

FREDERICTON
Chairman, O. I. Logue; *Vice-Chair.,* William L. Barrett; *Executive,* L. W. Smith, M. P. Estey, R. C. Ballance, K. O. Bartlett, R. S. Shepherd, G. D. Reeleder.
Treasurer, E. C. Garland.
Secretary, Robert D. Neill, 150 Miles St., Fredericton, N.B.

HALIFAX
Chairman, J. D. Kline; *Vice-Chair.,* W. J. Phillips; *Executive,* J. G. Belliveau, G. M. Haliburton, A. H. MacKinnon, K. R. Mitchell, M. C. Sutherland-Brown, J. R. Cameron, L. D. Hopkins, B. E. Langley, R. B. Killam, M. A. Marshall.
Sec.-Treas., J. E. Reardon, Public Service Commission, Halifax, N.S.

HAMILTON
Chairman, R. C. Mitchell; *Vice-chair.,* H. E. Seely; *Executive,* P. J. McNally, T. O. Watts, J. A. Michell, A. F. Barnard.
Sec.-Treas., W. A. H. Filer, 2 Maple Ave., Hamilton, Ont.

HURONIA
Chairman, H. C. Bates; *Vice-Chair.,* S. R. Walkinshaw; *Executive,* D. M. Harris, C. G. Campbell, J. L. Armstrong, J. E. Sears, J. W. Davies, R. G. Freeman.
Sec.-Treas., L. Morgante, 36 Borland Street West, Orillia, Ont.

KINGSTON
Chairman, R. B. Wotherspoon; *Vice-Chair.,* W. M. Campbell, *Exec.,* D. C. MacPherson, F. M. Wood, R. J. Kennedy.
Secretary, D. I. Ourom, 991 Princess St., Kingston.

KITCHENER
Chairman, C. A. Leicht; *Vice-chair.,* W. J. Horner; *Executive,* R. Dahmer, W. Bobbie, G. Tidswell, H. Walters.
Sec.-Treas., A. H. Austin, Armco Drainage & Metal Products of Canada Ltd., Box 300, Guelph, Ont.

KOOTENAY
Chairman, J. T. Higgins; *Vice-chair.,* D. J. Turland; *Executive,* R. F. Bailey, L. S. Piper, G. C. Rogers, E. Rohatynski, W. V. Nicholon, R. J. Portman; *Treasurer,* J. I. McClelland.
Secretary, J. L. P. Limbert, 649 Forrest Drive, Trail, B.C.

LAKEHEAD
Chairman, V. B. Cook; *Vice-Chair.,* W. D. MacKinnon; *Exec.,* W. H. Bulger, P. W. Pinn, J. W. Lukey, J. E. Rymes, G. S. C. Smith, G. A. Walker, J. H. Hargrave, A. T. Sherrett;
Sec.-Treas., C. M. Cotton, 320 North Syndicate Ave., Suite 2, Fort William, Ont.

LETHBRIDGE
Chairman, J. R. Milne; *Vice-Chair.,* W. B. Thomson; *Executive,* G. B. Davies, R. L. Francis, J. A. Wilihan.
Sec.-Treas., R. D. Hall; Utility Engineer, City Engineer, Lethbridge, Alta.

LONDON
Chairman, R. W. McMeekin; *Vice-chair.,* C. H. Osborne; *Executive,* G. W. Chorley, H. E. Martin, L. S. Lauchland, G. O. Hayman, G. E. Wilson.
Sec.-Treas., W. C. Sinkins, London Steel Construction Co. Ltd., P.O. Box 69, 48 Burslem Street, London, Ont.

LOWER ST. LAWRENCE
Chairman, Jean R. Menard; Vice-Chair., M. Lanouette; *Executive,* T. Bernier, R. Joncas, A. Leroux, G. Santerre.
Sec.-Treas., Claude St. Hilaire, 10 Rue St. Jean, Rimouski, Que.

MONCTON
Chairman, G. E. Franklin; *Vice-Chair.,* C. L. Trenholm; *Executive,* H. S. McCleave, L. McIsaac, G. A. Peck, C. E. Spear, W. M. Steeves.
Sec.-Treas., V. C. Blackett, 97 MacBeath Avenue, Moncton, N.B.

MONTREAL
Chairman, P. W. Gooch; *Vice-chair.,* R. A. Phillips; *Executive,* R. J. Harvey, R. J. Kane, L. L'Allier, H. Audet, C. A. Colpitts, J. O. McCutcheon.
Sec.-Treas., G. M. Boissonneault, Shawinigan Water and Power Co., P.O. Box 6072, Room 809, Montreal, Que.

NEWFOUNDLAND
Chairman, G. E. Knight; *Vice-Chair.,* C. W. Henry; *Executive,* R. P. Hunt, A. H. McKinnon, D. S. Templeton, G. N. Cater, R. W. Myers, R. F. Martin.
Sec.-Treas., R. L. Smyth, c/o Imperial Oil Limited, Centre Building, St. John's, Nfld.

OFFICERS OF THE BRANCHES

NIAGARA PENINSULA

Chairman, D. A. Barnum; *Vice-chair.,* D. O. D. Ramsdale; *Exec.,* R. T. Bailey, W. D. Tanner, H. S. Lundy, W. J. Smith, W. J. O'Reilly, F. R. Denham, G. E. Griffiths.
Sec.-Treas., Malcolm Stevenson, Box 196, Fonthill, Ont.

NIPISSING AND UPPER OTTAWA

Chairman, J. S. Cooper; *Vice-chair.,* J. M. Rosborough; *Executive,* J. Warburton, H. Staniforth, R. S. MacLennan, D. Catford, P. Rebin, D. W. Briden.
Sec.-Treas., R. A. Booy, Box 1, Temiskaming, Que.

NORTH EASTERN ONTARIO

Chairman, A. A. Kidd; *Vice-Chair.,* J. S. Whyte; *Executive,* C. McIntyre, J. Blakeman, J. N. Greggain, J. Shipman, M. McLean, W. Swann, G. Flett.
Acting Secretary, A. A. Kidd, P.O. Box 640, Cochrane, Ont.

NORTHERN NEW BRUNSWICK

Chairman, L. L. Marshall; *Vice-Chair.,* D. C. MacCallum; *Executive,* Stewart Henry, A. R. Bonnell, J. A. Mesereau, C. K. Steeves, Martin Cyr, R. A. Cameron.
Sec.-Treas., G. P. Milton, 272 Millhaven St., Bathurst, N.B.

NORTH NOVA SCOTIA

Chairman, D. J. MacNeil; *Vice-Chair.,* W. I. Fisher; *Exec.,* C. McGibbon, M. Wolfe, Rev. W. Fogerty, J. K. Godfrey.
Sec.-Treas., D. G. Dunbar, Pictou County Power Board, New Glasgow, N.S.

NORTH SHORE LOWER ST. LAWRENCE

Chairman, B. M. Monaghan; *Executive,* R. W. Kenway, M. Michaud, M. Storrier.
Sec.-Treas., L. E. Fisher, Iron Ore Company of Canada, Dock Terminal, Sept-Iles, Que.

OTTAWA

Chairman, Hector Chaput; *Vice-Chair.,* John S. Watt; *Executive,* A. H. Graves, T. M. Patterson, R. C. Silver, H. A. MacKenzie; *Treasurer,* Hugh C. Brown.
Secretary, W. V. Morris, 2078 Knightsbridge Road, Ottawa, Ont.

PETERBOROUGH

Chairman, I. N. MacKay; *Executive,* J. L. Olsen, V. Aare, R. A. Blount, W. H. Powell, J. G. Hooper, C. W. Holman, D. J. Kawaja, P. Tuck, G. W. McPhee, E. R. Shirley.
Sec.-Treas., G. M. Locke, 1269A Clonsilla Ave., Peterborough, Ont.

PORT HOPE

Chairman, T. F. Kennedy; *Vice-chair.,* J. A. Pollock; *Executive,* J. L. Sulvester, D. A. Runciman, T. S. Bradfield.
Sec.-Treas., R. Waterfall, 81 Hope Street North, Port Hope, Ont.

PRINCE EDWARD ISLAND

Chairman, C. W. Currie; *Vice-chair.,* A. Coles; *Executive,* J. D. M. MacDonald, L. E. Slaght, A. D. Cameron.
Sec.-Treas., R. D. Donnelly, P.O. Box 184, Charlottetown, P.E.I.

QUEBEC

Life Honorary Chairman, A. R. Decary; *Chairman,* Roger Desjardins; *Vice-chair.,* P. A. Duchastel; *Executive,* Lionel Boulet, J. B. Delage, Hugh Kane, P. E. Begin, L. Joncas, Jacques Roy.
Sec.-Treas., Marc Bergeron, Concrete Repairs and Waterproofing Co., 128 Blvd. Ste. Anne, Quebec, Que.

SAGUENAY

Chairman, J. Roch Boisvert; *Vice-Chair.,* F. A. Brown; *Executive,* L. Tessier, G. C. Gauthier, E. Paine, J. J. Falardeau, R. Bodie, P. R. Thomas.
Sec.-Treas., D. L. Aker, c/o Aluminum Company of Canada Limited, Arvida, Que.

SAINT JOHN

Chairman, H. W. M. Townshend; *Vice-chair.,* J. W. G. Scott; *Executive,* G. C. Robinson, P. W. Hastings, K. V. Cox, G. C. Mouland; *Sec-Treas.,* D. I. Higgins, 30 Elizabeth Court, Saint John, N.B.

ST. MAURICE VALLEY

Chairman, D. M. McKim; *Vice-Chair.,* J. B. Edwards; *Executive,* G. Boucher, J. W. Gathercole, P. Hansen, D. C. Kinley, E. A. Love, C. H. Neil, B. Pangborn, J. H. A. Pearson; *Treasurer,* T. J. Goddard.
Secretary, J. O. Hachey, 53 Spruce St., Apt. 13, Shawinigan Falls, Que.

SARNIA

Chairman, J. H. Douglas; *Executive,* M. Waghorne, J. Miller, A. W. Wirth, C. M. Stewart, M. Brown.
Secretary, R. F. Routledge, c/o Imperial Oil Limited, Sarnia Refinery, Sarnia, Ont.

SASKATCHEWAN

Chairman, J. C. Traynor; *Vice-Chair.,* J. B. Mantle; *Executive,* E. J. Cole, J. D. A. Mollard, M. F. Pardoe, K. W. Allcock, M. B. Pierce, B. B. Torchinsky.
Sec.-Treas., R. Bing-Wo, Box 101, Regina, Sask.

SAULT STE. MARIE

Chairman, R. H. Tooley; *Vice-Chair.,* L. F. Mason-Tulby; *Executive,* K. I. Fletcher, K. E. Kansikas, W. M. Hogg, W. B. Sproule.
Sec.-Treas., R. L. Wimperis, c/o General Delivery, Sault Ste. Marie, Ont.

SUDBURY

Chairman, W. B. Ibbotson; *Vice-chair.,* E. M. Powell; *Executive,* H. W. Whittles, B. Russell.
Sec.-Treas., W. J. Ripley, 14 Miller Crescent, Lockerby, Ont.

TORONTO

Chairman, R. Harvey Self; *Vice-chair.,* A. C. Davidson; *Executive,* L. F. Bresolin, A. M. Toye, G. F. R. Norton, R. R. McLaughlin, I. S. Patterson, R. A. Rule, B. L. Farrand, Cameron MacInnis, I. S. Gauley, M. H. Pryce.
Sec.-Treas., D. S. Moyer, c/o Canadian Radio Manufacturing Corp., 11-19 Brentcliffe Road, Leaside, Ont.

VANCOUVER

Chairman, W. G. Heslop; *Vice-Chair.,* C. P. Jones; *Executive,* C. H. White, J. F. Muir, E. S. Rhodes, W. J. Johnson, J. H. Swerdfeger, J. J. Kaller; *Treasurer,* R. H. Carswell.
Secretary, Ronald Clough, 1232 Dogwood Crescent, North Vancouver, B.C.

VANCOUVER ISLAND

Chairman, G. Griffiths; *Vice-Chair.,* H. Graham; *Executive,* H. T. Miard, L. C. Johnson, W. G. McIntosh, A. F. Paget.
Sec.-Treas., J. A. Cowlin, 3340 Richmond Rd., Victoria, B.C.

WINNIPEG

Chairman, L. A. Bateman; *Vice-chair.,* W. L. Wardrop; *Executive,* R. N. Sharpe, R. T. Harland, W. D. Hurst, T. E. Storey, J. P. C. McMath, N. Mudry, J. B. Striowski, N. S. Bubbis, N. M. Hall, H. A. Dalkie, L. E. Poyser, S. H. Eggertson, R. Barschel.
Sec.-Treas., C. S. Landon, Room 418—265 Portage Ave., Winnipeg 2, Man.

YUKON

Chairman, Lt.-Col. D. M. C. Saunders; *Treas.,* J. Scott.
Secretary, J. L. Phelps, 302 Elliott St., Whitehorse.

ONTARIO DIVISION

Chairman, M. A. Montgomery; *Vice.-Chair.,* H. R. Sills; *Treasurer,* G. R. Turner; *Board of Management,* P. E. Buss, H. G. Conn, E. R. Davis.
Secretary, J. G. Hall, 92 Heddington Ave., Toronto, Ont.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Lt.-Col. F. W. W. Doane, M.E.I.C., of Halifax, Canada's oldest practising engineer, and dean of engineering in Nova Scotia, died suddenly at Halifax on April 18, 1958.

Frances William Whitney Doane was born at Barrington, Nova Scotia, on May 31, 1863. He took up the practice of engineering in 1883 and for eight years was assistant to the provincial government engineer for Nova Scotia. In 1894 he was appointed city engineer for the city of Halifax. In 1900 he joined the 63rd Halifax Rifles as a lieutenant and later rose to command the battalion as colonel in 1919, retiring in 1924. He also saw active duty overseas with the 219th Battalion Nova Scotia Highland Brigade. Terminating his service with the city in 1924, he opened a private consulting practice which he conducted until 1932. He accepted work as a construction engineer with the Standard Paving Maritime Ltd. in 1932, continuing his active association with the firm up to the time of his death.

Colonel Doane was active in various engineering societies and was one of the founders of the Association of Professional Engineers of Nova Scotia as well as past president of the organization. He was a Dominion councillor of the Association representing Nova Scotia for a number of years.

Colonel Doane gave his services as lecturer at Dalhousie University on municipal and highway engineering and at the Nova Scotia Technical College on public water supplies for a number of years. He was a member of the Royal Commission on roads, 1920. He was a member of the board of examiners of provincial land surveyors.

In 1955 the Nova Scotia Technical College conferred on him the honorary degree of doctor of engineering in recognition of his accomplishments in the field of engineering and in developing the professional status of the engineer in Nova Scotia throughout a long and honoured career.

He was one of those men who pioneered in municipal engineering during the days of advancement from the horse and buggy days to modern transport systems.

Col. Doane joined the Institute as a Member in 1887, transferred to Associate Member in 1889, to Member in 1892 and attained Life Membership in 1931. The Institute named him an Honorary Member in 1952.

Lesslie R. Thomson, M.E.I.C., engineer, professor and government servant, died at Guelph, Ont., on April 27, 1958.

Lesslie Rielle Thomson was born at Toronto on January 12, 1886. Educated at the Model School, Toronto, and Upper Canada College, and the University of Toronto, he held B.A.Sc. and civil and electrical engineering degrees from the latter institution, 1906, 1907. What was to grow into a remarkable career began with appointments as lecturer and demonstrator at the University of Toronto and of Manitoba. He joined the permanent staff of the Dominion Bridge Company in 1912 and remained in this service in various capacities leading up to the post of resident engineer at Ottawa in 1918. Named secretary of the National Research Council, Ottawa, at that time, he also held the office of secretary of the lignite utilization board for a five year period. Appointed special lecturer in structural engineering, department of architecture, at McGill University in 1920, he became professor of fuel engineering eight years later. In 1924 he opened an office as consulting engineer, specializing in the fields of structural engineering and fuel economy in Montreal.

He retained his consulting engineering practice in Montreal until the outbreak of World War II. At that time he began an extensive period of government service, being appointed successively, executive assistant to the Minister of Transport, controller and secretary of the Department of Munitions and Supply, associate economic advisor and liaison officer of the same department and also of the department of reconstruction. He was also liaison officer of the government in connection with all atomic matters at home and abroad. For his war services he was awarded the O.B.E. by the Canadian Government and the Medal of Freedom with Gold Palm by the United States government, particularly for his work in connection with the development of the atomic bomb. He retired shortly after the end of World War II.

Mr. Thomson was responsible for one of the first surveys of the economics of the St. Lawrence seaway.

He was in 1926 awarded the Gzowski medal of the Engineering Institute for a paper in which he made the first public attempt to present the basic economic aspects of the Canadian Fuel Problem.

In 1938 he published a book entitled "The Canadian Railway Problem" for which he was known.

He joined the Institute as an Associate Member in 1911, transferred to Membership in 1919 and attained Life Membership in 1947.

Colonel H. G. Thompson, M.E.I.C., retired executive assistant general secretary of the Engineering Institute of Canada died suddenly on April 19, 1958, at Pickering, Ont.

Howard Grant Thompson was born at Belmont, Ontario, on August 21, 1896. He was educated at the University of Toronto where he was awarded a B.A.Sc. degree in mechanical engineering in 1922, after considerable experience with the Canadian Expeditionary Force and the R.A.F. during World War I. For several years following graduation he worked in the heating, ventilating and steam power plant field, as applied to industrial plants, particularly pulp, paper and power. These companies included the Canadian Sirocco Co. Ltd., the Roirdan Company Ltd., Temiskaming, Que., the Combustion Engineering Corporation Ltd., Toronto and Montreal, and the Affiliated Engineering Companies Ltd., Montreal. From 1932 to 1934, Colonel Thompson served on the staff of the Engineering Institute, Montreal, as editor of indices of the engineering catalogue.

In 1934 he joined Canadian Vickers Limited and was the following year appointed manager of the Toronto office of that firm.

He was selected to organize and command the first Canadian Reserve Army Field Workshop in 1937, with the rank of major and ordnance mechanical engineer. On the outbreak of war in 1939 this unit was mobilized to full strength and he was promoted to the rank of lieutenant-colonel. Major Thompson proceeded overseas with the First Canadian Division, under Gen. McNaughton. Toward the close of 1940 he was invalided home and early in 1941 was appointed chief ordnance mechanical engineer at Defence Headquarters in Ottawa with the rank of colonel.

In January 1942 he went to the Middle East as technical observer for the Canadian Army. He returned to England in a few months' time and served suc-

Lt. Col. F. W. W. Doane, M.E.I.C.

Col. H. G. Thompson, M.E.I.C.

Lesslie R. Thomson, M.E.I.C.

cessively as deputy director of ordnance engineering services and of mechanical engineering at headquarters First Canadian Army. After having supervised the formation of the Royal Canadian Electrical and Mechanical Engineers Corp., (R.C.E.M.E.), in the Canadian Army overseas, Colonel Thompson was returned to Canada in 1944 to become director of mechanical engineering at army headquarters, Ottawa, where he remained until the end of the war.

In 1945 Colonel Thompson was awarded the Medal of the Engineering Alumni of the University of Toronto, for outstanding achievement in the field of engineering. Following his retirement from the active army at the end of the war, he rejoined the active reserve in command of the workshop in the Toronto area and during this period assisted in organizing the R.C.E.M.E. Corps Association in which he served as president for the first three years.

In 1951 he was appointed to the post of assistant general secretary of the Engineering Institute of Canada. Shortly before his retirement due to ill health in 1956 he was named executive assistant general secretary of the organization.

Colonel Thompson joined the Institute as a Member in 1920, transferred to Junior Member in 1923, to Associate Member in 1928 and Member in 1940.

Brigadier Antonin Theriault, C.B.E., M.E.I.C., vice-president of Canadian Arsenals Ltd., a Quebec City, Que., Crown company, died there on March 31, 1958.

Born at Rimouski, Que., on May 10, 1887, Antonin Theriault attended the Seminaire de Rimouski, then went on to study at the Montreal Polytechnical School where in 1910 he received a B.Sc. in mining and civil engineering.

Soon after, he joined the Canadian Engineers in Ottawa, with the rank of captain. He had previously held a lieutenant's commission, since 1906, with the 85th regiment of Rimouski.

During the First World War he served in England and France and was twice mentioned in dispatches. Towards the end of the war he was attached to the War Office and also attended the Woolwich College of Science.

After the war in 1920, he was appointed chief superintendent of arsenals at Quebec and became chief superintendent in 1936. He was promoted to colonel in 1937 and to brigadier in 1942.

In World War II Brigadier Theriault was a part of the unprecedented expansion experienced by the Dominion Arsenal.

In 1946 the arsenals were re-organized into a Crown Company and Brigadier Theriault assumed the post of vice-president, held until the time of his death.

In 1944 Laval University conferred on him the degree of Doctor of Science. The United States government made him an officer of the legion of merit in 1946.

Brigadier Theriault joined the Institute as a Member in 1944.

Gil D'Aoust, M.E.I.C., plant engineer with the Powell River Company, Westview, B.C., died on February 25, 1958.

Joseph Gilbert D'Aoust was born at Vancouver, B.C. on June 14, 1905. He attended the Vancouver Technical School and the University of British Columbia, from which latter institution he graduated in 1927 with a B.A.Sc. degree in mechanical engineering. He was immediately employed as a mechanical draftsman with the B.C. Pulp and Paper Company and moved on to various short-term experience during the early nineteen thirties. He first became associated with the Powell River Company in 1934 working first as a mechanical draftsman, and three years later moving up to the post of junior engineer. In 1941 he transferred his services to Defence Industries Limited, Montreal. During the next few years he gained added experience in the service of Consolidated Paper Corporation, Port Alfred, Que., and the firm of Price Brothers and Company Limited, Riverbend, Que. In 1943 he returned to British Columbia to accept a position as mechanical engineer with the New Westminster firm of Heaps Engineering Company Limited, later with the Sorg Pulp Company, Port Mellon, B.C. In 1949 he returned to the staff of the Powell River Company as a development engineer. Promoted to senior project engineer in 1955, he became plant engineer later that year.

Recently he had served as senior project engineer on the large paper machine project completed a year ago.

Mr. D'Aoust joined the Institute as a Member in 1930, transferred to Associate Member in 1939, to Member in 1940.

A. E. Fry M.E.I.C., retired engineer with the Dominion Glass Company, Lachine, Que., died at Montreal on March 23, 1958.

Albert Edward Fry was born at Cornwall, Ont., on December 27, 1885. He received his general education in Montreal and then studied mechanical engineering with the International Correspondence Schools. Beginning his career as a machinist apprentice at Brockville, Ont., he became a machinist with the Toronto Paper Mills, Cornwall, and with the Canadian Pacific Railway at Montreal, within the next few years.

Master mechanic with the Dominion Textile Company, Montreal, in 1909, he was later with the Dominion Mahogany Veneer Company, Montreal. He undertook a number of projects for the Mooney Biscuit Company, Montreal and the Steel Corporation of Canada before joining the mechanical engineering department of Dominion Glass Company in 1920. Transferred to Montreal in 1927, he took charge of the engineering and drafting department of the firm at Pointe St. Charles. He moved to head office to take over a post in the sales department during World War II.

Mr. Fry joined the Institute as an Associate Member in 1928, transferred to Member in 1940, and attained Life Membership on January 1, 1958.

NEWS OF THE

Association and Corporation

Information received through co-operation of the provincial organizations.

Canadian Council of Professional Engineers President Elected

Professor W. O. Richmond of Vancouver, has been elected president of the 30,000 member Canadian Council of Professional Engineers, during the Council's three-day annual meeting in Vancouver. He succeeds C. N. Murray, of Sydney, N.S.

He is head of the department of mechanicial engineering at the University of British Columbia.

As president, he will head the national advisory body for Canada's eleven provincial and territorial professional engineering organizations.

A graduate in mechanicial engineering from U.B.C. in 1929, Professor Richmond received his M.Sc. from Pittsburgh University three years later. He has been associated with U.B.C. since 1937, and is also active as a consulting engineer.

He is a past-president of the B.C. Association of Professional Engineers.

QUEBEC

Engineers' Rights Protected

(Abstracted from the remarks of Premier Maurice Duplessis at the annual meeting of the C.P.E.Q., held on March 22, 1958, and reported in the May issue of the Journal)

"There is no country, on the North American continent at least, that offers as many, as good or as great opportunities as the ones offered by the Province of Quebec. The slogan of your convention is 'challenge', and God knows I always welcome a challenge, no matter where it comes from. So, the motto of your association goes to my heart and I am pleased to know that you realize more than ever the part that you have played in the past and will be called upon to play in the future towards the growth and expansion of your province.

In the province of Quebec we have built, through the work, patience, ability and assiduity of our engineers, the Bersimis enterprise, which has been appreciated by impartial experts. General McNaughton, chairman of the Canadian Section of the International Joint Commission says: 'It is evident that the responsible engineers of Hydro-Quebec, by the exercise of the highest art, have drawn an almost incredible advantage from these resources for the economic benefit of the people of Quebec and Canada. I express my admiration of the vision and the skill which they have applied and of the determination and vigour with which their plans are being driven to completion. It is indeed a great pleasure to have this opportunity to pay this most sincere tribute to the authorities of Quebec for the achievement which is Bersimis. 'Done by Quebec, by Hydro-Quebec, through engineers from the Province of Quebec.'

I am pleased tonight to be honored by your Association which has been kind enough to grant to me the title of honorary member. Your association can always rely on the government. You know, gentlemen, the prerogatives of the Province of Quebec are essential. If you want your Association to progress you've got to bear in mind that engineering is a wonderful job, engineering produces wonderful results, but the conservation and preservation of our rights in the matter of the professions is essential for the fulfillment of the destiny of our Province.

Because the Legislature of Quebec, or of Ontario, or of every other legislature, has exclusive rights in the matter of professions, and because we have these rights, you can be sure that we know our duty and that we will protect your rights and safeguard your interests."

C.P.E.Q. Golf Tournament

More than 200 golfers from the membership of the Corporation of Professional Engineers of Quebec are expected at the Grand'Mere Golf Club on Saturday, June 21, for the 5th annual Provincial Golf Tournament of the CPEQ.

Louis-George Boivin, P.Eng., of Three Rivers is chairman of the committee planning this year's tourney. Some 144 engineers teed off at the tournament last year and present indications are that at least 100 more will be out on the links this year.

New Public Relations Officer

Robert E. Martin, has been elected public relations officer of the Corporation of Professional Engineers of Quebec to succeed Norbert Prefontaine who is now engaged in immigration work.

Mr. Martin, has had experience as a newspaper man on the editorial staff of the Ottawa dailies, Le Droit and The Citizen and the Montreal Gazette. He comes to the services of the Corporation from the Ottawa Communty Chest where he was director of public relations for the fund-raising organization.

ONTARIO

Engineering Technician Meet

The first meeting of Ontario's engineering technicians and technologists was held at the Canadian National Exhibition grounds, Toronto, on May 12, when the five-hundredth engineering technician to be certified under the program established last year by the Association of Professional Engineers of Ontario received his certificate as an engineering technician, grade III, from a fellow grade II technician who had appointed an advisor to the certification board.

Dr. G. B. Langford, chairman of the meeting, discussed the function of the engineering technician certification board. Certification began in June 1957 when Premier Leslie Frost presented certificates to the first six men to qualify under a plan established by the Association of Professional Engineers of Ontario.

Professor W. O. Richmond, president of the Canadian Council of Professional Engineers, (*left*).

Robert E. Martin, public relations officer, Corporation of Professional Engineers of Quebec.

Guest speaker J. Herbert Smith, of Toronto, president of Canadian General Electric Company, declared, "Canadian industry today is spending more than $80,000,000 a year on research and development, three times more than at the end of World War II." He said that the accelerating increase in the development and research brought about by a continuing increase in population and technology pointed up the need for both professional engineers and engineering technicians.

"If we are to enjoy an increasing standard of living we can only do so by increasing our productivity. This means we have to create and innovate in the area of technology, including machines, facilities, processes and mechanisms of all kinds in order to make work less of a drudgery," he told his audience.

Mr. Smith called upon Canadians to "get busy and build here more of the manufactured products not now made in Canada," as he described the serious imbalance of trade with the United States as being due to the heavy importation of manufactured goods and components. He noted that in 1956, imports of fully manufactured goods into Canada amounted to $4.4 billions, representing a per capita figure of $273.00 of foreign manufactured goods for every man, woman and child in Canada. He compared this figure with $26.00 for the U.S.; $49.00 for Britain, $53.00 for West Germany.

"The way to correct our serious import situation," he said, "is not to change the source of import from one country to another, but for us to get busy and build here more of the manufactured products not now made in Canada. In accomplishing this, it would need the contribution of five groups, the investor, the manager, the professional engineer, the technician and the laborer." "For far too long," he said, "we have thought only of four contributors and have not included the technician as a distinct calling, quite separate from the engineer and from the laborer." Mr. Smith added that continued failure to do so will retard the tempo of our expanding economy. There must be encouragement of technicians to undertake self-development programs to fit them for the expanded opportunities and increasing complexity of our industrial life. And recognition must be provided them to bring about this encouragement." The certification program being carried out by the A.P.E.O. for engineering technicians and technologists was aimed specifically at this problem, he said.

"By granting public recognition to the technician through formal certification a clear identification of his work is established," he said.

Mr. Smith described the evolution of the engineering technician certification program which began last year when Ontario encouraged the A.P.E.O. to commence a program of recognition under the terms of the Professional Engineers' Act. He noted that the understanding was that the Association would operate the program in this manner until it had enough experience to advise the government on requirements for suitable legislation.

He pointed out that members of the Association's staff have been available to explain and discuss the certification program directly with personnel managers, chief engineers and groups of technicians.

Mr. Smith stressed that the A.P.E.O. was not attempting to make professional engineers of technicians.

The Association is using its knowledge of over 35 years to establish a group of men who work with and assist professional engineers," he said.

The Collective Bargaining Act

The Association of Professional Engineers of Ontario has recommended to the Ontario legislature's Select Committee on Labour Relations that professional engineers be excluded from participation in the Collective Bargaining Act.

In its brief signed by John A. Fox, immediate past-president and presented at Toronto on May 6 by Dr. G. B. Langford, of Toronto, the Association said it believes that "it would not be in the public interest to have members of the engineering profession included in labour legislation."

The brief referred to the fact that "members of scientific and learned professions" were excluded from the Collective Bargaining Act when it was enacted in 1943.

In asking that this exclusion be continued, the Association said it believes the majority of the employee professional engineers do not wish to be included under the provisions of the Labour Act.

"The members of the profession are required to adhere to a Code of Ethics, and it is felt that adherence to the Code and allegiance to a union might not be compatible," the brief said.

It is also noted that any strike action on the part of professional engineers would, in most instances, be directly opposed to the public interest, particularly in the utility field.

The engineers' code of ethics demands fidelity to the public, and loyalty to their employers.

The Association's brief also pointed out that it is in the public interest that Ontario together with Canada expands her export trade.

"This means new processes, new products and new forms of employment. In such a program, the professional engineer is a key figure and, as new developments are involved, he is in a confidential capacity," explains the brief. It adds that inclusion of professional engineers in labour legislation could "well weaken or restrict the full employment of technically trained professional persons in this type of development."

The Association also pointed out in the brief that it had established an employee members committee in 1956 which among other things, serves as a means of established employee groups negotiating with their employers on matters involving working conditions and salaries.

Under existing legislation in Ontario as well as in B.C., Alberta, Manitoba, Quebec, New Brunswick, Nova Scotia and Newfoundland, professional persons such as engineers, doctors, lawyers, dentists and architects are not deemed to be employees and are thus excluded from provincial labour acts.

BRITISH COLUMBIA

Discussion on Ethics

(From "What Can You Tell a Young Engineer About Ethics?", by Harold A. Bolz, associate dean, College of Engineering, Ohio State University, published in the April issue of The B.C. Professional Engineer)

"When the subject of engineering ethics was mentioned to a certain engineering student he replied, 'I expect to be a practical man, not a philosopher. As I face decisions in engineering practice, the question in my mind will be, "What is the best thing to do?" Right and wrong will be relative factors in each particular case.'

"The foundation stones of ethics may be labelled integrity, trust, consideration, and loyalty.

"Courage and integrity are prime requisites for a successful engineer. Do not continue in engineering if you are afraid to take calculated risks and to make decisions on the basis of available information, for very seldom will you be able to figure out a dead-sure answer in advance for any major engineering problem. Don't go in for engineering if you are satisfied just to 'get by'; shoddy work will not do where human lives and heavy investments are at stake. Engineers deal with the laws of nature. These are fixed and inescapable. The engineering practitioner, therefore, must be rigorously honest in thought and in action; no amount of brilliance will enable an individual dealing with such matters to ignore or to attempt to distort even the simplest laws of nature. Don't go in for engineering unless you are willing to live up to an inflexible code of integrity and honest dealing; the habit of straight thinking and honest action is just as important to an engineer as is the habit of cleanliness to a surgeon. The laws of man may be propounded, enacted, enforced and changed in accordance with the whims or expediency of the human mind. The laws of nature, however, require forthrightness and steadfastness if disaster is to be averted or the wastage of money and materials avoided. Engineering has no place for men who are merely smooth or clever. Clever argument and disputation may not be substituted for the integrity which an engineer must possess."

Personals

News of the Personal Activities of Members of the Institute

L. Austin Wright, M.E.I.C., (B.A.Sc., Toronto, 1911; D.Eng., Rose Polytechnical Institute, 1943), general secretary of the E.I.C. was elected president of the Pointe Claire Memorial Library Association, April 29, 1958. Also he was re-elected vice-president of the Canadian Arthritis and Rheumatic Society, Quebec division.

K. F. Tupper, M.E.I.C., (B.Sc., mech, Toronto, 1929; M.Sc., aeronautics, Michigan, 1938). Laval University, Quebec City, conferred on K. F. Tupper, of Toronto, president of the Engineering Institute of Canada, the honorary degree of doctor of science at a colorful ceremony during the 72nd annual meeting of the E.I.C. held at Chateau Frontenac Hotel, Quebec City.

C. M. Anson, M.E.I.C., (B.Sc., metallurgy, McGill, 1925), vice-president and general manager of the Dominion Iron and Steel Corporation Limited, immediate past-president of the Engineering Institute of Canada was conferred an honorary doctor of engineering degree on May 7. The event took place at the 49th annual assembly of the convocation of the Nova Scotia Technical College.

Colonel R. D. Harkness, M.E.I.C., (B.Sc., Queen's, 1913), president of the Northern Electric Company Limited, Montreal, was awarded an honorary LL.D. degree from Queen's University on May 17. Colonel Harkness, a trustee of that university, delivered the convocation speech for the faculty of applied science during the day's activities.

E. V. Buchanan, M.E.I.C., (A.R.T.C., Glasgow, 1908), has been awarded an honorary doctor of laws degree from the University of Western Ontario, at the annual spring convocation held May 24, 1958.

In 1957 he was appointed chairman of the Engineering Advisory Council of the University of Western Ontario.

G. A. Lowles, M.E.I.C.

P. B. MacFarlane, M.E.IC.

J. C. Hamilton, M.E.I.C.

R. L. Weldon, O.B.E., M.E.I.C. (B.Sc., mech., McGill, 1918; M.Sc., 1920), president and managing director of the Bathurst Power and Paper Company was awarded an honorary doctor of engineering at the 49th annual assembly of the convocation of Nova Scotia Technical College.

R. B. Winsor, M.E.I.C., (B.Eng., civil, McGill, 1927), of Canadian Industries Limited, Montreal, general manager of the textile fibres division, has been elected a director of the organization.

G. A. Lowles, M.E.I.C., (B.Eng., chem., McGill, 1937), of the International Nickel Company of Canada Limited, has been placed in charge of the newly opened Montreal office of the International Nickel Research and Technical Services Ltd. Since joining INCO in 1948 Mr. Lowles has been concerned with nickel and nickel alloy market developments in the petroleum, petrochemical and chemical industry throughout Canada.

Peter B. Macfarlane, M.E.I.C., (Royal Technical College, Glasgow, 1936), previously general sales manager with Atlas Asbestos Company Limited, Montreal, has been appointed vice-president and general sales manager of International Panel Boards Limited. International Panel Boards Limited, is a wholly-owned subsidiary of Atlas Asbestos.

Professor J. O. Dineen, M.E.I.C., (B.Sc., elec., Toronto, 1940; M.Sc., elec., New Brunswick, 1945), of the University of New Brunswick has been named a dean of engineering. He is associated with the department of electrical engineers.

J. C. Dale, M.E.I.C., (B.Sc., elec., Alberta, 1933), president and general manager of Canadian Utilities Limited, Edmonton, has been elected a director in the organization.

John C. Hamilton, M.E.I.C., (B.Sc., chem., Queen's, 1942), vice-president, manufac-

C. M. Anson, M.E.I.C.

turing, Canadian Resins and Chemicals Limited, has been appointed to Queen's University Advisory Council on Engineering. Mr. Hamilton will represent the chemical industry on the Council's chemical engineering sub-committee in a three-year term of office commencing July 1, 1958.

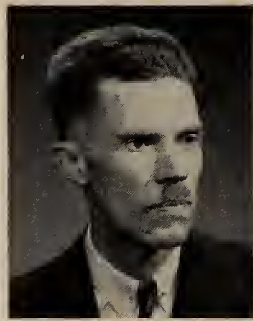
Per Hall, M.E.I.C., (B.Sc., civil, Royal Tech. Coll., Copenhagen, 1935), has been named president of the Foundation of Canada Engineering Corporation Limited. He was assistant chief engineer for the Foundation Company of Canada Ltd. from 1949 to 1953, then became vice-president of the firm he now heads.

R. E. Chadwick, M.E.I.C., (mech., Toronto, 1906), formerly chairman of the Foundation Company of Canada Limited, will continue to be associated with the company as consulting engineer. Mr. Chadwick retired from the presidency of the organization in 1952, after forty-three years service. The following year he became the first president of Foundation of Canada Engineering Corporation Limited.

F. G. Rutley, M.E.I.C. (B.A.Sc., Toronto, 1912), president of the Foundation Company of Canada Limited, at Montreal since 1952, has been named chairman of the company. He has been associated with the Foundation Company since 1914. Mr. Rutley was recently appointed Montreal regional director of the Dollar Sterling Trade Council.

R. F. Shaw, M.E.I.C., (B.Eng., civil, McGill, 1933), of the Foundation Company of Canada Limited, former vice-president in charge of special projects has been named executive vice-president of the organization. Mr. Shaw has been closely associated with many of Canada's outstanding construction projects including the building of the Eastern sector of the DEW Line.

W. E. Hickey, M.E.I.C., (B.Eng., civil, Nova Scotia Technical College, 1938), has been named vice-president and chief engineer of the Foundation Company of Canada Limited. Former vice-president of the Foundation of Canada Engineering Corporation Limited, he has been in charge of many of the company's major engineering projects.



R. C. Mitchell, M.E.I.C.

Lt. Col. D. M. Saunders, M.E.I.C.

J. S. Cooper, M.E.I.C.

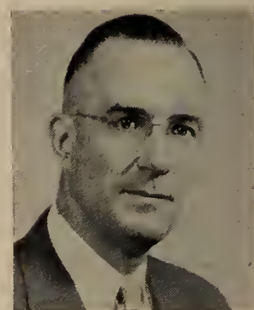
W. E. Soles, M.E.I.C., (B.Sc., mech., Queen's 1935), has been named president and general manager of the Anglo-Canadian Pulp and Paper Mills, Toronto. Mr. Soles has served the company in various capacities since 1935. He became general manager in 1952 and had been vice-president and general manager since 1954.

E. L. Ruggles, M.E.I.C., (B.Sc., civil, Sask., 1935), of the Bird-Archer Company Limited, has been appointed president of the organization. Mr. Ruggles was vice-president and general manager of the water treatment engineering firm since 1951. He joined the company in 1937 and has held responsibility in a number of positions within the firm at various centres since that time.

Warren S. Raynor, M.E.I.C., (B.Sc., mech., Queen's, 1939), of the Mathews Conveyor Company Limited, Port Hope, Ont., has been named to the post of chief engineer with the organization. A member of the staff since 1948, he has been engaged in special projects and for the last two years has been in charge of research and standards.

R. C. Mitchell, M.E.I.C., (B.A.Sc., Toronto, 1934), has been elected chairman of the Hamilton Branch of the Institute. Mr. Mitchell holds the post of manager of large rotating machine sales with the Canadian Westinghouse Company Limited in that city.

H. J. A. Chambers, M.E.I.C., (B.A.Sc., civil, Toronto, 1924; M.A.Sc., Toronto, 1925), has established the management consulting firm of Cybernetics Limited,



E. L. Ruggles, M.E.I.C.

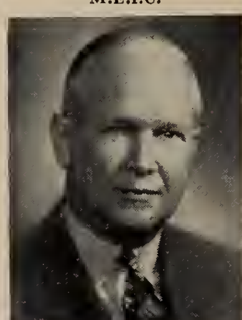
W. S. Raynor, M.E.I.C.

H. J. A. Chambers, M.E.I.C.

Per Hall, M.E.I.C.

R. E. Chadwick, M.E.I.C.

F. G. Rutley, M.E.I.C.



R. F. Shaw, M.E.I.C.

W. E. Hickey, M.E.I.C.

• PERSONALS

at Toronto. Experienced in senior engineering and management responsibilities for many years, Mr. Chambers has since 1946 been engaged in the machine tool manufacturing field and was president of Standard-Modern Tool Company Limited.

Mr. Chambers is a past-chairman and councillor of the Border Cities Branch of the E.I.C.

Lt. Colonel D. M. C. Saunders, M.E.I.C., (Royal Military College, 1939; B.Sc., civil, Queen's, 1948), of Whitehorse, Y.T., has been elected chairman of the Yukon Branch of the Institute. Commanding officer of the Northwest Highway Maintenance Establishment since 1956 Col. Saunders served with the Royal Canadian Engineers in World War II.

He became a lieutenant colonel and was assigned as assistant director of works, construction, at Army Headquarters, Ottawa, in 1953.

A. Benjamin, M.E.I.C., (B.Sc., elec., McGill, 1924), formerly head of A. Benjamin and Associates, consulting engineers of Montreal has joined the Flomen Electric Company Limited, in the capacity of vice-president. Mr. Benjamin was earlier employed with the Quebec Hydro-Electric Commission as a distribution engineer at Montreal.

C. M. Brant, M.E.I.C., (London Polytechnical, 1934), controller of radio regulations, telecommunications branch, Department of Transport, has been promoted to the newly created position of chief of technical co-ordination. Before the inclusion of Newfoundland in the Dominion of Canada, Mr. Brant, initially appointed by the U.K. ministry of civil aviation, was controller of radio (air) with the civil aviation division, Department of Transport, St. John's, Nfld.

L. P. Blaser, M.E.I.C., (B.Sc., chem., Sask., 1938), of the British American Oil Company Limited, has been appointed general manager of manufacturing with headquarters in Toronto. He joined the B.A. Oil Company in 1939 at the Calgary refinery. During the past 19 years he has held several key positions in the manufacturing department, most recently as chief engineer and previously as assistant manager of the Moose Jaw refinery.

J. S. Cooper, M.E.I.C. (B.A.Sc., civil, Toronto, 1934), assistant chief engineer with the Ontario Northland Railway, has been elected chairman of the Nipissing and Upper Ottawa Branch of the Institute.

Mr. Cooper has been active in Institute affairs as a charter member of the Sudbury branch, committeeman for the North Bay area, resident committeeman, councillor, 1956-57, and a vice-chairman of the branch in 1957.

After an extensive World War II

• PERSONALS

career with the R.C.N. he joined Ontario Northland Railway in 1945 in the capacity in which he now serves.

A. McDougall, M.E.I.C., (B.Sc., civil, Edinburgh, 1938), has relinquished his appointment as assistant project manager, Canadian British Aluminum at Baie Comeau, Que., in order to accept a position with the Vancouver firm of William Halcrow and Partners.

C. A. Leicht, M.E.I.C., of Kitchener, Ont., has been elected chairman of the E.I.C., for that region. Mr. Leicht is chief engineer with B. F. Goodrich Rubber Company of Canada Limited, and has been associated with engineering in Kitchener since 1909. He joined the Royal Flying Corps in 1916. He served with a number of companies before becoming associated with the Goodrich organization as a plant engineer in 1925.

Roy A. Phillips, M.E.I.C., (B.A.Sc., mech., British Columbia, 1939), has been appointed manager of marketing, appliance and television receiver department, with Canadian General Electric Company at Montreal. Prior to his present appointment, he was manager, marketing research and product planning in the appliance and television receiver department.

J. T. Madill, M.E.I.C., (B.Sc., elec., Alta., 1939; M.Sc., elec., M.I.T., 1940), manager of power operations B.C., of the Aluminum Company of Canada, Limited, has recently been transferred from Kitimat, B.C., to Montreal, Que. He will be assistant general manager, power division, operations, for the company.

R. R. Colpitts, M.E.I.C., (B.Eng., mech., Nova Scotia Tech. Coll., 1944), has been appointed manager of the industrial and commercial sales department of Northern Ontario Natural Gas Company Limited. He will head a department responsible for selling natural gas to large plants, mills and commercial establishments. Formerly he was in charge of industrial and commercial sales and gas utilization.

A. Butt, M.E.I.C., (B.Eng., civil, Nova Scotia Technical College, 1946), of the Imperial Oil Limited, has been transferred from Halifax to St. John's, Nfld. Mr. Butt who formerly served as operations analyst has taken on the duties of operations manager for the area.

J. B. Clarke, M.E.I.C. (B.Sc., elec., Manitoba, 1945), of the H. K. Porter Company (Canada) Limited, Federal Wire and Cable division, has been appointed general sales manager of the division. Mr. Clark joined Federal Wire and Cable in 1948. In 1950 he was assigned to the Lakehead, Manitoba, Saskatchewan and Alberta territories, as district sales manager. Mr. Clarke was appointed assistant general sales manager in 1957.

A. J. Harrison, M.E.I.C., (B.Eng., agriculture, Saskatchewan, 1950), has joined

• PERSONALS

the staff of the Edmonton firm of Petroleum Rubber Limited as sales engineer. Prior to his new appointment Mr. Harrison gained experience in construction, road building, pulp and paper, oil-field and agricultural equipment and supplies.

F. B. **Bunting**, M.E.I.C., (B.Sc., Belfast, 1949), has for a number of months been employed with the San Francisco firm of Porter, Urquhart, McCreary and O'Brien as section chief of the bridge department. Before transferring his services Mr. Bunting was a group leader with the design and construction department of the Foundation of Canada Engineering Corporation Limited at Vancouver.

Dave Pullan, JR.E.I.C., (B.Sc., engineering and business, Toronto, 1952), papers chairman for the Belleville Branch of the Institute has recently transferred to St. Catharines, Ont. He has been succeeded by Needham Throop. Mr. Pullan will be associated with American Cyanamid Ltd. at Niagara Falls.

A. D. **Cronk**, JR.E.I.C., (B.Sc., mech., B.C., 1952), is now associated with the B.C. Metals Protection Ltd., Vancouver. He will be engaged in the field of anti-corrosion protection, particularly with regards to coating and lining steel pipe. He was formerly associated with the Barrett Company Ltd.

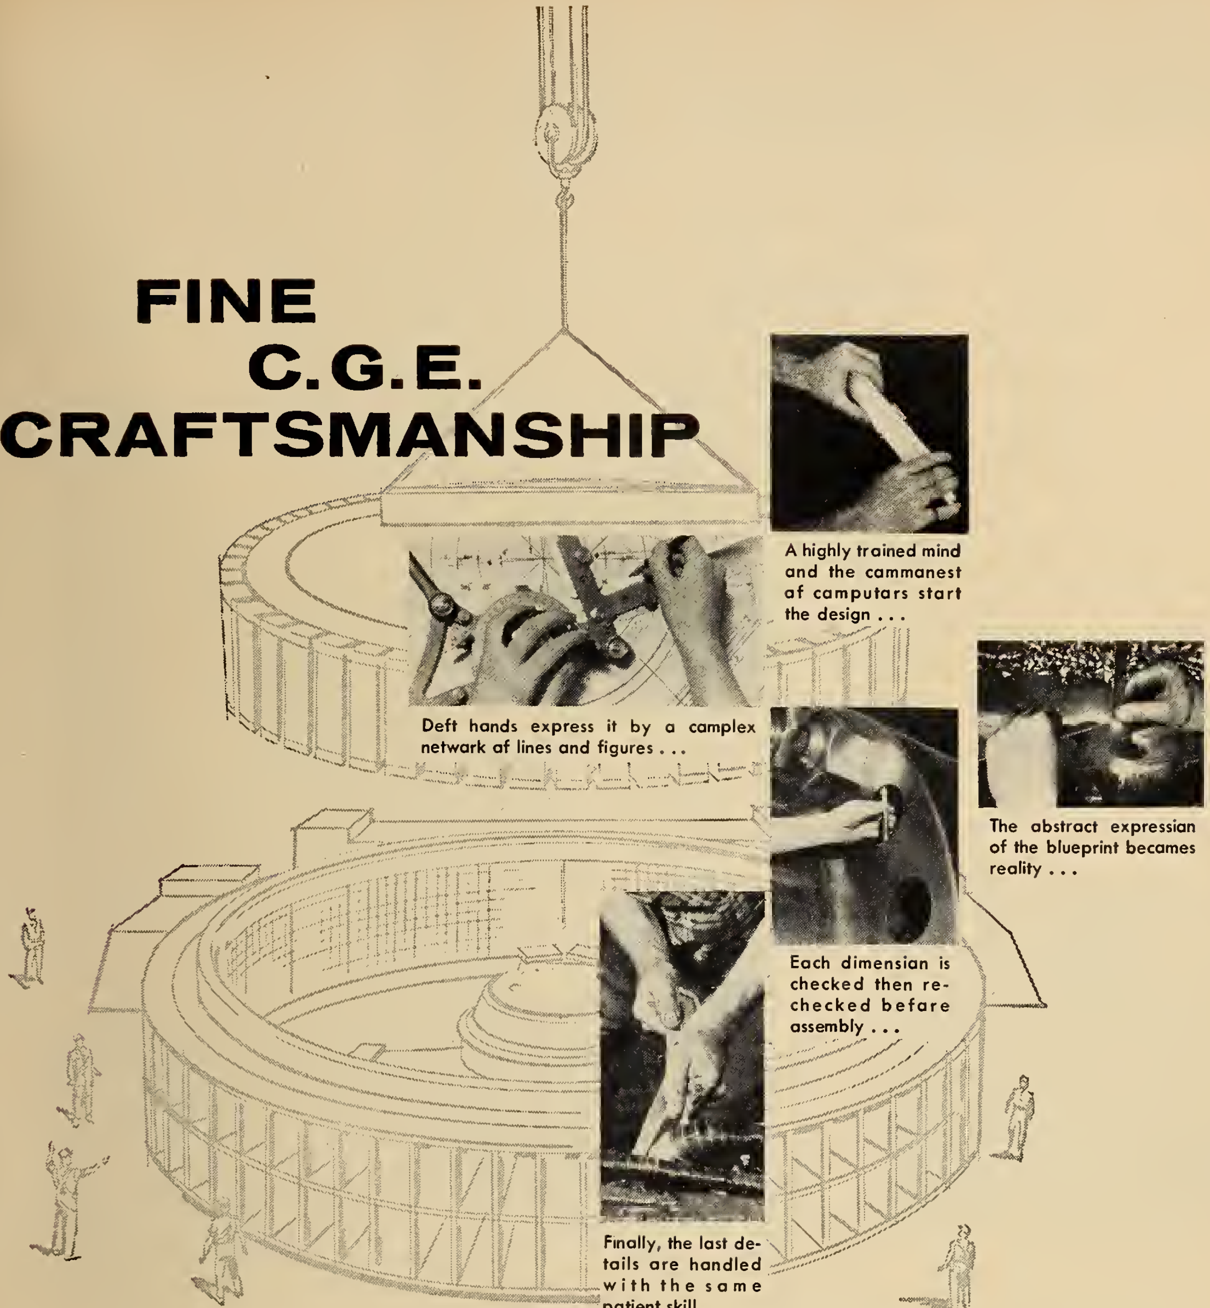
Robert I. Davis, JR.E.I.C., (B.Sc., elec., Queen's, 1949), of the Hydro-Electric Power Commission of Ontario, has been transferred from the Belleville area to Peterborough. Previously a meter engineer, East Central region, he now carries out the work of area meter engineer.

A. R. **Black**, JR.E.I.C., (B.A.Sc., Toronto, 1955), formerly employed with Sprostons Jamaica Limited, at Jamaica, B.W.I., has returned to Canada. He has accepted a position with McNamara-Brown and Root, at Pit Siding, Manitoba, on the Nelson River project.

Ray E. Jonasson, JR.E.I.C., (B.Sc., mech., Sask., 1949), of the Canadian General Electric Company Ltd., motor and control department, has been appointed district sales manager, central district, with headquarters in Toronto. With the organization since his graduation, Mr. Jonasson was most recently employed as sales representative for the motor and control department, mid-west district, with headquarters at Winnipeg.

Gerald McGurhill, JR.E.I.C., (B.Eng., chem., McGill, 1957), has left the department of Mines and Technical Surveys, Ottawa, in order to accept a position with the Montreal firm of John Struthers and Company Limited. His new post is that of chemical engineer.

FINE C.G.E. CRAFTSMANSHIP



A reputation is preserved . . . a craft advanced.

Today, mass production methods have invaded nearly every manufacturing process. Still, there remain a few types of equipment which can only be produced individually and by years of practised skill and craftsmanship. Giant hydro-electric generators are such equipment.

Sixty years ago, Canadian General Electric produced its first hydro-electric generator. That generator is still operating. Since its installation, hundreds of others have been delivered to power projects all over Canada as well as to many other parts of the world.

Today, this sixty-year-old skill in producing G-E Hydro-electric Generators is unparalleled . . . is known and respected the world over. For this reason, domestic orders *alone* have exceeded 10,000,000 KVA.

Canada depends upon the skill and craftsmanship of C-G-E generator builders. Without them, Canadians could not and would not enjoy such an abundance of low-cost electric power.

When you need electric equipment, small or large, consult Canadian General Electric. Whether it weighs 50 ounces or the 50 tons of the massive generator main bracket shown at left, the company that believes in and encourages *craftsmanship in all things* will make it for you . . . better.

NEWS OF THE BRANCHES

Activities of the Forty-Nine Branches of the Institute and abstracts of the papers presented at their meetings

BELLEVILLE

F. E. Moore, M.E.I.C., *Sec.-Treas.*

T. E. Flinn, M.E.I.C.,
Branch News Reporter.

DR. J. B. OKE, of the Dunlop Observatory, University of Toronto, on April 14 addressed the Belleville Branch on the subject of "The Chemical Composition of the Universe." The event marked the annual meeting of the Branch.

Dr. Oke described the efforts of astronomers to measure the chemical composition of the sun and the stars by making spectroscopic analyses. It has been found that the composition of sun and stars are similar — 70 percent hydrogen and 25 per cent helium by weight, with 62 other elements accounting for the balance. Helium was discovered on the sun before it was discovered on earth, hence its name, he pointed out. The region between the stars, the interstellar spaces have been investigated also. Thermonuclear reactions in the stars are constantly taking place with hydrogen being converted into helium, he said.

Election of Officers

Elected to office for the 1958-59 term were T. E. Flinn, chairman; W. Benger, vice-chairman; V. L. Lewis, E. T. Hilbig, and W. Canniff, for a two-year term on the executive; N. Throop and L. Law will serve a one-year term.

BORDER CITIES

J. M. REID, M.E.I.C., *Secretary*

A. W. MALMBERG, JR.E.I.C.,
Branch News Reporter

A JOINT DINNER MEETING of the Border Cities branch and the district membership of the Professional Engineers of Ontario was held on March 27. Among the special guests were C. T. Carson, vice-president and production manager of Hiram Walker and Sons, and president of the A.P.E.O., who addressed the meeting. Executive director Colonel T. M. Medland, B. H. Goodings, of the A.P.E.O., V. A. McKillop, past-president of the E.I.C., and Dr. Garnet T. Page, general secretary, E.I.C., were also present. In his talk president Carson said that the most important single factor in the expansion of Canada's economy in the past thirty-six years has been the rising influence of engineering. He stressed that the public is conscious of the importance of the profession because of what has been done in the past and because of a feeling of dependence on it for the maintenance of our comfortable way of life and indeed our national safety. Mr. Carson said that it is felt that an engineer is looked on as a perfectionist, and pictured as uncultured, even uncouth.

"I contend," he said, "that neither science nor applied science is far removed from culture and art." Higher education does not necessarily provide professional standing, he said. "It fails to do so unless its possessor is devoting his talents to the service of his fellow men, without undue regard to monetary rewards of such service."

Mr. Carson said that the feeling of professionalism is frequently absent in the young graduate. It comes only after a period of seasoning. But having developed that professional attitude, professional recognition must eventually follow.

BORDER CITIES: Several special guests attended a Branch meeting in March. Shown chatting are, left to right, above, V. A. McKillop, past-presiednt, E.I.C., and C. T. Carson, president of the Association of Professional Engineers of Ontario. Below left to right are: J. M. Reid, secretary, Border Cities Branch; B. H. Goodings, field representative, A.P.E.O.; V. A. McKillop, C. T. Carson, Colonel T. M. Medland, executive director, A.P.E.O.; Dr. Garnet T. Page, general secretary, E.I.C.; and C. M. Armstrong, chairman, Border Cities Branch.

EASTERN TOWNSHIPS

JEAN BOURASSA, JR.E.I.C., *Secretary*

THE DEW LINE was the subject of a talk by the vice-president of the Foundation Company of Canada, R. F. Shaw, at the joint meeting of the Eastern Townships Branch and the C.I.M.M. on April 11th. He described the way in which the defence project was constructed and advance parties, supplies, equipment and prefabricated buildings, landed by plane to establish campsites. Fuel, heavy equipment and structures were transported by ship during the short Arctic summer.

He added that no special problem had been experienced with the personnel as they had been carefully selected.

When asked during the question period whether the Dew Line would serve the

J. Whiteley, S.E.I.C.,
Branch News Reporter

Three student members of the E.I.C., graduating from the University of New Brunswick this year presented their theses to the Branch at an April 14 meeting. Competing for a prize awarded by the Branch, they represented electrical, mechanical and civil engineering respectively. G. T. Phinney spoke on crib fill wharf construction as used for pier extension, at Saint John, N.B. harbour during the summer of 1957. The talk was well illustrated and showed the crib construction method of placing, filling, and pouring the final pier top.

C. T. Cheeseman's talk on the production of sulphite pulps was based on his experience during his summer work with the Fraser's Company mill at Edmundston, and outlined the handling of wood from forest to finished product.

D. M. Caughey addressed the group on drift transistors. With the Defence Research Board during vacations, he gained background material while there and used it to show how the transistor was put together, explaining its characteristics and operation.

Mr. Phinney won first prize. Consolation prizes were awarded Mr. Cheeseman and Mr. Caughey.

Election of Officers

This meeting was the annual meeting of the Branch. Officers elected for the following year were: chairman, O. I. Logue; secretary, R. D. Neal; treasurer, E. C. Garland.

An encouraging report on confederation was given by D. O. Turnbull, M.E.I.C., of Saint John, president of the Association of Professional Engineers of New Brunswick.

Guided missiles and satellites was the subject of an address delivered to the Branch, March 20, by Dean D. L. Mordell of the department of mechanical engineering, McGill University.

Dean Mordell said "human travel among the planets of our system will be possible by 1993, and today's education must fit tomorrow's citizens for that kind of world, not for yesterday's." He added, "man is more than three quarters of the way to the moon in the present stage of satellite development. The range of

operation of the air supported vehicle and the air breathing engine will be extended to the point where it will replace the expensive first and second stage rockets of the satellite vehicle."

Canada now supports fundamental research which will help make possible the needed and inevitable breakthroughs in space travel, even though at present satellite production is too expensive for any but the largest nations, he said.

Dean Mordell preferred to take a wider view than the popular one in which crash programs in education have been advocated to produce more scientists, as a solution to the problem relating to the Russian achievement with the Sputnik.

He pointed out that if the free world was regimented in a manner similar to the Russian method, it would be overcome by the sheer weight of numbers in any test of strength, whether it be military, political, or economic, he suggested.

"We live in a changing world, not a static one, and the rigid patterns of training do not fit citizens to live in such a world."

He said that today's students will be faced with problems in life of which none of us are aware. In order to train a man to think, it is absolutely necessary that he have contact with another thinker who can probe him, who can test him and expose him to new tests as he progresses.

"If we want education, therefore, we need thinkers, and these thinkers must have time to have contact with the students. In many of the universities of today, and McGill is no exception, we are falling short of our ideal targets in this direction.

In explaining the situation within the universities today he cited the case of his own faculty, in which twice the present total income per student is needed to do the job sufficiently well. Since the students pay only one third the total operating costs at present, this would mean multiplying the fees five times.

"To do the job, universities need money, and there are basically three alternatives, not mutually exclusive," he said. These were, the underwriting by the state of all expenses of the universities; increased contributions by corporations and past graduates; if a satisfactory combination of these two schemes is not soon found, then student fees must be increased. This latter step, he pointed out, would exclude many good students with small means, from the universities.

ENGINEERING NEW PRODUCTS was the subject presented by Dr. R. A. Ramey, manager, new products engineering department, Westinghouse Electric Corporation at a joint meeting of the Branch with the Hamilton and Toronto Branches of the American Institute of Electrical Engineers.

Dr. Ramey introduced his subject by defining a new product as one with a new or added function. Vast expenditure are being made today for the development of new products, and the search for new products is regarded as one of management's most important duties. The need for new products is very real, Dr. Ramey stated, and emphasized the fact in prophesing that 15% of the products to be sold in 1959 would not have been available in 1955. In the last ten-year period, several companies were mentioned as having from 50 to 80% new product change.

Various charts and graphs were presented to illustrate the typical development of a new product line and various methods used by different companies to develop ideas which would lead to new products were discussed at length. One of the most important aspects of new product development discussed by Dr. Ramey was the importance of timing in new product introduction.

Dr. Ramey was introduced by Mr. G. L. Wilcox, president of Canadian Westinghouse, and thanked by R. C. Mitchell.

LONDON

A PANEL TYPE DISCUSSION on professional development was held on April 22, 1958 by the London Branch. R. W. McMeekin, chairman, welcomed guests to the meeting and congratulated E. V. Buchanan on receiving an honorary Doctor of Laws degree from the University of Western Ontario. This was the first time in the history of the university that an engineer has been honoured in this way. A. Furranna, M.E.I.C., was chairman of the panel which consisted of J. McLaren, field secretary. Object of the meeting was to discuss the professional development course given in London this year and to decide the nature of further courses. Opinion was registered in favour of offering fewer subjects and giving more time to each one.

THE ANNUAL MEETING and election of officers was held April 9.

Chairman J. F. Chantler presided. Secretary R. A. Booy announced the following officers were elected by acclamation for the ensuing year; chairman

• BRANCH NEWS

J. S. Cooper, North Bay, vice-chairman J. M. Rosborough, Temiskaming. The executive committee members with one year more to serve are J. Warburton, Temiskaming; H. Staniforth, Kiosk; and R. S. MacLennan, North Bay. Newly elected members of the executive for two years are D. Catford, Temiskaming; P. Rebin, Sturgeon Falls; and D. W. Briden, North Bay.

Retiring chairman J. F. Chantler presented his report indicating a successful year, and thanked the officers and committees for their support and co-operation, and particularly the secretary-treasurer R. A. Booy who has so conscientiously filled that position for the last two and one half years.

The treasurer's report showed a satisfactory financial condition with a larger bank balance than a year ago due to an improvement in the dues collected. Reports were presented by the committees on entertainment, papers, and membership. There are 68 members on the list, but there is a potential in the area of twice that number.

J. S. Cooper, newly elected chairman, took over the meeting and introduced the new executive. He also introduced John McLaren, Eastern field secretary, who was on tour of the northern section of Ontario. He visited members who due to distance did not find it convenient or possible to attend regular meetings of any of the branches.

Two Speakers Heard

Short talks were given by two members. The first was T. Chapman, chief engineer of Great Northern Woods, North Bay. He said that this firm manufactured bonded wood, the plant having been in operation about four years, and was the first of its kind in North America. A process had been developed by which small pieces of lumber normally unsaleable were finger pointed at the ends and edge glued to make long and wide boards of a higher grade than the original lumber. When the Russian minister of timber toured Canada in 1956, he was impressed with the process and eventually negotiated contracts whereby Great Northern Woods is to set up a smilar plant for the Russians at Archangel. Mr. Chapman spent a short time in Moscow and Archangel early in 1957. He briefly described what he had seen of the Russian people, and his impressions of their customs and mannerisms. Mr. Chapman was thanked by H. R. D. Graham.

Second speaker was D. Cullingham, shipping control chemist, Canadian International Paper Co., Temiskaming, who spoke on the simple application of statistics in evaluation of machine efficiencies. The talk was illustrated with an example from the pulp and paper industry. First he used the standard deviation formula, then the Students' T Test to assess the significance of a difference between two average values. Then he used the variance ratio of F Test to assess the significance of an apparent difference in variability.

Mr. Cullingham was thanked by Mr. R. R. Prescott.

PETERBOROUGH

G. M. LOCKE, JR.E.I.C., *Sec.-Treas.*

J. G. HOOPER, M.E.I.C.,
Publicity Chairman

THE MONTHLY SERIES of technical meetings for 1958 began in February with the discussion of the subject of "Models and Miscellaneous Marvels." The speaker, Professor L. E. Jones, associate professor of mechanical engineering at the University of Toronto has had a good deal of experience in the preparation and use of models of many different types for studying properties and performance of materials and proposed construction which can be done most readily and most economically only in this way.

Professor Jones pointed out the various types of models used in relation to engineering works with the applications of each. The five categories were display models, mechanical, abstract models used in an attempt to shape thoughts, convenience models used to reproduce hazards or test to failure without involving too great expense, imitative models, and demonstration models used to illustrate principles.

The talk was amply illustrated with slides and actual models that Professor Jones had brought with him and the easy manner of presentation made for a most enjoyable and informative evening for the members of the branch who attended.

Technical Meetings

The subject of steam turbine generators was discussed by a well-qualified team of three engineers from the Canadian General Electric Company at a March 20th meeting of the Branch. M. E. Gordon and V.L. Clarke discussed steam turbines while R. J. Gray dealt with the design of generators used in connection with steam turbines for the production of electric power. Slides were used to illustrate the paper.

Mr. Clarke began by outlining the growth in the use of steam generated power in recent years. Whereas the chief source of power, until recent years, was water-driven turbine generators, at present close to 50% of generation is from steam driven turbines. Hydro-electrical generation is expected to continue at about the same rate of development as at present but will only be able to supply about half the expected needs. For some years steam turbines are expected to drive the generators supplying most other requirements.

Most of the problems that make steam turbine design differ are the control of steam temperature and heat dissipation. Distortion of the casings during warm-

up and cooling are critical and the capacity of units is limited by the amount of steam that can be passed through.

Mr. Gordon detailed the problems and techniques relating to lubricating and control systems. He stated that these matters are in the process of continuous development. Protection devices are important and the goal is to keep them as simple as possible. At present they are mechanical.

Mr. Gray indicated the peculiar problems involved in the design of generators for use with steam turbine drive. Cooling, again, is a big factor. Hydrogen gas cooled generators up to 200,000 KVA are being produced. Liquid coolant of either oil or water-type has been developed successfully to permit installations up to 450,000 KVA.

After starting up a new installation the first shut-down for inspection usually is after six months. Following inspections and maintenance are at about three-year intervals. Down time in then about one month.

Vaino Aare, a designer of hydro-generator units, thanked the speakers.

Branch Plans

A large number of the executive of the Peterborough Branch are from the civilian atomic power department of the Canadian General Electric Company. For this reason, it is expected that the Peterborough Branch will hear plenty of news of atomic energy this year. It is expected that a group of the local branch will visit the NRU reactor in Chalk River, Ont.

The local executive of the Peterborough Branch have expressed the desire to become amalgamated with some of the American Societies such as the A.S.M.E., the A.I.E.E. and the A.S.C.E.

The branch has adopted the custom of inviting non-member engineers to the technical meetings in the hope of interesting them in membership in the Institute. A program for membership under the direction of Vaino Aare is underway. It is hoped that ten or 15 new members will be enrolled from the very potential Peterborough area.

SASKATCHEWAN

R. BING-WO, M.E.I.C., *Sec.-Treas.*

G. E. PADBURY, M.E.I.C.,
Branch News Reporter

THE SASKATCHEWAN BRANCH held a successful dinner meeting on April 28, 1958 at Regina. A committee of four, namely J. C. Traynor, R. J. Genereux, R. Harry, and L. Sirret was nominated to appoint an executive for the Regina section of the Branch.

Guest speaker, George R. Stewart, M.E.I.C., reservoir engineer, of the Imperial Oil Limited, was introduced by J. Crate before his talk, entitled the "Steelman Oil Field."

The Steelman oil field extends over two townships (80 acre spacing). It is located in the southeast corner of Saskatchewan, 20 miles east of Estevan in the Midale zone, between Carnduff and Weyburn. The oil reservoir is of the Mississippian, about twenty to thirty feet thick. Oil is trapped between dense anhydrites at a depth of between 4,500 to 4900 feet. The porosity is equivalent to a sandstone. The product is 34 to 40 degree light gravity oil with a gas in solution of 700 cubic feet per barrel, which is quite high. There are 550 wells. The wells are easy to complete, since there is not gas above the oil reservoir and no water below the reservoir. Some wells are capable of producing over 100 barrels per day, however they are held down to 70 barrels per day by government regulations. The productivity of a well varies with the permeability of the oil reservoir.

Three methods of obtaining oil were outlined. 1) gas cap drive by gas pressure above the oil reservoir, 2) water drive by water pressure under the oil reservoir, 3) dissolved gas drive by the gas in the oil reservoir.

Steelman oil field has been depleted approximately 5% and a pressure decline and gas oil ratio increase is predicted. An average well is predicted to produce about 200,000 barrels of crude oil. With this in mind, a secondary recovery pressure maintenance is being investigated, that is, to add energy to supplement or replace original energy. This can be done by various methods, but is usually obtained by the following methods: 1) combustion, 2) gas injection, 3) water drive.

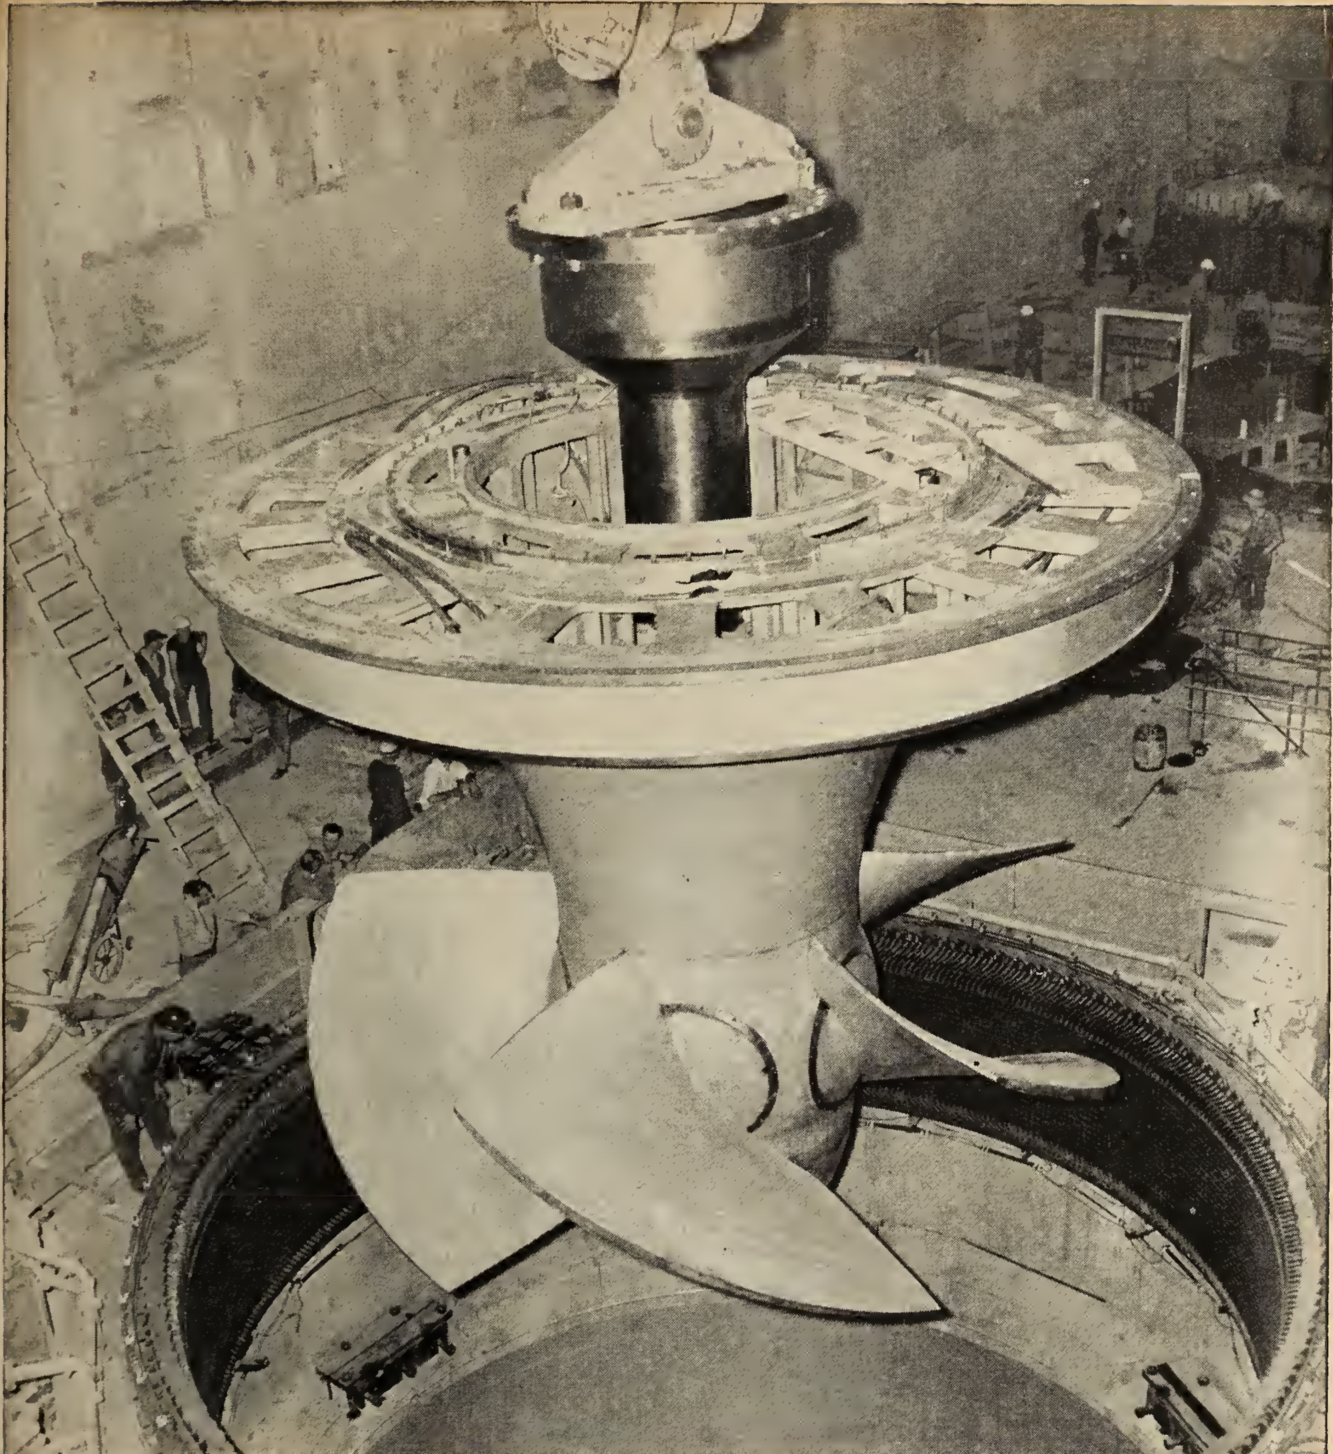
SUDBURY

W. J. Ripley, Jr., JR.E.I.C., *Sec.-Treas.*

M. D. Head, M.E.I.C.,
Branch News Reporter

TWENTY-EIGHT MEMBERS and guests attended the annual general meeting of the Sudbury Branch. After the minutes of the last meeting had been read, chairman J. Smith reviewed the activities of the branch over the past year. Statements or reports were presented by W. J. Ripley, Jr., secretary-treasurer, and by committee chairmen: R. Crawford, papers and publicity; C. Knight, for A. Finlayson, attendance; and Roy Smith, education. Other business included: discussion of branch representation in the separate technical branches of the Institute; an error pointed out by R. Moore, in the printed by-laws of the Branch, concerning the number of executive committee members.

Elected to office for the following year are: W. B. Ibbotson, chairman;



DOMINION KAPLAN TURBINES FOR BEECHWOOD

One of the 45,000 H.P. hydraulic turbine runners being lowered into position at the New Brunswick Electric Power Commission Beechwood power station on the St. John River.

Delegates to the World Power Conference Sectional Meeting, Sept. 1958 in Montreal, are welcome to visit our plant.

DOMINION ENGINEERING
COMPANY LIMITED, Montreal, Canada

E. M. Powell, vice-chairman; H. W. Whittles, resident committeeman; and Bruce Russell, non-resident committeeman. Following his election as chairman Mr. Ibbotson took the chair. To conclude the meeting R. Crawford presented a film entitled "The Pursuit of Wisdom," which was supplied by the University of Toronto.

Counselling

Recent activities of the Branch included arrangements for speakers to address senior high school students on the advantages of careers in engineering. Twelve schools in the greater Sudbury area, including Espanola, Corriston and Capreol, have, or will be visited for this purpose.

TORONTO

D. S. MOYER, M.E.I.C., *Sec.-Treas.*

GORDON F. R. NORTON, JR.E.I.C., *Branch News Reporter*

KON PIEKARSKI, M.E.I.C., of Toronto delivered a talk on "Education and Industrial Progress in Japan," at a March 27 meeting of the branch. The talk was based on a trip to that country.

Mr. Piekarski said that his Canadian attitude that all items produced by the Japanese are flimsy and cheap in price because Japan is a backward country, was unfounded.

Since his work had been in the field of solving production problems by automation methods, it was with surprise that he found himself watching the operation of a new machine which until that moment was merely an "idea" awaiting a Canadian owner's dubious "go ahead."

Strange to Canadian businessmen would be the big industry, classed as reliable, against small industry, as "not reliable."

Correspondence with Japanese is frustrating, for the Japanese businessman feels it more polite not to reply to a letter than to send an answer of "no." Japanese industry does not believe in sales promotion, trading companies act as the sales organization, both at home and abroad. The attitude seems to be to produce a useful item of quality and buyers will come. Mr. Piekarski felt that the Japanese system was superior.

Many production foremen are university graduates; many are employed in quality control and research programs of industry. A graduate engineer is highly respected, and there exists a greater incentive for higher education. Poorly equipped Tokyo university is able to accept only one out of every six applicants.

A sound and colour film produced in Japan showed Japanese industrial development. A massive hydro-electric project, producing electricity to power machines, to mine coal, which in turn is used to produce more electricity by firing huge steam plants, was dealt with. Many phases of modern life in Japan were shown, including electric commuter trains, household appliances, television and radio sets, modern buildings and factories. The highly mechanized shipbuilding industry, now the largest producer of ships in the world, was also seen.

Present also to answer questions were three Japanese guests representing trade, government and industry.

Labour unions are very active. The textile industry is 99% union, and affiliated with the U.S.A. Factory labour is cheaper, the administrative personnel is four times the ratio of this country. Labour is not anxious to become management, as is the case in this country. The number of workers exceeds the available jobs, with the result that the worker is more conscientious and more productive than the Canadian counterpart.

There are no typewriters and the 4000 symbols used in writing must be done by hand.

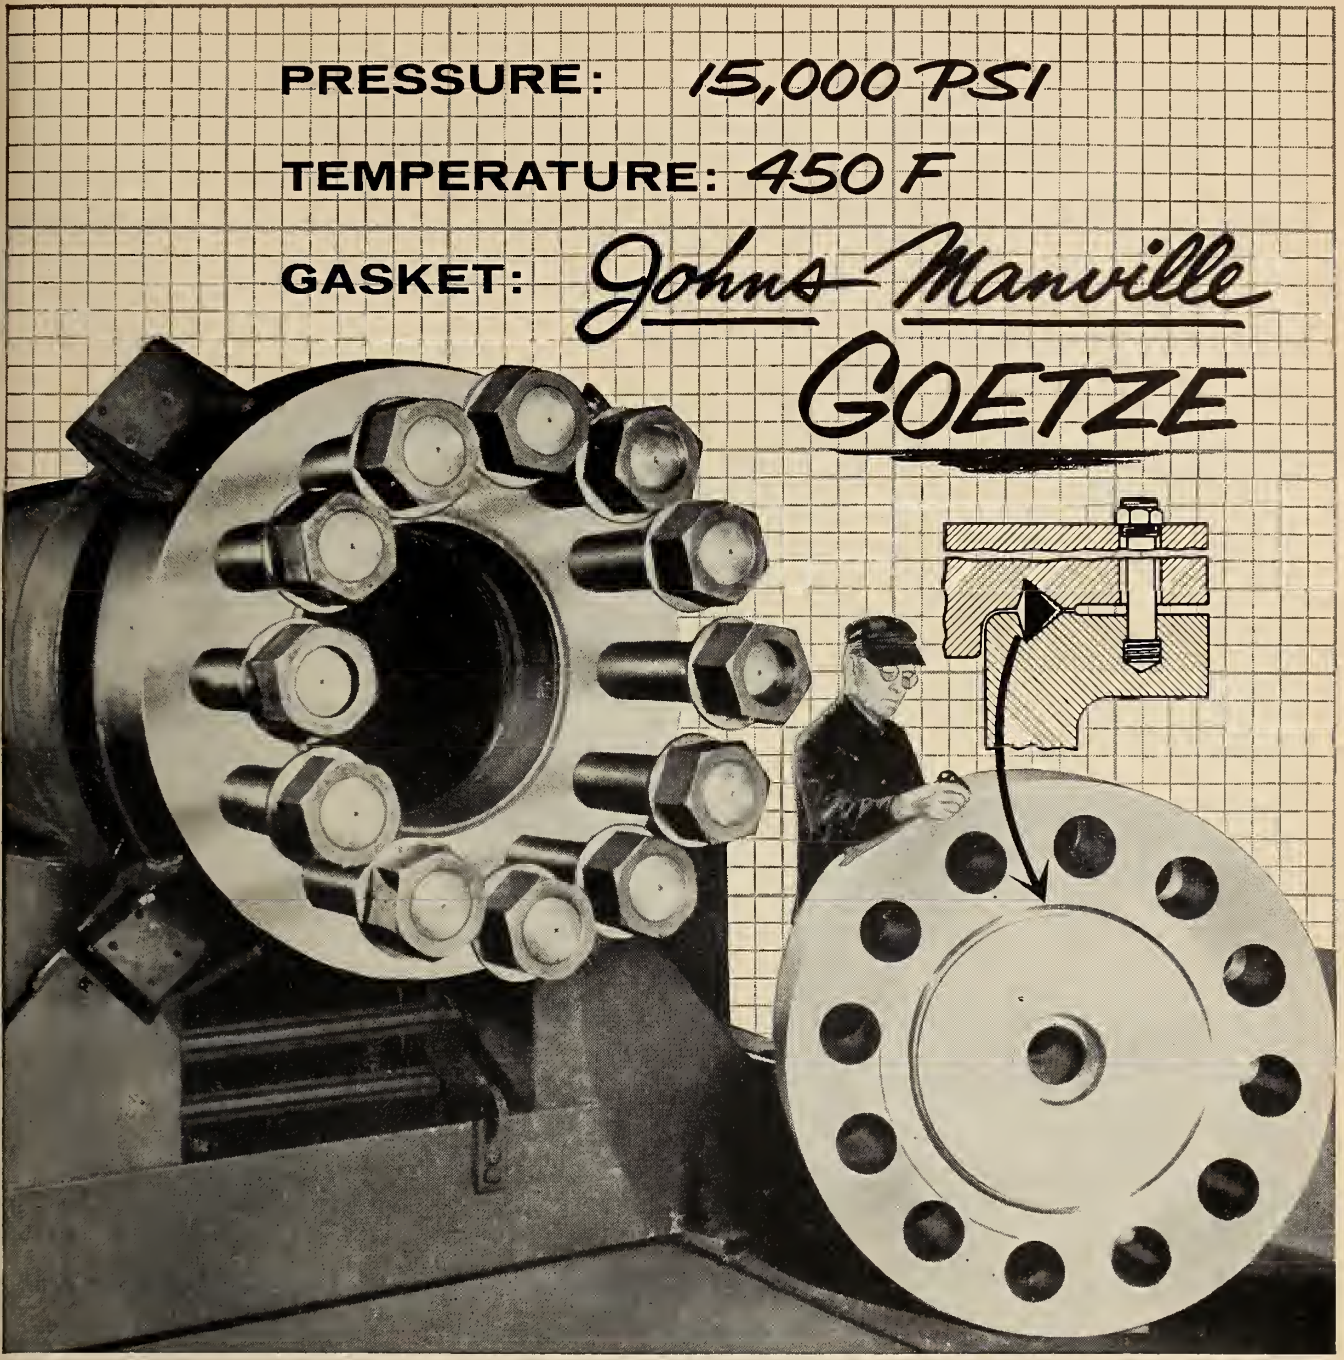
Canadian wheat sales to Japan in 1957 totalled 139 million dollars; the latter selling goods to us to the value of only 61.5 million dollars. Faced with this imbalance of trade, Japan looks to Canadian markets in the hope that, given a chance, Japanese manufactured goods can compete. Mr. Piekarski felt that Canadians could realize a saving by importing such items as custom built automatic machines and electronic equipment from Japan.

YUKON

CAPTAIN R. I. CROUSE, JR.E.I.C., *Secretary*

THE ANNUAL MEETING of the Yukon Branch which took the form of a dinner-dance took place on March 28, at Whitehorse Inn ballroom. Nineteen couples enjoyed cocktails, dinner and dancing. Toward the close of the evening retiring chairman Captain S. Thomson introduced the new members of the Branch executive. They are: chairman, Lt. Col. D. M. C. Saunders; secretary, J. Phelps; treasurer, John Scott. Following the introduction of the new executive, Captain Thomson commented briefly on the activities of 1957, which unfortunately were not as extensive as he had wished. This was due to the long periods of absence from Whitehorse of Captain Thomson and the secretary because of the failure of the Peace River Bridge.

Brigadier J. R. B. Jones, D.S.O., O.B.E., C.D., gave a vote of thanks to the committee for their work during the year.



How A. O. Smith maintains tight seals in giant "Multi-Layer" vessels

Today's tremendous pressures and temperatures have placed special demands on manufacturers of processing equipment. A. O. Smith has answered this need with a special type of "Multi-Layer" vessel construction. And Johns-Manville in turn has provided gaskets that assure tight seals under these exacting conditions. Typical of these is the delta type gasket, illustrated above, which was designed, for this application, to withstand pressures up to 15,000 psi. and temperatures to 500 F.

The development of special gaskets to meet special purposes has been the stock in trade of Johns-Manville's Goetze division for more than sixty-five years. Expert technicians possess a knowledge of metals and other factors related to gasket design and performance that is unmatched in the field. What's more, intensive specialization and modern production tooling provide substantial cost savings on J-M gaskets.

If you need gaskets for high pressure vessels for similar applications, send us a drawing or template for quotation. If you have a sealing problem of any kind, J-M technicians will work directly with your own engineers to develop new gaskets —or adapt existing styles—to meet your specific requirements. Write for further information to Canadian Johns-Manville, 565 Lakeshore Road E., Port Credit, Ontario.

C.G.R.A. Staff Changes

Changes in the staff of the Canadian Good Roads Association, necessitated by expansion in its technical program, are announced by G. W. Gilchrist, its managing director.

Gordon D. Campbell, formerly engineer-observer at the site of the road test project currently being conducted by the American Association of State Highway Officials, has been appointed director of technical services. Rowland Ian Kingham will replace Dr. Campbell as the Association's observer on the scene of the $22 million test at Ottawa, Ill.

As director of technical services, Dr. Campbell will work with the seven C.G.R.A. technical committees and assist in planning and carrying out their work programs. He will act as secretary of the advisory committee on technical information, and of the A.A.S.H.O. Road Test committee, and in addition, will maintain a technical information service at the Association's Ottawa headquarters.

Mr. Kingham, who is on leave of absence from the Highways Division of the Federal Department of Public Works, will be assigned to the test road to study and report on every phase of the comprehensive tests. His activities will complement and facilitate the work of the C.G.R.A. Illinois Observer Committee.

C.G.R.A. participation in the A.A.S.H.O. Test enables Canadian legislators, administrators, contractors and other professional groups and individuals to keep informed of all developments and conclusions of this significant project.

Engineering Applications of Automation

The British Group for Engineering Applications of Automation of the British Conference on Automation and Computation, has been formed.

The study of the techniques, machines, and concepts of automation, automatic control and computation has been intensified in Great Britain during recent years arousing interest in all branches of science and industry. A result of this is an organization known as the British Conference on Automation and Computation, which seeks to facilitate the exchange of information regarding the activities of the individual societies within the whole subject. The decsion to set up this conference was taken in April 1957.

This new organization has been divided into three groups;
A— The British Group for the Engineering Applications of Automation; B— the British Group for Computation and Automatic Control; C— the British Group for the Sociological and Economic Aspects of Automation Techniques. Group B was formally constituted in December, 1957.

The Engineering Applications Group was formally constituted in February, 1958, with 21 engineering societies associating themselves with the Group. Its aims are to foster the development of the engineering applications of automation; to afford a common meeting ground for the adhering organizations, whereby such of their activities as fall with the purview of the Group can, if so desired, be co-ordinated and extended; to maintain, as may be desirable, liaison with other Groups of the British Conference on Automation and Computation by direct contact and by representation on the general committee of the British Conference; to encourage and, if desired, to co-ordinate the presentation, at international conferences, of British papers whose subjects fall within the purview of the group; through the general committee of the British Conference on Automation and Computation, to maintain, as may be desirable, liaison with the corresponding national committees of other countries which support such international conferences.

The constitution of the Engineering Applications Group provides for the election of additional member societies.

Dr. D. F. Galloway, a member of the Council of the Institution of Mechanical Engineers, is chairman of the group. The secretarial services are provided by I.M.E., the honorary secretary being Brian G. Robbins, secretary of I.M.E. Correspondence should be directed to the honorary secretary, B.C.A.C., at 1, Birdcage Walk, Westminster, London.

Reports

C.C.A. Makes Recommendations

The Canadian Construction Association presented to the Federal Cabinet, in May, policy statements and resolutions adopted earlier at the Association's annual meeting.

The submission, made May 8, was signed by H. J. Ball, president of the organization and S. D. C. Chutter, its general manager.

Roughly three-quarters of the resolutions and statements adopted at the convention were addressed at least in part to the federal government. It was therefore essential that clear cut agreements be reached on these financial matters by the various governments in order to permit long-term planning of construction problems.

So much of the Canadian economy relies on the construction program that any sizable reduction in its volume would not only adversely affect the industry itself but also the general public.

The 1958 volume of construction will amount to approximately $7.1 billion.

Construction since 1945 has amounted to 13 per cent of Canada's gross national product. This proportion has risen roughly 21 per cent so that now one in every five dollars spent in end goods and services is a construction dollar; a dollar spent in fixed assets for an expanded future economy. There are two basic and related problems that have concerned the Assoc.: 1) the expansion of the industry's capacity in order to be able to carry out efficiently and economically larger and more complex construction programs and 2) the adoption of measures that will stimulate the demand for construction so that the potentially greater volumes ahead may be attained.

The submission presents the C.C.A. stand on the questions of housing, highways, tendering practices, labour relations, taxation and tariffs

C.I.G.R.E.

The 17th biennial session of C.I.G.R.E. (International Conference on Large Electric Systems) was held at Paris, June 4-14. Chairman of the Canadian Committee was E. V. Leipoldt of Montreal.

Attended by delegates from 50 countries these conferences are devoted to the discussion of technical problems of large high voltage transmission systems.

• OTHER SOCIETIES

Recent developments were discussed in the fields the design and operation of alternators, transformers, and circuit breakers; construction and operation of overhead lines and underground cables; tion of extra high voltage transmission of networks; the construction and operation of extra high voltage tarnsmission lines.

Four Canadian papers were presented at the conference.

Symposium on Ice Bearing Strength

A symposium on the bearing strength of ice, sponsored by the Associate Committee on Soil and Snow Mechanics of the National Research Council, was held at the Building Research Centre, N.R.C., April 16 and 17, 1958.

Eight papers dealing with the technical aspect of the bearing strength of ice were presented and discussed. These papers included field observations on the elastic properties and ultimate strength of ice. Consideration was given to special problems such as loading on the edge of an open crack.

C.S.A. Annual Meeting

The thirty-first annual meeting of the Canadian Standards Association was held at the Fort Garry Hotel, Winnipeg, May 30, 1958. Many representatives of the 500 technical committees of the organization were present.

C.S.A. standards were explained by President Dr. J. M. Thomson, as a broad field, and as specific applications. There are national standards for dimension and definition, for testing and performance and for safety. They are prepared by committees in which a balance of producer and consumer interest is maintained, with consideration given to representation on a nation-wide basis, in order to provide a standard that may be accepted throughout the country.

Dr. Thomson urged reduction of waste in manufacturing and raising of productivity through widespread use and development of national standards. This meant, he explained, wholesale use of the standards now available, and an accelerated program for developing the standards needed.

Dr. Thomson said that there is still no limit to the number of standards required and now is the time to develop co-ordinated standards in the rapidly advancing fields of technology.

We must also plan our standards in advance so that their use is co-ordinated from the raw materials to the finished article. He said that a special plea was being made to Canadian industry to help build a comprehensive, integrated set of national standards now when they are so vitally needed.

● OTHER SOCIETIES

Guest speaker at the luncheon meeting was Walter R. McLachlan, executive vice-president, administration and co-ordination, A. V. Roe Canada Ltd.

American Concrete Institute

The session on structural design of the 54th annual convention of the American Concrete Institute in Chicago was a joint session with the structural division of the American Society of Civil Engineers, which was holding its mid-west convention at the same time in Chicago. Topics on concrete structural design of interest to members of both societies were featured.

Another session, sponsored by A.C.I. Committee 215, included five reports concerned with fatigue of concrete.

A third session was devoted to construction technology, including descriptions of two recent outstanding projects, a discussion of control of concrete mixes on a large highway project, and a historical survey of failures with lessons to be learned from them.

Douglas McHenry, Portland Cement Association, and Joseph W. Kelly, University of California, were named president and vice-president of the American Concrete Institute.

Notices

National Water Safety Week

This summer the Canadian Red Cross Society will make a determined effort to reduce Canada's annual drowning toll in a campaign to be inaugurated by the second National Water Safety Week, June 15-21.

American Institute of Industrial Engineers

The Research Information Committee of the A.I.I.E. is endeavouring to secure abstracts of research performed in the period, July 1, 1952 to July 1, 1957. Sources from which information is solicitated are universities, industrial organizations, research institutions, and non-profit organizations including government agencies and professional societies. The committee has indicated that it will appreciate all information on industrial engineering research, past and present. Write Research Information Committee, A.I.E.E., Dept. Industrial Engineering, Washington University, St. Louis, Mo.

Nuclear Research Available

The latest nuclear research in the application of atomic energy to the engineering industry will be presented at the 1958 International Conference on the Peaceful Uses of Atomic Energy to be held in Geneva, 1-13 September 1958.

The Document Service of The Chronicle of United Nations Activities has inaugurated a complete service to supply the engineering industry with materials on the Conference. Available immediately are the lists of papers to be presented, including several hundred dealing with engineering research throughout the world.

Topics covered include reactor technology, plans for construction of nuclear power plants, properties of reactor materials, radiation effects on materials, use of isotopes in industrial technology, and hazards involved in disposal of radioactive products.

The lists may be obtained free by writing to: Engineering Document Service, The Chronicle of United Nations Activities, 234 West 26 St., New York 1, N.Y.

Calendar

Canadian Construction Association

C.C.A. National Housing Conference, Construction House, 151 O'Connor St., Ottawa, (C.C.A. h.q.), June 18-19.

Commission Generale d'organization Scientifique

International Congress, Brussels, June 25-28. Organized by CEGOS, 33 rue Jean-Goujon, Paris (8e).

International Union of Testing and Research Laboratories for Materials and Structures

Symposium on iron-frame for ferro-concrete and on iron-frame of pre-stressed concrete, Liege, Belgium, July 3-5.

Group for the Study of Atoms and Molecules from Radio-Electric Research

Annual colloquium on resonances, Paris, France, July 7-11.

Technical Association of the Pulp and Paper Industry

Seventh statistical course of the Canadian Pulp and Paper Association, Quebec City, Que., July 7-18.

Technical Association of the Pulp and Paper Association

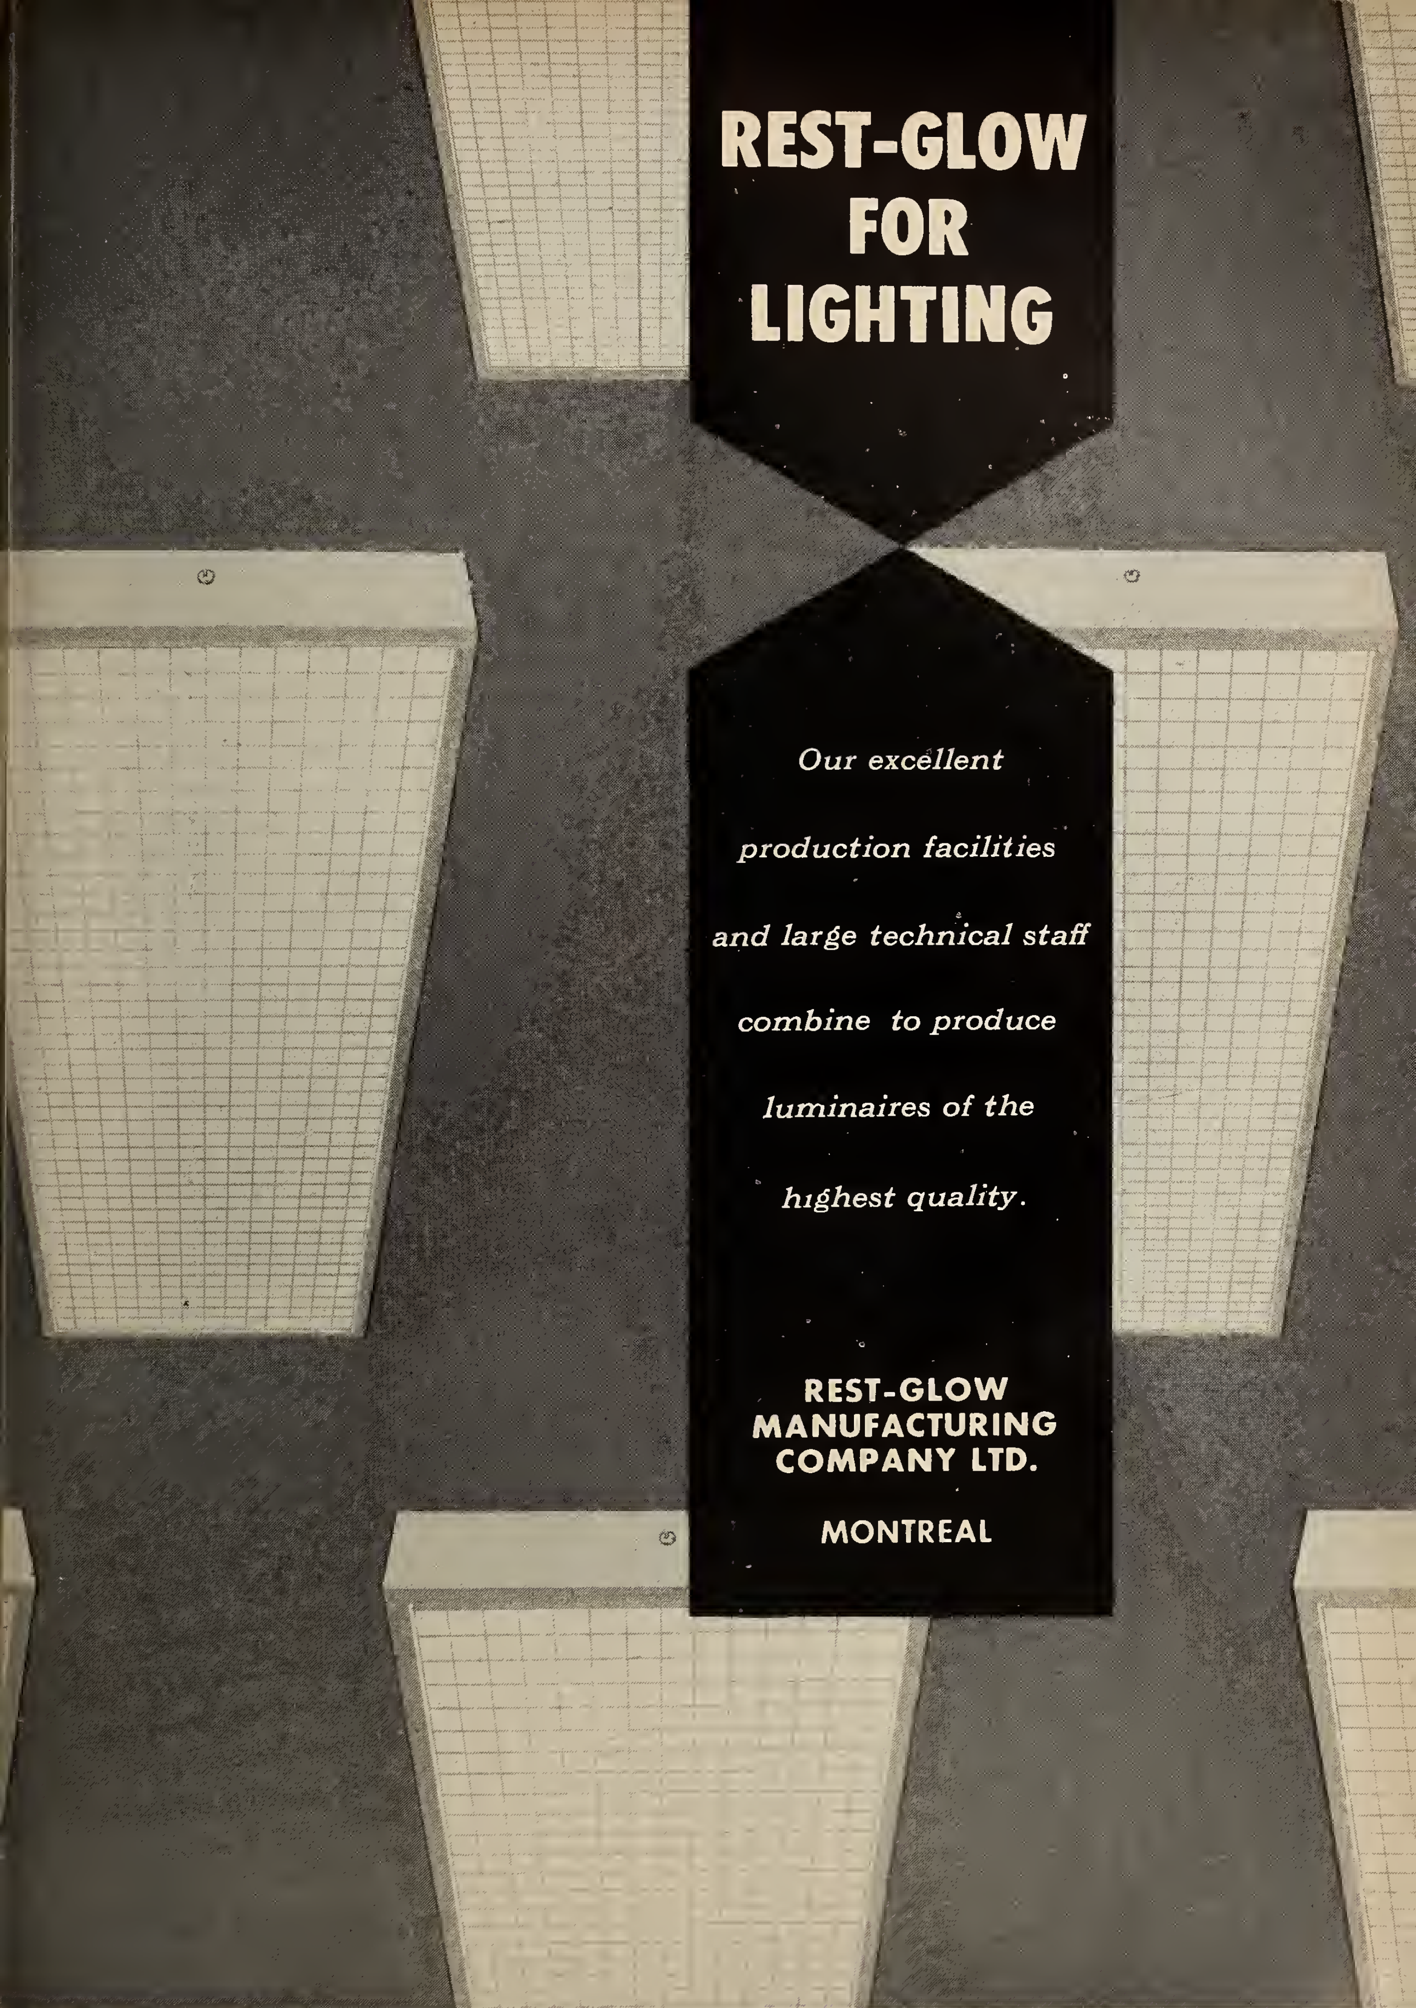
Thirteenth Engineering Conference, Portland, Ore., July 28-Aug. 1.

Institute of Aeronautical Sciences

National Summer Meeting, Ambassador Hotel, Los Angeles, Calif., July 8-11. Write: I.A.S., 2 East 64th St., New York 21, N.Y.

Canadian Electrical Association

The sixty-eighth annual convention of the Canadian Electrical Association, Banff Springs Hotel, Banff, Alta., June 30-July 2. Write: managing director, Rm. 320.



REST-GLOW FOR LIGHTING
Our excellent production facilities and large technical staff combine to produce luminaires of the highest quality.

BOOK REVIEW

IRRIGATION AND HYDRAULIC DESIGN, VOL. II, IRRIGATION WORKS

According to the author, this book is to be considered a handbook for the practical designer of hydraulic works, with special emphasis on the irrigation aspect. This is no doubt true, but in the opinion of this reviewer, it would be much more appreciated by engineers working in India or Egypt where conditions, both physical and economic, are much different from those in America.

The use of this volume by Canadian engineers, as a handbook, would be awkward and to some extent impractical; however, it is instructive and refreshing as supplementary reading. It shows clearly the differences in approach to the design of irrigation projects existing between American practice and that of Egypt and India.

Volume 11 begins with chapter 4 on the design of regulators (called "checks" in Canada). The hydraulic theory presented is elementary, the presentation very clear, with all the mathematical steps being painstakingly shown. The most uninitiated can follow the arguments, but the coefficients in the equations are based mostly on the metric system of measurement. This makes reading difficult for the Canadian, since one had to mentally convert to foot units in order to appreciate or grasp the implications.

A large number of empirical formulae are used in the sections on design. This is where one realizes the differences between the old world and the new, so far as irrigation engineering is concerned. The old world has centuries of experience in irrigation, and many rule-of-thumb formulae have accumulated. Some of these may not be too scientific, but are still standing the test of time. It should not be forgotten, also, that these traditional designs and construction methods are based on a plentiful supply of cheap labour.

In India and Egypt particularly, masonry is still largely used in the construction of hydraulic structures. This leads to a massive type of structure, which depends largely upon sheer weight for stability. Labor costs for such structures in Canada would be prohibitive; if indeed their construction would be possible, in view of the scarcity of stone masons these days. The author does, however, add a short section in each chapter in which he briefly describes American practice, and how it differs from that in Egypt, where his experience was apparently obtained.

It appears that the main difference in the design of hydraulic structures between the old world and the new, is in the provision for uplift. In Canada, an upstream cutoff wall of necessary depth is invariably provided, followed immediately by complete under-drainage of the structure. In Egypt and India, on the other hand, little use is made of vertical cutoff walls and/or drainage, except in large structures. An extremely heavy structure is merely set on the ground, the 'creep' line being almost exclusively horizontal. Another objection to this type of structure in Canada, in addition to the economic one mentioned earlier, is the frost problem. It is feared that undrained masonry floors and walls would not last long in our sub-zero weather.

Chapters 5 and 6 deal with the design of inverted siphons and weirs. Included is a section on sand and silt excluders and extractors, which is instructive. Sand and silt has always been a serious problem in the river delta irrigation projects in India and Egypt. This problem is almost non-existent on our table-land projects in Canada, but occasions may arise when a knowledge of preventive or corrective measures in this regard would be useful.

Chapter 7 deals with the layout and design of canals and distribution systems. Here, the procedures outlined in this volume come closer to our own. Differences in climate, crops grown, and soil conditions cause natural departures, but the principles underlying the procedures are the same.

Soil conditions in the delta countries require canal velocities to be set at about two-thirds of the values used in our Canadian glacial drift. On the other hand, it is interesting to note that canal capacities for a given acreage are about the same in Egypt as those being currently designed in Canada.

Chapter 8 covers the design of the bridges, aqueducts (flumes) and gates. The section on bridge design is quite detailed, and covers timber, steel and reinforced concrete types. There is also a lengthy section on the design of moveable bridges.

In general, the material in the book is very well presented. Explanations are painstakingly made, the English is good, and the impression of this reviewer is that the author knows what he is talking about. It is important however, that the Canadian user of this book keep in mind the experience background of the author, and how it differs from Canadian and United States practice. (Serge Leliavsky. London, Chapman and Hall, Toronto, Ryerson, 1957. 864p., $60.00.)

W. L. Foss, M.E.I.C.

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m. — 5 p.m.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*ANALYTICAL KINEMATICS OF PLANE MOTION MECHANISMS

Vector methods are used throughout this text to define the concepts of motion. Aspects discussed include the nature of motion transfer, displacement and loci, velocities and mechanisms, properties and transfer of accelerators, cams and cam mechanisms, and gears and gearing. (J. Huckert. Toronto, Brett-Macmillan, 1958. 209p., $7.75.)

WILEY BOOKS

AIRCRAFT AND MISSILE PROPULSION

By M. J. ZUCROW, Purdue University

The first volume of an important new three-volume work is now ready. Designed to give you a better understanding of the fundamental principles governing the functioning and operating characteristics of engines used to propel winged aircraft and missiles, both guided and unguided, at high speeds. Special features help you follow the subject matter with ease. *Volume I* discusses the thermodynamics of fluid flow and its application to propulsion engines.

VOLUME I

Thermodynamics of Fluid Flow and Application to Propulsion Engines. 1958. 538 pages. Illus. $11.50.

NETWORK SYNTHESIS, VOLUME I

By DAVID F. TUTTLE, Stanford University

A comprehensive, highly readable treatment of the most important ideas used in the synthesis of networks. This first volume of a two-volume work covers the two-terminal (one-port) network or one-terminal pair. Features a three-step procedure: — obtaining a working knowledge of the properties of networks; investigating ways of approximating desired behaviour; and carrying out the actual synthesis of networks to achieve such attainable ends. 1958. 1176 pages. Illus. $23.50.

PRINCIPLES OF NOISE

By J. J. FREEMAN, University of Maryland

Makes you familiar with enough of the principles, facts, and techniques used in noise analysis to enable you to read the literature and use it as a professional tool. Deals with such topics as probability, stationary random processes, and their transformation, power spectra, noise temperature, input signal-to-noise ratio, output signal-to-noise ratio, minimum detectable signal, etc. 1958. 299 pages. Illus. $9.25.

SWITCHING CIRCUITS AND LOGICAL DESIGN

By SAMUEL H. CALDWELL, Massachusetts Institute of Technology

A clear and practical presentation of fundamental principles which gives a better understanding of the complexities involved in the design of switching circuits. Deals with the methods used to handle the problems of circuit synthesis using various kinds of components, and enables you to create your own methods for handling new problems. 1958. 685 pages. Illus. $14.00.

NOTES ON ANALOG-DIGITAL CONVERSION TECHNIQUES

Prepared by Staff Members of the M.I.T. Servomechanisms Laboratory, ALFRED K. SUSSKIND, M.I.T., editor

Based on the 1957 M.I.T. Special Summer Program on Analog-Digital Conversion Techniques. Coverage includes: an introduction to the theory of sampling, quantizing, and coding; detailed analysis and evaluation of basic coding and decoding methods for electrical and mechanical analog quantities; and a case study showing how basic principles were applied in a digital flight-test instrumentation system. 1958. 417 pages. Illus. $10.00.

PROGRESS IN SEMICONDUCTORS, VOLUME II

Edited by ALAN F. GIBSON, Radar Research Establishment, Malvern, U.K.; P. AIGRAIN, Université de Paris; and R. E. BURGESS, University of British Columbia

The latest information on important aspects of semiconductor research by 13 top authorities. 1957. 280 pages. Illus. $10.50.

AIR CONDITIONING AND REFRIGERATION

By the late WILLIAM H. SEVERNS and JULIAN R. FELLOWS, both of the University of Illinois

Clear, useful descriptions of the devices employed in the control of air conditioning, with a discussion of the problems involved in specific types of plants. The broad coverage includes such topics as thermodynamics, fluid mechanics, combustion, and fuel selection. Examples of typical calculations are included. Based on the second edition of *Heating, Ventilating, and Air Conditioning Fundamentals* by the same authors. 1958. 563 pages. Illus. $10.25.

QUEUES, INVENTORIES AND MAINTENANCE

The Analysis of Operational Systems with Variable Demand and Supply

By PHILIP M. MORSE, Massachusetts Institute of Technology

Shows you how to analyze and solve problems involving maintenance and inventory by the application of the queuing theory. Gives a general description of the subject, defines terms, outlines analytic aspects of the theory, and discusses the effect of changes of arrival and service distributions on queuing results. Helps you set up your own model to fit your particular operation, and to compute your own formulas. The first volume in a new series, *Publications in Operation Research,* sponsored by the Operations Research Society of America. 1958. 202 pages. $6.50.

INSTALLING ELECTRONIC DATA PROCESSING SYSTEMS

By RICHARD G. CANNING, University of California, Los Angeles

A practical guide with a realistic approach to such key topics as planning the installation program, programming, installation, conversion to the EDP system, and the early phases of operation. Tells you how to organize the EDP section, select its personnel, the number and type of people needed, the total cost, auditing procedures for protection against fraud and errors, and how to operate during the conversion period. 1957. 193 pages. Illus. $6.00.

MOTION AND TIME STUDY, FOURTH EDITION

By RALPH M. BARNES, University of California, Los Angeles

Almost completely rewritten to bring you the best and most modern theory and practice. Contains new material on: developments in the industrial use of pulse rate as an index of physical activity; statistical procedures in time study; auditing of methods, time standards, and wage incentive plans, *plus* complete coverage of Work Sampling, and important background information on electronic processing equipment. 1958. 665 pages. Illus. $9.25.

BORON, CALCIUM, COLUMBIUM AND ZIRCONIUM IN IRON AND STEEL

By R. A. GRANGE, United States Steel Corporation; F. J. SHORTSLEEVE, D. C. HILTY, W. O. BINDER, all of the Electro Metallurgical Company, G. T. MOTOCK, Olin Mathieson Chemical Corporation, and C. M. OFFENHAUER, the Electro Metallurgical Company

A concise summary of all the available data on four of the important alloying metals for iron and steel. Complete, accurate information, some of it for the first time in published form. The fourth publication in the *Alloys of Iron Research New Monograph Series: Frank T. Sisco, Director.* 1957. 533 pages. Illus. $14.00.

UNIVERSITY OF TORONTO PRESS, Toronto, Ontario

RENOUF PUBLISHING COMPANY, Montreal, Quebec

• LIBRARY NOTES

*BASIC MOTION TIMESTUDY

Provides the principles of work measurement and motion identification necessary for the establishment of a system of predetermined motion times that has as its goal universal application. The present volume differs from similar studies by its use of "basic motion" which emphasizes clear-cut end points that may be applied to all body members. Practical procedures and examples are given. (G. W. Bailey and R. Presgrave. Toronto, McGraw-Hill, 1958. 195p., $5.00.)

*GRAIN BOUNDARIES IN METALS

A study of grain boundaries in metals which attempts to correlate and classify the basic problems involved. It includes a great deal of numerical data useful in approaching the subject. Starting with theories about the structure of grain boundaries and their influence on microstructure, diffusion, fracture and behavior during plastic deformation, the book then continues with energies of grain boundaries, migration of boundaries, and special features of low angle boundaries. (D. McLean. Toronto, Oxford University Press, 1957. 346p., $7.50.)

*THE GRAY IRON CASTINGS HANDBOOK

Provides information useful in the design, purchase, and applications of gray, ductile, white, and high alloy iron castings. Data is given on design: specifying and purchasing; properties; heat treatment in relation to improved wear resistance and strength; welding, joining and cutting; machining and grinding; abrasive finishing; metallic and non-metallic coatings. (Edited by C. F. Walton. Cleveland, Gray Iron Founders Society, 1958. 607p., $10.00.)

HEATING VENTILATING AIR CONDITIONING GUIDE, 1958

This thirty-sixth and largest edition of the Guide has again been brought up-to-date, and extensive revisions and additions made in many of the chapters. Some of the changes include the addition of a description and design method for high velocity air duct systems; an enlarged section on the heating pump; a simplified presentation of industrial drying principles; more information on heavy fuel oils; a revision of the chapter on radiators; and an enlarged section on air cleaners.

The Technical Data section is divided into seven sections: fundamentals; human reactions; heating and cooling loads; combustion and consumption of fuels; systems and equipment; special systems; instruments and codes. The catalogue section has also been enlarged, and the data in it revised. Both sections are well indexed. (New York, American Society of Heating and Air Conditioning Engineers, 1958. 1272+503p., $12.00.)

HUMAN ENGINEERING

A study of the adaptation for human use of work equipment, work space and environment, and consumer products. Topics included are illumination, visual displays, color, atmospheric conditions, arrangement of equipment, and the design and arrangement of controls. In addition several chapters deal with various aspects of the human organism and the way in which motor activities are carried out. (E. J. McCormick. Toronto, McGraw-Hill, 1957. 467p., $9.60.)

INDUSTRIAL CONTROL CIRCUITS

This text is concerned primarily with control circuits found most often in industrial electronics, where they form the basis of the regulation and control of many industrial processes. It is intended for those who have little knowledge of the field.

Considered are: electronic relay control and timing circuits; photoelectric control; power controls; control circuits for gaseous and vapour filled tubes; electronic d-c motor control; welding control; and industrial instrumentation control. Various specific industrial applications are described, and the book is illustrated with diagrams and photographs. (Sidney Platt, New York, Rider, 1958. 194p., $3.90.)

*INFLUENCE LINES FOR CONTINUOUS BEAMS

A series of three reports, each dealing respectively with two, three, and four span structures. Each report contains tables providing influence line data for continuous beams of constant moment of inertia. Influence lines for special points are developed, thus providing the data to investigate the occurrence of maximum positive moments under several conditions. Unsymmetrical cases are investigated and provide data of value in economic studies. (W. C. Boyer and J. I. Abrams. Baltimore, Johns Hopkins Press, 1958. Various pagings, $10.00.)

*INTRODUCTION AU GENIE NUCLEAIRE
VOLUME I: PHYSIQUE ET CALCUL DES RÉACTEURS NUCLÉAIRES.
VOLUME II: CONTROLE ET PROTECTION DES RÉACTEURS NUCLÉAIRES.

Vol. I of this two-volume set covers the fundamentals of nuclear physics, the basic theory of nuclear reactors, and the design and calculations of several types of reactors including brief discussion of one Russian installation. Vol. II deals with reactor control, and with the detection of radiation, radiation danger, and protection. A brief treatment of the liberation of energy from the fusion of light elements is appended. (T. Kahan and M. Gauzit. Paris, Dunod, 1957. 388 and 396p., 3,900fr. ea.)

*LIVING WITH THE SUN, VOL. I

Sixty plans selected from entries in the 1957 international architectural competion to design a solar heated residence. Two principal solutions to the design of solar energy units are utilized. In the first the solar collectors are assumed to be an integral part of the house, while in the second the heat-collecting mechanism is kept as a separate entity. Design notes offer an explanation of the design and proposed method of operation, with an indication of the estimated heat loss

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

• LIBRARY NOTES

and gain. (Phoenix, Arizona, Association for Applied Solar Energy, 1958. X11p., 60 plans, $6.00.)

*LA MECANIQUE DES ROCHES

The author presents, for the civil engineer, a treatise on the mechanical behavior of rocks and rocky terrain comparable to the numerous works on soil mechanics. In the first two sections he deals with theoretical aspects and experimental data. The third section covers applications: drilling and excavation work; foundations; tunnel supports and linings, and other aspects of tunneling related to underground conditions; cementation and sealing. Much information is given in tabular and graphic form and a considerable bibliography is appended. (J. Talobre. Dunod, Paris, 1957. 444p., 4800 fr.)

*MIRACLE BRIDGE AT MACKINAC

The story of the construction of the Mackinac bridge is told by the engineer who designed it, David B. Steinman. Purely technical factors have been avoided in the writing, but the reader is given an indication of the myriad of problems that were encountered in building the longest, costliest and safest suspension bridge in the world. Some of the difficulties faced are revealed by its center span which is 3800 feet long, towers which are 552 feet above the water and cables that are two feet in diameter. The story of its creation is a tribute to its engineer. Mr. Steinman is a member of The Engineering Institute of Canada. (Grand Rapids, Wm. B. Eerdmans, 1957. 208p., $4.50.)

*THE NAVAL ARCHITECTURE OF SMALL CRAFT

Concerned primarily with the design of working boats; inshore and middleground fishing vessels; patrol, pilot and customs launches; high speed craft. Consideration is given to such factors as stability and rolling, course keeping and dryness, rudders, frictional resistance and fouling, wave making resistance and hull form, installation and transmission of power, propeller design, and powering calculations. Also included is a discussion of sail and power yachts. (D. Phillips-Birt. New York, Philosophical Library, 1957. 344p., $15.00.)

NEW SOURCES OF ENERGY AND ECONOMIC DEVELOPMENT

This report was prepared by the Secretary-General of the United Nations in collaboration with five specialists.

The first part consists of a comparative study of the five new sources of energy; solar, tidal, wind, geothermic, and the thermal energy of the seas. It reviews the methods developed to control and use these energy sources, it considers their main characteristics, and examines the ways in which they might be used to produce electric power, and other uses to which they might be put. Finally, lines of future development are considered.

The second section comprises five studies on the five energy sources, abstracted from the papers prepared by the specialists. The final part of the report is an annotated bibliography of almost 500 items. (United Nations, Secretary-General. Toronto, Ryerson, 1957. 150p., $1.25.)

°ONCE ROUND THE SUN: THE STORY OF THE INTERNATIONAL GEOPHYSICAL YEAR

Because of the importance of the sun in the study of geophysics, various phases of the sun's behavior are discussed and its effects on the earth, including earthquakes, terrestrial magnetism, and the movements of the oceans and the great air masses, the auroras, and the melting of glaciers. The program of the International Geophysical Year is covered in detail: the 24 hour watch on the sun, the oceanographic program and the concentration of stations throughout the earth. A two-page conclusion is a summary of what the program hopes to achieve. (R. Fraser. London, Hodder and Stoughton, 1957. 160p., $3.95.)

PLASTICS PROGRESS, 1957

The eighteen papers in this volume were presented in an abridged form at the 1957 British Plastics Convention, and cover some of the most recent international advances in plastics technology. The discussions which took place at the meetings are included.

The authors are leading authorities on the subject from the United Kingdom, the United States and Germany, and much of the information in the papers is based on original work which has not previously been published. The subjects covered include polyolefins, polythenes, polyvinyl chloride, polystyrenes, reinforced plastics, fluorine polymers, and current developments in the theory and practice of extrusion and injection moulding. (Ed. by Philip Morgan. London, Iliffe, Toronto, British Book Service, 1958. 394p., $10.00.)

POWER SYSTEM COMMUNICATIONS

Based on a series of advanced lectures at the Heriot-Watt College in Edinburgh, this is the third volume to deal with a particular aspect of power system operation. The first two volumes dealt with power system transients, and power system plant, while this book covers communications, a specialized branch of the subject, a knowledge of which is, however, essential to the power engineer.

The different chapters are written by experts and cover communication circuits; various types of apparatus such as relays, switches and transformers: post office plant, including telephone and telegraph; carrier-current equipment; radio and television equipment, supervisory remote control; telemetering; and intertripping.

Some of the chapters include bibliographic references. This should prove a useful volume in an interesting series. (Ed. by E. O. Taylor, Toronto, British Book Service, 1957. 340p., $7.50.)

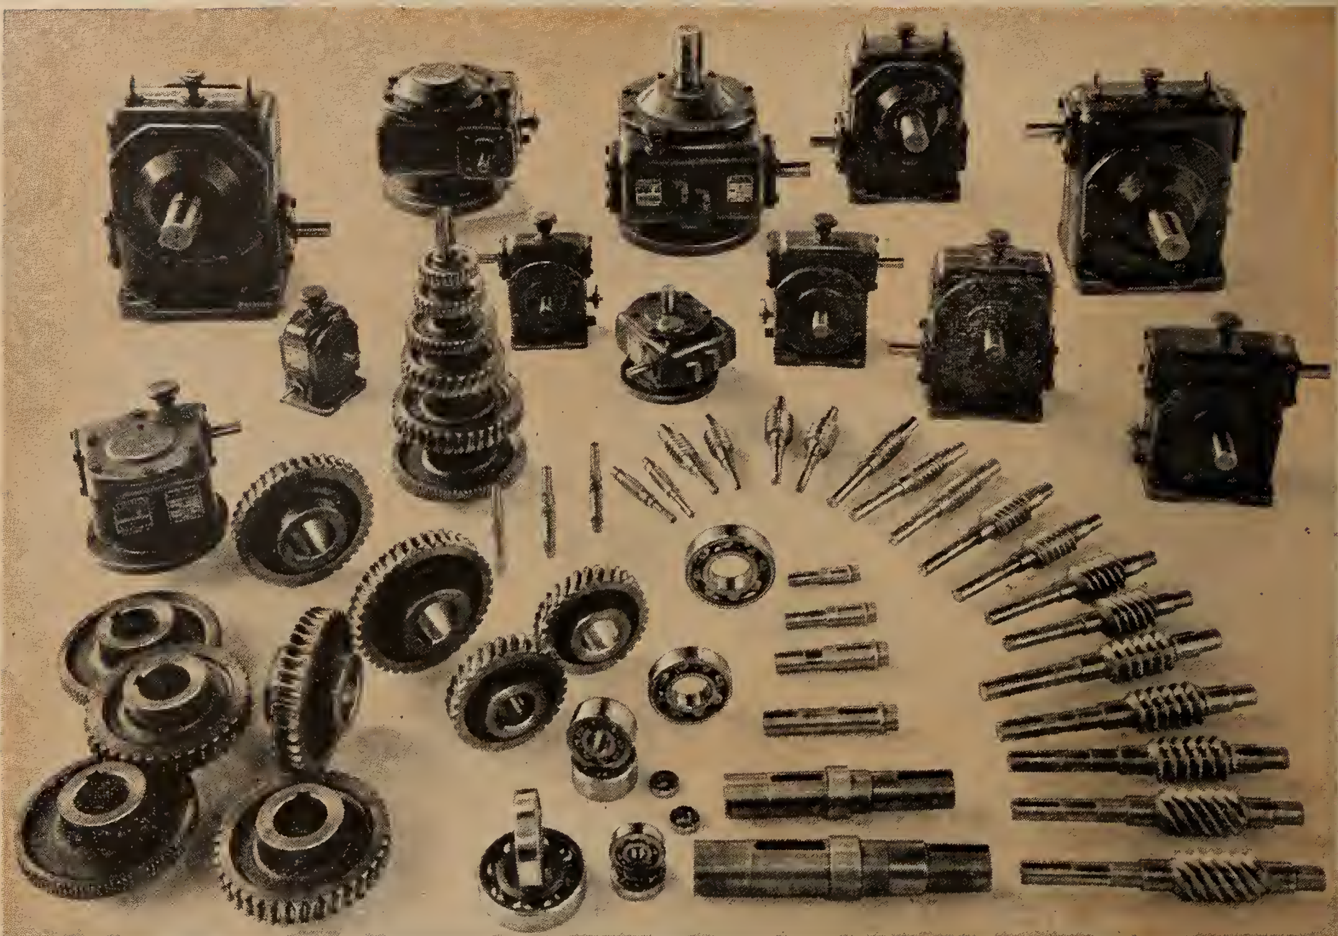
°LA PROPULSION PAR FUSEES

A thorough treatment of the theory and practice of rocket propulsion. The beginning chapters deal with the general aspects of energy production, propulsion tube theory, and the characteristics of rocket motors. The characteristics, manipulation, and combustion of both solid and liquid propellants are next considered in detail, including the fuel systems. Both low and high frequency instability of combustion are treated, and the last three chapters are devoted to the exterior ballistics of rockets. (M. Barrère and others. Paris, Dunod, 1957. 389p., 5600fr.)

RADIO AMATEUR'S HANDBOOK 1958

Now in its thirty-fifth edition, the Handbook has once again been brought up-to-date, and new equipment in all categories appears throughout the book. Both simple and complex designs are described in the chapter on receiver construction, and the transmitter section contains information for both the beginner

Stock Reducers



Hamilton Gear Carries a Complete Range of Worm Reducers and Replacement Parts

Partial view of stock part storage at Toronto plant.

For over 25 years, Hamilton Gear has carried one of the most complete stocks of worm reducers available in Canada. Replacement parts, being manufactured in our own plant, enable us to maintain an ample supply to meet standard requests. Stocks include both horizontal and vertical type reducers, ranging in size from 2″ centres to 5″ centres. This in plant service means that variations to standard equipment can be made to customer specifications promptly. Write for our catalogue No. 106 for a complete listing of reducers.

• LIBRARY NOTES

and the expert. High powered amplifiers and beam antennas have been added to the v.h.f. sections, and material has been added on radioteletype machines and circuits. There are the usual sections on basic theory, including one on semiconductors, and a large catalogue section. (West Hartford, Conn., American Radio Relay League, 1958. 746p., $4.00.)

RUSSIAN-ENGLISH GLOSSARY OF ELECTRONICS AND PHYSICS

One of a series of eight interim glossaries being published by the Consultants Bureau during the compilation of its comprehensive Russian-English Physics Dictionary, this particular volume lists terms in electronics, including idioms and a certain amount of general vocabulary. The terms are taken from seven Russian journals translated by the Bureau, and an appendix covers U.S.-Soviet vacuum tube equivalents, unit equivalents, circuit components and notations, and abbreviations.

The glossary is reproduced by multilith process from varityped copy, and is very easy to read.

The other seven glossaries, the first two of which are already available, will cover the fields of nuclear physics and engineering, solid state; electricity and magnetism; liquids and hydraulics; acoustics and shock waves; mechanics and general physics; atomic physics, spectroscopy and optics.

The Bureau is to be highly commended for the work it is doing in making available translations of Russian journals. (Ed. by P. Robeson, Jr. New York, Consultants Bureau, 1957. 343p., mimeog., $10.00.)

*THE SCIENTIFIC PAPERS OF SIR GEOFFREY INGRAM TAYLOR, VOLUME I: MECHANICS OF SOLIDS

This volume, which is the first in a series of four, contains all of Taylor's papers on elasticity, plasticity, the properties of metals, and dislocation theory. A number of studies prepared for government agencies are now made generally available for the first time. The three other volumes will be devoted to papers on the mechanics of fluids. (Ed. by G. K. Batchelor. Toronto, Macmillan, 1958. 593p., $12.75.)

SCIENTIFIC RUSSIAN

The recent intense interest in Soviet science has shown how few English-speaking scientists have any knowledge of the Russian language, and has emphasized how great the need is for those who can read it.

The author of this text realized many years ago the growing importance of Russian, learnt it himself, and published this book in 1950.

The purpose of the book is to teach a reading knowledge of scientific and technical Russian, and it is intended for class-room use, for self-study and for reference.

The text is divided into forty lessons, each devoted to some grammatical point. The reading exercises all discuss some scientific topic, for example vitamins, atomic energy, radar, etc. The emphasis throughout is on learning to read scientific literature, and once the initial difficulty presented by the strange appearance of the Russian alphabet is overcome, a careful, and continuous, study of this text should enable the reader to master ordinary technical articles. (J. W. Perry. New York, Interscience, 1950. 816p., $7.50.)

*SEMINAR ON WIND TUNNEL TECHNIQUES AND AERODYNAMICS

The papers of this seminar, held in Stockholm, May 1954, cover many aspects of the subject including the design and use of sonic and supersonic wind tunnels, strain gage balances, electronic apparatus, flow around various types of wings drag and air intakes. Swedish wind tunnels are described, and a final paper discusses the financial background and organization of aeronautical research and development in Sweden. (Stockholm, Royal Institute of Technology, 1955. Various pagings. Price not given.)

• LIBRARY NOTES

THE SOURCES OF INVENTION

This is a study of the inventions of the nineteenth and twentieth centuries their origins and effects. The authors discuss the inventor working on his own, research done for industry, and the development of inventions.

The information in the volume was obtained from scientists, technologists, patent lawyers, financiers and research administrators, and throws some light on various questions being discussed at present. What contributions are being made by the research departments of large corporations, and is this to be the main source of future inventions? Is it possible to predict the type of inventions and to control technological progress? Does a monopoly in industry encourage invention?

The second part of the book consists of brief case histories of some fifty inventions from automatic transmissions to zip fasteners, and including such things as cinerama, cyclotron, gyro-compass, Kodakchrome, radar, synthetic detergents and transistors. (John Jewkes, David Sawers, Richard Stillerman. Toronto, Macmillan, 1957. 428p., $6.25.)

SPECTROCHEMICAL ABSTRACTS, VOL. 5

The two hundred and fifty abstracts in this volume are for the years 1952-53, and cover emission spectroscopy in its analytical applications, including flame spectroscopy, but not X-ray emission spectroscopy.

The abstracts themselves are arranged by subject, while the source of the abstract is given in the author index. There is also an index of elements observed as minor constituents of samples.

It is hoped to publish the volume covering 1954-55 later in the year. (Ed. by E. H. S. van Someren and F. Lachman. London, Hilger and Watts, 1958. 66p., 20/-.)

SPRINGS: A BIBLIOGRAPHY

The entries in this bibliography are arranged chronologically, and cover the period 1678 to 1956. Until 1927 the references are listed alphabetically by author, but after this date they are arranged according to the subject headings used in the Engineering Index.

The references and annotations have been taken from: ASM Review of Metal Literature; ASME Research Publication; Chemical Abstracts; Engineering Index; Industrial Arts Index; Metallurgical Abstracts.

The bibliography has been compiled by the Research Committee of the Associated Spring Corporation. (Hamilton, Wallace Barnes Co., 1957. 386p., mimeog.)

*SYMPOSIUM ON DETERMINATION OF DISSOLVED OXYGEN IN WATER

This collection of five papers deals with current procedure for the determination of the concentration of dissolved oxygen in water, including both the manual spot-check methods and those using instruments providing continuous indication and record. The principle advantages and disadvantages of various procedures and apparatus are studied, and the conditions under which each can most appropriately be applied is indicated. Methods presented include polarographic measurement, the Beckman analyzer, the Hartman and Braun recorder for boiler feedwater, and the Cambridge analyzer. (Philadelphia, American Society for Testing Materials, 1958. 59p., $2.25. (S.t.p. no. 219)

*SYMPOSIUM ON INSULATING OILS

The two papers presented are: valuation of laboratory tests as indicators of the service life of uninhibited electrical insulating oils; the use of solid and liquid catalysts for the accelerated aging testing of transformer oil. They are concerned with insulating oil for use in transformers and related electrical equipment, with particular reference to the need for adequate test methods to evaluate new oils, oils in service, and reclaimed oils. (Philadelphia, American Society for Testing Materials, 1957. 39p., $1.75. (S.t.p. no. 218)

*SYMPOSIUM ON NONDESTRUCTIVE TESTING

Papers discussing the latest and most widely used techniques of nondestructive testing and their application to materials

inspection. Techniques discussed include radiographic testing, magnetic particle and penetrant testing, and ultrasonic testing. (Philadelphia, American Society for Testing Materials, 1957. 99p., $2.75. (S.t.p. no. 213.)

°SYMPOSIUM ON RAILROAD MATERIALS; LUBRICATING OILS

Seventeen papers on lubricating oils, cleaning compounds, fuels, and nondestructive testing methods. About one half of the papers deal with these materials in relation to diesel engines. (Philadelphia, American Society for Testing Materials. 169p., $4.50 (S.t.p. no. 214.)

°SYMPOSIUM ON TITANIUM

Papers on testing techniques and effects of various heat treatments on the properties and characteristics of titanium and titanium alloys. (Philadelphia, American Society for Testing Materials, 1957. 208p., $4.75. (S.t.p. no. 204.)

TELECOMMUNICATION ECONOMICS

This volume is intended primarily for telecommunication engineers, but the methods suggested will be of interest to other utility organizations. The author points out in his Preface that although much has been written on engineering economics and their application to commercial enterprises, their application to public utility plant engineering has not been widely investigated. In the text he shows how the same general principles can be applied to this field, especially when planning large utility schemes.

The author, who has had many years planning experience with the British Post Office which operates the telephone system, describes many of the factors and procedures applicable to the economic engineering of a telephone system, including sufficient information for working out cost studies. The factors include: interest and present value; depreciation; service life of equipment; economics of automatic telephone exchange systems; future requirements; replacement studies; the costs of exchange equipment; economics of traffic routing; automatic equipment in rural areas.

Mr. Morgan shows how to approach the question which is corollary to "Can we do it?" that is "Can we afford it?" (T. J. Morgan. London, Macdonald, 1958. 452p., 50/-.)

TRAFFIC TRANSIT PARKING: METROPOLITAN WINNIPEG; A REPORT

In common with every other city in Canada, Winnipeg has had its traffic problems.

This is the report of a comprehensive traffic and transportation survey of the Winnipeg Metropolitan area including the following: vehicle origin, destination, and parking needs; traffic movement; public transportation users; traffic counts downtown; travel time studies and traffic signal operation.

The report is well illustrated with graphs, charts, maps, etc. and should prove useful to any city interested in undertaking a similar survey. The survey was taken by Wilbur Smith and Associates, New Haven, Connecticut. (Winnipeg, Metropolitan Planning Commission of Greater Winnipeg, 1958. 319p., $3.00. Summary report free)

A TREATISE ON THE INTERNAL MECHANICS OF BALL, TUBE AND ROD MILLS

One of a series of monographs on powder metallurgy the object of this volume is to bring together information on the internal mechanics of the ball, tube and rod mills, to analyze it in the light of the authors' experience, and to present the results as far as possible in a systematic form.

Although there is literature available on the general design and operation of a tumbling mill, this is the first volume to be devoted solely to the internal processes, and it covers such topics as the motion of the mill charge; power required to drive a mill; the comminution of solid bodies; the actual grinding process in the mill; surging and vibration; metal wear in mills, and the role of additives.

Dr. Rose is well known for his earlier books on electrostatic precipitation and

This 16-foot robot was built entirely of DEXION Slotted Angles to symbolize the all-embracing versatility of this amazing, economical, modern material. The lady kindly stepped into the picture to emphasize the huge proportions of the structure.

DEXION

MUSCLE-MAN

at your service

Need a bench, a machine-stand, a storage rack, a conveyor system or a trolley . . . ?

You can make any of these — and hundreds of other items of basic equipment, permanent or temporary — right in your own factory, warehouse or shop — with DEXION. There's a size best suited to your purpose. Just cut it and bolt it — that's all. No need for detailed blueprints, even on complicated structures.

Whatever you build, every inch of your DEXION angle is reusable. No waste to up your cost.

Over 100,000,000 feet of Dexion Slotted Angles in use by over 60,000 firms all over the world — and 80% of Dexion sales are repeat orders!

ALL DEXION SIZES ARE AVAILABLE IN RUST-PROTECTED PAINTED STEEL or ALUMINUM ALLOY.

Put DEXION to work in your company, and be self-supporting equipment-wise . . . DEXION does almost anything — faster, better, cheaper.

BUY CANADIAN — KEEP CANADA GROWING

DEXION design and erection service is available to you as easily as the angle itself. Just call your local distributor. His technical representatives will gladly help you from a wide range of experience in many fields of warehousing, manufacturing and materials handling.

the measurement of particle size in fine powders. (H. E. Rose and R. M. E. Sullivan. Toronto, Longmans Green, 1958. 258p., $5.00.)

VACUUM TUBE RECTIFIERS

Vacuum tube rectifiers play an important part in much electronic equipment where an a-c current supply often has to be converted to d-c.

This book covers the fundamentals of vacuum tube rectifier theory, and discusses the physical characteristics of rectifiers, single and polyphase rectifiers, output filter circuits and rectifier and filter design data. Theory and circuitry are given for half-wave and full-wave rectifiers, voltage-multiplying circuits, polyphase rectification and filter circuits. (Alexander Schure. New York, Rider, 1958. 69 p., $1.50.)

°VIBRATION AND IMPACT

An introductory treatment of vibrations and of oscillatory phenomena in general that bridges the gap between introductory dynamics and advanced field of engineering analysis. Free vibration, damping, impact, steady forced as well as nonlinear vibration, systems with two degrees of freedom, waves, vibrating beams, and fatigue are discussed. Problems are directed toward the application of theory to practical situations. (R. Burton. Reading, Addison-Wesley, 1958. 310 p., $8.50.)

°VIBRATION CONTROL

Presents a broad coverage of the subject ranging from elementary vibration theory to specific areas such as rotor balancing, vibration isolation, steady state and transit response, and sound control problems. Diverse means of analysis are studied including the impedence method for steady state vibration, the operational calculus and electronic analogue computer for transient analysis, methods for analyzing non-linear systems, and possible uses of the electronic analog simulator. (John N. Macduff and John R. Curreri. Toronto, McGraw-Hill, 1958. 465p., $10.80.)

THE WORLD ALMANAC, 1958

The latest edition of this mine of information contains a chronology of the events of 1957, together with a list of the major events of that memorable year which saw the launching of the first earth satellite.

The editors are careful to state "The World Almanac does not decide wagers", but many arguments have been settled by consulting its pages. Much of the information given concerns the United States: government, population, education, states, associations, etc.

Other topics taken at random from the index include: alcohol, boiling point; Buddha; Cinerama; diesel engine; engineering associations. From A. A. V. champions to Zuider Zee, you name it, and The World Almanac probably has it. The Almanac deserves a place in every office and home. (Ed. by Harry Hansen. New York, World-Telegram, 1958. 896p., $1.50 pa.)

Sixth Commonwealth Mining and Metallurgical Congress, 1957

The Sixth Congress met in Canada in 1957, and for this event several volumes were produced on Canadian mining and related topics. Between them they cover the geology of Canadian ores and minerals and their mining and milling, and provide a survey of the subject which has long been needed.

Further details on each volume are given below. The volumes are all published by the authority of the General Committee of the Sixth Commonwealth Mining and Metallurgical Congress.

THE GEOLOGY OF CANADIAN INDUSTRIAL MINERAL DEPOSITS

The deposits described in this volume are, with few exceptions, those which are operated at present. Rock quarries are not described, but the geology of major rock formations and clay deposits is given. The papers have been contributed by various operating companies, and geologists from universities and Federal and Provincial governments.

Victaulic

OFFER A GASKET FOR EVERY NEED

Victaulic with over 30 years service and experience have proven that the commercial gasket compounds presently available will not cover all the varied industrial pipe services efficiently.

Why sacrifice full efficiency in your service to accommodate others. Victaulic recommend the following selection of gaskets for your needs.

	Recommended Service Temp. Fah. Min.	Max.
• HIGH TEMPERATURE Hot air Hot water Low pressure steom	— 0°	+ 250°
• HYPALON Oxidizing chemicols Pickling solutions Bleoch solution Freon 12	— 40°	+ 200°
• SILICONE Dilute ocids Alcohols Dilute Alkoli	— 100°	+ 500°

	Recommended Service Temp. Fah. Min.	Max.
• NATURAL RUBBER Air, Water Most diluted ocids Hot Air, water	— 50°	+ 180°
• VICTAULITE Oil Gosoline Most Petroleum Generol Service	— 15°	+ 180°
• LOW TEMPERATURE As above Where cold climates prevoil	— 50°	+ 180°
• NEOPRENE Hot Oils Sour crude Hot compressed oir	+ 30°	+ 200°

VICTAULIC GASKET TRIPLE SEAL FEATURES

Every Victaulic Gasket is moulded with Victaulic's famous C-shaped cross section. Note the important inwardly inclined lips. This basic and exclusive design is the key to the bottle-tight seal, under pressure or vacuum, of all Victaulic Couplings. It provides the following time-proven "Triple Sealing" features:

Sealing Feature 1
Stretching the Victaulic Gasket over pipe ends puts the angular lips in immediate and automatic sealing tension.

Seoling Feature 2
Application of the Victaulic Housing-Clamps automatically centralizes the Victaulic Gasket and seats it on the pipe ends firmly. It is neither compressed nor distorted.

Sealing Feature 3
Line pressure automatically strengthens the seal by acting internally on the gasket lips. The higher the pressure the tighter the seal!

For more informotion on Victoulic goskets & piping methods write today

VICTAULIC COMPANY OF CANADA LTD.

406 HOPEWELL AVE., TORONTO 10, ONT. MAILING ADDRESS: P.O. BOX 400, POSTAL STATION "T", TORONTO 19, ONT.

• LIBRARY NOTES

The minerals described range from Actinolite to Witherite, including more detailed coverage of asbestos, clay, gypsum, limestone, magnesite, mica, salt, sandstone and quartz, and talc and soapstone.

Information given on the various minerals includes location and size of deposits, annual production, working methods, etc., and references to further information are given for most minerals. (Ed. by M.F. Goudge. Canadian Institute of Mining and Metallurgy, Industrial Minerals Div. 247p., maps. $10.00.)

THE MILLING OF CANADIAN ORES

The aim of this volume is to present an outline of techniques used in Canadian mineral dressing plants. The material has been contributed by the different mining companies, and the government departments concerned.

The first four chapters form a general introduction, and cover the history of milling in Canada, mineral dressing and testing facilities, a general description of milling areas in Western, Central and Eastern Canada, and outline Canadian milling developments. There is also a list of mills operating or under construction at the beginning of 1957.

The remaining chapters cover the milling of the different ores etc. mined in Canada; gold, silver-cobalt, copper, lead-zinc, uranium, asbestos, coal, iron, and the less common minerals including molybdenite, tungsten, titanium, and mercury. Information is given on the different mines engaged in the production of the different ores, including type of ore, mill capacity, mill production, method of operation, etc.

The volume also includes a bibliography listing over 400 items on Canadian milling practice, and a special printing of the Department of Mines and Technical Surveys map of the principal mineral areas of Canada. (Ed. by John Convey, 447p., $10.00.)

MINING IN CANADA

This volume on Canadian mining practice has been produced in co-operation with the various mining companies and other individuals interested in the subject.

The topics covered are: shaft sinking; drifting and raising; mining methods including the following, open pit, trackless, caving, blasthole, shrinkage, cut-and-fill, square-set stopping, benching, stope filling and dredging; drilling practice; explosives; ground support; rockburst control; mine ventilation and fire control; hoisting; underground haulage; underground crushing, conveying and ore storage; drainage and pumping; mine safety; coal mining. The majority of the subjects are covered by papers referring to the practice at specific mines.

The tables included are compiled from questionnaires sent to all major producing metal mines in Canada, and give data on: mining methods, shaft sinking practice, drifting, raising, drilling, underground haulage, stope filling and hoisting. Many bibliographic references and illustrations are included. (Ed. by J. C. Parlee. Canadian Institute of Mining and Metallurgy, Metal Mining and Coal Divisions. 597p., $10.00.)

STRUCTURAL GEOLOGY OF CANADIAN ORE DEPOSITS, VOL. 2

The first volume of this set was published in 1948 to mark the 50th anniversary of the Canadian Institute of Mining and Metallurgy. The purpose of this volume is to cover the mines and districts discovered or developed since 1948, to describe those omitted in the earlier volume, and to revise the information where the geological picture has changed since the earlier volume was published.

The papers are again divided according to the main geological regions; Cordillera; Western Plains; Precambrian Shield, Western, Ontario and Quebec; Appalachian.

The book is well illustrated with photographs, diagrams and maps, and there are the usual references for further reading. It should prove a useful companion volume to the earlier one. (Ed. by Geoffrey Gilbert. Canadian Institute of Mining and Metallurgy. 524p., $10.00.)

(Continued from page 91)

Canada's Graduate Student Problem

Canada has a serious graduate student problem in science and engineering, in the opinion of R. R. McLaughlin, dean of the Faculty of Applied Science and Engineering, and professor of chemical engineering at the University of Toronto. He dealt with this subject in a speech to the Toronto section of the Chemical Institute of Canada in January.

Dean McLaughlin posed three questions about graduate students: (a) are there enough of them? (b) are they the best procurable? (c) are they working under the most desirable conditions? He answered these questions in the negative.

The question of quantity concerns the universities, and it also concerns the well being of the country. Although addition to the sum-total of human knowledge, essential to a university, could be taken care of by the staff, if necessary, there must at least be a body of graduate students sufficient to maintain the supply of professors at its present level. But, said Dean McLaughlin, universities are made great rather by the mutual stimulus provided by an active staff and an active body of graduate students. Graduate schools must be encouraged, especially in the engineering schools, where the general level of activity is much too low.

The second part of the question is more complex: "Are there enough graduate students so far as Canada is concerned?" If "the second half of the twentieth century belongs to Canada", we must help to make it so. The brains, ingenuity, and will, do exist but a suitable environment for their development is not present either qualitatively or quantitatively. A leaven of research and higher learning beyond the bachelor's degree is necessary if Canada is to be equal to her destiny. "We must develop our own scientific and engineering frontiers and take our place in the world of science, and not just export our brains to make their contributions elsewhere", Dean McLaughlin said.

On graduation with a B.A.Sc. degree, an engineer faces the choice of a salary of at least $4,500 in industry or the prospect of graduate work on a fellowship of $1,500 or less. Should he proceed to the Ph.D. degree there is the prospect of a long financial battle. It is hard to prove that it is financially as profitable over a lifetime to achieve a Ph.D. as it is to have a bachelor's degree—in view of salaries in industry.

While the universities are very grateful to the donors of graduate fellowships, it must be said that there aren't nearly enough and they aren't nearly big enough.

The practice is a wise one, by which worthwhile fellowships are usually not, because of their scarcity, awarded to students proceeding only to a master's degree, because it is only after a year of graduate work that a student can be proved to be of Ph.D. calibre. It is a foolish practice too, because it prevents many first class students from making a start.

Remedies are simple, Dean McLaughlin said. They are: an adequate number of graduate fellowships worth $3000 per annum, beginning at the master's level; allocation to the universities of an adequate sum of money to be dispensed to best advantage without specifications of neatly documented sums into which it must be subdivided. In contrast, the situation is "chaos and inefficiency personified", in Dean McLaughlin's opinion. To the professor who wants to carry out research and to encourage potentially good graduate students the inability to make early, firm offers is a very serious impediment. Without the monumental efforts of the National Research Council in fostering research, a very sorry situation would exist today. "But" he asked, "have we not reached the point where it should be recognized that supporting graduate students represents normal expense in running a university and that funds should be granted directly to the universities for administration in the normal way?"

Considering whether these graduate students would find satisfactory employment in Canada, Dean McLaughlin said that if graduate schools in engineering and science are not developed, the nation will fall behind in this scientific age. But if adequate positions for such graduate students, are not available, then we cannot keep the graduate schools at the proper level, or if we do, we will simply export some of our best brains. There are reasons why Canadian Ph.D.'s go to the U.S. for work commensurate with their abilities. For one, Canadian industry has in general given only lip service to research. Research requires "patient money", not vast quantities, and faith: and the results may be surprising. Another reason is that foreign companies with subsidiaries in Canada tend to reserve all research activity to their own country. A proportionate amount of the research now carried on outside Canada by parent companies would, if carried out in Canada, be productive and is essential to our economic growth, said Dean McLaughlin.

Did You Know That . . .

On a population basis the Engineering Institute is larger than any United States or British engineering society.

Nuclear Congress, 1959

Canadians Invited to Present Papers in Nuclear Field

The Fifth Nuclear Congress is scheduled for April 5-10, 1959 in Cleveland, Ohio.

The Engineering Institute of Canada, as a participating society, will provide for the Nuclear Engineering and Science Conference one or more technical papers. Authors are invited to submit summaries (300-500 words) of proposed papers. Summaries should be received at Headquarters by October 1, for transmission to the Congress Manager.

Authors will be notified in October of the selection of papers for the program, and will be given specifications for the preparation of manuscripts, to be received by the E.I.C. by November 28.

Interested authors should send summaries to: Dr. Garnet T. Page, The Engineering Institute of Canada, 2050 Mansfield St., Montreal 2, Que.

CRANE

MONTH TO MONTH

Athlone Fellowship Winners, 1958

Thirty-eight young Canadian engineers have been chosen to go to Britain this year for two years' further study under the Athlone Fellowship scheme.

The scholars will go to universities in Britain, technical colleges and many branches of British industry. Some will be trained both in university and in industry. No pains will be spared to ensure that they get the training that they want, and that they may return to Canada to resume their careers with improved qualifications and a knowledge that will be valuable both to Britain and Canada.

The Athlone Fellowships scheme is managed in the United Kingdom by a committee representative of industry, the universities and the United Kingdom Government. This committee exercises a general supervision over the administration of the awards and the arrangements for the reception and placing of the Fellows, and also concerns itself with their welfare and progress.

Hitherto the chairman of this committee has been Sir Arthur Fleming. He has recently resigned and has been succeeded by Sir Claude Gibb.

These are the 1958 Athlone Fellows:

1958 Graduates

University of British Columbia: J. H. Duerksen, s.e.i.c., chemical; A. G. Fowler, s.e.i.c., electrical; T. A. Nordstrom, electrical; R. S. Roger, s.e.i.c., electrical.

University of Alberta: D. A. Markle electrical; W. S. Pawluk, chemical; J. A. Sovka, chemical.

University of Manitoba: C. J. Brown, s.e.i.c., mechanical; A. Wexler, electrical.

University of Saskatchewan: C. E. Till, electrical.

University of Toronto: J. B. Ellis, electrical; J. D. Hardwick, engineering and business; A. E. P. Matthews, engineering and business; K. J. Merklinger, electrical; N. M. Seagram, s.e.i.c., engineering and business.

Ecole Polytechnique: M. Phaneuf, s.e.i.c., mechanical electrical; P. E. Tremblay, s.e.i.c., electrical mechanical.

McGill University: S. R. Borenstein, s.e.i.c., engineering physics; I. A. Soutar, mining; W. S. Wilson, metallurgy.

Laval University: L. Lachance, civil; C. Roy, s.e.i.c., metallurgy.

University of New Brunswick: D. M. Caughey, s.e.i.c., electrical.

Nova Scotia Technical College: G. L. Basso, s.e.i.c., mechanical; W. G. Roberts, s.e.i.c., mechanical.

Queen's University: F. C. Lockwood, s.e.i.c., mechanical; S. D. Robertson, s.e.i.c., electrical; H. R. Whiteley, s.e.i.c., civil.

Engineers from Industry

Queen's University: A. L. Barry, electrical; D. R. I. Low, chemical.

University of Toronto: B. G. Bodroghy, mechanical; B. G. Loncarevic, geophysics.

University of British Columbia: D. P. MacKinnon, mechanical.

University of Saskatchewan: R. F. Critchley, jr.e.i.c., mechanical

Nova Scotia Technical College: J. D. Brown, s.e.i.c., civil; W. A. Clarke, jr.e.i.c., mining.

Laval University: J. Y. Savard, electrical.

University of New Brunswick: E. M. Fanjoy, s.e.i.c., electrical.

THIRTY-FIVE YEARS AGO

Comment on the Journal of June 1923

H. D. Savage of Combustion Engineering Corporation, was the author of a paper in the June 1923 issue outlining the advantages to be gained from pulverizing Canadian fuels. While the costs quoted are out of date due to economic changes, the author reached the conclusion that all the coal native to Canada could be successfully used in pulverized form.

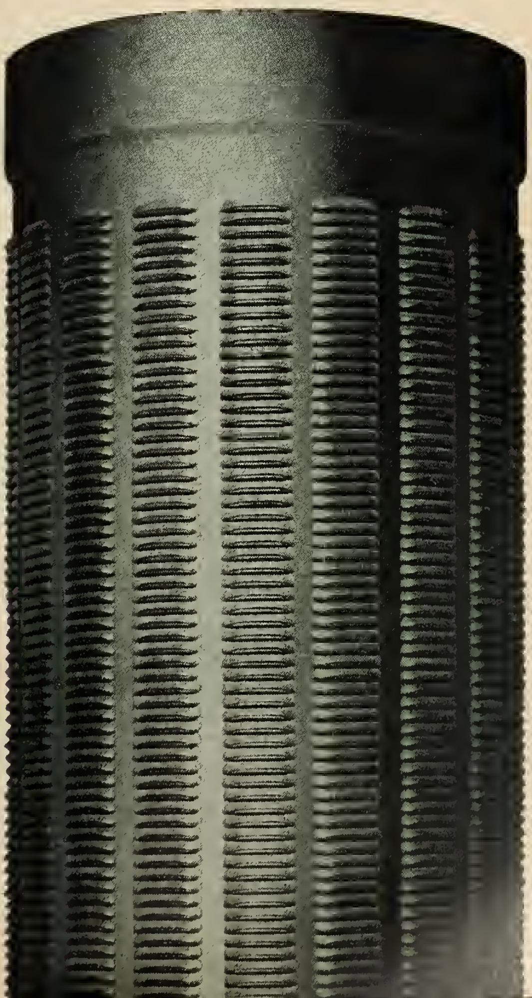
Editorially, reference was made to the National Conference on Education and Citizenship held in Toronto in April. The various engineering acts in effect in the various provinces were compared, giving for seven of the eight major provinces in which there were Associations of Professional Engineers, regulations as to admission, division of engineering as to branches, transfer fees, licenses and license fees, annual fees, minimum age for registration, penalties, examinations and restriction of activities of Associations.

A report was given on the spring meeting of the American Society of Mechanical Engineers, held in Montreal. Canadian arrangements had been under the direction of H. H. Vaughan, M.E.I.C., vice-president of the ASME. ASME president, John Lyle Harrington of Kansas City, in his presidential address, expressed his belief that it was the engineer's duty to take a more active part in politics. ASME secretary, Calvin W. Rice, who represented the Engineering Institute of Canada at the Great World Conference in South America in 1922, gave an account and travelogue of that meeting.

The Saint John Branch held their annual meeting on May 8, at which A. G. Tapley, A.M.E.I.C., the retiring chairman discussed economics of the Maritime Provinces, and in particular their fuel resources. In concluding, he remarked that "while provincial associations were purely business organizations, the Institute was our place of accounting for that which we are doing, for the exchange of ideas, etc., —our forum or campfire, if you like".

At the Ottawa branch, members had listened to President A. J. Nesbitt, of Nesbitt Thompson and Company as he described then current developments of hydro power in Canada, stating that only some 7 per cent or 3 million horsepower out of a potential of between 18 and 41 million hp. had yet been developed, most of it in Quebec and Ontario, used largely for the pulp and paper industry. The cost per developed housepower varied between $60 and 150. He predicted Canada would have 6 million hp. developed within the next decade.

Letters from members were published, dealing with the recent opening of the international bridge at Edmunston and with the compressive strength of cement. A third letter dealt with Canada's Fuel Problem by H. E. M. Kensit, M.E.I.C., in which it was pointed out that some 60 per cent of Canadian coal consumption was imported. Per capita coal consumption had decreased from 4.2 lb. in 1913 to 3.5 lb. in 1921. This he said, was due to the increasing use of water power. Use of coal in per cent of total consumption was divided as follows: steam railways, 29 per cent; bunker coal, 4 per cent; industries and coke, 34 per cent; electric light and power, 2 per cent; and domestic uses and gas, 31 per cent. *H.G.C.*



Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

New Officers—A. S. Austin has recently been elected president of The Austin Company Limited, Toronto, succeeding G. A. Bryant; G. Galloway has been appointed vice-president.

Canadian Bitumuls Company — E. M. Lorenzini, manager of Bitusize sales for the American Bitumuls & Asphalt Company, has been elected president of Canadian Bitumuls Company Ltd., a subsidiary of the American company. Mr. Lorenzini replaces retiring president, W. Summers.

Executive Appointment — Announcement has been made of the appointment of T. N. Beaupre as president of Columbia Cellulose Company, Limited and Celgar Limited, B.C.

C.G.E. Director — J. A. Béland, of Louiseville, Que., has been elected to the board of directors of Canadian General Electric Company Limited.

Bathurst Containers—E. H. Gibson has been appointed director of sales, Bathurst Containers with headquarters in Montreal. Mr. Gibson replaces H. S. Litteljohn, who resumes his former position as consultant to the president of Bathurst Power & Paper Company Limited, and will be located in Hamilton, Ontario.

Catalytic Construction — Recently announced by the Catalytic Construction Company of Canada Limited was the appointment of I. M. M. Buchanan as manager of the company's new Western office in Vancouver, B.C.

RCA Victor Company — J. D. Houlding vice-president, technical products, RCA Victor Company, Ltd., has been elected a director of the company.

Trans-Canada Pipe Lines—S. R. Sawyer, formerly of El Paso Natural Gas Company, has been named chief engineer of Trans-Canada Pipe Lines Limited, with headquarters in Toronto.

Technical Service Laboratories — The appointment of E. W. Warren as sales development consultant has been announced by Technical Service Laboratories, Toronto.

E. H. Gibson

H. S. Litteljohn

I. M. M. Buchanan

Inco Appointment — F. F. Wood has been named assistant to the vice-president (publicity and advertising) of The International Nickel Company of Canada Limited, and assistant vice-president (publicity and advertising) of the company's United States subsidiary, The International Nickel Company, Inc.

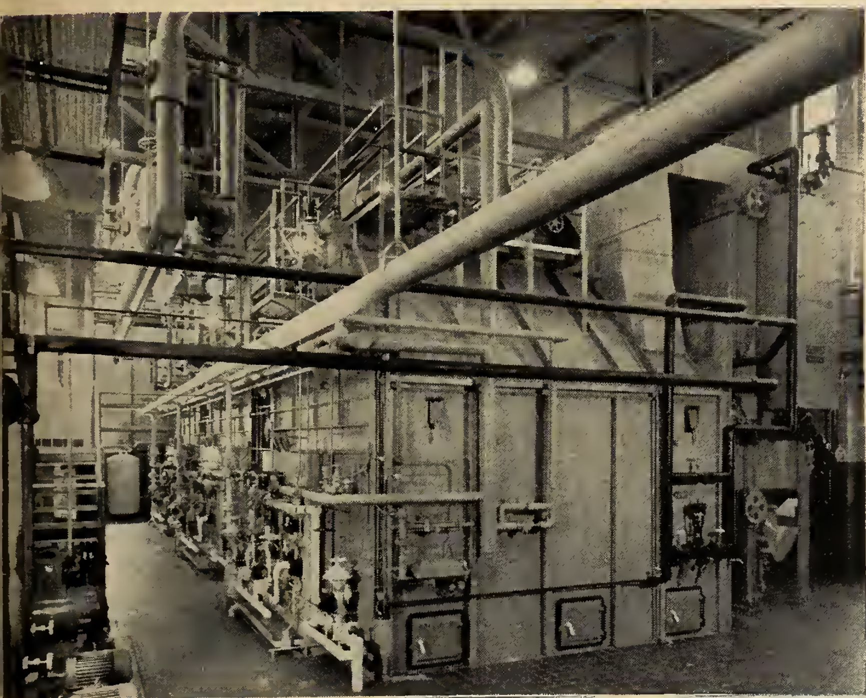
Stelco Appointment — The Steel Company of Canada Limited has announced the appointment of A. R. McMurrich as general manager, field sales, with headquarters in Hamilton, Ont. Mr. McMurrich will direct the company's branch sales offices and outside sales personnel from coast to coast.

C-I-L Appointments — W. A. Taylor has been made sales manager of the chemicals division of Canadian Industries Limited. He succeeds H. G. Campbell, who has been assigned special duties in the office of the division's general manager.

Canadian Resins and Chemicals — The following changes have recently become effective at Canadian Resins and Chemicals Limited: R. E. Hughes is appointed manager of development; A. G. Pinard becomes manager, industrial products

FOR DEPENDABLE STEAM GENERATION...

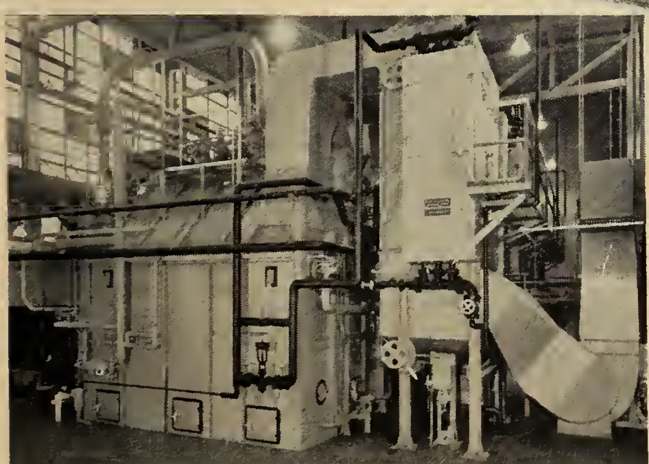
SA BOILERS by FW



The new Vancouver Shaughnessy Hospital of the Department of Veteran's Affairs is a modern and efficient institution.

Its construction is a tribute to the Department of Public Works of Canada and their architects and consultants.

Foster Wheeler is proud to add these three S A Boilers to the almost six hundred other units of this type in service across Canada.



THREE FOSTER WHEELER LIMITED
TYPE SA STEAM GENERATING UNITS

CAPACITY	20,000 LBS. PER HOUR
DESIGN PRESSURE	200 P.S.I.G.
OPERATING PRESSURE	125 P.S.I.G.
FINAL STEAM TEMPERATURE	SATURATED
FEED WATER TEMPERATURE	220° F.
FUEL/FIRING	OIL BURNERS
EFFICIENCY	84.8%

HALIFAX • MONTREAL • TORONTO • ST. CATHARINES • WINNIPEG • EDMONTON • VANCOUVER department; and E. A. Clout, supervisor, calendered materials division.

