The installed turbine capacity of 1882 h.p. represents some 48.3 per cent of the total available. Of this installed capacity, roughly one-fifth is in central electric stations, and the remaining four-fifths in other industries (which do not include pulp and paper mills).

The main producer of power is the Maritime Electric Co., Ltd., which operates a steam-electric generating plant in Charlottetown. This consists of six units, with a combined capacity of 21,500 kw. The last unit to be added was one of 7500 kw. capacity, which was installed in 1956. The first unit had been put into operation in 1926.

The only other installation of 1000 h.p. or more, at the end of 1956, was that owned by the Town of Summerside, which consisted of seven diesel-powered units (ranging from 300 h.p. to 1600 h.p.) with a total capacity of 4190 h.p.

A recent D.B.S. survey forecast that firm power requirements on Prince Edward Island would increase from 53 million kwh. in 1956 to 83 million kwh. in 1960. Maritime Electric Company plans to add a further 10,000 kw., to be commissioned in 1961, to the Charlottetown steam plant.

NOVA SCOTIA

The water power resources of Nova Scotia are the least among the Canadian provinces, except for Prince

Edward Island, and are very largely developed, though there are still plans for some major projects, as will be mentioned below. There are, however, many small rivers on which small power plants have been developed, and which are within economic transmission distance of the principal load centres.

The province has abundant indigenous supplies of coal, from which thermal power is produced to meet additional requirements.

The developed electric power generating capacity in Nova Scotia in 1957 totalled approximately 415,000 kw., of which 285,000 kw. was thermal and the remaining 130,000 kw. was generated by hydro-electric stations.

The power production in the Province in 1956 totalled approximately 1,500,000,000 kwh., hydro production accounting for 583,500,000 kwh., while thermal plants produced 916,500,000 kwh. The Nova Scotia Power Commission accounted for about one-third of the total output, or over 500,000,000 kwh., while the remainder was produced by privately owned utilities.

Probable power expansions planned in Nova Scotia in the near future by the Nova Scotia Power Commission include:

(1) Extensions to the Trenton steam plant of a 20,000 kw. unit, construction of which commenced in 1957.

(2) Hydro development on the Sissiboo River in Western Nova Scotia which will add 25,000 kw. of additional capacity to the western network.

(3) A development at Wreck Cove, Cape Breton, which promises to be the largest single hydro development in Nova Scotia to the order of approximately 70,000 kw.

The Nova Scotia Light and Power Co. Ltd., in 1957, completed construction of an additional 45,000 kw. unit at its Water Street steam plant in Halifax, and is building a similar steam unit for operation in 1959. Two units of 1150 h.p. each at this company's Hemlock Falls hydro plant are being replaced by a 5000 h.p. unit. A further prospect is a 6500 h.p. hydro-electric development at Alpena, on the Nicteaux River.

Seaboard Power Corporation Ltd. is adding an 18,750 kw. unit at its Glace Bay steam plant.

During the year 1957 steps were made towards the closer consolidation, from an operating standpoint, of the various electrical utilities in Nova Scotia and New Brunswick. The result of this will see in 1958 the beginning of construction of a high-voltage transmission link between Nova Scotia and New Brunswick, which will connect the systems of The Nova Scotia Power Commission and the New Brunswick Electric Power Commission; and, within Nova Scotia, between The Nova Scotia Power Commission and the Nova Scotia Light and Power Company. Completion date of the interconnections is set for 1 July 1959. The voltage will be either 138 kv. or 230 kv. It is estimated from recently completed studies that these transmission interconnections will save the combined electrical power systems of Nova Scotia and New Brunswick approximately $30,000,000 over the next 10 years.

The Atlantic Provinces Power Development Act was recently passed to give Federal financial assistance to the four Atlantic provinces for power development and to provide for coal subventions. The assistance is not a grant, but rather in the form of loans to provide money to the Provinces at Federal interest rates for construction of thermal power plants, and construction of transmission facilities within and between the provinces. The loans are to be repaid by the Provinces over a 30 or 40 year period. The basis of the subvention is the difference between the cost of coal delivered to thermal plants in Ontario and that delivered to thermal plants in Nova Scotia and New Brunswick.

The possible utilization of tidal power is not being overlooked in Nova Scotia. The Nova Scotia Light and Power Company have engaged consultants to investigate potential tidal sites at Minas Channel and Minas Basin, while the engineering department of The Nova Scotia Power Commission is investigating a possible project at Amherst Point in Northern Nova Scotia, and on the Annapolis River in Western Nova Scotia. The Federal Governments of both Canada and the United States are also doing extensive investigations of the tidal potential of Passamaquoddy Bay.

NEW BRUNSWICK

The water power resources of New Brunswick are small in comparison with other Canadian provinces, excepting Prince Edward Island and Nova Scotia, but much of the available power is conveniently situated for the development of moderate-sized sites within economic transmission distance of the major load centres. The most important of these developments is the Beechwood hydro-electric project on the St. John River, of which further details will be given.

As in the case of Nova Scotia, New Brunswick has indigenous coal supplies from which power is developed in thermal plants, and the future power needs of the province have been planned on the basis of large thermal units integrated with hydro-electric generating sources. Long-term plans have also considered the integration of possible nuclear energy power sources.

Hydro-Electric Developments

At the end of 1957 there were recorded nine hydro-electric installations with capacities not less than 2000 h.p. Of these, the only recent developments were the two-unit Narrows installation on the Tobique River, completed in 1953 (27,000 h.p.), and the Beechwood project, started in 1955, of which the first 45,000 h.p. unit was in operation.

The second unit at Beechwood started production in January 1958, and construction to provide for the third unit is well under way. The eventual potential of 135,000 h.p. will be derived from these three 45,000 h.p. Kaplan turbine units, operating under a head of 60 feet, each driving a 40,000 kva. generator.

Further technical details of the Beechwood development are contained in two papers which were presented at the 72nd Annual Meeting of the Engineering Institute of Canada, in May 1958. These are: 'Engineering Features of the Beechwood Development', by J. A. Thomas, M.E.I.C. and R. E. Grout, M.E.I.C.; and 'Beechwood Kaplan Turbines—Hydraulic and Mechanical Features', by L. M. Boyd, M.E.I.C. and W. S. McIlquham, M.E.I.C. It is hoped to publish some of these details in later issues of *The Engineering Journal*.

From a study started in 1952, the International Joint Commission recommended (in a report published in 1953) the Beechwood site for initial development on the main stem of the St. John River, which is one of the largest rivers draining into the Atlantic Ocean. Some difficulty in construction was to be expected because the River is liable to flash flooding, as indicated by a recorded run-off varying from 0.2 c.f.s. per square mile to 17 c.f.s. per square mile, the latter figure corresponding to a record flood of 238,000 c.f.s. at Beechwood in May 1923.

Studies show that there are four power sites on the main part of the river within New Brunswick, of which two have been developed. The first is at Grand Falls, completed in 1931, of 80,000 h.p. (57,000 kw.) at 132 feet head; the second is the Beechwood plant. About half way between these sites is Morrill, which is expected to develop some 66,000 kw. (at 53 feet head), and the fourth site is at Hawkshaw, about forty miles above Fredericton, with an anticipated capacity of 112,500 kw. from a head of 55 feet.

Within the integrated scheme, the Beechwood plant will be operated essentially as a peak load source during periods of low flow, while the thermal plants will be base-loaded.

A view at the site of the Beechwood hydro-electric power development of the New Brunswick Electric Power Commission. The installation is the largest and most recent of its type in the province, with an ultimate capacity of 135,000 h.p.

Thermal Power Generation

At the end of 1956 there were five major coal-fired steam-turbine installations in New Brunswick of capacity greater than 1000 h.p. One two-unit installation of 6050 h.p. capacity, completed in 1953, served mostly the pulp and paper industry (Fraser Companies Limited); the other four were operated by the New Brunswick Electric Power Commission. Of the latter, the most recent was a unit installed at Chatham in 1956 which brought the total capacity of that plant to 46,250 h.p.

The Power Commission has under construction a new 67,020 h.p. (50,000 kw.) steam plant at East St. John, scheduled for completion in 1959. This plant will operate at 1450 p.s.i.

Also at the end of 1956 there were six diesel-generating units of greater than 1000 h.p. capacity in the province—at Campbellton, Edmunston, Aroostock Junction, St. Stephen, Shippigan, and Grand Manan Island.

General

During the fiscal year to 31 March 1958, the total production from all generating stations of the N.B. Power Commission was 611,638,600 kwh., an increase of 8.6 per cent over the previous twelve months. Of this total production, 40.6 per cent was from hydro-electric sources and the remaining 59.4 per cent was from thermal units. The report of the Commission notes that during this twelve-month period hydro production more than doubled that of the previous fiscal period, and that the added power (from the Beechwood development) had successfully been absorbed into the system.

The introduction of power from Beechwood made possible the sale of electrical energy to the Maine Public Service at a rate, from November 1957, of up to 150,000 kwh. daily.

An interior view of the part of the Beechwood power plant on the St. John River, New Brunswick. Two units, each of 45,000 h.p., are already in operation.

Transmission Systems

The Federal Government's plan of financial assistance to the Maritime Provinces has already been mentioned with reference to the development of power in Nova Scotia, and the plans for interconnecting the electric systems of that province and of New Brunswick. The share of the interconnecting line within New Brunswick will be about 35 miles in length, from Moncton to the Nova Scotia border, and is due to be available for service by November 1959. Normal capability of the line will be 50,000 kw., with the ability of handling 75,000 kw. in an emergency.

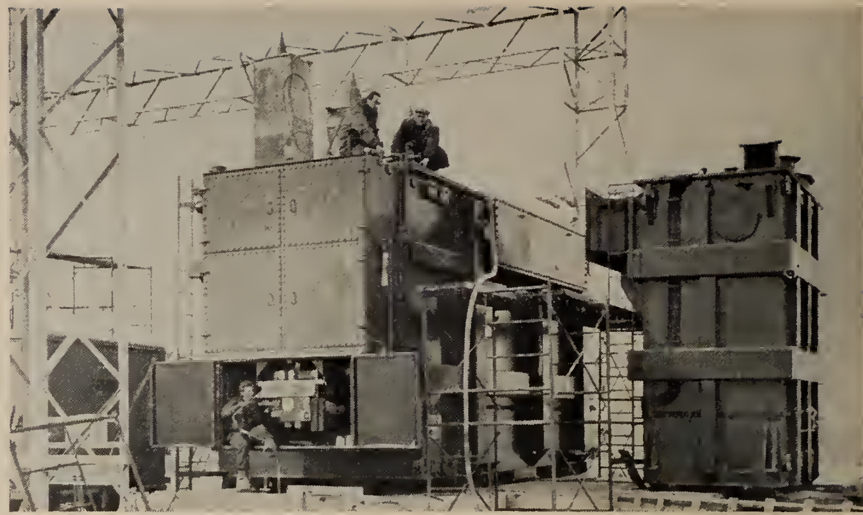
During 1957 the N.B. Electric Power Commission extended its transmission facilities by 68.4 miles of 138-kv. line from Beechwood to Fredericton and 30.4 miles of similar line from Fredericton to Grand Lake. Also, 25 miles of 69-kv. transmission line and 121.1 miles of rural distribution line were completed during the year.

Now under construction are about 190 miles of additional 138-kv. transmission line, and another substation, of 10,000-kva. capacity, at Moncton.

Three 40,000 kva. terminals were completed and energized in connection with the new 138-kv. grid—at Beechwood, Grand Lake, and Moncton. Two smaller substations completed were one of 7500 kva. at Woodstock, and one of 5000 kva. in Moncton.

The 30,000 kva. tie transformer station at Tobique now operates without having any personnel on duty at the site. Remote control equipment has been installed so that the Tobique plant staff can operate the system from Beechwood.

Low-voltage distribution facilities in the province now make electrical power available to nearly 98 per cent of the residential homes, and some 26,000 farms are supplied by the Power Commission, following an addition of about 1000 farms served during 1957.



The two installations of the Quebec Hydro-Electric Power Commission at Beauharnois have a capacity of over 1,400,000 h.p., and a third stage of 737,000 h.p. is to be added by 1960. Shown here is a 200,000 kva. transformer at the site.

QUEBEC

The Province of Quebec is the richest in water-power resources, with more than 35 per cent of the total recorded for Canada, in 1956. The province also ranks highest in developed power, and has some of the larger hydro-electric plants in the world; for example, the Hydro-Quebec development at Beauharnois, on the St. Lawrence River (1,424,000 h.p. from units Nos. 1 and 2); and the Shipshaw plant of the Aluminum Company of Canada, on the Saguenay River (1,200,000 h.p.).

Power production in the province is greatly facilitated by the regulation of stream flow by the Quebec Department of Hydraulic Resources through the storage dams it operates and controls.

Hydro-Electric Developments

At the beginning of 1957 there were completed and in operation some 93 hydro-electric installations of not less than 2000 h.p. turbine capacity. A further eight major plants were under construction, some of which are now operating, and there were plans for many other projects in this field.

When the Quebec Hydro-Electric Commission was instituted in 1944, the turbine installation in the Province represented 5,849,000 h.p. By the end of 1956, the same potential had risen to 8,417,000 h.p., which means that it had increased by nearly 50% in the space of thirteen years.

As turbine installation in Canada, at the end of 1956, represented 18,700,000 h.p., Quebec's installation was equal to around 46% of the whole country's available power. On the world scale, Quebec's developments were surpassed only by countries with a much larger population such as the United States, the USSR, France, Italy, Japan.