Dominion Engineering — Recent announcement was made of the promotion of W. L. Brown to the position of manager of purchases, Dominion Engineering Works Limited, following the retirement of A. A. Levick.

E. A. Burgess becomes advertising coordinator within the department; and D. G. Blackmore has been made supervisor of publications.

Sales Appointment—Philips Electronics Industries Ltd., of Toronto, announce the appointment of H. L. Pollock as sales engineer in the aviation and electronic components group.

Matthews Conveyer — J. S. Laurie has been appointed assistant manager and director of purchasing of Matthews Conveyer Company Limited and W. S. Raynor, M.E.I.C., becomes chief engineer.

News of Business and Industry

General Motors Appointment — H. F. Shepherd, formerly locomotive parts manager, has been named parts manager of General Motors Diesel Limited, London, Ont.

MAAG Appointment — Announcement has been made of the appointment of J. P. Kummer as manager of the newly established Lathem Time Recorder Division of MAAG and Company Limited.

Anthes-Imperial Company — S. R. Spence has been appointed general sales manager, Western division of the Anthes-Imperial Company Limited; and will be located in Winnipeg.

Emco Advertising Appointments — Reorganization of their advertising and publications department has been announced by Emco Limited of London, Ont.: J. M. Hunter has been appointed manager, advertising and publications;

Canadian Representatives — A new line of products is being introduced to the Canadian market by A. C Wickman Limited, Toronto. The company has been appointed representatives of Daytronic Corporation, Dayton, Ohio. Principal items distributed will be motion transducers, force transducers, controllers, transducer amplifiers; these are especially applicable to users of instrumentation, manufacturers and users of process control equipment, automatic inspection systems and automatic weighing systems.

Relocation of "3M" Sales Office — The relocation of their Toronto branch sales office has been announced by Minnesota Mining and Manufacturing of Canada Limited. The new address of the "3M" Toronto branch sales office is Keele and Lawrence Plaza, P. O. Box 1201, Postal Station "T", Toronto 19, Ontario. The telephone numbers are CHerry 4-5607 and ROger 6-6166 for suburban customers. The sales office for Thermo-Fax Copying Products will remain at its present location, 227 Eglinton Avenue West.

Dominion and Regional Safety Honours —Top Dominion and regional honours for outstanding achievement in the prevention of accidents have been awarded to The Consolidated Mining and Smelting Company's Bluebell Mine at Riondel, B.C., for 1957. It is the first time that the John T. Ryan Dominion Safety Trophy for metalliferous mines has been won west of Ontario.

Computer Program — Adalia Computations Limited with their technical personnel and the facilities of their Datatron 205 computing system have evolved a mathematical program which they state will help industrial and commercial concerns to improve their operations in a large measure. This program yields an economic forecast over a period up to 19 years and is said to be capable of handling monthly and seasonal adjustments and various statistical calculations. The electronic computer has been programmed in a very general manner so as to be adaptable to the needs of most clients: banks, insurance companies, investment dealers, wholesale distributors, department stores, consumer goods manufacturers or any other commercial or industrial ventures.

Foundation Company Contract — The WoodGreen master plan of development and expansion has entered its second stage with the signing of a contract for The Foundation Company of Canada Limited to construct the second group of buildings in the plan. The WoodGreen Foundation, non-denominational in nature, was incorporated by Ontario charter for charitable and social welfare purposes in the east Toronto WoodGreen area. Building of the WoodGreen Community Centre by the Foundation Company in 1947 was the first stage in the master plan. The second stage involves the construction of a new church, from funds already raised for that purpose, and of an adjoining non-sectarian building to be known as WoodGreen Neighbourhood House.

Company Acquisition — The Timken Silent Automatic Division of Scaife Company, Toronto, has been acquired recently by Iron Fireman Manufacturing Co., Toronto. The Timken Silent Automatic Division manufactures and distributes residential heating equipment, including oil and gas-fired burners, furnaces and boilers.

Canadian Distributor — Arrangements have been completed to link Kearfott Co. Inc., of Little Falls, New Jersey, designers and manufacturers of technical components and systems in the U.S., with Canadian Applied Research Limited. Applied Research will act as exclusive Canadian distributor for Kearfott products.

Latex Handling Plant — The opening of a new Latex handling plant was announced recently by the Polymer Corporation Limited. The latest addition in the company's expansion program is situated at the north end of Polymer's property near No. 40 Highway. Of steel, red brick, and transite, the unit was designed and constructed at a cost of 1.9 million dollars. Built to a height of three stories to take advantage of gravity flow its design is said to include novel and unique features. Notable among these are resin-lined tanks and glass piping throughout the latex handling systems to reduce fouling and plugging of lines.

New Affiliate — The formation of a new affiliate has been announced in Montreal by Canadian Liquid Air Company Limited. The new company, to be known as International Underwater Contractors Limited, will specialize in a wide range of underwater operations previously impractical because of the limitations imposed on a diver using conventional diving equipment. International Underwater Contractors claims to be unique as an organization of personnel specially trained to work with tools and equipment under water, and in locations and under conditions said to be impossible for the old-fashioned diver with his cumbersome suit and many other restrictions on his movements and diving time.

Polyethylene Plant Expansion — Another expansion in production capacity for polyethylene resins was announced recently by the Carbide Chemicals Company, division of Union Carbide Canada Limited. Work is now underway on a multi-million dollar addition to the company's Montreal East plant to increase polyethylene capacity by 12,000,000 lbs. per year. Scheduled for completion in April 1959, the project will increase the plant's total production of polyethylene resins by approximately 30% per year.

New 2-Way Radio Base Station — A new base station with remote control console has been designed and manufactured by Canadian Westinghouse Company Limited. Designated the WPM-10 series, these two units incorporate operating features not found in comparable equipment, the company claims.

A major problem of VHF transmission is the signal loss caused by geographical obstacles. To overcome this difficulty, the base station and antenna are mounted on the highest object in the vicinity; the base station is then operated by a remote console from a local office. Emergency standby power is provided by battery packs built into the control console and the base station.

Royal York Hotel Extension — About 3,500 tons of steel was fabricated and erected by Dominion Bridge Company Limited for 17 storey extension to the Royal York Hotel, Toronto. This company also erected the steel for the original Royal York Hotel in 1928. When the extension to the hotel is completed in December 1958, the British Commonwealth's largest hotel will have increased its number of guest rooms to 1,600 and approximately doubled its convention space. The tool being used to tighten the last bolt is an Ingersoll-Rand model 5340T torque control impactool for precision fastening of heavy bolted steel structures. It has an adjustable torque range up to 550 foot pounds.

Electronics Service Expansion—Expansion of the electronics division of A. C. Wickman Limited, Toronto, has been announced by the company; it is marketing, in Canada, products of Dynamic Instrument Company, of Cambridge, Mass., which include a complete range of strain gauge pressure transducers, flow meters and force transducers.

New Equipment and Developments

Mine Hoist Equipment — The electrical drive and controls for the skip and cage hoists at The International Nickel Company's Thompson mine, in northern Manitoba, have been ordered from the Canadian Westinghouse Company. Approximate value of the installations will be $500,000. This will be the first application of static controls to mine hoist equipment in North America. Westinghouse Cypak with Magamp controls and advance selector device will provide operation on the same principle as pushbutton control for automatic elevators. The application was made possible by a Canadian Westinghouse invention which allows the operator to select the level and activate the hoist with a permanent magnet.

The Thompson Mine is one of two nickel mines being opened up by Inco in a $175-million development in the Thompson-Moak Lake area some 400 miles north of Winnipeg.

Radiographic Unit—Dominion Foundries and Steel Limited announce that their new Cobalt camera has a power rating of 755 curies and that it is one hundred times as powerful as the unit which it replaces. The camera employs radioactive Cobalt 60 as its source of power and is used for the radiographic inspection of steel castings in Dofasco's foundry. Its high power source enable the machine to probe through solid steel in its search for hidden flaws. The device is located in a 3-foot-thick concrete walled pit, 14 feet below ground level. Operation of the unit is by remote control. In the event of either electrical or mechanical power failure during an exposure, the mechanism will automatically render itself harmless, by restoring the radioactive source to its radiation-proof compartment. There is no absorption of radioactivity by the steel during radiography and the object being tested is absolutely safe immediately the exposure is over.

The personnel who operate this unit have had considerable training and experience and all precautionary measures are taken to assure that no danger exists.

Semi-Automatic Welding Machine — Air Reduction Canada Limited has announced the new model 2700 magna-welder for semi-automatic welding of mild steel and for hardfacing applications. It is designed for use with fabricated, tubular wires for hardfacing, and is adaptable for submerged arc welding. The model 2700 with a ⅜ h.p. universal drive motor operates from any 400 ampere AC or DC welder. The only electrical connections required are to clip the electrode cable to the magna-welder and the ground cable to the work piece. The geared feed rolls permit the use of both solid and tubular wires. There is an "inch switch" that permits both short wire advance and wire retract. The motor has a dynamic brake to prevent wire overfeed when the arc is broken.

555 mw Turbo-Generator Set—The Central Electricity Generating Board have placed an order for a 550 mw turbo-generator, condensing and feed heating plant with C. A. Parsons & Co. Ltd. of Newcastle Upon Tyne, England. The machine is said to be the largest in the world to be ordered and is for the projected Thorpe Marsh Power Station in Yorkshire, England.

The turbine will operate with steam at a pressure of 2,300 lb./sq. in at the stop valve and a temperature of 1050° F. with reheating to 1050° F., the steam being supplied to the machine through two steam chests arranged on each side of the high pressure cylinder. The unit consists of two lines arranged in the line ahead, each line comprising four cylinders driving a 275 mw three phase generator.

Galvanized Steel Sheets — A Canadian metal fabricating firm has announced that they have found a new, functional, and decorative application for a U.S. Steel galvanized steel sheet product. Customarily used for tightly sheathed building roofs and sidewalls, U.S. Steel's 5V-crimp galvanized steel sheets have been adopted as a garage door material by Ladore & Company, Ltd., of Walkerville, Ontario. It is said to be the first

known garage door application for this type of sheet. The company claim that the finished door made of galvanized steel sheet costs less and resists denting.

Automatic Scanning Correlator — An automatic electronic device described by Canadian and U.S. Government experts as "a major break-through in the science of aerial mapping" has been produced by The Photographic Survey Corporation, of Toronto. The device speeds up the process of obtaining information from photographs formerly done by humans up to 100-fold. Overlapping aerial photographs of ground objects is said to reveal "3-D" detail when interpreted stereoscopically by trained operators who transfer the detail to maps or charts by the help of plotting instruments. The new device is known as Auscor (automatic scanning correlator).

Wire Stripper — A new design wire stripper, no. 299, has been announced by Proto Tools of Canada, Ltd. For the professional user, this improved tool which is only 5 in. long features a thumb-operated gauge and is said to strip all commonly used insulated wire from 14 to 24 gauge without nicking or cutting; the larger sizes of wire can also be handled with ease. An advantage of this tool is that it is claimed that all settings can be made quickly; the method is simply to turn the star gauge to the desired notch opening size, notch, and strip.

Wire Strand for Pre-Stressed Concrete — British Ropes Canadian Factory Limited has begun producing stress-relieved wire strand at the Grandview highway plant. Stress-relieved strand is one of the key elements in pre-stressed concrete, and is what provides longitudinal strength in concrete members through certain metallurgical properties that allow for controlled elongation of the strand. This results in complete reinforcing with only a fraction of the metal required under other methods, and marks the essential difference between pre-stressed and ordinary concrete.

Die Lube Stick—A new product, called Die Lube Stick, has been introduced by Lubricants, Inc., Detroit, Michigan. The purpose of the Die Lube Stick is to fill in the scratches or scoring left on the surface of the dies after grinding to remove metal pick-up or galling. It has been found that metal pick-up will not likely occur again in the same area.

Being in a convenient, dry form, much like a large crayon, it can be quickly applied to the area affected and dies need not be removed. Down time is said to be avoided and considerable saving in time and labor effected.

High Vacuum Pumps—The difficulty of deterioration caused by heavy wear, the Pulsometer Engineering Company Ltd. of Reading, England now fit air injection scavenging to their high vacuum pumps which are so arranged that the scavenging air enters the cylinder after the rotor blade has isolated the suction port. The air is then able to support a considerable amount of the water vapour without condensation occurring, particularly when the mixture is raised in temperature as a result of the pump's discharge action. As an example, a discharge temperature of 195° F. would mean that each cubic foot of injected air carries .0265 lbs. of water with it.

Hydraulic Motor Pumps — Tal Bending Equipment, Inc., Milwaukee, Wisconsin, announce the development of a small, portable hydraulic motor pump developing up to 10,000 p.s.i. pressure and weighing 65 pounds. The pump can be used with Tal Hydraulic Pipe Benders, or any other make of hydraulic benders, pipe pushers, knock-out punches, hydraulic jacks of any kind, and can be installed and adapted to give fast continuous power to existing equipment.

The pump is rated for 10,000 p.s.i. intermittent and 5,000 p.s.i. continued duty delivering 80 cubic inches of oil per minute and is driven by a standard ½ HP single phase, 60 cycle, 1,750 R.P.M. 110-220 volt motor.

Portable Compressors — A new range of 100% air cooled diesel-powered portable compressors has been introduced by Atlas Copco of Canada Ltd. on the Canadian market for the first time. Powered by economical Deutz diesel engines, the complete air cooled units are said to offer many advantages from a practical standpoint including large valve areas and high volumetric efficiency to assure long service life and low maintenance costs.

Pressure Filters — The Bird-Archer Company now design and supply pressure filters over a complete range of capacities. Sand and gravel types as well as anthrafilt units are available, and the filters are guaranteed to provide completely dependable filtering, plus clarified water that needs no repumping. Piping and fittings, together with either a nest of individual gate valves or a multiport valve, are supplied to control the operations.

Automatic Emergency Lighting Unit — A new emergency lighting unit, which operates automatically and instantaneously upon failure of normal power and automatically prepares itself for the next blackout, has been developed by Exide Industrial Division of The Electric Storage Battery Company (Canada) Limited. Immediately following an emergency discharge, the model A Exide lightguard automatically recharges its storage battery at a high rate. At the end of the high-rate charge the lightguard automatically returns the battery to a trickle-rate to maintain itself in a state of constant readiness. A temperature-compensated voltage-sensing relay eliminates the need for manual operation.

Dynel Filter Fabrics — Reduced material and labour costs through the use of Dynel filter fabrics in the refining of uranium ore is reported at Blind River, Ont., by a number of mining and milling firms according to Carbide Chemicals Company, division of Union Carbide Canada Limited. Refining mills connected with mines in the Blind River and Bancroft areas utilize Dynel fabrics in vacuum filtration of sulphuric acid solutions to obtain uranium oxide. Woven of Union Carbide's acrylic fibre Dynel, some of the cloths serve to support a distomaceous earth filtration medium in mammoth eimco disc and drum filter units. Other Dynel fabrics are used in clarifying bags as well as in Dorr-Oliver neutral bags.

New Taylor Recorder — Newest of the Taylor line of recorders is the 90J series four inch strip chart recorder. Designed for use with any of the Taylor line of miniature controllers, this instrument is said to provide more features in less panel space than any recorder regardless of size. For simple recorder applications, one to three pens or indicators may be provided. Use as a receiver for a Taylor controller requires only a simple change to include set point transmitter, automatic to manual switching lever and cascade selector.

Teflon Clipper Seals — New chempac teflon clipper seals, to enable industrial plants to obtain positive sealing in the presence of active solvents and corrosives are now available from Canadian Johns-Manville Co. Limited. The new J-M seals are claimed to have successfully contained oils with varying aniline points that are destructive to many compounds, and also proved effective against such widely diverse fluids as rocket engine fuel, perchlorethylene, destructive insecticides, and various refrigerants.

New A-C Vibrating Feeder — A vibrating mechanical feeder designed to facilitate handling of sticky material from hopper to plant has been developed by Canadian Allis-Chalmers Limited. The first two units—4 by 9-ft. feeders with no. 4 mechanism in operation in Michigan—are handling 150 long tons per hour of run-of-the-mine iron ore containing 2½ percent alumina and having 10 to 16 percent moisture content.

Gyroscopes — According to Sperry Gyroscope Company of Canada, Ltd., Montreal, early achievement of low cost, extremely accurate gyro systems for stabilizing and guiding missiles, aircraft and even sea vessels has been made possible by the development of "frictionless" gyros by its parent company, Sperry Gyroscope Company, Great Neck, New York. The development is said to hinge on a unique method for controlling ball bearings within "simple" gyroscopes; it represents the removal of a technical impasse in the gyro art that has blocked efforts to approach absolute precision since practical gyros were developed near the turn of the century.

MEET THE AUTHORS

Charles Miller, M.E.I.C., Construction Project Manager, Canadian British Aluminium Company Limited, Baie Comeau, Que. *(Aluminium Reduction Plant at Baie Comeau, Que.; and The Manicouagan Power Development.)* Mr. Miller graduated in engineering from Queen's University, Kingston, Ont. (B.Sc., Civil, 1930). He was chief hydraulic engineer and manager of construction during the building of Stage I of the Manicouagan power development. Mr. Miller was formerly general superintendent of the Beauharnois Light, Heat and Power Comany.

W. G. Street, Chief Plant Construction Engineer, Canadian British Aluminium Company Limited, Baie Comeau, Que. *(Aluminium Reduction Plant at Baie Comeau, Que.)* Mr. Street received his engineering training with W. H. Allen Sons and Co. Ltd., Bedford, England, and was subsequently employed as chief plant engineer, Star Aluminium Co. Ltd., Wolverhampton, and assistant engineer, Courtaulds Ltd., Coventry, England. In 1939 he joined the British Aluminium Co. Ltd. and held position of chief engineer at their Swansea smelter and Latchford recovery works, and chief electrical engineer at the Falkirk rolling mill; he became Senior Plant Engineer in 1947 at their head office, London. He took charge of the engineering team on technical design of Canadian British Aluminium Company Limited, in 1956; Mr. Street is a member of the Institution of Electrical Engineers, U.K., and of the American Institute of Electrical Engineers.

T. A. Hughes, M.E.I.C., Chief Field Engineer, C. D. Howe Company Limited, Montreal. *(Aluminium Smelter Dock at Baie Comeau, Que.)* Mr. Hughes received his engineering qualifications in Wales (B.Sc., civil, University College, 1942). Following service in World War II he gained professional experience in Great Britain prior to coming to Canada in 1953. He acted as co-ordinating engineer for the Canadian British Aluminium project at Baie Comeau, and has been closely associated with it through all stages from the preliminary studies to commissioning of the smelter plant. Mr. Hughes is an Associate Member of the British Institution of Civil Engineers and the Institution of Structural Engineers.

V. M. Wallingford, M.E.I.C., Resident Engineer, Canadian British Aluminium Company Limited, Baie Comeau, Que. *(Aluminium Smelter Dock at Baie Comeau, Que.)* Mr. Wallingford graduated from the University of Toronto in 1944 (B.Sc., civil engineering). He joined the Anglo-Canadian Pulp and Paper Mills, Forestville, Que., in 1945. In 1949 Mr. Wallingford became project engineer with the Ontario Hydro consulting division, Toronto, and he transferred to the Manicouagan power project No. 1, for the Ontario Paper Company as assistant resident engineer the following year. He took on the post of project engineer with the Anglo-Canadian Pulp and Paper Mill Ltd. in 1953. General superintendent, Eastern area, the following year for Mannix Ltd., he assumed duties as resident engineer, New Brunswick Electric Power Commission, Beachwood power project, in 1955.

J. M. Higgins, Manager of Construction, Quebec North Shore Paper Company, Thorold, Ont. *(Manicouagan Power Development.)* Mr. Higgins graduated from the University of Toronto in 1930. He served overseas with the Royal Canadian Engineers in World War II and retired with the rank of major. In 1946 he joined the Ontario Paper Company Limited, central engineering department. Mr. Higgins was promoted to his present position of manager of construction in 1953.

C. M. Stewart, Jr.E.I.C., Senior Engineer, mechanical design section, engineering division, Imperial Oil Limited. *(The Modernization of the Halifax Refinery.)* Mr. Stewart holds an engineering degree from the University of Saskatchewan (B.Sc., mechanical, 1948). After one year's experience with C. A. Energia Electrica de Venezuela he joined Imperial Oil Limited, and has since then been engaged in inspection, mechanical design and construction work. He was associated with the design and specification phase of the Halifax project and followed its construction in the field. He was resident engineer for the powerformer project at Halifax refinery.

COVER PICTURE

The aluminium project at Baie Comeau, Que., described in three papers in this issue, is the subject of the cover picture this month. The picture shows the smelter dock, with conveyor from wharf to silos.

Aluminium Reduction Plant at Baie Comeau, Que.

C. Miller, M.E.I.C. *Construction Project Manager*

W. G. Street, *Chief Plant Construction Engineer*

Canadian British Aluminium Company Ltd., Baie Comeau, Que.

Read at the 72nd Annual General and Professional Meeting of the Engineering Institute of Canada, Quebec City, Que., May 1958

A new major industry has been established at Baie Comeau, Que., on the North Shore of the St. Lawrence River, with the official opening, on 14th June, 1958, of the Canadian British Aluminium Company smelter. The reduction plant, smelter dock, and associated power developments are described in three papers.

THE FIRST aluminium ingot was cast at the Canadian British Aluminium Company smelter on December 23rd, 1957. This marked the starting of the first stage of production, a bare two years following the initial planning of the project.

The Canadian British Aluminium Company Limited was incorporated under the Province of Quebec Companies' Act on October 26th, 1955, for the purpose of aluminium smelting, with its head office in Montreal. The founder members were The British Aluminium Company Limited, who subscribed sixty per cent of the original stock, and the Quebec North Shore Paper Company, who subscribed forty per cent. Since then a large issue has been made in Canada and the public now own common stock as well as bonds and debentures.

Location

The choice of the site in Baie Comeau, Quebec, was influenced by:

(*a*) The availability of reasonably priced hydro-electric power and the possibility of power being developed quickly and being capable of further expansion as might be required.

(*b*) The availability of good facilities for a deep water harbour for berthing three 10,000 ton ships.

(*c*) The proximity of a modern town in the immediate area with its own harbour and an airport, and served by Highway No. 15 to Quebec City, which would greatly facilitate construction program.

(*d*) The location of the harbour relative to the proposed smelter site within economic road hauling distance and offered facilities for the economic handling of the considerable quantities of the process material to be used.

Project

The initial planning was to build a smelter in four stages, each stage to have a productive capacity of 45,000 tons* of aluminium ingot per annum; each stage to have two pot rooms with a rectifier station at one end and a casting shop at the other, together with the necessary carbon production factory, ancillary buildings, workshops, office, laboratory and raw material stores, etc. The target for these operations was to produce the first metal by the close of 1957, to complete the construction of stage I in the spring of 1958 and to bring stage II into full operation by the middle of 1959. The exact date covering stages III and IV is yet to be decided.

The design and construction of the dock is covered in a separate paper, but in this introduction it should be mentioned that the initial aim was to complete the dock and dock installations during 1957 in time to assist with the unloading of construction material and plant and to deal with the intake and storage of the process raw material required over the winter of 1957-1958.

All targets to date have been achieved with the first ocean going vessel, the M.V. *Luciana* berthing at the C.B.A. dock on May 29th, 1957, bringing material and machinery for the alumina-coke unloading and conveying plant which had been manufactured in Germany, and at the close of the shipping season 1957 a total of fifty-five ships had berthed at the dock, including vessels bringing the alumina and petroleum coke required for the operation of the process over the 1957-1958 winter period.

Preliminary Work

In order to get the job off to an early start the preliminary work was supervised by the Quebec North Shore Paper Company. In 1955 they carried out the clearing of the trees on the site which had been chosen for the plant. They also supervised a contract to a local contractor to start the main access road along the St. Lawrence river to the new wharf site. This work proceeded through the winter of 1955-1956.

Site Preparation and Access Roads

Bids were called in April 1956 and a contract awarded for the excavation and levelling of the industrial site, along with the completion of the main access roads.

The smelter buildings required a

* All weights are given in short tons of 2,000 lb.

space of approximately half a mile square and such areas of level ground are very rare on the rocky north shore of the St. Lawrence river.

In order to carry out the excavation and filling this contractor used over a million dollars worth of heavy construction equipment. The job included the moving of nearly 1,000,000 tons of solid rock and also about 300,000 cu. yd. of common fill.

The major items of construction equipment used by the excavation contractor were as follows: 2½ yard shovel, 1; 1½ yard shovel, 3; D8 tractors, 2; D7 tractors, 2; D6 tractors, 1; front end loaders, 2; road grader, 1; Euclid trucks (15 ton), 12; smaller trucks (sub-contract), 30.

Another job done by this contractor and which involved a very considerable amount of time was the grubbing of the whole area, including removal of the stumps. In a few areas there was a depth of three or four feet of organic material which had to be excavated and hauled out.

Construction Camps

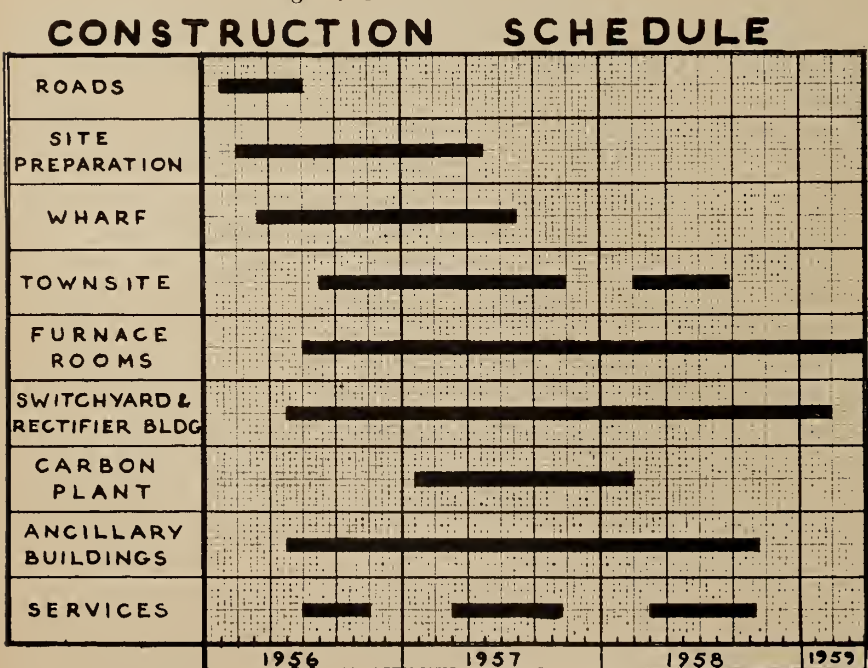
These were provided by the owner who built them in advance of the general contract. The type selected was a demountable two-storey panel camp, which had been successfully used by the Woods Department of the associated paper company. A cafeteria of a 1500-man capacity was built of a steel prefabricated building. Electrical distribution, laundry, commissary, boiler plant, water supply and sewerage system was built. The manpower required for the job was under-estimated, but the camp was expanded to accommodate 3000 men. In addition to construction camps a trailer park was built with complete facilities for 30 families.

General Contracts

The concrete requirements of the job amounted to approximately 120,000 cubic yards for the smelter site and the wharf. In order to efficiently meet the schedule and supply all the requirements it was decided to establish a central ready-mix concrete plant which would supply concrete to all the contractors. The successful bidder erected a ready-mix plant in the record time of four weeks, and delivered the first concrete in June 1956. Their plant was a gravity batcher with one 2 cubic yard concrete mixer. In general, the concrete was premixed in this tilting mixer and dumped into a hopper. To handle the concrete to the job a fleet of 8 ready-mix trucks was used, either as transit mix trucks, each carrying 6 cubic yards, or as agitators with a capacity of 8 cubic yards. In 1957 the single mixer at the batching plant turned out over 90,000 cubic yards of concrete.

The tenders for the construction of the main smelter were called in May 1956. The successful contractor started operations in June 1956 and substantially completed stage I by December 1957. Stage II will be completed in 1958.

Fig. 1. Construction schedule.



This work included the following: office, laboratory, service building, raw material stores, boiler and compressor house, workshops, carbon plant, briquette storage, pitch storage, rectifier building, switchyard, and four furnace rooms, together with casting shop.

The type of construction of the main smelter buildings is a structural steel frame with aluminium cladding. These four furnace rooms are each 1700 feet long and 76 feet wide. They are connected together by corridors at the centre and at each end. Along the west end of the furnace rooms is the rectifier building, and along the east end and connected to the furnace rooms by corridors, is the casting shop.

The ancillary buildings were nearly all built of structural steel frame with patent asbestos-cement insulated sandwich board cladding, and tar and gravel roofs. Only the office and laboratory were built of brick.

The following table shows the major quantities on the civil construction work:

Concrete	120,000	cu. yd.
Backfill	300,00	cu. yd.
Rock excavation	30,000	yards
Structural steel	14,000	tons
Sandwich board cladding	22,000	squares
Tar and gravel roofs	2,250	squares
Aluminium cladding and roofing	6,200	squares
Reinforcing steel	5,650	squares
Piping—steel	25,000	feet
cast iron	25,000	feet
wood stave	12,000	feet
concrete	5,000	feet

Wharf

Tenders for the wharf were called in March 1956. It consisted of building a steel pile wall 3,000 feet long, together with approximately 400,000 cubic yards of rock backfill.

The contractor started operations in April 1956 and completed the wharf in September 1957. Design and construction of the wharf is covered fully in another paper (p. 50).

Construction Materials

The favourable location of Baie Comeau on the trans-Atlantic shipping lanes had an important effect on the source of materials. It is interesting to note that the cost of freight between Montreal and Baie Comeau for less than 500 miles is the same as freight from Europe on a distance of over 3,000 miles. Accordingly, most of the structural steel and cement, some reinforcing steel and much of the equipment came from European countries.

All construction material had to be off-loaded at the wharf as there is no railway connection to Baie Comeau. This unloading was handled by the Quebec North Shore Paper Company's stevedores, and material was hauled to the site by the general contractor.

The total amount hauled amounted to over 120,000 tons.

Townsite

Since the initial two stages of the plant would employ about 900 men, and the complete plant would require about 1500 workers, it was necessary to develop a new townsite. The amount of accommodation for families in nearby towns of Baie Comeau and Hauterive was extremely limited, in fact a serious shortage of houses existed.

A suitable and picturesque site for the new housing development was chosen within a mile of the smelter and wharf. During 1956 municipal improvements were carried out for some 300 lots. During the following year a staff house for 30 guests, three apartment blocks to house 36 families and some 210 houses were built on the new development. In 1957 the townsite was expanded to a total of about 450 lots, and individual housing construction is in progress.

Due to the very rocky nature of the load, it was necessary to haul in to the site all the sand and earth fill, all the gravel for streets and roads and all the topsoil for landscaping. The total amount of this material hauled for the townsite development was 900,000 tons. While this seems to be a tremendous quantity, it was much more economical than the extensive rock blasting which would have been necessary otherwise.

The new townsite, as can be seen from Fig. 6, is very attractive.

Fig. 2 Site preparation. Excavation in progress for smelter site. Beginning of road to townsite at upper left. June 11, 1956.

Plant Installations

A single paper will not allow for anything like a detailed description to be given of the plant. An endeavour has therefore been made to present features that may be of particular interest or peculiar to this particular smelter installation.

Raw Materials Handling and Storage

To provide for the ultimate productive capacity of 180,000 tons of aluminium per annum it will be necessary to bring in something like 90,000 tons of petroleum coke, 360,000 tons of alumina and, in addition, supplies of pitch, fluxing materials, stores, etc. In all, it is necessary that the dock should be capable of handling a total of something like 500,000 tons of incoming raw material per annum with handling and loading facilities required for shipping 180,000 tons of outgoing metal.

A pneumatic unloading plant has been installed at the dock to deal with the handling of incoming alumina and coke which represents the bulk of incoming raw material—two suction towers will be installed under the initial two-stage development.

The towers run on tracks for the full length of one berth. Each tower carries two suction nozzles, each nozzle being capable of handling alumina and coke at a maximum rate of 80 to 90 tons per hour—the material is then passed by cross conveyors in the suction tower to a belt conveyor also running the full length of the berth, which in turn feeds to the main belt conveyor carrying the material to the storage silos which are located to suit the process.

Conveyor

The main belt conveyor system comprises five conveyors, three of which have 42 in. wide belts and two have 36 in. belts. The total length of the conveyors is approximately 3,200 feet and rise 347 feet to the discharge points at the storage silos. The 42 in. belts operate at a speed of 250 feet per minute and the 36 in. at 350 feet per minute. Both alumina and coke are carried by the first two 42 in. conveyors for a distance of approximately 2,400 feet, after which the alumina is carried to storage silos by the third 42 in. conveyor, and the coke to the coke silos by the two 36 in. conveyors, one of which utilizes a tripper for distributing the material to the respective silos. The conveyor drives are interlocked and the system is arranged to cover either the alumina or coke handling operation.

The integrated unloading and conveying system is thus capable of unloading at a maximum rate of approximately 330 tons per hour which can be stepped up to 500 tons per hour by the addition of a third suction unloading unit and by increasing the speed of the conveyor belts from 250/350 to 380/450 per minute. The motors and drive arrangements have been suitably rated to provide for this future development by effecting a change of drive sprockets only. The conveyor gallery is sheeted with aluminium, and the roof is one single curved sheet.

Before closing on this item it may be of interest to mention several of the special features of this section of the plant.

(*a*) Each suction hose of each tower may be regarded as an independent unit with separate exhauster and cross conveyor so that in the event of breakdown of one plant, the other can continue to operate.

(*b*) Bunker level indication shows the filling of the collecting containers, and over filling, with the possibility of entrainment of material into the blowers, is eliminated.

(*c*) All parts subject to abrasion by the alumina and coke (bends, elbows, etc.) have been protected by a fused basalt lining.

(*d*) The movements of the booms (lifting, lowering, drawing in and out of the telescopic pipes) can be controlled from the operator's stand in the elevator tower as well as from the ship.

(*e*) The idlers on the conveyor have "maintenance free" lubrication, lasting for several years, provided by means of triple labyrinth seals and dust arrester grooves.

(*f*) All points of transfer in the suction unloaders and in the conveyor systems have dust control, and the extracted dust is again transferred to the material being conveyed.

(*g*) Sequence interlocking, electrical and mechanical "holdback" locking safety devices are provided and the coke storage silos are equipped with two sets of level indicators, the first set to signal and the second set to put the stopping sequence into operation.

Storage

A total of five silos are provided for the winter storage of alumina. The silos measure 65 ft. in diameter by 100 ft. high, with a capacity of 8500 tons each. A sixth silo (No. 1) is designed with feed points for filling alumina-furnace charging vehicles.

After the alumina leaves the belt conveyor it is discharged into a circular hopper and then passed for intake into the selected storage silo by means of low pressure air fluidized conveyors passing over the tops of the silos. The alumina may be reclaimed from any of the five storage silos and conveyed by similar trough type fluidor conveyors to a pump chamber for pumping into the No. 1 feeding silo.

The pumps also make use of the fluidizing principle by first fluidizing the alumina in the pumping tank for lifting the alumina by compressed air through conveying pipes and into the top of the feeding silo No. 1. Two sets of pumps are provided for this purpose each of which has a capacity for pumping 33 tons of alumina per hour. Two group control stations with mimic control diagrams are provided to cover all operations. One station provides the control for distributing the alumina to storage as delivered from the main conveyor and this situated at the top of silo No. 6; the other provides for reclaiming and discharge and this is situated on one of the base floors in No. 1 feeding silo.

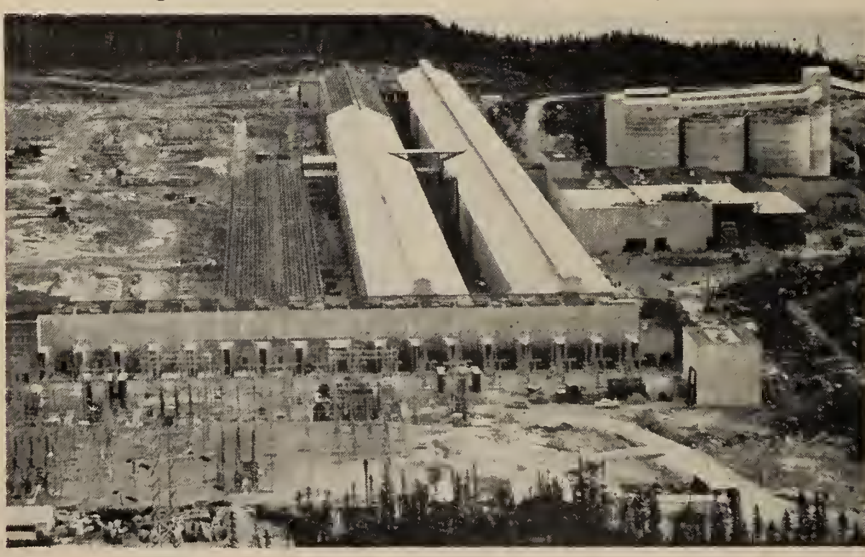
The timing of the various control operations is fully automatic with automatically operated compressor plant mounted in the basement of No. 1 silo immediately below the main control room.

As in the case of the suction unloader and the belt conveyor, the alumina storage and handling installation is provided with dust reclaiming plant for cleaning the process air before passing this back to atmosphere.

The distribution to the storage silos and subsequent handling of alumina is through equipment supplied by the British part of the successors to the original discoverers of the fluidizing principle. It may be of interest to mention that the installation at Baie Comeau is believed to be not only the largest of its kind, but apart from some minor applications in the cement industry, is the first supplied in North America.

Thus the unloading, belt conveying and alumina distribution to storage and reclaiming, form an integrated handling system under close automatic control with the addition of telephone communication between the dock, the conveyor, and the alumina and coke storage silos.

Fig. 3. General view of industrial site. Alumina silos at right, switchyard in foreground. Furnace rooms are 1700 ft. long. October, 1957.



Carbon Plant

It will be known that the reduction process for producing aluminium requires something like 0.5 to 0.6 lb. of anode paste for each pound of aluminium when using Soderberg electrodes. The above figures determine the capacity of the carbon plant and also illustrate that a carbon reduction plant must be regarded as a vital feature of a reduction smelter.

It should perhaps be mentioned that besides anode paste, the Baie Comeau carbon plant is designed to provide pot lining mixture for part of the lining of reduction cells.

The plant designed, engineered and erected specially for the Baie Comeau installation differs in a number of aspects from other conventional paste plants and it may be of interest to make some reference to these features which may be listed as follows:

(*a*) Operation is from central automatic control station.

(*b*) It is a continuous process with continuous mixers designed for the preparation of anode paste in briquette form.

(*c*) It is designed for the use of hard pitch in a molten state.

(*d*) The production train allows for the concurrent production of anode paste and pot lining mixture.

(*e*) The use of hydrotherm as a heating medium.

(*f*) The provision of raw material storage facilities for four to five months during the winter close of navigation.

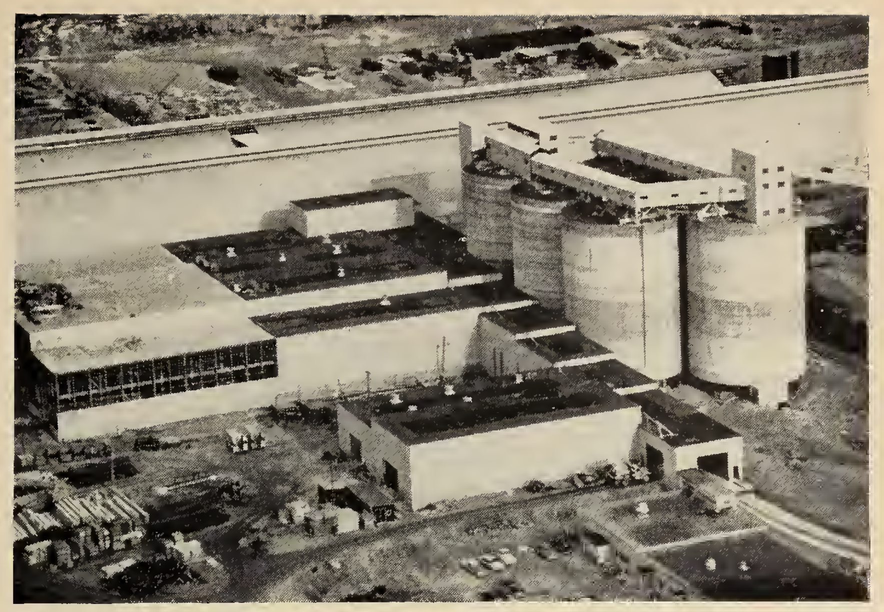


Fig. 4. Ancillary buildings—general workshops in centre. Ramp to central corridor at lower right. November, 1957.

Central Automatic Control

Since it is always the goal to find ways and means of automation, a few additional remarks on the central control arrangement may be of interest.

The control room, housing three different control boards with push-button electronic instruments and graphic control lights, represents the "brain" of the plant. These instruments indicate and record temperature, draft, bin level of storage and fraction bins, pitch level and temperature in melting and holding tanks, flow rate and quantity of pitch and grist for anode paste or lining mixture preparation. An annunciator panel indicates and informs the control operator of any abnormal conditions, and a graphic flow sheet gives the operator visual control by means of lights indicating the machinery in action and the direction of flow of the material.

All operational processes as described are performed by one operator, in addition to whom, four operator's helpers on the floor, one clerk, one general foreman and the superintendent form the complete operational personnel for the production plant, which is designed to give an output of 53,600 tons of anode paste per year and 2800 tons of pot lining mixture per year when working two shifts per day, five days a week.

Fig. 5. Completed wharf. November, 1957.

Continuous Process with Continuous Mixers

The preparation of grist as well as the preparation of anode paste is arranged for continuous operation.

The raw material, calcined petroleum coke, is first fed over the screen with the provision of three fraction separations in order to fill the first coarse fraction bins. As soon as the coarse fraction bins are filled the flow of the coarse fraction is automatically re-routed to the crusher surge bin where the coarse intermediate will be produced. Again, as soon as this coarse intermediate bin is filled an automatic re-routing to the fine crusher surge bin takes place. As soon as the fine intermediate bins are filled the overflow is routed to the mill feed bin for producing the fine fraction by means of airswept grinding. The product of the airswept grinding system does not change with the feed size, therefore such an overflow arrangement from the fraction bins toward the mill feed bin is possible.

By means of continuous scales the coarse fractions are rationed and a correct proportioning of fractions can be fed direct or via a heat exchanger and feed screws into the continuous mixer.

Simultaneous to this operation the molten hard pitch, at approximately 350° F., is controlled by metering pumps and flow meters and is fed to the continuous mixer. Here the final mixing and extruding takes place and the extruded paste is strung and cut to briquette size approximately 2 in x 2 in. x 3 in. by a cutting wheel, then cooled with water and conveyed to a briquette store by means of elevator and conveyor system.

Use of Hard Pitch in Molten Form

The hard pitch, which is delivered in 12 in. to 16 in. lumps, is transformed to a molten state in melting tanks which are provided with internal heating coils fed from the high temperature hydrotherm system.

Circulating pumps provide for the equal heating of the pitch within the melters which is then pumped from the melting tanks to large overhead holding tanks where the pitch is brought to its ultimate temperature before discharge by gravity, to be used for blending with the carbon grist fed via the continuous weighing scale for production of anode paste in the continuous mixer or into the batch mixers along with coke anthracite grist fed via a batch scale for the production of pot lining material.

Hydrotherm

Some mention of the heating medium used throughout the system for melting of hard pitch and for maintaining the temperature of the pitch in the holding tanks and process lines, the jacketing heating of the continuous and the batch mixers, etc., may be of interest. This heating fluid is pumpable between temperatures of 50° to 600° F. For the pitch melting operation hydrotherm is heated to 550°-580° F. for circulation in the melters. The heating medium has the advantage of being non-explosive and non-inflammable and is not poisonous. Other heating media such as steam would be more expensive due to the necessity for using high pressure to give equivalent heat transfer and, on the other hand, such media as oil which could give equivalent heat transfer rates would be dangerous and would introduce fire and explosion hazards at the temperatures needed. The hydrotherm system has been divided into a low temperature and a high temperature circuit where the high temperature system is used for pitch melting and the low temperature system is used for maintaining the heat of process lines and mixer jackets—the whole system being of a gravity and not a pressure type, arranged by means of an open expansion tank.

Fig. 6. View of a section of the townsite.

Hydrotherm fluid is highly penetrating at operating temperatures. This made it necessary to introduce a very rigid specification and control for jointing of the many thousands of feet of hydrotherm piping installed.

In the construction program, the erection of the carbon plant presented the greatest challenge to meeting the target dates. As the plant represented a completely new design the final designs of building steelwork and of the plant had to wait the near completion of the design of the system. Following manufacture and delivery of the steelwork it was mid-May 1957 before a start could be made on the erection of the building steelwork to be followed in early June with a start on the erection of the plant. In all, something like 1,850 tons of plant was involved, some of which had to be erected at elevations of up to 120 ft. along with 55,000 ft. of process pipe work, including about 2,500 valves of various sizes. As an indication of the intricate electrical installation involved it can be quoted that a total of approximately 200,000 ft. of cable was used with a large proportion of the electrical installations being to explosion proof specification.

Pot Rooms

As previously mentioned each stage is planned for the production of 45,000 tons of ingot per annum so that each stage has two pot rooms over 1,700 ft. long with the rectifier station running across the west end and the casting shop across the east end of the pot rooms. The pots are designed for 100,000 amp. operation and are vertical stub Soderberg type with 168 pots in each series or stage, comprising two rows of 42 pots in each building. It is not intended to give a description of the process, which will be well known to most of the readers. It can, however, be said that to stand up to the operating temperature of the molten fluxes and metal at about 1000° C. and in view of the highly penetrating characteristic of the cryolite flux it is necessary to protect and insulate the steel box comprising the cathode, first with a lining of refractory brick and then with the final lining of baked carbon block and a rammed carbon lining to completely seal the bath. The anode assembly is fully motorized to enable the distance between anode and cathode to be regulated to suit operating requirements.

Stubbing is effected by means of overhead travelling crane-mounted stubbing machines of French manufacture. These machines are of precision design arranged for automatic control of cross travel and extraction and can operate with an accuracy of 5 mm., the machines themselves being capable of exerting a torque up to 30 tons. The operation for extracting stubs is very similar to the extraction of a tooth in that the gripper is travelled to exact location above the stub to be withdrawn; the gripper is then lowered to bite the stub pin which is twisted through 90° and then extracted from the baked carbon forming the electrode. The carrier is then retracted along with the rejected stub which is placed in a carrier on the machine and following similar motions a new stub is inserted to rebake in the soft zone of the anode.

The overhead stubbing operation thus leaves a free furnace-room floor for crust breaking, metal-tapping, and anode paste replenishment vehicles. The tapping operation is by means of a large crucible mounted on a battery driven vehicle to run alongside the furnaces. The crucible carrier is provided with side crabbing, elevating, and tilting motions to enable the metal to be sucked from the furnace by compressed air ejector action. The crucible is then travelled to the casting shop where the metal is decanted into the holding furnaces.

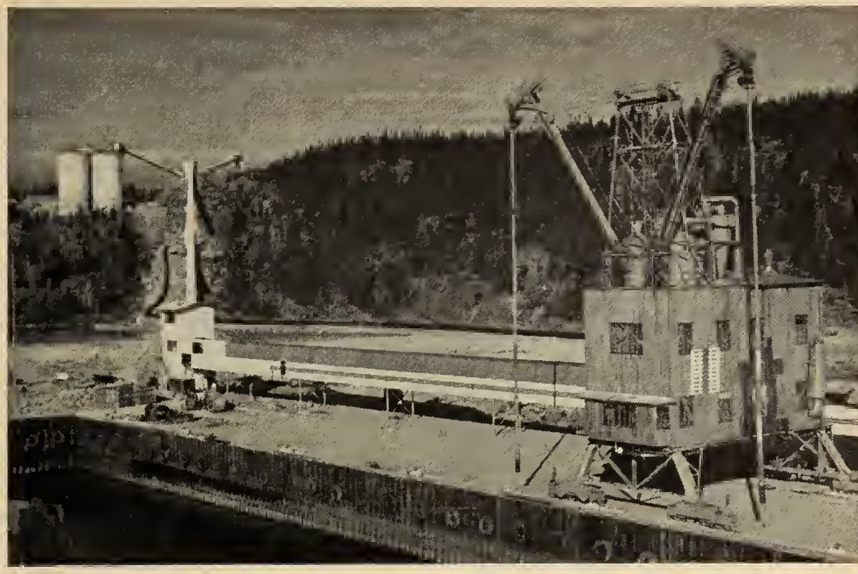

Fig. 7. Pneumatic unloader at right. Conveyor from wharf to silos.

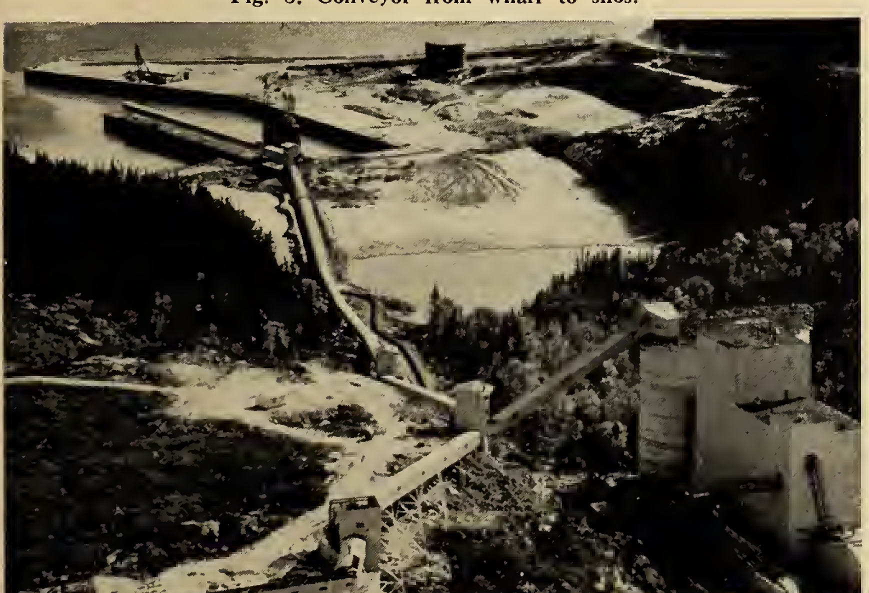
One feature which may be of particular interest is the design and form of fabrication for the main 100,000 amp. furnace conductors. In all, approximately 3568 tons of aluminium bar is used for each furnace series. This material was received from the parent company in lengths up to approximately 50 ft. The largest section used for the cathode conductors measures 24 in. x 5 in. in section and is fabricated in the site workshops up to maximum lengths of approximately 80 ft. including the flexible risers to the anode conductors. To deal with the fabrication on site special machines were ordered for the jig drilling of many tens of thousands of holes together with the scalping, bending and slotting operations. It can be said that the fabrication of the complete production series involved a total of approximately a quarter million operations comprising the drilling of 2 in. diameter holes, slotting, scalping for contact faces, bending, welding, tapping, sawing, etc. Some tens of thousands of welds had to be made and a special production line was installed for this purpose. Much of this welding required a special technique, involving as it did the welding of steel to aluminium, the welding of the packets of flexible conductor for the anode connections, and the welding of the heavy section conductors measuring up to 24 in. x 5 in. in section. For stage II, bars of the same section and length are now being produced at Baie Comeau by a continuous horizontal casting process, and we think it can be claimed that these are the first of this type to be used on the American Continent. To transport these cumbersome prefabricated bars from the prefabricating shops to the potrooms called for some ingenuity in the design of handling and carrying jigs.

Fig. 8. Conveyor from wharf to silos.



Casting Shop

As already mentioned the liquid metal from the reduction furnace is carried to the casting shop for blending, for additions or other treatment necessary before being cast into ingots, rolling slabs or conductor bar. These holding furnaces are oil fired and are mainly of lip axis tilting design for direct feed into the ingot casting machines. Machines are installed for the production of chill casting of 25 lb. and 50 lb. ingots, and semi-continuous machines for the production of rolling slabs, extrusion billets, and wire bars up to a maximum size of 84 in. x 9¾ in. rolling slab. In addition, a horizontal long casting machine is installed for the production of aluminium bar as previously described and we are now able to say that this machine is in regular operation.

Power Supply

The power supply for stage I and part of stage II is from the Manicouagan Power Company, and Hydro-Québec have contracted to supply the balance of the power needed for stage II and further power for stages III and IV. The power from Manicouagan is at present carried by a single tower, two-circuit 161 kv. transmission line approximately eleven miles long, to the C.B.A. smelter. One circuit is sufficient for the two stages, the other one may be regarded as a spare. With the ultimate four stage development a second tower carrying a single circuit will be installed so that during all stages of development a complete spare circuit will be available.

The two 161 kv. lines from Manicouagan terminate in an outdoor switchyard at two 1200-amp. air-blast circuit breakers which feed 161 kv. duplicate busbars. Each pot line is fed from the 161 kv. busbars by a 115 Mva. 161/33/13.2 kv. transformer. The secondary winding of this transformer feeds the pot line via a 33 kv. regulating transformer which is provided with off-load tap connections and on-load tap changing equipment designed to give a wide operating voltage range. The 13.2 kv. tertiary winding serves the works distribution supply for subsidiary power and lighting. Standby 33 kv. busbars are provided which can be fed from a spare 115 Mva. 161/33/13.2 kv. transformer together with a spare regulating transformer which can be used to serve as a standby for any of the ultimate four pot lines.

Pot Line D.C. Supply

For each pot line 100,000 amp. at 850 volts d.c. is required. This is provided by pumpless steel tank multi-anode air-cooled mercury arc rectifiers. The specification rating is for electro-chemical duty designed to a British standard specification which is identical to American standard C-34.1 — 1949 electro-chemical service rating. The equipment consists of a total of 144 rectifier tanks per pot line grouped to give 8 units—each unit being rated at 12,150 kw., 850 v., 14.285 amp. which enables the full pot room load to be carried on 7 units indefinitely, although under normal operation all 8 units are kept in circuit to provide for operation at maximum efficiency. Each unit thus comprises 18 pumpless steel tank rectifiers working in parallel which incorporate air cored anode reactors to ensure good load sharing between the rectifiers operating in parallel. These reactors are also designed to limit the maximum value of fault current to a safe value in the event of an arc-back. Special mention is made of this point as this system of control is not generally used by American and Canadian manufacturers who have hitherto relied on a.c. and d.c. switchgear to clear such faults.

Mention has been made of the off-load tapping points provided on the main stepdown transformer to facilitate voltage variation of the pot line. These off-load tappings are designed to give alternative outputs of 25.5 kv., 19.0 kv. and 14.7 kv. in addition to the normal 33 kv. operating voltage. The series regulating transformer provides for 21 position "on-load" tap change to give plus and minus 14½% buck or boost on the intermediate voltage. The above combination on the regulating transformer and offload tappings on the stepdown transformer provides continuous control of d.c. between 240 volts and 850 volts and control grids on the rectifiers are used to provide the fine control needed between on-load tapping positions. Likewise, this grid control of the voltage provides a means for load balancing between the eight separate groups and for short time voltage reduction required from any voltage down to zero for use when picking up or dropping load.

Fig. 9. Alumina silos under construction.

It could be mentioned here that no difficulty or trouble was experienced in operating the complete rectifier installation continuously over a long period at 100,000 amp. with busbars short-circuited during the initial drying and commissioning period.

Pot line control is by means of a master grid control phase shifter operating on all eight units in parallel. In addition to this each unit has its own grid control phase shifter to permit load balancing between units. Protection against arc-back is provided by a combination of reverse tripping d.c. high speed circuit breakers and arc suppression operating on the rectifier control grids. The arc suppression is actuated by a high speed mechanical relay triggered by reverse current only. This relay has an operating time of 1 millisecond. Each unit has its own 33 kv. a.c. circuit breaker and the starting sequence for the unit follows automatically upon the closing of the circuit breaker. In addition, a master 33 kv. pot line circuit breaker is provided for controlling the a.c. supply to a complete pot line equipment. This breaker permits change over to be effected from main to standby, stepdown transformers on load.

The rectifiers are air cooled with an individual propeller fan for each rectifier. Cooling air is drawn into the rectifier station basement by separate fans mounted in the outer walls of the building and adjustable louvres are provided in the ducts to these fans and outlet louvres in the roof above the rectifiers provide for temperature control of the cooling air. To cover the wide range of ambient temperatures from minus 40° C. to plus 32° C. both the rectifier and substation fans are also equipped with two-speed motors. The whole rectifier equipment is remotely controlled from a central control room and all protective relays are installed in an annex to this control room. Direct telephone and radio communication has been provided from the control room to the Manicouagan power station.

It may be of interest to repeat some of the features of this equipment which differ from the more usual North American installations:

(*a*) The use of multi-anode pumpless rectifiers instead of single anode ignitrons.

(*b*) The use of arc suppression with cathode high speed circuit breakers for backfire protection instead of anode breakers.

(*c*) The use of cored anode reactors to limit arc back current.

(*d*) The use of air cooling instead of water cooling.

(*e*) A wide range of voltage control by on-load tapping with a limited amount of grid control.

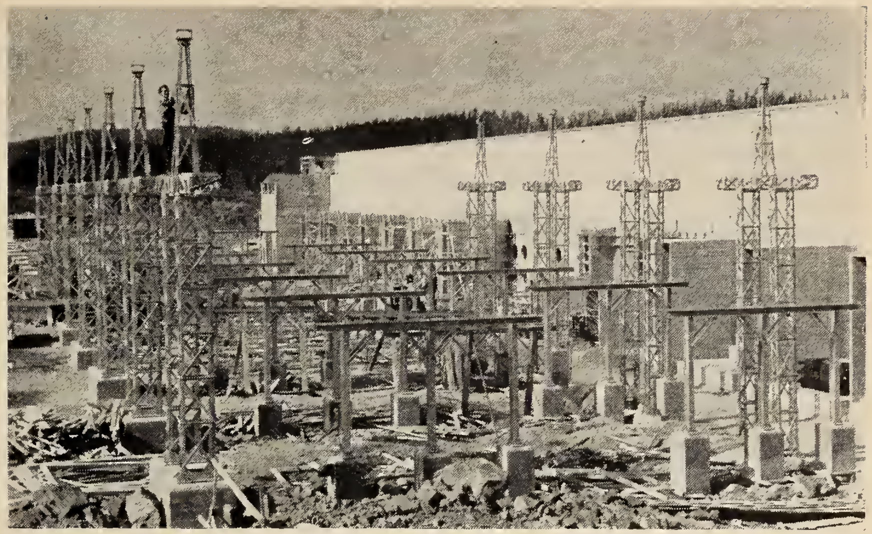


Fig. 10. Switchyard under construction.

Works Distribution Supply

The works distribution is at 13.2 kv. The supply is taken from the main transformers in the outdoor switching yard and brought into No. 1 main substation located near the rectifier station from which a 15 Mva. 13.2 kv. ring-main is taken to supply other works distribution substations throughout the plant and at the dock. These substations transform to 550 volts, 3 phase a.c. for secondary distribution and further local transformers fed at 550 volts provide for the 110 volt lighting and service receptacle connection points.

CONCLUSION

In conclusion, the following notes may be of interest and serve to give a general indication of the rate of plant erection and construction and to give an outline of the main plant erection contracts.

The main electrical contractor made a start in January 1957, building to a peak labour force of 330 in October 1957.

Mechanical plant contracts covered the construction of furnaces and the erection of plant and were placed over the period March to May 1957. An overall peak labour force of approximately 950 was reached on plant erection during August 1957.

Much has been achieved and much has been learned in the way of economic and efficient planning during the period of construction March 1957 to the completion, in April 1958, of all that is involved in stage 1.

These points, although well known, are often difficult to achieve, and it may be worth while to make special reference to the following essentials:

(*a*) The need to keep down the short-term peak labour force to a minimum, as accommodation facilities under the conditions that usually prevail with such a project are costly.

(*b*) To keep temporary construction electric lighting and power wiring to a minimum by earliest possible installation of the permanent electric distribution and permanent lighting installations.

(*c*) Also, as far as practicable, to plan for the earliest possible installation of permanent compressed air services to assist construction operations.

(*d*) The need for adequate and strategically located undercover storage.

(*e*) The steady and sequence-planned delivery of construction material to avoid expensive rehandling.

(*f*) The early and complete planning and programming must be regarded as an essential to the success of the project as the period of construction provides neither the time nor the right atmosphere for working changes to technical design and the engineering supervision is required out on the job and not at the desk and drawing board.

(*g*) Finally, to effect earliest possible erection of permanent cranes as, in common with most projects of this magnitude, there never seem to be enough cranes during the peak construction period. In all, and under the two-stage development, including 8 stubbing cranes, rated at 50 tons, one 100-ton crane in the transformer maintenance building, one 100-ton and one 50-ton crane in the furnace repair departments, one 100-ton stiff-leg derrick at the dock for unloading the heavy transformers and one 5-ton high-speed luffing crane at the dock. The importance of adequate craneage is emphasized and to illustrate this need it can be stated that over the period covering the completion of stage 1 development, the handling and erection of plant and equipment alone has involved the placing of approximately: 13,000 tons of furnace steel work; 8,500 tons of furnace refractory bricks and carbon blocks; 3,500 tons of aluminium conductor; and 6,000 tons of electrical plant and equipment, material unloading, conveying plant, cranes, compressors, machine tools and carbon plant crushing, grinding elevating plant, boiler plant, etc.

Acknowledgments

We wish to express our appreciation to the many people who have had a hand in supplying information for this paper.

Read at the 72nd Annual General and Professional Meeting of the Engineering Institute of Canada, Quebec City, Que., May 1958

As OUTLINED in a paper (on page 41) in this issue, large quantities of raw materials for making aluminium have to be received by ship, and the bulk of the aluminium produced is also shipped by boat. Hence, an all-weather dock with adequate unloading and loading facilities capable of handling ocean going vessels is of prime importance and the location of a suitable dock site was one of the prime factors influencing the selection of the smelter plant site. This paper describes the design and method of construction of the dock.

Selection of Site and Harbour

Considerable hydro-electric power is required for the smelting of aluminum. This, coupled with the desirability of locating the smelter as near the mouth of the St. Lawrence River as practicable (so that shipping distances to and from the United Kingdom, which is the principal market for the ingot produced by the smelter, would be as short as possible), suggested that the site should be located on the North Shore of the St. Lawrence.

Good natural harbours are few and far between on this rugged shoreline and the site finally selected was two miles north-east of the paper mill town of Baie Comeau, which is approximately 430 miles downstream from Montreal and 120 miles upstream from Seven Islands. Though not served by any railroad system, Baie Comeau did possess an existing dock capable of berthing 10,000 ton vessels, was linked to Quebec City by a secondary road, and was on a scheduled air line service. These facilities were of very great assistance during construction of the project.

The actual site selected for the dock was a small bay named Baie du Moulin, part of the larger English River Bay bounded at the north east by St. Pancras Point. (Fig. 1). Although the surrounding country is rugged and rocky, preliminary investigation, later confirmed by geophysical investigation, indicated that a sheet piled dock could be constructed in the bay without having to pin the steel sheet piling to rock and would involve the dredging of an economical amount of the original bay bottom.

Use of some of the heaviest and strongest steel sheet piling ever used in Canada enabled the new dock for C.B.A. at Baie Comeau to be designed, constructed and equipped ready for use in 22 months, which period included the cold winter of 1956-1957. The dock face is believed to be one of the deepest of its type ever constructed in an essentially cohesionless river bottom material without constructing a relieving platform behind the dock.

The maximum tide range in the bay is 15 ft. 0 in.

Requirements for the dock were that two sheltered berths were required initially, each 550 feet long, providing not less than 30 feet of water at low tide, and two future additional berths were desirable though not essential. The two initial berths would be equipped with loading and unloading equipment.

Siting of Dock

The prevailing winds in this area are off-shore but south-east and north-east storms do occur periodically each year, and it was therefore essential that a breakwater be provided, primarily as protection against south-east storms. It can be seen from the general layout (Fig. 1) that only a limited reach of open water would exist from the north east due to the high rock configuration that existed on the north side of the bay as far as St. Pancras Point. Figure 2 shows the layout adopted for the dock, and also indicates that the breakwater enabled a third general cargo berth to be constructed at a small additional cost. The layout provides for a fourth berth on the north side of the jetty by carrying out additional dredging together with construction of an inshore wing wall. If a fifth berth is required, a further slip can be constructed north of the existing one. Such a slip would not, however, be as protected from south-easterly storms. The present slip is well protected by the breakwater; from the western end of the slip, no open reach of water is visible.

In an average year it is anticipated that the shipping season need be closed only from mid-January to the end of March, due to ice conditions at Baie Comeau itself. With specially-designed ships (which are a distinct possibility for St. Lawrence traffic within 10 years) navigation to Baie Comeau would be possible almost all year round providing the Cabot Straits and similar areas were kept open by ice-breakers, and regular air reports on movement of ice were available. For the present, arrangements have been made to store five months supply of incoming raw materials and processed metal, to cover the period when ocean going vessels do not normally enter the St. Lawrence River and to provide a reasonable reserve.

Type of Dock

Ice movement during winter months restricts the use of open type docks on the North Shore. The choice of type of dock wall was therefore limited, and steel sheet piling was selected as being the most economically suitable for the conditions at the dock site. Due to the depth from top of dock to dredged bottom of 54 ft. 3 in. it was necessary to use very heavy piling. By careful selection of filling material behind the dock and using the heaviest section of piling available at the time it was possible to design the dock without a relieving platform. The original section of pile called for was Larssen No. 6 with a section modulus of 78.12 in.^{3} using high-tensile steel with a yield point of 51,520 p.s.i. and a working stress of 30,000 p.s.i. The pile lengths were 80 ft. 0 in. generally, reducing in increments to 48 ft. 0 in. at the south end of the breakwater where the sheet piles act as a cut-off only. The 80 ft. 0 in. length is about the maximum that can be rolled in the heavy section and approaches the maximum that can be handled by ship; in fact very few ships can handle this length in any quantity, which called for careful scheduling of deliveries from the suppliers.

The piles were rolled in England, and it was found impracticable to produce satisfactory piles of the heavy section in high tensile steel, as a large number of cracks developed, principally at the sharp bends, and the piles were very difficult to straighten. The specification was therefore modified and so-called medium tensile steel having a minimum ultimate strength of 73,920 p.s.i., a guaranteed minimum yield of 42,000 p.s.i., and a working stress of 25,000 p.s.i. was used. No particular problem was encountered in rolling this heavy section with this grade of steel.

Hydrographic and Soil Investigation

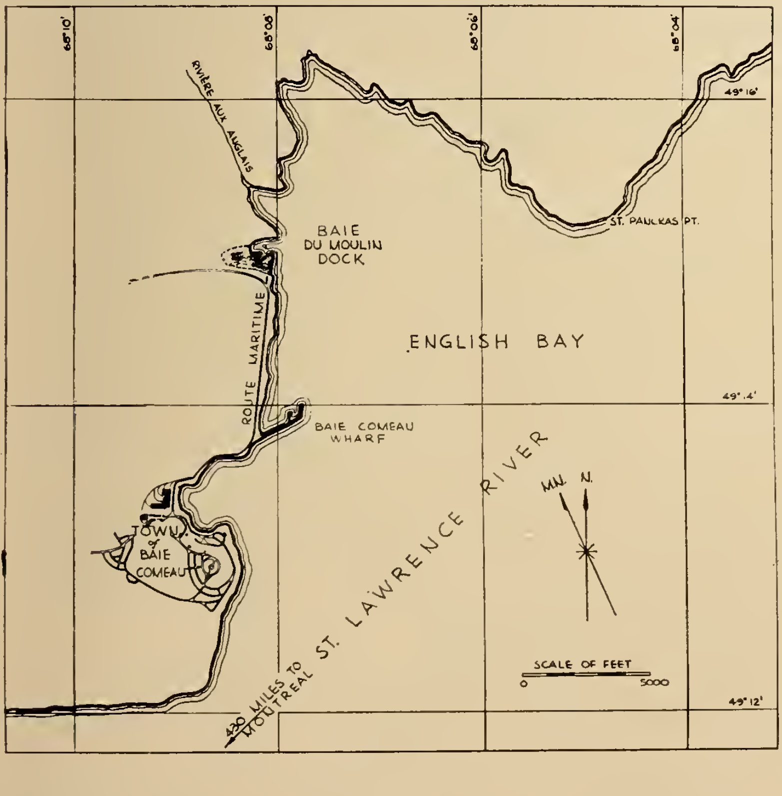
Preliminary soundings of the bay were obtained by the consulting engineers in the fall of 1955 and the underwater soil investigation program was awarded to a specialist company on a unit price and fee basis. In order that the soil investigation could proceed, a preliminary layout of the dock was prepared on the basis of visual site conditions and a pattern of boreholes laid out at the western end where bedrock was likely to be nearest the surface. Information from the first boreholes was passed to the engineer's office immediately it was obtained and the dock layout adjusted so that the necessary penetration of the sheet piles could be obtained at the inshore end. A further pattern of boreholes, penetration tests and wash borings was then laid out along the profile of the proposed dock face and a further series of boreholes and penetration tests in the area to be dredged.

Specifications called for borings to be taken along the dock face to 65 feet below L.W.O.S.T. or to rock (or dense boulder layer) whichever was higher, and in the area to be dredged to a minimum of 45 ft. 0 in. below L.W.O.S.T. Where refusal was encountered at an elevation higher than minus 65 ft. 0 in., the strata was diamond drilled to a depth of 10 ft. 0 in. to establish whether it was bed rock or a layer of boulders. A total of 15 BX size boreholes were put down with accompanying dynamic penetration tests, 8 additional dynamic penetration tests and 7 wash borings.

The underwater investigation was carried out with a machine drill rig mounted on an 80 ft. 0 in. x 30 ft. 0 in. scow. The scow was a little smaller than desirable but was the only size available economically at the time. The borehole locations were determined by normal survey methods using a base line on the south shore of the bay. Particular care was taken in anchoring the scow in position; secure positioning of a floating rig in tidal water is often the most difficult feature of the boring operation. That the late fall of the year is not the best time of year to carry out underwater ground investigation along the North Shore was confirmed, and considerable time was lost due to weather conditions. This is something to be considered carefully in assessing the probable cost of such an investigation. In this case the construction schedule for the dock could not have been met by delaying the investigation until the spring of 1956.

The borehole investigation indicated that the dock site was, in general, covered with loose, dark grey, organic silt underlain by sand varying from loose to very dense, dependent upon location and depth and containing gravel with increasing depth prior to reaching boulder layers or bedrock. As is to be anticipated resistance of penetration tests at individual boreholes varied considerably but in most cases a minimum value of 20 blows per foot was recorded at the dredged level, and if certain penetration tests were representative hard driving for piles could be expected in certain areas. From the results of the borings and other tests it was estimated that the silt had wet and submerged weights of 110 and 48 pounds per cubic foot and an earth pressure coefficient of 0.35 after dissipation of pore pressure induced by the rock infill material placed over the silt following driving of the piles. The sand and gravel was estimated as having an average angle of internal friction of

Fig. 1. Location of dock.



35°, and wet and submerged weights of 125 and 63 pounds per cubic foot respectively.

At the west end of the bay where original bay bottom was highest, the silt layer was 10 to 15 deep. To avoid excessive pressure on the sheet piled wall, it was considered advisable to remove approximately 8 ft. 0 in. depth of the material for a width of at least 15 ft. 0 in. on the inshore side of the sheet piling for the critical area, the area so excavated being filled with quarry rock after the sheet piling was driven. Actual construction timing enabled the silt to be removed by the dredge.

The above information confirmed that a steel sheet piled dock could be constructed and that no rock dredging would be required. Some boulders too large to be disposed of by the suction dredge by normal pumping would be encountered.

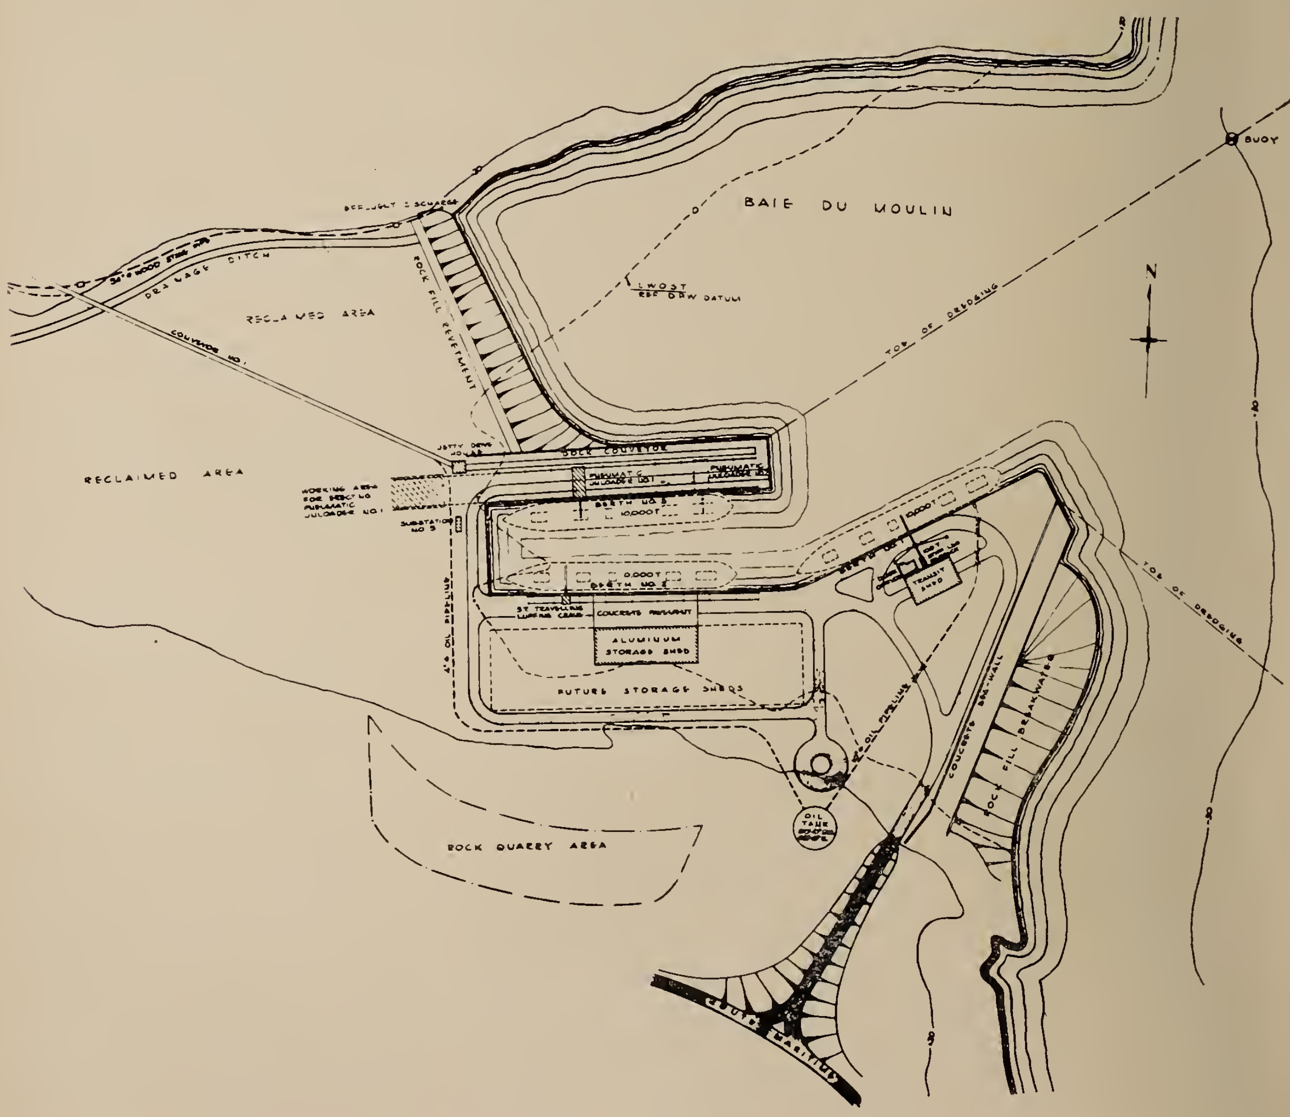
Dock Construction

The decision to build the dock in Baie du Moulin was taken in October, 1955, and all planning was based on handing the dock over for operations by August, 1957. As it would not be practical to complete designs, call for bids and commence construction before the spring thaw of 1956, in order to safeguard material supplies and to avoid delays in starting construction, all main materials including sheet piles, wales, tie rods, and large bolts and washer plates were ordered by the owner against competitive bids, and definite delivery dates established. When the contract was awarded these materials were handed over to the dock contractor.

Main quantities of materials ordered were: steel sheet piling, 7,100 tons; tie rods, couplers, and miscellaneous steel, 1,300 tons.

A typical cross section of the loading dock is shown in Fig. 3. Each of the 80 ft. 0 in. long Larssen No. 6 piles weighs 6.75 kips. Tie rods spaced every fourth pile are 3⅜ in. diameter with ends upset to 4 in. diameter. The individual lengths of tie rods were agreed with the supplier to suit the size of rolling billets available. Hexagonal sleeve nuts were used to connect adjoining lengths of tie rods, these being cheaper than turnbuckles. A small inspection hole was provided at the centre of each sleeve nut to observe that the nut had been tightened sufficiently. The tie rods did not pass through the web of piling, as has been the more common practice over the years, but were secured to the lower wales. This has the disadvantage that the stress from the tie rods has to be transferred via

Fig. 2. Layout of dock.



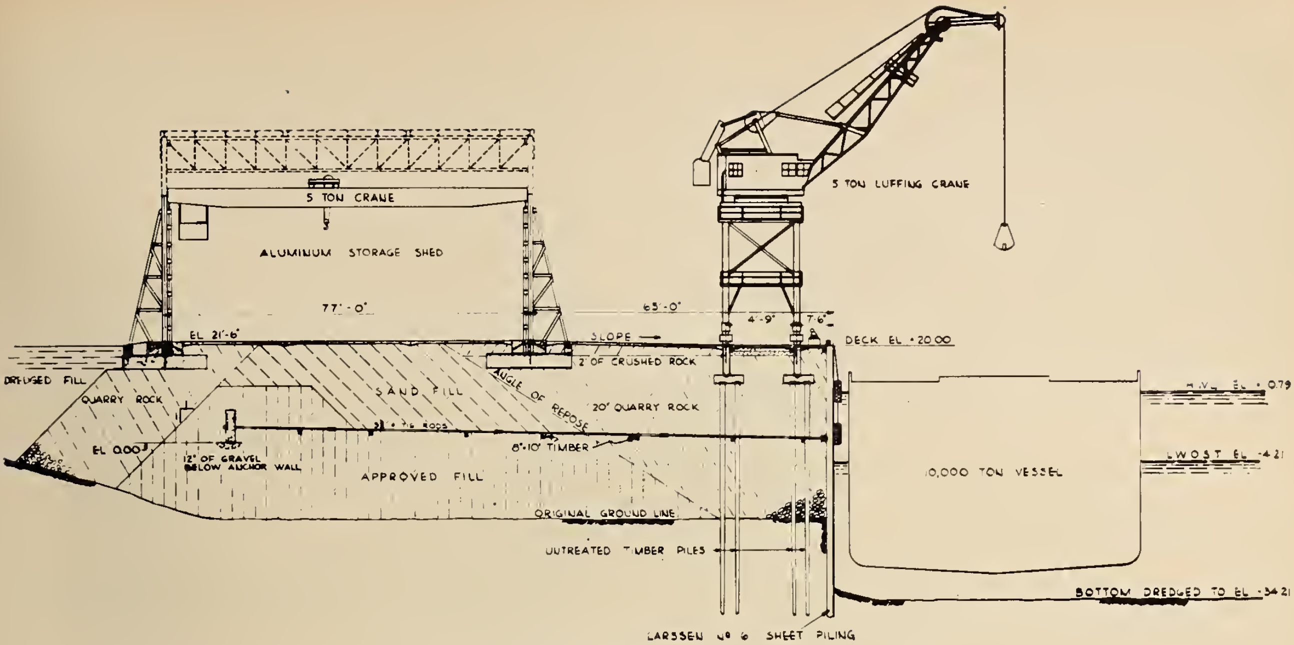


Fig. 3. Typical cross section through loading dock.

the walers to the piling by substantial bolts but it was considered desirable to avoid burning large diameter holes in the medium tensile steel piling. On the credit side placing of tie rods is also simplified; with the system used all work can be done from one face of the piling.

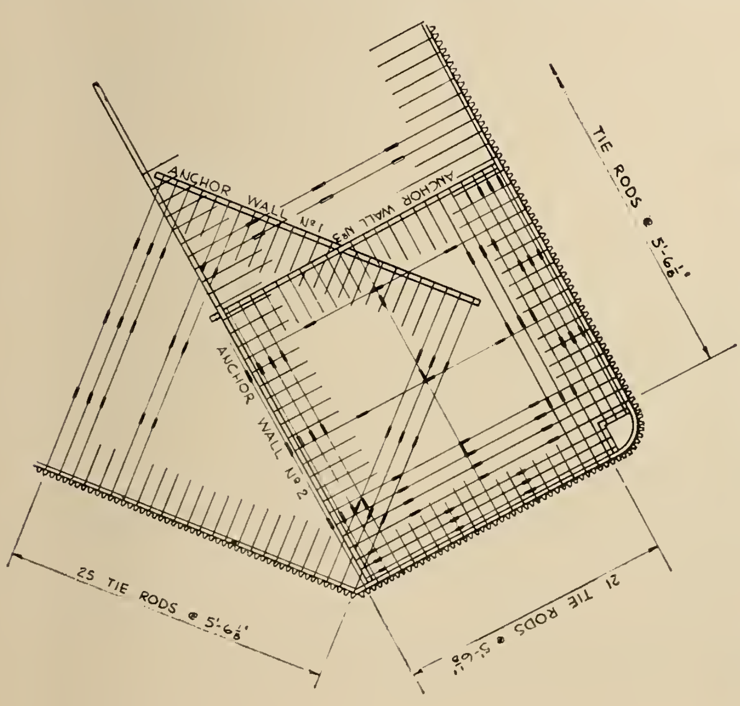
The upper waler in conjunction with the 1 in. thick coping plate stiffens the top of the piling and assists in distributing berthing stresses. The waler is also used in the final lining up of the top of the piling. Where locally the final line of piling is not as straight as it might be, there is a natural construction tendency to run the coping plate straight and to hide "waves" in the piling when viewed on plan. Caution should be exercised in permitting this practice; too much overhang of the coping plate beyond the face of the piling can cause considerable damage to ships.

From the typical section of the dock it can be seen that rock fill is placed so that, other than dock surcharge loads, the only load on the piling above original river bottom is from the broken rock fill. Due to the substantial depth from top of dock to dredged bottom (54 ft. 3 in.), such a procedure was necessary to keep the stress in the sheet piling within acceptable limits. It is believed that this dock is one of the deepest ever built with steel sheet piling driven into an essentially cohesionless material, without a relieving platform behind the dock.

Nose of Breakwater

Considerable thought was given to the shape and details of construction of the nose of the breakwater, and the final solution shown on Fig. 4,

Fig. 4. Left: Arrangement of tie rods at nose of breakwater. Below: Tie rods at nose of dock (before tightening).



though not the ideal shape, was considered to be the most practical. The proposed schedule of construction indicated that this nose would be constructed during a period when storms were quite probable and it was essential to ensure that steel sheet piling, when driven, could be tied back with the minimum of delay. It can be seen that there are three levels of tie rods in certain areas, and the anchorage walls were detailed so that the successive layers of tie rods were higher than previously placed ones.

Fig. 5. Construction of breakwater.

Anchor Walls

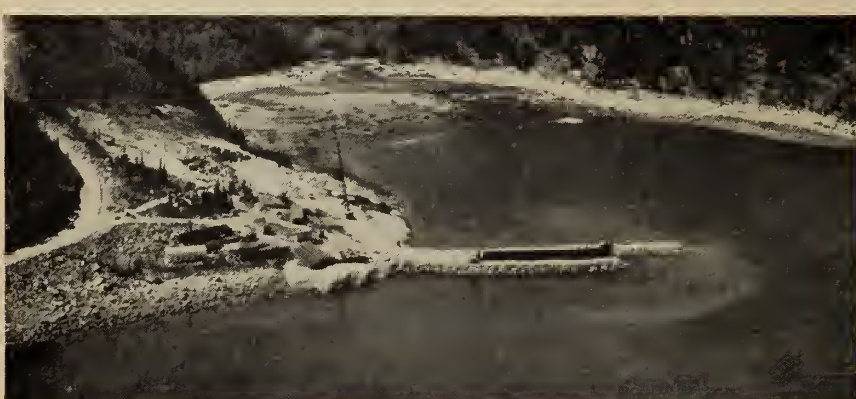
Figure 3 indicates that for berths 1 and 2, tie rods were inclined slightly upward from the face of the dock to place the base of the anchor wall as high as practical, so that concrete work could be done largely in the dry in low water periods. The initial plans and specifications called for the anchor wall to be a continuous *in situ* wall. Towards the late fall of the first year of construction it was found difficult to obtain satisfactory results, due to air and water temperatures, and the contractor was permitted to precast the walls in approximately 11 ft. 0 in. lengths, each precast wall anchoring two tie rods and weighing 23 kips. The size of each wall was determined by the handling capacity of the contractor's cranes and by the tie rod spacing.

Award of Dock Contract

Competitive bids were invited during February 1956 on a unit price basis against an estimated bill of quantities prepared by the engineer. No construction method was specified, and contractors were permitted to adjust the quantities of fill material behind the dock to suit their construction method, subject to the approval of the engineer. Such adjustments were taken into account in summarizing the bids received prior to awarding the contract. One point of interest regarding fill material is that the contract required the contractor to install a weigh scale at the dock and all fill material, by classification, was paid for by the ton. This system worked well, and was fair to both owner and contractor as it is difficult to forecast how much settlement of fill material into the original river bottom will occur. Some loss by tidal action is also inevitable.

The contractor was required to commence construction of the dock at the breakwater and to complete steel sheet piling as far as the northwest corner of the slip by the end of 1956, thus providing two berths, and to complete the entire dock except for surfacing by June 15th, 1957.

Fig. 6. Breakwater construction showing sheet pile cut-off.



Breakwater Construction

Work commenced on site in March, 1956. During the winter of 1955-1956, a road a little less than a mile long had been constructed along the shore to the dock site under separate contract giving direct access from the town of Baie Comeau and from the existing paper company dock.

A quarry for the rock fill was established in the hill immediately south of the dock, and with the contractor's cooperation it was worked in such a way that on completion it provided a reasonably level bottom approximately 8 ft. 0 in. above the top of the dock thus providing useful additional future building space.

Rock dumping for the breakwater began immediately, but no attempt was made to achieve the flat slope on the river side; the profile of the breakwater was adjusted so that the rock was dumped to its natural angle of repose (about 1 in 1 to 1 in 1¼) and the slope allowed to flatten under the action of the waves. (Fig. 5). During quarry operations, the larger stone obtained (3 tons and over) was stockpiled to be used later as armour stone on the breakwater. Due to the folded and fissured nature of the natural rock (mainly granite gneiss) very large armour stone is not obtained by normal blasting methods in any appreciable quantity. To date the size of armour stone obtained has performed satisfactorily. It is, however, anticipated that local wash-out may occur under severe storms, which is the reason the steel sheet piling has been carried as far south along the breakwater as bedrock levels permitted, to act as a cut-off. (Fig. 6).

Dock Construction

When the breakwater reached the point where steel sheet piling commenced, the general construction method adopted, except for the jetty section, was as follows:

(*a*) A rock dumped causeway was constructed inshore of the line of steel sheet piling, except for the south end of the breakwater where the initial causeway was constructed on the river side of the steel sheet piling to provide more protection to free standing piles, top width of causeway except at turning points being about 24 ft. 0 in. at elevation 12 ft. 0 in. It was specified that the toe of this causeway be kept a minimum of 10 ft. 0 in. from the face of the piling line. The quarry run rock contained sufficient fine material that no special surface treatment was required to give a reasonable construction trucking surface. When driving of sheet piling was sufficiently advanced an additional causeway was constructed from shore to the junction of berths 1 and 2 enabling the construction causeway to be advanced west along berth 2 and north-east towards the nose of the dock. (Fig. 7).

Fig. 7. Aerial view of dock construction, October 1956.

Fig. 8. General view illustrating placing of tie rods and fill material.

These causeways formed a work road from which the sheet piles could be pitched and driven. This latter work was done by a 3½ yard Lima 1201 assisted by a Lima 802. The 1201 was fitted with a 105 ft. boom and 30 ft. jib. Piles were pitched generally in panels of 8 or more and guide frames were supported from temporary timber piles. Driving was done using either a McKiernan Terry 10B3 or Vulcan 50C, steam for the hammers being provided by 100 h.p. oil-fired boiler, supplemented where necessary by vertical coal-fired boilers. Driving conditions varied considerably but in general were hard. In many instances resistances of 50 blows per inch and more were obtained. Locally, as might be anticipated in such a bay, obstructions were encountered in the form of boulders. These were, wherever possible, moved or broken by jetting, blasting or other means. In isolated instances it was found to be not economically possible to move these obstructions and, provided a reasonable penetration had been obtained and adjoining piles had full penetration, those refusing on such obstructions were cut off.

Fig. 9. Precast anchor walls in position.

In the appendix to this paper is tabled the relative proportion of time spent in a 35-day period on pitching and driving when driving conditions were very hard. Also given is a breakdown of lost time.

The steel piling did not drive to the exact theoretical dimension. Whilst dimensions of individual piles conformed to rolling tolerances, panels of piles when driven were slightly shorter than the theoretical distance for the number of piles in the panel. For the whole dock the calculated requirement was 2,300 piles whereas 2322 piles were actually driven. The number of tie rods used also increased proportionately.

(*b*) Installation of lower and upper waler systems followed closely behind the driving of steel sheet piles. Holes for the bolts securing the walers to the piling were burned using a guide template and very neat holes obtained. Walers were delivered with a shop coat of paint to give a degree of protection during storage. No additional protection was provided once they were in place. When ordering bolts and washers for securing walers to the piles it is necessary to include for a reasonable allowance for the losses of bolts and washers dropped into the water.

(*c*) Concurrently with construction of item (*a*) an embankment was constructed inshore up to the underside of the anchor wall. Selected approved fill material was used, in this case a mixture of quarry run rock and gravel. It is important to select a material or combination of materials which will stand to a fairly steep slope with the rise and fall of the tide and with a minimum of wash-out, otherwise fill quantities become very large.

(*d*) When a sufficient length of steel sheet pile wall had been driven the adjacent length of rock causeway was excavated to a little below tie rod level, see Fig. 8. The rock material excavated was used to fill the area between the causeway and the sheet piling which had already been tied back, or if construction sequence required it was blended with gravel and used in areas where selected fill material was specified. Precast anchor walls (Fig. 9) were placed concurrently with this operation and timbers placed on the rock fill, packed to correct level ready for tie rods to be placed.

Since the tie rods were located only 4 ft. 0 in. above low water level, all tie rod placing had to be very carefully scheduled with the tides, due allowance being made to cater for neap tide periods when tie rod placing was not feasible.

(*e*) With the tie rods in position, sufficient fill material was placed over the anchor walls to enable the tie rods to be made taut. The remaining area between the anchor wall and the piling was then progressively brought up to grade with the specified fill materal working from the anchor wall towards the dock face.

Permanent Equipment

The following equipment was to be installed.

(*a*) On berth 1, a 120-ton derrick.

(*b*) On berth 2, a 5-ton luffing crane.

(*c*) On berth 3, two pneumatic unloaders for discharging alumina and petroleum coke to a receiving conveyor gallery extending almost the whole length of the jetty and forming part of a conveyor system to transport these materials to storage bins and silos at the smelter site.

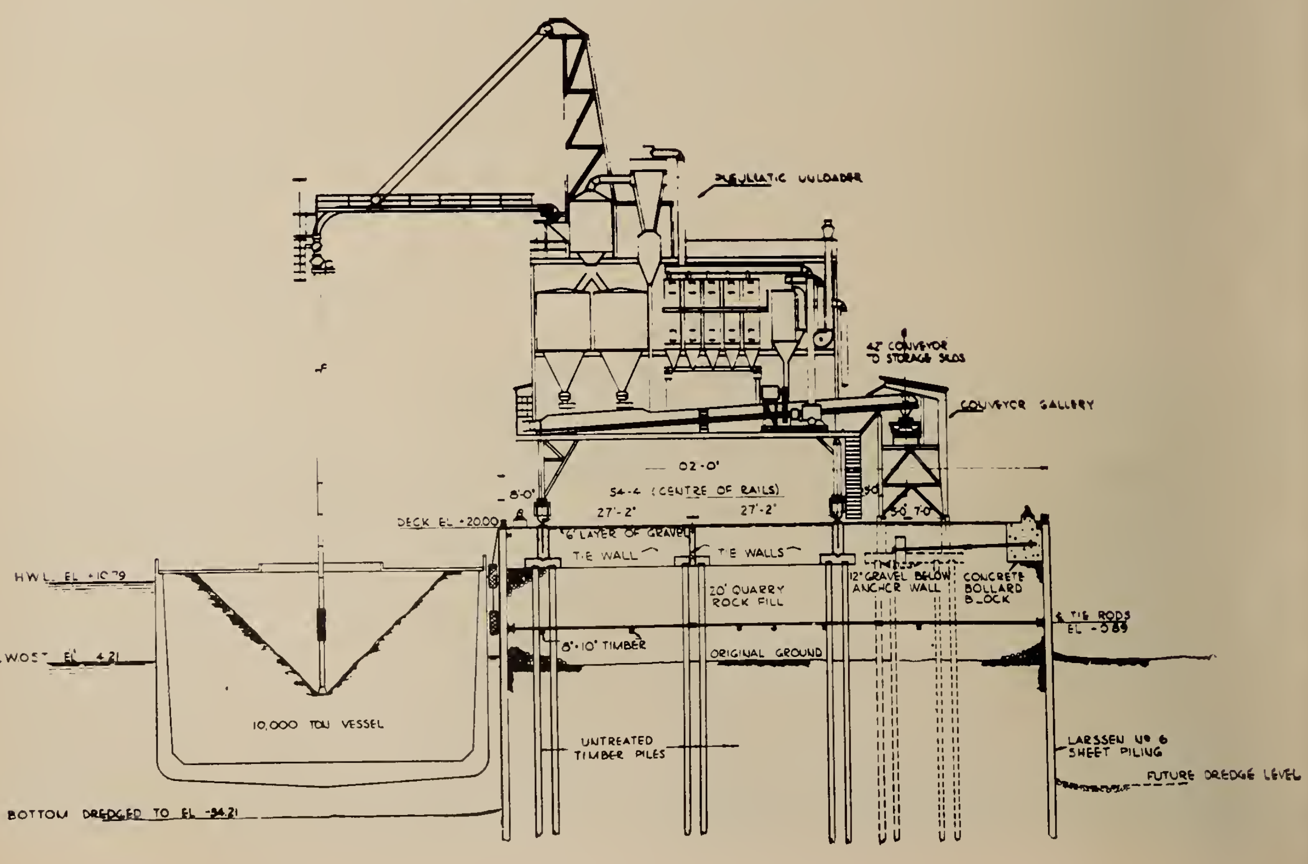
Foundations for the above were all supported on timber piles.

Timber Piling

Concurrently with the driving of steel sheet piling, timber piling for equipment foundations was driven from floating equipment. Timber piles were 60 ft. long, untreated Class "C". Considerable difficulty was encountered in driving these piles to the required penetration and location in the initial stages. It is believed that earlier and more extensive use of correct jetting methods might have simplified this problem. It was essential to obtain full penetration of these piles to distribute as much as possible of the load from piles close to the sheet piling below dredged level.

Both McKiernan Terry No. 7 and 9B3 hammers were used in driving the piles dependent upon the hardness of driving. Jetting in areas where very hard driving was encountered proved beneficial but at one stage presented a problem as some of the hardest driving coincided with a spell of cold weather resulting in freezing up of jetting equipment. In one area good results were obtained with the use of a steam jet. The very hard driving in certain areas is attributed primarily

Fig. 10. Typical cross section of jetty.



to a layer of very dense sandy silt approximately 20 ft. below low water. During the dredging operations in the slip itself when this layer was encountered, it was found impracticable to remove it to final dredged level by suction dredge, and the final dredging had to be completed by dipper dredge. A similar material was encountered locally on the smelter site and it is of interest to note that in its undisturbed state it could not be excavated with a 1½-yard machine equipped with either drag line or back-hoe equipment.

The maximum design load for the timber piles was 25 tons. Actual spacing of piles was selected to be a multiple of the tie rod spacing, and it is very necessary to see that specified driving tolerances are adhered to when timber piles are driven prior to tie rod placing. Otherwise considerable difficulty in placing tie rods is likely to result. The original driving tolerances specified were not more than 3 in. out of place and not more than 3% out of plumb. Due to hard driving and obstructions it was found very difficult to drive to the tolerance and it was later relaxed with the owner's consent, and the timber piles were required to be driven not more than 6 in. off-centre transverse to the line of the dock and not more than 9 in. off-centre parallel to the dock provided, in the latter case, that the longitudinal distance between any consecutive pair of piles did not vary more than 12 inches from the theoretical centres.

As soon as it was practical, i.e., when truck access to the timber piles for the luffing crane was available, a test load was applied to a group of four piles already driven. A loading platform surmounted by a large sand box was constructed symmetrically on the four piles. The sand box was designed to hold 200 tons of sand to be placed in 50-ton increments. The sand was weighed on the construction weigh scale before being placed in the loading box. The average time taken for each 50-ton load increment was 2 hours. The load test was carried out in accordance with the procedure set out in the National Building Code, . Appendix 4.2.c.

The maximum and minimum settlements of the pile group were 1⅜ in. and ¾ in. respectively with full test load applied, and 1⅛ in. and ½ in. respectively residual settlement on removal of the test load. In the jetty construction the majority of piles were driven using the same construction method as used for the steel sheet piling, the remainder were partially driven by floating equipment and finished off by machine as dock construction brought time within reach. The total number of timber piles driven was 850.

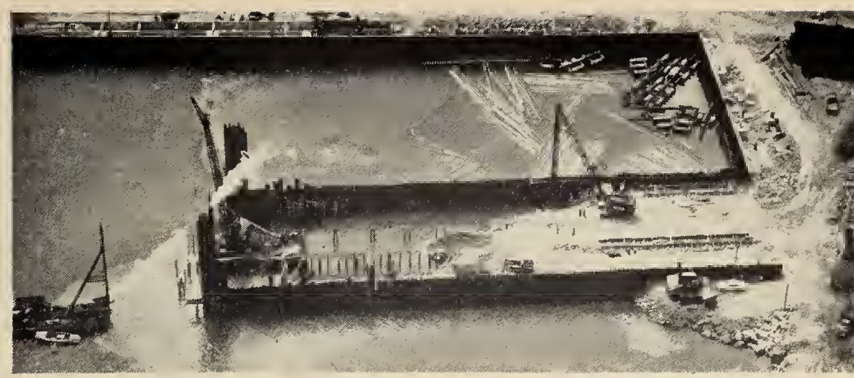


Fig. 11. Aerial view of jetty construction, June 1957.

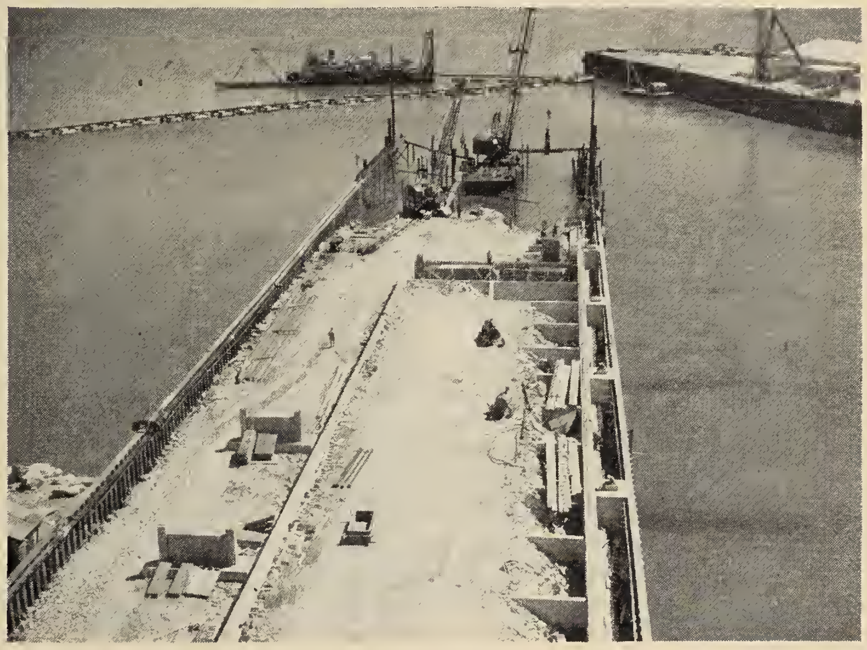

Fig. 12. Jetty construction showing unloading equipment foundations. Dredge working in background.

Construction of Jetty

A typical cross section of the jetty is shown in Fig. 10. Construction commenced at the west end and a truck-dumped rock-fill causeway up to tie rod level was constructed progressively. Timber piles which would be within this causeway were driven ahead of the causeway. A series of cribs were constructed of 12 in. x 12 in. timbers, and these were placed end to end on the causeway. Rock fill was placed up to the level of the rearmost crib which enabled the 1201 Lima machine to "walk" on to the cribs. Top of the cribs was elevation 14 ft. approximately. Sheet piles for the north and south walls were pitched and driven concurrently up to the limit of reach of the crane, and wales and tie rods placed. Thereafter the cribs were leap-frogged forward by the 1201 machine and rock-filled once more to extend outwards to the rearmost crib, (Fig. 11 and 12).

Rock fill behind the cribs was brought up to the level of the underside of the unloader foundations, the unloader foundations concreted, services installed and thereafter the dock area brought up to grade and surfaced initially with crushed gravel.

Construction Schedule

Throughout the construction of the wharf it was very fortunate that no major storms occurred and no part of the dock suffered damage. It is of general interest to note that during construction work on the existing Baie Comeau wharf in 1953, sudden and severe storms coincident with a critical phase of the construction resulted in damage in excess of one million dollars. As mentioned earlier, the most critical section of the C.B.A. dock was the bullnose of the breakwater where of necessity appreciable lengths of piling had to be driven and left free standing for fairly long periods before the piling could be tied back and fill material placed inshore from the piling. The danger of fall storms gave considerable anxiety and the work was pushed as rapidly as possible, including night shift work, with the aim of securing the bullnose section before September 1956. The completion dates called for in the contract proved to be realistic and the piling for berths 1 and 2 was completed in the late fall of 1956 within three days of the scheduled completion date. The first ocean vessel unloaded at berth No. 1 on 29 May 1957.

No dock construction was carried out during the winter but work resumed in the spring and the entire dock contract was completed on 20 September 1957. The first shipment of material was unloaded by the suction unloader at berth No. 3 on 3 October 1957.

The number of men employed on the contract reached a peak of 117 during the summer of 1957.

All concrete was supplied from the ready mix plant established adjoining the smelter site.

In order that the pneumatic unloader would be ready for unloading operations by September 1957 an erection area was provided inshore from the west end of the jetty leaving sufficient access space for the dock contractor. At the erection area, rails were laid on ties, the rails lining up with the permanent unloader rails on the jetty. By the time major erection of the unloader was complete, jetty construction was sufficiently advanced to enable the unloader to be towed on to the permanent rails on the jetty.

The second pneumatic unloader will be erected on the jetty during 1958. The completed dock (Fig. 13) is now in constant use during the shipping season and provides one of the finest harbours along the north shore of the St. Lawrence.

Fig. 13. Dock largely completed.

Fig. 14. Twenty-inch suction dredge and tug at anchor.

Dredging

The dredging was carried out under the supervision of the Department of Public Works. Dredging was carried out to 30 feet below low water using a 20 in. suction dredge (Fig. 14). Dredging commenced in October 1956 and all material dredged during the first year was pumped to partially fill the extreme west end of the bay.

The dredge wintered at the dock site and when dredging re-commenced in the spring of 1957 dock construction was sufficiently advanced to enable the dredged material to be utilized to reclaim the area between the dock and the shore line. This work progressed from east to west, the progress of filling being controlled by strategically placed dykes. The dredged material provided an excellent reclamation.

As mentioned earlier, in certain areas a very dense layer of sandy silt overlying the final dredged depth could not be removed by the suction dredge and this material was dredged by a Department of Public Works dipper dredge (Fig. 15).

As anticipated a substantial number of large boulders were encountered during the dredging. No particular difficulty was experienced in sinking these below the final dredged depth.

Final dredged quantities will be approximately 520,000 cubic yards.

Miscellaneous

Bollards are provided at approximately 75 ft. centre on each berth.

Each bollard is tied back by tie rods to precast anchor walls (or to foundation beams where these are conveniently located) to minimize load transfer to the sheet piling.

Weep holes 3 inches in diameter were provided in the sheet piling at elevation minus 1 ft. 0 in. every 9th pile.

Two ladders were provided on each berth, and one ladder centrally at the west end of the slip and east end of the jetty.

Fenders comprise a double row of used Euclid or similar tires suspended from the coping plate by galvanized wire cable. The spacing of the lower row of tire fenders is three times that of the upper row. At the close of the navigation season these fenders are lifted on to the dock.

Fig. 15. D.P.W. dipper dredge at work.

Ancillary Buildings and Services

A prefabricated transit shed, 60 ft. span 100 ft. long, is located inshore from the 120-ton derrick on berth 1. The harbour masters office makes an extension to this building at its north-west corner. A metal storage gantry, 75 ft. span by 200 ft. long, to carry a 6-ton overhead crane is provided inshore from berth 2. This gantry is designed so that it can be converted into a closed storage later by the addition of roof trusses, purlins, and girts. It is also designed for the addition of a second 75 ft. span bay and can also be extended either east or west or both.

The floor area of the gantry area which is subject to heavy loading comprises a 7 in. slab thickened to 12 in. at expansion joints. Joints are placed at close centres as some differential settlement is anticipated due to the comparatively short time that the fill material has been placed.

Reclaimed dredge fill was not used under this building. Quarry run rock was used up to the underside of the foundations and well compacted gravel fill from this level to grade level. A concrete apron extends from the north column line of this gantry to the face of dock. The luffing crane rails are set flush with top of the concrete, and timber filler pieces are provided on each side of each rail. In the event of substantial differential settlement of the rail tracks, which it is hoped will not occur but might do so, removal of these filler pieces would enable the rails to be packed level. Ample thread projection of the bolts securing the rails to the concrete foundations was provided to permit this to be done. Service water for the dock is brought from the main plant supply after chlorination by a 6 in. wood stave pipe to the west end of the bay where it connects to a 6 in. buried cast iron pipe. Line pressure at the dock is 175 p.s.i., which is adequate for fire protection as well as serving the general dock and ships requirements. Provision is made for draining the line for the winter period when the dock is not operated. Dock office sewage is fed to a septic tank which in turn discharges its overflow into the dock.

A 1,470,000-gallon oil company storage tank located inshore from berth No. 1 is connected to this berth by 10 in. oil line. From this oil tank a 4 in. oil line traverses the dock area and rises to the smelter plant itself enabling oil to be pumped direct from the marine tank to day storage tanks located in the smelter plant.

Electrical

A 1500 kwa. outdoor type substation is located at the west end of the dock and supplies all power and lighting requirements. All feed cables are buried. The substation is fed by the 13.2 kv ring main from the smelter plant the ring main cables being located within the conveyor gallery. All dock equipment operates on 550 volts, 60 cycle.

Dock lighting, which is of a high standard, is supplied by four 80 ft. floodlighting poles supplemented by additional floodlights on the dock equipment.

APPENDIX

Pile driving performance during 35-day period under hard driving conditions

	DAY SHIFT	%	NIGHT SHIFT	%
Number of shifts	35		32	
Total hours	346	100%	371	100%
Pitching of piles (hours)	139	40%	19	5%
Driving piles (hours)	98	28%	168	45%
Lost time (hours)	109	32%	184	50%

Breakdown of Lost Time

	DAY SHIFT	%	NIGHT SHIFT	%
Weather conditions	33	30%	26	14%
Steam supply breakdown	18	16.5%	28	15%
Hammer breakdown	10	9.5%	27	14.5%
Awaiting piles to be pitched	15	14%	3	1.5%
Flood lighting failure			4	2%
Sundry	33	30%	96	52%

When two shifts were worked very little pitching was done by the night shift but the number of piles driven at night was 70% greater than were driven during the day shift.

Rate of Pitching and Driving

During the above period during a typical week working two shifts for pitching and driving, the minimum and maximum rate of piles completely driven were 3 and 17 respectively per shift, the average per shift being 9 piles.

THE MANICOUAGAN Power Company constructed its first stage of development in 1951-52 with the initial two units of 100,000 h.p. Associated with the building of the Canadian British Aluminium Company Limited the powerhouse was further expanded to a total of 250,000 h.p. during 1956-57.

This paper describes the first and second stages of construction. One of the outstanding features of the initial construction was the unwatering of the main damsite without the aid of cofferdam, probably for the first time in history that water has been diverted to leave the bottom almost bare for the foundations of a large dam. The second section of the paper describes the construction of the stage II development.

Initial Development

The initial development consisted of constructing a dam, spillways, powerhouse and associated switching station and transmission line for two units generating a total of 100,000 h.p. The work was started in March 1951 and the first generator was energized on the line in December 1952.

Flow Characteristics of the Manicouagan River

The Manicouagan River is the third largest tribuary of the St. Lawrence River, only surpassed by the Ottawa and Saguenay Rivers. It flows into the St. Lawrence River near its mouth, approximately 250 miles below Quebec City.

Figure 1 shows the location of the Manicouagan River, which drains from 19,000 square miles of the Quebec interior into the St. Lawrence River.

The flow is characteristic of the rivers in the northern part of Canada. During the winter the flow is low, but is followed by a tremendous increase during the spring flood period, amounting quite often, to 50 times the low winter flow (Fig. 2).

A typical hydrograph of the Manicouagan River (for 1947) is shown by Fig. 3. It will be noted that the winter flow is down to 6,000 c.f.s. However, when spring comes, and the accumulated snow-fall begins to melt, this results in a high spring flood which, in 1937, went up to 213,000 c.f.s. which is the normal flow of Niagara Falls. After the spring flood, the summer and fall floods are between 25,000 and 50,000 c.f.s.

Description of Power Development

The Quebec North Shore Paper Company plant at Baie Comeau was built in 1937. At that time, the powerhouse was built at Outardes. However, with the increased production at the mill, additional power was necessary in order to supply a reserve and safeguard the paper company's operations. Also, the company has large timber limits on the Manicouagan River and it was necessary to build a dam to provide a safe holding ground for the pulpwood.

The power expansion scheme on the Manicouagan was studied by the company's engineers since 1946, with H. G. Acres & Company as consultants. A decision was made in May, 1950, to proceed with the power development. After studying approximately 26 layouts, the final scheme selected is shown by Fig. 4. The damsite is approximately 4,630 feet long and, at its highest point where it blocks the main channel, it is 97 feet high. Water is supplied from the intake to the powerhouse by a rock tunnel and the tailrace discharges to the estuary of the Manicouagan River. The head will be approximately 125 feet.

The dam, named after Colonel Robert R. McCormick, owner and publisher of the *Chicago Tribune*, will create a lake about 11 miles long. Colonel McCormick, together with Arthur A. Schmon, president and general manager of the Ontario Paper Company and its subsidiaries, are responsible for initiating and planning the development. For many years, engineers thought it was too expensive to harness the Manicouagan River. Hence, paper companies sought limits on smaller, more manageable streams. Now the Manicouagan has been harnessed for pulpwood operations as well as for the development of power.

The greatest problem presented was to provide for a dry bed for the dam foundations. Unusual risks from flash floods and deep water would be incurred in constructions of cofferdams; the normal procedure. A new scheme of unwatering was developed from an hydraulic model study.

Model Studies

During the studies a decision was made in 1949 to build an hydraulic model, in a scale horizontally of 200 feet to the inch and vertically 50 feet to the inch. This model, some 30 x 60 feet, was built at Baie Comeau.

The contours of the First Falls were such that a great number of layouts of dams and powerhouses were presented. All of these were placed on the model and tried out for low flow and the extreme flood of 320,000 c.f.s. Fig. 5 shows a view of the model. Accurate contours of the Manicouagan River bed and valley were moulded in sand to the proper scale and covered with concrete. This model proved of great value in the design of the dams and powerhouse.

Building of a dam across a large

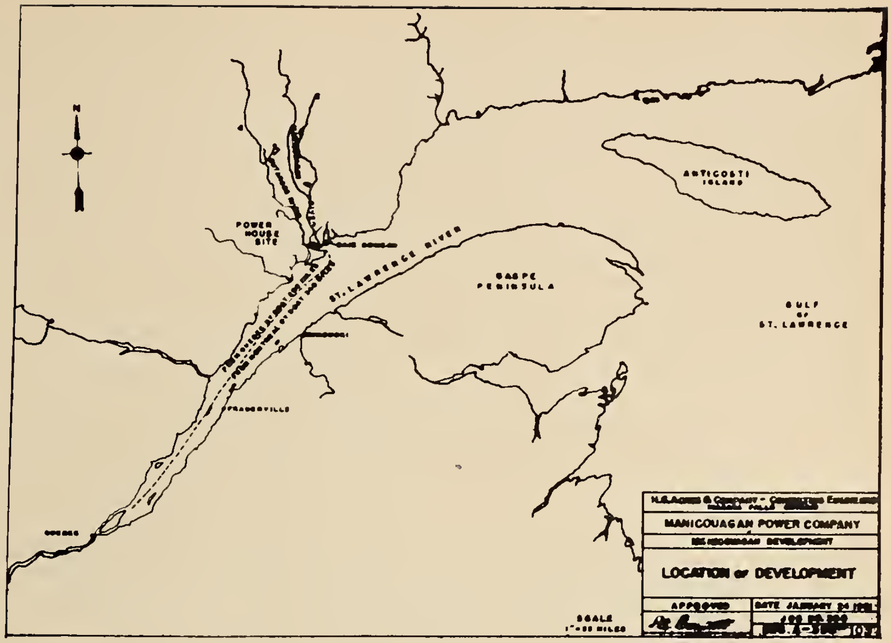

Fig. 1 (above). Location of the Manicouagan River.

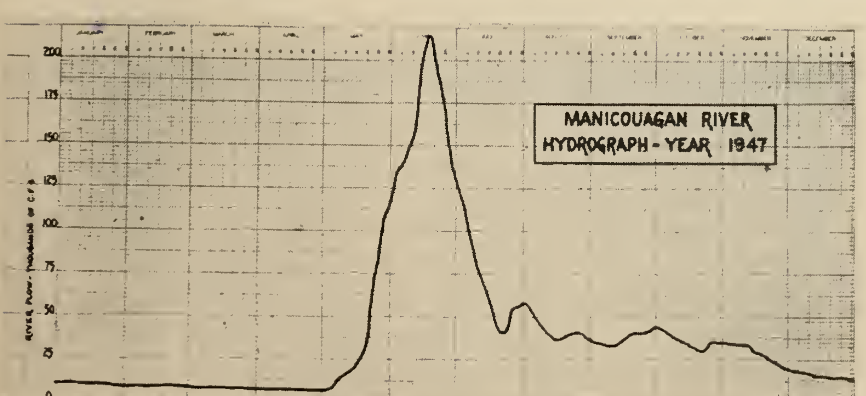
Fig. 3 (bottom). Hydrograph of the Manicouagan River for the year 1947.



river is a difficult construction job. The first plan was to build the dam in the conventional way, in two stages; that is, a cofferdam on one side of the river to build the foundations. This, of course, would have to be carried out during the low flow stage of the river, in the wintertime. Following this, the water would be diverted through the completed section and the opposite side would be cofferdammed and the remaining part of the dam completed. Due to great depths of the river, the cofferdamming would require most of the low flow periods.

In the course of the studies to build the dam three different schemes were investigated:

(a) Cofferdams.

(b) Diversion channel and cofferdams on north side of Schmon Rock.

(c) Dropping 15,000 ton obelisk.

All of these schemes would have required a 2½-year construction program and involved large hazards of high cofferdams and swift water.

While carrying out the model studies, it was also decided to carry out a study on the model of diversion. In the progress of this work, a unique scheme presented itself. If an unwatering tunnel or channel could be built from a deep pool upstream to the estuary, it would drain out the pool above the upstream of the damsite and make bare the dam foundations.

The next problem was the design of the tunnel. Fig. 6 shows the average weekly river flow from October to May. It was decided that if an unwatering tunnel or channel of a capacity of 20,000 c.f.s. was selected, it would give approximately 4½ months to close the main dam.

It was necessary to make accurate soundings of the river bottom. This was very difficult on account of the rapids at the First Falls. Some soundings were obtained through the ice and additional soundings were taken with echo sounders.

Relative to the design of the unwatering tunnel, three schemes were studied:

(a) Rock-cut.
(b) Tunnel.
(c) Combination rock-cut and tunnel.

The lay-out is shown by Fig. 7. The tunnel was excavated by a ramp at the south-end, the rock was taken out, leaving the upstream and downstream plugs. A shaft was made for the closure gates. It will be noted that the floor of the upper end of the tunnel is 70 feet below the water level in the river. This was necessary in order to drop the elevation of the pool to make bare the dam foundations. The upper and lower plugs would then be blasted to divert the river through the unwatering tunnel.

In the fall of 1951 an additional hydraulic model was built by H. G. Acres & Company to study the best design of inlet for the unwatering tunnel. This model was of considerably smaller size than the previous one and built to a larger scale (in this case a true model scale of 1 to 72). The purpose was to develop an intake which would provide no throttling action on the capacity of the tunnel, would be economical and feasible from a construction standpoint, and would provide a sump for the retention of large rock, resulting from the blasting of the plug. It was calculated that all rock smaller than 2 cu. yd. in volume would be swept through the tunnel by the high velocity.

A large number of tests were run on this model and the final design of the intake was based to a large extent on the test results.

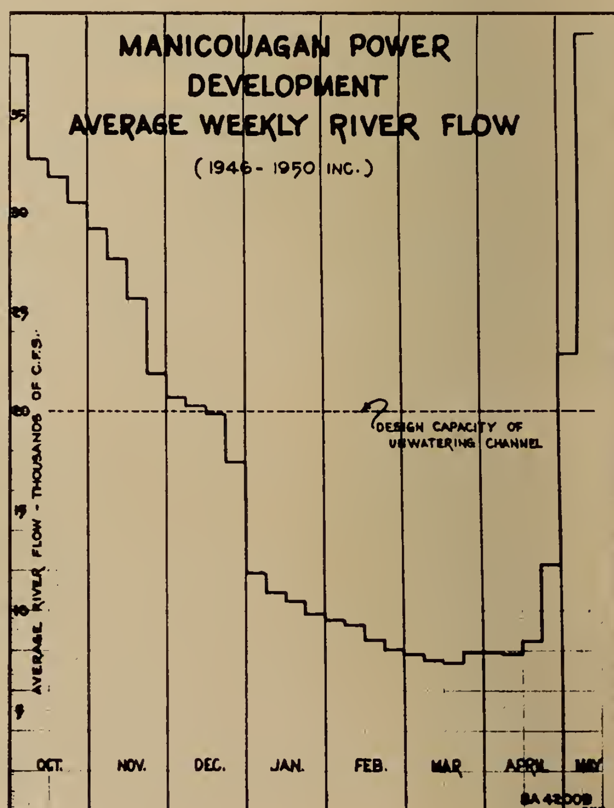
Unwatering Tunnel Construction

The construction of the unwatering tunnel started in April, 1951, and was completed eight months later on

Fig. 4 (above). Manicouagan Power Company—First Falls development.

Fig. 5 (below). Hydraulic model of the project.

Fig. 6 (right). Average weekly river flow (1946-1950 inc.).



December 1st, 1951. The tunnel was ramped down from the south end to grade. Also, a sump was made to receive broken debris from the plug. The diameter of the tunnel was the equivalent of 35 feet as, actually constructed, it was a horse-shoe shape with a flat bottom.

The face was drilled off with a jumbo with approximately 12 ft. steel. This gave an average of 10.5 ft. advance. The average advance was approximately 9 ft. per day.

Fig. 8 shows the tunnel shovel excavating the muck. A standard 1½ yard shovel was used with a short shovel boom. The muck was hauled out with heavy 16-yd. diesel trucks (Fig. 9).

Blasting of the Tunnel Plugs

The blasting of the tunnel plugs was a hazardous operation. Fig. 10 shows the lower plug before blasting. The rock was excavated as close as possible to the river.

The coyotes underneath the river had to be carefully drilled, and an exploratory hole was drilled ahead to make sure that water would not be encountered. Fig. 11 shows this work in progress.

After their completion, the coyote tunnels were loaded with dynamite (Fig. 12). The upper plug contained 7,027 cu. yd. of rock; it was loaded with 36,000 bl. of dynamite or an average of 5.1 lb. per yd. The lower plug contained 2,027 cu. yd. of rock; it was loaded with 8,188 lb. of dynamite or an average of 4 lb. per yd.

Before blasting, very elaborate plans had to be made at the site, in order to have all machinery and people cleared. A system of roadblocks was set up and notices posted. No one was allowed within 2,000 feet of the blast.

On December 3rd, 1951, the lower plug was blasted at 11:00 a.m. (Fig. 13). The highway bridge was covered with drier felt to protect the steel members. An examination showed the blast had cleared all the rock down-grade.

The upper plug was blasted 35 minutes later (Fig. 14). As previously stated, this blast contained 36,000 lb. of dynamite which hurled rock and water 200 feet into the air and splintered 7,000 cu. yd. of granite rock into fragments, leaving a trench that lead to the tunnel entrance. Seconds later, the river was roaring through the tunnel and one hour later the river channel was almost dry. Fig. 15 shows the river rushing through the tunnel, 5 minutes after

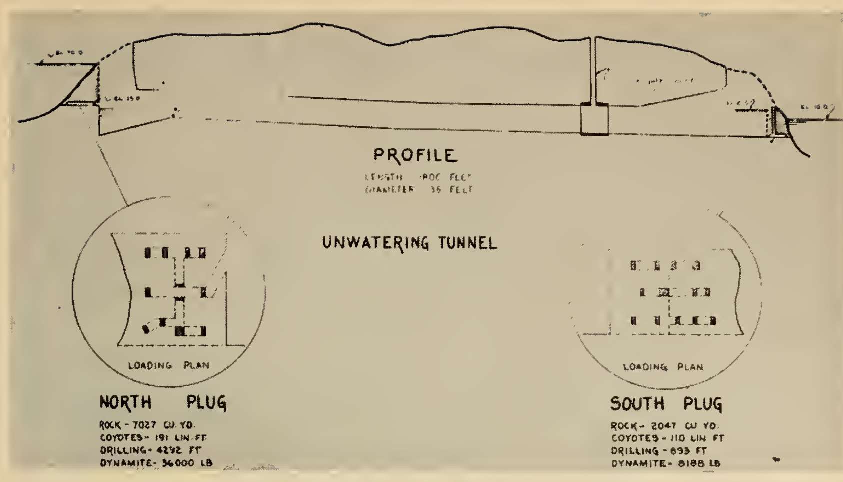


Fig. 7. Lay-out of the design of the unwatering tunnel.

Fig. 8. McCormick Dam. View of tunnel shovel loading truck in unwatering tunnel. June 18, 1951.

Fig. 9. McCormick Dam. View of trucks in unwatering tunnel. June 18, 1951.

the blast. Hence, this blast was unusual, not only as a spectacle in a river diversion, but, probably for the first time in history, this diversion lowered the water level at the damsite some 30 feet to leave the river bottom almost bare for the foundations of the large McCormick Dam.

Fig. 16 shows a comparison after and before the shooting of the plug. It will be noted that after shooting not only was the level diverted, but the water level exposed the dam foundations and allowed the contractor to proceed immediately. Hence, the main dam was completed without the aid of coffer dams.

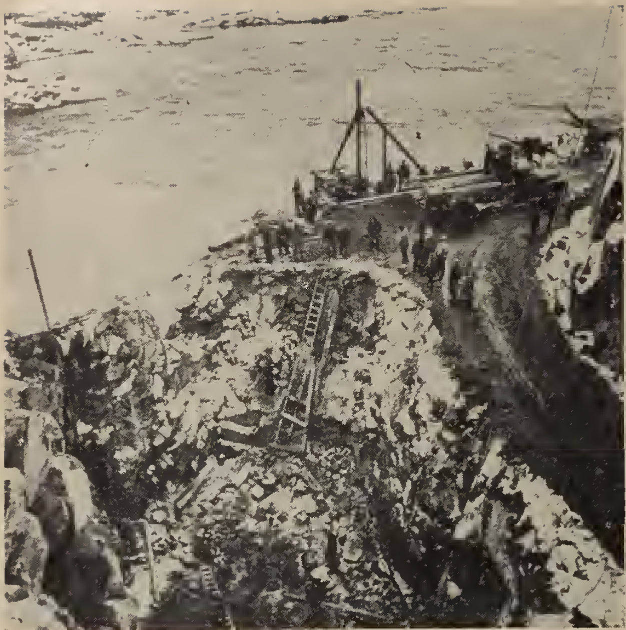

Fig. 10. McCormick Dam. Downstream plug as seen from above lower tunnel portal. December 1, 1951.

CONCLUSIONS

In conclusion, the objective to divert the Manicouagan River and complete the main dam was realized. This diversion has resulted in:—

(1) Cost of the diversion tunnel was less than the conventional cofferdam system.

(2) The diversion tunnel scheme was less hazardous than building cofferdams in fast water.

(3) We were able to cut at least 10 months off the 2½ yr. construction schedule. Hence, the power will be available 10 months in advance of the conventional methods.

McCormick Dam Project No. 2

Late in 1955 a decision was taken to extend the Manicouagan Power Company's McCormick dam plant at Baie Comeau, Quebec, by adding three additional units.

H. G. Acres and Company, consulting engineers, were asked to proceed to develop plans and specifications, and immediate steps were taken to safeguard the position with the manufacturers for the supply of generators and turbines.

Specifications were developed for the new units and "on power" dates for the three units were set as follows: Unit No. 3 - December 1, 1957; Unit No. 4 - February 1, 1958; Unit No. 5 - April 1, 1958.

The completion dates for the three new units at McCormick Dam were established to suit the requirements of the Canadian British Aluminium Company, in order that they could complete their stage one on schedule.

In order to provide a firm block of power, it was necessary to provide storage on the Manicouagan River, and it was decided that this could best be done at Lake Ste. Anne on the Toulnoustook River, a tributary of the Manicouagan. Quebec Hydro undertook to provide this storage and plans were then put in motion to have a storage dam completed at Lake Ste. Anne in time to store at least twenty billion cubic feet of water by the fall of 1957. The total storage capacity of the dam is 126 billion cubic feet and full run-off of the watershed above this dam was to be stored during the spring run-off of 1958 and be available for the winter of 1958-59.

The main purpose of this paper is, therefore, to describe briefly the major steps taken in the construction of the extension known as the McCormick Dam Project No. 2 and to touch briefly on the development of storage at Lake Ste. Anne.

Statistical and Design Data

During the first stage of construction in 1951-52 the main dam and spillway gate sections were constructed, and in addition, a powerhouse to accommodate two units. These generators were rated at 37,-

Fig. 15. McCormick Dam. Manicouagan River flowing through unwatering tunnel, at 11.40 a.m. View of the south portal. December 3, 1951.

Fig. 16. A comparison after and before the shooting of the plug.

Fig. 17. Erecting structural steel in power house.

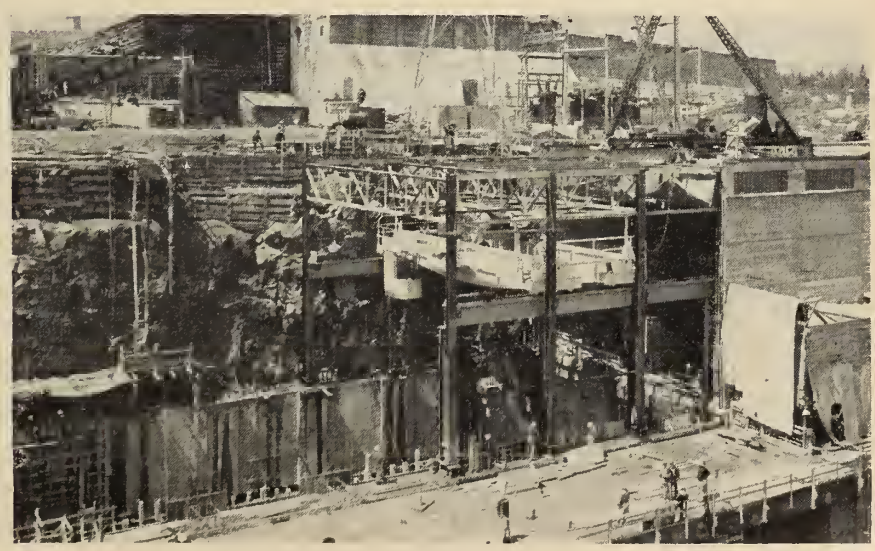

Fig. 18. Tailrace excavation.

500 kva., and it was decided to install 50,000 kva generators for the new development. The turbine rating for the original two units was 56,000 h.p. and the turbine rating for the new units was set at 60,000 h.p.

The headworks was constructed for only two units during the first stage, and a temporary rock-filled timber crib cofferdam, together with a rock-filled gravity section, were left in place for the future construction of the balance of the headworks. This was designed to take a further five units, and it was constructed so as to allow for the building of the new section of the headworks completely in the dry.

It was decided to design the extension to the power house to accommodate only the three units to be installed during stage two, but to carry the excavation of the power house for a further single unit in order to ease the rock excavation problem when it came time to add the final two units.

It was also decided to complete the headworks for the balance of five units rather than put in any temporary timber cribs or rock-filled dams, and therefore stage two includes headworks for five additional units.

The tailrace for the three new units was designed to take the flow (approximately 15,000 c.f.s.) from the three units, and to do this required a rock cut 60 feet in width from the power house to tide water.

Transmission of the power from the new units to the Canadian British Aluminium plant at Baie Comeau was designed as a 161,000-volt line. In order to transmit at this higher

Fig. 21 (below). Bailey bridging across tailrace No. 1.

Fig. 19. Pouring concrete in headblock No. 7.

Fig. 20. Powerhouse excavation and portals to all tunnels.

voltage it was therefore necessary to build a new switching station and to put in step-up transformers to step up from the stage one transmission of 69,000 volts.

The construction schedule followed very closely the pattern of the first stage of construction carried out five years previously; this called for rock excavation to start in the spring of 1956 with the first unit to be "on power" by December 1st, 1957. The time allowed, therefore, from the inception of the work by the general contractor to the time the first unit produced power, was a matter of only eighteen months.

General Construction

The general construction can be divided into four main sections: the rock excavation; the headworks concrete; the power house concrete; and finally the 161 kv transmission line.

The calls for tenders for the general contract work was made in the winter of 1956, and the general contract awarded. Rock excavation was started in April 1956 and substantially completed during the year, and a start was made on the concrete work.

From experience during the first stage of construction, it was realized that to meet the "on power" schedule it would be necessary to carry out winter concreting, and the operations were designed to pour concrete during the first winter.

The tailrace excavation, which comprised the major part of the rock excavation, included the leaving of a rock plug at the downstream end until the second year in order that the powerhouse could be constructed in the dry.

The rock excavation in the powerhouse area, as well as part of the tailrace area, had to be carefully carried out due to the close proximity of the existing powerhouse, switching station, etc. Seismographs were set up in the powerhouse area, and throughout the rock excavation in this area the amplitude of vibration was kept within an allowable figure of twenty-thousandths. Throughout the blasting this figure was never reached, and for the most part the vibrations were not more than 50% of the figure allowed.

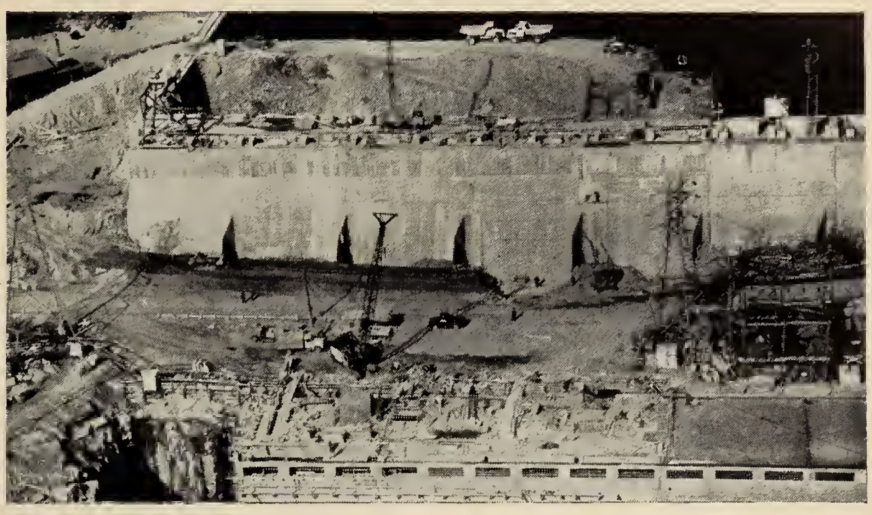

Fig. 22 (top). Powerhouse excavation with rock filled timber crib in the background.

Fig. 23. Headworks and start of timber crib removal.

Fig. 24 (below). Drilling tailrace plug after toe blast.

Stage two construction, being an extension to the present power house, also involved two other unusual features, the first of which was the construction of a bridge across tailrace number one to carry the extension to the 69 kv switching station. This involved a number of difficult operations as it was closely confined on one side by the new tailrace excavation and on the other side by the existing switching station. Also, it was necessary to design for heavy loads in order to take care of the circuit breakers, and erection over the tail-

Fig. 25. Tailrace plug blast.

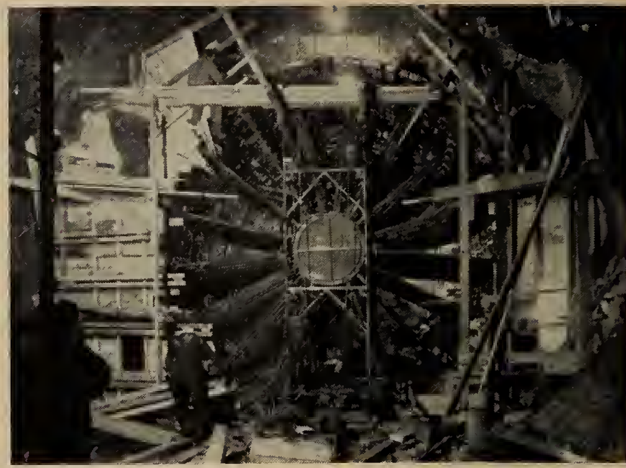

Fig. 26. Circular travelling form in conduit No. 3.

race presented a difficult forming problem. After considerable investigation and consultation, it was decided to use Bailey bridging for falsework and construct a reinforced concrete beam and deck bridge. This worked out very well and the use of the Bailey bridging made it possible to complete the erection of the bridge almost on schedule.

Another difficult problem was the removal of the timber crib which was placed during the first stage of construction as the connection piece between the section of the headworks then built and the rock-filled dam connecting across the future headworks intake area. The removal of the timber crib was studied very carefully by the general contractor and the consulting engineers, and the schedule for the removal was very tight as it had to be out in sufficient time to allow water into the passages of No. 3 unit by 1st December, 1957, and at the same time it could not be removed until all of the headworks construction had been completed.

After discussing various schemes, the contractor decided that it could best be done by using a back hoe and working from the top of the crib, taking it down in stages and in various sections, with the last of the material to be clammed out under water. This program was instituted and the pull shovel method worked remarkably well. The crib was taken out on schedule and the cleanup of the bottom by clam was all that could be desired.

The tailrace plug was a difficult problem due to the fact that rock shelved off gradually into the main river channel and this necessitated considerable amount of drilling and blasting of the toe section under water.

The general contractor originally planned on using the coyote method of excavating the rock plug left in the end of the tailrace, but due to shattering of the rock possibly from the first stage of construction, also due to fissures in the rock, a water problem indicated that the coyote method would be very difficult. It was then decided to go to vertical drilling only and to remove the plug in two stages. The first stage, that is, the underwater section downstream from the plug, worked very well but unfortunately the main plug of rock was badly shattered, with the result that the tailrace was flooded. It was, therefore, necessary to re-drill a great deal of the major part of the plug, and these drill holes were carried down to five feet below the finished grade. A drilling pattern of 6 by 6 was laid out and the total of 96 holes was drilled with an average depth of 40 feet. Millisecond caps with nine delays were used and a powder factor of 3.27 pounds per cubic yard was the actual loading. The results obtained from this plug blast, at the time of the blast, appeared good. However, it was later found that a great deal of the muck, although broken, was not broken up as well as expected and most of it stayed in position. This resulted in a long clamming operation which although successfully completed, was expensive and it took a long time finally to clear the channel.

As mentioned earlier, concreting was carried out throughout the winter of 1956-57 and a very close system of concrete control was put into effect for the whole job. Aggregates obtained from crushing the rock taken from the tailrace and the power house excavations were used, together with the sand for fine aggregate found in the vicinity of the project. This sand was so fine that blending was not required and a very good concrete mix was obtained by using two sizes of coarse aggregate together with the local sand.

Throughout the job the general contractor employed panel forms consisting of plywood sheet on lightweight steel frames, and these were light enough for one man to handle and worked out very well. An unusual type of travelling metal form was used for pouring the horizontal sections of the three water conduits. This form, of English design, worked very satisfactorily, with one form used for all three tunnels.

Transportation of heavy lifts was again a problem, because limits on highway bridges made it impossible to carry the runners, the upper bearing brackets, and the auto-transformers from the wharf at Baie Comeau to the job site. It was, therefore, necessary to charter a shallow-draught motor ship—an L.S.T. of 147 gross tons, which could safely navigate the Manicouagan estuary at high tide. Eight trips were required to carry the three 50-ton runners, the three 40-ton upper bearing brackets, and the two 90-ton auto-transformers. This operation involved unloading at either the Baie Comeau Government wharf or the C.B.A. wharf on to a low-bed trailer already positioned on the barge and transporting the whole load, including the tractor, out into the St. Lawrence and thence up the Manicouagan estuary to one of two landing stages on either side of the

Manicouagan River. The tides and the river flow made this operation rather difficult, and a great deal of time and study were required to carry it out successfully.

Lake Ste. Anne Storage

As mentioned earlier, Quebec Hydro undertook the construction of the Lake Ste. Anne reservoir on the Toulnoustook River to provide sufficient storage to operate the new Manicouagan Power Company units. This storage will hold approximately 126 billion cu. ft., which comprises approximately 18% of the Manicouagan watershed, or an area of 3,160 square miles.

The construction of the reservoir and the storage dam comprises a control section with three upper and three lower gates, with a total discharge capacity of 102,000 c.f.s. The main dam is a rock-filled gravity structure having a total height of 124 feet. The construction of this dam was started in 1956 and the gates were finally closed in late '57. Although it was only expected that 20 b.c.f. would be stored the first year, the storage actually amounted to over 31 b.c.f. before it was started to draw down late in March.

Electrical Installations

The electrical installations include the provision of an entirely new switching station for the 161 kv transmission and the construction of a ten-mile transmission line to Baie Comeau. The present 69 kv switching station was also extended to take in the first step-up in voltage from the generator voltage of 13,800. It was also necessary completely to change the control room and the control board and bench board to accommodate the three new units, and at the same time make provision for the final two generators which may be installed at some future date.

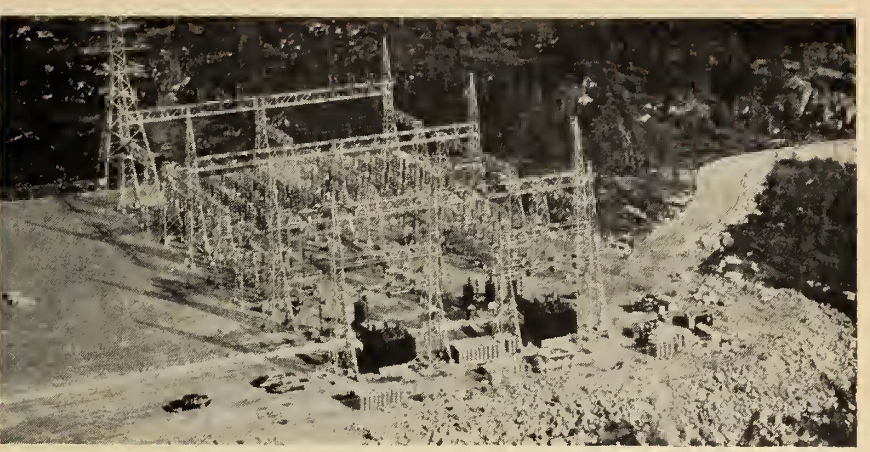

Fig. 27. 161 kv switchyard with 125,000kva auto-transformers in foreground.

Two separate contracts were awarded to carry out this work, one for the transmission line, and the electrical contract, which included all the switching station work as well as the power house and station service installations. It was necessary to supply C.B.A. with a limited amount of power from the present two units, by October, 1957, and the transmission line contract was completed, on schedule, and power transmitted to C.B.A. late in October, 1957. The generators were purchased on an installed basis and these were installed, on schedule, by the suppliers.

CONCLUSIONS

Despite a general strike in the winter of 1957 which caused a five-week delay, the general contractor completed his work on schedule, getting the first generator on the line on December 3rd, 1957. This "on-power" was about two days behind the original schedule, but the five weeks' delay earlier in the year did not materially affect the final on-power date. The other two units, although a few days late in each case, were on the line within reasonable time of scheduled dates and sufficient power was available for the C.B.A. plant as the aluminum pots were brought on the line.

The turbines were installed by the suppliers on time, and although some difficulties were experienced during the installations, necessitating the dismantling of two of the units, these were overcome and the units brought on the line according to schedule.

In concluding, it should be pointed out that not only were the three units brought on power on time, but also the cost has been maintained within the budget allowed.

Fig. 28. Winter view of completed project.

Acknowledgments

It was only possible to carry out this construction with the help and assistance of our own management together with our consulting engineers and our contractors. The following personnel played a big part in assisting those who were entrusted with the actual field work.

Manicouagan Power Company
Arthur A. Schmon, president and general manager; J. E. Vallillee, executive vice-president; M. H. Jones, M.E.I.C., vice president and chief engineer; W. L. Eliason, chief electrical engineer.

Stage I. Charles Miller, M.E.I.C., chief hydraulic engineer and manager of construction; J. P. Sterling, M.E.I.C., resident engineer; V. M. Wallingford, M.E.I.C., asst. resident engineer.

Stage II. J. M. Higgins, manager of construction; G. M. Mikkelborg, resident engineer; A. H. C. Carson, senior field engineer; D. G. Kitson, superintendent of power houses.

The Modernization of Imperial Oil Refinery at Halifax

C. M. Stewart, JR.E.I.C. *Imperial Oil Limited, Sarnia, Ont.*

On October 11, 1956, the completely modernized 42,000 barrel per day Halifax refinery of Imperial Oil Limited was officially opened by the Honourable Henry D. Hicks, Premier of Nova Scotia. Since that date, additional units have been added to this construction program. This article indicates some of the reasons behind rebuilding the refinery and some of the design and construction problems encountered in the execution of this project. The total expenditure on this modernization program amounted to approximately $30,000,000.

This Halifax refinery has been of considerable importance in the economic life of the Maritimes since it was initially established early in 1918. It served as an important supplier of petroleum products during two world wars and through the intervening and subsequent peace time expansion. It was the base for the 'shuttle service' during this past war, where neutral American tankers hauled oil into a number of tanks belonging to the British Petroleum Board; the products were then taken overseas by allied ships. The refinery also fuelled the multitude of convoys and their protective warships that gathered in Halifax Harbour before leaving for overseas.

Following World War II the quality of petroleum products required by new automobile designs increased very rapidly. No sizable additions or modifications were made to the refinery during this period and, as a result, the equipment became outmoded. This made it necessary either to close down the refinery and import all the required products from the Gulf area, using the facilities as a bulk plant, or to replace the existing plant with a much larger, completely modern manufacturing installation. Extensive economic studies were carried out and future Maritime requirements were assessed both with regard to quantity and quality. On the basis of these studies it was decided to modernize and expand Halifax refinery to bring it completely up to date.

Process Facilities

The new process facilities consist of seven main units which are shown in Fig. 1 and 2. The generalities of the flow of raw material and resultant products through the refinery are shown on Fig. 3. The refinery units were designed to operate on Venezuelan crude with Middle East crude as an alternative feed. All crude is brought to the refinery by tanker.

The first unit, a 45,000 b.p.s.d. atmospheric and vacuum unit, essentially splits the crude into gasoline constituents, fuel oil products, and fractions which are further processed in succeeding units.

The catalytic cracking unit breaks the heavier hydro-carbon into lighter, higher octane fractions in the presence of a catalyst which is continuously regenerated to maintain high activity. Gases, gasoline stocks, heating oil, and bunker flux are produced. The cat. cracker is a 15,000 b.p.s.d. Esso Research and Engineering Model IV design, which includes a preheat furnace to maintain unit heat balance.

In the refining of products in the atmospheric and vacuum unit, the cat. cracker, and the powerformer, a considerable amount of gases are produced which entrain high boiling point fractions with them. The light ends recovery unit recovers these potential gasoline stocks which would otherwise be lost to fuel gas. The light ends unit also produces the feed stock, for the 5,000 b.p.s.d. catalytic polymerization unit, which consists of butylenes and propylenes.

The 'cat. poly.' plant in general works in reverse to the cat-cracking unit. Where the cat. cracker breaks heavier fractions down, the cat. poly. plant builds light fractions into heavier hydrocarbons. Polymerization is carried out at elevated temperatures and pressures in the presence of a phosphoric acid catalyst to produce liquid polymer, a constituent of high octane gasoline.

An 800 b.p.s.d liquified petroleum gas plant further processes gases from the cat. poly. plant to produce propane. Also associated with this plant are storage facilities, loading compressors and a tank car rack.

The gasoline octane rating required

Fig. 1 (above). Overall view of the process area, Halifax modernization. Left to right: the A & V unit, model IV cat cracker, light ends recovery unit, catalytic polymerization plant, and L.P.G. unit and powerformer.

by automotive engines is now as high as was required by aeroplanes during this past war. To produce these high quality gasoline stocks a 7,000 b.p.s.d. Powerformer is utilized. This cyclic regeneration unit is charged with relatively low octane natural naphthas. In the presence of a platinum catalyst the molecular structure of the feed is reformed to produce high octane gasolines. This plant incorporates a feed pretreatment hydrofiner to desulphurize the hydrocarbon feed.

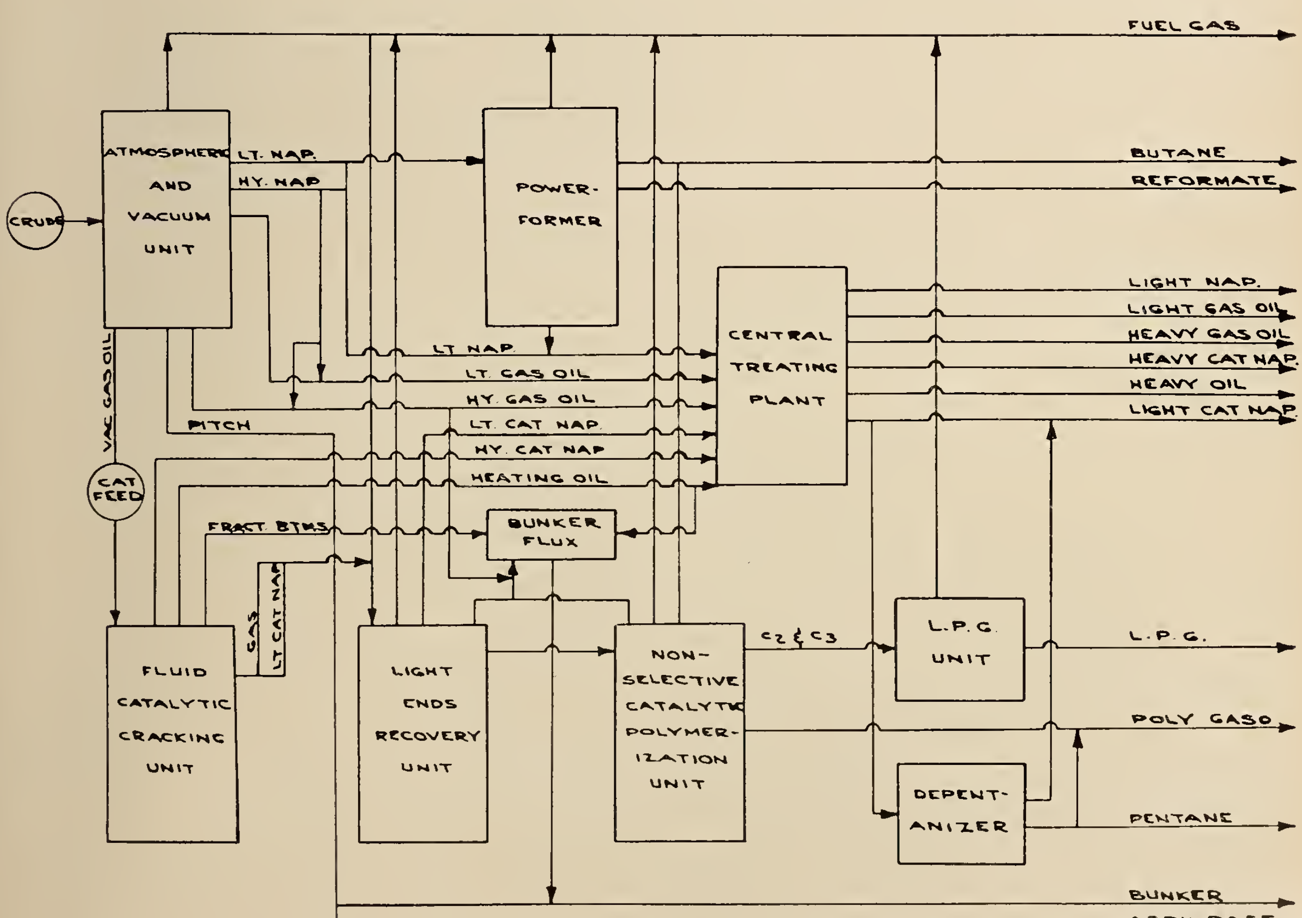
A central treating plant, made up of six treating systems, removes from the raw products constituents which are undesirable in the finished products. Inhibitors are also added at this plant to prevent product deterioration in storage. These plants are shown in Fig. 4.

The process equipment incorporates a number of recent design features. For example, electrical coalescers using a potential field of 45,000 volts d.c. are used in the treating plants to separate emulsions in heating oil streams. Float valve trays having variable capacity orifices were used in the lower section of the absorber demethanizer tower in the light ends unit.

Central control facilities serve the a. and v. unit, cat. cracker, light ends recovery unit, and the cat. poly. plant. Figure 5 shows a section of the graphic panel which uses miniature

Fig. 2. General view of A & V unit and cat cracker with cat poly plant in background.

Fig. 3 (below). Schematic flow diagram of Halifax refinery.



strip charts to outline the process operation. Similar facilities are provided at the Powerformer and a much less elaborate arrangement is included in the treating plant.

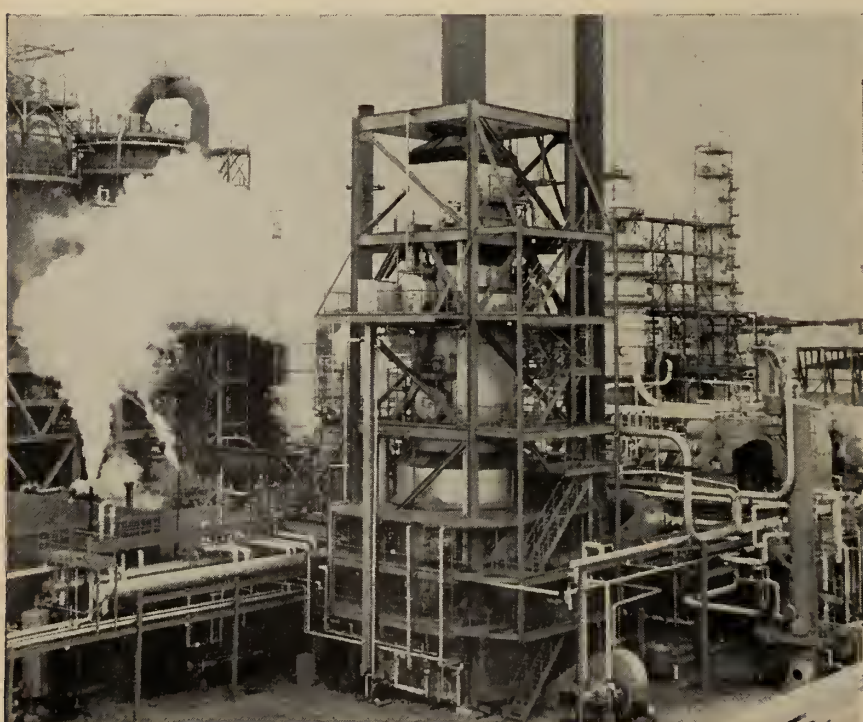
The process units have been designed for operation with minimum manpower. This type of operation makes rapid communications between process personnel on the units essential. To accomplish this, a communication system was installed at each major unit whereby operators in the control building could call personnel on the unit by loud speaker. They in turn could go to a talk-back station and establish telephonic contact directly with the control room. This feature will also greatly assist maintenance work on unit turn-arounds.

A new steam plant was included in the modernization. This plant consists of three 125,000-lb. per hour, 625 p.s.i.g. outdoor boilers. Two of these boilers are of conventional design while the third is a CO boiler. This boiler utilizes 1100°F. gases from the cat. cracker regenerator in addition to standard types of fuels. These gases contain carbon monoxide and other combustibles which result from the burning of coke, formed in the cat. cracking operation, from the catalyst. The CO boiler recovers the heat of combustion and sensible heat from these otherwise waste gases. This results in a substantial fuel saving. The regenerator gases can be diverted to atmosphere through a water seal arrangement permitting boiler firing entirely on auxiliary fuel. This boiler is shown in Fig. 6.

Fig. 4. Central treating plant.

Fig. 5. Section of graphic panel in combined control room.

Fig. 6. 125,000 lb. per hour 625 p.s.i.g. CO boiler with conventional boilers at extreme right and utility building at extreme left.



A utility building houses the control panel for all boilers and their auxiliaries, all pumps, internal chemical treatment facilities, and yard and instrument air compressors. A 3,000 U.S.g.p.m. fire pump which feeds a looped fire protection system is also included.

To supply electrical power to the new plant, Nova Scotia Light and Power Company ran five miles of 69 kv. line on wooden H-form transmission towers. This voltage is stepped down at the refinery to 23 kv. and tied into two other 23 kv. power sources to ensure as reliable a source of power as possible. The voltage is further stepped down to 13 kv. and distributed to the process unit substations at this level, through a ring system. This is the highest distribution voltage used in any of Imperial's refineries. From the substations, power is distributed to the various area users at 4160, 480 and 120 volt levels. In all, eight substations were required for the new distribution system. The ultimate power demand of the refinery is equivalent to a domestic community of 20,000 people.

The layout of new equipment was made with a view to facilitating maintenance. In general, equipment such as pumps, exchangers, furnaces and towers are grouped, with ample clear space left adjacent to these items to permit removal of their component parts for inspection and repair. Process pumps and compressors are located out-of-doors with only the protection of a roof slab which also serves as a pipe rack. An exception to this is the cat. poly. plant where no protection is provided. This simplifies access for maintenance purposes. Equipment groups are separated by roads and access-ways having adequate clearance for mobile equipment.

The addition of future equipment such as pumps and exchangers was taken into account in the design. The main pipe racks have been sized to permit addition of another tier of piping to accommodate future requirements.

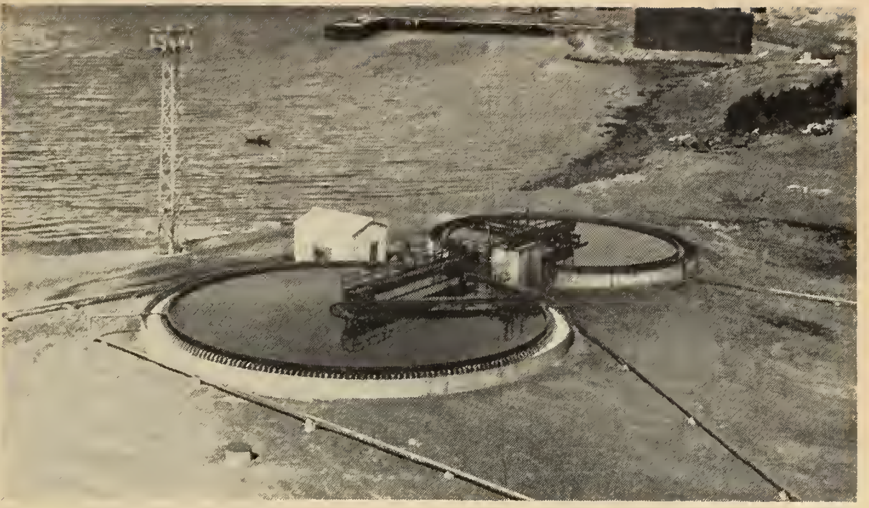


Fig. 7. Refinery separators.

Corrosion

It has been estimated that corrosion annually costs the petroleum industry $300,000,000. To minimize corrosion in the process equipment the following steps were taken in the design of the Halifax units:

(1) Extensive use was made of alloy steels, such as 11-13% chrome in the flash zones of a. & v. unit and cat. cracker fractionating equipment to resist high-temperature sulphur attack and use of 1¼% chrome, ½ molybdenum, in Powerformer furnace tubes and associated piping to prevent high temperature hydrogen attack.

(2) Use was made of refractory linings to a considerable extent, for example, the cat. cracker reactor, regenerator, and associated U-bends, and the Powerformer reactors are lined in this fashion.

(3) Injection of corrosion inhibitors into fractionation tower overhead streams was carried out to minimize deterioration of condenser equipment.

(4) To reduce the corrosive effect of salt water which is the normal cooling medium employed, the channel surfaces of all coolers are neoprene lined and aluminum brass tubes and tube sheets are used.

(5) Box coolers are refractory lined and the internal piping equipped with cathodic protection systems utilizing rectifiers.

It is the practice of Imperial Oil to obtain fixed price bids for the various projects where possible. All the process units and the utilities plant were included in one package and bids were requested from four major contractors, all of whom had previously completed large projects for Imperial.

Very extensive specifications were prepared by the engineering division of Imperial Oil Limited at Sarnia, Ontario, and these were furnished to all bidders. They included:

(i) Complete process design for all units.

(ii) Mechanical design and utilities specifications covering the new facilities.

(iii) Plot plans covering equipment spacing and location.

The contract covering this work was awarded in November 1954. The general contractor carried out all detailed mechanical and utility design within the limitations of Imperial's specifications, preparation of all construction drawings, material procurement and inspection, equipment application and actual construction. The main contract represented 50 per cent of the total construction program.

In addition to this contract, a large number of subsequent contracts were let to cover extensive offsite facilities required to integrate the new process area with the existing refinery. These included two new docks and complete renovation of a third, a salt water pumphouse, two refinery waste water separators, a waste disposal plant, offsite piping, pumping and electrical, extension and centralization of mechanical shops, a technical building, additional tankage, and an automotive garage. The complete engineering for the majority of offsite projects, includ-

Fig. 8. Waste disposal plant showing incinerator with trash destructor in the foreground.

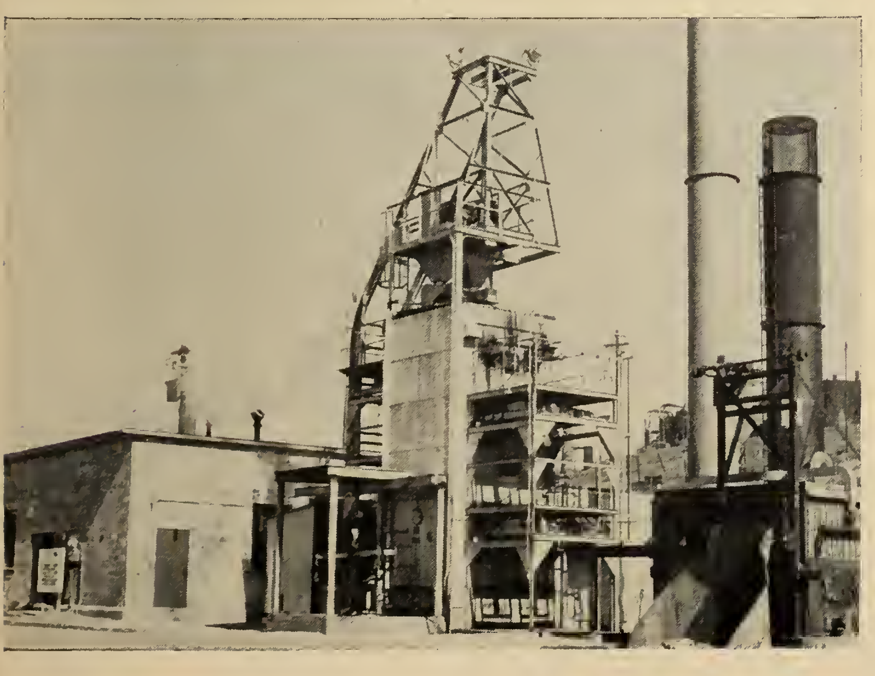

Fig. 9. 175 ft. high elevated flare and ground flare.

ing the preparation of all construction drawings and specifications was provided by Imperial's engineering division at Sarnia. An exception to this was the new docks which were designed by the consulting engineering firm of O. J. McCulloch and Company. To complete all phases of this construction program, nineteen separate contractors were engaged by Imperial Oil. The majority of these were Maritime firms. With the number of contractors working in the refinery, close co-ordination was required to ensure that construction work proceeded smoothly.

A considerable amount of water is required to cool hydrocarbon streams at various phases of the process and to cool products prior to sending them to storage. Salt water is normally used for this purpose. This is supplied by three 15,000 U.S.g.p.m. deep well pumps, of which two normally are in operation. This water flows through a 7-ft. diameter reinforced concrete intake line, laid some 160 ft. into the harbour, into a large concrete basin below the pumphouse. A travelling screen removes foreign objects, and chlorination prevents algae formation. The cooling water distribution lines inside the process area are cement-lined cast iron. The quantity of cooling water circulated is three times as great as the amount of water used by the City of Halifax.

Fresh water is in short supply in the area and is brought some two miles from Morris Lake. This is used for special services such as pump and compressor cooling and desalter operation where salt water would be unsatisfactory.

Halifax refinery is surrounded by residential and commercial developments. To make the plant a good neighbour, equipment was installed to minimize air and harbour pollution. Spent caustic from the treating plant is neutralized and sour water streams deodorized with hot flue gas prior to release to the sewer system. The malodorous materials removed are burned in the CO boiler.

Clean and oil-bearing waste from the new process area is carried through new 48-inch and 30-inch reinforced concrete sewers to two circular separators 75 feet and 60 feet in diameter. These facilities supplement the existing system which handles the remaining portion of the refinery. The separators are equipped with continuous top oil skimming and bottom sludge scraping facilities and are shown in Fig. 7. The efficiency of these separators is very high, with a hydrocarbon effluent content of only 5 to 7 p.p.m.

The sludge and oil removed from the separators are pumped to the waste disposal plant. They are slurried with a two-stage centrifuge system. The oil recovered is pumped back to the process area for re-running. The remaining material is transferred through a screw conveyor and an automatically timed skip hoist to an incinerator where it is burned. A smoke indicator in the incinerator stack automatically commissions secondary burners when the smoke density entering the stack exceeds the desired value. A trash destructor is also included in this plant to dispose of miscellaneous combustibles. This plant is shown in Fig. 8.

To dispose of surplus gases produced during periods of unit upset or when equipment is out of service for maintenance purposes, two flares are provided:

(i) a 24-inch diameter, 175-ft. high, guyed steel elevated flare equipped with a heat-resisting alloy tip which is designed for smokeless operation.

(ii) A refractory-lined steel-shell ground flare, designed to contain the flame inside the surrounding shell. These flares are shown in Fig. 9.

An investigation was made to determine the feasibility of mining underground caverns in the underlying rock strata to store butane, pentane, and liquified petroleum gas. After

Fig. 13. Portion of storehouse facilities in mechanical shop building.

deep core tests had been taken it was decided that it was not practical. The underground strata were too porous and contained minerals which would have adversely affected product quality. Above ground pressure-storage, consisting of three 15,000-barrel butane spheres, a 15,000-barrel pentane hemispheriod, and five 30,000-U.S.g. liquified petroleum gas storage drums, was provided.

In addition to the above, approximately 1.3 million barrels of new tankage capacity was added to store the increased number and volume of products. Five 120 x 48 ft. floating roof tanks were built for crude storage service.

To permit grouping tanks in similar service and to tie new products into storage, loading, and transfer points, an extensive offsite piping and pumping program was required. Over fifty miles of pipe, ranging in size from one inch to thirty inches, was installed on new structural stanchions. Thirty field pumps mounted outside on slabs adjacent to their product source were also installed as part of the program. The majority of these field pumps are remotely controlled at tank car, tank truck, and dock loading facilities. Of particular note is the electronic gasoline blending system. The required blend is set up on a control panel in the Ethyl Building. This sends a pulse to the automatic control valves some one-half mile away to control the flow of each constituent making up the final product.

The existing docking facilities were obsolete and inadequate. These were replaced by two new docks, and a third dock was completely modernized. The new docks are capable of handling some of the largest supertanks afloat. Two 800-ft. supertankers and a T-2 can be handled simultaneously. A supertanker is shown at one of the new docks in Fig. 10.

Each new dock consists of two 40-ft. diameter cells of interlocking sheet steel piling which are filled with rock. The cells are tied together by 14-inch steel H-piles supporting a reinforced concrete deck. Similar piles tie each new dock to mooring dolphins and to shore, serving also to support the pipe racks and precast concrete roadways to each dock. The docks are equipped with spring fendering and rubber bumper block system to cushion impact loads from approaching ships.

Fig. 14. Technical building housing laboratory, personnel, medical, administrative and technical departments.

An additional ten miles of pipe were required to service the new docks. This piping permits crude to be unloaded at a rate of 20,000 barrels per hour and products to be loaded at rates up to 7,500 barrels per hour.

All three docks are equipped with motor driven mooring and hose handling facilities to reduce manual labour required. Hoses are taken from their stowed position inside the hose handling towers and accurately positioned over the ship's connections by hoists associated with these facilities. All hoists are remotely controlled from console panels on the operating deck. A typical hose tower is shown in Fig. 11.