In proportion to the population, water power development in the Province of Quebec is the greatest in the world. In 1956 it represented 1.832 h.p. per person. Two years before that it was 1.33 h.p. per person compared to 0.73 in the United States and 0.32 in France.

In 1956, the electricity produced in the Province of Quebec represented 45% of the Canadian production, that is, 36,801,000,000 kilowatt-hours out of a total of 81,658,000,000 for the country as a whole. In 1954, a production of 35,500,000,000 kilowatt-hours meant 8,100 kwh. per person in comparison with 6,280 in Norway, 3,360 in the United States and 1,000 in France and Holland.

Because the increasingly high level of industrial activity is resulting in a constantly growing demand for electric power, the Provincial authorities and the companies which produce and transmit electricity have a number of developments under construction, some of which will eventually be among the greatest in the world.

Among the central electric stations constructed within the past ten years are: Beauharnois II, La Trenche, Chute à la Savane, Chute du Diable, McCormick, Shipshaw, Rapide II, and Bersimis I. The Bersimis development has resulted in the erection of the town of Labrieville, with modern dwellings, a church, a school, a hospital, civic, business and recreational centres, etc. When completed the underground power station at Bersimis will be capable of producing 1,200,000 h.p. generated by eight units driven by an 875-foot head of water. This project has required great feats of engineering. To raise the level of Lake Cassé and regulate the flow of the River, two dams were built, respectively 2,210 feet and 1,035 feet in length. About 200 feet high, the width of the dams at the base varies between 800 and 900 feet, and they are between 40 and 50 feet wide at the top. The dams are linked to the power-house by a tunnel 31½ feet in diameter and 7½ miles long.

The new sub-station at Pointe-aux-Trembles was built to relay to the Montreal region around 700,000 h.p. generated in the central station at Bersimis, about 450 miles away. The power produced at Bersimis will, in fact, be transmitted throughout the entire Province with the exception of the more distant northwest Abitibi regions. Since 1954, electricity generated at Bersimis has been relayed to the Gaspé Peninsula by means of the 31½ mile long submarine cable, which links the South and North Shores of the St. Lawrence, and is the longest of its kind in the world.

The Bersimis station is also linked to the Quebec region by means of a re-transmission station at Charlesbourg.

Bersimis Station No. I is about halfway toward being completed. Five of its eventual eight units of

150,000 h.p. each are in operation and three others will be installed in 1958 and 1959. This means that the work left to be done at Bersimis No. I will add 450,000 h.p. to the power now installed.

During the year 1957 alone, the Province of Quebec put into operation new installations with a potential of more than 383,000 h.p. and several other projects are being carried out. The Shawinigan Water and Power Company will complete its 330,000 h.p. station at Rapide Beaumont within the next twelve or fifteen months. A million h.p. station is being constructed by the Aluminum Company of Canada at Chute-des-Passes on the Peribonka River. The Manicouagan Power Company will add 180,000 h.p. to its McCormick station.

Price Brothers Company will shortly put into operation its new 78,000 h.p. power station at Murdoch Falls on the Shipshaw to replace its existing 10,000 h.p. plant, and the Eastern Smelting & Refining Company has just completed the installation of 42,000 h.p. on the Chicoutimi River.

Apart from completing Bersimis No. I, Hydro-Québec will speed up work at Bersimis No. II (855,000 h.p.) Beauharnois No. III (810,700 h.p.), and build a dam at the mouth of Lake St. Ann in order to regulate the flow of the Manicouagan River, which will eventually become one of the greatest sources of hydro-electric power in the Province. The preliminary estimates made along that river some years ago fixed its potential at something like 2 million h.p., but recent and more detailed surveys indicate that the Manicouagan may be capable of generating 5 million h.p. if not 6 million, which would be as much as all the power generated in the Province a dozen years back.

When all the developments now under construction are completed, that is, in 1961, water-power harnessed in the Province of Quebec will represent over 11,500,000 h.p.

For some years now, Quebec-Hydro engineers have been collecting data in connection with a plan to erect a central electric station near Lachine, just outside Montreal, which would be capable of producing 1,500,000 h.p. and another (some 500,000 h.p.) at Carillon, on the Ottawa River, about forty miles from the Canadian capital.

From the point of view of hydro-electric power Quebec is still very far from having developed even half of its resources, and the future holds promise of a much greater supply of power than has been made available to date. For although, at the end of 1957, the Province's turbine installation represented around 8,800,000 h.p., its potential is actually estimated to be some 30 million h.p. In other words, Quebec has only put to use less than a third of its recorded water-power resources.

A number of the sites recognized as capable of development are situated at great distances from the more populous regions of the Province. But electricity is now transmitted to Montreal from the plant at Bersimis, more than 400 miles away, with an average loss of less than 6%. On the other hand, the mining operations now under way in the Quebec section of the Canadian shield, can count on the plentiful supplies of hydro-electric power available there, just as the pulp and paper industry has done in other parts of the Province.

Another factor which has played an important part in the industrialization of the Province of Quebec has been the low cost of electricity. The average price of electricity is, in fact, less than half a cent per kilowatt-hour, in comparison with 4/5 of a cent for Canada as a whole, a cent and a half for the United States and two and 3/10 cents for France.

Progress at Chute-des-Passes

Construction of the one million horsepower Chute-des-Passes project of the Aluminum Company of Canada —150 miles north of Arvida, Que.— began in August 1956 with the first of five 200,000 horsepower units scheduled to go "on-power" on 1st August 1959 and the final unit on 1st February 1960, which will complete the ultimate development. This power is being developed mainly for projected additional Alcan smelter capacity in the Saguenay area and will also serve other industrial and domestic requirements.

As at the end of August 1958 excavation was complete for the intake structure, supply tunnel, surge shaft and powerhouse. In the intake tunnel, beneath the reservoir, a pilot drift has been excavated for a distance of about 200 feet ahead of the face of the top heading, of which, approximately 400 feet has been removed. Excavation operations continue in the surge tank, switchyard and tailrace aread with the top heading of the tailrace tunnel now daylighted and open cut work well advanced at the discharge location.

Over 8,000 feet of supply tunnel arch lining has been placed, and in the powerhouse, concrete work is essentially complete except for the unit concrete. Both powerhouse cranes are in operation. The installation of turbine scroll cases is proceeding and the placing of the steel penstock liners is nearly finished, with the welding and stress-relieving operations progressing rapidly.

Overall the project remains to schedule, and no change is proposed for the original "on-power" dates.

Manicouagan Power Development

The advent of the new aluminum smelter of the Canadian British Aluminium Company in the Baie Comeau area of Quebec required a suitable supply of power. The Manicouagan Power Company, which had a development on the Manicouagan River in 1951-52, largely for the pulp and paper industry further expanded this development in 1956-57 to supply the aluminium project. The story of this development has been told in *The Engineering Journal* for July 1958 (pp. 60 to 69).

Thermal Power Generation

Because of the ready availability of hydro-electric power in the province, as has been indicated above, the part played by thermal generating stations is relatively very small.

The only two recorded steam installations with a capacity of over 1000 h.p. (end-1956) were standby plants: one of 22,000 h.p. total capacity at Cedars, on the St. Lawrence River, and one of 10,724 h.p. total capacity operated by the City of Westmount (Montreal).

Five diesel-operated plants in the over-1000 h.p. range were recorded at the same period, mostly serving local needs in certain areas. Additions were made to all these plants during the years 1953 to 1955. The total capacity involved is some 19,710 h.p.

ONTARIO

About 90 per cent of the electric energy used in Ontario is supplied by the Hydro-Electric Power Commission of Ontario (more familiarly known as Ontario Hydro), which came into being in 1906 and started to supply power in 1910 from its resources of 7400 kw., all of which was purchased under contract. The Commission's first hydro-electric plant was built in 1914 at Wasdell Falls, on the Severn River.

By 1945 the Commission's resources had increased to 1,937,500 kw., but since then capacity has been increased by 150 per cent, through the addition of 15 new sources of power.

Projects now under way will bring into service during the next few years additional resources totalling nearly 3,000,000 kw. Details of these major projects are summarized in the accompanying table.

Integrated Scheme

Projected estimates suggest that the demand on Ontario Hydro will be of the order of 6,000,000 kw. by 1960, with the possibility of some 20,000,000 kw. by 1980. It was mentioned in the introduction to this review that plans are being developed in the province to integrate power from large thermal and hydro-electric sources, and it will be noted that this is the first province to make a start on the use of nuclear energy as a source of electrical power, though the first unit will be used mainly to gain experience for the future development of large nuclear plants.

Southern Ontario

In the Southern Ontario System, the main developments now under way are at the Sir Adam Beck—Niagara No. 2 generating station; the R. L. Hearn thermal station, in Toronto; and the Robert H. Saunders—St. Lawrence generating station.

At Niagara, of four 75,000 kw. generators to be added, two were in service at the end of 1957. It is at this site that the unique pumping-generating station has been incorporated. When the present additions are completed, the total installed capacity of this station will be 1,370,000 kw.

The Richard L. Hearn thermal station, with a present capacity of 400,000 kw., will have a further four 200,000 kw. units, the first to be operating in 1958, with the remaining three following in 1959 and 1960. This will bring the total capacity of the plant to 1,200,000 kw.

The St. Lawrence project, already partly in operation, will ultimately provide 820,000 kw. from 16 units. This is, of course, the Canadian half of the powerhouse in the International Rapids section of the St. Lawrence River, the other half, of equal capacity, being operated by the Power Authority of the State of New York. The progress of this development has been followed in some detail in *The Engineering Journal* since 1955, notably in the issues of September 1956, October 1957, and September 1958.

Northern Ontario

Mining developments in Northern Ontario, particularly in the Blind River area, have influenced the production of power, which has recently been accelerated in this region.

To meet these ever-growing power needs in the north, Ontario Hydro has under way a program of construction which includes the building of three new hydro-electric generating stations on northern rivers and extensions to four existing stations. At the the same time, plans are going ahead for the construction of the Commission's first thermal-electric station in Northern Ontario—in the Fort William-Port Arthur area. This plant is scheduled for service in 1961. The initial capacity with one unit will be 100,000 kw. with provision for enlarging it to 1,000,000 kw. as required.

The 54,000-kilowatt Whitedog Falls plant, on the Winnipeg River, and the 67,500-kilowatt Caribou Falls station on the English River are now nearing completion and are scheduled to come into service during 1958, while the

Alexander G.S.—Capacity of extension only; present capacity of the station is 60,900 kw. including extension.
R. L. Hearn G.S.—Capacity of extension only; present capacity of the station is 400,000 kw. (4 units) ultimate capacity 1,200,000 kw. (8 units), respectively.

H — Hydraulic T — Thermal

45,500-kilowatt Silver Falls development on the Kaministikwia River is expected to be in operation by the fall of 1959.

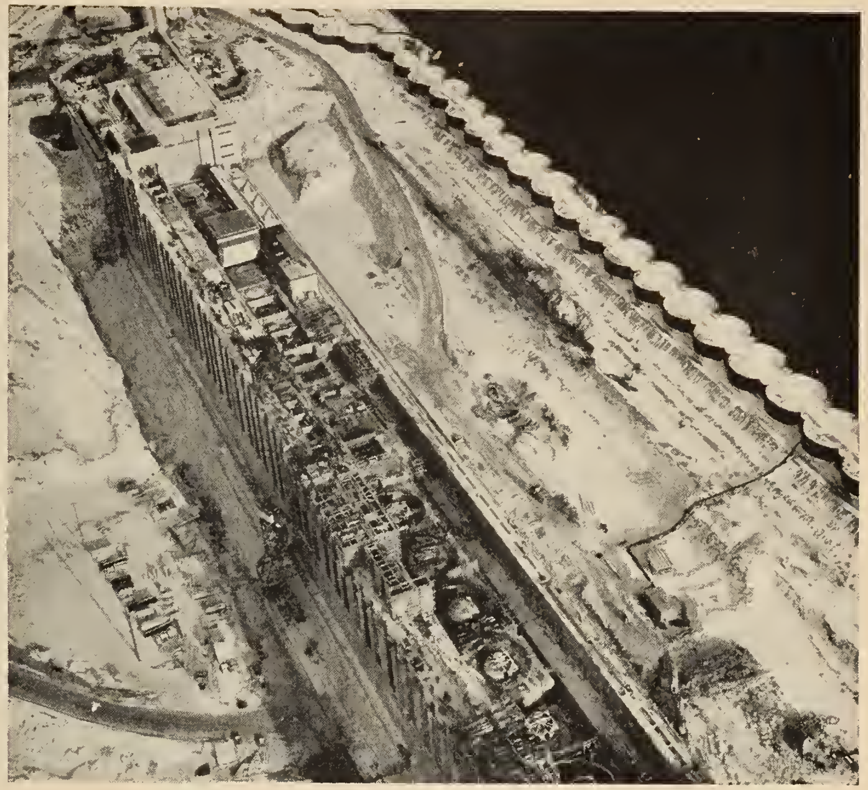
Rapid progress is being made also on the extensions to two existing plants on the Nipigon River. An additional unit at the Cameron Falls station is scheduled to be operating by the middle of 1958 and will increase the capacity of this plant to 76,700 kw. The new unit being installed at the nearby Alexander generating station is expected to be in operation early in 1958 to increase this station's capacity to 60,900 kw.

Meanwhile, an additional generator of 45,000-kw. capacity has been authorized for the Abitibi plant on the Abitibi River, 250 miles north of Sudbury, and installation was started in the Spring of 1958. Scheduled to be in service early in 1959, this unit will bring the capacity of the Abitibi station up to 226,000 kw.