As part of the modernization program, all maintenance crafts were consolidated in a central mechanical shop. Three existing buildings were joined together and considerably extended to provide additional shop space plus lunch, locker, and toilet facilities, and offices for craft foremen and the maintenance engineering group. New equipment, such as travelling cranes, horizontal boring mill, dynamic balancing machine, were added to speed up shop maintenance work. A view of one section of the shops is shown in Fig. 12.

Additional mobile maintenance equipment, such as a 25-ton crane, straddle truck, high lift truck and low boy was purchased to expedite unit turn-around work.

An enlarged storehouse forms part

of the mechanical shops building making materials readily available to the various maintenance crafts. Use is made to a considerable extent of palletization and mechanical equipment. Figure 13 shows a portion of the storehouse, one feature of which is automatic door opening equipment. The truck driver can push a button on the dashboard to initiate a magnetic signal which starts the door opening motor. After the door reaches its fully open position, a timing relay automatically starts to close it after 10-40 seconds. An electric eye guards the entrance to prevent the door closing on any object.

A new L-shaped technical building was included in this project. This was designed by a local firm of architects. One wing houses the laboratory where products manufactured are analyzed to ensure that they meet quality and process specifications. The other wing contains the management and technical offices, and the medical and personnel departments. This building is shown in Fig. 14.

Colour Scheme

A departure was made from the conventional black and aluminum colours which normally characterize refineries. In all, twenty-three different colours were used. The colour scheme of the new process area was selected to give an overall harmonious effect using greens, blues, beiges, yellows, reds, tans and whites. All new tankage was painted chalking white to reduce evaporation losses. The use of colours encourages good housekeeping, which in turn is reflected in fire and accident prevention. The final result is most impressive.

Construction problems arise on all projects. The principal problems faced at Halifax were primarily due to the necessity of building the new facilities on the site of existing refinery equipment which had to continue in operation to meet product commitments. This necessitated detailed planning and close liaison with refinery personnel in making changes and tie-ins to existing equipment.

Labour Force

As construction projects of this size and type are not common in the Maritimes, the local supply of skilled craftsmen was exhausted and some 200 men had to be brought in to the Halifax area from as far away as the Montreal, Toronto, and Winnipeg areas. During the peak period, more than 1,500 men were employed on the overall project with 1,100 concentrated in the main process area.

A large part of the construction was carried out under severe winter conditions. A record snowfall of 142.7 inches affected labour productivity and morale to some extent. Normal winter precautions such as protection of concrete, brickwork, and refractory were followed.

Labour relations on the entire project were, in general, very good. The project safety record was also excellent.

Imperial Oil was represented in the field by a resident engineer and field staff, which at the peak of the construction program consisted of five engineers, two inspectors, and two accounting personnel who closely followed the project in the interest of quality, economy, and speed.

Fig. 15. Erection of the feed splitter tower at the powerformer.

Use was made of x-rays, gamma rays, dye check and trepans to check welding quality. All trays, piping, electrical work, furnaces, boilers and vessels were subjected to very rigid field tests.

All major vessels which could not be shipped by rail were field fabricated. Special attention was paid to field welding techniques. Hoisting operations were co-ordinated very closely with the local weather bureau to minimize difficulties due to sudden storms which are prevalent in the area.

In the main, all piping both alloy and carbon steel was shop fabricated. This expedited pipe installation and minimized field required. Prefabrication of concrete sewer and electrical manholes was also carried out.

To clear the site for the new units, nine tanks had to be floated to a new location in improvised dikes. Following this, field construction in the main process area started from grass roots in April, 1955. Within seventeen months all major units, except the Powerformer, which was added at a later date, were in operation at or above design capacity. This was a major achievement in refinery construction.

The Television Backbone of Canada

Transcontinental television network officially opened by the Canadian Broadcasting Corporation, 1 July 1958

"A MARI USQUE AD MARE", Canada's motto, meaning "from sea even unto sea", was given a new dimension in the field of communications and Canada's unity, on 1st July when the Canadian Broadcasting Corporation officially opened a backbone transcontinental television network with an hour-long Dominion Day production that featured "live" pick-ups from many parts of the network.

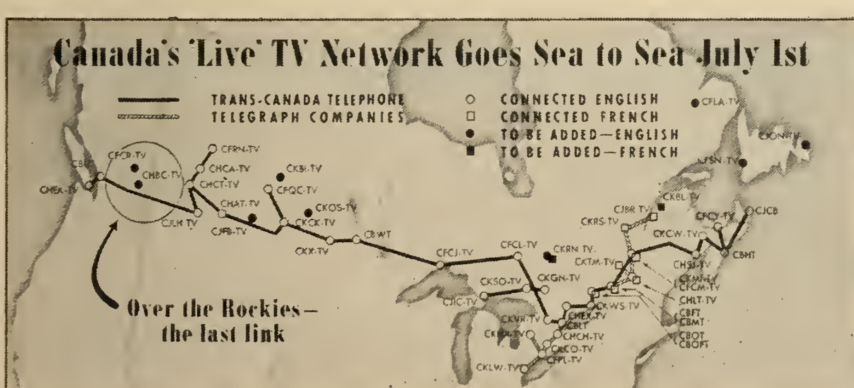
Fittingly, the television broadcast over the world's longest, publicly-owned microwave system marked the 91st anniversary of Confederation. This historical achievement has united 3,900 miles of Canada, enabling "live" television to be seen simultaneously in 3,000,000 TV homes.

Built at a cost approaching $50,000,000, the microwave project was a major engineering and construction undertaking that involved pioneering in a real sense. Pushing the chain of microwave towers across Canada meant struggling through some of the roughest terrain and the severest weather this country can offer.

The astounding engineering and construction problems behind this network, however, do not match the vital impact on Canadian life that will now occur with the CBC's use of this "sea to sea" backbone television "skyway" that links Sydney, Nova Scotia, with Victoria, British Columbia. For the first time, some 80 per cent of Canada's population can see national and special events on a simultaneous basis. This is not the final goal. A "link" is at present being constructed by the railway companies to extend the network from Sydney, N.S., to St. John's, Newfoundland.

The July 1st CBC telecast demonstrated how the CBC's network television service, linking both the CBC and private stations across the country, will now be able to knit the people of Canada more closely together. "A unique vehicle for telling the story of Canada, both past and contemporary, the CBC's television service will now become—even more than previously—the eyes of Canadians upon their nation", is the comment of J. A. Ouimet, M.E.I.C., CBC General Manager.

The sociological and economic changes that will take place in Canada with the full operation of the television skyway will provide a source of entertainment and give new scope to the talents and imagination of all Canadians. Simultaneous live television can now be brought into almost every Canadian TV home. Important national and local events covering every field of activity will be seen instantaneously across the entire breadth of Canada. Viewers who saw the March 31st federal election coverage this year numbered 5,600,000 and made up the largest audience thus far for a CBC television production. About 5,500,000 Canadians watched Queen Elizabeth give her address to the nation last October, and last fall's Grey Cup game drew an audience of 4,850,000.



There are 50 licensed television stations in Canada. Eight are CBC stations, two French and six English. Forty are privately owned. In addition, there are stations at Goose Bay and Harmon Field, Nfld., operated by U.S. Air Force personnel for servicemen and civilians in these areas. The stations are, however, under CBC management.

Video Tape Relay Centre at Calgary

July the first also marked "opening day" for the CBC's video tape relay centre at Calgary.

Canada's six time zones from Newfoundland to the Pacific (compared with just one in the United Kingdom and only four in the United States) make many problems for the CBC in scheduling programs for the full network.

For example, a program produced in Toronto at 8 p.m. Eastern time appears in the Maritimes' Atlantic time zone at 9 p.m. In Vancouver it is only 5 p.m. Pacific time, and a good percentage of viewers are still travelling home from work. Thus, the scheduling of such programs so that they appear at a convenient local time across the country, is an exacting job.

In the past, TV stations west of Winnipeg have been served by kine-recordings (television film) which might be delayed one, two, or three weeks by recording and distribution processes. The video tape relay centre in Calgary will now shorten the delay to a matter of an hour or so for most western stations. Thus network programs will be seen the same day at times more convenient to local viewers.

The CBC operates the relay centre, leasing space and distribution facilities. At the centre, live television signals are received over the microwave network and fed to six Ampex VR-1000 video tape recording machines. These machines capture both picture and sound on a reel of magnetic tape two inches wide. The tape is then rewound and the program played back from the recorder to two control booths where audio and video is monitored for quality. From these booths the program is transmitted at suitable local times, once for the connected prairie stations except Winnipeg, and again for Lethbridge and the connected British Columbia stations.

The VR-1000 greatly reduces the use of kinerecordings for television delays. Tape requires no processing, as does kinerecording, and can be re-used many times. One hour of programming can be recorded on a standard 4,800-foot reel of video tape.

The relay centre handles an average of seven hours of programming

The 350-ft. microwave tower at Olive, 40 miles north of North Bay, Ont. Largest in the Trans-Canada Telephone System's coast-to-coast microwave network, the Olive tower weighs 120 tons and contains the largest steel angle sections ever rolled. The huge antennae, each weighing 1,700 pounds, simultaneously transmit scores of telephone messages as well as CBC television programs.

daily and uses an estimated 663 miles of video tape per month.

On the VR-1000, the picture is recorded instantaneously on the tape by a high-speed rotating disc, containing magnetic recording heads, turning at 14,400 revolutions per minute while the tape passes at 15 inches per second. Sound is recorded and reproduced along the upper edge of the tape. Along the lower edge, a control track is recorded, to serve a purpose similar to that of the sprocket holes on a movie film. During the playback this track keeps the tape motion in step with the rotating head assembly.

Video tape is the latest development in television recording technique, providing high quality almost identical to the live program and ease of operation.

The microwave facilities are owned, operated, and maintained by the communication companies across Canada. The CBC rents the network to transmit its programs. Calgary was chosen by the CBC for the relay centre as this location requires a minimum of network facilities to provide efficient and economical relay service in the west.

CONSTRUCTION

Three major communication organizations have contributed to the provision of this coast to coast television network; namely, the Trans-Canada Telephone System, the Canadian National Railways and the Canadian Pacific Railway. The Trans-Canada Telephone System, which has built the major portion of the network, consists of seven member companies: The British Columbia Telephone Company, the Alberta Government Telephones, Saskatchewan Government Telephones, the Manitoba Telephone System, the Bell Telephone Company of Canada, The New Brunswick Telephone Company and the Maritime Telegraph and Telephone Company.

This major portion of the over-all network provided by the Trans-Canada Telephone System consists of the backbone structure from Sydney, N.S. to Victoria, B.C. and includes branch lines to Edmonton, Lethbridge, Saskatoon and Sault St. Marie. The railway companies provided a branch section between Toronto and Windsor and a section paralleling the Trans-Canada System between Montreal, Quebec, and Rimouski, the latter for transmission of French-language TV. Also the extension to St. John's, Newfoundland, mentioned earlier.

The Trans-Canada Telephone System's "skyway" comprises 139 relay stations on the backbone network and over 30 more relay points on the spur lines that add several hundred additional miles to the 3900 miles from the Atlantic to the Pacific.

Decision to build a microwave system to handle the ever-increasing number of long distance calls had already been taken when the CBC called for tenders for the provision of network television facilities to join Toronto-Ottawa-Montreal by 1953. The Bell Telephone Company of Canada was awarded the contract and, in May 1953, the link went into service—carrying telephone calls as well as television programs. A connection to Buffalo to connect with U.S. television networks had been placed in operation shortly before.

Further contracts to the Bell Company (acting on behalf of the Trans-Canada Telephone System) followed, and the huge task of spanning almost 4,000 miles of the Canadian landscape rapidly got under way. In the summer of 1954, a 180-mile link to Quebec City was opened by the railways and on 30 September 1956 the 1,200-mile Toronto-Winnipeg section was inaugurated by the Trans-Canada System.

The Saint John-Moncton-Halifax-Sydney section went into service in December, 1956; the Winnipeg-Regina section in April, 1957; the Regina-Calgary section and the Edmonton-Calgary-Lethbridge section in November, 1957. The Maritimes were linked with the main network on 2 February 1958, when the Quebec City-Saint John section and the link to Charlottetown came into operation. The Calgary-Vancouver section went into service on 1 July, marking the completion of the microwave network "from sea to sea."

Small Army Required

Establishing Canada's only transcontinental microwave system required the co-operative efforts of a small army of telephone and construction people, with the Northern Electric Company manufacturing and installing the complex electronic equipment.

After picking out a tentative route from topographical maps, engineers path-tested the transmission between adjacent tentative sites. This was done by mounting small antennae on temporary aluminum test towers that could be erected to a height of 200 feet in a matter of hours. The testing might indicate that the site was unsatisfactory because of reflection or because the path was blocked by a hill or other obstacle. They also indicated the height of tower required —usually between 50 and 200 feet, though there is a 350-foot tower at one site near Olive in Northern Ontario.

Then bids were called from contractors for the foundation and tower erection work. Roads were built—usually short—but in one B.C. site 12 miles long; sites were cleared of trees—as much as six acres in some locations—to act as a fire-break; power was brought in and other facilities provided.

The towers are galvanized steel structures anchored to four concrete footings containing a total of 170 cubic yards of concrete. Weighing as much as 120 tons, the towers are so strong that even in a 100-mile an hour hurricane they will not be deflected more than half a degree.

To build mountain-top relay stations for the Trans-Canada Telephone System's microwave network to the West Coast, roads had to be cut through mountains, even above cloud level (upper left). At Hedley, B.C., a mountain top was blasted away to form a site (lower left). So high are many of the sites that buildings are often buried in snow (upper right). Access roads could not be built at two sites, so aerial tramways were constructed. The Dog Mountain tramway (lower right) is one of the biggest in the world—more than two miles—with a lift of 4,400 ft.

Problems

Winter and summer, in snow and mud, on mountain-tops and in forest, by truck and snowmobile and aerial tramway and even helicopter, the work went on unremittingly in order to meet the 1 July date for transcontinental television and telephone service over the new "skyway".

At Dog Mountain, near Hope, B.C., a massive steel microwave tower had to be erected on a 4,840-foot mountain peak. First, men and equipment were flown in by helicopter to test the transmission. Then, permanent means of access was required. A road was impracticable, so an aerial tramway 11,800 feet long with a lift of 4,400 feet had to be built. All through the winter construction men struggled in bitter cold, fog and snow. Food supplies came in by helicopter. Often buildings were literally buried in snow. Finally the tramway, one of the world's biggest, was ready. Now the heavy equipment could be lifted in and soon another microwave tower rose to the sky.

A second, shorter, tramway was required at Crow's Nest Pass in Alberta.

The mountains presented plenty of other problems. At Hedley, B.C., the rocky peak measures only 65 by 75 feet, with precipitous drops on every side. Here rock was blasted to level the site, and the foundation of the equipment building had to be extended 13½ feet down the edge of the cliff.

At Creston, B.C., the two-mile access road has a 20 per cent grade and 33 switchback turns. At another site a 12-mile access road had to be built. Ten of the 13 sites in British Columbia are on mountain ridges, the highest 7,000 feet above sea-level. And always in the mountains the workers had to keep a wary eye out for bears and rattlesnakes.

But each area of the vast country had its particular difficulties. In the prairies the deep gumbo soil offers poor anchorage for the 100-ton towers and footings have to be extra large and of unusual designs to provide the needed rigidity.

In Northern Ontario there is a forbidding mixture of forest, brush, muskeg, swamp, and rocky hills. Forest fires are a hazard so at least six acres of land was cleared around each site; Indian workers were hired to do the job.

There was pioneering, too, in other aspects of the $50,000,000 project. Design of the network was a major engineering accomplishment with many "firsts" for Canada. For example, a method of "stacking" both a television program and scores of telephone circuits on the same channel was implemented in the Trans-Canada microwave system for the first time anywhere, with resulting economies because fewer channels and less equipment were required.

In manufacturing, production equipment had to be designed and installed to make the delicate electronic equipment in quantity.

Railway Contribution

The railway contribution presented construction problems in Quebec's northern bush when Canadian National and Canadian Pacific Communications were adding a link to the French television network and a line to Jonquière, Que., on the same network.

But in spite of tight schedules and natural obstacles the line was built right on time. So tight was the timing, in fact, that the system was extended to Jonquière on the very day the network was scheduled to go into operation. It pushed the railway-operated CBC French network from Montreal through Quebec, Three Rivers, Sherbrooke, Jonquière, and Rimouski.

Engineers had other problems too. One incident involved the purchase of land for an access road to a microwave station site. All 3000 feet of the road was in the hands of 19 owners and involved the use of maps dating back to the early 1700's.

Typical of the speed and precision involved in building such lines was the way in which engineers constructed the CNT-CPC network, in Southwestern Ontario, one of the earlier completed lines in Canada.

The line was first installed with temporary and mobile equipment so network transmission could begin immediately. Construction men then doubled back and built a permanent network while service continued uninterrupted.

But it is in Newfoundland, where construction of the final link in Canada's trans-continental TV network is beginning, that Canadian National Telegraphs faces its most formidable problems.

At Cape North, on the tip of Cape Breton Island, for instance, CNT must construct a station with a 200-foot tower located 1400 feet above sea level to carry television signals in a line of sight 69 miles across Cabot Strait to Red Rocks, Newfoundland. At Red Rocks the tower will also reach 200 feet and the site is 650 feet above sea level. It is the longest cross-water path in the country.

The two towers will each support two sets of antennas, spaced vertically apart so that if the signal decreases or increases on one set of antennas the opposite effect will be obtained on the other set.

Special devices will combine these two signals to produce a constant signal and thus overcome the fading which is characteristic of long over-water paths. This technique is known as diversity reception.

Each station will receive a signal of about a millionth of a watt and retransmit the signal at five watts. This is from five to ten times greater than the power normally used in equipment of this type and will result in greater reliability of service.

OPERATION

The type of microwave radio relay system provided by the Trans-Canada Telephone System is known as TD-2. This system has been described very adequately in a previous article in *The Engineering Journal*[1] and therefore will only be touched on briefly here. The system operates in the frequency band 3700-4200 Mc/s. and a single structure accommodates six radio channels in each direction. Each of the radio channels can handle one monochrome or colour video signal or upwards of 480 telephone channels.

To provide greater reliability, one radio channel is assigned as a stand-by facility. A breakdown in any portion of the network is automatically detected and the standby switched into service to bridge the break in a fraction of a second. Radio relay stations located along the TD-2 route at intervals of approximately 30 miles are completely unattended. Troubles occurring in these remote stations are automatically detected and an alarm sent out to a master control and alarm centre. By means of an intricate interrogation system, an attendant can identify the type of trouble and immediately dispatch a trained maintenance technician. During inclement weather in winter, difficulties are encountered in gaining access to some repeater locations despite the best engineering efforts in the system design. To overcome these handicaps, maintenance people use all types of transportation: snowmobiles, snowcats, tractors, jeeps, aerial tramways.

With a structure such as the TD-2 system, one or more television program facilities can be made available at the same time to meet this vast country's communication needs.

The video tape relay centre at Calgary.

Use of Network

A full understanding of the operation of this network requires first of all an appreciation of the centres of population, the points of origin of television network material, time zones, and last, but not least, Canada's two languages.

The main centre for the origination of English-speaking program material is the Canadian Broadcasting Corporation studios in Toronto. At this point also U.S.A. network programs are received from Buffalo, N.Y., and fed to CBC studios where they are monitored and re-edited for commercial material and fed back into the network as required.

French network program material originates in CBC Montreal and is fed into the French network at that point. There are also a number of other CBC program centres across Canada, namely, Winnipeg, Vancouver, Halifax, and Ottawa. There will also be from time to time special-occasion temporary insertions of program material at any number of Canadian points, for example, the Calgary Stampede at Calgary. All of these were provided for in the design and layout of the television network.

To meet the individual needs of the various sections of the country's population from the point of view of density, community of interest, time zones, etc., the corporation has divided the network into roughly five parts: the Maritime, Quebec, Ontario, Prairie, and Pacific networks.

For part of a program day each of the individual networks' air material is of local origin and during this period the networks are set up in that manner.

However, for other portions of the program day, networks use material produced in Toronto and therefore require connection to that point. In

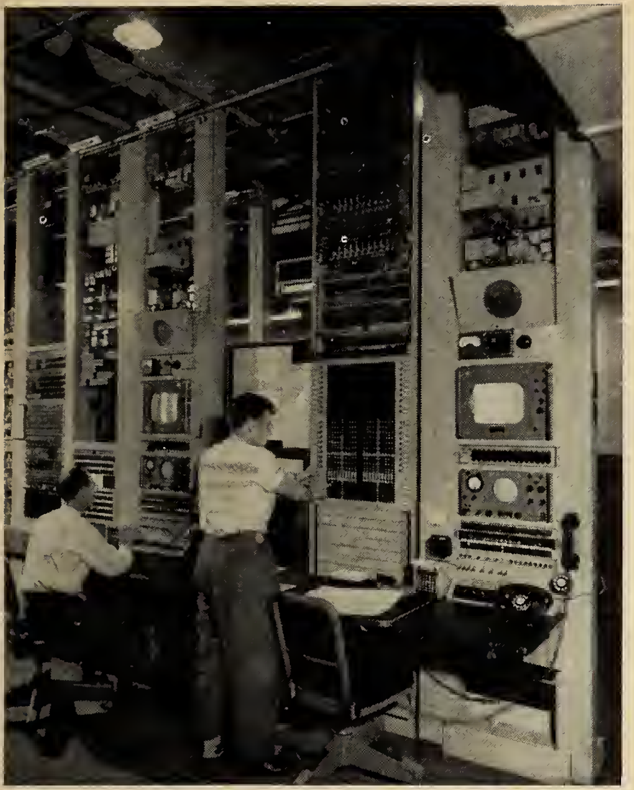

Fig. 1. View of television operating centre showing the switch control unit and monitoring positions on either side. Attendant is making a switch.

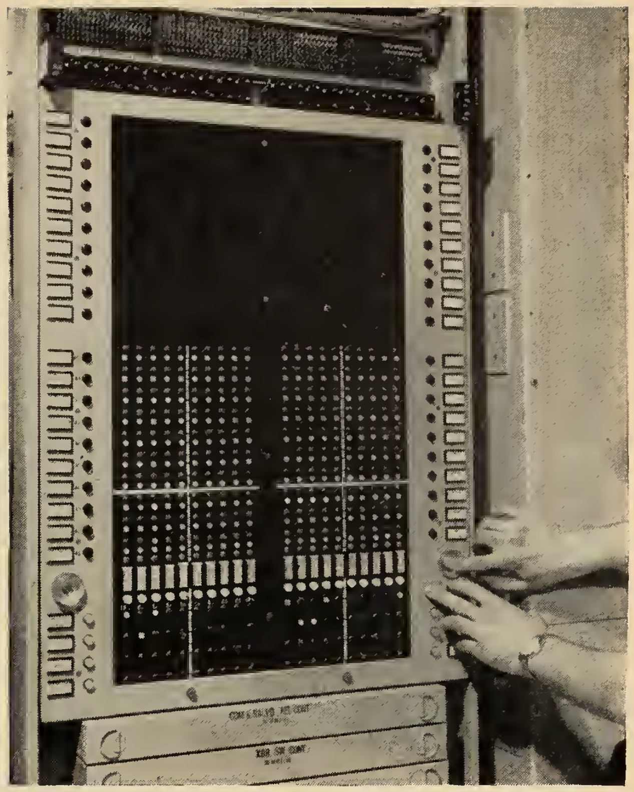

Fig. 2. View of switch control panel located in television operating centre.

the case of the Maritime network this is done by connecting Toronto to the Halifax studios directly and then feeding back into the Maritime network at that point. Montreal and Ottawa can be connected to the same feed from Toronto if desired or served by a duplicate feed.

Similarly TV stations between Toronto, Ont., and Winnipeg, Man., are served from Toronto over the western branch of the network. The same material as fed to Halifax can be used or, if required, different material may be used since the network can be simply divided at Toronto. In fact, at any point where there are CBC studios the network can be broken to feed material either independently east or west or simultaneously.

West of Winnipeg, due to the time zone difference, it has been found desirable to delay a broadcast originating in Toronto by a period of two to three hours. This is being accomplished by passing the program from Toronto through to Calgary. Here it is fed to the CBC video tape relay studio, mentioned earlier, where the program is recorded on tape and at the appropriate hour re-inserted into the Prairie or Pacific networks. This, of course, requires the use of both east and west-bound facilities between Calgary and Brandon simultaneously.

Material of national interest required to be received simultaneously throughout Canada, or the North American continent for that matter, causes no insurmountable difficulty because the design of the system envisaged such requirements.

A nation-wide program such as the federal elections or a Royal visit requires the insertion into the network of material at widely separate locations. This is provided by duplicate facilities, intricate switching mechanisms, and close co-ordination between the CBC and the Communications companies.

Television Operating Centres

Control and switching of such a network is accomplished at the television operating centres (TOC) operated and maintained by the telephone companies (Fig. 1). To appreciate more fully the complexity of such a control point a description of the Toronto centre follows.

Toronto is a main hub of the Trans-Canada Telephone System network. Three major microwave routes converge at this point: (1) a route to and from the U.S.A. through Buffalo, N.Y.; (2) a route to Western Canada via North Bay and Winnipeg; (3) a route to Eastern Canada via Ottawa and Montreal.

In each route, radio channels assigned to the CBC television network are connected to the CBC studios through a television operating centre.

The basic functions of this centre are:

1. The termination of all video facilities under its control.
2. Rapid switching of audio and video facilities.
3. Rapid detection of trouble throughout the system and the control of restoration facilities.
4. The monitoring and testing of both audio and video facilities.
5. Centre of communication with all broadcasters and maintenance personnel for the reporting and clearing of trouble.
6. A point of adjustment of all video facilities, both microwave and cable, controlled by the centre.

To perform the above functions a TOC comprises:

(a) Terminating equipment such as equalizers, level adjusting amplifiers, impedance adjusting devices.

(b) Switching equipment.

(c) Switching control equipment.

(d) Testing and monitoring equipment.

(e) Communication centre.

A simplified schematic of a typical television operating centre is shown in Fig. 3. This shows the termination of video and audio trunks from the cities, television studios, and pick-up points The heart of the operating centre is the switch control arrangement shown in Fig. 4. The nerve centre of this is a control panel (Fig. 2) fitted with an array of coloured lamps and push buttons. The panel merely actuates video and audio switches which are located, for transmission reasons, as close to the terminating or switched equipment as possible. This switch panel not only activates switches in Toronto, but also remote switches located many miles away. This is accomplished by extending the control leads over wire lines to the remote point.

For example, the feed to Peterborough which is taken from the backbone route at a remote repeater station can be reversed, re-established or restored, by the push button controls on the Toronto panel.

The switching operations at a TOC make possible switching functions which vary from very simple connections to a complete re-arrangement of the network. For example, by means of pre-select buttons, a new arrangement of the network can be set up in advance of the actual switch time. To eliminate errors, white lamps indicate the arrangement that has been selected. The arrangement of a network program in progress is displayed by red lights. At the instant of switch "cue" the operator merely pushes a "salvo" button and a specially marked "execute" button and in a fraction of a second the new network is established.

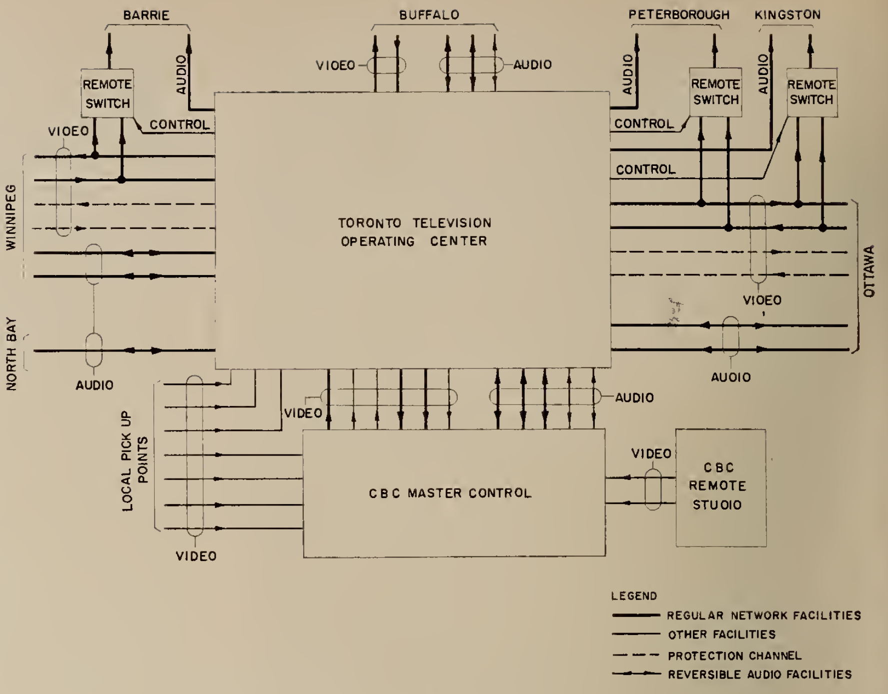

Fig. 3. Television network switching in Toronto.

The speed of operation of the switches is so fast that the change is hardly detectable.

Figure 4 also shows a video monitoring and test position linked to the switch control panel. The monitoring position consists of a high quality picture monitor and oscilloscope. From the test position, various video wave forms and multifrequency signals can be transmitted into the network and monitored at distant TOC's. Thus test centre attendants can quickly observe the performance of the system and make minor adjustments of signal level and frequency response. This is a routine performed daily at line-up time just previous to turning the network over to the CBC.

CBC master control is also equipped to transmit and receive these same signals and test patterns. These are jointly observed by CBC and the communication companies, thus obtaining an overall studio-to-studio performance check just before program time.

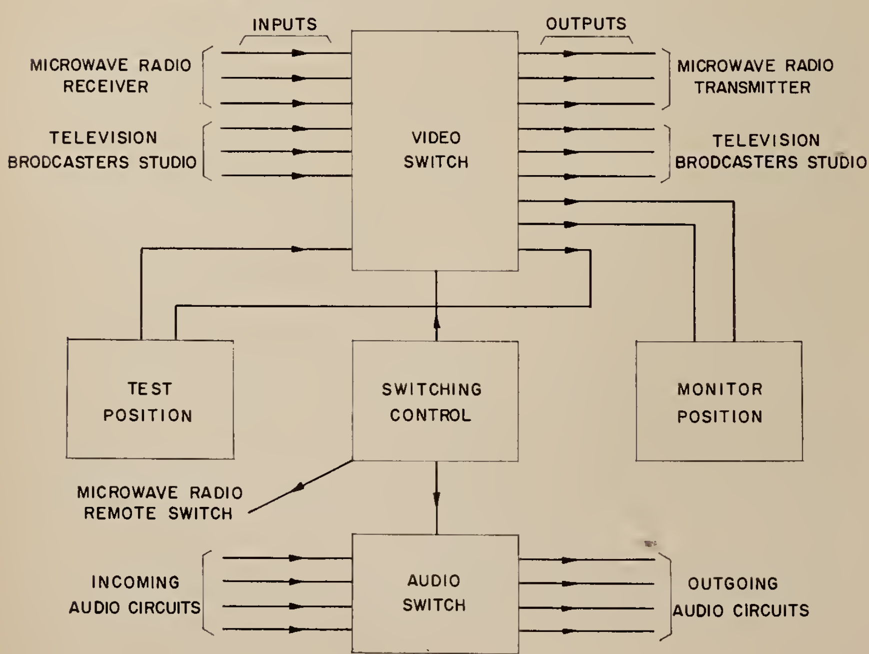
Few adjustments can be made to the network by the communication companies during the program period. It is therefore essential that an extremely high degree of stability be built into the network.

Major adjustments to, and testing of the network, require longer and more detailed attention and are performed at regular intervals as established routines by the Communication companies.

To keep failures to a minimum the network has been equipped with spare equipment, standby video loops, standby power, and standby radio channels. Most of these facilities are arranged for automatic restoration or manual push-button switch-over.

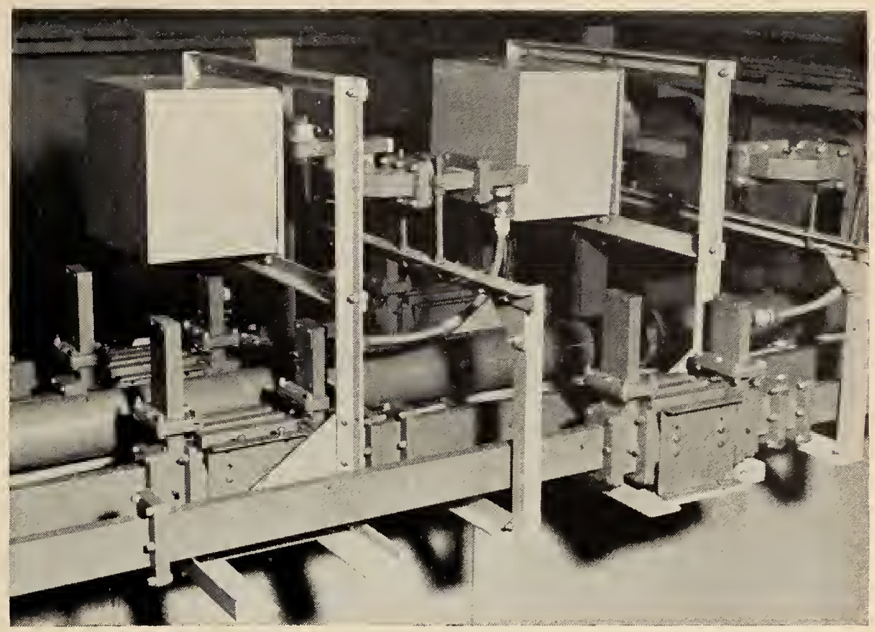
Due to the length of the system and the intricacies of the equipment, some failures are inevitable. Peculiar weather conditions upset the operation of radio channels. Occasionally, an antenna or a waveguide may be

Fig. 4. A typical television operating centre layout.



punctured by a hunter's stray bullet. These things occur infrequently and in the overall it is expected that the Trans-Canada network will maintain a high record of reliability due to safeguards and extra insurances built into it.

Little has been said of the audio or sound portion of the television service. It, however, is just as important as the video portion. Oddly enough, the sound portion of the TV program is not transmitted with the picture over the network. Normal practice is to use a network of high quality land-line facilities, with alternate standby, in many cases, over program channels on the microwave system. The facilities provided by the Trans-Canada Telephone System use high speed line carriers. This is essential to reduce to an acceptable minimum the delay at the observing point, between the picture and sound.



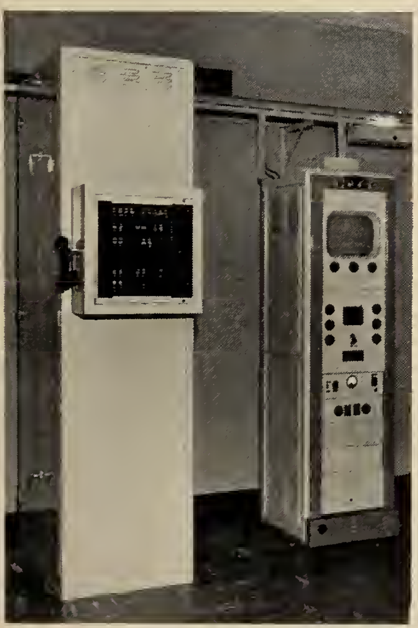
Waveguide runs; CN-CP microwave system.

Short Radio Waves

Making all this possible in the Trans-Canada's microwave system, are radio waves of the order of three inches in wavelength, compared with 10,000-inch wavelengths of the ordinary broadcast channels.

These microwaves have many of the characteristics of light. For example, microwaves—like light—travel in straight lines and once over the horizon, they fail to return to the surface of the earth at a predictable point. This means that the range of reliable transmission is limited to line-of-sight, and the relay points (even taking advantage of high land and tall towers) are on the average only 25 to 30 miles apart.

Supervisory and monitor bays in the Canadian National / Canadian Pacific microwave system.



On the other hand, microwaves can be focussed into a beam and aimed directly at a receiving antenna so efficiently that only half a watt of power—about the amount needed to operate a flash-light bulb—is needed to span the distance between the two stations.

Since the microwaves have the velocity of light (186,000 miles a second) an event being televised from Victoria would be seen at Sydney a mere 1/50 of a second later.

CONCLUSION

It is important to note that while the Communications companies handle the technical operation of this television network for the CBC, the CBC on the other hand maintains similar controlling and monitoring facilities to achieve the necessary broadcast standards. At this point, numerous problems exist since the network must not only perform with technical perfection, but, it must also maintain certain standards of quality broadcast performance, to enable the CBC to supply full value on a production and artistic basis.

Joint technical committees made up of personnel from both the CBC and the Communication services meet frequently to discuss problems and to find methods that will maintain quality broadcast performance. It is extremely vital to the success of the network that constant steps are taken towards a mutual understanding of the many varied problems.

Probably the most difficult problem faced by the CBC and its networks suppliers is one which is common to comparable organizations in the U.S.A. This is the difficulty of determining the nature and the degree of degradation which can be tolerated in the composite television wave forms before significant impairment of the television picture occurs. Next to this problem is the difficulty of measuring wave form impairments, which in some cases can be very slight while at the same time their effect on the final picture is quite serious. Thus, in the role of customer, the CBC tends in the interests of high broadcast standards, never to be satisfied with the performance of its leased network services.

The existing close co-operation provided through the medium of joint technical committees is constantly dealing with many minor and a few major problems which are fundamental to good television service and the effect of this work is to supply the Canadian public with a continuing improvement in the technical quality of the programs they see and hence a greater return on their investment.

Canadians everywhere can take pride in their television network. To Canada belongs the distinction of establishing the longest stretch of television network facilities for public service in the world.

DISCUSSION

of Technical Papers and Other Articles

THE MANICOUAGAN POWER DEVELOPMENT

J. M. Higgins, and Charles Miller, M.E.I.C.

The Engineering Journal, 1958, July, p. 60

F. L. Lawton,* M.E.I.C.

The paper on the Manicouagan hydro-electric power development, as one in the symposium on the Baie Comeau plant of the Canadian British Aluminium Co. Ltd., is significant because it demonstrates in a very positive manner the advantages of the thoroughgoing study of a project by hydraulic models. The achievement in unwatering the site for the McCormick dam, without the use of cofferdams, rests partly on the recognition of the site potentialities. However, the actual achievement rests on the confidence provided by the extensive model studies, it would appear.

The diversion tunnel, of 35 feet equivalent diameter and 20,000 c.f.s. capacity, with the floor at the intake end 70 feet below river level constitutes a fairly unusual diversion. It would be interesting to have the authors' explanation for the 3 feet lower water level above the dam than shown by the model tests. Was this due to lower tunnel friction losses or to superior entrance and exit conditions?

Following closure of the diversion tunnel, was any rock smaller than 2 cu. yd. in volume found on the invert downstream from the closure?

During stage II construction, blasting was apparently controlled by seismographs in the powerhouse area, the allowable amplitude of vibration being set at twenty-thousandths and actual amplitudes "— for the most part — were not more than 50% of the figure allowed". Did these actual amplitudes cause any relay tripping?

Reference was made by the authors to the difficulties associated with removal of "the timber crib which was placed during the first stage of construction as the connection piece between the section of the headworks then built and the rock-filled dam connecting across the future headworks intake area." Would the authors care to state if they would follow the same procedure if they were building stage I again?

With reference to the use of the L.S.T. for transport of the turbine runners, upper bearing brackets and the auto-transformers through the Manicouagan estuary, what was the depth of water at high tide and the draft of the loaded L.S.T.?

*Chief Engineer, Power Department, Aluminium Laboratories Limited, Montreal.

Authors' Reply

Mr. Lawton's comments are well taken. In reply to his first question the 3 ft. lower water level above the dam was due to a gravel bank which existed in the bed of the river. As the water level decreased with an increase in velocity, this bank was washed out and lowered the level immediately above the entrance.

In reply to the question about rocks smaller than 2 cu. yd. found, none were observed larger than 2 cu. yd. Rocks could be heard rumbling along the tunnel floor for about two or three hours after the diversion.

The blasting control records indicate that vibrations as low as 0.0023″ were sufficient to upset oil level controls. To overcome this a knife switch, in parallel with the mercoid switches, was put in operation and used on every blast. This procedure satisfactorily prevented the switches from tripping.

The timber crib constructed during the first stage of construction would not be repeated if we were carrying out a similar program in the future, but rather it would be more economical to construct the whole of the headworks in concrete in the first instance.

The transport of the turbine runners, upper bearing brackets and the auto-transformers through the Manicouagan estuary required at least five feet of water at high tide over the sand bars, and the L.S.T., when loaded, had a draft of 36″. It was necessary in every case to come up the estuary on a rising tide.

FORCES INVOLVED IN PULPWOOD HOLDING GROUNDS

R. J. Kennedy, M.E.I.C.,

The Engineering Journal, 1958, January, p. 58.

C. B. Dunham†

Professor Kennedy's paper is a significant contribution to the knowledge of the strain on holding grounds.

I understand there are several holding grounds in Eastern Canada receiving 200,000 to 300,000 cords of pulpwood annually; new installations average one a year, and may cost up to $1,000,000.

The stress tables will aid those responsible for designing, constructing and maintaining holding grounds to assess the risk of wasting money in over design in the holding ground against the loss of wood from broken booms or piers.

The holding grounds covered by the study cross the channel from bank to bank are designed to catch individual logs 4 to 16 ft. long.

Members will be interested in the recent development of bundle driving on the Fraser River in British Columbia. Here the bundles are guided by river boat to the holding ground which occupies about one quarter of the river channel.

The Fraser river rises in the interior plateau and flows in a 200 mile canyon through the coast mountains, then through a wide valley for 50 miles to tidewater. May 1 to Sept. 30 is high water with an average flow of 130,000 c.f.s. and a rise of 40 to 70 ft. in the canyon.

The 60 mile section of river below the canyon was improved between

ABSTRACTS

BASED ON CURRENT ENGINEERING LITERATURE

AUSTRALIA'S FIRST REACTOR

Engineering, v.185 n.4808, May 1958

Last April the Australian Atomic Energy Commission's research establishment at Lucas Heights, near Sydney, was opened. This is the first nuclear reactor in Australia and is called "Hifar" (short for high-flux Australian reactor). Construction began in October 1955.

Recruitment of the senior research staff had been mostly completed by mid-1955. They began work at the UKAEA research centre, Harwell. Subsequently, other scientific and assistant staff was engaged, bringing the total up to its present level of about 250. The first laboratory was occupied in December 1956 and by 1957 analytical services, workshops, design offices, electronic instrumentation, library and health physics facilities had been provided. About this time work on the laboratories research program was begun and developed.

The main objectives are as follows: (1) development of atomic power reactors suitable for Australian conditions; (2) research into problems associated with power reactors such as fuel and moderator purification and fabrication, chemical processing of spent fuel elements, and treatment of radioactive waste products; (3) to provide isotopes and radiation sources for which there are rapidly expanding uses in industry, agriculture, medicine and research; (4) to provide a national centre with equipment and trained staff facilities to aid Australia in the development of the use of atomic power, and to provide any specialist advice or experimental facilities necessary for this task; (5) to train scientists and technologists in atomic energy techniques.

The reactor types selected for investigation were chosen on the basis that the program should not duplicate work already done elsewhere and in advanced state, and also that it could be carried out on a cooperative basis with other countries, particularly the United Kingdom. The reactor systems are to be adaptable to the small power systems Australia is likely to provide outside the larger industrial areas in New South Wales and Victoria.

Research is being undertaken on two systems, the first and perhaps most promising is the high-temperature gas-cooled system using beryllium as a moderator, which has advantages over equivalent graphite systems for small electrical generating units in the range 5 to 20 Mw.; and the second, a liquid metal fuel reactor system using a sodium slurry as the coolant and fuel carrier.

TRANSFER PLANT PRODUCES STRUCTURAL STEELWORK

The British Constructional Engineer, v. 8 n. 5, March 1950.

A transfer plant for the production of structural steel sections, combining three machines into one integral unit which can cut and drill steel sections, has been built in Britain. Basically the plant consists of the three machines served by a power-driven roller conveyor system and other mechanical handling aids.

The first of the machines is a cold saw and the steel sections are conveyed to this by rollers through a hatch from the stockyard. After trimming of rough ends, a measuring device, with provision for fine manual adjustments, marks off the required length, and the section is fed forward into the jaws of the sawing machine vice. Any length of up to 40 ft. can be cut, and the measuring and cold sawing is controlled by an operator from the control cabinet. Machine scrap is ejected down a chute and usable ends are returned to stock.

After cutting. the sections pass on to a horizontal drilling machine which makes the holes in the flanges. On its way between the two machines the section can be shunted to one of several laybys if not immediately required. Any number of holes up to 12 can be drilled simultaneously. Spindles are arranged in four sets of three mounted on a horizontal cross-slide and can be raised and lowered by a feed-screw. A 4-speed gearbox gives a range of speeds suitable for drilling hole 5/16 in. to 1¼ in. in diameter, and a wide variety of patterns can be set for the drills.

The final machine to which the sections pass is a 4-spindle vertical machine for drilling holes in the webs. As in the horizontal drilling machine the spindles are adjustable and are also equipped with gags allowing any required number to be selected without removing the drills. Finished sections are moved from the machine by cross-feed dogs to a delivery point, and from here they are conveyed by roof gantry to the last lay-by for assembly, painting and despatch.

Any of the machine processes can be by-passed. Since the plant was installed, with an addition of only four men to the payroll the turnover of the company has been doubled. Men can be instructed to operate the machines very quickly, most of them being unskilled or semi-skilled. Output, depending upon the type of work, varies between 60 and 150 tons a week.

AEROTHERMODYNAMIC TEST PLANT

The Engineer, v.205 n.5333, April 1958

A high altitude test plant to be used principally for the testing of ramjets by Bristol Aero-Engines, Ltd. has been recently opened. It is the only one in operation in Britain such that the test cell can be evacuated to reproduce the conditions of running at high altitude. The pressure in the test cell can be brought down to 1½ p.s.i.a., for zero mass flow, by steam ejectors. At present ramjets up to 32 in. in diameter can be tested although 36 in dia. engines could be handled with minor changes. The pipework has been made initially of mild steel and thus working temperatures are limited to 450° C. Consequently Mach number 3.5 cannot be exceeded until chrome-molybdenum piping is in use.

The ejectors are run for high and medium altitude tests and compressed air is supplied to the plant for low and medium altitude tests. Up to four "Proteus" Mark III compressors can be used for air supply. The motors have a total rating of 26,000 h.p. for two hours or 21,000 h.p. continuous; two compressors can be driven at 12,000 r.p.m. to give 84 lb. per sec. at 8 atmospheres pressure and 315° C. temperature, or 4 at 11,000 r.p.m. delivering 150 lb. per sec. at 6 atmospheres and 260° C. An electric heater of 1,500 kw. and two coolers using up to 50,000 gallons of water per hour may handle all or part of the air flow; 80 lb. per sec. of air can be raised from 260° to 350° C. for ten minutes and outlet temperatures up to 450° C. are available; the coolers can reduce the maximum air flow of 160 lb. per sec. to 95° C.

The test cell is 75 ft. long and 10 ft. in diameter, weighing 108 tons. It has been tested to extreme pressures of 90 and 1.0 p.s.i.a. Water-cooled glass windows face the control room, and a series of glass windows are also incorporated which are shattered by explosive charges if the pressure in the cell during a test exceeds the safe limit of 25 p.s.i.a. At the rear of the cell are water sprays to cool the exhaust. Exhaust gases leave the cell for a silencing tower by means of an underground ductwork. To reduce the risk of damage by an accumulation of unburnt fuel vapour in the tunnel, Graviner explosion suppression equipment is installed to flood the duct with chlorobromomethane if light is sensed by the detector.

The ejectors can expend up to 98,000 lb. of steam by exhausting the accumulators under maximum flow in 6¾ minutes. This steam can be replaced in 2½ hours by three oil-burning boilers.

Engine fuel tanks hold a total of 26,000 gallons. There is no indication of fuels other than hydrocarbons being used. In the opening ceremony a "Thor" was ignited at a simulated Mach 2 at 30,000 ft.; for a 16 in. diameter engine this corresponds to approximately 1,800 lb. thrust.

The cost of the plant, as distinct from the buildings and services is understood to have been met by the Ministry of Supply.

HYDRAULIC PROBLEMS SOLVED BY GIANT WORKING MODEL

The Consulting Engineer, v.14 n.4, April 1958.

Despite research carried out over a period of 100 years by topographers and engineers, San Francisco Bay, California, has long posed problems which have remained unsolved. The huge crescent bar menacing the approaches to the Golden Gate is created and maintained by forces still unknown; the slow drift of sediment into ships' channels is unmeasured and unconfined; and salt intruding from the sea into the fertile region at the confluence of the San Joaquin and Sacramento Rivers, is a dangerous and unmeasured enemy to all whose living depends on the land surrounding the area of the bay.

To study these and a score of other problems, U.S. Army Corps engineers at San Francisco have designed and started to build an exact scale model of the Bay at Sausalito, California. The complete replica of the bay covers one full acre. It is built to a horizontal scale of 1 ft = 1,000 ft. and a vertical scale of 1 ft. = 100 ft.

Although the model does not look exactly like the real bay its action is similar to that of the prototype in reproducing to proper scale the rise and fall of the tide, flow and currents of water, mixing of fresh and salt water, and indicating trends in the deposition of sediments. The overall investigation is scheduled for completion in 1960.

The model was constructed principally of precast, lightweight, reinforced concrete slabs, each weighing some five tons. The rise and fall of the tide and accompanying tidal currents in the model bay are created by generating the tide in the model ocean. Salt water is pumped from a storage pump into the ocean headbay. Ebb and flow are regulated by an automatic tide-control operating a motor-driven valve in a separate outflow pipe connecting the headbay and sump. One tidal cycle requires 14.9 min. River flows are introduced from separate water supply systems around the model. Precise instruments measure elevations of the water and its velocity and salt content. When the model is adjusted so that these and other measurements agree with similar measurements from the actual bay, the model acts to scale the same as in nature. Physical changes made in the model will then show what effects would be in the bay itself. The action of silt is simulated by a light bituminous material called gilsonite.

To determine the effects of a salt water barrier on the bay, a miniature barrier and related works in the model are operated according to plan. By comparing measurements from the model of water-surface elevations, flows, current velocities and directions, mixing of fresh and salt-water, and deposits of silt, with and without the barrier, forecasts can be made of what would happen if a barrier were to be constructed. Deposits of mud and silt in bay shipping channels continually interfere with vessel traffic. An average of 8 million cu. yd. of material are dredged annually at a cost of about two million dollars. From measurements in the bay, analysis of dredging practices, and model experiments, specific information is obtained on the complex factors producing shoaling. Tests of remedial measures are conducted in the model.

PROCEEDINGS OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS: HIGHWAY DIVISION

v.84 n.AW2, May 1958. Paper 1625

Trip origin and destination necessary for realistic highway location and design may be outmoded if they do not reflect current economic and transportation conditions. A system for collecting origin and destination information on a continuing basis using more exact statistical methods being used in traffic-counting programs, and a better trained interviewing staff would provide more reliable data.

A continuous sampling survey appears to offer advantages in technique improvement and possible reductions in cost. To be successful the driving public must be convinced the studies are being conducted to determine where traffic is going, what improvements are necessary, and that they can be successfully developed only if each driver co-operates by taking time to answer the questions.

INTERNATIONAL NEWS

Hydro-Power Construction in the U.S.S.R.

Fyodor Loginov, Deputy Minister of Electric Stations of the U.S.S.R.

The creation of a power base for development of the country's national economy began in the very first years of the establishment of Soviet power in the U.S.S.R. In 1920, on the initiative of V. I. Lenin, the State Commission for the Electrification of Russia was set up to draw up a long-range plan for the development of the national economy on the basis of electrification (known as the GOELRO).

The GOELRO plan provided for the building, among others, of 10 big district hydroelectric stations. The first of them were built under extremely difficult conditions, when there was not enough machines, materials or qualified workers. Nevertheless, in the period of 1920 to 1927 the Volkhov Hydroelectric Station on the river of the same name, the Zemo-Avchala station on the Kura River, and the Kondopozha Station on the Suna were built.

The basic principles of Socialist electrification—extensive use of water resources and local fuels, concentration of capacities and creation of power grids, rational relocation of productive forces throughout the country — have been embodied in Soviet power development. In the First Five-Year Plan period (1928-1932) the V. I. Lenin hydroelectric station, biggest in Europe, was built on the Dnieper River. At this development mechanization was already widely applied in earth handling and concrete pouring.

During the prewar Five-Year Plan periods power development proceeded extremely rapidly in the country: the Nizhne-Svirskaya station near Leningrad, the Rioni station in Georgia, the Kanakar and Dzoraget plants in Armenia, the Niva and Tuloma stations in the North-West, the Komsomolskaya and Tavakskaya in Central Asia were built. With the launching of the Nizhne-Svirskaya development, the first 220 kilovolt high tension transmission line in the Soviet Union connecting the station with Leningrad went into operation. New power grids were created through a high-tension network connecting electric stations within many districts, such as Moscow, Leningrad, the Donets Basin, the Dnieper River Valley and the Urals districts. Later these grids began joining up into interdistrict power systems. The Donbas grid was joined with that of the Dnieper River area.

As a result of the successful implementation of the GOELRO plan and the building of power plants during the First and Second Five-Year Plan periods, by 1935 the Soviet Union had moved up to third place in the world in electric power production.

Soviet people did a big job in restoring the electric stations destroyed by the Germans during World War II. Parallel to this, construction of new hydro developments continued. The big Rybinsk hydrostation on the Volga was finished, the Chirchik-Bozsu cascade, the powerful Farkhad station on the Syr Darya, and other hydroelectric plants were built in Central Asia. Several stations went up in the Urals.

In postwar years hydropower construction in the U.S.S.R. has acquired new impetus. During the Fifth Five-Year Plan period (1951-1955) such big developments were commissioned as the Ust-Kamenogorsk, Tsymlyanskaya, Verkhne-Svirskaya, Mingechaur, Gyumush and Narva hydroelectric stations. The first sections of the Kama, Gorky, Knyazhegubskaya and others have begun generating current. The Kakhovka hydro development on the Dnieper was built and commissioned ahead of schedule. In these years construction began of the big Kuibyshev, Stalingrad, Irkutsk, Novosibirsk, and Bukhtarma stations. On the Angara river the mammoth Bratsk hydroelectric development is under construction.

New equipment is being produced for these projects. For the Kuibyshev and Stalingrad stations, for example, 105,000 kw. hydroturbines have been manufactured. The diameter of the turbine's wheel is 9.3 metres (30.5 ft.), and the installation's overall height is 28 metres (92 ft.). Most of the existing stations have gone over to automatic control, and on several remote control from a single dispatcher's post is effected.

During 1951-1955 the increase in electric power production was 79,000 million kwh., which is more than envisaged by the plan. The total amount of electricity generated by hydro stations increased from 12,700 million kwh. in 1950 to 23,200 million kwh. in 1955. During this latter year alone hydroelectric stations helped to save 20 million tons of coal.

Soviet industry has equipped its power projects with firstclass construction machinery. In a short time the necessary quantities of many types of earth handling machines were produced. At the Verkhne-Svirskaya, Narva, Gorky, and Kuibyshev stations continuous-production concrete plants were set up. By the beginning of 1955 there were 58 concrete plants in operation at hydroelectric developments with a daily output of over 68,000 cubic metres (89,000 cu. yd.).

The introduction of progressive methods of construction and assembly and the use of modern machinery have made it possible sharply to reduce time limits. At the Kuibyshev development up to 395,000 cu. m. of concrete per month was laid, the daily quantity at times exceeding 19, 000 cu. m. This is more than the world record which belonged up till then to American builders who had laid 15,700 cu. m. in 24 hours at the Grand Coulee project.

At the construction of the Gorky station a new method of concrete pouring was introduced in which 70-ton reinforced falsework panels were used. These panels, made of a reinforced frame with the falsework or a casing of ferro-concrete plates mounted on it, are prepared in advance at a special site, and the concrete can be poured as soon as they are assembled.

The damming of such big streams as the Irtysh, Kama, Volga, Dnieper, Angara, and Syr Darya from pontoon bridges has been mastered. At many developments the hydro-turbine installations were assembled in large sections which made it possible to reduce assembly time and commission the stations ahead of schedule.

Electrification will be developed further under the 1956-1960 plan. In this period hydro-power capacities are to grow by 170 per cent. Besides the central industrial areas of the country, hydro-stations will be built in Siberia and Kazakhstan, Uzbekistan and Georgia, Armenia and Azerbaijan, in Lithuania, Moldavia and the Karelian ASSR. The Volga-Kama cascade, six stations of which are already in operation, three are under construction, and four are being designed, will be finished. In 1957 the Kuibyshev hydroelectric station — largest in the world — was launched to full capacity. Construction of the still bigger Stalingrad station is continuing on a broad scale, as is work on the Dnieper cascade where the Kremenchug and Dnieprodzerzhinsk plants are going up.

A number of powerful stations are being erected in Siberia which possesses approximately 60 per cent of the country's hydro-resources. Building of the 3,600,000 kw. Bratsk station is proceeding apace. This is the second plant on the Angara; the first—the Irkutsk station—will reach its peak load this year. Work has begun on harnessing the mighty Siberian river Yenisey, where the 4,000,000 kw. Krasnoyarsk station, which will be the biggest in the world, is already going up.

In Kazakhstan and Central Asia the big Bukhtarma project and the Kairak-Kum station, commissioned in 1957, will be supplemented by the Golovnaya station on the Vakhsh River, the Uch-Kurgan station on the Naryn, and several others, construction of which will begin shortly.

Hydropower development is continuing in the Northern Caucasus and Transcaucasia. In the Sixth Five-Year Plan period the Sevan-Razdan cascade in Armenia will be completed as a whole. Four stations are already in operation, two are being built, and three are in blueprints. In Azerbaijan the Varvarinskaya station has been finished below the Mingechaur development. In Georgia three hydro-stations will be finished and one more started.

By 1960, electric power production by hydro-stations will reach 59,000 million kwh., 155 per cent more than in 1955.

Work is in progress to create a single power grid for the European part of the Soviet Union. The Kuibyshev and Stalingrad stations will be connected with the Central, South, and Urals grids with high-tension transmission lines of 400-500 kilovolts. A D.C. power transmission line with a voltage of 800 kv. will connect the Stalingrad station with the Donbas.

A single power grid will be created in Central Siberia joining the Irkutsk, Bratsk, Krasnoyarsk hydroelectric stations and the big fuel power stations. The Georgian, Azerbaijanian, and Armenian grids will also be linked up.

As a result of the consistent implementation of the plan for the electrification of the country, the Soviet Union has scored great successes in developing the power base for the national economy. In 40 years electric power production has grown more than 100-fold and reached 209,500 million kwh. in 1957, including 39,300 million kwh. of hydroelectric power.

GREAT BRITAIN

NEW "CHURCHILL" COLLEGE

A new college is to be built at Cambridge University and named after Sir Winston Churchill in recognition of his long-standing interest in provision of facilities for study of science and technology. An appeal has beeen launched for nearly 3½ million sterling to build and endow this college.

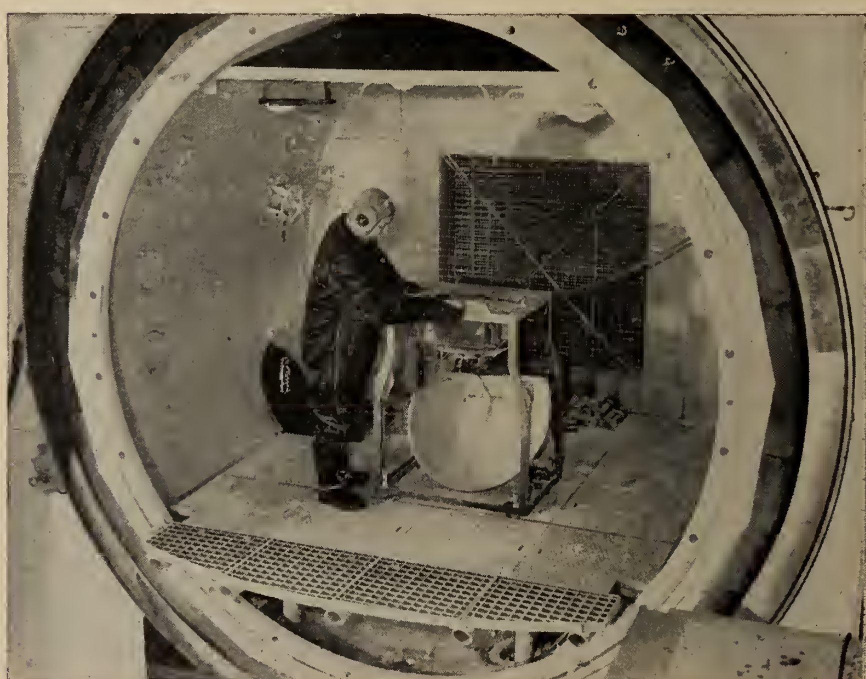
The aim of the men's college will be to help increase Britain's output of technologists, and under present plans at least seventy per cent of students will study scientific or technological subjects. The trustees also state that the college would also try to attract postgraduate students from foreign countries and the Commonwealth and to create a number of visiting fellowships for overseas specialists.

Sir Winston, who is one of the trustees, has offered to donate £25,000 from his birthday trust fund towards the cost of the college. An offer of £50,000 has come from the Calouste Gulbenkian Foundation in Lisbon as what Foundation authorities describe as a "willing tribute to the greatest living Englishman". The Gulbenkian grant will provide three studentships for graduates of universities outside the U.K.

While the appeal for funds is primarily directed to industrial, commercial, and financial circles, support is welcomed from institutions and individuals. Donations may be sent to Churchill College Trust Fund, at Cambridge.

STRATOSPHERE CHAMBER AT ROYAL RADAR ESTABLISHMENT

The Royal Radar Establishment, at Malvern, Worcestershire, is concerned with the development and testing of equipment for Britain's defence system. Extensive use is made of computers, simulators, and experimental test vehicles. The picture shows a radar scanner installed for testing in the Establishment's stratosphere chamber. In this chamber, temperature and humidity can be varied to simulate conditions in the Earth's atmosphere from sea level to an altitude of 100,000 feet. Equipment can be tested under extremes of temperature, pressure, humidity, vibration, and shock. Research is also carried out in a wide field of physics and electronics.



Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Progress by Ontario Hydro

Weather throughout the month of May was generally favourable for construction. The work force was increased slightly in May and a total of 2,750 persons was working on the Ontario Hydro half of the project.

Concrete placing on the Canadian half of the international power-house had reached an advanced stage on the deck at the end of May.

Meanwhile, removal of the steel cell cofferdam in the tailrace area in front of the power-house was progressing steadily on both sides of the international boundary. On the Canadian side, seven cells had been removed at month end. This will permit the tailrace water to be discharged when first power is produced in July.

In the power-house, work was started on assembling the rotor for unit seven. The stator winding was started on unit seven and was completed on unit five. Control wiring for the first four units was about 85 per cent finished. Assembling the transformer bank for units five to eight was progressing and work also was proceeding on the bus installation for these units. The 230-kv. cable circuit for the first four units was installed through the tunnel and technicians were busy hooking up the high voltage connections.

The first five turbines had been installed and rotation tests had been completed on units one and three. Forty-six headgates and 36 headgate hoists had been installed. The service piping had been fully installed for the first four units. Nine unit covers had been assembled. All three ice sluice drum gates were in position and tests were underway.

All eight sump pumps and dewatering pumps had been installed and were in service. On the tailrace side of the power-house, assembly of the 15-ton gantry crane was well advanced.

The necessary installations to take power from the generating station to the St. Lawrence transformer station and then into the Ontario Hydro system were more than 80 per cent completed. Work had started on the footings for the 115-kv. circuit from the transformer station to Kingston. Metering equipment was being installed in the control building at the transformer station and was about 95 per cent completed.

Progress by NYSPA

During May, concrete in place for all structures passed the two million cubic yard mark or 98 per cent of the estimated total. Excavation quantities had reached 50,600,000 cubic yards or 95 per cent of the estimated total. Employment averaged 3,470 for the month.

The American half of the power plant some 8,300 cubic yards of concrete was placed bringing the total to 98.5 per cent complete. Work preparatory to flooding the reservoir was nearing completion. Intake gates and hoists were being installed. Installation of the main grounding mat upstream of the power-house was started. Four of the generators were more than 95 per cent installed. The installation of telephone equipment in the power-house and switchyard service building was started. Erection of the elevated water tank was started.

At Long Sault dam, removal of the bridge and plug in Cut "C" was completed. Some 26,000 cubic yards of concrete was placed in sluiceways and pier noses. Approximately 96 per cent of the required concrete had been placed. Installation of electrical and mechanical equipment in the north bulkhead sections and the elevator continued.

Construction of the seaway power facilities was virtually completed, except for several miscellaneous items to be completed as material is received.

Progress by SLSDC

All excavation, concrete placing and gate installation on the two American locks had been completed by the end of May. The mainland section of the Long Sault canal had also been completed, though some excavation remained at downstream end of the Grass River (now "Snell") lock for the 27 ft. depth, which is not scheduled for completion until year-end.

Work continued on the Cornwall Island north channel. On the south channel all contracts will be completed to 14 ft. depth by July 1. The cofferdam had still to be removed.

The labour force had been reduced to some 400 persons.

Progress by SLSA

Vessels are now using the Iroquois lock. At the upper Beauharnois lock all concrete was to be poured by mid-June for the lock proper. Some concrete remained to be placed in the upstream and downstream approach walls. Trains are now using the New York Central bridge over the lock.

On the lower Beauharnois lock the lock walls were all poured by month's end. The entire structure, including upstream and downstream approach walls, was to be completed before end of June. Lock gate machinery installation was progressing.

At the Cote Ste. Catherine lock all concrete was placed with exception of part of the upstream approach wall. Piers were poured for the spillway to serve the Hydro-Quebec power development. Excavation was completed for the wharf near Cote Ste. Catherine and some 9,000 yards of concrete had been placed by the end of May.

At the St. Lambert lock, with gates and machinery all delivered, erection of mitre gates was nearing completion. Water had been let in on the stretch of channel between Jacques Cartier and Victoria bridges and on another two mile stretch from a short distance above Victoria bridge to Brosseau. Excavation of the channel from the Mercier bridge to Lake St. Louis had reached various stages of completion, and was reported to be on 'schedule'.

Dredging through Lake St. Louis was reported to have reached 90 per cent of completion at end of May, while at the upstream approach to the Beauharnois canal dredging in Lake St. Francis was some 55 per cent done.

Bridges: Jacking of the superstructure on the south half of the Jacques Cartier bridge had reached full height excepting at piers 7 to 11 inclusive. On the Victoria bridge, with lift spans in raised position, the lift machinery was being installed on the towers. A start had been made assembling structural steel on the ground for the lift spans on the diversion over the upstream end of St. Lambert lock.

On the Mercier Highway bridge, with steel erection complete, the concrete deck had all been poured between the remaining part of the old bridge and the south abutment. Steel for the span across the seaway channel was 100 per cent erected and 90 per cent riveted, though the deck had not been poured.

All steel erection was complete at end of May on the Caughnawaga rail bridge and painting was under way. Rail traffic was diverted over the new east or downstream span on June 5.

Employment during May averaged some 5,700 persons.

Tenders for the new Nun's Island Bridge between Verdun and the South Shore were to close June 19, according to the National Harbours Board. Target date for completion is late 1961 or early 1962. Construction will be in three stages; the span to Nun's Island; the level roadway across the island; and the third and longest section from the island to the South Shore. Total length will be almost four miles from end to end.

Canadian Pipeline Projects

Alberta Gas Trunk Line

Work commenced on May 1 on the Company's main line system and on the north lateral. Work includes 49 miles of 34-inch main from Princess to Cavendish, 24 miles of 26-inch lateral from Cessford to Princess and 6600 feet of 18-inch line in the Cessford field. A $1½ million contract was awarded to Fulton Bannister Ltd. Including materials and construction the 74 miles will cost some $9 million. Completion is planned for August 31. A major crossing of the Red Deer River is already completed. Some 250 men will be employed.

Trans Canada Pipelines

Some 4,500 men are working this year in the field building the final 853-mile link of the Trans-Canada natural gas pipe line from Alberta to

Eastern Canada. Completion of the line is scheduled for the fall of 1958. Constructors worked through severe winter conditions on the 853-mile section of 30-inch pipe line from Port Arthur to be completed this year. A total of 510 miles of right-of-way already have beeen cleared, 140 miles have been graded and pipe has been received, strung or stock-piled along the route for over 800 miles of line.

Twelve pipe line construction crews are preparing for all-out operations as soon as weather and terrain conditions permit. Five of the contractors will be working on the 367 miles of line from Port Arthur to Kapuskasing, being built by the Northern Ontario Pipe Line Crown Corporation, with construction under supervision of Trans-Canada, and seven of the contractors will be working on Trans-Canada's section, 486 miles from Kapuskasing to Toronto.

In addition to the actual pipe line construction, six compressor stations will be built, with a total of 48,500 horsepower, an increase of 20,800 horsepower over what was originally planned for this year. The compressor stations will be built at Burstall, Caron, Moosomin, in Saskatchewan; Winnipeg, Manitoba; Port Arthur and North Bay, Ontario.

By end of 1957 a total of some 1,360 miles of pipe line had been constructed and placed in operation, including 586 miles of 34-inch line from Alberta to Winnipeg; 395 miles of 30-inch line from Winnipeg to Port Arthur, and 379 miles of 24-inch, 20-inch and 12-inch line from Toronto to Montreal and including the Ottawa extension.

Since the fall of 1957 Trans-Canada has been supplying natural gas to customers from Saskatchewan to Port Arthur and along the eastern section of the line between Toronto and Montreal. To enable building of distribution system and building of load in Montreal and points between Toronto and Montreal a year before the arrival of Alberta gas, arrangements were made to borrow gas for this section from Union Gas Company of Canada Limited.

Work on the five main line spreads from Lakehead to Kapuskasing opened up late in May. Some contractors had already moved in equipment but frost in the ground had retarded ditching. The major river crossings of the Nipigon, Kenogami and Missinabi rivers had been awarded to Pentzien (Canada) Ltd., of Toronto. Awards of contracts for the five spreads west of Kapuskasing by Northern Ontario Pipeline Crown Corporation were reported in the February issue.

Saskatchewan Power Corporation

Contracts have been awarded by SPC for laterals and local distribution systems comprising the entire 1958 program of local extensions. The largest jobs at Weyburn and Estevan were awarded to Banister-Helm Ltd. at $800,000. The Maple Creek lateral and distribution system went to Robb Construction Company for $200,000. The Lampman distribution system was awarded to Shamrock Construction Company. Further contracts totalling $365,000 were awarded for smaller jobs.

Northern Ontario Natural Gas

Construction of laterals and distribution systems in northern and northwestern Ontario franchise areas was ahead of schedule for 1958, according to a report issued in mid-May, and projects for 1958 should be completed by September. Almost $3 million will be spent for completion of laterals outlets and distribution lines started in 1957. New projects involving 2,920,000 ft. of short laterals, industrial takeoffs, local systems and two major laterals will cost $18.7 million.

Contracts for laterals and distribution systems in Orillia, Bracebridge, Gravenhurst and Huntsville have been awarded to Triton Constructors Ltd.

for scheduled completion in November.

Additional large industrial gas sales have been signed up, making up nearly one third of the company's total expected industrial demand.

International Nickel takes 6 million c.f.d. at Sudbury, while Great Lakes Paper Co. will take up to 16 million c.f.d. at Fort William. The Company has negotiated a new contract with Trans Canada under a 90 per cent load factor, compared with a former 75 per cent load factor. This will result in a saving of 2 cents per 1000 cubic feet. The Minnesota and Ontario Paper mill at Kenora will be the first such plant in Northwestern Ontario to be served by the company and its affiliate, Twin City Gas under contracts totalling 67 million c.f.d.

Union Gas Company

The Company's 142-mile main pipeline across southwestern Ontario was completed last December and is now being operated by Ontario Gas Storage and Pipelines Ltd., a wholly owned subsidiary. The Company's expansion program will continue during 1958. Union acquired the major portion of Dominion Natural Gas Company's facilities in April and will extend its facilities to existing markets and new communities. Transmission lines will be built from the Windsor area to Amherstburg, from the Stratford area to Goderich and from the 26-inch main pipeline to St. Marys. For fiscal year ending March 31 the company reported an 11 per cent increase in net earnings, and a new record high volume of gas sales of some 17.5 billion cubic feet.

Free Piston Gasefier

A. Braun of the Mechanical Engineering Department at Queen's University has designed a free piston gasefier. The Free Piston Development Co. Ltd. has been incorporated, a prototype engine built and successfully operated to prove the design.

The design is not based on Muntz or Pescara patents. It is an *outward* compression type, Mr. Braun's design incorporating features that make it even more simple and compact than the conventional inward compression units, it is reported. It can therefore be considered a major advancement in the engine field.

Queen's University is underwriting the patents and part of the development costs. The prototype has Mechanite pistons (to keep the speed down until injection timing, cooling, lubrication, etc., are thoroughly tested and properly regulated). It is designed to develop 42½ gas horsepower at 2,100 cycles per minute and weighs 180 lb. It is calculated that light alloy pistons will step the speed up to 3,300 cycles per minute and the power to 66½ gas horsepower and that the production unit weight need not exceed 130 lb. Larger sized units will not involve nearly as severe design problems.

This type of gasefier should have applications for marine, automotive, tractor and locomotive power.

What Goes On

Iron Ore Activity

Quebec Cartier Mining Company recently invited bids to build a 193,-mile railroad alongside the access road from Port Cartier to Lac Jeannine and also to construct a 60,000 horsepower hydro electric plant on the Hart-Jaune River, a tributary of the Manicouagan River, a few miles south of the Company's main mining area in the Mount Reed-Mount Wright region.

It is anticipated, the Company reports, that bids for other portions of the project will be invited as engineering designs are completed. These will include a deep-draft harbour and loading facilities at Port Cartier near Shelter Bay, the preparation of a large open pit mine, and construction of a concentration mill capable of producing 8 million tons of high grade concentrates per year. These installations will also require the founding of two new towns to accommodate about 5,000 people.

International Nickel Report

Continuing favourable results in the exploration program at the Thompson Mine in Manitoba, have led the International Nickel Company of Canada, Limited, to the decision to concentrate their efforts on bringing this property into production. Dr. John F. Thompson, chairman of the board of International Nickel reported this to the annual meeting of the company in April.

The company's expansion in Manitoba and Ontario will increase its annual nickel production capacity to 385 million pounds by 1961.

The year 1958 marks the fortieth anniversary of the beginning of operations at International Nickel's refinery at Port Colborne, Ont.

Engineering and Physics Building, Mount Allison

Mount Allison University

Mount Allison University, Sackville, N.B., by means of new facilities, will be able to accommodate up to 350 engineering students, an increase of about 100.

The University gives three years of engineering. No major changes have taken place in the curriculum, it is reported. Mount Allison does, from time to time, adjust the course to meet the requirements of the universities with which it is affiliated, such as McGill University, Nova Scotia Technical College, and the University of New Brunswick.

A general expansion of the University is proposed, which would supply in the future an addition to the library, a home economics and geology building, additional residences, a new gymnasium and a new arts building, and a chapel.

The Engineering Department moved into a new Engineering and Physics Building at the beginning of 1958. This is a three-storey building, containing 30,000 sq. ft., 365,000 cu. ft., and located at College and York Streets.

The building provides, on the first floor, an auditorium, three lecture rooms, faculty laboratories, offices, library and reading room, storage for surveying instruments, etc. The second floor accommodates first and second year and advanced physics laboratories, electrical laboratory, stockrooms, optical laboratory, dark room, museum, computing room.

The third floor, given over entirely to engineering, has two large draughting rooms, lecture room, offices, faculty draughting rooms, blueprint and model rooms, and general utility room.

The building for Geology and Home Economics will affect engineering to the extent of providing suitable facilities for the geology courses. Construction of this building began this summer. Construction of the library addition and of three residence units will begin about the first of August.

Some new equipment is being purchased. This is largely additions to standard equipment, required to meet the demands of the increased enrolment in engineering.

Ontario Agricultural College

The Ontario Agricultural College at Guelph, Ont., is affiliated with the University of Toronto for academic purposes. The program in engineering is designed primarily for educating engineers and others for employment

The *Journal* Reports Growth in Engineering Faculties in Canada

Seventh article of a series

Engineering Building, Ontario Agricultural College

in agricultural and associated industries. It consists of a terminal B.S.A. (bachelor of science in agriculture) degree course, and two others which are co-ordinated with the School of Applied Science and Engineering, University of Toronto. In these, students take the first four years at Guelph and then complete the fifth year at the University of Toronto in mechanical engineering or civil engineering. The students in these two courses receive both the B.S.A. degree and the B.A.Sc. degree.

Although the mechanical engineering program has been in operation for three years, the past season was the first year for the civil program.

With the development of a Service Building on the campus, the Engineering Building was utilized almost entirely for teaching and research this year. The gymnasium, adjacent to the engineering building, was also used to expand the engineering program in teaching and research. This has permitted an expansion of the hydraulics laboratory, draughting laboratories, materials testing, and heat engineering laboratories.

This year additional materials testing equipment, cement and concrete equipment, and photogrammetry equipment, together with a fully instrumented laboratory type gas turbine heat engine, have been added to the laboratories. An R.C.A. electronic trainer and other special electrical equipment have been added to the electrical engineering laboratory for the expanded program.

There is considerable physical plant expansion going on at the College, with the completion early this year of a new Soils Building and an extensive Physical Education Building. Scheduled for start of construction this year is a new Biology Building, with a new Chemistry and Bacteriology Building scheduled for next year. This will permit considerable expansion in student body in all phases of the present teaching and research responsibilities of the College.

The Curriculum

A number of courses in civil engineering, including advanced structural design, cement and concrete, photogrammetry, astronomy, construction surveying, have been added for the new civil engineering program. The engineering library has been expanded extensively to include all recognized professional engineering journals and new reference engineering text books and microfilm equipment.

In preparation for next year's program, a major change in the curriculum is being undertaken. This will result in an opportunity for more mathematics, more time on engineering sciences and more time on humanities.

Secondary School Science

Ten Canadian secondary school teachers of science and mathematics from Nova Scotia to British Columbia have been named by Cornell and Stanford Universities to receive 1958 Shell Merit Fellowships. The Fellowships provide special leadership training.

Throughout the 6-8 week seminars, the Fellows will participate in courses, special lectures, discussions, visits to research and production establishments.

AND TRANSFERS

Report to the Members*

by

C. M. Anson, M.E.I.C.
Sydney, Nova Scotia

THE PAST YEAR has been the most interesting and most enjoyable year of my life. As your president, I have been privileged to journey throughout this great country of ours, to visit other countries as your representative. I have been particularly fortunate in that my wife was not only able, but at all times more than willing, to share with me the so-called hardships of travel.

During the 12 months starting with the trip to Banff a year ago, I have travelled over 70,000 miles, by ship, train, airplane and car. To emphasize the variety, the boys at Trail even had me travel some distance by ski lift. We have visited 36 of the 50 branches of the Institute. By so doing the presidential office has been made available to over 15,000 of the 18,000 members. I regret that time did not permit a visit to all branches and to the members of those branches I did not visit I herewith tender my sincere apologies and regrets.

Of particular interest is that I have been privileged to take part in the inauguration of three new branches of the Institute, one of the many indications of the healthy condition of the Institute. One of those branches, that at Sept Isles, is helping to push back the physical boundaries of Canada, another at Baie Comeau involved in extending Canada's industrial empire, and the third at Chalk River, specifically concerned with pushing back the frontiers of knowledge, not only for the benefit of Canada, but for all mankind. These and many other worthwhile projects, from one end of our country to the other, have been planned by, are being erected and operated by engineers, members of the Institute, engineers who are anxious to take part in Institute affairs. Such men desire the facilities which permit them to advance their own technical knowledge, to discuss their own and the problems of others with fellow engineers, the opportunity to tell by means of technical papers of the interesting features of jobs performed by them or under their direction, to listen to papers from other engineers. It is gratifying to be able to report that the demand among engineers across Canada for such facilities is keen and widespread. Only so long as our profession continues to regard such matters as of vital necessity to them, in fact to consider such services to themselves and to their fellow engineers as of prime importance, will the interests of our profession be further advanced, will the community at large continue to regard the profession with the respect with which it is regarded today.

I bring this subject to your specific attention, because I am disturbed about an attitude I have found in some quarters, again rather generally across the country. As I interpret my impressions, there seems to be a feeling that any body representing engineers should be primarily concerned with the advancement of the engineer as an individual; that it should concern itself principally with registration, wage scales, pensions, insurance schemes and such other matters as affect the personal welfare of the individual. Now let me state quite emphatically that I support to the utmost what is to me a basic principle, that the engineer who does good work should be well paid, that he is deserving of a pension system, preferably a contributory one, that there should be some system devised which will protect him from disaster arising from unexpectedly heavy medical expense. But, if the day should come when the engineer depends upon registration and suchlike to perpetuate the profession, upon security emanating from his own desire and ambition, then I say to you, as from that date onwards the profession will retrogress.

From being the proud upholders of a professional tradition of well-merited standing, we shall deteriorate to a lower status of being, hewers of wood and drawers of water for those with more venturesome spirit. Our profession needs to perpetuate and foster that spirit of individuality which up to this time has been a hallmark of it. I recently heard John Fisher plead for more of the I's and We's and less of the Me's and They's. Unless we get an affirmative response to that plea we shall degenerate into a profession that will deserve just what is handed out to it and nothing more.

Institute, an Influential Factor

Apart from that disturbing feature, I can report to you that your Institute is in a particularly healthy condition. Never before in Canada's history has the profession been so highly regarded. Your Institute has had no inconsiderable part in bringing about that condition. It is no mere coincidence or accident that all recent appointments to the Canadian membership of the International Joint Commission have come from the ranks of engineers. Only a few years ago all such appoint-

*This address was delivered before the 1958 annual general meeting of the Engineering Institute of Canada, at Quebec City, Que., May 21, 1958.

ments were of a political character. Direct representations by your Institute have been an influential factor in bringing about this desirable change. I could go on for hours instancing improvements to the profession that have been similarly brought about. Favourable response to our representations have come about only because we have been a society above reproach, a society interested primarily in the advancement of our profession to serve humanity, a society against which no one could level even the slightest charge of individual gain. Let us keep it that way.

Leadership in Education

We must continue our program of leadership in the field of engineering education. Few people realize that in Canada the Institute has done more in that field during the past three years than has been done by all other agencies together. By our sponsorship and financing of the meetings of deans of engineering schools, our students' conferences, our faculty advisors, our prizes, our Bennet Fund, we are playing a leading roll in the search for more and better engineers. It is of interest to note that during 1957-58 we have had 1,500 applications from students for membership.

With increasing frequency our members are being asked for advice in respect to matters of education, to serve on boards of governors of universities, on committees having to do with the establishment of courses at new engineering schools, or with changes to existing courses.

Our interest and participation in educational matters, is not confined to learned institutions. The branches have continued and expanded Professional Development Courses. At this point may I pay a well-merited tribute to Past-President Col. Leroy Grant, who was responsible for the inauguration of this phase of Institute work. These courses are being given by more and more branches to increasing numbers of not only members of the Institute but to others who are taking advantage of their availability. The Calgary Branch is a splendid example of what is being accomplished. During the past winter, some 350 people were enrolled in the courses organized by that Branch.

We are sponsoring an exhibit, presently circulating the Branches, entitled "Atoms for Peace in the U.S.S.R." The exhibit depicts in some 60 montages, what is being accomplished, in Russia, in the fields of agriculture, medicine, industry and so on, by the release of energy from the breaking down of the atom. We hope that as many Canadians as possible will arrange to see this exhibit. Canadians can be justifiably proud of what its scientists and engineers have accomplished in this same field, indeed could present an exhibit from which the whole world could learn. By seeing what is being accomplished elsewhere, our people will be alerted to the need for continued research and development in the atomic energy field, and the work of our own people in that field will be facilitated and advanced.

Having witnessed for many years the success of the regional meeting sponsored jointly by the Maritime Professional Associations and the Institute as represented by its branches in those provinces, and in furtherance of the evident need for more opportunities for engineers to foregather, the Hamilton Branch held the first such regional meeting in that area this year. It was an unqualified success, admirably organized by the Hamilton Branch. A registration of some 700 people indicates the need for further meetings of that character.

The *Journal* is one of the barometers indicating the state of the health of your Institute. All will agree with me as to the improvements that have brought the *Journal* up to what it is today, and join me in complimenting those responsible for its publication. With a monthly circulation of over 19,000, averaging in excess of 200 pages per issue, carrying articles and news of interest to the profession, it occupies a most prominent part in the publication field.

This year we have resumed publication of *Transactions*, an important service to the profession. Through it we expect to further that aim of the Institute having to do with the dissemination of knowledge among members of the profession. It will fill the need for means of publication of papers by members and others, papers usually of very high standards, but whose subject matter is such as to preclude publication in the *Journal*.

In furtherance of the policy of focusing favourable public attention on the profession, we have published the first of what we hope will become a library of biographies of prominent Canadian engineers. "Daylight Through the Mountain" has been well received, and is a credit to the profession and to the Institute. We are indebted to its author, Dr. Walker.

The Cambie Memorial plaque was unveiled in its permanent place in the Canadian Pacific Railway station in Vancouver, in the presence of a most distinguished gathering, which included a son and two daughters of Henry John Cambie.

We have published, for the first time, "Engineering Careers in Canada". Its distribution among students has been remarkably well received. Its purpose is to attract students to engineering by letting them know of the different branches of engineering open to them and what employers expect of engineers in the respective fields.

No report would be complete, at this particular time without some mention of confederation. To the Branch officers, and whenever the opportunity has offered, to the members of every Branch I have visited, I have talked on the subject. There exists without question, a widespread desire for confederation. Your Council and officers, both elected and appointed, and the Committee appointed by Council to deal with this matter have, and are, in every respect diligently following out the wishes of the membership towards that end. A report from the two committees representing the Canadian Council of Associations of Professional Engineers and your Institute is presently before Council.

Thanks to good management and an alert Finance Committee the financial position of your Institute was never better.

Finally, I would like to make a few observations arising out of my impressions from branch visits.

It is quite evident that closer liaison between branches and between branches and headquarters is needed. As between branches, the extension to other districts of regional meetings such as those held in the Maritimes and the one in Hamilton this year, would bring the branches closer together. Occasional interbranch visits by specifically organized groups could help. Continuation and extension of Regional Council Meetings will similarly promote interbranch communications.

For some time past it has been recognized that communication between branches and headquarters is inadequate. This condition has been improved by the appointment of field secretaries in the East and the West.

The regional meeting of councillors, held in Edmonton in March, is a move in the right direction.

The occasion of the president's visit to branches is, however, the only occasion which offers opportunities for full and frank discussion between representatives from Headquarters and branch officers, and in some cases

(Continued on page 144)

MARITIME PROFESSIONAL ENGINEERS CONFERENCE

September 2 - 5, 1958
Digby Pines, Digby, N. S.

Sponsored by the Branches of the Engineering Institute of Canada in the Atlantic Provinces and the Associations of Professional Engineers of Newfoundland, New Brunswick, Prince Edward Island and Nova Scotia.

Program

Tuesday, September 2.

4.00 p.m. - 9.00 p.m. Registration.

9.00 p.m. - 10.30 p.m. Operation "Nite Cap".

Wednesday, September 3.

8.00 a.m. Operation "Eye Opener".

8.15 a.m. Early Bird Breakfast.

10.00 a.m. Professional Sessions
CANADA'S PROGRESS TOWARD ECONOMIC NUCLEAR POWER, by J. L. Olsen, manager, product planning, civilian atomic power department, Canadian General Electric company, and
THE SHIPPEGAN ISLAND AND CAMPBELLTON BRIDGES, by Dr. T. A. Monti, consultant engineer, Montreal.

11.00 a.m. Ladies' Sherry Party.

12.01 p.m. Maripenco Room.

1.00 p.m. Luncheon.

2.30 p.m. Golf Tournament for men.

3.00 p.m. Ladies: bridge, putting, or shuffleboard.

6.30 p.m. Maripenco Room.

7.30 p.m. Dinner.
ADDRESS by the Honourable R. A. Donahue, Q.C., Attorney General, Nova Scotia.

10.00 p.m. Informal Thrash, featuring "The Continentals".

Thursday, September 4.

10.00 a.m. Professional Sessions,
SUBJECT TO BE ANNOUNCED, J. C. Floyd, vice-president in charge engineering, Avro Aircraft.
INDUSTRIAL APPLICATION OF COMPUTERS, by a member of Computing Devices of Canada.

10.30 a.m. Ladies Shopping Trip to Digby.

12.02 p.m. Maripenco Room.

1.00 p.m. Luncheon.
"OLD INNS OF ENGLAND," an address by J. C. Richardson, Northern Electric Company Limited, Montreal.

3.00 p.m. Don't Miss It.

6.30 p.m. More Maripenco.

7.30 p.m. Dinner.
ADDRESS To be announced.

10.00 p.m. Closing dance, featuring "Don Warner and His Orchestra".

√ HOTEL. All meetings, functions, at The Pines. Rate: $13.00 per day, double, $15.00 per day, single, including meals. All rooms, twin beds and bath. If number persons attending exceeds capacity of hotel, arrangements will be made for outside accommodation. Rates, details, available at registration desk. For further details write: W. T. Windler, chairman, registration committee, Maritime Professional Engineers' Conference, Box 460, Halifax, N.S.

√ DRESS. Informal at all functions.

√ LADIES. Ladies may attend all sessions, technical and other. Special entertainment arranged by Ladies' Committee.

√ FEES. Registration. $7.00 for members, $3.00 for ladies. Includes all costs, including gratuities. Does not cover cost of golf, swimming pool fees, or hotel.

√ TRANSPORTATION. Delegates planning to cross the Bay of Fundy from Saint John to Digby on S.S. Princess Helene should arrange immediate reservations with C.P.R.

Fiftieth Branch Inaugurated

A real milestone was reached when president Anson inaugurated at Chalk River the fiftieth branch of the Institute.

The president and Mrs. Anson, accompanied by the general secretary and Mrs. Wright, were present and the Ottawa Branch was well represented by Hector Chaput, the chairman, and M. V. Morris, the secretary. Ottawa presented a substantial cheque to aid the new branch in its first endeavours. The inauguration of the branch took the form of a dinner followed by a business meeting.

The meeting was opened by C. A. Crawford who was provisional chairman, but who during the course of the evening was elected to the chairmanship of the branch for the year. Also he was appointed councillor to attend the annual meeting of Council to be held in Quebec City.

Lorne Gray, M.E.I.C., newly elected president of Atomic Energy of Canada Limited, was a head table guest.

The balance of the officers elected at that meeting are as follows: J. G. Melvin, C. E. L. Hunt, J. S. Flavelle, and secretary, W. O. Findlay.

The branch has a great potential as far as activities and membership are concerned. It is expected that it will provide an outlet for many engineers around the plant who previously have not had a technical organization to which they could direct their activities.

All in all the occasion was a bright and pleasant one. The president was the official speaker but later the meeting was turned over to questions and observations from the floor. This carried on to a late hour. There was a festive air about the whole gathering, not only because the branch had become an asset to the community but because its inauguration marked a great period in the life of the Institute.

The Institute now starts out on the second half of its first hundred branches.

Did You Know That...

As a member of The Engineering Institute of Canada, you can get the periodical publications of Sister Societies at reduced rates.

Minutes of the 72nd Annual General Meeting

The seventy-second annual meeting of The Engineering Institute of Canada was convened in the Ball Room of the Chateau Frontenac, Quebec City, on Wednesday, May 21, 1958, at ten o'clock a.m. with President C. M. Anson in the chair.

The minutes of the seventy-first annual general meeting as published on pages 1154, 1156 and 1157 of the August 1957 *Journal* were taken as read and approved.

Nominating Committee

The membership of the Nominating Committee of the Institute for the year 1958 is as follows:

Chairman: Frank R. Pope, Peterborough.
Amherst, O. M. Sweetser.
Baie Comeau, Charles Miller.
Belleville, T. J. McQuaid.
Border Cities, C. G. R. Armstrong.
Brockville, J. G. Kerfoot.
Calgary, H. R. Hayes.
Cape Breton, C. N. Murray.
Central British Columbia, H. D. DeBeck.
Corner Brook, T. P. Pumphrey.
Cornwall, G. B. Stidwell.
Eastern Townships, Georges P. Cote.
Edmonton, H. L. Roblin.
Fredericton, H. W. McFarlane.
Halifax, G. Frank Bennett.
Hamilton, L. C. Sentance.
Huronia, S. R. Walkinshaw.
Kingston, D. I. Ourom.
Kitchener, M. A. Montgomery.
Kootenay, T. W. Lazenby.
Lakehead, G. S. Halter.
Lethbridge, C. S. Clendening.
London, Howard L. Hayman.
Lower St. Lawrence, Jean R. Menard.
Moncton, H. S. McCleave.
Montreal, H. Gaudefroy.
Newfoundland, C. A. Knight.
Niagara Peninsula, C. G. Cline.
Nipissing and Upper Ottawa, T. C. MacNabb.
North Eastern Ontario, T. M. Devine.
Northern N.B., V. G. MacWilliam.
North N.S., R. S. Morrow.
North Shore Lower St. Lawrence, Mel Storrier.
Ottawa, R. E. Hayes.
Peterborough, Barry Ottewell.
Port Hope, W. S. Raynor.
Prince Edward Island, H. R. Miller.
Quebec, Gilles Sarault.
Saguenay, F. H. Duffy.
Saint John, F. L. Doty.
St. Maurice Valley, E. R. McMullen.
Sarnia, S. V. Antenbring.
Saskatchewan, Wm. R. Staples.
Sault Ste. Marie, F. H. McKay.
Sudbury, P. E. Semler.
Toronto, W. H. Paterson.
Vancouver, S. S. Lefeaux.
Vancouver Is., T. A. J. Leach.
Winnipeg, T. E. Storey.
Yukon, J. R. B. Jones.

Honorary Memberships

The general secretary reported that the following had been elected to honorary membership in the Institute and that certificates would be presented at the luncheon on Friday, May 23rd.

Armand Charles Crepeau, D.S. (Hon.), Dean of the Faculty of Science, University of Sherbrooke, Sherbrooke, Que.

Sir Claude Dixon Gibb, C.B.E., F.R.S., D.Sc., M.E., Chairman and Managing Director, C. A. Parsons & Co. Ltd., Newcastle-upon-Tyne, England.

Philip Louis Pratley, B.Sc., B.Eng., M.Eng., D.Eng., Structural Engineer, Montreal, Que.

Irving Richard Tait, B.Sc., D.Sc., formerly Chief Engineer, Canadian Industries Limited, Montreal, Quebec.

Earle Oliver Turner, B.Sc., D.Sc., formerly Dean of Engineering, University of New Brunswick, Fredericton, N.B.

Leslie Austin Wright, B.A.Sc., D.Eng., General Secretary, The Engineering Institute of Canada, Montreal, Que.

Awards of Medals and Prizes

The general secretary announced the awards of various Institute prizes as follows stating that the formal presentation would be made at the luncheon on Friday, May 23rd.

On behalf of all the members of the Institute the president congratulated the winners whose names had just been presented.

Julian C. Smith Medals—"For achievement in the development of Canada", to Richard Edgar Heartz, B.Sc., LL.D., M.E.I.C., President and Director, The Shawinigan Engineering Company Limited, Montreal, Que. and Robert Edwards Jamieson, B.Sc., M.Sc., O.B.E., M.E.I.C., formerly Dean of Engineering, McGill University, Montreal, Que.

Robert W. Angus Medal—"For the best paper on a Mechanical Engineering Subject", to Russell J. Kennedy, M.E.I.C., Assistant Professor, Queen's University, Kingston, Ontario, for his paper, "Forces Involved in Pulpwood Holding Grounds".

Duggan Medal and Prize—"For papers dealing with the use of metals for structural and mechanical purposes", to Robert David, M.E.I.C., District Engineer,

(Continued on page 142)

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Dr. I. F. Morrison, retired professor of the faculty of engineering, University of Alberta, who for thirty-five years, commencing with the first graduating class, taught every engineering graduate at the University of Alberta, died at Edmonton on February 27, 1958. He was active in his professional interests to within a few hours of his death.

Born at Braintree, Massachusetts, U.S.A., in 1889, Ibrahim Follansbee Morrison was educated at Boston and studied engineering at the Massachusetts Institute of Technology. In 1911 he was awarded a B.Sc. degree in civil engineering.

Appointed a lecturer in civil engineering on the staff of the University of Alberta in 1912, he became a professor of applied mechanics in the department of civil engineering in 1922. He continued in this position until his retirement from university life in 1954.

During the course of his career he served in World War I in the United States army as an infantryman, and machine gun instructor. He was sent overseas in 1918 where he served in France.

During his academic career he was active in research and in professional practice in his special field of competance.

In recognition of his teaching and professional contributions to the welfare of the province, he was awarded the degree of Doctor of Laws, honoris causa, by the University of Alberta, at the fall convention in 1953.

Lt. Col. George Addie, M.E.I.C., retired soldier, consulting civil engineer and land surveyor died at Quebec City, Que., on May 15, at the age of 89.

George Kyle Addie was born at Sherbrooke, Que., on June 16, 1868. He attended Sherbrooke Academy, Bishops College School, and the Seminaire Nicolet for his general education. In 1889 he graduated from McGill University with a B.Sc. degree and qualified as a Quebec Land Surveyor a short time later. In that year also, he opened a private consulting practice which he carried on until recently.

George Addie joined the 53rd (Sherbrooke) Regiment as a second lieutenant in 1890. He attended the Royal School of Infantry in 1891 at St. Johns, Que., and was soon promoted to the rank of captain and quartermaster. In 1903 he transferred to The Corps of Guides with the rank of major. Moving from Sherbrooke to Quebec in 1906 he was promoted to the rank of lieutenant colonel, and took over the post of divisional intelligence officer, for Military District No. 5. He retired from active service in 1912, receiving the long service decoration. In 1914 on the outbreak of World War I, Lt. Col. Addie returned to active service. He was responsible for the formation of Valcartier Camp and was later assistant transport officer.

Lt. Col. Addie joined the E.I.C. as a Student Member in 1887, transferred to Associate Member in 1898, and to Member in 1935. He attained Life Membership in 1938.

E. V. Gage, M.E.I.C.

Herbert O. Keay, M.E.I.C., retired manager of the research laboratory, Consolidated Paper Corporation Limited, Three Rivers, Que., died at Sudbury, Ont., on May 14, 1958.

Born at Laconia, New Hampshire, U.S.A., on August 15, 1875, he attended the Massachusetts Institute of Technology and graduated with a B.Sc. degree in mechanical engineering in 1900. He served a special apprenticeship during the summer vacations in Boston and Maine, with the Nicholson File Company and the railroad shops. He was an assistant plant engineer with the Pennsylvania Steel Company, Steelton, Pa., from 1900-1902, chief draftsman, motive power department, Boston and Maine railway and later mechanical engineer from 1902 to 1906. Named assistant professor of mechanical engineering at McGill University, Montreal, from 1906, this was followed by the appointment as professor of railway mechanical engineering and transportation in 1908. He retained this office until 1917. Mr. Keay became a consulting engineer with the Laurentide Company Limited in 1913. Three years later he took over the post of manager of the research department, retaining the appointment until 1928. At that time he undertook the responsibility of director of research, Canada Power and Paper Corporation. In 1931 he transferred his services to the firm with which he was associated at the time of his death.

He was an honorary life member, and past chairman of the technical section of the Canadian Pulp and Paper Association.

Mr. Keay joined the Institute as a Member in 1909. He attained Life Membership in 1947.

Dr. Benjamin Franklin C. Haanel, M.E.I.C., former chief of the fuels division of the department of mines and technical surveys, died in Ottawa on April 24, 1958.

Dr. Haanel was born at Cobourg, Ont., on September 2, 1877. He followed studies proceeding to the B.Sc. degree at Syracuse University, graduating in 1899. This was followed by a two-year period of special engineering at the Massachusetts Institute of Technology. Later he worked for the American Bridge Company, New York, the United Engineering and Contracting Company and other structural engineering compaies. In 1905 he moved to Ottawa to accept an appointment with the Department of the Interior and in 1910 was appointed chief of the fuels division, mines branch.

He was awarded the Gzowski Medal of the E.I.C. for a paper written in 1918 on "The Fuels of Canada."

In 1954 Dalhousie University conferred on him an honorary Doctor of Laws degree. Dr. Haanel was a Life Member of the American Institute of Chemical Engineers. He was a member of the Dominion Fuel Board; a member and secretary of the joint peat committee of the Dominion and Ontario governments.

Dr. Haanel joined the Institute as a Member in 1918. He attained Life Membership in 1942.

E. V. Gage, M.E.I.C., president of Byers Construction Company Ltd., and national vice-president of the Canadian Construction Association, 1957-58, died at Montreal on April 27, 1958.

Edward Victor Gage was born at Pearcetown, Que., on November 21, 1893. He received his engineering education at McGill University and graduated in civil engineering with the degree of B.Sc. in 1915.

He joined the firm of A. F. Byers Construction Company Limited later that year and remained with it throughout his lifetime. In 1942 he asumed the presidency of the organization.

In his work with the Canadian Construction Association Mr. Gage was first appointed to the C.C.A. management committee in 1944. He headed up the general contractors' section and had served four terms as chairman of the Standard Practices Committee before becoming national vice-president in January 1957.

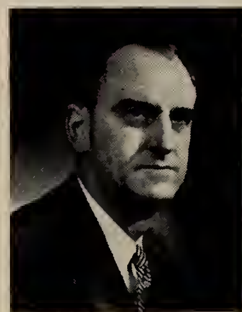
Mr. Gage was active in the affairs of the E.I.C. for a great many years.

Mr. Gage joined the Engineering Institute in 1914 as a Student; transferred to Associate Member in 1919; to Member in 1940. He became a Life Member of the organization in 1955.

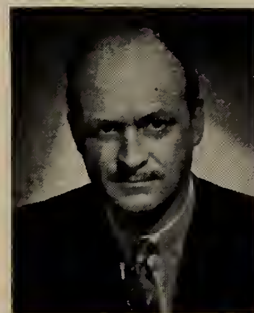
Personals

News of the Personal Activities of Members of the Institute

R. A. Phillips, M.E.I.C.



N. S. Crerar, M.E.I.C.



C. P. Beaubien, M.E.I.C.

J. Herbert Smith, M.E.I.C., (B.Sc., elec., New Brunswick, 1932; M.Sc., New Brunswick, 1942), president of the Canadian General Electric Company Ltd., was awarded an honorary doctorate in science at the convocation exercises of the University of New Brunswick in May. Mr. Smith has maintained an active interest in the affairs of the University during his business career.

E. M. Little, M.E.I.C., (B.A.Sc., elec., Toronto, 1925), president of the Anglo-Canadian Pulp and Paper Mills, Ltd., Quebec, Que., since 1945 has been elected chairman of the board.

I. F. McRae, M.E.I.C., chairman of the board of the Canadian General Electric Company Ltd., was elected president of the Canadian Manufacturers Association for the ensuing year at the annual meeting of the group held at Montreal recently. Mr. McRae is general manager of the civilian atomic power department of C.G.E., in addition to his duties as chairman, in the organization.

J. A. Brusset, M.E.I.C., (National School of Mines, St. Etienne, France, 1921), president of the West Canadian Oil and Gas Ltd., and the Battle River Coal Company has been appointed to the Calgary Advisory Board of the Toronto General Trusts.

A. McDougall, M.E.I.C., (B.Sc., civil, Edinburgh, 1938), has been appointed a director in the firm of Sir William Halcrow and Partners (B.C.) Ltd., at Vancouver. Recently he had had professional association with the British Thomson Houston Company (Canada) Ltd., Vancouver, and with the Canadian British Aluminum Company, Baie Comeau, Que.

T. F. Rahilly, M.E.I.C., (B.Sc., mech., Queen's, 1939), of Hamilton Ont., has been elected to the board of directors of the Bridge and Tank Company of Canada Ltd. Mr. Rahilly is general manager of the Hamilton division of the company and president of two subsidiary companies, the Vulcan-Ford Smith Ltd., and the Ford-Smith Machine Company Ltd.

A. Meade Wright, M.E.I.C., (B.Eng., elec., McGill, 1941), has been appointed vice-president of Dow and Company, Inc., Rochester, N.Y., and president of the Rochester Equipment Distributors, Inc. Mr. Wright joined Foundation Company of Canada in 1945 after service with the R.C.N.V.R. as a lieutenant commander. In 1948 he assumed the post of assistant manager for Atlantic Tug and Equipment Company, Inc., Syracuse, N.Y. He became associated with the firm of Dow and Company, Inc., in 1952, and served as a branch manager of the organization.

Claude P. Beaubien, M.E.I.C., (B.Sc., bus., and engineering admin.), of the Aluminum Company of Canada Limited has been appointed an additional vice-president of the organization. Mr. Beaubien has had twenty-three years of service with Alcan in sales and personnel work in the province of Quebec. He leaves the post of manager of the Montreal district sales office to head the department of engineering.

N. S. Crerar, M.E.I.C., (B.Sc., elec., Manitoba, 1938), general manager of power operations for the Aluminum Company of Canada Ltd., has been appointed an additional vice-president of the organization. He has taken over the direction of Alcan's activities in the field of public relations and advertising. With Alcan since 1939 he has been during the last few years vice-president and general manager of Sagpower and manager of Eastern power operations for Alcan.

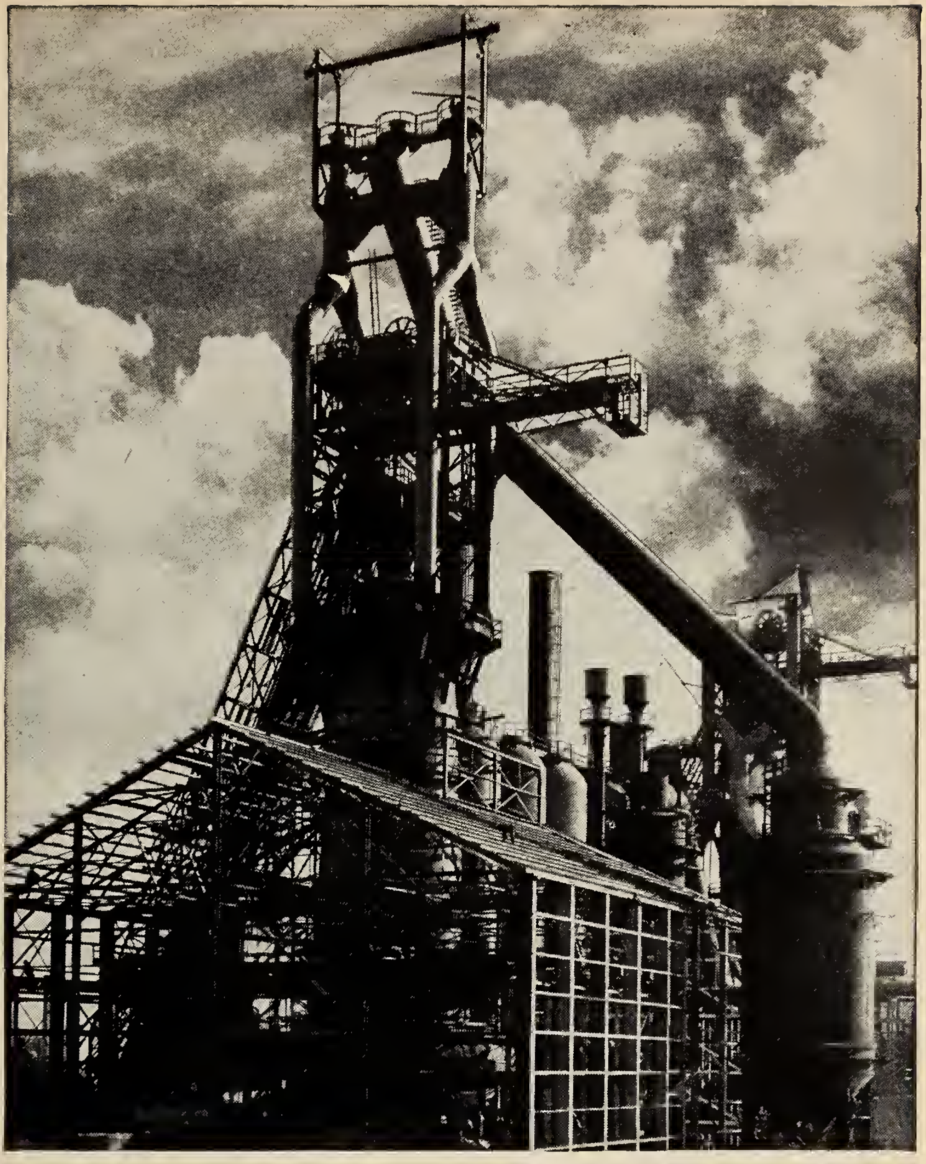
Roy A. Phillips, M.E.I.C. (B.A.Sc., British Columbia, 1939), has taken over the post of manager, marketing, in the Canadian General Electric Company's appliance and television receiver department, at Montreal. Prior to his present appointment he was manager, marketing research and product planning, in the appliance and television receiver department.

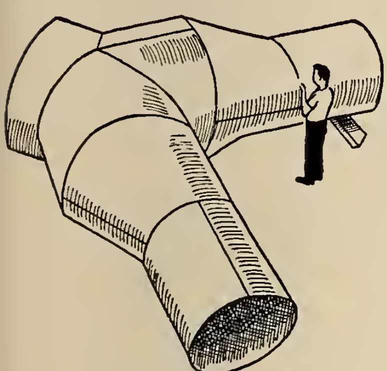
M. P. Whelan, M.E.I.C., (B.Sc., elec., McGill, 1921; M.A. Sc., elec., Toronto, 1922), has been elected to serve the

J. H. Smith, M.E.I.C.

A. M. Wright, M.E.I.C.

M. P. Whelan, M.E.I.C.





• PERSONALS

Toronto Branch of the E.I.C., as one of its councillors for a two-year term, replacing K. F. Tupper, now serving as president of the E.I.C. He has served on the executive committee as well as other committees of the Toronto Branch for a number of years.

Mr. Whelan joined the staff of the Toronto Hydro-Electric System in 1922 and has devoted most of his time to technical sales or administrative work. For several years he was industrial electric heating engineer and at the present time is manager of the demand and rates department. He has served for a number of years on the rates committee of the Association of Municipal Electric Utilities. As a member of the Toronto Board of Trade, he has been active on their advisory engineering and planning committee. Mr. Whelan is also a member of the American Institute of Electrical Engineers and the Canadian Electrical Association.

W. G. Palmer, M.E.I.C., (I.C.S., 1921), of Calgary, formerly vice-president for engineering with the firm of Mannix-Gill Limited, Calgary, has transferred his services to the Canadian Fina Oil Limited, also in that city. His present appointment is that of chief gas engineer.

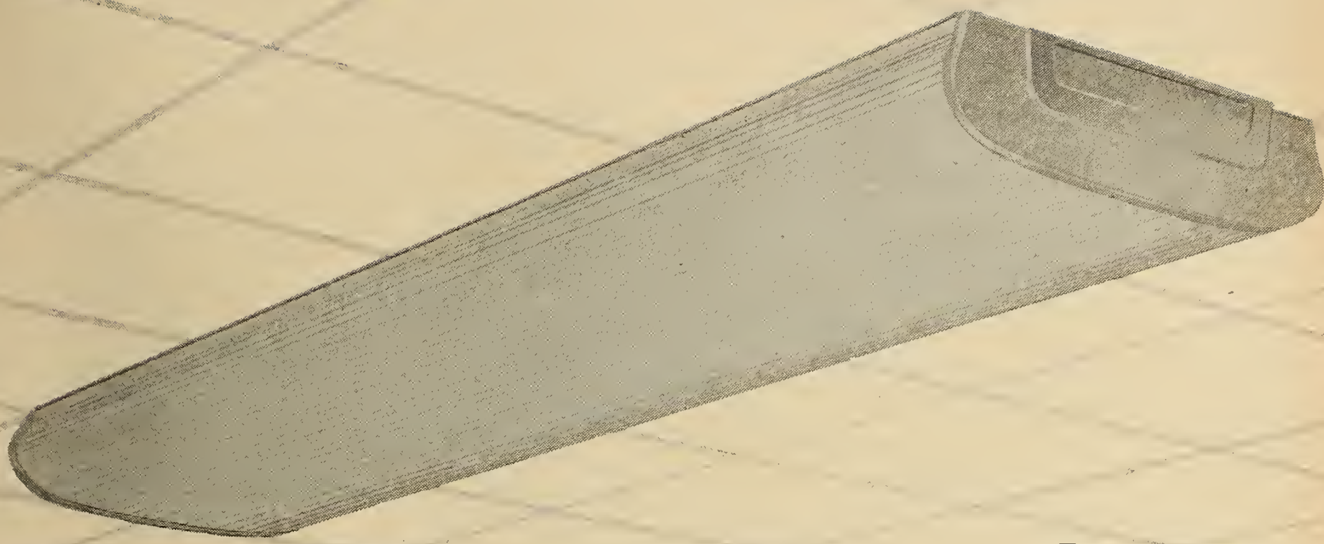
Charles M. Harding, M.E.I.C., (B.Sc., elec., Alberta, 1936), of Seattle, Wash., has for several months held the post of electrical engineer with the Boeing Airplane Company, of Seattle, Wash., Earlier Mr. Harding was associated with H. A. Simons Ltd., Vancouver, Canadian Carborundum Company, at Shawinigan Falls, Que., and the Calgary Power Company.

J. C. Traynor, M.E.I.C., (B.Sc., civil, Sask., 1942), is the newly elected chairman of

J. C. Traynor, M.E.I.C.

the Saskatchewan Branch of the E.I.C. He also serves as president of the Association of Professional Engineers of Saskatchewan. Mr. Traynor is associated with the Department of Transportation, surveys branch.

G. D. Lewis, M.E.I.C., (B.Eng., elec., N.S.T.C., 1942), of Dominion Engineering Works Ltd., Montreal, has been appointed manager of the paper machinery



● PERSONALS

division of the firm. Mr. Lewis transferred to the paper machinery division of the company in 1956 following service as secretary of the firm and was, until his present appointment, employed as manager of contracts.

Fred L. Perry, M.E.I.C. (B.Sc., chem., Queen's, 1942), process superintendent, Imperial Oil Refinery, Calgary, has been named chairman of the Calgary Branch, E.I.C. Mr. Perry has been associated with the manufacturing department of Imperial Oil for the past sixteen years, at

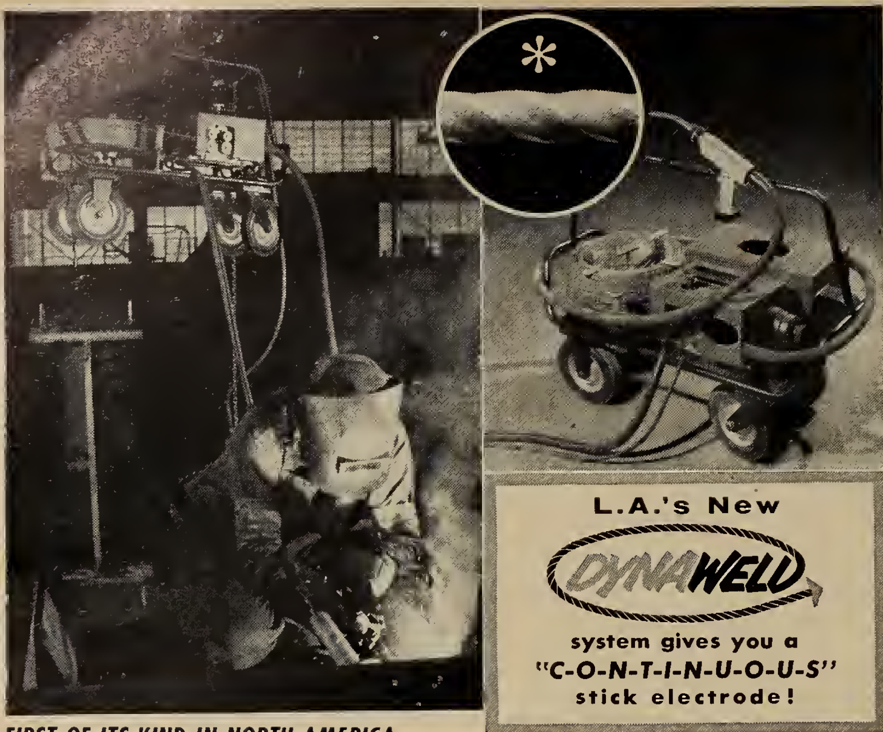
F. L. Perry, M.E.I.C.

the Halifax refinery, and as technical superintendent at Calgary, before taking over his present duties. He has shown interest in professional development programming and in various annual meeting and local technical program activities.

L. MacC. Allison, M.E.I.C., (Dalhousie, 1911), of Armdale, N.S., for many years associated with the Department of Public Works of Canada, has retired. Mr. Allison began his career with the Department of Railways and Canals on railway construction. At about this time he took part in preliminary surveys carried out in connection with the development of the St. Lawrence River. During World War I he served with the 25th battalion Canadian Expeditionary Force. He gained experience on highway construction, as resident engineer for the Department of Highways, for the province of Nova Scotia in the early nineteen twenties. In 1924 he took on the work of junior engineer, Public Works, at Halifax. In this service he was engaged in harbour and river construction and maintenance. He remained in this work until the time of his retirement as assistant to the district engineer in 1957.

R. N. Coke, M.E.I.C., (B.Sc., elec., McGill, 1914), chief engineer for the metropolitan operation division of the Quebec Hydro-Electric Commission has retired. He continues to be associated with the organization as a consulting engineer.

Following service in World War I and early experience with a number of electrical and power companies Mr. Coke joined the staff of the Montreal Light, Heat and Power Consolidated as assistant general superintendent in 1929. In due course the firm became known as



FIRST OF ITS KIND IN NORTH AMERICA ...

*New Dynoweld precision-twisted, cooted filler wire, mognified to double size.

Features High Production Semi-Automatic Welding

Metal fabricators have looked for a mild steel welding system as simple to use as stick electrodes, but without the disadvantages of low duty cycle, stub waste, etc. The new L.A. Dynaweld continuous arc welding system completely fills that need. Designed and developed by Canadian Liquid Air Research and Engineering teams, the new process has just been released after more than a year of extensive field tests under practical conditions in several major industries in Canada.

Among its many advantages is the substantial increase in productivity when the system is properly used on suitable applications. This results from the high duty cycle and the higher-than-usual current rates used, with consequent greater deposition of weld metal. Simple to use, the L.A. Dynaweld process is *completely independent of water cooling or gas shielding.*

Basically, the heart of the Dynaweld system is a precision-twisted coated filler wire which is essentially a "*continuous*" *coated mild steel stick electrode.* The wire is drawn off its power-driven supply reel at predetermined speeds through associated equipment and fed through a specially designed pistol-type electrode holder. Welding current is supplied from any standard AC or DC welder, the latter being preferred.

No complex mechanical or electronic apparatus is involved in the Dynaweld system, nor is any auxiliary apparatus (other than the source of welding current) required in its operation. Extremely portable and flexible in use, the ruggedly built machine has few moving parts and maintenance is negligible.

The L.A. Dynaweld system is highly recommended for production mild steel welding operations where presently large quantities of conventional or iron powder stick electrodes are being used. Metallurgically, weld deposits from Dynaweld wire are comparable in every way to those from standard mild steel stick electrodes in the AWS E 6012, E 6024, and E 6020 classifications.

For further information about the new L.A. Dynaweld system, contact your local Branch office of Canadian Liquid Air Company Limited, where arrangements can be made for a practical study of your plant's welding applications to determine the suitability of this process for your operations.

Canadian LIQUID AIR Company
LIMITED
Branches, plants, stores and dealers from coast to coast.

• PERSONALS

the Quebec Hydro. He was appointed vice-chief engineer, and general superintendent in 1934, and promoted to chief engineer, operating division, Montreal, a few years later.

P. V. Palmer, M.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1945), chief engineer with the Howard Smith Paper Mills Limited, Montreal, now serves the firm at Cornwall, Ont. The central engineering department, previously located at Montreal, was moved to the Cornwall division of the company in May.

K. K. Hyde, M.E.I.C., (Kingston Tech. Coll., Surrey, England, 1952), who has been following his career in Malaya for some time, has taken over the post of resident engineer with Messrs. Keith Edmunds and Associates for Sungala Camp, Port Dickson, Malaya. Last year Mr. Hyde was an assistant engineer with the Federation of Malaya drainage and irrigation department.

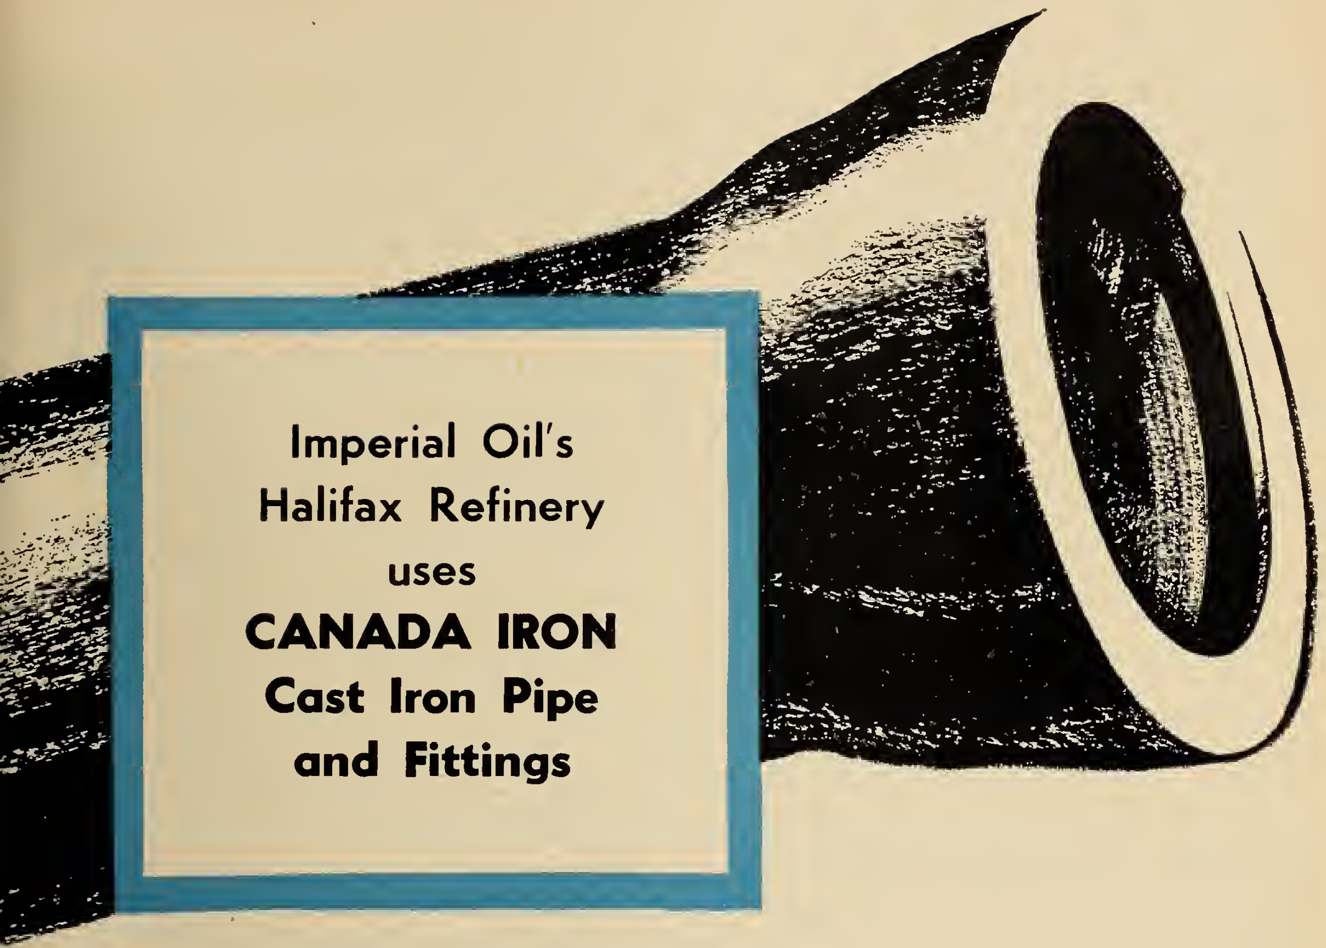
T. A. Jull, M.E.I.C., (B.A.Sc., mech., Toronto, 1943), has been named vice-president, sales, with Eastern Steel Products Ltd. Mr. Jull held executive sales posts of a technical and engineering nature with the John Inglis Company Ltd., Montreal, and other major Canadian companies prior to joining Eastern Steel.

J. W. Forster, M.E.I.C., (B.Sc., civil, Alberta, 1944; M.Sc., hydrology, Iowa State, 1947), is superintendent of hydraulic and power studies with the Aluminum Company of Canada Ltd., of Kitimat, B.C.,

G. E. Baldwin, M.E.I.C., (B.Sc., civil, Sask., 1955), has transferred from Saskatoon to Swift Current, Sask., as division engineer with the Department of Highways and Transportation. Last year Mr. Baldwin worked as a project engineer with the construction branch of the department.

W. A. Pangborn, JR.E.I.C., (B.Eng., civil, McGill, 1953), of the Three Rivers, Que., firm of John F. Wickenden Company Ltd., was chosen to represent the province of Quebec and Eastern Ontario at the zonal contest of the Toastmasters' International in Boston this month.

John A. Maguire, JR.E.I.C. has recently completed a fifteen-month training program in the production engineering department at Pratt and Whitney aircraft division of United Aircraft Corporation, East Hartford, Connecticut, U.S.A. He has returned to Canadian Pratt and Whitney Aircraft Company Limited, Longueuil, Que., where he will work in the production engineering department.



Imperial Oil's Halifax Refinery uses CANADA IRON Cast Iron Pipe and Fittings

For its new refinery at Halifax, Imperial Oil Limited chose Canada Iron cast iron pipe and fittings for its underground water distribution services, and Canada Iron cement--lined cast iron pipe and fittings for its underground drainage system.

These extensive systems are just two of many hundreds of specialized systems throughout the nation for which Canada Iron has supplied reliable, long-lasting cast iron pipe. For any water or gas distribution project, count on Canada Iron's experience and service.

Information received through co-operation of the provincial organizations.

BRITISH COLUMBIA

Is It Ethical?

(Taken from the B.C. Professional Engineer bulletin of the British Columbia Association of Professional Engineers, May issue.)

A discussion on ethics is presently being carried in the B.C. Professional Engineer in the form of questions and answers.

The questions are taken from those submitted to a panel discussion meeting held in January, the answers being reviewed by the Ethics Committee.

Question 3. Is it ethical for a consulting engineer to accept a manufacturer's commission on certain specific types of machinery to the exclusion of competitive equipment?

Answer: The Code of Ethics is quite explicit on this in Section III (9). This reads as follows: "He will not receive, directly or indirectly, any royalty, gratuity, or commission on any patented or protected article or process used in work upon which he is retained by his client, unless and until receipt of such royalty, gratuity or commission has been authorized in writing by his client."

It is covered again by Section III (7) which reads as follows: "He will inform his clients of any business connections, interest or circumstances, which may be deemed as influencing his judgement or the quality of his services to his clients." If a consulting engineer, therefore, acts also as a manufacturer's agent for certain types of equipment, he should at the outset, when retained by a client, advise that client in writing that he is the agent for that equipment.

Question 4. Would you comment on the responsibility of the employed engineer to the public in regard to unethical stock promotion by his employers?

Answer: Again we should refer to the Code of Ethics, namely Section I (4), which reads as follows: "He will not associate himself with, or allow the use of his name by, an enterprise of doubtful character." I do not believe there is any question about his action in such a case, whether as an employed engineer or as a consulting engineer. If the former, he should resign and if the latter, he should advise his clients that he does not wish to carry on with his commission. In doing so, he should, of course, advise his clients or employers in writing of his reason for his action. Whether he should make a public statement as to these reasons is another question, of course, and much would depend upon the circumstances surrounding the case.

Taken at the E.I.C. annual meeting, Quebec, this photo shows Members of the C.P.E.Q. reviewed plans for the fifth annual provincial golf tournament at Grand' Mere, Que., June 21. L to r., seated, C. G. Cook, P.Eng., F. A. Patterson, P.Eng., L. G. Boivin, P.Eng., committee chairman, W. J. Riley, P.Eng., vice-pres., C.P.E.Q. Back; J. P. Woods, P.Eng., P. Vincent, P.Eng.

ONTARIO

Canadian Council Annual Meeting

(Taken from "The Professional Engineer, Journal of the Association of Professional Engineers of the Province of Ontario.)

Early in May official representatives of the provincial registering bodies of professional engineers met in Vancouver, B.C., for the 21st annual meeting of Canadian Council of Professional Engineers. If a co-operative spirit of approach to the solution of problems of mutual concern is any indication, the meeting should certainly be regarded as highly successful.

Foremost in interest were the proposals regarding Confederation presented by the joint committee of Canadian Council and the E.I.C. The recommendations of the joint committee to proceed toward the formation of a new national body were approved unanimously by the Council but subject, of course, to the approval of each member Association.

The licencing of foreign engineers to permit them to temporarily undertake professional engineering in Canada also was a topic which affected most Associations. There was complete agreement that there is no readymade solution to the problem but there was also agreement with the policy that where competent Canadian engineers are available, these engineers should be employed or retained rather than call upon engineers from outside of the country.

With an agenda of over forty items of general business, space does not permit of more than the naming of a few—the move towards uniform or standardized registration by all associations: the creation of a code of ethics which could be adopted by all member bodies: the syllabus of examinations, now employed by all Associations; the annual Canadian Council Survey of Salaries and a new form of salary schedule; professional pay for members of the armed services; civil defence; counselling of students as to the engineering profession; the accreditation of engineering courses in universities; progress in the certification of engineering technicians; abuse of the word "engineer," or "engineering," in corporate names. These were but a few of the topics discussed and which action was taken during the three-day sessions.

what Tod should know

about TOBACCO

Jenkins Gate Valves on the dryers at the Aylmer, Ont., Plant, Imperial Leaf Tobacco Company of Canada Limited. Dryers reduce moisture content of tobacco prior to storage.

When tobacco was first introduced to Europe in the 16th century, miraculous healing powers were attributed to it. However, like Tod and millions of modern smokers, they soon discovered tobacco offers no panacea but plenty of enjoyment. To bring cigar, cigarette and pipe smokers a variety of top-quality brands, Canadian manufacturers employ a staff of specialists — men who know the secret of selecting and processing fine tobacco. Jenkins employs a team of experts, too — men who set a high standard for materials and workmanship on valves bearing the famous "Diamond" trade mark, found on the production lines of major tobacco manufacturers.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings

BAIE COMEAU

Norman Lapierre, JR.E.I.C., *Sec.-Treas.*

George W. Scott, M.E.I.C., *Branch News Reporter*

THE ALUMINUM INDUSTRY throughout the world, was the subject of the greater part of a talk delivered to the Baie Comeau Branch toward the close of the spring season. More than fifty persons turned out to hear W. J. Thomas, managing director of the British Aluminum Company Limited and vice-president of the Canadian British Aluminum Company. Mr. Thomas traced the history of the industry throughout the world and its development and expansion up to the present day. The various factors affecting its growth and economy were discussed, and some reference was made to possible future developments.

The remaining part of the address covered the activities of the British Aluminum Company of which the new smelter at Baie Comeau is now an operating subsidiary, under the Canadian British Aluminum Company.

Film Evening

A film evening on May 14 featured two construction films which were well received by the members. They were "Blasting a New Niagara," and "The Dounreay Sphere."

Resolution on Confederation

At a general meeting of the E.I.C. held on May 14, 1958, in Baie Comeau, Que., it was agreed that the following resolution, voicing the opinion of the members of this Branch regarding Confederation, be presented to the Council of the Engineering Institute of Canada.

1. Whereas, it is desirable that a national body be representative of the whole engineering profession throughout Canada.
2. Whereas, it is desirable that the requirements for the practice of the engineering profession be uniform throughout the country.
3. Whereas, it is desirable that registration in a national body permits the practice of the profession throughout the land.

Whereas, it is desirable that one fee covers registration at provincial and national levels.

Therefore it is resolved that the members of the Baie Comeau Branch of the E.I.C. support and second the work of the Council of the Engineering Institute of Canada towards the forming of a national body representing the engineering profession throughout Canada.

BELLEVILLE

F. E. Moore, M.E.I.C., *Sec.-Treas.*

T. E. Flinn, M.E.I.C., *Branch News Reporter*

TWO GUEST SPEAKERS described the growth of the plywood industry in Canada and industrial research and uses, at a talk given May 13, 1958. They were Evan L. Fowler, Eastern field supervisor, Plywood Manufacturers' Association of British Columbia, and Robert Armstrong, field supervisor of the organization for Central and Northern Ontario. It was pointed out in the course of the talk that Canada, on a per capita basis is the greatest user of fir plywood. A film entitled, "The Plywood Story" was shown.

N. Throop introduced the speakers. They were thanked by W. Benger.

A.P.E.O. Report by E. Pugh

E. Pugh presented a report on the proceedings of a recent council meeting of the Association of Professional Engineers of Ontario at Toronto which he attended as an observer. Confederation was one of the subjects discussed. Members of the A.P.E.O. of the Belleville area who were not members of the Branch received a special invitation to attend the meeting in order that they might hear Mr. Pugh's report.

HALIFAX

J. E. Reardon, M.E.I.C., *Sec.-Treas.*

THE ALASKA HIGHWAY and the collapse of the Peace River Bridge was the matter brought to the attention of the Branch April 16, when Lt. Col. M. C. Sutherland-Brown addressed the meeting.

Lt. Col. Sutherland-Brown is the assistant-quarter-master general, at headquarters, Eastern Command, Halifax. Formerly senior highway engineer with the Northwest Highway System in the Northwest Territories, he discussed the work in this area in general terms. In the second part of his talk he related events leading up to the collapse of the Peace River Bridge, and data correlated from the investigation of the collapse of this structure.

A tour of the National Research Laboratory at Halifax was enjoyed by the Branch on May 13. A tour and inspection of the Royal Canadian Naval Air Station, H.M.C.S., Shearwater, was slated for June 21.

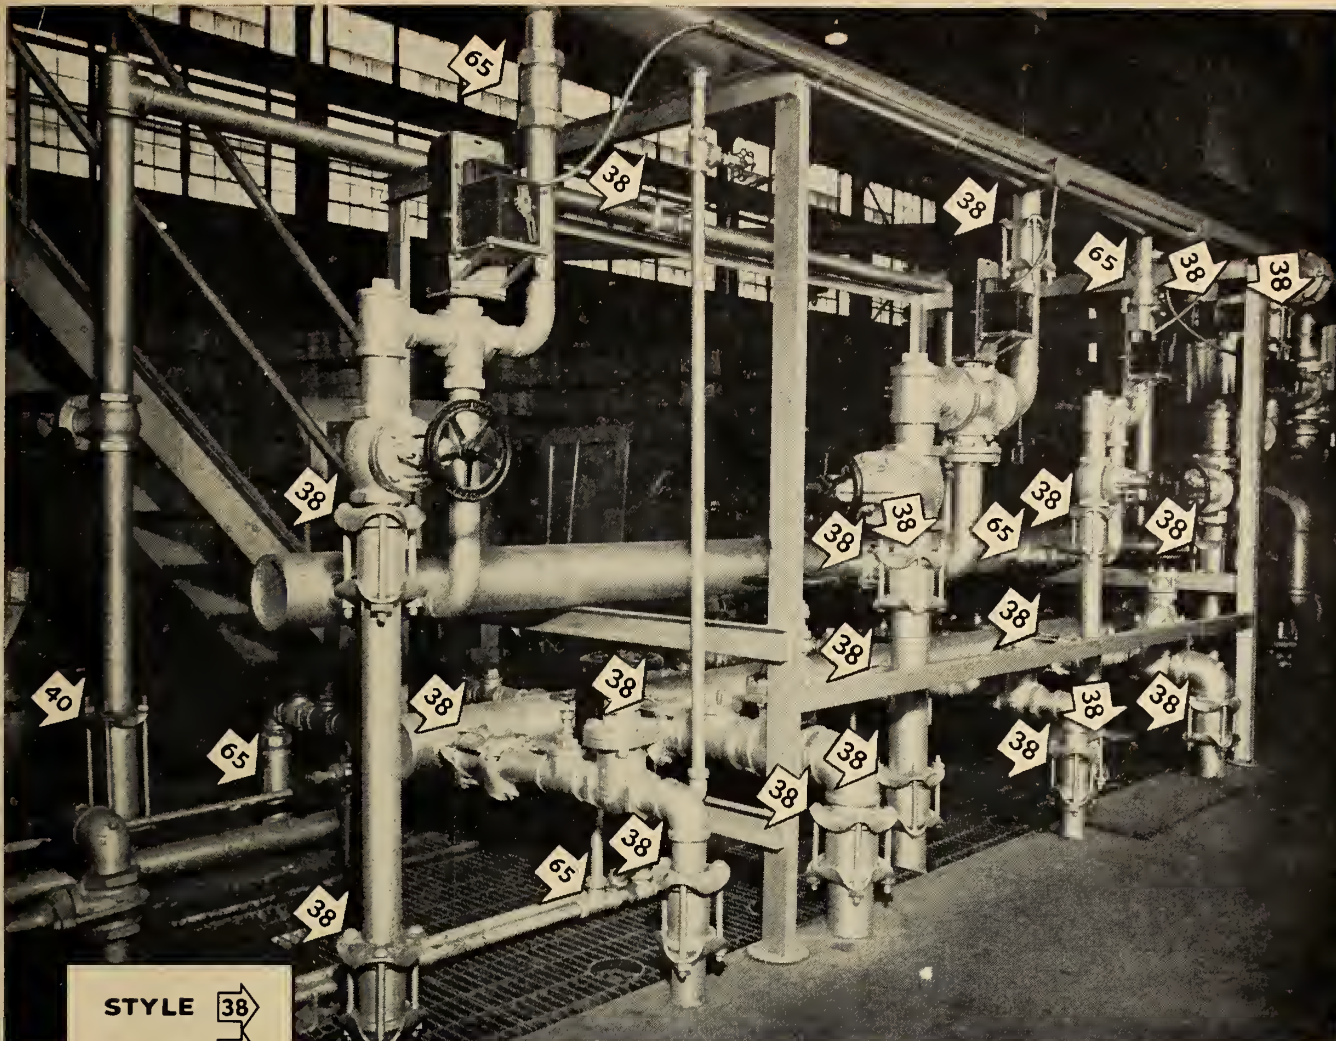
LONDON

W. C. Sinkins, JR.E.I.C., *Sec.-Treas.*

J. Wartena, M.E.I.C., *Branch News Editor*

NEW CONSTRUCTION at Wolseley Barracks, London, Ont., was discussed by Major D. C. MacMillan, camp engineer, at a May 20 meeting of the Branch. The talk was preceded by a visit to the new

The department of engineering science, University of Western Ontario, has completed a four-year engineering science curriculum. Graduates are: (back, l. to r.), J. G. McLarty, J. B. Robinson, R. F. Hunt, L. H. McGill, J. M. Trenouth, J. S. Bedggood, K. P. Bellis, H. H. Keys, R. C. Robotham, T. B. Collings, R. L. Judd, and R. E. Durnin.



STYLE 38
STYLE 40
STYLE 65

This picture shows you
26 Ways to Save Time, Labor and Money!

Every Dresser Coupling and Compression Fitting is a way to save money — no threading, no exact pipe fitting, no welding, no grooving, no caulking. (And there are 26 of these money savers in this piping setup alone.)

Take those five Style 65 Dresser Compression Fittings, for instance. You simply stab *plain pipe ends* into the fittings and tighten the end nuts. Time: about 30 seconds per joint!

Or take the twenty Style 38 Dresser Couplings (and one Style 40). They're wrench-installed in only two man-minutes per bolt!

For a full range of sizes and shapes . . . save time, save money . . . see your nearest piping supplier.

Dresser Manufacturing Company, Ltd. 21 Coronet Road, Toronto 18, Ontario; 1220 11th Ave. W., Calgary, Alberta.

MANUFACTURING CO., LTD.

ONE OF THE DRESSER INDUSTRIES

buildings. Thirty members of the E.I.C. heard Major MacMillan outline the way in which military camps in Canada are composed of standard buildings, modified to site conditions by local consultants. The duties of a camp engineer and of the R.C.E.M.E. were also summarized.

The improved layout and facilities of the camp impressed members who saw a mess with a seating capacity of five-hundred, a drill hall, administration building, barracks block, central heating plant, physical training centre, chapel, officers' mess and a swimming pool of particularly modern design.

OTTAWA

W. V. Morris, M.E.I.C., *Secretary*

A. H. Graves, S.E.I.C., *Publicity Chairman*

MAJOR CITY PROJECTS were reviewed by F. E. Ayers, director of planning and works, City of Ottawa, before an attendance of seventy-five, at a Thursday luncheon meeting of the Branch, April 17.

Mr. Ayers predicted that a giant thruway system would be "real" within months, as major improvements in roadway facilities were effected. These would include Queensway Limited Access Highway, Carling Avenue, Bronson Canal Bridge and other major projects scheduled for the immediate future.

He predicted among other things, that when the eastern approaches to the $31,000,000 limited access Queensway are completed next year it will be possible for incoming traffic to travel non-stop directly into Nicholas Street and on to the heart of the city.

Rockets and Satellites

At a joint meeting with the A.I.E.E., the Ottawa Branch, on May 1, heard Gordon D. Watson, director of weapons research, Defence Board, in a lecture on "Rockets, Earth Satellites and Space Travel." Mr. Watson is responsible for the co-ordination and planning of the Canadian research program in the weapons field. His illustrated lecture provided up-to-date information about rockets and earth satellites, which are forerunners of the space travel age.

It is hoped that the lecture will be published in abstract form in an early issue of the Journal.

Colombo Plan Talk

John P. Sterling, chief engineer, Defence Construction, 1951 Ltd., addressed the Thursday luncheon meeting of the Branch on "The Colombo Plan – Canadian Engineers Look Eastward," at a May 15 meeting.

Defence Construction 1951 Ltd., is technical adviser and contracting authority for the Colombo Plan Administration, Department of Trade and Commerce. Mr. Stirling, who has recently returned from an inspection trip to construction pro-

jects in India and Pakistan, spoke on the engineering features and construction methods of various projects. Coloured slides accompanied the talk.

MONTREAL

G. M. Boissonneault, Jr.E.I.C.
Sec.-Treas.

J. D. DENOVAN, Jr.E.I.C.
President Publicity Committee

THE CIVIL SECTION of the Montreal Branch, at a special meeting on April 23 heard Fred N. Severud, of Severud, Elstad and Krueger, Associates, consulting engineers of New York, in a talk on the developments in the field of hung structures.

Chairman of the meeting was Dr. P. L. Pratley.

Mr. Severud, one of America's foremost structural engineers, and author of several books (co-author of "The Bomb, Survival and You.") is the designer of many of the world's most impressive and advanced structures and presently consulting engineer on the Ville-Marie Plaza development in Montreal. Invited to attend the meeting also were members of the Province of Quebec Association of Architects.

SAULT STE. MARIE

R. L. Wimperis, Jr.E.I.C., *Sec.-Treas.*

A GUIDED TOUR of the Mannesmann Tube Company plant in Sault Ste. Marie was held on May 2, 1958, replacing the usual formal dinner meeting of the Branch. The tour was a follow-up of a talk given January 1957, by E. A. Gilmore, general superintendent of the mill. (See March 1957 issue of the Journal, p. 346). Production of seamless tubes, primarily for oil-well consumption and for the transmission of overland oil and gas began in 1957.

The mill was shown in order of production and was briefly as follows: No. 1 piercer where the first hole is pierced in the white hot tube round; No. 2 piercer where the hole is enlarged and the round is lengthened; plug mill, where the inside and outside diameters are roughly formed; reeler, where the outside diameter is exactly formed; sizing mill, where the exact outside diameter is formed; cooling beds; tube straightening; x-ray inspection; coupling screw-on machine; 13,000 p.s.i. hydrostatic tester; coating tube with rust preventative.

The mill also produces the tube couplings. It is the most modern seamless tube mill in the world and almost all operations are automatically operated.

TORONTO

D. S. Moyer, M.E.I.C., *Sec.-Treas.*
Gordon F. R. Norton, Jr.E.I.C.,
Branch News Reporter

THE COST OF HOUSING was reviewed by R. F. Legget, director of the National Research Council, division of building research, Ottawa, on April 10, 1958.

Mr. Legget opened his remarks by extending warm greetings from the Ottawa Branch to the Toronto Branch. He discussed the costs involved in housing under the headings of capital cost, and systematically followed the steps involved in assessing each of these. A comparison was made between the cost of buying a home as opposed to renting, and from the figures used, it was shown that there is little difference, except that the home buyer does have an equity in the building as the mortgage is paid off. Mr. Legget suggested some possibilities for reducing housing costs as: smaller houses, greater concentration of units (to reduce transportation and facilities), technical improvements, and an increase in the period of amortization.

The Joint Area Committee held a panel on civil engineering on April 3, 1958 at the University of Toronto. D. D. Whitson acted as moderator. D. F. Morrison answered questions on structural problems; Dr. A. E. Berry, municipal questions; D. G. Huber, the hydraulic queries; W. L. Sagar, soil mechanics; and A. M. Toye, highways and bridges.

METHODS USED IN RUSSIA as opposed to those used in the Western world were discussed from an engineering point of view when P. E. Cavanagh, of the Ontario Research Foundation addressed the Toronto Branch, April 24, on "The Iron and Steel Industry in Russia."

Recently returned from that country, he noted the lack of understanding between both groups.

Mr. Cavanagh was shown production records, and by cross-checking determined that these records were very accurate. The Russians did not object to questions on politics and showed a willingness to meet other engineers to discuss engineering ideas.

He said that Canadian technical bulletins are distributed almost as soon as they are received. It was found that they would be pleased to make their information available if requested.

Russians and Canadian industry is developing at about the same rate. Industry in Western Russia is reasonably well advanced and organized, but the Eastern part of Russia leaves much to be desired and is badly disorganized.

Mr. Cavanagh found the Russians to be good engineers and very progressive, and paid about ten times the figure for ordinary workers. Professors are the most highly paid persons.

Guests at the meeting were the officials of two British societies T. E. Goldup, president and W. K. Braker, secretary, Institution of Electrical Engineers; and Brian Robbins, secretary, Institution of Mechanical Engineers.

News of Other Societies

Chemical Institute of Canada Annual Meeting

The forty-first annual conference and exhibition of the Chemical Institute of Canada, held at the Royal York Hotel, Toronto, May 26 -28, 1958 drew an attendance of 1300.

Elected president of the organization was C. E. Carson of Toronto, president of Imperial Oil Limited, replacing Osman J. Walker, retiring president.

E. Gordon Young, director, Atlantic Regional Laboratory, National Research Council, Halifax, was named vice-president. Twelve councillors elected during the proceedings were: W. A. Rabb, Shawinigan, Que., D. H. Andrews, McMasterville, Que., L. V. Clegg, Montreal, Que., R. U. Lemieux, Ottawa, D. G. Ritchie, Toronto, L. J. Rubin, Toronto, T. H. Evans, Guelph, Ont., A. M. Kristjanson, Regina, Sask., W. A. E. McBryde, Toronto, J. A. McCoubrey, Toronto, J. Y. Harcourt, Ottawa, and T. L. Davies, Sarnia, Ont. They will serve with other officers whose terms of office continue.

Twenty-two prominent chemists and chemical engineers were elected Fellows of the C.I.C.

More than 150 technical papers were presented at the two-day meeting. They were given at sessions arranged by Divisions of the Institute concerned with the subjects of agricultural chemistry, chemical education, chemical engineering, biochemistry, organic chemistry, physical chemistry, analytical chemistry, protective coatings, inorganic chemistry, rubber chemistry, chemical economics, etc. Several were joint subject division sessions.

Sixteen chemists and chemical engineers from the United States, and England were among those reporting to the meeting on advances in research or development.

Dr. Carl A. Walker of McGill University was awarded the C.I.C. Medal (1958), in recognition of his outstanding contribution to chemistry. The Medal, made of that rare metal, palladium, is provided by the International Nickel Company of Canada Limited. In a special address on this occasion, Dr. Winkler discussed the subject, "Active Nitrogen". He explained that when nitrogen is passed through a suitable electrical discharge a very active form of nitrogen is obtained with which most ordinary substances will react readily, often with beautifully coloured flames. Many of these reactions have been systematically studied at McGill during the past ten years. Dr. Winkler discussed some of them in a relatively non-technical way. The nature of the nitrogen species responsible for the reactivity of active nitrogen was also discussed briefly.

Dr. H. G. Khorana, B.C. Research Council, Vancouver, presented the Merck Lecture on the subject, "Recent Progress in the Synthesis and Structural Analysis of Polynucleotides," sponsored by Merck and Company Limited. Dr. Khorana pointed out that structural analysis of polynucleotides depends greatly on the use of enzymes as tools. A discussion of chemical synthesis was followed by a review of the enzymic studies carried out in the author's laboratory which have elucidated the mode of action of the snake venom and spleen phospodiesterases on polynucleotide chains. These studies have provided promising methods, he said, for the end group determination and stepwise degradation of polynucleotides.

The Montreal Medal was awarded to T. W. Smith, Montreal, formerly associated with Canadian Industries Limited, in recognition of significant leadership in the profession of chemistry or chemical engineering in Canada.

Groups of delegates availed themselves of plant visits to the British American Oil Company Limited, Clarkson Refinery, Dunlop Canada Limited, Whitby, Ont., the Steel Company of Canada Limited, Hamilton, Ont., and the Canadian Packers Limited, Toronto. There was also a demonstration of the sub-critical reactor now installed in the Walberg Building of the University of Toronto.

Several panel discussions were provided for subjects of urgent interest. The subjects were: High School, University and Industry, What Each Expects of the Other in Chemical Education; Promotional Methods in Canadian Chemical Selling, and Techniques.

The physical chemistry subject division invited two guests to present papers. They were Professor A. Sehoh, of McGill University who spoke on "Bond Dissociation Energies," and Dr. C. A. McDowell, U.B.C., on, "The Paramagnetic Resonances of Free Radical", Dr. Paul E. Gagnon of Laval University, Que., was guest speaker at luncheon on May 26, his subject being "The Old Chemist", L. T. Rosser, Mansfield Rubber (Canada) Limited, spoke at luncheon on May 28, on the subject of "Economics in the Canadian Rubber Industry".

His Worship Mayor Nathan Phillips, Q.C., graciously and officially opened the conference and the exhibition.

The exhibition consisted of the latest developments in laboratory and chemical process equipment, scientific instruments, chemicals, and technical literature. Fifty-five manufacturers and distributors took part in the display.

Calendar

I.R.E.–A.I.E.E.
Electrical and Radio Standards Conference, Boulder, Colorado, Aug. 13-15, 1958.

Illuminating Engineering Society
National Technical Conference of the Illuminating Engineering Society, Royal York Hotel, Toronto, Aug. 17-21, 1958. Write: R. W. Sclater, Public Relations, 280 Lakeshore Rd., Toronto 14, Ont.

A.I.C.E.–A.S.M.E.
Heat Transfer Conference, Evanston, Ill., Aug. 18-21, 1958

Ninth International Astronomical Congress, Amsterdam, Netherlands, Aug. 25-31, 1958.

British Association for the Advancement of Science, 120th Annual Meeting, Glasgow, Scotland, Aug. 27-Sept. 3, 19558.

A.M.S.–A.S.C.E.
Second National Conference on Applied Meteorology; Engineering, sponsored by the American Meteorological Society and the American Society of Civil Engineers, at University of Michigan, Sept. 9-11, 1958. Write: University of Michigan News Service, 3564 Admin. Bldg., Ann Arbor, Michigan.

Canadian Construction Association
Summer Regional Meeting, Delaware, Inn, Honey Harbour, Georgian Bay, Ont., Sept. 6-9, 1958. Write: C.C.A., Construction House, 151 O'Connor St., Ottawa 4, Ont.

Institute of Aeronautical Sciences
First International Congress of the Aeronautical Sciences, Palace Hotel, Madrid, Spain, Sept. 8-13, 1958. Write: Inst. of Aeronautical Sciences, 2, East 64th St., New York, 21, N.Y.

The Textile Technical Federation of Canada
Sixth Canadian Textile Seminar, Queen's University, Kingston, Ont., Sept. 11-12, 1958. Write: 223 Victoria Ave., Westmount, Que.

Societe des Radioelectriciens
International symposium on nuclear electronics organized by the Societe des Radioelectriciens, sponsored by the Commissariat a l'Energie Atomique and International Union for Pure and Applied Physics, UNESCO House, 2, Place de Fontenoy, Paris, (7); Sept. 16-20, 1958.

LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

AIR POLLUTION

This volume is based on lectures given at a course on air pollution held by Sheffield University in 1956.

The first three papers define the problem, and cover the characteristics of solid and gaseous pollutants, the measurement of air pollution and instruments for measuring smoke in chimneys. The next two chapters consider the effects of air pollution on health, vegetation, buildings and metalwork.

A discussion of the geographical factors affecting pollution, and the flow of chimney gas is followed by several papers on methods to be adopted in the elimination of pollution from domestic heating, vehicle exhaust fumes, industrial boilers, the iron and steel industry, refractories, ceramics and cement manufacture. There is also a chapter on selection of equipment for air cleaning.

Two final chapters discuss air pollution legislation, and the British Clean Air Act.

Although much of the information given in the book applies to England, it will prove of interest to all those concerned with the elimination of this serious menace. (Ed. by M. W. Thring. Toronto, Butterworth, 1957. 248p., $8.50.

ANNUAIRE DE L'EQUIPMENT DES INDUSTRIES MECANIQUES, 1957-58

The first part of this Directory comprises an alphabetical list of manufacturers and importers giving for each the address, trademarks, agents in France and abroad, and equipment manufactured indicated by symbols, keyed to section 2.

The second section is a classified list of equipment manufactured.

The three Appendices list trade-names and trade-marks, foreign manufacturers and their French agents, and an alphabetical list in French of the equipment listed in Section 2.

This is a useful directory for any firm interested in machinery, etc., and trade with France. (Ed. by M. Coyaud. Paris, Dunod, 1957. various paging, 1200 fr.)

*BASIC FEEDBACK CONTROL SYSTEM DESIGN

Servomechanism theory and design is presented from a fundamental point of view by means of practical examples. The approach utilized is based on a combination of the root-locus and frequency-analysis method, and while emphasis is on linear servomechanism design, nonlinear servomechanism analysis is included. Along with basic material, information is provided on components, gyroscopes, force-balance transducers, and inertial navigation. (C. J. Savant. Toronto, McGraw-Hill, 1958. 418p., $11.40.)

THE BEAMA CATALOGUE, 4TH ED.

The 1958 edition of the Catalogue issued by the British Electrical and Allied Manufacturers' Association contains over 690 pages of announcements of products manufactured by firms who are members of the Association. The announcements are divided into three sections covering electrical power plant; electrical equipment in industry, transport and communications; domestic and commercial appliances, lighting, accessories and installation material.

There is a Buyers' Guide listing everything electrical, and a five-language glossary of the terms used in it. The Catalogue also contains a Directory of the members of BEAMA. This catalogue will prove most useful to any firms interested in purchasing electrical equipment. (London, Iliffe for BEAMA, 1958. Various paging, £6.)

DISINTEGRATION OF FIELD CONCRETE. INVESTIGATION OF THE EFFECT OF SOME POZZOLANS ON ALKALI REACTIONS IN CONCRETE

These are the first of a series of progress reports to be issued by the Committee on Alkali Reactions in Concrete of the Danish National Institute of Building Research, which is investigating the deterioration of concrete structures caused by reactions between alkalies and reactive silica of the aggregate. It is intended to prepare a code of practice based on the findings of the committee.

The reports are in English, with a Danish resume, and contains many illustrations, tables and references. This should prove a most useful series. (Copenhagen, Danish National Institute of Building Research, 1956-57. mimeog., 12 D.Kr. each.)

*DRAINAGE OF AGRICULTURAL LANDS

The methods and means used to drain land are studied in relation to water tables, movement of water through soil, and the relationships that exist between water tables and crops. Aspects dealt with include the physics and engineering aspects of land drainage, drainage investigation methods, and land drainage in relation to soil and crops. There are 32 pages of references at the end of the book. (J. N. Luthin. Madison, Wisc., American Society of Agronomy, 1957. 620 p., $11.00.)

ECONOMIC APPLICATIONS OF ATOMIC ENERGY

Prepared for the 24th session of the Economic and Social Council of the United Nations, this report considers the possible applications of atomic energy in the fields of power, industry and agriculture.

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m. — 5 p.m.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

• LIBRARY NOTES

The first section considers such topics as the present demand for electric power; the economic aspects of power generation by conventional and nuclear power plants; industrial uses of radioactive materials and radiation; the potential uses of atomic power in agriculture and related industries.

The second section of the report contains the replies to questionnaires sent to the governments of Canada, France, the U.S.S.R., the U.K., and the U.S. These were concerned with each country's electric power needs, the objectives of its nuclear power programme, its present and future activities in the field, the factors determining the use of conventional power plants. Also considered in this second section were labour and training problems associated with the use of atomic energy. (United Nations, Secretary-General. Toronto, Ryerson, 1957. 108p., 50 cents.)

*ELSEVIER'S DICTIONARY OF ELECTRONICS AND WAVEGUIDES IN SIX LANGUAGES

Contains terms which relate to electronic engineering rather than to physical electronics. Over 2,000 words are defined in English according to the most precise international standard available. Corresponding terms then appear in French, Spanish, Italian, Dutch, and German arranged in a horizontal fashion. An index to the foreign term provides access to the related English term and its definition. Where necessary, a difference between British and American usage is made clear. (W. E. Clason. Toronto, Van Nostrand, 1957. 628p., $17.50.)

EXTRUSION OF PLASTICS

The first of a series of ten monographs to be issued under the auspices of the Plastics Institutee, this volume is concerned with one of the most important processes in the manufacture of plastics.

The subject is covered from both the theoretical and practical points of view, and chapters are included on the basic principles of extrusion and the complete extrusion process; single and multi-screw extrusion machines; materials for extrusion; the extrusion of thermosets. References are included in each chapter.

Other volumes to be published in the series will cover compression moulding design, compression and injection moulding plant, calendering, polyamides, polyesters, and ethenoid plastics. (E. G. Fisher. London, Iliffe for the Plastics Institute, Toronto, British Book Service, 1958. 114p., $4.50.)

FINANCIAL POST SURVEY OF OILS, 1958

According to this year's Survey, natural gas is the driving force in Canada's oil and gas industry, having taken over from oil which has set the pace in the ten years since Leduc. The Trans-Canada pipeline should be completed this year, and will provide a large new market. Westcoast Transmission is already operating to the west coast.

The survey reviews some 500 oil producing, refining, pipeline, exploration and drilling companies, giving for each company its address, activities, subsidiaries, if any, directors, capitalization, property, development, dividends, etc.

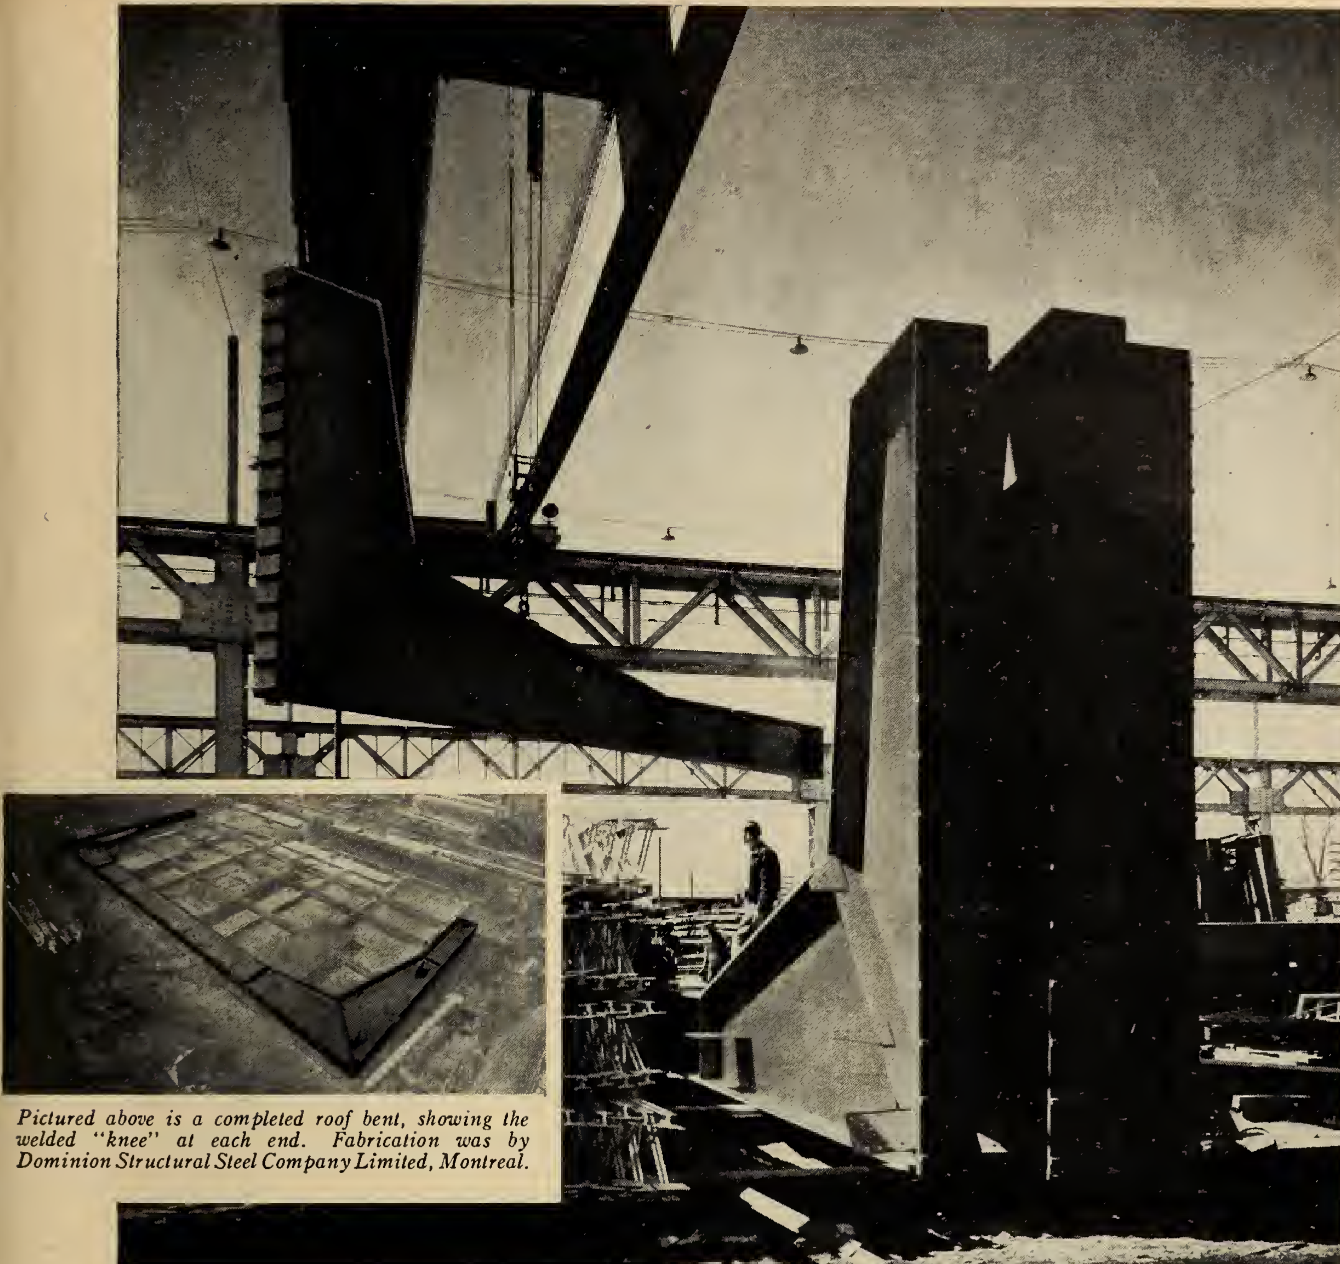
Also included are maps of oil and gas fields, an eight year price range of stock movements, oil and gas production and reserves, imports, etc., and a list of inactive and defunct companies. (Toronto, Maclean-Hunter, 1958. 248p., $4.00.)

PHYSIQUE ELECTRONIQUE DES GAZ ET DES SOLIDES

The main purpose of this volume is the study of the properties of the electron in matter, and its visible results, especially electrical and thermal conductivity. As little is known of the action of electrons in liquids, the author has concentrated on solids and gases.

The first part of the work is theoretical, although purely mathematical proofs are put in the appendix. There is an introductory chapter on physics and mechanics, and other sections cover corpuscular physics, the results of the kinematic theory of gases formed from one or more types and a discussion of "Lorentz gas".

In part two the results of the passage of an electric current through gases and solids is discussed, giving proven results of general interest, referring to



Pictured above is a completed roof bent, showing the welded "knee" at each end. Fabrication was by Dominion Structural Steel Company Limited, Montreal.

other works on the same subject.

This book will be useful to those interested in the study of problems connected with the kinetic theory of gases, to physicists interested in solid state, and to engineers wanting an overall view of the whole problem. (Michel Bayet. Paris, Masson, 1958. 246p., 4900 fr.)

PRECIS DE METALLOGRAPHIE

Based on lectures given at the Ecole Centrale in Paris, this volume contains a concise outline of the phenomena observed during the solidification of metals and alloys.

The first part of the book is concerned with the structure and properties of metals and alloys, including atomic structure, plastic deformation, binary and ternary alloys, etc. In the second part there are studies of several industrial alloys, including special steels, cast iron, copper and its alloys, light weight and ultra-light alloys such as aluminum and magnesium, and electrochemical corrosion. (Leon Guillet. Paris, Masson, 1958. 254p., 1800 fr.)

QUEEN'S UNIVERSITY

Two Professors of

Mechanical Engineering,

To do Research and Teaching in Thermodynamics

PH.D., preferred, but not necessary

Apply to:

Dean H. G. Conn,
Faculty of Applied Science,
Richardson Hall,
Queen's University,
Kingston, Ontario.

lated to construction and house building industry and product application (no sales), want a through training program in British Columbia to equip you for the job. Write to File No. 6462-V.

CANADIAN ELECTRONICS COMPANY requires a mechanical or electrical engineer with production operation experience and a good knowledge of production control, methods, material control and shop practice applicable to the production of a variety of highly-engineered electronic and electro-mechanical devices. Precision machine shop experience necessary. Age over 35. Salary $10,000 upwards according to qualifications. File No. 6465-V.

ENGINEER REQUIRED by Ontario Manufacturer of packaging films to assume responsibility for the plant engineering department. Must be a graduate with a minimum of ten years' industrial experience. Some design experience of chemical or process equipment would be a recommendation. Age 30 to 38 years. This is a permanent and interesting position with a growing company in a rapidly developing industry. Apply giving full details of experience, age and salary expected. File No. 6466-V.

SEVERAL YOUNG ENGINEERS to train as technical assistants towards positions in production supervision. Metallurgical and Mechanical Engineers are preferred and we should like to interview applicants who have been engaged in steel making or any other basic industry from one to three years. We are prepared to consider 1958 graduates. Location Ontario. File No. 6467-V.

THE FACULTY OF ENGINEERING, McGill University, invites applications from suitably qualified persons to fill three new Professorships: (a) in the field of control engineering; (b) in the field of aircraft and missile propulsion; (c) in the field of applied mechanics with particular reference to such problems as soil and rock mechanics. The essential quality sought in applicants is the ability to initiate programmes of graduate study and research and to develop strong graduate schools. The normal academic session is seven months leaving four summer months for full time research activities. Funds will be available to initiate such research. The initial salary will be in the range $10,000 to $13,000 per annum. Applications, including a statement of academic, industrial and research experience, and the names of three referees, should be sent to Dean D. L. Mordell, Faculty of Engineering, McGill University, Montreal 2, Quebec. File No. 6468-V.

UNUSUAL OPPORTUNITY for a professional engineer, age 28-35, for ultimate top management position with a modern, aggressive, industrial enterprise in Halifax, Nova Scotia. Applicant should have a mechanical or electrical background, and possess the necessary experience and qualifications to handle people in a successful manner. Basic function of position with be the management of entire manufacturing operations of the Company. This is a challenging life-time opportunity. Initial letter to outline complete background and recent photo. Salary range will definitely allow for adequate compensation for high level qualifications. Only those engineers interested in working hard to learn and then to ultimately assume the responsibilities that this position demands need apply. File No. 6475-V.

DISTRICT SALES ENGINEER. A well-established Saskatchewan industry has an opening in Saskatoon for a District Sales Engineer to represent the company in sales and technical services to customers. Applicants should be graduate civil engineers or equivalent, with sales and construction experience, particularly related to concrete. Ability to write technical reports and promotional material essential. Must have the capacity to work with a minimum of supervision, and to manage the activities of a branch. Age range 28-35 preferred. Initial salary $500-$600 per month plus fringe benefits and a car. This is a favourable opportunity for a man capable of assuming substantial responsibilities. Write in strict confidence, giving full information and a recent photograph if possible. File No. 6477-V.

DEVELOPMENT ENGINEERING

Intermediate and Senior Professional Engineers, graduates in electrical engineering or engineering-physics, are needed for original, interesting work in the fields of navigational, nuclear, test and other instrument and control engineering, embracing transistor, radar, servo and computer techniques.

If you are interested in a position which offers scope for originality, initiative and technical competence above the average, please send me a detailed resume of your background, education and experience. All replies held in confidence.

Chief Engineer,
Sperry Gyroscope Company
of Canada, Ltd.,
P.O. Box 710, Montreal.

AN OPENING EXISTS for a graduate engineer, qualified for membership in the Association of Professional Engineers. Requires two to three years' experience in pressure vessel design, fabrication and inspection, and materials specification, and/or experience in metallurgy, metallography, and corrosion inspection. A sound knowledge of paints and protective coatings is highly desirable. Excellent company benefits and pension plan available. When replying, please develop qualifications and experience in full. Location Edmonton, Alberta. File No. 6485-V.

MECHANICAL or AGRICULTURAL ENGINEER. Agricultural Engineering Department of a well established University is seeking an alert and personable staff member. Duties to include taking full charge of Agricultural power and machinery classes for Agricultural Degree students, and also to give a course in Dairy Engineering. The latter course deals with the production and use of steam in a Dairy, some elementary electrical principles and applications, and principles of refrigeration. The desired staff member should be mature, responsible, and hold a satisfactory academic record. A man with some experience after graduation would be desirable. File No. 6491-V.

CIVIL ENGINEER with experience in construction or concrete, required by established manufacturer of construction chemicals in four Western Provinces. Preference given applicants now residing in West. Position involves contact with architects and engineers in support of distributors. All replies will be treated in confidence. Interviews can also be arranged in East. File No. 6492-V.

Report of Council, Report of Finance Committee, Financial Statement and Treasurer's Report

The president announced that as Mr. Deschamps, the chairman of the Finance Committee had to return to Montreal, he was asking Dr. Solandt the treasurer to report for both officers.

Dr. Solandt reported that the Institute's activities for 1957 had been very satisfactory. He pointed out that the revenue was the highest on record but he noted also that expenses had increased substantially with the effect that the overall surplus was reduced.

He commented that some of the increased expenditure was due to normal inflation but the greater part came directly from increased activities and services to the members.

As far as the figures for the Institute assets are concerned he said this was an understatement of the real values inasmuch as the property itself was shown only at the assessed value instead of the real value.

During the year investments were handled by a special sub-committee in consultation with experts in the financial field. As a result some changes were made in the portfolio with considerable advantage to the Institute.

In summary, Dr. Solandt pointed out the financial situation of the Institute is very satisfactory. He asked the members to note, however, that income for *The Engineering Journal* from advertising, was being reduced noticeably. The outlook for the future is not as bright as it had been in the past. He felt he should warn the membership of that change. He felt that in the future "membership should look very carefully at proposals for new expenditures so that the money is spent as wisely as possible".

On the motion of E. D. Gray-Donald, seconded by M. P. Whelen, it was resolved that the report of Council, the report of the Finance Committee, the financial statement and the treasurer's report be accepted and approved.

Committee Reports

The president stated that before asking for approval of the committee reports he wanted to express on behalf of Council and the membership, appreciation of the splendid work done by the great number of chairmen and their committees. These people have carried on the business of the Institute extremely well—the burden of all the work, as usual, falling on the chairmen.

On the motion of Sydney Sillitoe, seconded by J. A. Watters, it was resolved that the reports of the following committees be taken as read and approved: Admissions, Board of Examiners, Life Members Committee, Professional Interests, Professional Development, Prairie Water Problems, Technical Operations, Property, Legislation, Library and House, Publication, Papers, Report of Field Secretary, Western Field Secretary, Library Report, Employment Service, Canadian Chamber of Commerce, Canadian Standards Association, Ontario Division.

Branch Reports

On behalf of the members of the Institute the president extended to the chairmen of branches, and the members of branch executives, appreciation for the wonderful work they had done throughout the year. He emphasized that these officers usually carry on the work of the branch at great inconvenience to themselves. However, their contribution to the life of the Institute was outstanding.

On the motion of H. L. Johnston, seconded by J. H. Racey, it was resolved that the reports of the branches be taken as read and approved.

Confederation

The president reported that the joint committee set up by the Engineering Institute of Canada and the Canadian Council of Professional Engineers had met at different times and at different places throughout the year—eventually a report had been presented to a special meeting of Council held on the previous Monday, May 19th. After a discussion which lasted many hours the meeting came to the unanimous approval of the following resolution:

> "That this plenary meeting of the Council of The Engineering Institute of Canada unanimously accepts, with appreciation, the report of its Committee on Confederation, its first seven clauses as a guide to further action, its eighth clause in principle but subject to further discussion with the other part of the joint committee, and the General Clauses as amended at its meeting earlier to-day; and the Council requests that the joint committee continue its work and prepare as quickly as is practicable a statement, embodying its report and the objectives of the new national body, for presentation to and balloting upon by the membership of the Institute and of the Associations and Corporation after approval by the respective Councils."

Election of Officers

The general secretary presented the list of the newly elected officers of the Institute as follows:

President

K. F. Tupper, Toronto, Ont.

Vice-Presidents

J. B. Angel, St. John's, Nfld.
E. T. Buchanan, Grand Mere, Que.
H. G. Conn, Kingston, Ont.

Councillors

Vancouver Branch, F. M. Cazalet.
Edmonton Branch, S. J. Hampton.

Cape Breton Branch, M. R. Campbell.

Vote of Thanks to Retiring Officers

Dr. Heartz proposed a vote of thanks to the retiring officers accompanying his resolution with the following remarks: "Gentlemen, I deeply appreciate the privilege and honour of expressing on your behalf our thanks to the retiring president and the officers. While this is usually looked upon as routine matter, it has, I think, this year a special touch of regret that you, Mr. President, and your splendid councillors and officers finally drop out of the picture for the time being. Thank you, Sir, and your group for having done an outstanding job of work. We would like to express to you our appreciation and recognition of all the stress and strain of all the work you have carried on throughout the year. While you are retiring officially I am sure you will appreciate that we want you to continue your interest in the Engineering Institute to help build it into a bigger, finer and still stronger organization. It gives me much pleasure to move, Sir, on behalf of those present and others throughout the country a hearty vote of thanks to you and your officers for their services throughout the year".

This was seconded by Dr. Ira P. Macnab, and carried with enthusiasm.

Dr. J. B. Stirling asked for the privilege of addressing the chair. He made the following remarks: "Mr. President and gentlemen—I think it is particularly fitting and appropriate that at this 72nd Annual Meeting of the Institute we go on record as expressing our deep appreciation of the services of one of the most outstanding officers the Institute has ever had in its employment—that is the retiring secretary, Leslie Austin Wright. Coupled with these remarks I would like to add as part of this resolution that the Institute regrets extremely the necessity of his retirement. We certainly hope that his interest will not be lost as we desire that he shall continue to work for the Institute. Mr. President, it is difficult under the circumstances to express precisely what I feel and I do not wish to add further to Dr. Wright's embarrassment, but I would like to see it placed on the record that we appreciate deeply the work that Dr. Wright has done for us and we regret his retirement". This motion was seconded by George Schneider, with applause and a standing salute.

The meeting was adjourned at 11.30 A.M.

REPORT TO THE MEMBERS

(Continued from page 96)

the members of a branch. Unfortunately the Institute has grown to a point where it is almost impossible for a president, during the one year he is in office, to visit all branches.

The practice heretofore, of the General Secretary accompanying the President on branch visits, has proved most convenient for the President, yet it does mean that two of the principal officers are visiting the branch at one and the same time, and that some branches are not even afforded any contact. I suggest the possibility that the visit of the president and general secretary to branches might be divided, to an extent so that every branch will be visited at least once each year, and insofar as it is possible the branch receive two visits each year. The possibility of having the immediate past president, during the year immediately following his term of office, visit such branches as he was unable to visit during his presidency, might be well worth investigating.

The services of the assistant secretaries could be perhaps used to greater advantage by having them attend branch business meetings.

These suggestions are advanced as a result of the impressions I have received, that closer liaison must be established between the branches and headquarters.

At this point may I publicly acknowledge my depth of gratitude to the general secretary, to Miss McLaren and the other members of the staff of the Institute, who gave of their time and effort unstintingly towards advancing the interest of the Institute and making the president's term of office a year never to be forgotten. May I also thank the branch officers, the members of the branches and their good ladies for their many courtesies to Mrs. Anson and me throughout the year. We have met most interesting people, we have made many friends. We are looking forward to renewing those friendships from year to year.

In closing, let me again express to you, members of the Institute, my fond gratitude for the honour you extended to me, by permitting me to enjoy the office of president of the Institute during the past year. It is a privilege extended to few men and one which I prize beyond any other honour that has been accorded me. You can be assured that my services will always be available to the Institute in any manner in which they can be used. I shall never be able to repay you.

Thanks to You All

Life is full of changes, but one of the greatest is that which takes place when a person retires from a post which he has occupied and enjoyed for many years. This truth is just recently borne in on me.

Retirement is a natural development and one to be looked forward to with pleasurable anticipation. This I have done for several years and therefore have prepared myself for it, but the one thing that has been unforeseen by me has been the way in which my many friends and associates have greeted me on reaching this important turning point in my life. As I said at the Annual Meeting "I am 'flabbergasted'!" by it all.

It is not easy or perhaps even possible to thank adequately all the people for all they have done, but I do want to make a try. Such a great number of members participated in the project promoted by the president that it is impossible to write them individually. Hence I hope they will accept this as a manifestation of my appreciation. It is wonderful to know that so many people within the Institute cared enough to take part in the proposal to present me with a "souvenir" or "memorial". I am deeply touched.

The beautiful camera with all its "gear" will be a close companion for the rest of my life, and I hope that in one way or another, at one time or another, I may catch each one of you within its perfect lenses.

L. Austin Wright

Plant Visits for Nigerian Students

On behalf of the Nigerian Liaison Office at Washington, and of McGill University, the Engineering Institute of Canada is arranging an itinerary of visits for a group of 3rd year Nigerian Engineering students at McGill to industries and projects in Canada during this summer.

Nigeria expects to be granted its independence next year. Recalling the difficulties confronting Ghana recently on attaining nationhood, in creating its own civil service on short notice, the Nigerian Government is determined to educate and train a nucleus of its young men and women ready to take over civil service posts in science, medicine, arts and education. The Institute, in cooperation with McGill authorities, has prepared a list of construction projects to be visited of every type the students may encounter in their own country. Inspection will be made of many Canadian industrial plants whose production is based on raw materials similar to those found in Nigeria, or whose end products if imported by Nigeria may require maintenance there.

In addition, visits are being planned to the National Research Council laboratories, the Meteorology Branch of the Department of Transport, the Mines Branch of the Department of Mines and Technical Services, the Central Mortgage and Housing Corporation, the Photographic Survey Corporation, and the Canadian Pacific Railway electronic computer. A two-day tour of the Seaway will be made and if time permits a number of mining developments will be included.

Arrangements for visits within the Montreal area are being made by E.I.C. headquarters direct with the plants and projects concerned. Establishments in other provinces are being contacted by correspondence, and the assistance of chairmen of Branches of the Institute is being enlisted to coordinate the arrangements locally.

The student group members are supplied with funds by the Nigerian Government, and apart from advance arrangements for living accommodation by McGill authorities, and letters of introduction, they will be self conducted. The wholehearted cooperation of executives and staffs of both industries and government services so far contacted has been most gratifying.

Elections and Transfers

On the recommendation of the Admissions Committee the following elections and transfers were effected at the meeting of Council on May 23, 1958:

Members: R. Bonnaud, Montreal; T. S. Brandon, Shawinigan; J. Y. Essayan, Montreal; D. C. Leavitt, Toronto; A. R. Le Feuvre, Waterloo, Ont.; N. W. McGuinness, London; G. M. McHenry, London; F. E. Miller, Toronto; E. F. Pariset, Montreal; H. A. Price, Penticton; D. P. Ryan, Toronto; G. Sebastyan-Yishai, Ann Arbor, Mich.; G. Sfaellos, Montreal; E. Shaw, England; D. W. Urquhart, Montreal; F. E. Vuia, Montreal; T. J. Walsh, Sudbury.

Juniors: R. G. Blair, Winnipeg; J. E. Goulet, Chicoutimi; D. R. T. Marshall, Calgary; W. D .West, Toronto.

Junior to Member: A. J. Barker, Windsor; J. Bourbeau, Montreal; J. E. Knecht, Whitby; E. J. Lockwood, Vancouver; R. W. Lowe, Philadelphia; E. P. Mascarin, Walkerville; R. M. Moore, Sudbury; J. E. Sinnott, Walkerville; J. Zowtiak, Edmonton.

Student to Junior: S. D. Curran, St. Catharines.

STUDENTS ADMITTED

Loyola College: E. Batiuk; J. P. C. Fortin; M. B. Kelly; G. W. Labelle; J. G. McQuade; F. G. Montelpare; J. N. C. Nagy; M. P. Shinners; K. F. Sloan; J. Sopko.

University of Toronto: W. R. Cooper; C. M. King; W. Kostiw; G. D. Lynch; H. E. Seegmiller; W. J. Simpson.

St. Francis Xavier University: G. F. Farmer; R. L. MacKinnon; R. J. Pitre; R. D. Richard.

University of New Brunswick: J. F. Gronan; S. Rubin; W. A. Stothart.

McGill University: P. J. F. Rolf; P. H. Savard; R. M. Southey.

University of Alberta: M. B. Morin.

Nova Scotia Technical College: A. G. Melanson.

University of British Columbia: R. F. Jefferies.

Royal Military College: R. D. Hall.

Ontario Agricultural College: F. J. Brown.

Michigan College of Mining and Technology: K. T. Desai.

C.P.E.Q. Student: M. S. Fleiszer.

Applications Through Association

By virtue of the co-operative agreements between the Institute and the Association of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members: D. W. Purdy; **Juniors:** J. N. Bowersock; G. G. Jacox; **Junior to Member:** P. J. Dowling; **Student to Junior:** G. R. McDonagh.

SASKATCHEWAN

Members: S. L. Ashley; D. Bradwell; H. C. Daugherty; G. E. Drysdale; F. A. Gerard; F. M. Hewitt; A. G. Kennedy; B. K. Smith; J. H. Smith; **Junior:** H. Lee; **Students:** D. D. Baldwin; L. A. Brown; D. L. T .Chapman; R. G. Martin; R. G. McIntosh; S. R. Meek; B. J. Pannell; D. G. Perkins; B. G. Rosser; W. Shtenko; V. M. Strijack; R. J. J. Trudel; P. E. Walsh; **Junior to Member:** H. K. Bowers; N. A. Meneley; L. H. Sawatsky; Z. E. Wasarab; **Student to Junior:** D E. Cherry; D. V. Gilewich; G .B. Lipsett; L. Morrison; K. C. G. Pritchard.

NOVA SCOTIA

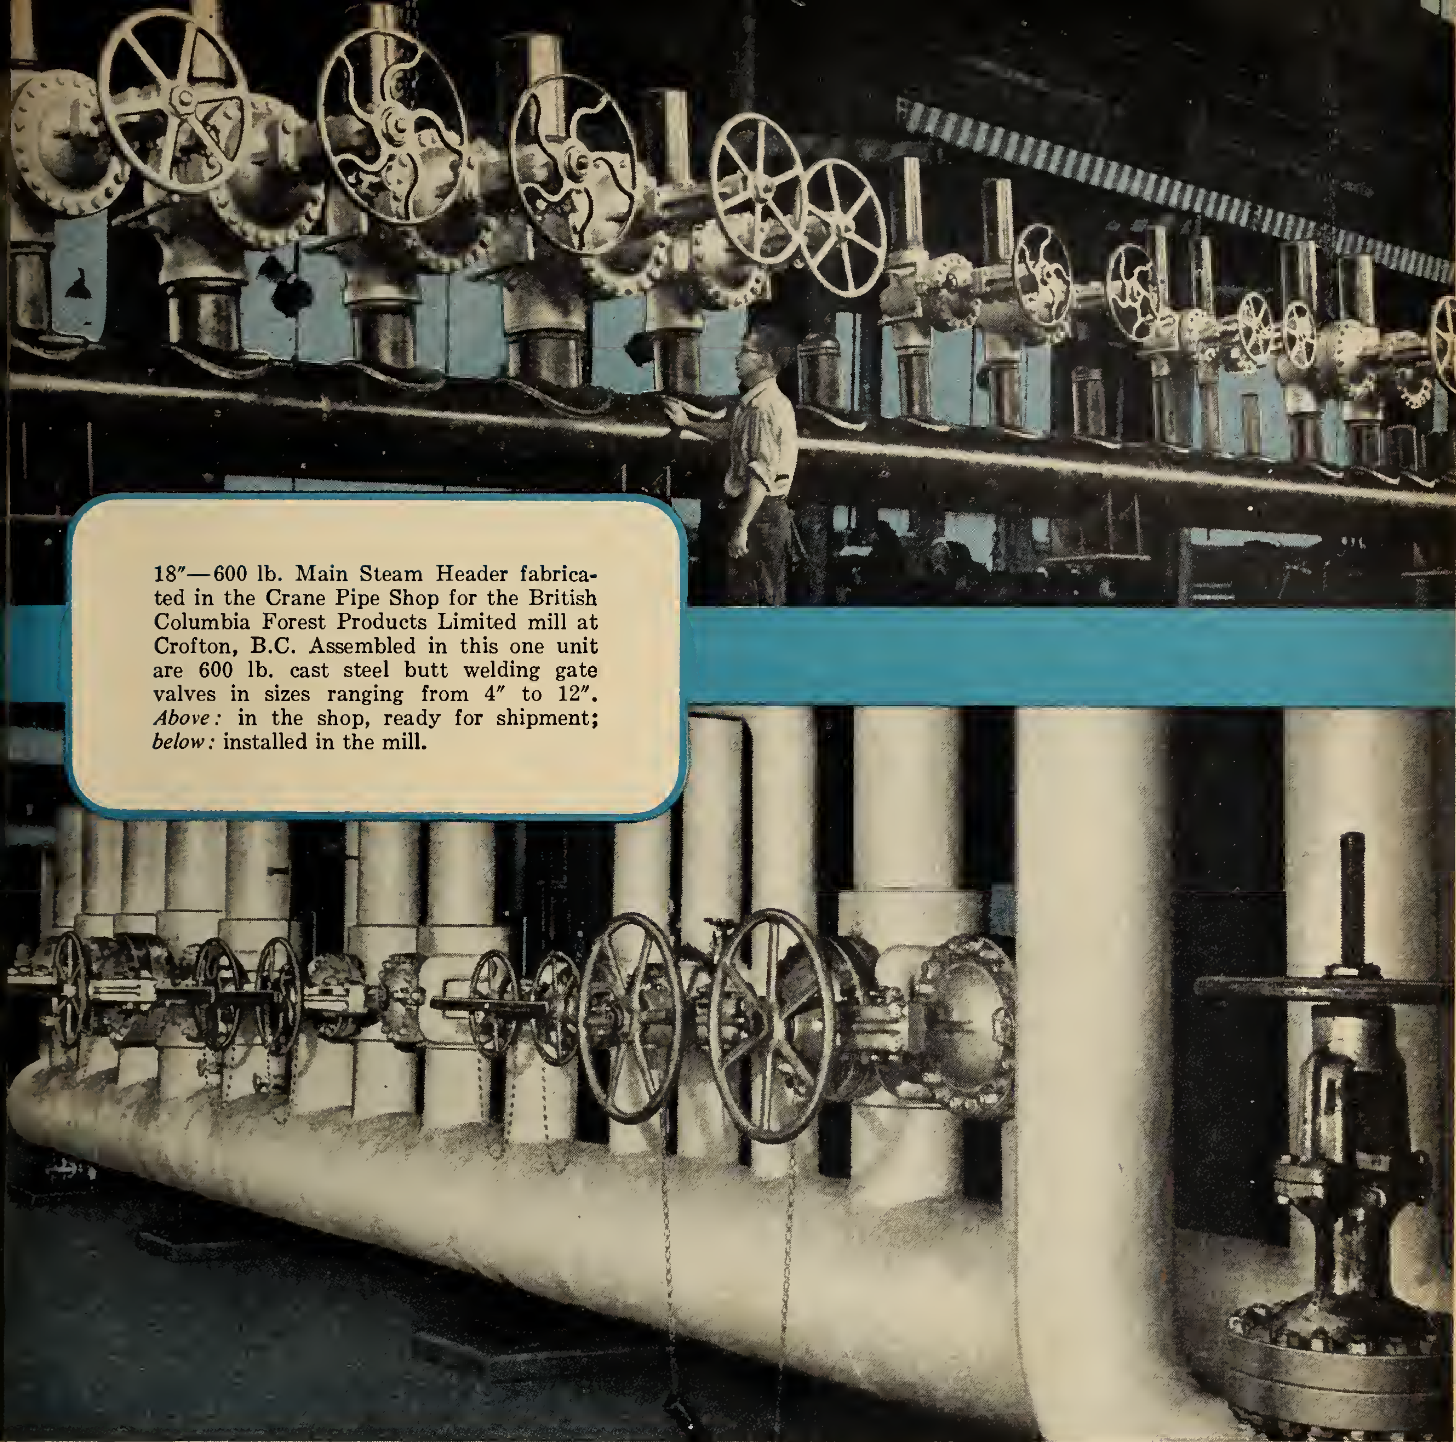
Members: G A. Blackman; A. T. Kosacz; J. W. Mason; J. F. Miles.

NEW BRUNSWICK

Junior to Member: L. R. Ward.

PRINCE EDWARD ISLAND

Member: M. B. Lodge.



18″—600 lb. Main Steam Header fabricated in the Crane Pipe Shop for the British Columbia Forest Products Limited mill at Crofton, B.C. Assembled in this one unit are 600 lb. cast steel butt welding gate valves in sizes ranging from 4″ to 12″. *Above:* in the shop, ready for shipment; *below:* installed in the mill.

Headers without headaches!
Unit fabrication in the CRANE PIPE SHOP *saves you time and money, avoids trouble. You get a* complete *unit built precisely to applicable codes, and to your drawings and specifications—and* pre-tested *before being shipped to the job. Contact your local Crane Branch.*

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Foundation Company Appointments — L. J. McGowan has recently been elected president of The Foundation Company of Canada Limited succeeding F. G. Rutley, M.E.I.C., who has been elected chairman of the board. Further executive appointments: R. F. Shaw, M.E.I.C., executive vice-president; R. E. Chadwick (former chairman), consulting engineer; W. E. Hickey, M.E.I.C., vice-president and chief engineer; F. W. Maund and L. H. Rowe, vice-presidents. Changes in subsidiary companies include the appointment of J. P. Lockett as vice-president and general manager, The Foundation Company of Ontario Limited; A. G. Sullivan, president and general manager, Foundation Maritime Limited; Per Hall, president, Foundation of Canada Engineering Corporation (F. G. Rutley becomes board chairman).

Canadian Utilities—The following executive officers were recently appointed by Canadian Utilities Limited: H. R. Milner, chairman; J. C. Dale, M.E.I.C., president and general manager; F. A. Smith, vice-president finance; K. L. MacFayden, comptroller; A. M. Anderson, assistant comptroller; T. A. Montgomery, secretary; A. M. Irvine, treasurer and assistant secretary; H. Brown, assistant treasurer.

R. A. Reid

Ferranti-Packard — T. Edmondson has been appointed president and chief executive officer of Ferranti-Packard Company Limited, Toronto, which has been formed to consolidate operations of Ferranti Electric Limited, Toronto, and Packard Electric Company Limited, St. Catharines, Ont. Other executive appointments are: J. M. Thomson, chairman, board of directors; J. Fogarty, vice-president and general manager, electronics and ordnance division, Toronto; W. L. Hetherington, M.E.I.C., vice-president and general manager, power transformer division, Toronto; D. F. Martin, vice-president and general sales manager, marketing division; G. L. Murray, vice-president and general manager, distribution transformer and metering equipment division, St. Catharines; H. S. Wigley, vice-president and controller.

Canadian Westinghouse — Announcement has been made of the appointment of H. Thomasson as consulting engineer for Canadian Westinghouse Company Limited, Hamilton, Ont.; Mr. Thomasson has recently been awarded a life-membership in the Canadian Welding Society. Other appointments announced: M. J. Lavigne, manager, metallurgical-mechanical section of the Canadian Westinghouse research and development laboratory, and W. E. McBride, manager, union relations.

New Treasurer—Announcement has been made of the appointment of J. F. Kidner as treasurer of Canadian Oil Companies Ltd., Toronto, succeeding C. W. Walker, who is retiring after 45 years' service.

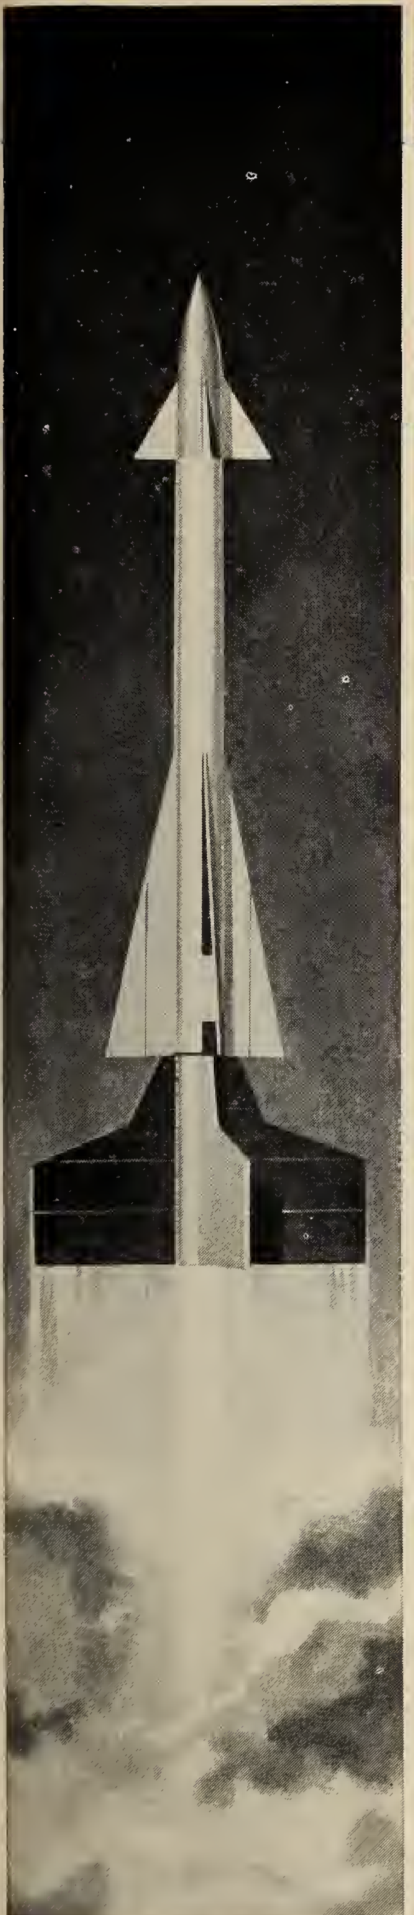
L. J. McGowan

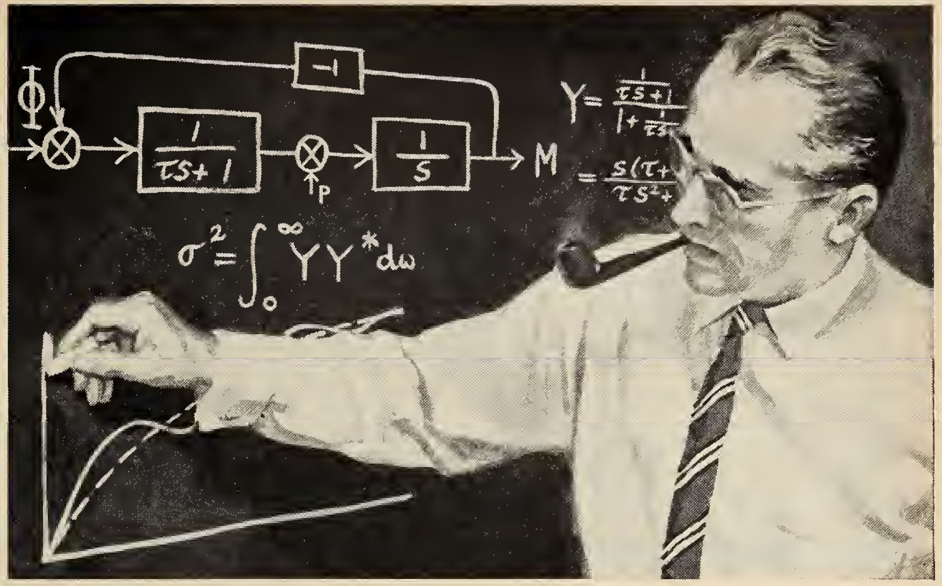
Dominion Bridge—R. A. Reid has been appointed to the newly created position of manager of the Winnipeg branch of the Dominion Bridge Company Limited. Mr. Reid, formerly works manager at Winnipeg, will be succeeded by M. J. Lyons.

C-I-L Sales Appointments—J. J. F. Smith has been made Quebec district sales manager in the explosives division of Canadian Industries Limited, replacing J. C. Lowrey, who has retired. Also announced is the appointment of L. J. Lagimodiere as manager construction sales of the explosives division, with headquarters in Montreal.

Neptune Meters Promotion — R. M. James, formerly sales agent in Southwestern Ontario, has been promoted to the position of manager of the Vancouver office of Neptune Meters Ltd.

American-Standard—H. Adams has been named works manager in charge of manufacturing operations for American-Standard Products (Canada) Ltd., Toronto. P. Britton succeeds Mr. Adams as





• BRIEFS

manager of the company's Sirocco plant in Windsor, Ont.

Field Aviation Company—The following appointments have recently become effective at Field Aviation Company Limited: R. J. Quigley, manager, aircraft sales division, and R. E. McCullough, manager, maintenance hangarage operations at Calgary, Alta.

Senior Geologist — Hunting Technical and Exploration Services Ltd., Toronto, has recently announced the appointment of N. Hogg as senior geologist for the organization.

Recent Appointments — Following a realignment of the sales districts of J. A. Wilson Lighting and Display Ltd., K. R. Meyrick has been appointed Ontario district sales manager, and A. J. Cahill, assistant sales manager for the district.

Du Pont Plastics Division—The following appointments have been made in the recently organized plastics division of Du Pont Company of Canada (1956) Limited: R. P. Eyres, Toronto district sales manager; R. D. Tillotson, sales representative, Toronto; P. E. Quesnel, sales representative, Montreal.

Canadian Liquid Air — The appointment of two sales supervisors has recently been announced by Canadian Liquid Air Company Ltd.: G. W. Gaboury, for the central Quebec Province district, and G. Reeve for the Lakehead area.

News of Business and Industry

Nationwide Tribute to Tool Engineering — North American Van Lines, Inc., Fort Wayne, Indiana, recently sponsored a very interesting program on machine tool engineering when a report on this subject was presented by A. Dreier in their NBC-Monitor show "America on the Go."

New Premises — E.C.C. Canada Limited has recently moved to newly constructed premises at 66 Colville Road, Toronto 15, where standard products and spare parts are available for immediate service. The company is responsible for the consultation, sales and distribution services of the products of its English principals, The Electric Construction Company Limited and George Ellison Limited. The products include rotating machines, rectifiers, transformers, high and medium voltage switchgear, automatic and hand-operated motor control gear, hydraulic valves and "Tufnol", a material used for a wide variety of engineering components.

New Plant — A new Canadian company, Link-Belt Speeder (Canada) Ltd., has commenced construction of a plant in Woodstock, Ont. to manufacture power cranes, shovels and draglines. The new company is a subsidiary of Link-Belt Speeder Corporation of Cedar Rapids, Iowa, manufacturer of power shovel-cranes. The plant will be constructed on a 39-acre site and will consist of two crane bays comprising some 32,000 sq. ft. of space. It has been designed so that it may become the first section of a larger, fully integrated plant when future expansion is required.

Standard Steel Framed Buildings — Sanders & Forster Ltd., a member of the Chamberlain Group of Companies, of London, England, designers and manufacturers of S & F standard buildings, have now designed three buildings within this range to conform with the special requirements of the Canadian and Scandinavian areas. Using a tied portal frame as the basis of design, a "Superload" building has been developed which has the clean lines of a rigid portal frame and uses less steel than the conventional truss and stanchion type of structure.

Record Size Single Compartment Ball Mill — The biggest single compartment ball mill built in the United States — a 13 by 20 ft. unit — has been shipped to a midwestern cement plant by Allis-Chalmers. Because of its unusual size, the ball mill had to be shipped in two pieces set sidewise on the car and then reassembled at the erection site. Along with the huge ball mill, which is expected to be in operation by summer, Allis-Chalmers is supplying this installation with a 2000 h.p. motor and control equipment. The motor is designed to operate at the slow speed of 180 r.p.m. at 2300 volts as a wound rotor type as it starts up and as a synchronous motor when it is well underway. In this manner, low starting current and high torque get the big mill turning without a major drain on the power system.

Magnet Wire Plant — A 113,000 sq. ft. magnet wire division plant of Canada Wire and Cable Company Limited has

recently been put into operation at Simcoe, Ont. This automatically-operated factory for producing all sizes of enamelled and textile-covered magnet wire is located on 13½ acres of ground and is centrally-located to supply by road or rail the principal markets of magnet wires in Toronto, Hamilton and St. Catharines as well as throughout Canada. This is Canada Wire's sixth plant, the others being located at the head office in Toronto, Montreal East, Smith Falls, Ont., Fort Garry, Man., Annacis Island near New Westminster, B.C., and now Simcoe.

New Distributor — The appointment of Midwest Mining Supplies Limited of Winnipeg as sole G.M. diesel distributor in Manitoba has been announced by General Motors Diesel Limited, London, Ont. The new distributor is responsible for the sale of G.M. industrial and marine diesel engines and factory-engineered parts as well as service. Their servicemen perform free on-the-site inspections and tune-ups on new G.M. diesel engines. They also provide operator instruction and information on preventative maintenance procedures. Midwest Mining Supplies Limited bring to 45 the number of G.M. Diesel distributors and dealers across Canada.

Consultants Firm — The Warnock Hersey Company Ltd., has recently announced the formation of Warnock Hersey Management Consultants Ltd. to consolidate and expand the management consulting services of the firm: Montreal office — 128 Elmslie St., HU. 1-0351; Toronto office — 600 Sherbourne St., WA. 4-9691.

Epoxy-Type Resins — The first Canadian plant to produce epoxy-type resins went into production recently at Montreal East. The Shell Oil Company of Canada built the $1 million plant adjacent to its other chemical manufacturing facilities in that community. The company claims that the capacity of the new plant is sufficient to supply Canada's demands for these relatively new products. Shell of Canada has marketed epoxy resins in this country for a number of years under the trademark EPON, importing them from Shell Chemical Corp. in the United States. Since their introduction, Epon resins have set new standards for the surface coating industry due to their unique combination of adhesion, chemical resistance and flexibility. In addition to their wide use in the surface coating industry, Epon resins are also used in adhesives for the aviation industry and in laminates and castings for electrical uses.

DISCUSSION *(continued from page 84)*

FORCES INVOLVED IN PULPWOOD HOLDING GROUNDS:

The Engineering Journal, January, 1958.

1941 and 1950 to give a 5-month log towing season. The canyon is the end of boat navigation.

Possibilities of river transportation directed attention to the large volume of timber within trucking distance of the canyon. Railways and highways provided access to the canyon but it was not economical to move logs by this method to coast mills.

No operator was prepared to risk driving individual logs as there was no apparent place where a holding ground for individual logs could be installed without interfering with navigation.

The method finally used was to truck the logs to the river, place three wire rope straps around the load and dump in the river. This formed a bundle of 10 to 12 wide, 40 ft. log averaging 8 M f.b.m. (16 cords). These bundles travelled down river without damage and were caught at the lower end of the canyon by river boats, boomed and towed to coast mills.

In 1955 a holding ground was constructed in a section of the river where one boat could guide bundles to the entrance of the holding ground.

Since 1952, 50 million f.b.m. (100,000 cords) have been bundle driven for distances up to 180 miles with no expenditure for channel improvements. Bundles generally travel in the main current and pass backwaters that will catch individual logs. Bundles caught by falling water clear on high water the following year.

The disadvantage to bundle driving compared to individual log driving is the cost of wire or steel strapping and the need for 6 to 8 ft. of water in the river channel.

The advantages of bundle driving over individual log driving as they apply to B.C. are:

(1) Bundles can be held on lakes and rivers waiting for high water with less danger of loss from sinkage, wind and waves.

(2) When river conditions are favourable bundles will float in the main channel and clear backwaters and where the river is navigable can be guided by river boats.

(3) Holding grounds tended by river boats can catch bundles without catching driftwood or interfering with navigation.

(4) If bundles pass the holding ground the owner can easily identify his logs and salvage while afloat.

Bundle driving is a possible method of transporting logs on several large British Columbia rivers emptying into lakes or salt water where it is necessary to move timber long distances to mills. It may be applicable to other Canadian rivers where limited timber volumes or other conditions make this cheaper than driving individual logs or hauling by truck or railroad.

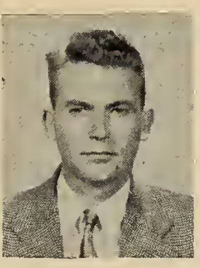
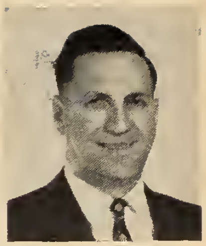
MEET THE AUTHORS

D. C. Rose, M.E.I.C., Principal Research Officer, National Research Council, Ottawa, Ont. *(The International Geophysical Year.)* A graduate of Queen's University, Kingston, (B.Sc., 1923; M.Sc., 1924), Dr. Rose obtained his Ph.D. from Cambridge University in 1927. He has been a member of the National Research Council staff since 1930, and is at present in charge of research on cosmic rays; during World War II he was on loan for five years to the Department of National Defence. Dr. Rose is chairman of the Canadian National Committee for the International Geophysical Year.



R. F. Chinnick, Superintendent, Electronics Wing, Canadian Armament Research and Development Establishment, Quebec, Que. *(The CARDE I.G.Y. Upper Air Research Program.)* Mr. Chinnick is an engineering graduate of Queen's University, Kingston, (B.Sc., electrical, 1943), and obtained his M.Sc., physics, from the University of Toronto in 1946. Since 1950 he has been employed by CARDE on electronics associated with missiles, missile ranges and research.

F. R. Park, Senior Research Officer, Upper Atmosphere Research Section, National Research Council, Ottawa, Ont. *(An Observatory for the Study of Meteors.)* Graduating from the University of Alberta (B.Sc., electrical engineering, 1936), Mr. Park joined the radio division of N.R.C. in 1941 after a period in industry and other government service. During the war he served as project engineer of several naval radar projects, and from the end of the war until 1956 was head of the civil radar development section, N.R.C. Mr. Park is a senior member of the Institute of Radio Engineers, and a life member of the Royal Astronomical Society of Canada.



D. R. Graham, M.E.I.C., Waterworks Engineer, City of Saskatoon, Saskatoon, Sask. *(Tunnelling Saskatoon's 14th Street Storm Sewer.)* Mr. Graham graduated from the University of Saskatchewan in mechanical engineering in 1947, after which he spent a year on waterworks construction and three years as maintenance supervisor, Saskatoon Transit System; he was in charge of the 14th Street storm sewer project for the major part of its construction. Mr. Graham has held his present position for the past five years and is now in charge of the waterworks utility.

N. L. Iverson, M.E.I.C., P.F.R.A. Engineer, Department of Agriculture, Saskatoon, Sask. *(Tunnelling Saskatoon's 14th Street Storm Sewer.)* Mr. Iverson graduated from the University of Saskatchewan, civil engineering, in 1945, and spent one year with the Standard Fruit and Steamship Company in Honduras. Since that time he has been employed with the Prairie Farm Rehabilitation Administration, primarily in design and construction of earth dams and pertinent works. He was engaged on consulting and testing of soil samples on the 14th Street storm sewer project.

R. G. Gustavson. *(Education for Tomorrow.)* Dr. Gustavson (doctor's degree in chemistry, U. of Chicago, 1925) taught chemistry at a number of institutions; he became dean of the graduate school of the University of Colorado, and later president of the university. Subsequently he went to the University of Chicago as vice-president and dean of faculties. Dr. Gustavson served for five years on the Board of Governors of the Argonne National Laboratories, whence he went to the University of Nebraska as chancellor, and from there to his present position which is that of president and executive director of Resources for the Future, Inc. This is an organization supported by the Ford Foundation; (their primary interests are making economic studies in connection with research, such as energy, land ease and management, water sheds and river basing and regional development.)

COVER PICTURE

Part of the International Geophysical Year program consists of investigations of the upper atmosphere by means of instrument-carrying rockets. The Canadian Armament Research and Development Establishment is taking part in a joint rocket program with the United States at Fort Churchill, Manitoba, where instrumentation and communication facilities have been installed. The work is described in an article on page 61. The picture shows an Aerobee rocket after firing, with some of the radio telemetering equipment.

The International Geophysical Year

D. C. Rose, M.E.I.C. *Division of Pure Physics, National Research Council*

Chairman of the Canadian National Committee for the International Geophysical Year

Read at the 72nd Annual General and Professional Meeting of the Engineering Institute of Canada, Quebec City, May 1958

THE INTERNATIONAL Geophysical Year (July 1, 1957 to December 31, 1958) was organized because experience has shown the advantage of a concentrated effort in attempting to realize a better understanding of the physical laws of nature. This applies particularly in geophysics where the objective requires measurements all over the surface of the earth. The objective in this case is a study of the physics of the earth and its immediate environment. Although we are in much closer contact with the earth than any other part of the universe, that very contact makes it difficult to study this planet as a whole. We know much more about the thin layer on its surface to which we are confined (at least for the present) than we do about any other planet but there has always been a desire to look at it from some distance away. There are also large gaps in a complete understanding of things with which we are reasonably familiar such as for example the circulation of the atmosphere and the complete radiation spectrum of the sun.

To the geophysicist who is interested in the planet as such, the earth is not solid firmament but a dynamic mass continuously undergoing change. It has a hot and probably liquid core. Thermal and material movements in the core influenced by the earth's rotation result in the generation of a very interesting magnetic field. The surface is constantly changing. Ice ages on the surface come and go. Continental areas move and rise and fall. Cracks and folds make mountain ranges which are eroded away by the action of a very dynamic atmosphere.

Fortunately, in the life of man these changes are very slow but it would be nice to know more about them. The energy exchanges are tremendous. A good sized hurricane has more energy than an atomic bomb and the energy released in a large earthquake makes even the largest hydrogen bomb look trivial.

To study these things, data are required all over the surface of the earth. Data over a limited region are of little use to anyone and there is so much to be learned that the need for exchange of information breaks down political barriers and international jealousy. This makes it much easier to organize a cooperative scientific project such as the International Geophysical Year than it is to solve some of the problems of the United Nations.

This is the third effort of this type. The first two were in 1882-83 and in 1932-33. They were known as International Polar Years. The objective back in 1882-83 was to learn more about such geophysical problems as air circulation, the occurrence of the aurora, geomagnetism, and atmospheric electricity in the comparatively unexplored parts of the world. It was realized that exploration merely for the sake of exploration without taking scientific measurements could be of no particular value. Further, the joint concentration of effort by interested groups whose individual facilities were limited produced results far greater than the proportional increase in numbers.

There were three expeditions into Northern Canada in the 1882-83 International Polar Year. One of them was partially financed by the Canadian Government, that was a British expedition to Fort Rae not far from the now thriving town of Yellowknife. A German expedition went to Kingua Fiord in Cumberland Sound, a little over a hundred miles north of the growing town of Frobisher on Baffin Island. An American expedition studied the coasts of Greenland and Ellesmere Island. This expedition discovered Hazen Lake in Northern Ellesmere Island where a party is

The International Geophysical Year (July 1, 1957 to December 31, 1958) is an effort on the part of geophysicists to pool their resources in studying the physics of the earth, particularly in regard to problems which require simultaneous or synoptic measurements over the whole surface of the earth. Two previous similar efforts in 1882-83 and 1932-33 were limited to polar regions and were called "International Polar Years". In the present paper the history and organization of the project is presented briefly. In each of the fourteen different disciplines (fifteen in the Canadian program) the highlights of the scientific objectives are presented with a description of the Canadian Program. The different disciplines are: I World Days, II Meteorology, III Geomagnetism, IV Aurora and Airglow, V Ionosphere Physics, VI Solar Activity, VII Cosmic Rays, VIII Latitudes and Longitudes, IX Glaciology, X Oceanography, XI Rockets and Satellites, XII Seismology, XIII Gravity, XIV Nuclear Radiation, XV Meteor Studies.

now studying the glaciation of that area.

During the second International Polar Year there were six special expeditions in Northern Canada and the network of meteorological stations in existence then contributed to the program. One of these expeditions was British the rest Canadian. The British group was again at Fort Rae. Canadian groups worked at Cape Hopes Advance, Chesterfield Inlet, Coppermine, Meanook, and Saskatoon. Some of the Canadian scientists who took part in these expeditions are now playing an active role in this International Geophysical Year. Fig. 1 is a map showing the location of these stations.

Our Canadian program this year lists eighty stations taking measurements in Canada. Only two or three of these were established because of the I.G.Y. The rest are in existing laboratories, at weather stations or similar outposts which have been extended right to our most northerly land during the last twenty-five years' growth. Fig. 2 is a map showing the location of the 1957-58 stations. When the suggestion was put to us about six years ago that a third International Polar Year be organized there was not much enthusiasm among the Canadian scientists concerned because we felt we were pretty well extended into Arctic regions. The change from polar to world-wide objective raised our enthusiasm considerably and the whole program has had a very wide popular appeal.

THE INTERNATIONAL ORGANIZATION

The I.G.Y. has been organized under the supervision of the International Council of Scientific Unions. This is a body made up of representatives from the various International Scientific Unions. An International Committee was formed about five years ago known as the Comité Special de l'Année Geophysique Internationale (C.S.A.G.I.). This Committee was formed by selected representatives from nine International Scientific Unions concerned with geophysical problems. There is an Advisory Council to C.S.A.G.I. which may have representatives from all countries taking part in the organization. About seventy countries have formed national committees. The C.S.A.G.I. and the Advisory Council meet together once a year and a number of delegates attend so that working groups can be formed in the various branches of the program.

A bureau is maintained at Uccle, Belgium, under the direction of Dr. M. Nicolet, the secretary general of C.S.A.G.I. This bureau acts as an information headquarters for the distribution of the instruction manuals and other publications prepared by the working committees and the organization of data centres. The bureau itself has five senior officers, one of whom is the coordinator.

In Canada the organization grew out of two National Research Council Associate Committees: one on Radio Science and one on Geodesy and Geophysics. The former is the Canadian National Committee of the International Radio Science Union and the latter the Canadian Committee of the International Union of Geodesy and Geophysics which held its Eleventh General Assembly in Toronto in August 1957. A Canadian National I.G.Y. Committee was organized in 1953, under the chairmanship of F. T. Davies, Assistant Chief Scientist, Defence Research Board. Mr. Davies had both Arctic and Antarctic experience having been a member of the first Byrd Expedition to Antarctica and the leader of the Canadian expedition to Chesterfield Inlet in 1932-33. This Committee drew up a preliminary program which was adopted in 1955. The problem in planning the program was one of selecting projects that could be undertaken rather than the planning of an ideal program. The amount of geophysical research to be done in Northern Canada is prodigious, as may be gathered from the outline of the objectives in the various subject headings in this paper. We can only hope to tackle a little year by year and the objective in the I.G.Y. program was to direct our efforts along the lines that fitted the international plans as closely as possible, by expanding our efforts as far as finances and the availability of trained personnel would permit.

When the preliminary plans were adopted and the time for action approached a small I.G.Y. Coordinating Committee was formed consisting of C. S. Beals, the Dominion Astronomer; F. T. Davies; D. W. R. McKinley and D. C. Rose, of the National Research Council. D. C. Rose was named chairman of this committee and a small coordinating headquarters was established in the Division of Pure Physics in the National Research Council. The Canadian organization is largely decentralized. This was convenient because there is one natural headquarters for each of the disciplines, either in a Government laboratory or in a university. This decentralization meant

Fig. 1. Map of Canada showing the stations especially established for the 1932-33 International Polar Year. Meteorological stations which also contributed are not included.

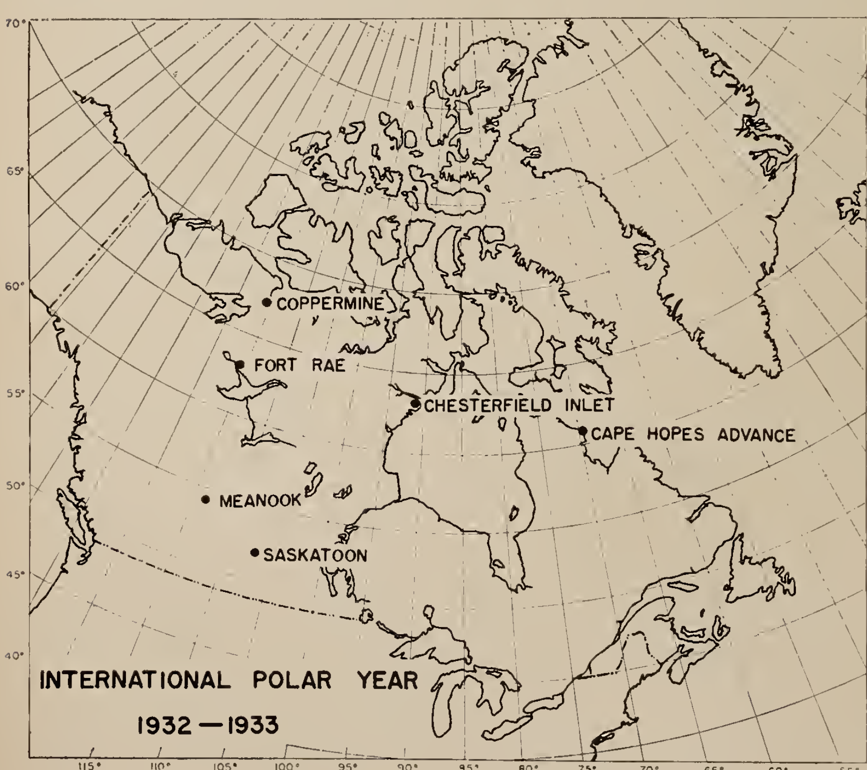

Fig. 2. Map of Canada showing stations included in the 1957-58 International Geophysical Year Program. The location of measurements in the various disciplines is shown.

that only a small headquarters was necessary and W. F. Mahoney, Administrative Officer of the National Research Council was appointed secretary of both committees. Financing of the projects is handled through the normal channels in the Government departments and by assisted research grants from the N.R.C. to universities. In 1957 Mr. Davies withdrew from the chairmanship of the larger National Committee and D. C. Rose was elected in his place.

In the international planning it was seen at an early stage that objectives must be limited to those that require synoptic or simultaneous measurements over the whole surface of the earth for their solution. There are so many problems of this type that any projects of local interest only could not be accepted as part of the I.G.Y. Another point that is of interest in this regard is that no project accepted as part of the I.G.Y. program has security classification of any sort. Although the armed services of many countries are making a large contribution to the plan any project undertaken as part of the program is unclassified and it is fully anticipated that the resulting data will be freely exchanged.

The international program is divided into fourteen separate disciplines, fifteen in the Canadian program. These are the natural subdivisions of geophysical research with the addition of "World Days" and "Rockets and Satellites". The former is included as a discipline because a working committee was formed parallel to the others and the communication problems involved made it a very important part of the plan. Rockets and Satellites are a specialty in their own right even though the data derived from their use fits into several of the other branches.

The fifteen disciplines are: I World Days; II Meteorology; III Geomagnetism; IV Aurora and Airglow; V Ionosphere Physics; VI Solar Activity; VII Cosmic Rays; VIII Latitudes and Longitudes; IX Glaciology; X Oceanography; XI Rockets and Satellites; XII Seismology; XIII Gravity; XIV Nuclear Radiation; XV Meteor Studies.

In the following paragraphs a short explanation of the problems in each is presented. The I.G.Y. objective is discussed, and Canada's part. Space restrictions make it necessary to pick only a few highlights in each case and the discussion is very superficial.

I. WORLD DAYS

"World Days" can hardly be called a discipline but the title is listed as such since an international committee was formed to select them, similar to the committees in the other specialized fields. The purpose was to select days or periods during which measurements would be more concentrated or special measurements taken. The cost of sending up larger than normal meteorological balloons, firing rockets or arranging special observing parties for aurora or meteors, was sufficient to try and arrange a concentration of effort during particular periods.

World Days that could be selected in advance include about four days each month arbitrarily chosen in relation to phases of the moon, special meteorological intervals of ten days every three months, days of solar or lunar eclipses and periods of meteor showers. A special calendar showing these days was prepared and distributed to all national committees.

There is a second type of World Days which cannot be planned long in advance. It was mentioned earlier that a large part of the I.G.Y. objective relates to solar terrestrial relationships and in later sections the possibility of predicting effects on the upper atmosphere due to solar activity are included in discussions of relevant disciplines. By a careful watch on the sun around the world and the use of up-to-date aurora, geomagnetic, and ionosphere data, periods can be predicted when there is likelihood that intense solar flares will occur facing the earth and large disturbances will result.

A World Warning Agency has therefore been established at Fort Belvoir, Virginia, near Washington. Communication channels have been set up between this and key stations all over the world. Up to date data in a coded form are sent in and warnings are sent out to every national group who wants to receive them. If conditions look right for solar activity an alert is called. This merely means that a special world interval may be arranged on short notice. Special world intervals are periods of 24 hours or multiples of 24 hours which are equivalent to world days. One channel of communication is over the United States Time Signal Station (W.W.V.). Anyone who listens to this may have noted that at about 4½ minutes after each half hour a morse signal is transmitted giving the letters A.G.I. "Année Geophysique Internationale" followed by a single letter repeated five times. "A" indicates a state of alert, "E" indicates normal conditions — no alert, "S" indicates that a special world interval will start at 0001 hours GMT the following day. Three long dashes indicates a special world interval is in progress. "T" indicates that a special world interval terminates at 2359 GMT of that day. The predictions also go out over the meteorological communication networks on most continents.

In Canada since we are near the World Warning Agency we use long distance telephone communications between Ottawa and Fort Belvoir. Two telephone calls per day are made during which ionisphere data from all our stations and solar data from Ottawa are sent to Fort Belvoir. The current summary of information about solar activity is returned. The ionospheric data from the northern stations which we send to the World Warning Centre are transmitted to Ottawa by Department of Transport communication channels.

Most of the Canadian I.G.Y. activities are on a continuous basis, therefore, World Days or Alerts have little effect on our projects though they are very important for a program like the rocket project at Churchill. This project has direct service communication channels. Therefore, communications to our remote stations about alerts and special world intervals involved no particular problem for us.

II. METEOROLOGY

Meteorology perhaps more than any other discipline is the one having a practical application that makes geophysical measurements over the whole world necessary. Meterologists admit that a practical forecaster should have some experience in the district in which he is working and to that extent his craft is an art but he bases his analyses on sound scientific measurements at all levels in the atmosphere that affect the weather. He must also be thoroughly familiar with the theoretical, hydrodynamic, and thermodynamic principles that govern the movement and modification of air masses as well as the use of practical measurements to make the calculations necessary for his prediction. There is always a compromise between the cost of a dense net of meteorology stations and getting enough data for forecasting and climatological studies.

One of the important problems in the I.G.Y. is the world-wide circulation of the atmosphere; the difference in radiation from the sun received at the equator and poles results in a circulation of the atmosphere which is broken up into motions resembling vortex rings surrounding the earth more or less parallel to latitude circles. The rotation of the earth introduces Coriolis forces which complicate the pattern through the production of meridional circulations; the inclination of the earth's axis to the ecliptic and the effects of topography and of oceans add to the complication. The cellular structure of the general circulation results in the well known wind zones—the tropical easterlies or trade winds, the middle latitude westerlies, and the polar easterlies. In middle latitudes, the circulation at any instant is dominated by migratory cyclones and anticyclones. The succession of cyclones, with their associated frontal systems, and of anticyclones result in the weather changes that are so familiar to people living at our latitudes.

A more detailed study of the world-wide circulation was obviously an objective to be undertaken at the time of the International Geophysical Year when international co-operation could make possible a considerable expansion of the normal meteorological program.

To make this world-wide study three lines were chosen from pole to pole about equally spaced around the earth but adjusted to convenient land masses. On these lines as many as possible meteorological stations have been established, taking advantage of those already in existence and filling in gaps where necessary. One of these lines is at longitude about 80° West and, therefore, passes through the Canadian Arctic, Southern Canada, the United States, Central America, the west coast of South America, the Falkland Islands, and Antarctica.

The objective is to make twice daily or if possible four times daily rawinsonde balloon ascents up to 30 kilometres and get a complete profile of that part of the atmosphere from pole to pole. This, of course, is being done without any decrease in activity of normal aerological stations; in fact, it has been recommended that 30 km. be the height objective of all aerological stations during the I.G.Y. There are 33 such stations operating in Canada.

The second heavily emphasized I.G.Y. objective is a study of the energy budget of the earth and atmosphere; that is, the heat exchange between the surface of the earth, the atmosphere, and outer space. To give some information which will emphasize the importance of the atmosphere in this regard, with clear skies only about 70% of the sun's radiation reaches the earth, 30% being absorbed in the atmosphere or scattered back to outer space. With overcast skies only about 40% of the sun's radiation gets through to the surface, the rest is scattered back to space or absorbed by the atmosphere. The mean cloudiness over the whole earth is estimated to be 52% and as a result the atmosphere on the average absorbs apphoximately 12% and scatters back to space about 35% of all the radiation we get from the sun. It is interesting to note also that water vapour, though it represents only about 0.2% of the atmospheric gases present, absorbs five or six times as much solar radiant energy as all the other gases combined.

A study of the heat balance involves the continuous measurement of radiation from the sun and atmosphere downwards and radiation from the earth upwards. It involves also some knowledge of the so-called "micro-meteorology" at the surface; that is, the vertical heat exchange by turbulence and conduction in the air close to the surface.

A station to study this heat exchange requires considerable equipment. Since knowledge is lacking more in the Arctic than in temperate zones, in Canada we are concentrating such measurements at two stations, Resolute in the Queen Elizabeth Islands and Moosonee in Northern Ontario, though continuous radiation measurements are being taken at 17 other stations across Canada.

At Resolute there is a 100-foot tower for measurement of profiles of temperature, humidity and wind. Fig. 3 is a photograph of this tower. In addition, there are radiation-recording instruments covering the spectrum from infrared to ultraviolet.

Another important objective is the measurement of ozone in the atmosphere. Ozone is formed from dissociated oxygen and oxygen molecules in the atmosphere at levels from 20 to 60 kilometres. Although it represents only a small fraction of the gas at these levels, ozone is responsible for the abrupt short-wavelength cutoff of solar radiation received at the ground, since it is very opaque to ultraviolet light of wavelengths below about 3,000 angstrom units. Absorption of ultraviolet radiation by ozone and by molecular oxygen is the reason for the temperature maximum in the atmosphere in the vicinity of 50 km., with temperatures of the same order as those observed at the ground.

The integrated ozone amount can be determined by comparative spectroscope measurements using sunlight or moonlight. Ozone in the surface layers is most readily determined by a chemical technique. Both these measurements are being undertaken at Resolute, with total ozone being observed also at three other stations. The surface measurements combined with upper atmosphere measurements give some information on vertical distribution of ozone and, indirectly, on dynamical processes at very high levels.

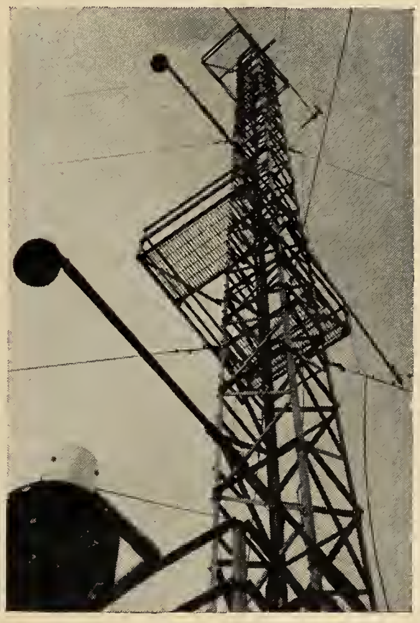

Fig. 3. The meteorological tower, 100-feet high, at Resolute, latitude 74.7°N, longitude 95.0°W. This tower carries instruments to study micrometeorology in the first 100 feet of the atmosphere. (Meteorology Division, Department of Transport).

The distribution of data for the meteorological program is interesting. The World Meteorological Organization (W.M.O.) has been in operation for many years with headquarters in Geneva. They are undertaking the reproduction of routine and special data from every major meteorological station in the world during the eighteen months of the I.G.Y. This will be done on microcards and copies will be available to anyone who is willing to pay the cost of reproduction, about $6,000. These cards are the equivalent of many volumes of printed data.

The meteorological program in Canada is the responsibility of the Meteorological Branch of the Department of Transport, whose headquarters are in Toronto.

III. GEOMAGNETISM

The earth's magnetic field is still of some importance for navigation. It is far from constant in intensity and its variations are of the greatest scientific importance both in studying the interior of the earth, the upper atmosphere, and solar activity. The source of geomagnetism is mostly within the earth. Theories suggest that it is caused by a dynamo action in the molten centre of the earth resulting from its rotation and thermal effects. These create an actual flow of the liquid core and a magnetic field is developed. This internal field changes slowly but at such a rate that secular changes can be observed in a life time.

The perturbations or short term variations are, however, more clearly a part of the I.G.Y. program. The diurnal variation varies in amplitudes in a way that is related to solar activity, and magnetic storms can often be associated with particular outbursts of activity on the surface of the sun. For instance, a solar outburst is very often followed 1 to 4 days later by a magnetic disturbance. The delay represents the time taken for a beam or cloud of particles to reach the earth. This beam or cloud, being ionized, is electrically conducting and on interacting with the earth's field forms a system of electrical currents outside the earth's atmosphere. These can account in some detail for changes in diurnal variation and the form of the commencement of magnetic storms.

The objectives in geomagnetism in the I.G.Y. are to get more information over the whole surface of the earth on the details of the variations found during magnetic storms. Continuous measurements on the earth's magnetic field have been carried out for well over a century and there is a permanent network of stations. During the I.G.Y. this network is being enlarged to include magnetic measurements at remote points not normally occupied, such as the stations in Antarctica. Magnetic measurements are also of considerable importance in studying the aurora and ionospheric disturbances, both of which are related to solar activity. Therefore, a record of changes in the earth's magnetic field is being taken whenever possible at every auroral observing station, that is, every station where a continuous watch with electronic or photographic instruments is kept on the aurora. The onset of a magnetic storm is an indication of a high probability of aurora for several nights following the start of the storm.

In Canada geomagnetic investigations are one of the fields of activity of the Dominion Observatory in the Department of Mines and Technical Surveys. The Observatory normally operates magnetic stations at Resolute, Baker Lake, Agincourt, and Meanook. Starting with the I.G.Y. additional stations have been established at Yellowknife and Victoria, and recording magnetometers have been located at the chain of aurora stations between Resolute at latitude 75°N and Winnipeg. More will be said about this chain of stations in discussing I.G.Y. aurora observations. Magnetic measurements are being taken at eighteen stations in Canada.

Besides direct measurements in the earth's magnetic field, a study of currents in the earth which are probably induced by magnetic changes is very interesting. The study of earth currents is also a very old science but interest in it has been revived recently because it is a convenient way of studying rapid pulsations in the magnetic field, these pulsations having periods from a fraction of a second up to a few minutes.

Modern technology has made it possible to develop an airborne magnetometer which has sufficient precision for geomagnetic surveys and can measure three components independently. Only about four such instruments have been built throughout the world and the Dominion Observatory built one of these. It is being used in connection with the I.G.Y. program.

IV. AURORA AND AIR GLOW

The aurora which makes a brilliant display in the northern sky is caused by streams of particles coming from the sun. Near the earth they are deflected by the earth's magnetic field and make their display in the upper atmosphere, most frequently in a broad ring roughly about 20° of co-latitude away from the geomagnetic poles. The geomagnetic poles represent the axis of an imaginary magnetic dipole at the centre of the earth, the field of which would most closely represent the earth's magnetic field.

The details of the interactions that cause these northern lights are not known but it is clear that an important role is played by streams of protons and electrons. X-rays and ultraviolet light are also known to be present. These particles and radiations collide with air molecules in various stages of dissociation and ionization and in so doing make the brilliant display the spectral analysis of which took many years to unravel. Exchanges between energy levels in atoms and molecules which are normally classed as forbidden and do not occur in laboratory experiments often occur in aurora spectra. This is because of the extremely low pressure and hence long free path of atoms or molecules between collisions which could not be duplicated in any experiment of laboratory dimensions.

One of the important problems in the aurora is the location of the belt of maximum frequency and the frequency of occurrence of various types of auroral patterns. These are being analyzed in relation to solar activity, magnetic and ionosphere disturbances. The height of the aurora varies from about 75 km. up to about 1,000 km., the maximum frequency being just above 100 km. During the 1932-33 International Polar Year height measurements were considered of great importance. A great many such measurements have been made then and in the intervening years, so many that in the current effort the emphasis is more on geographic distribution of the various types and frequency of occurrences.

Several methods of attack are being undertaken. Since the auroral discharges result in or are associated with increases in electron density, radar reflection is a means of studying aurora and this method has been used extensively during the past decade. This has the advantage that the detection of aurora is not limited to darkness or to nights of clear sky.

A photographic technique involves the use of a camera which sees the whole hemisphere of the sky from horizon to horizon (see Fig. 5). This instrument is simply a movie camera mounted on a light frame, usually four thin legs, with the lens pointing downward. It is focussed on a convex mirror and the whole hemisphere of the sky is reflected from the mirror. Photographs taken every minute are studied individually or projected at standard motion picture frequency to study the changing pattern and motions throughout the night. Patrol spectographs are also being used at auroral stations. This is an instrument by means of which the light from a band across the zenith from horizon to horizon is focussed on a slit spectrograph and a photograph of the spectrum is taken every few minutes. Analysis may then be made of the type of excitation and molecule involved in the display.

Another instrument is a photoelectric auroral intensity recorder. This instrument scans the sky in steps from the horizon in the north upwards through the zenith to the horizon in the south. Such a scan is completed in under two minutes. The measured intensity is put automatically on punched tape and the data can be handled by machine methods.

The location of stations to study the aurora has been carefully considered. Though the band of maximum frequency is known to be approximately 20° off the geomagnetic axis it will take a great deal of observation to be certain of the location of this band, how it moves with season and with changes in solar activity. Some groups of auroral physicists have suggested an inner auroral band north of the well known region or alternately a spiral shape for the band rather than a circle.

The location of the auroral band is such that the large portion of it that is not over oceans is in Canada. The geomagnetic pole is in Greenland about 100 miles north of Thule. The band of maximum intensity passes roughly through central Labrador, the south end of Hudson Bay, Churchill, the northern tip of Alberta, central Yukon and northern Alaska, out through the Chukchee Sea, touches the coast of Siberia and northern Norway and Sweden. The only country where a chain of stations crossing the auroral band can be established on land is in Canada. Our responsibilities, therefore, in auroral observations for the I.G.Y. are considerable, and it is not unnatural that auroral research is considered one of the most important parts of the Canadian program.

In addition to instrumental stations which will be described below, visual observers, many of them voluntary, have been organized throughout Canada and northern United States. This is a cooperative effort by the upper Atmosphere Research Group at the National Research Council, organized by P. M. Millman, and an Auroral Research Group at Cornell University led by C. W. Gartlein.

To do this a graphical auroral report form has been designed on a 4 x 6 inch format. This form is quite simple to use and by filling appropriate places on the form the position of the aurora in the sky can be indicated. The shape of the display is drawn in an appropriate place on the card which indicates the quadrant in which it is observed and its angular height. The observer then marks the location of his site, the time to the nearest minute, signs his name and mails it to the aurora centre at the National Research Council, if in Canada, or to a corresponding centre at Cornell University, if in the U.S.A.

The primary aim of this visual program is to secure material for synoptic charts of aurora over North America. Data from the forms are handled by an I.B.M. punched card data analysis system. Both the visual data and instrumental data are being plotted on special maps prepared for the purpose which will be used to present a synoptic picture of the occurrence and type.

Ideally these forms should be filled in every fifteen minutes during auroral displays but all data are valuable and even at places where an observer can only go out and look at the sky occasionally and fill in a card, the data are useful. Valuable cooperation in this project is being given by many types of activity where night crews are necessarily on duty. Radio stations, meteorological stations, aircraft pilots, amateur astronomical groups are examples of people making useful contributions.

In selecting the sites for the instrumental stations, an attempt was made to arrange a fairly dense array of stations at points where there was already a scientific station of some sort and to form a line across the band of maximum auroral activity. A chain of stations was chosen roughly on a line from Alert (the most northerly tip of Canadian territory on Ellesmere Island) to Winnipeg. The stations include Alert, Resolute, Baker Lake, Ennadai Lake, Churchill, Bird, Flin Flon, the Pas, Saskatoon, and Winnipeg. Saskatoon has been a centre for aurora research since the International Polar Year of 1932-33. B. W. Currie, in the University of Saskatchewan, has taken aurora measurements there and jointly with the Defence Research Laboratories at Churchill has built an auroral research centre of considerable international importance.

Besides the concentrated group of stations there are stations scattered in eastern and western Canada. Another less dense line of stations towards the west would include Resolute, Fort Norman, Yellowknife, and Meanook and Victoria. In the east measurements are taken at Knob Lake, Goose Bay, and Ottawa. The equipment scattered among these stations consists of 18 all-sky cameras, 10 photoelectric auroral intensity recorders, 4 auroral radar sets, 5 automatic patrol spectrographs, and height-determining photographic equipment near Churchill. This latter height-determining project is part of the Canadian contribution to the U.S.A. Rocket Project which will be described in more detail in a later section.

The airglow from the night sky is also included in the title of this branch of geophysics. Airglow at high altitudes in the night sky represents the radiations emitted by recombination of ions and molecules which were acted on by sunlight. From spectroscopic studies of the night sky a great deal has been learned about the chemical constitution of high levels in the atmosphere. At Canadian latitudes it is of course difficult to separate airglow from aurora, therefore, not much research has been done in Canada in this field. It is normally studied at more southerly latitudes or at least further away from the aurora band. We have no systematic study of the night sky in our Canadian I.G.Y. program.

Fig. 4 (left) The Dominion Observatory's Research Station at Meanook, Alberta, where a large number of I.G.Y. measurements are being taken. An auroral display is shown, the all-sky camera can be seen on the roof, and a comet is seen to the left of the tower. This picture was taken on 7 August, 1957, by the Dominion Observatory staff.

Fig. 5. The all-sky camera being adjusted by Mr. K. W. Christie of the National Research Council's Upper Atmosphere Research Group. The pictures at the bottom are a row of frames taken with the camera showing aurora.

V. IONOSPHERE

The ionosphere really came to its own during World War II when ionosphere data were used extensively to improve communications. In summary the ionosphere consists of three layers or regions high up in the atmosphere which are kept in such a state of ionization by radiation and particles from the sun that there are enough free electrons and they have sufficiently long free paths to reflect radio waves. The pressures and electron density suitable for reflection of radio waves begins to be effective at heights of about 100 kilometres. There is a maximum in electron density at about 110 km. (at least in daylight) after which the electron density falls off a little, then increases again to a second maximum around 200 km. and a third at 350 and 400 km. These are known as the E, F_1, and F_2 regions respectively. Their heights and electron densities vary with sunlight (the E layer is usually absent at night) with the season of the year, and with the sunspot number representing an index of solar activity. Besides these rather regular variations there are ionosphere storms which are caused by bursts of solar activity.

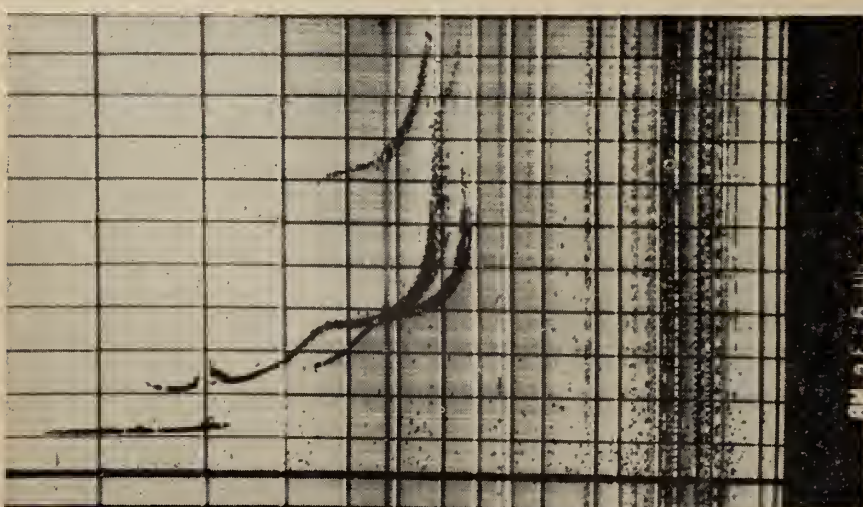
A fourth region lower down, called the D region, forms sometimes at a level of pressures and electron densities which absorbs all of those radio waves which are normally used for communication and causes a complete blackout. This D region occurs at periods of high solar activity and the blackout usually occurs at the same time as magnetic storms and aurora. The ionization which forms the D region is believed to be due mainly to soft X-rays or light waves in the far ultra violet. Radiation from the sun in this region is enormously variable and can only be measured directly by rockets fired to appropriate heights.

The reflecting layers by no means have a smooth and regular pattern. It was mentioned above that besides the diurnal and seasonal variations they are subject to storms. In fact like the weather, though average conditions may be well defined, average weather is rarely experienced. Mean heights and electron densities and their diurnal and seasonal variations are published and these are important in planning radio communication but the variation from the mean is considerable.

The surface of the reflecting layers, like clouds, is broken up into patches and is subject to winds. The main objective in the I.G.Y. is to study the fluctuations rather than the regular behaviour. There has been a network of stations throughout the world studying the average conditions and their variations for fifteen years or so. The I.G.Y. program is adding something to these, covering regions where data are lacking, for instance, Antarctica, and installing special equipment at other stations to study particular phases of the storminess or irregularities in the ionosphere.

The Canadian program has its headquarters in the Radio Physics Laboratory of the Defence Research Board at Shirley Bay, near Ottawa, with a second ionsphere headquarters in the University of Saskatchewan at Saskatoon. Stations are operated at various points in the Arctic and across Canada many of them manned and maintained by the Department of Transport's Telecommunication Division.

Fig. 6. Vertical sounding ionosphere record. This is an actual photograph of the oscilloscope pattern. The vertical lines represent frequencies from 1 to 20 Mc./sec. The horizontal lines are virtual height in hundreds of kilometers. Reflections from the E region and F_1 and F_2 regions are shown with a multiple reflection from one of the latter. (Defence Research Board's Radio Physics Laboratory).



1. Absorption Measurements

The critical frequency at which reflection of a pulse at vertical incidence stops and the beam penetrates the layer gives a measure of the electron density. The time delay of the return echo gives the virtual height. These are the normal measurements recorded at ionosphere stations. A study of the intensity of the reflected signal related to the intensity of the pulse sent out gives a measure of the amount of absorption in the intervening space between the ground and the reflecting layer. This is one of the I.G.Y. projects and is being carried out at five stations in Canada.

2. Audio-frequency Waves (Whistlers)

This is a very interesting natural phenomenon which has led to a greatly increased knowledge of the environment outside the earth's atmosphere. When a lightning flash makes an electromagnetic wave the low frequency components (that is in the audio range from a few cycles per second up to a few kilocycles) are transmitted upwards through the ionosphere. In a conducting media even at very low densities where there is a magnetic field the action of the electromagnetic wave as scattered by conducting electrons makes the wave travel effectively along the lines of force of the magnetic field. Such a lightning flash say at our latitude sends out a burst of energy which follows a magnetic line and returns to the earth at a corresponding geomagnetic latitude in the southern hemisphere. In travelling over this path dispersion of the different frequencies takes place and what is heard is a whistle starting at a high pitch and going through the audio range in a second or two. The wave may be reflected back again and in fact several reflections are often heard.

The path of such a wave from temperate latitudes such as ours travels out from the earth a distance equivalent to three or four earth's radii. This path can be calculated and the minimum electron density in the path can be estimated. This comes to over 500 electrons per cubic centimetre showing a much higher density of matter than had been expected at such levels. Canadian and U.S.A.

groups are working jointly on Whistlers at six stations in Canada.

3. Scintillation and Cosmic Noise Absorption

In trying to measure absorption in the ionosphere at frequencies which can penetrate it, we take advantage of sources of radio waves from the sky. Particular radio stars are used in which the scattering causes the radio source to scintillate like the visible light from a star. Cosmic noise from the sky can also be used to measure the total absorption in the lower ionosphere, the measurements being taken on a simple antenna looking vertically. These measurements are being taken at three stations in Canada.

4. Vertical Incidence and Tides

Vertical incident ionosondes were mentioned early in this section. Five regular stations and nine special I.G.Y. stations take measurements regularly in Canada, the farthest north being Alert. Another type of study is ionospheric tides or changes in E layer levels caused by lunar variations. Continuous measurements on a fixed frequency of the E layer height is used to study this.

5. Forward Scatter

Irregularities in the ionosphere will act as scattering centres of waves of a frequency which normally penetrates the ionosphere. In Canada, near the auroral zone, many irregularities occur in the lower ionosphere which are capable of scattering these very high frequency radio waves, even when very little power is used. A study of these irregularities, some of which are associated with visible aurora is being made from a transmitting station at Yellowknife with receivers at Baker Lake, Churchill, Saskatoon, Sulphur Mountain (near Banff), and The Pas.

This type of measurement is complicated by the presence of meteor trails. These cause bursts of ionization at ionosphere levels which will reflect much higher frequencies than will the ionosphere.

Fig. 6 is a photograph of an actual ionosphere record showing the way the frequency vs. virtual height is displayed by a cathode ray oscilloscope. The vertical lines represent frequency, the range covered being from 1 to 20 megacycles per second. The horizontal lines are vertical height in hundreds of kilometres.

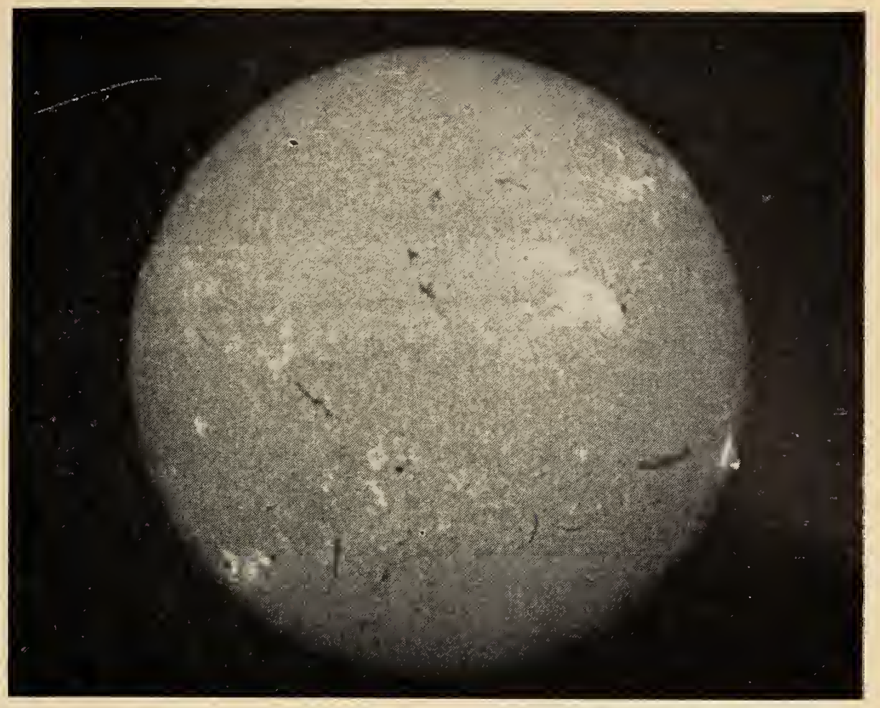


Fig. 7. The sun taken through a filter which passes only the hydrogen red spectral line. A solar flare is seen at the limb (lower right). (Dominion Observatories' photograph).

VI. SOLAR ACTIVITY

As mentioned in the introduction, so many of the branches of physics of the upper atmosphere display phenomena closely related to conditions on the sun that observations of the sun must be a part of the I.G.Y. program. A very simplified description of the behaviour of the sun which produces terrestrial phenomena is the following: Dark spots appear on the surface of the sun in irregular intervals but their average number follows a well known eleven year cycle. (*The present I.G.Y. period was chosen because it coincided with the peak of one of these cycles.*) When the sun is viewed through special filters, bright patches are seen to occur in the region of the sunspots. These events are known as solar flares. While a sunspot or group of sunspots may last several months, individual flares last usually a few minutes, rarely over an hour. A typical series of events is as follows. A strong solar flare will appear near the region of activity containing one or several sunspots. If this is an intense flare, a radio blackout will take place simultaneously on the sunny side of the earth. A small disturbance may be noted on the magnetic record. About 24 hours later (not exactly 24 hours but some time within one or two days), a magnetic storm will start. Ionosphere disturbances will take place, aurora will be seen, and a decrease in the intensity of cosmic rays may be noted.

Like all averages, actual events are never exactly like the typical or average one, and some of the above phenomena may not be seen every time there is a large flare. The simplest explanation of the so-called average sequence of events is that at the time of the flare there is an intense burst of radiation, particularly in the far ultraviolet, which reaches the earth with the speed of light and causes the immediate effects such as a radio blackout on the sunny side of the earth. At the same time a beam or clouds of particles are shot out from the sun with a wide range of energies, but with a velocity much below that of light, reaching the earth hours later and producing the aurora, ionosphere disturbances, and magnetic storms.

Since the correlation with what is observed on the sun and what is measured on the earth is far from perfect, a detailed watch on the sun is an important part of the I.G.Y. program. As the sun rotates, disturbed areas on its surface may be seen as they come over the limb of the sun. A disturbed region if at all large usually lasts for several periods of solar rotation which is approximately 27 days. By watching for these and keeping a close watch for solar flares a prediction can be made for ionospheric and magnetic disturbances. It is much like weather forecasting in that knowledge of all phases of the complicated phenomena is far too incomplete for certainty in forecasting. However, in large experiments like firing a rocket into an auroral display it takes only a few days to get ready and once ready, firing must take place within a few hours; hence any forecast is of considerable value.

A continuous watch can be kept only by having observatories scattered around the earth with suitable equipment for recording what is going on on the sun's surface. A solar flare cannot be seen in the ordinary light from the sun but stands out very clearly if photographed in the light of certain spectral lines, for instance, the hydrogen red line. As many observatories as possible having suitable equipment are taking photographs of the sun minute by minute in this way. Even though practically all large observatories are co-operating, the coverage is not perfectly complete. A whole continental area may be clouded over, making observations impossible.

Another index of solar activity is the intensity of radio waves received from the sun. The intensity of radio waves in the microwave and VHF region varies considerably with conditions in the solar atmosphere. This field of radio astronomy is comparatively young, having grown with the rapid advances in radio technology since World War II.

In Canada our Dominion Observatory at Ottawa is taking pictures of the sun twice a minute at all times the sun can be seen. These are developed every day and data are sent to the World Warning Agency at Fort Belvoir near Washington. Fig. 7 is a photograph showing a solar flare taken by the solar physics group of the Dominion Observatory.

Three groups are also taking measurements on solar radio emissions. The National Research Council has extensive equipment working at a wavelength of 10.7 centimetres. A large fan type antenna has a resolution of only 2 minutes of arc, so that the location of the emission on the sun's surface can be observed at least to the extent of looking at a slit across its disc. The Defence Research Board at Shirley Bay, near Ottawa, are taking measurements at 50 and 500 megacycles, and the University of Toronto is using 300-megacycle equipment at the David Dunlap Observatory at Richmond Hill.

Much could be written on the problem of organizing the collection of data at the World Warning Agency at Fort Belvoir and distributing it to remote stations who want to use it. The data comes from many countries and a great variety of communication channels are used.

VII. COSMIC RAYS

The study of cosmic rays is important in geophysics because they represent another phenomenon that is strongly influenced by solar terrestrial relations. Cosmic rays are the nuclei of atoms of the known elements, the relative number of particles of different masses being about the same as the numbers of different elements throughout the universe. Primary cosmic ray particles are about 85% protons, all but 1% of the remainder are helium nuclei or α-particles, and the 1% represents the heavier elements presumably through the mass spectrum. Their energy is very high, much higher than the energy of individual particles found in nuclear physics. The highest energy available in any one particle from nuclear interactions is of the order of 20 x 10^6 electron volts. Cosmic rays would hardly be classed as such unless they were in the hundreds of millions of electron volts and the highest energies observed in individual events are of the order of 10^{18} electron volts.

These energetic particles come from interstellar space. The exact process by which they acquire their energy is not definitely known but theory suggests that charged particles having moderate energies and interacting with moving clouds of matter containing magnetic fields can gain energy up to the amounts observed.

Since the cosmic rays are charged particles their motion is affected by the earth's magnetic field. The theory of this has been well worked out and measurements agree to the extent that the flux of particles reaching the equator is considerably less than that reaching polar regions. When the distribution in intensity over the surface of the earth is examined in detail, discrepancies are found which we hope will be cleared up by some of the I.G.Y. measurements from satellites.

The discrepancies lie in the fact that the theory is based on the assumption that the earth's magnetic field can be represented by a magnetic dipole near the centre of the earth. Surface anomalies make the location of the magnetic poles some distance away from the axis of the dipole but it would be expected that the surface anomalies would not be effective at any great distance from the earth and the cosmic rays would react as though affected by the nearest equivalent dipole. Recent surveys over equatorial regions show that this is not the case and the measurements indicate that the more complicated pattern of the earth's field must have considerable influence on cosmic ray particle orbits. In this type of study cosmic rays are being used to obtain information about geomagnetism just as much as the inverse has been true.

Surface measurements are complicated by the fact that the primary particles do not penetrate far into the atmosphere without colliding with an air nucleus. The collision results in an exchange of nuclear energy and in interactions at such high energies all the fundamental particles of nuclear physics may be created. In fact many of them were discovered in studying cosmic rays. Enough is known about the penetration of the secondary particles to sea level to use sea level measure-

Fig. 8. The National Research Council's Cosmic Ray Laboratory on top of Sulphur Mountain near Banff, Alberta. Altitude 7,490 feet. The antenna in the background is for ionosphere scatter experiments from a transmitter at Yellowknife. (Alberta Government photograph).

ments to interpret intensity changes in the primary flux. The energy loss in penetrating the atmosphere, however, limits surface measurements to the interpretation of the behaviour of primaries above a minimum energy of about 10^9 electron volts. The interpretation is also complicated by atmospheric corrections.

There is a great advantage, therefore, in being able to take measurements outside the atmosphere in a satellite, in rockets or near the top of the atmosphere with balloon-borne equipment. The first U.S.A. and the second U.S.S.R. satellite both contained cosmic ray measuring equipment. A considerable part of the effort of the rocket program at Churchill is devoted to cosmic rays.

Fig. 9. The camp at Hazen Lake. This is the Defence Research Board's expedition to Hazen Lake on Northern Ellesmere Island about 500 miles from the North Pole. (G. F. Hattersley-Smith, leader of the expedition).

In spite of the advantage of high altitude measurements, long-term intensity changes can still best be studied with large and heavy apparatus at ground level, preferably on mountain tops. These are very important because of the intensity changes that are connected with solar activity. Five times in the history of cosmic rays sudden increases in intensity have been observed, each one associated with a strong solar flare on the sun. Many such flares have occurred without any observable effect on cosmic rays. Analysis of these indicates that a burst of particles of energies up to perhaps 30 x 10^9 electron volts must be produced in the sun but their motion is modified by some form of clouds of very tenuous interplanetary matter having a large electrical conductivity and magnetic fields bound to the cloud because of the high conductivity.

Other types of variations in intensity are: occasional rapid decreases associated with magnetic storms, a quasi-periodic variation of the same period as the sun's rotation, a slow change in intensity following changes in solar activity but in the opposite sense, and a diurnal variation.

The Canadian program was largely planned with the objective of studying these intensity changes. We have four stations: Ottawa, Resolute, Churchill, and one on top of Sulphur Mountain near Banff. These are operated by the Division of Pure Physics of the National Research Council. A further group of measurements is being undertaken at Deep River by a research group in Atomic Energy of Canada Limited.

In order to study the nuclear interactions we are also sending special nuclear photographic emulsions on balloon flights to heights in the atmosphere as high as 140,000 feet. Nuclear interactions take place between primary cosmic rays of high energy and the elements in the emulsion. This is a well known technique of studying the nature of the primary cosmic rays.

Fig. 8 is a photograph of the laboratory on top of Sulphur Mountain built there for cosmic ray studies.

VIII. LATITUDES AND LONGITUDES

The I.G.Y. objectives in latitudes and longitudes is largely related to the rotation of the earth and its exact shape. The title "Latitudes and Longitudes" refers to the fact that the earth's axis has small precessional motions, and the position of the poles on its surface changes slightly throughout the ages. These changes have been studied for years. Some changes are regular or periodic and can be predicted, others are not. The results of these motions are changes in mean solar time.

Geodetic measurements across a country like Canada are referred to the spheroid accepted as the most exactly known shape of the earth. The actual measurements, of course, are made on the geoid or the surface of uniform gravitational potential. Correcting to the spheroid is done if gravity anomalies are known. A survey of one continent is referred to the spheroid calculated from measurements on that continent and is not necessarily the same spheroid as used in some other continent's net. One of the objectives of the I.G.Y. is to try to get a more accurate knowledge of the exact shape of the whole earth.

The satellite program is very important in that objective. The ellipticity of the earth causes precessions in the satellite's orbit, the measurements of which gives a measure of the shape of the ellipsoid that is independent of surface geodetic measurements. Further, by accurate timing of the satellite from several stations, intercontinental distances can be calculated.

Another technique recently developed is the dual-rate moon-position camera. The dual-rate feature of this camera makes it possible to take a photograph of the moon and stars holding both still on the the photographic plate. Since the position of the moon is known with high accuracy each photograph makes possible a measure of the observer's co-ordinates with respect to the centre of the earth. Similar observations from several stations may produce another measure of the shape of the earth without reference to gravity. Also each photograph aids in the determination of ephemeris time, which in turn defines the unit of time, the second. Canada's program in this field is to operate one of the Markowitz dual-rate moon cameras mounted on the Dominion Observatory's 15-inch equatorial telescope.

The Dominion Observatory, by use of the photographic zenith telescope, is also co-operating with other observatories around the world in studying variations in solar time, in measuring the variation of latitude, and in the distribution and reception of radio time signals.

IX. GLACIOLOGY

About one-third of the important glaciers within the Northern Hemisphere are in Canadian territory. Glaciers have an important bearing on hydrography of land areas and considerable influence on climatology. In the section on meteorology the importance of the energy balance between the sun, the earth, and its atmosphere was emphasized and some complications in its measurements were suggested. The heat balance is very critical in changing the surface of the earth, and geological studies in the past suggest more than one ice age. The amount of the earth covered with ice would be expected to change considerably with comparatively small changes in solar radiation or small changes in the inclination of the earth's axis to the ecliptic.

It is, therefore, rather important that glaciers be studied, particularly, that studies of as many ice fields as possible be made from time to time so that slow movements and growth or recession can be recorded. Melting and growth are important and there is a great storehouse of climatological data in glaciers because by digging into them the annual layers of melting can be seen for many decades of years back just like rings in a tree.

Glaciological studies were rather neglected in Canada until a few years ago but there is an active group now in the University of Toronto, Institute of Geophysics, McGill University's Geography Branch, and research is starting in the University of British Columbia and the University of Alberta. The Defence Research Board has an active interest and is operating a glaciological expedition in Northern Ellesmere Island during the I.G.Y. The National Research Council's Division of Building Research has an active interest in snow, ice, and permafrost problems related to buildings and transport.

The following expeditions were undertaken as part of the I.G.Y. program. During the summer of 1956 an expedition organized by the University of Toronto went to the Salmon Glacier near the British Columbia coast. This was considered a pre-I.G.Y. expedition. It was repeated during 1957. Measurements were taken on the thickness of the ice by seismic methods. Samples were collected down to considerable depth, movements of the glacier and ablation were studied, gravity and magnetic surveys were made and, of course, meteorological observations.

The Defence Research Board is now operating an expedition to the glaciers near Hazen Lake in the northern part of Ellesmere Island about 500 miles from the North Pole. A party of four spent the winter there in 1957-58 and will be augmented during 1958 to take more scientific measurements during the summer. Geological work will be carried out in this area and studies of erosion as well as the

Fig. 10. An Aerobee rocket being fired at Churchill, Manitoba. The tilted launching tower is shown and some of the radio telemetering equipment. (Official U.S. Army photograph).

measurements mentioned in the previous paragraph.

The National Research Council's Committee on Soil and Snow Mechanics is carrying out a modest survey of snow, largely a study of its mechanical properties in relation to meteorology at seven stations spread across Canada.

A group in the University of Toronto has just completed a map and listing of all Canadian glaciers. This has been prepared from aerial photographs and will be of immense value in planning future studies.

Fig. 9 is a photograph of the camp of the Defence Research Boards' group at Hazen Lake.

X. OCEANOGRAPHY

The physics, chemistry, and biology of our great oceans are very complicated, but of great importance to the world's economy. A casual look at standard books on the oceans shows unanswered research problems in every branch of science. The I.G.Y. objective centres around co-operative studies of the circulation of the great oceans, the exchange of water between layers near the surface and at great depth, and more detailed observations of mean sea level.

A complete survey of the circulation in the great oceans cannot be carried out very often. One of our objectives is to see what changes have taken place in the layering and the physical and chemical properties of the Atlantic Ocean since surveys made by a group of ships twenty-five to thirty years ago. In the Pacific an attempt is being made to get a reasonably complete picture of its circulation. Certain other areas have been chosen where more detailed studies will be carried out. For instance, a detailed survey of the Western North Atlantic is being carried out in the Baffin Bay, Davis Strait, and Labrador sea area. This is being co-ordinated by the International Commission for Northwest Atlantic Fisheries. In the Eastern Pacific several co-operative surveys have been planned under the NORPAC Committee of the International North Pacific Fisheries Commission.

Canada has two oceanographic stations taking part in these measurements, one on each coast. These stations are part of the Fisheries Research Board's station at St. Andrew's, New Brunswick, and Nanaimo on Vancouver Island. Two or three ships operated by the Royal Canadian Navy are usually available on each coast for oceanographic work. Measurements at sea consist of temperature measurements and sampling for salinity and other chemical constituents at various depths in the ocean. Some of the chemical measurements require immediate analysis; therefore, ships for this purpose have to be equipped with laboratories as well as special winches for handling the equipment.

All levels of land are referred to a level known as mean sea level. Mean sea level would represent a surface of constant gravitational potential except for modification by winds and circulation of the oceans. One of the I.G.Y. objectives is to establish recording tide stations in remote areas such as Arctic and Antarctic regions. This is not only to measure tides at such points but to establish mean sea level. Canada normally operates six sea level recording stations, but because of the I.G.Y. established two new stations on difficult locations on Brevoort Island off the Labrador coast and at Resolute in the Arctic. Establishing a tidal station on a shore that is continuously pounded by ice is not very easy. One way is to build a channel below the ice, running it inland then up to the surface where equipment can be installed. Part of this may be through permafrost and has to be kept warm enough to avoid freezing.

Tidal measurements are the responsibility of the Hydrographic Survey of the Department of Mines and Technical Surveys. The Department of Transport operates two weather ships, one in the Atlantic and one in the Pacific Oceans. Oceanographic measurements are also being taken from these ships.

XI. ROCKETS AND SATELLITES

Although the science of firing large rockets and getting satellites on a stable orbit involves many branches of physics and chemistry and the actual launching is an engineering project of considerable magnitude, as far as the I.G.Y. is concerned rockets and satellites are merely vehicles to be used to carry instruments into the upper atmosphere or outside the atmosphere so that direct measurements can be taken some distance away from the earth's surface. This technique, during the past decade, has made it possible to get information that previously could only be deduced indirectly from spectroscopic or radio measurements. The military requirement for weapons of this sort has created the opportunity for great advances in the physics of the interesting space surrounding the earth. Of course, knowledge of the nature of the space in which a long range ballistic missile must travel is a necessary adjunct to the practical use of such missiles, but the international political rivalries that have made the development of these tools possible for scientific measurements will be by no means wasted even if, as we hope, they are never to be used in anger.

The I.G.Y. published program shows that several countries are undertaking rocket projects. These are U.S.A., U.S.S.R., U.K., France, Australia, and Japan. Only two countries are attempting to launch satellites, U.S.A. and U.S.S.R., and at the time of writing both have succeeded. Although Canada has no rocket or satellite of its own we are acting as hosts to a very large United States rocket project at Churchill. We are contributing a share of the ground work in meteorology, height recordings of the aurora, and ionosphere measurements. In the satellite field we are unable to see the United States satellite because its orbit does not reach far enough north but measurements were taken on both the U.S.S.R. satellites that were fired up to the time of writing this paper. Radio measurements were taken by the Defence Research Board's laboratories at Shirley Bay near Ottawa. By a study of the Doppler shift in frequency during two successful passages of the satellite and further measurements 24 hours later a very precise calculation of the orbit was made. The Dominion Observatory staff undertook visual and photographic observations and collaborated in the orbits calculations.

Fig. 11. The track of an Aerobee-Hi rocket as it was fired at Churchill, Manitoba. Firing of July 5, 1957. (Official U.S. Army photograph).

A study of the atmospheric structure is a simple way of expressing the objective of a large number of ingenious rocket-borne experiments. Several different methods of measuring temperature, pressure, and density variation with height right up to the limits of the range of the rockets are being used. The general structure of the atmosphere is represented by a decrease in pressure from the surface up to some undefined level which might be considered a transition from the atmosphere to interplanetary space. Since it is becoming accepted that the solar atmosphere extends out to the orbit of the earth we never reach the low density of interstellar space but at any altitude within the range of rockets or present satellites there is still a residual density of gas probably hundreds of times greater in density than instellar space but still many thousand times less dense than the most perfect vacuum obtainable in the laboratory.

The temperature of the atmosphere decreases with height up to the tropopause then after a short isothermal layer increases to a temperature about equal to that at the surface of the earth at a height of about 50 km. It then decreases again to a minimum at a height of 80 km. and from there up into the sun's atmosphere increases again probably to thousands of degrees. The layer showing the lower increase is that at which ultra-violet sunlight is absorbed by ozone and oxygen. The magnitude of the increases and decreases even above about 40 km. varies with latitude and season. When one gets into the electrically conducting layers from 100 km. up there is evidence of considerable turbulence and large variations related to solar activity. These are the regions of the aurora and ionosphere storms which have already been mentioned. The conductivity remains high and at heights perhaps of the order of the earth's radius some theories suggest turbulent motion controlled by a combination of electromagnetic and gravitational forces.

The instruments used in the rockets and satellites are much too varied to be presented in any detail here. A few of those used in American rockets at Churchill might be mentioned. A simple way to study the density of the atmosphere is by firing explosive grenades from the rocket at intervals as it ascends. From radio and photographic observations the position of the rocket at any instant is known, and by sound ranging on the explosive charges the temperature can be measured. Density can also be measured by a light falling sphere containing a very accurate accelerometer which telemeters the data to the ground station. Magnetometers are carried to record the earth's magnetic field and a mass spectrograph measures its chemical composition and state of dissociation. Radiation from the infrared to the ultra-violet and X-ray region is measured by photoelectric methods, geiger counters, and scintillators. Cosmic rays are measured by counter or ionization chamber techniques.

In the case of satellites, the instrumentation problems involve the best known techniques of miniaturizing and operating with a minimum of battery power. One problem in satellites is the storage of data and making it available on interrogation. In many objectives, for instance, the measurement of cosmic rays, it is important to have continuous measurements yet it would be quite impossible to organize a great enough density of radio listening stations to keep constant contact with it. The data are therefore put on recording systems or memory circuits and played back on interrogation so that all the data collected in one or several passages around the earth can be played back in a few seconds. The University of Iowa, Cosmic Ray Group, have developed a very ingenious magnetic tape recorder which carries enough tape for 120 minutes of operation that is enough to complete one orbit. Actually the tape is moved in steps every second and data put on in that interval. On interrogation by a radio frequency signal the tape record is played back in a few seconds. At the same time the signal on it is wiped off and the tape is ready for another record.

Instrumentation for tracking both rockets and satellites is large and complicated. Tracking equipment for the rocket program at Churchill includes automatic tracking radar sets feeding a rapid electronic computer which produces an instantaneous plot of the rocket's position as it travels. The accuracy of such tracking is considered to be ±500 feet. For more accurate positioning a system known as DOVAP (Dopper Velocity and Positioning System) is also used. The velocity of the rocket can be obtained very accurately and, combing this with radar and cine-theodolite photography, the position of the rocket can be obtained to within a few feet.

Precision in the tracking of satellites is also very important. The ellipsoidal shape of the earth and large gravity anomalies introduce perturbations into the satellite orbit, and precise measurements will give information on the earth's shape which is very difficult to get from geodetic surveys. In planning their satellite the United States group chose 108 megacycles per second for their signal frequency to be transmitted from the satellite, since that frequency would be high enough so that ionosphere diffraction effects would be very small. The U.S.S.R. chose 20 and 40 Mc/sec. but did not announce these frequencies far enough in advance of their firing to give other countries much time to prepare for precision measurements. It has been found that quite accurate positioning can be done on the U.S.S.R. satellite and the two frequencies, being considerably affected by the ionosphere, give information about the ionosphere as well. It might be mentioned here that the electron density above the F_2 layer cannot be measured from below since frequencies below the critical for the maximum electron density are all reflected, and above the critical frequency penetrate the layer and are lost. It is very desirable, therefore, to be able to transmit downwards from above the F_2 layer to study radio wave transmission at higher levels. Rocket and satellite experiments both include such measurements in their plans.

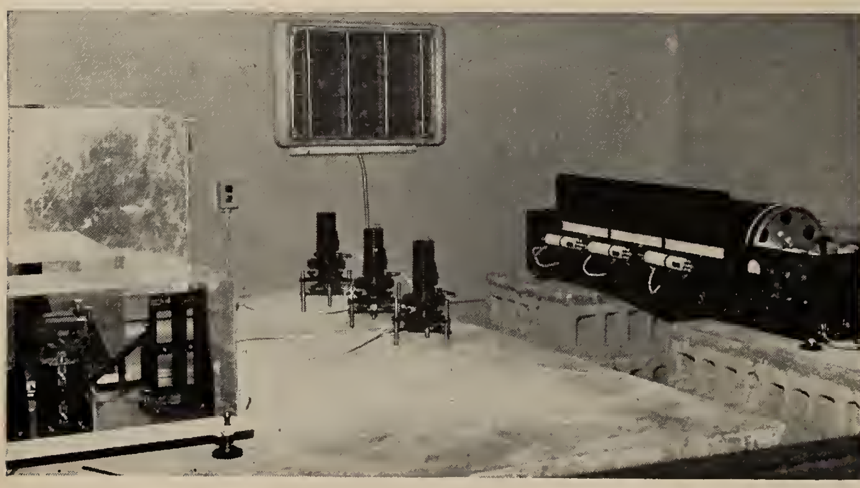
Before leaving this branch of I.G.Y. activities a word about the launching of rockets should be included. Three types of rockets are commonly used for scientific measurements by the U.S.A. groups. Two of these types are being used at Churchill during I.G.Y. activities. The largest of these is the Aerobee or Aerobee-Hi. This is a rocket propelled by liquid fuel consisting of red fuming nitric acid as an oxidizer and a mixture of aniline and furfuryl alcohol as the fuel. The rocket is 15 inches in diameter and normally 23½ feet long. However, an extension may be put on the rocket head between the body and nose cone to carry a variety of instruments. A booster is usually added to the rocket to assist at take off but this only burns for 2½ seconds. The height reached, of course, depends on the payload but a typical performance at Churchill is the carrying of a payload of about 150 lb. to a height of approximately 150 miles.

The second and smaller rocket is called the Nike-Cajun which is a Cajun rocket with a Nike booster. Solid fuel is used in this rocket and its launching procedure is very much simpler. It carries a payload of about 50 lb. to a height of 100 miles.

The exact number of these two rockets to be fired at Churchill is not known as plans change from time to time but the total may well be near 100 and this will represent a large fraction of the total U.S.A.-I.G.Y. rocket program. Two of the Nike-Cajun rockets have been allotted to Canadian use and will be instrumented by the Canadian Armament Research and Development Establishment at Valcartier. The measurements will be in the infra-red spectrum of the radiation encountered at high altitude.

A third type of rocket used extensively in I.G.Y. measurements is the Rockoon or a balloon and rocket combination. Large plastic balloons filled with helium can carry payloads of 230 lb. to an altitude of about

Fig. 12. The interior of the seismological vault at Resolute, latitude 74.7°N, longitude 94.9°W, on Cornwallis Island. This vault is built underground in rock permanently below freezing temperatures. (The Dominion Observatory).



80,000 feet. This takes it through all but about 5% of the atmosphere. A relatively small rocket carried by such a balloon and fired at 80,000 feet can carry a useful payload of about 8 lb. up to 75 miles. Rockoons will not be released at Churchill and are usually fired at sea because it is impossible to predict where they will come down.

The firing site at Churchill involved considerable engineering construction. The tower which guides the take-off of the Aerobee-Hi is 112 feet high and may be set at an angle up to 10° from vertical in any direction. Associated with this, fuel handling buildings, rocket preparation buildings, a laboratory for assembling and testing the instrumentation, and a complete power plant had to be constructed. There are in all eight buildings connected by tunnels and a number of auxiliary huts and trailers at recording sites. Special problems were involved in that the launching tower for the Aerobee-Hi had to be enclosed so that it could be heated during the loading and preparation of the rocket, then the walls opened up to vent the gases when it was fired. Figs. 10 and 11 are photographs of the Aerobee launching tower. In both pictures a rocket has just been fired and is still visible in Fig. 10.

Fig. 13. The meteor observatory at Springhill near Ottawa, showing the observatory building, the antennae for auroral radar and the visual meteor observing station in the background. The observatory represents one of the activities of the Upper Atmosphere Research Group, Radio and Electrical Engineering Division, National Research Council. (See article on page 68).

XII. SEISMOLOGY AND XIII. GRAVITY

These disciplines are presented together because they both refer to studies of the interior of the earth and both are necessarily organized on an international scale quite apart from the I.G.Y. The inclusion of seismology and gravity measurements in the I.G.Y. was largely to take advantage of expeditions to remote parts of the earth such as Antarctica and even at sea when ships on voyages for scientific purposes may be used.

Canada normally operates twelve seismological stations. These belong to the Dominion Observatory and the data from these are fed into the international pool for earthquake studies throughout the world.

The station at Resolute is considered the most important in Canada and perhaps one of the most important in the world. This is because the majority of the seismological stations are located where there is a reasonable density of population, thereby neglecting polar areas. We have land nearer the north pole than other countries (except Greenland) and to take advantage of this the Dominion Observatory is enlarging its seismological station at Resolute. A new vault was built last year and it is now equipped with a variety of the best designs of seismographs. Fig. 12 is a photograph taken inside the underground vault.

Measurements on gravity are important in geodetic work and in geophysical exploration, and a network of gravity stations is gradually being extended over the whole of Canada. One of the most important problems at present is to obtain series of measurements over as much of the world as possible using the instruments that can be related to the same absolute standard of calibration. Another problem is the measurement of gravity on an unstable foundation such as at sea, on floating ice or over soft soil areas. The Dominion Observatory is undertaking research in this field.

The interesting phenomenon of earth tides, which has received increasing attention during the last decade is included in the I.G.Y. program. The surface of the earth expands and contracts under the influence of solar and lunar gravity just as the oceans do. This may be recorded on the most sensitive gravity meters. Measurements on earth tides are being undertaken by the Dominion Observatory at a number of stations throughout Canada.

XIV. NUCLEAR RADIATION

The study of radioactive matter in the atmosphere and in the oceans was accepted as an international program very late in the planning of the I.G.Y. It was first considered in 1956 with the result that the program is more limited than might be. Since Canada is taking part in the program the objectives should be included in this survey.

The overall objectives are twofold, to carry out a world-wide survey of natural radioactivity in the atmosphere before it becomes completely swamped by further nuclear explosions, and secondly to make a world-wide survey of the artificial radioactivity that is in the atmosphere at this epoch. A complete and detailed survey throughout the atmosphere would be beyond present facilities and the quantity is not believed to be very serious at present. It is known, however, that a great deal of the radioactive matter shot into the upper atmosphere from an atomic explosion remains there for months and slowly filters out. Sometimes appreciable quantities are brought down by precipitation, particularly heavy wet snow.

The natural radioactivity in the atmosphere consists of the products of the radioactive minerals near the surface of the earth. The gaseous products diffuse into the atmosphere and can readily be measured. The active decay product most easily measured is radium C and, to measure it, immediate counts have to be taken after exposure of a filter.

The simple procedure we have adopted is to draw outside air through a special filter at a known rate and for a definite period. An immediate measure of the activity after stopping the filter gives information about the radium decay products. After about three days the natural radioactive matter has decayed away to a very low background and the atomic explosion debris may be measured.

A great deal of work is being done along these lines by the United Nations Health Organization with the objective of keeping a watch on health hazards. The I.G.Y. program on the other hand is intended as a study of the physical processes involved in the maintenance of the material in the atmosphere, how it gradually falls out, and a world-wide survey of the present situation.

The international program also recommends the carrying of filters in aircraft to high altitudes, and measurements at sea. Samples of water from deep in the sea are also part of the I.G.Y. program. From these samples, interesting studies can be made of sea circulation, particularly showing evidence of stagnant water at great depth by measuring its tritium content.

The Canadian program is limited to taking filter samples at fourteen stations distributed as uniformly as possible in Canadian territory. Arctic stations as far north as Resolute are included, and stations from Victoria to Halifax. All these are sending in daily filter samples and immediate measurements of natural radioactivity are being taken at some of them. The nuclear radiation program is being organized by the X-Rays and Nuclear Radiations group of the National Research Council's Division of Applied Physics.

XV. METEOR STUDIES

Meteor studies are not listed as a separate discipline in the International program but because an organized program has been carried out in Canada for some years we have listed the Canadian contribution separately. In most other countries meteor studies in relation to the I.G.Y. are included in ionosphere or aurora measurements.

Meteor studies contribute a great deal to the physics of the upper atmosphere. They are important astronomically because they are believed to represent a part of the solar system that is not completely known. They are small particles of matter travelling either individually or in clouds at suitable velocities to stay in an orbit about the sun, sometimes an elliptical orbit of high eccentricity. When they strike our atmosphere their surfaces are heated and vaporized through collision with the atmospheric molecules. They ionize the gas in the atmosphere particularly at levels between 80 and 120 kilometres. They also leave a trail of ionized particles of their own material. This trail is visible at night as a shooting star and the density of ionization is great enough and lasts long enough (sometimes for seconds or minutes) to reflect a radar wave.

Studies of meteors give valuable information about turbulence and variations in the density of the atmosphere at the levels at which they burn out. They are very important in cosmological studies of the growth of planets and raise problems about the amount of matter that the earth may be collecting from the meteors which strike it.

The meteor work in Canada is carried out jointly by the National Research Council's Upper Atmosphere Research Group and the Dominion Observatory. One of the objectives is to correlate visual observation with radar observation. Visual observation can only be carried out at night but radar observation is continuous.

There are a number of well-known meteor swarms whose orbits cross that of the earth at times that can be predicted. These times are listed in the calendar of special world intervals which was mentioned in an earlier section of this paper. Accurate density measurements, that is, numbers in the swarm, are part of the program.

The National Research Council has a special meteor observatory at Springhill about twenty miles south of Ottawa (see Fig. 13). Radar measurements are continuous here and visual measurements are organized on selected nights. Additional radar measurements are taken on world days. The aurora radars at Resolute, Baker Lake, Ottawa and Saskatoon will also observe meteors. Ionosphere scatter experiments mentioned in the section on the ionosphere also show reflections from meteor trails. In fact the Defence Research Board's Radio Physics Laboratory has recently perfected a communication system wherein messages may be transmitted by reflection from a meteor trail. The system waits until a suitable reflection occurs, then transmits automatically at high-speed. The number of meteors is quite sufficient to provide a useful communication channel and frequencies may be used that are not subject to ionosphere disturbances.

The Dominion Observatory's station at Meanook, Alberta, has special photographic equipment for meteor studies. Two Super-Schmidt cameras located 26 miles apart are used to measure heights and velocities by triangulation. These cameras are of special design having a very large aperture ratio and wide angle coverage but of short focal length.

A voluntary visual program extending across the continent has also been organized jointly by the Dominion Observatory and the National Research Council.

CONCLUSION

It is hoped that this brief review of the objectives and program of the International Geophysical Year gives some picture of what is being attempted throughout the world. It will be some years before the total results can be published and in fact some parts of the data will be retained mainly to represent conditions in this epoch to be compared with a future effort at some later date.

From beginning to end the effort is one of co-operation not only on an international scale but even in countries undertaking a large program. It has reached a stage now that the year is more than half over that there is assurance that most of the planned program is being carried out successfully. Our Canadian program is proceeding except for minor details exactly as planned in the report "The Canadian Program for the International Geophysical Year" issued in May 1957 by the Associate Committee on Geodesy and Geophysics of the National Research Council.

To emphasize the importance of cooperation, although this paper is under the authorship of one individual, the information in it could only be presented after discussion, correspondence and meetings with the leaders and members of the various groups undertaking the works. The assistance of these scientists, too numerous to list here, is appreciated by the author. The author would also like to express appreciation of those who supplied the photographs. Acknowledgment is made where appropriate in the captions.

The CARDE I.G.Y. Upper Air Research Program

R. F. Chinnick, *Superintendent, Electronics Wing,*

Canadian Armament Research and Development Establishment

Read at the 72nd Annual General and Professional Meeting of the Engineering Institute of Canada, Quebec City, May 1958

A brief review of the objectives of the CARDE high altitude experiment is given, and the design considerations and techniques employed in preparing a nose cone are discussed.
Methods of packaging electronic components and problems resulting from the environment are considered. Instrumentation techniques for transmitting data are described.

THIS PAPER describes a programme undertaken by CARDE to measure characteristics of the night air glow at altitudes from 70 to 100 kilometres employing test rockets fired from Fort Churchill, Manitoba. The CARDE programme is an integral part of the International Geophysical Year and as such it is hoped that information obtained will contribute to the general knowledge of upper atmospheric physics.

Upper air research programmes employing guided missiles such as the V-2 were initiated on this Continent in 1946 and since that time several sounding rockets have been developed for transporting scientific instruments to high altitudes. By far the majority of the early work was carried on at the White Sands proving grounds in New Mexico. From many points of view, however, it is most desirable to extend the explorations of the upper atmosphere to other geographical sections of the earth and in particular to Polar regions where somewhat different conditions may exist especially with respect to auroral activities.

Early in the planning of the I.G.Y. programme, arrangements were made between the Canadian and United States Government to employ the Fort Churchill area for many portions of the rocket programme. Fort Churchill is ideally suited for this purpose since it is in the auroral belt, sufficient land exists for rocket impacts, and technical facilities and logistical support are available.

Initial planning called for the firing of 33 Aero Bee and 43 Nike-Cajun rockets of which two of the Nike-Cajun Rockets were made available to CARDE for the programme which is about to be described. The Nike-Cajun Rockets which are being made available to CARDE are relatively inexpensive test vehicles capable of carrying pay loads in the range of 30 to 100 lb. to altitudes varying from 175 to 100 kilometres depending on the pay load. Further, to reduce the load on the research organization making the measurement, the I.G.Y. Committee have installed at Fort Churchill the necessary instrumentation and communication facilities to ensure the obtaining of trajectory information, and of providing a telemetry link between the rocket and the base station.

Each research agency therefore has the task of designing an instrumented nose cone capable of making the measurements for which it is committed and transforming this information into electrical energy in a form suitable to be injected into the Dovap (Doppler velocity and position system) telemetry system for transmission to the ground.

The following information will help to introduce the measurements being made and present some background data on the problem.

Thermal Emission from the Night Airglow

The night airglow or the " permament aurora " as it used to be called consists of the radiation emitted by the atmosphere during the night. In addition to the thermal emission of the low atmosphere, four emissions are well known. These are the red and green lines of oxygen, the yellow sodium doublet, and the vibration-rotation bands of the hydroxyl molecule. The atomic lines lie in the visible and are readily observable with photo-multipliers. The hydroxyl radiation extends from 4.3 microns to 5000A but the radiations in the visible are rather weak. The greatest intensity is from 2.8 to 4.3 microns where the atmospheric attenuation makes ground level observation impossible.

Nine sequences of hydroxyl vibration-rotation bands are believed to occur. Those in the visible have been observed spectroscopically by Meinel and Dufay. The region from 8000A to 11000A has been investigated by Krasovski[1] using an image tube at the focal plane of an auroral grating spectograph. Vallance Jones[2] and co-workers at the University of Saskatchewan have investigated the spectrum from 1.0 to 2.0 microns with a PbS cell and are currently attempting to extend their observations to 4 microns using a PbTe cell .In addition to these spectroscopic observations, several observers[3] have used filter photometers with various detectors to find the total amount of radiation emitted in various spectral regions.

Height of the Emitting Layer — Using the Van Rhijn technique,[4] Roach, Pettit and Williams obtain an altitude of 70±20 kilometres for the centre of gravity of the OH layer. Meinel measured rotational temperatures and obtained 220°K. which corresponds to about 70 km. also. However, Krasovski has observed rotational temperatures as high as 400°K.

The Van Rhijn technique involves several assumptions which make the value obtained very doubtful. The only good method for altitude determination is to observe the intensity changes as one passes through the layer.

Mechanism of Formation of Excitation—There are two theories of the formation of excitation processes. The first, suggested by Herzberg is a reaction between atomic hydrogen and ozone:

$$H + O_3 \rightarrow OH + O_2 + 3.3e\nu$$
$$OH + 3.3e\nu \rightarrow OH^*$$
$$OH^* \rightarrow OH + h\nu$$
$$OH + O \rightarrow H + O_2$$

This reaction should theoretically occur with maximum rate at 70 km. in agreement with the observed height by the Van Rhijn method. This theory is attractive also because 3.3 $e\nu$ is just enough to excite OH to the ninth vibrational level. No bands from greater than the ninth level have been observed.

The second mechanism, suggested by Krasovski[5] involves the reaction of vibrationally excited oxygen molecules with atomic hydrogen.

$$O_2 + H \rightarrow OH^* + O$$
$$OH^* \rightarrow OH + h\nu$$
$$OH + O \rightarrow O_2 + H$$

This reaction should occur at about 100 km.

The CARDE Nike-Cajun Experiment

The Purpose of the Experiment—The main objective of the experiment is to establish the altitude of the emitting layer. A secondary objective is to observe the radiation (in the 2.8 to 4.3 μ. region) which has never been seen because of atmospheric attenuation. Knowing the altitude of the emission is an important step in establishing the mechanism of formation of the molecules. This mechanism will give an understanding of the photochemistry of water vapour in the upper atmosphere.

Method—Four lead sulphide filter photometers will be installed in the nose cone. One will observe the strong radiation near 1.6 μ. two will observe the 2.8 to 3.3 μ. region and one will observe the 2.4 μ. region where no OH emission is expected.

In addition, filter photometers will be used to observe a visible OH band

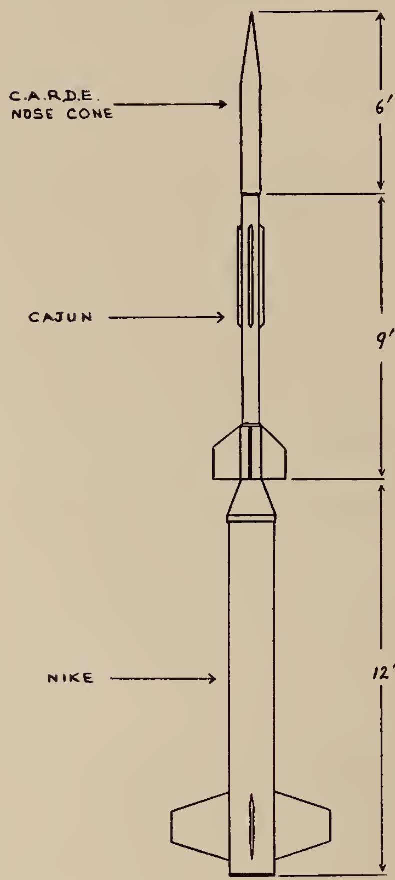


Fig. 1. Nike-Cajun vehicle and nose cone.

centre on 6257A. and to confirm and improve the measure of altitude of the NaD emission at 5893A.

Nike-Cajun Performance and Design Considerations

The design of a rocket test vehicle from the point of, view of configuration and air frame is a field in its own right and can only be mentioned very briefly in this paper. In order to provide a fuller appreciation of the problems however, general considerations will be presented together with specific references to the particular case of the Nike-Cajun for CARDE's I.G.Y. experiments. Figure 1 indicates the general outline of the complete Nike-Cajun vehicle including the nose cone.

Data has been published on the firings of earlier Nike-Cajuns and by extrapolation of the curves and selection of an approximate nose cone geometry it was possible to arrive at a pay load weight for the altitudes specified by the experiment. With a preliminary configuration established estimates of trajectories can now be calculated and initially these can be quite unsophisticated factoring for vacuum conditions. This is justified at this stage as the computations are lengthy and laborious, though computers can be and are frequently used and the geometry itself is subject to change as the design progresses. With the desired trajectory and preliminary configuration known, velocities, dynamic pressures, and altitudes (all against time) are used to calculate the stability of the combination unburnt, at allburnt, and at separation, also the sustainer at unburnt and allburnt. In our case the geometries and centres of gravity, with the exception of the nose cone, and stability margins (the distance between the Cajun sustainer CG and CP) were known for certain U.S.-I.G.Y. nose cones. However, the data did not cover our estimated weight and nose cone length, and for these reasons the stability margin was increased from 1.0 to 2.0 body diameters by re-locating the centre of gravity of the nose cone.

This leads to a re-assessment of the internal layout and more frequently than not a re-arrangement of equipment. This is a period of close liaison between the designer of the experiment, the electronics, instrumentation, and the structure and mechanical engineers, and compromise becomes necessary when limits are reached. At this stage, the structural and mechanical design can be started. The philosophy here is not unlike that followed in the aircraft field though design factors are reduced since the vehicle does not carry a pilot or crew.

Nomenclature varies with countries but for the purpose of this paper it is sufficient to state that limit loads should not cause excessive permanent deformation of the structure and that the structure should collapse at the ultimate load. The limit loads are the maximum loads anticipated during the life of the vehicle and are generally factored by one for the design loads. Under certain considerations the design factor may be less than one.

The loading cases are treated in two separate phases, preflight and flight. The former includes transport and handling. The basic flight loads we considered were boost phase, gusts, separation, aerodynamic pressure, and local inertial loads. In the general case manoeuvre and control system loads, etc., have to be considered. Since weight is at a premium a statistical approach is used in preference to combinations of the worst conditions occurring simultaneously. Another and important design consideration is aero elasticity. This is a phenomena involving the interchange of aerodynamic forces, elastic structural forces and inertia forces. These in turn affect the overall stability of the vehicle and lead to structural vibration and control surface flutter. To overcome these and other problems it is necessary to establish a criterion for stiffness.

In our case, stiffness tests will be conducted at room temperature and studies are in hand to establish the effort, cost, and value of limited tests at flight temperatures. In vehicle design reliability engineering is playing an increasingly important role. Since overall reliability is the product of the reliability of individual components it will be appreciated that to achieve an acceptable figure for the complete vehicle, component reliabilities must be high. The experiment described in this paper involves two vehicles only, not a large production as generally is the case in service missiles. This therefore presents a problem of its own, for two is a very small number to depreciate the cost of the mechanical, structural, electronic and systems test necessary to ensure a high degree of success.

Tests under sea level conditions will be undertaken but the greatest emphasis will be placed on environmental tests, where components, subassemblies, and finally the complete nose cone will be tested under conditions simulating the pre-flight and flight environment. These will include shock, vibration, temperature (not aerodynamic heating), pressure, humidity, moisture. Other environmental tests which will not be done for this vehicle include abrasion (sand, dust, snow, ice), corrosion and fungus. The parameters for these tests are derived from a knowledge of transport handling, motor characteristics, aerodynamic and aeroelastic forces, and the trajectory.

The selection of structural materials and electronic components must take into consideration, not only the loads to be carried but also the environment and the ever-present weight limitations.

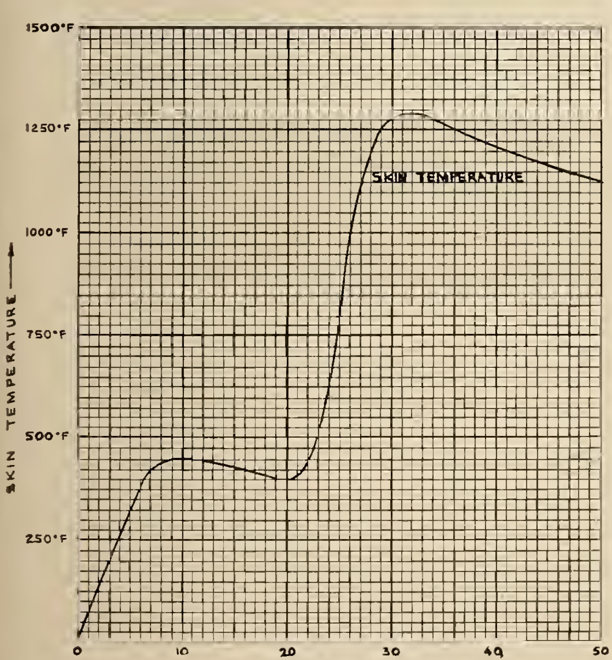
The penalty of a structural failure, while not involving the loss of life, except in the region of the launcher, cannot be overshadowed by the importance of a saving in weight.

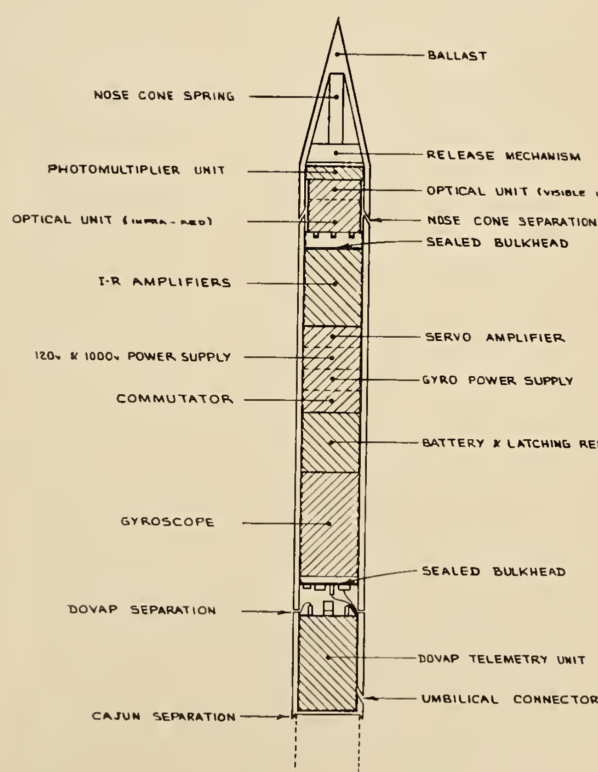
In the selection of material the strength-weight ratio and strength-weight temperature ratio are important parameters. Time is an important factor, for while high stagnation temperatures exist, the interval over which they act is comparatively short. Thin skins with low heat capacity can quickly reach equilibrium temperatures. Thermal conductivity, heat sinks, and the use of suitable insulations must all be considered and evaluated. Thermal co-efficients of expansion for the various materials must be satisfactory or the design must ensure that thermal stresses do not lead to failure of the structure or mechanism. In our case, calculations indicate that the skin temperature may rise as shown in Fig. 2, due to the two phases of boost. The experiment demands an increase of not more than 5°C. black body in certain areas, and this has introduced local problems. Frequently non-magnetic materials are required by the experiment, and this narrows the field of usable materials as well as introducing other complications.

During flight the vehicle is expected to roll at between 1 and 5 revolutions per second. This is not a disadvantage since each radiometer "scans" the sky and the way in which the measured intensity varies can give useful information provided the altitude of the rocket is known.

Fig. 2. Variation of skin temperature with time.

Fig. 3. Layout sketch of instrumented nose cone.





Instrumentation Requirements

Primary Measurements — Infra-red. Ektron plumbide detector cells are available for infra-red measurements in the region 0.4 to above 3 microns, and filters placed in front of the detectors limit measurements to the required wavelengths. The cells have a sensitivity of about 70 microvolts per microwatt and a noise equivalent power of around 6 x 10^{-9} watt in a 5 c.p.s. band. The inherent noise output of the cell is therefore of the order of 0.5 microvolt, and in order to make full use of the cell's sensitivity a high-gain low-noise amplifier is required. The amplifier must handle signals in a total bandwidth of 10 c.p.s. to accommodate the maximum roll of the vehicle (5 c.p.s.) and this bandwidth implies a minimum equivalent noise voltage of 0.7 microvolt at the input. The maximum input to the telemetry system is 5 volts and the minimum resolvable input is 0.1 volt. The noise input of approximately one microvolt must be amplified to about 0.3 volt, a gain of 300,000 or 100 db. In order to make measurements of intensity over a fairly wide range, three telemetry channels are required for each of the four amplifiers. The dynamic range accommodated by a single channel is 24 db. so that the overall dynamic range of measurement is from noise level to 72 db. above noise. The gain of the amplifier from input to the first telemetry channel must be roughly 62 db., to the second 86 db. and to the third 110 db.

Visible light. The expected intensity of radiation at 5893 A. is between 5 x 10^{-13} and 1 x 10^{-11} watts with the aperture used in the optical system. Measurement of this level of intensity is possible with a multiplier phototube, without additional amplification. The range of intensities expected is greater than can be accommodated in a single telemetry channel and two channels must be used. A similar system is used for measurement of intensity of radiation at 6257 A. due to OH radicals. Optical filters in front of the phototube cathodes restrict measurements to the required wavelength.

Secondary Measurements

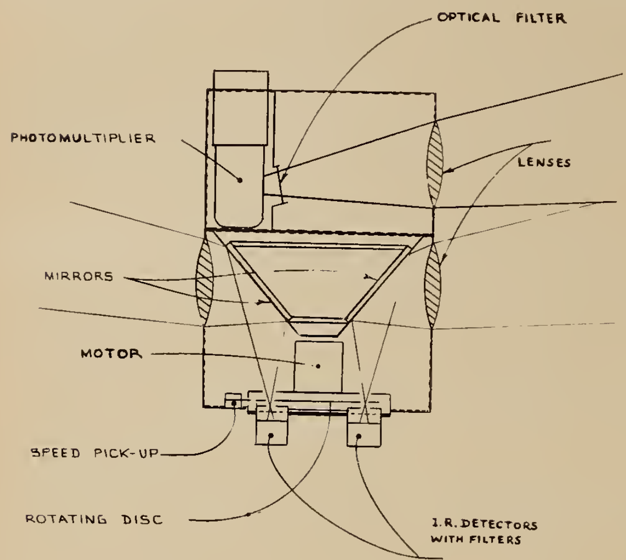
In order that the recorded data shall be meaningful, position and altitude of the vehicle must be determined continuously during flight. The DOVAP telemetry system[6] measures range to the vehicle from the ground station by integration of the Doppler frequency shift of the received carrier. It may be possible to estimate the roll position of the vehicle by reference to the record of measurement at 5893 A. which should show fluctuations at the roll rate. Some other means must be found to determine the altitude of the vehicle, so that the zenith angles of the various radiometer axes may be calculated.

Ancillary measurements are required of the temperatures of parts of the infra-red optical system since detector sensitivity decreases rapidly with rise in temperature.

Recording of data. The measurements will be telemetered to the ground station by the DOVAP system which is briefly described later. The DOVAP unit in the vehicle is self-contained with its own batteries and is in the form of a cylinder 5 in. in diameter, 10 in. long, and weighing 10 lb. As it requires direct connection to the antennas on the Cajun, it is mounted at the rear of the nose assembly.

Design

General. A layout diagram of the nose cone is shown in Fig. 3. The most severe aspect of the environment imposed on the nose assembly is heating of the skin at the lower altitudes. This necessitates a high degree of thermal insulation, despite the short duration of the flight. For this reason the nose assembly is constructed in the form of an inner shell 5½ in. in diameter and an outer skin 7 in. in diameter, the material used being stainless steel in both cases. The space between inner shell and outer skin is filled with fibre-glass. Even with this precaution the lenses and the skin around the lenses would become so hot that infra-red radiation from them into the optical system could exceed in intensity the radiation to be measured. The solution to this problem is to mount the optical unit well forward within the inner shell and to expose the lenses only when the rocket has reached a region of rarefied atmosphere where heating by friction is no longer a problem. This is done by sliding forward a front portion of the skin 40 sec. after launch, at an altitude of about 48 km. The necessity for a double wall and a mechanism for sliding the nose cover limits the space and weight available



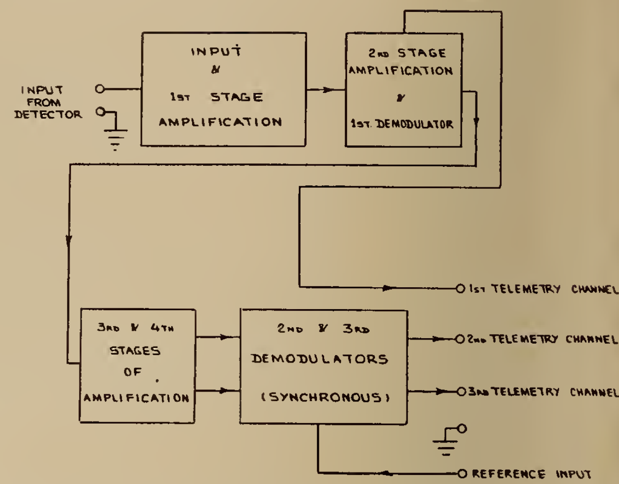


Fig 4. (left) Optical unit. Fig. 5. Block diagram, I.R. amplifier.

for instrumentation, since the payload must be kept low if the required maximum altitude is to be attained.

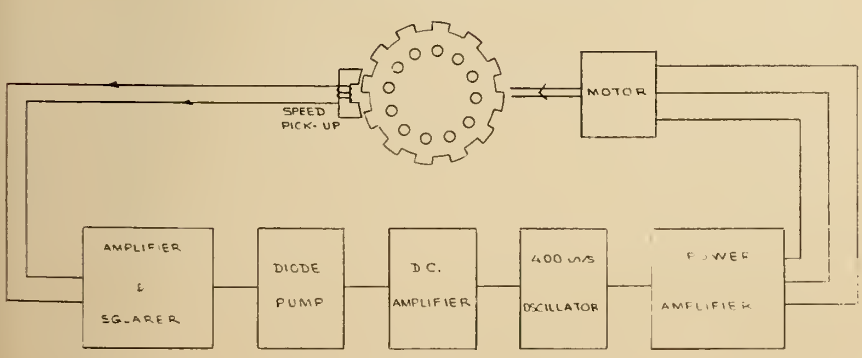
Infra-red measurement. The requirements have been outlined previously. In order to meet space limitations it is clear that the electronic circuits must use transistors rather than vacuum tubes.

Infra-red Photometers. Calculations of semi-conductor noise, and I.R. cell time constants for the detector chosen indicate that the maximum signal to noise ratio is obtained in the region of 750 c.p.s. The equipment is therefore designed to interrupt the optical path at a rate of 750 times a second in order to obtain peak performance from the system. A diagram of the optical unit is shown in Fig. 4. Four quartz lenses are mounted symmetrically around the vehicle axis. Radiation entering a lens from a direction 10° forward of the beam of the vehicle is reflected by a mirror and brought to a focus in the plane of a thin steel disc situated in front of the cell.

Holes are drilled in the disc at a fixed radius and are spaced so that the cell is alternately exposed and obscured for equal intervals of time. A diaphragm with circular iris is mounted between the disc and the cells, and circular irises are drilled in this to limit the illumination of the cell. The disc is driven by a small motor at 3750 r.p.m. and as there are 12 holes in the disc the frequency of the signal from each cell is 750 c/s. The four amplifiers are identical and the block diagram of one of them is shown in Fig. 5. To obtain a low noise factor the first stage comprises a subminiature triode in a cathode follower circuit, followed by a transistor amplifier incorporating negative feedback to stabilize its gain. A second stage of amplification, with negative feedback, raises the level of the signal before demodulation for telemetering. A series tuned circuit between the first and second stages of amplification restricts the bandwidth to 400 c/s. so that noise cannot overload the later stages of the amplifier. Since the noise level is still very low at this point, a simple diode circuit is adequate for demodulation. A third stage amplifies the signal by 24 db. before applying it to the second demodulator which is of the synchronous type and has a bandwidth of 10 c/s. The signal is again amplified by 24 db. in a fourth stage and applied to a synchronous demodulator. All three demodulator outputs are taken to the telemetry system. As the signal level increases above noise the third telemetry channel will be the first to record a signal and the first to overload. Reference signals for operation of the synchronous demodulators are obtained from the servo amplifier described below.

Servo Amplifier. If the small 400 c/s. motor used for driving the chopping disc is driven from a constant voltage source, its speed can vary drastically with change in temperature, change of load due to windage as the air pressure decreases, etc. It is therefore necessary to control its speed by including it in a servo loop[7]. The servo amplifier block diagram is shown in Fig. 6 and comprises a 400 c/s. oscillator and power amplifier and a circuit for measuring the speed of the disc. Near the edge of the disc is mounted a small U-shaped yoke of iron whose magnetic circuit may be completed via teeth cut on the edge of the disc. A total of twelve teeth are cut on the disc so that when it is rotating at the correct speed of 3750 r.p.m. an alternating emf at 750 c/s. is induced in a coil wound on the yoke. This signal is amplified and limited in two stages and applied to a diode pump circuit. If the speed of the disc is too high the current supplied by the pump circuit exceeds the current drain on its storage condenser, and the voltage on the latter increases. This voltage is amplified and used to decrease the current in the transistor of the 400 c/s. oscillator. This reduces the drive to the motor, which then slows down. A reverse effect occurs if the motor speed drops below 3750 r.p.m. The reference voltage for the synchronous demodulators in the I-R amplifiers is the signal applied to the diode pump circuit. The servo has a zero frequency loop gain of 200 and a wide stability margin. Variation of speed of the disc is less than 5% from no load to full load for temperatures between —50°C. and +65°C.

Fig. 6. Block diagram, servo amplifier.



Visible light measurement. Referring again to Fig. 4, the forward part of the optical unit contains two photometer systems for the visible light measurements. The two lenses are mounted in the wall of the optical unit with their axes at right angles. Radiation entering a lens from a direction 10° forward of the beam of the vehicle is brought to a focus at the cathode of a 1P21 multiplier phototube after passing through the appropriate optical filter. The plate load of the photomultiplier is very high (around 100 megohms) in order to achieve the required sensitivity. This high impedance is matched to the lower impedance telemetry circuits by a subminiature triode cathode follower, the full output of which is applied to one telemetry channel. The signal is also divided in the ratio 1:5 before being applied to a further telemetry channel.

Attitude Determination. Two possible methods of attitude determination have been considered. The first uses a gyroscope, the rotor axis of which is set vertically prior to launch and remains vertical during flight. The other method employs a magnetometer which is capable of measuring a component of the earth's magnetic field. The magnetometer is considerably lighter than the gyroscope and takes up a little less room. However its use requires an accurate determination of the strength and direction of the earth's magnetic field and evaluation of the roll position of the vehicle from one of the measurement records.[8] The first choice is therefore the vertically erecting gyroscope, but considerations of overall weight may necessitate use of the magnetometer.

The gyroscope is being developed by a company in Canada from an existing design. The gyro motor requires 11 watts of power at 115 volts, 400 c/s., which must be supplied within the vehicle. Power for starting the motor, about 40 watts, and for the torque motors which erect the gyro can be supplied from an external source since it is only required prior to launch. The angular displacement of the gimbals supporting the rotor are measured by the potentials at the sliders of the potentiometers which are supplied with a reference voltage. The three voltages are telemetred to the ground station; inclination of the vehicle axis to the vertical may be calculated from this information.

The magnetometer which may be used is the heliflex magnetic aspect sensor. Until this unit can be mounted in a vehicle and tests carried out, little is known of its characteristics and accuracy in such an environment. Its power requirement is 20 milliamps at 6 volts, much less than that required for the gyroscope.

The Telemetry System. Telemetered data is transmitted over the DOVAP system and will be briefly described. A block diagram is shown in Fig. 7.

The ground station helical antenna radiates a signal at 38 Mc. to two dipole antennas fixed along opposite sides of the Cajun vehicle. The received signal is amplified and its frequency doubled to 76 Mc. in the DOVAP transponder unit. The signal to be telemetred sets the frequency of a sub-carrier oscillator comprising a multivibrator whose mean repetition rate is 30 kc. This repetition rate is deviated over a range of ±40% by the full range of 0 to +5 volts of the input signal. The output from the sub-carrier oscillator gates the 76 Mc. signal which is then amplified and radiated to the ground station by two transmitting antennas fixed along opposite sides of the Cajun vehicle 90 degrees around from the receiving antennas. At the ground station the received signal is recorded for later analysis.

In order to telemeter all the measurements made in the nose assembly, each signal source in turn is connected to the sub-carrier oscillator by means of a high speed rotary switch or commutator. A synchronizing signal is produced at each revolution of the switch, so that the recorded signals can be de-commutated and identified for analysis. The commutator chosen for this purpose has 60 contacts and the slider is rotated by a 28-volt motor at 10 revolutions per second. Alternate contacts require a small negative bias to assist channel identification when the inputs to several successive channels are zero. Thus 12 channels are required for the I-R measurements, four for the visible light measurements, and three for the gyroscope outputs. In addition it is required to make two measurements of temperature in the vicinity of I-R detector cells and to have an indication of operation of the sliding cover. The synchronizing and calibrating signal requires the use of three channels bringing the total to 25. The remaining five channels may be regarded as spares but use will be made of them to repeat some of the measurements. Since the vehicle may roll at up to 5 c.p.s. and the commutator samples the inputs at only 10 c.p.s. it may be advantageous to use all the spare channels for measurement of radiation at 5893 A. since the roll position of the vehicle is determined from fluctuation in this record.

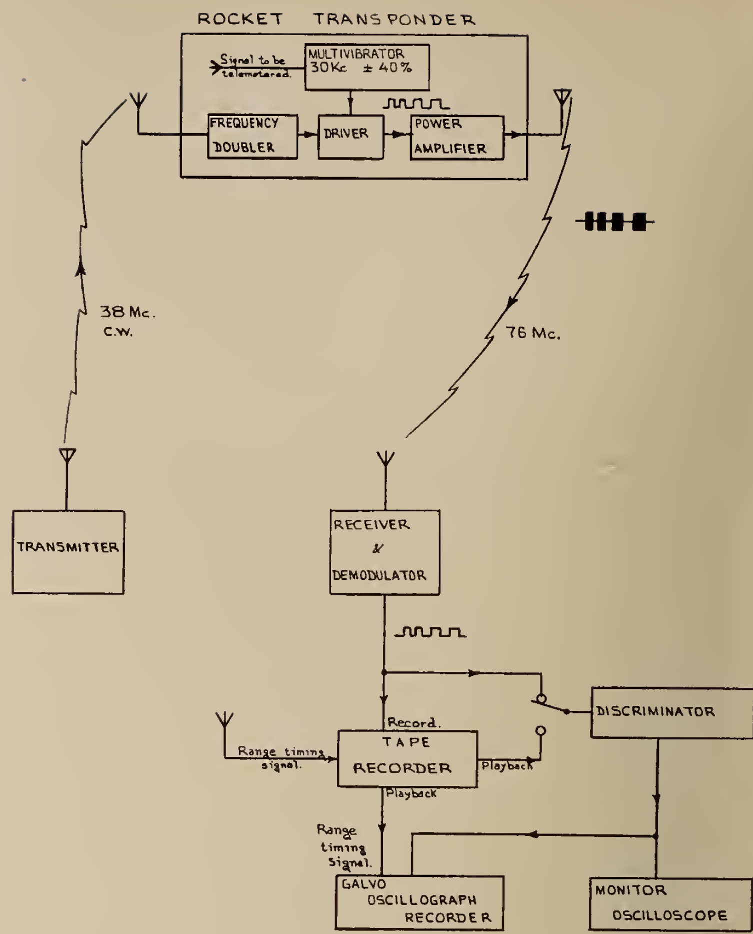


Fig. 7. Telemetry system.

Power Supply Requirements. The transistor circuits operate from low voltages which can conveniently be obtained from batteries. The anodes of the cathode follower, however, require 120 volts positive and the photomultiplier cathodes require a fairly well regulated supply at —1000 volts. The gyroscope also requires a source of 115 volts, 400 c.p.s. Three separate power supply units have been designed to meet these requirements, and all draw their primary power from batteries. The 120 volt and 1000 volt power supplies are similar in design, each employing a transistor relaxation oscillator with a step-up transformer, semi-conductor rectifiers and filter circuits. The gyro power supply consists of a 400 c/s. sinusoidal oscillator and power amplifier.

The battery requirements are summarized in the table of Fig. 8. The cells used to make up the battery pack have silver peroxide and zinc electrodes and are activated by potassium hydroxide electrolyte. This type of cell is characterized by high electrical capacity per unit weight and bulk, and by very good regulation during discharge. Once activated it may stand for 48 hours before use, but must be kept in an upright position to prevent leakage of the electrolyte. For the short duration of the launch phase and flight, leakage is slow enough not to present a problem. There could be a problem with this type of battery at high altitudes, however, since the atmospheric pressure above 32 km. is low enough to permit boiling of the electrolyte. It is therefore desirable to seal off the battery section of the vehicle so that pressure in it does not drop appreciably below atmospheric pressure at ground level. In practice it is convenient to place the forward sealed bulkhead just in front of the I-R amplifier section and the rear sealed bulkhead behind the gyroscope.

Monitoring. It is essential that tests be made to check functioning of the instrumentation right up to the moment of launch. Since such tests may take a considerable time it must be possible to power the electronics from external suplies. It is also necessary to lead in power for starting and erecting the gyroscope. All the circuits required are made through a single multi-way connector called the "umbilical plug" at the end of a cable. The socket for this is mounted at the rear of the nose assembly at a small angle to the vehicle skin. When the rocket is launched the plug will pull away from the socket since it is only retained by the friction of the pins. When the umbilical connection is made it is possible to switch between internal and external battery supplies by means of a six-pole latching relay inside the nose assembly. One method of monitoring the instrumentation is to bring out the single telemetry lead connected to the pole of the commutator. The nose assembly breaks into two parts just in front of the DOVAP unit and provision is made for more detailed monitoring through a connector in the rear bulkhead of the forward portion.

Packaging. Restrictions on space and weight for instrumentation and the high degree of reliability required in a severe environment call for modern techniques of miniaturization and packaging. Each circuit is broken down into small blocks of components which can be interconnected and mounted compactly. After electronic test these blocks are placed in moulds and a compound consisting essentially of an epoxy resin with a mica dust filler is added. When the compound has hardened the blocks are mechanically and electrically stable; the only terminals exposed being the necessary signal and power connections. In the event of failure of a block it may be quickly replaced; normally the old block would be disposed of, but if the faulty component can be located it may be possible to drill it out, replace it, and re-seal the unit with potting compound. After potting units are environmentally tested by subjecting them to the same degree of mechanical shock and temperature, pressure, and humidity change as they may experience during the handling and firing of the rocket. Planning of the package takes into account the requirement for maximum accessibility of units for replacement purposes. The units are interconnected by a cable and miniature connectors, the backs of which are potted in a rubber type compound which imparts mechanical strength and electrical insulation in minimum space.

After final assembly, the entire nose cone is given an overall environmental test to ensure satisfactory performance, and is then complete and ready for firing.

Totals	1.22 Amp.	25 ma.	1 ma.	29 ma.	1.7 Amp.

Acknowledgments

The design and preparation of such a vehicle is the result of the efforts of many individuals, departments and facilities. Further, support from several industries in the form of specialized components and engineering assistance have greatly assisted in this program. In particular I would like to thank Messrs. T. Courtnay, R. Lowe, R. Blake and F. Smith, all of CARDE, for their assistance in preparing this paper.

An Observatory for the Study of Meteors

F. R. Park, *Senior Research Officer, Upper Atmosphere Research Section,*

Radio and Electrical Engineering Division, National Research Council

EVERY DAY many millions of tiny particles from interplanetary space strike the earth's atmosphere and are consumed by heat generated through friction before they reach the earth's surface. At night, many of these objects produce streaks of light in the sky and are commonly referred to as "shooting" or "falling stars." Until the end of the eighteenth century these streaks of light were thought to be a phenomenon associated with the earth's lower atmosphere and hence were called meteors.

At the beginning of the nineteenth century it was found, by making simultaneous observations from points separated by several miles, that meteors occurred at heights well above the earth's lower atmosphere and travelled with very high velocities. More recent measurements by radio and photographic methods have shown that these heights are in the range of 50 to 75 miles above the earth and the velocities between 7 and 45 miles per second. From a large number of radio observations carried out by the National Research Council, no meteor velocities were found that were sufficiently large to prove that meteors travel in parabolic orbits and come from outer space. It is now well established that meteors are particles of matter from interplanetary space which circle the sun in elliptical orbits, frequently occurring in great swarms. Whenever the earth encounters such a swarm of particles, a strong meteor shower is observed. Many such meteor showers have been recorded. The greatest shower of the past few centuries occurred on November 12, 1833 and marked the beginning of a new branch of astronomy, the study of meteors.

Most of the visible meteors are produced by particles, which range in size from a grain of wheat to a walnut. Billions of smaller particles reach the earth each day but without sufficient energy to produce visible light. Occasionally a very bright meteor or "fireball" is seen and it may have a mass ranging from about an ounce to several pounds. If the fireball is very large it may not be completely consumed in its fiery dash through the atmosphere and some part or parts of the original mass may reach the earth as meteorites. Seeing such a fireball is a rare and unforgettable experience.

The meteor observatory at Springhill, near Ottawa, Ont., was built during 1956-57. This gave the National Research Council improved facilities for its meteor study work in time for the period of the International Geophysical Year.

The question might be asked why man is interested in studying such upper atmospheric phenomena as meteors. To the research scientist it is sufficient if his investigations yield new information about the physical universe, provide him with proof for his theories and permit him to inquire further into the unknown. This is the principal motivation for pure research, and no immediate practical application is necessary or important to the research scientist. However, in the case of meteor research, several practical applications are already apparent for the knowledge that is being gained in this field. By studying the flight of meteors in our upper atmosphere we are able to learn a great deal about the tenuous gas in the outer regions of the earth's atmosphere. A new system of radio communication depends upon the scattering of radio waves from meteor trails to obtain very high frequency propagation well beyond the normal line-of-sight distances. A knowledge of diurnal and annual meteor rates is important to this recent development. Intercontinental ballistic missiles reach heights where collisions with meteor particles are possible. Such collisions are even more important in considerations of space travel by manned vehicles and the maintenance of satellite space stations.

Meteors are the only interplanetary objects that we can examine at close range and meteorites are the only interplanetary material available to us for detailed analysis. Through careful study of how they reach the earth, and of their composition and structure, we may be able to learn what types of material move between the planets and what their past history has been.

Since the end of World War II the National Research Council and the Dominion Observatory have co-operated in carrying out a continuing program of meteor research using radio, photographic, and visual methods. Both continuous wave and pulsed radar have been used to measure range and velocity and to study the diurnal and annual meteor rates. Three-station radar triangulation has been employed to determine the instantaneous positions of meteors as they streak through the upper atmosphere. Combined radar-visual programs are conducted to study the diurnal and annual variation in meteor rates and to correlate the radar and visual data.

From 1947 till the spring of 1957, the greater part of this work was carried out at the Metcalfe Road field station of the National Research Council, a site located about seven miles south from the centre of Ottawa. With the increased building in suburban areas and the extension of the city limits to within a mile of this station it rapidly became unsuitable as a site for meteor observations. The increase in scattered sky light and radio interference seriously handicapped visual, photographic and radar observations. As a result, it was decided that a more suitable location for meteor observing should be established before the beginning of the International Geophysical Year.

The principal factors considered in choosing a new location were those which would ensure satisfactory observing conditions at both optical and radar wavelengths. Furthermore it was important to know that these conditions were likely to exist for the next fifteen or twenty years if the move was to be worthwhile. To obtain good optical observing conditions, the site should be remote from any existing or possible future industrial built-up areas because of reflected sky light, and it should be higher than the surrounding area and reasonably well wooded to avoid difficulty from existing local lights. Although at the wavelength (about 9.25 metres) used in the meteor radar much of the daytime interference is from distant radio signals, it is essential that the site should be free of locally generated electrical noises in order that the best possible records can be obtained. Other factors considered in choosing a new location were access to good roads, and the supply of electric power and water.

A survey was made of the country surrounding Ottawa within a radius of 25 miles and a suitable site was found just off Highway 31 about 16 miles south of the city limits. Thirty-five acres of land were purchased in a tree-covered area behind Springhill Cemetery, about halfway between the villages of Metcalfe and Vernon. The average elevation of the site is 310 ft. above sea level and is from 30 to 50 feet higher than the surrounding country. The trees, though mainly deciduous, are small and quite thick, providing excellent screening against lights from local farmhouses. The distance from the centre of the property to the highway is about a half mile. The highway is in a shallow cut where it passes the cemetery and the sideroad, so that car headlights are well hidden below the horizon.

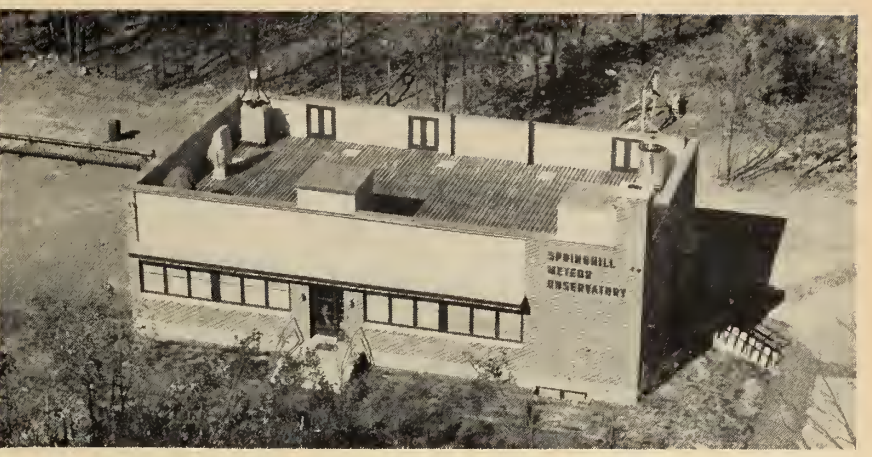

Fig. 1. Main observatory building.

Fig. 2. General view, showing radar antennas.

During the fall and winter of 1956-57, the Springhill Meteor Observatory was built on this site. The observatory is specially designed to provide facilities for the operation of electronic and photographic equipment and for the accommodation of personnel engaged in night-time observations. The building was designed by the architectural firm of Dobush and Stewart, of Montreal, and the construction was carried out by A. Bruce Benson Ltd., of Ottawa. In the early summer of 1957, radio and photographic equipments were transferred from the Metcalfe Road field station to Springhill, and meteor observations were commenced at the new station in July. On November 25, 1957, the facilities of the station were demonstrated to 150 guests and staff members at a small, informal opening reception.

The main Observatory building (Fig. 1) is 62½ feet long and 35 feet wide. The lower floor is constructed with reinforced concrete columns and walls which support a steel superstructure. The roof is a reinforced concrete slab carried on steel beams. One inch of rigid insulation was laid on the slab followed by a built-up tar and gravel roof. Seven special instrument-mounting pads are cast into the roof slab and a duck-board decking is installed which permits traffic over the entire area. A five-foot high parapet surrounds the roof area to protect the observers and instruments from the wind and chance lightning flashes on the horizon. Figure 1 shows four instruments located on the mounting pads. The two with canvas covers are special meteor spectrographs. The other two instruments are auroral all-sky cameras specially designed for use during the I.G.Y. The small hut in the centre of the front parapet provides a shelter for the operators and a place where they can prepare their records. Since the photograph was taken, a three-foot diameter, clear-plastic dome has been installed in the roof of the observers hut. From here a watch can be kept of the night sky during an observing period.

The exterior treatment of the observatory is red brick with the front and rear parapets covered with grey asbestos board, providing a pleasing appearance to a rather difficult architectural subject. The interior of the building provides operating space for meteor radar equipments, photographic darkrooms, offices, a fully equipped lunch room, and dormitory accommodation for the use of staff members on night duty shifts.

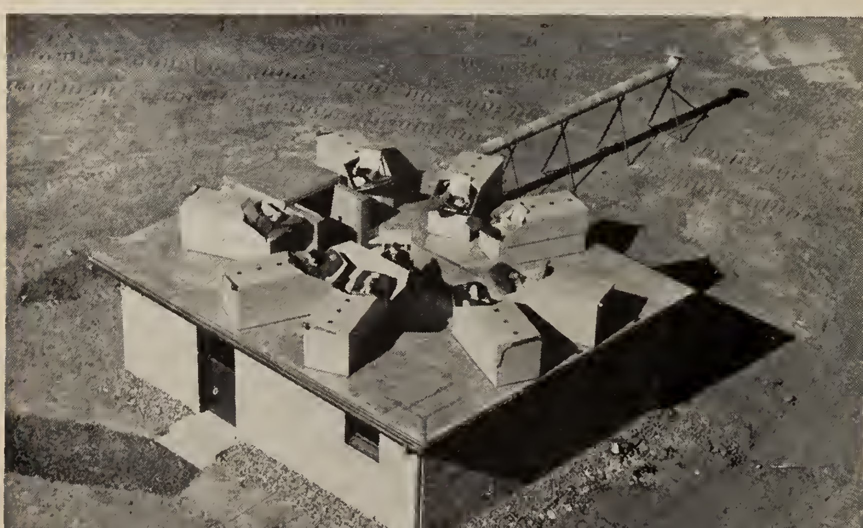
Two pulse radar equipments, operating on a wavelength of approximately 9.25 metres and equipped with special display units and cameras to obtain a continuous photographic record of the meteor echoes, are installed at the Springhill Observatory. One of these radars was designed specially for the I.G.Y. program and operates continuously on a 24-hour basis. It has a peak power output of 20 kw. and incorporates special features to insure stability of its operating characteristics. Separate transmitting and receiving aerials using crossed dipoles spaced 0.4λ (where λ is the operating wavelength) above elevated conducting groundscreens, produce stable omnidirectional radiation patterns. These antennas can be seen in the upper left and lower centre of Fig. 2. The groundscreens are located above ground by approximately 3 feet so that the effective height of the antenna is not altered by the accumulation of snow on the ground. The ground-screens consist of 6-inch square galvanized wire mesh, joined by compression sleeves and stretched over a framework of 2-inch by 6-inch cedar planks supported on 4-inch square cedar posts. The posts, which are bolted to the plank framework, rest on 12-inch square by 4-inch thick concrete blocks set in crushed stone. The diameter of the ground-screens is 105 feet, being sufficient to control and stabilize the radiation pattern down to within a few degrees of the horizon.

The second meteor radar, operating on the same wavelength but with simple horizontal-dipole antennas, was built some years ago and was moved to Springhill from the Metcalfe Road field station. It has a peak power output of approximately 400 kw. and is operated during special observing periods. During the I.G.Y., full-scale meteor observations are being carried out on 81 specially selected dates.

From 1947 to the spring of 1957, the National Research Council had established facilities for visual meteor observing at the Metcalfe Road field station. The visual station consisted essentially of eight reclining seats arranged in a circle and facing outward. The recorder sat in the centre and a canvas windscreen surrounded the whole to provide some protection against the wind and low level lights.

A new visual platform (Fig. 3) was constructed at Springhill during the summer of 1957. The experience of conducting visual meteor programs during the previous ten years was utilized to make the new unit as efficient as possible. Raising the level of the observers above the ground avoids some of the problems of dew formation, provides for centre access to the visual platform without disturbing the observers, and for space below to permit storage of cold weather equipment and the installation of an oil-fired forced-air furnace. Special cubicles have been built for the eight observers to provide greater protection against cold weather. Heated air from the furnace is piped to each observing cubicle and to the recorder's position in the centre. Since the photograph was taken, a pipe railing and a canvas windscreen have been installed around the platform. Buried cables provide for electric service to the building, and the necessary electronic and control circuits between the visual platform and the observatory.

Fig. 3. Visual observation platform.



The Springhill Meteor Observatory serves as a field station for the Upper Atmosphere Research Section of the Radio and Electrical Engineering Division. The radio work is carried out entirely by this section while the photographic and visual programs are conducted with the co-operation of the Stellar Physics Division of the Dominion Observatory. As a site for carrying out photographic and visual observing programs, the Springhill Observatory has proved to be a very great improvement over the Metcalfe Road station. Since there is little or no local radio interference, the radar records are superior to those obtained in the past. It is anticipated that this station will become the headquarters for most of the meteor research programs to be conducted in the Ottawa area for several years.

Tunnelling Saskatoon's 14th Street Storm Sewer

D. R. Graham, M.E.I.C.,* and N. L. Iverson, M.E.I.C.†

THIS STORM sewer serves an area of approximately 800 acres in east Saskatoon. There is no natural surface drainage for this area despite its proximity to the South Saskatchewan River. The required depth of sewer, general soil conditions in the area and the necessity of disturbing surface traffic and shallower water and sanitary sewer services as little as possible indicated the desirability of installing the sewer by tunnelling methods.

Soil Conditions

The design of the tunnel was started in early 1950 and a number of churn drill holes were put down along the proposed route late that year. The holes were drilled to obtain a general idea of soil conditions and no samples were taken. The general geological conditions in Nutana (the area lying on the south and east side of the South Saskatchewan River) are alluvial deposits overlying a dense glacial till. The alluvial deposits are extremely variable in nature, and in depth (see Fig. 1), but they generally consist of a layer of fine silty sand from 0 to 40 ft. thick overlying a firm blue clay of medium to high plasticity. The depth of sand varies very erratically within a short distance, the contact between sand and clay often sloping at a 1:1 gradient. The water table varies but is generally about 15 to 25 ft. below the ground surface. The quantity of seepage encountered in excavations in the sand below the water table is not great but it usually causes the sand to cave or run. The glacial till underlying the alluvial clay is generally a dense clay but it contains frequent lenses or layers of fine to coarse water bearing sand. Table I gives the results of routine classification tests made on samples of alluvial and glacial clay obtained from the area in 1952.

Although the required tunnel depth was somewhat less it was decided to tunnel about 50 ft. below the ground surface with the hope of avoiding sand for most of the tunnel length.

Hand Excavation

It was decided to use 60 in. diameter tunnel liner rather than 54 in. to provide more working room at a slight additional cost. Ten-gauge Armco tunnel liner plate was used throughout. Work started 1 June, 1951 using conventional hand tunnelling methods and digging the blue clay with an air spade. Material was transported in earth buggies pushed by hand on tracks installed on the tunnel invert.

This paper describes briefly some of the troubles encountered in attempting to tunnel through overburden deposits and the methods used to overcome them. The greatest difficulty was due to running ground in the form of saturated silt and sand. The various techniques used, such as concrete grouting, chemical stabilization, electro-osmosis, etc. are described briefly. Two types of mechanical shields are described and their relative advantages and disadvantages discussed.