In addition to generating stations in service or under construction in northern Ontario, power supply to this part of the Province is further protected through interconnections. The northeastern section has been connected with Hydro's Southern Ontario System since 1950. This tie is now being further strengtened by the construction of a new 230,000-volt line over a distance of 110 miles from the Commission's Otto Holden Station, on the Ottawa River, to Sudbury. Increasing power demands in the Blind River area necessitated the building of a similar type of line between that area and Sudbury. To meet the needs of the active uranium community of Elliot Lake, this line was placed in service in December 1957, at 115,000 volts until such time as a 230,000-volt transformer station is built at Blind River.

During 1957, Ontario Hydro also entered into an agreement with the Great Lakes Power Corporation at Sault Ste. Marie to deliver power over a line between the Commission's George W. Rayner station on the Mississagi River and Sault Ste. Marie, for a distance of 48 miles. Designed and engineered by Ontario Hydro, this line is being built by the Great Lakes Power Corporation.

With the idea of augmenting the output from its plants on the English River, the Commission completed a project during 1957 to connect the Root River with Lake St. Joseph. Construction forces succeeded in driving a 10,000-foot-long channel through



Seen here during the construction period is part of the Canadian half of the St. Lawrence power development, now known as the Robert H. Saunders — St. Lawrence generating station. Already partly in service, completion is due for 1960.

the difficult terrain of the northwestern Ontario forests to link this river and lake. The additional water from Lake St. Joseph has permitted the installation of the fifth unit at the Manitou Falls plant and has also influenced plans for the Caribou Falls station. At he same time, installation of larger capacity units will be possible when Hydro develops its Maynard Falls site on the English River. Generating stations on the Winnipeg River in the Province of Manitoba are also favourably affected by this unique undertaking.

Frequency Standardization

The Commission's program of frequency standardization, the largest of its kind ever undertaken, was launched in 1949 and involves changing over from 25 to 60-cycle operation a total of some 6,800,000 frequency-sensitive items for 1,014,000 customers. By the end of 1957 the program was approximately 90 per cent complete. The principal areas remaining to be standardized in southern Ontario include certain parts of Toronto and Leaside as well as a few communities to the southwest surrounding Burgessville, Embro and Cayuga.

A relatively small section in the northeastern part of the Province was to be changed over from 25 to 60 cycles, commencing in the Spring of 1958. With the completion of the program—in both the north and the south—by 1959, virtually the entire Province will be on the 60-cycle frequency which is more or less standard on the North American Continent. The uniform frequency will facilitate interconnections between Ontario and neighbouring provinces and also between Ontario and utilities in the United States.

Transmission Lines

A one-mile transmission test line of the extra-high voltage type is scheduled for completion early in 1959. During 1959 and 1960, studies of the transmission of electricity within a range of 260,000 to 600,000 volts will furnish data for the construction of two EHV lines, 250 miles long, in northeastern Ontario. Survey and location of these lines, to run between Sudbury and a point on the James Bay watershed, begins this fall with the first scheduled for service in late 1962. Ontario Hydro's long term planning calls for development of eight hydraulic sites with an estimated 1,000,000 kilowatts to be carried by these EHV lines.

MANITOBA

Power in Manitoba is generated and distributed through a three utility integrated system that was formed following recomendations made by the Provincial Government after submission of the Hogg Commission Report in 1948. The three utilities (The Manitoba Hydro-Electric Board, The Manitoba Power Commission, and The City of Winnipeg Hydro-Electric System) have clearly defined areas of responsibility and operate jointly in accordance with the terms of an agreement known as the Power Agreement.

The Manitoba Hydro-Electric Board is the primary generating authority in the group and is vested with the responsibility of ensuring an adequate supply of power to meet the Manitoba system requirements. It has a combined hydro and thermal turbine rated generating capacity of 763,000 h.p. Power from the Board generating stations is transmitted to Board owned terminal stations located in and close to the outskirts of Greater Winnipeg. From these points it is transmitted to either The Manitoba Power Commission or The City of Winnipeg Hydro-Electric System lines for distribution.

The City of Winnipeg Hydro-Electric System own and operate turbine rated generating equipment amounting to 273,000 h.p. Power from their generating stations is transmitted to and distributed within the City of Winnipeg on an exclusive franchise.

The Manitoba Power Commission services the rural areas of Manitoba and the suburbs and cities adjoining Winnipeg.

The Power Agreement is unique in many respects in that a new concept of the common bus was introduced which resulted in a simplification of both the sale and purchase of power between the three utilities. As generating stations constructed before the Second Great War had a much lower per-horsepower capital cost than those constructed after the war and those visualized to meet future requirements it was apparent that the cost of producing a kilowatt hour in the older stations would be much less than it would be from new stations. By using the pre-war developed generating capacity of The City of Winnipeg Hydro-Electric System as a basis The Manitoba Hydro-Electric Board alloted low capital cost generating Power Commission in ratio to the two distributing agencies' firm loads that existed at the time of the agreement. Power required from The

A view of the Amy Street steam-turbine generating station of the City of Winnipeg Hydro Electric System. This coal-fuelled plant produces over 68,000 h.p.

Manitoba Hydro-Electric Board in excess of the generating capacity of the City Hydro and the generating capacity allocated to the Power Commission is supplied from a Residual Pool. The Pool being the remaining available generating capacity of the Board. Both distributing utilities obtain power from this source at a higher cost as new stations have since been added to the system. The agreement has resulted in a very fair and equitable distribution of the cost of producing power in Manitoba and has contributed greatly in maintaining low rates in the province.

Another factor in holding energy costs down in Manitoba is the water heater control program inaugurated by The City Hydro in 1938 and accelerated during the war years to conserve badly needed electrical energy for more essential services The program has since been extended by the City Hydro and put into effect by the Power Commission in areas surrounding Winnipeg. It has resulted in probably the greatest number of remotely controlled water heaters in use in any city on the continent with an approximate load of 52 megawatts being controlled to conserve peak generating capacity for more profitable purposes.

The Manitoba power industry having faced the problem of hydro-steam integration or the development of northern hydro sites to supply the Southern power system decided in favor of hydro-steam integration until such time as it was economically advisable to develop the potential 4½ million horsepower available from the northern sites. The problem of thermal-hydro integration is not new to those producers who have exhausted their hydro resources and firmed their systems with steam. In Manitoba there is insufficient hydro installed capacity to meet winter peaks although providing river flows maintain average values the hydraulic generating stations are capable of meeting the load requirements for the greater part of the year. The Brandon generating station, a thermal station of 120-megawatt capacity will be completed this fall. The Selkirk generating station of the same capacity for the first stage of its development will be producing power in 1960. The Amy Street thermal station of the City Hydro of 51-megawatt capacity has been in operation for a number of years. The 315 megawatts from these thermal stations will be welded with the hydraulic present generating capacity of both the Board and City Hydro. The time is fast approaching when either through reduced river flows or increased firm load, the integration of hydro and thermal generated power will be of great importance to the overall cost of power in Manitoba. Continuing studies are being made to determine the best method of operation within the province and a joint study between The Manitoba Hydro-Electric Board and members of Ontario Hydro Electric Power Commission has been proposed towards fully integrating the resources of the northwest pool of Ontario Hydro and those of the Manitoba electrical industry.

The construction of the Kelsey Generating Station on the Nelson River in Northern Manitoba is well under way. This station will supply the International Nickel Company of Canada with an initial load of 102 megawatts and be capable of generating additional power should other industries be established in the adjacent area.

Permafrost exists in the majority of the overburden at the site and has created problems particularly in respect to working it with power equipment. In the summer when the thin layer of surface soil and timber is removed the permafrost areas are reduced to a semi-liquid state making it impractical to handle in a normal manner. Consequently excavation work where permafrost was known to exist was done during the winter months when it could be handled in its natural frozen state. Permafrost has been encountered during test drilling at most of the tower locations along the 58 mile transmission line route between Kelsey and Thompson. The construction of tower lines under these conditions will present many problems but the development of new methods has been and will be a necessary part of this project.

Interest in rural area electrification in Manitoba was intensified following the Farm Electrification Enquiry Commission of 1942 conducted by Messrs. Sanger, Schmidt and Caton in which the recommendation was made to the Provincial Government that a concerted effort be made to establish a test zone for farm electrification. The program was undertaken by The Manitoba Power Commission immediately following the war as materials and manpower became available with very satisfactory results. Approximately 8,500 farms were electrified annually until to-day ninety-three per cent of the farms in Manitoba are electrified.

In a province where the per capita use of power according to the Dominion Bureau of Statistics is fifty per cent higher than the national average it is essential that new generation and new distribution facilities be made available within economic limits to maintain a continuity of supply at the lowest possible price.

SASKATCHEWAN

Although Saskatchewan has considerable water-power resources within its borders, these resources are largely in the northern part of the province and far from the more heavily populated areas. Consequently, hydroelectric power has been developed mainly for mining purposes in the north, while thermal plants have been developed to serve the settled and industrial areas in the southern part of the province.

Large reserves of coal, oil, and natural gas are available in both Saskatchewan and the adjoining province of Alberta, and these fuels provide economic sources of thermal power.

Hydro-Electric Power

The main hydro-electric developments are: on at Island Falls, on the Churchill River, with a capacity of 106,500 h.p. (Churchill River Power Company); and the Consolidated Mining and Smelting Company plant at Wellington Lake, on the Charlot River, with an installed capacity of 3300 h.p., which is eventually to be doubled.

The largest development in the province, the South Saskatchewan River Dam, is discussed below.

The Hudson Bay Mining and Smelting Company has started construction of an additional 19,000 h.p. standby unit at the Island Falls plant. This should start operation early in 1959.

Thermal Power Development

Records of thermal power plants (over 1000 h.p. capacity) installed at the end of 1956 show that there were six main steam-turbine plants (fuelled by coal, oil, gas or a combination of these) with a combined capacity of 399,810 h.p.

At the same time there were ten diesel-powered plants with a total capacity of some 52,840 h.p.

Planned for installation in 1960 is an oil/gas-fuelled gas turbine unit of 21,450 h.p. capacity for the City of Regina. Apart from this unit, the major thermal power developments in the province planned and under construction since 1956 are within the operations of the Saskatchewan Power Corporation, the largest single supplier of power, whose transmission network covers a large part of the southern part of the province.

In 1957 the Corporation added a 40,220 h.p. (30,000 kw.) unit to the existing steam-turbine plant at Estevan, an 8000 kw. gas turbine unit to the new plant at Kindersley, and a 3000 kw. unit to the diesel plant at Swift Current.

Now under construction by the Corporation, and due to be completed by about 1959, are: a second gas turbine unit of 8000 kw. capacity at the Kindersley generating station; two 66,000 kw. units at the Boundary Dam steam plant, near Estevan; and two 66,000 kw. units at the South Saskatchewan River steam station, in Saskatoon.

Transmission and Distribution

Extensions to 72-kv. main transmission lines during 1957 totalled some 181 miles.

A 30,000 kva. substation was built at Estevan, and others totalling 22,500 kva. were completed at Fort Qu'Appelle, Ogema, Eston, Davidson, Prince Albert, North Battleford, and Unity.

During the same year, rural electric service was extended to an additional 6500 farms, making a total of about 46,500 farms in the province supplied with electrical power.

South Saskatchewan River Dam

A controversial project that has been studied for many years is the South Saskatchewan Dam. In July 1958 a federal-provincial agreement was signed which detailed the apportioning of costs and the division of responsibility for the approved project between the two governments.

Some details of the scheme were given in the September 1958 issue of *The Engineering Journal* (p. 105).

A main earth dam is to be built on the Saskatchewan River, between the towns of Elbow and Outlook, with an auxiliary earth dam in the Qu'Appelle Valley; and a large system of canals and pumping stations will eventually provide irrigation for 500,000 acres of soil. The work is under the supervision of the Prairie Farm Rehabilitation Administration, in Regina.

An addition to the water-control aspects of the project, a powerhouse is to be built at the site of the main dam. The installed capacity of this station will be determined when consideration has been given to the part it will play in the future plans of the province for an integrated thermal/hydro-electric system.

The potential of the project is estimated to be an average annual output of 475 million kwh., with 100 million kwh. of power for irrigation pumping.

ALBERTA

All four major energy sources—water power, natural gas, coal and oil—are used to produce electric power in Alberta. A pattern of use has evolved in which each energy source has taken its appropriate place in the generation of electricity. This assures

Alberta's industries of low and relatively stable power rates for the future, based on virtually unlimited sources of energy generally well located to serve major centres. In contrast, Eastern Canadian industry is faced with power costs that are likely to increase much faster as new plants are established in areas where low cost power resources are fully utilized.

Alberta's fuel resources exceed those of all the rest of Canada combined. They have played a major role in the economic development of the Province and, through export to other areas, promise to play an important part in the future development of Canada as a whole. While these resources have many applications in their primary form of coal, gas and oil, they become a much more versatile form of energy when converted into electricity. In this respect Alberta is well provided for, with an extensive network of transmission and distribution lines from the many generating plants to the industries, commercial establishments, residences and farms of the Province. Power for industrial needs is available in the areas adjacent to the main transmission lines at rates which compare favourably with other points in Canada.

Electric Power Facilities

Three privately-owned and three municipal corporations supply over 99 per cent of the electric power needs of the Province. The privately-owned corporation supplied 74 per cent of the total energy requirements in 1957. Of this total Calgary Power Ltd. supplied 65 per cent, Canadian Utilities Limited 8 per cent and Northland Utilities Limited 1 per cent. The municipal corporations supplied 26 per cent, with the City of Edmonton supplying 21 per cent, the City of Medicine Hat 3 per cent and the City of Lethbridge 2 per cent.