Progress for the first 740 ft. was excellent, about 3 rings (4½ ft.) were regularly installed per 8-hour shift. The first trouble was encountered at Sta. 7+42 in mid-December, 1951. Work stopped at noon Saturday and when the workmen returned on Monday they found the tunnel completely filled with sand, water, and clay for a distance of 12 ft. and partially filled for a distance of 60 ft. from the face. Apparently the clay cover gradually yielded and gave way, allowing the water-bearing sand to pour into the tunnel. The material in the tunnel was composed of what appeared to be a very fine silty sand mixed with chunks of highly plastic alluvial clay. Tests on samples revealed that the fine silty "sand" was actually silt. Four samples were analyzed in a hydrometer test and the average test results were as follows:

- Medium sand 0-1%
- Fine sand 9-27%
- Silt sizes 59-66%
- Clay sizes 11-29%

The task of removing the material in the tunnel was started immediately. Partial bulkheads were used to stop further flow of silt into the tunnel. It was found that little or no progress could be made by this method. The tunnel was bulkheaded off and a shaft started a few feet beyond the face of the tunnel. A cavity 18 ft. deep and 12 ft. in diameter was found immediately below the frost line.

At this time six churn drill holes were put down along the tunnel route. The first four were spaced at 20 ft. intervals starting about 10 ft. from the tunnel face. Their logs are included on the profile, Fig. 1, and the data for Table I were obtained from these tests. The logs indicated

Paper read at the 71st Annual General Meeting of the E.I.C., June 1957.

that, while the tunnel would soon be beyond the immediate trouble spot, the depth of sand and silt varied erratically and more difficulties could be expected at frequent intervals. In many places where difficulty was encountered a portion or all of the tunnel face was in firm blue clay, but the clay cover was insufficient to support the weight of cohesionless sand and water above.

The shaft was successfully completed and excavation again attempted in the tunnel. It was evident that a different procedure would have to be used.

Freezing Method

An attempt was made to freeze a horizontal curtain over the tunnel face by using dry ice packed in two-inch pipes six feet long and spaced on 12-in. centres above the tunnel. This was partially successful and two rings were installed. The method was slow (about 36 hours freezing time was required) and further attempts at freezing were unsuccessful, probably because even a small movement of ground water towards the tunnel face reduced the effectiveness of the freezing. Consequently this method was abandoned.

Use of Poling Plates and Grout

About this time an attempt was made to support the silt above the tunnel face by jacking sheet piling horizontally about three feet above the tunnel face. This attempt was unsuccessful because of the fluid nature of the silt. Up to this time pressure grouting had not been attempted, mainly because the type of soil giving difficulty was silt and very fine sand. Grouting of material finer than coarse sand is usually not successful because the grout will not penetrate the voids in the material.[1] However it was attempted here as a matter of expediency and with the hope that grout would fill some of the voids left by the caving material. A converted steam pump was used and driven by compressed air. A cement-sand mixture of 1 part cement to 2 parts sand with 4% bentonite added was used. Some progress was made but not sufficient to warrant any optimism; at that time the value of high pressures and the necessity of continuing to grout until pressure became effective was not appreciated.

After consultation with officials representing the manufacturer of the liner plate it was decided to use interlocking steel poling plates five feet long over the top of the tunnel. A 50-ton capacity power-operated hydraulic jack mounted on a four-wheeled carriage was built to press the poling plates forward as the tunnel advanced.

Table I. Results of Classification Tests

		Density lb./cu. ft. Wet	Density lb./cu. ft. Dry	Water Content %	Liquid Limit	Plastic Limit	Plasticity Index	Unconfined Compressive Strength lb/sq. in.
Alluvial Clay	No. Tests	(62)	(62)	(64)	(11)	(11)	(11)	(11)
	Average	114	85	34	57	20	37	17
	Range	108-120	79-99	23-43	36-78	17-24	12-55	6-26
Glacial Clay	No. Tests	(14)	(14)	(14)				
	Average	132	118	12				
	Range	106-142	93-128	7-17				

A power hoist was installed at the shaft so that earth buggies could be brought up and dumped. At the same time a high-pressure air-operated grout pump with a booster feature capable of producing a discharge pressure of 200 lb. per sq. in. was designed and built.

By using a combination of grouting and poling plates twelve rings (or 18 ft. of tunnel) were installed in six weeks. The poling plates gave some protection but the tunnel face had to be left partially open for a considerable time while they were manipulated. Grout also presented a serious obstacle to their advance. However the grouting procedure worked better than had been expected, despite the fineness of the sand and silt. The grout, when under sufficient pressure, forced its way into the sand in sheets, and provided some overhead support. The quantity of water flowing into the tunnel was never a serious problem if the pressure head could be coped with. It was decided to abandon the poling plates and proceed with pressure grouting alone. After considerable grouting it was possible to remove the jacking heads and abandon the poling plates. By this time they were badly bent from being jacked through grouted material.

Grout Only

Tunnelling was continued by grouting with a cement-sand-sawdust mixture of 1:2:2 proportions in combination with a small amount of bentonite. By applying plenty of pressure this mixture could be forced into the silt where it would remain stable for from five to ten hours. Then the material would get progressively wet, start to spall in large pieces, and finally start to slowly squeeze into the tunnel. If bulkheading was not installed at this stage it was invariably followed by a rush of silt and water under considerable pressure which could not be controlled until the tunnel was completely filled for some thirty feet back from the face and partially filled for a much greater distance. This unfortunate circumstance occurred a few times until enough experience was gained to know when to stop excavation, bulkhead the face, and regrout.

An objectionable feature of pressure grouting is that invariably the bulkhead is subjected to very high pressures which distort the tunnel liner and make grade and bearing very difficult to control. In all cases where silt pockets were overcome with pressure grouting the grade and bearing were erratic and compensations had to be made. However the grouting procedure worked quite well and by 8 January, 1953 fifty-nine rings (88½ ft.) had been installed and the tunnel was through the silt pocket.

The next 700 ft. of tunnel was installed with only one silt pocket being encountered and this was stabilized with a single grouting.

Use of Splinter Boards

It was found that, where loose or spalling clay was encountered, a semi-circular shield could be quite easily installed and was very useful where the hydrostatic pressure was low. This shield was constructed by driving in 3 or 4 ft. lengths of 2 in. by 4 in. fir. A levering tool was made to lift the heel of these boards up, and pull them back, so that the rear ends rested on the perimeter of the tunnel liner. If properly placed these did not interfere with the installation of the liner plate section and fairly rapid progress could be made.

Attempt at Electro-Osmosis

Another bad silt pocket extending for about 80 ft. was encountered on 9 March, 1953. In an effort to find a quicker and cheaper method of control an attempt was made to use electro-osmosis.[2, 3] Four cathodes were

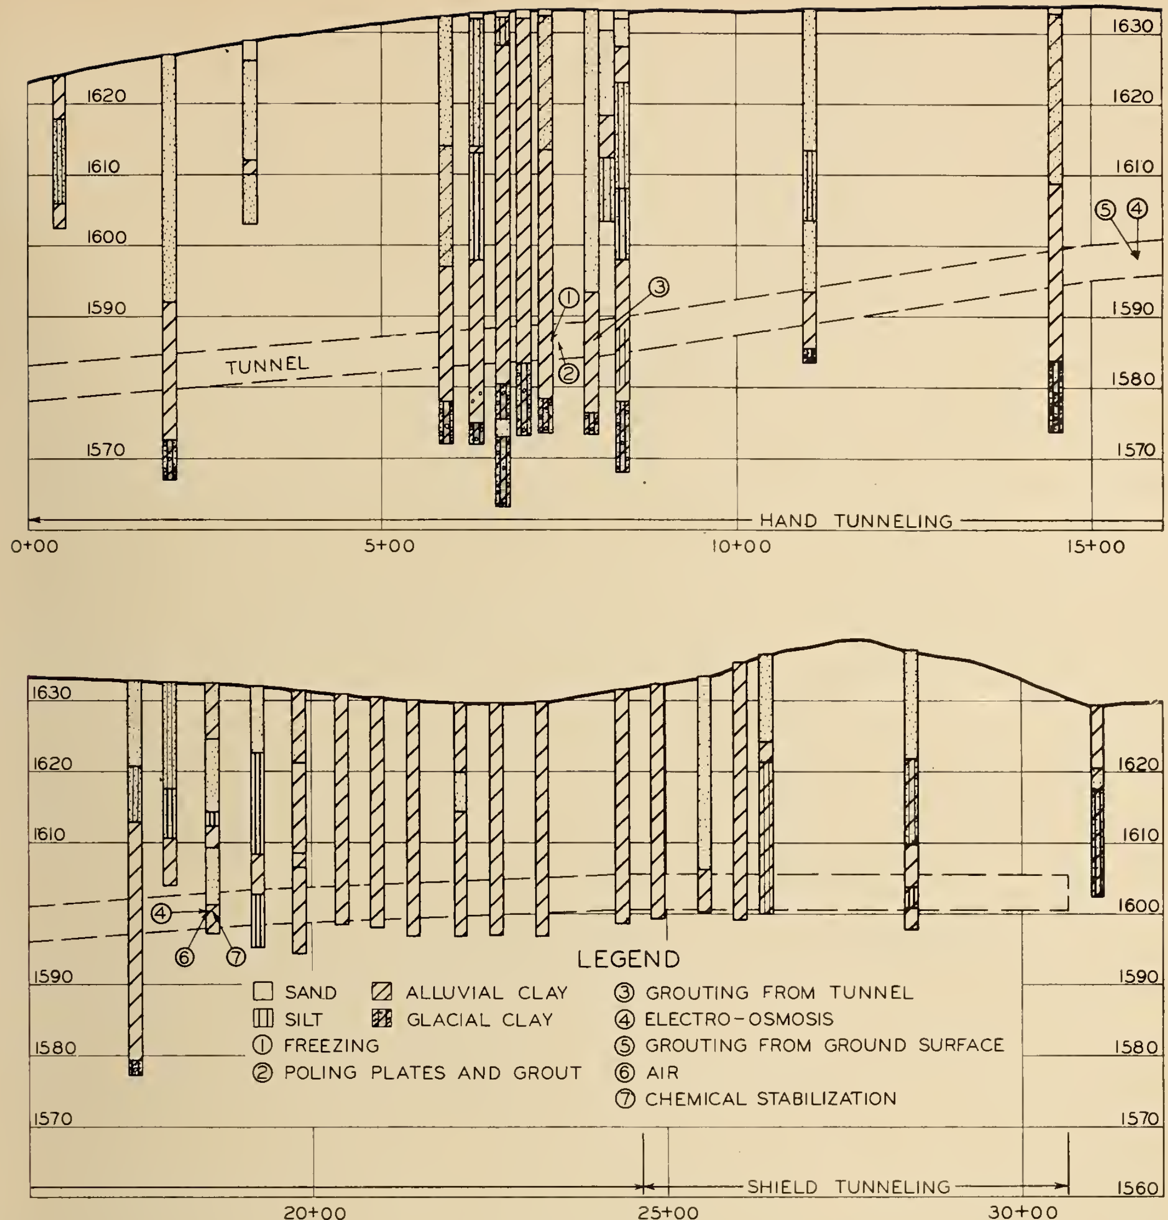

Fig. 1. Soil profile.

put down from the surface about 20 ft. ahead of the tunnel face. The tunnel liner was used as an anode, and current from two 500-amp. welding generators in series was supplied for four days. This did not result in any improvement in conditions at the face of the tunnel probably due to the coarseness of the unstable material.

Grouting from the Surface

Pressure grouting was again used to overcome the difficulty but this time the grouting was done from the surface. Two-inch diameter pipes were put down at 10 ft. intervals and grouted. This worked very well, and by 9 May, 1953 the tunnel had reached Sta. 15+66. A shaft was put down at Sta. 15+40 but no further tunnel work was done until 4 Dec., 1953.

Work progressed well until 27 Dec., 1953 when a bad break occurred at Sta. 18+52. At the time of the cave-in the face of the tunnel was mostly in clay with only the upper foot or two in sand. Over 350 bags of cement were used in grouting before any results were obtained. At this point the surface of the street raised noticeably and a crack appeared in front of, and at right angles to, the tunnel. A grout pressure of possibly 100-150 lb. per sq. in. was being used. The tunnel invert at this point was only about 33 ft. below ground surface so that from this point it would be unlikely that sufficiently high pressures could be developed to effectively grout the sand.

Use of Air

An attempt was then made to displace the water in the sand with air pressure. Four two-inch pipes were put down about 25 ft. in front of the tunnel. Air at 20 lb. per sq. in. pressure was supplied for forty-eight hours. An attempt was then made to work at the tunnel face. While there was some apparent decrease in the water content of the sand the results were not sufficiently good to make any progress, and the idea was abandoned.

Electro-Osmosis

A sample of the sand was taken and tested. The sample was a silty fine sand; over 65% was between the 100 and 200 mesh sieve, with about 15% finer than the 200 mesh sieve. Thus of the various methods of soil stabilization and de-watering the only methods that could be expected to be successful would be a well point vacuum system or the use of compressed air.[4] The soil would be too coarse for electro-osmosis, too fine for ordinary gravity well point systems, and on the borderline or too fine for chemical soil stabilization. The use of compressed air was considered as a last resort because of its probable expense and lack of experienced labour. The use of a well point system from ground level would require two stages due to the lift, and consequently would require an open cut. This was considered as extremely undesirable because of the interference it would cause with traffic and existing water and sewer services at shallower depth.

It was decided to attempt one or more of the methods that were of doubtful applicability, such as electro-osmosis or chemical stabilization. Electro-osmosis was attempted first because the equipment was available and it was the less expensive alternative. The tunnel was made the cathode, and two 1½-in. steel pipes driven into the face of the tunnel for a depth of about 15 ft. were used as the anodes. The anodes were covered for the first 10 ft. with rubber hose so that the current would flow from the ends of the anodes to the sides of the tunnel. The idea was to assist natural drainage into the tunnel and away from the face of the tunnel. The generator output was 125 amp. at approximately 90 volts. After three days of continuous operation the face was opened. It was found that some drying had taken place near the anodes but that the electro-osmotic pressure had not been enough to stabilize the silty sand.

Use of Chemical Solidification

Experiments were made in the laboratory using sodium silicate and various acids in order to produce a suitable gel in the sand. It was found that a solution of 32 parts water, 7 parts sodium silicate, and one part glacial acetic acid produced a firm gel with a setting time of approximately 30 minutes.

It was found that the gel, when injected, stabilized the sand to a considerable extent but did not have sufficient mechanical strength to withstand the head of water above the tunnel. It was often necessary to use air spades to remove grout-hardened sand and the vibration hastened the squeezing-in and rupture of the tunnel face.

It was therefore necessary to consider the use of a calcium chloride solution with the sodium silicate solution. These two chemicals react to form a crystalline solid with considerable mechanical strength. Considerable experimentation was necessary in order to establish the correct and economical amount of chemicals to use. Solutions of 10 gallons of sodium silicate to 10 gal. of water and 40 lb. of calcium chloride to 20 gal. of water gave the best results. Also it was necessary to construct an injection device. This was made from two small steam pumps connected to a ⅜-in. copper tube inside a ½-in. pointed pipe with holes near the point so that the two chemicals did not mix until they reached the discharge end. The procedure was to pump in five to eight gallons of sodium silicate solution and then an equal quantity of calcium chloride. A small jet of compressed air was used to agitate the calcium chloride solution and ensure good mixing. This gave good results although it was quite expensive. The approximate cost for chemicals alone based on the amount used for this portion of the tunnel was $80.00 per foot. The cost of cement grout often exceeded this amount so that it cannot be considered an excessive cost for overcoming fairly short stretches of difficult tunnelling. However, the use of chemical solidification did not prove successful for routine tunnelling work. Under the existing 20 ft. head of water the tunnel face would often spall or break out, making it difficult to replace the bulkhead before the sand and water began pouring into the tunnel. It was also quite slow as a routine procedure. Consequently it was abandoned except as an aid to mechanical shield tunnelling.

Rotary Auger Type Shield

The last 600 ft. of the tunnel was driven using two types of shields. First a rotary auger type shield was tried. This was designed and built in January 1955. The essential features are shown in Fig. 2 and two photographs of the shield in operation are shown in Figs. 3 and 4. The idea was to bolt the tunnel liner in a continuous spiral, rather than in concentric rings. The shield consisted of a double-bitted auger with an 18 in. lead and 9 in. pitch. The auger was 64 in. in diameter and was rotated by means of three power-operated hydraulic jacks with 3 in. bores and 12 in. strokes set tangentially and spaced at 120° intervals on the inner shell of the shield. A continuous expanding shoe made in three segments was used to grip the bolt heads in the liner plate flange. The shaft end of each jack was connected to one segment of the shoe. In this way even pressure was exerted on the liner plate when rotating the shield. A corded rubber seal was used to prevent silt from flowing in between the shield and tunnel liner.

Steering was controlled by a truncated outer shaft 6 in. in diameter and five feet in length. This steering bar could be rotated with the auger when no change in direction was required, or held stationary when making a correction in either grade or bearing.

The shield was powered by a 3 h.p., 3600 r.p.m., 3-phase, 220-volt motor driving a hydraulic pump through a 3 to 1 speed reducer. A hydraulic pressure of 2500 p.s.i. was used. Suitable fourway valves were used for reversing; these valves also had a neutral position.

Rotation for one segment, 90° of rotation, required approximately fifteen minutes and required seven strokes of the rams. Ten segments in an eight-hour shift was considered normal progress. This corresponded to an advance of 45 in. per eight hour shift as compared to 54 in. for good hand tunnelling.

In hard blue clay or semi-stable silt this machine worked very well. It required a relatively small amount of power and did not exert excessive strain on the tunnel liner. No extra bracing was necessary as far as the liner plate was concerned.

Fig. 3. Auger type shield installed.

Fig. 4. Auger type shield showing expanding shoe and jack.

Two hundred and thirty-five feet of tunnel was completed with this machine.

Steering presented some difficulty as the tendency was for the machine to rise. An analysis of the forces acting at the cutting edges will show that this can be expected. However this problem was overcome by lengthening the steering bar and restricting the flow of earth through the opening on the up cutting side of the machine. Hinged gates were installed on these openings and were made adjustable.

The shoes providing forward thrust gave some trouble and on one or two occasions bent the liner plate flange very badly. This difficulty was never adequately solved although there are one or two ways it could be done.

The third and greatest difficulty was the rubber seal at the back of the shield. It was two failures of this seal that was the deciding factor in abandoning this type of shield in favour of a push type machine.

Since that time however a type of seal consisting of metal segments hinged at one end and overlapping each other has been evolved. This should effectively solve the seal problem.

Specially designed liner plate, having the correct forward spiral and counter-sunk threaded nuts, should be developed and used for this type of shield.

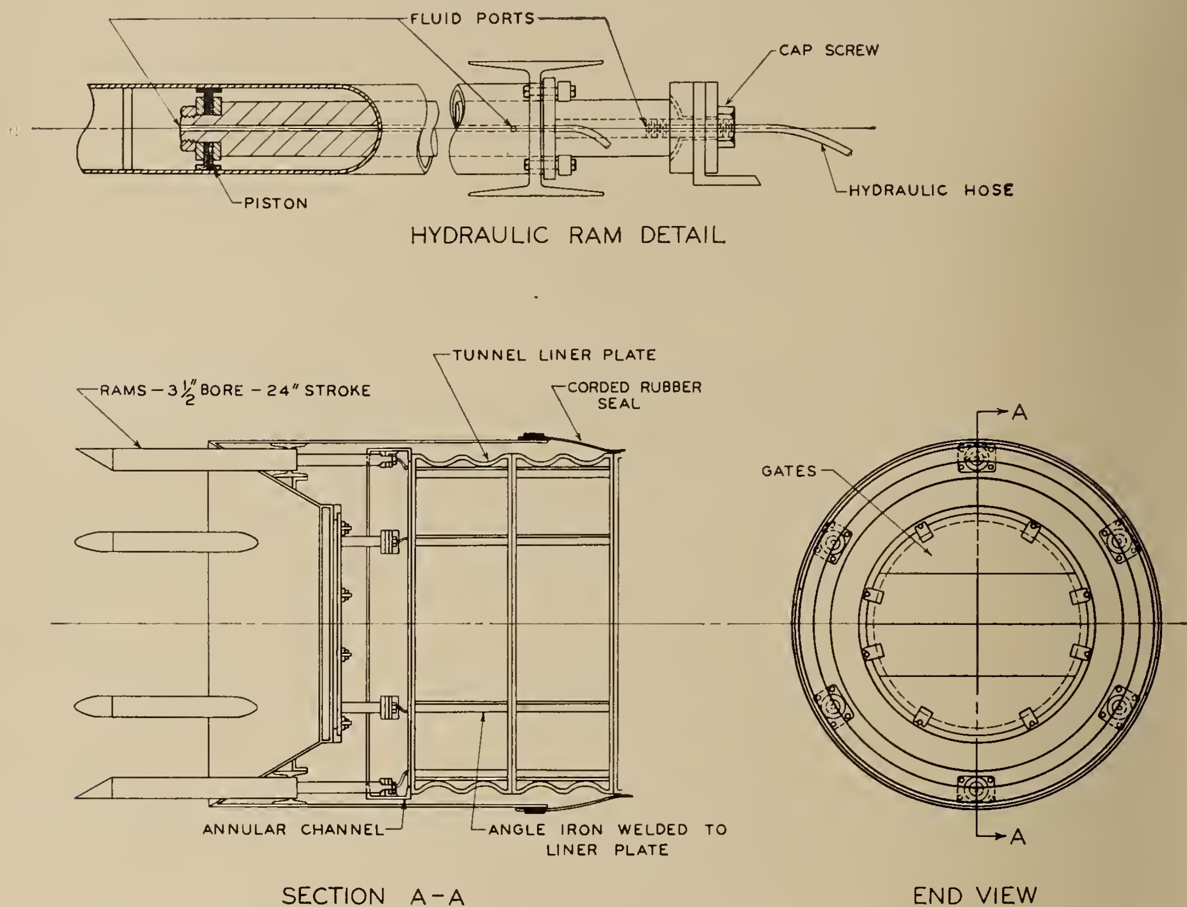

Fig. 5. Sketch of push type shield.

Experience with the Push Type Tunnelling Shield

After two failures of the seal on the rotating tunnelling machine and with the most difficult portion of the tunnel still to be completed it was decided to abandon that method for the time being.

A push type shield of the type shown in Fig. 5 was designed and built. A single outside shell of ⅜ in. mild steel plate with a corded rubber seal at the rear was used. The front 30° cone reduces from the cutting edge of 64 in. to a centre opening of 42 in.

Originally eight doors, hinged at the centre and latched at the periphery of ¾ in. bolts with thumb nuts and slotted tongues, were used (Fig. 6). It was found that the centre bar offered considerable resistance and it was subsequently removed, and four gates extending across the opening were substituted. This seemed to work much better.

Forward motion was effected by six hydraulic rams having a 24 in. stroke and 3½ in. bore. Hydraulic pressure used was 3000 p.s.i. An annular channel served to distribute pressure against the tunnel liner, and the shaft ends of the six jacks were connected to this ring by means of sockets which allowed some swivel action.

The liner plate had to be reinforced by 2 x 2 x ⅜ in. angle iron opposite each jacking point in order to withstand the thrust. This required considerable extra labour and added substantially to the expense.

The same power unit previously described was used. However, it was now working at considerably higher pressure, and maintenance became quite costly. In order to prevent excessive delay a spare unit was kept in readiness.

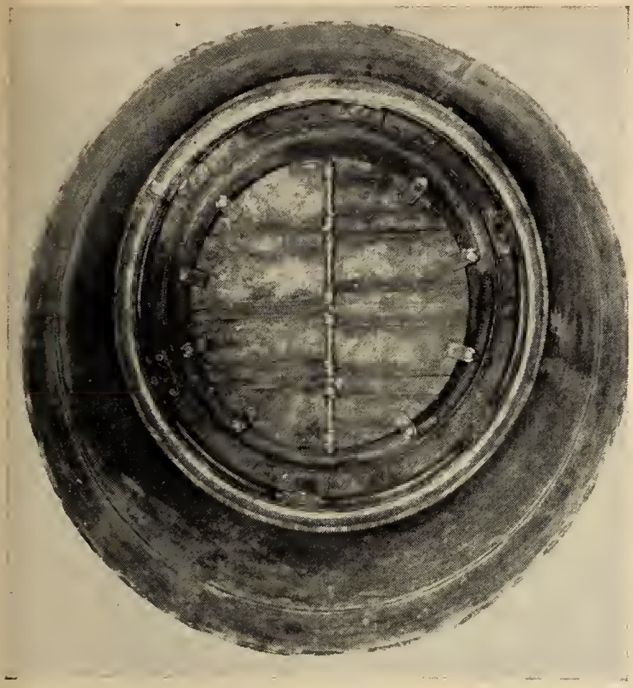

Fig. 6. Push type shield as constructed.

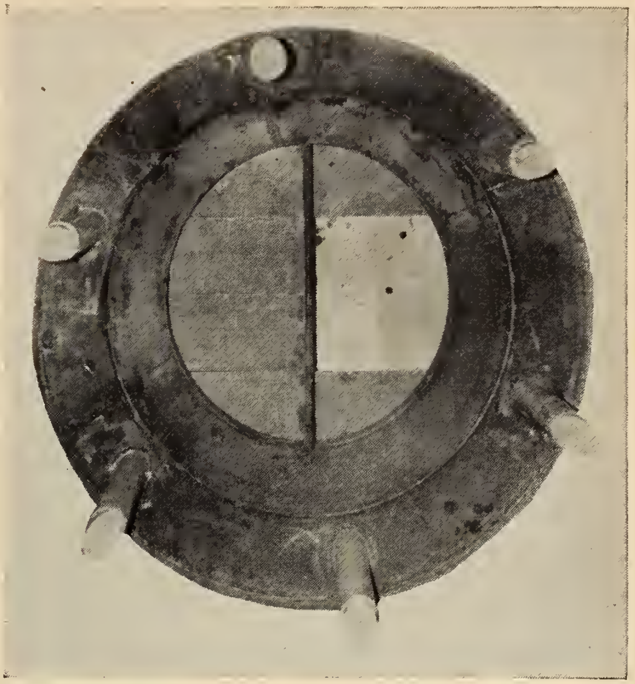

Fig. 7. Front end of push type shield.

The seal at the rear of the shield gave some trouble and considerable leakage occurred. This was never serious and it was possible to make continuous progress. Steering was a difficult problem with this machine also. The tendency was for the front end to go down. This is understandable when one realizes that all the earth excavated by the bottom one-third of the cutting edge must be lifted in order to pass through the opening while that excavated by the top portion of the cutting edge moves down.

An attempt to steer by shutting off the oil supply to the top rams resulted in serious loss of power.

This had been forseen to some extent and the machine was designed with the rams projecting through the front end of the machine about 18 in. with the ends of each ram terminating in a 30° inclined plane (Fig. 7). By rotating the body of the ram the inclined plane tended to exert radial force on the machine. It was found that bearing and grade could be controlled quite effectively by this means. It also materially reduced the overall required length of the shield.

Progress with this type of machine was 48 in. per shift. Under favourable conditions this could probably be considerably increased.

Some mention should be made of the use of sodium silicate — calcium chloride solutions for soil stabilization in connection with shield tunnelling.

In installing the push type machine the rotary machine had to first be removed. This was accomplished by first sinking a shaft 12 ft. wide and 14 ft. long, 38 ft. deep in wet, fine, running sand. A wood cribbing of double spruce 2 in. x 8 in. was first put down 12 ft. Inside this crib 30 ft. interlocking steel piling was driven to form a cofferdam. Excavation was then proceeded with until silt and water began to boil up from the bottom of the excavation.

Several barrels of sodium silicate grout were then injected through small holes cut through the steel piling at about 3 ft. intervals. Grout was also injected inside the cofferdam. Excavation was then proceeded with and small additions of grout were injected whenever boiling recurred. This was usually at from four to twelve hour intervals.

By using this method it was possible to remove the rotary machine and install the push type without a great deal of difficulty. The excavation was then partially backfilled and the piles pulled.

Conclusions

In the course of construction of this tunnel many different procedures were used and under certain conditions most of them had some value.

Concrete grouting was found to be useful in coarse sand or gravel or in cohesive clay at sufficient depth to obtain good compression. Under these conditions the water content of the soil can be reduced to the point of good stability. Work can then proceed until the water re-infiltrates. This was usually a matter of three to twelve hours under the pressure heads encountered on this project.

Chemical grouting was useful in fine sand and silt and as an aid in shield tunnelling. The grout did not have sufficient strength to withstand high water pressures and had a useful life of only a few hours under pressure.

Electro-osmosis was unsuccessful, probably because the type of soil was too coarse and considerable water pressure existed.

Short wood piling of 2 in. x 4 in. fir driven to form a short semi-circular shield proved very useful in combating loose soil or spalling clay but was of no value where water pressure was high.

Freezing proved too costly and slow, although for short distances where cost is not a predominant factor it can be very effective.

Tunnelling with a mechanical shield proved to be the most effective method of coping with unstable soils. By this means success is assured even under the most adverse conditions and progress is nearly as rapid as with hand tunnelling. The cost of constructing a shield for a five-foot bore

Canada is Host to the

World Power Conference Sectional Meeting

To be held 8-11 September 1958

Queen Elizabeth Hotel, Montreal, Quebec

FOR THE FIRST time in her history Canada, one of the world's great producers and consumers of power in all its forms, will act as host nation next month (September) to a Sectional Meeting of the World Power Conference.

The event is expected to attract more than 1,000 scientists, engineers, economists and other experts. Converging on Montreal from some 50 different countries, they will gather to consider "Economic Trends in the Production, Transportation and Utilization of Fuel and Energy".

The Technical Sessions

Within that framework, roughly 150 technical papers will be presented, Canada contributing nearly 20 of them. Pre-prints of these, along with general reports summarizing them by groups, have been mailed in advance to all delegates, in order to keep as much time as possible available for discussion and debate on selected topics.

Sessions, all to be held at The Queen Elizabeth Hotel in Montreal, will open on Monday, September 8. That morning will be devoted to hydraulic energy, covering both system planning and design and operation. In the afternoon delegates will discuss the more general aspects of hydraulic energy, including economic trends in power development.

Tuesday morning's sessions will consider production of thermal energy from coal, oil and gaseous fuels, and delegates will turn their attention that afternoon to nuclear energy and nuclear fuels.

On Wednesday morning, September 10, sessions on transportation will open, with global trends in electiic transmission and in carriage by rail, water and pipeline all being examined.

Sessions on utilization will begin on Wednesday afternoon, as conference delegates meet to review the use of power in industry and commerce. They will continue the following morning, Thursday, as the four-day meeting ends with discussions covering utilization of power on the farm, in the home, and by railways and airlines.

Procedure for conducting the technical sessions will be as follows:

At least 48 hours before the Conference anyone wishing to submit formal discussion must submit a brief summary of what he proposes to say, limiting his remarks to the points listed in the general reports.

The chairman of the session will open the proceedings by announcing the topics chosen for discussion, and outlining the rules of debate. He will then call on selected speakers who have submitted summaries of formal discussion.

Discussion will be carried on in French and English, for which simultaneous translation facilities will be provided. If time permits, the chairman will then call on other speakers who are prepared to limit their remarks to the points listed in the general report, after which he will call on the general reporter for a summary.

If enough interest is shown, moreover, informal gatherings may be arranged for those who want to take up more fully a topic associated with any particular session. Announcements of these gatherings will be carried in the daily bulletin, to be issued each morning during the meeting.

Associated with the conference will be a number of study tours. One of these will enable delegates to visit the St. Lawrence Power and Seaway Project at and above Cornwall, Ontario, power developments at Niagara Falls, and an atomic reactor at Shippingport, Pennsylvania. Other points of interest to be visited include hydroelectric developments on Quebec's Sagnenay, Peribonka and Bersimis Rivers, and at Shawinigan Falls on the St. Maurice.

National Delegates

Nations whose delegates are scheduled to present papers at the September meeting include Canada, Austria, Great Britain, Italy, Poland, Spain, Russia, the United States, Yugoslavia, Czechoslovakia, France, Switzerland, Germany, Brazil, Australia, India, Japan, Portugal, Uraguay, Roumania, Sweden, Belgium, Finland, Indonesia, Hungary, Trinidad and Tobago, Luxembourg, Bulgaria, Denmark and the United Arab Republic.

Canadian Contributions

Canadian delegates will present papers on nearly every aspect of the meeting.

On hydraulic energy, T. Ingledow, vice-president of British Columbia Electric Company will cover "Integration of Gas Turbines in Hydroelectric Systems"; T. D. Stanley, production superintendent at Calgary Power Company, the "Economics of Centralized Control of Electric Generating Plants"; C. G. Miller, of the Manitoba Hydro-Electric Board and H. Teekman of Ontario Hydro, the "Thermal-Hydraulic Generation Integration in Southern Manitoba and Northwestern Ontario".

Canadian papers on thermal energy have been prepared by C. L. O'Brian, assistant to the chairman of the Dominion Coal Board, on "Coal Production in Canada"; J. W. Flanagan, of Imperial Oil Limited, on "Petroleum in Canada"; Charles Buckel, chief gas engineer of British American Oil Company, on "Producing and Processing Sour Natural Gas in Western Canada as Typified by Pincher Creek Gas Field and Gas Plant"; Dr. W. B. Lewis, vice-president of Atomic Energy of Canada Limited, on the "Economics of Uranium and Thorium for the Generation of Electricity"; and by R. E. Barrett and Arvid Thunaes, both officials of Eldorado Mining and Refining Limited, on "Uranium Production in Canada".

Canadian spokesmen on electric transmission will include D. M. Farnham and J. R. Hango, both of Hydro-Quebec, whose paper deals with the "Economics of Transmission from Bersimis River Developments".

On transportation by rail, water, etc., R. W. Warren of Canadian National Railways will discuss "Economic Trends in Canadian Railway Transportation with Special Reference to the Transport of Fuel"; R. D. Walker of Trans-Canada Pipe Lines Limited and A. B. Jones of Inter-provincial Pipe Line Company the "Economic Trends in the Transportation of Fuel by Pipeline".

Several Canadian papers are to be presented on the utilization division of the Canadian Sectional Meeting. They include those by John Davis, director of research and planning for British Columbia Electric Company on "Economic Trends in the Utilization of Energy in Industry"; by L. M. Pidgeon, University of Toronto professor, on "Electrical Energy and the Production of Metals".

P. H. Southwell and C. G. E. Downing, both from the Ontario Agricultural College, will discuss "Utilization of Energy in Canadian Agriculture", while Paul E. Lamoureux, of Trans-Canada Air Lines, will cover "Utilization of Fuel in Aviation".

History of the Conference

The World Power Conference was founded in Great Britain thirty-four years ago, on the initiative of the late D. N. Dunlop. It was to form a link between the different branches of power and fuel technology, between experts of the countries of the world, and between scientists and engineers on the one hand and economists and administrators on the other.

The first World Power Conference opened in the Conference Hall of the British Empire Exhibition, Wembley, on June 30, 1924. From 43 nations more than 1,000 members had gathered to consider technical papers centring round the problems of making an inventory of the world's power and fuel resources and of using those resources to the greatest possible advantage.

Since then 14 plenary and sectional meetings, most of them in Europe, have been held. The most recent, in Belgrade last year, considered power as a factor in the development of underdeveloped countries.

Major General H. A. Young, M.E.I.C., Deputy Minister of Public Works, is Chairman of the Canadian Committee of the World Power Conference.

An international non-governmental agency, the Conference has consultative status in category "B" with the Economic and Social Council of the United Nations. It is also a member of the Union of International Engineering Organizations.

Its central office is located in London, and 52 member nations are represented through national committees.

Meeting Organization

Representatives of companies and other organizations operating in the associated fields of production, transportation and utilization of energy form the Canadian National Committee. The federal government itself, moreover, recognizing how important it is to develop Canada's power resources and how desirable that nations share the scientific knowledge and skills by which power may be produced most efficiently, gives strong support. It has its own representatives on the Committee, and contributes the annual fee to the central office in London.

More than two years of detailed planning have been necessary to prepare for the September meeting, which first originated during a meeting of the International Executive Council, in Paris in 1955. Only once before had the Conference been held in North America, and that was in Washington, in 1936. But at the Paris meeting, the Canadian Committee formerly extended an invitation to visit Canada. This was accepted.

The choice of Montreal as the conference site reflects several factors affecting the convenience of the delegates. For one thing, the city is a terminus for ships, trains and planes. Moreover, it has plenty of first-class hotel space. And since English and French were to be the two official languages for the meeting, it seemed fitting to stage the event in a bilingual city.

Canadian Officials

Major-General H. A. Young, Canada's Deputy Minister of Public Works, is chairman of the Canadian Committee, and a list of Canadians prominent in power and associated fields has been responsible for making arrangements for the event.

Hugh Crombie, vice-president of Dominion Engineering Works Limited, is general chairman of the various sub-committees involved in making arrangements for the Canadian meeting. General secretary is T. M. Patterson, director of the Water Resources Branch of Canada's Department of Northern Affairs and National Resources.

Chairmen of the sub-committees include: J. A. Fuller, president, Shawinigan Water & Power Co.; R. Latreille, commissioner, Quebec Hydro-Electric Commission; A. C. Abbott, vice-president, Shawinigan Water & Power Co.; R. L. Hearn, consulting engineer; B. C. Fairchild, managing director, Canadian Electrical Association; M. P. Murphy, executive vice-president, Northern Electric Co.; R. L. Dunsmore, president, Champlain Oil Products Ltd.; Alan Field, director, Canadian Government Travel Bureau; L. Austin Wright, general consultant, The Engineering Institute of Canada; A. W. Manby, general manager, The Hydro-Electric Power Commission of Ontario; and Louis O'Sullivan, commissioner, Quebec Hydro-Electric Commission.

Education for Tomorrow

R. S. Gustavson
President, Resources for the Future, Inc., Washington, D.C.

Address given at the Banquet during the 72nd Annual General and Professional Meeting of the Engineering Institute of Canada, Quebec City, May 1958

FREEDOM AND SCIENCE are two words that come with increasing frequency from the lips of men. Freedom has been concerned with political freedom, with the right of free speech, and the freedom to worship as one's conscience dictates. Within the last few decades, these two basic freedoms have been related to two other fundamental freedoms, namely, the freedom from want and the freedom from fear. The people of Asia and two hundred millions in Africa are either in their swaddling clothes with respect to freedom or are demanding its birth. These people are not only looking forward to a higher standard of living with freedom from want; they are demanding it. The new freedom is being sought by the underdeveloped countries at a time when the world is divided between two great ideologies. The ideology of a democracy and the ideology of totalitarian government. These underdeveloped countries are looking to science and technology to achieve this goal of freedom. The big question today is whether these underdeveloped countries will work out the answer to this fundamental question within the framework of democracy or within the framework of totalitarian government.

Standard of Living

The standard of living enjoyed by the United States and Canada today makes tremendous demands upon the resource base not only of their own countries but great demands upon resources of countries great distances from them.

The United States today, with approximately seven per cent of the world's population, is consuming about 50 per cent of the world's goods. In fact it is so rich that it can consume about two-thirds of the world's production of oil, leaving only one-third for all of the other countries. The very high consumption of the world's available resources by the United States will increasingly meet competition from many parts of the world where there is an insistent demand for a higher standard of living, which will not be denied. The United States has been thrust into the leadership of the world by two world wars. It is difficult to see the possibility of any other leader for a long period of time — perhaps several centuries. Basically this means that the United States has become on a world-wide scale our brother's keeper, or shall we say democracy's guardian. This means accepting the responsibility for helping the underdeveloped countries conquer their poverty and disease within the framework of democracy. Leadership is a very simple role to discern but an awful responsibility to live up to. We did not seek the position of world leadership but it is our destiny to fulfill it.

In the world of science, man's greatest achievement has been the realization that he lives in a consistent universe; that is, if he asks nature a question by way of experiment at two different times and the conditions of the experiment are the same, nature will give identical answers on both occasions. The path from the concept of a universe ruled by caprice to the concept of law is a long and difficult one. Gradually a body of knowledge which we now call science has been established. Professor Niels Bohr, distinguished atomic physicist of Denmark, has described this body of knowledge as resulting from "the finding of techniques that have enabled man to place limiting values on his preconceptions."

The important thing to notice in Professor Bohr's statement is that it is not the preconception which is most important in science but the techniques by which man can determine the limitations for his preconception. Let me illustrate.

If you would paint a portrait of Abraham Lincoln you must first develop within your own mind a conception of the painting. You decide whether you are painting the rail splitter, the Indian fighter, the weary war president. You examine paintings, photographs, and various pieces of art representing the great emancipator and then you start to work with brush and paint and canvas. But there is nothing in the painting process that tells you whether you are right or wrong and your success as a painter depends upon how closely the final product represents in the concrete the preconceptions that you started with.

Recent Achievements of Science

Let us review some of the recent achievements of science. The outstanding discovery in the realm of physics has been the conversion of matter into energy so beautifully described by the Einstein equation, namely, $E = M\ C^2$ where M is the mass of the matter destroyed and C is the velocity of light. The velocity of light is 186,000 miles per second and this number squared, is 35 billions. So even if the amount of matter destroyed is small the energy liberated is very large. The discovery of the conversion of matter into energy rests upon a half century of basic research. At the turn of the century, studies made in connection with the element radium, revealed that this element was giving off energy to its environment in the form of strong X-ray-like penetrating radiations called gamma rays; negative electrical particles called electrons and positively charged atoms of helium which are called alpha rays. These helium particles were thrown off from radium with a velocity of 10,000 miles per second and represented at the time of their discovery the greatest concentration of energy known to man. Comparison of the energy of the steam particle with the alpha particle reveals that the alpha particle contains approximately 400 million times as much energy as the steam particle. Rutherford bombarded the element nitrogen with this high energy alpha particle and found hydrogen atoms were formed as a result of the bombardment. This was one of the great fundamental discoveries of the past half century. In following up this kind of experiment it was found by Bothe and Becker in Germany, that when the element beryllium was bombarded in a similar fashion, a strong penetrating radiation was given off which was erroneously interpretated by the German workers as being a type of X ray. Chadwick in England corrected this impression by showing that the beryllium under bombardment with the alpha particle was giving off an electrically neutral particle of about the same mass as the hydrogen atom but with a velocity of approximately 10,000 miles per second. Workers then began to bombard the elements with this neutral particle. It was in the course of this kind of experimentation that it was discovered that when natural uranium is struck by the neutron, some of the uranium atoms go to pieces and elements of smaller atomic weight are found in the debris. Matter is destroyed and tremendous quantities of energy are liberated. This was the work of Enrico Fermi in Italy and Otto Hahn in Germany. On the basis of these experiments, atomic bombs have been built, two of which have destroyed Japanese cities, and high temperatures have been made possible which approach those of the sun. These experiments are also the basis of the great effort which is being made today to work out peaceful uses for this energy in the form of electrical power, space heating and many other uses which we could describe if the time were available.

Attempts are now being made to realize experimentally the reactions producing heat in the sun and stars. There, at temperatures of ten to twenty million degrees centigrade, atoms of hydrogen stripped of their electrons strike each other with such force that the nuclei combine to form helium. Experiments in Russia, the United Kingdom and the United States indicate some success in duplicating this process in the laboratory. So far the energy liberated is a very small fraction of the energy used, but there is every reason to believe we are witnessing the birth of a new age—that of man-made thermonuclear reactions, until now known only in the sun and stars.

Importance of Energy Supply

The standard of living enjoyed by any country is directly related to the amount of energy which is available to the people of that particular country to carry on its work. If you want to dramatize the differences in the standards of living between India and the United States, there is probably no better way to do it than to indicate that in India the per capita amount of energy available to do the work of the Indian people is about 6000 large calories per day. The per capita daily amount of energy available to the people of the United States is roughly estimated at 120,000 large calories per day. The advent of atomic power now brings about the possibility of almost unlimited power for all of the nations of the earth, and therefore the possibility of a higher standard of living for all the people of the world looms large today.

I say "possibility" because the establishment of an atomic energy program requires a large capital investment. Where can this capital be found? Not in the underdeveloped countries where 90 per cent of the people are engaged in elemental agriculture and capital growth takes place slowly. For this reason it is possible that the gap between the highly industrialized nations of Europe and North America and a country such as India will widen with time unless ways and means are found for increasing the capital from outside sources.

Biological Sciences

Some of the recent work of Professor Stanley of the University of California in connection with viruses has indicated tremendous advances in understanding the chemical structure of these very complex bodies. It is in this field of large molecules that we have every reason to believe that the key to the cancer problem will be found.

In the field of biology the area of genetics is opening up very rapidly insofar as basic understanding is concerned. The new tools of biochemistry and biophysics are giving us the opportunity to carry out work in this field undreamed of a few years ago. As a result, new varieties of barley, for example, have been developed by irradiating the plant which gives a higher yield, stronger straw, and greater resistance to disease. In the mustard plant changes have also been brought about genetically which have given very large increases in yield. This field is in its infancy. As a result of studies in the field of radiation genetics, science is now not only pointing to the possible results that may be of benefit to mankind coming through work in the field of radiation genetics, but is also setting up a very definite warning against what may happen if in the age of atomic power and atomic bombs we are not careful about powerful radiations altering some of the genetic characteristics of man himself.

Implications for Education

These examples of significant work that is going on in the physical and biological sciences today are typical of course of a great many that might be described if time permitted. What are the implications for education? Surely one thing that stands out is the fact that all of our sciences — physics, chemistry, biology — are becoming increasingly quantitative in character. As information becomes quantitative it becomes subject to mathematical analysis and to description in mathematical terms. Mathematics is the language of quantitative data. This means of course that in our schools for those who are going to go into technical work, mathematics becomes increasingly a necessity. Our public schools have done a remarkably fine job in the field of teaching reading, and it is obvious now that some very fundamental work must be done in the field of teaching arithmetic. I am not ignorant of the progress that has been made, but research must be intensified. Our social organization has been undergoing change. Numbers today for the youngster in the kindergarten and early primary years are related to television channels, radio wave lengths, telephone numbers, license numbers, house numbers, in all of which cases the number has no quantitative significance. The research that is taking place today at the University of Illinois, under a grant from the Carnegie Foundation, in the mathematical curriculum for the ninth, tenth, eleventh, and twelfth grades is indeed promising. But much more research work needs to be done in the early grades, especially I would say from the fifth grade to the ninth grade because it is here that the antagonisms and the distaste for mathematics seems to be born.

In the opinion of many qualified scientists, biology may well be the next field in which great progress will take place.

Traditionally the effective tools have been the microscope, with dyes as secondary tools. The emphasis has been on morphology and classification, and ecology. The underlying theory which has given guidance to research has been the theory of evolution. This gave a strong stimulus to the study of taxonomy, comparative anatomy and embryology.

The new fields are the detailed structure and chemical reactions which characterize the protoplasm of cells and tissues. The new tools are the electron microscope, the spectroscope, ultramicrotomy (cutting biological material into sections so thin as to permit its study with the electron microscope). The radioactive isotopes are also powerful tools for metabolic studies.

It would seem to me that serious consideration must be given to the high school and college curriculum in biology. It is important that the high school student who has talent in mathematics, physics and chemistry should be aware of the possibility of using these tools in exploring the field of biology.

The Stimulus of Curiosity

Basic research has as its objective to understand the world about us with no other objective than to know; it is the kind of research that grows out of pure curiosity. This kind of research has found its home very largely in Europe, but today this responsibility is increasingly falling on the United States. The recent tremendous advances that Russia has made in the development of technical skills and engineering has undoubtedly precipitated a crisis in the minds of many people. I do not share this anxiety. It does seem to me, however, that it can be a stimulus to increase the efforts that we can make and should make in this field. It has many implications for education. It means at the elementary level that curiosity must be fostered. It means that asking students to merely repeat experiments in cookbook fashion must be increasingly eliminated from our educational program. I think if once we begin to explore the possibilities of rewriting the textbooks and reorganizing the experiments we shall find great fun in this task.

It was my privilege to teach sixth grade students one afternoon a week for a period of three years. I never had more fun.

Let me just describe one situation that took place and I think you will see what I mean. One of these afternoons I took a Pyrex test tube, placed some ice in it and asked the youngsters what they thought would happen if I heated it in the flame of the Bunsen burner. Almost with one voice they said: "The tube will crack."

To their surprise they found that it didn't crack, the ice melted. We wrote an equation on the board in their own language: *Ice + heat = water.*

We then heated the water to the boiling point and noted the steam which was formed, and again we wrote an equation in their own language: *Water + heat = steam.*

We then took some paraffin wax and I asked the youngsters what they thought would happen if I heated the wax. From their experience of course with the burning candle they told me it would melt. We heated the wax, it did melt. We wrote the equation: *Wax + heat = watery wax.*

The question: "What will happen if we heat the liquid wax?" *The answer*: "It will form steam wax." We heated the wax, the wax did become "steam wax." I then placed some pieces of rolled sulfur in the tube and said: "What do you think will happen if we heat the sulfur?" *The answer*: "It will form watery sulfur." We heated the rolled sulfur, it became watery sulfur.

The question: "What do you think will happen if we heat the water sulfur?" *The answer*: "It will become steam sulfur." We heated the liquid sulfur and to their surprise it solidified. "Let's see that again", they said with one voice.

Now I am not holding myself up as a master teacher, I am merely trying to indicate what I mean by organizing experiments to stimulate curiosity.

I then asked one of the youngsters what he made of all of this. I shall never forget his answer. He spoke with a kind of a drawl. "Well," he said, "it seems to me what it means is that just because you know something about water or ice and wax is no sign you know anything about sulfur." What wisdom!

Balanced Education

Let us seek balance in our educational programs. One of our outstanding dangers is that we tend to go to extremes in times of crisis. Many of us can remember the strong forces to eliminate the teaching of foreign languages in our schools during and after World War I. Today we see the folly of this attitude. Today the success of Russian scientists in putting satellites into space is giving rise to strong forces to emphasize the physical sciences and mathematics. Up to a certain limit this is good. We need to periodically review our work but let us not forget the social sciences and the humanities. May I point out some examples from the work of a man who is working entirely in the realm of psychobiology, Professor Richter of the Johns Hopkins University. Professor Richter for many years has recognized the fact that rats are very sensitive to their well-being and seemed to be able to react in a way that cultivates their well-being. For example, if rats are given a choice of many different fluids to drink and among them various strengths of alcohol, the rat will not touch alcohol in greater concentration than 6 per cent. Or let me give you another example. If you remove the pancreas from a rat, that rat becomes diabetic. It becomes necessary to revise the diet from the normal diet for both rats and human beings to a modified diet that will conserve the strength of the diabetic. We have worked on this problem for decades. When you do this to the rat, if you give him an opportunity to balance his own diet by placing in front of him isolated proteins, fats, carbohydrates, mineral salts, and water, and vitamins, in the course of a few days he will arrive at a balance that is just as good as we human beings have been able to work out after decades of study. And so on.

Psychological Influences

Now I want to discuss a new field that is just opening up and which is very hard to describe. Let me attempt it by outlining some recent experiments. Professor Curt P. Richter, of Johns Hopkins Medical School, in a paper presented recently before a memorial seminar in honor of the late Professor Walter Cannon, begins his paper with the following statement:

> "'Voodoo Death'—that is the title of a paper published in 1942 by Walter Cannon. It contains many instances of mysterious, sudden, apparently psychogenic death, from all parts of the world. A Brazilian Indian condemned and sentenced by a so-called 'Medicine man,' is helpless against his own emotional response to this pronouncement—and dies within hours. In Africa a young Negro unknowingly eats the inviolably banned wild hen. On discovery of his 'crime' he trembles, is overcome by fear, and dies in 24 hours. In New Zealand a Maori woman eats fruit that she only later learns has come from a tabooed place. Her chief has been profaned. By noon of the next day she is dead. In Australia a witch doctor points a bone at a man. Believing that nothing can save him, the man rapidly sinks in spirits and dies.
>
> "Cannon made a thorough search of reports from many primitive societies before he convinced himself of the existence of voodoo deaths."

Professor Cannon then asked himself the question: "How can an ominous and persistent state of fear end the life of man?" Having accepted then the possibility of "Voodoo Death", Professor Richter proceeded to set up experiments trying to place limiting values on this preconception. His experiments in my opinion are fundamental. He found, for example, if he trapped rats, wild rats, in a sort of leather bag which provided ample air for their living purposes but kept them trapped, they struggled for awhile, then apparently gave up the struggle and died. Why did they die? Not for lack of air, not for lack of stored chemical energy in their muscles. What physiological and psychological processes were involved? If one repeats the experiment, only this time after the animal has made a struggle he is temporarily liberated, and then trapped again, this second time the struggle goes on to complete exhaustion, a much longer struggle than the initial one. The crux of the experiment apparently is that if the rat has reason to believe, by virtue of a single experience, that the situation is not hopeless, he makes a struggle far beyond what he would make and lives much longer than he would ordinarily do under the same conditions. The implications of this kind of study for the world in which we live which is one dominated by fear, must be obvious.

Science and technology lead to engineering and large-scale production with tremendous implications on our social organization. Eventually this calls for social judgments. No better illustration of this can be given than the question of radioactive fallout which is a difficult problem before the world today.

We recognize in radio and television marvelous instruments for the education of young and old. Not long ago I heard a fine interview with Mr. de Valera of the Irish Republic. Another time we were given an opportunity to review by way of television some of the life of Mahatma Gandhi. On the other hand, we also know the abuses which take place through the same medium of communication. We are led to believe that certain drugs will take care of us when we are ill, through the most false kind of presentation. These call for social judgments. Where will we develop these social judgments? In science? No. Science is not interested and cannot be interested in social judgments. These are value judgments. Where will you find a finer dramatization of the age-old problem of how to do justice without doing an injustice than in Shakespeare's Hamlet. What kind of foreign policy should we have? Perhaps we should listen to Immanuel Kant making his plea to act, to act, to act, so that our actions may become the standards of conduct. When we are being placed as educators under pressures to teach the law of the thing in terms of the physical sciences to the neglect of the social sciences and the humanities, shall we listen to Emerson when he warned us:

There are two laws discrete,
Not reconciled, —
Law for man, and law for thing;
The last builds town and fleet,
But it runs wild,
And doth the man unking.

When we are under pressure by the crowd to think and work with the crowd rather than to maintain our independence in our thinking, should we listen to Emerson:

> "It is easy in the midst of the crowd to be true to the crowd's opinion; it is easy in the solitude to be true to one's own, but the great man is he who in the midst of a crowd keeps the independence of the solitude."

What to do about it? It is obvious that technology will play an ever-increasing part in our culture. The teaching profession will be given heavy responsibilities for preparing our young people to play their part in this world of change. Young people having talents in the field of mathematics must be given the opportunity to grow in this field. They must also be given the opportunity to become aware of the increasing importance of mathematics to physical and biological science. At the same time the door must not be closed to young people having a "blind spot" for mathematics. History shows many examples of great creative research work in the field of the physical sciences by those who are not highly trained in the field of mathematics. There is much research to be carried on in fields that are not yet quantitative as I have tried to show.

For the teacher it means better preparation and this means the opportunity for advanced study. Our universities must re-examine their requirements for the master's degree for teachers who have only two years' preparation in given subject matter fields. A comradeship which has been broken during the past decade or so, that existed between the university teacher and the high school teacher must be re-established. For the citizen it means that our teachers must be paid yearly salaries commensurate with the responsibilities that they carry. The prestige of the teacher must be such that the profession will attract young people from all economic sectors of our society. Perhaps in concluding I should paraphrase George Eliot by saying: "Let us not be pessimists, because educators have done a magnificent job in educating our young people to work within the framework of democracy: let us not be optimists, because optimism can dull our sense of what is critical and what is significant in a changing world and lead us into a chronic state of mediocrity. Let us rather be ameliorists, that is, if things in education are not as they should be all of us will lend our hands, our heads, and our hearts to making them so."

The prestige of the teacher must be such that the profession will attract young people from all economic sectors of our society.

DISCUSSION

of Technical Papers and Other Articles

ECONOMICS OF PUMPED STORAGE

C. Jaeger, *The English Electric Company Limited, England*

The Engineering Journal, 1958, June, p. 67

(This discussion refers to the full paper, as presented at the Annual Meeting and published in Water Power *(London) June, July, Aug. 1958)*

F. L. Lawton,* M.E.I.C.

The Institute is particularly fortunate in having Dr. Jaeger's most realistic treatment of a subject which is usually wrapped in a mass of complexities — more bluntly, a long series of "ifs", "ands" and "buts". This realistic treatment has long been needed.

The author's down-to-earth treatment arises only partly, although very significantly it is suggested, from the question he posed, after referring to the use of computing machines, when he said "The 'answer' given by such a calculating machine depends on which parameters have been fed into the computor and how they have been fed into it. Is not some simple basic thinking possible relying on more elementary mathematical analysis"?

The other element, complementary to the foregoing, is that basic thinking which is so characteristic of European engineering practice, arising from the relatively low cost of engineering man-hours and the relatively high cost of materials. The reverse is, of course, true in North America.

Computing machines can relieve the burden of tedious computations but cannot do any thinking. Reliance on computers will, no doubt, constitute a hidden potential hazard which engineers will need to guard against carefully in the future.

Although largely based on nuclear generation in conjunction with pumped storage, the author's treatment is equally relevant to thermal and hydro generation.

It may be of interest to note that pumped storage appears to be receiving close attention for the hydro-thermal Japanese power systems where normal storage reservoirs are not easily developed on account of geological and land-use problems.

With reference to Table II the terminology is a bit obscure. It is presumed the author is referring to two circuits of overhead transmission in columns two and three, and to two circuits of overhead transmission in column four, the only difference in column four being that multiple or bundle conductors are used.

*(1) Chief Engineer, Power Department, Aluminium Laboratories Limited, Montreal.

I. W. McCaig,† M.E.I.C.

Dr. Jaeger's analytical study of the economics of pump storage has, I am sure, got many of us trying to remember these complicated integrals which we had in our mathematics course at school. Dr. Jaeger manipulates them with great skill and brings out several important points which would not have been obvious without his mathematical analysis. He first shows how pump storage can aid the economic production of energy by nuclear and thermal stations and then indicates how, even in a system where all the energy is generated by hydro-electric developments, pump storage can be utilized for storing excess energy from run-of-river plants and for increasing the capacity of long transmission lines and cables.

Before coming to Canada, I had the pleasure of being associated with some of the economic studies for the Sron Mor pump storage unit, the first in Britain, which formed part of the larger Shira hydro-electric scheme. At that time, it was difficult, with the assumed difference between on peak and off peak power costs, to justify the installation of a pump unit in this mixed hydro-electric and pumped storage scheme. However, it is interesting to note, in retrospect, that even before the Sron Mor plant was completed plans had gone ahead and construction had started in Britain on the 300,000-kilowatt Ffestiniog pump storage scheme.

With hydro-electric sites in Canada becoming scarcer and further from load centres, the mixed storage scheme now being completed at Niagara Falls may well be the forerunner of a number of pump storage schemes designed to cater for peak loads at industrial centres.

†Hydraulic Engineer, H. G. Acres & Company Limited, Niagara Falls, Ont.

T. J. Hobson,§ M.E.I.C.

With reference to part III of the paper, sections 3 and 4, all cases taken assume that $t_1=t_2$.

This means that over the entire period of any cycle of operations, the pumped storage station is in use as either a pump or a generator.

For the simplified and theoretical condition that the base load station operates with unity load factor, this is necessarily true. However, for the more general case in which $\theta_B<1$, it is not necessary although it does give the most efficient operating results.

Does the author think that this condition can ever be achieved in actual practice?

Would the author care to discuss the effects on his calculations of a substantial period of time during which the pumped storage station is neither pumping nor generating, such as might occur on a weekly cycle with nearly all the pumping done over the weekend, and the generating limited to a few hours daily?

W. G. Lockett,‡ M.E.I.C.

Among the most important factors which have to be considered in the study of pumped storage projects are the increase of the load and the

§British Newfoundland Corporation Ltd., Montreal.

‡Niagara Falls, Ont.

possible variation of load factor which will take place during the life of the scheme. As the author has demonstrated, it is possible, for a given load-duration curve, to arrive at optimum relative values for the installed generating capacity, pumping capacity, and energy storage. However, when absolute values for these quantities are considered, it is clear that the figures will "fit" the load curve only once as it increases with time.

Now in practice, while it will be possible to increase the generating and pumping capacity of a scheme by the progressive extension of the power station (unit by unit or stage by stage), it will not usually be practical to increase the storage capacity in a similar manner. It is suggested that the tendency will be to provide in the initial stage of a development the maximum storage capacity consistent with site conditions. This will allow for flexibility of operation and provide to some extent for errors in the long-term prediction of the energy demand and load factor. In effect, over the years the pumped storage scheme would probably be called upon to operate at widely varying load factors. In the study of such problems the author's equations should be particularly useful, as they would enable a multiplicity of different conditions to be studied without much difficulty.

It is tempting to speculate on the position pumped storage is likely to occupy in Eastern Canada, where there is a forseeable limit to the development of conventional hydro resources. The author hints at this problem when he states in section IV of the paper: "Where gravity water storage and pumped storage are being compared, marginal prices for a pumped storage will have to be compared with the cost of an enlarged hydro-power station." We have to assume that the base load will be taken by thermal and nuclear power plant of ever increasing capacity. Hydro stations, existing and projected, will tend to move progressively up the load curve, where it will be found that, while their energy output may for a time be adequate, there will be a constant demand for more and more kilowatts. Later on the energy output of the peak load hydro schemes will not be sufficient and pumped storage on a large scale will be required. The important point is that all this will occur during the useful life of schemes at present on the drawing board or in the report stage. Would the author agree with the conclusion that from now on every hydro project with adequate pondage and a relatively short development should be regarded as a potential peak load scheme? This would entail careful consideration of future additional intake works, tunnels, and the extension of the power station itself. The possibility of having to provide a tail pond for a later pumping installation would also have to be borne in mind.

In conclusion, I should like to ask the author for his comments on the subject of differential tariffs. Suppose C_1 represents the capital required to subsidize a vigorous policy of differential tariffs, and C_2 the cost of the additional pumped storage scheme necessary to arrive at a certain overall operating characteristic. Is it not possible that $C_1 + C_2$ will be less than the cost of the larger pumped storage scheme required to produce by itself the same characteristic?

The Author

The author is much indebted to Mr. F. L. Lawton for the backing he gives to his efforts to analyse the complexities of the economics of pumped storage. His interpretation of Table II is correct. The problem of high voltage long distance transmission in connection with pumped storage becomes so important that the author has started an enquiry in order to get more reliable figures and facts.

The remarks by Mr. I. W. McCaig concerning the economics of the Sron Mor pump storage unit are pertinent. There is no better proof that pumped storage is economical than the efforts made by large power distributors all over the world to develop more pumped storage capacity as soon as they have started their first scheme.

Mr. T. J. Hobson raises an important question which has to be answered in two parts. He notes that Figures 17 and 18 are drawn assuming the pumped storage station to be always in use as either a pump or a generator. Can this condition ever be achieved in actual practice and how does it affect the author's calculations if this is not the case?

(a) Fig. 20 and the equation

$$\Delta N = \left(\frac{dN}{dt}\right)_{t_1} . \Delta t$$

solve the problem for a "time lag Δ t", and Fig. 19, 20, 21 give a method for estimating the loss in capacity ΔN and energy ΔE caused by the time lag. If this time lag is long, a direct calculation will replace the simplified equation for ΔN.

(b) It is most probable that, when a pumped storage station is equipped with reversible pump-turbines with variable pitch, full use of their versatility will be made and the daily load diagram will tend to reduce the time lag to a minimum.

If the pumps have no movable blades, then they will always absorb a constant power and cannot be adapted to the variations of the demand. Longer time gaps will be inevitable, which means loss of power energy and revenue, and more work for those other stations which inevitably will have to be equipped with variable pitch runners for correctly balancing power production and demand.

(c) Mixed pumped storage stations superimposed on conventional hydropower stations could work more efficiently for longer hours than pure pumped storage stations, which usually are designed for short hours and high installed capacity.

Mr. W. G. Lockett's first remark raises one of the most important points of the discussion and the author's answer to it is: "Definitely yes!

Every hydro project with adequate pondage and a relatively short development should be regarded as a potential peak load scheme. This would entail careful consideration of future additional intake works, tunnels, and the extension of the power station itself. The possibility of having to provide a tail pond for a later pumping installation would also have to be borne in mind."

In a previous article (*Water Power*, February/March, 1957) the author has discussed some implications of this change of attitude with regard to high-head or medium-head schemes. Another typical example concerning the extension of schemes with heads of 200 to 400 feet was shown during the presentation of the paper in Quebec, where it was also pointed out that the availability of a tail pond or downstream reservoir was one of the main points to be investigated.

A look at diagram Fig. 27 representing a yearly power duration curve may illustrate some further points directly connected with Mr. Lockett's question. Suppose a low-head power plant with little (daily) storage has been developed for a power N_w, corresponding to the discharge not available on the river for t_0^* days and available for $(365—t_0^*)$ days. If this power is increased by ΔN_w (measured on the duration curve and supposed to be available all the day long), this additional power would be available only $(365—t_0^*)$ days (possibly 120-170 days) and produce about ΔN_w

$(365—t_0^*)$ x 24 kwh. of intermittent base load energy of little value.

Suppose now that pump/turbines are installed on the same existing plant with an installed capacity $\Delta N'$. If θ_g is the "generating load factor" of this plant we can write that $\Delta N' = \frac{\Delta N}{\theta_g}$ (θ_g may be 3-5 hours a day). This additional installed capacity could work during $(365—t_0^*)$ days as peak load plant, using a limited daily reservoir capacity. During t_0^* days a year the plant would work as a day and night generating and pumping station. Instead of a capacity ΔN available only over a short period of the year for producing intermittent base load, a substantially larger capacity $\Delta N'$ would be available all the year round for peak load.

This leads to Mr. Lockett's second question. Differential tariffs are used directly or in a more concealed manner by most producers of electrical energy. They are favoured by energy producers using systems mainly fed by water power (as are some such systems on the continent of Europe) rather than by producers of thermal energy. They will most probably become still more favoured in the future and industries will have to adapt themselves—to some extent—to differential tariffs. Forecasts are difficult to make, as new inventions may reverse the trend (for instance, in some large towns, air conditioning has already shifted the peak load period).

Mr. Lockett foresees that hydro stations will tend to move progressively up the load curve. This is probably true in general. But there are also some potential hydro power sources—still available in Canada in the Far North (east and west) — which probably will be developed as base load because of the long transmission lines.

The general analytical approach to problems of power production introduced by the author can be further developed. A very promising extension of the method considers "differential" prices and costs as caused by changes in the load N, the efficiencies η, the load factor θ and so on, and a comparison of alternative solutions.

FINAL REMARKS

A final remark concerns the author's firm belief that more run-of-river stations, when built in continuous series on the same river, should be equipped with reversible pump-turbines. A modern run-of-river station will usually be designed for a discharge slightly in excess of the yearly average flow (usually the flow occurring (365—250)=115 days on the duration curve or something like this). During the dry season the station can neither face the demand for energy nor for capacity.

Now suppose some of the runners or even some additional runners were reversible pump-turbines. Then, whatever the duration and severity of the dry period, capacity would be available for peak load; this is a definite improvement on a station designed merely as a run-of-river station, unable to guarantee any peak load.

During the flood period, the additional reversible runners would be used as turbines, with no need for pumping.

In many cases this additional peak capacity will be reasonably cheap compared with alternative solutions. The technique of "over-equipped" run-of-river stations may be a sound policy if reversible runners are used and a reasonable storage capacity is available upstream and downstream of the station.

THE INTERNATIONAL GEOPHYSICAL YEAR

D. C. Rose, M.E.I.C. *National Research Council, Ottawa, Ont.*

The Engineering Journal, 1958, August, p. 45

D. A. G. Waldock,* M.E.I.C.

Dr. Rose is to be complimented on his comprehensive and interesting paper. I am sure that it must be a source of considerable pride to all of us and a pleasant surprise to many of us to learn what a relatively large and varied contribution Canada is making to the International Geophysical year. Since we are privileged to possess a large share of the earth's surface extending from one pole more than halfway to the equator, it surely behoves us to take an appreciable interest in the study of its physics.

In listening to Dr. Rose's paper, two questions arose in my mind. When one hears about the various phases of the International Geophysical Year program and the enormous amount of valuable scientific information that is being gathered over a wide variety of disciplines, when one thinks of the numerous applications to which this information will be put, when one realises the extent of the international co-operation and good-will which this program is stimulating, one cannot help but wonder as the year moves along — what happens at the end of I.G.Y.? Does it just peter out to be revived again in another 25 years' time? Is consideration being given to prolonging these international studies on a continuing but less intense basis? Perhaps Dr. Rose could enlighten us on what is likely to happen at the end of this year. With the rapidly increasing strides of modern technology and the more widely awakened interest in scientific research throughout the world, surely there must be a strong drive to perpetuate the international programs that have been launched as a result of I.G.Y.

The second point that occurs to me concerns the reduction, correlation and interpretation of the vast amount of data that is being collected during I.G.Y. We have been given some idea of the amount of effort that is being devoted to collecting this data, but this must be only a fraction of the effort that is going to be required to assimilate it. Perhaps our capacity to digest this data will itself limit the extent of future international geophysical programs. Would Dr. Rose care to comment on the arrangements for handling all the data that will be forthcoming from the various I.G.Y. programs?

*Chief Superintendent, Canadian Armament Research & Development Establishment, Quebec, Que.

The Author

In regard to the first question about the continuation of measurements after the end of 1958, a great deal of thought is being put on what should be done. Proposals for continuing observations in some disciplines have already been circulated. Considerable care is necessary in agreeing to these because the ultimate desired objective is the use of the data to learn more about the nature of the earth and its surroundings. We do not want the analysis and digestion of data hampered by enthusiasm to continue taking measurements that will only be put on the shelf. During the I.G.Y. period so much time is being given by scientists in just getting data that it would be quite impractical to continue at the present scale. On the other hand, without doubt, some of the observations will be continued, for instance, some of the stations on Antarctica. Decisions in this regard will be discussed at coming International meetings but probably the various scientific groups will decide themselves how they can best meet the research objective.

(continued on page 146)

ABSTRACTS

MONORAIL TRANSPORTATION

The Consulting Engineer, March, 1958.

A PROPOSED MONORAIL between the centre of London and London Airport is under consideration by the Ministry of Transport and Civil Aviation. The cost per mile is estimated at some £280,000 for a double track system complete with rolling equipment. Over 3 million passengers passed through London Airport in 1956. By 1970 it is estimated during busy periods the airport may be handling 4,700 passengers per hour with an occasional peak of 6,000/hr.

The London to Heath Row airrail would consist of highspeed pneumatic-tired coaches running on elevated concrete beams. Coaches would also be equipped with road wheels for handling at the terminal direct to the air-craft. Time of journey would be about 15 minutes. The cost will be much less than that of any other of the various systems so far suggested.

NO ABSTRACTING AGENCY NECESSARY

Chemical & Engineering News, May 19, 1958.

PROPOSALS TO SET UP a monster central government agency in the U.S. for abstracting and indexing scientific literature seem about dead. It would be extremely costly, unwieldy and impractical. Abstracting and indexing should remain in the hands of scientific societies now sponsoring it, according to E. J. Crane, Director of Chemical Extracts Service. The government role should be to catalyze the work now going on.

OPENING THE RUSSIAN ARCTIC

Canadian Aviation, May 1958, p. 30.

TODAY THE U.S.S.R. ranks with leaders in the successful use of aircraft under arctic conditions. Russia's reputation as a leading arctic air power rests mainly on use of aircraft for solving scientific and economic problems of the soviet arctic. Aviaartica, basically a cargo airline, is probably the world's largest. Emphasis on ice concentration data is explained by the Soviet Union's desire to increase the length of the navigational year by making it possible for vessels to operate even through severe ice conditions.

Development of airport equipment to meet Arctic flying conditions is also reported. Considerable success has been achieved with new methods of speed braking on touchdown. Ice free runways are established by electric circuits underneath long concrete runways at main arctic bases of Russia's strategic air command. The chances are Russia will exert even greater effort in the next quarter century to establish itself as the world leader in arctic aviation.

PHILIPPINES ENGINEERING

Engineering Times, v. 1 n. 1, April 1958

THE FIRST ISSUE of *Engineering Times* (Manila) appeared in April 1958. This newcomer to the field of engineering publications aims to serve as an intermediary between the growing Philippine engineering profession and the general public. There is considerable engineering development in the Philippines, and one of the most controversial subjects is the Marikina Multi-Purpose Project, which is dealt with in an editorial and the first of a series of articles.

The project was authorized to regulate and store the flow of the Marikina River; to use the water for irrigation of agricultural lands and to increase the industrial and municipal water supply of Manila and its environs; and to generate and distribute electrical power. Initial plans for plant capacity of 180,000 kw. with a first stage of 120,000 kw. were amended to 90,000 kw. and 60,000 kw., respectively, and the distribution of costs between the various parts of the project was revised to make the scheme generally more attractive.

Because of difficulty in obtaining financial support from the United States, the project co-ordinating committee turned to Japanese reparations as a means of getting necessary finances, and a contract was concluded in September 1957 with an organization in Japan covering engineering consulting services, under the reparations agreement between the two countries.

Although these efforts to get the project started have generally been well received, strong protests against the employment of Japanese engineers have been made, particularly by the president and members of the board of directors of the Philippine Association of Civil Engineers. The chairman of the project committee has defended the legality and practicability of the Japanese contract, and pointed out that the proposed concrete arch type dam is new to indigenous engineering and justifies the use of foreign consultants.

Tunnelling Saskatoon's 14th Street Storm Sewer

(continued from page 77)

is from 3000 to 5000 dollars, depending on the availability of materials and machine shop service. The cost certainly is not excessive when distributed over a thousand feet or so of tunnel.

Acknowledgements

Mr. C. Fisher, of Armco Metal and Drainage Products Ltd., provided much helpful advice and assistance during tunnelling operations. The writers would also like to express appreciation to Mr. W. A. Friebel, City Engineer, Saskatoon and Mr. R. Peterson, Chief Soil Mechanics Engineer, P.F.R.A., for their help and encouragement in preparing this paper.

INTERNATIONAL NEWS

Development of Semiconductors in the U.S.S.R.

Academician A. F. Joffe

The modern history of semiconductors dates from Grondale's discovery of copper protoxide rectifiers of alternating current in 1927. The significance of this original physical phenomenon was correctly understood by Soviet physicists from the beginning. Up till World War II the study of semiconductors and their practical application proceeded at a rapid pace. Already its significance was understood not only for the transformation of alternating into continuous current but also for the conversion of luminous and thermal energy into electric current with the help of photoelectric cells and thermocouples. The war temporarily diverted Soviet physicists from the work on this problem.

Later semiconductors passed from electrotechnics to radiotechnics where they served to replace vacuum tubes. But their significance was not confined to this. They have promoted the rapid progress of automation, signalization and remote control; they protect high-voltage transmission lines against lightning discharges, save electric current in daylight lamps, and ensure the efficient work of the scores of thousands of elements in electronic computing machines. In radio apparatuses semiconductors substitute not only vacuum lamps but also other parts, reduce them to fractions of their original size and cut the consumption of electric energy.

Semiconductors have called forth new measuring techniques, new apparatuses and new potentialities. Soviet physicists are making good use of these potentialities in industry, agriculture and science.

Agricultural Applications

A series of semiconductor apparatuses has been developed for agricultural purposes to measure the temperature of the soil, the air and the plant itself, to determine the direction and intensity of light, and many other things. With their help it is possible to observe from one point all that takes place on a field.

Here is an example. An apparatus containing microscopic grains of a semiconductor makes it possible to follow the temperature and moisture at any point of a leaf or of the nearest layer of air. This led to the discovery of hitherto unknown physiological phenomena in the mechanism of evaporation and in the reactions of plants to light and warmth similar to the conditioned reflexes of animals and to other external influences.

Power Engineering

Another trend in the application of semiconductors is connected with the problems of power engineering. Soviet semiconductor thermocouples transform thermal energy into electric current with a heat efficiency which, although small as such, is neverthless sufficient for many practical purposes. For instance, the heat from the glass of a kerosene lamp supplies enough electric current to feed a large radio set, while with the help of a kerosene burner thermocouples can operate a small radio station. These apparatuses are demonstrated in the Soviet pavilion at the 1958 International Exhibition, in Brussels.

Thermocouples can produce electric current if there is a temperature difference in them. But they can be used in the reversed order: by passing electric current through them a drop in temperature may be obtained and the heat will pass from one side of the thermocouple to the other. In contrast to ordinary heating where warmth is carried from a warm medium to a colder one here a part of the heat can be carried from a cold source to a hotter one. Thus, in heating premises with electric current, with the application of thermocouples the building will receive only a part of the heat from the current, the rest will be transmitted by the thermocouple from the water supply or the outer air. In this case only 1/2-1/3 of the energy consumed by an ordinary electric stove will be spent.

Thermocouples are also used for producing cold. A home refrigerator will be demonstrated at the Exhibition which works without a compressor, ammonia or freon. A trap for vacuum pumps will be also exhibited. This trap, cooled by thermocouples, freezes oil or mercury vapours which under ordinary conditions decrease the vacuum when these liquids are used for pumping out air.

It was impossible to observe many fine physical phenomena due to the heat movement of molecules which interfere with the work of an apparatus under room temperatures. The thermocouple reduces the temperature in an apparatus by 50-60°C. and thus makes it possible to improve its work considerably (sometimes a hundred-fold).

Since the thermocouple, depending upon the direction of the electric current, either heats or cools, it can therefore keep the temperature of a medium at a constant level. The semiconductor thermostat demonstrated in the USSR Pavilion at the Brussels Exhibition markedly improves the quality of many radiotechnical apparatuses and other devices.

Soviet physicists gained all these practical results because they are keenly interested in the theory of semiconductors and strive to understand and study their properties. The development of the theory of semiconductors advanced simultaneously with the elaboration of the means of applying them in radio communications, industry, agriculture and transport.

Research

Many research institutes of the Academy of Sciences and the colleges are engaged in the theoretical study of semiconductors. Scores of industrial institutes conduct work on the application of semiconductors in radiotechnics, and these devices are already produced by a number of plants. Much literature has been published on the theory and practice of semiconductors.

In the U.S.S.R. many-sided work is being conducted with semiconductors. Not only the electric but also the thermal, mechanic, chemical, optical, and magnetic properties of semiconductors are studied. Semiconductors are used not only in radiotechnics and electrotechnics but also in power engineering, refrigeration, chemical catalysis, for different types of measurements, in agriculture, automation, illumination and signalization. The more widely they are applied the more promising is their future. Ever new possibilities present themselves and we are gaining deeper knowledge of the processes that occur in semiconductors.

UNITED KINGDOM

Giant Turbo-Generator

Believed to be the world's largest turbo-generator, a plant to be built in Newcastle-upon-Tyne, England, for the Central Electricity Generating Board, will be of 550 Mw. capacity. The manufacturers are C. A. Parsons and Company Ltd.

The plant will be a cross compound unit of two lines arranged in line ahead. Each line will have four turbines driving a 275 Mw. hydrogen and liquid-cooled generator. All eight turbines will be of the double flow type.

A single row velocity wheel will be used in the initial stage of both the high-pressure and the first intermediate-pressure turbines — each of these of double shell design; the rest of the blading is the reaction type.

The machine will operate with steam at an initial stop-valves pressure of 2,300 p.s.i. and a temperature of 1,050°F. Steam will be led to the turbine through two chests arranged one on each side of the high-pressure cylinder.

TRACKLESS CROSS-COUNTRY TRAIN. Most recent development in "rubber-tired trains" is this 52-wheel unit, of which a model has been built and operated to prove the advance design. Produced by R. G. LeTourneau, Inc., Longview, Texas, the train is intended for possible use of nuclear energy instead of conventional engines. The train features drive by electric motors to each of the 52 wheels and a unique steering arrangement which ensures that the last car of the train will follow in the tracks of the first, regardless of the number of cars. The train can thus be manoeuvred on a winding path through obstacles and can be reversed to travel with equal speed in either direction. The length of the train is about 450 feet, and the tires are 10 feet high by 4 feet wide. Gearing of the available 2000-odd horsepower will depend on operating conditions, but a probable compromise speed will be about 20 miles per hour.

Owing to the reheat system's large storage capacity, steam must be stopped from flowing into the turbine when sudden loss of load occurs: intercept and reheat emergency stop valves will therefore be incorporated in the reheat system. Valves which simultaneously release the steam to the atmosphere are an additional safeguard.

The turbine will have two governors — the main speed control governor, driven from the high-pressure turbine shaft, and an auxiliary governor driven from the first intermediate-pressure turbine shaft. There will be one governor mounted on a cross shaft driven through a worm and wheel on each line of turbines.

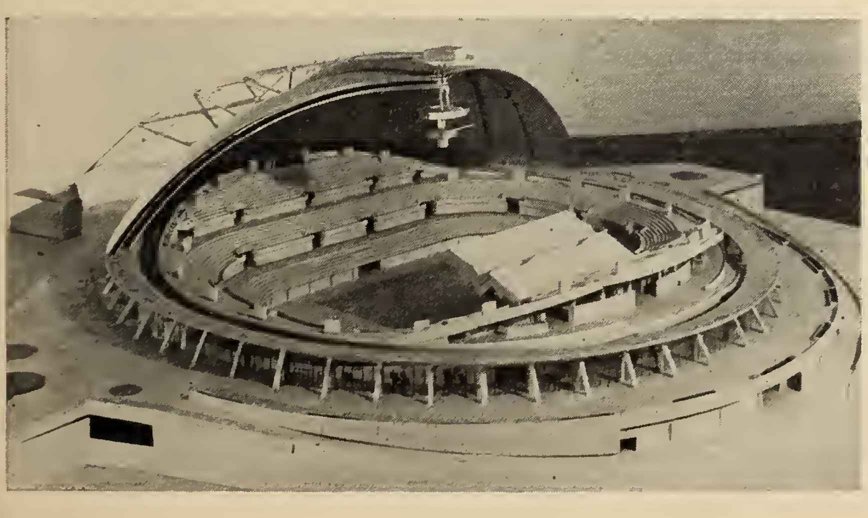
Steam can be extracted from the turbine at seven pressure points to heat the condensate returning to the boiler to a temperature of 486°F.

Motor-driven rolling gears will ensure uniform heating and cooling of the four turbine spindles and generator rotor on each line, when starting up or shutting down the machine, to avoid distortion due to unequal temperature distribution.

Steam from the turbine's eight exhausts will be dealt with by four condensers with a total cooling surface of 330,000 square feet. The generators will operate at 18,000 volts.

The rotors are to be of the direct gas-cooled type operating in hydrogen at a pressure of 45 pounds per square inch. Each stator will have a direct-cooled winding, using demineralized water as the cooling medium circulating through the conductors which are built up of hollow rectangular copper tubes.

MOVABLE DOME FOR PITTSBURGH CIVIC ARENA. The $20 million Pittsburgh Civic Arena is to have a retractable stainless steel dome roof, 415 feet in diameter. Six movable sections, three on each side, will roll over two fixed sections to open the arena to the sky. Structural steel for the dome will cost some $4 million, and a further $890,000 will be required for the mechanical seals and the stainless steel covering, which will be 20 and 22 gauge type 302 18/8 steel in a special dull finish. *(Stainless Steel News Bureau).*



Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

Construction Resumed on NPD

Construction has been resumed on NPD (Nuclear Power Demonstration), Canada's first atomic power station located close to Rolphton, Ontario and near Ontario Hydro's Des Joachims generating station on the Ottawa River, about 150 miles northwest of Ottawa.

The plant will produce 80,000 kilowatts of heat that will be used to generate 20,000 kilowatts of electricity, which will be fed into Ontario Hydro's power distribution system when NPD goes into operation in 1961. Atomic Energy of Canada Limited, Canadian General Electric Co. Ltd., and the Hydro Electric Power Commission of Ontario are collaborating on the construction of this project, undertaken in 1955.

The NPD station will not produce power at a cost competitive with that produced by coal-burning power plants. It will serve as a pilot plant for stations with outputs of 150,000 to 300,000 kilowatts of electricity. A.E.C.L. recently set up a Nuclear Power Plant Division in Toronto to produce a preliminary design for a 300,000-kilowatt atomic power station known as CANDU (Canadian Deuterium Uranium Reactor).

Work on the NPD site was stopped last year to allow important technological advances to be incorporated in the design of the station's reactor. The basic system pioneered at Chalk River — the use of natural uranium for fuel and heavy water for moderator — has not been altered in the redesign of the station, but a different type of vessel to contain the fuel and a new method of charging and discharging the fuel are to be used.

The original NPD reactor was to have a vertical steel pressure tank to contain the uranium rods and the heavy water moderator. The core of the new reactor will be a barrel-shaped, horizontal, aluminum tank about 13 feet long and about 15 feet across its greatest diameter. Through this tank run 132 aluminum tubes into which are inserted zirconium alloy pressure tubes that contain the fuel rods and the heavy water "coolant". The latter flows over the fuel rods, becomes heated, then travels to a heat exchanger or boiler where the heat is transferred to ordinary water to make steam. The steam is fed into a conventional steam turbine that drives an electricity generator. The heavy water is recirculated through the reactor to carry more heat to the heat exchanger.

The other major design change involves the method of inserting new fuel rods and removing used rods. In the original design, the rods were to be inserted and removed from the top of the reactor. In the new fuelling system there will be a remotely-operated fuelling machine at each end of the reactor vessel, thus permitting the loading and unloading of fuel rods from both ends. This arrangement will give a more even distribution of fresh and partially used fuel throughout the reactor and permit the most efficient use of the uranium. The fuelling operation will be carried out while the reactor is under full power.

Canadian Exhibit at Geneva

A model of the NPD will be featured at Canada's exhibit at the Second United Nations International Conference on the Peaceful Uses of Atomic Energy, Geneva, September 1 to 13, 1958.

Canada's exhibit covers the full range of atomic energy developments. Included are fifteen models of atomic power reactors, cancer treatment machines, a uranium mine mill, the Port Hope Refinery of Eldorado Mining and Refining Limited, the research and production reactors at Chalk River, and a beta ray spectrometer.

Campus Plan, University of Toronto

The Faculty of Applied Science and Engineering, University of Toronto

A Report on Growth in the Engineering Faculties in Canada

Eighth article of a series

The principal recent development related to new engineering courses or additional teaching facilities in the Faculty of Applied Science and Engineering is the procurement of a sub-critical reactor, primarily for graduate work. This installation was made during the early part of the year, but the reactor was officially inaugurated on June 19 by Premier Frost.

Though incapable of initiating a chain-reaction, the new reactor is otherwise similar to operating reactors. In addition, special electronic equipment is provided so that students can see actual operating conditions "simulated" and face problems that might arise in working with a full-scale reactor.

The new project marks the first entry of the Faculty of Applied Science and Engineering into the nuclear physics field, while the Department of Physics has already launched a concurrent program in nuclear physics.

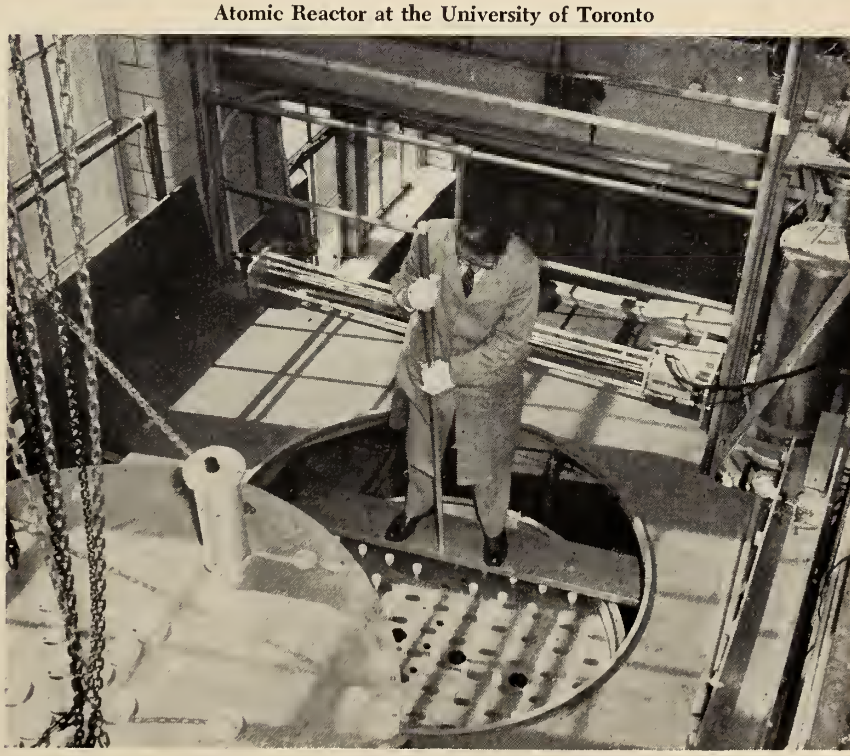
The whole equipment cost $439,000, with heavy water accounting for $200,000 of this sum. In addition, Eldorado Mining and Refining Limited have supplied on loan three tons of uranium worth $100,000, and a radium-beryllium neutron source was obtained from the Commercial Products Division of Atomic Energy of Canada Limited.

It was built by Canadair Limited and installed in the chemical engineering laboratory in the Wallberg Building, occupying two floors. This reactor is of the natural uranium, heavy water type, since it has so far been Canada's policy to build such reactors. It consists essentially of a cadmium-clad stainless steel tank five feet in diameter and six feet high, containing 820 gallons of heavy water, into which can be lowered natural uranium rods of one inch diameter, up to a total weight of three tons.

Dean R. R. Laughlin, expressed the general view of the faculty and described the general development of the curriculum, in an article in the "Varsity Graduate" of January, 1957, which is summarized very briefly here.

He traced the existence of the var-

Atomic Reactor at the University of Toronto



ious branches of engineering we know today to a diversification necessitated by the growth of the scientific basis of engineering. This system does not involve the student, for utilitarian purposes, in "greater detail concerning an ever-narrowing field" as it is sometimes supposed. Indeed, the purely informational courses have dwindled towards the irreducible minimum. The need for diversification, Dean McLaughlin wrote, lies in the growth of science itself, and the necessity in any true educational process of requiring the student to study some one discipline in depth". In this process he must "specialize", in one sense of that word, but it is the very mastering of one discipline that equips him to undertake a diversity of activity after graduation.

There has also developed an awareness that an engineer must be more than a technologist, and a resulting activity in providing courses in the engineering curricula designed to supply a broader, non-technical background for the young engineer.

Research and graduate work, which go together, are assuming a growing importance in the life of the faculty. "This is necessary," Dean McLaughlin wrote, "not only for the academic health of the faculty as a unit in the university, which is reason enough, but also because industry will need in increasing numbers young men educated beyond the bachelor's level".

Four academic sessions form the structure of the engineering course at University of Toronto with the three summer sessions being used by the student usually for application of the principles he is learning.

Dean McLaughlin reported that, with over 2,000 students, the school of engineering had "passed the region of satisfactory academic environment" for the students. It was clear that before increased facilities were available, enrolment would have to be restricted. And there was another question also: how far should the faculty be permitted to grow? Not indefinitely large, in the dean's opinion. Development has been evolutionary and it should continue to be so, even in the face of these problems.

The University has a plan for the "University of 1968", which was presented in 1957 by an Advisory Planning Committee, in anticipation of an increase in enrolment from 13,000 to 23,400 in 12 years. A unified campus, as illustrated, is the basis of the plan, with new land and buildings complementing old land and buildings. The plan offers a means of accommodating and teaching the increased number without loss of tone or academic performance. It uses 26 acres of new property west of St. George Street.

A priority schedule of new construction and alteration-rehabilitation projects exists. Under this schedule (which allows for successive stages of preliminary study, detailed design and actual construction) the faculty of applied science and engineering will be affected. New buildings are scheduled for 1959 and 1961, and rehabilitation of old buildings in 1960.

As a result there will be a large addition, virtually a new building, attached to the present Physics Building and facing on St. George Street. Working drawings for this building are now in preparation. Engineering will take over the present Physics Building (McLennan Laboratory) and the Chemistry end of the Wallberg Building (Physics and Chemistry will be housed in new buildings on the west campus). Civil and Electrical Engineering will move into the new

Engineering buildings, with new addition (centre), University of New Brunswick

building, and Mechanical Engineering will take over the present Civil and Electrical Building. Ultimately, the old engineering building will be torn down, but not until the expansion plans are nearly complete.

Increase in Engineering Enrolment University of New Brunswick

When Mr. McMahon Cregan was appointed to give the first lectures in civil engineering at a Canadian university in the winter of 1854, twenty-six students enrolled in the new course which was given in the Arts Building. Freshmen engineering students still receive some of their lectures in this venerable old building. In the 103 years that engineering instruction has been given at the University of New Brunswick, the size of the classes, the variety of special instruction, and the physical plant have grown steadily, if not spectacularly. Until the year 1949, a graduating class in engineering of 60 was huge. This year the university will graduate approximately 45 civil engineers, 20 electrical engineers and 20 mechanical engineers, additional space for engineering instruction. It was decided that the existing buildings must continue to be with the prediction of about a 15 per cent increase next year.

Expanded enrolment resulted in the conversion in 1944 of an old gymnasium building into quarters for the electrical engineering department. In 1947 an addition was made to the building which housed the civil and mechanical engineering departments. These two buildings contained the engineering departments until the fall of 1957 when a building linking the two was put into operation.

Limited funds were made available for capital expansion at the university by the government of the Province of New Brunswick. A new building to accommodate the Chemistry Department was planned and a portion of the amount was made available for utilized and that the most practical, if not the most desirable solution to the problem of increasing the facilities with the least cost would be to construct a building joining the two old buildings. This solution had the very attractive feature of collecting all the engineering departments under a common roof.

The final plan made allowance, considering future needs, for relatively easy expansion of the addition to the north-east where some additional available land exists. The possibility of a wholly new building was beyond the foreseeable future.

The floor area of the addition amounts to 45 per cent of the total provided by all three buildings. Lecture space in the addition is limited to rooms for the intermediate and senior civil and mechanical and the senior electrical students. These rooms are equipped with desks and draughting tables and are also used for calculation type laboratory periods and drawing exercises. The remainder of the addition consists of offices for the staff, laboratories, and space for the heating plant. A central heating plant is planned for the campus in the near future, and when it is connected and in operation, the new 100-hp. high pressure heavy oil fired boiler now used for heating will become available for other purposes.

The new building is of fire resistant construction and is protected from the

Draughting room in Engineering Building Addition

Mechanical Engineering Laboratory

old buildings, which have wood floors and framing, by a series of fire doors. General heating is provided by low pressure steam convectors and unit heaters. The draughting rooms were equipped with unit ventilators using hot water as the heating medium. The units were arranged so that they could at a future time be made to operate during the summer months with cooled water (from a source yet to be provided) giving a limited amount of cooled ventilation air.

The rear wall is of the curtain type with glass block fenestration. A steel frame with open web steel joist was used. Welded spandrel trusses between the floor and window sill were used to support the floor and exterior wall. The trusses were covered with corrugated asbestos lumber. Interior partitions were in general made of foamed slag concrete block.

A rather elaborate electrical distribution system was installed to supply power to the various laboratories. Cable trough systems extend to the various parts of the building with laboratories and individual machines being connected to the system at various points. Single and polyphase alternating current at various voltages and direct current at a variety of voltages is thus available in many parts of the building. Platforms were provided on the roof for use in antenna studies.

On the 26th of November, 1957, the Honourable Hugh John Flemming, Minister of Public Works and Premier of New Brunswick, officially opened the new building. Mr. C. M. Anson, president of the Engineering Institute of Canada, was guest speaker at a dinner held in the Lady Beaverbrook Building.

Courses leading to undergraduate degrees in civil, electrical and mechanical engineering are presently given. Three year preparatory courses in chemical and mining engineering are also given with plans to offer a degree course in chemical engineering and engineering physics in the near future. A complete revision to a five year course (four years after senior matriculation) took place in 1949, the first degrees being granted under this plan in 1952. A thorough study of curriculum in the three degree courses was made last year. Changes were made to concentrate the engineering science courses in the earlier years and to restrict the professional courses to the later years. Further revision of the program in the later years is expected in the near future as more staff become available and the intermediate and senior classes become too large in size to deal with in single groups. Preliminary study is being given to the establishment of degree courses in engineering physics and chemical engineering.

Graduate degrees in courses have been given for a number of years by the electrical department. Next year the first regular graduate students in course in the civil and mechanical departments are expected. Graduate work will be increased as more specially trained staff become available.

Acquisition of a variety of new equipment has been possible through the generosity of interested industries and individuals as well as through regular departmental funds. A grant of approximately $9,000.00 was received this year from the Associated Alumni. This grant will also be used for new equipment. The major addition to civil engineering equipment will be a 300,000-pound Young testing machine. The electrical department has recently acquired an analogue computer and four channel oscilligraph, an elaborate model power transmission system with simulated lines and loads, complete protective relaying and three generators have been constructed by the department. A high quality Collins communication receiver is to be delivered during the summer. Recent additions to the equipment of the mechanical department include a Terry steam turbine, an Orenda engine from the R.C.A.F., and a Rover gas turbine which is expected in the near future. All departments expect to continue work during the coming summer holidays on the completion of laboratory arrangements.

Three new staff members in each of the civil and electrical departments are expected in the fall of 1958. Each of these departments will then have nine while the mechanical department which obtained an additional man in 1957 will continue with a staff of five. In addition, the civil and electrical departments each have one technician and the mechanical department has two.

Present undergraduate enrolment indicates that the major increases in number of students will come in the electrical department. The other departments expect smaller steady increases. A policy of accepting students who have engineering diplomas from other universities, into the fourth year of the civil and mechanical courses was adopted three years ago and is expected to be continued. This policy has resulted in unpredictable sizes of classes. Present indications point to the need for additional space in about five years, or at the time a degree course is offered in chemical engineering.

St. Lawrence Seaway and Power Project

At the end of June 1958, progress on completion of all structures of the power and navigation projects had reached a stage to permit the raising of water in the headpond, on July 1, as originally scheduled at the start of construction in 1954. During the month, employment by Ontario Hydro averaged 2,625 persons, while employment by the New York State Power Authority averaged 3,160 persons.

Progress by Ontario Hydro

With percentage completion to date for the structure at 93 per cent, mechanical equipment 70 per cent, and electrical equipment 55 per cent, on the Canadian half of the international power-house as of the end of June, concrete placing was completed except for the deck of the last three units, 3 transformer bank pockets, parapet walls and deck surfaces. Seven turbine runners had been installed. Four generators were ready for test operation with necessary controls, transformers and power lines. Headgates were all in service. The gap in the downstream cofferdam was of adequate size to discharge tailrace water.

Progress by NYSPA

With percentage completion to date for the structure at 90 per cent, and mechanical equipment and electrical equipment each 90 per cent on the American half of the international power-house by end of June, 99 per cent of the concrete had been placed, including all major placements in the intake, ice sluices and in units 23 to 32 inclusive. General erection on four units was completed and four main transformers were being erected on the power-house deck.

On the Long Sault dam, Stage III concrete placement had been completed with 648,600 cubic yards in place. Fixed gate hoists were being installed and steel for the north guardhouse had been erected. Painting of metalwork and equipment, and electrical and mechanical equipment erection was in progress.

Flooding Sequence

At 4 a.m. on June 30 shipping was cut off between Cornwall and Prescott, Ontario on existing 14-ft. draft canals. At midnight stoplogs were placed in the closure structure after the last downbound vessel had cleared. At 4 a.m. July 1, gates of the Iroquois dam were opened to pass 310,000 cubic ft. per second, while at 6 a.m. the tunnel ports of Long Sault dam were progressively closed.

At 8 a.m. on July 1 cofferdam A-1 above the Long Sault rapids between Sheik and Barnhart Islands was blasted with some 35 tons of explosives, releasing a 30 ft. wave of water which over a three day period would slowly inundate 38,000 acres of land, creating an international lake 35 miles long and five miles wide at its widest point. At 9 a.m. the cofferdam at Ogden Island near Waddington, N.Y. was breached.

With filling of the pool completed July 4, power production was commenced, with two units on the Canadian side, while navigation was resumed on July 5. For the balance of the 1958 navigation season vessels will travel through the old Soulanges canal but will be diverted through the Long Sault canal and the two locks on the American side, and through the new Iroquois Lock.

Progress by SLSA

At the St. Lambert lock all concrete was placed at the end of June, all mitre gates installed and four fenders in place and machinery for all gates delivered. At the Cote St. Catherine lock all concrete was placed except for the grouting of the gate gains in the regulating spillway. Erection of the gates was proceeding.

At the Lower Beauharnois lock all concrete was placed for the lock structure and placing was being continued on the upper and lower entrance walls. Installation of lock gate machinery continued. On the upper Beauharnois lock, placing of concrete was underway for the north and south walls at the upstream entrance and on the lower entrance wall.

On overland portions of the channel above Caughnawaga, portions as completed were being allowed to fill to river level from drainage, with all sections expected to be completed by September. Dredging in Lakes St. Louis and St. Francis was reported to be on schedule though some of it will carry over into 1959. Dredging of the south Cornwall channel to 14 ft. depth was completed. In the north Cornwall channel, dredging to 14 ft. depth was not yet finished but this was not yet necessary for navigation. Dredging continued on the Welland at Port Colborne, Port Weller and Thorold.

Bridges: Awards of contracts are pending on piers for the Nun's Island Bridge across Nun's Island, and for the superstructure across the Seaway channel on the piers poured last year at the south shore.

The final 'jacking' operation on the Jacques Cartier bridge was completed on July 2. For all practical purposes the lifting of the southern end and installation of the new span over the seaway channel had been completed.

On the Victoria bridge work continued on the highway spans across the seaway channel. Four bridge piers had been completed to carry the upstream railway line diversion.

At the Honore Mercier bridge, new spans at the south end of the bridge on the route eastward to Laprairie were completed including the approach embankment at the east end. Seven steel spans were also in place for the northbound lane from Malone.

The new double-track CPR-NYC bridge over the seaway channel was in service.

On the high-level highway bridge at Cornwall, with steel in place for both approaches, decks were being poured. Tower frames for the main suspension span were erected and guide wires strung, soon to be followed by the catwalk, then the spinning of cables.

Report of Tolls Committee

The St. Lawrence Seaway Authority and the St. Lawrence Seaway Development Corporation, in a simultaneous announcement on June 18, made public the proposed tolls which may form the basis of the recommendation to their respective governments to meet the requirements of the legislation of each country.

The main features of the proposed toll structure are as follows:

For each passage through the entire seaway—Montreal to Lake Erie; a vessel will be assessed 6 cents per gross registered ton of the vessel; and, in addition, 42 cents per ton of bulk cargo and 95 cents per ton of general cargo carried.

For each passage—Montreal to or from Lake Ontario only; a vessel will be assessed 4 cents per gross registered ton of the vessel; and, in addition, 40 cents per ton of bulk cargo and 90 cents per ton of general cargo carried.

For partial transit of the new seaway facilities—between Montreal and Lake Ontario—where there are seven locks, the user will be charged 15 per cent of the applicable toll for each lock transited.

For each passage through the Welland canal only; a vessel will be assessed 2 cents per gross registered ton of the vessel; and, in addition, 2 cents per ton of bulk cargo and 5 cents per ton of general cargo carried. In the Welland canal, a partial transit will be assessed 50 per cent of the toll, irrespective of the number of locks used.

Commercial vessels carrying passengers will be charged 50 cents per passenger for each lock transited between Montreal and Lake Erie, in addition to the vessel charge.

The charging of tolls on the Welland canal in order to defray the capital cost of deepening as well as operating and maintenance expenses is a requirement of the St. Lawrence Seaway Authority Act, passed by Parliament in 1951. The Act pertains to a deep waterway between the port of Montreal and Lake Erie.

The suggested tolls should be sufficient to meet all financial requirements as the anticipated traffic develops. It is believed by the members of the tolls committees that the revenue derived will provide for the annual cost of operation and maintenance of the new seaway facilities and of the Welland canal; meet interest charges and amortize borrowed moneys over the next fifty years. They have estimated that in the first year of operation the traffic through the new portion of the seaway would approximate 25 million cargo tons, rising gradually to 50 million tons by 1968. The latter figure has been used for the forty years after the development period, since this is considered to be the workable capacity of the facilities presently existing and under construction between Montreal and Lake Erie. For the Welland canal, the Canadian committee estimates the tonnage of cargo at 40 million in 1959, with a gradual annual increase to 60 million tons in 1968.

The traffic estimates of the committees anticipate a development period extending to 1968, that is, a period of ten years during which there may not be sufficient revenue to meet the annual financial requirements. However, with the proposed tolls and the level of traffic which is anticipated beginning with the year 1968, they say that the annual revenues will be sufficient to compensate for the deficiencies incurred during the development period, and that all other financial requirements will be taken care of within the period of fifty years.

A simple method of toll collection is proposed, based on the necessity of non-interference with prompt passage by any user. Toll collection and invoicing of accounts, as well as the preparation of statistical data, will be assigned to SLSA. SLSDC has agreed to participate and share in the annual cost of these services.

SLSDC will hold public hearings at Washington on August 6, 1958, at which interested parties may express their views on the proposed charges. The SLSA, as a matter of policy, will hold public hearings at Ottawa, commencing the same day.

Canadian Pipeline Projects

Alberta Gas Trunk Line

Contract for 18¾ miles of laterals of 8 inch and 6 inch diameter from Sibbald, Atlee-Buffalo Princess and Steveville fields has been awarded to Preston-Clarke Ltd. The general contract for measuring stations was awarded to Mannix Ltd. Completion date for laterals is August 15. Mannix Ltd. was also awarded a contract for a 20-mile gathering system in Pincher Creek field by B.A. Oil Company.

Work on the main line extension and the Pincher Creek lateral was proceeding rapidly at mid-June, on a contract awarded to Piggott Construction Co. Completion is scheduled for the end of July.

Gas from the Cessford field is scheduled for delivery to Trans-Canada in the fall. Initial capacity of the gas refrigeration plant will be about 125 million c.f.d. though initial output will be about 90 million c.f.d. The plant will also provide some 250 barrels daily of stabilized gasoline. It will cost about $3.5 million. $3 million has already been spent on exploration and development.

Trans-Canada Pipelines

Contracts for installing the first six main line compressor stations were awarded early in June.

Trans-Canada announced on July 5, it will purchase the northern Ontario Pipeline Crown Corporation's main pipeline now under construction between Lakehead and Kapuskasing, Ontario.

Northern Ontario Natural — Twin City Gas

More than $3 million will be invested in welded steel pipes and valves to build gas distribution systems in 34 Northern Ontario communities this summer.

Export of Services

The exporting of Canadian engineering services is discussed in the May 10, 1958 issue of *Foreign Trade** by R. A. Frigon, M.E.I.C. Mr. Frigon listed the opportunities and the benefits, the problems, and some of the solutions already found by Canadian firms already practising in foreign markets. Some of the problems and their solutions are as follows:—

Prospecting for work: knowledge of foreign local conditions; travel, for the personal approach; contact with government services, such as the International Bank, International Finance Corporation, United Nations.

Development of a contract: travel for this purpose; appointment of an agent, or partnership with local firms; knowledge of local business practices, and personnel supply.

Financing: contact with Export Credits Insurance Corporation, a Canadian government agency; contact with initiators of foreign projects.

Execution of the Work: adaptation to foreign environment, as regards personnel, taxes, climate, geology; partnership with foreign firm for this purpose.

A characteristic of Canadian technology has been experience in pioneer development in time of rapid economic and social expansion. Engineering firms may find in foreign markets a solution to the ups and downs in domestic demand, challenge, and an opportunity to give technological assistance to countries in need of it.

Some of the instances mentioned in the report were: frequency conversion work on a Panama Canal lock, by Canadian Comstock Limited, through a foreign operations company; nine years of operations in half a dozen foreign countries, largely in pulp and paper mill development, by Stadler Hurter and Company, consulting engineers; work in Pakistan under the Colombo Plan, by Photographic Survey Corp. Ltd.; aerial mapping in Kenya by Spartan Air Services Ltd.; aerial surveys in the far east by Canadian Aero Service Ltd.; building of a newsprint and specialty paper mill at Khulna, East Pakistan by the Canadian engineering firm, Sandwell & Co. Ltd., consultants, and Provincial Engineering Ltd., and Balfour Beatty & Co. (Canada) Ltd., joint venture contractors; building of a conveyor system for an Indian iron ore development, by Hewitt-Robins (Canada) Ltd.

Engineers of the British Commonwealth Meet in Australia

The fourth meeting of the Engineers Institutions of the British Commonwealth met in Australia from Wednesday, March 19 until Tuesday, April 1. Sessions were held in Sydney, Melbourne and Canberra.

This conference meets every four years, the first meeting being held in London, England, in 1946. In 1950 it was held in Johannesburg, and back to London in 1954, and to Australia in 1958. The likelihood is that it will come to Canada in 1962.

The member countries of the Conference are now United Kingdom, Northern Rhodesia, South Africa, Australia, New Zealand, and India. The Australian Conference was attended by observers from two more countries that are desiring membership. These are Ceylon and Pakistan.

The numbers of people attending these conferences are not large inasmuch as in most instances the maximum numbers consist of two voting delegates from each society. This meant that the entire delegation as far as voting members were concerned consisted of eighteen persons. Observers and guests brought the total to twenty-three.

The meetings in Sydney were held in Science House, the home of the Institution of Engineers (Australia). In Melbourne the sessions were held at the University of Melbourne and in Canberra all sessions were held in the Canberra Hotel.

As well as the business sessions there were several opportunities to

PHOTOGRAPH (taken at doorway of the Institution of Engineers (Australia))

Front row, left to right—I. R. Tait, The Engineering Institute of Canada; J. E. B. Jennings, The South African Institution of Civil Egineers, N. A. Jabbar, vice-president, The Institute of Engineers (Pakistan); T. E. Goldup, president, Institution of Electrical Engineers (U.K.); Sir Arthur Whitaker, president, The Institution of Civil Engineers (U.K.); W. G. Morrison, president, Institution of Engineers (New Zealand); D. M. Myers, president, Institution of Engineers (Australia); T. P. R. Cassad, president, Institution of Engineers (India); C. M. Anson, president, Engineering Institute of Canada; M. Hewitson, president, South African Institute of Electrical Engineers; D. A. Dallamore, president, South African Institute of Mechanical Engineers; H. G. Furphy, vice-president, Institution of Engineers (Australia).

Second row, (left to right)–C. H. D. Harper, secretary, Institution of Engineers (Australia); B. G. Robbins, secretary, Institution of Mechanical Engineers (U.K.); S. Rajanayagam, honorary secretary, Institution of Engineers (Ceylon); D. V. Darwin, past-president (Australia); W. K. Brasher, secretary, the Institution of Electrical Engineers, (U.K.); B. Seshadri, secretary, the Institution of Engineers (India); G. I. D. Hutcheson, vice-president, Institution of Engineers (Australia); B. L. Bedingfield, secretary, New Zealand Institution of Engineers; L. Austin Wright, general secretary, the Engineering Institute of Canada.

Back row (left to right)–A. McDonald, secretary, Institution of Civil Engineers (U.K.); D. D. N. McGregor, assistant secretary, the Institution of Engineers (Australia); A. J. Adams, secretary to the Institution of Civil, Mechanical, Electrical Engineers (South Africa).

visit outstanding engineering projects —one of these was a coach tour to Port Kembla for an inspection of the Australian Iron & Steel Limited plant and the new inner harbour now being built for the same company.

On another day the entire party, the guests of Metropolitan Water and Sewage and Drainage Board, went on a tour of inspection of the Warraganba Water Supply Project. On the return from this trip the party were guests of the Commissioner for Railways and enjoyed a luxurious ride back to Sydney and a delightful dinner.

One of the most interesting trips took the group out of Melbourne by private train to Yallourn where they were met by officers of the various companies there and shown the Yallourn power station, the Yallourn open cut brown coal mine and the briquette works. This was the first time many of the delegates had ever seen brown coal and it was most interesting to see how it was handled and used.

Undoubtedly the most outstanding tour was that which took three days and gave a close-up view of the Snowy Mountain hydro electric and irrigation project. Here the delegates were guests of Sir William Hudson, chairman of the Authority, and were guests of the Authority two nights at different hostels of the billion dollar project.

Subjects discussed at the many business sessions included among others, the following:

Registration of engineers; supply and demand of engineers; definition of engineer and technician; the education and training of the engineer and the requirements of membership of the various institutions.

The contribution of industry to engineering education; post-graduate study; training of technicians; non-professional personnel; the training of overseas graduates.

Reciprocal privileges to visiting members; technical investigations; public relations; relations with non-professional institutions; abstracting services;

Relations with international organizations in the engineering field; conservation of natural resources; impact of new techniques and developments on existing engineering institutions; research, etc.

It is hoped that at one time and another there may be some detailed account of many of these engineering projects published in *The Engineering Journal*. Also arrangements are underway in an endeavour to get the full story of the most remarkable Snowy Mountain project told at the next annual meeting of the Institute. Hence it is that in this short article no detailed references are made to the projects.

For identification of the delegates please see the adjoining picture.

The Institute was represented by its president, C. M. Anson and the general secretary, L. Austin Wright. Irving R. Tait was also present as an observer on behalf of the Institute. Both Dr. Anson and Dr. Tait were accompanied by their wives.

ASME-E.I.C. Education Conference

Ann Arbor, Michigan — October 15 - 16th, 1958

The third Biennial Education Conference of the ASME and E.I.C. will be held at Ann Arbor, Michigan, October 15 and 16, 1958. The theme will be "How Should Industry Aid Engineering Education?"

The first of these activities was held at Clarkson College of Technology, Pottsdam, New York in 1954 with the theme "Trends in Mechanical Engineering Education". The second conference occurred at the University of Western Ontario, London, Ontario in 1956. The topic was "The Continuing Education of the Graduate Engineer". At the conclusion of the 1956 conference, plans were promulgated for the third conference to be held at the University of Michigan, Ann Arbor, in October 1958.

The representatives of the ASME and E.I.C. have met several times in the past year and it has been agreed to schedule events as in the previous conferences and to have four panel discussions, two general luncheons and a social period with a banquet on the evening of the first day. After considerable deliberation, decisions were reached regarding the general theme and topics for the individual sessions, as follows:

Theme — "How should Industry Aid Engineering Education?"

Panel A — The philosophy of co-operation between industry and higher education; Panel B — Continuing education by industry in industry; Panel C — Support by industry of higher education; Panel D — The three moderators will develop the conclusions reached by the conference participants and one of them will be selected to present the results of the deliberations.

It is also expected that two addresses will be given by senior members of the ASME and the E.I.C., possibly by the presidents of these societies.

Attendance is by invitation only. It is not desired to secure large numbers of delegates but rather a reasonably sized group of persons who are really interested in the subject.

The Canadian invitations are generally being restricted to persons in Ontario and Quebec, with exceptions being made in cases of obvious interests. Branches have been asked to submit the names of interested members to headquarters, so that they may be added to those to be invited.

UPADI

The Union of Pan American Engineering Associations (UPADI) will hold its fifth regular convention at the Queen Elizabeth Hotel in Montreal, September 2-6, 1958. The Engineering Institute of Canada, as the Canadian participating body, will be the host society. As such it is responsible for making all the arrangements for the meetings. A special committee of the Institute has been established, with Dr. I. R. Tait as chairman, to implement the Institute's responsibilities in regard to this important function.

UPADI is made up of engineering societies representing twenty three countries in North and South America. Every two years a convention is held, the four previous conventions having been held in Havana, Cuba, New Orleans, Louisiana, Sao Paulo, Brazil and Mexico City. The program consists of a number of formal functions, committee meetings and social events. Considerable emphasis will be placed on the study of problems relating to engineering education in the participating countries. No technical sessions will be held, since the convention is purely administrative and policy-making. It is expected that over two hundred delegates will participate in the Conference.

The Engineering Institute of Canada, in common with each other participating society, will be represented by ten official delegates, to be named by the E.I.C. Council. However, provision has been made for a number of alternative delegates from Canada to attend, and the purpose of this notice is to request any E.I.C. members who would be interested in attending the sessions to advise the General Secretary, so that they may be provided with information.

Reviewing the Institute's Activities

Recent events in which the Institute and its members have taken part.

Russian Engineers Visit Montreal

At the request of the Ambassador of the U.S.S.R. to Canada, His Excellency Dimitri S. Chuvahin, and with the concurrence of the Canadian government, arrangements were made through the Engineering Institute of Canada to organize visits to various industries and projects in the Montreal area during June 16-18, for a group of five Russian engineers.

The names of these engineers, and the subjects in which they were interested, were as follows:

Mr. Victor A. Kargopolov — Machine Building, Foundries

Mr. Jan O. Eger — Building Construction

Mr. Georgi K. Bodunov — Building Materials

Mr. Evgeni G. Dimitriev — Building Materials

Mr. Gennadi S. Boljshakov — Electrical Apparatus

Mr. Eger is a deputy minister of construction for one of the main geographical divisions of the U.S.S.R. Mr. Dimitriev is general manager of a large Russian asbestos production industry. Information regarding the industries they visited was interpreted through Mr. C. E. Stepanov, the Commercial Counsellor to the U.S.S.R. Embassy at Ottawa, who accompanied the group.

Members may participate in Conference

The Power Industry Application Conference has been organized by the American Institute of Electrical Engineers for September 15-17 in Toronto.

This will be the first international conference on this continent specifically dealing with digital computer applications in the power industry.

Members of the E.I.C. are invited to participate on the same terms as A.I.E.E. members. Information is available from Dr. J. Ham, Electrical Engineering Department, University of Toronto, Toronto, Ont.

Awards for Architectural Competition

Kenneth F. Tupper, was present at the ceremony on May 8 of the Bituminous Coal Institute at which winners of the B.C.I. architectural competition received their awards. Dr. Tupper is seen in the illustration, with George Everest Wilson (left), president, Ontario Association of Architects, who congratulated Donald E. Skinner (right), Toronto, winner of first award, and William P. Smith, Toronto, associate engineer who collaborated with Mr. Skinner in the "boiler house" design.

At the luncheon held in Montreal at which the Institute was host to five visiting Russian engineers.

Nuclear Congress, 1959

The Fifth Nuclear Congress is scheduled for April 5-10, 1959, in Cleveland, Ohio. Canadians are invited to present papers in Nuclear Field.

The Engineering Institute of Canada, as a participating society, will provide for the Nuclear Engineering and Science Conference one or more technical papers. Authors are invited to submit summaries (300 to 500 words) of proposed papers. Summaries should be received at Headquarters by October 1, for transmission to the Congress Manager.

Authors will be notified in October of the selection of papers for the program, and will be given specifications for the preparation of manuscripts, to be received by the E.I.C. by November 28.

Interested authors should send summaries to: Dr. Garnet T. Page, The Engineering Institute of Canada, 2050 Mansfield St., Montreal 2, Que.

The President at Philadelphia

Kenneth F. Tupper, president of the Engineering Institute of Canada represented the E.I.C., at the fiftieth anniversary celebration of the American Institute of Chemical Engineers, June 25, 1958, in Philadelphia, Pa.

During a special ceremonial celebration, he presented the president of A.I.Ch.E. with an illuminated scroll conveying the good wishes of the officers and members of the Institute.

British Guest of E.I.C.

Sir George Barnett, chief inspector of factories, of the Ministry of

Labour, Britain, visiting Montreal in May was greeted at an informal luncheon reception on May 5 with the following people participating: R. S. Eadie, C. G. Southmayd, Claude Beaubien, R. L. Dunsmore, J. B. Stirling, R. E. Heartz, S. Ferrabee, and W. S. G. Smele, United Kingdom Information Office.

Sir George was in Canada to attend a convention at Toronto, of the Industrial Accident Prevention Association, and was also visiting local branches of the I.A.P.A. in Toronto.

E.I.C. Represented at International Meeting

The Institute was represented at the sixty-second annual meeting of the American Academy of Political and Social Sciences, Philadelphia, April, 1958.

S. Logan Kerr, M.E.I.C., and William S. Pardoe, M.E.I.C., of Philadelphia, were the Institute's representatives, as they have been many times. William L. Batt, HON.M.E.I.C., was also present and presided at the third session of the meeting.

Many different viewpoints were expressed with respect to the theme, "Asia and Future World Leadership". The sixteen excellent papers are published in the *Annals* of the Academy.

Photographic Exhibit

The winning entries of the 1958 exhibition of photographs have been selected. The exhibition, was one of the features of the 72nd annual meeting of the Institute at Quebec City, Que. Five photographs were selected as the best of the show. They are listed in random order: "105,000-hp. Dominion Francis Runner", Dominion Engineering Company Limited, Montreal. "Burlington High Level Bridge", Bridge and Tank Company of Canada Limited, Hamilton, Ont. "Autoclave in which Metal-to-Metal Bonding and Magnesium Forming is Carried Out", Avro Aircraft Limited, Toronto. "Second Narrows Bridge," Dominion Bridge Company, Limited, Montreal. "Hortonspheroids", Horton Steel Works Limited, Toronto.

CORRECTION

In the June issue of the *Journal*, Month to Month section, under the heading, Athlone Fellowship Winners, 1958, it was stated that D. M. Caughey, S.E.I.C., of the University of New Brunswick, was the choice from that institution. As it was however, Mr. Caughey was unable to accept the award. In his place Hugh W. Walford, S.E.I.C., was named for the Fellowship.

DID YOU KNOW THAT

Last year *The Engineering Journal* circulated 40 million individual pages of technical and other material.

Polish Engineers Honour L. Austin Wright

The Association of Polish Engineers in Canada held a reception on Thursday, June 26, in honour of the retiring general secretary of The Engineering Institute of Canada in their club premises on MacKay Street, Montreal. The feature of the reception was the presentation of a beautiful leather bound portfolio of etchings—fourteen in number, showing famous old buildings in Poland.

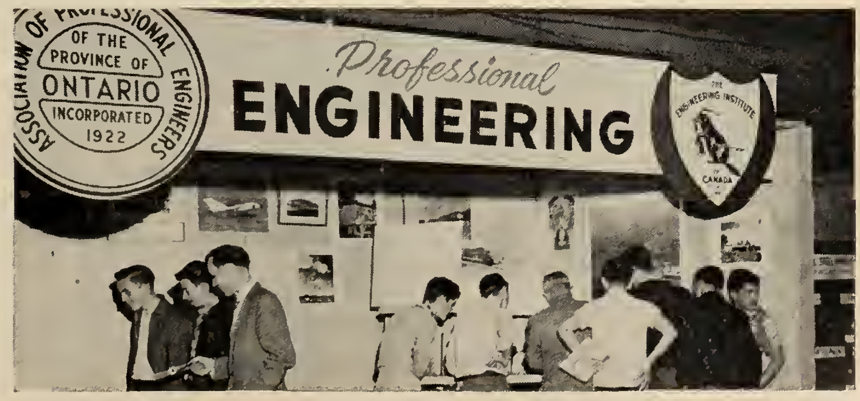
V. Buzek, vice-president of the Association, presided and the presentation was made by Past-President J. Pawlikowski, M.E.I.C. There were about sixty members and their wives present.

Mr. Pawlikowski, in making the presentation, reviewed some of the events that had taken place since the arrival of the first Polish engineers in Canada in 1941. He spoke of the letter of welcome from The Engineering Institute of Canada and the complimentary membership privileges offered them and those who followed them. These things had meant much to the new arrivals in a strange land and had gone a long way towards giving them an appreciation of their new home.

Mr. Pawlikowski recalled that he and most of his associates had passed through the hands of Dr. Wright either in Ottawa or Montreal, at which time Dr. Wright was assistant director of the Wartime Bureau of Technical Personnel. It was on his approval that the Polish engineers were selected for admittance to Canada and it was largely through his efforts that satisfactory employment was found for them on arrival.

On behalf of all his countrymen now established as good Canadians, he expressed thanks and appreciation to the Engineering Institute of Canada and its former general secretary.

A Career Counselling Display, sponsored by the London, Ont., school board was held in that city during the spring for the benefit of high school students. The students viewed the exhibits over a two-day period at scheduled times, in an effort to show what was offered by the various professions. Among those working at the display were professional librarians, accountants, professional soldiers, etc. This photograph shows the joint E.I.C.-A.P.E.O. booth.



Sixth Annual Regional Professional Development Conference, May, 1958

Professional Development Programs

Stride toward Maturity within the E.I.C. Branches

by: Robert L. Wright, JR.E.I.C.
Publicity Co-ordinator,
P. D. P. Co-ordinating Committee

The legion of engineers participating in professional development programs across Canada has been swelled by an additional nine hundred during the past year. The annual reports given by the participating branches at the regional conference revealed the growing impetus of the program. Professional development is becoming of age and is finding its true place in the training of engineers towards the broadening and public-spirited outlook of professional men.

Apparent trends can sometimes be misleading so it is only fair to ask why this movement is so evident within our society. In the post-war years there was a need to rehabilitate the engineering ranks augmented by the additional number of older students. These men were entering the profession at a relatively older age and if they were to understand the responsibilities of their chosen career, some form of training had to be undertaken. Professional development courses were inaugurated to arouse the interest of these engineers. Soon middle and upper management groups, as well as the younger graduates, began to perceive the value of the programs.

Primarily, the function of the program was to bridge the gap between graduation and professional recognition in such a manner as to orientate and integrate the student into the engineering profession. These related problems were eloquently stated by the Committee on Professional Training of the Engineer's Council for Professional Development in 1950.

"The most critical period of the young engineer's whole career is, undoubtedly, the first five years after leaving college. During this period he is finding his place in professional practice, attempting to understand himself, and shaping his professional goals. Frequently, he is establishing his family, and generally his salary is modest. He steps into an organization at a relatively high level and has had no opportunity to understand its problems."

This preliminary program gradually became modified as experience pruned the trimmings and the more basic philosophy shone forth. Experience also demonstrated that unless the young engineer formulated a plan for personal development soon after he left university, he was not likely to ever do so. The core of his plan should relate the basic principles of science and of the humanities to his experience in technical matters and in his association with people. This evolving process is far from complete for, even now, a Co-ordination Committee has been formed to reassess the work done and to plot a course for the future. Most of the programs have had grass-root beginnings with the resultant difficulties but this humble beginning has been essential to the program. Diversity has been the foundation and local need the building blocks. To illustrate the divergence of the programs, one could compare the Sarnia Branch with its ten lectures on "Nuclear Energy" to the Vancouver Branch with its eight lectures on "The Economics of the Province of British Columbia." Both these branches could, in turn, be compared to the Hamilton Branch where a four-year program of twenty lectures each year has been developed, tailored to personality improvement, human relations and business management. Whatever courses will be given in future years, always their ultimate goal will be towards preparing the engineer to shoulder the responsibilities of his profession in society.

A logical question at this point might be—With all this diversity and home-grown course content, how valid are the results? Upon review of the submitted program reports, the validity of the course content has been substantiated, for all program planners have asked and received aid from universities, business organizations and professional men engaged in the fields under review. Many of the lecturers have been top management personnel from organizations actively engaged in the subjects under discussion. Not only does management in general support the program but it has been found that many executives actually participate and, by doing so, not only enrich the program by their mature influence but, in turn, review subjects which may have suffered enforced dormancy.

The Professional Development program extends an invitation to all members of the engineering profession to participate in this rewarding extension of their education. To many, the enforced restriction of an engineering education at university is becoming increasingly apparent but the opportunity for enlarging that education is now presenting itself. Within a few short weeks the majority of branches will be having their registration evenings. Ultimately, of course, the choice rests with the individual, but how long can he afford not to avail himself of supplementary knowledge in this era of rapidly changing techniques, ideas and values. Many will claim the pressure of business makes such a course impractical but one has only to reflect momentarily to realize that the value of an hour's discussion with an expert is worth many hours of factual research. All topics covered in the program are well worth the time given to them for many new facets are revealed at each lecture.

An evening kept free for this coming winter season to join the Professional Development program in your branch will become an enjoyable habit with rewarding dividends. The Professional Development program can function only if the individual members lend their support, so why not investigate its program to see if it can satisfy your goals for professional advancement?

Listed on this page are the names and addresses of ten men, each active in his local Professional Development organization. They have consented to act as advisers to anyone in their area who wishes to contact them.

Should your district not be represented in this group, it may be that their program has not crystallized to the point of supplying us with the required information. The secretary of your local branch can supply you with all the available information.

Professionalism results through service to society. Working on the Professional Development program in your branch area can be an initiation to professionalism. The program committees are usually set up on a rotating basis and there is always an opportunity to be creative. This is an opportunity for all engineers to participate in an interesting and maturing endeavour from which the individual will reap dividends.

SIXTH REGIONAL PROFESSIONAL DEVELOPMENT CONFERENCE

At the Sixth Annual Regional Meeting, Peterborough, May, 1958. Some representatives are shown, left to right: T. E. Flinn, M.E.I.C., chairman, Belleville, W. W. Walker, M.E.I.C., director, Toronto, K. R. Crean, JR.E.I.C., director, Hamilton, Robbin Bowes, M.E.I.C., assistant chairman, Brockville, Robert Wright, JR.E.I.C., assistant director, Niagara, H. R. Sills, M.E.I.C., past president, E.I.C., Peterborough, Colonel L. F. Grant, Hon. M.E.I.C., Kingston, Brian Ahern, JR.E.I.C., chairman, Peterborough, M. M. Brown, JR.E.I.C., chairman, Sarnia.

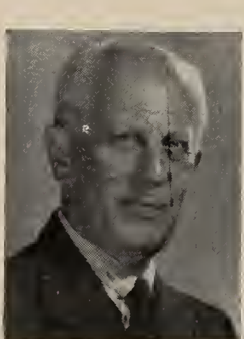
OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Dr. Francis William Gray, HON. M.E.I.C., of Victoria, B.C., retired assistant general manager of the Dominion Steel and Coal Corporation, Sydney, N.S., died at Victoria, B.C. on June 10, 1958.

Dr. Gray was born at Hoyland, Nether, Yorks, England, on April 15, 1877. He received his higher education at Firth College, Sheffield. After obtaining early experience in the coal mining industry of Great Britain, he moved to Canada in 1904. His first appointment was that of assistant to the general manager of the Dominion Coal Company, Sydney, N.S. In 1908 he was named assistant to the president of the Nova Scotia Steel and Coal Company. From 1919 to 1921 he was editor of The Canadian Mining Journal and Iron and Steel of Canada. Named assistant to the vice-president of the British Empire Steel Corporation, in 1921, he was promoted to assistant to the president two years later, a post he held for five years. He was appointed assistant general manager of the Dominion Steel and Coal Company Limited, Sydney, N.S., in 1928 and continued in this capacity until his retirement in 1945.



Dr. F. W. Gray, M.E.I.C.

Dr. Gray was an outstanding authority on undersea mining, and for his work in this field was awarded an honourary doctor of laws degree by Dalhousie University in 1937.

He was also responsible for the introduction of many improved fire fighting and mine rescue appliances into Eastern Canada. On more than one occasion he was called into consultation by coal mining operators of Western Canada, as well as to act as representative at international meetings in other countries. For his outstanding services and contributions to mining engineering Dr. Gray was at various times throughout his career awarded the Leonard Medal of the E.I.C., the Barlow Memorial Prize of the Canadian Institute of Mining and Metallurgy, the Julian C. Smith Medal of the E.I.C., and the honorary degree of Doctor of Laws by Dalhousie University, Halifax, N.S.

Besides his interest in the Engineering Institute affairs, Doctor Gray found time for other professional engineering organizations. He was for many years a member of The Canadian Institute of Mining and Metallurgy and of The Mining Society of Nova Scotia. He served as president of both organizations. He was elected an honorary life-member of the Association of Professional Engineers of Nova Scotia in 1950. He completed his fiftieth year as a member of the Institution of Mining Engineers of Great Britain in 1954.

He attended two conferences in Europe of the International Labour Organization as a representative of Canadian industry in recent years.

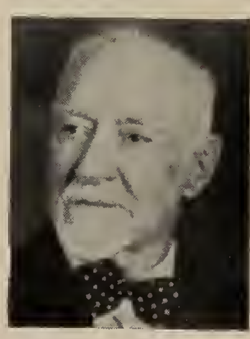
Also, Doctor Gray distinguished himself in many fields not always associated with engineering. He was known for his oil painting, sculpture, writing, both prose and poetry. Many of his works have been published.

Dr. Gray became an Associate Member of the E.I.C. in 1921 and a Member in 1924. He was active in the Cape Breton Branch and served as a councillor of the Institute in 1942. He attained Life Membership in the Institute in 1952. Honorary membership in the E.I.C. was conferred in 1956.

Louis Stanisleau Pariseau, M.E.I.C., retired superintendent of Canals, Quebec, for the federal government, died in his one-hundred and second year at Montreal, on June 7, 1958, after a retirement of more than a quarter of a century.

Born at St. Martine, Laval, Que., on October 23, 1856, Mr. Pariseau received his engineering qualifications with the first class ever graduated from the Ecole Polytechnique, Montreal, in 1877. Immediately he joined the ranks of the professors of that institution. In 1879 he began work with the federal Department of Railroads and Canals as a chainman. He took part in work on the Grenville canal, surveys of the Richelieu river, and surveys for the Lachine canal. He was appointed superintendent of canals for Quebec in 1923. He retired in 1930, well-known as a pioneer in construction methods for public works after fifty-one years of public service.

L. S. Pariseau, M.E.I.C.



At the end of a long career Mr. Pariseau was awarded an honorary degree of Doctor of Applied Science by the University of Montreal and Laval University.

Honoring him on the occasion of his one hundredth anniversary, the E.I.C. presented him with a badge as a token of admiration and respect.

At the grand age of 99 Mr. Pariseau was asked to take part in the laying of a cornerstone for the new building at Ecole Polytechnique, Montreal, his alma mater.

Mr. Pariseau joined the Engineering Institute as an Associate Member in 1887, transferred to Member in 1940. He attained Life Membership in 1917.

Homer Wilson Sutcliffe, M.E.I.C., retired head of the New Liskeard, Ont., firm of Sutcliffe Company Limited, died on March 10, 1958.

Born on April 27, 1884, at Forest Hill, Ont., Mr. Sutcliffe received his general education there and then went on to engineering studies at the University of Toronto where he was a 1907 graduate. He was immediately articled to an Ontario Land Surveyor and received his commission as an O.L.S. in 1908, at which time he entered the firm of Sutcliffe and Nulands. In 1909 and 1910 he took part in the laying of waterworks and sewage systems at Cobalt, Ont. The following year he carried out work for the Province of Ontario. He charted township lines and rivers flowing into Hudson Bay.

In the municipal field he was consulting engineer for New Liskeard, Cobalt, Cochrane, and Timmins, and served Atikokan, Virginiatown and Mattawa in consulting capacities.

He took part in the formation of the Sutcliffe Company Limited in 1924 in association with the late T. S. Armstrong. During his career he located and built several power lines in Ontario and Quebec. He was consulting engineer for the power project at Snare River in the North West Territories.

Mr. Sutcliffe was appointed a member of the Royal Commission for the Province of Ontario in 1943 to enquire into various matters related to the mining industry.

Due to illness Mr. Sutcliffe retired from active practice of engineering in 1953.

Mr. Sutcliffe joined the E.I.C. in 1908 as a Student Member, transferred to Associate Member in 1913, and to Member in 1940. He attained Life Membership in 1948.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

ALBERTA

Annual Meeting Held

The thirty-eighth annual meeting of the Association of Professional Engineers of Alberta held at the Macdonald Hotel, Edmonton, was called to order by President J. C. Sproule, on March 29, 1958. Attending were approximately two hundred professional engineers and engineers in training.

Visitors representing the Ontario, B.C., and Saskatchewan associations were welcomed by the president.

Dr. G. W. Govier reported for the Act and By-laws committee and outlined the steps, taken by the committee to draft a new Act following representations made to the Association by a group of Foresters and a group of Chemists within the province. He reported that this new draft Act has now been prepared and submitted to Council, and there had received approval in principle. The new act would permit registration of other professional physical scientists in an expanded organization. It was pointed out that the draft would permit separate designations for the various professions. Clauses would spell out that only a professional engineer would practice engineering, and only a professional chemist would practice chemistry, etc. Dr. Govier said that both the committee and Council had studied the pros and cons of this proposal and had come to the conclusion that the advantages outweigh the disadvantages, and that no insurmountable problems would be involved in dealing with other professional associations. Only members registered as professional engineers would be allowed to avail themselves of present transfer arrangements under Canadian Council. Dr. Govier pointed out that in Alberta the University Act places the responsibility for assessing applications to various professional associations with the General faculty council of the University of Alberta. rather than with the professional associations. It was suggested that the borderline between pure scientists and applied scientists is diminishing. and that people who have graduated from University in pure science were found practicing along side of engineers. Dr. Govier said the committee, so far has been considering only physical scientists and engineers. The report was adopted.

Reports of the various committees were heard.

Elected for the 1958-59 season were: president, by acclamation, Dr. G. W. Govier, Edmonton, vice-president, C. A. Stollery, Calgary, councillors, for a three-year term, N. J. Allison, Edmonton, Dr. George Ford, Edmonton; W. A. Smith, Calgary; B. F. Wilson, Calgary; councillors for a two-year term, J. C. Scott, Calgary.

Panel discussions on "Should the Association Sponsor Technical Programs," and another which dealt with a series of questions were held. The questions were: 1) How best can consultants serve the public 2) Is the "package deal" good for the engineering profession 3) do contractors and manufacturers supplying free consulting services adversely affect the profession.

BRITISH COLUMBIA

Municipal Engineers' Convention

Annual convention of the Municipal Engineers' Division of the Association of Professional Engineers of B.C. will be held in Prince George on September 18th, 19th and 20th. George P. Harford, P.Eng., City Engineer of Prince George, will be host to over 200 city and municipal engineers, representatives of supply firms, and their wives from 51 communities throughout the province.

The Hon. R. G. Williston, Minister of Lands and Forests, will be guest speaker at the annual banquet on Thursday, September 18th.

Two full days of business sessions will feature papers followed by discussion on a number of subjects applicable to the municipal engineering field, as well as field trips to interesting projects in the vicinity. A pre-convention meeting of the Municipal Suppliers Association will be held in the Prince George Civic Centre on Wednesday, September 17th.

A special ladies' program has been arranged.

ONTARIO

Engineers in the News

Stephen Gramlewicz, P.ENG., formerly with Crompton Parkinson Electric Ltd., in Brantford, Ont. has joined Canadian Line Materials Ltd., Scarborough, Ont., in the capacity of a metalclad switchgear engineer.

Brian G. Butler, P.ENG., has left H. G. Acres & Co. Ltd., Niagara Falls, Ont., to join the atomic energy department of Canadian General Electric Co. Ltd., Peterborough.

D. E. Noble, P.ENG., is project engineer for microwave and industrial products with Canadian Motorola Electronics Ltd., 105 Bartley Drive, Toronto 16, Previous to accepting this position he was with Canadian Radio Mfg. Corp., Toronto.

D. Laschuk, P.ENG., has moved from Chibougamau, Que., to Spragge, Ont., where he has joined the engineering department of Consolidated Denison Mines. He was formerly chief engineer at Copper Rand Chibougamau Mines Ltd., in Chibougamau.

Glenn N. Hutchinson, P.ENG., has left Fort William, Ont., to accept an appointment as an electrical project engineer with Universal Cyclops Steel Corporation at its new mill in Coshocton, Ohio. Prior to accepting this new post he was assistant electrical superintendent at Great Lakes Paper Co. in Fort William, Ont.

Carl J. Jamieson, P.ENG., who has been conducting a consulting mining engineering practice at Chibougamau, Que., is now located in Whitby, Ont., where his postal address is P.O. Box 340, Whitby.

T. M. De Vroom, P.ENG., has left the employ of Dominion Bridge Co. Ltd., to join the development engineering branch, structures division, of the Department of Public Works of Canada, Hunter Building, Ottawa.

Wesley M. Smardon, P.ENG., is now employed in the distribution Standards section of the British Columbia Power Commission, Victoria, B.C.

Mr. Smardon formerly was located in Niagara Falls, Ont., where he was plant engineer of Lionite Abrasives Ltd.

William J. Laskaris, P.ENG., is with the Department of Public Works of Canada and is presently located in Banff, Alta., where he is engaged in engineering administration with the department of highways division.

Personals

News of the Personal Activities of Members of the Institute

Dr. R. L. Hearn, M.E.I.C., (B.A.Sc., Toronto, 1913), has been elected a director of the Brazilian Traction, Light and Power Company, Limited. Dr. Hearn is a director of Atomic Energy of Canada Limited, the British Newfoundland Corporation and the Canada Wire and Cable Company Limited and other companies.

R. F. Shaw, M.E.I.C., (B.Eng., civil, McGill, 1933), has recently been elected president of the Foundation Company of Quebec Limited. This new company, with head office in Montreal, is a subsidiary of The Foundation Company of Canada Limited and has been formed to better serve Foundation clients in the province of Quebec.

Mr. Shaw is executive vice-president of the parent company.

J. H. Mowbray Jones, M.E.I.C., (Toronto, 1927), vice-president and general manager of the Mersey Paper Company Limited has been named president and general manager of the firm, at Liverpool, N.S. He is also a director of the Bank of Canada, Bowater's Newfoundland Pulp and Paper Mills Ltd., Moirs Limited, the Nova Scotia Light and Power Company and the Eastern Trust Company.

Jean St. Jacques, M.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1929; B.Sc., McGill, 1931), director of sales and contracts, has been appointed a vice-president and a director of the Quebec Power Company following service with the organization since 1932.

David S. Lloyd, M.E.I.C., (B.A.Sc., elec., Toronto, 1925), formerly a vice-president and director of Pyrofax Gas Limited, a subsidiary of Pyrofax Gas Corporation, has been elected president of the organization. Mr. Lloyd joined the Dominion Oxygen Company Limited, more than thirty years ago. From 1954 to his new appointment he held the office of president of Union Carbide's Linde Air Products Company.

J. M. Courtright, M.E.I.C., (B.Sc., civil, Queen's, 1941), has been appointed Eastern division manager of the Shell Oil Company of Canada, Limited, at Montreal. Mr. Courtright's services have been transferred from Toronto where he was manager, purchasing stores, in the company's head office.

Colonel E. G. M. Cape, M.E.I.C., (B.A.Sc., McGill, 1898), has retired from the office of chairman of the board of the firm of E. G. M. Cape and Company, Montreal. Colonel Cape who established the firm in 1907 will continue to serve as a member of the board.

Brigadier John M. Cape, M.E.I.C., (Royal Military College, 1932), has assumed the office of chairman of the firm of E. G. M. Cape and Company, Montreal, following the retirement of Colonel E. G. M. Cape. Brigadier Cape has been with the firm since 1934. He received the M.B.E. in 1945 after service with the R.C.A. during World War II.

V. A. Ainsworth, M.E.I.C., general manager, Newfoundland Light and Power Company, St. John's, Nfld., has been elected president of the Canadian Electrical Association. Mr. Ainsworth was chairman of the Newfoundland Branch of the E.I.C. in 1956.

Milton Eaton, M.E.I.C., (B.Sc., elec., McGill, 1921), consulting electrical engineer, of Shawinigan Falls, Que., has recently been made a Fellow of the American Institute of Electrical Engineers. Mr. Eaton was the chairman of the St. Maurice Valley section, A.I.E.E., when it had its beginning as a subsection of the Montreal Section.

M. E. Hornback, M.E.I.C.

R. A. H. Hayes, M.E.I.C., (B.Sc., McGill, 1928), of the firm of H. G. Acres and Company Ltd., has been appointed a vice-president of the organization. Mr. Hayes was previously chief engineer, technical division.

Jasper H. Ings, M.E.I.C., (B.A.Sc., civil, Toronto, 1925; C. E., Toronto, 1931), of the firm of H. G. Acres and Company Ltd., consulting engineers, Niagara Falls, Ont., has been made a vice-president of the organization. Mr. Ings who has given more than twenty years service to the company was previously chief engineer on specific projects.

M. E. Hornback, M.E.I.C., (B.Sc., Missouri, 1912), of Montreal, has been named director and consultant to the Simon Engineering Companies of Canada Ltd. Until recently Mr. Hornback was chief mechanical engineer to the Aluminum Company of Canada Ltd., which he served for eighteen years. Earlier he was with the John S. Metcalf Company Limited.

H. A. Oaks, M.E.I.C., (B.A.Sc., mining, Toronto, 1922), has become a partner in the firm of T. A. Richardson and Company, Toronto. Mr. Oaks has had considerable mineral exploration experience in the North country and has operated as a mining consultant, Port Arthur, Ont., area, and as a partner in the Mining Evaluation Company in Noranda.

R. B. Wotherspoon, M.E.I.C., (Royal Military College, 1935), of Kingston, and

D. S. Lloyd, M.E.I.C.

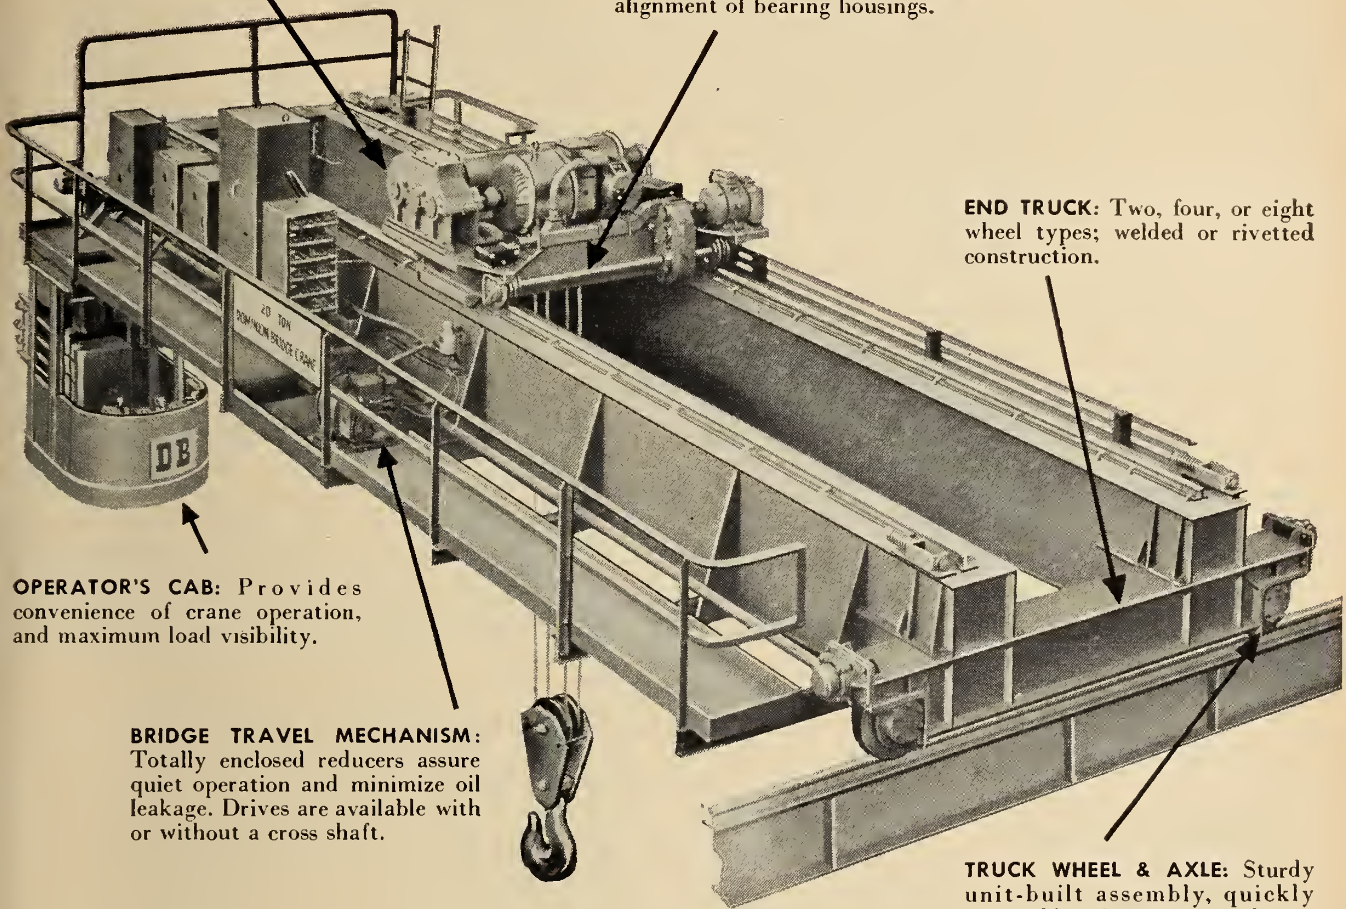
J. M. Courtright, M.E.I.C.

R. B. Wotherspoon, M.E.I.C.

TROLLEY: Carries totally enclosed hoisting and trolley travel mechanisms. Design provides maximum lateral travel, easy maintenance and great rigidity under all possible working conditions.

TROLLEY FRAME: All welded construction, stress-relieved before machining, positive alignment of bearing housings.

END TRUCK: Two, four, or eight wheel types; welded or rivetted construction.



OPERATOR'S CAB: Provides convenience of crane operation, and maximum load visibility.

BRIDGE TRAVEL MECHANISM: Totally enclosed reducers assure quiet operation and minimize oil leakage. Drives are available with or without a cross shaft.

TRUCK WHEEL & AXLE: Sturdy unit-built assembly, quickly removable, incorporates heavy duty bearings.

Just a few of the features which make Dominion Bridge General Service Cranes the soundest possible *investment* are shown on this page. For details of all Dominion Bridge Cranes write for Crane Handbook No. MF -100 to Dominion Bridge Company, Limited, Box 280, Montreal, Quebec.

CRANES BY DOMINION BRIDGE

DOMINION BRIDGE COMPANY LIMITED. Plants: MONTREAL • OTTAWA • TORONTO • SAULT STE. MARIE • WINNIPEG • CALGARY • VANCOUVER. Assoc. Company Plants: AMHERST, N.S.: Robb Engineering Wks., Ltd. QUEBEC: Eastern Canada Steel & Iron Wks., Ltd. WINNIPEG: Manitoba Bridge & Eng. Wks., Ltd. EDMONTON: Standard Iron & Eng. Wks. Ltd.

Divisions: Mechanical • Warehouse • Platework • Boiler • Structural.

formerly of Montreal, has been elected chairman of the Kingston Branch of the E.I.C. for the 1958-1959 season. Mr. Wotherspoon is associated with Imperial Chemical Industries of Canada Limited, at Kingston, Ont.

Peter B. MacFarlane, M.E.I.C., It was stated in the June issue of the Journal that P. B. MacFarlane, M.E.I.C., was vice-president and general sales manager of the International Panel Boards Limited. It was also stated that this firm is a wholly owned subsidiary of Atlas Asbestos Company Limited. It is however a subsidiary of the International Paper Company. The Journal regrets the error.

Thomas J. Hogg, M.E.I.C., (B.A.Sc., mech., Toronto, 1947), has joined H. S. Gellman and Company Limited, data processing consultants, Toronto, as vice-president of the firm. Mr. Hogg was formerly engaged in program co-ordination with the Hydro-Electric Power Commission of Ontario.

A. G. W. Lamont, M.E.I.C., (B.A.Sc., chem., Toronto, 1943; M.Sc., Queen's, 1947), has joined W. S. Atkins and Associates Ltd., consulting engineers, Toronto, as chief process engineer. He was previously with A. H. Ross and Associates as a consulting metallurgist.

Over the past eleven years Mr. Lamont has been engaged in a wide variety of uranium and other metallurgical activities in Canada and the U.S., with the Eldorado Mining and Refining Company and Gunnar Mines Ltd., metallurgical division.

D. R. Burns, M.E.I.C.

A. G. W. Lamont, M.E.I.C.

P. S. Jagger, M.E.I.C.

C. D. Smith, M.E.I.C., (B.Sc., civil, Alberta, 1948), has resigned as senior hydraulic engineer of the P.F.R.A., Regina to accept an appointment as associate professor of civil engineering at the University of Saskatchewan. Mr. Smith became associated with the P.F.R.A. design division in 1949 as a designer, and since 1952 has been engaged in experimental research on hydraulic structures.

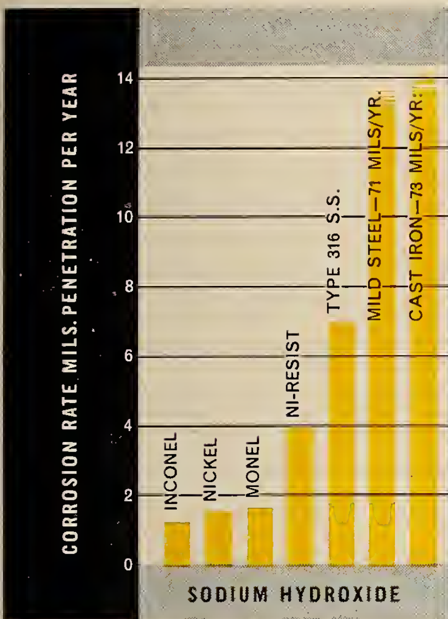
C. D. Smith, M.E.I.C.

Donald R. Burns, M.E.I.C., (B.A.S.C., mech., Toronto, 1947), has been appointed sales engineer for the hydraulic division of the Dominion Engineering Company, Limited. He has been engaged in the manufacture and sale of hydraulic turbines since becoming a graduate engineer.

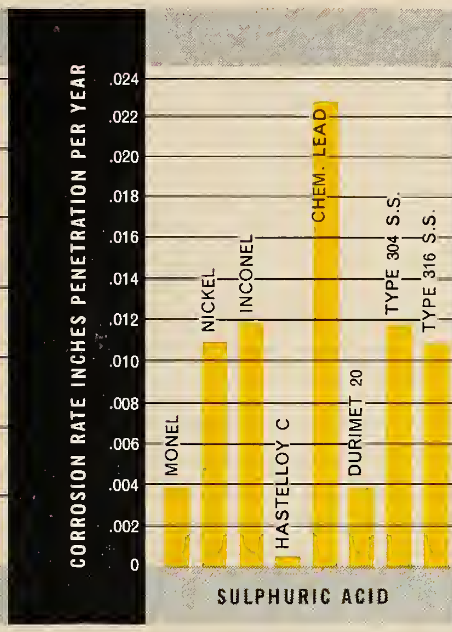
Paul S. Jagger, M.E.I.C., (B.A.Sc., mech., B.C., 1944), has taken over the ownership and active management of Asbestos Cement Products Limited at North Sur-

Is corrosion eating away your profits?

Inco Customer Service can help you!



This test was conducted in a plant manufacturing caustic soda. The test spool carrying duplicate specimens of each of the metals shown above was immersed in a solution of 75% sodium hydroxide at a temperature of 275°F. for 35 days.



Plant test in sulphation of vegetable oils with 66° Baumé sulphuric acid and an acid-to-oil ratio of 20-25% by weight at temperatures ranging from 68°F. to 140°F. for a period of 7 Days.

Plant test in distillation of crude fatty acid (cottonseed). Corrosion test spool was located at top of the batch still near the vapour outlet for 42 days. Temperature 480°-520°F.

The graphs above show you what can happen—and may be happening—to equipment handling acids or caustics in your plant, if you're not using the right material for the job. And they're only examples from more than 300,000 similar tests Inco has conducted in a wide range of acids, alkalies, organic compounds and other environments.

The results of these tests have been carefully documented and are available from Inco to help you select the right metal for your corrosive applications. If your corrosion problem has not been covered by these tests, Inco's research and development engineers will undertake to find a solution for you without cost. Just outline your problem on a Corrosion Data Work Sheet, also available from Inco.

Use the coupon at right to order List "B", itemizing Inco publications dealing with corrosion, and the Corrosion Data Work Sheet.

rey, B.C. Mr. Jagger has been engaged in the manufacture of building materials in both Eastern and Western Canada for the past fifteen years.

R. F. P. Bowman, M.E.I.C., (B.Sc., civil, Alberta, 1928), formerly assistant superintendent, Canadian Pacific Railway, Minnedosa, Man., has been transferred to Lethbridge, Alta., as superintendent.

Colonel Carl Rice Boehm, M.B.E., M.E.I.C., (B.A.Sc., Toronto, 1929), former head of the Corps of the Royal Canadian Electrical and Mechanical Engineers, and until very recently director of scientific liaison of the Defence Research Board, Ottawa, retired to civilian engineering some months ago, at Victoria, B.C.

J. M. Richardson, M.E.I.C., (B.Sc., elec., New Brunswick, 1941), has been appointed manager-marketing in the motor and control department of Canadian General Electric Company Limited, at Peterborough.

Mr. Richardson brings a broad application and sales engineering background to his new position. For the past two-years he has been manager-sales for the motor and control department.

W. C. Miller, M.E.I.C., (B.Sc., civil, Queen's, 1917), City Engineer of St. Thomas, Ont., for thirty-nine years on June 1 went on leave prior to retirement from the post. After a long vacation Mr. Miller plans to accept a few consulting engagements in municipal work specializing on the problems of the smaller municipalities.

Major C. Ben Bate, M.E.I.C., (B.Sc., civil, Queen's, 1915), has retired from Public Service and has gone into private practice as a civil engineer at Sillery, Que. Major Bate was a plant engineer with the Defence Research Board, Department of National Defence, Quebec, Que.

J. A. Cunliffe, M.E.I.C., (B.A.Sc., ceramic, Washington, 1931; M.Sc., ceramic, Washington, 1932), has transferred from Medicine Hat, to Edmonton, Alta. Formerly with Medicine Hat Brick and Tile Company Limited, he has accepted work with the Northwest Ceramics Limited in the northern city.

W. E. Currie, JR.E.I.C., (B.Sc., mech., Queen's, 1952), has been transferred from Du Pont of Canada Limited, head office, Montreal, to the position of design engineer at the Maitland, Ont., works of the company. Mr. Currie resides in Brockville, Ont.

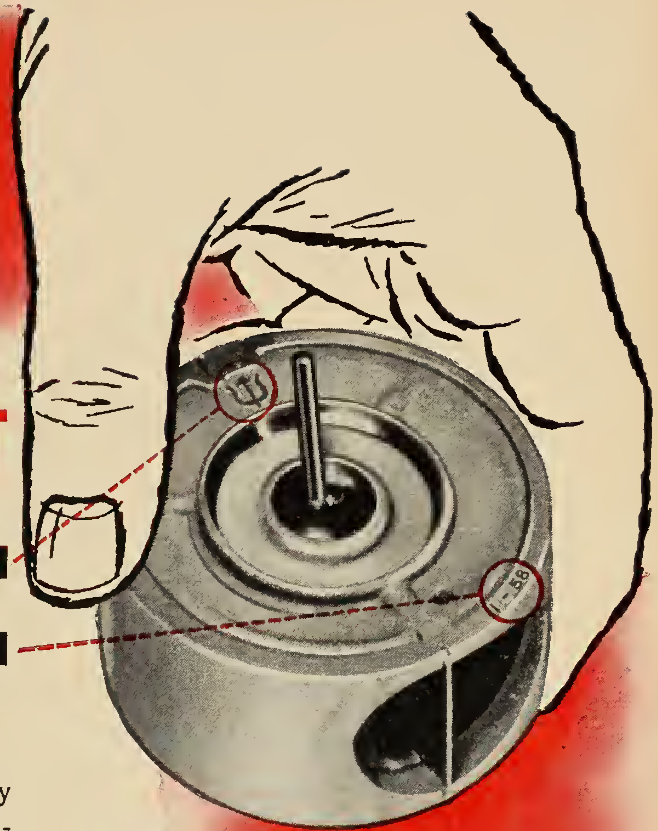
W. G. Gerry, JR.E.I.C., (B.A.Sc., mech., Toronto, 1951, M.Sc., soil mechanics, Colorado State, 1952), has been named to the staff of R. C. Thurber and Associates Ltd., Victoria, B.C. Mr. Gerry has had previous engineering experience with Haddin, Davis and Brown, consulting engineers, Calgary, has operated his own consulting practice in that city and has been associated with the Saguenay-Kitimat Company at Kitimat, B.C.

Flight Lieutenant Paul F. McNichol, JR.E.I.C., (B.Eng., Nova Scotia Technical College, 1950), of the construction engineering branch, A.M.C., Ottawa, has been promoted recently to the above named rank from that of squadron leader.

E. A. Mahr, JR.E.I.C., (B.Sc., civil, Manitoba, 1951), has accepted employment with the Bell Telephone Company of Canada as an engineer. His earlier professional experience included work with the Bituminous Paving Company Limited, Toronto, and the Central Mortgage and Housing Corporation.

Albert Nakash, JR.E.I.C., (B.Sc., civil, New Brunswick, 1952), has founded a construction company under the name of Nakash and Fong Yee Engineering Company Limited, at Kingston, Jamaica. This development in his career follows experience gained with Sprostons (Jamaica) Limited also at Kingston.

G. F. Buck, S.E.I.C., (B.Sc., civil, Alberta, 1958), has accepted employment with the Canadian Pacific Railway as an engineer in bridge design at Montreal.



Every TRIDENT Unit Identified and Dated

Trident water meters are precision instruments . . . every part made to extremely close tolerances . . . every material carefully selected and tested to give longest life in *your* water system.

Most important, every improvement made in new Trident meters immediately becomes available in repair parts for your older meters. You re-order only the latest parts. As you replace worn, out-dated parts over the years, your Tridents are *automatically* modernized.

To protect you from substitutes . . . and to make sure you're getting the benefits of Neptune progress . . . the Trident trademark is put on most all Trident parts . . . and the *date* is put on every major Trident part. Take a look at these date marks. They show you how well Tridents last. They also show you how your older meters have been kept up to date over the years with improved Trident repair parts.

Insist on genuine Trident parts . . . and check to be certain.

for your protection

BAIE COMEAU

N. Lapierre, JR.E.I.C., *Secretary*

A SPECIAL MEETING was held in the Manoir Comeau on June 4, 1958, on the occasion of the visit of Dr. J. C. Read, of the British Thomson-Houston Company Ltd., Rugby, England.

Dr. Read joined the British Thomson-Houston Company as an apprentice in 1920, after service with the Royal Engineers in World War I. He worked on the first industrial rectifier built in England in 1926 and organized his company's rectifier division in 1947. Since that time he has held office as manager of the division.

He was responsible for the design of the multi-anode air-cooled mercury arc rectifier installation at the Baie Comeau plant of the Canadian British Aluminum Company which installation is the largest of its type in North America.

Dr. Read, who has travelled extensively, last year visited Moscow with a party of British engineers.

In two parts, the talk was concerned firstly with mercury-arc type rectifiers. Outlining the fundamental principle behind the operation of this type of unit, Dr. Read went on to analyze the various design features associated with rectifier construction, including vacuum preservation, cooling, and the merits of multi-anode versus single anode types of unit. An analysis of the conditions leading to "Backfire" was discussed. Dr. Read concluded his remarks on mercury-arc rectifiers by summarizing the factors which led to the establishment of the particular design of installation used for feeding the Baie Comeau potlines.

Second part of the talk was devoted to the theory and construction of the semi-conductor type of rectifiers with particular reference to germanium and silicon based units. Some of the problems of commercial production were discussed. Dr. Read concluded the talk by assessing the operational and economic limitations of the various types of rectifier unit with particular reference to suitability for use in different sizes of aluminum reduction plants. In this connection he referred to a new plant under construction in France, where germanium rectifier units would be used for 500 volt pot-lines of 100,000 amp. capacity.

It was agreed that Dr. Read's talk, although highly specialized, had been of great interest to members and had provided the most stimulating medium of discussion to date.

Premier L. M. Frost and Professor D. M. Andrews of Great Britain are shown taking part in the opening ceremonies for the new University of Toronto sub-critical reactor held there on June 19, 1958. The reactor which has been installed in the Wallberg building of the University, on College Street, takes up a large part of two floors.

TORONTO

D. S. Moyer, JR.E.I.C., *Sec.-Treas.*

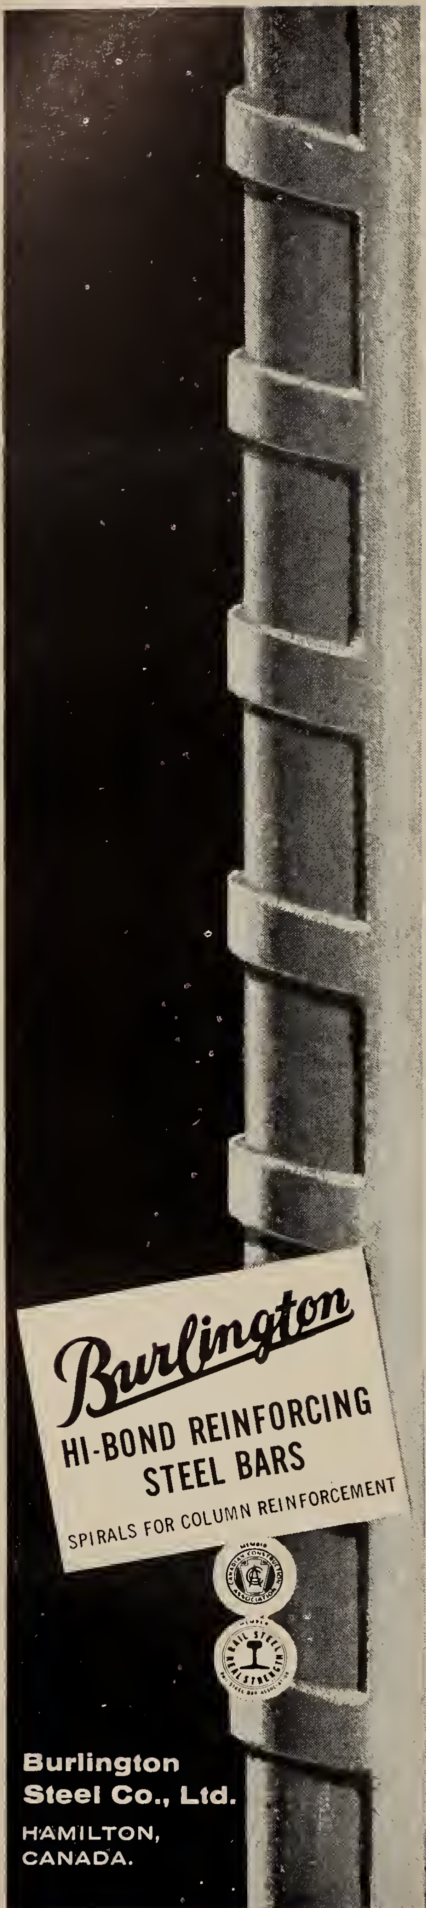
A. C. Davidson, M.E.I.C., *Branch News Reporter*

A $439,000 SUB-CRITICAL REACTOR WAS inaugurated at the University of Toronto on June 19, 1958, with the Hon. L. M. Frost, Prime Minister, Province of Ontario as guest speaker.

The educational purpose to be served by the sub-critical reactor is to provide an opportunity for graduate engineers to study the principles basic to atomic reactors and to gain some experience in the application of those principles by actual experimentation. By definition and design the reactor cannot become "critical", and hence is perfectly safe for instructional purposes. It has limited, but nevertheless significant research potentialities.

In harmony with the policy of Atomic Energy of Canada Limited, it is of the natural-uranium heavy-water type.

It consists essentially of a five-foot diameter tank filled with 700 gallons of heavy water in which are set over one hundred aluminum-sheathed natural uranium rods (three tons) arranged in the form of a lattice, the shape of which may be varied. To provide the necessary neutron concentration a radioactive source is placed when required, directly under the tank and the resulting neutron flux



at various points within the reactor, determined. Such measurements require the use of counting equipment housed in a separate room especially designed for the purpose.

So far as operation and control is concerned, the behavior of a reactor when it is "critical" can be simulated by electronic devices. Such an assembly is available so that students can see, so far as a control room would indicate, what occurs during the operation and control of a reactor during the approach to an arrival at criticality.

In addition to its basic cost of $439,000, of which $200,000 went for heavy water, the reactor will use three tons of uranium, worth $100,000, loaned by Eldorado Mining and Refining Limited, and a radium-beryllium neutron source obtained from Atomic Energy of Canada Limited.

Workings of the reactor were described by Professor Douglas Andrews of Great Britain who has supervised its construction and who will be in charge of its academic use.

Lt. Col. W. E. Phillips, chairman of the board of governors of the University of Toronto was chairman at the inauguration.

LAKEHEAD

George A. Walker, JR.E.I.C.,
Chairman, Publicity Committee

C. M. Cotton, JR.E.I.C., *Sec-Treas.*

THE ANNUAL MEETING of the Lakehead Branch of the E.I.C., was held June 4, 1958, in the Port Arthur Golf and Country Club.

A new slate of officers was presented for the coming year. V. B. Cook, retiring chairman passed the gavel to W. D. McKinnon, newly elected chairman, for a few comments.

J. A. MacLaren, field secretary of the Institute, and Mr. Halter, Lakehead representative to the annual council and general meeting of the Association of Professional Engineers of Ontario contributed interesting comment on the subject of confederation. This movement is followed with interest by the Lakehead group who note that progress is being made. It is also felt that the status of the professional engineer continues to grow in the eyes of the public.

NOVA SCOTIA TECHNICAL COLLEGE

John Devlin, S.E.I.C.,
Student Representative

THE E.I.C. PHOTO CONTEST: During the 1957-1958 term, a portion of the annual grant of $100.00, which the Institute gives to each university granting degrees in engineering, was used to sponsor an E.I.C. photo contest.

Entries to this contest consisted of a photo or photos taken by the student of an engineering project in Canada with which he was associated, together with a short write-up describing the subject. The contest was open to all students at the college, E.I.C. members, and others.

The entries were judged by a committee of faculty and students and the winner was awarded a cash prize of $10.00, which was presented by Professor Max Baker at the annual meeting of the Students' Society. The winning entry by Tom Jeary, senior, mechanical engineering, consisting of three colour photos of aircraft in flight, was reproduced in the N.S.T.C. yearbook, the "Tech Flash." The photos were taken at Gimli, Man., where Mr. Jeary underwent jet pilot training at the No. 1 Advanced Flying School, R.C.A.F., during the summer of 1957.

Placing second in the contest was S. H. James, also a senior, mechanical engineering.

Winner of an E.I.C. photo competition held at the Nova Scotia Technical College was Tom Jeary, senior mechanical engineer student.

The project was considered quite successful, and with the greater interest it helped to stimulate, a much larger and better contest is envisaged for next year.

SASKATCHEWAN SASKATOON SECTION

Reginald Bing-Wo, M.E.I.C., *Sec.-Treas.*

Roger Dupis, M.E.I.C., *Branch News Reporter*

THE PRAIRIE FIREBOARD PLANT at Saskatoon provided the subject for a tour of fifty members on June 5, 1958, following the dinner meeting.

J. E. Hanson, general superintendent in charge of production gave a short description of the operation of the plant. Following this members were guided around the enterprise. A special shift of employees were at work that members might see the plant in operation.

The Prairie Fireboard plant produces soft wallboard from poplar wood pulp.

July Meeting

At a July 5 luncheon meeting of the section J. Snelgrove, resident design engineer at the new Saskatchewan Power Corporation generating station gave a talk highlighting the major equipment of the generating station. After the talk Mr. Snelgrove guided the E.I.C. members through the generating station, pointing out major aspects of the unit. A report on the station was made by R. R. Keith before the annual meeting of the E.I.C. in June 1957.

Reports were also heard on the annual E.I.C. meeting held in Quebec City in June 1958, by Professor J. B. Mantle, of the University of Saskatchewan, and on the meeting of the "Canadian Council of Professional Engineers, held in Vancouver, by W. G. McKay.

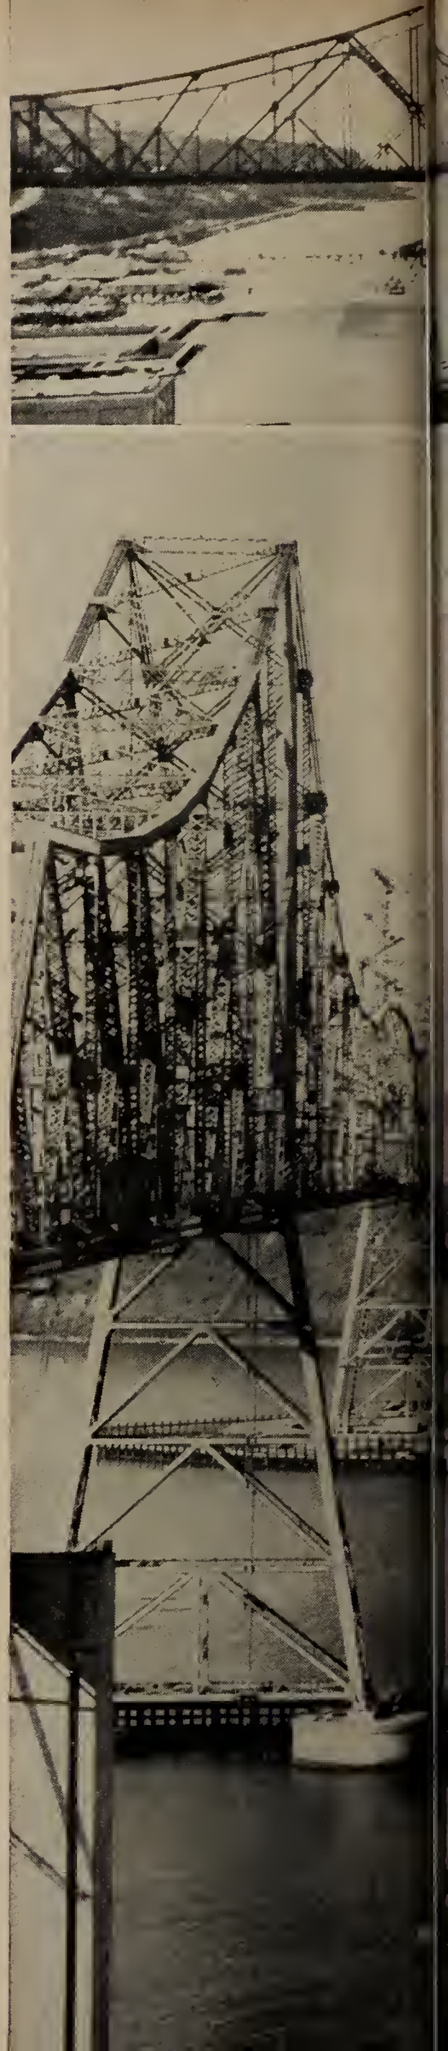
VANCOUVER ISLAND

J. A. Cowlin, JR.E.I.C., *Sec.-Treas.*

H. F. Coupe, M.E.I.C., *Branch News Reporter*

THE PACIFIC NAVAL LABORATORY, Esquimalt, B.C., was toured by the Vancouver Island Branch during May. Dr. W. L. Ford, superintendent of the laboratory delivered an address entitled, "The Role of the Pacific Naval Laboratory." Dr. Ford outlined the operation of the laboratory as a division of the Defence Research Board and explained that the problems dealt with involved investigation of underwater sound propagation, fluid dynamics, geomagnetism, paint and corrosion studies, and consulting work for various branches of the defence department in the Pacific coast area. Following Dr. Ford's talk the group was taken on a conducted tour of the laboratory by staff members to observe the equipment and facilities available for carrying out the laboratory's research program.

D. E. MacLean extended a vote of thanks to Dr. Ford and his staff on behalf of the engineers present for an extremely interesting evening.



News of Other Societies

CGA Meeting Held at Murray Bay

More than 400 delegates and guests attended the Canadian Gas Association's 51st Annual Meeting at the Manoir Richelieu, Murray Bay, Quebec, June 24/27. Dr. H. L. Purdy of Vancouver was elected president for the ensuing year, with N. E. Tanner of Toronto and R. C. McPherson of Calgary as vice-presidents.

Robert W. Otto, president of the American Gas Association, the guest speaker, said U.S. gas reserves had reached a new high in 1957 of some 46 trillion cubic feet and the number of gas appliances in use at year's end approached 100 million. There were 31 million gas consumers in the U.S.

There were many signs that the larger gas appliance manufacturers in the U.S. were preparing to come forward for the first time with a complete line of gas appliances.

E. D. Loughney, senior vice-president B.A. Oil Co., and newly elected director of the Association, pointed out that over the past decade the petroleum industry has spent some $3.2 billion, of which only $1.9 billion had been recovered to date.

Referring to the Gordon Commission's prediction that oil and gas will fill 70 per cent of the nation's expanded energy needs by 1980, Mr. Loughney warned that if the industry had to wait 25 years to market the tremendous reserves already formed, the industry would never mature. He added that if markets are available the industry felt that more than 100 trillion cubic feet could be discovered over the next 25 years.

CTA Meets in Toronto

The Canadian Transit Association held its 53rd annual meeting at Toronto on June 8-11 this year. T. D. Robertson, treasurer, Montreal Transportation Committee was elected president of the association for the forthcoming year, with D. L. MacDonald, superintendent, Edmonton Transit System as vice-president.

General manager H. E. King reported membership included 32 operating member companies, 68 associate member companies and five associates. Revenue passengers carried by 28 operating companies for 1957 totalled 1,043 million, down 3.32% from the previous year. Two companies had reported increases; 13 had reported decreases of 5% or less; 12 companies had reported decreases of from 5% to 10% and one company a decrease of over 10%. Passenger revenue decreased by 2.45% compared with 1956, while combined operating expenses reported by 28 companies showed an increase of 5.82% over the previous year. Ten out of 31 cities served had reported increases in fares during the past year.

The Canadian National Committee of the World Power Conference: back row, left to right: Dr. B. G. Ballard, M.E.I.C., H. L. Briggs, M.E.I.C., L. O'Sullivan, M.E.I.C., D. Cass-Beggs, M.E.I.C., Dr. L. A. Wright, HON.M.E.I.C., A. Ignatieff, R. E. Heartz, M.E.I.C., W. E. Uren, N. Webb, M.E.I.C., Hon. E. E. Fournier. Front row, left to right: T. M. Patterson, M.E.I.C., honorary secretary, D. M. Stephens, M.E.I.C., G. Gale, M.E.I.C., H. Crombie, M.E.I.C., H. Young, M.E.I.C., A. W. Manby, M.E.I.C., and F. L. Lawton, M.E.I.C. (Please refer to Page 78 of this issue for information about the Canadian meeting.)

CALENDAR

Fifth Upadi Convention
Fifth convention of the Union of Panamerican Engineering Associations (UPADI), Queen Elizabeth Hotel, Montreal, September 2-6, 1958.

World Power Conference
Canadian Sectional Meeting, Montreal, September 7-11, 1958.

Sixth International Congress on Large Dams, Hotel Statler, New York City, September 15-20, 1958.

Chemical Institute of Canada
Western Regional Conference, University of Manitoba, Winnipeg, Man., Sept. 4-6.

Society of Chemical Industry
Annual meeting. Includes meeting of American Section and Chemical Industry Medal Award (Sept. 18). Royal York Hotel, Toronto, Ont., and Montreal, Sept. 14-23.

American Institute of Chemical Engineers
38th National Meeting. Hotel Utah, Salt Lake City, Utah. Sept. 21-24.

Community Planning Association National Planning Conference 1958, King Edward Sheraton Hotel, Toronto, Sept. 21-24. Write: C.P.A.C., 77 MacLaren St., Ottawa 4.

Canadian Good Roads Association
C.G.R.A convention, Canada's 39th "Parliament of Roads," Queen Elizabeth Hotel, Montreal, Que., Sept. 30-Oct. 3. Write: C.G.R.A., 270 MacLaren St., Ottawa.

National Northern Development Conference
Edmonton, September 17-19, 1958; sponsored by the Edmonton Chamber of Commerce and the Alberta and Northwest Chamber of Mines and Resources. The speakers will include several well-known members of the E.I.C.

At left; Westeel's "Richmond", free-standing partition. At back and right; Westeel's movable "Hudson" partition.

BOOK REVIEW

HYDRO-ELECTRIC ENGINEERING PRACTICE

These three volumes are recommended by the publishers as authoritative sources on modern British and Continental Hydro-Electric design, construction, operation and maintenance, and include the work of some twenty-five specialist contributors chosen principally from the staff of well known British firms engaged in Hydro-Electric engineering.

It is understood that the work has taken ten years to complete. The scope of the three volumes is impressive and represents one of the most comprehensive treatments of the subject produced. The text refers primarily to British and to a lesser extent Continental practice. Whilst it has not been possible to cover all subjects in full detail, the extensive bibliographies given throughout the book should lead the reader to further information on any specific problem encountered. Some indication of the contents of each volume is given in the following notes:—

Volume I is concerned primarily with Civil Engineering aspects, and is divided into three sections. The first deals with "Preliminary Hydraulic Considerations" and covers rainfall and run-off, flow measurements, hydraulics and hydraulic models. The second section is on "Planning of the Scheme" and refers to basic principles of development, overall design and site investigations. The third section forms the major part of the volume and is entitled "Design and Construction of Civil Engineering Works". This includes chapters on dams of all types, spillways, intakes, outlet works, canals, tunnels, pipelines, surge and water hammer, power stations, aesthetic design of hydro-electric structures, and finally, a chapter on the problem of fishery interests.

Volume II is concerned with Mechanical and Electrical Engineering, and is divided into four sections. The first is on "Turbines", the various types, governing and testing. The second section covers "Generators", general arrangement, performance and testing, construction, etc. The third deals with "Control and Transmission Equipment" and covers transformers, switchgear, cables and transmission, and the final section is on "Power Station Planning" and includes planning and layout with specific reference to pumped storage schemes.

Volume III is entitled "Economics, Operation and Maintenance". Under "Economics" the first section, a review of world resources is followed by details of cost analysis, combined operation of hydro and thermal plant, pumped storage schemes and multi-purpose projects. Chapters are included on storage, load prediction and planned development and reports. The second section covers various aspects of maintenance and management, and three appendices are added on wind power, medical aspects of reservoir construction and nuclear power.

The books are well presented and bound, and should find a place on the bookshelf of all Hydro-Electric Engineers. (Ed. by J. Guthrie Brown. Glasgow, Blackie, 1958. 3 vols., 19 guineas.)

R. E. Coxon,
Shawinigan Engineering Co. Ltd.

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m. — 5 p.m.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

AIDE-MEMOIRE DUNOD: MECANIQUE-PHYSIQUE GENERALE

This sixth edition of a useful handbook has been brought up to date, and includes condensed information on mechanics and vectors, kinematics, statics, dynamics, gravity, fluid mechanics, thermodynamics, and vibration and acoustics. (M. Denis-Papin. Paris, Dunod, 1958. 270p., 480fr.)

*AIR CONDITIONING AND REFRIGERATION

Based on the second edition of the authors' "Heating, ventilating and air conditioning fundamentals", this volume has been considerably rewritten, and in addition contains an added chapter on fluid flow. Emphasis is placed on practical application and problems are included involving the design of an air washer, of hot water heating systems, fan duct systems, and all-year air conditioning systems. (W. H. Severns and J. R. Fellows. New York, Wiley, 1958. 563p., $10.25.)

*ANALYTICAL PHOTOGRAMMETRY

A general analytical treatment of photogrammetry. It begins with the definition of a point in connection with an exposition of the geometric laws of perspective and concludes with the equations for the determination of the position, spatial configuration, and orientation of an irregular object surface without object space control. To provide a general geometric understanding of the basic problems of photogrammetry, explicit and iterative equations are developed for the single and multiple camera stations. (E. L. Merritt. Toronto, Pitman, 1958. 242p., $7.50.)

ALUMINIUM IN BUILDING

The increasing use of aluminum in the building and allied industries has prompted the publication of this book which attempts to bring together the available information on the subject.

After an introductory chapter giving the history of the production of aluminum and its properties, the author

• LIBRARY NOTES

considers its architectural applications as ornaments, wall facings, in entrances and store fronts, doors, partitions, stairways, etc. The use of aluminum in windows and as roofing and cladding is also discussed. The following chapters consider structural aluminum and aluminum buildings, and general applications in piping, kitchen fittings, heating and air conditioning, lighting, etc.

The two final chapters cover the practical aspects of fabrication, forming, machining, riveting, weldings, brazing, etc., of aluminum, and its durability, protection and finish. There are numerous illustrations and a five-page bibliography. (E. I. Brimelow. London, Macdonald, 1957. 378p., 42/-.)

L'AUTOMATIQUE DES INFORMATIONS

An introduction to the principles of automatic machines, especially computers, written by an expert on the subject.

After an introductory chapter to the whole subject of automation, the other topics covered include: the principles of numerical representation; the structure of an analogue computer; the coding of information; the construction of an automatic digital computer, etc.

This is the ninth volume in the series "Evolution des Sciences" issued by this publisher. (F. H. Raymond. Paris, Masson, 1957. 185p., 1600 fr.)

BETON-KALENDER, 1958

The first part of the 1958 edition of this well known handbook contains new tables for uniformly loaded square slabs, and the necessary calculations for road bridges, including DIN 1078.

There are more changes in the second part, where the articles on the following topics have been revised and enlarged: prefabricated building parts of concrete and reinforced concrete; building construction; road construction; superstructures; concrete and reinforced concrete pipelines. (Ed. by Georg Ehlers. Berlin, Ernst, 1958. 2 vols., 19.20 DM.)

CHEMICAL ENGINEERING PRACTICE; V. 4 FLUID STATE

The fourth of a projected series of twelve, this volume is the first of two dealing with chemical engineering operations and processes involving fluid systems.

The book is divided into three sections, the first of which deals with the thermodynamics of physical systems; first and second laws, definitions of thermodynamic functions, properties of mixtures, Joule-Thomson effect and liquid flow, and compression and refrigeration. The second section covers the transport properties of fluids, including fluid statics and dynamics, the flow of viscous fluids, turbulence, boundary layers, flow in ducts, tubes and channels, flow around objects, and the flow of compressible fluids. The last section considers the measurement of pressure, fluid flow and temperature.

Five experts have joined in the writing of this volume. (Ed. by Trefor Davies. Toronto, Butterworth, 1957. 623p., $17.50.)

A GUIDE TO PLASTICS, 2ND ED.

The rapid developments in the plastics industry since the first edition of this book was published in 1951 have prompted the publication of this second edition which has been largely rewritten.

The author describes the different types of plastics and their manufacture, the raw materials used, and the fabrication of finished goods from plastic materials. There are 17 flow charts showing all stages of manufacture of the main categories of plastics, and a list of British Standards on plastics. (C. A. Redfarn. Toronto, British Book Service, 1958. 150p., $4.25.)

*HIGH SPEED DATA PROCESSING

Covers high speed data processors of all types and all manufacturers. There is a detailed study of coding and programming with special emphasis on the value of flow charts in the analysis of

problems. A variety of examples and illustrations are given for typical applications in the major fields. Recent aspects are discussed such as overall reliability and checking of results, use of large random-access stores, and form of files. (C. C. Gotlieb and J. N. P. Hume. Toronto, McGraw-Hill, 1958. 338p., $10.95.)

HUMOR IN DER TECHNIK, BAND 3

This is a collection of anecdotes and jokes in verse and prose, drawn from all branches of technology, and about well known men of science. There are also numerous cartoons. (Comp. by Walter Haas. Essen, Vulkan-Verlag Dr. W. Classen, 1958. 317p., 17.60 DM.)

HYDROMECHANIK

This book, a translation from the Russian, describes the basic problems of technical hydromechanics, with complete mathematical examples. The author relies on the classical analytical methods and basic equations of Euler and Bernouilli, founders of modern hydromechanics, and also gives the latest results of work in this field.

The book is a text for Soviet colleges of water transport, adapted for the German reader, and gives the basic knowledge of hydromechanics required by engineers and technicians interested in waterworks, pipelines and shipbuilding. (M. J. Alferjew. Leipzig, Teubner Verlagsgesellschaft, 1958. 226p., 11.30 DM.)

*INTERNATIONAL ASSOCIATION FOR BRIDGE AND STRUCTURAL ENGINEERING: PUBLICATIONS. VOLUME 17, 1957

Papers dealing with a variety of bridge and structural engineering problems such as the impact resistance on prestressed concrete masts, a general theory of deformations and membrane shells, a theory of prismatic folded plate structures, influence surfaces for moments in continuous slabs over flexible crossbeams, and stress and strain in thin shallow spherical calotte shells. (Zurich, Verlag Leeman, 1958. 268p., 38 DM.)

*AN INTRODUCTION TO THE DYNAMICS OF AIRPLANES

Presents the basic principles and ideas underlying airplane dynamics problems involved in aircraft design, construction, and operation. Because of the importance of vibration problems, the first third of the volume is devoted to this topic while the rest is devoted to aeroelasticity, impulsive loading, flight stability, and miscellaneous problems. (H. N. Abramson. New York, Ronald, 1958. 225p., $4.50.)

*THE MEASUREMENT OF COLOUR

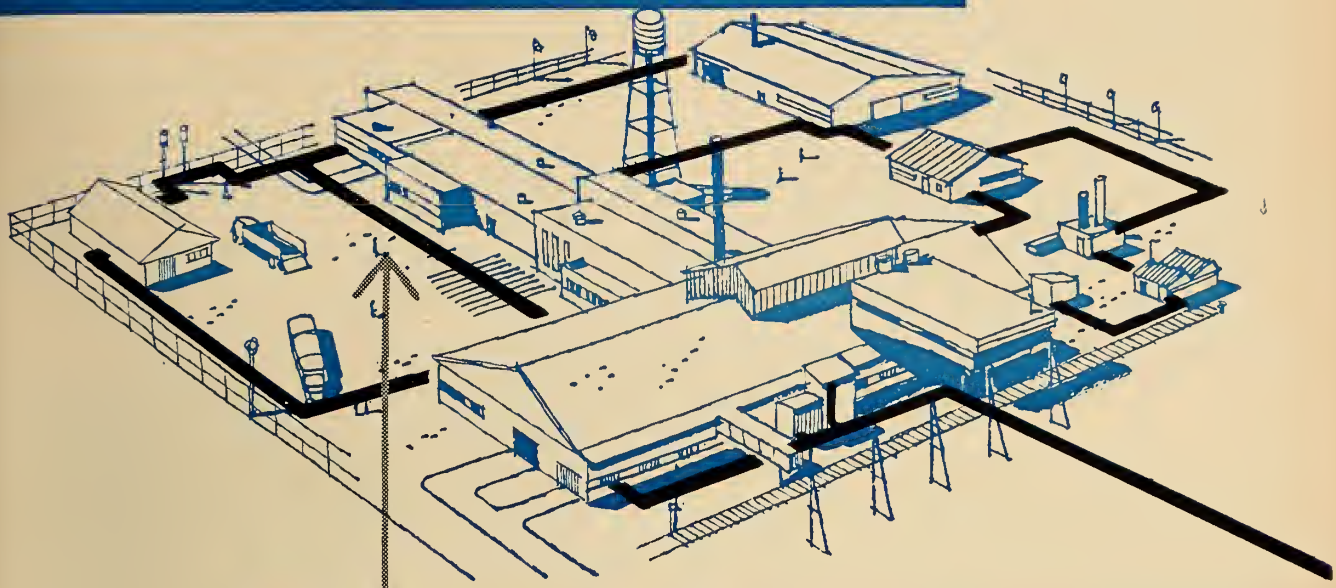
Describes the principles, methods, and applications of the trichromatic system of colour measurement. Areas covered are radiation in the visible spectrum; principles of photometry and colorimetry; colorimeters and spectrophotometers; colour spacing and the colour atlas; colour mixture data applied to three colour reproduction; practical applications of colorimetry. (W. D. Wright. Toronto, Brett-Macmillan, 1958. 263p., $10.75.)

MECANIQUE APPLIQUEE. T.1 MECANIQUE DES FLUIDES

The first of two volumes intended to give students the general basic theories of applied mechanics, this work is concerned with fluid mechanics, treating the subject more as a branch of physics than mathematics.

It covers such topics as the statics and kinematics of fluids, dynamics of viscous fluids, flow in conduits and channels, theory of lubrication, dynamics of compressible fluids, aerodynamics and experimental fluid mechanics. (R. Ouziaux and J. Perrier. Paris, Dunod, 1958. 466p., 2800fr.)

THE MODERN WAY TO TRANSMIT POWER



UNDERGROUND CABLES *protected by*

GENUINE
Cornwall Fibre Conduit

permanent protection against:—

- SHEATH ABRASION
- PULLING TENSION ON CABLE
- INFILTRATION OF GROUND WATER
- ACID AND ALKALI CORROSION

With the installation of underground cables in industrial locations, plant appearance is greatly improved, obstructions are removed for easier materials handling and the way is clear for plant expansion. When underground cables are protected by Cornwall Fibre Conduit you can be sure they are permanently safe.

Cornwall Fibre Conduit offers complete resistance to corrosion, abrasion and water seepage, and acids or alkalies will not leach out of, or through, this time-tested conduit. Cornwall Fibre Conduit has been providing excellent service in protecting power, telephone, television cables, commercial, residential and industrial installations across Canada for over 30 years. The long, light-weight lengths are easy to handle and it costs less to install than any other conduit.

So, for dependable, long-term service and economy specify Genuine Cornwall Fibre Conduit.

Send for illustrated catalogue showing applications and installation methods of Cornwall "Standard" (for use with Concrete) and "Nocrete" (for direct burial) Fibre Conduit including data on adapters, bend sections and other accessories. Write to your nearest Distributor.

Appointments and Transfers

Dosco Appointment—A. L. Fairley Jr. has been appointed executive vice-president and a director of the Dominion Steel and Coal Corporation; he will also serve as executive vice-president of the Dominion Coal Company, Limited and the Nova Scotia Steel and Coal Company, Limited, Dosco subsidiaries.

Executive Changes—Canadian Johns-Manville Co. Limited recently announced the following executive changes in the Canadian Products Division of the company: A. G. Sinclair has been appointed assistant general manager; L. M. Adamson becomes general sales manager for the industrial products and pipe sales department; F. A. H. Gallop has been made general sales manager, and G. A. Hall, product manager for the building materials sales department.

Senior Executive Appointments—The appointment has been announced of W. S. Wyman as president of Linde Air Products Company, division of Union Carbide Canada Limited, and of G. W. Patterson as president of National Carbon Company, also division of Union Carbide Canada Limited.

W. S. Wyman

Canadian General Electric—C. E. Hipp has been elected to the board of directors of Canadian General Electric Company Limited, and W. H. Pipe has been appointed secretary of the company.

Aluminum Company—D. W. Evans has been appointed general chemical manager of the new chemical division of the Aluminum Company of Canada Limited, and R. T. Hyland has been made assistant general sales manager, Canadian sales.

Sales Appointments—Canadian Liquid Air Company has announced the appointment of P. Fleming as branch sales manager, Toronto, and J. Saul as manager of gas sales, head office, Montreal.

Simon Engineering—P. N. Veale has been appointed manager of the Montreal offices of Simon Engineering Companies of Canada Limited; W. J. Hopkins has relinquished his post as managing director of the Canadian company to take up a new appointment with the parent company, Simon Handling Engineers Ltd., of Cheadle Heath, England.

G. W. Patterson

P. N. Veale

The Canadian company is concerned in the design and supply of materials handling and storage plants specializing both in the fields of pneumatic and mechanical handling in industry and for port equipment.

Aeroquip (Canada) Ltd. — The appointment of D. A. Rumgay as vice president and general manager has been announced by Aeroquip (Canada) Ltd. Mr. Rumgay was formerly assistant general manager and he succeeds R. W. Bowman, who was acting general manager since the formation of Aeroquip (Canada) Ltd. several years ago. Mr. Bowman has been promoted to another position with Aeroquip Corporation.

B.C. Electric — H. J. Merilees, public information manager of the B.C. Electric Company Limited since 1946, has been appointed executive assistant.

Canadian Westinghouse — The appointment of A. A. McArthur as manager, apparatus sales for the Canadian Westinghouse Company Limited, has been announced. Mr. McArthur, who will be responsible for operations of the company's utility, industrial, and aviation, marine and transportation sales departments, will also provide assistance to the vice president in charge of apparatus and industrial sales, in the commercial activities associated with the development of these markets.

Aluminium Laboratories—A. E. Edwards has been appointed director of research for Aluminium Laboratories Limited, Montreal, succeeding R. H. Rimmer, vice president of the company, who has retired after 36 years of service.

C-I-L Appointment — J. F. C. Dixon has been appointed research manager of the explosives division of Canadian Industries Limited.

J. F. C. Dixon

News of Business and Industry

Plant Facilities Expansion — Barber-Greene Canada, Ltd., Don Mills, Ont., recently completed the expansion of both the physical facilities of their plant and their line of products, which will now include portable and permanent belt conveyors, and certain of the company's ditchers, asphalt mixing plants and railroad car unloaders. The plant was established in 1952 and since then has produced many components of the Barber-Greene line of standardized belt conveyors. The newly completed expansion incorporates a wide range of machine tools, welding, shot blasting and other fabrication machinery, enabling the plant to manufacture in its entirety, any of the Barber-Greene line of conveyors, construction equipment or material handling machines.

High-Speed Graders — A 25-page illustrated brochure giving a description of the design and construction of seven Adams high-speed graders has been produced by LeTourneau Westinghouse Company. Adams heavy-duty graders have an 8-speed constant-mesh transmission, providing eight standard forward speeds and four reverse speeds. For wider speed range, three creeper gears are available — making a total of 15 full-power speeds — in Adams 660, 550, 440, and 330 graders. Copies of the brochure are available through local LeTourneau Westinghouse distributors.

U.S. Products Marketed in Canada — Analogue Controls Inc., Mineola, New York, have announced that their products will be marketed exclusively in Canada by Philips Electronics Industries Ltd., Toronto, Ont. Analogue Controls are manufacturers of high precision potentionmeters, both single and multiturn types. Trigonometric functions are offered to conformities of .015% and linear functions are offered to accuracies of .002%. All models are designed to meet aircraft and missile environmental specifications. Literature is available on request.

Thorium Recovery Plant Contract — The contract for the engineering and construction for what is believed to be the world's first thorium recovery plant has just been awarded by Rio Tinto-Dow Limited to Humphreys and Glasgow (Canada) Limited. The plant will be located on a site adjacent to the Algom Quirke Mine at Blind River, five miles north of Elliott Lake. Humphreys and Glasgow will be responsible for the design engineering and construction of the plant itself and for the installation of the special equipment and machinery needed for the processing of thorium concentrates, thorium sulphates and thorium oxide.

New Dominion Corporation — Allied Chemical Canada, Ltd., a newly established Dominion corporation, have announced that they will be responsible for the conduct and future development of a business backed by an investment in Canada of more than $50 million. Effective on June 1, 1958, Allied Chemical Canada, Ltd., is the successor to the chemical, building materials and related businesses of five long-established Canadian companies: The Barrett Company Limited; Brunner, Mond Canada, Limited; National Aniline & Chemical Company, Limited; The Nichols Chemical Company, Limited, and Semet-Solvay, Limited. Head office of Allied Chemical Canada, Ltd., will be located at 1450 City Councillors St., Montreal.

New Pressure Pipe Plant — The Pressure Pipe Company of Canada Limited, a member of the Canada Iron group, recently opened their new metropolitan Toronto plant at 60 Vulcan Street, Etobicoke. Visitors to the modern 100,000 sq.

ft. Pressure Pipe plant saw the latest in machinery and equipment for manufacture of Hyprescon reinforced concrete steel cylinder pressure pipe and prestressed concrete steel pressure pipe.

Pressure Pipe Company of Canada Limited supplies Ontario and western provinces with pipe and fittings for water and sewage transmission service.

In business since 1932, the company has supplied pipe to municipalities and industries from Halifax to Vancouver. A plant in Montreal serves eastern Canada. Both plants have large storage areas for Hyprescon, available in diameters from 16 in. to 84 in.

Rocol Sales Canadian Export Drive — J. G. Gershon, sales director of Rocol, Ltd., a British firm which develops and manufactures molybdenised and other specialised lubricants for industrial purposes, recently made a two-week's intensive tour of Canada to establish Rocol selling agents.

"Robot" Representation — Canadian Applied Research Limited, Toronto, have announced the completion of arrangements to represent Robot Berning and Co., Dusseldorf, West Germany, manufacturers of fine cameras and accessories. The agreement covers sales and service for Canada in the industrial and scientific fields. The "Robot" cameras have a reputation for engineering and dependability in the amateur and scientific camera field. A complete range of automatic accessories, both mechanical and electrical, inter-changeability of attachments and lenses, is said to make the "Robot" camera the most versatile available on the Canadian market.

Publications

Flame-Cutting Machines — A complete line of "Oxweld" flame-cutting machines are described in a 28-page catalogue available from Linde Air Products Company, Division of Union Carbide Canada Limited. They range in size from small portable models that can be carried around a shop by one man to large multi-blowpipe shape-cutting machines. Also included are complete specifications, illustrations of typical installations, and a description of accessories such as automatic and magnetic tracing units.

Drop Forgings — The Steel Company of Canada, Limited have recently issued a new bulletin entitled "In-formation". This bulletin has been produced to reach those who design, specify or use parts which can be made by the drop forgings process. It will be published quarterly, and sent at no cost to those requesting it.

Air Conditioner Thermostat — The new Robertshaw model "EA4" electric thermostat, a single-pole, single-throw, reverse-acting unit for air conditioners, refrigeration and heater applications, is described in a new bulletin, RT-802, issued by Robertshaw-Fulton Controls (Canada) Limited. Bulletin RT-802 includes a detailed cut-away drawing and installation data, and is available on request.

Skimmer Centrifugal Dust Collector — A new bulletin has been introduced describing the AAF Skimmer dust collector, a centrifugal precipitator. Bulletin 276 (available without charge) includes drawings and photographs which show the AAF Skimmer construction, dimensions, and different arrangements. American Air Filter of Canada Ltd.

Vacuum Arc Furnace — An eight-page publication issued by Canadian General Electric Company Ltd. emphasizes savings in cost and space, reduced maintenance, maximum utilization and manufacturing quality made possible by vacuum-arc melting as a production technique. The three-color bulletin describes the principle used in designing such furnaces and discusses in detail the components, controls and instrumentation of General Electric's vacuum arc furnaces for laboratory, pilot plant and production operations. Cutaway view illustrates key features of the furnace.

Moulded Packing — A new illustrated moulded packing catalogue, No. PK-126A, which describes the design and construction of J-M moulded packings for hydraulic and pneumatic applications, is now available from Canadian Johns-Manville Co. Limited. This catalogue features a cross-section illustration of each available moulded design and gives specific data for rod and plunger applications.

Tellurium Copper — Noranda Copper and Brass Limited have issued a brochure describing the recently developed Noranda tellurium copper. This new alloy contains 99.5% copper and 0.5% tellurium. Noranda states that the addition of this small amount of tellurium has the effect of improving the machinability rating to 90, as compared with 20 for electrolytic copper.

ASEA Journal—The ASEA Journal, the house organ of Canadian ASEA Electric Limited, has been modernized, coinciding with the 75th anniversary of the founding of ASEA. A fresh layout with colour photographs has been adopted

• BRIEFS

and a diversified content will be presented reflecting the widely differentiated activities of the company.

"Franki Facts"—This booklet is mailed six times a year by Franki of Canada Ltd., and each issue deals with a case history taken from various Franki jobs across Canada. All back issues are available.

Lightweight Aggregate Concrete — A 20-page brochure published by The Master Builders Co. illustrates the wide use of lightweight aggregate concrete in modern construction. Photographs and job stories present a clear picture of the wide variety of uses for this relatively new building material. Thirteen construction projects are featured with discussion covering the use of lightweight concrete as a strong, durable structural material for columns, beams and floor slabs, and in multi-story structures, thin shell concrete and bridge decks.

"Products and Processes" — The 1958 edition of "Products and Processes" produced by Union Carbide Canada Limited, has recently been released. The publication describes the varied fields of interest of the company: alloys and metals, carbon products, chemicals, industrial gases, and plastics.

New Aircock Literature — Peacock Bulletin PAC-383, gives up-to-date information and specifications covering the complete line of Peacock aircocks. Spring-loaded inverted-plug aircocks are illustrated with standard screwed or victaulic ends. Lubricated plug cocks for general mill and mine service are also included in the bulletin, which is available free. Made in Canada, these aircocks are available in sizes from ¾" to 4" and are stocked at strategic locations from coast to coast.

New Data Book For Oil Explorers — The use of Kodak linagraph materials in seismic methods of oil exploration is the subject of a new data book, "Kodak Materials for Geophysical Exploration." The 32-page booklet includes a complete description of Kodak linagraph papers, films, and chemicals, plus information on other related products used for geophysical exploration. Also in the booklet are sections on basic processing data, record duplication, storage and handling of photographic materials, and information on how to order materials. The reader will also find a section on helpful hints for processing under field conditions.

Practical Rules on Lightning Safety — The hazardous antics of lightning and means of protecting life and property against this destructive force are contained in a new booklet, "Lightning Facts and Figures," prepared by the Lightning Protection Institute, Chicago, Ill. The colorful, liberally illustrated booklet, easy to read and understand, is available free upon request. It explains

• BRIEFS

in detail how lightning "happens"; how often it is likely to strike in an area; how individuals as well as homes, schools, churches, farms, commercial, industrial, civic buildings and other structures can be protected against lightning loss or damage.

Motor Pulley Drives — A 30-page catalogue, illustrating many actual applications of variable speed motor pulley drives, is now available. The Roto-Cone variable pitch motor pulley operates on a V to V principle. It utilizes an exclusive rack and gear arrangement which imparts a positive and equal linear movement to both pulley discs. Infinitely variable speeds can be changed while the equipment is in operation. Capacities range from fractional h.p. to 20 h.p. Speed ratios range up to 8:1.

New "Siporex" Folder — A new folder on "Siporex" masonry blocks is now available. "Siporex" is a precast cellular concrete combining structural strength with light weight, insulation, fireproofing and easy workability. It is manufactured as reinforced slabs for walls, roofs and floors, and as masonry blocks. The folder describes the properties of this precast building material and gives construction details. It is illustrated and provides detailed tabulations of weights, insulating values, laying dimensions, sound absorption coefficients and sound transmission loss.

Floodlighting — A new 48-page catalogue on floodlighting has just been announced by Canadian General Electric Company Limited, and is obtainable on request. This catalogue contains the latest information on incandescent and fluorescent lighting for a wide range of applications, such as sports fields, service stations, loading ramps, plant areas, industrial yards, advertising posters, fountains and architectural settings.

DISCUSSION *(continued from page 86)*

THE INTERNATIONAL GEOPHYSICAL YEAR

The Engineering Journal, August, 1958.

his second comment about the reduction, correlation and interpretation of data being a vastly greater job than merely taking the measurements. In the final analysis the important advances will be made by individuals or small groups who will apply these data to a great variety of specialized research objectives. Some of these will be accomplished quickly, some will take years. Every effort is being made, however, to see that all data can be made available to anyone who wants it. A description of the organization of World Data Centres would have added a lot more to this already lengthy paper.

CARDE I.G.Y. UPPER AIR RESEARCH PROGRAM

R. F. Chinnick

CARDE, Que.

The Engineering Journal, 1958, Aug. *p.61.*

B. O. Baker,† M.E.I.C.

I welcome the opportunity of congratulating Mr. Chinnick on his paper and to expand on a few of the structural design problems that he mentioned. The model is basically identical to the flying models and will be used for structural testing, design of packages, wiring harnesses, etc. As each experiment in this field is usually very special, there is little or no opportunity of obtaining an already proven body design. Due to the time element, we have little opportunity of production-engineering each design and in fact, if the design concept misses the requirement, little hope of meeting any time schedules exists. Therefore, this first model has been rushed through, to prove as much of the design as possible and permit other groups to design their equipment to suit.

One of the major problems, due to stringent weight and space limitations, is to provide suitable accessability for the Dovap and instrumentation packages, to permit check-out, servicing, etc.

The skin design of this nose cone is of particular interest. Two skins have been used, permitting insulation to be added to combat the transfer of heat from the outer skin. The inner skin is designed as a structural member and is dimensionally stable temperature-wise. The outer skin is designed to permit it to float with the expansions and contractions due to temperature changes. Stainless steel was chosen as the most readily available suitable material that would be easily fabricated.

†Superintendent, Design Wing, Canadian Armament Research Development Establishment, Quebec, Que.

How Franki Caissons overcame marshy, erratic soil conditions

The Franki Caisson

The Franki caisson is a pressure injected footing, with an expanded base forged by blows of 140,000 ft.-lbs. of energy.

In granular soils, the standard Franki caisson will carry a load of 120 tons or more.

The problem:

To erect a plant extension of a type capable of supporting concentrated, heavy loads such as those common to the huge travelling cranes employed by the Company in daily production.

The whole area, at one time a swamp, consists of erratic and lenticular formations of fill, mostly cinder, saturated peat and very soft, silty clay varying in thickness from 9′ to 34′, overlying a limestone bedrock.

The solution:

Due to this lack of uniformity and to the presence of very compressible layers of peat, spread footing type foundations were absolutely unsuitable.

The ability of Franki cast-in-place caisson piles (22″ Ø) to adapt to the bedrock variations, and their high carrying capacity (up to loads of 125 tons), were the main technical factors which, along with a substantial saving in costs, made the Company decide on the Franki solution to this difficult foundation problem.

Literature-This series of job highlights, as well as other descriptive literature, will be sent to you upon request to Franki of Canada Ltd.,

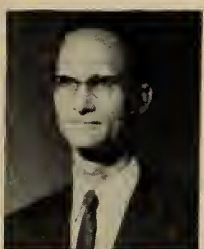
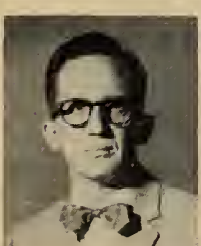
QUEBEC OTTAWA TORONTO EDMONTON VANCOUVER

MEET THE AUTHORS

L. H. Burpee, M.E.I.C., Deputy Chief Engineer, The St. Lawrence Seaway Authority, Montreal. *(Planning and Constructing the Lachine Section).* Mr. Burpee graduated from the University of Toronto (B.A.Sc., 1925), and during the early part of his career held positions with Quebec Hydro, Foundation Company of Canada Limited, W. S. Lee Engineering Corporation, Montreal Light Heat and Power Company, Beauharnois Construction Company, Gatineau Power Company, and The Hydro-Electric Power Commission of Ontario. Prior to joining the St. Lawrence Seaway Branch of the Department of Transport in 1952 Mr. Burpee was with Northern Construction Company and J. W. Stewart Limited for six years. He is a member of the American Society of Civil Engineers, The Corporation of Professional Engineers of Quebec, the Association of Professional Engineers of the Province of Ontario, and The Association of Professional Engineers of B.C.



F. L. Peckover, M.E.I.C., Senior Assistant Engineer (Soils), The St. Lawrence Seaway Authority, Montreal. *(Soil and Foundation Problems).* Mr. Peckover holds a bachelor's degree, civil engineering from the University of Toronto (1944). After two years with the National Research Council, he took leave to obtain a master's degree at Harvard University (civil, soils and foundations, 1947), returning to the Council's newly formed Division of Building Research as head of the soil mechanics section; he served as a member of the panel on foundations and excavations, National Building Code of Canada (1953), and as secretary, Associate Committee on Soil and Snow Mechanics. In 1953 he joined The St. Lawrence Seaway Authority, Montreal, and has since been in charge of the soil engineering section, engineering branch. He is an associate member of the American Society of Civil Engineers. *(Photo: Van der Aa.)*



T. G. Tustin, JR.E.I.C., Assistant Engineer (Soils), The St. Lawrence Seaway Authority, Montreal. *(Soil and Foundation Problems).* A graduate in civil engineering from the University of Alberta (B.Sc., 1948), Mr. Tustin did post-graduate study there (soil mechanics and geology), and has since undergone further post-graduate study in business administration at McGill University. He joined the Department of Agriculture in 1949 where he carried out foundation and design studies on the South Saskatchewan Dam. He joined the Columbia Cellulose Company, Prince Rupert, B.C. in 1952, carrying out watershed investigations, and has held his present position since 1954. *(Photo: Van der Aa.)*

J. V. Danys, M.E.I.C., Senior Soils & Foundation Engineer, St. Lawrence River Joint Board of Engineers, Canadian Section, Cornwall, Ont. *(St. Lawrence River Diversion by a Rockfill Cofferdam).* After graduating from the University of Vytautas the Great in Kaunas, Lithuania, in 1939 (civil engineering), Mr. Danys studied hydraulic engineering, soil mechanics and foundations at Munich Technical University, Germany for two years. He was associate professor of civil engineering with the University of Vytautas the Great for four years and later joined the Power Corporation of Canada Ltd., Montreal. Mr. Danys has been connected with the construction of the Power and Seaway Project in the International Section of the St. Lawrence River since 1955.

R. M. Fullerton, Project Engineer, Generating Stations, The Hydro-Electric Power Commission of Ontario, Toronto. *(Electrical Features of the Robert H. Saunders-St. Lawrence Generating Station).* Mr. Fullerton received the degree of B.Sc., electrical engineering, from the Nova Scotia Technical College in 1933, and engaged in electrical construction in the gold mines of Northern Quebec until 1937 when he joined the Northern Electric Company, Montreal. During the period 1938 to 1946 he was associated with the Saguenay Power Company at Arvida, Quebec., the Isle Maligne Generating Station, and the Aluminum Company of Canada, Arvida Works. Mr. Fullerton joined The Hydro-Electric Power Commission of Ontario in 1946; became electrical project engineer for the Otto Holden Generating Station in 1948. In 1952 he transferred to the R. H. Saunders-St. Lawrence Generating Station and in 1954 was appointed to his present position.

A. Matheson, M.E.I.C., Project Engineer, Stations Department, The Hydro-Electric Power Commission of Ontario, Toronto. *Features of the St. Lawrence Transformer Station).* Mr. Matheson graduated in electrical engineering from the University of Manchester in 1924 (B.Sc. (Tech.)), after which he spent five years with Ferguson Pailin Limited, England. He then came to Canada and joined the Canadian Westinghouse Company, Hamilton. In 1938 Mr. Matheson joined Bepco Canada Ltd., Montreal, and in 1940 moved to The Hydro-Electric Power Commission of Ontario, Toronto in the Transformer Stations Project Group of the Stations Department. He is a member of the Association of Professional Engineers of Ontario.

N. J. McMurtrie, Senior Design Engineer, Transmission Department, The Hydro-Electric Power Commission of Ontario, Toronto. *(Design of 230 kv. Transmission Lines).* A graduate in electrical engineering from the University of Toronto in 1945 (B.A.Sc. (E.E.)), and in business administration, 1957 (M.Com.), Mr. McMurtrie spent a year in the R.C.N.V.R. before joining Ontario Hydro in 1946. He was appointed to his present position in 1955. Mr. McMurtrie is a member of the Association of Professional Engineers of Ontario and an associate member of the American Institute of Electrical Engineers.

Major-General H. A. Young, C.B., C.B.E., D.S.O., C.D., M.E.I.C., Deputy Minister of Public Works, Ottawa, Ont. *(Development of Great Lakes Harbours).* General Young graduated from the University of Manitoba in 1924 (B.Sc., electrical engineering), and has spent a long and distinguished career in the Canadian Army. He served in both World Wars, and in 1946 was appointed vice-president of the Central Mortgage and Housing Corporation. In 1950 he became Deputy Minister of Resources and Development and Commissioner of the Northwest Territories, and in 1953 Deputy Minister of Public Works. General Young continues as a director of the Central Mortgage and Housing Corporation; he is a member of the board of governors of the Arctic Institute of North America; chairman, Canadian section of World Power Conference; and president, Royal Canadian Geographical Society.

Historic Inundation Blast at Cornwall Signals Final Stage of St.Lawrence Seaway and Power Project

Canada celebrates opening of key International Rapids Section for navigation, start-up of the Robert H. Saunders-St. Lawrence powerhouse as major engineering achievement nears completion

Loading "Nitrone" blasting agent at the cofferdam. Since some of the charges were placed as much as 3½ months before the July 1st blast, it was essential that they be unaffected by water. "Nitrone" which comes in hermetically sealed steel containers, was accordingly recommended by C-I-L Explosives Technical Service Representatives, seen in the picture above consulting with an Ontario Hydro blaster.

On July 1, 1958, a blast of 30 tons of "Nitrone" breached the cofferdam upstream from the giant new international powerhouse . . . second largest in North America.

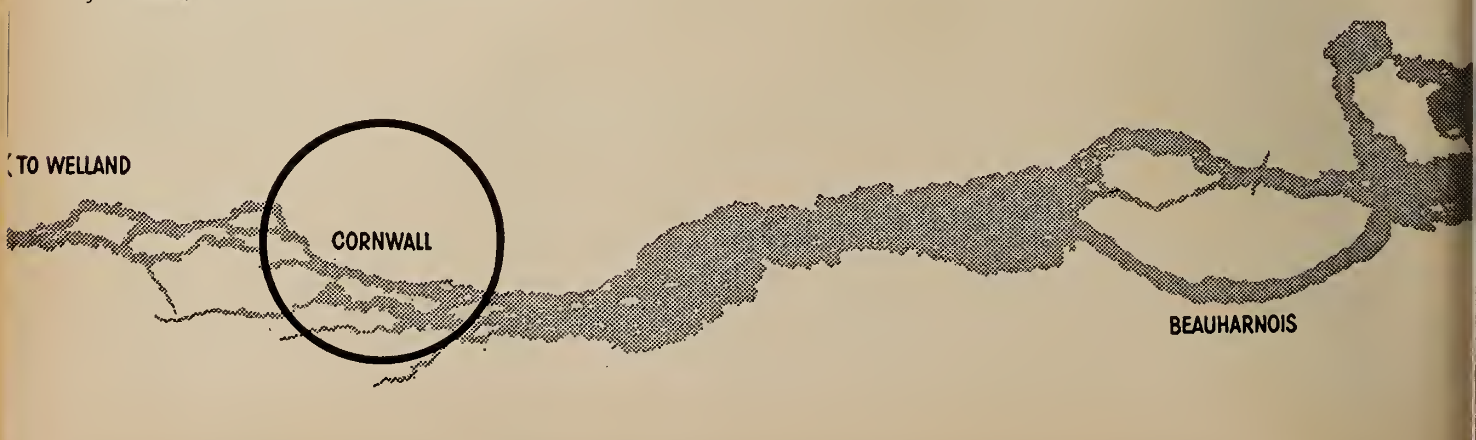
A 35-mile-long lake, ninety feet deep at the powerdam, today covers the site of former towns, villages and farms. The first of thirty-two generating units installed by Ontario Hydro and New York State Power Authority have begun to turn. And shipping will henceforth move through new channels and locks south of the power development.

Some 20,000,000 pounds of explosives used to date

"Inundation Day" climaxed four years' work on one of the world's greatest construction projects. From Montreal westward to the Welland Canal, some 20,000,000 pounds of C-I-L Explosives have been used to dredge and deepen channels; blast excavations for dams and powerhouses; quarry rock for tremendous quantities of aggregate for concrete.

Seaway blasting operations shape Canada's history

C-I-L Explosives have provided the "muscle". And C-I-L men have kept the right quantities of the right explosives moving at the right time to contractors' magazines; have worked with construction companies on big problems and small; have helped get work done on time, at lowest cost. C-I-L is proud to have served on one of the greatest undertakings in our country's history; one which will contribute greatly to Canada's growth and development.



The Construction Period 1954 to 1958

This review records the various agencies and the principal officers involved in the construction of the St. Lawrence Seaway and Power Project. A history of the Seaway from its inception and a record of many of the engineers associated with the project was published in the September 1956 issue of The Engineering Journal, together with several papers on various engineering aspects of the undertaking. A further comprehensive report on the progress of the development appeared in October 1957. Monthly reports have appeared since January 1955.

WITH THE FILLING of the headpond above the International Powerhouse at Barnhart Island near Cornwall during the first week of July, 1958, the billion dollar St. Lawrence Seaway and Power Project entered its final stage. In this special issue of *The Engineering Journal* to commemorate the event it is timely to record briefly the highlights of the construction period now drawing to a close. It is also fitting here to complete the historical review of the project published in our special issue of September 1956, by paying tribute to those engineers into whose capable hands the project passed in August 1954 at the time actual construction was commenced.

It will be recalled that with the passing of the St. Lawrence Seaway Act in 1951 by the Canadian Parliament, Canada had set up a Canadian Seaway Authority to build a seaway navigation channel entirely through Canadian territory, while the International Joint Commission, in October 1952, had approved joint development of the power project by Canada and the United States.

This challenging declaration of intention by Canada to build the navigation channels singlehanded had been instrumental in finally bringing about approval by the U.S. Congress for the joint navigation project, by passage on 13 May, 1954 of the Wiley-Dondero Act. This legislation authorized a U.S. government agency, the St. Lawrence Seaway Development Corporation, to undertake the navigation development through the International Section on the American side of the river.

International Joint Commission

At the time construction was commenced in August 1954, members of the Canadian Section, International Joint Commission, were the Hon. A. G. L. McNaughton, M.E.I.C., as chairman, with Col. J. Lucien Dansereau, M.E.I.C. and George Spence, AFFIL. E.I.C., as members. Dr. D. M. Stephens, M.E.I.C., succeeded Mr. Spence at the time of the latter's retirement in 1957. Members of the United States Section at the time the project was started were the Hon. A. O. Stanley, as chairman, with Roger B. McWhorter and Eugene W. Weber as members. Len Jordan replaced the Hon. Mr. Stanley in 1955, after the latter's retirement in 1954. (Mr. Stanley died on 13 August 1958, aged 91.) Mr. Jordan resigned in 1957 to be followed by Douglas McKay. Mr. McWhorter retired on 31 July 1958.

St. Lawrence River Board of Control

Responsible to the I.J.C. for regulation of the flows of the St. Lawrence is the St. Lawrence River Board of Control. Throughout the period of construction T. M. Patterson, M.E.I.C., was chairman, with J. B. Bryce, M.E.I.C., and Dr. René Dupuis as members, Canadian section. During early stages of construction G. A. Hathaway, U.S. Army Corps of Engineers, was chairman of the American Section, with Frances L. Adams and Bertram D. Tallamy as members. Present members are Brig. Gen. L. G. Rummagi as chairman, with Francis L. Adams and J. Burch McMorran as members.

Joint Board of Engineers

The St. Lawrence River Joint Board of Engineers, which supervises and co-ordinates the engineering of the four 'authorities' within the international and Thousand Island sections, was composed in 1954 of the Hon. Geo. Marler, Minister of Transport, and the Hon. Lionel Chevrier, president, Canadian Seaway Authority, with Max Sauer, M.E.I.C., as chief engineer and member and H. W. Lea, M.E.I.C., who had succeeded Brig. Archer as alternate member. Following Mr. Sauer's death in 1955 Mr. Kohl became chief engineer. Following a change in government in June 1957, the Hon. George Hees replaced Mr. Marler, and Charles Gavsie succeeded Mr. Chevrier as president of the Canadian Seaway Authority and as member of the Joint Board.

Seaway 'Authorities'

Charles Gavsie was himself succeeded in February 1958 by Bennett J. Roberts, C.B.E., at the time of Mr. Gavsie's retirement. Jean-Claude Lessard, M.E.I.C., was appointed in July as vice-president to fill the vacancy left by Mr. Gavsie's elevation to the presidency. C. W. West, M.E.I.C., has remained as a member during the entire construction period. A. Gordon Murphy, M.E.I.C., and Lawrence H. Burpee, M.E.I.C., have continued as chief and deputy chief engineers throughout the life of the project.

Ever since the commencement of the construction period Lewis G. Castle and M. W. Ottershagen have continued as administrator and deputy administrator, respectively, of the St. Lawrence Seaway Development Corporation in charge of improvements to navigation on the American side of the International Section. W. S. Chapin has been general manager, Raymond F. Stellar chief engineer, and L. W. Angell assistant chief engineer.

Power Authorities

In 1954, development of power was undertaken jointly by the Hydro-Electric Power Commission of Ontario and the New York State Power Authority. James S. Duncan, C.M.G., was appointed chairman of the Ontario Hydro following the resignation of Dr. Richard L. Hearn, M.E.I.C., in 1957. Dr. Otto Holden, M.E.I.C., and Gordon Mitchell, M.E.I.C., have remained as general manager, engineering, and chief engineer and project manager, respectively throughout the construction period. Robert Moses, William Wilson, and J. Burch McMorran have continued as chairman, vice-chairman, and chief engineer, respectively, of the New York State Power Authority during the life of the project.

Many Professional Engineers Engaged

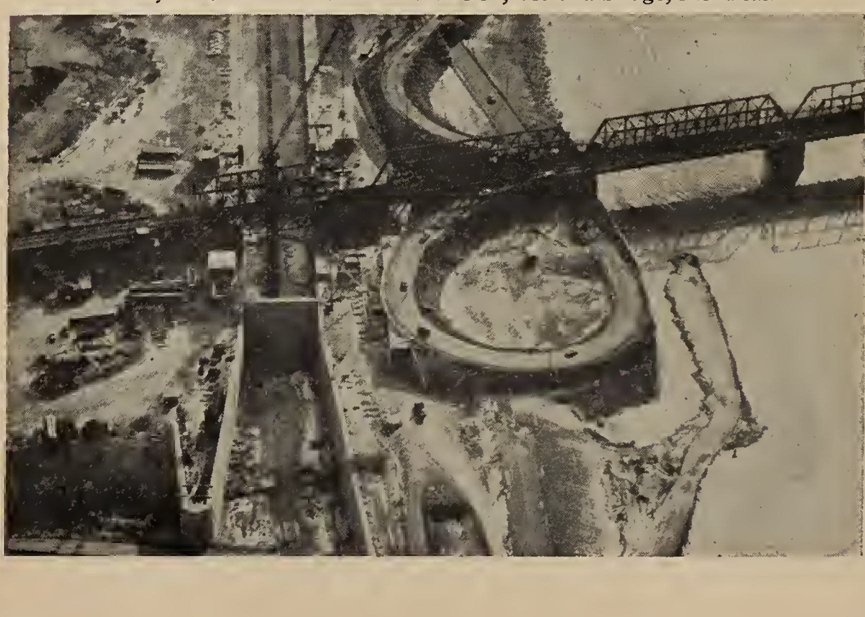
Assisting the executive management of the four 'authorities' during construction were some 475 Canadian and American professional engineers, 120 of whom, on an average, were in responsible charge of design or supervision of construction of the various aspects of the Canadian navigation works, and some 50 of whom were engaged in supervising construction of the Canadian power development, channel improvement, rehabilitation of towns in the areas to be flooded, and various other aspects. Behind them was Ontario Hydro's design staff in Toronto composed of some 66 more professional engineers. The majority of these engineers are members of the Engineering Institute of Canada. (Figures exclude junior engineers.)

On the American side some 35 civilian engineers and members of the U.S. Army Corps of Engineers were engaged in supervising construction of the navigation channels, while design was undertaken by some 30 personnel of the Buffalo section, U.S. Army Corps of Engineers. There were a further 100 American professional engineers or thereabouts engaged in the supervision of construction for the consultants and New York State Power Authority, while some 75 were engaged in design by that Authority and by the consultants to the Power Authority, Messrs Uhl, Hall and Rich, of Boston.

A further undetermined number of professional engineers, both Canadian and American, were employed throughout the design and construction periods by various manufacturers and suppliers of material and equipment, and by the various contractors who were carrying out the work.

Though space does not permit the recording of the names and titles of these men, many of them outstanding members of the profession, each and every one of them may take satisfaction in the part he has played in bringing one of the greatest engineering projects of all time to a successful conclusion.

Seaway construction and traffic diversion, Victoria bridge, Montreal.



Cordial co-operation between the several Boards and Authorities has been conspicuous throughout the construction period, with meetings informal and on a 'first name' basis. Friendly rivalry, such as that between the New York State Power Authority and Ontario Hydro respecting the merits or otherwise of placing concrete during sub-zero temperatures added a zest to the proceedings.

Conspicuous too in the development of engineering design were the economies effected by the use of hydraulic scale models of various stretches of the river at the Islington, Ontario, model testing laboratory by Ontario Hydro during early stages of design. The use of these models was invaluable to designers, and to contractors in planning their construction programs. It undoubtedly resulted in many instances in savings on bids and on costs amounting to a total of many millions of dollars.

Magnitude of the Project

The total cost of the entire seaway and power project based on contracts awarded plus equipment purchased, but exclusive of the $150 million being spent by the U.S. Government for improvement of navigation channels in the Upper Lakes, will amount to somewhere between $1,100 million and $1,200 million. Cost of the power project alone will reach a total of some $650 million, shared approximately equally by the New York State Power Authority and the Hydro-Electric Power Commission of Ontario. Canada's expenditure on navigation facilities will reach a total of $340 million, while U.S. expenditure on navigation facilities will add up to about $141 million.

The entire project involved 166 million cubic yards of dry excavation, 35 million cubic yards of dredging and 25½ million cubic yards of materials placed in dykes. Total concrete placed will amount to about 6½ million cubic yards. The power project involved 82 million cubic yards of dry excavation and 12 million yards of dredging, the placing of some 18 million cubic yards of earth in dykes and the placing of 3½ million yards of concrete.

Eight communities in a 20,000 acres flooded area on the Canadian side, containing a population of 6,500 persons, have been rehabilitated, with 525 homes moved and 450 new homes built, together with new schools, churches, shopping centres, streets and services. Forty miles of mainline double railway track were relocated and 35 miles of new highway built. Ultimately 1,880,000 kw. of power capacity will be installed, divided equally between the New York State Power Authority and the Hydro-Electric Power Commission of Ontario.

The navigation facilities on the Canadian side called for moving 55 million cubic yards of dry excavation and 18 million cubic yards of dredging, 7½ million cubic yards of materials placed in dykes and more than 2 million yards of concrete.

One double track rail bridge, one double track and four-lane rail-highway bridge, and two highway bridges across the St. Lawrence are being raised to provide 180 ft. clearance for shipping by Canada in the Montreal area. A start has also been made at Montreal on the four-lane four-mile long Champlain Bridge across Nun's Island between the city and the south shore of the river.

Navigation channels and locks on the American side called for 25 million cubic yards of dry excavation and 5 million yards of dredging, while concrete placed totalled over 1 million cubic yards. Canada and United States are sharing the construction and cost of a high level highway bridge over the river near Cornwall, Ont., to replace the N.Y.C. rail-highway bridge.

Some Bankruptcies, Some Losses

Many of the successful bids were submitted by 'joint venture' groups composed of leading construction companies with special skills and 'know-how' or with ownership of special suitable equipment. This was the case on both sides of the river. Only in very few exceptions were American firms associated with Canadian contractors doing work on the Canadian side, or vice versa.

Bidders on early contracts on both sides of the river, particularly on excavation, bid the work at prices generally far too low to show them a profit. This was due in part to their desire to become associated with a project destined to get much publicity, and in part to lack of judgment with respect to cost of handling the heavy marine clay and dense till in the foundations.

There were three early failures among contractors on the American side and the work had to be renegotiated at sharply higher unit prices. Elsewhere the cost of excavating tough rock on the Canadian side resulted in losses. Several claims for additional compensation to contractors totalling some $10 million

Long Sault dam site during removal of cofferdam.

have already been met on the American side and others are said to be pending. It is doubtful whether more than a few contracts showed handsome profits.

The summer of 1957 witnessed the period of peak employment, with close to 22,000 persons employed in late summer and early fall on all phases of the project. Little time was lost through strikes, but both labour and some materials were in short supply at times during the construction boom days of 1955/56.

In the main, the original progress schedule has been closely adhered to. Progress on excavation of the Iroquois Lock fell behind in 1955 due to difficulty in excavating the heavy marine clay, but time lost was regained during concrete placing operations. The second stage of the Long Sault dam on the American side got away to a bad start due to several months delay in starting the diversion of the river flow in the spring of 1957, but despite a tight schedule the job was finished on time.

With another 6-7 months to go before the first vessel makes its historic voyage through the new 27-foot draught seaway channels, construction now stands at some 90 per cent of completion. Contracts on excavation are well advanced, work is proceeding as rapidly as hoped for, and no delays are anticipated which would affect the opening date for navigation early in April 1959.

Only on dredging will the schedule not be fully met, and this has been mainly due to the scarcity of dredging equipment, largely because of requirements for improving the upper lake channels by the American government. Another five years will be needed to complete the Beauharnois power and navigation canal between lakes St. Francis and St. Louis, but this will not interfere with navigation next year. Dredging of the channels through these two lakes above and below the canal may have to be acceptable at 450 ft. width during initial stages of operation instead of the full 600 ft. width called for.

All bridge raising operations to give clearance for shipping will be completed before year-end. Only the new Champlain Bridge across Nun's Island at Montreal will not be ready for the opening, but it was never considered as an integral part of the seaway.

(The alternate C.N.R. track at St. Lambert lock will also be completed later.)

On the power project, with four units at least from each half of the International Powerhouse delivering power, the headpond is being held at 4 ft. below full level until the St. Lawrence Board of Control and the International joint Commission are assured that properties along the shorelines are protected.

Some Outstanding Features

Outstanding among accomplishments was the raising of the southern half of the 2½-mile Jacques Cartier highway bridge over the St. Lawrence at Montreal Harbour, to provide 180 ft. clearance for seaway vessels. The roadway profile was changed by jacking the spans and building up the bridge piers on which they rested to increase the clearance by 50 feet.

A further 33 feet was gained by replacing one of the original deck-truss spans with a new through-truss span, built on falsework on one side and slid laterally into place, pushing the old span on to falsework on the other side. This was done in a Sunday morning last October, with traffic closed down for only four hours. The late Dr. P. L. Pratley, M.E.I.C., distinguished Canadian bridge engineer who designed the original bridge as well as this modification being completed this year, incorporated these changes without in any way destroying its artistic or practical value.

Another notable achievement is seen in the smooth working of the gate machinery in the two American locks and in the Canadian Iroquois lock, now opened for navigation. These three giant locks can be filled or emptied in some six minutes with a minimum of disturbance to the water. Similar performance is expected on the other four Canadian locks not yet in service. It compares with a time of some 12 minutes for filling or emptying the older Welland Canal locks built some 25 years ago.

Yet another achievement has been the shortening of the customary dry-out period on the Canadian generators in the International Powerhouse, permitting the first two to be placed 'on-line" within one week following the raising of water in the headpond.

But the greatest accomplishment of all has been the perfect co-ordination between the joint Commission, the Board of Control, the Joint Board of Engineers, the four Authorities and the many contractors and suppliers. This co-ordination has resulted in meeting the exact date set four years ago for first delivery of power and partial opening of navigation through the new locks as scheduled.

Traffic and Tolls

Joint conclusions by the tolls committees of both nations were published in mid-June. Public hearings will follow throughout August and September. The Canadian tolls committee is chaired by J-C. Lessard, M.E.I.C., vice-president of the St. Lawrence Seaway Authority, with George A. Scott and Col. Donald Purves as members. The U.S. committee is chaired by E. Reece Harrill, assistant administrator, S.L.S.D.C., with Dr. Charles Taff and Cmdr. Edward A. Bacon as members. Separate and joint meetings have been held regularly over the past three years, with prime objectives being the lowest tolls consistent with self liquidation within 50 years, a simple toll structure, and the most convenient toll collection method.

Traffic was estimated at 25 million tons in 1959 between Montreal and Lake Ontario, growing to 50 million by 1968; and at 40 million tons through the Welland in 1959, growing to 60 million tons by 1968 and thereafter. Total toll revenue on the Montreal to Lake Ontario section over the 50 year period of $1,254 million would accrue 71% to Canada and 29% to the United States. The entire toll revenue through the Welland Canal estimated at $150 million would accrue to Canada.

Tolls of 4 cents per ton of registered tonnage plus 40 cents per ton of bulk and 90 cents per ton of general cargo were recommended for the Montreal-Lake Ontario portion, while tolls of 2 cents per registered ton plus 2 cents per ton of bulk cargo and 5 cents per ton for general cargo were recommended for the Welland Canal. The entire debt would be amortized by year 2009.

Two Separate Seaways being Considered

There is evidence that tolls for the Welland Canal are being vigorously opposed by the United States. The heart of the matter revolves around the question of whether the Welland is part of the Seaway or merely a connecting channel. Ottawa takes the former view, while the U.S. Cabinet apparently took the same view when it approved U.S. participation in building the seaway. The U.S. Corps of Engineers on the other hand, feels the Welland is a connecting channel. The argument is somewhat academic, however, since only Canada can alter the Welland tolls.

Critics of seaway traffic estimates see the Welland as a future bottleneck. They claim Welland locks will have to be 'twinned' to accommodate the 60 million tons of cargo per season from 1968 on. Estimate of cost for twinning, if traffic demands it, is about $100 million at today's prices. Talk of an 'all American canal' from the south shore of Lake Erie across country to Buffalo, New York, to bypass the Welland, has increased lately and Congress has authorized the U.S. Army Corps of Engineers to make a study of it. Its cost is variously estimated at from $300 to $600 million.

Canada, too, may eventually have an all-Canadian Seaway. When it was agreed in 1954 that the United States would build two locks for the Seaway on the American side, Canada announced her intention of building a canal with two more locks on Canadian soil "if and when it considers parallel facilities are required to accommodate existing or potential traffic." The north Cornwall Island channel now being dredged to improve flows is partly a step in this direction.

Threats for the Future

Two other threats to the Seaway's future more immediate than questions of duplicate navigation channels and locks, are facing the "big ditch". One of these is a recent disclosure by President Eisenhower that the U.S. portion of the Seaway will soon come under the jurisdiction of the U.S. Department of Commerce instead of under the U.S. Army Engineers as at present. U.S. seaway supporters, fearing the tampering with tolls, have fought against the change, lest U.S. railroads may be able thereby to exert influence to get higher tolls or to throw roadblocks in the way of seaway shipping. Best way for Canada of countering such a threat is to have an all-Canadian navigation route in being as a standby, or at least ready to be undertaken.

A second threat is the vast transportation federation planned by Hoffa's International Broatherhood of Teamsters, embracing workers in every field of industry with their partners the International Longshoremen's Union and the National Maritime Union. Such a labour tie-up, if its influence were extended to embrace Canadian Unions, would wield a power that could affect every industry in the U.S. and Canada. The Seaway, being a new field, offers the best opportunity to get a start with this master plan.

Official Opening of the Seaway

Her Majesty Queen Elizabeth II has graciously expressed her willingness officially to open navigation on the new Seaway next spring. Being, as it is, a joint national project, it is probable that President Eisenhower will participate in the ceremonies. Ceremonies, protocol and itineraries are customarily handled through Canada's Department of External Affairs. While there is as yet no specific information regarding the event, plans for the official opening are now in the hands of a special committee responsible for the itinerary of Her Majesty during her tour of Canada in 1959.

The Royal Party might travel through the new Seaway to the head of the lakes in the Royal Yacht *Britannia*. Prime Minister Diefenbaker has announced that the Queen's visit will last about six weeks, from mid-June 1959, and will take in 'all parts of the country'.

Planning and Constructing the Lachine Section

L. H. Burpee, M.E.I.C.
Deputy Chief Engineer, The St. Lawrence Seaway Authority

THE LACHINE SECTION covers that part of the Seaway extending from Montreal Harbour to Lake St. Louis, in which there is a lift of around 50 feet from the Harbour water level to the Lake. The canal is 27 ft. deep at low water level and has a length of 18.5 miles, and has two locks which are at St. Lambert and Côte Ste-Catherine.

The purpose of this paper is to explain the general planning of the Lachine section of the Seaway, and to describe some of the more important construction problems which had to be met and the methods of dealing with them.

The Lachine section is being constructed entirely as a navigation project, but with a number of features arranged and designed so as to permit the future development of power without any serious difficulties being caused by the present navigation works. Nearly two thirds of the cost of the Canadian part of the Seaway is for work in this section.

Prior to about 1950, all planning was based on a canal on the north side of the St. Lawrence River. By 1950 it had become apparent that, due to the very extensive development of the Montreal side of the river, the construction of a canal there would be costly and impractical. In 1952 the decision was made that the Seaway would be constructed along the south shore of the river. Detailed surveys and planning were commenced at that time.

Many variations of channel location and positions of locks were possible. Many studies and estimates were made before the final layout was adopted (Figure 1).

Paper received 4 August 1958.

Location of Canal

There was no choice as to the Seaway location at Victoria bridge as the canal and the lift span had to be located between the last pier and the south abutment of the bridge. Any other location farther out in the river would have caused excessive flow restriction, and would have encroached on the space which will be needed by Quebec Hydro when the future power development is constructed there. Any location south of the existing abutment would have cut heavily into the City of St. Lambert and been far more costly.

The purpose of this paper is to explain the general planning of the Lachine section of the Seaway, and to describe some of the more important construction problems which had to be met and the methods of dealing with them.

Jacques Cartier bridge had a downgrade between St. Helen's Island and the south shore. The spans nearest to St. Helen's Island are 250 feet, and those towards the south shore vary from 200 feet down to 125 feet at the abutment. For the easiest adaptation of the bridge to suit the Seaway, the channel had to be located at one of the 250-foot spans, and for uninterrupted traffic the bridge had to be raised. It was decided that the Jacques Cartier bridge could be raised to provide a high level crossing. The best location for the Seaway was through the last of the 250-foot spans, or between piers 9 and 10. This location will cause very little restriction to the river, is suitable for a modified highway approach system, and provides a good alignment at the junction with Montreal Harbour.

The Seaway channel follows around Laprairie basin at distances from shore varying from 1,000 feet to 2,500 feet. The actual location of the channel was selected after many estimates of quantities and costs, and after many studies of suitable navigation alignment.

From Côte Ste-Catherine to Caughnawaga the channel had to be located overland, as the Lachine Rapids could not be obstructed. The actual selected location has been based on providing sufficient space between the Seaway and the river shore for a future enlargement of the river cross-section by Quebec Hydro for the Lachine power development.

From just west of the Canadian Pacific Railway and around Caughnawaga village, the channel has again been located in the river. The cost would have been prohibitive and the number of persons displaced would have been too great to have constructed the channel overland through the town. It was important to keep the restriction of the river to a minimum, and the canal follows close to the shoreline.

In addition to the canal and locks, the Lachine section required the following modifications to existing features or construction of new features.

Raise Jacques Cartier bridge.
Provide lift span for Victoria bridge.
Modify various existing municipal water supply and sewage discharge systems.

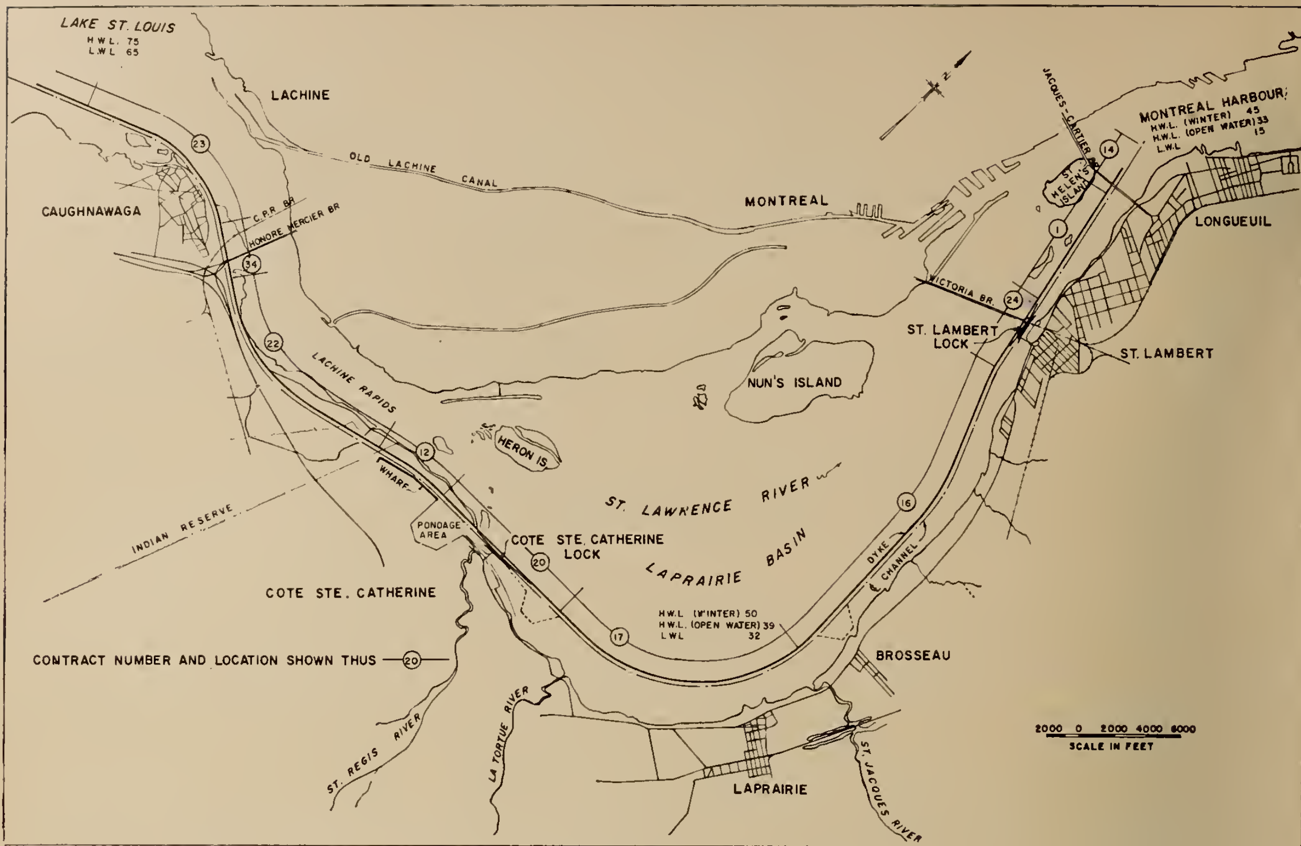


Fig. 1. General plan of the Lachine section.

Relocate highways (principally at bridge approaches).
Relocate and modify various power and communication lines.
Construct high level overhead extension to Honoré Mercier bridge.
Construct lift bridge for Canadian Pacific Railway.
Raise the C.P.R. approach embankments to provide an easier grade.
Construct a wharf at Côte Ste-Catherine.

Only a few brief general facts relating to the above works will be mentioned in this paper.

References to lock equipment will be omitted from this paper, except for brief facts relating to schedules.

Lock Locations

The best location for the lower lock was at the upstream side of Victoria bridge. This bridge carries highway as well as double track main line traffic of the Canadian National Railways. There were a number of advantages to this location, the principal ones being:

(1) A lift span for an 80-foot gap could be used at the lock, as compared to a 200-foot gap if the bridge crossed a canal reach.

(2) The bridge pier enlargement and lowering of the foundation was simplified when combined with the lock wall structure. Safety of the bridge piers during construction was assured.

(3) A dual lift bridge arrangement for uninterrupted highway traffic could be provided.

(4) Better control and dispatch of vessels since the bridge operates as a lock feature.

The best location for the upper lock was opposite the foot of the Lachine Rapids, or near the village of Côte Ste-Catherine. The final choice of location for this lock was entirely a matter of lowest overall cost, when considering the variations in excavation, concrete, and dyke construction quantities, and some variations in property affected.

Water Levels and Flows

Montreal Harbour has had a natural range of water level from 33 feet above mean sea level during the highest flood flow to 15 ft. at the extreme low flow. Ice jams cause winter water levels below Jacques Cartier bridge frequently to reach 40 ft., with a high recorded of about 45 ft. Lake St. Louis has a natural range of water level from 75 ft. to 65 ft., and is rarely affected by ice conditions. Laprairie Basin has a natural range of water level during open river conditions from 39 ft. to 32 ft., and has had occasional extremes during winter ice conditions of over 50 ft.

The locks have been designed to suit the extremes of water levels for Montreal and for Lake St. Louis, and for a regulated water level in the Laprairie Basin pool of 38 ft. It is probable that the locks will be operated initially with an intermediate pool level somewhere between 35 and 38 ft.

There is a drainage area of 180 square miles tributary to Laprairie Basin, largely made up of three small rivers: St. Jacques (63 sq. miles), La Tortue (57 sq. miles), and St. Regis (36 sq. miles) (Figure 2). A spring run-off from this area will normally be around 5,000 c.f.s., and it is estimated that the flow might reach 10,000 c.f.s. for a brief period of time.

The regulating works adjacent to St. Lambert Lock have been designed to discharge 10,000 c.f.s., with the pool level at 38 ft. The regulating works at Côte Ste-Catherine Lock have been designed to discharge 5,000 c.f.s. with normal Lake St. Louis level. This flow was adopted as an adequate amount to be discharged intermittently to keep Laprairie Basin channel fresh during summer low flow periods.

Dykes

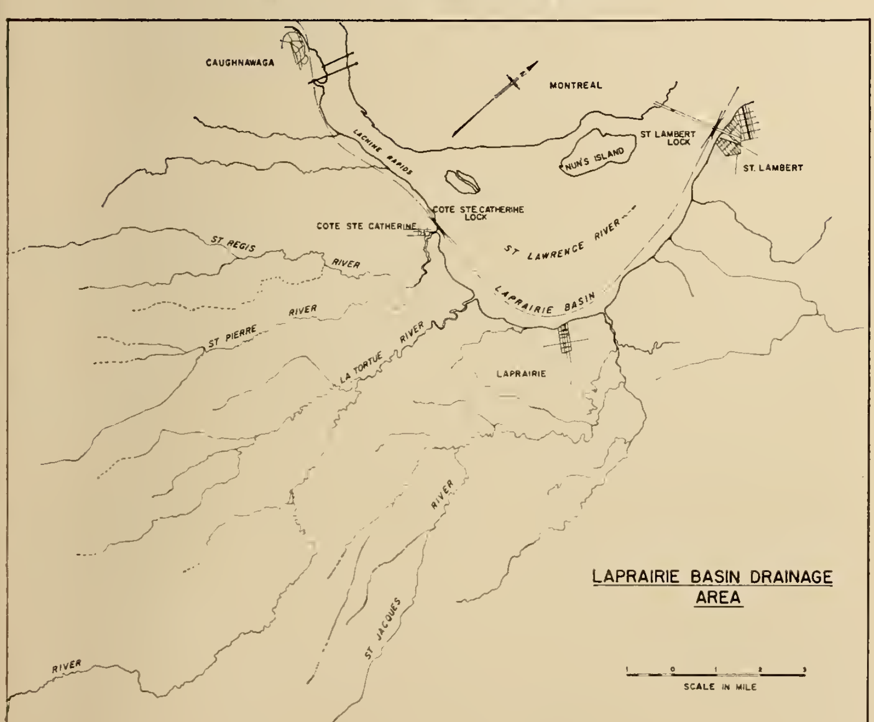
The dyke separating the canal from the river has a top width of 40 feet, and is continuous on the north side of the canal extending for the entire 18½ miles from Montreal Harbour to Lake St. Louis. There is also a 1½-mile section of dyke on the south side of the canal above Côte Ste-Catherine Lock. Typical dyke sections are shown in Figure 3. The top elevation of the dyke is 40 at the harbour entrance. From a location near Jacques Cartier bridge, a slope of 1 foot per thousand extends for a length of 18,000 feet until the top elevation becomes 58. This dyke elevation then extends uniformly for the remainder of the distance around Laprairie Basin. The slope from elev. 40 to 58 is roughly the same as the natural river slope between Victoria Bridge and Jacques Cartier Bridge, in which distance the river drops about 10 feet. Above Côte Ste-Catherine Lock the dyke has a uniform top elevation of 80.

The dyke below St. Lambert Lock will have a maximum head against it of only about 10 feet. The principal purpose of the large cross-section is to withstand the ice shoves from the river. The 8-mile dyke around Laprairie Basin has to serve two purposes. In normal operation the Seaway Canal water level will be a few feet higher than the river, but under winter ice conditions the river water level might be as much as 20 feet higher than the canal level for short periods of time. There is also the pressure from ice movements to be provided against. In all of the dyke construction around Laprairie Basin and below St. Lambert lock, the head on the dyke during the period of use as a cofferdam was greater than will occur during operating conditions. The highest and most important parts of the dyke work are along the two sides of the canal immediately above Côte Ste-Catherine lock. These dykes will have a maximum head against them of about 40 feet. Further details relating to dyke construction and the materials used will be found in paper by F. L. Peckover and T. G. Tustin, in this issue of *The Engineering Journal* (p. 69).

Channel Widths

The channel below the St. Lambert lock has a bottom width of 225 feet, which was considered to be the minimum for good operation where ships first enter the Seaway. The bottom width of the channel around Laprairie Basin was adopted at 300 feet, which provides an extra width of channel around the long curve. The decision as to the width of this part of the channel was also influenced by the necessity to have adequate materials of suitable types for dyke construction. Two turning basins have been provided in the Laprairie Basin reach. Above Côte Ste-Catherine lock there is a large pondage area for surge control, and beyond the pondage area a 4,000-foot wharf has been constructed. The channel is 280 feet wide at the wharf to provide ship clearance. From the Côte Ste-Catherine wharf to the canal entrance in Lake St. Louis the bottom width is 250 feet.

Fig. 2. Laprairie Basin drainage area.



Lock Dimensions

All of the Seaway locks have the same general dimensions, and these are essentially similar to those of the Welland Canal. The basic dimensions are: width 80 feet, usable length (fender to breast wall) 766 feet, and depth on the sill at low water level 30 feet. All locks have been designed so that a future twin lock at each site can be constructed without any serious interferences with ship movements.

St. Lambert Lock and Victoria Bridge (Fig. 4)

The lift at St. Lambert lock will vary from a maximum of 23 feet to a minimum of 5 feet depending on the water level in the harbour. The equipment for the lock and its arrangement is described by R. W. Willis, J. F. Pilon and J. E. Coke[1], The hydraulic design of the lock has been covered by D. McIntyre[2].

Victoria bridge crosses the lock immediately below the lower set of lock gates. Another bridge crosses the upstream end of the lock, just above the upper set of gates. Uninterrupted highway traffic will be maintained by the use of the alternate bridges.

The entrance walls are 2,950 feet long downstream and 2,300 feet upstream. They have been designed with a flare from the lock entrance of 1 in 10, and the flare has a length of 890 feet, to give a sufficient offset for a 75-foot beam vessel to lie alongside the parallel wall without hindering a vessel leaving from or entering into the lock.

Côte Ste-Catherine Lock (Fig. 5)

The lift will vary from 40 feet to 30 feet, depending on the water level of Lake St. Louis, and on the regulated level of the Laprairie Basin pool. The arrangement of equipment is generally similar to that at St. Lambert. A rolling lift bridge has been provided across the upper end of the lock for operating purposes.

The entrance walls are similar to those at St. Lambert, except that the angle of flare is 1:12, and the length of flare is 900 feet. The total lengths are 1,600 feet downstream and upstream.

Modifications to Canadian National Railway

No relocation has been required for the C.N.R., as the lift span has been constructed at the location of the old south span of the existing Victoria bridge. The modifications to the C.N.R. were almost entirely those connected with the excavation and construction of the lock structure under the bridge between pier 24 and the south abutment, and the erection of the new lift span.

After the Seaway Authority had decided on the dual bridge arrangement for uninterrupted highway traffic, the Canadian National Railways decided to proceed with a similar general arrangement to avoid any delays to railway traffic. The piers being constructed by the C.N.R. for the alternate railway route are seen in Fig. 6.

Modifications to Canadian Pacific Railway

The double track main line of the Canadian Pacific Railway near Caughnawaga now crosses the canal on two new single track lift bridges located about 75 feet east of the old railway embankment. The former tracks had a 0.75 per cent grade, which had to be eased to a 0.5 per cent grade as a compensation for placing a lift span in the line. The change of grade extended over 1½ miles and necessitated a track raising job of as much as 10 feet at the point of maximum raise.

Highway and Bridge Modifications

There have been no extensive highway changes other than the actual new approaches to the three bridges. The fact that a large part of the canal has been located in the river bed has minimized the effect on existing highways. One mile of new highway had to be constructed to replace the former highway at Côte Ste-Catherine, and one mile of highway had to be relocated to the east of the new Honoré Mercier bridge approach. Temporary diversions had to be provided during the construction of each of the bridges, and for a short distance along the canal.

The modifications to Jacques Cartier bridge required the raising of the structure south of St. Helen's Island by heights up to 40 feet, the enlargement of the piers, and the substitution of one through truss span in place of an existing deck span[3].

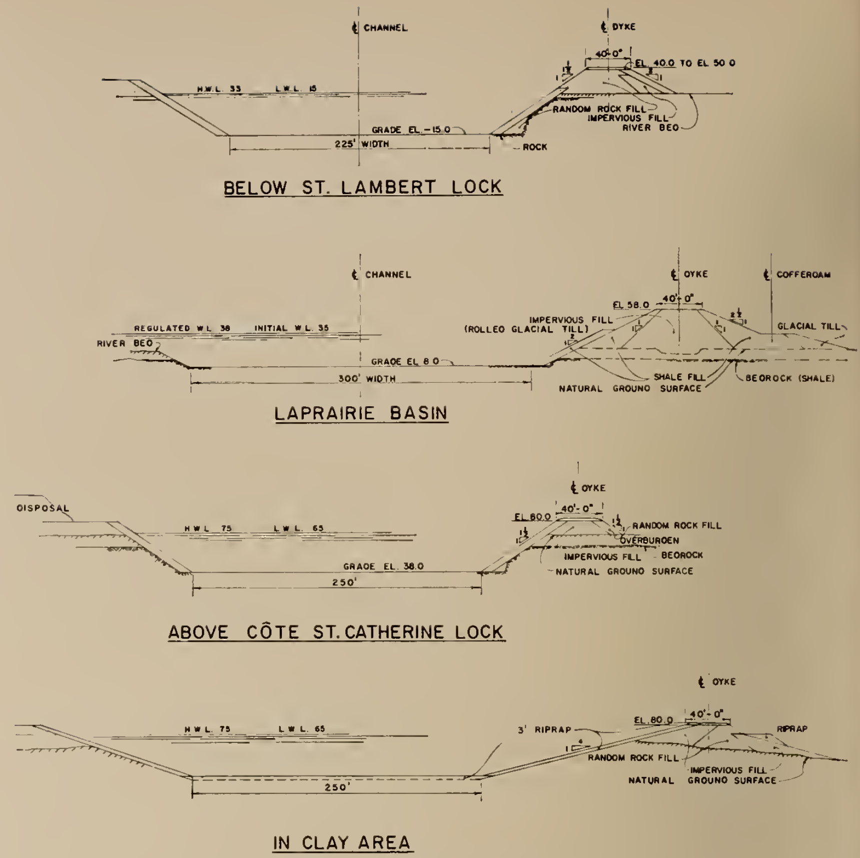


Fig. 3. Typical dyke sections.

The modifications to Victoria bridge approaches provide for the alternate use of either of the bridges across St. Lambert Lock.

The modifications to the Honoré Mercier bridge consist of a new extension to the south of the existing bridge. The old bridge had a descending ramp on the south side of the river, which has been demolished. The new extension has an ascending ramp (4.25%) to provide a high level crossing over the Seaway. South of the Seaway the new bridge provides for separate highway approaches to the east and to the west.

Municipal Services

Water intake and sewer discharge works have had to be constructed at a number of points along the canal to serve all of the affected municipalities.

Power and Communication Lines

A number of high voltage transmission lines and telephone lines have had to be relocated, and at each of the railway crossings extensive signal and telegraph lines were affected.

SCHEDULE FOR CONSTRUCTION

In June 1954, the final decisions were reached which permitted the power and navigation development of the International Section of the river to proceed. In July, the St. Lawrence Seaway Act was proclaimed, after which all of the Canadian Seaway construction was authorized to proceed.

In August 1954, it was agreed between Canada and the United States that the Seaway would be ready for deep draft traffic at the opening of navigation in the spring of 1959. Thus, just a little over four years were allowed for the final planning and constructing of the Seaway. It was appreciated that the schedules would be tight, and the engineers of the Seaway Authority had no choice but to fit the planning and constructing into the time available. All planning and all construction schedules have therefore been governed by the basic requirement that the Seaway would be ready to open in April 1959. The end date for completion of construction was fixed. Along with the preparation of the plans for the channels and structures was the general problem of splitting up the work into the most convenient contract units for construction, scheduling each contract, and fitting the contracts together as they reached completion.

A basic schedule to meet the completion date was prepared, from which a number of critical facts relating to the Lachine section became apparent:

(1) All major construction should be completed by the end of August 1958, in order to be able to complete all lock installations by October 1958.

(2) Three and a half years would be required for the general construction at the locks and for the installation of all the equipment.

(3) The Victoria bridge pier protection and lift span work could be done within three years.

(4) Three years would be required for the raising of Jacques Cartier bridge.

(5) Three construction seasons should be provided to complete the Laprairie Basin channel and construct the dyke. The closures at the local rivers could not be made before the summer of 1958.

(6) Two and a half years would be adequate for the work above Côte Ste-Catherine, including the lift bridges and other modifications to the Canadian Pacific Railway, and the extension of the Honoré Mercier bridge.

(7) A minimum of three months would be required at end of 1958 construction season for the opening of the canal at each end by dredging.

(8) All lock equipment contracts and contracts for steel for bridges should be awarded by early 1956.

Detailed schedules then had to be prepared for the locks, which would provide for building the structures, installing the equipment, and leave some time for testing. It was possible to gain about four months' time at each of the locks by arranging for the large river cofferdams to be constructed under separate contracts, during the time that the lock plans and specifications were being prepared. Detailed schedules were also prepared for all of the other work, which influenced the split up into the other eight canal contracts.

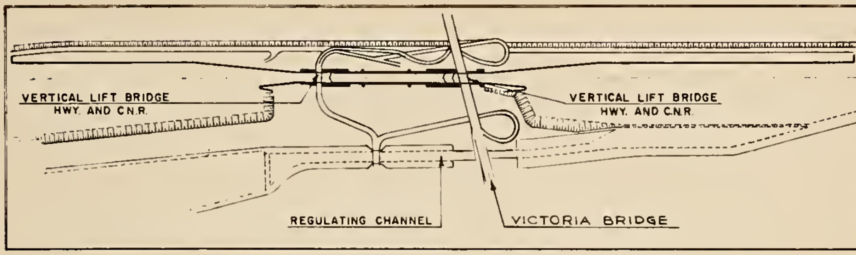

Fig. 4. St. Lambert lock.

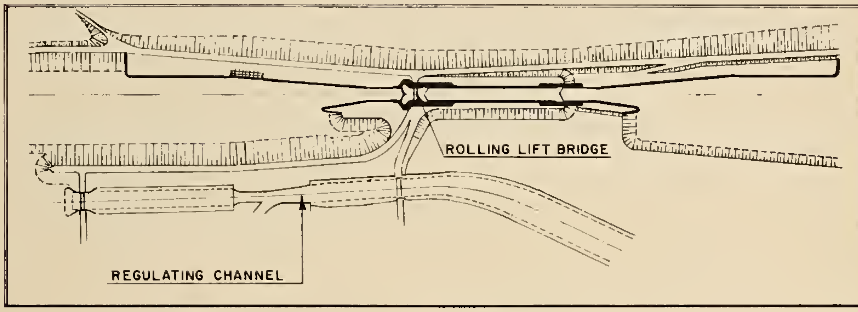

Fig. 5. Cote Ste-Catherine lock.

Every effort was made to inform the prospective contractors (when tendering) of the actual completion dates required, and of the necessity of meeting those dates. With the object of keeping a measure of control over progress, all contract specifications contained one or more intermediate dates, at which times certain phases of the work were required to have reached a certain state. These intermediate dates were in many cases not met, but they did prove very helpful in the continuous effort to keep all contracts up to a reasonable rate of progress. The intermediate dates were of particular importance where adjacent contracts were dependent one on the other. Each of the lock contracts had specified limiting dates for starting of concrete, and each one had a specified hourly output capacity of the concrete mixer plant. No attempt was made to specify contractors' equipment, but controls of contractors' rates of progress and general performances were written into the specifications of most of the contracts in several ways. These controls included:

(1) Specified early starting dates on certain parts of the work.

(2) Requirements that excavating equipment capable of a specified total rate of excavation be provided.

(3) Installation of a concrete mixer plant of stated minimum hourly output.

(4) Specified completion dates for various intermediate stages of the work.

Construction got under way in November 1954, by the awarding of Contract No. 1.

Fig. 6. General view of St. Lambert lock area and Victoria bridge, with Jacques Cartier bridge and Montreal Harbour in the background.

In a general way, 1954 and 1955 covered the basic planning. 1955 and 1956 were the heavy excavation years. Concrete work started in 1956 and was in full production during 1957. Installation of equipment and erection of bridges started in 1957 and has continued almost everywhere throughout most of 1958.

Many of the contracts have had very tight schedules, but it has been necessary to insist that these be closely adhered to in order to achieve the required Seaway completion date. In a number of instances contractors have claimed that the Seaway construction schedules have been too tight. The fact is quite apparent from the amount of work to be done in four years that the schedules could not have been otherwise than tight — and it was also apparent during the early period of construction that a few of the contractors did not take very seriously the schedule requirements set out in their contracts.

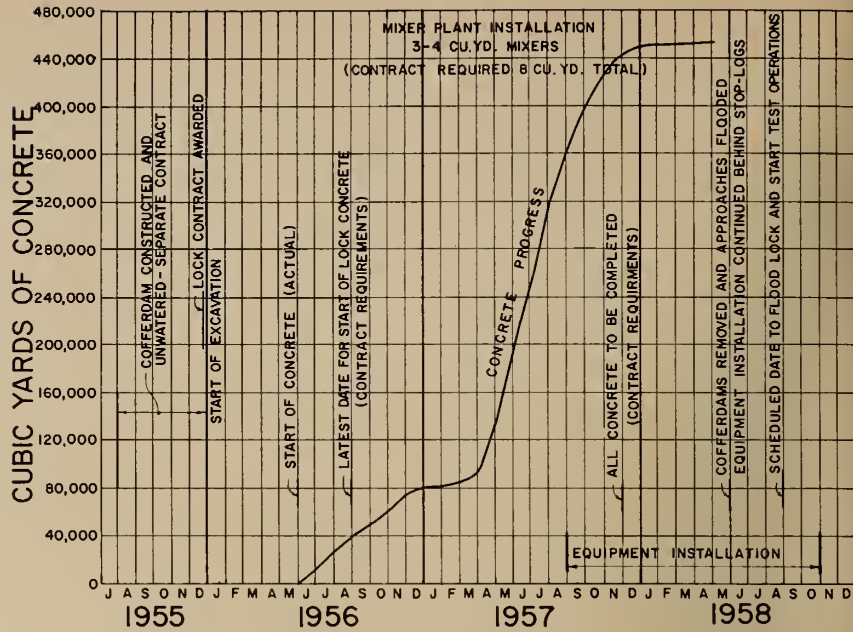

Fig. 7. Schedule and progress record, St. Lambert lock.

CONSTRUCTING THE CANAL

The first step towards construction was the splitting up of the 18.5 miles of work into reasonable size contracts, giving consideration to types of work, site limitations, acquisition of property, time for the preparation of plans, and overall schedule requirements. The contracts on which extensive subsequent work depended got early attention.

The next step was the setting of the sequence in which contracts would have to be awarded, so that the preparation of contract plans and specifications could proceed in the required order. Factors which influenced the sequence of contract advertising included designing time, minimum time which had to be provided for construction, acquisition of property, agreements with existing interests (provincial, municipalities, railways, transmission lines, etc.).

The 18.5 miles from Montreal Harbour to Lake St. Louis required the excavation of 18,000,000 cu. yd. of common material and 20,000,000 cu. yd. of rock (60% shale and 40% limestone with the line of separation mid-way through contract 12). The two locks required a total of 840,000 cu. yd. of concrete. The connecting dykes required 9,000,000 cu yd. of fill. In addition, a total of approximately 7,000,000 cu. yd. will have been excavated by dredging at the Montreal Harbour and Lake St. Louis entrances to the Seaway canal.

The canal and its two locks have been constructed in ten main contracts. Two of the ten main contracts covered the St. Lambert and Côte Ste-Catherine Locks with adjacent parts of the channel and dyke. The other eight contracts made up the remaining fifteen and a half miles of channel and dyke. It is noteworthy that three of these eight contracts were essentially completed well ahead of their schedules.

The ten main contracts, as awarded, have ranged in value from less than $1,500,000 to over $7,500,000. Channel and dyke contracts have ranged in size from less than 2,000,000 cu. yd. to 7,500,000 cu. yd., and these contracts have ranged in length from ¾ mile up to nearly four miles. Table I lists the ten contracts into which the construction of the 18.5-mile canal was divided. The following

Table I. Excavation and Dyke Summary

Contract No.	*Length of Channel* Miles	*Location*	*Award of Contract*	*Approximate Quantities* *Common Excavation* cu. yd.	*Rock Excavation* cu. yd.	*Dyke Construction* cu. yd.
14	0.9	Above Jacques Cartier Bridge to Harbour Entrance	June 1955	900,000	1,200,000	300,000
1	1.4	Below St. Lambert Lock to Jacques Cartier Bridge	October 1954	—	4,100,000	500,000
24	1.0	St. Lambert (1)	December 1955	—	2,500,000	—
16	3.8	St. Lambert to Laprairie	July 1955	4,800,000	2,300,000	3,200,000
17	3.0	Laprairie to Côte Ste-Catherine	July 1955	2,500,000	1,200,000	2,100,000
20	2.0	Côte Ste-Catherine (2)	September 1955	2,800,000	1,700,000	1,400,000
12	0.8	Côte Ste-Catherine	April 1955	400,000	1,300,000	—
22	2.7	Indian Reserve	November 1955	4,600,000	2,900,000	500,000
34	0.7	Honoré Mercier and C.P.R. Bridge Area	August 1956	800,000	800,000	50,000
23	2.2	Caughnawaga and Lake St. Louis Entrance	June 1956	1,200,000	2,000,000	600,000
	18.5		TOTAL:	18,000,000	20,000,000	9,000,000

NOTES: (1) Includes St. Lambert Lock. (2) Includes Côte Ste-Catherine Lock. (3) See contract locations in Figure 1.

are explanatory notes for the ten contracts, listed in chronological order as to date of award.

Contract 1

Contract I was planned to get work actually under way before the end of the 1954 construction season. The limits of the contract were set to keep entirely clear of any work at the Victoria bridge and Jacques Cartier bridge. (Up to that time no detail plans had been prepared for the work at either of these bridges.) Contract I covered a part of the channel which could have been adapted to a combined power and navigation scheme which Quebec Hydro engineers were studying, but about which no decision had been reached up to that time. It was particularly desirable to get at least one contract awarded and started in 1954 in order to establish many of the details and procedures which were necessary for contracting the work. A small amount of work, but not much more than a token, was actually done during the fall of 1954.

Contract 12

There were three reasons for selecting this contract as next to be awarded:

(1) Limestone rock to be excavated from this contract was one of the possible sources for concrete aggregates, and it was desirable to have an actual quarry size excavation in order to get full information on the suitability of this rock for concrete. (This rock was found to be unsuitable.)

(2) Limestone rock from this area was required for the riprap on the dyke of contract 1.

(3) It had been decided to use rock and common material excavated under this contract for the construction of the initial stage of the large cofferdam in Laprairie Basin for Côte Ste-Catherine lock.

The upper limit of this contract had to be kept clear of the Caughnawaga Indian Reservation as no rights had been obtained from the Reserve up to that time.

Contract 14

This contract included the downstream end of the canal, adjacent to the dredging contract at the Montreal Harbour approach. Included in this contract was the channel excavation forming the first cut for the enlargement of piers 9 and 10 at Jacques Cartier bridge. See Fig. 15 (stage one first cut). By this time, the general plans had been worked out for the raising of Jacques Cartier bridge, the scheduling for which required a very early start.

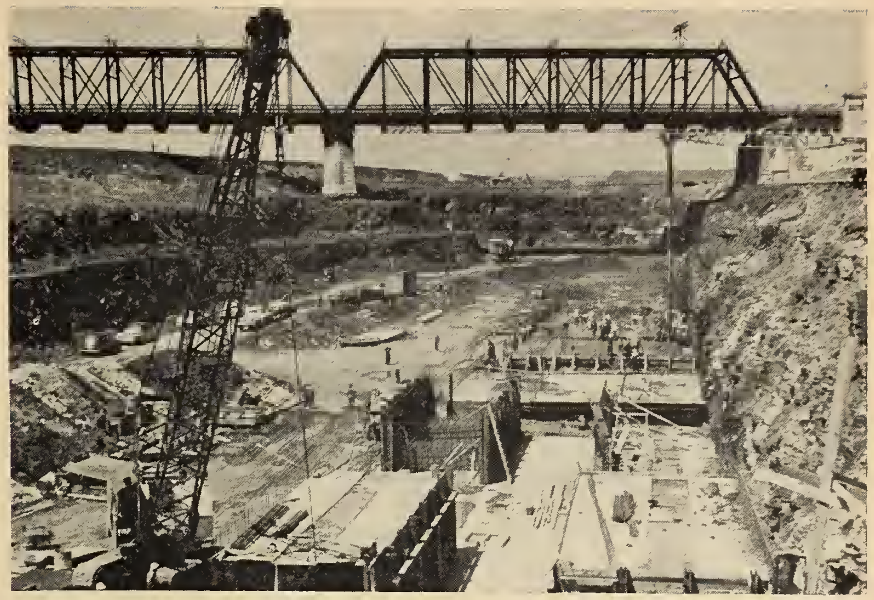

Fig. 8. Initial construction at St. Lambert lock with first stage of excavation at Victoria bridge piers.

Fig. 9. St. Lambert lock construction essentially completed. No change in Victoria bridge.

Contracts 16 and 17

These two contracts cover seven of the eight miles of the channel excavation and dyke construction around Laprairie Basin. With the large cofferdams to build, and with the large volume of excavation and dyke construction, it was apparent that this work would have to extend through from 1955 to 1958. On account of the 20-foot rise of water level due to ice jams, it was not planned that work would continue through the winters. It was therefore essential to get these contracts going early so that advantage could be taken of a part of the summer of 1955 to get the first cofferdams built and the procedures of excavation and dyke construction established. These two contracts were advertised on the same date.

Included in contract 16 was the complete construction of a high cofferdam for the St. Lambert Lock, and also its unwatering.

Included in contract 17 were the closures of the river gaps in the summer of 1958. Also included in this contract were extensions to the Laprairie water intake pipe and sewer discharge.

Contract 20

This contract included Côte Ste-Catherine Lock and about one mile of the channel and dyke construction. This lock contract was awarded in advance of the St. Lambert lock because this lock structure was independent of any existing railway or highway facilities, and it was more practical to complete these plans and specifications quickly than those for St. Lambert.

Contract 22

This is the largest volume excavation contract of the Lachine section, and of the whole Canadian Seaway. It included three miles of deep channel, a relatively low dyke, and was located entirely within the Indian Reservation land. Both from the point of view of the large quantities of excavation involved, and the problems which might arise from the expropriation of lands, this contract came next in sequence. This contract had 2,000 feet of canal to be excavated through soft clay.

Contract 24

This contract included St. Lambert lock and the substructure for the lift span at Victoria bridge. It also included modifications to the St. Lambert water intake. This was one of the most congested areas of the whole Seaway. With the many railway, highway, communications and municipal problems, it would have been desirable to have started this contract earlier. However, it had been impossible to complete the general layout and prepare the plans earlier. This lock has the largest volume of concrete of any of the five Canadian locks. A very stiff construction schedule had to be specified when advertising the work, so that the contractors tendering could properly appreciate the problems to be met.

Contract 23

This contract included the most difficult cofferdams of the Lachine section, which had to be constructed in fast and deep water along the shore of the village of Caughnawaga.

Contract 34

This was the last of the ten main contracts to be awarded for the canal in the Lachine section. It was only ¾ of a mile in length but it included all of the work relating to the C.P.R. embankment widening and the substructure for the new C.P.R. bridge. It also included some of the work relating to the extension to the Honoré Mercier bridge. Large quantities of the excavated rock were used for railway and highway embankments. This contract was quite complicated in its schedule requirements, as parts of the work were dependent on the diversions of railway and highway traffic on to the new bridges.

Other Contracts

Separate contracts were let covering features other than the actual canal. Among the larger features included in separate contracts were the following:

- Enlargement of Jacques Cartier bridge piers.
- Raising the bridge and erecting the new channel span.
- Victoria bridge lift spans (two).
- Regulating works at St. Lambert.
- South shore collector sewer.
- Water intake at Longueuil.
- Côte Ste-Catherine wharf.

Fig. 10. St. Lambert lock completed. Victoria bridge lift span being erected.

- Honoré Mercier bridge substructure.
- Honoré Mercier bridge superstructure.
- Canadian Pacific Railway lift bridges.
- Highway paving.

Further references to these features will be confined to any direct effects on the construction of the actual canal.

PROBLEMS OF CONSTRUCTION

The main problem of construction was the very large volume of work to be done within the tight schedule limits. Another construction problem of great importance was the co-ordin-

Fig. 11. General view of construction of Cote Ste-Catherine lock.

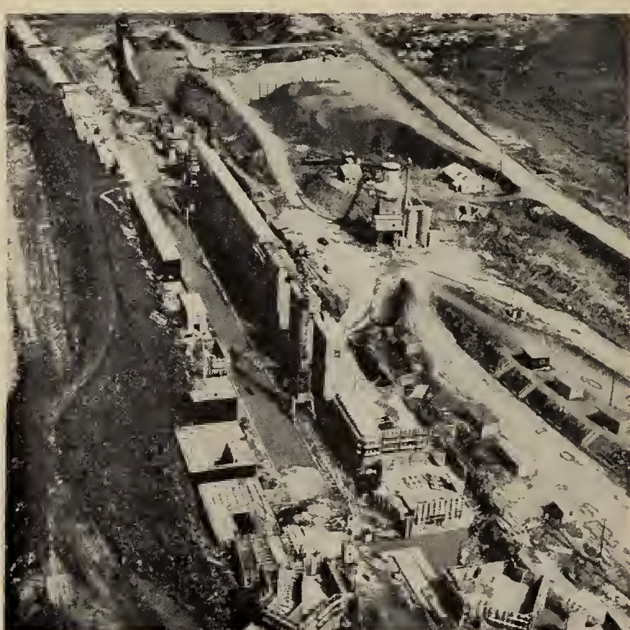

Fig. 12. Cote Ste-Catherine lock, showing monolith construction.

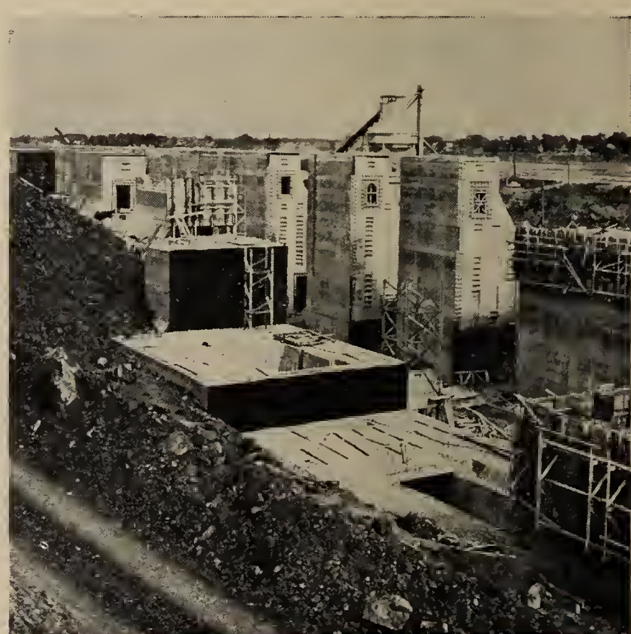

ation of the work of the many contractors, and the co-ordination of construction with the maintenance of all existing services (railways, highway traffic, power and communication lines, water supply and sewers, etc.). These were largely problems for the Seaway Authority to solve in the split-up of the work into contracts, and in the general planning of the work.

Some of the problems relating to the actual construction methods and procedures are described hereunder.

St. Lambert Lock

The lock is located in the former bed of the river, and the first step was the construction of a large cofferdam to unwater an area of about 150 acres. This cofferdam has a length of approximately one mile parallel to the river with connections to the shore at each end. The part parallel to the river was constructed to the full section and quality required for the permanent dyke of which it later became a part. The upstream shore connection was of similar construction. The downstream shore connection was somewhat of a lighter construction as no ice shoves were possible. As the schedule of lock construction required uninterrupted work throughout two winters, it was necessary to construct the cofferdam to an elevation which would make it safe against overtopping by floods caused by ice jams. This cofferdam was therefore constructed to elevation 49, to take a 20-foot rise of water level.

It was necessary to get the construction of the lock underway during the winter of 1956, and in order to be sure of completing the cofferdam during the fall of 1955, this part of the work was included in contract 16. In the following table are shown a few of the schedule dates and some approximate actual dates for the complete construction of the St. Lambert lock.

These dates show a brief record of the performance, which terminated in a satisfactory manner.

July 8, 1955	Contract 16 awarded for four miles of channel and dyke, which included the cofferdam for the lock.
Dec. 1955	Cofferdam for lock completed.
Dec. 23, 1955	Lock contract awarded.
Jan. 1956	Start of excavation
June 1956	Start of placing concrete (almost three months ahead of the date required by contract).
Sept. 1957	Start of equipment installation.
Nov. 1957	Concrete essentially completed.
Sept. 1958	Equipment installation essentially completed.

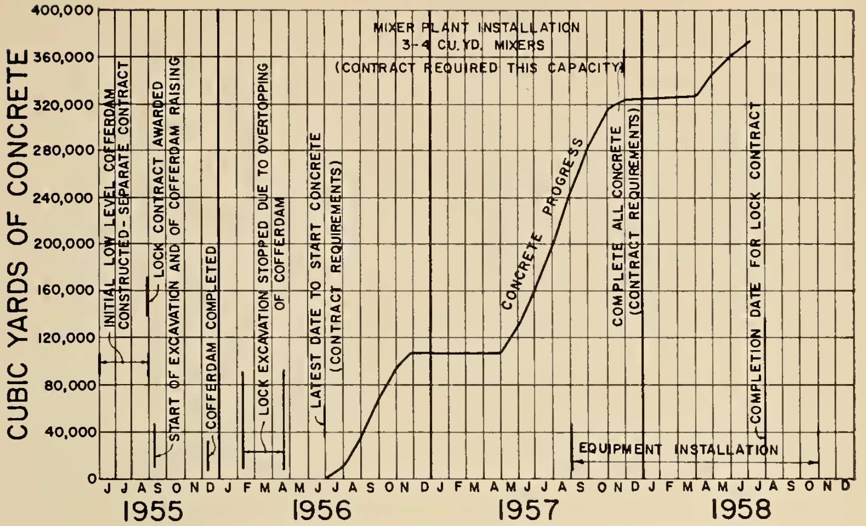

Fig. 13. Schedule and progress record, Cote Ste-Catherine lock.

Figure 6 shows the lock, nearing completion. Figure 7 is the general progress record for the work, and shows the periods of time for cofferdam construction, for the construction of the lock and entrance walls structures, and for the installation of equipment.

The whole cofferdam was constructed in advance of the awarding of the lock contract and was turned over to the lock contractor in an unwatered condition, ready for the start of excavation. The total construction time available to the main contractor was 32 months (January 1956 to August 1958).

All blasting had to be conducted under very strict regulations, particularly as the excavation approached close to and under Victoria bridge. Highway traffic on the bridge, (up to 2,000 cars per hour), had to be interrupted for every blast.

According to specifications, the contractor was allowed eight months in which to advance the excavation and get started on concrete. Concrete placing actually started three months earlier than had been required, but did not progress at an adequate rate in 1956 to meet the schedule. Note the excellent production performance by the contractor during 1957, reaching a peak rate of over 70,000 cu. yd. per month.

The construction procedure for the strengthening and enlarging of pier 24 and the south abutment of Victoria bridge was one of the most critical problems of the job. The piers of this bridge are stone masonry and were constructed over 90 years ago, and are founded on shale. It was necessary to take extreme precautions to avoid any damage to the foundations during the period of excavation for the lock and construction of the enlargement of the piers. The excavation for the lock required going about 40 feet below the elevation of the river bottom shale on which the piers were founded. The first operation was the excavation of a 100-foot wide cut to grade for a distance of over 200 feet along the centreline of the lock under the bridge. The next step was the excavation of a lateral trench in shale to grade through to the abutment on the one side of the lock and to pier 24 on the other side of the lock. A 12-foot section of the lock structure was then constructed against the rock underlying pier 24, and similarly for the south abutment. In a series of seven steps the shale was excavated up to the backline of the concrete in 12-foot trenches, and was followed after each excavation step by the construction of another 12-foot block of concrete. The whole operation of constructing the portion of the lock about 100 feet along pier 24 and along the south abutment required a total time of almost one year. It was not until this portion of the lock had been completed and had made the bridge piers completely safe that any change was made in the steel work. All during the time of the above work, railway and highway traffic passed over the bridge without interruption, except during blasting.

Figures 8, 9, and 10 show the first step, the concrete lock work completed, and the bridge almost erected.

Côte Ste-Catherine Lock

This lock is also located in the former bed of the river and the first step had to be the construction of a large cofferdam to unwater the area. The initial part of the cofferdam (up to elevation 40) was constructed under a separate contract. This initial low cofferdam was turned over to the lock contractor ready to set up pumps and start unwatering. This procedure saved about four months in time for the lock construction. The first obligation of the lock contractor, as provided for in the specifications, was to unwater the initial cofferdam and to immediately proceed with the raising of it to at least elev. 50 which was considered to be an adequately safe height to protect the work against high water level conditions in the winter due to ice jams. Extremely severe conditions did occur during the winter 1955-56, and in early February a large amount of the ice which had formed in Lake St. Louis broke away and formed an ice jam at the upper end of Laprairie Basin, which created water level conditions at the lock site higher than any which had previously been recorded. The cofferdam was overtopped and approximately two months of time was lost before the cofferdam could be again unwatered and excavation proceed.

The total construction time available to the main contractor was 34 months (October 1955 to July 1958).

The following tabulation shows an outline of the schedule and a record of the performance.

May 1955	Contract 12 awarded for ¾ mile of channel to the west of Côte Ste-Catherine lock, which included the initial cofferdam for the lock.
Aug. 1955	Initial cofferdam for the lock completed.
Sept. 1955	Lock contract awarded.
July 1956	Start of placing concrete (exactly on the date required by the contract, in spite of having lost two months by the cofferdam being overtopped).
Sept. 1956	Start of equipment installation.
June 1958	Concrete essentially completed.
Oct. 1958	Equipment installation essentially completed.

Figure 11 is a general view of the lock under construction and Fig. 12 shows an enlarged view of typical lock wall arrangement and methods of construction. Figure 13 shows the general progress for the work and shows the periods of time for initial cofferdam construction, the time during which the cofferdam was flooded, the construction of the lock and entrance walls structures, and the installation of equipment.

This contractor had a mixer plant installation of three 2-cu. yd. mixers, only half the capacity of that at St. Lambert.

Victoria Bridge Lift Span

The modifications to Victoria bridge required the installation of a lift span in place of the old 250-foot truss span. The construction of a lift span for Victoria bridge had been planned and estimated by C.N.R. engineers for earlier north shore layouts for the Seaway, and the general procedures had been pretty well worked out.

In October 1957, highway traffic was diverted completely off the last two spans of the bridge on to a road along the dyke and thence to the south shore across temporary structures (See Fig. 6).

The highway will not be restored on to Victoria bridge until the lift span has been completely erected. Superstructure erection was tied in very closely with train movements, and many interruptions were necessary. The procedure for the removal of the old structure and the replacement of the new railway lift span can be briefly described in the following steps:

(1) Construction of falsework across the lock and the loads of the old railway floor system transferred to the falsework.

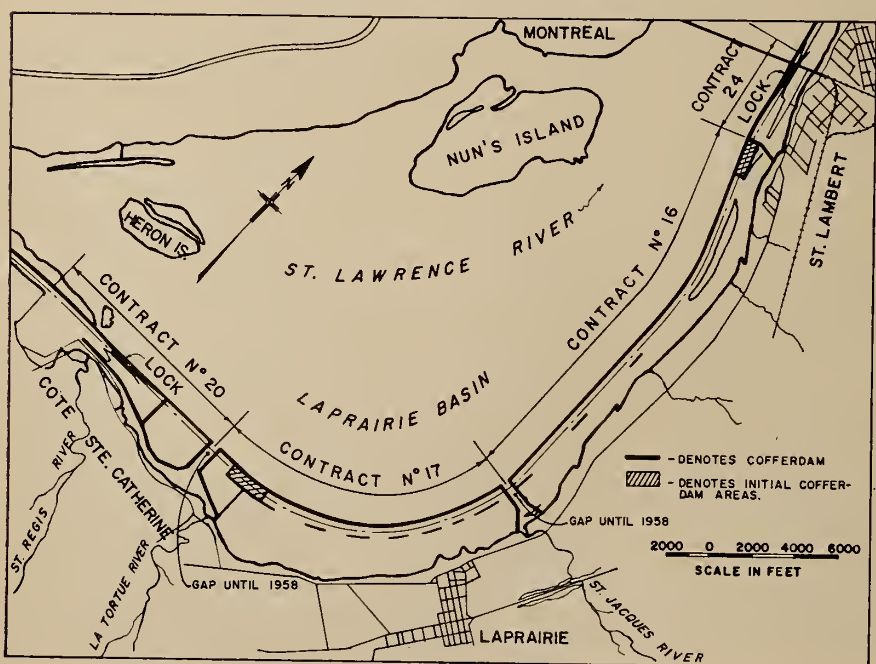
(2) Demolition of the old trusses and the old highway brackets.

(3) Construction of pier seats for the new lift span girders.

(4) With a short complete railway interruption, and with the floor system cut apart for the two tracks, the old floor system and falsework for one track was removed and a new plate girder span placed.

(5) Second new girder span placed in the same manner.

Fig. 14. Plan of cofferdams, Laprairie Basin.



Laprairie Basin Channel Excavation and Dyke

It is roughly 8 miles from St. Lambert lock to Côte Ste-Catherine lock, and all of this part of the channel has been located in the former bed of the river. Figure 14 shows the limits of the two Laprairie Basin contracts and the two locks. This figure shows the cofferdams for contracts 16 and 17, and also shows the gaps separating the contracts, providing for the flows of the local rivers until they could be taken down the Seaway channel and through the St. Lambert regulating works to the lower channel and thence to the St. Lawrence River at Longueuil. The closures at the gaps were made in the summer of 1958, after the spring run-off. This location around Laprairie Basin required large cofferdams, which were designed to be incorporated into the finished dyke. The quantities of excavation here were roughly double the quantities required for dyke construction, and made possible a reasonable amount of selection of materials. Excess excavation went to reclaim low land along the shore.

The contract plans suggested that the construction should be done by

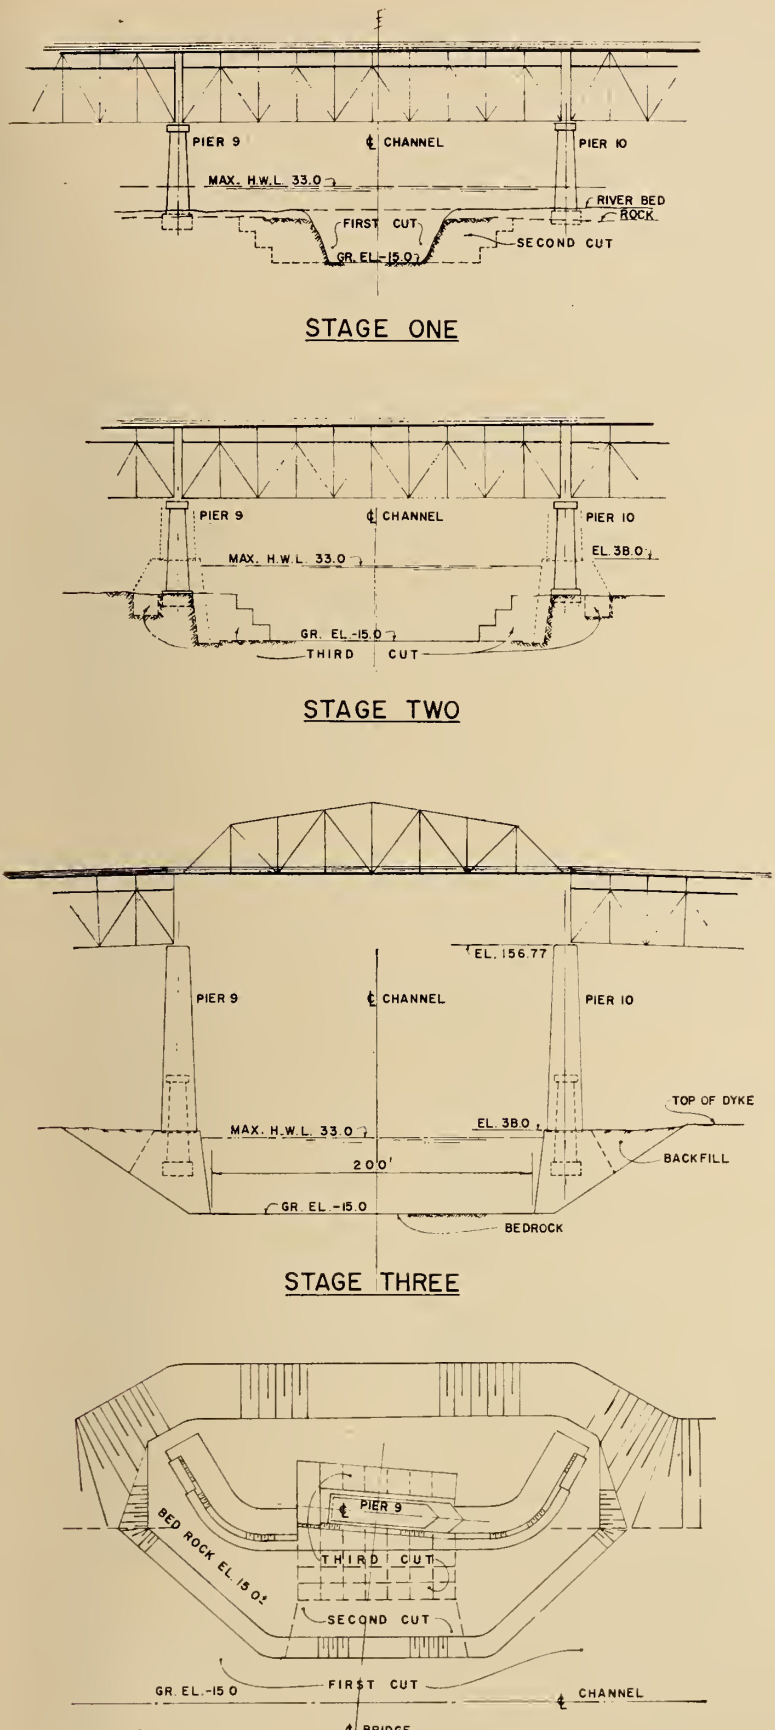


Fig. 15. Jacques Cartier bridge, pier enlargement and channel excavation.

the initial construction of a cofferdam around a convenient area with materials brought in from adjacent areas. When the first area was unwatered, it would provide large quantities of fill material for extending the cofferdams. The contractors for 16 and 17 both adopted this procedure. Figure 14 also shows the initial cofferdams constructed by the contractors.

The St-Jacques, La Tortue, and St-Régis Rivers have a normal spring run-off of as much as 2,000 c.f.s. each, but become almost dry during most of the summer months. The construction planning had to provide for the unrestricted flow of these rivers until the summer of 1958.

As the Laprairie dyke work was planned to have construction start in 1955 and as the work would extend through parts of four seasons, the general design of the channel and dyke construction and the contractor's operations had to be planned to handle the flows of these three rivers. As a result, this part of the channel and dyke was split into three separate contracts with specified gaps left at two points between the contracts. Three separate sections of the channel and dyke could be completed independently with the closures at the two gaps made in 1958 after the spring run-off had occurred. This plan has been followed.

In order to provide for the flows of these rivers regardless of what the discharge might be, the general schedule required the completion of the St. Lambert regulating works and the opening up of all the cofferdams below St. Lambert lock not later than early spring of 1958. The general schedule also required the portion of the Laprairie Basin channel and dyke from St. Lambert to Laprairie to be completed by the end of 1957 season, thus the flow of the St. Jacques River could be diverted into the completed channel downstream of Laprairie and flow through to the St. Lawrence River at Montreal. A small cofferdam was required across the upper end of the completed channel to permit the completion of the excavation and the closure of the gap in the dyke where the two contracts had been separated (see Fig. 16).

The following tabulation shows an outline of the schedule and a record of the performance.

July 1955	Contracts 16 and 17 awarded.
Oct. 1955	Initial cofferdam of contract 16 completed.
Nov. 1955	Initial cofferdam of contract 17 completed

Dec. 1955	St. Lambert lock high level cofferdam completed by contract 16.
Oct. 1956	All cofferdams completed contract 16.
June 1957	All cofferdams completed contract 17, (except closures at gaps).
May 1958	Channel and dyke completed between St. Lambert and Laprairie (contract 16).
June-July 1958	St. Jacques River gap (between contracts 16 and 17) closed, and channel and dyke completed.
July-Aug. 1958	St-Regis — La Tortue River gap (between contracts 17 and 20) closed, and channel and dyke completed.
Aug. 1958	Channel and dyke completed between Laprairie and Côte Ste-Catherine.

The actual time of construction for the 8-mile section channel and dyke was three years, or an actual working time of about 24 months for 12,000,000 cu. yd. of excavation — an average of 500,000 cu. yd./month.

Jacques Cartier Bridge—Enlargement of Piers 9 and 10

The modification work at Jacques Cartier bridge had to be one of the first jobs to get started due to the slow, step by step, program which had to be followed. The only phase of bridge work which will be covered in this paper will be the excavation of the Seaway channel between piers 9 and 10, and the strengthening and enlarging of the foundations of these two piers. Figures 15 and 17 indicate the problem of excavating the 200-foot channel between piers 9 and 10 to a depth of about 30 feet below the original shale foundation.

The initial channel cut 60 feet wide midway between piers 9 and 10 was included in contract 14, and was made during August and September 1955. The step by step channel widening and pier base enlargements started in late 1955 and took most of the 1956 construction season. In this work all precautions were taken to avoid any disturbance to the shale underlying the piers. The first step of this contract was to excavate a 15-foot wide trench laterally from the first excavated channel into the face of the pier on each side. A 12-foot section of the concrete for extending the pier downward was then placed and subsequent steps of a 12-foot excavated trench and a 12-foot addition to the new concrete of the pier completed the new piers in seven steps. The whole operation of the enlargement and strengthening of piers 9 and 10 extended over a period of twelve months, all of which was scheduled for completion and was completed before the start on the erection of the new truss.

The progress record for the work at Jacques Cartier bridge is summarized hereunder:

May 1955	Contract 14 awarded (included initial channel excavation cut at bridge).
Sept. 1955	Initial channel cut completed.
Sept. 1955	Contract awarded for pier enlargements.
July 1956	Contract awarded for bridge raising.
Oct. 1956	Channel completed to full width at bridge and bases for piers 9 and 10 enlarged.
Oct. 1957	New through truss span between piers 9 and 10 completed.
July 1958	Bridge raising completed.

Fig. 16. General view of canal from Laprairie looking north. Victoria and Jacques Cartier bridges in the distance; Laprairie turning basin in the foreground.

Honoré Mercier Bridge Extension

In relation to scheduling, it was necessary to have highway traffic entirely diverted to the new bridge not later than July 31, 1958, in order to permit the removal of the rockfill which had been constructed across the Seaway channel to provide for the temporary diversion of the highway traffic. The temporary highway diversion was constructed during the period from September 1956 to February 1957, immediately after which the old south approach ramp was demolished. Highway traffic remained on the diversion from February 1957 to July 1958, (see Fig. 18).

Canadian Pacific Railway Relocation

Before starting to raise the track, the shoulders of the existing embankment had been widened using rockfill from the canal excavations. In addition to the C.P.R. work, about a half mile of New York Central track which joins the C.P.R. at Adirondack Junction had to be raised. The track raising and relocation work required about 500,000 cu. yd. of rockfill, plus about 200,000 cu. yd. of crushed stone ballast.

The procedure of construction consisted of the excavation of the channel east of the railway embankment up to the site of the new bridge. In the planning of the relocation with the C.P.R. engineers the bridge was located as close to the embankment as possible without affecting the safety of the embankment. The piers for the new bridge were constructed during the period April to September 1957 and the erection of the superstructure followed. The railway traffic was diverted on to the bridge on June 5, 1958, and excavation of the old embankment followed immediately thereafter, (see Fig. 19).

Track raising work was done by railway forces and equipment. Four months were required to complete the jacking and ballasting, after the initial widening with heavy rockfill had been completed.

Notes on Cofferdams

Thirteen miles of the channel has been constructed in the former bed of the river and the construction of the cofferdams has been a large item of cost. Of the ten contracts, only the three extending from above Côte Ste.-Catherine lock to just beyond the C.P.R. embankment were constructed on land. The six contracts below Côte Ste.-Catherine were entirely constructed in the bed of the river. The upstream contract covering 2¼ miles along the river at Caughnawaga required large cofferdams constructed in fast water, for which two-thirds consisted of rockfilled timber cribs with steel sheet piling.

The remainder of the cofferdams throughout the work were of fill, generally obtained from the excavations.

A portion of the fill cofferdam at the extreme downstream limit stretching into deep water at Montreal Harbour required steel sheet piling driven through the fill to obtain adequate water tightness where the head exceeded about 10 feet.

The total cost of cofferdams and unwatering for the whole canal was of the order of $5,000,000, of which about $3,000,000 represents the cofferdams for the contract at Caughnawaga, and $1,000,000 represents the cofferdams and unwatering for all of the Laprairie Basin work.

Fig. 17. Jacques Cartier bridge. Third stage of channel excavation with three steps of concrete completed at pier 9.

Winter Conditions—Ice Jams and High Water Levels

The St. Lawrence River at Montreal has always been subject to ice jams and consequent flood conditions. Records for the past 50 years were available and the construction schedule for all of the work of the Lachine section had to be related to the probable winter conditions.

Contracts 14, 1, 16, and 17 which included only excavation of the channel and construction of dyke, were scheduled on the basis that low level cofferdams would be all that would be required, i.e. the contractors on these parts of the work would have to provide enough equipment to do the work within the non-winter months available to them. It was also planned that in these four contracts, suitable arrangements would be made for flooding the work prior to high water conditions in order to avoid large volumes of erosion which could occur if they were overtopped. In one case the cofferdam was overtopped in early January as a result of trying to take advantage of a late ice build-up. When the ice jam and flood did come, there was insufficient time left to control the flooding of the cofferdam, and about 10,000 cu. yd. of material eroded into the channel and subsequently had to be re-excavated.

The construction of the St. Lambert and Côte Ste.-Catherine locks required the entire time available, and it was therefore necessary to plan on high level cofferdams adequate to cope with expected ice conditions. The specified minimum cofferdam elevation for Côte Ste-Catherine proved inadequate and the Côte Ste-Catherine cofferdam was overtopped. The winter conditions of 1955-56 were substantially more severe than any previous known occurrence. The consequence of this overtopping was to interrupt the excavation and to delay the start of concrete by about two months.

The two contracts covering the seven miles of channel excavation and dyke construction around Laprairie Basin were planned on the basis that the cofferdams would be flooded early in the winter. The contractor who had the 4-mile section from St. Lambert to Laprairie (contract 16) elected to construct a high cofferdam and continue work throughout the winter. During the winter of 1956-57, there was a period of several weeks when water level was within a foot or so of the top of the cofferdam, but no overtopping occurred and work did proceed all winter. The cofferdam

Fig. 18. Honore Mercier bridge crossing of canal. Remainder of temporary rock-fill for highway diversion in foreground.

Fig. 19. Canadian Pacific Railway twin lift bridges, Caughnawaga. This railway crosses alongside the Honore Mercier bridge.

for contract 16 was further strengthened and raised before the winter of 1957-58, and was never in any danger of being overtopped. Unfortunately, the work was stopped for three months by being flooded out due to very heavy thaws in December and again in March, causing large surface run-off.

Filling the Canal

The filling of the canal at the end of construction presented a few small problems. This operation was naturally separated into three distinct areas:

(1) The section below St. Lambert lock was flooded to equalize the water level with that existing in Montreal Harbour, after which the remainder of the cofferdam below Jacques Cartier bridge was removed. The final cleanup at that barrier is now being done under a dredging contract. Three weeks were taken to fill this area.

(2) The Laprairie Basin section extending from St. Lambert lock to Côte Ste-Catherine lock required the diversion of the three local rivers into the channels downstream for the completion of the work at the gaps which had originally been left for their flow. The initial filling of this part of the canal up to Montreal Harbour water level (actually slightly higher to allow for slope) was the first step to permit the local run-off to flow through the regulating works to the harbour. The final filling of this section of the canal to operating water level will be done by passing water through the Côte Ste-Catherine regulating works to fill the intermediate pool.

(3) The section above Côte Ste-Catherine lock extending up to Caughnawaga required complete filling to Lake St. Louis level before the cofferdam at the upstream end could be removed. This required an inflow of 1,000 c.f.s. per day for five days.

After equalizing water level in the canal with Lake St. Louis, the upstream cofferdam was removed, and the remainder of the channel excavation will be done by dredging.

Lowering of Ground Water

Along the 13 miles of the south shore roughly from the town of Preville (or a mile above Victoria bridge) to the upper limits of the Village of Caughnawaga, there are several hundred residences and a few schools and other occupied buildings. Many of these homes depended on wells for their water supply.

The construction of cofferdams around Laprairie Basin, and particularly the excavation into the shale underlying the glacial till, had the effect of lowering the ground water around the shore of Laprairie Basin with the consequence that several hundred wells were dried up. Studies and estimates were made of various means of supplying the residents, the final conclusion being that for assurance of water supply during summer or winter, delivery by tank trucks into 250-gallon tanks furnished by the Authority to individual residents was the most satisfactory way of meeting the situation. With the Seaway channel located such a distance out from shore, it was not expected that the wells in this area would run dry, and the two contracts did not make any provision for the local water supply.

Around the shoreline in the Village of Caughnawaga, the Seaway channel is entirely in rock and close to the shore. It was expected that wells in this area would run dry and the construction contract provided for the supply of water to local residents. As it turned out, the wells in Caughnawaga did not run dry and there was no problem.

CONCLUSION

During 1955 and early in 1956 there was scattered excavation under way in many parts of the 18.5 miles of Seaway route. By 1957, the excavations were mostly joined up. 1958 has seen completion of all channels and dykes, and the start of permanent flooding. Dredging at the Montreal Harbour and Lake St. Louis entrances is in progress.

Most of the problems that have been encountered in the construction of this part of the Seaway are those which would be encountered in hydro-electric projects, municipal works, and transportation construction, but the area covered by the whole project caused many of the problems, as far as quantities were concerned, to be big ones. There were few new problems encountered, except those relating to a large number of contracts fitted into a tight over-all schedule.

Construction of the Seaway was nearing completion by August, and progress in general had been reasonably close to the planned schedules. Three of the ten main canal contracts were completed ahead of schedule, and the other seven have been completed essentially on schedule or certainly within the permissible tolerance.

The completion of the work essentially within the four years available can be taken as showing successful planning and excellent performance on the part of the contractors.

Soil and Foundation Problems *(Cont. from p. 76)*

have added one-third of one per cent to this amount. The total expenditure on soil and foundation work has therefore been little more than one half of one per cent of that on the related construction.

ACKNOWLEDGMENTS

Professor J. E. Hurtubise, P.Eng., M.E.I.C. acted as consultant on all of the investigations described. Mr. E. B. Owen, of the staff of the Geological Survey of Canada, was on loan to the Authority and assisted the work as engineering geologist.

Soil and Foundation Problems

F. L. Peckover M.E.I.C.* and T. G. Tustin JR.E.I.C.†

Soil Engineering Section, The St. Lawrence Seaway Authority

THE INTENSIVE WORK of the past six years on the design and construction of the Canadian section of the St. Lawrence Seaway project has seen the application of soil and foundation engineering practice on a scale unsurpassed on a single project in this country. The urgent schedule of the work has made it essential that delays due to unforseen soil, rock, and groundwater conditions be kept to a minimum. This need has underlined the importance of continuing soil and foundation studies from initial exploration through the design and construction phases.

This same urgency has necessarily confined the consideration of particular problems to an *ad hoc* basis. Nevertheless a number of interesting solutions have been reached among the variety of questions dealt with, and some of these will be described.

The connection of soil and foundation difficulties with the construction of canals is a traditional one. The function of canals inevitably locates them on low ground and interferes with natural geologic processes. Under such circumstances, problems of stable excavation slopes, foundations for structures, and water seepage are to be expected.

The field of soil mechanics owes some of its greatest advances to investigations which arose from difficulties in canal construction. Before 1946, Alexandre Collin, one of the less recognized pioneers of civil engineering, analyzed a number of landslides which had occurred along canal banks in France. The conclusions which he reached have been substantiated by recent investigations [1].

During the first World War treacherous ground encountered in excavating the Kiel Canal, in Germany, and slope failures which delayed completion of the Panama Canal promoted special investigations which aroused world-wide interest in the study of soil as an engineering material.

Such problems are not confined to other countries. Soil and drainage conditions along the route of Canada's Welland Ship Canal have led to many slope movements during construction and operation. These are now being analyzed and the results will add a Canadian contribution to tradition.

Site Investigations

The need for an extensive investigation of subsurface conditions along the St. Lawrence Seaway route has puzzled many engineers. The channel lies through one of the first settled, most populated and historical parts of Canada and it would be expected that construction conditions would be well established. However, for economic reasons about 80 per cent of the excavated length of the channel is in the bed of the St. Lawrence River and the remainder passes through agricultural land. This is shown in the general location plan of the route in Figure 1. For this reason detailed information on soil and rock conditions along the channel was almost completely lacking before 1952 when final design studies were started. Subsurface exploration has since played a most important and continuing part in the work.

In all, some 1,700 test borings have been made, with a total footage of 32,000 ft. in overburden and 40,000 ft. in bedrock, supplemented by numerous test pits, auger holes and other special investigations [2]. Of this total number of borings, about two-thirds were made prior to the start of actual construction. The testing of soil samples obtained from exploratory work is done in a consulting laboratory in Montreal. Boring and testing are still continuing to assist in the solution of construction problems as they develop.

For maximum economy, the means of exploration are tailored to the particular needs of each investigation. In granular soils, split spoon samples are usually taken for identification and testing, the number of standard hammer blows during sampling serving to show their relative densities. Where the general soil profile is known, the driving of a penetration cone is often sufficient to show the boundary between loose and dense materials. This test has been particularly useful for the rapid extrapolation of the results of sample borings.

Considerable time is saved in the investigation of clay deposits by using a rotating vane apparatus in conjunction with the usual "undisturbed" sampling with thin-walled tubes. More consistent values for the strength of marine clay are found *in situ* by the vane apparatus than from laboratory tests, due to the varying amount of sample disturbance. Design values for this particular clay are usually taken as two-thirds of the vane shear strength. Investigations of the marine clay at the Beauharnois upper lock site were made by these means in co-operation with the Division of Building Research, National Research Council[3].

Groundwater

Groundwater observations have a special significance in the site investigations. With the river nearby it is most important to detect water-bearing layers which may be a source of difficulty with excavation slopes and the foundations of dykes and cofferdams. Observation wells, permeability and discharge tests in bore holes, and fluoresce in dye have assisted in obtaining a complete and continuing record of groundwater occurrences where required.

During the course of this explora-

*Senior Assistant Engineer (Soils)
†Assistant Engineer (Soils)

tory program, extending over a distance of 120 miles along the river, the importance of thorough and competent drilling practice has been emphasized. If deficiencies or inaccuracies in any particular part of the work are found, they can invariably be traced to either an insufficient number of borings or observations, or inadequate inspection and logging of the results.

Table I. Typical Properties of Soil Deposits

Soil Deposits	Till				Clay		
Properties	Lachine — Upper Unweathered	Lachine — Upper Weathered	Lachine Lower	Iroquois Upper	Beauharnois — Marine Unweathered	Beauharnois — Marine Weathered	Lachine — Lacustrine
Natural Water Content (%)	15	18	10	7	57	44	28
Optimum Water Content (%)	—	15	8	8	—	30	—
Natural Dry Density (p.c.f.)	119	113	132	138	71	79	96
Optimum Dry Density (p.c.f.)	—	116	133	133	—	89	—
Liquid Limit (%)	19	—	16	—	57	68	38
Plastic Limit (%)	16	—	13	—	29	37	19
Plasticity Index (%)	3	—	3	—	28	31	19
Strength:							
Triaxial Compression			"quick" test		Triaxial compression tests made only on samples of low strength		
angle of internal friction (°)	—	—	33	38			
cohesion (p.s.f.)	—	—	1100	900			
Unconfined Compression (p.s.f.)	—	—	—	—	900	2700	1600

There is no other field of engineering in which details which may seem trivial at the time can later assume such great importance and there are few which can give the satisfaction of recognizing such details and developing their full implication.

Soil Deposits

The exploration program revealed conditions which are generally favourable for heavy construction. A brief resumé of the regional geology will show the relation of the various deposits.

The St. Lawrence River valley has been subjected to at least two glaciations, followed by an inundation by the sea and finally uplift above sea level. During glaciation the bedrock surface was reduced in relief and dense glacial till laid upon it, ranging in thickness up to 100 ft. but usually of the order of 20 to 30 ft.

Till deposits of the first glaciation are found at all locations along the Seaway route, but those from the second are found only in the International Rapids section and at scattered locations in the Lachine section. Between the two deposits, lacustrine clays and poorly graded sands and gravels are occasionally present. In the river bed, fines from the upper layer of till have been washed out leaving a mixture of coarse sand, gravel and boulders.

During submergence by the sea, the till was covered by a deep bed of marine clay, capped with marine sand. As the land surface emerged above sea level, the sand and clay were removed by erosion except for local remnants, the most important of which are at Beauharnois and Cornwall along the Seaway route.

The till generally is a most useful construction material as shown by its inclusion in nearly all dykes and its use as a seal in all rock cofferdams. It is a dense, well-graded soil mixture appearing as illustrated in Figure 2, with approximately equal silt, sand and coarse fractions in a typical sample. Wide variations occur in the proportions of silt and sand.

The marine clay found at Beauharnois and Cornwall is relatively weak and soft in its natural state and becomes very soft and sticky when disturbed by excavation. The weathered portion of this deposit is suitable for compacted fill. The unweathered portion may be considered as a general liability in construction operations.

Typical values of the engineering properties of these soils are given in Table I.

Bedrock Conditions

The stability of the bed of the St. Lawrence River can be attributed to the resistance to erosion of the glacial till and the bedrock formations of which it is composed. The river flow is controlled at intervals by outcropping ledges of the more resistant rock. A series of rapids and intervening pools is thus formed between Cornwall and Montreal. The rapids of the river, skirted by canals and locks, are thus separated by broad reaches such as Lake St. Francis and Lake St. Louis which require only dredging for improvement for navigation.

Bedrock which occurs along the river between Lake Ontario and Montreal is mainly sedimentary. Igneous rock is found in the Thousand Islands section and as intrusions in some of the sedimentary beds. The latter include shale, limestone, dolomite, sandstone, and various combinations of these.

From the viewpoint of foundation quality the bedrock is relatively free from large fault zones or folding. Bedding is generally horizontal with local dips not exceeding 10 degrees.

The limestone and shale from channel excavation are used extensively in embankment and dyke construction. The shale is a cemented nonplastic rock which disintegrates into angular particles on exposure to air. Since broken shale was readily available for use in pervious zones of the dykes, detailed studies of old shale dumps in the area were made. These confirmed that weathering of the shale does not reduce it to an impervious condition.

The geology of the St. Lawrence River region is well described in various references[4,5,6].

Design of Dykes

In the course of design and construction the problems encountered have touched on almost every aspect of the soil and foundation field. The nature of the work, however, laid heavy emphasis on problems of excavation, construction of fills, the stability of slopes, groundwater and drainage, and foundations for large structures. Other problems were generally offshoots of these major considerations.

The construction of dykes, embankments and backfills has involved placement of some 3.4 million cu.yd. of compacted fill and 9 million cu.yd. of other fills requiring treatment. Of these, the placement of compacted fill in dykes has required the most attention. The total excavated on the project was 46 million cu. yd. of overburden and 24 million cu. yd. of rock.

Nearly all the dykes required for the project are located in the Lachine section. Their function is to confine the navigation channel and keep its water level constant in the face of fluctuating river levels. The relative position of channel and dykes is therefore as shown on the plan in Figure 3 and in the aerial view in Figure 4.

Since ice jams in Montreal Harbour can cause a rise or fall of the water level in Laprairie Basin of several feet in a few hours, the rapid drawdown condition was an important consideration in the design of dykes in this area. Dyke sections were chosen to utilize excavated materials to the maximum and were zoned to suit the supply of materials and to incorporate the necessary cofferdams, where possible. The general section consisted of an impervious core of compacted earth between pervious shoulders of broken rock. The zoning of this section was varied depending on the importance of the dyke as illustrated by the two typical sections in Figure 5.

Glacial till proved to be an ideal material for the impervious core and broken shale or limestone was used for the pervious shoulders. High factors of safety were inherent due to the granular nature of all the materials.

Water-bearing layers found in dyke foundations were blocked, either by a cutoff of impervious fill under the centre core for section (a) of Figure 5 or by a blanket of impervious fill extending as far down on the channel side as necessary for section (b).

Construction of Dykes

The construction of dykes was started in the spring of 1955 and is now complete. This schedule required the placement of compacted fill at rates as high as 225,000 cu.yd. per month by individual contractors.

Compaction of both the glacial till and clay was carried out almost without exception by sheepsfoot rollers although other means of rolling were permitted. A view during placement of one of the larger dyke fills is shown in Figure 6. At junctions of earth fill with rock foundations and con-

Fig. 2. Typical exposure of glacial till.

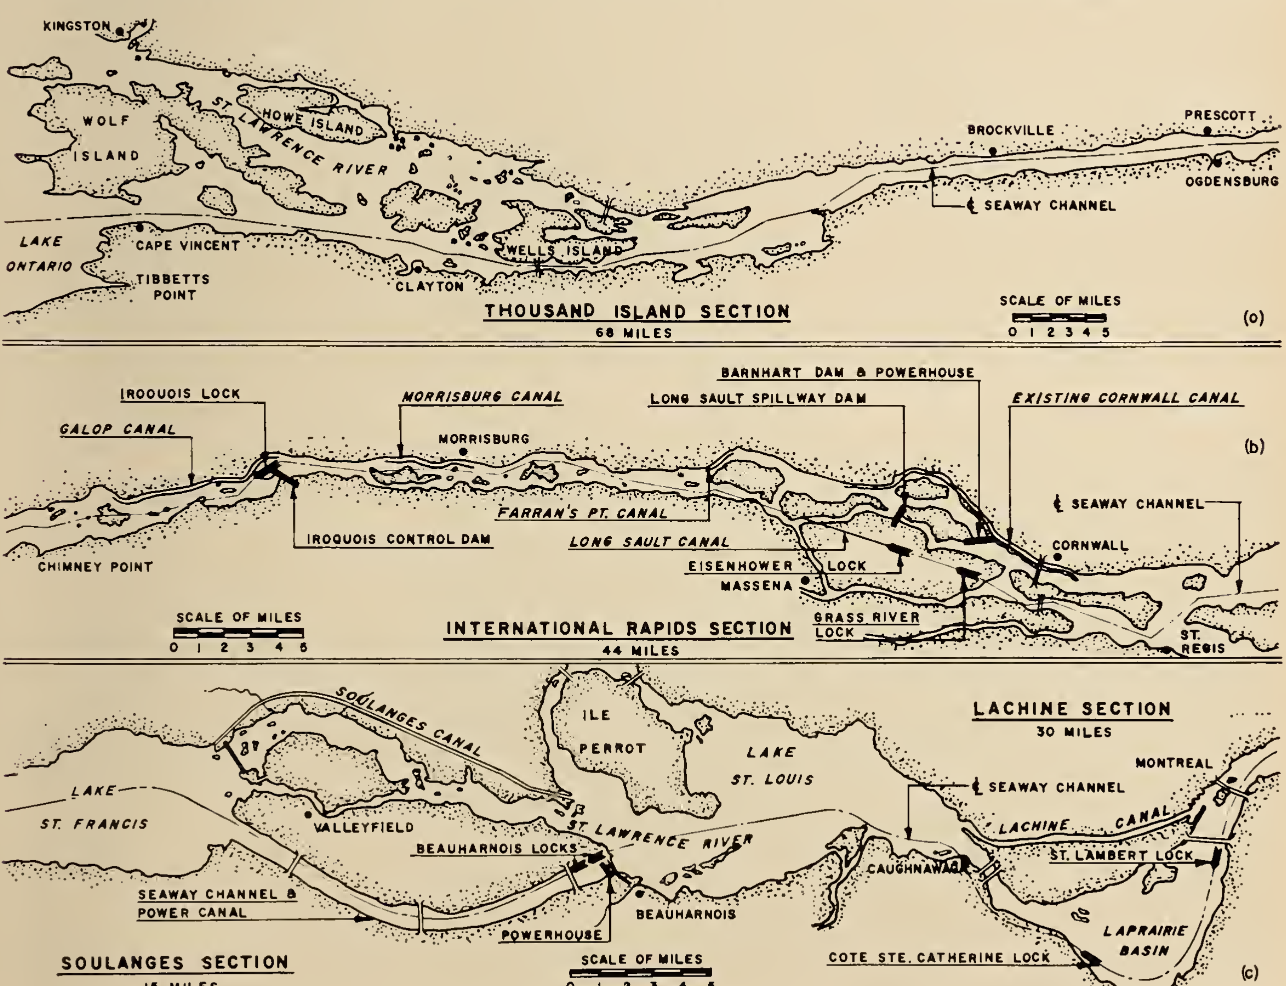

Fig. 1. General location plan of Seaway route.

crete walls, power tampers were originally specified for compaction. However, in practice it was found to be more satisfactory and economical to use heavy loaded trucks. The squeezing action of the truck tires was particularly effective in compacting fill over irregularities in rock and against sloping concrete walls.

Winter Compaction of Fills

On some occasions it was found necessary to compact small quantities of earth fill in winter to meet construction requirements. Materials so placed were not allowed to remain in important fills. When unavoidable the problem was successfully met in all but the most extreme weather by working rapidly with heavy equipment in small areas.

The fill material was spread in 6-in. layers and frozen clods were removed. Heavy loaded trucks were used for compaction in preference to sheepsfoot rollers in order to leave a minimum surface area of fill exposed to the air. The densities thus obtained were in the range of 90 to 95 per cent of standard Proctor density for both glacial till and clay, except when the temperature was too low.

It was found that freezing of the earth before compaction, resulting in lower densities, occurred at a temperature which was characteristic for each type of fill material. For till at a water content of 10 per cent this temperature was about 20° F., whereas with weathered marine clay at a water content of 24 per cent it was near 0° F. The difference seems to be associated with the higher water content and latent heat of fusion of the clay.

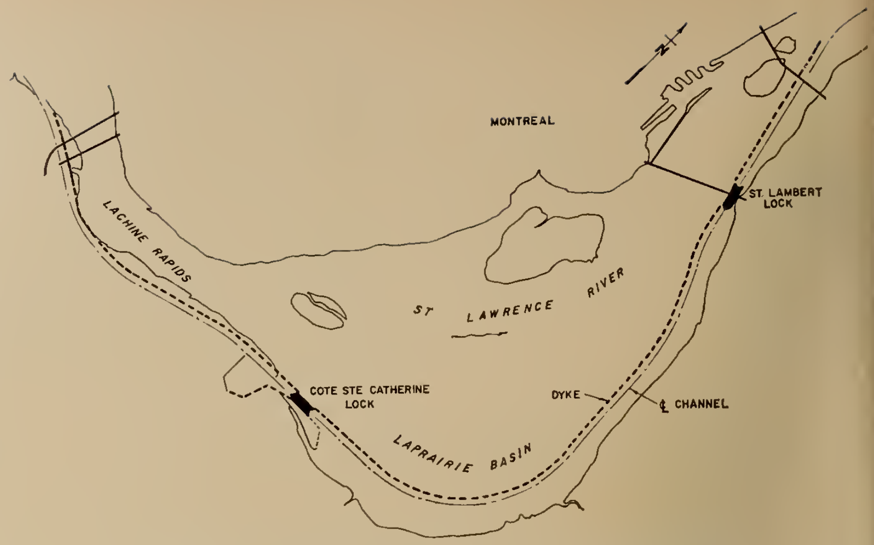

Fig. 3. Location of channel and dykes in Lachine section.

Compaction Control

The practical field control of the compaction of glacial till is not difficult. The soil as obtained from the borrow pit usually has a water content slightly higher than required. The grading of the material and its consequent very low void ratio is such that the addition of only 2 or 3 per cent of water softens it and prevents the successful operation of the hauling equipment over the fill. Material placed at natural water content is always trafficable. Good drainage at both the borrow face and the fill is needed to handle the material effectively.

Field control testing for compacted fill operations was done in three regional field laboratories, supplemented by a mobile testing unit which proved most useful for isolated parts of the work.

The density of fill in place was checked against the standard Proctor density of the soil used, to ensure adequate strength and watertightness. Early in the program, however, it was found that the usual field density test, involving measurement of the volume of a hole dug in the surface of the fill, was difficult and time-consuming on account of the high density and number of stones. A means of direct volume measurement was therefore used which gave results consistent with standard methods.

Representative chunks of soil quickly dug from the fill were immersed in a cylinder filled with oil and their volume found by displacement. The apparatus is pictured in Figure 7. The method is naturally limited to soils with low permeability and some cohesion, but gives satisfactory results with some elementary precautions.

Fig. 4. Aerial view of channel and dyke; Laprairie Basin toward Montreal Harbour.

Fill Performance

The performance of various fills has been followed closely. In some locations dykes were subjected to high water levels in winter while the adjacent navigation channel was dry. Leakages observed in such extreme conditions were satisfactorily small.

In many locations the performance characteristics of fills have been followed by means of measurements of various types. Measurements were taken in connection with a roadway embankment on Cornwall Island which was founded on dense till after 20 ft. of clay were excavated from the foundation area. The embankment fill, which was also glacial till, was compacted against the natural clay along the side of the excavation on a face which was nearly vertical. The general proportions of the fill are shown in section (a) of Figure 8.

Calculations showed some possibility that the lateral component of the weight of the embankment might rupture a wedge of the clay and cause damage to the body of the fill. To check on any tendency of the clay to squeeze thus, a number of plastic pipes, sealed against the entry of water at the lower end, were installed vertically at the location shown. These were checked visually for plumb during construction by lowering a flashlight inside. The embankment is now complete and no movement of the clay has been detected.

Settlement of Fills

Another section of this same embankment is founded on the surface of the clay. Here, it was of concern to follow the progress of settlement of the top of the fill before final grading and paving were done. Since this total settlement was the sum of the consolidation of the compacted embankment fill and of its clay foundation, it was desirable to measure these two effects separately. To do this, a pipe was laid from the centre to the edge of the foundation area of the fill. Short vertical sections were added to the ends to enable the pipe to act as a manometer. The compacted fill was then placed. This installation is shown schematically in section (b) of Figure 8. By adding water at the outer end of the pipe until it overflowed at the inner end, changes in the level of the embankment foundation were measured and, with the aid of bench marks on the top of the fill, the separate consolidation effects evaluated.

Settlement observations on fills have been useful in dealing with many problems and have been made from the start of construction. As work in the vicinity of the locks progressed it became necessary to found structures on various fills which had been in place for varying times, and the rate and degree of settlement to be expected of these fills became a matter of importance. The problem, as with so many others, was aggravated by the close scheduling of the work.

Some of the fills involved were built as roadways, embankments or working areas, but many were simply backfills for lock or approach walls, or random disposal. Of the fill materials, only compacted glacial till was in any way subject to consolidation according to the conventional theory. Others were generally granular, ranging from mixed earth and rock to heavy igneous rock. Some were required to be compacted by construction traffic but most received no special treatment during placement and some were even dumped in water. Settlement of these fills was due to subsequent traffic, slow weathering and the fracturing of overstressed particles.

A search of literature on the problem showed little available information, mostly referring to rockfill dams in which the fill placement was carefully controlled. Fills of many types and sizes on the project were therefore put under observation and the conditions of placement noted. At one time, more than 100 observation points were being checked.

Although preliminary, the findings have been applied to many foundation problems. Some of the basic data are given in Figure 9. Measurements were started at an arbitrarily chosen time of 10 days after fills were completed, as their initial rapid settlement was not usually of practical sig-

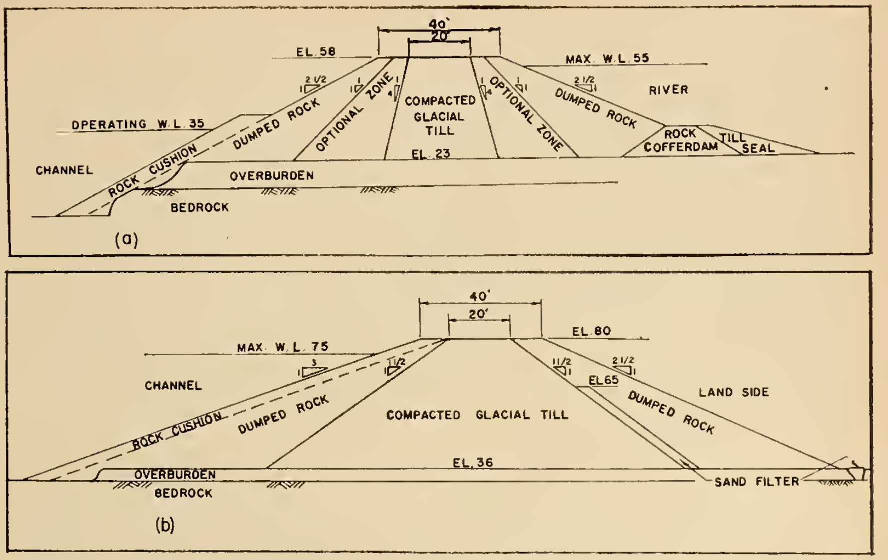

Fig. 5. Typical dyke sections: (a) for heights up to 20 ft.; (b) for heights from 20 to 40 ft.

Fig. 7. Oil immersion apparatus for field density testing of soils, with lowering basket and sample.

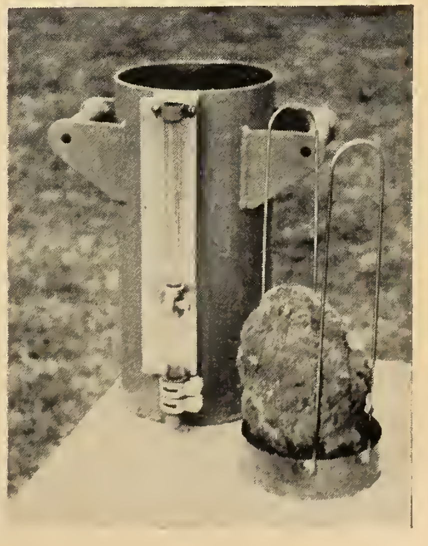

Fig. 6. Compacting glacial till in impervious core of dyke.

nificance. Due to the complexity of construction operations, simple examples of uninterrupted fill placement were seldom found and some of the individual results varied widely from those shown. The large number of observations taken compensate in part for this, but the curves should be applied cautiously with allowance for natural variations between these materials and those elsewhere.

One of the problems associated with the settlement of fills involved some of the dykes built according to section (a) of Figure 5. Longitudinal cracks appeared at the junction of the compacted till core and the broken shale zone on the outer side and these were followed shortly afterward by supplementary cracks near the centre of the core. The first appearance of these cracks seemed to coincide with a sudden rise in the river level against the dyke. Subsequent measurements showed that the differential settlement between the two zones was suddenly increased by inundation of the broken shale. The cracks near the centre of the compacted earth core were induced by friction with the shale as it settled.

Cracking was confined to portions of the dyke which were subject to low heads and was not considered serious enough to warrant repairs. Test pits were excavated and it was shown that the cracking did not recur after the large initial settlement of the shale had passed. In later construction the slope of the till-shale boundary was flattened to 1 on 1 to increase the stability of the core and no further trouble was met.

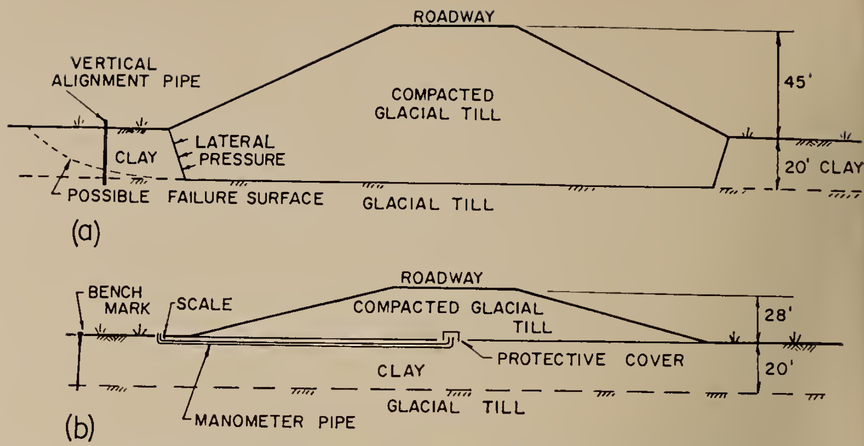

Fig. 8. Measurements on highway embankment on Cornwall Island: (a) for lateral movement of clay; (b) for vertical movement of clay.

Foundations for Lock Structures

The Seaway locks and approach walls are concrete gravity and semi-gravity structures, ranging in height from 38 to 87 ft. They are generally located so as to be founded on bedrock. An exception is Iroquois lock where approximately 2,500 ft. of the upper approach wall rests on glacial till.