Power Generation in Alberta

Alberta is endowed with both hydro and fossil fuel resources within economic range of the principal load and population areas. An extensive network of high voltage transmission lines already links all the Province's major hydro and thermal power plants, and this makes possible the orderly and economic development of both sources of power as may be required to provide for the growing power needs.

To take advantage of cheap "peaking capacity" at existing hydro plants, extensions have been made or are under way which will at least double the present capacities.

The Wabamun thermal-electric plant of the Calgary Power Limited, which has two units of 66,000 kw. operating on natural gas, with provision for a coal-fuelled unit.

Principally on the Bow and Athabasca Rivers, there remains possibly several million kilowatts of potential peaking capacity within reach of the more thickly settled parts of Alberta. Plans are being prepared for the development of this hydro potential as and when required to keep the proportion of hydro peaking and base load thermal capacities such as will ensure the most economical future electric supply.

Though natural gas is currently in wide use in Alberta's thermal plants, it is a premium fuel because of its convenience for house heating and its value as a raw material in petrochemical plants. Futhermore, it can be economically transported by pipe line to distant markets where fuel costs are high. It would therefore appear only a matter of time before natural gas will price itself out as a fuel in base load thermal plants, particularly where low cost strip coal is available.

Alberta has large deposits of coal, and where these can be mined mechanically, the cost is low as compared to natural gas and it should be possible to maintain a high degree of price stability. This is particularly true in strip mines, but it also holds in highly mechanized underground operations. These coal reserves are therefore a major source of supply for the long term energy requirements of Alberta.

The Calgary Power Ltd. Steam plant on Lake Wabamun is a good example of the use of available fuels for base load generation. Assuming that gas would soon price itself out of the market as the cheapest means of providing its base load requirements, a site was chosen on Lake Wabamun, some 40 miles west of Edmonton, where there is ample cooling water and large reserves of cheap strip coal in close proximity. Although now fired with natural gas, the increase both in the price of gas and in the quantity required will soon make it economical to set up a strip mining operation as the main source of fuel.

Future Prospects

Looking to the future, and having regard to the rising cost of labour, the best hope of keeping down the cost of power lies in concentrating the production of energy in a few large steam plants adajacent to strip coal mines, and bringing in peaking and stand-by power from suitable hydro-electric developments.

Hydro-Electric Developments

The main hydro-electric power developments under construction or planned since 1956 are being carried out by Calgary Power Limited. In October 1957 a second unit of 23,000 h.p. was installed at the company's Cascades plant. To be used mainly for peak load purposes, the unit consists of a 23,000 h.p. Francis type turbine, under a head of 320 feet, connected to a 20,000 kva. generator.

Under construction are extensions to the Spray Lakes development which will approximately double the existing capacity. Scheduled for completion in October 1959 are: a second 62,000 h.p. unit at the Spray plant; and a 40,000 h.p. unit at the Rundle plant.

The company is continuing investigations of a possible development at the Big Bend site, on the Brazeau River. Investigations on the North Saskatchewan River at and near the Big Horn site were suspended when poor foundation conditions were revealed by exploratory drilling.

Steam-Electric Generation

Major additions to steam-turbine generating plants have been built or planned since 1956. Calgary Power Limited has added a second 66,000 kw. unit to the Wabamun plant, and has on order a third unit, of 150,000 kw., for completion in 1960. As mentioned earlier, this station exemplifies the changing trend in the use of fuels, since the second unit, now installed, operates on natural gas (as does the first unit), whereas the third unit will use coal as fuel.

The City of Edmonton is adding a further 66,000 kw. unit to the Edmonton steam plant, to be completed in 1960. This unit will use natural gas.

Gas Turbine Units

The gas turbine was first used in a Canadian central electric station in 1954 at the Vermilion plant of Canadian Utilities Limited. The same company has since constructed a 10,000 kw. gas turbine unit at the new Sturgeon plant near Valleyview in the Peace River district.

The City of Edmonton will shortly have added two 30,000 kw. gas turbine units at the Edmonton steam plant, and the City of Lethbridge has a new 7500 kw. gas turbine installation at the Lethbridge steam plant, with the proposed addition of a further unit of this type.

Another 7500 kw. gas turbine unit is in the Elk Point plant, at Two Hills, of Western Chemicals Limited.

The City of Medicine Hat has also proposed the addition of a gas turbine unit to existing facilities.

Oil and Gas Engine Plants

Canadian Utilities Limited and Northland Utilities Limited, in a joint operation, installed a new 3000 kw. gas engine generating unit in 1957 at the Fairview thermal plant. Northland Utilities also added a 1250 kw. gas engine unit at the Jasper thermal-electric station.

BRITISH COLUMBIA

The province of British Columbia ranks second in Canada in available resources, and is exceeded only by Quebec and Ontario in installed capacity.

During 1957 the total of 607,500 h.p. of new hydro-electric capacity installed was the highest among the provinces. A further 192,000 h.p. was under construction for 1958 operation, and considerable additional potential is being planned or in the early development stages for later service. The November issue of *The Engineering Journal*, which will mark the centenary of the province, will contain a more detailed article on the long-range planning of power development in British Columbia.

Kemano-Kitimat

The hydro power development at Kemano, in northern British Columbia, which supplies the Kitimat smelter of the Aluminum Company of Canada, was increased during 1957 to a total of 900,000 h.p. by the addition of a fifth and sixth generating unit. The seventh unit to be added will have a capacity of 150,000 h.p.

B.C. Power Commission

The B.C. Power Commission have estimated that in the next 10 years, the publicly owned utility's energy output must be quadrupled, from the present level of 1,000,000,000 kilowatts a year to a predicted load in 1967 of 4,000,000,000 kilowatts.

The Commission serves 212 communities in the province, the largest being Nanaimo on Vancouver Island with a population of 12,000.

Total installed capacity is 331,000 kw. Plants under construction will add a further 115,000 kw. in 1958 for a total of 446,000 kw. It is predicted that an additional 850,000 kw. will be needed in the area served by the Commission by the year 1970.

The Power Commission has 1,000 miles of transmission lines and 4,000 miles of distribution lines. During 1957, high-voltage transmission line interconnections included the 138,000 volt interconnection on Vancouver Island with the B.C. Electric's mainland system, and a 60,000 volt interconnection with the East Kootenay Power Co. for the Commission's Upper Columbia Valley system. Construction is also completed on the 138,000 volt interconnection between the Commission's Kamloops-Okanagan lines and those of the West Kootenay Power and Light Company.

New circuits from Ladore Falls to the John Hart station, and the third 138,000 volt line to the Dunsmuir station improved the supply and reliability of power on Vancouver Island.

During 1957, two major additions were made to the hydro capability. An initial 52,000 kw. was put into service at the Ladore Falls Plant in the Campbell River system of Vancouver Island. In the interior, a third unit with a capacity of 11,000 kw. was added to the Whatshan Hydro development on Lower Arrow Lake. Capacity increases were made at seven diesel electric stations at scattered points in the interior and the Commission completed and put into operation, three gas-diesel stations with a combined capacity of 30,000 kw. The gas diesel plants are located in the growing central interior centres of Quesnel, Dawson Creek, and Prince George, and operate on natural gas from B.C. wells.

The Commission became the first utility in B.C. to enter the gas turbine field when the first 20,000 kw. unit at the Georgia generating station, located at Chemainus on Vancouver Island, was put into operation in September 1957. With completion of the plant during 1958, it will have a capacity of 75,000 kw.

Some of the main hydro developments now under way are mentioned below.

Construction is under way at the powerhouse of the Upper Campbell Lake - Buttle Lake project, two miles below the outlet of Upper Campbell. Installation of the first 42,000 h.p. generating unit was completed during 1958.

Work on a project to divert water from the Heber River into Upper Campbell Lake, to provide additional water for the Upper Campbell development, will increase annual output of the total development by 40,000,000 kwh.

A recently completed diversion directs the Salmon River into the Lower Compbell to provide more water for power generation at Ladore Falls and John Hart developments. The project boosts annual output of the two plants by 100,000,000 kwh., and a Quinsam River diversion into Lower Campbell Lake increases the two plants' capacity even further — an additional 30,000,000 kwh. annually.

Vancouver Island needs the additional power these projects will provide. Though it has about 19% of the province's population, it is endowed with only 4% of the hydro potential. Because of this, the Commission is engaged in the first stage of a major source of hydro power in the Alberni valley. Several hydro developments on the Somass River system would enable 80,000 h.p. to be harnessed. The first step at Ash River is under construction. This plant will produce 35,000 h.p.

As another means of meeting the Island's future requirements, surveys are being made of the Homathko River with a view to bringing additional power from the Bute Inlet of the nearby mainland. There are several sites on the Homathko-Chilko systems capable together of producing to the order of 1,000,000 h.p.

B.C. Electric Company Limited

The British Columbia Electric Company Limited has had large hydro-electric developments in hand since 1956, but is also planning for major thermal power production.

The first two units of the company's Cheakamus hydro development came into operation late in 1957. Each unit consisted of a 95,000 h.p. turbine and 80,000 kva. generator. A 4000 h.p. two-unit installation at Clowhom Falls, on Sechelt Peninsula (bought in 1956 from B.C. Power Commission), was replaced in 1957 by a single-unit 40,000 h.p. turbine with 31,500 kva. generator. This involved raising the concrete gravity dam to a height of 71 feet.

At the company's Bridge River system, a 30,000 h.p. turbine and 24,500 kva. generator went into service late in 1957 at the La Joie dam power plant. Continuing work on the Bridge River development, for its final stages, involved a large storage dam on the River, a second tunnel through Mission Mountain, and a new powerhouse, Bridge River No. 2, on Seton Lake, about one-half mile upstream from the present plant. The effect of the storage dam is expected to increase the capacity of the four units in the existing plant from 248,000 h.p. to 276,000 h.p.

At the Bridge River No. 2 project, four units, each of an 82,000 h.p. turbine and 65,500 kva. generator, are due to be installed during the second half of 1959. This will provide a total plant capacity of 328,000 h.p.

In the thermal field, B.C. Electric started work in 1957 and has progressed with the construction of a gas turbine plant at Port Mann, consisting of four 32,500 h.p. turbines, each driving a 30,000 kva. generator. The units can operate on either oil or natural gas.

Looking further into the future, the company has made preliminary arrangements for a large steam plant at Ioco, on Burrard Inlet. This will have an ultimate capacity of over 1,200,000 h.p. from six units, each rated at 210,000 h.p. It is planned to put the first unit into operation in January 1961, the second in October 1961, and subsequent units as required.

In 1957 some 202 miles of 345 kv. transmission line were brought into service, and in 1958 a second line was added to the 138,000-volt cable linking the mainland with Vancouver Island. The story of this interesting engineering will be developed further in the November *Journal*.

Other Developments

The Consolidated Mining and Smelting Company of Canada Limited is investigating the second power site on the Pend d'Oreille River, about six miles upstream from its Waneta plant.

The Whitehorse Rapids project on the Yukon River, shown here during construction, comprises two 7500 h.p. units, with provision for further expansion.

In 1957 the Wenner-Gren Foundation, with the sanction of the B.C. government, started an investigation into the possibility of developing about 40,000 square miles in the far northern Rocky Mountain Trench. The general plan includes a possible 4,000,000 h.p. hydro-electric development on the Peace River. Surveys are to continue until the end of 1959.

YUKON AND N.W.T.

Yukon Territory water-power resources are relatively small, but it may be possible to divert the headwaters of the Yukon River through the coastal mountains to provide a high head for use in the northern part of the province.

Because of the remoteness of the areas and the lack of indigenous fuels, water power is very important to mining areas such as Yellowknife, N.W.T., and Mayo, Yukon Territory. Recent developments (in 1957) include a second 3000 h.p. hydro unit at Mayo River, and progress on the Whitehorse Rapids project (both in the Yukon). At the latter site two 7500 h.p. units are to be completed in 1958, with provision for a third.

Investigations have been made since 1954 by Northwest Power Industries Ltd. (subsidiary of Frobisher Ltd., and associated mining companies Ventures Ltd. and Quebec Metallurgical Industries Ltd.) into the possibilities of the Yukon-Aklin-Taku project which might ultimately provide some 5,000,000 h.p. for electro-chemical and metallurgical industries around Taku Inlet.

Thanks are due to the many power companies and public utilities who supplied information for this review, and also to the Water Resources Branch of the Department of Northern Affairs and National Resources, and the Fuels Division of the Department of Mines and Technical Surveys.

Nuclear Power Development in Canada

M. H. Thomas

Atomic Energy of Canada Limited, Chalk River, Ontario

Although the development of power from nuclear energy on a large scale is still far from realization in most industrial countries, the subject is of the widest current interest. This article reviews the general subject, with particular reference to the thinking of engineers and conditions in this field in Canada.

Since the day in 1945 when the first atom bomb exploded over Hiroshima, the world has been aware of atomic energy, firstly through fear of the new military weapon and secondly through man's desire to harness this new form of energy to his own use. This second awareness is now becoming paramount since history clearly tells us that our advances in civilization have been directly related to our supplies of usable energy, whether slave, fossil fuel, or hydro-electric power. Atomic energy is a common subject for every day discussion; the newspapers and magazines are filled with stories telling of the wonders of the new source of energy. Our actual status today could probably be compared to the time the first electric generating plants in the 19th century attempted to light a town and run electric motors in a factory as far as our knowledge of nuclear power producing equipment and engineering is concerned. This is exemplified by recent reactor equipment failures in UK, USA, and Canada. These failures have been no more hazardous than those in the 19th century steam plants.

Historically, Canada became engaged in nuclear research during World War II. In 1942, after scientists, chiefly British and American, had made their governments aware of the possibility of a completely new weapon, "the atomic bomb", the first crude but successful nuclear reactor was operated in Chicago. Immediately a major program was started with the object of preparing a military weapon. Decisions were made which resulted in the United States, building and operating plutonium producing graphite reactors and uranium-235 producing gaseous diffusion plants, and a British-Canadian team undertook the building of a natural uranium-heavy water reactor for research and production complementing the major British and American efforts.

The concrete results of this wartime collaboration as far as Canada is concerned were twofold; firstly, two heavy water natural uranium reactors were built and, secondly, a team of highly trained scientists and engineers with well-equipped facilities was assembled due to the active role Canada assumed. This team has continued to make valuable contribution to the new technology through the experience gained in the successful operation of the two reactors. The two initial reactors built were: ZEEP with a very low power rating, the first built outside the United States, and used for experimental purposes particularly relating to fuel arrangements for experimental reactors (NRX, NRU), and latterly for power reactor designs; and NRX originally of 10 Mw. but later raised to 40 M. thermal power rating.

Operating initially in 1947, NRX was the world's first high flux reactor, and has been a useful research and development tool ever since. The primary objectives of NRX operation on which its original design was based were production of neutrons for various basic research programs, production of radioisotopes such as cobalt-60, and production of plutonium in the irradiated uranium fuel.

About 1950, it was becoming very apparent that the scientific and engineering development was progressing so rapidly that the application of nuclear energy on an industrial or commercial basis should be considered. Since that time, the primary objective of the Canadian program has been the development of economic nuclear power. Atomic Energy of Canada, a crown company, has endeavoured to provide facilities for the research and engineering work required, and to encourage Canadian industry to participate in the practical application in order to suit the particular Canadian requirements and economy.

Initially, NRX was re-adapted to engineering test programs for power fuels. Programming was delayed due to an accident in 1952, but work in this field in collaboration with Westinghouse Atomic Power Division led to the formation of a Nuclear Power Branch in 1954 which included industrial participation, the proposal of a power demonstration reactor, NPD, and a study on the feasibility of full-scale power reactors. Simultaneously, additional equipment to implement the program was built at Chalk River. Two new reactors became operative in 1957; a low power Pool Test Reactor primarily to be used for fuel evaluation and NRU, a 200 Mw. power high flux reactor. NRU will serve a triple purpose of a plutonium production reactor, radioisotope production reactor, and an experimental facility for high flux testing of fuels and engineering equipment. NRU became operational early in November. The construction of NPD has been undertaken, and will be completed by late 1961.

In March, 1958, a nuclear power plant division was set up by AECL in Toronto to extend the original feasibility study into an engineering development study of a proposed power reactor now called "Candu", and to approve the construction plans for the NPD reactor.

In a manner very similar to conventional steam plants but at present with several more variables, a number of different types of reactors are being considered by different countries. At the present time, all countries are working with uranium as the fuel for short-term programs. The actual fuel cycle is a nuclear one, but the heat removal problem is a conventional mechanical one. A brief description of the nuclear process will serve to highlight the variables.

Fission Process

Natural uranium metal which can be rolled and machined just like steel, contains one atom of U-235 in 140 atoms; 0.7% by weight, the balance being U-238 atoms—99.3%. Of these two isotopes, it is the U-235 isotope which takes part in a chain reaction. Thus, if we consider a rod of uranium say in the NRX reactor, the following possible sequence occurs. A neutron, which is a very small uncharged particle making up part of a nucleus of an atom approaches a U-235 nucleus, enters the nucleus, making it unstable. The nucleus is forced to seek a more stable condition and does so by splitting into two fragments called fission fragments or products. These two fragments, which are actually nuclei of lighter elements such as barium, strontium, etc. have a combined mass very slightly less than the mass of the original U-235 nucleus. It is the conversion of this mass to energy in accordance with the Einstein theory which gives rise to the so-called nuclear energy. The fission fragments fly apart with tremendous energies, but cannot move far as they are restrained by adjacent atoms. Hence, they slow down rapidly and in doing so give up their energy in the form of heat.

At the time of "splitting" or "fissioning" of the U-235 nucleus, something else happens. Two or three neutrons are ejected at very high velocities. These neutrons can potentially cause fissioning to take place in adjacent U-235 nuclei and this in fact is the way the chain reaction progresses. However, these very energetic neutrons are inefficient in causing fission to occur in U-235 nuclei and are much more effective when "slowed-down" to a point where they are called "thermal" neutrons. This slowing down or thermalizing is accomplished by allowing the fission neutrons to bounce around amongst the nuclei of light atoms such as hydrogen or carbon. Common materials used are water, graphite, and heavy water containing a heavy hydrogen isotope, deuterium. Heavy water is a much more effective moderator than graphite or water because of certain nuclear properties. Having bounced back and forth among heavy water nuclei, the neutron gradually loses most of its energy, becomes thermal and eventually is either captured in a U-238 nucleus, escapes to structural materials, or causes fission to occur in a U-235 nucleus to maintain the chain reaction.

A realization of the number of such events occurring simultaneously may be gained from considering that the neutron flux or intensity of, say the NRX reactor, is in excess of $10^{13}/cm^2$-/sec. That is to say ten million-million neutrons per second would pass through a thin window one quarter inch square if such a window were placed inside the "core" of the reactor.

There are a very large number of fission "events" occurring in each fraction of a second and the resulting energy release causes the uranium rod to get hot. This is the point in the process at which a real limitation exists. Were the power of the reactor not controlled, the heat output of the uranium would increase to the point that it could not be removed fast enough and the temperature would rise until the uranium melted. This is in fact what happened to some of the uranium fuel rods in the NRX reactor at the time of the major accident in 1952.

The extraction of this heat in an efficient manner is one of the problems which is being continuously investigated in the development of nuclear power reactors. At these rather high temperatures, uranium metal and most of the uranium alloys are severely corroded by the coolant which is forced over the surface of the fuel to carry away the heat. Hence, it is necessary to clad or sheath the fuel with a non-corroding material. For low temperature reactors such as the ones at Chalk River, aluminum is satisfactory. For higher temperatures which exist in the power reactor, aluminum does not have the required physical properties, and it is necessary to use such materials as stainless steel, zirconium, etc.

So, in general, reactors are characterized or typed—

(a) by the type of fuel used, natural uranium or alloys of fissionable elements (enriched reactors).

(b) by the kind of moderator used to slow down the neutrons.

(c) by the type of coolant used to extract the heat which primarily determines the steam conditions which can be attained.

Decisions on each characteristic has fundamental effects on the design criteria for a particular reactor—

The existing Canadian reactors at Chalk River are shown in Table I.

A number of countries have large supplies of uranium. In the free world, the estimated annual production for uranium oxide, U_3O_8, is about 30,000 tons per year in 1958. The leading producers are United States, Canada, and South Africa, with Canada producing about 14,000 tons per year. This uranium production is equivalent energy-wise potentially to 70 billion tons of coal per year. Reserves of economic ore are being increased rapidly. In addition, by the use of another nuclear process not described above, very high efficiency in the use of the fuel in the longer term stages of nuclear power development appears to be perfectly feasible.

A brief word should be said about the general program of various countries before discussing the Canadian program in greater detail. Generally, all countries in their initial programs are using natural uranium as the fuel, mostly as the metal. The major exception to this statement is the United States. Having had available gaseous

Table I. Canadian Nuclear Reactors at Chalk River

	Power (Thermal)	Fuel	Moderator	Coolant
ZEEP	up to 5 kw.	natural U	heavy water	heavy water (1)
NRX	to 40 kw.	natural U	heavy water	water
NRU	to 200 Mw.	natural U	heavy water	heavy water
PTR	to	enriched U	water	water (1)

(1) convection cooling only.

diffusion plants producing very highly enriched uranium-235 for military purposes, the United States has a two-way program on reactor development with regard to fuel and the chief emphasis has been placed on the use of U-235 enriched fuel in their general program.

Other Programs

From this point on, the programs of most major countries show considerable divergence based on their national requirements which may be illustrated by the few examples.

The United Kingdom plans to have in operation by 1965 nuclear plants producing five to six thousand Mw. electrical, equivalent to eighteen million tons of coal per year. For this first stage she is building advanced Calder Hall type stations. The nuclear reactors are natural uranium fuelled, graphite-moderated and CO_2-cooled, and represent Stage I of United Kingdom's move into the nuclear power field. They are expected to be competitive with thermal stations in England by 1962, and produce power at 6-8 mills in the English accounting system. Improvements announced in the last few months have increased the confidence in this type of reactor markedly and lowered the capital installation cost. Future stages will have reactors whose principles will be tested in small development reactors currently being constructed. The United Kingdom has a dire and urgent need for power, and wishes to reduce her imports to thirty million tons of coal per year.

Western Europe (Euratom) plans a target of 15,000 Mw. electrical by 1967, buying a portion of initial plant designs from countries with the engineering knowledge, chiefly United States and United Kingdom. They expect to buy a billion dollars worth of equipment from countries with the nuclear engineering facilities. France is the only country in this area with a highly developed nuclear technology, and is one of the "big" five in the nuclear field. Like the United Kingdom, the urge to turn to nuclear power is spurred on by a mounting coal and oil import cost as the area is no longer self sufficient in fossil fuel supply.

Scandinavia, which also imports considerable coal, is pressing a vigorous nuclear power development program concentrating on natural and enriched uranium reactors using heavy water moderators. Their program emphasis has been on ultimate use of the heat for process steam and space heat since considerable hydroelectric power development is still practical. Sweden for instance is planning a group of eight reactors for space heating in the Stockholm area.

Neither the United States nor the U.S.S.R. are in great need of nuclear power at the present time. The present forecasts are for 3,000-4,000 Mw. in U.S.A. by 1965 and 1500 Mw. in Russia by 1961. However, the United States has embarked on a three stage program of development reactors aimed chiefly at finding the economical types. As mentioned earlier, the United States program is largely based on the use of enriched fuel chiefly to keep the capital outlay per Mw.d. of power low and partly influenced by the capital accounting system. The most common forms of reactor in the U.S. program to date are pressurized water reactors and boiling water reactors using light water for both moderator and coolant. Recently two of the proposed reactors have been delayed or deleted because estimated costs were obviously rising very high and the proposals did not appear competitive.

Operating Prototypes

Five operating power plant prototypes are on stream in the Western World — Calder Hall (U.K.), two at Marcoule (France), EBWR and Shippingport (U.S.A.). Both Shippingport and Calder Hall are being scaled up to commercial units and show considerable promise. International competition for potential export markets is already beginning with several potential customers surveying the existing plants and evaluating their value with respect to their economics.

The Canadian situation as far as power demand is concerned may be summarized as follows: Canada has 49 thousand Mw. potential hydroelectric power of which, on Jan. 1, 1957, some 13.6 thousand Mw. had been developed. For 1955, 95.5% of our power consumed (69.5 million kwh.) was generated by water power and 4.5% (3.5 million kwh.) by thermal power. The result has been that Canadians have enjoyed one of the lowest rates per kilowatt hour in the world. Compared to the United States, the only other country exceeding Canada in amount of power generated, the rates (including transmission) to the consumer are as follows:

	Domestic	*Commercial*
U.S.	2.64 cents/kwh.	1.3
Canada	1.66	0.7

However, in certain sections of the country, our utilization of water power has been very high, particularly in Southern Ontario and the Maritime Provinces. Potentially, the Maritimes still have the possibility of water power from tides. Ontario has started to swing to thermal power already and the long range planning of the Hydro-Electric Commission indicates the lack of available hydropower.

Currently, Hydro-Electric Commission forecasts hydro usage remaining essentially static until 1980 at 5.5 thousand Mw., while thermo conventional advances to 10.6 thousand Mw. and nuclear thermal to 7.5 thousand Mw. by 1980.

Canadian Approach

With this brief background we can now consider the general Canadian approach. Although the Canadian effort is on a much smaller scale than a number of other countries, it has been successful and a significant contribution has been, and is being, made to the science and technology of nuclear power production. The Canadian authorities have reasoned that the Chalk River establishment should be primarily a research and development centre and that nuclear power plants should be operated by the utilities. Also, it has been established policy that as far as possible Canadian engineering firms should do reactor design and that Canadian manufacturers should fabricate the various reactor components.

To keep Canadian industry fully informed on the progress in the Canadian program, an Advisory Committee on Atomic Power was formed with representation from all the major Canadian utilities. This committee convenes as required and members are supplied with information which permits the evaluation of the economic importance of nuclear power in terms of their respective future power requirements. As a result of such an evaluation, the Ontario Hydro-Electric Power Commission joined Canadian General Electric and

Atomic Energy of Canada Limited in the Nuclear Power Demonstration project.

Construction of NPD was started about the middle of 1956 near the Des Joachims hydro electric station on the Ottawa river some 20 miles north west of the Chalk River project. The reactor will be Canada's first power producing unit, and will be a natural uranium fueled, heavy water moderated and cooled, reactor in keeping with Canada's experience at the Chalk River project. It is expected that the station will produce approximately 20Mw. of electricity which will be fed into the grid system of the Ontario Hydro Electric Power Commission.