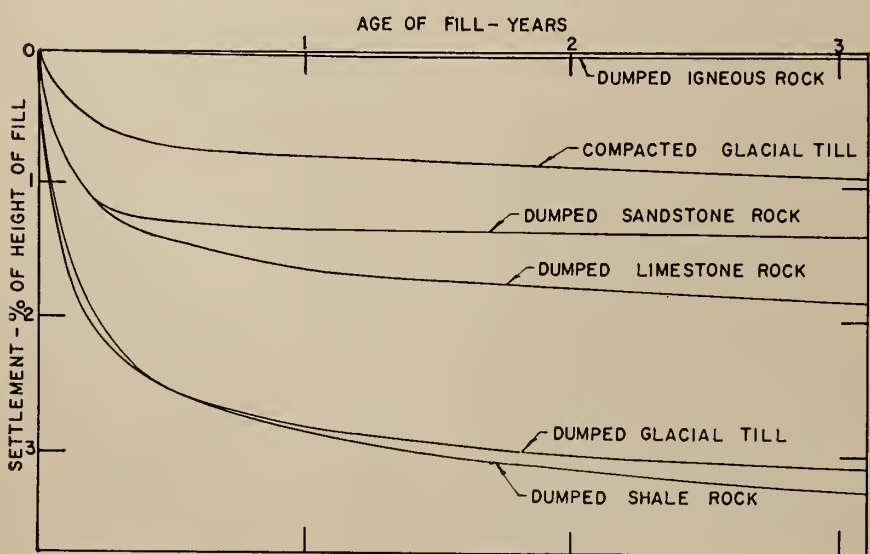
Evaluation of a safe bearing value for till is not usually a problem in ordinary construction since it is amply strong and dense to support the heaviest loads (see properties in Table I). At Iroquois lock, however, the differential settlement of adjacent wall monoliths was a construction as well as a design consideration, and bearing values on this basis were required. Loading tests were quite unsuitable for this purpose because of the very dense and stony nature of the soil.

Indirect means of evaluation were therefore used. Standard penetration test results were corrected for the high silt content of the material and applied on the assumption of 1.0 in. of allowable settlement[7]. This gave a value of 6 t.s.f. for a continuous wall 32 ft. wide.

Samples of till obtained from borings were then recompacted to natural density and water content and subjected to consolidation tests in the laboratory. Calculations based on the results of these tests showed a settlement of 0.7 in. to be expected under a unit load of 6 t.s.f. This design bearing value was therefore used.

The natural density of the till is so great that it is difficult to imagine any noticeable settlement taking place under a loaded area. However, careful measurements taken during construction on one of the wall monoliths showed an average settlement of 0.4 in. under the front edge with full backfill. Considering normal variations in test methods and natural soils, this agreement with calculated values seems reasonable.

Fig. 9. Typical time-settlement curves for granular fills.



Shale Foundations

The main lock structures are variously founded on dolomitic limestone at Iroquois, sandstone at Beauharnois, and shale at Cote Ste. Catherine and St. Lambert. Of these, the only deposit which warrants special mention is the shale.

Its tendency to weather rapidly on exposure to air has already been noted. For this reason it was necessary to protect shale surfaces which were prepared for concrete. Early in the work a number of different protective coatings were exposed on a test area of shale. Best protection was found to be given by two spray coats of bituminous mastic. This treatment was subsequently used on all shale surfaces which were to be left exposed for longer than one week. For exposures longer than one month it was found that disintegration had commenced even where a protective coating was applied but this did not assume serious proportions unless exposures lasted longer than three or four months.

Groundwater Problems

As would be expected in a construction project of this size, involving continuous excavation along miles of river bank, water seepage into work areas was the rule rather than the exception. Records of flows and levels were maintained where the work was affected.

The various sources of leakage soon became well recognized. The boulders and coarse material strewn over the river bed sometimes increased the difficulty of making an effective earth seal for rockfill cofferdams, and always impeded the driving of sheet pile cutoffs for timber crib types. Fortunately, this river bed material was sufficiently well graded to minimize the danger of piping.

In excavation work, groundwater occasionally flowed from lenses of uniform sand within the till but these did not usually connect with a permanent source of water and could be drained. The actual quantity of water involved was invariably small.

The chief source of water in all excavations was the sedimentary bedrock. Shale, found between Montreal Harbour and Cote Ste. Catherine was generally massive in structure and yielded little water. Limestone, underlying the channel between Cote Ste. Catherine and Lake St. Louis, was weathered in the top few feet and contained occasional faults. It gave little water in most areas, but produced as much as 15,000 g.p.m. in a particular 3,000-ft. length of channel. Observation wells here showed that the drainage effected sufficient drawdown to reduce greatly the uplift under adjacent earth slopes. No internal erosion of slopes was observed and with continuous pumping the excavation proceeded on schedule.

The sandstone, and particularly that underlying the Upper Beauharnois Lock site, produced the greatest quantity of seepage. This rock is weathered to a depth of a few feet and contains zones of shattered rock. In some locations the shattering has been extreme and left a pulverized material which acts as a barrier to the water circulating through the general joint pattern. More often, however, the rock is broken to such a degree that it channels the water in large quantities.

Fig. 10. Identical views of approach to Upper Beauharnois lock, looking west along power canal: (a) before work started; (b) before flooding to dredge out canal dyke.

Site Conditions at Beauharnois Upper Lock

Since the site conditions at Beauharnois were responsible for the most difficult excavation and drainage operation on the entire project, some of their details may be of interest.

The Beauharnois power canal has been dredged since 1930 by successive stages to conduct water from Lake St. Francis to the Beauharnois powerhouse (see Figure 1). The canal provides, by agreement with the federal government, a navigation channel along its north side from which ships will enter the Beauharnois locks.

Dredging of the canal has changed the groundwater conditions in the area considerably. It introduces an unlimited source of water directly to the bedrock at a head some 12 ft. higher than the original groundwater table. As a result, the blanket of soft marine clay overlying the bedrock in the vicinity of the canal is under artesian pressure from this fresh source of water below.

Numerous test borings made prior to the start of the work at the upper lock site showed flows of water under artesian head. To gather additional subsurface information a braced and sheeted test pit was put down to bedrock in the approach area. In conjunction with this, a pumping test was done and the effectiveness of sheet piling and grout as a cut-off was noted. The sheet piling reduced seepage through a thin layer of coarse-grained till lying between the soft clay and bedrock and grouting reduced seepage through the rock but, even in combination, they were not effective to a satisfactory degree.

The approach area to the lock appeared as in Figure 10 (a) before any work was started. The general layout in this area is shown in Figure 11 (a). The construction plan which was adopted required the installation of a sheet pile wall driven to rock along the canal dyke before the start of any excavation. This wall was not intended to reduce seepage but rather to strengthen the dyke to resist any piping which might develop.

Initial excavation was then made, limited as shown on the plan to that necessary to build a barrier secure against the possibility of an accidental breaching of the canal dyke. This barrier consisted of a clay dyke, the approach wall, sheet pile cells across the future entrance for a twin lock, stop logs between the two present lock walls, and a sheet pile wall between the lock and the canal dyke.

On completion of the barrier the remaining dry excavation was continued to safe limits inside the canal dyke. This stage is pictured in Figure 10 (b). The excavation was then flooded, the sheet pile wall removed, and the dyke and remaining overburden and rock removed by dredging. This plan was carried through satisfactorily, but only with the most careful attention to changing conditions as the work progressed.

Of considerable help in dealing with changing groundwater and soil conditions promptly and with adequate facilities was a special item included in the construction contract. This called for the supply of equipment and personnel at any time on a cost plus basis to do drilling and sampling, drainage trench excavation, pumping, grouting, and pile driving. This item was instrumental in promoting safety and avoiding delays in the work on many occasions.

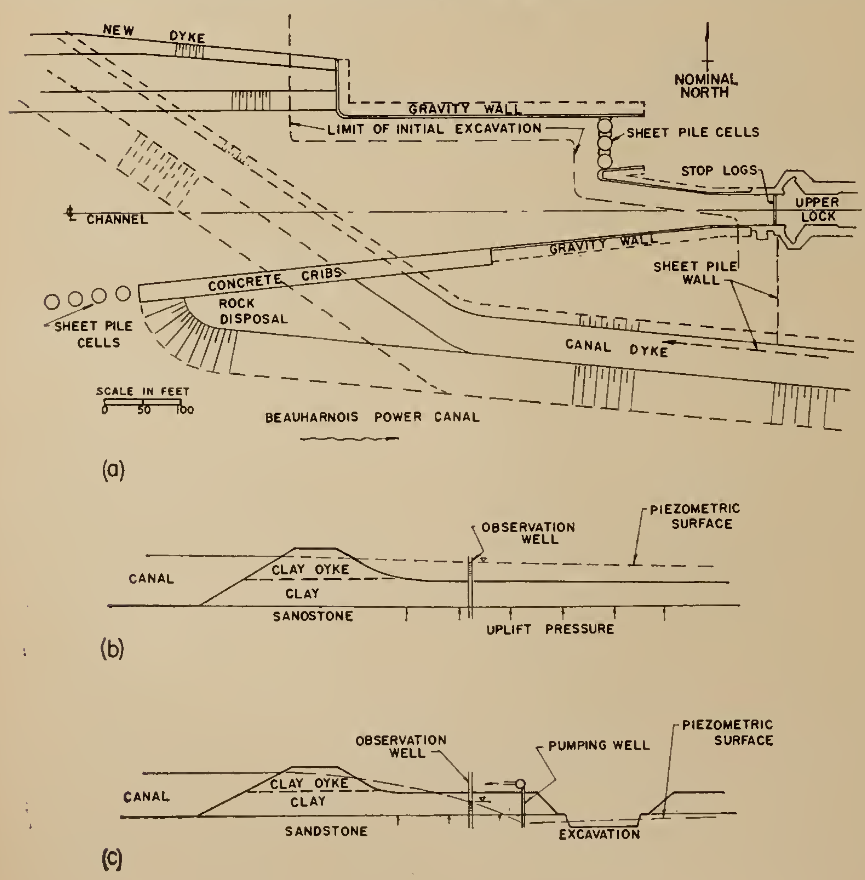
Groundwater Control during Excavation

The artesian head under the clay blanket at the start of the work was such that excavation to a depth of only 10 ft. over any appreciable area would have caused uplift and rupture of the layer with consequent possible piping through the canal dyke. These conditions are shown schematically in section (b) of Figure 11.

The first step in maintaining control of the groundwater problem was the installation of a pattern of observation wells to enable pressures throughout the area to be checked at any time. These wells were maintained throughout the work and proved essential in evaluating each new development affecting the groundwater.

The second step was drainage. The excavation was carried down to bedrock in one lift. This was so that natural drainage could take place and reduce the uplift pressure ahead of the excavation face. The effect was assisted by drainage trenches dug in advance of the general excavation.

Fig. 11. Control of groundwater conditions at Upper Beauharnois lock. (a) Plan of approach area. (b) Groundwater conditions at start of work. (c) Groundwater conditions as maintained during excavation.



This type of drainage was observed by means of the wells to have a far-reaching effect on the piezometric head, sufficient in itself to insure against the possibilities of uplift and piping.

As the initial excavation proceeded west and approached the inner side of the canal dyke, it became necessary for safety to achieve a drawdown additional to that from natural drainage. Pumping was therefore started from three 12-in. wells, drilled into bedrock around the western perimeter of the excavation area. One of these wells proved to be particularly effective due to its fortuitous location in a shattered bedrock formation supplying most of the water to the area. With a specific yield of 275 (g.p.m. per ft. of drawdown) this well produced a drawdown of 4 ft. at a distance of 250 ft. It remained in continuous operation until the excavation was finally flooded in July 1958.

When the permanent barrier was being constructed during the winter of 1957-58, groundwater conditions were maintained as shown schematically in section (c) of Figure 11, with respect to the excavation slopes. The total flow into the excavation was steady at about 10,000 g.p.m.

Between March and June 1958 the clay and rock excavation in the remainder of the area was carried out. Each successive rock blast increased the flow of water noticeably until the total inflow was more than 30,000 g.p.m. This was finally turned to welcome advantage in flooding the area by simply stopping the pumps.

Throughout the construction operation, a thorough knowledge of site conditions combined with constant observations of groundwater levels, pump discharges and slope performance gave assurance that the critical water and soil problems which have been described could be dealt with promptly and effectively.

CONCLUSION

This review has dealt with some of the major soil and foundation considerations in planning and construction of the St. Lawrence Seaway. The cost of the subsurface exploration and testing phase of this work has been about one-quarter of one per cent of the value of contracts directly involved. Design, assistance with the preparation of contracts, and construction consultation and control

St. Lawrence River Diversion by a Rockfill Cofferdam

J. V. Danys, M.E.I.C. *Senior Soils and Foundation Engineer,*
St. Lawrence River Joint Board of Engineers, Canadian Section, Cornwall, Ont.

IN BUILDING the gigantic St. Lawrence Seaway and Power Development in the International Section of the river between Cornwall and Prescott, Ontario, engineers were faced with a number of problems which had to be solved during design and construction. One difficult and spectacular problem was the harnessing of the river during the construction period. With an average flow of 240,000 cubic feet per second the St. Lawrence River is one of the largest in the world. Fortunately for construction and power development, the Great Lakes regulate the flow almost ideally. In the past the maximum mean monthly flow was 265,000 c.f.s., and the minimum mean monthly flow was 212,000 c.f.s.; recorded maximum and minimum daily flows were 330,000 c.f.s. and 152,000 c.f.s.

The St. Lawrence River was harnessed by numerous cofferdams while building the Seaway and Power Development. Spectacular diversion of 200,000 c.f.s. near Long Sault Rapids at Cornwall was made by a rockfill cofferdam. Work was complicated by swift currents and necessary co-ordination of construction operation with navigation and power development.

Sequence of operations and size of stones required for various stages of construction were planned in advance, but in the field operations were adjusted according to the available material and changing conditions.

Construction of the cofferdam supplied very useful information concerning the building of rockfill cofferdams in swift current and proved to be economical.

Many different types of cofferdams were built for the various structures. The largest of the entire project was the downstream cofferdam at Barnhart Island powerhouse (Fig. 1). The cellular cofferdam, designated cofferdam "C-1", spans the 3,600 ft. wide river channel between the southern tip of Barnhart Island and the Canadian shore. Steel cells are 65 ft. in diameter and up to 65 ft. high. This cofferdam was probably the largest of its type ever built, but the most spectacular construction of a cofferdam and diversion of the river was during the second stage construction of Long Sault dam. A cofferdam (cofferdam "E") was required immediately upstream from the famous Long Sault Rapids to divert the entire river flow.

FOUR CONSTRUCTION STAGES

Long Sault dam is located at the western end of Barnhart Island. It closes the southern channel of the river just at the eastern tip of Long Sault Island. The south abutment of the dam is located on the right bank of the river, and the north abutment reaches Barnhart Island. Construction of the dam was planned in four stages.

In the first stage, the cellular cofferdams "A" and "B" (Fig. 2) provided a dry site for the first half of Long Sault dam in the south Long Sault channel of the river. A temporary cut (cut "C") was excavated to divert the flow of the south channel. In this stage, concrete piers had to be built to final height, but the spillway rollways were to be built to elev. 162 only, (roughly as high as the river bottom) and 55 ft. short of the final height. Spillway openings had to be adequate to discharge the entire river flow without raising the water levels at Dickinsons Landing lock, some two-and-one-half miles upstream.

Second stage construction of the dam had to be in the north channel of the river, and it was necessary to divert the entire flow to the south Long Sault channel. Under natural conditions, the south channel carried only some ten per cent of the entire flow. To accommodate all flow, a 600 ft. wide cut (cut "F") had to be excavated through Long Sault Island. Also, the south channel near the dam had to be widened. Cofferdams "E" and "D" were required to unwater the site for the second stage construction of the dam (Fig. 2).

In the third stage, the river was diverted back to the north Long Sault channel, and the entire flow was discharged through 34 tunnel ports, each 16 ft. by 18 ft. in the second half of the spillway. In this stage, the spillway rollways of the south half of the dam will be raised to the final height.

In the fourth stage of construction, the discharge tunnels will be plugged after the water has been raised in the reservoir.

The most difficult stage was the second one, because the entire flow of 200,000 c.f.s. had to be rerouted by a cofferdam through cut "F" into the south Long Sault Island channel. The designers first proposed to build a rock-fill cofferdam with an impervious blanket on the upstream side. However, the contract was let with a stipulation that cofferdam "E" was the full responsibility of the contractor, and that alternative closure methods might be used, if approved. In fact, the contractor did choose the design method with some minor variations.

Co-ordination of Construction Operations

Construction of cofferdam "E" was difficult because of the huge flow in the river, and because of the swift current. But there were a number of additional factors affecting its construction.

The existing 14 ft. draught Cornwall navigation canal starts at Dickinsons Landing, some 5000 ft. upstream from the site of cofferdam "E", and lock 21 is located near the entrance to the canal. Water level at the lock may fluctuate only 4 feet without disturbing navigation. Therefore, all excavation and construction work at cut "F" and cofferdam "E" had to be carried out so as to maintain the river levels at lock 21 during the navigation season within these limits.

At the west end of Long Sault Island a diversion canal takes approximately 25,000 c.f.s. for ALCOA's hydro plant in Massena, N.Y., returning it to the St. Lawrence River via the Grasse River. Water levels could not be drawn below the natural river levels during the winter as this would cause head-loss at the entrance to the power canal and, consequently a reduction of power output. Also, any sudden large flow retention or release was not desirable because of power developments downstream from Cornwall and navigation in Montreal harbour.

Long Sault Rapids before construction of cofferdam 'E' (PASNY)

Construction Operations Checked by Hydraulic Models

Thorough planning and co-ordination of all river diversion operations was required. The hydraulic laboratory of Hydro-Electric Power Commission of Ontario, at Islington, did extensive model testing and set up a program for construction operations as follows:

(*a*) A plug had to be left in cut "F" after the cut was excavated to grade.

(*b*) A "choke" dyke had to be built at the shore of Long Sault Island opposite lock 21. This dyke would be extended into the river so as to maintain adequate water levels at the entrance to lock 21. Without the choke dyke, necessary excavation upstream from the plug in cut "F" would have lowered the water levels at the entrance to the navigation canal and lock.

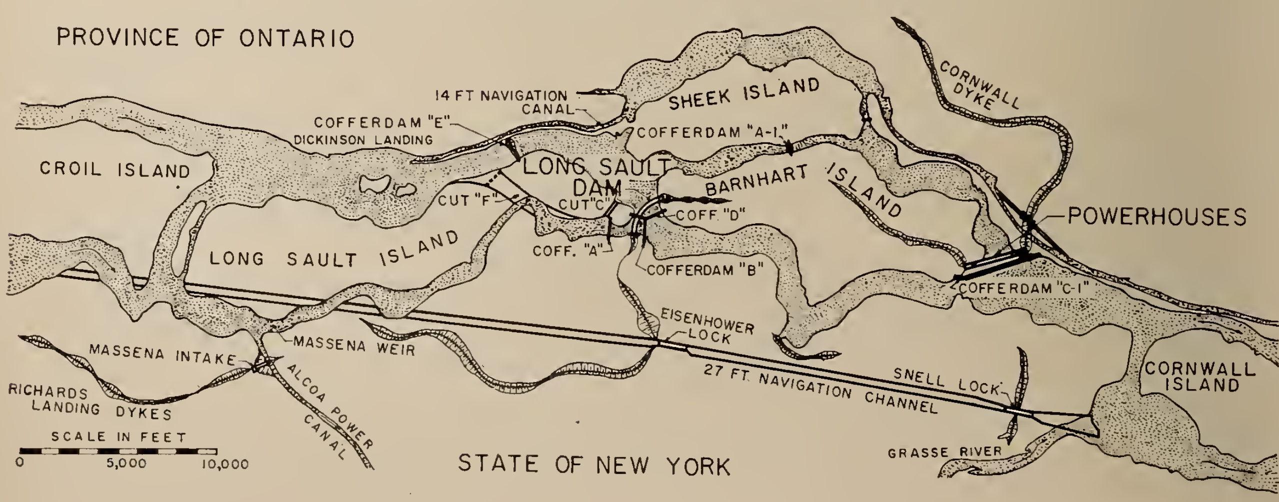
(*c*) Certain heights were established to which the rockfill could be built as a submerged weir without any adverse effect on water levels. The choke dyke had to be removed gradually when cofferdam "E" was being built to elev. 179. After the cofferdam reached elev. 179, a further increase in height could be made, only if the plug in cut "F" was removed for a sufficient width to provide an adequate additional area for the flow through the south Long Sault Island channel.

(*d*) Thirteen sluices with temporary gates had to be completed in the Long Sault dam before breaching the plug in cut "F". After removal of the plug, and completion of cofferdam "E", river levels had to be controlled by operating these gates.

Planning of Cofferdam Construction

Rockfill cofferdams with an earth blanket are common structures today. Generally their construction is much simpler than any other type, and very often they are the most economical. The simplest and most common way to build a rockfill cofferdam is by end dumping of rock into the river

Fig. 1. General plan of structures in Cornwall, Ont., and Massena, N.Y., area.



from one or both shores. Of course, as the gap becomes narrower, the stream velocity is increased and, generally, there is a critical stage which is difficult to overcome merely by continuing to dump rock of the same size, as rock must be heavy enough to withstand the moving forces of flowing water.

Constructors of the cofferdam at Long Sault Rapids had to consider the very large flow and comparatively great velocities. Such a large flow, naturally, makes the task much more difficult as restricted flow creates velocities and forces of momentum which cannot be met by speedy rock placing. Uniform river flow was advantageous for construction as all operations could be planned for a known discharge. Diversion of flow through cut "F", with the bottom elevation approximately at the same level as the average elevation of the river bed at cofferdam "E", also facilitated construction of the cofferdam.

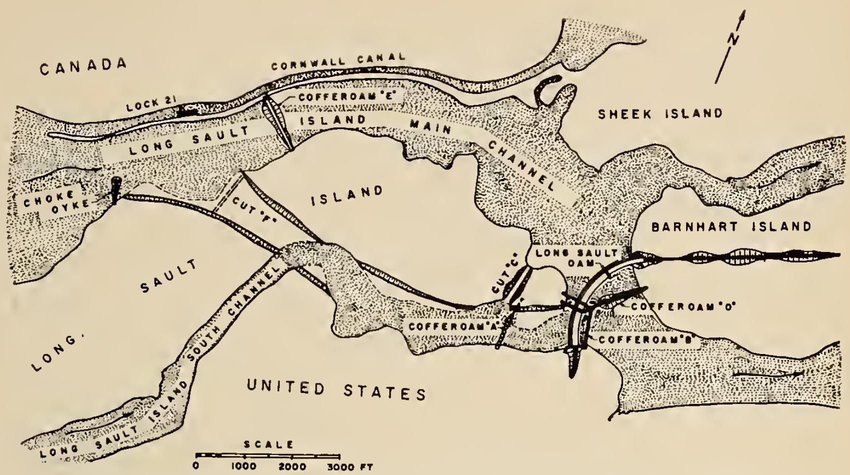


Fig. 2. General plan of cofferdam 'E' and structures in vicinity.

Already early design (1941) had emphasized the difficulties of building a rockfill cofferdam in the swift and very large stream. Fig. 3 indicates the measured mean velocity, 7.4 f.p.s., and the maximum velocity, exceeding 10 f.p.s. at the surface. Use of an overhead cableway and skip was suggested for dumping rockfill into the water. The cofferdam would be built in horizontal layers; it would be raised slowly, and thus diversion of the flow through cut "F" would be gradual.

One of the early designs for the cofferdam (Fig. 4) indicates big stones on the downstream slope. This barrier of big stones should be able to withstand the increased velocities and would give support for small or quarry-run rock.

First, following experience at the McNary dam on the Columbia river, it was suggested that 8- to 12-ton stones be used for the heavy rock zone of the cofferdam. The heavier rock had to be in the lower zones (Fig. 4: A, 24,000 lb.; zones B and C, 20,000 lb.; and zone D, 16,000 lb.). Later, ascertaining the necessary size of the heavy stone was tried by theoretical calculations. Model investigations by S. Isbash[1] were studied and, using his suggested charts (Fig. 5) for assumed hydraulic and structural conditions, the weight of the required heavy stones was calculated to be from 1 to 7 tons. It was also suggested that the heaviest rocks should be placed in the middle zones of the heavy rock barrier. (Fig. 4: zone A, 2,500 lb.; zone B, 6,500 to 14,000 lb.; zone C, 14,000 to 5,000 lb.; and zone D, 200 lb.)

View of site after start of construction of cofferdam 'E'. Water ripples left of island indicate location of partially built cofferdam. Cut 'F' across Long Sault Island is also seen at right; upstream plug is still in place. Dickinsons Landing (lock 21) is at left. Long Sault Dam under construction in background at right. (PASNY)

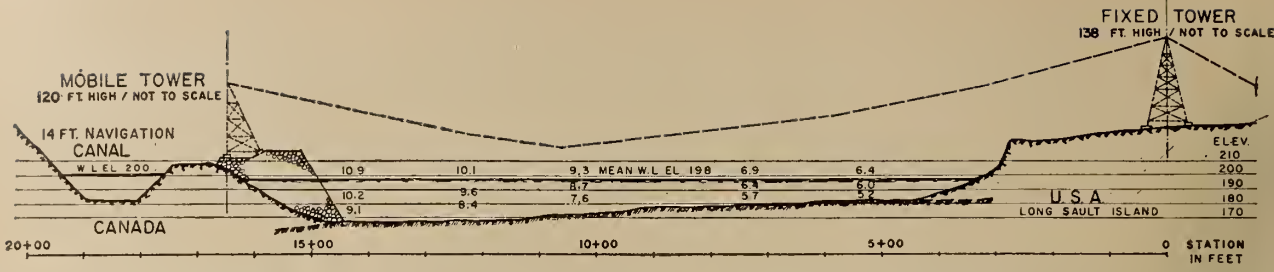

Fig. 3. Profile along centre line of cofferdam 'E' and arrangement of cableway for dumping rock into river. Measured velocities in feet per second are shown for the total river flow of 250,000 c.f.s., of which 204,000 c.f.s. were discharged through the north Long Sault channel. Mean velocity was 7.4 f.p.s. and maximum velocity 10.9 f.p.s.

After the work had started, it was thought that a satisfactory barrier could be built with much smaller rock than earlier suggested. It was suggested that stones from 800 lb. to 2,000 lb., placing the heaviest stones in the middle zones, would be heavy enough for a rock barrier. (Fig. 4: zone A, quarry-run rock; zone B, 2,000 lb.; zone C, 1,000 lb.; and zone D, 500 lb.)

Experience indicated that none of the above assumptions was quite correct. As a matter of fact, design was empirical or semi-empirical, without any model testing. The available rock, moreover, was not suitable to produce stones of the specified weight without going into great cost. Hydraulic calculations and checking progress in the field helped to direct construction of the cofferdam, adjusting the operations to suit available material and equipment.

An overhead cableway was installed for placing rock (Fig. 3). It was felt that rock should be placed in thin horizontal layers, which would gradually divert more and more water through cut "F".

A fixed tower was located on Long Sault Island, and the mobile tower placed at the canal embankment on the Canadian side. The loading capacity of the skip was 25 tons, and the mobile tower could move 200 ft. along the shore. All operations of the skip and the mobile tower were automatically controlled from an operating room.

COFFERDAM CONSTRUCTION

Dumping of rock for the cofferdam was started by a cableway and continued to elev. 188. Water level in the river during construction was approximately elev. 198. Then, the upper part to elev. 207 was completed by end-dumping of rock by Euclid trucks. Actual operations were done more or less in three typical stages.

First Stage—Small Rock

In the first stage, no rock selection was made at all. A few experiments indicated that the stream would carry a 100 lb. stone about the same distance as the depth of the river at the rock dropping point. Rather fine rock with a considerable amount of spalls excavated from nearby cut "F" was dumped by the skip. Of course, fines and rock spalls, which made some 30 per cent of the volume, were washed away by the stream. The short haul and easy loading compensated for the loss of fines.

The average size rock was some 9 inches in diameter and weighed about 50 lb.

In this stage the cofferdam was raised to elev. 183 and the mean stream velocity over the crest increased from 7.5 f.p.s. to 12 f.p.s. During the interim stage, when the cofferdam was built to elev. 174, the mean velocity was 9.5 f.p.s., and the maximum velocity at the water surface was measured as high as 14 f.p.s.

Second Stage—Heavier Rock

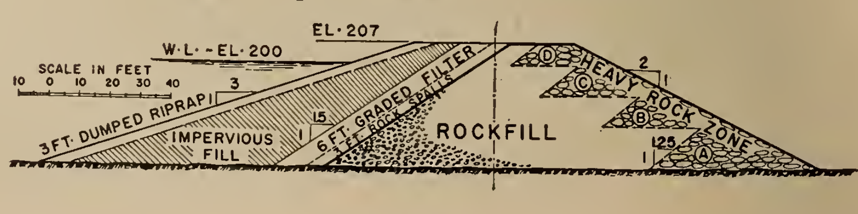
In this stage the cofferdam was raised from elev. 183 to elev. 188. Rock was dumped by skip, but heavier rock was necessary as the mean velocities over the crest increased to about 13.5 f.p.s. Part of the river flow was diverted through cut "F" as the plug was being removed and the gates at Long Sault dam were gradually opened. In this and in the following stages, no direct measurement of velocities was made. Velocities were computed from the known discharge through the measured flow area on the crest of the cofferdam with the estimated velocity coefficients for the various observed flow conditions.

Care was taken to pick up larger rocks and to place them on the downstream side of the cofferdam in such a way that smaller rock would be retained by the barrier of heavy rock (Fig. 4). Rock was taken from a quarry four miles away from the cofferdam, just east of Sheek Island. Quarry-run rock was dumped by the cableway skip into the cofferdam. Rock varied in size from 1 to 60 inches, weighing up to 10,000 lb., but the average rock was some 20 inches in diameter, weighing approximately 500 lb.

Formation of rock in the quarry where most of the material was obtained was not suitable to produce heavy rock. Several feet of the upper rock consisted of thick, large, flat blocks of dolomite. The deeper layers of rock were parted by numerous shale interbeddings, and blasting produced comparatively small rock with a very high percentage of fine rock and spalls.

It was obvious that selection of rock of a certain size would be very expensive. Some sorting of the truck loads was attempted, but generally rock was used as produced in the quarry, and the major portion of the cofferdam was built from unsorted rock. A number of big boulders and large pieces of rock excavated from cut "F" were stockpiled to one side

Fig. 4. Proposed cross-section of cofferdam 'E'.



and individually dumped in certain locations in the cofferdam.

In the first and second stages of the cofferdam, an effort was made to deposit the rock in uniform horizontal layers within the designed outline of the cofferdam (Fig. 4). The cableway operator had a schedule indicating the number of loads to be placed in certain locations. Periodical survey with echo sounding equipment was carried out to determine the shape and height of the rockfill during the various stages of construction. According to the survey results, additional rock was placed in low areas in order to ensure uniform rise of the cofferdam and to avoid flow concentration and high velocities at certain points.

Third Stage—Dumping from Trucks

In the third stage the upper part of the cofferdam, from elev. 188 to elev. 207, was built by dumping rock from trucks. At this stage the gap was gradually narrowed and removal of the plug in cut "F" continued. More and more water was diverted through cut "F". Mean velocities of the current on the crest through the gap of cofferdam "E" were gradually increased from 13.5 to some 15 f.p.s., and later they remained rather constant on the crest of the rockfill because the flow per lineal foot of opening remained more or less constant, owing to gradual water diversion. But, at later diversion stages, tailwater dropped fast and increased the velocity of the overflowing water at the toe of the cofferdam to approximately 24 f.p.s.

End of second stage construction of cofferdam 'E' by dumping rock from cableway skip; rockfill is built within 10 ft. of water surface. (PASNY)

Closure

The actual cross-section of the cofferdam, as built, differed considerably from the suggested section. In Fig. 6 one can see the actual sections of the cofferdam as built. The downstream slope became flatter as the gap for the flow was being narrowed. Although the flow per linear foot was kept fairly constant as gates at Long Sault dam were gradually opened, coinciding with the closure of the cofferdam, the tailwater at the cofferdam was consistently lowered because of a smaller volume of the total flow downstream from the cofferdam. This accounted for the continuous increase of sweeping velocities on the downstream slope of the rockfill near the tailwater level. The increased sweeping velocity carried the dumped rock farther and farther from the centre line of the cofferdam.

The closure of the last hundred feet of cofferdam presented some difficulty. The mean velocity of the flow reached its maximum, about 17 f.p.s. on the crest and 28 f.p.s. at the tailwater, and erosion started on the south end of the cofferdam near the island where a channel about 50 ft. wide

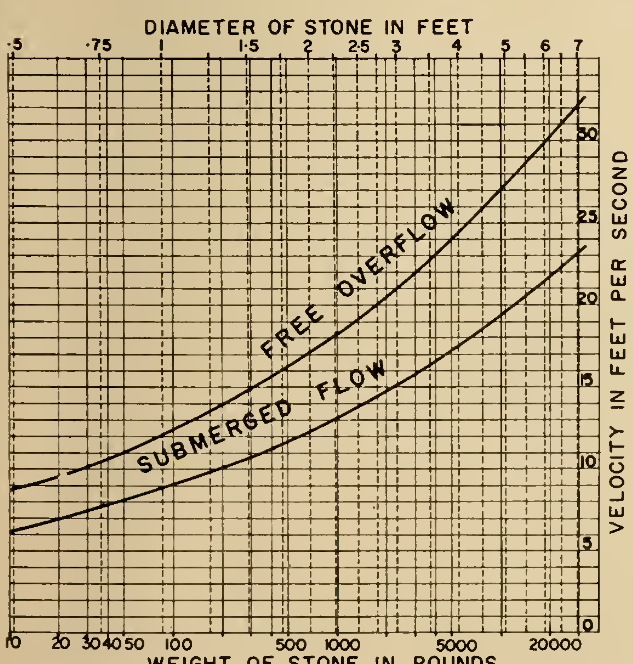


Fig. 5 (left). Critical transporting velocities and weights and sizes of stones dumped in flowing water (after S. Isbash). Specific weight of stone assumed to be 165 lb./cu. ft.

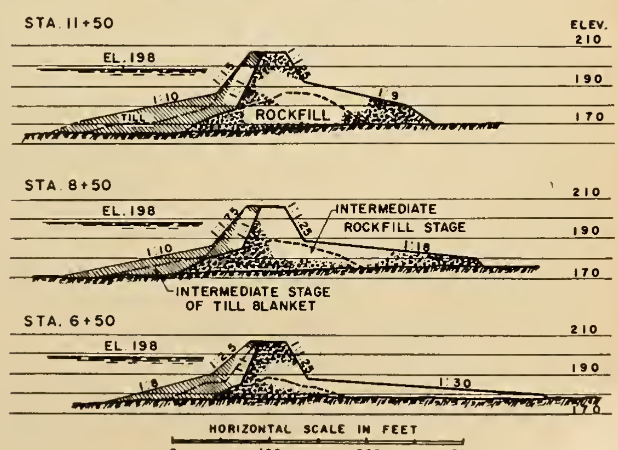
Fig. 6. Actual cross-sections of cofferdam 'E' as built. Downstream slope became flatter when construction advanced nearer closure section.



was eroded in the glacial till as well. Large rocks weighing up to 5,000 lb., dropped in this opening, were swept downstream. Finally, a few steel and timber frames were made from scrap steel beams and dropped in the gap. These frames were held in place by 1½-inch cables anchored to trees upstream from the cofferdam. After placing the frame barrier, the last 60 ft. gap was closed with quarry-run rock in a few hours, by skip and end dumping.

Construction of rockfill section of cofferdam stage 3, by truck dumping of rock. (HEPCO)

Earth Blanket Upstream

Seepage through the rockfill cofferdam was approximately 10,000 c.f.s., compared with the former flow through the north channel of 190,000 c.f.s. Sealing of the cofferdam was effected by placing an earth blanket, which reduced seepage to approximately 12 c.f.s.

Till used for the blanket was very suitable for sealing the cofferdam, as the local till consists of silt, sand, and gravel with a little clay and numerous boulders. As the rockfill was quarry-run rock containing spalls and small rock, the designed filter section between the rockfill and the earth blanket was omitted. But some gravel and small rock was placed on the upstream slope of the final closure; the rockfill here consisted mostly of large rock.

Till was dumped by trucks along the upstream face and initially took a slope 1 on 1½ for the upper 15 ft. under water, but the slope was 1 on 5 to 1 on 7 below that level. As more till was dumped to increase the thickness of the blanket and to extend it further upstream, the final slope for the upper section became about 1 on 2 and 1 on 10 for the section more than 15 ft. under water. It seems that lateral dumping along the sloping face of the rockfill accounted, mainly, for the flat slopes.

Experience Confirms Model Tests

Observations in the field at Long Sault dam and other projects substantially proved the correctness of the model tests in the laboratory by S. Isbash[1] and others regarding the stability of stones and rockfills in flowing water. It seems there are some definite stages of construction of rockfill dams or cofferdams in flowing water.

Closure gap approx. 80 ft. wide. Cableway skip is ready to drop first frame. Sweeping velocities at toe of cofferdam increased to 28 f.p.s.

Initially the profile of the dumped rockfill takes the form of an isosceles triangle with side slopes of 1 to 1.

After reaching a certain height, the downstream slope becomes elongated and the profile loses the true isosceles form. There is also a more pronounced drop in the water surface over the dam at this transition stage and the downstream water surface becomes slightly undulatory in appearance (Fig. 7).

With further dumping of stones, we reach a stage in which it is very difficult to make progress in the vertical direction as the dumped material tends to flow or roll downstream. The profile of the submerged section becomes trapezoidal in outline. The difference in elevation between the head and the tailwater also becomes larger and the tailwater surface shows marked undulations.

The dumped stones are transported noticeably in a lateral direction by the increased velocity. After reaching the downstream face, many of the stones do not remain in place, but roll along the downstream slope until reaching a stable position at a lower elevation. The length of the submerged section increases rapidly, but the accompanying increase in height is retarded. The downstream slope becomes from 1 on 5 to 1 on 10, or even flatter if the rock is fine or contains much fines. Finally, a critical stage is reached at which it is necessary to increase the size of the stones to resist displacement by the overflow. From the standpoint of hydraulics, the critical stage indicates a transition from the condition of submerged flow to the condition of free overflow over the crest and downstream slope.

It appears there are two deceiving stages during construction by dumping stones in flowing water. First, rather light stones stay in place and build up a triangle, and give the impression that no large rocks will be required to complete the cofferdam. Then comes a stage when progress in height is so small compared with the volume of rock dumped, that there appears to be no hope of completing the cofferdam.

Importance of Stone Size and Interlocking

An individual stone is affected by the overflow and percolation forces which tend to push and to roll the stone down. Resisting force, first of all, is the weight of the stone, but it is evident that shape and the mutual interlocking and sheltering action are of great importance. This interlocking effect reduces stone weight required to withstand certain velocity during the stage of "free overflow". A well graded rockfill would offer little resistance to the rolling stones. Small rock fills the voids between the large rocks and a fairly smooth pavement is obtained on which dumped rock is rather easily carried downstream. The slope of fill consisting only of very large stones has a rough surface and comparatively high resistance to rolling or sliding, but percolation flow is high and may lessen the advantages due to improved interlocking power to a certain degree.

Fig. 5 shows a chart indicating the relation between the weight of a stone and stream velocity, which was used for hydraulic calculations of cofferdam "E". This chart was suggested by S. Isbash on the basis of model tests, and it agrees with test results of other researchers. There is considerable difficulty in computing velocity and, eventually, the required stone size, as friction of the rockfill and heads cannot be accurately ascertained in advance. Further, it is very difficult to produce uniform size rock in a quarry, and is usually very expensive. Therefore, a theoretical calculation of the size of stone required to build a stable cofferdam is not a rigid solution but only an approach to estimate the possible conditions.

View of downstream slope of completed cofferdam. Note increasing width of downstream berm nearing closure gap. (HEPCO)

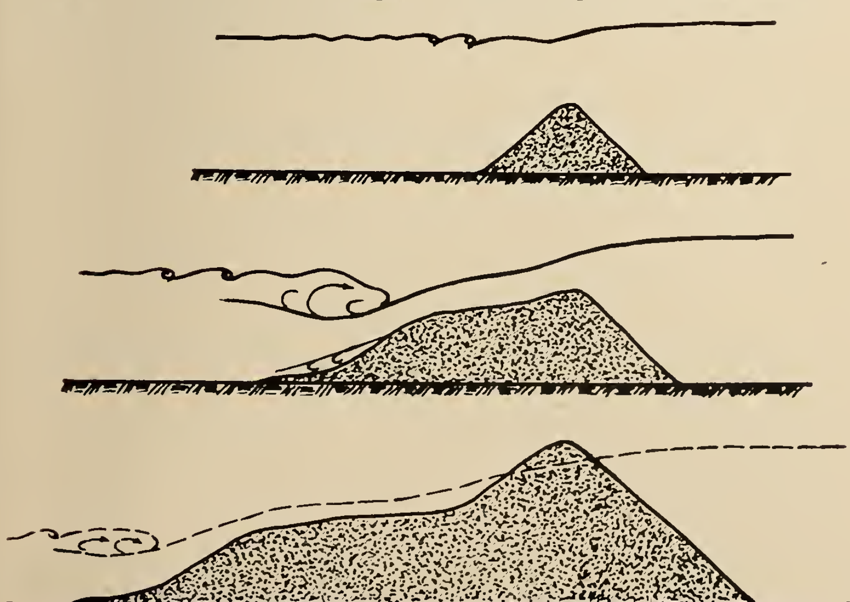
From the hydraulic standpoint, the most rational method of construction is to use only small stones at the beginning and, subsequently, to change to larger sizes for the downstream part of the cofferdam. This would give the smallest volume of rockfill, a minimum percentage of large size stones and reduced percolation flow. It is particularly important at the critical stage to ensure uniform dumping of material along the entire length of the dam. Any attempt to raise the dam at separate points increases velocities adjacent to the higher spots and results in slides of rockfill.

During construction such a slide occurred at the north end of cofferdam "E" in the deepest section (approx. 35 ft. deep) of the river. Here the tower ramp (Fig. 3) projected into the river and increased stream velocities. Ice jams interrupted dumping of rock for a couple of weeks, and during that time the rockfill was eroded almost to the river bottom. This eroded gully was in the shape of a large "V", and approximately 5,000 cu. yd. of heavy rock was required to backfill the gap to uniform height. A considerable amount of selected stones weighing 4 to 6 tons were placed in the gap.

Cofferdam Built With Steep Slopes

The actual cross-sections of cofferdam "E", as built, differed considerably from the design cross-section (Fig. 4 and 6). Smaller size rock than originally planned, containing a high percentage of fines, is the main reason for the difference. But during construction of the McNary dam on the Columbia River[2] it was proved that a rockfill cofferdam with rather steep slopes 1 on 2 can be built in swift water if the size of the rock (or concrete blocks) is right, and if construction is preceded and accompanied by a thorough hydraulic model testing.

Fig. 7. Typical construction stages of rockfill dumped in flowing water.



The Columbia River flow was between 120,000 and 150,000 c.f.s., of which 80,000 c.f.s., was discharged through a closure gap 240 ft. wide and up to 55 ft. deep. Model experiments before construction indicated maximum velocity of 15 f.p.s. at the beginning of the closure, but velocities would go as high as 28 f.p.s. over the crest, and 38 f.p.s. near the toe of the rockfill cofferdam during construction by dumping blocks and stones with a cableway.

The downstream section of the Columbia cofferdam was built of 12-ton concrete blocks, and selected 2-ton or heavier stones were placed in the upstream section (Fig. 8). The concrete blocks were formed as tetrahedrons, as this shape is the most stable in flowing water.

Extensive model testing was done before dumping commenced and a 1:24 scale model of the entire 240 ft. closure gap was built at the site of the dam. This permitted very close inspection and coordination of construction of the cofferdam.

It is interesting to note that while being built the McNary cofferdam had taken triangular and trapezoidal shapes before the crest emerged from the water (Fig. 8). One can clearly see the transition, or critical stage, when the flow changed from the submerged stage to the overflow stage.

CONCLUSIONS

Experience and model studies indicate that large rocks are required only for the downstream zone of the rockfill. A substantial part of the lower zone and upstream part of the cofferdam can be built of small or quarry-run rock.

The originally-suggested 24,000 lb. stones were certainly unnecessary for cofferdam 'E'. It seems that 5,000 lb. stones were the maximum size required to build an adequate downstream barrier for the cofferdam with a steep downstream slope. Of course, the heavy rock zone could not be mixed with fine rock as such mixture reduces the interlocking effect of the stones. The heavy rock zone should be shaped as indicated in Fig. 8; the barrier zone in Fig. 4 does not correspond to the natural shape formed by the overflowing water. The rock could be smaller than the maximum size above and below the critical zone of the barrier, but a detailed division in the vertical zones is not recommended as it is very difficult to maintain during the dumping operation, and the advance hydraulic computation is not accurate enough to establish precise limits.

Rockfill will take a much flatter downstream slope if only unsorted quarry-run rock is used. The success of building a cofferdam by end dumping of rock only depends on the feasibility of diverting the river flow gradually and quickly, and on the velocity of the flow during the final closure stage.

Construction of cofferdam "E", and the diversion of the large flow of 200,000 c.f.s., were very successful. The contractor followed the scheme suggested by the designing engineers, but made changes and alterations to suit the available material and changing working conditions.

End dumping by trucks could place the rock five times as fast as skip dumping, although placing of rock only by cableway skip would have required less material. Approximately 205,000 cu. yd. of rock was used to build the rockfill section. The estimated quantity for the designed cross-section with slopes 1 on 2 was 115,000 cu. yd., including 40,000 cu. yd. of selected heavy rock (up to 7 tons weight), which could be produced at the available quarry only at a very high cost. The contractor used surplus rock from cut "F" and quarry-run rock which was considerably less expensive than any selected rock.

Cofferdam "E" was completed in April 1957, in time for the second stage construction of Long Sault dam, although early in February a heavy ice jam in cut "F" forced the interruption of construction of cofferdam "E" for five weeks.

It took twelve working weeks to complete the rockfill section and a further three weeks to place the upstream blanket.

It appears that cofferdam "E" was one of the most economical major cofferdams on the project.

The St. Lawrence Power Project

Electrical Features of the Robert H. Saunders-St. Lawrence Generating Station

R. M. Fullerton

Project Engineer, Generating Stations, Hydro-Electric Power Commission of Ontario

The Robert H. Saunders-St. Lawrence station is the Canadian half of the joint Canadian and United States powerhouse at the International Rapids section of the St. Lawrence River. This paper describes the installation and electrical equipment.

WHILE CONTROL structures, dyking, channel improvement and rehabilitation associated with the flooding of the headpond area were all major considerations in developing power from the International Rapids section of the St. Lawrence River, the focal point and largest single feature of the project was located some two miles west of Cornwall. There, the Canadian and United States' powerhouses merge at the international boundary, forming a continuous structure with an overall length of 3,300 feet and having a maximum height of 162 feet above foundation.

The powerhouses, which themselves serve as gravity dams, will contain 32 generators, 16 in each powerhouse, with a combined installed capacity of 1,640,000 kilowatts. Uniformity of design was maintained with regard to the external features for aesthetic and engineering reasons, and while the two participating agencies, Ontario Hydro and the Power Authority of the State of New York, maintained the closest liaison during the design and construction period, the electrical and mechanical arrangements in the two powerhouses differ considerably.

The main electrical connections for Ontario Hydro's Robert H. Saunders-St. Lawrence Generating Station are illustrated by Fig. 1. This shows the four unit arrangement adopted, each group consisting of four 60,000 kva. generators with their associated low-voltage switching, 258,000 kva. step-up transformer bank, and 230 kv. transmission circuit to the St. Lawrence transformer station, situated about two miles distant. At this location the output of the station is fed into the 230 kv. and 115 kv. Ontario Hydro systems, as well as to certain 44 kv. circuits for transmission to neighbouring communities.

Generators

The generators were supplied by two Canadian manufacturers, each supplying eight. In each group of four generators, two of one make are connected to one low-voltage winding of the transformer bank, and two of the other are connected to the remaining low-voltage winding. Each generator is rated 60,000 kva., 13.8 kv., 3 phase, 60 cycles, 94.7 r.p.m., 0.95 power factor. Class B insulation is used throughout and the machines are designed to deliver their rated output without exceeding the temperature rise for Class A insulation, and to operate at 15% above that rating without exceeding the temperature limits for Class B insulation. Both manufacturers have located the thrust bearing below the rotor, using the edge of the thrust block as a journal for the single guide bearing. High pressure oil lift is provided for use during starting of the generators.

Concrete walls below the powerhouse deck form the generator enclosure (Fig. 2). Access for major maintenance work is provided through motor-operated hatches, permitting the 300-ton gantry crane to lift heavy parts and transport them to the erection bay. Vertical lift doors on the two sides of this crane can be lowered to provide a heated enclosure for work on a generator. Minor maintenance or repairs may be done without opening the hatches. A two-ton capacity monorail hoist for handling parts is provided to facilitate such work.

Cooling of the generators is accomplished by passing the ventilating air through air-to-water heat exchangers. One of the manufacturers has located the exchangers in the corners of the concrete enclosure. The other has located them circumferentially on the generator frame. Provision has been made to bleed-off warm air for powerhouse heating. The generators ventilation system is separated from the turbine pit by baffles located on the lower generator bearing bracket.

Copper-constantan thermocouples are provided to measure the temperature of turbine and generator bearings, stator iron, incoming cooling water, outgoing water from each cooler, heated air leaving the stator iron, and cooled air entering the rotor. The temperature of the field is measured by a temperature simulator developed by the Research Division of Ontario Hydro.

Carbon dioxide fire protection is provided for the generators. This protection may be actuated by the operation of the split phase relay protection, the operation of thermostats located in the machine, or from break-glass stations. Sprinkler rings, to which water may be applied by manually operated valves, are provided.

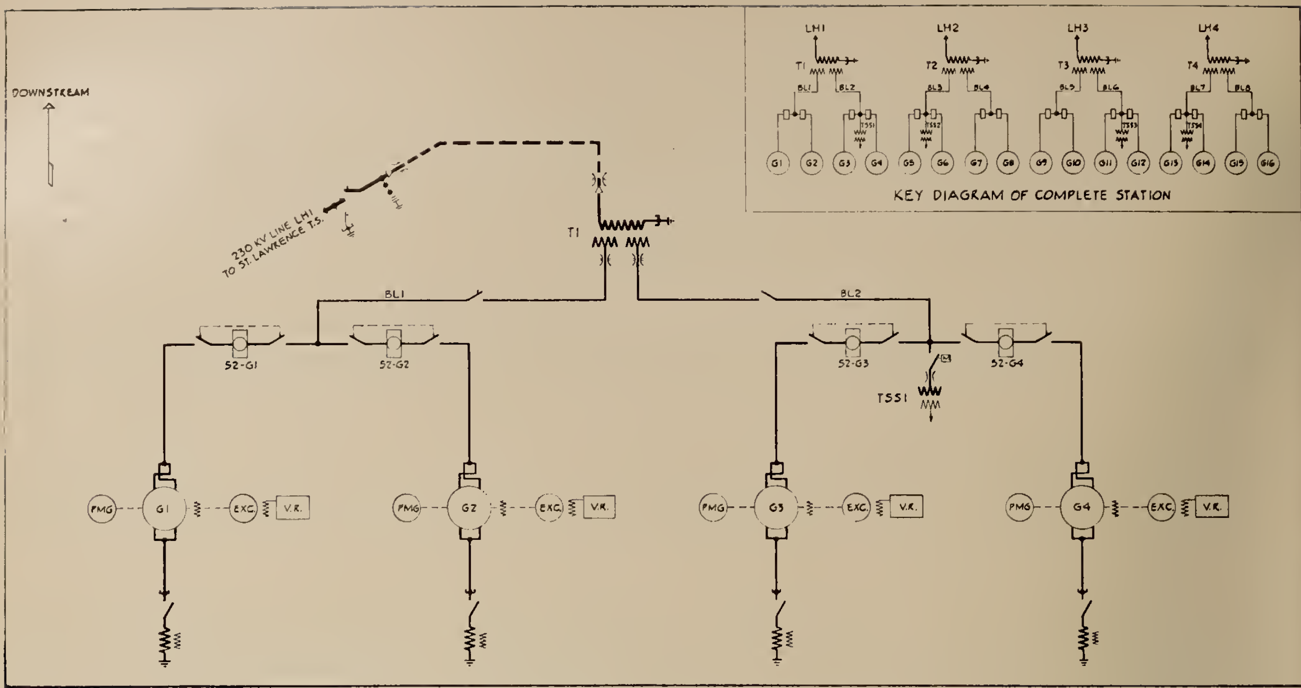

Fig. 1. Main schematic (one-line) diagram.

The generator neutral is grounded through the high-voltage winding of a 13.8 kv./115-230 volts distribution type transformer. The low-voltage winding of this transformer is loaded with a resistor designed to draw sufficient current so that the kilowatts consumed in the resistor are approximately equal to the kilovars of the capacitance current between the generator winding, generator leads, power transformer low-voltage winding, etc. and the ground.

A current relay is used on the secondary winding of this transformer to detect 13.8 kv. ground faults.

Voltage Regulator Equipment

Both generator manufacturers supplied automatic highspeed continuously acting voltage regulators of the static type, one using a magnetic amplifier and the other a rotating amplifier. Cross-current compensation is provided and provision is made for the later addition of line-drop compensation.

Isolated Phase Bus

The connections from the generator terminals to the low voltage switchgear and from the switchgear to the transformer low-voltage terminals are made by means of isolated-phase bus. Between the generator terminals and the 14.4 kv. bus, 3,000 ampere bus is used. The connection between the 14.4 kv. bus and the transformer delta is 6,000 amp. From the delta connections to the transformer terminals 3,500 amp. bus is used. Isolated-phase bus, 3,000 amp. capacity, is also used between the 14.4 kv. bus and the high-voltage terminals of the 3,000 kva. station service transformers. Both the conductor and housing of the isolated-phase bus are of aluminium.

L.V. Switchgear

The metal enclosed 14.4 kv. switchgear comprises eight structures each housing two 3,500 amp., 2,000,000 kva. air-blast circuit breakers, the necessary potential and current transformers, and bus connections for two generators. Four of the structures include a tap for a 3,000 kva. station service transformer.

Main Power Transformers

The four main step-up transformer banks each consist of three 86,000 kva., 13.5-13.5/132 kv., 900 kv. BIL, 3-winding forced-oil water-cooled single-phase transformers, connected delta-delta/grounded Y to give a bank ratio of 13.5-13.5/230 kv. One full-capacity 5% tap is provided above 230 kv. The capacity of the transformers was chosen so that the generators could operate at 15% over their rating without seriously overloading the transformers. Consideration was given to using three-phase units, but the economic advantage offered was outweighed by transportation problems. Tenders were obtained for various types of cooling and forced-oil water cooled units were chosen on the basis of lowest installed cost. Fire protection is provided by an automatic deluge system, actuated by rate of rise devices.

Because of the length of the powerhouse and the amount of power involved, it was not physically or economically feasible to transmit the power to the shore at generator voltage. The transformers were therefore located on the downstream deck of the powerhouse structure, making the low voltage connections as short as practicable.

High Voltage Cable

With the decision made to locate the main power transformers on the downstream deck of the powerhouse, considerable study was given to the problem of getting the high voltage circuits to the shore. Because of the length of the power-house and the angle at which it sits with respect to the shore, transmission of the power by overhead circuits presented considerable difficulty. A number of schemes using this method were studied and offered some economic advantages over. the use of 230 kv. cable. They were, however, undesirable from the aesthetic, operating, and maintenance points of view and it was decided to use cable.

An oil-filled cable with a single copper conductor 960 MCM in area was selected. Each circuit is designed to carry continuously the output of four generators operating at 15% above their rating with the ambient temperature at 40°C. The cables are located in ventilated tunnels under the downstream deck of the powerhouse and they are connected to the overhead lines at a terminal structure located just south of the 14-foot navigation canal.

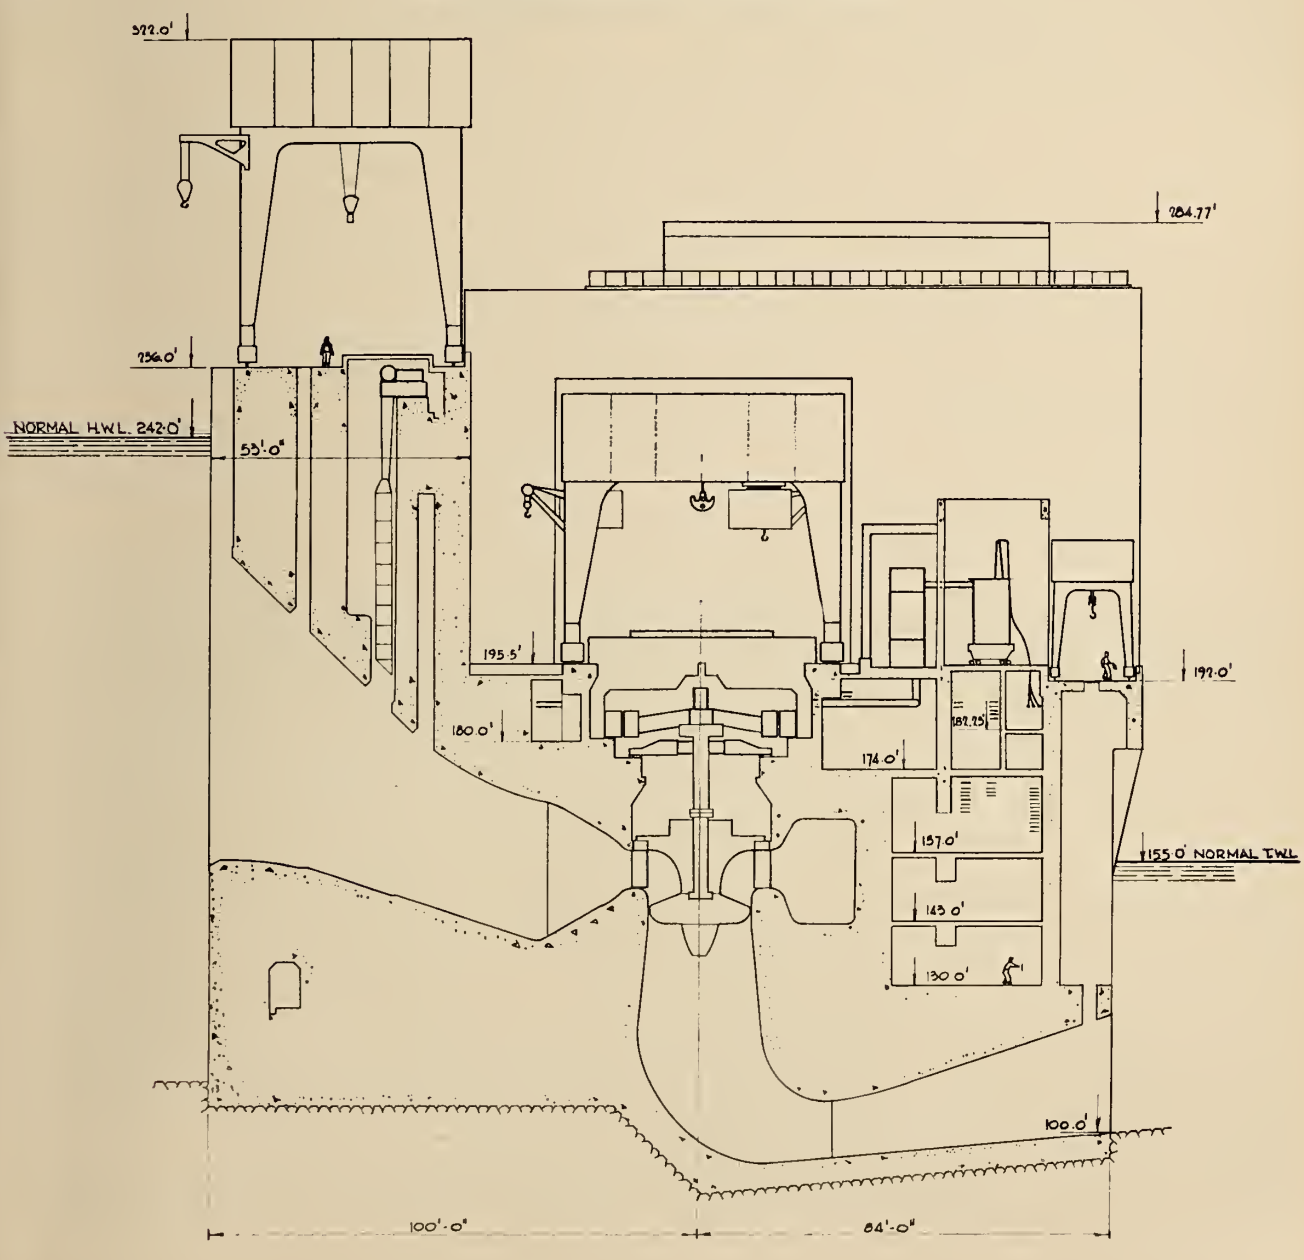
Control and Metering

All generators and associated equipment are controlled from a central control room in the administration building located at the shore end of the powerhouse structure. Operating controls, dummy bus and indicating lights are mounted on a benchboard 13 feet in length. The vertical instrument switchboard is of a horseshoe shape, with those meters essential to the operation of the plant mounted on a 15 feet long section of switchboard, so located that it is immediately in front of the operator when standing at the benchboard and is readily visible from his desk. Graphic meters, annunciators, etcetera, are mounted on switchboards to the right and left of the operator. Instruments for recording historical data are mounted on a switchboard parallel to, and behind, part of the main switch-board. Those control facilities and meters essential to the operation of the plant are duplicated on control switchboards located on the operating floor adjacent to the generators. These facilities are grouped so that one switchboard serves four generators. The switchboards also incorporate the protective relays associated with the four generators and step up transformer bank concerned.

To reduce the number, size and installed cost of control cables between equipment and the control room, 48 volts d.c. is used to energize interposing relays to apply 125 volts d.c. to operate the equipment. Similarly 5/0.5 amp. auxiliary current transformers are used on all current circuits for remote metering.

Four 60-cell 320-ampere-hour lead-

Fig. 2. Typical cross-section of the powerhouse.



acid batteries are provided to supply the 125 volts d.c. requirements for the station. Each battery normally supplies the control requirements for four generators. Emergency connections are provided so that loads can be paralleled in the event of the failure of a battery. The 48 volts d.c. control requirements are supplied by two 24-cell lead-acid batteries. One of these is normally the operating battery with the other serving as stand-by. The function of the two batteries is alternated at regular intervals. Rectifier chargers are used on all batteries.

Automatic 'start-stop' control is provided for all generators; i.e., the generator is started, brought up to speed and synchronized automatically upon the operation of the appropriate key. The machine is then loaded manually. Similarly, when shutting a machine down, it is unloaded manually and the appropriate key operated. The generator then shuts down automatically without any further attention from the operator.

Automatic load and frequency control provides a means for regulating the 16 generating units on sustained and/or fringe control from a signal transmitted over power-line carrier from the power supervisor's office in Toronto. Means are also provided for distributing the regulating burden among the 16 generators on the basis of equal per cent participation by each unit. Station total kilowatts and

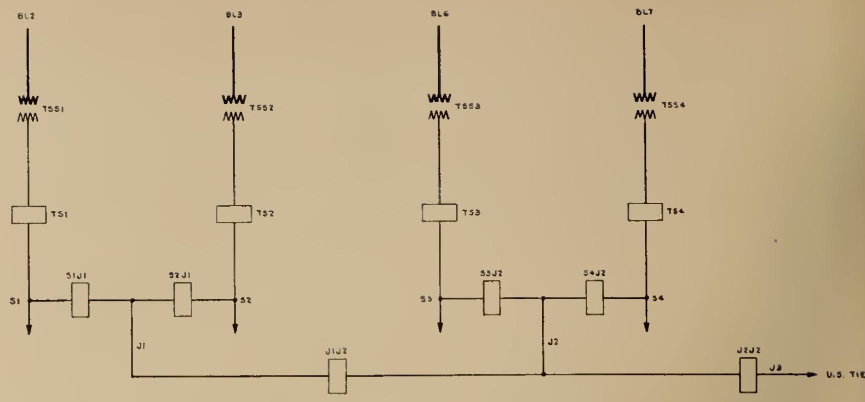


Fig. 3. Station service key diagram.

kilovars are telemetered to the power supervisor's office.

Those temperatures which give a picture of the proper functioning of the elements of the plant are measured by copper-constantan thermocouples. The output of these thermocouples is transmitted to instruments centralized at two locations on the operating floor, one between generators 4 and 5 and one between generators 13 and 14. Each location accommodates the instruments measuring the temperatures associated with eight generators. The following temperatures are continually monitored:

Generator thrust bearings.
Generator and turbine guide bearings.
Generator stator iron.
Generator incoming and outgoing air.
Generator field temperature.
Transformer oil temperature.

In general, all instruments are normally indicating; they automatically start recording and sound an alarm when any temperature exceeds the predetermined maximum setting. Recording may also be started by the operation of a manual switch.

Protection

The relay protection provided at this station is in accordance with modern accepted practice for large generating stations. Since no high-voltage circuit-breakers are provided at the generating station end of the transmission circuits to the St. Lawrence transformer station, remote tripping circuits are provided to operate 230 kv. circuit-breakers at the transformer station end of the lines for

Fig. 4. This is how the powerhouse area appeared from the air shortly after the upstream cofferdam was breached, 1 July 1958, by 30 tons of high explosive. The Canadian mainland is in the background, the adjoining powerhouses are shown centre, and Barnhart Island left. The downstream cofferdam, partly removed, was breached 31 March 1958.

transformer, line, or bus faults.

The main protection for the 230 kv. circuits to the St. Lawrence transformer station is provided by wire-pilot relays at both ends of the circuits. Back-up protection at the transformer station end is provided by directional over-current relays for phase and ground faults. At the generating station end the transformer back-up protection serves also as back-up protection for the 230 kv. circuits.

Differential protection, phase and ground back-up protection, and gas-detector relays are provided for the four 258 Mva. transformer banks. The 14.4 kv. bus is protected by differential and ground relays. Induction overcurrent relays provide protection for the 3,000 kva. station service transformers.

The sixteen 60,000 kva. generators are protected by differential, split-phase, phase current balance, stator ground, and phase back-up relay protection. In addition, devices used to detect mechanical failures will operate to shut down the generator affected. These include: low governor oil pressure; overspeed; incomplete starting sequence; high thrust bearing temperature.

A complete system of annunciators and alarms is provided to monitor the above protections and other abnormal conditions.

Fig. 5. This close-up view of the headworks of the generating station was taken shortly after the headpond was flooded. Debris visible in the forebay was flushed down the channel when a cofferdam was breached some 2½ miles upstream from the powerhouse.

Station Service

Power for the operation of the station auxiliaries is supplied by four 3,000 kva., 3-phase, 13.8 kv.-600 volts self-cooled transformers. These transformers are equipped with ± 10% underload tap changers. A station service transformer connection is taken from the 14.4 kv. bus of generators 3 and 4, 5 and 6, 11 and 12, and 13 and 14. Each transformer normally supplies the service requirements for four generators. The generators supplied by any station service transformer are alternated with those supplied by an adjacent station service transformer. For example No. 1 transformer supplies generators 1, 3, 5 and 7, while No. 2 supplies generators 2, 4, 6 and 8. Since the governor hydraulic systems of odd and even numbered turbines are interconnected, loss of one station service transformer will not result in the shut-down of the four generators supplied by that transformer. Neither will it result in a large area of the station being without illumination. In addition, the 600 volts switching arrangement (Fig. 3) is such that the load of any station service transformer can be paralleled with that of any other. The capacity of the transformers was chosen so that one transformer can, in an emergency, carry the essential services for eight units.

An emergency tie with the 480 volt station service system of the United States powerhouse is provided by means of a 500 kva. 480/600 volts autotransformer. This tie is of sufficient capacity to provide start-up

Fig. 6. A section of the powerhouse with part of the Cornwall dyke stretching into the background. The 3½-mile long dyke, which helps to retain the headpond, involved placing and compacting more than 5 million cubic yards of glacial till. (all photos: Ontario Hydro.)

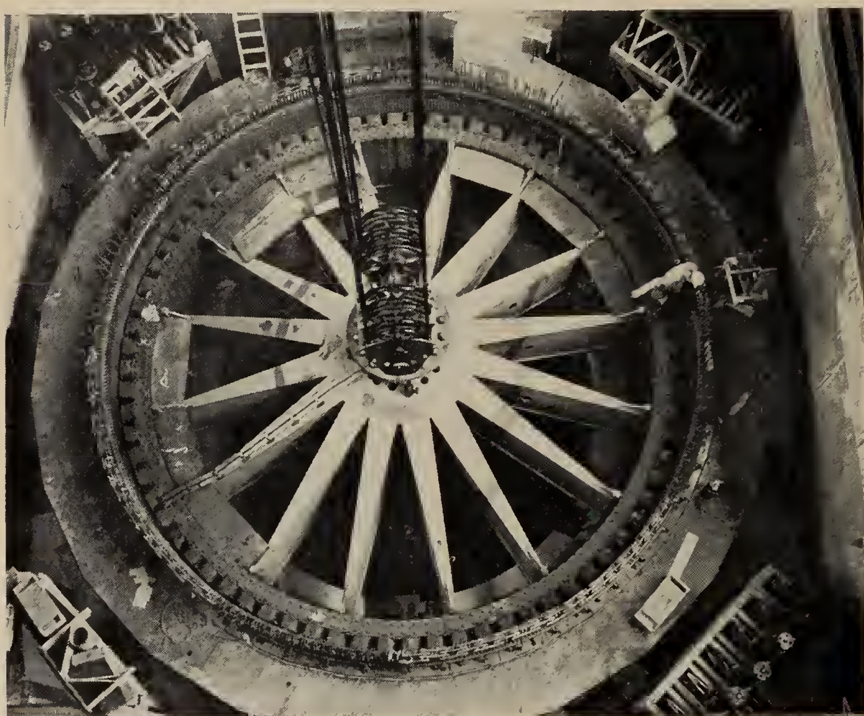
power in the event of a complete shut-down of either the American or Canadian powerhouse.

Lighting

The station lighting system operates at 208/120 volts, 4-wire. The main control room is lighted by fluorescent fixtures mounted above a translucent plexiglass ceiling; a type of installation successfully used at the Commission's Otto Holden and Sir Adam Beck-Niagara No. 2 generating stations. This installation is designed to give an average initial illumination of 150 foot candles on a horizontal plane 30 inches above the floor, and an average initial illumination of 70 foot candles on vertical surfaces 66 inches above the floor. The operating level is expected to be approximately 115 foot candles and 50 foot candles respectively. All other operating and maintenance areas are lighted by fluorescent fixtures. Incandescent lighting is used in all other areas of the powerhouse. Exterior lighting for the Canadian and American powerhouses was closely co-ordinated to provide uniformity of appearance. The headworks structure is illuminated by mercury vapour floodlights and the generator deck by recessed incandescent fixtures mounted on 40 foot centres on each side of the deck.

Failure of the a.c. supply operates contactors to put into service emergency lighting supplied from a 125 volt control battery. A separate battery is provided for the supply of emergency lighting to the administration building.

Fig. 7. First power from the Robert H. Saunders-St. Lawrence generating station was made available to the system 5 July 1958, when unit No. 2. was placed in service. The remaining 15 units will be brought into operation progressively until late 1959. This photograph shows the rotor being installed in unit No. 4.



Heating

The operating area of the powerhouse is heated by air extracted from the generator ventilating circuits and circulated through the area. Heat extracted from generator and transformer cooling water by means of heat pumps is utilized for the heating of the administration building. Areas not readily accessible for heating by either of these methods are heated by electric space heaters.

Because of the semi-outdoor type of construction used, it was anticipated that, during the winter, large quantities of snow would accumulate on the powerhouse deck, interfering with normal traffic and with major maintenance or repairs which might have to be carried out during the winter months. After investigating several methods of snow removal, it was decided to use electrical heating of the concrete deck slab for this purpose. The installation consists of copper - sheathed mineral - insulated cables with a resistance wire core, embedded in the concrete slab. Experimental tests indicate that the installation is effective for the purpose intended.

The St. Lawrence Transformer Station

A. Matheson, M.E.I.C.

Project Engineer, Stations Department, Hydro-Electric Power Commission of Ontario

The St. Lawrence transformer station is situated about two miles north of the Robert H. Saunders-St. Lawrence powerhouse. Power is also received from the Beauharnois generating station. This paper describes the transformer installation.

THE St. Lawrence Transformer Station is a key component in the Ontario Hydro system for the transmission of power to Toronto and Western Ontario. It receives the output of the new Robert H. Saunders-St. Lawrence Generating Station as well as power from the Beauharnois Generating Station. It has replaced the smaller Cornwall Transformer Station, now dismantled, which supplied 44 kv. power in that area. Tie lines to the United States from this station connect with the system of the Power Authority of the State of New York. The station has been designed to permit its expansion to an ultimate capacity consisting of four autotransformers, four stepdown transformers, two regulating transformers, seventeen 230 kv. lines, sixteen 115 kv. lines, and twelve 44 kv. feeders.

Site

The station site covers an area of 25 acres within the new Cornwall city limits and it is situated about two miles north of the powerhouse. The soil consists of hard-packed glacial till, containing a large quantity of boulders. A spur from the Canadian National Railway enters the west end of the station, so that heavy equipment can be brought in by rail.

230 kv. Switchyard

Airblast circuit breakers with an interrupting capacity of 15,000 mva. are installed in the 230 kv. switchyard. The bus arrangement features 1⅓ breakers per element and 14 breakers are scheduled for service by 1959. The switch structures and equipment are designed for 900 kv. BIL, with 196 kv. insulation class. Each breaker is equipped with two motor-operated isolating switches.

Each 230 kv. outgoing line terminal is equipped with a gang motor-operated 1,200 amp. disconnecting switch with three-pole manually-operated grounding switch, three potential coupling capacitors, power line carrier and communication equipment.

115 kv. Switchyard

Airblast circuit breakers of a "dead" tank design having an interrupting capacity of 5,000 mva. have been installed. A total of nine will be in service by 1959. The bus arrangement gives 1½ breakers per element. The design is for 550 kv. BIL with 115 kv. insulation class, except disconnecting switches, which are 138 kv. The outgoing lines are equipped with potential transformers.

44 kv. Switchyard

Conventional oil circuit breakers with an interrupting capacity of 1,000 mva. have been installed. These may be by-passed for maintenance. Six breakers are now in service.

Structures

All switchyard structures are hot-dipped galvanized steel, 600 tons of structures having been erected to date. They are supported on concrete piers, resting on spread footings designed for three tons per square foot soil pressure.

Transformers

By 1959, there will be in service two 115 mva., 230-115-13 kv. autotransformers; two 25/41 mva., 115-44 kv. stepdown transformers, and one regulating transformer, installed in the 230 kv. tie line to the Power Authority of the State of New York. This regulating transformer will have a capacity of 250 mva. with an operating range of 248/230 kv. and is equipped with an "on load" tap changer. It is protected by lightning arresters. Cascade type potential transformers and high accuracy current transformers will be installed for metering on the tie line.

Station Service

The low voltage power for the station auxiliaries, compressor plant, electrical heating and lighting is provided by two outdoor, three phase, 1,500 kva. each, 60 cycle, 44 kv.-600 volts station service transformers located in the 44 kv. switching yard. These transformers, connected to 44 kv. buses, supply outdoor metalclad switchgear equipped with main air-circuit breakers, distribution panelboard and cable terminals for the outgoing 600-volt feeders. Four outdoor load centres conveniently located on the station site are installed and are equipped with automatic changeover switches, distribution cabinet, local 600 volt-120/208 volt transformer and its protection. These load centres supply service power for transformers and other auxiliaries and to each of the station buildings.

The direct current for station controls and protections is provided by two 250 volts, 116 cell lead acid storage batteries, 210 ampere-hours and 300 ampere-hours respectively, which are installed in the battery room in the control building basement. Two selenium type battery charging rectifiers, each rated 60 ampere, are provided to maintain the capacity of the storage batteries.

Relaying

Relaying equipment is located in three relay buildings, two in the 230 kv. area and one in the 115 kv. area. Long lines at 230 kv. have directional comparison relays with power line carrier for the high speed protection. The phase relays have a timer which will open the circuit breakers whenever a fault occurs at the remote end of the line while the carrier equipment is out of service. A directional overcurrent relay is used as a backup protection for phase-to-ground faults. An overcurrent line test protection for phase and ground currents is put in service automatically whenever the line is being energized after being off potential for five seconds or more. The circuit breakers for these lines can be reclosed without supervision within half a second from the time the fault occurred by single shot reclosing relays.

Lines at 230 kv., which connect to the generating station two miles away, have pilot wire relays for the high speed protection. Induction overcurrent relays with directional control are used as backup protection against phase and ground faults. Circuit breakers for these lines will be reclosed by single shot reclosing relays with high speed undervoltage supervision with a delay of less than one second from the time the fault occurred. Since the transformers in the generating station at the remote end of each line do not have a 230 kv. circuit breaker, direct current is used on pairs of control wires between the two stations for tripping the breakers at the transformer station. All the long and short 230 kv. lines will have definite time protections for phase and ground faults which will trip the same breakers on the second time step. The contacts of the timers for the first time step will be used in the 1959 stage for opening the 230 kv. bus tie breakers and separating the station into halves. This operation will reduce the equipment removed from service if a circuit breaker in the station fails to open, or when some other equipment fails and is not removed by a high speed protection.

Transformer backup protections will operate timers giving two steps in the tripping sequence. The station would be separated into halves on the first step because both auto-transformers are on the same half of the station. The contacts for the second step will be used to open the low voltage breakers earlier than the others in an attempt to clear a low voltage fault without any further disturbance to the 230 kv. connections in the stations.

Other protections in this transformer station have standard circuits which are not described.

Control Building

The control building is centrally located in the station. It is a one-storey brick building and has a 45-foot by 60-foot control room. A "honeycomb" aluminum ceiling with fluorescent lighting above the "honeycomb" provides a high level of illumination throughout the control room.

The station is controlled from a benchboard, which is installed in an arc facing the operators. All control devices and wiring are suitable for use on 250 volts. d.c. Each control point consists of a telephone type lever key, two indicating lamps and a suitable escutcheon plate. The mimic bus consists of ⅛-inch thick plexiglass attached with concealed fasteners.

Two enclosed type indicating meter boards are installed, one for the 230 kv. and the other for the 115/44 kv. areas. Meters supplied consist of ammeters, indicating watt and varmeters, voltmeters and voltmeter switches, reclosing selector switches, ground detecting voltmeters, synchronizing equipment, and transformer tap changer position indicators.

The recording instrument switchboard is a duplex type, with hinged doors and locks at each end. Metering instruments for the 230 kv. PASNY tie line and for the 115 kv. line to Massena are mounted on these boards.

Fig. 1. Aerial view of the St. Lawrence transformer station. The 230 kv. switchyard is at left, the existing 115 kv. area right, and the 44 kv. facilities and part of the control building in the foreground. The terminal towers of the transmission lines from the St. Lawrence generating station are visible, upper right.

Megawatt and megavar electronic indicating and recording station totalizing meters with impulse transmitting contacts for telemetering are installed. Similar meters without the telemetering contacts are supplied for transformer load totalizing. Recording voltmeters and frequency meters for the various voltage levels are provided.

The annunciator consists of a cabinet mounted above the 230 kv. indicating instrument board. Trip features give visual and bell alarms, while sustained alarm features give visual and buzzer alarms. Illuminated transluscent windows with a total of 250 trip and 150 sustained alarm features are provided. Relays are the plug-in type with dust covers.

Control cables are carried from the equipment being controlled to the relay and control buildings in buried concrete trenches from two to four feet wide. The individual layers of cables are carried on galvanized supports in the trenches. The trenches are covered with light weight precast concrete covers. Parallel lines of tile provide drainage.

Air Supply for Airblast Breakers

The most interesting mechanical feature of this job is the high pressure compressed air supply to the 115 kv. and 230 kv. circuit breakers. This is divided into two systems; compression and storage at 600 psig and distribution at 350 psig. The compressors are package-type comprising 25 horsepower Vee-belt electric motor drive, liquid-to-air radiator, air-to-air aftercooler, cooling air fan and liquid coolant circulating pump. Outside air is used for cooling, automatically damper throttled, to prevent condensate freezing in winter. The air and water temperature controls are pneumatic, operating at 15 psig through pressure reducing valves from the discharge of each compressor, thus being operative only when a compressor is running. The compressor building is designed to accommodate five compressors of 50 cubic feet free air per minute capacity, with three currently installed. Space is provided at the north end of the building for twelve 60 cubic foot capacity vertical receivers, 36 inches in diameter by 11 feet high, with six installed to date. Each compressor has a full complement of auxiliaries, alarms and lockout, aftercooler trap, cyclone oil and water separator with automatic trap, ceramic filter, dual-tower activated alumina dryer with electric reactivation, the necessary stop, check, by-pass and drain valves, thermometers, relief-valves, pressure gauges and pressure switches. All equipment and piping except the compressors and after-coolers are 300 pound WSP class (600 pound WOG). The compressors and after-coolers are adaptable to operation at 1000 psig. The three types of airblast circuit breakers installed operate at pressures of 250 psig, 325 psig, and 350 psig. Each breaker in the first two categories is equipped with a pressure reducing valve (the supply is at 350 psig). The switchyard air piping is laid horizontally on each wall of a buried cable trench on rollers just beneath the trench covers. It is thus always available for inspection, and isolating valves are convenient. Each side of the dual system is capable of handling the total breaker requirements alone. The yard pressure is automatically maintained by pressure reducing valves. By means of fully valved ring manifolds, any combination of compressors, receivers and switchyard circuits can be selected to suit operating conditions. The activated alumina reduces the moisture content of the air such that its dew-point is always at least 50° F. below ambient in the receivers. The reduction to 350 psig lowers it still further and hence drainage and freezing is not a problem in the distribution lines.

Fig. 2. Close-up view during construction of the 230 kv. switchyard at the St. Lawrence transformer station. The airblast circuit breakers are shown, left, parallel with the disconnecting switches. (*Ontario Hydro photos.*)

Maintenance

Transformers can be moved from their pockets to the maintenance building by a transfer truck. They can then be moved into the building by being transferred to a cross transfer truck. The heaviest transformer has a shipping weight of 105 tons; 169 tons when filled with oil.

The maintenance building has a high erection bay, with structural steel columns supporting a metal roofdeck, and a 50-ton travelling electric crane. The upper walls of the erection bay are of insulated aluminum panels, and there is a vertical lift motor-operated entrance door 32 feet wide by 34 feet high. The crane is of sufficient capacity to handle heavy components of large transformers, and also complete transformers from smaller stations in the region that are sent to St. Lawrence Transformer Station for repairs.

Roads are provided for equipment maintenance to all parts of the station, with weeping tile under-drainage along the edges of gravel roads and curbs and catch basins along the paved roads.

A permanent insulating oil handling system for the transformers, regulators, etc., is installed. It consists of a building, two 40 i.g.m. blotter type filter presses, outdoor steel storage tanks totalling 37,700 imperial gallon capacity, and some 1,900 feet of buried, two-, three-, and four-inch steel pipe line. The buried pipe is protected from corrosion by wrappings and protective compound.

Design of 230 kv. Transmission Lines

N. J. McMurtrie,

Senior Design Engineer, Transmission Department, Hydro-Electric Power Commission of Ontario

THE 230 KV. transmission lines associated with the St. Lawrence Power Project provide an interesting comparison in the application of light towers versus regular weight towers. By far the greater portion of the transmission scheme for this project utilizes towers which are much lighter than those normally employed. Substantial cost reductions have been achieved with the extensive application of lighter designs, and the use of longer spans, shallower footings, and a newly designed conductor. Heavier towers have been used, however, in those places where the greater structural security was considered worthwhile.

Figure 1 illustrates the outline and dimensions of the four types of suspension towers, both single circuit and double circuit, which were used on the St. Lawrence 230 kv. transmission lines. Table I gives some application data regarding these towers. In all cases, the conductor diameter and final loaded tension were the same: 1.34 inches and 15,000 lb. respectively. The type W1 and type X1 are the lighter tower designs and the St. Lawrence type and 1951 type are the heavier or regular tower designs. (The word regular is used since these heavier towers represent the usual design practice on transmission lines up to this time.)

The major portion of the new 230 kv. transmission lines involves the lighter tower designs, type W1 and type X1. These are employed to carry the St. Lawrence power from the transformer station into the existing Southern Ontario System. This required the construction of 138 miles of single circuit (type W1) and 116 miles of double circuit (type X1) transmission lines. These lines extend generally west and north from the project area near Cornwall.

The heavier tower designs were used in the immediate vicinity of the project. Four single circuit lines (St. Lawrence type) each 2.2 miles in length, carry the power from the powerhouse to the transformer station. A double circuit transmission line (1951 type), 2.6 miles in length, connects the transformer station to the 230 kv. lines on the United States side of the river. Special high towers (335 ft.) were used on this latter line at the point where it crosses the river with a 3,300 ft. span. The crossing towers, which were designed to a specially high structural security, are not included in this comparison.

Most of the transmission scheme of the St. Lawrence power project uses towers which are much lighter than those generally employed. This paper describes the design of the towers and compares the various types and the associated equipment. A considerable saving in the cost of the line has been achieved.

Structural Design Loadings

Since the essential difference between these light and heavy tower designs is in their structural design loadings (or design assumptions, as they are sometimes called), it would be well to say a few words on this subject before proceeding with the comparison of the towers. The weight of a tower and the size of its foundation is governed mostly by the structural load for which it is designed. Since the most severe load encountered in practice is usually a combination of wind pressure and ice, acting on the conductor, the design load is expressed in these terms. It consists of a vertical load of ice-covered conductors, a transverse load of wind pressure, plus a longitudinal unbalance in conductor tension such as might be caused by a broken conductor.

Until recently, Ontario Hydro, along with most of the Canadian industry, has been using, as a design load, ½-inch radial thickness of ice on the conductors, plus a wind pressure of 8 lb. per square foot. Combined with this load is an unbalanced tension in one conductor equal to the final tension under these conditions of ice and wind (15,000 lb. for the St. Lawrence lines). This load, or its equivalent, is the basis for the design of the St. Lawrence type and the 1951 type towers.

For most of the St. Lawrence transmission lines, however, the design load has been reduced to either (*a*) or (*b*) below, whichever is greater:

(*a*) ¾ inch radial thickness of ice on the conductors, plus a wind pressure of 3 lb. per square foot;

(*b*) a wind pressure of 8 lb. per square foot on the bare conductors (ice-free).

An unbalanced tension in one conductor equal to the final tension at 60°F. (7,900 lb. for the St. Lawrence lines) is also used but is not combined with either (*a*) or (*b*) above. Instead, it is combined with a wind pressure of only three lb. per square foot on the bare conductors. These two combinations of structural load are the basis for the design of the lighter type W1 and type X1 towers.

Although this change in design load represents a significant departure from Ontario Hydro's previous practice, it is based on studies of weather records and many years experience in line maintenance. The basis of the design of a transmission tower is different from that of other steel structures, such as the superstructure of a bridge for example, because the magnitude and frequency of the loading which will be applied to the tower during its lifetime depends almost entirely on the weather, and is likely to vary over quite wide limits. The severity of this real structural loading on transmission lines also varies widely according to geographical locations. Because of the lack of precise measurement of the effect of storm loading on transmission lines, and the variations in their probability of occurrence, there has been a natural tendency among transmission engineers toward conservative design. As years of experience have been obtained in transmission line construction and maintenance, together with increasing knowledge of the effect of these loadings on the towers, design loadings in the industry have been reduced. This latest reduction by Ontario Hydro represents another step in that direction.

Along with the previous heavier loadings, the working stress in tension, for CSA grade G40.4 steel, had been taken as 24,000 psi. On a guaranteed yield point of 33,000 psi, this represented a factor of safety of 1.38. On the new lighter designs, this working stress has been increased to 28,000 psi, which reduces the factor of safety to 1.2. This step was taken as a result of much test data which demonstrated the reliability of our design

formulas and also as a result of the industry's production of consistently good quality steel.

Comparison of Towers and Foundations

Data concerning the four suspension tower designs are presented in Table I. All the towers were designed for the same conductor size and tension. The main differences are in structural design loading and span length application.

It should be noted first that the single circuit towers are not directly comparable in transverse strength. The St. Lawrence type, which was designed for a specific site, will take a maximum tangent span of 1,320 ft. Since the actual average span was 1,130 ft., this means the St. Lawrence type could not be used to support an angle in the line. The W1 suspension tower on the other hand was designed as a general purpose tower to support an angle in the line of 3 degrees on an 1,100 ft. span. This gives the W1 tower a theoretical maximum tangent span capability of something in excess of 1,750 ft.

The two double circuit tower designs, however, are directly comparable since they were each designed to support an angle in the line of 3 degrees on an 1,100 ft. span. A comparison of the type X1 and 1951 type suspension towers, therefore, gives a clear picture of the result of using the lighter structural design loadings.

To begin with, the total weight of steel used per mile has been cut in half. This applies, of course, to long transmission lines such as the St. Lawrence application of the X1 tower. On shorter lines, with a significant proportion of anchor towers, this reduction would not be as great.

The second point to note is that the average number of towers per mile has been reduced by one. This use of a higher tower and longer span in the X1 application does not contribute to the reduction in weight of steel. Preliminary designs showed that, had the type X1 used a tower height and span length similar to the 1951 type, the reduction in weight of steel used per mile would still have been of the same order. The real saving in the use of a longer span is the reduction in the number of sites to which access must be gained with excavation equipment and in the number of foundations which must be set.

It will be noted that the arms on the type X1 tower are slightly shorter than those on the 1951 type tower. This change reflects a trend which has continued since Ontario Hydro's first double circuit 230 kv. tower designs were introduced in 1940, and is based on experience with the patterns described by galloping conductors. The limiting factor which sets the length of the short arm on the type X1 tower is the requirement to support a 3 degree angle in the line. Under this condition, the string of insulators will swing toward the shaft through an angle of approximately 35 degrees.

The foundations on all of these suspension towers are of the steel grillage type. Those on the lighter towers are not set as deeply as on the heavier ones. Although a deeper foundation on the type X1 would have resulted in a further reduction in weight of steel, it would have produced a more costly foundation. Excavation and setting costs on foundations rise rapidly as the depth increases beyond six feet.

The installed cost of foundations contains a greater proportion of labour man-hours than does the installed cost of the towers. The increasing ratio of labour to material costs over the past 12 years has caused foundations to form a greater proportion of the cost of the whole transmission line. For this reason, it is in the tower foundations that the greater savings can be made by the use of more efficient designs, and much work is still in progress on this problem.

Conductor

The four types of towers were designed to support Grackle ACSR (1192.5 MCM, 54/19). Subsequently, during the survey for location of structures, the Aluminum Company of Canada, in collaboration with Ontario Hydro, produced a new conductor designed specifically to meet the requirements of the St. Lawrence lines. It has been given the appropriate name Seaway ACSR (1277.5 MCM, 42/7). It has the same diameter as Grackle and is designed for the same tension (loaded with ½-in. ice and 8 p.s.f. wind) of 15,000 lb.

The new conductor has a smaller steel core and a greater cross section of aluminum. Since it is loaded to the same tension as Grackle, its unit stresses are greater. At 0°F. without ice or wind, the new conductor reaches a load in tension of 25% of its ultimate strength.

The advantages of using this special design are a decrease in electrical resistance of 7% and a decrease in conductor cost of 6%.

Ground Cables

An interesting feature of the type X1 tower is its adaptability to the use of either one or two ground cables (sky wires), whichever is considered necessary. There is an interchangeable double ground cable peak, similar to the 1951 type, which may be used with the type X1. It may also support two ground cables by using a single peak, as shown in Fig. 1, for the first ground cable, and stringing the second through the centre of the shaft, supported at a point slightly below the middle crossarm. A single ground cable at the top of the tower provides sufficient shielding. The second ground cable adds to the capacitive coupling between ground cables and conductors and may be used in those areas where lightning activity is severe or on lines where the resulting increase in service security is worthwhile. The advantage in having the support position for the second ground cable located lower on the shaft is in the facility with which such cable can be added if experience should indicate that this is necessary.

Overall Cost Comparison

Theoretically, if the 116 miles of transmission line, on which the type X1 towers were used, had instead been designed and constructed using 1951 type towers, the total cost of the line (excluding right-of-way) would have been increased by approximately one third.

World Power Conference Sectional Meeting

The October issue of The Engineering Journal will contain a report of the technical highlights of the World Power Conference Sectional Meeting, which was held in Montreal 7 to 11 September.

Development of Great Lakes Harbours

Major-General H. A. Young, M.E.I.C.

Deputy Minister, Department of Public Works of Canada

MANY ARTICLES have been written about the St. Lawrence Seaway and the ships that will come up from the ocean, but still some normally intelligent people believe that the *Queen Mary* will tie up at Yonge Street dock in Toronto and the aircraft carrier *Bonaventure* will tie up alongside the navy wharf in Hamilton. At the risk of repeating facts that are already well known, some basic information considered by the Government of Canada in considering the questions of what harbours should be developed and the nature of that development is presented here.

The Seaway is not something new; Canada has had a Seaway for many years and deep sea vessels have been coming into the Great Lakes for over half a century. The new Seaway will open the door a little wider; as a matter of fact, there are still quite a few locks on the door and these locks have to be opened one at a time to allow ships to come into and to leave Lake Ontario.

The size of ships using the St. Lawrence Seaway is strictly limited by the size of the locks and depth of the channels. The number of ships coming up is limited by the number of ships a lock can pass through in any season. Ships that come up must also go down, and they go out of that same door as in they came. Therefore, the amount of freight entering and leaving the Great Lakes has a physical limitation. The most recent estimate of the probable maximum tonnage which the locks of the Seaway can pass, is in the neighbourhood of 35 million tons annually. The present tonnage carried by the existing St. Lawrence canals is approaching 10 million tons. The difference of 25 million tons is the likely increase until the Seaway facilities are doubled.

Many of the communities on the Great Lakes optimistically expect to receive a big percentage of this 25 million tons. Not only Canadian cities, like Toronto, Hamilton, Windsor, Sault Ste. Marie, Port Arthur and Fort William, and the many small Canadian ports, but United States' cities, such as Rochester, Cleveland, Chicago, and Duluth, will share part of this tonnage.

This paper reviews the effect of the St. Lawrence Seaway on the ports of the Great Lakes, and some of the work being done by the Department of Public Works of Canada.

At present the bulk of traffic entering and leaving lake ports is lake traffic and it is likely to remain so for many years. For example, in 1956 the tonnage of freight handled in Toronto Harbour reached almost 6 million tons but only 165,000 tons or 3% was foreign shipping other than United States. It is probable that from 80 to 85% of the traffic through the canals will be bulk cargoes such as iron ore, wheat and coal. However, the nature and volume of general traffic will depend to a large extent upon the toll structure which at the time of writing has not yet been finally agreed.

Until such time as definite predictions can be made about the freight potentials of lake harbours, and actual patterns of trade have been established, the Department of Public Works will concentrate its assistance on the establishment of deep water facilities in Toronto, Hamilton, Fort William and Port Arthur. The cities of Windsor, Sarnia, and Sault Ste. Marie are being given serious study and when conditions warrant the development of port facilities, the Department will be prepared to cooperate in carrying out the necessary work. This, of course, does not mean that other ports will not receive assistance in the maintenance and establishment of facilities to lesser depths.

The cities of Toronto and Hamilton will have facilities to receive vessels coming up the St. Lawrence at the opening of navigation in the Spring of 1959. Port Arthur and Fort William will not need the deep water until 1962 because the channels leading into Lake Superior will not be dredged to Seaway depth until then. This latter work is being carried out by the United States Corps of Engineers.

With the exception of some of the more understandably enthusiastic advocates of other municipalities, most people will accept the validity of giving top priority to these four harbours. As the need for providing facilities at other locations becomes evident, they will receive serious consideration by the Department of Public Works.

Harbours in Canada fall under three classes for purposes of administration. The National Harbours coming under the National Harbours Board include Halifax, Saint John, Quebec City, Chicoutimi, Three Rivers, Montreal, Churchill, and Vancouver. Eight other harbours such as Toronto, Hamilton, and Windsor, come under what is known as Local Harbour Commissions. The Government proposes to establish a Harbour Commission at Fort William and Port Arthur which will bring the total of Commissions to nine. All other harbours, amounting to several thousand, come under the direct administration of the Department of Transport.

In the case of the National Harbours, the Board is generally responsible for works of a public nature, although in a few special instances the Department of Public Works will carry out certain dredging.

In the Commission harbours, there is less uniformity of practice because of differing antecedents and stages of development, as well as varying local conditions. Each has its own Act of Parliament, however, and the tendency is to make them more self-sustaining. For the remainder, the Department of Public Works carries out all public dredging and the building and maintenance of all public structures.

The major activity of the Department of Public Works in Toronto is the improvement of the main channel in the harbour, and its approaches. In the neighbouring harbour of Hamilton, both dredging to accommodate Seaway traffic and the construction of certain terminal facilities are under way. At the other two of the four harbours to which special reference has been made, Fort William and Port Arthur, the Department is engaged in a programme of Seaway dredging that is scheduled to coincide with the completion of the deepening of channels in the St. Marys River, the entrance to Lake Superior.

Fig. 1. General plan of Toronto Harbour.

CHANNEL STANDARDS

It was agreed by the Governments of Canada and the United States that the Seaway would provide channels adequate for ships drawing 25½ feet. This was generally accepted as a channel with a minimum depth of 27 feet.

In deep sea ports, the mean sea level never changes and ships can be assured that the water level in the harbour will be at mean sea level four times a day and many harbours can only be entered at or approaching high tide. Ships can, therefore, enter these harbours for a good percentage of the time every day, year in and year out.

The levels of the lakes vary too, but for different reasons; basically the difference is a reflection of the variation in the hydrologic cycle, but the high levels of the lake may occur once in fifty or sixty years, so ships could not afford to wait until high water for entry into a harbour. Even mean lake level would sometimes not be equalled or exceeded for several years.

Therefore, it is important to select a zero datum from which to measure this agreed channel depth which will give access to main harbours for vessels with a 25½ foot draught for most of the time.

In the past, the level of Lake Ontario has fluctuated widely, with a recorded mean monthly minimum level of 242.6 feet above mean sea level and a maximum mean monthly level approaching 250.0 feet above mean sea level. This is a variation of about 7½ feet. As well as channels, docks and loading and unloading facilities must be prepared for this difference.

With the completion of the control structure at the outlet of Lake Ontario and the assumption of lake regulation by the International St. Lawrence River Board of Control, the levels of Lake Ontario will be kept between a mean monthly elevation of 244.0 and a maximum mean monthly level of 248.0 feet above sea level. This artificial control will be very helpful for the planning of harbour developments.

Lake Superior has been under regulation by the International Lake Superior Board of Control for many years and harbours in the upper lake are not subjected to lake level variations that are as great as the other lakes. This is due both to the control exercised at Sault Ste. Marie and to the larger area of Lake Superior.

The figures mentioned above for Lake Ontario are mean monthly levels and the water levels fluctuate daily, and the mean daily level may be as much as one foot different from the mean monthly; and the instantaneous levels may be as much as a foot different from the mean daily level.

It would be ridiculous to design harbour facilities for water levels that would only be reached once every fifty years; it would be uneconomic to design channels that would only be used to the maximum capacity 1% of the time. To add an additional foot to the depth of Toronto Harbour would mean the expenditure of up to 4 million dollars. Considered as insurance, the annual premium of $300,000 is quite a big sum to pay for the extra few tons of shipping which would only use the maximum harbour facilities for as little as 1% of the time. After due consideration, the level of Lake Ontario selected by the Department of Public Works as the zero datum for channel construction is 243.0 feet above mean sea level. For Lake Superior, this zero datum is 601.6 feet above mean sea level.

In determining the depth of the channel to be provided, it is necessary that certain clearance be considered. Sufficient clearance must be provided under the keel of the vessel to permit it to move safely and at an efficient speed. Increased clearance must be provided for rock bottom over that for soft bottom because of the serious damage which would result to a vessel it it strikes ledge rock or boulders and for a factor of safety against fragments of rock or boulders that might be turned up to extend above the project depth plane during the periods between maintenance operations in the channel.

Additional clearances must be provided in exposed areas, as compared to sheltered areas, as vessels are subject to vertical movement because of storm and wave action.

Fig. 2. Western entrance to Toronto Harbour. Channel dredging by dipper dredge *A. L. Quinlan*.

In the inter-connecting channels, the following general principle has been adopted for establishing the amount of this clearance;

"Total clearance allowances should be 0.5 feet in sheltered channels with soft bottom; 1.5 feet in exposed channels with soft bottom; 1.5 feet in sheltered channels with hard bottom; and 2.5 feet in exposed channels with hard bottom."

In addition to the clearances which must be provided between the draught of a vessel and depth of channel, an allowance must be made for the "squat" of a ship when under way. Squat is defined as the increase in draught assumed by a vessel when under way over that when it is at rest. The squat increases with increase in speed, the rate of increase becoming greater as the speed increases. The older vessels of the present Great Lakes cargo fleet operate at a speed of 10 to 12 miles per hour and the standard allowance of one foot for "squat" that has been made in the past is considered to be adequate for the present need. However, many of the newer vessels operate at speeds of 17 to 18 miles per hour and the trend of new construction is toward such higher speeds. Therefore, additional allowance for squat will be necessary in unrestricted channels to provide adequately for the fleet as it may be expected to be constituted during the life period of the improvement.

TORONTO HARBOUR

The design depths of Toronto Harbour vary; the western entrance to Toronto Harbour is exposed and the bottom is in rock, therefore, clearance allowance of 2.5 feet is to be made. As vessels approaching will be at a slow speed, no allowance for squat is required. Therefore, the channel depth required is 28 feet (25.5 and 2.5 feet) below the zero datum of 243.0 (U.S.L.S. 1935).

Inside Toronto Harbour no allowance for squat is required and as the channel is protected, a clearance of 1.5 feet is all that is necessary. A channel depth of 27 feet, measured from selected minimum water level, is all that is required in Toronto Harbour.

A study of the directions of the prevailing winds on Lake Ontario indicates that winds from the southwest in excess of a Beaufort No. 5 occurred on 217 occasions during the navigation season from 1943-52 inclusive. (A Beaufort scale of 5 is equal to a wind of 19 miles per hour.)

The channel between the breakwaters is in a general direction southwest—north-east and might be considered exposed waters when the wind is from the south-west, but considering the number of times this would occur during periods of low lake levels no additional allowance can be justified.

Based on the standards established by the Department, a contract for excavation of the western channel entrance has been let for the removal of 165,000 cubic yards of Class "A" material and 520,000 cubic yards of Class "B" material. The time limit of the contract is 18 months, to be completed by November 30, 1958.

The Department has also let a contract for dredging the first section of the channel inside the harbour, extending from the western channel entrance to Parliament Street Slip. The tenders for the second section of the Harbour channel dredging have also been received and this part of the project will be completed by April 1, 1959.

The channel dredging inside the Harbour, included in these two sections, is about 180,000 cubic yards of Class "A" material, which is rock, and about 800,000 cubic yards of softer material, Class "B". Fig. 1 shows the general dredging programme being carried out by the Department of Public Works, and Fig. 2 is a view of part of the equipment being employed in this location.

These items include all the immediate plans that the Department has for harbour improvements in the Toronto area. The Toronto Harbour Commission, however, has made some long-range plans for the development of the Harbour, but the timing of the various parts of these long-range plans will depend on the effect of the St. Lawrence Seaway following the establishment of toll structures.

Fig. 3. General plan of Hamilton Harbour.

HAMILTON HARBOUR

The Department is now carrying out dredging in the channel and some construction of structures in Hamilton. Contracts for structures now under way include the Strathearne Avenue Wharf, 1200 feet long, of pile bent concrete deck construction; the new Ship Street Terminal No. 3 Wharf, 1292 feet by 833 feet, also of pile bent concrete deck construction; and the Wellington Street Wharf Extension, 1106 feet by 619 feet, of steel sheet pile construction. It is expected that these structures will be completed in the Spring of 1959. A dredging contract for 700,000 cubic yards will be completed this year. The removal of an additional 500,000 cubic yards is now under way and a contract for another 200,000 cubic yards has been let scheduled for completion before the opening of navigation in 1959.

The dredging being done by the Department of Public Works is shown on Fig. 3.

Burlington Channel, which is a bottleneck at the entrance to Hamilton Harbour, is to be improved. The Ontario Government is building a new high-level bridge to carry through traffic over the canal (Fig. 4). As a Federal Government project, two existing old moveable bridges over the canal are being replaced by one lift span to carry both rail and highway traffic. The centre piers will be removed and the channel dredged to Seaway depth for the whole width of the canal. This project is scheduled for completion during 1960.

The Hamilton Harbour Commission has long-range plans for development, but, as with Toronto, the timing of the various parts of these long-range plans will depend on the effect of the Seaway.

FORT WILLIAM AND PORT ARTHUR

Getting ships into Lake Ontario is only one of the steps on the way to Lake Superior and the upper Lake ports of Fort William and Port Arthur. The St. Marys River channels will not be completed to Seaway depth until 1962, so that the pressure on facilities in the upper Lake ports will not be felt until that time. The dredging programme for the upper Lake ports is, therefore, scheduled over a longer period than that for the Lake Ontario Harbours. Contracts for the removal of about 700,000 cubic yards from these two harbours are scheduled for completion during 1958. Future dredging requirements will depend on the plans for development to be carried out by the Harbour Commission which will be ap-

Fig. 4. The Burlington 'skyway', a high-level bridge to carry traffic over the entrance canal to Hamilton Harbour. (Part of the Queen Elizabeth Highway)

pointed after the legislation setting up this authority has been given Parliamentary approval.

Under the new legislation, public wharf facilities will be provided by the Department of Public Works as a joint development of the two cities of Fort William and Port Arthur. The proposed new facilities will be located adjacent to the common boundary of the two communities and will be transferred to the Harbour Commission for administration.

When the exact location of the wharf has been determined, a survey of dredging requirements will be made and the necessary work carried out by the Department of Public Works.

OTHER GREAT LAKES PORTS

There are a large number of ports on the Great Lakes that are used by fishermen, fuel carriers, and package freighters, which are of considerable local importance and which receive assistance from the Department of Public Works in the maintenance of dredged channels, and in the construction and maintenance of wharves.

One of the most serious problems is the maintenance of adequate channel depths by dredging or remedial works. Littoral drift along the lakeshore in some places fills in channels almost as quickly as they are dug out.

The Department, in co-operation with the National Research Council and Queen's University, have undertaken a comprehensive study of this problem. It is hoped that this investigation will result in the saving of many hundreds of thousands of dollars annually to the Canadian taxpayers and produce more satisfactory harbour conditions for the many ports in the Great Lakes area.

CONCLUSION

The Department of Public Works is spending many millions of dollars annually in the improvement and maintenance of harbour facilities and channels in the Great Lakes area. With the expanding requirements likely to result after the opening of the deeper waterway, it is expected that the annual contribution to these services will be even greater.

MODIFICATIONS TO THE JACQUES CARTIER BRIDGE

The picture below shows the start of the Seaway channel opposite the harbour of Montreal. The Jacques Cartier road bridge is in the foreground, with the Victoria road and rail bridge behind. Some of the work involved in altering these bridges where they cross the Seaway channel is described in the article on page 55 to 68 in this issue. There will be a further paper 'Modification of the Jacques Cartier Bridge for the St. Lawrence Seaway' by R. E. Chamberlain, M.E.I.C. in the December *Journal*. *(Photo: Dominion Bridge)*

INTERNATIONAL NEWS

Industrial Notes from Italy

ITALIAN BUSINESS and industry have developed remarkably in recent years, and many industries are enjoying a flourishing export trade. Some typical examples are mentioned briefly here, though the field covered is far from comprehensive.

Balance of Payments

Italian gold and foreign currency reserves increased by $343.7 million between 1 July, 1957 and 31 March, 1958, compared with $31.4 million in the corresponding period of 1956-57. For January-February 1958 the overall balance of current payment showed a surplus of $24.3 million as against a deficit of $3.3 million the previous year. Foreign investments rose from $8 million in the first quarter of 1957 to $26.6 million in 1958.

The largest deposits of white marble in the world are in the Apuan Alps, an offshoot of the Appenines. Used since before the Christian era, some 500,000 metric tons are taken each year from 550 quarries. Exports of block and sawn marble in the first half of 1957 totalled 3,383 million lire.

Six prestressed concrete conduits, 11,707 ft. long, are being installed in the plain of Taranto, southern Italy. Each element is 52½ ft. long, 63 in. i.d., and 7-3/32 in. thick, with a 15¾ in. section ring at the ends, and weighs 47.4 tons. Hydraulic head is 57 ft. There is no circumferential prestressing, but longitudinal prestressing by rectangular-section steel bars is used to counter tensile stresses in the lower section amounting to about 470 p.s.i. Concrete is poured in horizontal steel moulds, with vibration, followed by steam curing for 36 hours. The Ferrocemento Company, of Rome, is doing the work as part of the Mezzogiorno development.

Development of roads in southern Italy includes the Salerno-Pompeii highway along the steep coastline. Seven of eight bridges were built by E. Grassetto, of Padua, with two tracks at different levels to reduce the amount of rock excavation involved.

Development of Southern Italy

The outstanding undertaking within the country is the program for the development of the southern part of Italy (the Mezzogiorno). A new law facilitates the efforts of government and private enterprise to alleviate social and economic conditions in the region by encouraging new agricultural and industrial initiative and providing an interdependent program involving road construction, land reclamation, pilot industrial zones, schools for professional instruction, and training of specialized workers.

In just over seven years, to mid-1958, $1,393.6 million have been invested in the Mezzogiorno, divided as follows (in $ millions): reforestation, land reclamation, irrigation, 366.4; soil improvement, 262.4; additional land reform agency works, 372.64; roads, 148.0; railroads, 76.8; aqueducts and sewage, 124.8; and tourist development, 23.0. In addition, three Southern Institutes have, in four years, contributed $400 million for fixed installations and $80 million for operational credit.

Some 6850 miles of country roads have been repaired, and 870 miles of new main roads built plus 2500 miles of roads in reclaimed areas. Savings on transport costs from this development are estimated at several million dollars a year.

Aircraft Industry

The aircraft industry, long known for its engineering quality, has been boosted by the acceptance of the Fiat G.91 as the NATO standard light tactical fighter. The plane, equipped with a Bristol Orpheus B.OR 3 turbo-jet engine made by Fiat under license, will be mass-produced in Italy, France, and Germany.

Another jet aircraft, built for the Italian Air Ministry, in agreement with NATO, is the Ariete, from the Aerfer plant of Pomigliano d'Arco. This interceptor aircraft first flew on 27 March 1958. It has a maximum speed of Mach 1.1, with a rate of climb of 4 min. 20 sec. to 12,000 metres (about 39,400 feet). Take-off and landing runs are only 1640 feet and 2950 feet, respectively. The main engine is a Rolls-Royce Derwent, which discharges under the fuselage, and there is a rear auxiliary for additional thrust during take-off, attack, and so on. This engine has its air intake on the top side of the fuselage and exhausts from the tail of the aircraft.

The Aerfer Ariete light interceptor fighter.

Industrial Training Schools

The importance of technical and professional training is widely recognized by Italian industry. Two examples of the training schools organized by private industry are those of the Olivetti Company, manufacturers of office equipment, and the Fiat organization, which is noted for automobiles and aircraft.

The Olivetti School

The Olivetti family, father and son, have been prominent in the field of Italian industrial architecture and the industrial design of equipment. Their efforts towards the highest standards of quality and efficiency have been helped by the availability of suitably trained personnel. The company's training school for mechanics, at Ivrea, was organized a few years before World War II. Courses last five years and are divided into two terms. For the first three years the trainees spend about two-thirds of their working day in the school workshop, as unskilled workers, alternating practical work with theoretical lessons. At the end of the five-year course, the successful pupil receives a government-recognized diploma, and can then specialize according to his aptitude and the plant requirement for such trades as mechanic for assembly and repair, electrician, toolmaker, draughtsman, and so on.

The trainees, who may be admitted between the ages of 14 and 16 by examination, have the same working conditions and benefits as qualified employees, and salaries are only 17 per cent below the regular rates.

Machinery, machine tools, and precision instruments are produced, and largely designed, by the school, which includes a planning department responsible for the production schedule and cost control.

The tools and machinery produced in the school are distributed to the company's plants throughout the world.

Selected students can proceed to university or Polytechnic Institute, and there is also a 'specialization course' of five years, from which a diploma, also recognized by the government, is obtained. Graduates from this course qualify for administrative jobs in such fields as control and planning.

The Fiat School

Fiat has established the 'Giovanni Agnelli' central apprentice training school in Turin, where the company, founded in 1899, now employs 80,000 people. Boys of 14 to 16 years old with a secondary professional school certificate are admitted by examination and are given a three-year course in practical and theoretical subjects. English is taught, particularly as far as technical terminology is concerned, as well as Italian, mathematics, physics, chemistry, drawing, and electrical and mechanical technology, together with physical education.

Under the direction of Prof. Aldo Peroni, 80 teachers instruct some 900 apprentices in theory. A similar number of technicians give practical instruction. In addition, some thousands of workers are given special one-year vocational guidance courses to maintain the supply of semi-skilled employees.

The new school is exceptionally well equipped with locker rooms, washrooms, and a large medical department. Equipment includes some 400 machine tools, many of which have been built by the apprentices themselves. In addition to the large machine-tool shop there are shops for electrical work, electronic testing, and machine tool production.

Newly-graduated engineers are also given a two-year course, including six months in the school workshops to gain experience on the various machine tools.

Fiat was the first major industrial concern in Italy to establish its own apprentice training school, in 1922. Many of the early trainees now hold managerial positions in the company.

The information and illustrations for these notes were supplied by the office of the Commercial Attache to the Italian Embassy, in Ottawa, and from material published by the Confederazione Generale dell' Industria Italiana, Rome.

UNITED KINGDOM

Typewriters for Scientists

A development that should also be of interest to editors who receive scientific manuscripts is a two-keyboard typewriter for reproducing scientific and mathematical formulae.

Designed by the Imperial Typewriter Company, in England, for the Atomic Energy Research Establishment at Harwell, machines can be produced to meet the individual requirements of other organizations or scientists.

The two keyboards are mounted side by side, with a common moving carriage unit. One keyboard is more or less standard, the other carries the required symbols such as the Greek alphabet, root and integral signs, and so on. Symbols from this keyboard fall accurately into position in the main text. Altogether 180 characters are available on the machine.

Similar machines have been exported to Australia (in connection with research at the Woomera rocket range), Belgium, Switzerland, and South Africa, while orders are due from Denmark and the United States.

Apart from this special application, typewriters are also available in such languages and script as Siamese, Hebrew, Russian, Arabic, Eskimo (engineers in northern Canada, please note), and Braille.

Training for Nuclear Power Work

The Harwell Reactor School was founded in 1954 to train men from industry who were to design and build nuclear power stations. Originally for British subjects only, courses are now open to foreign students.

The school caters primarily for graduate engineers and physicists in the respective fields of reactor engineering and reactor physics, with lectures on basic physics for the engineers and on engineering subjects for the physicists.

Some of the subjects covered include design of biological shields, reactor control and instrumentation, moderator and fuel manufacture and chemical processing, metallurgy, reactor safety, and radioactive effluent disposal.

The standard course lasts 16 weeks, the first part being held at one of three Colleges of Advanced Technology (at Birmingham, Bradford, and Salford, near Manchester). The more specialized part of the course is held at Harwell, where experimental work is carried out.

By mid-1958 a total of 718 students attended standard courses at the school, including 144 from abroad. A standard course, for 60 students, will run from 10 November 1958 to 6 March 1959. Any student of degree standard may attend, but foreign students must be sponsored by their government or by a recognized atomic energy agency in their country. Fee for the course is £250 (without accommodation).

There is also a two-week senior technical executives course (fee £50) for senior industrialists who have a technical background, and special courses have been held for such groups as scientific correspondents of the press, professors from European universities (at the request of OEEC), and technical college teachers (run for the Ministry of Education).

SWITZERLAND

Geneva Conference on Atomic Energy

The second United Nations International Conference on the Peaceful Uses of Atomic Energy was held in Geneva 1 to 13 September. At the first conference, in August 1955, some 1070 papers were submitted, 300 advisers and observers attended, and proceedings were reported by about 1000 representatives of press, radio, and television.

This issue goes to press during the present conference, but it is known that the program dealt with the five series of physics, reactors, chemistry, isotopes and radiological protection, and raw materials and metallurgy in a total of 77 sessions, compared with 55 sessions in 1955.

The special exhibit, in which 21 governments were represented, increased from 1600 square metres (9 countries represented) in 1955 to some 7000 sq. m. this year. Canada was strongly represented both at the technical sessions and in the exhibition of material.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

South Saskatchewan River Dam

Another important step forward in the development of Canada's resources has been taken, with the signing of the federal-provincial agreement on the South Saskatchewan River Dam. Years of discussion and study were climaxed in July by signing of a cost sharing agreement outlining in detail the responsibilities of the two governments in construction and maintenance of the earth dam and other structures.

Work was to start immediately, supervised by the PFRA director at Regina, Gordon McKenzie, assisted by George Munro, chief engineer.

This is a gigantic project, surpassed only by the St. Lawrence Seaway in size and economic importance, according to one commentator.

It can provide irrigation for 500,000 acres of soil in an area of 300 miles, directly benefiting 50,000 farms. The ultimate benefit will require more than 25 years to be achieved. An area of 50,000 irrigated acres will be the first target, soon after the dam is completed, a six to eight year program.

The project will require the construction ot an earth dam, between the towns of Elbow and Outlook on the Saskatchewan River, at what is called the Coteau Creek site. Associated with the dam will be a powerhouse having an installed capacity yet to be determined by the place this project will have in an integrated steam-hydro system which the province is planning. An auxiliary earth dam in the Qu'Appelle Valley will prevent escape of waters impounded by the main dam. The irrigation development would require the installation of 500 miles of main canals and laterals as well as 12 pumping stations.

The Federal Government will pay 75 per cent of the cost of the dam works, and the province the remaining 25 per cent. Saskatchewan will pay for the power works and for the irrigation system.

A dam at this site is not a new or recent proposal. Captain John Palliser and Prof. Henry Youle Hind investigated the same area in 1857 and 1858. The purpose in those days was navigation, but they then recognized the effect of a dam at the location now chosen.

Project Statistics

RESERVOIR: Length, 135 miles; area, 116,000 acres; total storage, 8.4 million acre feet; usable storage, 3.1 acre feet; length of shoreline, 475 miles; water depth at dam, 180 feet.

MAIN DAM: Height, 205 ft.; length, 16,700 ft.; volume of embankment, 40 million cu. yd.; volume of excavation, 52 million cu. yd.

SPILLWAY CHUTE: Length, 17,000 ft.; crest width, 520 ft.; capacity 265,000 sec. ft.

OUTLET WORKS: Length, 2,750 ft.; No. of barrels, 4; Size of barrels, 25 ft. dia.

QU'APPELLE VALLEY DAM: Height, 135 ft.; Length, 6,700 ft.; volume of embankment, 5.3 million cu. yd.

DRAINAGE BASIN: Total for river, 65,500 sq. miles; above damsite, 48,500 sq. mi.

IRRIGABLE AREA: 500,000 acres.

POWER: Installed horsepower, to be decided; Av. annual output, 475 million k.w.h.; power for irrigation pumping, 100 million k.w.h.

George Spence*, in *Regina Leader Post*

"This development will not only be of great benefit to the community and to the province but will ultimately strengthen the whole economy of the nation. Specifically the development is designed, among much else, to: (1) stabilize the agriculture of the region on a livestock basis; (2) provide hydro-electric power for domestic and industrial use; (3) provide a more abundant supply of good water for municipal and industrial purposes; (4) create greater facilities for recreation and other amenities of pleasurable living."

D. Cass-Beggs**, quoted in the *Regina Leader Post*

"The upstream storage would improve the power potential, and therefore, increase the value of the power sites that could be developed at points lower down the river."

* Former director of the Prairie Farm Rehabilitation Administration and an ex-member of the International Joint Commission.

**General manager of the Saskatchewan Power Commission.

A Report on Growth in the Engineering Faculties in Canada

Ninth article of a series

McGill University Makes Ready for Future Developments in Engineering

Engineering education has received more attention and attracted more discussion than at any other time, during the past year, McGill University's dean of the Faculty of Engineering, D. L. Mordell, M.E.I.C., wrote in his annual report of the 1957-58 term. He discussed the place of engineering education in a great university, and also reported on attempts to delineate the future development of the faculty. The conclusion is that at a time when man's knowledge of materials and machines is as vital for survival as man's knowledge of man, no university could be considered complete without an engineering faculty.

"We recognize the need for two types of engineers", said Dean Mordell. They are defined as the creative and operational engineers. In a general overall sense he does not regard one to be necessarily more gifted than the other. He recognizes in each a different kind of talent. Essentially the creative engineer is conscious of abstract ideas; he is likely to compose new technologies, in the abstract. The operational engineer may be no less creative, but his ideas will be in the application or device synthesis level. In both cases the capacity of independent thought, analysis, and synthesis is required. The university must provide the surroundings in which any latent creative ability can be developed. Those better suited to working with abstract ideas will usually show to better advantage in mathematics and other fundamental sciences, and for them more rigorous courses should be provided. Those men suited to application must take courses which will prepare them for the applications to be met in twenty years' time.

During the year the Faculty has recommended a study of the complete curriculum, and has modified its rules of promotion and standing. The aim is to establish as soon as possible whether a student is capable of following the courses. This helps also to correct the situation whereby the final year courses had become more analytical and exact, although no major changes in the curriculum as a whole, and particularly in the lower years, had been made.

It is hoped a new curriculum can be introduced in 1959, which will meet these criticisms. In combination with changed rules of standing and promotion, the new curriculum should raise standards and meet the objectives mentioned, Dean Mordell reported.

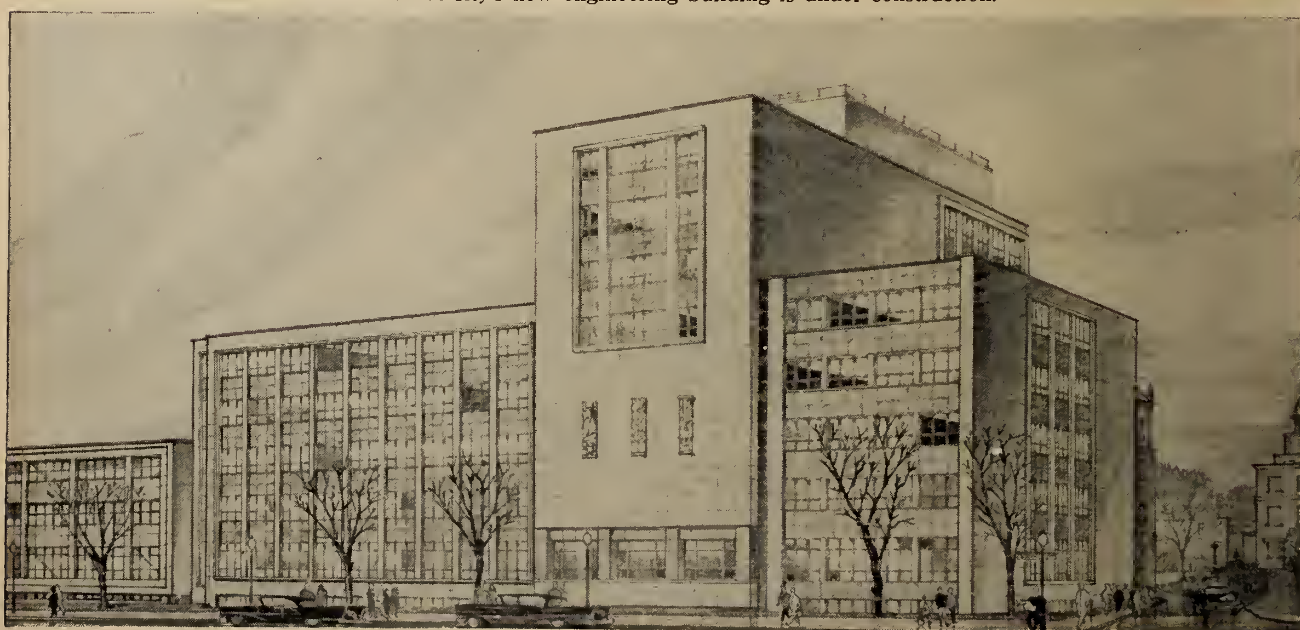
The year is noteworthy for the graduation of the first two students to complete the Mechanical Sciences Option in the Department of Mechanical Engineering, a new course requiring considerable mathematical capacity and calling for a large amount of independent work including a design dissertation.

In the past decade graduate study and research has steadily developed in the Faculty, though its growth had been hindered by numerous factors.

Staff changes are headlined by the retirement of Prof. George A. Wallace from the chairmanship of the electrical engineering department, and the succession of Dr. G. L. d'Ombrain. Assistant professors G. W. Farnell, T. J. F. Pavlasek, and J. W. Stachiewicz have been promoted to associate professors. Assistant professors T. H. Barton, K. A. Shelstad, and W. Mathison have been appointed.

Donors have made possible the creation of two new chairs, (in mining engineering and control engineering) and the Board has agreed to create a new professorship in the mechanical department.

McGill University's new engineering building is under construction.



Engineering building, McMaster University, is being built.

Facilities

In 1957 about 3,000 feet of additional laboratory space for the Department of Civil Engineering and two new classrooms were built. With this extra space it was possible to accommodate the increased enrolment.

The new building is under construction at the corner of Milton and University Streets, and the plan is for occupancy for the session of 1959-60. This will provide completely new quarters for the Department of Electrical Engineering and for the School of Architecture, as well as releasing space for expansion of other departments. It will make possible the implementation of programmes presently deferred for lack of space.

Outlook for the Future

In looking at the future, the considerable stature of McGill is associated with several favourable factors reported by Dean Mordell: the new building, the considerable salary increase in spite of financial difficulties, the hope of a solution to constitutional problems which prevent McGill from enjoying the support of the Canadian people. There are also the advantages of a larger enrolment and of the general awareness that the education of engineers and scientists is of national importance.

The plans envisage development of an active graduate school of larger proportionate size. There would be by 1965 an increase of student population to about 2500, distributed as follows: in ordinary courses, 1750; in honours courses, 500; in graduate course, 250.

First Year of Engineering Completed at McMaster

At McMaster University, Hamilton, Ont., the engineering students have completed their first academic year; the engineering building is under construction; the first staff members in the new engineering department have been appointed.

In September 1957, the first class of 48 students registered in the new course of Engineering Studies. These students will proceed in four-year courses leading to the degree of bachelor of engineering (B.Eng.) in chemical, electrical, mechanical and metallurgical engineering, and engineering physics. Registration in first year civil engineering will be accepted in 1959. The academic record of this first engineering year has been encouraging.

After a common first year, the course divides into two main branches—physical, and chemical engineering. The physical engineers pursue substantially the same curriculum through the third year, and specialization in all the engineering fields is developed in fourth year. The curriculum is being developed as a result of consideration of the following factors:

(I) The necessity of emphasis on fundamental science and mathematics;

(II) Opportunity for study in depth of humanities and social studies;

(III) The requirement that modern engineers be professional men capable of solving unfamiliar problems with imagination and judgment;

(IV) The considerable research activity in the physical sciences already well established on the McMaster campus.

As a result of these considerations, the curriculum has been planned with its primary objective the education of design and research engineers, and this same objective has governed the design of the new engineering building now under construction. The first year course in Engineering Studies is almost identical with Science Studies, except for the omission of English and the addition of graphic description and a mathematics laboratory. Either French, German, or Scientific Russian must be studied. In Second Year, English is a required subject, and one choice must be made from a list of six humanities and social studies. Laboratory time is available to all engineers for elementary design problems. This emphasis on original design is continued in third year, accompanied by intensification of Engineering Studies. In fourth year, each student is required to carry out an original engineering design or research project. A six-unit choice must be made in this year, too, from a list of electives in humanities and social

Progress on McMaster's Engineering Building, August, 1958.

studies. The time available for study in these latter disciplines amounts to about 19 per cent of total class time. Details of courses in the senior years will be worked out by the staff being assembled now.

The Engineering Building

Architectural design of the new building is by William R. Souter and Associates. The engineering consultant is O. M. Moffat, and C. C. Parker and Associates did the structural design. All branches of engineering will be accommodated in the three-story building, which has a total floor area of about 200,000 square feet and is located immediately south of the Physical Sciences Building, facing University Avenue. The "non-laboratory" services, such as offices, drawing rooms, lecture rooms, machine shops are in the central core, while the laboratories comprise the attached wings. This method has resulted in considerable economy in structure and laboratory services, as well as the isolation of fumes and noise. Consolidation of all of the engineering departments into a single building was considered desirable.

The main entrance to the building is by a covered terrace formed by the large lecture theatres which are supported on four circular columns. The lobby is paved with terrazzo. The central core of the building contains four draughting rooms (44 students each), six design-lecture rooms (35 students each), two standard lecture rooms (70 students each), two lecture theatres (200 and 300 students, respectively), machine shops, the professors' offices, and staff and student lounges.

The floor area of each of the chemical, electrical, mechanical and metallurgical engineering laboratory wings is 16,500 square feet. Since graduate and undergraduate work are stimulated by proximity, about 25 per cent of the total laboratory space is specifically allocated to research activities. All of the services are carried exposed on the columns or in the corridors; all fume-ducts are vertical to minimize corrosion; coloured concrete flooring is used in all laboratories, and the walls are painted concrete block.

In the chemical engineering laboratories, floor slots will accommodate equipment in the building up to 36 feet high, and a roof hatch will allow for very tall towers.

Provision has been made in the metallurgical engineering laboratories for a helium liquefier, nuclear magnetic resonance equipment, and a splendid photomicrography section. In addition to the machinery and electronics laboratories, a roof laboratory has been designed in electrical engineering for research on antenna design.

In mechanical engineering, there are to be laboratories for fluid mechanics, thermal power, heat transfer, and vibration studies.

The materials laboratories at the rear of the central core have 16 foot ceilings, a two-ton crane, and truck entries. All of the heavy testing equipment and concrete and asphalt fabrication will be located in these laboratories.

With the exception of the lecture theatres, which are faced with cut stone, the stonework on the building will be split-face Ashlar stone. Windows are continuous, and the wall sections between the horizontal window rows are panelled with coloured enamelled steel spandrels, edged with stainless steel.

W. H. Cooper Construction Company, Hamilton, is carrying out the construction on the basis of occupancy of the completed building on April 7, 1959.

Engineering Staff

By September 1959, the lecture and laboratory courses will be presented for the first time in third year, and the research laboratories will be available for graduate studies. The staff is prepared to cope with the stimulating and formidable task of purchasing and installing the necessary equipment. In addition to the original staff (Dr. Hodgins, Dr. Kirkaldy, Dr. Petch, Mr. Newcombe), four new appointments have been made: Dr. D. G. Huber as associate professor of mechanical engineering, Dr. A. S. Gladwin as associate professor of electrical engineering, Dr. T. W. Hoffman as assistant professor of chemical engineering, and Dr. G. Oravas as assistant professor of civil engineering. The complete academic staff will number about 30, for a total undergraduate student population of about 550.

Equipment

Laboratory equipment is to be purchased mainly from funds in the capital budget for the faculty of engineering. One major item, an electronic digital computer has already been bought, since there are research projects under way which now require this facility. The computer has many applications for the numerical solution of research problems in almost every phase of engineering. Other laboratory equipment is being acquired through the generous co-operation of philanthropic foundations, industry, and federal and provincial government grants. The one-megawatt nuclear reactor will be available for research work in the autumn of 1958.

First Year of Co-operative Engineering Studies Completed at Waterloo, Ont.

Early in April of this year, 71 students enrolled in Canada's first co-operative higher education course, completed Year One of their engineering studies at Waterloo College Associate Faculties. The following month an important Industrial Conference was held on the Waterloo campus, under the auspices of the Associate Faculties.

Attending the conference were more than 200 delegates, representing Canadian industry and the realm of industrial research. They met with top educators to learn about and discuss the philosophy and application of co-operative education in the field of engineering.

Co-operative education was introduced in Canada by the Associate Faculties at Waterloo in July, 1957. Under the Waterloo plan, student engineers spend alternate three-month terms on the campus and in industry. Teaching facilities are in operation 12 months of the year. One of the prime objectives of the co-op plan, the College officers explain, is to bridge the gap between academic theory and practical application so that students, upon graduation, possess a sound working knowledge of industrial processes, conditions and environments.

Said Dr. J. G. Hagey, president of Waterloo College and Associate Faculties: "The main difference between co-operative education and the traditional form is that the industrial assignments are a required part of the student's college course and that these assignments are controlled, guided and supervised by the College, in partnership with the companies committing themselves to the plan."

More than 100 Canadian companies

Industrial Conference at Waterloo College, May, 1958. The gentleman standing to ask a question is W. H. Evans, president of Honeywell Controls. Also prominent in the picture are Sir Robert Watson-Watt, and H. Barnett of Waterloo College.

participate in Waterloo's co-op education plan, the delegates were told. Ideally, two students are assigned to each job, so that while one student is pursuing academic studies his counterpart is working on a job, or "in-plant" assignment. At the end of each three-month term the positions are reversed. This arrangement gives participating companies the equivalent of one full-time employee.

The alternate academic and "in-plant" terms continue for six years (five years for Grade XIII matriculants) and lead to a B.Sc. degree in electrical, mechanical, civil or chemical engineering, or engineering physics. By the time the first class (July '57) graduates, in 1962, the Associate Faculties at Waterloo expects to have almost 3,000 students enrolled in engineering courses. This estimate is based on plans to admit a new class of 100 students every three months, or 400 per year. Already, the conference was informed, applications are exceeding enrolment limitations.

During open discussion Dr. Hagey was asked why Waterloo chose to establish co-operative engineering courses, rather than the traditional, or conventional, form of engineering.

"We were convinced," he replied, "that Waterloo, being in the stage of developing a new university, is in a preferred position to establish a co-operative course. Canada, not having previously had a co-operative college, did not develop a demand, even if there was a need for this type of education. Consequently, our established universities have not been under pressure to provide it. Waterloo, not having had an engineering course, found it just as easy to establish a co-operative course as it would have been to have established a traditional engineering course".

Dr. Hagey explained that while a degree-granting university charter is not actually required by the Associate Faculties until 1961, a "University Bill" for that purpose is being prepared, which would cause the Associate Faculties to emerge as the University of Waterloo.

Great importance has been attached to maintaining the high academic standards that exist in other professional engineering courses throughout Canada. The curriculum has been specially designed for this purpose. The teaching staff has been strengthened by highly qualified personnel and is attracting men of wide experience to this new venture in higher education.

The president emphasized that co-operative education is designed to supplement, not replace, the traditional forms of higher education. It makes university education available to qualified students who otherwise might not attend. It produces graduates who possess industrial experience along with their academic achievements. And it permits students to meet most, if not all, of their college expenses from their earnings in industry. In the case of Waterloo, it also takes higher education to a local area. "Our course is designed to produce better-than-average engineers, in quantity," Dr. Hagey stated.

Addressing the conference, Samuel Bronfman, President of Distillers Corporation Seagram Ltd., said, "To preserve our proper status in the world it is minimal that we keep pace with the advance of contemporary scientific and technical development. The path between the campus and the plant should be open and unhindered."

Sir Robert Watson-Watt, M.E.I.C., another conference speaker, called for the "utmost freedom of thought and action in scientific education." "Give universities and colleges much more money than you think they need and then, for Heaven's sake, leave them alone," was his recommendation to Canadian business and industry.

Estimated capital expenditures for buildings and equipment to develop the University of Waterloo during the next eight years is approximately $15 million.

As a voice of industry in co-operative education, Waterloo has an Industrial Advisory Council. Its function is to serve the specific needs of co-op engineering. It interprets industry's changing trends to the Faculty of Engineering and it helps keep the curriculum abreast of industrial developments and requirements.

St. Lawrence Seaway and Power Project

Progress by Ontario Hydro

With concrete placing in the Canadian half of the international power-house practically completed, and the power-house building ready for occupation, three generators were producing power at end of July. Some 2,100 persons were working on the Ontario Hydro half of the project at month-end.

Progress by NYSPA

With employment maintained at an average of 2,730 during July, placing of concrete in all structures had reached 97 per cent of the estimated total by month-end, while excavation had reached 91 per cent of the estimated total. Four units were generating power from the American half of the power-house at the end of July, with headpond level held at 4 ft. below maximum level.

At Long Sault dam the final stage of concrete placement was underway by early in July. Installation of the aluminum panels on the spillway gates continued, with work completed on five gates by month-end.

Channel improvements, exclusive of the tailrace were 98 per cent complete by month-end. A contract was awarded for channel improvement in the tailrace below the power-house and work had been started on construction buildings and cofferdams:

Thirty-seven miles of the Barnhart-Plattsburg transmission line were completed and the Plattsburg and Kent Falls substations were completed, with good progress being made on other transmission lines.

Progress by SLSDC

With the American navigation channel and Snell and Eisenhower locks in service since July 5, little remained to complete, and labour force was reduced by month-end to some 500 persons. Dredging of the south Cornwall Island channel was continued for fully 27 ft. depth.

On the new high level highway bridge opposite Cornwall, with decks completed on both approaches, cable stringing on the main span was completed, vertical cables hung and a start had been made on installing the steel for the main-span roadway.

Progress by SLSA

Excavation and clean-up operations on the overland channels are now in their final stages. On the St. Lambert lock, installation of gate machinery is complete except for electrical equipment and testing of pumps, etc. The last cofferdams holding water back from the river channel were removed in mid-July. At the Cote St. Catherine lock, gates are in place, with testing of gate machinery and clean-up proceeding.

On the Lower Beauharnois lock, with concrete all placed, only a small amount of dredging on the approach channel remains to complete. Installation continues on sector gates and on mitre gates and machinery. At the Upper Beauharnois Lock, with all concrete placed except for small sections of the upper approach walls, and with installation of gates and machinery under way, a suction dredge cleared the entrance channel upstream in mid-July. Test runs will be made in November on the four uncompleted Canadian locks.

Bids were called July 10 for a 3,600-ft. channel on north side of Cornwall Island to assure proper distribution of river flow around the island.

Other Seaway News

Lakehead cities moved a step closer in mid-July to getting their modern $4 million seaway-type harbour terminal, with second reading in the House of Commons to Bill C-26 incorporating the Lakehead Harbour Commissioners.

The long-awaited report on the impact of the Seaway on the Port of Montreal, prepared by the Montreal Research Council of McGill University during the past three years, was published July 27. Its findings: Montreal should gain substantially in grain, coal and iron ore traffic, with 50 per cent more grain handled by 1965 than in 1956; there would be little or no change in local petroleum traffic, probably a 35 per cent loss in general cargo handled; there was no particular stimulus for industrial location in the Montreal area, and thus little prospect of a major industrial boom.

Canadian Pipeline Projects

Westcoast Transmission:

The company's annual report March 31, 1958, reported a net income loss of some $2.8 million during the first six months start-up period. No trouble had been encountered with the pipeline even during the first spring thaw and rainy period in 1958, and compressor stations were working smoothly. By April 1958 both Inland Gas and B.C. Electric were on schedule in the attachment of customers, and B.C. Electric was proceeding with a $50 million installation program. By early fall, with completion of the 1958 gathering lines, construction over 80 per cent of the company's contracted gas reserves will be connected to the pipeline with an initial capacity to deliver 400 million cubic feet daily.

Alberta Gas Trunk Line Co.

Alberta Trunk's 1958 construction program of main line extensions and new laterals was almost completed at the end of July. The 144½ miles of 24 inch line from the Pincher Creek field to junction with Trans Canada at Princess was ditched out on July 27 and doping out completed by August 1.

Trans Canada Pipelines:

With over 1,300 miles of completed pipeline behind them, 12 construction spreads are at work between Port Arthur and Toronto with some 4,500 men. Their task is to lay 853 miles of 30 inch pipe from Lakehead to Maple, near Toronto, to bring Alberta gas to eastern cities. Total cost of 1958 construction will be about $165 million.

Five of the 12 contractors are working on the 367 miles of line from Port Arthur to Kapuskasing, being built by Northern Ontario Pipeline Crown Corporation, under supervision of Trans Canada. The other seven contractors are working on Trans Canada's 486-mile section from Kapuskasing to Toronto. There will be nine river crossings under separate contracts. Besides actual pipeline construction, six compressor stations will be built this year, five of them by Trans Canada and one by the Crown Corporation, with a total capacity of 48,500 hp. installed.

Canadian Western Natural Gas has begun construction on the new addition to gathering and transmission facilities, with some 140 men employed, to meet coming winter peak requirements. A 59-mile 16-inch lateral costing $2.8 million will be built from near Drumheller to supply the S.E. outskirts of Calgary. Overall expenditure on this lateral, the field gathering system, the Bow River Crossing and certain gas reserves will be $9.4 million.

Saskatchewan Power Corporation:

The S.P.C. reported at end of July that its 1958 construction program involving 47 miles of various sized pipelines, about half consisting of extensions to main lines and the balance laterals and distribution systems, at a total cost of $16 million, was nearing completion. Gathering systems at Hatton and Many Island Fields were completed. Main line from Moose Jaw to Regina was completed in June and the 124 mile extension to Steelman was welded out on July 20.

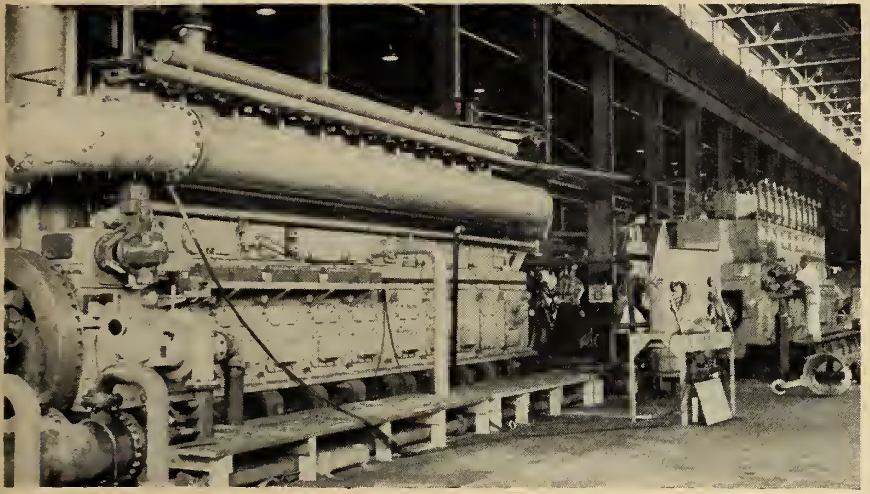
Union Gas Company:

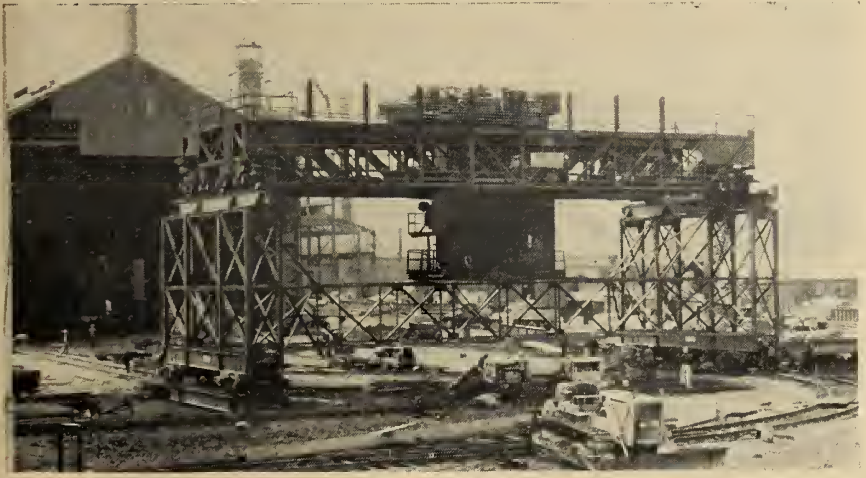
The Company's 1958 construction program consists of some 350 miles of main pipeline extensions, laterals and local distribution system footage. The work is divided about equally between new construction and extensions to existing systems. Largest single item is 45 miles of 8 inch line extending the main transmission system from Stratford to Goderich. Ten miles of 8-inch line will be laid to Amherstburg. Ten miles of 21-inch replacement line will also be laid for a new feeder between Galt and Brantford. Union will also extend the existing systems in Guelph, Waterloo and several other cities and towns and is considering adding 4,000 hp. to compressor facilities.

What Goes On

Some of the recent engineering developments are illustrated on these pages.

Right: Laboratory of the Ontario Water Resources Commission, being built at Etobicoke, Metropolitan Toronto, is designed for the future, with such equipment as an infra-red spectraphotometer for water analysis and other photometers for testing metals and gases. It is to be completed in 1959.





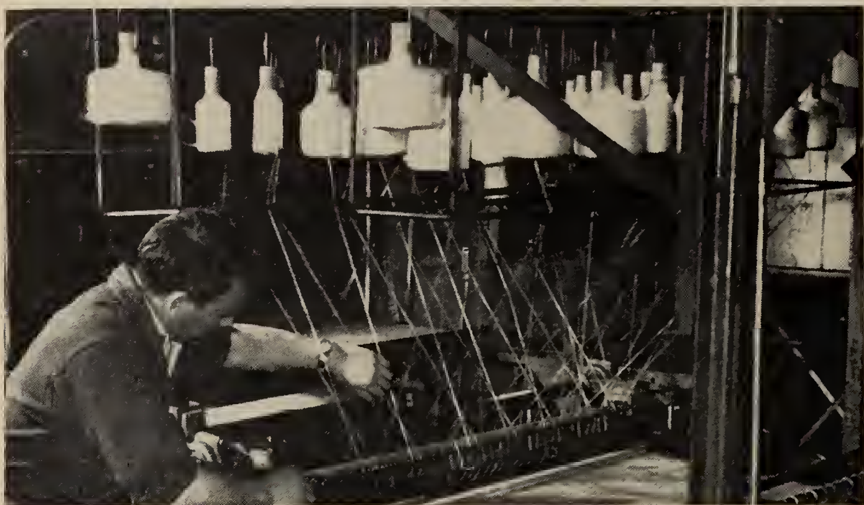
Top left. These 10-cylinder gas engines are being supplied by Dominion Engineering Company Ltd., to Trans Canada Pipeline to be installed in the first station at Burstall, Sask., and used to drive gas through the pipeline. Each engine is 30 ft. long, 12 ft. high, and weighs 120 tons, developing 3,500 hp. (at 330 r.p.m.).

Centre left. The task of moving a 360-ton stripper crane a distance of 380 feet, including a right angled turn, was accomplished by Dominion Bridge Company and Algoma Steel Company at the Algoma plant at Sault Ste. Marie, Ont. A special gantry-carrying bridge was designed and fabricated; tracks were laid between the old and new buildings, a turntable was built to carry the crane through 90 degrees, and the move was made in a down-time of 58 hours.

A vital part of the new Chute Murdock Willson power generating plant at the Ship Shaw river in Northern Quebec, is this 250-ft. high differential surge tank supplied by Horton Steel Works Limited. Price Brothers, in building this hydro power development provided an independent source of electric power.

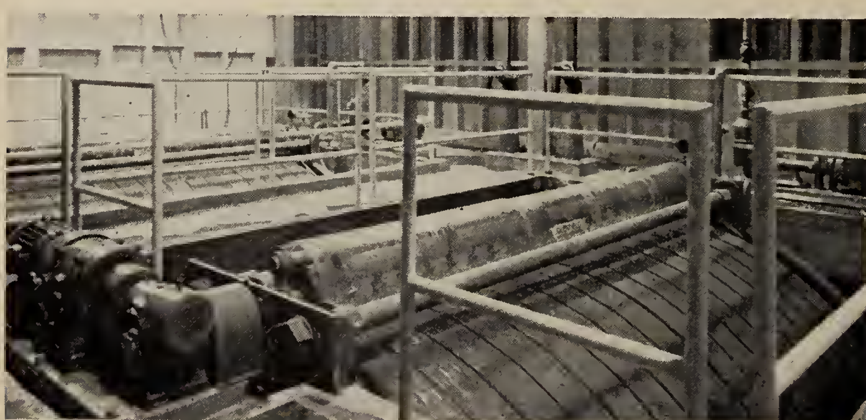
Close check is made on stator of the 12,500-kw. double extraction steam-turbo generator manufactured by Canadian Westinghouse for the Fraser Company, Edmundston, N.B.

A new bridge spans the Mattagami River at Smooth Rock Falls, Ont., designed and constructed for the Ontario Department of Highways by Foundation of Canada Engineering Corporation Ltd. The bridge forms part of the Trans Canada Highway.



Proximity to the Alberta oil and natural gas fields and the booming pipeline market, and to a readily available supply of the essential raw material, silica sands, at the Peace River sands, made possible the establishment of the Peace River Glass Company Ltd., Fort Saskatchewan, Alberta, for the manufacture of glass fibre. The operation pictured is the application of reinforcing yarn to glass fibre mat.

New headquarters of the Pulp and Paper Research Institute of Canada at Point Claire, Que., provides research facilities for approximately 200 persons.



Two micro-strainers supply 15,000 g.p.m. of filtered water to the bleach plant and machine room of the expanded chemical cellulose mill of Alaska Pine and Cellulose Limited at Port Alice, B.C.

What Goes On

New Canadian Aeroplane

The *Caribou,* the DHC-4 cargo-passenger utility type transport plane designed and built by The Dehavilland Aircraft of Canada Ltd., is scheduled to have its public unveiling this fall.

Featuring take-off and landing from limited space or improvised strips, and adaptable to military and civilian uses, the *Caribou* contains 7,000 pounds of Alcan aluminum sheet and extrusions. It will carry 28 fully equipped combat troops, will operate at a gross weight of 24,000 pounds. It has a 5,580-pound payload, over a 600-mile range, at 180 m.p.h. Using the short field technique, its take-off run is 490 feet. It will require only 770 feet to clear a 50-foot obstacle in zero wind conditions.

Length of *Caribou* 68.8 feet; height, 31.8 feet; wing span, 96 feet; capacity, gross volume, 1,000 cubic feet.

Increase in Steel Production

Dominion Foundries and Steel Ltd. has announced it will spend some $15 million on additional hot and cold rolling and finishing equipment at its Hamilton plant. The result will be an increase of flat rolling and finishing capacity by 250,000 tons.

Besides having the effect of increasing the concentration in Hamilton of Canada's steel production capacity to about 60 per cent, this will also increase the Canadian production of finished steel to more than 70 per cent of consumption.

(Abstracted from Daily Commercial News, Aug. 5, 1958)

"Buy Alberta" Program

A "Buy Alberta" program was approved in principle at a day-long conference of leaders of business, association and municipal administration in June. The conference was under the sponsorship of Department of Economic Affairs and the Department of Industries and Labour of the Alberta Government, and was supplemented by a display of some sixty Alberta-made products.

Road Spending, 1958

For the first time in Canadian history government expenditure on highways, roads, streets and bridges will top the $1 billion mark, says "Road and Wheel", bulletin of the Canadian Good Roads Association. The estimated total of $1,044.6 million, is for road construction, maintenance and administration. Provincial governments will be responsible for the expenditure of $669 million; municipal governments, $260 million; and federal government, $116 million.

Papers for E.I.C. Annual General and Professional Meeting, 1959

Members will be interested to know that Council has entrusted the Committee on Technical Operations (CTO) with responsibility for the preparation of the program of technical papers for the 1959 Annual General and Professional Meeting.

CTO and its Technical Divisions are responsible for the provision of leadership and the development of ideas in respect of the technical activities of the Institute. In practice, the activities of the Technical Divisions are carried out with the assistance of the Headquarters staff of the Institute which serves as the normal channel of communication for Institute business and provides the secretariat for each Technical Division, and for CTO.

The function of each Technical Division is to promote and to coordinate technical activities in its specific field and to organize its activities in such a way as to serve best that portion of the Institute membership whose work, activity and interest lie in the field covered by the scope of the Division. This is because one of the most important functions of the Institute is the dissemination of technical knowledge and experience to the membership and the advancement of the science and practice of engineering, as so well expressed in the Institute's motto:—

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

The membership of CTO, for the year 1958-9, consists of:—

C. E. Frost
Dean R. M. Hardy
A. R. Harrington
W. H. Patterson
D. L. Rigsby
E. R. Smallhorn
S. Sillitoe
B. G. Ballard—*Vice-Chairman*
F. L. Lawton—*Chairman*

The Chairmen of the six Divisions are:—

Chemical Engineering Division,
C. R. Whittemore
Civil Engineering Division,
E. R. Smallhorn
Electrical Engineering Division,
S. Sillitoe
Hydro-electric Engineering Division,
J. L. Feeney
Mechanical Engineering Division,
Prof. J. S. Campbell
Mining Engineering Division,
Prof. A. V. Corlett

Since the 1959 Annual General and Professional Meeting is being held in Toronto, the theme of the meeting is planned to bear a close relationship to the Seaway. The several Divisions of CTO have been actively planning their contributions to the program since the last meeting of CTO in May.

All members are invited to submit papers to CTO if they think the subject matter would constitute a worthwhile contribution to engineering literature. The Institute welcomes such contributions.

In order to properly plan for the necessary processing of papers submitted for Annual Meetings, CTO have adopted certain deadlines which authors are asked to observe. These deadlines are listed below.

The attention of authors is drawn to Institute standards for papers. These were printed in *The Engineering Journal* for January, 1957, on page 39, under the caption "Guide for Authors". Copies are available on request to Headquarters.

Members are reminded that the Division Chairmen of CTO will welcome suggestions for papers on subjects which fall within the scope of the individual Division. They will also welcome any constructive suggestions for future activities.

Deadlines for Annual Meeting Papers, 1959

Receipt of title of paper and name of author or authors	November 1, 1958
Receipt of abstract of paper	December 1, 1958
Receipt of manuscript	February 1, 1959

E.I.C. Annual Meeting
1959
Toronto, Royal York Hotel, June 8, 9, 10

Engineers Can Provide Direction

or

What Happened at the Birthday Party

by G. R. Henderson, M.E.I.C.
Manager, Sun Oil Company Limited, Sarnia, Ont.

Will the history books in 1999 accuse the engineers of losing the lukewarm wars of the current decade? If such an accusation should materialize—and we don't believe it will—the historian would undoubtedly record that the democracies had lost the race because of their inability to develop enough qualified engineers to solve the problem in time.

So the present educational system doesn't produce the necessary product, either quantitatively or qualitatively, and unless we neither listen to, nor believe what everyone seems to be currently talking about, we must realize that there is a shortage of trained personnel. Furthermore, industries are complaining about the calibre of the engineer who has been graduated from university after a rugged struggle through the last few years of high school and the four years of his overcrowded university curriculum.

Don't let anyone tell you that the present generation is any less sincere than their parents or their grandparents. Don't let anyone tell you that the teachers and professors are less dedicated than they were thirty years ago. Don't suggest that educators don't realize their problems, and don't believe that the boards of education are not trying to provide the necessary facilities for the ever increasing school population, while the irate taxpayer is moaning about the burden he is forced to carry.

Facts are obvious. The current graduates have lived through an era which has been more unstable than anything in history. Two wars and a constant fear of a third with a broadcasting system that delights in proclaiming the worst that could happen every hour on the hour. Together with this, the scientific progress of the last fifteen years has relegated certain physical phenomena to the obsolete files, and the present generation of graduates are expected to be able to express themselves as orators, write letters like Winston Churchill, and have a full understanding of business economics and the human relation problems involved in handling large numbers of organized workmen.

Let's face it! The youngsters of today are confronted with a much more difficult course than the grads of the twenties, and the overcrowding of secondary schools forces the teaching staff to concentrate on what they feel is their most important responsibility. The universities do not waste time on those who fall by the wayside. Talk to the young men currently in university—its a hard cold factual existence and there is no second chance.

The human race is not too different from those people about whom John Galsworthy wrote in his "Forsyte Saga". Their wants, their ambitions and their learning ability is about the same. Since that time, a few gifted individuals have changed the basic scientific concept and schools are forced to bring the curricula up to date so that the new crop of high school students will have an understanding of nuclear physics—and that isn't too simple. But when Galsworthy told his story of Soames and James and the sister who always was looking after a "lame duck", education was based on the three "R's".

Perhaps the meaning of the foregoing should be considered for a moment. In the Victorian era study was confined to the fundamentals, and the frills, including shop practice, household economics, and the various humanities were left for the development of the youngsters as they progressed into responsible life. Preceding generations depended on the apprenticeship system to teach the practical knowledge required by the specific individual and the products of these former ages were really not too bad. Newton and Watt, Shakespeare and Voltaire, Darwin and Freud, Pitt and Lincoln, Edison and Einstein are pretty good products of ancient schooling, and our own great names of the present do not seem to have suffered from the educational system even though one historian recorded that Winston Churchill didn't pass from Harrow, he climbed underneath it with the help of a tutor.

There isn't any doubt that North American schooling is based on mass education and the level of understanding of the average citizen has been immeasurably increased in the last few decades. But this doesn't necessarily produce "the greats" and the pressure system which has been developed is hard on Mr. Average North America. Consider again the educational levels—government adminstrators, boards of education, local directors, principals, teachers and students, are all under pressure trying to satisfy the demands of a public egged on by radio and television and magazines and newspapers, and our new adventurer in space "Sputnik" hasn't done anything to relieve the situation.

But enough of the problem—what is the cure—who is doing anything about it, and who is suggesting what can be done about it? The answer to the last question is probably the easiest and is answered by the simple word, "everybody". The critics and suggestors start with parents, progress through the service clubs and the boards of trade, and discussion ranges from the little groups in the home to the erudite debates of the senior governments. This discussion, however, should be cut short or the author will be criticized for trying to add "two bits worth" to the printed matter on the subject which there isn't time to read.

Common logic indicates that if the engineering education, which is necessary to produce the personnel required for national existence, is to be corrected, it should be corrected by the engineers. Who should know the problems as well? Who should be able to outline the requirements of the hungry industry and who knows better than this group the struggles and heartaches necessary to acquire the parchment which declares that the holder has been awarded the degree of bachelor of applied science or some other similar description.

There was a birthday party recently in one of the large New York hotels at which the head waiter carried in a huge cake decorated with twenty-five candles. He walked too rapidly and the candles went out, but a match repaired the damage and the party was a huge success. What did it celebrate? Oh you should have been told before. It was the twenty-fifth annual meeting of the Engineers' Council for Professional Development and the initials "ECPD" have been used to set up the title of this discussion. The birthday party was a combined meetwith the Engineers Joint Council and the presidents of all the national engineering societies graced the head table. It is suggested that their presence was a tangible expression of a unity of purpose and a desire to provide guidance and help to our future generations of young engineers.

This article is being written because of the lack of knowledge and understanding of the work and progress being made by the men who constitute ECPD and its hard working committees. No explanation could be as effective as the introduction of the 25th Annual Report of ECPD submitted by the president, M. D. Hooven.

"After twenty-five years of expanding operations of the Engineers' Council for Professional Development, no drum beating is needed to draw attention to the success it has achieved. More in order, perhaps, is an acknowledgement of the tremendous contributions that are made to ECPD, largely in voluntary individual services, but also in terms of money. ECPD is a federation of engineering societies, which does the specific job of sponsoring the intellectual development of the individual engineer. It carries this responsibility in the United States and Canada with the general support of all engineers and engineering societies although its formal organization encompasses only eight bodies".

"ECPD's most valuable help comes from the contribution of time and interest by individuals widely dispersed geographically and hundreds of engineers have contributed their time and thought. Because of this large voluntary effort, the general operating expenses are almost unbelievably low—".

Committee activities include the guidance given some two hundred thousand students during the last twelve months — 1800 schools were visited and amongst other activities, 2000 speakers were provided for interested groups.

Studies and conclusions have been presented concerning the development of the students and these encompass such current problems at "Attrition in the Engineering Schools". The report outlines the vital need for careful selection of students and the overall advisability of retaining the trained engineer on engineering work, so vital to our national existence.

However, no attempt is being made to duplicate the annual report and the foregoing illustrations only serve to outline the findings and recommendations of the men who have studied these problems throughout the length and breadth of the land.

Perhaps the outstanding work of ECPD is the accreditation of university curricula by teams organized into geographical districts so that universities who request recognition of their various curricula can be visited by qualified individuals. It isn't surprising that most of these teams are made up of men from the teaching profession, and many are deans of the science faculties. These men enthusiastically attempt to provide help and guidance for the institutions they visit.

All types of problems are discussed from the administration of the school to details of the curricula. Studies have been made by these groups in analysing all problems confronting the engineering schools, together with suggested curricula which tend to standardize at an optimum level the training given to undergrad students.

universities who request their accreditation. Nevertheless, this statement, taken at face value, indicates the recognition already given to the endless task, and the nation should be eternally grateful to the group of men who have given unstintingly of their time for the advancement of engineering education.

If the reader will be patient for a few more minutes, it would be well to outline the contribution made by a relatively small group, to the engineering educational conferences covering western Europe and North America. The organization is known as "EUSEC" and three sessions have been held during the past seven years. ECPD was requested to represent the North American engineering societies and their choice proved excellent. The report on engineering education in the United States, prepared by ECPD and submitted to the Paris Conference in September, 1957, has received widespread acclaim for its clarity and thoroughness.

It is almost a limitless task to appraise the difference of the educational systems in all the countries represented at the EUSEC conferences, but it is obvious that fundamentals of an engineering education are unaffected by international boundaries. The profession, the practicing engineers, and the world, all will benefit from a universal training of engineers and the subsequent common background to enhance the interchange of knowledge for the benefit of man's development.

But it is time to return to the birthday party, and no excuses are offered for the lapse into a record of achievement of which ECPD should be justifiably proud.

At a luncheon during the annual meeting, the guest speaker, an eminent educationist, outlined with convincing clarity, that the university he represented had already embarked on curricula which deleted practical instruction from the undergraduate years and taught as much mathematics and physics as possible during that time. He reviewed what he considered the fundamental requirements of the engineer and lucidly outlined the impossibility of digressing from this principle, because of the limitations of hours available during the four years of the undergraduate's life. At the same time, he outlined how much easier and more effective was

The author is one of the three representatives of The Engineering Institute of Canada on the Council of ECPD. The two other representatives are Dr. Otto Holden and Col. W. S. Wilson.

A recent article in the *Saturday Evening Post* describes the procedure of a recruiter for a major industry. This man is quoted as follows:

"Last year a mere 26,306 bachelor degrees were awarded by the nation's 213 engineering schools, of which only 153 had one or more of their curricula accredited by the all powerful Engineers' Council for Professional Development".

It is doubtful whether any of the accrediting teams would regard themselves as belonging to an all powerful group, and as stated before, it is with a spirit of co-operation that they visit the practical training which could be given to the new engineer when he entered specific engineering organizations.

Following the luncheon, four speakers representing widely diversified industries, outlined their procedures for training peculiar to their own industry, together with post-graduate education for recent graduates. One major industry employs graduates with the understanding that they will obtain additional academic credits equivalent to two full years of university standing. In this particular instance, adequate accommodation and resident professors from an accredited university, are provided at the plant. All tuition is paid by the company and the students are allowed approximately twenty per cent of their normal working week for attendance at the formal school classes. The other examples outlined during the afternoon, were variations of the same principle and all these industries provide time and money for post-graduate study. Furthermore, and most important, the men who are fortunate enough to be included in these programs were given full university post-graduate credits for all successfully completed work.

So much for the birthday party. The guests departed for their homes located in widely dispersed areas of the United States and Canada. Next year most of them will return and report what has been accomplished during their extracurricular activities, and who knows what their influence will produce during the next twenty-five years.

In retrospect, the birthday party indicates a trend, and one that is developing rapidly. It is impossible, and probably undesirable, to divorce engineering education from the general course of the secondary schools. This discussion has been specifically concerned with the undergraduate training of the engineer, but it is fully appreciated that the other professions and the very important study of the humanities are equally important to our progressive development. It is generally conceded that students who enter university for the purpose of studying any of these vocations have not acquired the training which the universities would like them to have and there is an indication that the essentials have been curtailed in an attempt to increase the breadth of education by the very desirable, but somewhat unnecessary, information which overloads the courses of study.

It seems to be impossible to make pseudo historians or writers of potential engineers, just as much as it is impossible to reverse the process. Members of the present generation entering university have a broad appreciation of the direction in which they are heading and that it would appear impossible to stop the development of the youngsters toward the vocation they set for themselves. At a recent luncheon speech, the speaker eloquently and forcefully presented a program of health education and requested a very few hours of the secondary school term for enlightenment on the important subject. The director of education for the municipality listened to the discussion with considerable interest, but as he walked out he remarked "Norman was convincing, but this is just another suggestion to work into a term already much too overcrowded".

Industry recognizes that when workers are under continuous pressure, the unit of production falls off. What then can be expected from our schools? A halt should be called to the "rat race" and the courses should be reduced to an essential minimum. Eliminate options in the academic courses and permit the students to take additional subjects, if they have the ability, and as a reward for academic proficiency—but clearly outline to the students and parents the requirements for university entrance when the child enters secondary school. Children of fourteen are really much too young to have any conception of what they would eventually like to do—and those few who have a burning desire don't require direction, so why worry them. These are the years which are much too short—when they should be keen about sports and parties with lots to eat, and movie stars and jazz singers — why try to make them decide their future forever and ever when they all know for certain that they are going to be presidents or prime ministers. Conclusion — teach the three "R's" adapted to 1957 but allow time and exhibit patience enough to make a good job of it.

It is suggested that the universities would welcome the students from a simplified standardized secondary school system and their responsibility for selection of students, and the training of undergrads would be immeasurably simplified. First year university to-day is almost a review of the last year of high school.

The most qualified persons to set up our educational standards are undoubtedly those who have been trained for the work. It is difficult to visualize anything more confusing or frustrating than to have home and school clubs or parents and teachers

(Continued on page 177)

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of Council on July 18, 1958.

Members: C. R. E. Allen, Montreal; D. F. Caveen, Rimouski; H. R. Edwards, Arvida; D. Eyres, Montreal; E. Godard, Montreal; J. T. Gregg, Toronto; K. Hailstone, Montreal; D. L. Harris, Montreal; J. M. H. Heines, Montreal; J. E. Hillier, St. John's; C. W. Hodgson, Toronto; G. A. Johnson, Toronto; H. P. Kerstens, Woodstock; W. Kitson, England; G. J. Lane, Baie Comeau; D. B. Nazzer, Toronto; P. S. Mani Sandaram, Halifax; J. M. Stevens, London; R. C. Warren, Toronto; F. E. Winter, Montreal.

Juniors: D. L. Anderson, Edmonton; R. W. Barker, Sault Ste. Marie; J. B. Couderc, Montreal; P. R. Hart, Port Hope; M. Marenghi, Arvida; R. R. Muirhead, Sudbury; N. R. G. Paget, Victoria; V. S. Pendakur, Port Hardy; A. J. Powell, Montreal; P. J. Pride, Shawinigan.

Affiliate: R. E. Fischer, New York.

Junior to Member: W. B. Arnold, Toronto; B. E. Babcock, Kingston; L. Bell, Winnipeg; R. M. Benjamin, Bathurst; N. S. Hepburn, Victoria; J. R. McWhinnie, Windsor; J. E. Ste. Marie, Montreal.

Student to Member: D. M. N. Smith, Scarborough.

STUDENTS ADMITTED

McGill University: R. S. Duquette; U. Thaung Sein.