Although construction started in mid-1956, a decision was made early in 1957 to reconsider some of the basic design features and construction was temporarily suspended. This change in plan resulted from data produced by the Nuclear Power group at Chalk River which has been assembling information for the technical assessment of a large power reactor program. The modified design is now essentially complete and construction was restarted in the fall of 1958, with the hope that power will be produced in 1961.

Long-Term Proposals

But what are Canada's longer term proposals for power development? Since 1954, a group of engineers have been working at Chalk River on power reactor feasibility studies. This group has been studying the feasibility of full scale nuclear power plants for central electric generating requirements. The general aim was to investigate the possibility of using such plant to supplant conventional fuel thermal plants since the country now must consider these to meet expanding power requirements. A report was issued in January, 1958, (AECL No. 557), in which it has been concluded that a natural uranium-heavy water nuclear plant of about 200Mw. electrical output could be designed and constructed to give power competitive with conventional fuel plants. The first two units built to such a concept would be more expensive but with the engineering developed on these units, future units would be competitive. It was estimated that units developed in such a program could become competitive with conventional thermal power plants within 10 years. The proposed units are estimated to cost $60 million dollars as capital investment, and to deliver power at less than 6 mills per kilowatt hour. On the basis of Ontario figures mentioned, if such plants were available, Ontario would save importing from the U.S.A. about 20 million tons of coal per year and would use instead uranium mined in Ontario.

This study was well received by the authorities in industry, government, and Atomic Energy of Canada. As a result, in March, 1958, a new AECL division, the Nuclear Power Plant Division, was formed with headquarters in Toronto with the responsibility of preparing an engineering development study of an approximately 200 Mw. electrical output reactor of the type recommended and of approving the work associated with the NPD reactor. (J. L. Gray, AECL No. 561). This division includes personnel contributed to this program by Ontario Hydro-electric Commission and industry.

Canadian Experience

It is not practical to attempt in this paper to present the various technological reasons for Canada's decision to forge ahead with the natural uranium-heavy water reactor concept. Due to our national viewpoint and with consideration of many factors, political, military, engineering capacity, etc., we have not built gaseous diffusion plants, and are bound in our initial program to uranium fuel. In Canada, we have had experience with high flux reactors in which the fuel was "burned-up" more completely; that is, greater heat output per ton of uranium was attained than in other types of thermal reactors. The feasibility study has justified our confidence in this approach. Since Canada produces a considerable quantity of natural uranium, it is naturally desirable for us to use our own fuel as economically prepared as possible. Theoretically, a ton of uranium has a heat potential of 20 billion kilowatt-hours or the equivalent of 2,600,000 tons of coal. At present, only a small fraction of the heat can be recovered since the fuel must be removed due to irradiation damage and the accumulation of fission products or "ashes" of the fission reaction. The study of ways and means to lengthen this fuel life has been one of the important developments in the Canadian program. The use of uranium oxide instead of metal assists materially in this problem and our first power reactors will probably use uranium oxide fuel.

Canada's experience with heavy water as moderator in NRX has led her to apply heavy water for both fuel coolant and moderator in NRU. Although the heavy water is expensive at $28 per pound, its use is justified in savings in capital expenditures, fuel inventory, etc. The use of heavy water improves the neutron economy and the power density in the fuel.

The studies made so far in Canada are on central electric generating stations, effectively base load plants. These studies indicate the size must be about 200 Mwe. to be economic at this time. This size will be competitive with conventional fuel thermal stations in Canada. It may be possible to lower this size or improve its costs as operating and engineering experience is gained. For other types of power generation such as ships, enriched fuel reactors are indicated since these can be built in very much smaller space requirements. Small reactors capable of 25 Mwe. capacity, say, are estimated by U.S. studies as producing power at more than 15 mill kwh. To date, Canada has made little effort to study small plant designs since the power costs are expensive and enriched fuel appears necessary. Both United States and United Kingdom are developing reactors in this field primarily for ship propulsion and military use.

Engineers and scientists at Chalk River are very optimistic about the future of nuclear power, but a tremendous amount of engineering development work still remains to be done. However, now that actual power units are being built or studied in detail, more rapid progress should be made.

SUMMARY

In summary, we can say Canada has a small well-equipped team of scientists and engineers actively engaged in the field on nuclear power development. Their work and study are directed primarily at economic basis load stations designed to meet our particular needs and applying Canadian raw material as fuel. Simultaneously, she is trying to develop in Canadian industry the necessary know-how to build such nuclear equipment as is required and to give industry the knowledge of how and where to use nuclear power.

International Passamaquoddy Tidal Power Project

G. Millar

Chief Engineer, Harbours and Rivers Engineering Branch, Department of Public Works of Canada

The economic feasability of developing large scale tidal power in Passamaquoddy Bay is being investigated jointly by the United States and Canada at an estimated cost of $3,300,000. The investigations will consist of a comprehensive survey of every phase of the proposed project, and will include any possible effect on the fisheries in the area. A two-pool arrangement has been adopted for purposes of design whereby continuous power will be generated at a capacity varying between 100,000 and 375,000 kilowatts, having an annual energy output of approximately 1,800,000,000 kilowatt hours. It is expected that these investigations will be completed by the fall of 1959.

ON THE EAST coast of North America, lying between Canada and the United States, is Passamaquoddy Bay. As part of the Bay of Fundy, Passamaquoddy is affected by the high tides which course up and down between the Provinces of Nova Scotia and New Brunswick (Fig. 1).

The derivation of the name "Passamaquoddy" indicates one of the major problems to be considered in connection with the development of tidal power at this location. Derived from the Indian word "peskutumaquahdic" meaning "the place where the fish are", the name Passamaquoddy refers to a large body of water where there are some important Canadian and United States fisheries.

Tidal power has been a dream of men for many years, and many schemes have been proposed for the development of such power. At the present time, a project for the development of the tides is under way at the River Rance in France. Other schemes for the development of tides have been proposed for San Jose in Argentina, the Severn River in England, and for Mont Saint Michel in France.

In addition to the Passamaquoddy project, investigations have been carried out for another proposed development in the Bay of Fundy. The Memramcook and Petitcodiac estuaries in the upper reaches of the Bay have been the subject of a tidal power investigation by consulting engineers employed by the Government of Canada.

The first serious proposal for a tidal power development, using the waters and the tides in Passamaquoddy, was proposed by Dexter P. Cooper, a distinguished Canadian hydraulic engineer, in the early 1920's.

The original Cooper plan was based upon the use of two bays; Cobscook Bay, located wholly within the United States, and Passamaquoddy Bay, partly within both the United States and Canada. Power was to be generated by drawing water through turbines located between the two pools at Carrying Place Cove on Moose Island near Eastport. Cobscook Bay was to be closed by a series of barriers extending between Lubec, Dudley and Treat Islands, and Eastport. Dams between Moose Island, Eastport and the United States mainland were to separate Cobscook and Passamaquoddy Bays. Passamaquoddy Bay was to be closed by a dam between Eastport and Deer Island and a series of dams between Deer Island and the Canadian mainland in the Letite Passage area. Each bay was to have appropriate filling or emptying gates and ship locks to facilitate navigation.

In 1924, Cooper filed an application with the United States Federal Power Commission for a preliminary permit for his two-pool international tidal power development. Charters were secured from the State of Maine in 1925 and from the Province of New Brunswick in 1928, and an application for project license was filed with the United States Federal Power Commission in 1929. With the advent of the depression, Cooper was unable to secure continuing financial backing to undertake construction.

In 1935, as a relief project, the Government of the United States took over the proposal to develop a tidal project using only the waters of the Bays on the American side of the international boundary. This work was suspended in 1936 before any major construction works could be undertaken. Although the project was not completed, the surveys, investigations and the work completed by the Corps of Engineers is of great value for the present investigation.

The people of Maine and New Brunswick have been continuously interested in this great project, and in 1948, as a result of this interest, the Governments of the United States and Canada instructed the International Joint Commission to review the various reports that had already been made on the Passamaquoddy tidal project, and to make an estimate of cost of carrying out a complete study which would determine the engineering and economic feasibility of this development. In 1950, the International Joint Commission reported to the two Governments that the investigation, required to determine the practicability of the project, would cost approximately $3,900,000.

It was not until 1956 that the two Governments requested the International Joint Commission to undertake this extensive study.

This investigation has been broken down into two parts. An investigation into the engineering aspects of the work and an investigation into the possible effects that the proposed works would have on the fisheries in the area. In order to carry out these two separate studies, the International Joint Commission established two boards, one consisting of engineers and the second consisting of fisheries experts. This paper deals mainly with the studies being carried out by the International Passamaquoddy Engineering Board.

In general, the investigations consist of a comprehensive survey of every phase of the project in sufficient detail to determine the type and cost of the most economical structures necessary to convert the enormous power of the tides into electrical energy.

The International Passamaquoddy Engineering Board, which has been delegated with the responsibility of carrying out the feasibility and economic studies, consists of two representatives of the Government of the United States and two representatives of the Government of Canada. The work in Canada is under the direction of the Harbours and Rivers Engineering Branch of the Department of Public works and in the United States under the Corps of Engineers, Department of the United States Army. Associated with this work in Canada is the Water Resources Branch of the Department of Northern Affairs and National Resources, and in the United States, the Federal Power Commission.

GENERAL FEATURES

The project area includes Passamaquoddy and Cobscook Bays, with a total area of approximately 140 square miles. These bays are partially separated from the Bay of Fundy by numerous islands, including the large islands of Deer and Campobello. Cobscook Bay has an area of 38 square miles, all of which lies south of the international boundary. The area of Passamaquoddy Bay is 103 square miles, of which 87 square miles are in Canada, and 16 are in the United States. (Fig. 2.)

The waters of these two bays rise and fall with the Bay of Fundy tides. The tide range varies from day to day, with a maximum of 27 feet, a minimum of 15 feet, and an average range of approximately 19 feet. During each high tide cycle, a volume of about 3,800 square-mile-feet, or 100 billion cubic feet of water regularly enters and leaves the two bays at an average rate of over 5,000,000 cubic feet per second. The depth of water, the high turbulence, and fast currents, as well as the uncertain foundation conditions add to the difficulty facing this project.

There are two basic schemes for the development of large scale tidal power. They are the one-pool and the two-pool schemes and each has advantages and disadvantages.

The one-pool scheme[1] is simplest in design. It consists of a single barrier or dam containing the power units, gates and locks separating the bay or basin from the ocean. There are three variations of the one-pool scheme.

(1) The single effect: power is generated, from basin to sea during part of the falling tide.

(2) The double effect: power is generated during the falling tide from basin to sea as well as during the rising tide from sea to basin. This is possible by the use of reversible pitch propellor blades or by gate arrangements.

(3) The double effect with pumping: an additional pumping feature minimizes the shutdown period and increases the range within the basin.

The advantage of the one-pool proposal is the economy to be gained by a minimum number of structural components. Its major disadvantage is the discontinuity and variation of the power output.

The two-pool scheme consists of three barriers or dams: one separating the high pool from the sea and containing the filling gates; one separating the low pool from the sea and containing the emptying gates, and a third dam separating the high pool from the low pool and containing the powerhouse.

The operation of the two-pool scheme is simple. The upper pool filling gates are opened only during times when the ocean level is higher than the upper pool and the emptying gates of the lower pool are opened only when the ocean level is lower than the lower pool. The sequence of operations would be:

(1) The filling gates are closed soon after high tide when the inflow ceases and the level in the upper pool is the same as the level in the ocean. At this stage the upper pool is at its maximum elevation. The emptying gates have been closed for some time and the powerhouse has been discharging into the lower pool.

(2) The emptying gates are opened when the level of the falling tide and the level of the lower pool become the same. At this stage the lower pool is at its highest elevation.

(3) The emptying gates are closed soon after low tide when the outflow ceases and the level of the lower pool is the same as the level in the ocean. At this stage the lower pool is at its minimum elevation.

(4) Both gates remain closed as the tide continues to rise until the elevation of the upper pool, which has been falling, and the elevation of the sea, which has been rising, becomes the same, and then the filling gates are opened. At this stage the upper pool is at its lowest elevation.

(5) The filling gates remain opened until soon after high tide when the inflow ceases and they are closed, completing the cycle.

The head on the turbine is the difference in elevation between the upper and lower pools and there are two maximums and two minimums during a single tidal cycle. The maximum heads occur at high tide and at low tide and the minimum heads occur soon after mean sea level is reached on both the rising and falling tides. (Fig. 3).

The advantage of the two-pool development is the continuous output of power. Its major disadvantage is the additional structure components required and lower energy output.

INVESTIGATIONS

In the initial phase of the study the two-pool scheme was selected as being preferable for the Passamaquoddy development. After considering the sociological as well as the engineering and political factors, Passamaquoddy Bay was selected to be the high pool and Cobscook Bay to be the low pool.