University of Toronto: B. Wolchak.

St. Francis Xavier University: E. Lukan.

Loyola College: P. Tang.

A.P.E. Ontario Students: R. Colthoff; R. H. Patterson.

Graduates: J. F. Baird, B.Eng. (Elec.), N.S.T.C., 1958; O. Grieco, B.Eng. (Chem.), McGill University, 1958.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members: G. L. Colborne; G. E. Golden; J. C. S. Heathcote; R. L. Higgins.
Junior: B. A. Donnellan.
Junior to Member: I. D. Finnan.
Student to Junior: C. N. Ellert.

SASKATCHEWAN

Members: R. H. Clarke; E. J. Cuyler; G. M. Greenwood; G. M. Hasegawa; A. A. Janusz; B. Marosi; W. B. Reed; W. Stichling; B. S. Wheeler.

Students: R. S. Forrest; L. J. T. Pollock.

Junior to Member: F. K. Gerbrandt; T. P. Gilchrist; J. A. Haynes; H. G. Kindred; P. Kozicki; N. E. Parsons; G. A. Patterson; A. C. Schuster; W. J. Serne.

Student to Junior: A. M. Campbell; F. W. Fossey; D. A. Meneley; J. H. Peterson.

NOVA SCOTIA

Member: R. J. Richard.

MANITOBA

Member: W. H. Mitchell.
Junior to Member: W. J. Ducharme.

Professional Development Courses

sponsored by The Engineering Institute of Canada

are available at the following Branches:

HAMILTON BRANCH

The Professional Development Program, Hamilton Branch, will be a four-year co-ordinated program covering such non-technical subjects as Public Speaking, the Humanities, Law, Government, Financial Control, Business Management, and Human Relations. The initial years use the lecture and discussion method extensively, while the case study method is used in the more advanced years.

Registration night will be Wednesday, September 17, 1958, at 8.00 p.m. at the Royal Canadian Artillery Mess of the James Street Armouries. The fees for Groups 1, 2, and 3, are $12.00 for E.I.C. members, and $15.00 for non-members. Group 4 fees are $27.00 for E.I.C. members, and $30.00 for non-members. To obtain a brochure and registration card, interested people should attend registration night or contact J. A. Walsworth, at LI. 9-3095 or FU. 5-8902, Hamilton.

NIAGARA PENINSULA BRANCH

The Niagara Peninsula Branch presents a Professional Development Program as a four-year course designed to develop self-confidence and afford the participant an insight into the world of Human Relations and Modern Business Management.

Registration night will be Tuesday, September 23, 1958, at 8.00 p.m. at the Sir Adam Beck Power Station Assembly Hall, Queenston. Registration cards are being mailed out to all engineers in the area and will also be available on the evening of registration.

SARNIA BRANCH

The Sarnia Branch of the E.I.C. will sponsor a fall program consisting of an eight-week course based on Canadian Economy. Four lectures will be given by professors of the Department of Economics of the University of Western Ontario, and four lectures by representatives of industry and labour.

The first lecture will be held on Thursday, October 2, 1958, and the course will continue on succeeding Thursdays. Registration cards are being sent out to all local engineers and can also be obtained on the first evening of the lectures.

TORONTO BRANCH

The Professional Development Program for the Toronto Branch this year will be a four-year course, revised to provide increased participation and improved continuity from year to year. The program covers Personal Development, Business Environment, Social Environment, and Human Relations.

Registration night will be Tuesday, September 30, 1958, at 7.30 p.m. at the 48th Highlanders Hall, 519 Church Street, Toronto. Advance registration forms can be obtained and this is advisable as numbers are restricted. For information please contact, W. W. Walker, at HI. 4-6424, or the E.I.C. Office at HU. 7-0221.

The following Branches will also have Professional Development Programs and details are available by contacting the men listed below:

BROCKVILLE, ONT.: D. B. Ashenden, c/o Phillips Electric Co. Ltd., Brockville, Ont.

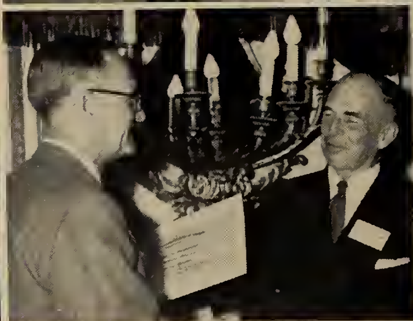
LONDON, ONT.: W. C. Simkins, c/o London Steel Construction Company, P.O. Box 69, 48 Burslem Street, London.

SAINT JOHN, N.B.: G. C. Robinson, P.O. Box 824, Saint John.

ST. MAURICE VALLEY, QUE.: J. O. Hachey, 53 Spruce St. (Apt. 13), Shawinigan Falls, Que.

SAGUENAY, QUE.: D. L. Aker, 309 Racine Street, Arvida, Que.

VANCOUVER, B.C.: T. H. White, 2461-51st Ave., Vancouver 14.



Awards of The Engineering Institute for 1957

Six honorary memberships were announced at the 1958 annual meeting of the Institute, and thirteen awards of medals and prizes, as listed in *The Engineering Journal*, June, 1958, Page 87. Awards were made at the annual meeting to those who could be present, and the presentations by President C. M. Anson are recorded here: *Above*: Newly created honorary members: Sir Claude Gibb, The late Dr. P. L. Pratley, Dr. I. R. Tait, and Dr. E. O. Turner. Photograph of Dr. Armand C. Crepeau, HON. M.E.I.C., was unfortunately not available for this issue. For photograph of Dr. L. Austin Wright, HON. M.E.I.C., please see June *Journal* Page 88.

In the right hand column: Julian C. Smith medal winners, R. E. Jamieson, and Dr. R. E. Heartz; and first winner of the Robert W. Angus Medal, R. J. Kennedy, as he receives the award from Robert W. Angus.

Left to right, Award winners: Robert David, G. G. Meyerhof, Dr. Martin Griffith (accepting for his father, R. G. Griffith), Wilfred Pegusch, E. O. Lilge, Dr. H. R. L. Streight, and C. M. Stewart.

E.I.C. Awards, 1958 (Continued)
Left to right: Award winners R. D. Neill, Gilles Gagnon and D. A. Chamberlain.

IAESTE 1958

This year for the first time since Canadian participation began, the number of IAESTE students coming to Canada has shown a decline from the previous year. It is believed that this has been due to two principal causes. First the general business recession now being felt in Canada and, second, the fact that several projects of national importance involving engineers have come to an end within a few months of each other, thus temporarily satisfying the immediate demand for engineering manpower. Events of this kind must be expected to have an adverse effect on summer employment for undergraduate engineering students.

On the other hand, it has been most encouraging to note that the number of Canadians participating in IAESTE who went abroad for summer training this year has doubled any previous year. The causes for this increase may of course be the same as those outlined above. Nevertheless the effect has been good so far as Canadian interest in the exchange plan is concerned. Inquiries by Canadian students reached a new high of about 50 odd applications, and this undoubtedly has been largely due to the splendid work done by many of our E.I.C. Faculty Advisers.

Referring to the actual figures for the 1958 exchange, we have provided places for 94 European students from 11 countries with us in Canada, and in the other direction 25 Canadians have accepted offers in 10 different countries of Europe. These figures may, of course, be subject to slight revision, due to a few possible additions late in the season. If the total participation in both directions is compared with the same total for last year, it can be noted that the overall drop for 1958 is only about 12%. Considering the factors affecting the operation of the plan this year this is not too discouraging.

Collection of funds to continue the Canadian IAESTE Travelling Bursaries was also difficult this year and one must assume the same basic reason again, that is, general business conditions. The result has been that the individual amounts granted have had to be drastically cut. With more Canadian students participating, and less money available, there was no alternative. This problem will have to be faced squarely by the Canadian Committee before we embark on another year's operation. At the same time it was felt that the Canadian students were extremely grateful for the assistance they did receive.

Earlier in the year, E. C. Luke of Institute Headquarters had the privilege of attending the IAESTE Annual Conference in Madrid, as secretary of the Canadian Committee. This was a profitable and instructive experience. Mr. Luke learned a great deal about the operation of the plan in Europe and met many of those other officials, for the first time, with whom he has been working for the past several years. Visitors to Canada this year were Mr. James Newby and Dr. H. V. Walters, both of the IAESTE Committee for Great Britain, of which Mr. Newby is still executive secretary. They spent several weeks in Canada during July visiting Montreal, Ottawa, Winnipeg, Edmonton, and Toronto on general IAESTE promotion.

As a final item of interest it has been noted that some important statements about IAESTE have come out of a report by a Working Party on Scientific and Technical Personnel under the Organization for European Economic Co-operation. This report, dated in Paris October 21st, 1957, states "The mission found the work done by IAESTE in organising the inter-change of technical students among various countries extremely valuable, and strongly recommends that O.E.E.C. support this work." It is hoped that Institute members, and other Canadian industrial leaders, will continue to feel the same way about it.

DID YOU KNOW THAT

The E.I.C. Library handled approximately 25 enquiries a day in 1957; and supplied more than 3,000 items to some 500 members.

Nuclear Congress, 1959

Canadians Invited to Present Papers in Nuclear Field

The fifth Nuclear Congress will be held in Cleveland, Ohio, April 5-10, 1959. The general theme of the congress will be "For Mankind's Progress".

The Congress will be made up of four major activities: (a) Nuclear Engineering and Science Conference, (b) Atomic Energy Management Conference, (c) Hot Laboratories and Equipment Conference, (d) Atomfair.

The Engineering Institute of Canada as a sponsoring society, is responsible for obtaining technical papers for the Congress.

Authors are invited to submit summaries (300-500 words) of proposed papers. October 1, 1958 is the deadline for receipt of summaries at E.I.C. Headquarters for transmission to the Congress Manager.

Authors will be notified in October of selection of papers for the program, and will be given specifications for the preparation of manuscripts, to be received by the E.I.C. by November 28.

Interested authors should send summaries to: Dr. Garnet T. Page, general secretary, The Engineering Institute of Canada, 2050 Mansfield St., Montreal 2, Que.

COMMITTEES

Admissions: Roger Brais, *chairman;* W. H. Gauvin, D. H. Hobbs, R. J. Harvey, D. G. Laplante.

Board of Examiners: J. L. deStein, *chairman;* J. M. Cape, J. Hurtubise.

Canadian Standards Association (Technical Council): *Institute Representative,* (to be appointed).

Finance: Albert Desehamps, *chairman;* J. M. Breen, R. L. Dunsmore, T. W. Eadie, R. A. Emerson, F. G. Ferrabee, O. M. Solandt, R. L. Weldon.

Canadian Chamber of Commerce: F. G. Rutley, *Institute Representative* on National Board of Direetors.

Legislation: R. B. Winsor, *chairman;* C. G. Kingsmill, D. C. MacCallum.

Library and House: C. E. Frost, *chairman;* W. D. Kirk, E. D. Gray-Donald, W. C. M. Luseumbe.

Membership: R. H. Self, *chairman.*

Publication: H. A. Mullins, *chairman.* (committee to be appointed).

Papers: J. H. Budden, *chairman;* R. Boueher, D. H. Hobbs, H. L. Johnston, M. McMurray, E. R. Smallhorn, H. S. Van Patter.

Prairie Water Problems: G. A. Gaherty, *chairman;* P. M. Sauder, *vice-chairman;* T. D. Stanley, *secretary;* C. S. Clendening, D. W. Hays, B. Russell, G. L. MacKenzie, H. J. McLean, J. M. Wardle.

Policy: Albert Deschamps, *chairman;* B. G. Ballard, R. L. Dunsmore, R. L. Hearn, R. E. Heartz, I. P. Macnab, D. M. Stephens, J. B. Stirling, W. G. Swan, I. R. Tait.

Professional Interests: E. B. Jubien, *chairman;* G. A. Gaherty, *vice-chairman;* W. E. Brown, G. J. Currie, W. G. Swan, H. L. Branchaud, E. K. Phillips, I. R. Tait.

Property: F. G. Rutley, *chairman;* A. Desehamps, V. B. King, C. N. Murray, R. C. Pybus, L. Austin Wright.

Student Policy: C. G. Southmayd, *chairman;* J. Dubue, R. E. Jamieson, E. J. Muszinski, A. Pakalnins, J. F. Riel.

Technical Operations: F. L. Lawton, *chairman;* B. G. Ballard, C. E. Frost, R. M. Hardy, A. R. Harrington, W. H. Paterson, D. L. Rigsby, S. Sillitoe, E. R. Smallhorn.

Confederation: I. R. Tait, *chairman;* L. J. Hammerschmid, *secretary;* C. M. Anson, H. W. L. Doane, T. Foulkes, H. T. Libby, J. McMillan, W. S. Wilson, L. Austin Wright.

OFFICERS OF THE BRANCHES

AMHERST
Chairman, J. W. Wilson; *Vice-Chair.,* D. J. Rockwell; *Executive,* F. C. Wightman, L. E. Burrill, R. G. Baxter.
Sec.-Treas., G. R. Pond, 7 Victoria Street West, Amherst, N.S.

BAIE COMEAU
Chairman, V. M. Wallingford; *Executive,* Peter Suttie, G. Scott, J. M. Pope; *Treasurer,* T. G. Rust.
Secretary, Norman Lapierre, P.O. Box 1073, Baie Comeau.

BELLEVILLE
Chairman, T. E. Flinn; *Vice-Chair.,* W. Benger; *Exec.,* V. L. Lewis, E. Hilbig, W. Canniff, N. Throop, D. Law.
Sec.-Treas., F. E. Moore, 71 Golfdale Blvd., Belleville, Ont.

BORDER CITIES
Chairman, C. Maurice Armstrong; *Vice-Chair.,* J. E. Dykeman; *Executive,* R. H. Darke, F. P. Mascarin, A. W. Malmberg; *Treasurer,* E. R. Carpenter.
Secretary, J. M. Reid, 1511 York Street, Windsor, Ont.

BROCKVILLE
Chairman, W. N. Simmons; *Vice-Chair.,* D. C. Turner; *Executive,* R. B. McRuer, W. E. Morden, F. E. Trewartha, K. R. Bullock, J. F. Preston.
Sec.-Treas., G. R. Bowes, 152 King Street East, Brockville, Ont.

CALGARY
Chairman, F. L. Perry; *Executive,* D. F. Kobylnyk, P. S. Grant, G. A. Hutton, T. Covello; *Treasurer,* R. G. Price.
Secretary, O. O. Junker, c/o Cumming Galbraith Ltd., 1510a - 1st St. S.W., Calgary, Alta.

CAPE BRETON
Chairman, J. V. Palmer; *Vice-Chair.,* W. L. Dodson; *Executive,* G. Ross, J. R. Wallace, H. Maitland, R. Bradley, P. Terry, J. Stevens; *Treasurer,* C. A. Campbell.
Secretary, H. M. Aspinall, P.O. Box 485, Sydney, N.S.

CENTRAL BRITISH COLUMBIA
Chairman, E. R. Gayfer; *Vice-Chair.,* P. Tassie; *Executive,* R. G. Harris, D. G. Hepburn, D. Wales.
Sec.-Treas., W. J. M. Owen, 634 Eckhardt Avenue West, Penticton, B.C.

CHALK RIVER
Chairman, C. A. Crawford; *Exec.,* J. G. Melvin, C. E. L. Hunt, J. S. Flavelle.
Sec.-Treas., W. O. Findlay, P.O. Box 339, Deep River, Ont.

CORNER BROOK
Chairman, E. J. Leja; *Vice-Chair.,* K. F. St. George; *Treasurer,* W. S. Read.
Secretary, Eric R. Skanes, c/o Bowater's Engineering Dept., Corner Brook, Nfld.

CORNWALL
Chairman, W. Rothwell; *Executive,* L. H. Snelgrove, J. Moriarty, J. Pescod, M. Broadbent, M. S. Thompson, F. J. Willis.
Sec.-Treas., D. W. C. McEwan, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.

EASTERN TOWNSHIPS
Hon. Chair., A. C. Crepeau; *Chairman,* R. D. Mawhood; *Vice-Chair.,* G. P. Cote; *Executive,* J. P. Champagne, J. E. Freeman, C. D. McKinney, E. T. Harbert, M. Lafreniere, G. B. Moffat; *Treasurer,* A. S. Mitchell.
Secretary, Jean Bourassa, 450 Belvedere St., S., Sherbrooke.

EDMONTON
Chairman, T. H. Newton; *Vice-Chair.,* S. R. Sinclair; *Executive,* I. G. Finlay, J. C. Moon, A. Sandilands, G. A. McNeill, H. Hole, R. H. Gardener, R. H. Nicolson, J. Longworth.
Sec.-Treas., G. Hodge, 10615 - 146th St., Edmonton, Alta.

FREDERICTON
Chairman, O. I. Logue; *Vice-Chair.,* William L. Barrett; *Executive,* L. W. Smith, M. P. Estey, R. C. Ballance, K. O. Bartlett, R. S. Shepherd, G. D. Reeleder.
Treasurer, E. C. Garland.
Secretary, Robert D. Neill, 150 Miles St., Fredericton, N.B.

HALIFAX
Chairman, J. D. Kline; *Vice-Chair.,* W. J. Phillips; *Executive,* J. G. Belliveau, G. M. Haliburton, A. H. MacKinnon, K. R. Mitchell, M. C. Sutherland-Brown, J. R. Cameron, L. D. Hopkins, B. E. Langley, R. B. Killam, M. A. Marshall.
Sec.-Treas., J. E. Reardon, Public Service Commission, Halifax, N.S.

HAMILTON
Chairman, R. C. Mitchell; *Vice-Chair.,* H. E. Seely; *Executive,* P. J. McNally, T. O. Watts, J. A. Mitchell, A. F. Barnard.
Sec.-Treas., W. A. H. Filer, 23 Maple Ave., Hamilton, Ont.

HURONIA
Chairman, H. C. Bates; *Vice-Chair.,* S. R. Walkinshaw; *Executive,* D. M. Harris, C. G. Campbell, J. L. Armstrong, J. E. Sears, J. W. Davies, R. G. Freeman.
Sec.-Treas., L. Morgante, 36 Borland Street West, Orillia, Ont.

KINGSTON
Chairman, R. B. Wotherspoon; *Vice-Chair.,* W. M. Campbell; *Executive,* D. C. MacPherson, F. M. Wood, R. J. Kennedy.
Secretary, D. I. Ourom, c/o Aluminum Company of Canada Ltd., Kingston, Ont.

KITCHENER
Chairman, C. A. Leicht; *Vice-Chair.,* W. J. Horner; *Executive,* R. Dahmer, W. Bobbie, G. Tidswell, H. Walters.
Sec.-Treas., A. H. Austin, Armco Drainage & Metal Products of Canada Ltd., Box 300, Guelph, Ont.

KOOTENAY
Chairman, J. T. Higgins; *Vice-Chair.,* D. J. Turland; *Executive,* R. F. Bailey, L. S. Piper, G. C. Rogers, E. Rohatynski, W. V. Nicholson, R. J. Portman; *Treasurer,* J. I. McClelland.
Secretary, J. L. P. Limbert, 649 Forrest Drive, Trail, B.C.

LAKEHEAD
Chairman, W. D. MacKinnon; *Vice-Chair.,* J. E. Rymes; *Executive,* G. A. Walker, J. A. Brown, L. B. Walker, J. W. Lukey, P. W. Pinn, W. H. Bulger, J. H. Hargrove.
Sec.-Treas., C. M. Cotton, 2-304 N. Syndicate Ave., Fort William, Ont.

LETHBRIDGE
Chairman, W. B. Thomson; *Executive,* G. B. Davies, R. L. Francis, J. A. Wilihan.
Sec.-Treas., R. D. Hall; Utility Engineer, City Engineer, Lethbridge, Alta.

LONDON
Chairman, R. W. McMeekin; *Vice-Chair.,* C. H. Osborne; *Executive,* G. W. Chorley, H. E. Martin, L. S. Lauchland, G. O. Hayman, G. E. Wilson.
Sec.-Treas., W. C. Sinkins, London Steel Construction Co. Ltd., P.O. Box 69, London, Ont.

LOWER ST. LAWRENCE
Chairman, Jean R. Menard; *Vice-Chair.,* M. Lanouette; *Executive,* T. Bernier, A. Leroux, G. Santerre.
Sec.-Treas., Donald F. Caveen, c/o Public Works Dept. of Canada, Federal Building, Rimouski, Que.

MONCTON
Chairman, C. L. Trenholm; *Vice-Chair.,* W. M. Steeves; *Executive,* F. F. Burchell, L. F. Clifton, D. A. Foster, H. S. McCleave, C. E. Spear, R. F. Weir.
Sec.-Treas., V. C. Blackett, 97 MacBeath Avenue, Moncton, N.B.

MONTREAL
Chairman, P. W. Gooch; *Vice-Chair.,* R. A. Phillips; *Executive,* R. J. Harvey, R. J. Kane, L. L'Allier, H. Audet, C. A. Colpitts, J. O. McCutcheon.
Sec.-Treas., G. M. Boissonneault, Shawinigan Water and Power Co., P.O. Box 6072, Room 809, Montreal, Que.

NEWFOUNDLAND
Chairman, C. W. Henry; *Vice-Chair.,* A. M. Butt; *Executive,* R. P. Hunt, D. S. Templeton, G. A. Myers, H. W. Goudie, S. Miller, J. P. Pike.
Sec.-Treas., R. L. Smyth, Imperial Oil Limited, Centre Building, St. John's, Nfld.

OFFICERS OF THE BRANCHES

NIAGARA PENINSULA

Chairman, D. A. Barnum; *Vice-Chair.*, D. O. D. Ramsdale; *Exec.*, R. T. Bailey, W. D. Tanner, H. S. Lundy, W. J. Smith, W. J. O'Reilly, F. R. Denham, G. E. Griffiths.
Sec.-Treas., Malcolm Stevenson, Box 196, Fonthill, Ont.

NIPISSING AND UPPER OTTAWA

Chairman, J. S. Cooper; *Vice-Chair.*, J. M. Rosborough; *Executive*, J. Warburton, H. Staniforth, R. S. MacLennan, D. Catford, P. Rebin, D. W. Briden.
Sec.-Treas., R. A. Booy, Box 1, Temiskaming, Que.

NORTH EASTERN ONTARIO

Chairman, A. A. Kidd; *Vice-Chair.*, J. S. Whyte; *Executive*, C. McIntyre, J. Blakeman, J. N. Greggain, J. Shipman, M. McLean, W. Swann, G. Flett.
Acting Secretary, A. A. Kidd, P.O. Box 640, Cochrane, Ont.

NORTHERN NEW BRUNSWICK

Chairman, D. C. MacCallum; *Vice-Chair.*, J. A. Mersereau; *Executive*, K. A. W. MacDonald, T. H. McSorley, P. Dallien, P. J. Delicaet, F. B. Ervine.
Sec.-Treas., S. K. Henry, P.O. Box 269, Dalhousie, N.B.

NORTH NOVA SCOTIA

Chairman, J. E. Clarke; *Vice-Chair.*, J. K. Godfrey; *Executive*, J. L. Cavanagh, Wm. Fogarty, F. C. Morrison, J. Ferguson.
Sec.-Treas., R. S. Morrow, 151 Almont Ave., New Glasgow, N.S.

NORTH SHORE LOWER ST. LAWRENCE

Chairman, B. M. Monaghan; *Executive*, R. W. Kenway, M. Michaud, M. Storrier.
Sec.-Treas., L. E. Fisher, Iron Ore Company of Canada, Dock Terminal, Sept-Iles, Que.

OTTAWA

Chairman, Hector Chaput; *Vice-Chair.*, John S. Watt; *Executive*, A. H. Graves, T. M. Patterson, R. C. Silver, H. A. MacKenzie; *Treasurer*, Hugh C. Brown.
Secretary, W. V. Morris, 2078 Knightsbridge Road, Ottawa, Ont.

PETERBOROUGH

Chairman, I. N. MacKay; *Executive*, J. L. Olsen, V. Aare, R. A. Blount, W. H. Powell, J. G. Cooper, C. W. Holman, D. J. Kawaja, P. Tuck, G. W. McPhee, E. R. Shirley.
Sec.-Treas., G. M. Locke, 1269A Clonsilla Ave., Peterborough, Ont.

PORT HOPE

Chairman, T. F. Kennedy; *Vice-Chair.*, J. A. Pollock; *Executive*, J. L. Sylvester, D. A. Runciman, T. S. Bradfield.
Sec.-Treas., R. Waterfall, 81 Hope Street North, Port Hope, Ont.

PRINCE EDWARD ISLAND

Chairman, C. W. Currie; *Vice-Chair.*, A. Coles; *Executive*, J. D. M. MacDonald, L. E. Slaght, A. D. Cameron.
Sec.-Treas., R. D. Donnelly, P.O. Box 184, Charlottetown, P.E.I.

QUEBEC

Life Honorary Chairman, A. R. Decary; *Chairman*, Roger Desjardins; *Vice-Chair.*, P. A. Duchastel; *Executive*, Lionel Boulet, J. B. Delage, Hugh Kane, P. E. Begin, L. Joncas, Jacques Roy.
Sec.-Treas., Marc Bergeron, Concrete Repairs and Waterproofing Co., 128 Blvd. Ste. Anne, Quebec, Que.

SAGUENAY

Chairman, F. A. Brown; *Vice-Chair.*, J. S. Taylor; *Executive*, G. C. Gauthier, L. Tessier, J. J. Falardeau, D. W. Stairs, R. Thompson, S. Solinski, A. Sinclair.
Sec.-Treas., D. L. Aker, 309 Racine St., Arvida, Que.

SAINT JOHN

Chairman, H. W. M. Townshend; *Vice-Chair.*, J. W. G. Scott; *Executive*, G. C. Robinson, P. W. Hastings, K. V. Cox, G. C. Mouland.
Sec.-Treas., D. I. Higgins, 30 Elizabeth Court, Saint John, N.B.

ST. MAURICE VALLEY

Chairman, J. P. Woods; *Vice-Chair.*, W. A. Pangborn, T. W. Ross; *Treasurer*, M. G. Fraser.
Secretary, J. Carson, 568-6th Ave., Grand'Mere, Que.

SARNIA

Chairman, J. H. Douglas; *Executive*, M. Waghorne, J. Miller, A. W. Wirth, C. M. Stewart, M. Brown.
Secretary, R. F. Routledge, c/o Imperial Oil Limited, Sarnia Refinery, Sarnia, Ont.

SASKATCHEWAN

Chairman, J. C. Traynor; *Vice-Chair.*, J. B. Mantle; *Executive*, E. J. Cole, J. D. A. Mollard, M. F. Pardoe, K. W. Allcock, M. B. Pierce, B. B. Torchinsky.
Sec.-Treas., R. Bing-Wo, 2043 Cameron St., Regina, Sask.

SAULT STE. MARIE

Chairman, R. H. Tooley; *Vice-Chair.*, L. F. Mason-Tulby; *Executive*, K. I. Fletcher, K. E. Kansikas, W. H. Hogg, W. B. Sproule.
Sec.-Treas., R. L. Wimperis, c/o General Delivery, Sault Ste. Marie, Ont.

SUDBURY

Chairman, W. B. Ibbotson; *Vice-Chair.*, E. M. Powell; *Executive*, H. W. Whittles, B. Russell.
Sec.-Treas., W. J. Ripley, 14 Miller Crescent, Lockerby, Ont.

TORONTO

Chairman, R. Harvey Self; *Vice-Chair.*, A. C. Davidson; *Executive*, L. F. Bresolin, A. M. Toye, G. F. R. Norton, R. R. McLaughlin, I. S. Patterson, R. A. Rule, B. L. Farrand, Cameron MacInnis, I. S. Gauley, M. H. Pryce.
Sec.-Treas., D. S. Moyer, c/o Canadian Radio Manufacturing Corp., 11-19 Brentcliffe Road, Leaside, Ont.

VANCOUVER

Chairman, W. G. Heslop; *Vice-Chair.*, C. P. Jones; *Executive*, C. H. White, J. F. Muir, E. S. Rhodes, W. J. Johnson, J. H. Swerdfeger, J. J. Kaller; *Treasurer*, R. H. Carswell.
Secretary, Ronald Clough, 1232 Dogwood Crescent, North Vancouver, B.C.

VANCOUVER ISLAND

Chairman, G. Griffiths; *Vice-Chair.*, H. Graham; *Executive*, H. T. Miard, L. C. Johnson, W. G. McIntosh, A. F. Paget.

WINNIPEG

Chairman, L. A. Bateman; *Vice-Chair.*, W. L. Wardrop; *Executive*, R. N. Sharpe, R. T. Harland, W. D. Hurst, T. E. Storey, J. P. C. McMath, N. Mudry, J. B. Striowski, N. S. Bubbis, N. M. Hall, H. A. Dalkie, L. E. Poyser, S. H. Eggertson, R. Barschel.
Sec.-Treas., C. S. Landon, Room 418–265 Portage Ave., Winnipeg 2, Man.

YUKON

Chairman, Lt.-Col. D. M. C. Saunders; *Treas.*, J. Scott.
Secretary, E. W. King, P.O. Box 1189, Whitehorse, Y.T.

ONTARIO DIVISION

Chairman, M. A. Montgomery; *Vice-Chair.*, H. R. Sills; *Treasurer*, G. R. Turner; *Board of Management*, P. E. Buss, H. G. Conn, E. R. Davis.
Secretary, J. G. Hall, 92 Heddington Ave., Toronto, Ont.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

T. A. McGinnis, M.E.I.C., of Kingston, Ont., president of McGinnis and O'Connor, contracting engineers, died at Kingston, on June 18, 1958.

Thomas Alexander McGinnis was born in the Ontario town of Belleville, on April 9, 1887. He attended Queen's University and attained a B.Sc. degree in 1909. Some of his first engineering experience was gained with the Canada Cement Company Limited and the Missisquoi Marbles Limited. In 1918 he became the senior partner in the firm of McGinnis and Connor. He carried out highway construction for the Province of Ontario.

He retained his close connections with Queen's University throughout his career and was in 1955 awarded an Ll.D. from that institution. He was a member of the board of trustees of Queen's and the Queen's University Council. He was also chairman of the university's building committee and was one of the leading figures in postwar construction at the institution.

He also served as superintendent of construction for Lehigh Portland Cement Company, (Canada), and construction engineer for Canada Cement Company until he finally formed his own firm.

Mr. McGinnis joined the Institute as a Student Member in 1908, transferred to Associate Member in 1912 and to Member in 1923. He attained Life Membership in 1947.

P. C. Kirkpatrick, M.E.I.C., of Montreal, died at his home at Baie d'Urfee, Que., on June 30, 1958.

Paul Chester Kirkpatrick was born at Parrsboro, N.S., on November 13, 1889. He attained a B.Sc. degree in civil engineering from McGill University in 1916. His long and varied engineering career began with the Dominion Bridge Company Limited, Montreal, shortly after his graduation, with the post of assistant metallurgist. The following year he worked with Fraser Brace and Company Limited. The association continued for a great many years. Mr. Kirkpatrick was involved in the building of a number of major projects including the building of the Gouin Dam, St. Maurice River, Que., the Great Falls Power House on the Winnipeg River, the Island Falls Power House, Abitibi River, the Deer Lake Power House, Nfld., the Abitibi Canyon Development, and the extension to the International Nickel refinery at Port Colborne.

During World War II Mr. Kirkpatrick was resident engineer for H. G. Acres and Company, consulting engineers of Niagara, on the Shipshaw power project. In 1947 he was sent by that firm to South Island, New Zealand, to explore a site for producing power.

Within the last few years Mr. Kirkpatrick had been involved in projects for the Quebec Iron and Titanium Corporation, the Dufresne Construction Company, The St. Lawrence Seaway Power development, Cornwall, Ont., and the Campbell River, B.C., power development for the firm of H. G. Acres.

Mr. Kirkpatrick joined the Engineering Institute as a Student in 1915, became an Associate Member in 1919 and a Member in 1940. He attained Life Membership in 1954.

H. O. Keay, M.E.I.C.

H. O. Keay, M.E.I.C., retired manager of the research laboratory, Consolidated Paper Corporation Ltd., Three Rivers, Que., who died at Sudbury, Ont., on May 14, 1958.

An obituary item appeared in the July issue of the *Journal*.

Robert James Gibb, M.E.I.C., retired official of the City of Edmonton, died in that city on May 14, 1958.

Born at Kinross, Scotland, on May 1, 1897, he attended the George Watson's College and the Herriot Watt Technical College at Edinburgh. In 1895 he began a four-year apprenticeship in Edinburgh with a civil engineer. At the end of that time he took over the post of resident engineer on dock work with trustees of the Clyde Navigation, Glasgow, Scotland. Named agent and engineer for the J. Urquhart Contracting Company at Uddington, Scotland in 1902, he was resident engineer and assistant engineer in the bridge construction, for the Grand Trunk Pacific Railway. Moving to Canada he assumed charge of work in the sewer and water department at Edmonton, in 1913 under the city engineer. He was named assistant city engineer in 1915. This was followed by the appointment of city engineer and superintendent of waterworks. In 1936 Mr. Gibb became third city commissioner of that city, having charge of public works and civic utilities.

A Life Member of the Institute Mr. Gibb joined the E.I.C. as an Associate Member in 1910, and transferred to Member in 1914.

Major H. E. Maple, V.D., M.B.E., M.E.I.C., retired military engineer, of Ottawa, died in that city a number of months ago.

Harold Ernest Maple was born at Brighton, England, on July 3, 1883. He attended the School of Science and Art at Brighton, later followed a three-year course in architecture, and devoted two years to the study of military engineering and surveying, at Chatham, England. He moved to Canada in 1903 to accept the post of assistant instructor, survey and military engineering, at the Royal Military College, Kingston, Ont. Three years later he began work on a militia survey, 1906 to 1911. During World War I he was engaged in the general construction of a number of armouries across Canada. He continued at the same time to carry out instructional duties in military engineering. Later he became a superintending engineer with the Department of National Defence, Ottawa.

Most recently he held the post of chief engineer, Q.M.G. Branch, Army, Dominion Government, Ottawa.

Major Maple was an Associate Member in 1917, transferred to Member in 1940, and attained Life Membership in 1954.

G. E. Templeman, M.E.I.C., of Montreal, chief engineer for the City of Montreal, electrical commission, died in that city on May 30, 1958.

George Earl Templeman was born at Waubaushene, Ont., on June 26, 1879. He attended the School of Practical Science, Toronto in 1896-1897. He was engaged in construction work with Allis Chalmers Bullock, and with the firm of Dietrich Ltd., early in his career. In 1915 he joined the City of Montreal, electrical commission. Two years later he was named to the post of chief engineer in the organization. On his retirement in 1954 Mr. Templeman was made a member of the Commission.

For eighteen years he was a member of the City Council, Montreal West.

Mr. Templeman joined the Engineering Institute as an Associate Member in 1919, and transferred to Member in 1927. He attained Life Membership in 1950.

Major H. B. MacConnell, M.E.I.C., retired engineer, of the Barnett-McQueen Construction Company, Fort William, Ont., died in that city on July 2, 1958.

Howard Bruce MacConnell was born at Springbrook, Ont., on August 14, 1886. He attended Albert College, Belleville, Ont., and obtained engineering qualifications through studies with the International Correspondence Schools, and the Chicago Millwork Bureau. Beginning his career in 1908 he worked for the first few years on railway construction in Eastern Canada. During World War I he served with the Canadian Army. A millwork estimator at Detroit from 1923 to 1927, he became a certified millwork estimator in 1924. For a great many years Major McConnell conducted a private contracting business throughout Ontario. At the end of the depression era of the 1930's he became associated with the firm of Barnett-McQueen Construction Company in 1938, and was a member of the engineering staff for a period of twenty years, until his retirement at the close of 1957. For the past few months Major MacConnell had been associated with the firm of Mickelson, Fraser and Haywood, engineers and architects, Fort William, as a field inspector. Major MacConnell joined the Engineering Institute as a Member in 1923.

H. W. Furlong, M.E.I.C., of Wollaston, Mass., retired structural and consulting engineer with Stone and Webster, Inc., Boston, died there on May 30, 1958.

Henry Walter Furlong was born on June 16, 1888, at Guildford, Eng., and attended the University of London, where he acquired a B.Sc. degree in 1908. That year he became associated with the firm of Mssrs. G. H. Williams and Son, sewerage engineer, London.

Transferring his engineering skills to Canada in 1909 he went to work for the Toronto firm of Unwin, Murphy and Esten, surveyors. From 1909 to 1915 he was associated with the Dominion Bridge Company Limited, Montreal, in various posts. In 1915 he joined the Canadian Government Railways, now the Canadian National Railways, at Moncton, N.B., and continued in this work until 1920. He became an assisant engineer with Stone and Webster Inc., industrial engineers, at Boston, in 1920.

In 1934, he was briefly with the staff of Sir Alexander Gibb and Partners, London, Eng., but returned to the staff of the Stone and Webster Engineering Corporation the following year.

He continued to serve Stone and Webster Inc., until his retirement in 1953.

Mr. Furlong joined the E.I.C. as an Associate Member in 1924, and became a Member in 1940.

Axel L. Oddleifsson, M.E.I.C., of Winnipeg, died in that city on May 28, 1958.

A native of Winnipeg, Mr. Oddleifsson was a graduate of the University of Manitoba, where he attained a degree in electrical engineering in 1931. His early experience included service as a junior engineer with the Winnipeg Electric Company on the Seven Sisters Falls, and as electrical engineer with the Manitoba hydro-electric board. Later he was superintendent of the Pine Falls generating plant; in 1953 he was named assistant to the manager of the operating division of the Winnipeg Electric Company.

Mr Oddleifsson joined the Engineering Institute as a Student Member in 1929. He transferred to Junior in 1936 and became a full Member in 1943.

Franz Joseph Marie Raskin, M.E.I.C., of Montreal, founder and president of the firm of F. J. Raskin Incorporated, combustion equipment manufacturers and power plant specialties, Montreal, died at Montreal on November 29, 1957.

Born at Modave, Belgium, on April 14, 1900, Mr. Raskin received his general education in that country and moved to Canada in the early days of World War I. His first work was that of apprentice in the Montreal shops of the Grand Trunk Railway. He was employed in the munitions field in World War I. In 1918 he accepted work with the Abitibi Pulp and Paper Company research department, Iroquois Falls, Ontario. In 1919 he enrolled at McGill University, faculty of applied science, and continued throughout the second year. Obliged to pursue his studies as well as earn a living during the next few years, he was associated with the Canadian Pacific Railway, design department, at Montreal, and the Lake St. John Power and Paper Company in 1926. He became a designer and estimator for heavy mechanical equipment in 1928. Later he was associated with the consulting engineering firm of Messrs. Wilson and Jas. A. Kearns. In 1932 he acquired the legal qualifications to enable him to practice engineering.

F. J. Raskin, M.E.I.C.

The present firm of F. J. Raskin Incorporated was founded in 1932.

Mr. Raskin joined the E.I.C. in 1945 as a Member.

Edwin G. P. Lang, M.E.I.C., of Montreal, died on June 23, 1958.

Born in England, at Winbledon, on March 5, 1896, Edwin George Power Lang attended the Royal Military College at Sandhurst, England, the Croydon Polytechnic, London, and the Stanley Technical, London, and undertook university courses in highway and municipal engineering and economic geology. In 1924 Mr. Lang accepted a post with the C.N.R. as an instrumentman at Montreal, and during the next ten years gained experience also with the Shawinigan Engineering Company, Montreal, and the Canadian Car and Foundry Company. In 1935 and 1936 he was engaged in private geological investigations. This resulted in the post of geological investigator with the Canada Cement Company, Montreal, and Toronto. In 1940 he became senior assistant engineer with the Department of National Defence. Throughout the war, from 1941 to 1945 he served as a works officer in the capacity of a flight lieutenant, D.N.D., for Air, at Montreal and Moncton. At war's end he transferred his services to the Canadian Pacific Railway, Montreal, as construction engineer. Later he was associated with the Hydro Electric Power Commission of Ontario on tunnel development. In 1948 he was associated with the Aluminum Company of Canada Limited, Montreal.

Mr. Lang joined the Engineering Institute as a Member in 1947.

Michael Sylvester Kennedy, M.E.I.C., of the Department of Highways, construction branch, Victoria, B.C. died at Victoria, recently.

Mr. Kennedy was born at Quyon, Que., on January 24, 1896. He attended high school in Ontario. His engineering career began in Saskatchewan where he was associated with the provincial government as rodman, instrumentman and resident engineer with the department of highways from 1921 to 1935. From that time until 1948 he served as district engineer for the department. Transferring his services to Alberta, in 1949, he became project engineer, for the Eastern Rockies Forest Conservation Board. Two years later he moved to the Department of Public Works, highway division, at St. John's, Nfld. In 1952 he assumed the post of resident engineer, with the Province of British Columbia, construction branch, Department of Public Works, at Victoria.

Mr. Kennedy joined the Institute as a Member in 1949.

R. A. W. Bond, JR.E.I.C., of the firm of H. G. Acres and Company Limited, died in an accident at work a number of months ago.

Raymond Arthur William Bond was born on July 3, 1922. He studied engineering at London, England, and graduated with a B.Sc. degree in engineering in 1949. Moving to Canada at that time he accepted employment with the Foundation Company of Canada Limited. The following year he was associated with the firm of Sproston's (Jamaica) Ltd., Jamaica, B.W.I. In the years which followed he was associated with the Montreal Engineering Company at Chicoutimi, the Canadian International Paper Company at Hawkesbury, Ont. At the time of his death he was engaged in area engineering for the powerhouse at the Chute-des-Passes hydro-electric project of the Aluminum Company of Canada Limited.

Mr. Bond joined the Engineering Institute as a Junior Member in 1950.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

MANITOBA

(Taken from the Manitoba Professional Engineer, June issue, and written by L. A. Bateman, P.Eng.)

The President's Message

"Your Association is continuing to enjoy a healthy growth as more of the eligible engineers are being registered. The work of Council never seems to decrease despite the increased number of committees that have been appointed this year. I would like to review the work of some of these.

Our public relations committee has been most active, theirs is a continuing job of attempting to improve the status of the professional engineer in the community. They also have several projects underway, of which we shall hear more later.

The chairmanship of the night university committee was turned over to your past president, who has been doing a good job. A council, along with this committee, had a meeting with the University Senate to explore the problems of establishing credited night courses in engineering. This will be reported on more fully later.

The sports committee, under the chairmanship of Harry Benditt, had a very good turnout to the spring golf tournament and you will read of this elsewhere on these pages. It is hoped that the fall meet can break the record again.

The advisory committee has been reconstituted under the chairmanship of Mr. M. A. Roche and has been assigned the important task of investigating permanent quarters for your Association. We would like to know what you think about this problem and whether you are in favor of establishing permanent quarters, and any suggestions you might have on how such a program would be financed.

The writer and Mr. Bubbis attended the annual meeting of Canadian Council in Vancouver. Mr. Bubbis was again elected an executive member of Canadian Council. Next year, on invitation from your Council, the Canadian Council meeting will be held in Winnipeg, the dates have not been settled as yet. This will provide an opportunity for Winnipeg engineers to sit in on some of the deliberations and learn of the very important work that is being done on a Dominion basis for our profession. The last meeting of Canadian Council held in Winnipeg was in May, 1950, and many will recall our excess moisture at that time. The meeting was postponed until the fall of that year.

This year following the pattern that was inaugurated last year of visiting some of the outlying areas where professional engineers are located, who have difficulty in attending our Annual Meeting, Council is planning a visit to Camp Shilo, Brandon and Virden, Man. Just as in the case of Council's visit to Flin Flon last year, it is hoped that a down-to-earth meeting can be held with groups in the areas referred to, in order that the work of Council on behalf of the members can be reviewed. It is hoped that non-registered engineers in areas referred to can attend these meetings."

BRITISH COLUMBIA

(Taken from the B.C. Professional Engineer, July issue.)

Nominating Committee Elected

This spring members of the Association elected a Nominating Committee for the Association. This Committee is charged with the responsibility of providing a slate of nominees for election to the 1959 Council of the Association. It is composed of the following members: civil: T. V. Berry, H. R. Wooster; electrical: L. B. Stacey, M. A. Thomas; mechanical: P. N. Bland, W. O. Richmond; mining, geological and metallurgical: D. F. Kidd, A. D. Turnbull, chemical: C. A. Moore; forest: W. Hall; structural: R. A. McLachlan.

The committee was elected from candidates nominated at the 1957 Annual Meeting, and it will meet for the first time between the dates of September tenth and seventeenth as provided for in the By-laws of the Association. In the event that a group of members wishes to nominate someone for Council in addition to those nominated by the Committee, provision is made in the by-laws for the committee's nominees to be published during the month of October, and for nomination to be made in writing by twenty-five or more members not later than November 1st.

If any members have nominees to suggest to the Committee, the members of the Committee would appreciate being contacted before September tenth.

Gold Medal Award

At the meeting of Council on June 18, President G. C. Lipsey, P.Eng., presented the Association Gold Medal, awarded annually to the graduating student at the University of B.C. with the best record in four years of applied science to T. A. Nordstrom, a 1958 graduate in electrical engineering. Normally this presentation is made at the annual meeting, but as Mr. Nordstrom is leaving for England in August on an Athlone Fellowship, it was made at this time.

ONTARIO

Engineers in the News

J. David V. Adams, P.ENG., has accepted a position as engineering co-ordinator with Cockshutt Farm Equipment Co. Ltd., in Brantford, Ont. He recently obtained master's degree in business administration at the University of Western Ontario, London, Ont.

Dr. Franc R. Joubin, P.ENG., Toronto consulting geologist, and **Donald H. James**, P.ENG., of his staff, have returned to Canada following the completion of a study of the uranium resources in Sweden for Swedish clients. They report that the Swedish people are making considerable progress towards producing their own domestic requirements of uranium oxide.

Major J. H. Gillett, P.ENG., of the Canaadian Army has completed the U.S. Army Command and General Staff Course at Leavenworth, Kansas, and has resumed work allied with communications engineering as production expeditor and co-ordinator at NATO headquarters in Paris, France.

Ernest C. Shirazee, P.ENG., is with Avro Aircraft Ltd., Malton, Ont., in the capacity of a service engineer. He was formerly employed by the Minnesota Mining and Manufacturing Co. of Canada Ltd., in London, Ont.

Arthur A. Webster, P.ENG., who is employed with the Public Works of Ceylon, Columbo, Ceylon, has returned to Kingston, Ont., for a period of home leave. He expects to return to Ceylon in November.

T. D. Martin, P.ENG., formerly of Burlington, Ont., is now employed as mechanical engineer on the design and development of vending machines with Ideal Venders Ltd., Desoronto, Ont. This company is a subsidiary of Eddy Match.

Personals

News of the Personal Activities of Members of the Institute

J. Lefort, M.E.I.C., (B.Eng., McGill, 1936; B.C.L., McGill, 1938), has been appointed managing director of Warnock Hersey Management Consultants Ltd., at Montreal. Active in this field for many years, Mr. Lefort was in recent times associated with the Ford Motor Company of Canada Ltd., on special products in the office of the executive vice-president, and was manager of the dealer planning department at central staff.

Philip B. French, M.E.I.C., (B.Eng., mech., McGill, 1934), for many years a well-known figure in the anti-friction bearing field, has resigned from a vice-presidency of Lyman Tube & Bearings Limited to form his own Company. Mr. French has devoted his entire professional life to work in the bearing field. He will concentrate on the application and distribution of highly specialized precision bearings designed to meet today's complex needs.

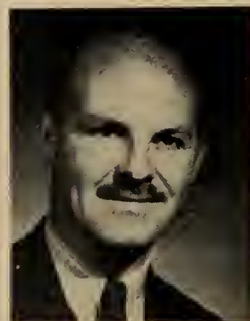
Incorporation arrangements for his new organization are now in hand for the opening of offices in Montreal and Toronto.

J. Morgan, M.E.I.C., (Loughborough, 1944), has been appointed a division engineer with the Foundation Company of Quebec Limited. Mr. Morgan joined Foundation in 1952, was transferred to Geocon Limited in 1954, and became chief engineer the following year. In 1957 he was named vice-president of that organization, and gained a directorship in 1958.

Ottis I. Logue, M.E.I.C., (B.Sc., civil, New Brunswick, 1946; M.Sc., civil, New Brunswick, 1954), 1957-1958 chairman of the Fredericton Branch of the E.I.C., is a consulting engineer with the Fredericton firm of Associated Designers and Inspectors.

Active in the affairs of the E.I.C., for some time, Mr. Logue was secretary of the Fredericton Branch, 1954 to 1956, and vice-chairman for the 1956-1957 term of office.

H. F. Morrow, M.E.I.C.



Philip B. French, M.E.I.C.

A. M. Stevens, M.E.I.C.

W. L. Hetherington, M.E.I.C., (B.A.Sc., elec., British Columbia, 1939), has, following the merger of the Ferranti Electric Limited and the Packard Electric Company Limited, been named to the executive post of vice-president and general manager, marketing division, Toronto.

Harold Francis Morrow, M.E.I.C., (B.Sc., geology, Sask, 1937; M.A., Queen's; Ph.D., McGill), a consulting geologist with Low and Morrow has transferred from the Western Canadian office at Regina to Victoria, B.C.

A. M. Stevens, M.E.I.C., (B.Sc., civil, New Brunswick, 1947; M.Sc., civil, New Brunswick, 1957), associate professor of civil engineering, University of New Brunswick has been awarded the Canadian Salt Good Roads Scholarship according to an announcement of the award of six scholarships to Canadian engineers by the Canadian Good Roads Association. Mr. Stevens is also a partner in the consulting engineering firm of Associated Designers and Inspectors.

H. C. Lawton, Affiliate, M.E.I.C., electrical contractor of Saint John, N.B., has announced that his business is henceforth a limited company to be known as H. C. Lawton (Electric) Ltd. Mr. Lawton, the president, has been connected with the electrical trade in Saint John for fifty years, having been apprenticed to the former Vaughan Electric Company in 1907.

Cdr. (E) V. F. O'Connor, R.C.N., M.E.I.C., (B.Sc., mech., Nova Scotia Technical College, 1934), principal naval overseer, Toronto area, was recently transferred to this post from Montreal where he was with the Naval Engineering Test Establishment.

B. Hardcastle, M.E.I.C., (B.Sc., civil, Edinburgh, 1945), has resigned from the post of division engineer with McColl Frontenac Oil Company Limited, Toronto, and has, of June 1, assumed the responsibility of manager of operations, Ontario division, with BP Canada Limited, Toronto. Mr. Hardcastle is secretary of the Joint Area Committee of the Toronto Branch, E.I.C.

D. A. Barnum, M.E.I.C., (B.S., civil, Michigan, 1928), manager of the transmission tower division, Provincial Engineering Ltd., Niagara Falls, Ont., is the chairman of the Niagara Peninsula

J. Lefort, M.E.I.C.

O. I. Logue, M.E.I.C.

D. A. Barnum, M.E.I.C.

Branch of the E.I.C. Mr. Barnum was associated with the Canadian Bridge Company from 1929 to 1953, at which time he accepted his present appointment.

Gordon T. Haig, M.E.I.C., (B.Sc., elec., Manitoba, 1929), of the Prairie Pipe Manfacturing Company Limited, Regina, Sask., has been promoted to assistant general manager of the firm. Earlier he was plant manager with the organization.

E. W. King, M.E.I.C., (B.Sc., elec., Alberta, 1943), has moved from Edmonton to Whitehorse, Y.T., in order to take over the general managership of the Yukon Electrical Company Limited, and the Yukon Hydro Company Limited. Mr. King was formerly transmission and distribution superintendent with Canadian Utilities Limited.

John G. Beresford, M.E.I.C., (B.Sc., Michigan, 1945), has been appointed manager of the Toronto apparatus factory, Linde Air Products Company, division of Union Carbide Canada Ltd. In his new capacity Mr. Beresford will be in charge of the manufacturing and warehousing of welding equipment and supplies.

W. F. Allen, M.E.I.C., (B.A., civil, Sciences Tripos, Cambridge, 1949; M.A., Cambridge, 1953), is carrying on his engineering career at Toronto with the firm of Sherwood Properties Limited. Formerly at Edmonton, Mr. Allen was chief engineer for A. C. Trowbridge and Associates Limited.

Percy C. Toft, M.E.I.C., (B.Sc., civil, New Brunswick, 1949), resident engineer with the Canadian General Electric Company Limited, civilian atomic power department, Peterborough, has accepted employment as project engineer with Humphreys and Glasgow of Canada Limited, Toronto.

J. S. Foster, M.E.I.C., (B.Eng., mech., N.S.T.C., 1943; B.Eng., elec., N.S.T.C., 1946), has moved from Peterborough, Ont., to Toronto. Mr. Foster is employed with Atomic Energy of Canada Limited, nuclear power plant division.

A. Klain, M.E.I.C., (diploma, Brunn, Czechoslovakia, 1946), formerly of Montreal, is now employed as a town planner with the Regional Planning Commission, Cleveland, Ohio. During the 1956-1957 term Mr. Klain followed a graduate level course in community planning at McGill University.

M. L. Zirul, M.E.I.C., (B.A.Sc., civil, British Columbia, 1941), has been appointed chief of operations division, water rights branch, Department of Lands and Forests, Government of British Columbia. Employed with the Province of British Columbia, water rights branch, since 1946, his former post was that of senior hydraulic engineer of the improvement district engineering section with the branch.

Donald L. Halsall, M.E.I.C., (B.Sc., elec., Queen's, 1949), has transferred his services from the Sylvania Electric Products Inc., Seneca Falls, New York, to the International Resistance Company Limited, Toronto. A supervisor of quality control in the former post, he will now carry out the duties of chief engineer.

Beno A. Eskenazi, M.E.I.C., (B.Sc., civil, Istanbul, Turkey, 1946; M.Eng., civil, McGill, 1949), consultant in structural engineering has opened a private practice in Montreal. Mr. Eskenazi was formerly chief engineer with the firm of Henry Jason, consulting engineer, Montreal. Mr. Eskenazi spent more than four years as a structural designer with T. Pringle and Sons, Montreal, at an earlier date.

David A. Foster, M.E.I.C., (B.Sc., mech., British Columbia, 1951), of Moncton, N.B., has been appointed Maritime district superintendent of motive power and car equipment for the Canadian National Railways. Since 1956 he has been engaged in the work of regional mechanical engineer.

F. R. Denham, M.E.I.C., (B.Sc., mech., Durham, England, 1950; Ph.D., Durham, 1953), a member of the executive of the Niagara Peninsula branch of the E.I.C., has been named assistant to the superintendent of the Electro Metallurgical Company, division of Union Carbide Canada Ltd., Fonthill, Ontario.

R. J. Pryor, M.E.I.C., (B.Eng., mech., Sheffield, 1945), formerly of Kelowna, B.C., and of Racey, McCallum & Associates, Ltd., Montreal, has moved to Alameda, Calif., with the Pacific Bridge Company.

Maurice Armstrong, M.E.I.C., (B.Sc., civil, Michigan, 1950), of Windsor, Ont., is the 1958 chairman of the Border Cities Branch of the Institute. Mr. Armstrong studied engineering following service in World War II. Later he became associated with C. G. Russell Armstrong in a consulting engineering practice on projects dealing with waterworks, municipal engineering, surveying land assembly development and other fields. At present he is a partner in the firm.

C. J. Karasek, M.E.I.C., (B.Sc., civil, London, 1953), project engineer with the construction branch of the Saskatchewan department of highways, has been awarded the Standard Gravel Good Roads Scholarship for postgraduate studies in the highways and highway transportation field.

Professor W. G. Heslop, M.E.I.C., (B.A. Sc., Toronto, 1930), of the University of British Columbia, department of civil engineering, was named chairman of the Vancouver Branch of the E.I.C., for the 1958-1959 term of office.

Guy L. Rainville, M.E.I.C., (elec., mech., B.A.Sc., Ecole Polytechnique, 1947) formerly resident engineer, roads department, Province of Quebec, has transferred his services to the traffic signals section, traffic department, City of Montreal, to work on the timing and co-ordinating of traffic signals.

J. M. Richardson, M.E.I.C., (B.Sc., elec., New Brunswick, 1941, has been appointed manager, marketing, with the Canadian General Electric Company Limited, motor and control department, Peterborough. For the past two years Mr. Richardson has been manager, sales and motor control department.

A. F. Brooks, M.E.I.C., (B.Sc., chem., McGill, 1950), has been appointed plant superintendent, nitrate and nitric acid plants, Warfield department, chemicals and fertilizers division, Consolidated Mining and Smelting Company of Canada Limited.

Thomas A. Bowles, M.E.I.C., (B.A.Sc., civil, Toronto, 1950), is construction manager of the firm of Bedford Construction, Toronto. He was formerly a district engineer with Geocon Limited, also at Toronto.

D. E. Rudolph, M.E.I.C., (B.Sc., elec., New Brunswick, 1952), will return to Canada

Percy C. Toft, M.E.I.C.

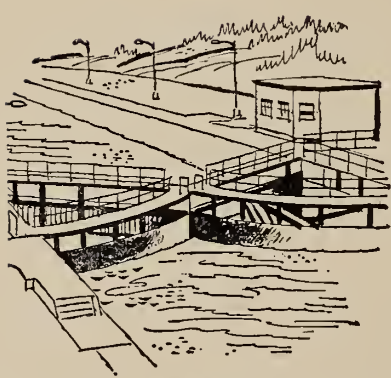
C. J. Karasek, M.E.I.C.

W. G. Heslop, M.E.I.C.

7 Major St Lawrence River Projects

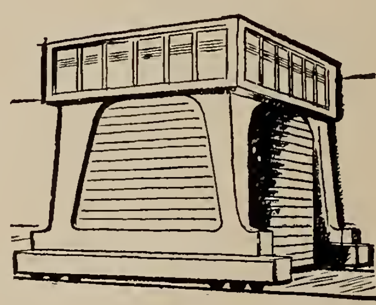
BY DOMINION BRIDGE

ONE engineering company . . . Dominion Bridge . . . is currently at work on several of the largest steel structures for the St. Lawrence Seaway and Power Developments. The diversity of this work—which includes design, manufacture and erection—is matched by the diversity of Dominion Bridge facilities. Seven of these major projects are described here. These, and others, will make an important contribution to the St. Lawrence River developments and to the economic advancement of Canada.



SIX PAIRS OF SECTOR GATES

have been built for the shipping canals. Each pair is 45 ft. high and weighs about 500 tons. Four pairs have been installed at Iroquois, Ont. and will act as the operating gates of the lock. There is also one pair of guard gates for each of the Beauharnois and Cote Ste. Catherine canal reaches in Quebec.

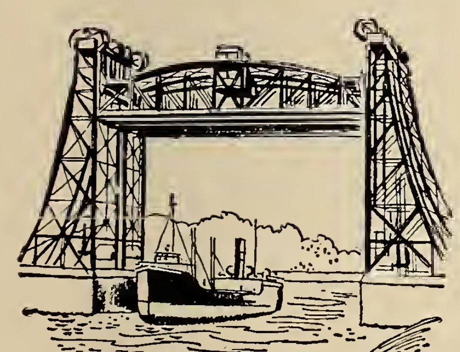


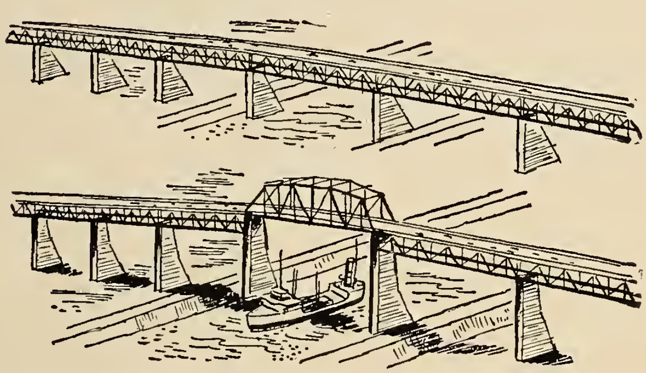
HUGE CRANE ACTS AS "TRAVELLING POWER HOUSE"

A 300-ton gantry crane, the largest ever built in Canada, was designed and fabricated for the Canadian half of the Barnhart Island Power House. Completely enclosed, the crane illustrates a modern trend in design and serves, in effect, as a "travelling power house."

48 GATES FOR BARNHART ISLAND POWER PROJECT

These hydraulic head gates comprise the largest order of its kind ever placed in Canada and were fabricated for Ontario Hydro. They are designed for openings 17 ft. wide by 37 ft. high. Each will withstand a pressure of 3,000,000 lbs. under a 93 ft. head of water.





• PERSONALS

shortly from Taplow, near Maidenhead, Berks, England, following a year spent in England on a scholarship provided by Phillips Electrical Company of Brockville, and British Insulated Callendar's Cables. Mr. Rudolph was employed with the Maritime Telegraph and Telephone Company before winning the scholarship.

J. H. Douglas, M.E.I.C.

J. H. Douglas, M.E.I.C., (B.Eng., mech., McGill, 1946), was some months ago elected chairman of the Sarnia Branch of the Engineering Institute. Professionally Mr. Douglas is associated with Dow Chemical of Canada Limited, Sarnia.

H. F. Pragnell, JR.E.I.C., (Royal Military College, 1942; B.Eng., civil, McGill, 1949), has been appointed office engineer with Henry Kaiser Company (Canada) Ltd., Montreal. He was formerly associated with the Foundation Company of Canada and the Eddy Match Company on various engineering projects. Mr. Pragnell was a member of the committee to organize the Chalk River Branch of the Institute.

Major S. M. Bancroft, JR.E.I.C., (B.Eng., civil, N.S.T.C., 1949), has left the Canadian Army Staff College, Kingston. Major Bancroft has been transferred to the directorate of design and development, Army Headquarters, Ottawa.

Robert William McBain, JR.E.I.C., (B.M.E., Detroit, 1954, has taken over the post of sales engineer with the American Standard Products (Canada) Ltd., at Windsor.

CORRECTION:
Squadron Leader Paul F. McNichol, JR.E.I.C., (B.Eng., Nova Scotia Technical College, 1950), of the construction engineering branch, A.M.C., Ottawa, was recently promoted to this rank. The Journal regrets that an error was made in naming the promotion in the August issue of the Journal.

Captain R. L. Hamel, JR.E.I.C., (B.A.Sc., mech., elec., Ecole Polytechnique, 1953), now serves as officer in command of the inspection and servicing at 4 Coy. R.C.E.M.E., Montreal. Captain Hamel has returned to Montreal from the Middle East where he was officer in

To Promote SAFE Handling of Explosives

Where blasting operations are involved, safety begins with on-the-job instruction. To protect the men who handle explosives and to keep them well-informed in their "do's" and "don'ts" Du Pont of Canada has placed a safety folder in every case of Du Pont Explosives. This helpful folder, "Prevention of Accidents in the use of Explosives", is bilingual and easily readable. Quantities are available for your own safety program.

Contact your Du Pont representative or mail this coupon:

command of the vehicle section, 56 Canadian Infantry Workshop, R.C.E M.E., United Nations Emergency Force, Egypt. He also carried out the duties of Military Observer with the U.N.T.S.O., the Israeli Syrian Mixed Armistice Commission, Tiberias, Israel.

K. H. Cram, JR.E.I.C., (B.Eng., chem., McGill, 1947), has left Montreal, where he held the post of assistant professor of chemical engineer, at McGill University, in order to accept an appointment with E I. dePont de Nemours and Company.

J. H. Goar, JR.E.I.C., (B.Sc., elec., Man., 1948), formerly manager of the Hamilton Branch, Canadian Westinghouse Company Limited, has been appointed sales manager for the company's power transformer division in that city.

John H. Flett, JR.E.I.C., (B.Eng., civil, McGill, 1949), assistant engineer for the Canadian Pacific Railway for the past two years at Saint John, N.B., has been named roadmaster of the railway at North Devon, N.B.

N. D. Heaslip, JR.E.I.C., (B.A.Sc., chem., British Columbia, 1951), formerly of the West coast, with Canadian Industries Limited, Victoria, has been transferred to Montreal. He is with the explosives division, production department of C.I.L. in his new location.

T. B. Lounsbury, JR.E.I.C., (B.Eng., elec., McGill, 1950), has been appointed manager of the Canadian Westinghouse lamp division, Trois Rivieres, Que., Mr. Lounsbury has been manager of the meter and relay division of the company at Burlington, Ont.

C. Cameron Johnson, JR.E.I.C., (B.Sc., civil, New Brunswick, 1950), has been transferred from Fort Smith, N.W.T., to head office, Ottawa, with the Department of Northern Affairs and National Resources. He is with the northern administration and lands branch, works, research and planning division.

H. Maissonneuve, JR.E.I.C., (B.A.Sc., mech., elec., Ecole Polytechnique, Montreal, 1952), formerly with the Northern Electric Company, Montreal, has transferred his service to the Montreal Engineering Company Limited, Montreal.

Paul R. Bennett, JR.E.I.C., (B.Sc., mech., Queen's, 1956), has since June 1, been employed with the Spruce Falls Power and Paper Company Limited, as an instrument engineer in the Spruce Falls and Kimberley-Clark of Canada mills, Kapuskasing, Ontario.

W. Laskaris, JR.E.I.C., (B.Sc., civil, Queen's, 1952), who joined the Department of Public Works of Canada, high-

Resilience, colour-fastness, shrink-resistance, durability — these are the qualities beyond pattern and colour Carl needs in carpeting for his office and home. And these are qualities built into the newer viscose carpets.
Ensuring a uniform high standard in viscose manufacture demands rigid control of the mixture and flow of uncontaminated chemicals . . . with reliance on valves designed and made by valve specialists.
For accurate control in plants throughout Canada, manufacturers are using Jenkins for new installations and replacement.

Call for a Jenkins specialist-representative to help you choose precision-engineered valves that cut operating costs . . . are dependable, high in efficiency and low in upkeep.

way division, early in 1958, is engaged in the work of highway engineer at Banff, Alta., Mr. Laskaris is involved in an extensive highway construction program in the National Parks in Western Canada and in particular the Banff district, including Jasper, Yoho, Kootenay, Glacier and Revelstoke National Parks.

J. O. Down, JR.E.I.C., (elec., Poplar Technical College, London, 1953), recently at Asbestos, Que., with Canadian Johns Manville Company Limited, is now employed with the Canadian British Aluminum Company as an electrical maintenance engineer.

H. J. Bredin, JR.E.I.C., (B.Sc., civil, Alberta, 1950), has relinquished the post of Town Engineer at Flin Flon, Man., in order to accept responsibility as Town Engineer for Jasper Place, Alta.

Frank E. Barrett, JR.E.I.C., (B.Eng., elec., McGill, 1950), has been elected president of the Lions Club of Montreal. Mr. Barrett is chief engineer of the Thomson Electric Works Ltd.

David Hay, JR.E.I.C., (B.A.Sc., mech., British Columbia, 1956), has left the employment of H. A. Simons Ltd., Vancouver, and has accepted a post with MacMillan and Bloedel Ltd., in their Western district engineering department at Port Alberni, B.C.

F. E. Barrett, JR.E.I.C.

John Martin, JR.E.I.C.

J. Ross, S.E.I.C.

John Martin, JR.E.I.C., (B.Sc., mech., Sask., 1957), has completed a course in business administration at the University of Saskatchewan, where he received a diploma. He has accepted training as a sales engineer in the air-conditioning department of the Canadian Ice Machine Company Limited at Winnipeg.

J. D. Norman, JR.E.I.C., who a number of months ago left his work as contracts engineer, with the St. Lawrence Power Project, New Town, No. 1, Ontario Hydro-Electric Commission, is with the M. M. Dillon and Company Limited, London, Ont. in the municipal engineering section of that organization.

Colin C. Nicholson, JR.E.I.C., formerly of the Canadian General Electric Company Limited, Toronto, has for a number of months been employed with the Canadian Westinghouse Company Limited, electronics division, at Hamilton, Ont.

Gilles Rousseau, S.E.I.C., (B.Sc., civil, Ecole Polytechnique, 1957), is an engineer trainee with Perini Quebec Inc., general contractors. In 1957 employed on the Chutes des Passes Power Development, he was recently transferred to the Bersimis No. 2 Development.

Wayne E. Randall, S.E.I.C., (B.Eng., civil, Saskatchewan, 1958), has begun his professional career as a project engineer with the Department of Agriculture, conservation and development branch, Swift Current, Sask.

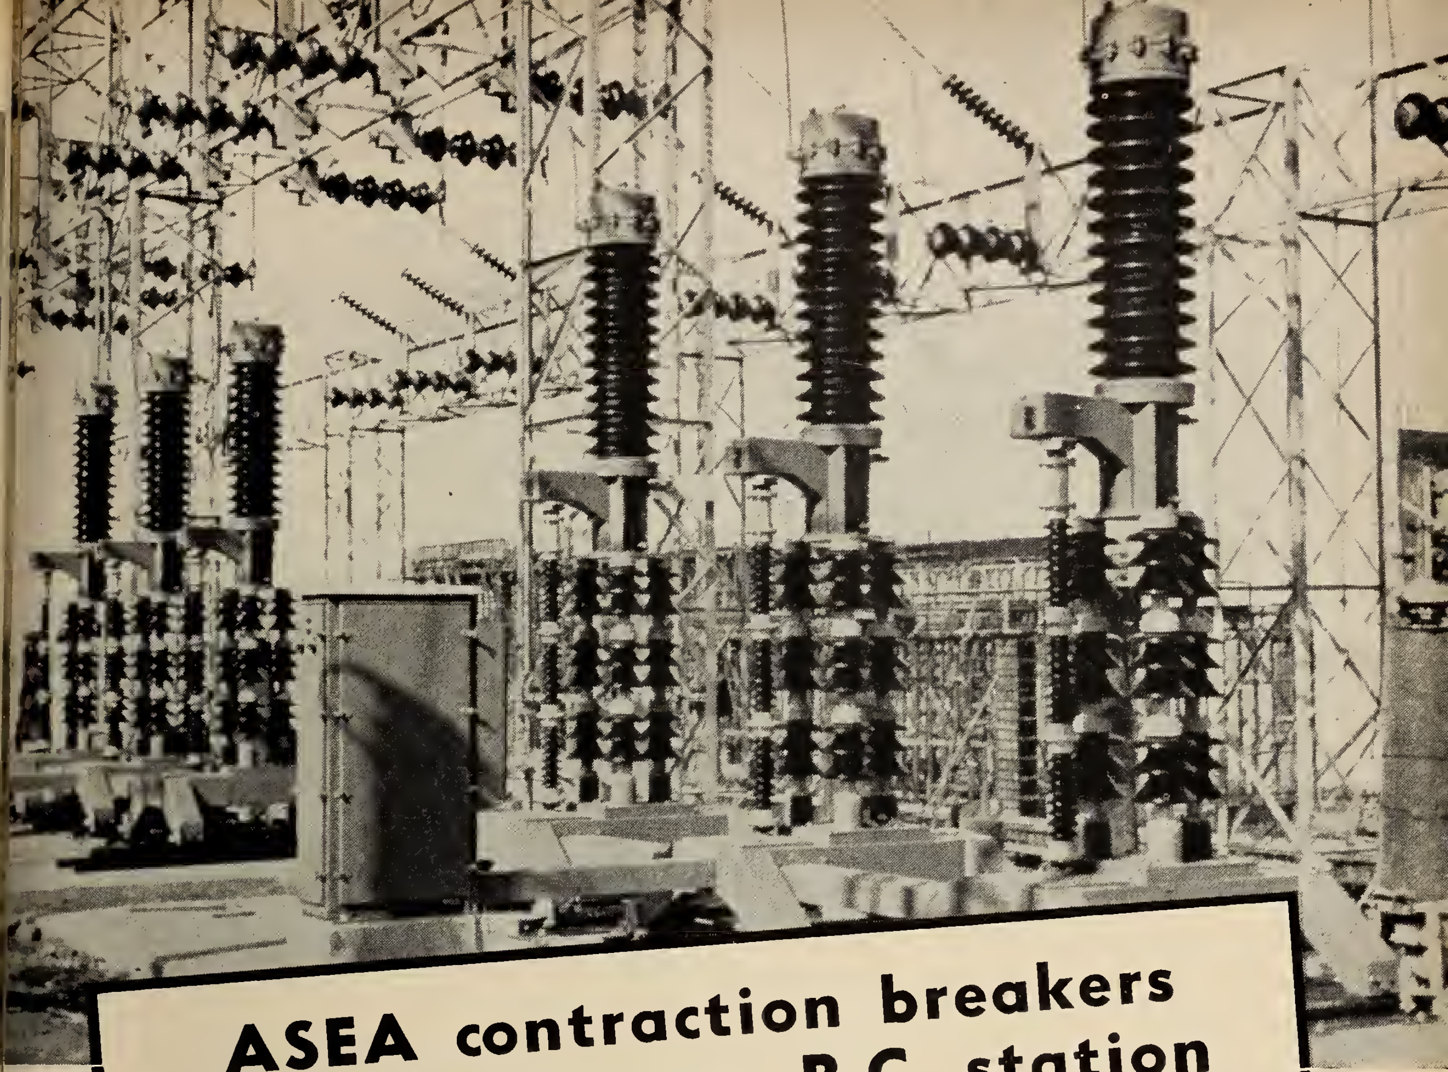
Flying Officer Emil Bizon, S.E.I.C., (B.Eng,. elec., McGill, 1958), has begun his graduate engineering career with service in the telecommunications branch of the Air Material Command Headquarters, Rockcliffe, Ont.

Stephen V. Allison, S.E.I.C., (B.Eng., civil, McGill, 1958), has embarked on his graduate career in engineering in the services of the Canada Green Construction Company, Calgary.

Donald Murray Watt, S.E.I.C., (B.Eng., mech., Nova Scotia Technical College, 1958), is working as an engineer trainee with the B.A. Oil Company Limited, Montreal East refinery.

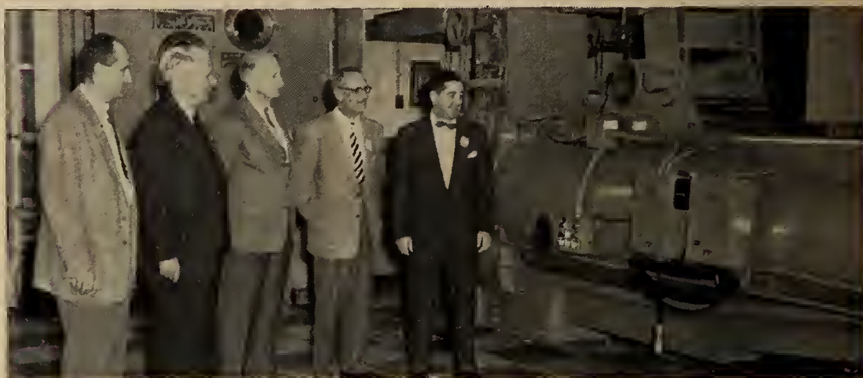
W. J. Ross, S.E.I.C., (B.Sc., civil, New Brunswick, 1958), has been awarded the Union Tractor Good Roads Scholarship for post-graduate studies in the highway and transportation field.

F/O Thomas Jeary, S.E.I.C., (B.Eng., mech., Nova Scotia Technical College, 1958), has recently been stationed at the R.C.A.F. station, Portage, Man., where he was engaged in flying T-33 aircraft.



NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings



During the visit of President Anson and Dr. L. Austin Wright to the Chalk River Branch for its inauguration the N.R.U. reactor building was inspected. The photo shows the shielded flask and storage block for handling radioactive material from the N.R.U. reactor. Left to right are: C. A. Crawford, Branch chairman, Dr. D. A. Keys, Dr. L. A. Wright, Dr. Anson, and J. L. Gray, president of Atomic Energy of Canada Limited.

CHALK RIVER

W. O. Findlay, M.E.I.C., *Secretary*

C. A. Crawford, JR.E.I.C., *Branch News Reporter*

The recent inauguration of the Chalk River Branch of the Institute was the occasion for a visit by President Anson and Mrs. Anson, Dr. L. Austin Wright, then general secretary, E.I.C., and Mrs. Wright. Also present were Hector Chaput and W. V. Morris, chairman and secretary of the Ottawa Branch, which provided a substantial cheque as an aid to the new group in its first endeavors.

The provisional chairman for the evening, C. A. Crawford, was elected Branch chairman and appointed a councillor to attend the annual meeting of Council held in Quebec City a short time later. Also elected to office were J. G. Melvin, C. E. L. Hunt, J. S. Flavell, and secretary W. O. Findlay.

Lorne Gray, M.E.I.C., newly elected president of Atomic Energy of Canada Limited was a head table guest.

President Anson was the official speaker for the evening and later the meeting was turned over to questions and observations from the floor.

VANCOUVER ISLAND

H. F. Coupe, M.E.I.C., *Branch News Reporter*

Engineering Training in Victoria was advised by Dr. L. Austin Wright, immediate past general secretary of the E.I.C., in a recent visit to that city. Dr. Wright's recommendation that the first two years of the four-year engineering course to be completed at the University of British Columbia, Vancouver, should be given at Victoria College has been followed up by a preliminary study on the part of J. B. Nuttall, JR.E.I.C., into the possibility of establishing such a course. Mr. Nuttall's report submitted to Grant Griffiths, Branch chairman, states that considerable precedent exists in this field. The Nova Scotia Technical College provides the final two years of study to students from four colleges in the province. Mount Allison University, N.B., the University of Sherbrooke, Que., and the University of Alberta, Calgary division, provide similar facilities to those envisaged for Victoria College, and serve comparable populations. Feasability of the course depends on the number of students to be served, quality of training, as well as the place which such an endeavor would occupy in the overall scheme of higher education in British Columbia.

An estimate of the size of the prospective student body reveals that if training were begun in 1959 as estimated 50 students would seek admission. The number would increase to 70 by 1962. Annual cost to maintain students regis-

tered in both first and second year courses has been estimated at $38,000, $21,000 to be made up from government and private sources. Direct cost to the province would be 10 per cent higher than the same training given at Vancouver. Annual cost to a student in the Victoria area would be $400.00 less.

The majority of professional engineers in the area were enthusiastic about the establishment of an engineering course for the College. Opinion was however unanimous that training at the University would be better than at Victoria College if the cost to the student was no object.

Mr. Nuttall's study concluded that while changes in methods of technological education may in another decade make engineering training in Victoria impractical, it is now in the public interest. Copies of the study circulated to Branch members created a response which was overwhelmingly in favour of directing the Branch executive to take a public stand favouring the measure. As an initial stand it is planned to pass the report of the preliminary study to the appropriate committee of the Victoria Chamber of Commerce, which has been active in the matter in the past.

Naval Tour

The United States aircraft carrier Bennington was the object of a Branch tour on July 11. The Bennington, along with several smaller ships of the U.S. Navy and the cruiser Newcastle, of the Royal Navy, were a part of the naval review of 32 warships held July 15 in honour of the B.C. Centennial and the visit of Princess Margaret.

A 40,000 ton cruiser with a length of 889 feet and an extreme width of 206 feet, the Bennington was commissioned originally in 1944, saw service at Okinawa and in bombing raids on Tokyo. Completely modernized since then, it includes the addition of an angle landing deck to enable aircraft to land and take off simultaneously. Three squadrons of jet fighters, two helicopters, and aircraft for heavy bombardment and high altitude photography are carried, totalling eighty aircraft, some of which were on display for close inspection by the engineers. The ship's engines develop 150,000 h.p., using four screws to attain a maximum speed of thirty knots. A complement of 2800 officers and men are required to man the ship, including representatives of thirty professions and trades.

the American Institute of Electrical Engineers and the Canadian Institute of Mining and Metallurgy, Ottawa branch. Gordon D. Watson, director of weapons research, Defence Board, is responsible for the co-ordination and planning of the Canadian research program in the weapons field. His talk, "Rockets, Earth Satellites and Space Travel," was mentioned in the July issue of the Journal, Branch News section, page 112. It is summarized on page 146 of this issue.

JOHN P. STERLING, M.E.I.C., chief engineer Defence Construction 1951 Ltd., Ottawa, at a May 15 meeting of the Ottawa Branch E.I.C., gave a talk heard by seventy-five members, on "The Columbo Plan — Canadian Engineers Look Eastward." Mentioned briefly in the July Journal, page 112, it is here dealt with in greater detail.

Mr. Sterling said that Canadian engineers working on eleven Columbo Plan projects in the Far East are making a valuable contribution to the development of a free world. Canadians helping to create these $188 million worth of power plants, and other schemes in India and Pakistan are producing results far beyond their technical and material aspects. The Department of Trade and Commerce, International Economic and Technical division directs Canadian aid to these countries. Defence Construction Limited is the technical advisor and administrative agency for engineering and for construction products.

Largest major project under way with Canadian aid is Warsack in West Pakistan, a combined hydro-electric and irrigation project, slightly smaller than the Des Joachims plant on the Ottawa River. Mr. Sterling presented coloured slides to outline the project. It will replace thermal power with 220,000 horsepower of electricity. One hundred and twenty-five thousand acres of land will be irrigated and opened up for settlement.

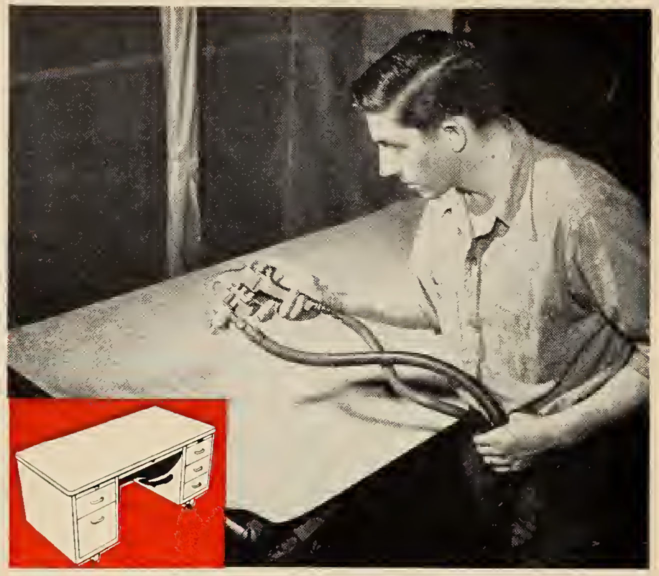
Canadian engineers and contractors are working on jobs at Shadiwal hydro-plant in West Pakistan; Ganges Kobadak thermal power plant in East Pakistan, Kundah hydro-power project in South India, the Maple Leaf cement plant at Daud Khee in West Pakistan and a fish refrigeration and by-product plant in Columbo, Ceylon.

Other Canadian Columbo Plan projects include Umtru, a small hydro-electric plant in Assam, India; Canada Dam and Mayurakshi Reservoir, in India; the Goalpara steam generating station in East Pakistan and two power transmission line projects, one of 70 miles in Ceylon, and one in East Pakistan of 150 miles.

Mr. Sterling was introduced by branch chairman Hector Chaput and was thanked by treasurer Hugh Brown.

A SEAWAY TOUR was enjoyed by the Ottawa Branch for its May 31st meeting.

TRANE CO. OF CANADA LTD. SAVES TIME insulating air conditioners by using specially designed 3M Adhesives. These adhesives hold the insulation tightly to the metal. No drying time is needed. The insulation never comes loose.



OFFICE SPECIALTY MFG. CO. LTD. SAVES COSTS in production by using another specially designed 3M Adhesive. Every desk they make has its top laminated with 3M Adhesive. Speed of application and holding power are just two of the reasons.

CONCRETE PIPE LIMITED SAVES LEAKS by using rubber gaskets adhered tightly to concrete by a 3M Adhesive. The combination of the adhesive and gasket defies the elements.

● BRANCH NEWS

Seventy persons travelled by bus to New Iroquois, to join a guide from the Ontario Hydro-Electric Commission. Following a tour of the Iroquois Lock, control dam, and the new townsite, a ten-minute film covering the overall project was shown. A second tour which included the powerhouse, headworks, and other points of interest in the Cornwall section concluded the day's events.
For picture turn to page 138.

A DINNER MEETING was held on May 26 by the Ottawa Branch, E.I.C., in honour of the I.E.E. and the general secretary of the latter organization, Mr. K. Bracher, of London England.

APPLICATION FOR MEMBERSHIP in the E.I.C. has been received from Robert Owen King by the Ottawa Branch. Mr. King graduated in engineering from McGill University in 1895; and received a master's degree from that institution in 1898. He is presently employed with the Defence Research Board, Department of National Defence and is in his eighty-fourth year.

AN ANNUAL EVENT of great interest to engineers of Ontario and Quebec, the fourth Ottawa Valley Engineers Annual Golf Tournament was held June 13, 1958 at the Arnprior Golf Club, at Arnprior, Ont.

Engineer members of six engineering groups were invited to participate and combined to produce a total enrolment of one hundred and fifty persons for the event. Taking part in the tournament were: The American Institute of Electrical Engineers; the Association of Professional Engineers of Ontario; The Canadian Institute of Mining and Metallurgy; The Chemical Institute of Canada; the Corporation of Professional Engineers of Quebec, and The Engineering Institute of Canada.

Sponsor for 1958, the Corporation of Professional Engineers of Quebec, presented The Quebec Corporation Trophy to the individual player having the lowest gross. This was M. Ross whose score was 76. For the first low gross Mr. Ross was also awarded a portable radio. Seventeen other prizes were awarded.

Review of Talk on Rockets, Earth Satellites and Space Travel

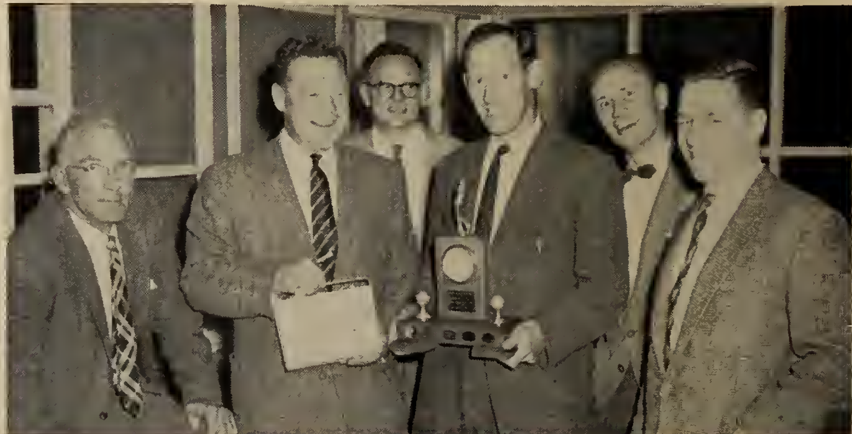
Mr. Watson reviewed the history of rocketry and dealt with the scientific data only recently obtained from orbiting earth satellites. He outlined the known problems relative to space travel and discussed current approaches to their solution.

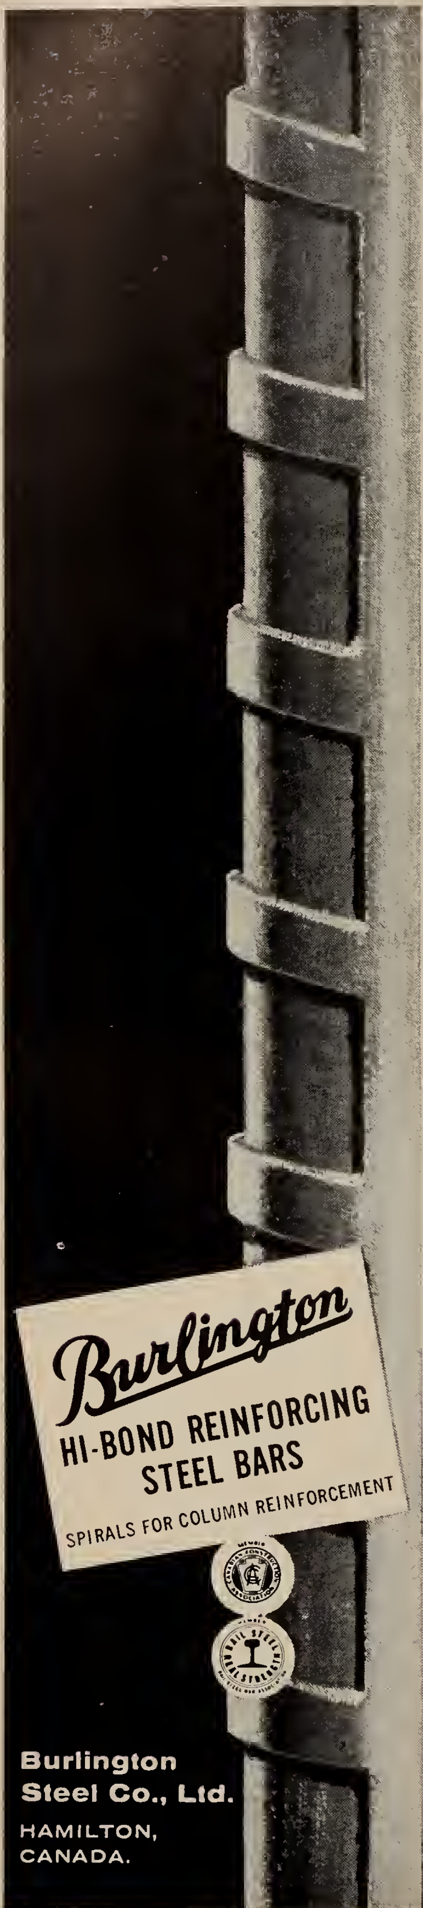
Fuel Systems

Chemical fuel systems are reaching the limit of their capability. Although some improvement is possible, it is unlikely that specific impulse can be raised more than a few percent. Nuclear reactions offered the best possibility for obtaining high energy per unit weight of fuel. The combination nuclear-chemical engines in which a nuclear reactor is used to heat liquid hydrogen might prove to be the earliest practical rocket engines with major improvements. Controlled fusion reactions might also be used to heat liquid hydrogen, but practical fusion reactors are probably further away than the fission reactor already operative for fixed power plant use. The limitation of chemical rockets, the velocity with which the gas molecules can be ejected at temperatures than can be contained in the rocket, has led to examination of the possibility of accelerating nuclear particles, ions and photons, and using the reaction of these particles for thrust. The ion rocket has been the subject of current research and a U.S. scientist recently expressed the opinion that it is likely to be the first practical power-plant using charged particles.

These motors are not yet practical however, because of the excessive weight

At the Fourth Ottawa Valley Engineers Annual golf tournament on June 13, at Arnprior, Ont. Shown left to right are Fred Wrangell, representing Arthur Bidden, C.P.E.Q. regional representative; Blake Goodings, field representative, A.P.E.O.; Rudy Meyer, golf committee chairman, C.P.E.Q.; M. Ross, who was awarded the Quebec Corporation Trophy for the first low gross; Hector Chaput, chairman, Ottawa Branch, E.I.C., and Pierre Bournival, general secretary, C.P.E.Q.





• BRANCH NEWS

of the machinery required to convert nuclear to electrical energy. U.S. scientists have pointed out that before particle rockets can be practical, a more direct conversion from nuclear to electrical energy is needed.

Ballistic Rockets and Satellites

Mr. Watson discussed ballistic rockets as forerunners of satellites and outlined at some length the scientific laws governing the trajectories both of ballistic rockets and satellites. The job of establishing an earth satellite is not easy. The force of gravity demands the expenditure of a considerable amount of energy to lift the satellite; the earth's atmosphere demands that any satellite which is to have a reasonable life span must be launched at about 5 miles per second above the majority of the atmosphere at an altitude of 150 or 200 miles. Multiple stage rockets are particularly important in satellite launching, as fuel tanks and unwanted structure can be discarded when their purpose has been served.

I.G.Y. Satellite Projects

A number of interesting facts which have resulted from the International Geophysical Year Satellite projects were enumerated.

Sputnik I with the lowest orbit, and Sputnik II have both already re-entered the atmosphere and either burned up or impacted. The U. S. Explorer and Vanguard satellites, both lighter than their U.S.S.R. counterparts, were moving in higher level orbits and could therefore expect longer lives.

The rate at which satellites are slowed up depends on the density of the atmosphere. The satellite program indicates that the atmospheric density at 150 to 200 miles altitude may be several (figures from 9 to 14 times have been quoted) times higher than had been estimated previously.

The temperature measurements obtained from Explorer I have recently been published and indicate that the methods used to control the internal temperature of the satellite have been successful in keeping the temperature between 97° and 120°F. These are quite reasonable limits for human endurance. The satellite's skin temperature lies between 63° and 143°F.

The Moon and Other Planets

Mr. Watson forecast that the next phase in space experimentation would be exploration of the moon employing techniques similar to those used for launching earth satellites. Possibilities are: impact on the moon, orbit and return to earth, and orbit an instrumented satellite around the moon. Eventually these instrument carriers might be landed on the moon and remotely controlled to explore and send back information. The velocity of a moon-rocket would have to be accurate to about 100 ft./sec. in 36,000 and the angle of launch should be within about 0.2 degrees.

CEA Meets at Banff

The 68th annual meeting of the Canadian Electrical Association was held at the Banff Springs Hotel, Banff, Alberta, June 30-July 2, 1958, with over 600 delegates in attendance.

V. A. Ainsworth, general manager, Newfoundland Light and Power Co., was elected president for the coming year. In his annual report, managing director, B. C. Fairchild noted membership had increased from 754 members in 1943 to over 1,600 this year.

CEA President, J. C. Dale told delegates that net generating capability at the end of 1957 for Canada's electric utilities was some 16,469 megawatts, up 9.9% over 1956. Forecast over the next four years is for an increase of 42.6%, with capacity in 1961 of 23,484 megawatts. Firm peak load in 1957 was 14,925 megawatts, up 7.2% over 1956, compared with the 11% increase in the previous year.

Margin of reserve capacity is beginning to widen sooner than expected. If the trend continues it will result in further and additional postponement of capital outlays for new plant, he observed. While current forecasts now predict for 1961 what was previously forecast for 1960, there was no need to be unduly pessimistic. Overall long-term growth would almost certainly not fall below 7%.

Nuclear power would not be a serious competitor on this continent in the electrical generation field for some time to come, he said. Actual costs of construction are running around $1,060/1,120 per KW, with power costs of 64 mills or 9 times that produced in a conventional plant. But the electrical industry could not afford to ignore the competition offered by the natural gas industry. In water heating, cooking, air conditioning, etc. natural gas was going to offer its greatest challenge.

From all reports, he remarked, the Canadian Electrical Manufacturer was facing serious competition from imports. While competition was generally conceded to be in the best interest of the consumer in the long run, advantages obtained by lowering standards and reducing safety factors were not . . . in the long run it was in the best interests of Canada to have a strong versatile electrical manufacturing industry.

President A. E. (Dal) Graver of the British Columbia Electric Co. Ltd. predicted deliveries of electricity were likely to go on doubling every ten to twelve years during the 'sixties' and 'seventies'. Electricity would probably continue to gain relative to other forms of energy. About 20 per cent of all the fuel and power used in Canada now took this form. Twenty-five years from now the proportion might increase to 30 per cent. Main effect of atomic energy would be to set a ceiling on the cost of electricity.

In a strong appeal for switching 15% of our imports from the U.S. to Canadian manufacturing rather than from the U.S. to U.K., Stuart Armour, economic adviser, The Steel Company of Canada, pointed out manufacturing had contributed $12 billion more to our national income in the past decade than had farming, fishing, forestry, mining and construction combined. If we even doubled our exports of primary products we should not progress without a corresponding growth in Canadian Manufacturing. Such growth, he emphasized would not be brought about by the encouragement of exports.

Speaking for the electrical manufacturing industry, H. B. Style, pointed to the problem it faced due to extreme variatons in demand for its products during the past 10 years. The industry's output had about doubled between 1947 and 1957. But orders for large transformers and generators from utilities from 1952 to 1954 averaged less than half those placed in 1951, while in the period 1952-1954 they had averaged over 2½ times the orders placed in the previous three years. Surely, he observed, there was some way to the advantage of both utilities and manufacturers of evening out these extreme swings.

It was inconceivable, he declared, that with the growing importance of thermal power in Canada we continue to place ourselves 100% in the hands of foreign suppliers for such basic prime movers as steam turbo-alternators. Where would we be in case of war or other major disturbances?

Addressing delegates on the application of Calder Type Atomic Stations to North American conditions Dr. H. S. Arms, M.E.I.C., of English Electric Co. of Canada, Ltd., estimated that a large Calder Type reactor might cost as much as 55 per cent more to build in Canada than in the U.K. on the basis of 120 per KW net sent out for Hinkley Point, this would give a cost of $480 per KW net sent out for Canada. No particular reasons could be seen for expecting operating costs significantly different from those for a conventional thermal plant in Canada, nor to suppose fuel costs in Canada would exceed those in the U.K. except for relatively small costs of freight and insurance.

IIW Conference Held at Vienna

The annual assembly of the International Institute of Welding, held June 29 to July 5, at Vienna drew the interest and attention of more than 800 persons from twenty-four countries. The event co-incided with the tenth anniversary of the foundation of the I.I.W. The opening session of the Assembly at the Vienna town hall was addressed by a number of eminent Austrians. Among them were the president of the Austrian republic, Dr. Adolf Scharf, the minister of trade and commerce and construction, Dr. Fritz Book, and Mr. Franz Jonas, mayor of Vienna.

The public session, following upon the opening session, was presided over by Professor Franz Rapatz, vice-president, I.I.W. and chief of the Austrian delegation, on the governing council of the organization. Authors of the thirty-one papers from fifteen different countries dealt with the various aspects of the principal theme, "Welding in the Chemical Industry."

Reports to be drafted by the chairmen of commissions will contain details of the principal business carried out at the Vienna meetings. These reports will be available during the year for publication in the world's technical press.

Thirty working documents were released with a view to their publication in specialized technical reviews.

A handbook on radiographic apparatus and techniques will be published under the auspices of the Institute.

Also marking the ten-year anniversary, the I.I.W. made a general report of work to date in a bilingual illustrated book of two hundred and fifty pages, published by the Belgian delegation. Yet

CF 105

another work publicised welding in Roumania.

Certain amendments were made to the constitution of the I.I.W.

There was close collaboration between the I.I.W. and the International Organization for Standardization, the governing council having approved the transmission to I.S.O. of a certain number of reports prepared by the commissions. Various questions raised by the I.S.O. will be investigated.

Arrangements were made to carry out a more detailed study of certain subjects, such as metalization problems and the welding of non-ferrous metals. Work will also start on new subjects such as the inspection of welded assemblies in plastics.

Two excursions, to the south and to the west of Austria, enabled members to visit the principal industrial centres of that country.

The 1959 Assembly will be held at Opatija, Yugoslavia, from June 28 to July 4. The public session will deal with welding and allied processes, gas cutting, building-up, bronze welding, surface hardening, metal-spraying in maintenance and repair work.

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*AIRPLANE DESIGN MANUAL

A guide to the practical aspects of airplane design. Information is provided on the principles of aerodynamics, structural design, installation requirements, and the application of materials. In addition there is data on the economics of design, performance calculations, and allied problems. In this revised edition greater emphasis is placed on the analytical approach to design problems. (F. K. Teichmann. Toronto, Pitman, 1958. 489p., $8.50.)

*AN INTRODUCTION TO AUTOMATIC COMPUTERS

Intended to convey the computer's functions from a business systems point of view, with its uses and limitations. A discussion of major analysis techniques is included, with reference to applications, programming and operation. Many specific examples are included for purposes of illustration. Appendices provide extremely detailed data on automatic computers commercially available, including information on the arithmetic and logic unit, the storage unit, and input-output equipment. (N. Chapin. Toronto, Van Nostrand, 1957. 525p., $10.25.)

DAS LUSTIGE ATOM

This is a book of humorous verse, dealing with man's quest for knowledge, from Adam and Eve to the modern scientist and his atom bomb. Man's theories on the composition of matter from historical times to the present day atomic theory are included. The book goes on to talk about chain reactions, nuclear physics, uranium, and the explosion of the first atomic bomb, and concludes with what the future of the atom may have in store for mankind. Profusely illustrated throughout, it is amusing and entertaining reading. (Fritz Wolf. Essen, Vulcan-Verlag Dr. W. Classen. 192p., 9.60 DM.)

*MAN, METALS AND MODERN MAGIC

A history of the role that metals have played in the development of civilization. Beginning in 6000 B.C. and continuing to the present, the author traces the use of bronze and iron, the development of alloys, the expansion of metallurgy, and the metallurgy of nuclear fission. (J. G. Parr. Cleveland, American Society for Metals and Iowa State College Press, 1958. 238p., $2.95.)

MESURE ET DETECTION DES RAYONNMENTS NUCLEAIRES

This volume is adapted and translated from the second editions of two English monographs, Nuclear Radiation Detectors by J. Sharpe and The Measurement of Radio Isotopes by D. Taylor.

The adapter has arranged the material in three sections, the first of which includes all the information needed for the correct measurement of radioactivity; measuring instruments, Geiger counters, etc., statistical and geometrical methods, protective shielding, etc. The third section discusses apparatus for the detection of radiation; ionization chambers, Geiger-Muller counters, scintillation counters, dosimeters, safe doses of radiation, etc.

The second section is theoretical, and explains the theories on which the operation of radiation detectors are based.

The material is presented very concisely, and there is a useful bibliography. (J. Chatelet, ed. and trans. Paris, Dunod, 1958. 321p., 3400fr.)

*METALS

Twelve papers dealing with corrosion, fatigue, and strength properties of metals. Specifically, they cover shotpeening, effect of forming on properties, axial stress fatigue, and results of studies on steels, aluminum, magnesium, and beryllium copper. (Philadelphia, American Society for Testing Materials, 1958. 175p., $4.50 s.t.p. no. 196.)

*MINING ROUND THE WORLD

A record of the struggles and achievements of miners and mining engineers. The author gives an account of the mining methods first used and how they have been developed up to the present, and in addition she examines the nature and contemporary role of such key minerals as uranium, tin, copper, lead, silver, zinc, diamonds and gold. (June Metcalfe. Toronto, Oxford, 1956. 123p., $2.50.)

*NOTES ON ANALOG-DIGITAL CONVERSION TECHNIQUES

Presents the subject matter in three parts. The first discusses systems aspects of digital information processing which influence the specifications for analog-to-digital and digital-to-analog conversion devices. In the second part a detailed engineering analysis and evaluation of a variety of conversion devices is presented. The third part is devoted to a case study based on development work done at the Servomechanisms Laboratory of the Massachusetts Institute of Technology. The book has been reprinted with corrections from the edition published by the Technology Press of Massachusetts Institute of Technology in 1957. (Ed. by A. K. Susskind. New York, Wiley, 1958. Various paging, $10.00.)

*NUCLEAR REACTOR EXPERIMENTS

Problems relating to the design, construction, and operation of nuclear reactors are outlined with details of equipment and experiments. Areas included are nuclear radiation detection, moderator and sub-critical assemblies, cross sections, operating reactors and their characteristics, heat removal from a reactor, corrosion and radiation effects, fuel preparation, and separation processes. (The Staff

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m. – 5 p.m.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

• LIBRARY NOTES

of the Argonne National Laboratory. Toronto, Van Nostrand, 1958. 480p., $7.25.)

*THE OILMAN'S BARREL

A short history of the standard oil barrel, the units which make it up, and the legalities connected with it. It contains historical sidelights on the petroleum industry in its early years and of the quest for scientific accuracy in gauging oil. (R. E. Hardwicke. Toronto, Burns and MacEachern, 1958. 122p., $4.75.)

LES PILES ATOMIQUES A NEUTRONS LENTS

This brief account of thermal neutron reactors will be useful to those wanting an overall view of the subject, as well as to students and specialists interested in theories.

The author has based his work on several texts published in the United States, which he cites in his introduction. The treatment of the subject is essentially theoretical and mathematical. (J. Maurin. Paris, Dunod, 1958. 197p., 980fr.)

PRECIS D'ENERGIE NUCLEAIRE, 2ND ED.

The field of nuclear energy is expanding so rapidly that the authors have thought it advisable to bring out a revised edition of their work. New topics covered include: kinetics of nuclear reactors, and the means of regulating the different classes of reactors: a comparison of the different types of reactors; the method of ascertaining the absorption of radiation, and the application of nuclear energy to power production and to transportation.

This is an introduction to the subject of nuclear energy, and its first chapter consists of a survey of modern physics, a knowledge of which is essential to an understanding of nuclear physics. Other chapters cover: the elements of nuclear physics; nuclear reactors, construction and operation; fissionable materials; radiation, its measurement and effects, and protection measures; industrial uses of nuclear energy and radioactive materials. (G. Cahen and P. Treille. Paris, Dunod, 1958. 356p., 3100fr.)

PROSPECTION ELECTRIQUE PAR COURANTS CONTINUS

The first of a series of manuals on geophysical prospecting, this volume is concerned with the various methods of geoelectrical exploration. Geophysical prospecting has been given a great impetus by the search for new sources of oil, and the methods used in this type of exploration can be applied to the fields of mining, public works, hydrogeology, etc.

The methods studied include potential gradient, resistivity, potential drop ratio, the use of the phenomena of spontaneous polarization, and induced polarization.

The author is the chief engineer of the Bureau Minier de la France d'Outre-Mer. (Pierre Lasfargues. Paris, Masson, 1957. 290p., 3000fr.)

*REGISTER OF DAMS IN THE UNITED STATES

In anticipation of the holding of the next International Congress on Large Dams in the U.S., this extensive compilation has been prepared, presenting essential statistics on over 2,800 important dams in the U.S.—completed, under construction, and proposed. The main part of the book is an alphabetical listing of the dams, giving location, structural data, reservoir capacity, ownership, by whom the engineering was performed, and the construction contractors. Additional data: a section containing photographs of over 300 dams; lists of the 100 highest and 100 largest dams, and of the 100 largest reservoirs: an alphabetical list of reservoir names; and a summary of the laws of all 48 states dealing with the supervision and control of dams. The book is sponsored by the United States Committee of the International Commission on Large Dams. (T. W. Mermel. Toronto, McGraw-Hill, 1958. 429p., $15.00.)

• LIBRARY NOTES

*REINFORCED CONCRETE IN ARCHITECTURE

Studies the impact upon modern architecture of the engineering principles underlying reinforced concrete, particularly in the field of thin-shell construction. Surface-resistant forms, prefabricated and prestressed units are analysed, with many drawings and photographs to show the principles involved and their applications. (Aly Ahmed Raafat. New York, Reinhold, 1958. 240p., $15.00.)

SERVOMECANISMES: THEORIE ET TECHNOLOGIE

The first part of this text on servomechanisms is concerned with the theory of the subject, and is primarily of interest to engineers and engineering students. It explains the different methods of calculation of servomechanisms, both linear and non-linear equations and presupposes a knowledge of higher mathematics.

The second section covers the technological aspects; circuits, comparators, amplifiers and motors, regulators, etc.

A brief bibliography completes this survey of the field of servomechanisms. (M. Bonamy. Paris, Masson, 1957. 284p., 4200 fr.)

*SYMPOSIUM ON ION EXCHANGE AND CHROMATOGRAPHY IN ANALYTICAL CHEMISTRY

Papers dealing with materials available, or under development, for ion exchange and chromatography; the basic theory of their use; and examples of their application for separation and analysis of materials. (Philadelphia, American Society for Testing Materials, 1958. 57p., $2.25. s.t.p. 195.)

*SYMPOSIUM ON RADIOISOTOPES

Papers dealing with testing techniques utilizing radioisotope tracing. The wide range of possibilities are illustrated by case histories involving electroplating, the evaluation of rubber deterioration, the mechanism of detergency, and the achievement of process control by means of tracers during refinery operation. (Philadelphia, American Society for Testing Materials, 1958. 94p., $2.75. s.t.p. No. 215.)

*TELEVISION IN SCIENCE AND INDUSTRY

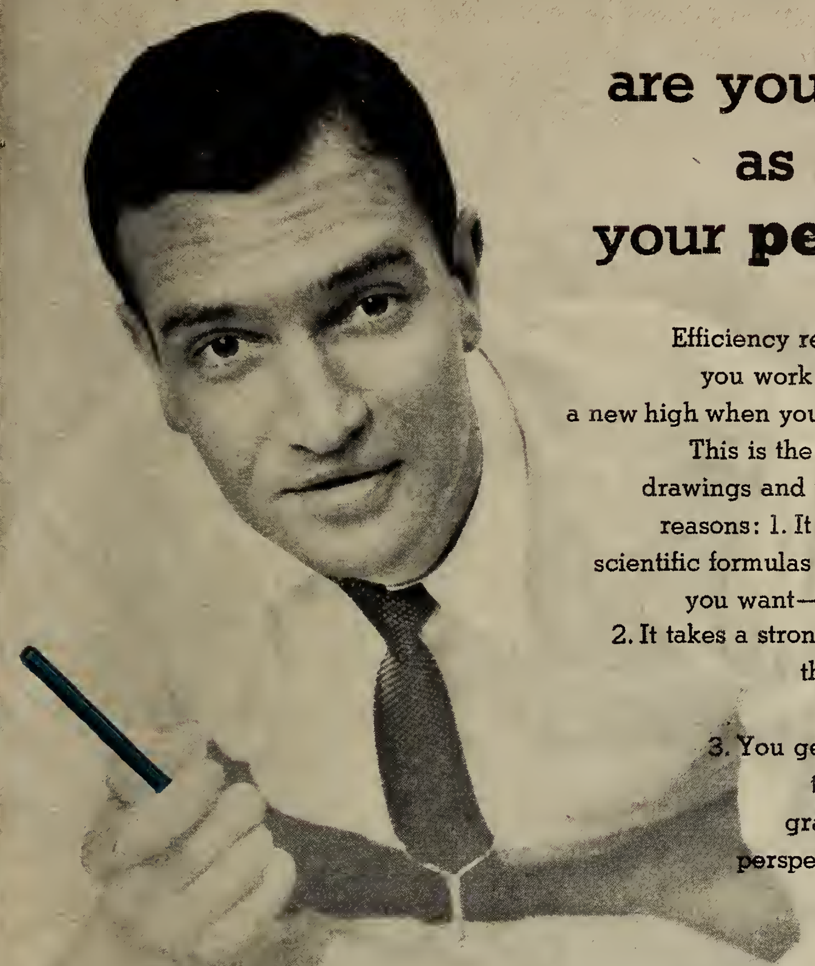
Following an introductory section on the application of television to industry, medicine, and other purposes, the equipment that has been developed is described in detail. Camera design and circuitry of conventional equipment is discussed along with colour and stereo-television apparatus, the electron microscope, and new developments in miniaturization made possible by the introduction of the half-inch vidicon and the transistor. (V. K. Zworykin and others. New York, Wiley, 1958. 300p., $10.00.)

*TRANSIENTS IN ELECTRICAL CIRCUITS

Following introductory chapters on the classical method of solving ordinary linear differential equations by using electrical circuits as examples, the Laplace transform method of solving integro-differential equations is presented. A number of applications are discussed including steady rate response to nonsinusoidal wave shapes and the extension of circuit theory methods to mechanical and electrochemical systems. The concluding chapters deal with Fourier series, integrals, and transforms in the solution of various circuit problems. (G. W. Lago and D. L. Waidelich. New York, Ronald, 1958. 393p., $7.50.)

*TRANSISTOR TECHNOLOGY, VOL. I

An extensive study dealing with the theory and fabrication of germanium transistors. This volume, which is the first of a series, presents the basic framework, and covers the technology of germanium materials, preparation of single crystals, principles of device fabrication, principles of transistor reliability. The presentation follows approximately the chronology of the development of knowledge concerning the subject. An appendix gives definitions and letter symbols relating to semiconductors. (By Members of the Technical Staff of Bell Telephone Laboratories. Toronto, Van Nostrand, 1958. 661p., $19.00.)



are your **pencils** as sharp as your **perspectives?**

Efficiency reaches the vanishing point when you work with an inferior pencil—but hits a new high when you pick up an Eagle TURQUOISE. This is the pencil that tops 'em all for crisp drawings and reproductions, and these are the reasons: 1. It gives you *uniform grading* (17 scientific formulas guarantee exactly the blackness you want—from every pencil, every time!). 2. It takes a strong *non-crumbling needle point* that stays sharp for line after long line of unchanging width. 3. You get inimitable smoothness—thanks to Eagle's exclusive "Electronic" graphite. TURQUOISE makes your perspectives look sharp—and *you,* too!

• **TURQUOISE DRAWING PENCILS:** With 100% "Electronic" graphite. 17 grades, 6B through 9H.

WRITE FOR FREE TURQUOISE SAMPLE
Write for a free Turquoise pencil or drawing lead, specifying grade desired, to Eagle Pencil Company of Canada, 217 Bay Street, Toronto.

• **TURQUOISE DRAWING LEADS:** Fit any standard holder. Grades 5B through 9H.

• **TURQUOISE LEAD HOLDERS:** Hold any grade of Turquoise lead—so firmly that lead cannot be pressed back.

EAGLE TURQUOISE

PENCILS, LEADS AND HOLDERS

are the largest-selling in the United States and Canada!

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Eldorado Mining and Refining Ltd. — The appointment of W. M. Gilchrist as president of Eldorado Mining and Refining Limited has recently been announced.

Dept. of Public Works — E. J. Marten has been named chief of the information services for the Department of Public Works, Ottawa.

Frost Machinery Company — J. P. Frost, founder of the Frost Machinery Company Limited, Winnipeg, has retired from active business after 48 years and named his son, D. P. Frost, president and general manager of the company. R. A. W. Vidler has been appointed vice-president in charge of sales and office management.

Foster Wheeler — G. Merritt has been appointed manager of the process plants division of Foster Wheeler Limited, with headquarters in St. Catharines, Ont. He replaces B. L. Denker who has been transferred to Foster Wheeler Corporation in New York.

G. Merritt

Foundation Company Appointments — R. F. Shaw, M.E.I.C., has recently been elected president, and D. J. Watkins, vice-president, of The Foundation Company of Quebec Limited. Appointments to the Foundation Company of Ontario Limited include: G. Stewart, Toronto district manager; H. V. Koring, divisional engineer; F. G. Pumple, district manager, Sudbury district; R. N. Clark, assistant district manager, Sudbury district; J. M. Cross, district superintendent, London district.

Mersey Paper Company—J. H. M. Jones, M.E.I.C., has been appointed president and general manager of Mersey Paper Company Limited; he succeeds B. J. Waters who will remain as a director. Other appointments announced—J. A. Parker, vice-president, and G. E. Parker, woodlands manager, succeeding R. L. Seaborne who has retired.

Kramer Tractor Company—The appointment of D. E. Kramer as general sales manager of Kramer Tractor Company, Ltd., Regina has been announced by the company management. He now succeeds E. G. H. Robbins, who resigned his position to become vice-president and sales manager of Street Robbins Morrow Ltd., of Calgary.

Molson's Appointment — Announcement has been made of the appointment of C. R. Ostrom as director of production, Molson's Brewery Limited.

Abitibi Power & Paper Co. — J. G. Morrison has been named assistant manager, manufacturing — pulp and board, of the Abitibi Power & Paper Company, Limited, Toronto. T. C. Anderson, M.E.I.C., becomes mill manager, Fort William division.

Hunter Douglas Appointments — The management team for Hunter Douglas Ltd., Montreal, has been announced as follows: P. Kaye, general manager; G. B. Dobby, manufacturing manager; J. A. Bowen, marketing manager; R. C. Griffin, industrial sales manager; and J. M. Riley, comptroller.

D. J. Watkins

B. F. Goodrich — K. Norris has been named power plant engineer for B. F. Goodrich Canada Limited, Kitchener, Ont. He succeeds G. Bruce who retired after 30 years service with the company. F. D. Carney has been appointed to the newly created position of manager, sales services.

Executive Appointment — H. J. Barker has been appointed executive vice-president of Standard Telephones and Cables Manufacturing Company (Canada) Limited; he has also been appointed a director of the company.

Dosco Promotions — As part of the Dominion Steel and Coal Corporation's major reorganization program, the following personnel promotions have been made at the company's new Toronto area plant at Malton, Ont.: P. Bennett has been named general manager succeeding J. C. Coppick who becomes special consultant; E. J. Flannery becomes assistant general manager; A. K. Lajeunesse, industrial and public relations manager; J. Adamson,

● **BRIEFS**

chief accountant; C. R. Sullivan, procurement manager; and P. B. Caldwell, industrial engineer.

Canadian Westinghouse — The appointment of M. C. Lowe as manager of the power transformer division of Canadian Westinghouse Company Limited, Hamilton, has been announced. J. H. Goar, JR.E.I.C., becomes sales manager for the division, and D. Lee, engineering manager. Also announced is the appointment of E. P. Zimmerman as general sales manager for the Company's consumer products operation.

Bechtel Corporation — W. K. Davis has recently been elected a president of Bechtel Corporation. He will be responsible for advanced engineering projects in the nuclear field.

Chemcell Announcement — Canadian Chemical & Cellulose Company, Ltd., has announced the appointment of D. Keefe as president of Chemcell Fibres Limited, a new company established to carry out the yarn and fibre business of its parent company. Mr. Keefe will continue as a vice-president of Canadian Chemical and Cellulose Company Ltd.

International Equipment Co. — D. Carpenter has been named manager, sales and promotion of Bull Moose cranemobiles and lift trucks for the Napanee Iron Works division of International Equipment Company, with headquarters in Toronto. D. Hampson has been appointed branch manager at London, Ont., in the industrial division of the company.

Atlas Asbestos — Announcement has been made of the appointment of W. H. Selby as western branch manager of Atlas Asbestos Company Limited. H. W. S. Grasett has been named Toronto branch manager.

Noranda Mines Appointment — J. N. Anderson has been appointed director of smelting operations for Noranda Mines Limited and its subsidiary, Gaspe Copper Mines Limited.

News of Business and Industry

U.K. Trade with Canada — John Booth & Sons (Bolton) Ltd., England, who have marketed their steel rolling shutters in Canada during the past few years, chiefly around Montreal and Toronto, are interested in increasing their export trade to Canada. They have arranged for A. V. Booth to visit Canada during the autumn of this year with the objects of assessing the market in other parts of the country, appointing further agents and meeting present and potential customers. Mr. Booth arrives in Montreal on September 18th, and his itinerary includes Montreal, Ottawa, Toronto, Winnipeg, Vancouver and Victoria, B.C.

New Location — R. C. Thurber and Associates Ltd., consulting engineers, are now located at 43 Songhees Road, Victoria, B.C., where they have their soils and concrete testing laboratory accommodated in a large new section of the premises. Headed by R. C. Thurber, M.E.I.C., personnel include D. D. Coffey, W. G. Gerry, and T. Glynn. The firm also has an office and a complete concrete and soils testing laboratory in Fort St. John under the general direction of D. N. Roberts.

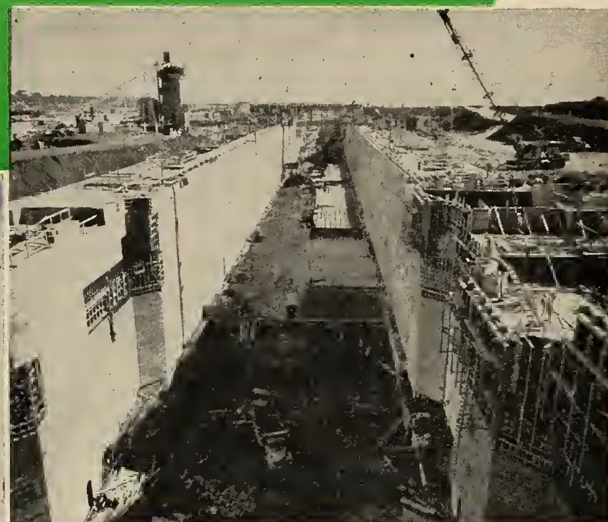
New Armco Plant — Armco Drainage and Metal Products of Canada Ltd. has announced the opening of their 9th Canadian plant, the Dawson Road plant in the Guelph industrial basin. It is designed and equipped as a modern, efficient type for production of steel drainage products. With the transfer of drainage product production to Dawson Road, the existing George Street plant, expanded several times in recent years, will afford greater production facilities for the Company's other metal products, particularly its growing "system of steel buildings". Executive offices remain at the George Street location.

New Maritimes Power Development — The official opening took place recently of the New Brunswick Electric Power Commission's Beechwood Hydro-Electric Development. Completed before schedule by the Maritimes branch of The Foundation Company of Canada Limited, the huge turbines on the project first went into operation in November of last year. The new power development is located on the St. John River ninety miles upstream from Fredericton and sixteen miles from Perth, and commands the outflow of a watershed of some 26,000 square miles.

U.S. Navy Award to Otaco — An Ontario company, Otaco Limited of Orillia, has been awarded the U. S. Navy's Certificate of Merit for "outstanding contribution" to the Department of the Navy. Believed to be the first time a Canadian company has been so honored, the award recognizes Otaco performance in supplying heavy-duty sleds for Navy use in Little America. The sleds, used in the 600-mile trek to a U.S. geophysical expedition near the South Pole, had to withstand the stresses of 20-ton loads carried over rough terrain at temperatures as low as 70 degrees below zero. The problem was met by fabricating essential sled parts at Otaco from ductile iron, a new cast material developed by the International Nickel Company.

Canada Iron Foundries Expansion — Canada Iron Foundries, Limited, Montreal has recently purchased Western Bridge & Steel Fabricators Ltd. Vancouver. At the same time, Canada Iron

ST. LAMBERT SEAWAY LOCK



The electrical lighting, power to operate the St. Lambert Seaway Lock, located on the South Shore of St. Lawrence River, near Montreal Victoria Bridge, is NOW BEING INSTALLED by

• BRIEFS

Foundries have also announced their purchase of C. W. Carry Ltd., Edmonton, and Calgary Structural Steel Ltd., Calgary. These three companies become members of The Canada Iron Group of Canada-wide industries, which means that Canada Iron will now have steel fabricating plants operating in Vancouver, Edmonton, Calgary, Toronto, Ottawa, Montreal and Halifax.

New Foundation Subsidiary—The formation of a new subsidiary, The Foundation Company of Quebec Limited, has been announced by The Foundation Company of Canada Limited. The company will have its head office in Montreal, and will be headed by R. F. Shaw, M.E.I.C., executive vice-president of the parent company. D. J. Watkins has been named vice-president and general manager: other officials include J. F. Masterson, vice-president; E. T. Grearson, secretary; W. J. Daly, treasurer. J. F. Benjafield, M.E.I.C., has been appointed district manager.

Parts & Service Centre—A sign of expansion at General Motors Diesel Limited, London, Ont. is the recently completed parts and service centre, situated east of the main plant and offices. With a floor area of 34,650 sq. ft. the warehouse section stocks parts for customers. Facilities for receiving and shipping include a recessed track capable of handling two railroad cars and up to three trucks. New type dock ramps, operated by counterbalances, automatically compensate for changes in the height of the truck racks as they are loaded or unloaded.

Automatic Letter-Sorting Machine — Automation has come to one of the United States' busiest post offices. In ceremonies on the work floor of the City Post Office recently, a chrome-plated electromechanical letter-sorting machine that is handling more than a quarter of a million pieces a day, was placed in official operation. Built by a Belgian subsidiary of Standard Telephones and Cables Mfg. Co. (Canada) Ltd., the semi-automatic machine permits each of six operators, sitting at keyboards, to sort 3,000 letters to 300 destinations every hour. It is being used to sort mail from the Washington Post Office to all principal cities in Virginia and many states throughout the country.

Iron Ore Processing—Developments in Canadian iron ore processing prompts Allis-Chalmers to extend pilot plant operations at Carrollville, 15 miles south of Milwaukee. The plant's larger and improved equipment will make possible expanded activity in the processing field. The facilities will be adaptable to almost any process involving burning materials in a rotary kiln. One would be the burning of lime, quantities of which are used in the chemical, paper manufacture, and water conditioning industries. However, the main work will be on iron ore processing and manufacture of cement clinker.

New Basic Industry at Dawson Creek—Canadian Liquid Air Company Limited

recently announced that construction of a new manufacturing plant for oxygen and acetylene will start this season in Dawson Creek, B.C., bringing to 44 the number of production installations established by Liquid Air. Initial investment will be in excess of a quarter million dollars. From its Dawson Creek plant Liquid Air will serve users of compressed gases and welding products in north-eastern British Columbia, the Peace River area or north-western Alberta, and the rapidly developing Northwest Territories, Mackenzie River Valley, and Yukon Territory.

"Dyfoam" Distributor—Appointment of Dominion Tar and Chemical Company as exclusive Canadian distributors of "Dyfoam," the new light-weight, expanded polystyrene, has been announced. The building supplies division of the company will handle the new product recommended for refrigeration and perimeter insulation and general building construction as well as for the buoyancy and novelty fields. Dyfoam is said to have exceptionally low thermal conductivity (K=0.25 at 40° F.) and high compression strength, and at the same time to be extremely light in weight (1 lb. per cu. ft.). It is claimed that, because of its resiliency, Dyfoam does not splinter or crack in handling or application.

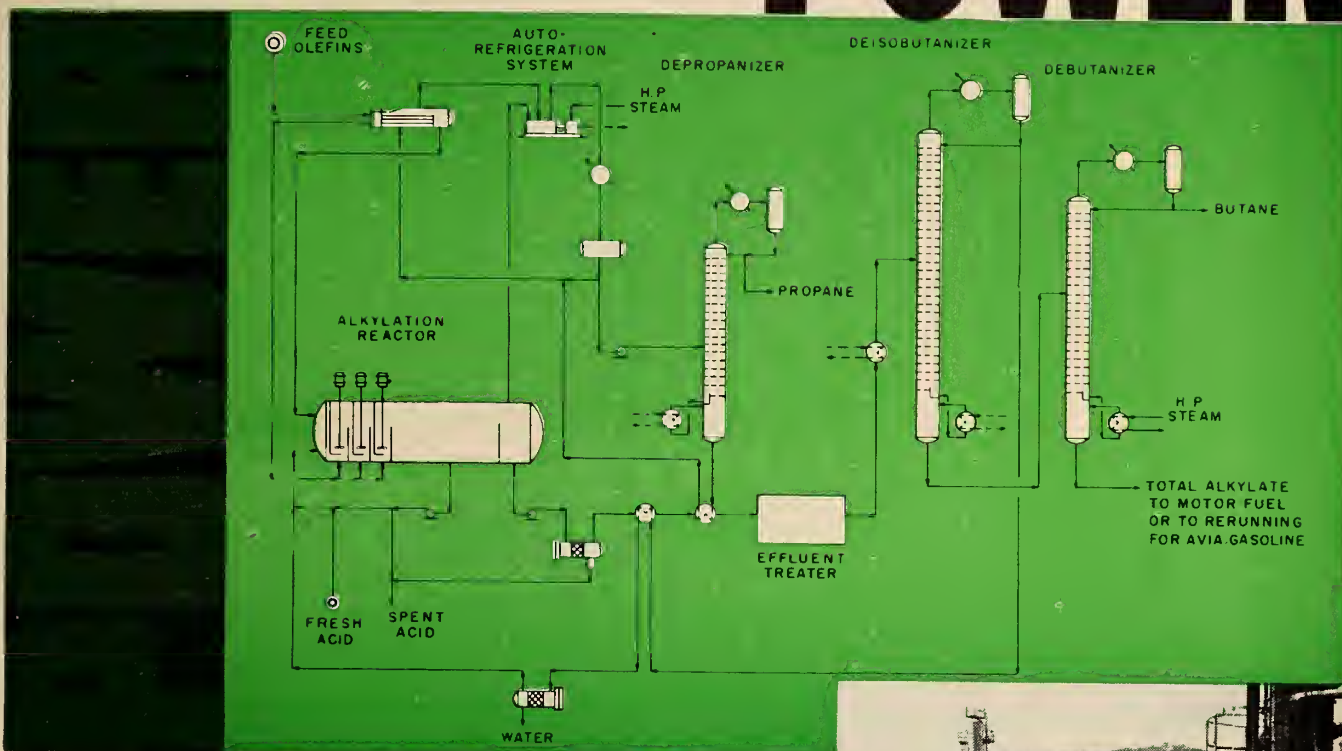
Expanded Erco Technical Facility—The Electric Reduction Company of Canada, Ltd., Toronto, will expand its present chemical research facilities 100% by February, 1959, according to a recent announcement from the company. Electric Reduction Company is one of Canada's leading suppliers of phosphoric acid, sodium and calcium phosphates, organic phosphates, and sodium and potassium chlorates with plants at Buckingham and Varences, P.Q. and Vancouver, B.C. The department will be established in its own building in Toronto and its facilities will aid in maintaining the company's contribution to research in pulp and paper, uranium extraction, mining and metallurgical, paint, petroleum, plastics, detergent, metal finishing, food processing and agricultural industries in Canada.

Nuclear Power Station — The Taylor Woodrow Group, which consists of over 40 subsidiary or associated companies operating throughout the world, report that among other projects in hand is the building and civil engineering work on the world's largest nuclear power station, Hinkley Point, designed by the English Electric-Babcock and Wilcox-Taylor Woodrow atomic power group in association with the Central Electricity Generating Board. Work on this is well in hand, reports Taylor Woodrow, an excellent start on construction having been facilitated by the speedy execution of the six-mile access road contract.

Lighting Research — The first research laboratory in the Canadian lighting industry was officially opened recently at the plant of J. A. Wilson Lighting & Display Limited in Toronto. The new laboratory provides complete up-to-date facilities to investigate the performance of lighting units and light sources. Constant investigation and control of materials will provide a means of increasing the efficiency and comfort factors in lighting. Temperature testing is conducted to the requirements established by the Canadian Standards Association. A unique feature is that customers may witness or conduct their own tests on lighting products and make comparisons.

New Technical Laboratory—Du Pont of Canada (1956) Limited announced recently that a technical laboratory costing about $700,000 will be built at its Maitland Works, on the St. Lawrence River between Brockville and Prescott, Ont. The two-storey brick and concrete structure, 150 by 85 feet, will house general purpose laboratories, two-man research units, a metallurgical laboratory, a two-storey semi-works area, library, conference room and offices. The present technical laboratory then will be used as an addition to the Works' analytical laboratory which performs much of the routine chemical analyses for the plants on the Maitland site. Since opening of the original nylon intermediates plant at Maitland in 1953, two additional plants have been erected on the site and a third is under construction. The additional plants produce "freon" fluorinated hydro-

Alkylation points the way to POWER



Power to win the Octane Race

The pace-setters in the octane race are adding alkylate to their gasoline pools. Alkylate raises the octane number where it counts—on the road.

In the refinery, Kellogg's Sulfuric Acid Alkylation process has proved to yield a superior alkylate. Measured by every standard—by quality and quantity of yield . . . by initial investment . . . by operating costs—Kellogg's process gives optimum results.

Kellogg offers unequalled experience in this field. Present advanced designs, utilizing a unique multiple-stage cascade reactor and auto-refrigeration system, provide greater isobutane efficiency, low acid consumption, minimum investment in recycle and auxiliary equipment and lower power costs.

Canadian Kellogg welcomes the opportunity to discuss its alkylation process in detail . . . and to acquaint refiners with improvements its engineers are continually making.

Latest Canadian Kellogg Alkylation Unit constructed at the British American Oil Company Limited refinery in Vancouver.

Our affiliates, T. I. W. Western, Ltd., Edmonton, Alberta, with their modernized and expanded plant facilities, are well qualified to look after your fabrication needs.

The **Canadian Kellogg**

COMPANY LIMITED—TORONTO, ONTARIO

OIL — CHEMICAL PLANTS · REFINERIES · POWER PIPING carbons, gases used in the refrigeration and aerosols industries, and "orlon" acrylic fibre used by the textile industry. The third, scheduled to go into operation this summer, will produce hydrogen peroxide.

Distillate Hydrodesulphurizer—Shell Oil Company of Canada, Limited, announce that they will build a distillate hydrodesulphurizer at their Shellburn refinery, North Burnaby, B.C. A contract for the construction of the new unit has been awarded to the Fluor Corporation of Canada, Limited. Shell Oil state that construction will be completed by February, 1959. Total cost of the project including the addition of necessary auxiliary equipment is in excess of $2 million. The operation, called trickle-phase hydrodesulphurization, employs a patented Shell process designed to reduce the sulphur content of distillate oils. The company state that it is a process which is becoming increasingly important in the production of fuels of still higher quality for future diesel, heating oil, and aircraft applications.

WHERE ARE OUR BANNERS?

Headquarters regrets having to report that during the last night of the Annual Meeting at Quebec City in May, 1958, the four large Engineering Institute banners disappeared from where they were hanging, and have not been seen since.

These banners are expensive and difficult to obtain and the task of replacing them would not be an easy matter. If any members know of their present whereabouts they are urged to have them returned at once to Institute Headquarters in Montreal.

Sewer Project—Construction of the new Humber Valley trunk sewer for the municipality of Metropolitan Toronto, one of the most ambitious pollution control programs ever undertaken on this continent, is now proceeding. The two-mile conduit, large enough to drive a car through, will serve 50,000 acres with 350,000 residents; an anticipated population of 800,000 within a few years. Because of the developed residential area it penetrates, Metropolitan Toronto authorities called for an alternative to the conventional drill and blast method of tunnelling. The contractors for the Humber sewer project, The Foundation Company of Ontario, developed, in collaboration with J. S. Robbins, designing engineer, a 60-ton, 25 foot machine which is now boring steadily through rock fifty to a hundred feet below ground, undetected by thousands of residents in the immediate vicinity.

Long Safety Record—Consolidated Mining and Smelting Company employees worked 36 consecutive accident-free days in April and May, according to a company release. The record was established by a force of over 7,000 men involved in mining, plant and shop work and totals 1,404,576 man-hours. The best previous company record was 16 accident free days, a mark set in 1953.

New Polyethylene Film Plant—Visking's new polyethylene film plant is now operating in greater Winnipeg, according to an announcement from the Visking Company, Division of Union Carbide Canada Limited. The Winnipeg plant is Visking Company's second polyethylene film plant in Canada; the other film operation is at Lindsay, Ont.

Electronic Communication System — A new British electronic communication system which many experts believe to be one of the most important advances in its field for many years, has recently been opened. "STRAD", as the new system is called, is made by the British associate of the telecommunications company Standard Telephones and Cables Mfg. Co. (Canada) Ltd. "STRAD" stands for Switching, Transmitting, Receiving and Distribution System. Its job is to make a decisive reduction in the time taken to handle the many telegraph messages vital to the control of modern aircraft, a fundamental necessity in the new jet

age. Messages from many sources overseas pour into "STRAD" where they are recorded, sorted into their proper priorities and directed to the correct recipients or, if required, to many recipients simultaneously. This switching and sorting function is carried out at high speed by the electronic devices which are built into the system.

Bestpipe Expansion — A concrete pipe manufacturer, Bestpipe Ltd. of Kitchener, Ont., has recently added 7,500 sq. ft. of new manufacturing space to their Kitchener plant. Bestpipe develops and manufactures the 6 ft. pipe in sizes up to 84 in. and the 8 ft. pipe in sizes 18 in. to 36 in. Along with the 6 and 8 ft. pipe, Bestpipe has introduced the press-seal rubber concrete pipe gasket joint to Canada.

New Equipment and Developments

Welding Products—The development of two new welding products has been announced by The International Nickel Company, Inc. The new products are Inco-Weld "A" wire, for welding of dissimilar alloys by the inert-gas welding process, and Inco-Hard "1" electrode, for hard-surface overlaying of low-alloy steels and cast irons. Developed at Inco's Bayonne, N.J., research laboratory, each of the products are said to offer specific advantages for the welding field.

Photo-Recording Paper — A new photo-recording paper which is said to be capable of providing an instantaneous visible record of instrumentation tests data, is now availablee from Canadian Kodak Co. Limited. Designated as Kodak linagraph direct print paper, the new photo-recording material may be used in conjunction with several new, special-type moving-mirror galvanometer oscilligraphs. Kodak points out that the new paper should find wide application for immediate read-out of test results in the missiles and aircraft field, oil exploration, automatic, medical, nuclear, and many other control, production, and computing.

New Tooling Compounds — Two new two-component (steel oi aluminum and epoxy-type resin) punch-and-die materials designated as "3M" brand tooling compounds 113 and 112 have been announced by the new products division of Minnesota Mining and Manufacturing of Canada Limited. According to the company, these tooling compounds require no critical weighing, mixing nor timing, thus needing no special equipment. Unused portions of both parts can be returned to their containers for future use. There are no pot-life problems nor toxicity hazards to trouble the tool maker. Also, semi-skilled labour can be easily trained to use the material.

Airborne Profile Recorder — Canadian Applied Research Limited, Toronto, announced recently that its MK5 airborne profile recorder has been installed in specially designed Lockheed prop-jet aircraft for a U.S. Air Force mapping project. The airborne profile recorder, designed and built in Canada by CARL, is an improved precision radar designed for air survey work, and measures and records the rise and fall of land the aircraft is flying over. It is capable of measuring topography from 1,000 to 35,000 feet with a high degree of accuracy, and provides two records simultaneously on a paper chart recorder. One record gives the height of the terrain beneath the aircraft in reference to sea level; the other gives the distance between the aircraft and the ground.

New MIGet Aircomatic Gun — Air Reduction Canada Limited is introducing to the Canadian welding trade a new aircomatic gun and the control unit known as the MIGet. Airco pioneered the aircomatic metal inert-gas process ten years ago The new light-weight portable MIGet handgun is said to make the hardest-to-reach joints a simple matter. Continuous wire feed, from a spool in the gun, is claimed possible at speeds up to 400 in. per minute. Wires of 3/64"

Jet Piercing is a development of Linde Air Products Company, Division of Union Carbide Canada Limited

3,000° F. JET FLAME DRILLER

... relies on tough Goodyear Hose

To increase tempo of blasting schedules on the St. Lawrence Seaway and Power Project, a Jet Piercing machine was used. The Jet Piercer literally burned blast holes in the hardest spallable rock formation up to 12 times faster than any other method.

Here's how it works: A burner, suspended from a long tube combines oxygen with a petroleum base fuel to produce a jet-type flame of well over 3,000° F. that disintegrates or spalls rock in its path. The force of burning gases, plus steam formed from cooling water which flows to the burner, carry the spalled particles out of the hole.

The problem was to supply fuel to the burner. Hose was the answer but exposure to steam, fuel, oxygen and searing hot abrasive particles played havoc with ordinary hose.

The Goodyear Representative analyzed this situation and recommended that Emerald Cord Hose be used. This super-tough, oil-resistant hose takes rough treatment in stride . . . lasts for months . . . is now included in standard specifications.

If you are ever in doubt of what hose to use, call the Goodyear Representative at . . . Moncton, Saint John, Quebec City, Montreal, Toronto, London, Windsor, Winnipeg, Regina, Saskatoon, Calgary, Edmonton, Vancouver, or Head Office . . . New Toronto.

INDUSTRIAL RUBBER PRODUCTS ENGINEERED FOR THE JOB

GOODYEAR

THE GREATEST NAME IN RUBBER

and 1/16" diameter in aluminum and 3/64" diameter hard wires are available in one pound spools making the total weight of the gun 4½ pounds.

Air-Cooled Diesel Engines—Rushton & Hornsby Ltd. have extended their range of air-cooled engines with two new diesels identified as the 'YWA' and the 'YDA', and these new units embody all the design features which past experience has revealed to be desirable. The Class 'YWA' is a 4-cycle air-cooled engine of 4 in. bore x 4⅛ in. stroke, manufactured in 1 and 2 cylinder sizes providing a power range from 6-24½ b.h.p. at an automotive rating over a speed range of 1000-2200 r.p.m. The British Standard rating is from 6-19 b.p.h. at 1000-1800 r.p.m. The class 'YDA' is a 4-cycle air-cooled engine of 4⅜ in. bore x 5 in. stroke, manufactured in 2, 3, 4 and 6 cylinder sizes, providing a power range from 16-110 b.h.p. at an automotive rating over a speed range from 1000-2200 r.p.m. The British Standard rating is from 16-87 b.h.p. at 1000-1800 r.p.m.

New Pressure Regulator—A new development in a single-stage pressure regulator has recently been brought about by design engineers of Canadian Liquid Air Co. Ltd. The main feature of this new regulator is an inexpensive replaceable cartridge which contains all the vital components. Now, with only one spare part, over 90% of all normal regulator repairs can be made in a few minutes by anyone, Liquid Air states. A simple key or tool will remove the defective cartridge which can be replaced by a new one in a few minutes. This feature, exclusive to Liquid Air regulators, has been adopted for both the oxygen and acetylene single-stage L.A. regulators.

Airborne Television Transmitter—A low-power television transmitter has been developed by Electronics Development Co. Inc., of North Hollywood, Calif. Incorporating a wideband sub-carrier channel diplexed as a part of the video signal, the unit may be used to transmit a high resolution 6.5 mc. television picture complete with sound, or for transmission of fast rise data pulses combined with telemetered information. Amplitude modulation is employed between 370-450 mc. Canadian representative: Tele-Radio Systems Ltd., 3534 Dundas St. W., Toronto 9.

"Secar 250" Hydraulic Binder—Ciment Fondu Lafarge (Canada) Ltd. announce availability in Canada of Secar 250, a super-duty high purity white calcium-aluminate hydraulic binder, with less than 1% iron compounds and silica, providing service temperature to 3300° F. The introduction of Secar 250 will answer many problems formerly confronting the refractory concrete user, particularly resistance to slag, spalling and corrosive atmospheres, the company claims.

As Secar 250 and Ciment Fondu are complementary to one another, the refractory user now has the choice of two aluminous cements, which between them will make refractory concretes (refractory castables).

Speed Reducers—Foote duti-rated shaft mounted speed reducers with capacities from ¼ to 40 h.p. are now offered through their distributor Jeffrey Manufacturing Company Limited of Montreal, with branches and distributors throughout Canada. An important design feature of the new units is the incorporation of Foote Bros. duti-rated lifetime gearing, which is high hardness, high capacity gearing designed to provide optimum power transmission efficiency and service life.

Heavy-Duty Foot Switches—A redesigned line of heavy-duty, foot-operated switches to meet a greater variety of operating needs has been announced by the Allen-Bradley Canada Ltd., Galt, Ont. The Bulletin 805, Style A, foot switch base and cover are sturdy, lightweight aluminum die castings. Three different styles are available to provide a guard extending over the top of the foot treadle, a guard covering the top and sides of the treadle, and an open treadle. The broad treadle is easy to reach and is placed close to the floor to minimize operator fatigue.

Motor - Alternator Set — The British Thomson - Houston Company has announced a new type of vertical medium rating (75-300 kW) high - frequency generating equipment for induction heating and melting applications at a frequency of 8.7 Kc/s. The new motor-alternator set, being arranged for vertical operation, is said to occupy far less space than a normal horizontal machine of the same rating. Furthermore, it is claimed to be very quiet in operation.

Electronic Scales — Philips Electronics Industries Ltd., Toronto, have recently announced the availability of custom installations of electronic scales. These scales will eliminate entirely all moving parts in the balancing mechanism which is therefore completely free from wear and resulting maintenance. The object to be weighed is either placed on or supported by one or more strain gauge load cells which are individually sealed against moisture and dust. The company claims the load cells are so constructed that no maintenance of any kind will be required for years.

Tilting Motorbases—The latest addition to the Lovejoy line of tilting motorbases is known as model 203, and is especially designed for motors from 1 to 3 horsepower. It is made to fit both old and new NEMA frame sizes. Model 203 is said to have positive tilt operation through a very practical spiral screw mechanism, which increases or decreases the distance between drive and driven pulleys and provides easy means of belt tension adjustment without the need of an idler. Where cone step pulleys are used, this feature can well be appreciated by anyone who has had to deal with this type of work. The Lovejoy line is distributed

NEW TORONTO ONTARIO

● **BRIEFS**

in Canada by Irving Smith Limited, Montreal 28.

New Product—Production of oxygard, ditertiary-butylpara-cresol, has commenced at Naugatuck Chemicals plant, in Elmira, Ont., according to an announcement by the Naugatuck Chemicals division of Dominion Rubber Company Limited. Oxygard is a technical grade antioxidant for industrial applications, supplied in a non-dusting flake form. It is used in gasoline and lubricants as a general antioxidant and gum formation inhibitor. In the plastics industry it is finding application as an antioxidant for polyethylene and high impact polystyrenes, while it is also used in rubber product manufacture as a non-staining and non-odorous antioxidant.

New Rex Truck Mixer—High-speed cycle, along with achievements in design and operational simplicity, keynote the new Rex 6-yard adjusta-wate moto-mixer, now in production by Chain Belt (Canada) Ltd. Styling of the new model shows modern, functional treatment, resulting in easy operation and clean-up. There is new single-lever operation and a newly designed instrument panel with all the controls clustered close helping to insure overall operating efficiency.

Publications

Tar Derivatives — "Coal Tar Products" is a new folder offered by the tar division of Dominion Tar and Chemical Company, Limited. The folder describes available coal tar derivatives and their typical applications.

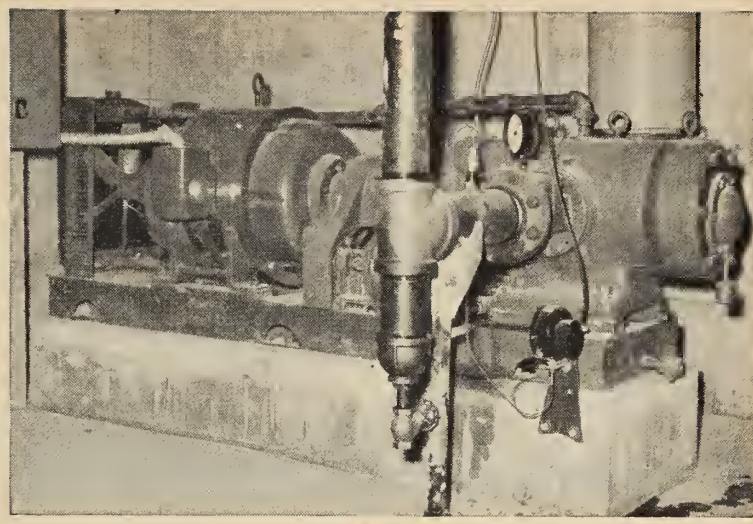
"Progress With Power" — The Canadian General Electric Company Limited has issued an attractive pamphlet, available on request, entitled "Progress with Power" which shows in graph form Canada's yearly electrical output from 1929-1957. Prepared from DBS statistics, the chart shows firm energy (total output including industrial energy, less export and secondary energy), indicating separately the amount of export and secondary energy. Sub-charts illustrate the yearly rates of growth since 1949 of utility and industrial power generation in the five principal economic regions of Canada. Another chart shows the Canadian power industry capacity from 1950-1960, based on 1957-60 estimates.

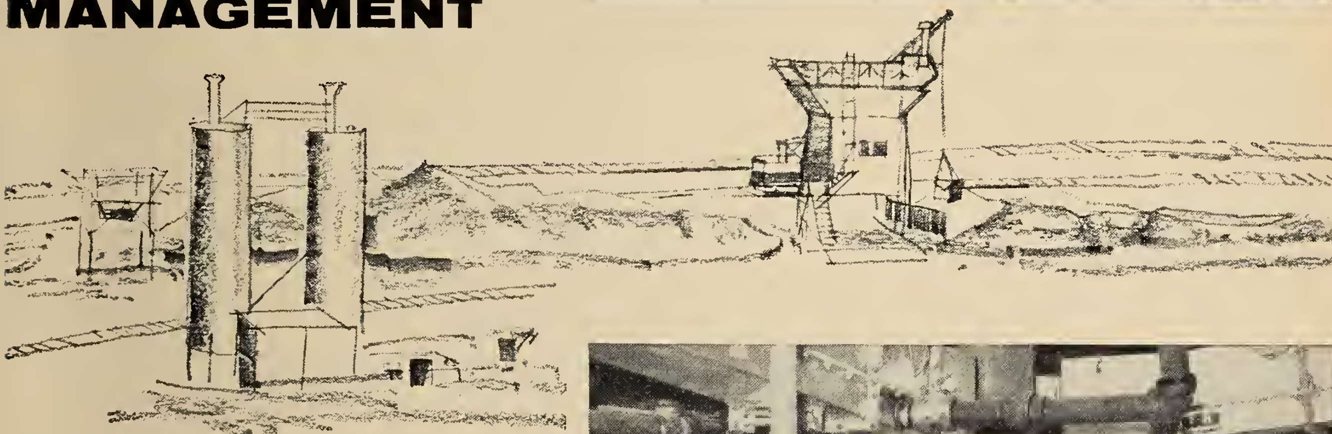
Vari-Basic Units — Performance characteristics and important dimensions of Vari-Basic blower units in No. 916, No. 1020 and No. 1220 sizes have recently been published for the first time in a six-page technical bulletin which is obtainable on request. A set of performance curves for each of two widths of each unit size gives static pressure and brake horsepower as functions of flow-rate output at four motor speeds. In addition, four tables give 15 dimensional specifications for the three Vari-Basic

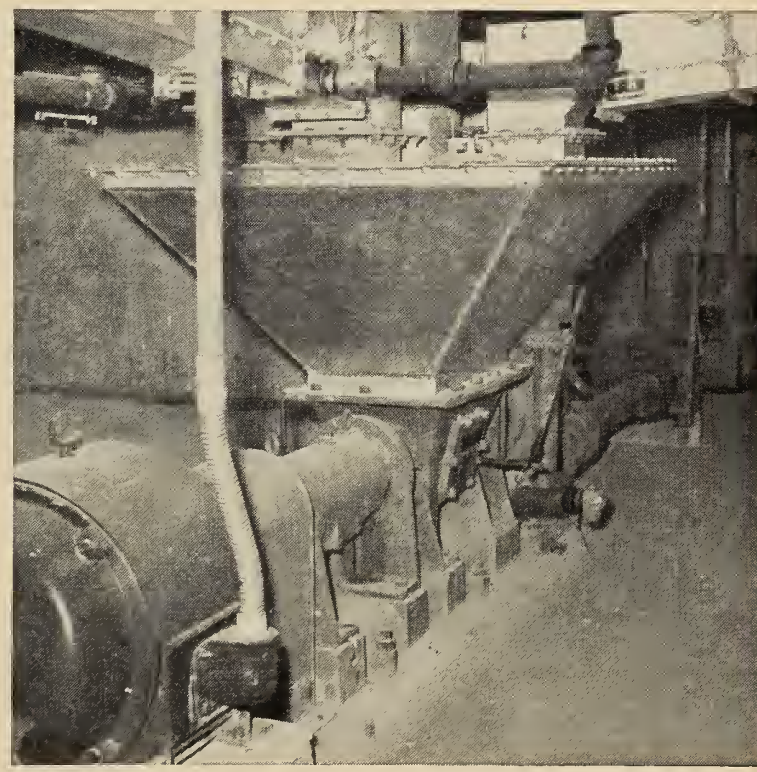
FUNCTIONAL LAYOUT

PROPER EQUIPMENT

EFFICIENT MANAGEMENT







Shown above is a fraction of the well-run S. McCord & Co. Limited yard at Rexdale, Ontario. Recently added to the McCord facilities are these two ERIE cement silos providing a storage capacity of 3000 barrels, and the ERIE Batching Plant at rear.

Cement is delivered by bulk trailers or rail cars and carried by FULLER-HURON Airslides to a 6″ FULLER-KINYON pump beneath the floor of the pump house. The cement is pumped from here to storage in the silos. Reclaiming from the silos is achieved through remote control by the batching plant operator. The FULLER-KINYON pump fills his needs through 300 feet of 5″ underground conveying line at the rate of 180 barrels per hour. This pump is powered by a 50 h.p. motor.

Air for this operation is supplied by a FULLER C-100 Rotary Compressor, a self-contained unit including radiator, fan and 50 h.p. motor.

These photographs have been left completely unretouched so that you can observe the cleanliness and compactness of this FULLER installation—typical of the many advantages of FULLER Air Handling Systems.

sizes in two widths for four discharge positions: top horizontal, bottom horizontal, upward and downward. The Torrington Mfg. Co. of Canada Ltd.

Dominion Bridge Booklet — A 64-page illustrated booklet entitled "Builders in Steel" has recently been issued by Dominion Bridge Company Limited, Lachine, Que. It provides a comprehensive account of this company's activities and its manufacturing facilities from coast to coast.

New Waldron Coupling — Peacock Brothers Limited have recently published a bulletin, No. 58, in which complete details are given on a new Waldron gear-type flexible coupling.

Cylinder Piles of Prestressed Concrete — The Raymond Concrete Pile Company have published a 24-page well-illustrated catalogue, CP-3-C, describing the Raymond cylinder piles and related prestressed concrete products.

Sewage and Drainage Pipe — The No-Co-Rode Company Limited has recently printed a new fully illustrated and detailed catalogue on No-Co-Rode sewage and drainage pipe. Available from Alexander Murray & Co. Ltd., 1661 Sun Life Building, Montreal.

Home Heating — A specially-written, thoroughly-illustrated booklet "Gurney Guide to Better Housewarming" describing how to judge the effectiveness of a home heating system, has recently been published by American-Standard Products (Canada) Limited. Explanations in simple terms, along with clear diagrams, are used to explain the network of ducts and the functions of the furnace. The booklet is obtainable free through American Standard Products (Canada) Limited, Toronto.

NEWS OF OTHER SOCIETIES *(Continued from page 156)*

The first moon rocket vehicles will undoubtedly be relatively small and rockets with sufficient power already are under construction. Convair has reported preliminary designs for a 200 foot, 90-ton two-stage chemo-nuclear vehicle capable of landing a payload of 22,000 pounds on the moon during 1958-60. Company engineers say that during 1964-70 it will be possible to land instrumented vehicles on the moon, send out manned rockets for lunar reconnaissance, and finally to land small scouting parties. A successful moon landing will require a manned-vehicle.

The US Air Force X-15 aircraft is being designed to fly short hops on ballistic trajectories up to the height of satellite orbits, but flights would be of short duration and carry out the re-entry manoeuvre on each trip. Mr. Watson believed the manned vehicle will be placed in orbit with the capability of re-entering the atmosphere at a pre-determined point.

Convair has presented a serious proposal to establish a manned space station of more than seven tons, using seven Atlas rockets to transport the component part into orbit.

To achieve travel beyond the moon, space ships would need to attain an escape velocity of seven miles per second. Because the planets travel about the sun in practically the same plane, the velocity of the earth around the sun will contribute to establishing an orbit about the sun for a space vehicle. If it leaves the earth in the correct direction, a space vehicle would require a velocity only slightly greater than the escape velocity to establish an orbit about the sun which would intercept Venus or Mars, the two planets of greatest interest to us.

Venus is on an inferior orbit to our own and Mars is on an orbit greater in diameter than ours. The first trips to the moon or either of these planets will be on a return basis in which a space vehicle might orbit about the destination a number of times and then accelerate sufficiently to return to earth. Since the moon, Venus, and Mars are all smaller masses than earth, the escape velocity and, therefore, the fuel required for return would be less than that needed to escape from earth.

Mr. Watson pointed out that for many years people have been speculating about travelling to the moon. Contributing to the difficulties of such a project is the fact that the moon has practically no atmosphere and that it is very hot during the lunar day and very cold at night. To live there would require the establishment of dwellings, workshops, and vehicles — all pressurized and air-conditioned in a fashion similar to that of high altitude aircraft.

The moon nevertheless, would offer many advantages as an intermediate station for space travel, particularly because it has an escape velocity of only 2 miles/sec. and already possesses a velocity which corresponds closely with the earth's solar orbital velocity.

The year 1958 corresponds with that period when explorers returned from the discovery of the North American Continent. Their return stimulated activity for exploitation of the New World and provided man to meet the challenge of long distance travel. Ships were improved, the provisioning of food supplies for long voyages was undertaken, improvements were made in navigational methods and many other related activities were stimulated.

The challenge of space travel lies before the inhabitants of the world today and the large rockets and earth satellites now in existence have changed this subject from one of incredulity to one of general acceptance.

On this new basis, Mr. Watson believed that rapid progress would be made in the conquest of space.

IN THIS ISSUE

During September there were many important meetings concerned with power, including the World Power Conference, Canadian Sectional Meeting; the International Conference on Large Dams; and the Geneva Conference on the Peaceful Uses of Atomic Energy.

Because of this current interest, the October issue of the *Journal* is largely devoted to the subject of power, and includes a review of recent developments in all the provinces of Canada, with a special article on nuclear power in Canada.

There are also reports of the Canadian and Geneva meetings, and the engineering problems of using tidal power are discussed in a paper on the Passamaquoddy Tidal Power Project.

MEET THE AUTHORS

Gerald Millar, Chief Engineer, Harbours and Rivers Engineering Branch, Department of Public Works, Ottawa, *(The Passamaquoddy Power Development).*

Mr. Millar studied engineering at Ecole Polytechnique, University of Montreal, graduating in 1937 with the degree of B.A.Sc.

After survey work in northern Quebec, he joined the engineering branch, Federal Department of Public Works, in June 1937 as a junior engineer attached to the Ottawa district office.

Enlisting as a sapper in the Royal Canadian Engineers in February 1943, Mr. Millar was discharged in November 1945, with the rank of Lieutenant. He then returned to the Department of Public Works and served in the Rimouski and Quebec District Offices.

Mr. Millar rejoined headquarters at Ottawa in September 1947, and served there until June 1949 when he was transferred to St. John's, Nfld., as District Engineer. In February 1955, he returned to Ottawa from Newfoundland on being promoted to the position of Supervising Engineer—Eastern region. He eventually became chief of the Maintenance and Operations Division of the Branch and was promoted to chief engineer in March 1957.

M. H. Thomas, General Superintendent, Chemical Operations, Atomic Energy of Canada. Attended University of New Brunswick, B.Sc. (*A special report on nuclear power developments in Canada*), (Hons. Chem.), University of Toronto, M.A. Physical Chem. Chief Chemist for Defence Industries Ltd. at Valleyfield and Nobel during the war years in explosive manufacturing. In 1945 with Defence Industries at Chalk River where associations have been with Chemical Control, Isotope Productions, Chemical Extraction and general chemical problems relating to Reactor Technology.

The Ontario Hydro pumping-generating station has an installed capacity of 282,000 h.p. from its six units.

POWER

A REVIEW OF RECENT CANADIAN DEVELOPMENTS

THIS REVIEW attempts only to indicate the general growth of electrical power developments in Canada during approximately the past two or three years, and to record, where possible, the major power projects that are in hand or planned for a similar period ahead. The review will discuss these power developments in each province.

It is well known that Canada has ample resources, such as water power and fossil fuels, from which to produce sufficient electrical power to meet the needs of a rapidly-growing population and industry for many years to come. However, it is equally well known that these resources are by no means all available in the right place or at the right price.

A recent estimate shows that rather less than 28 per cent of the available water power in Canada has yet been developed. There is therefore a very large potential still available, but here the 'wrong place' principle may be well illustrated by the highly-industrialized province of Ontario, which needs large amounts of power but which has already developed so much of its major water power resources within economic distances of the large load centres, that plans in the province are turning towards additional thermal stations to supply the needed power.

Coal is a suitable source of thermal energy for such stations, and at the same time Nova Scotia not only has plenty of coal, but depends to a large extent, economically, on selling it. There is little physical difficulty in moving large amounts of this coal from Nova Scotia to Ontario, particularly now that the new St. Lawrence Seaway route is shortly to be opened to traffic. However, this is where the principle of 'wrong price' is exemplified, and it is an unfortunate fact that, speaking generally, coal can be delivered to a thermal station in Ontario more cheaply from United States sources than from the Canadian coalfields.

(It is true that the government has assisted the coal industry in Nova Scotia to market at competitive prices by an appropriate allowance for reduced freight rates, but the example is true under normal conditions.)

Integration of Sources

To be more specific than the general points mentioned above, the problem of supplying power economically and reliably to both large centres and small, scattered consumers (such as in rural areas) can be resolved only after considering many inter-related physical and economic factors. Today, and looking at future demands, increasing consideration is being given to providing power from integrated systems that may combine both hydro-electric and thermal sources. In Canada, such provinces as Quebec can continue for a considerable time to rely mainly on developing their available water power resources, though such developments will almost certainly eventually be integrated into large networks, rather than being planned to serve only a specific area.

Since thermal power stations operate most efficiently at a steady load, it is often desirable, in an integrated scheme, to use thermal stations to supply the estimated steady base load, bringing in additional power to meet peak loads from the more flexible hydro-electric generating station.

Another development which is receiving wide attention is the use of pumped storage associated with hydro-electric generating stations. A notable example of this is the pumping-generating station of Ontario Hydro at Niagara Falls, Ont., which will be mentioned later.

Trend to Thermal Power

At the end of 1957, the total installed capacity of water-power plants in Canada was recorded as 19,871,008 h.p. (equivalent approximately to 14,821,800 kw.). The net generating capacity of central thermal stations in Canada in 1956 was 2,142,000 kw. (a 272 per cent increase since 1950), with a projected total, by 1960, of 4,316,000 kw. — more than double the 1956 figure.

It is estimated that the growth trend ratio of thermal to hydro-electric capacity was 1 : 15 in the ten-year period 1935 to 1945; 1 : 7 during 1945-55; will be 1 : 4 for the ten years 1950-60; and projected over a thirty year period 1951-81 will reach a ratio of 1 : 2. Thus, for the period 1950-60, the compounded growth rate for thermal power amounts to 18.5 per cent, in comparison with 7.6 per cent for hydro.

Hydro Power Growth

New hydro-electric plant capacity added in Canada was some 845,000 h.p. in 1956. Expansion was much more rapid in 1957, when a further 1,501,560 h.p. was installed, and it is expected that this figure will be exceeded during 1958 with an estimated further addition of capacity of about 2,200,000 h.p. Plans for the succeeding few years would add more than 4,300,000 h.p., according to estimates made at the end of 1957.

Table I. Hydraulic Capacity, 1957 Regional Distribution

Province or Territory	% Total Capacity
British Columbia	15.71
Alberta	1.56
Saskatchewan	0.50
Manitoba	3.90
Ontario	29.35
Quebec	45.11
New Brunswick	1.05
Nova Scotia	0.93
Prince Edward Is.	0.01
Newfoundland	1.70
Yukon & N.W.T.	0.18

A view during construction of the penstock and powerhouse of the Bowater Paper Company hydro-electric station at Corner Brook, Newfoundland. The installation has a total capacity of 12,000 h.p. from two similar units.

Distribution of Capacity

A general impression of the present relative importance of hydro-electric power in the various areas of Canada may be gained from Table I, which shows the proportion, in each province or territory, of the total installed water-power capacity at the end of 1957. This total, as mentioned above, was 19,891,008 h.p.

An exact comparison is not readily available for the regional distribution of total thermal-electric installed capacity at the same period. However, considering only the major thermal plants operated by the Canadian central electric station industry, details of about 1775 megawatts of total installed capacity are available for 1957. (This should be contrasted with the total thermal capacity of 2142 Mw. in 1956.) Of this 1775 Mw., the percentage distribution between provinces was: British Columbia 0.61; Alberta 18.10; Saskatchewan 18.81; Manitoba 2.82; Ontario 37.50; New Brunswick 5.32; Nova Scotia 15.01; P.E.I. 1.27; and Newfoundland 0.56.

Because of the rapid growth of thermal capacity, and the current construction programs for very large plants in all the provinces from Ontario westwards to British Columbia, there will be a considerable change in this distribution in the next few years.

The major developments in the power industry will now be discussed as they occur in the individual provinces.

NEWFOUNDLAND

The potential of Newfoundland's important water-power resources has only been estimated tentatively, for lack of data on steam flow. The installed turbine capacity totalled 336,750 h.p. in 1956, but several developments and investigations since then will lead to an appreciable increase in this figure in the next few years.

Recently completed were two units for the Maritime Mining Corporation Limited: one of 460 h.p. on Venamas Brook, at Green Bay; the other of 760 h.p., also at Green Bay. This year, 1958, two new 6000 h.p. turbine units go into operation at Corner Brook for the Bowater Power Company Limited, who also had under construction a 6600 kw. standby steam unit at Corner Brook.

Several other developments were planned for completion in 1958. Newfoundland Light and Power Co., Ltd., have a 17,000 h.p. hydro development (in two units) on Rattling Rock, near Norris Arm, and an additional 20,000 kw. unit for their St. John's oil-fired steam plant. Union Electric Light and Power Co. Ltd. are to complete present expansion of the Trinity River hydro plant with an additional 2000 h.p. unit. Another hydro expansion stage will be completed with a third unit of 3600 h.p. at

Lookout Brook for United Towns Electric Co. Ltd.

The developments referred to above are on the island itself (Labrador will be dealt with separately), which has a large undeveloped water-power potential, though the largest sites are mainly inconveniently situated in relation to main load centres. The many small coastal streams, though their individual potential is small, could possibly be developed economically under specific favourable conditions.

One major development that is being actively considered by British Newfoundland Corporation Limited is at Bay d'Espoir, in central Newfoundland. With the possibility of developing industry in this area, surveys have been carried out and a scheme recommended which would give 350,000 h.p. at the site, using the watersheds of both the Salmon and Grey Rivers. The project could be developed in five stages of 70,000 h.p., the first of which could be completed a little over two years from the time construction was committed.

A reconnaissance and preliminary study of a transmission line from Bay d'Espoir to central Newfoundland has been carried out, and it is indicated that a suitable line could be built economically within the time required for completion of the first stage of power production.

Two further hydro developments are under active consideration by Bowater in the Grand Lake Watershed. One, on Hinds Brook, would be of 50,000 h.p. in two units (679 ft. head); the other, on Little Grand Lake, would be a single unit of 14,000 h.p. (205 ft. head).

In the field of transmission, the Union Electric Light and Power Company Limited is to complete 33 miles of 48-kv. line between Lockston and Clarenville, Trinity Bay.

LABRADOR

The potential for power production in Labrador differs very considerably from the situation on the island of Newfoundland. Apart from great possibilities of developing mineral resources, and the fact that is it part of the mainland, Labrador has, in the Hamilton River, a water-power potential that has been described as possibly the largest single undeveloped source of power in Canada.

Roughly 170 miles west of Goose Bay, Labrador, is the site of Hamilton Falls, which has been investigated by the British Newfoundland Corporation Limited for several years. By 1956 it was announced that it would be feasible to develop power at Hamilton Falls, and an access road was built to the site from mile 286 on the Quebec North Shore and Labrador Railway. During 1957 the 106-mile long road was improved for all-weather use. A 'catwalk' was built across the river above the Falls to help in the construction of a 25-ton transporter cableway, completed in 1957, to carry materials and equipment.

From the many surveys, engineering investigations, and cost estimates that have been made, it was confirmed that a first stage development of 1,000,000 h.p., including transmission facilities, could be completed in four years.

During development of the Hamilton Falls site on the Hamilton River, in Labrador, a 25-ton cable-way was constructed. The footbridge shown here provided initial access over the river. There is a potential of 4 million h.p. at this site.

The start of construction depends on finding customers for the power, and investigations have been made into long-distance transmission to reach the widest possible market. It has been estimated that high load factor power from the first stage might cost the consumer about 3 mills per kwh. at the busbars, and that, for a projected 4,000,000 h.p. development, the cost could be as low as 2 mills.

With a reserve of some 6,000,000 h.p., the Hamilton River is considered to be one of the few remaining sources of low-cost energy in Canada within economic transmission distance of a wide market.

PRINCE EDWARD ISLAND

Prince Edward Island has the smallest water power resources of any of the Canadian provinces. The small size of the streams limits water power sites to capacities of the order of those used for small mills.