Some of the important engineering

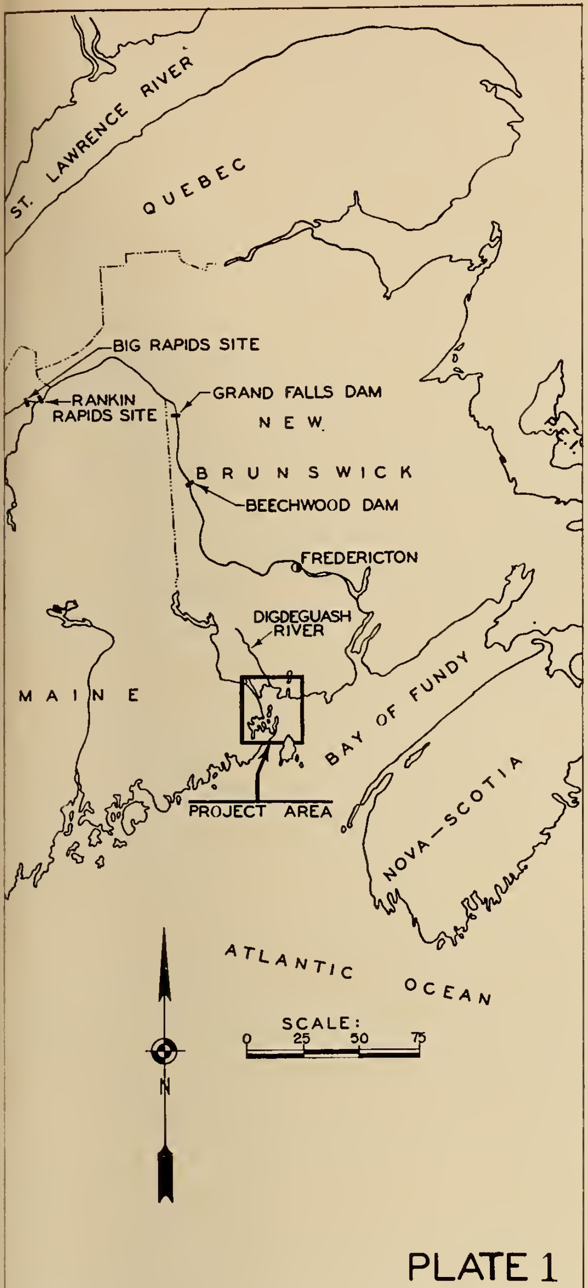

Fig. 1. A general map of the area of the Bay of Fundy, between New Brunswick and Nova Scotia, showing the region in which the proposed power project might operate.

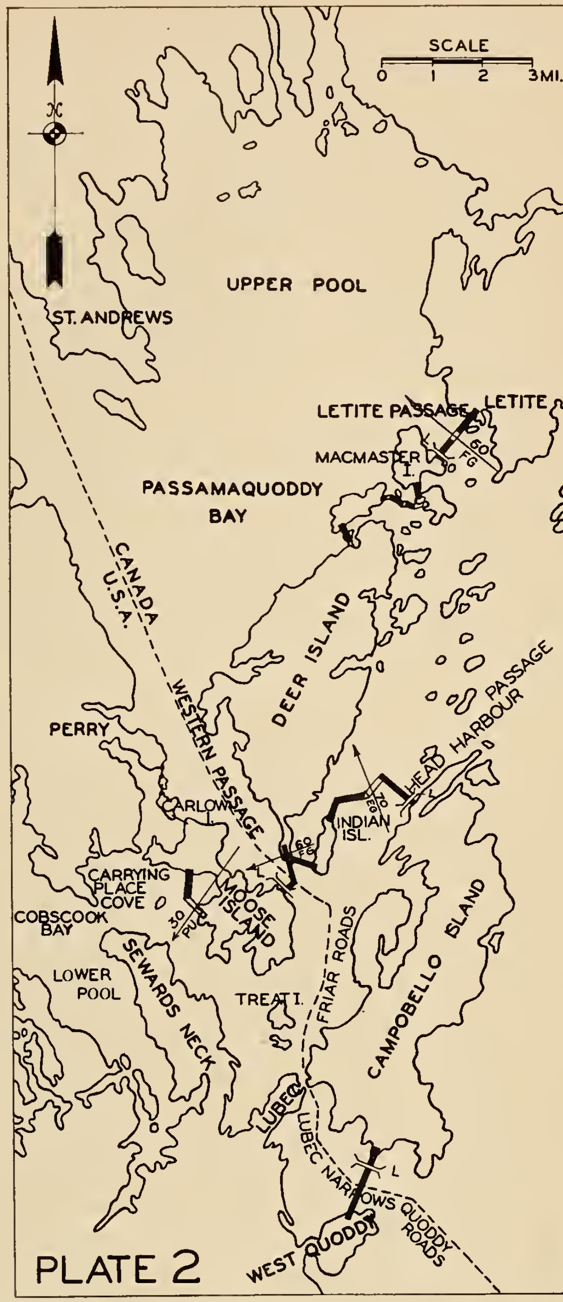

Fig. 2. Detail of the project area, with particular reference to Passamaquoddy Bay and the adjacent islands. Of the Bay, about 84.5% is in Canada, the rest in the U.S.A.

investigations and studies undertaken include the following:

(a) Project Layout Studies: Sixty different general arrangement schemes were reviewed and comparative cost and power estimates were developed. Five of these were given detailed study and from this group two were selected for submission to the International Joint Commission for approval. The project layout approved by the International Joint Commission for further study is shown on Fig. 2.

The features of this layout include: (i) over 7 miles of dams; (ii) a 30-unit powerhouse at Carrying Place Cove; (iii) 50 filling gates at Letite Passage dam; (iv) a navigation lock in the Letite Passage dam; (v) 60 filling gates at the Dog's Island–Deer Point dam; (vi) a lock at the Dog's Island–Deer Point dam; (vii) 70 emptying gates located between Indian Island and Pope's Island; (viii) a lock located at the Head Harbour Passage dam; and (ix) a lock located at the Quoddy Roads dam.

The generator capacity with this proposed arrangement would vary from 100,000 kw. during neap tides to 375,000 kw. during high tides and the annual energy output would be approximately 1,820,000,000 kwh.

(b) Studies to Determine Optimum Number of Turbines and Emptying and Filling Gates: The study and calculations for the determination of the optimum selection and arrangement of power units and gates involves a tedious procedure of multiple trial runs. The estimation of the output of the project is complicated by the fluctuation of the levels of the two pools due to variations in the tide range and the rate of flow from the high to the low pool. The greater the capacity of the turbine-generator units that are assumed in operation the greater will be the rate of rise of the lower pool and the rate of fall of the upper pool.

The cost of adding incremental power generating units must be weighted against the extra power generated by adding these units. At some particular number of generating units, according to their size, there will be diminishing returns. The optimum size and number of generating units must be determined. This is also true for the filling and emptying gates. There were many combinations of the number of generating units, number of emptying gates, and number of filling gates to be studied and related to cost and benefit.

Through the use of electronic computors results were obtained in a much shorter time than would have been possible otherwise. The results or answers obtained with the computors were related to the costs of the different type of structural components, and a selection of the most favourable and economical combination of units and gates for the project was made. (Fig. 2).

(c) Turbine and Generator Study: The study on turbines and generators is to determine the size and type best suited to the unusual conditions of low and rapidly changing head prevailing at the project. Dexter P. Cooper, in his plans, included an initial installation of 20 fixed-blade propellor type units, throat diameter 320 inches, 40 r.p.m., at a spacing of 65 feet; with an ultimate installation of 44 units. The proposed generator capacity was 16,667 kva. at a head of 23 feet.

During the course of its 1935-36 studies, the Corps of Engineers, United States Army, received from turbine manufacturers, proposals for 320-inch, 40 r.p.m., fixed-blade propellor turbines. The manufacturers recommended a unit spacing of 95 to 105 feet. However, preliminary Corps' studies at that time indicated 80-foot spacings to be a reasonable minimum. Because unit spacing is a major factor in the cost of the powerhouse, model studies were carried out. The report on the various tests is quoted in part as follows:

". . . It was soon apparent that the narrow unit spacing was having no serious effect upon the performance and at three laboratories tests were made at a spacing equal to 70 feet. These tests showed that the further reduction in width to 60 feet had a slight effect upon the performance, but in two cases the impairment was unimportant . . ."

". . . As a result of these tests it was found that the width of the water passage and the unit spacing could be materially reduced without affecting the turbine performance and that the depth of excavation had a greater effect upon the performance than did the width of the water passage. In general it was established that a deeper draft tube was necessary with a narrow unit setting and a width of water passage equal to 65 feet clear opening was found satisfactory . . ."

The current studies were initiated by reviewing the findings of the 1935 investigations. It was considered that the most economical powerhouse design would result from the use of the largest practical turbine size. Preliminary discussions with the various manufacturers and others indicate that a 320-inch turbine is about as large as can be conveniently manufactured. Because the cost of generating equipment would increase rapidly for lower speeds, a speed of 40 r.p.m. is considered to be most economical. The excavation costs for the longer powerhouse would increase with smaller units at higher speeds.

Performance curves were obtained for 320-inch, 40 r.p.m. Kaplan and fixed-blade turbines in their standard settings from various manufacturers.

Studies showed that to equip each unit with individual wicket gates and governors, and install a travelling gantry to insert or remove emergency stop-logs was more economical than to equip each unit with individual head and tail gates.

The cost of the wicket gates and governors increases the total cost of each unit, but this cost is offset by the saving in cost of providing only sufficient stop-logs for a nominal number of units. This arrangement would result in greater flexibility of operation and increased efficiency with a minimum of labour.

Preliminary investigations and studies have been made of the European bulb - type generator - turbine - pump unit as proposed for the Rance project in France, the sloping-axis unit, and gear-drive connections between the turbine and generator. Sufficient detailed data concerning the performance of these alternate possibilities is not available as yet to permit any satisfactory conclusion. Consequently, for the purposes of the feasibility survey, further consideration has been discontinued until more factual information is available.

For the purposes of the present investigation the following basic assumptions have been made:

(a) The turbine diameter to be 320 inches.

(b) Operating speed to be 40 r.p.m.

(c) The turbines to be fixed-blade type with blades at the angle of best efficiency.

(d) Each turbine to be provided with governor operated wicket gates.

(e) The turbine to be set vertically in a powerhouse unit having a gross water passage width of 65 feet and the draft tube to extend 73.5 feet below the centre line of the distributor.

(f) The generator capacity to be a minimum of 10,000 kilowatts.

(d) Filling and Emptying Gate Study: The purpose of this study is the determination of the best type of gate for the efficient filling and emptying of the two pools. The problems are the same for the emptying gates as for the filling gates and the study applies to both, except that the emptying gates must be at a lower elevation. Studies were carried out by Cooper and by the Corps of Engineers in 1935. The present investigation includes a review of these earlier studies.

Dexter P. Cooper selected a 30 x 30 foot vertical lift type of gate. The structure housing the gate had a curved-shaped roof entrance and a uniformly expanding discharge section to reduce head losses and to regain velocity head. This was designated as a "Venturi" gate. Model studies carried out by Cooper indicated a possibility of reducing the length of the Venturi roof without appreciably reducing the discharge coefficient.

Model tests carried out by the Corps of Engineers in 1935 indicated a significant improvement in capacity with the Venturi roof removed completely and further tests were made on this basis.

Extensive model studies conducted at the Worcester Polytechnic Institute in connection with the 1935-36 construction program of the single effect single pool project, showed that the crest type of structure can pass more water than the submerged Venturi type for the same width and bottom elevation. This advantage, however, was offset by the several constructional and operational factors, such as higher head frames for the higher gates, increased operating cost, increased maintenance costs due to icing conditions and increased possibility of malfunctioning of the units due to freezing, and interference from floating debris and ice.

The present gate studies do not include further model tests as sufficient data are available from the previous tests. The studies indicate that, using the available test data, the relative capacity of any type of gate can be estimated to within 10 per cent. Further model studies will, however, be required if the project is authorized for construction.

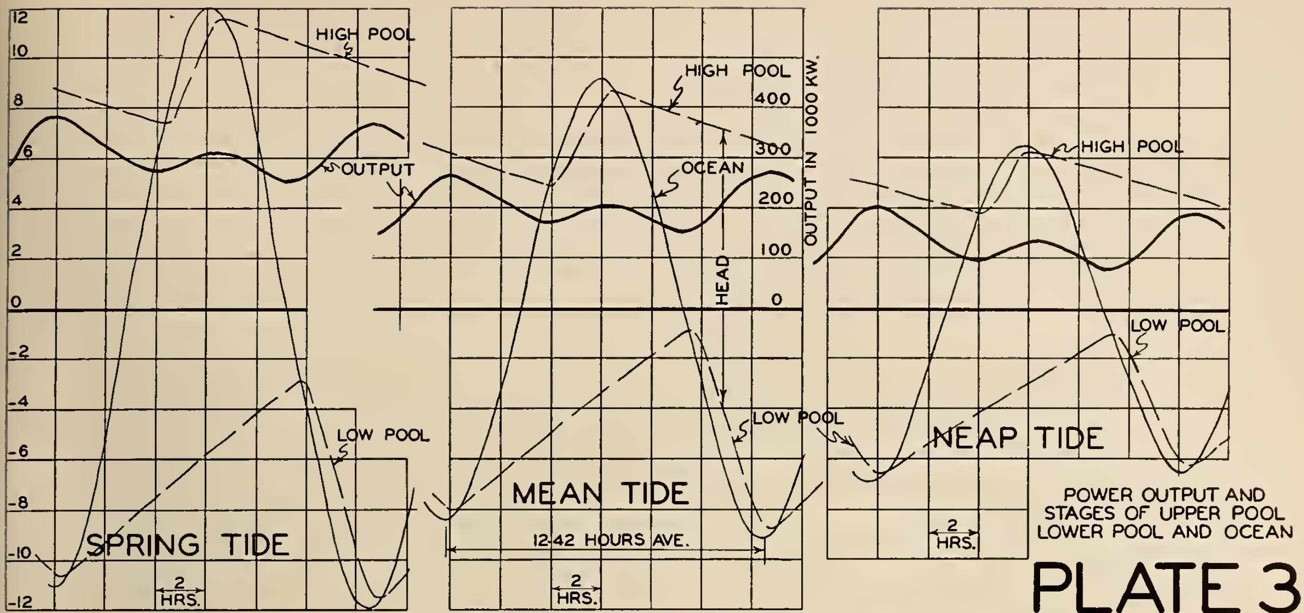

Fig. 3. Variation of tides at different seasons, indicating the resulting power output under the various probable stages of level of upper and lower pools and the ocean.

The power output computations carried out to determine the project layout, and number of generators and gates were based on the assumption that the gate operations would be instantaneous. In actual practice this is not possible. If the time required to close the filling gates is 25 minutes in duration, in this interval the upper pool would be lowered by one-tenth of a foot. This amount would be insignificant for river plants, but it represents nearly one per cent of the average head for the tidal project, and would result in an annual loss of 12 million kilowatt hours. The corresponding loss resulting from the same time of closing for the emptying gates would be about 8 million kwh, a total loss of 20 million kwh. for the both operations. A 5-minute gate operating period is considered to be the maximum. This would reduce the energy loss to one-seventh without a significant increase in the machinery cost.

The minimum head on the turbine occurs at the same time that the gates must be opened. It is, therefore, important that the power required to operate the gates should be kept to a minimum so that the project power output will not be further penalized at the critical time. Because of the need for operating a large number of gates within a short interval of time, individual operating machinery for each gate will be necessary.

Each of the 160 gates would open and close with each tide, and in one year there are 706 tidal cycles, so that each gate would be operated 1,412 times. The total number of operations for all the gates in one year would be 225,920. With this large number of operations it is possible that several malfunctions in gate operations would be encountered each year, and would result in loss of output. If one filling gate was not operating and remained in the open position for one tide cycle of 12.4 hours the loss would be 49,000 kwh., or in closed position for the same time the loss would be 3,500 kwh. Similarly, if one emptying gate was not operating and remained in the open position for one tidal cycle, the loss would be 80,000 kwh., and 3,300 kwh. in the closed position. These losses are relatively small and, therefore, facilities for emergency remedial action should not exceed the value of energy loss. For all gates the greater loss of energy occurs when they are stuck in the opened position. In the construction of the dam each sluice will be provided with bulkhead slots or gains on each side of the service gate slot, and a minimum number of stoplogs or gate leaves will be required for any emergency closure.

In the project area wind-driven spray can form heavy coatings of ice on that part of the structures above the water line. Studies of records of daily air and water temperatures, wind vectors, and 'on-the-spot' investigations, indicate that the type of gate to be used should be such that the danger of malfunctioning due to icing should be a minimum.

Research and study on the use of wood and steel gates under salt water conditions are being carried out. The use of metals having a reasonable degree of inherent corrosion resistance is not economic, and dependence must be placed upon protective measures such as frequent painting as well as cathodic protection, or the use of treated timber in lieu of steel. Other factors to be considered in the selection of suitable material for gates, are marine borers, fungus, barnacles, and other incrustations.

If steel gates are used, painting will be required every two or three years, as well as some type of cathodic protection. The fungus and borer problem would not exist and an anti-fouling compound to protect against the barnacles could be included in the topside paint coating.

If properly treated timber gates are used, a useful life of at least twenty years can be expected. The fungus and borer problem would be minimized, but the barnacles would have to be scraped off periodically. Damage due to debris jamming against the wooden gates would be greater than for steel.

Preliminary investigations have been carried out on the various possible types of gates. For the submerged setting, the vertical lift, the wicket, the mitre and the sliding gates were considered. For the open crest setting the studies included the vertical lift, the wicket, the taintor, the drum, the roller, and the flap types. As a result of these studies on the different types, the vertical lift gate in both the submerged and crest settings, and the wicket gate in the submerged setting were selected for further study.

(e) Auxilliary Power Study: The purpose of the auxilliary power study is to determine the capacity, type and location of other sources of power which will be required to firm up the tidal plant output to satisfy a given load requirement.

Although the energy produced from a two-pool tidal plant is referred to as being continuous, it varies greatly between minimum and maximum limits and is not adaptable to significant regulation. The tidal plant output, assuming no turbine regulation, would be at a maximum or minimum at the same relative position on each tidal cycle. These maxima and minima will be repeated every 12.42 hours but will be increased or decreased depending on the amplitude change of each successive tide. The energy cycle is, therefore, advanced by about 25 minutes every tidal cycle. The load cycle remains constant related to time, but the maximum and minimum will depend on the weekly, daily, and hourly needs of the customers. Therefore, a given load condition will occur with equal probability on all phases of the tidal plant output, and at times the tidal plant output will not be sufficient to supply a given load while at other times it will exceed the load.

Tidal plant energy output is closely predictable because of the predictability of tides. Some regulation within a tidal cycle can be made to meet some load conditions, but not without considerable loss in total energy. With a fixed optimum number of generating units and gates, any temporary pondage or savings of load will be eliminated unless utilized before the next gate operation. It is, therefore, indicated that operating for maximum energy is the optimum method of operation for the tidal plant and that its output should be integrated with some other dependable and flexible source of power so that a given load can be supplied at all times by the combined output of the tidal plant and the auxiliary plant.

The tidal plant output will increase and decrease between certain low limits during neap tides and between certain higher limits during high tides so that at no time will the output be constant. The auxiliary power plant will be required to supply the difference between the varying load and the varying tidal plant output. During high tides the required output from the auxiliary plant will be a minimum and during low tide will be a maximum.

If the auxiliary power is provided by a river hydro-plant, the pondage requirements will differ from that required for normal river operation, and some storage might be required to provide downstream regulations to maintain reasonable water levels.

The tidal plant without auxiliary capacity is only feasible if the variable tidal output, or a great percentage of it, can be utilized directly as generated by such industries as metallurgical reduction processes having a high degree of automation, where the rate of production can be made a function of the tide.

Studies are being made to evaluate the economic feasibility of the following combinations as well as the tidal plant without any auxiliary: (1) the tidal plant with a pumped storage as an auxiliary; (2) the tidal plant with a river hydro-plant as an auxiliary, and (3) the tidal plant with a steam generating plant as an auxiliary.

(f) Topographic Survey: Topographical information of areas not previously mapped, and additional information of the immediate project areas was required for project planning. The required aerial and ground work has been completed of all areas at the tidal project site; the Digdequash River Basin, which is being investigated as a pumped-storage site; and the Upper Saint John River Basin, which is being investigated for auxiliary hydro sites.

The information obtained from these surveys is required to determine storage capacities of reservoirs, location of structures, and areas of land to be flooded.

(g) Fathometric Survey: This survey was carried out to obtain subaqueous contours of the tops of the overburden, the top of the bedrock and information regarding the stratification of the overburden. The work was carried out employing a method similar to echo sounding for depth determination, and a method similar to Shoran for boat positioning.

The sounding equipment was carried in a 30-foot boat and consisted of a transmitter and receiver capable of emitting high-frequency waves that could penetrate through the overburden, be reflected at the various surfaces of the layers of the overburden and the bedrock, and recorded as reflected impulses on a time graph.

The electronic positioning equipment consisted of a mobile master transmitting and receiving station located in the sounding boat, and a number of fixed beacons or slave transmitting and receiving stations located at known positions on shore. The transmitters and receivers of the master and slave stations were tuned to the same operating frequencies. At the master station the time required for the impulse to go to a slave station and return was measured. From the known frequency and wavelength of the impulse, measured time could be converted to units of length. The positioning equipment used in this survey had a maximum range of 50 miles and an accuracy within 20 feet.

After the soundings have been reduced to mean sea level, contour maps will be produced to show the required details.

(h) Underwater Investigation: To obtain core samples of the overburden materials for foundation study purposes, and to aid in the interpretation of records from the fathometric survey, it was necessary to carry out drilling in deep water. Fourteen holes were drilled, two in depths of water exceeding 225 feet; three in depths between 150 and 225 feet, and nine in depths of water less than 100 feet. In each case the drill penetrated through the overburden and into the bedrock.

Undisturbed core samples were obtained for the entire depth of each drill hole. A specially constructed drill boat equipped with an oil-drilling derrick mounted over a well was used. (This boat and its equipment were previously employed in drilling in the Gulf of Mexico for oil companies.) The boat was held stationary over the drill spot with four anchors attached to long heavy cables which required constant adjustment to compensate for the changing tide stage, fast currents, and heavy turbulence.

A guide pipe, 12 in. diam. and in 75-foot sections, was secured to the boat with cables. Three of the 75-foot sections were required for the drilling of the two holes in deep water. Two sections were used where the depth of water was between 150 and 225 feet, and one section only was required where the depth of water was less than 100 feet.

A drill casing consisting of various lengths of pipe was then coupled and inserted through the guide pipe and into the top layers of the overburden, and the anchor cables adjusted to maintain the casing centred in the guide pipe. This permitted the drill to re-enter the same hole after each sample was removed.

(i) Land Drilling: Land drilling has been carried out in three areas to provide information for structural foundations and for structural materials.

A total of 750 feet in overburden and 6,550 feet in the rock was drilled at the project area, the Digdeguash pumped storage site, and at the Upper Saint John River area. Additional borings and test pits are contemplated where satisfactory construction materials have been indicated.

(j) Tidal Investigations: Automatic recording tide gauges have been installed at five locations in the bays of the project area. Charts from these gauges are being studied to determine ranges and characteristics of the tide in the various bays.

The cycle of variations, due to changing influence of the moon and sun, is repeated every 19 years. Records from the tide gauging station at Eastport, Maine, since 1930, have been studied. The plot of the 10-year average of the annual mean tide, plotted each successive year at the mid-point of the 10-year period, indicates that the tide ranges are apparently increasing at the project area.

One important problem to be resolved in this investigation is the influence, beneficial or otherwise, that the proposed tidal project may have on the existing natural range of the tides in the Bay of Fundy. To determine the answer to this problem, special investigations are being carried out.

(k) Navigation Locks Study: The project includes four navigational locks required for continued navigation during the construction period and after the project is completed. One lock located in the Letite Passage will permit traffic between the upper pool and the ocean. A second and third lock located at Head Harbour Passage, and at Quoddy Roads will permit traffic between the lower pool and the ocean, and a fourth lock located at Dog Island will permit traffic between the upper and lower pools.

A detailed study has been made of existing waterborne traffic within the project area, including number of vessels, ports entered, routes taken, loaded dimensions, frequency of trips and cargo, and so on.

Based on this study lock requirements have been estimated. The two

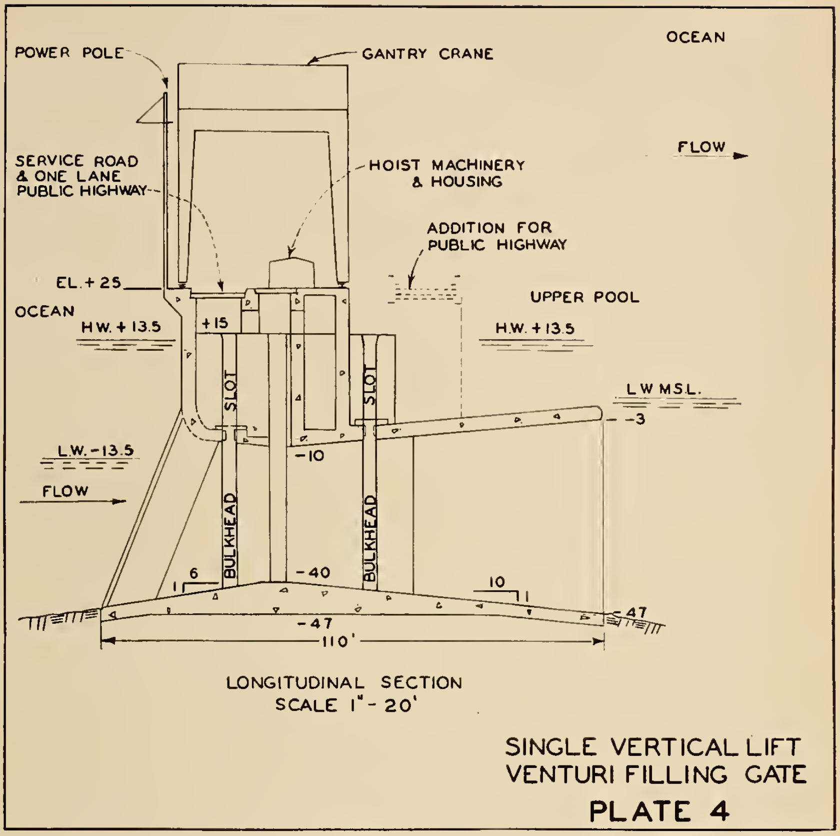

Fig. 4. From hydraulic model studies to determine coefficient of discharge on a proposed Venturi gate, the design shown above was selected for consideration.

main channel locks at Dog Island and at Head Harbour Passage will require dimensions of 450 x 60 x 21 feet and the two smaller locks at Letite Passage and Quoddy Roads will require dimensions of 100 x 25 x 10 feet. These locks will not provide for any increased traffic requirements created by industrialization of the area, but would be the maximum legitimate charge against the tidal power project, for maintenance of present navigation.

The tidal power project, if built, will spur industrial development in the area. This, in turn, may make it necessary to provide locks suitable for larger vessels than are in use at present. Future shipping requirements for the maximum industrial development of the area will probably require main channel locks with dimensions of 860 x 80 x 30 feet. The locks in the secondary channel which will be primarily used by the fishing fleet would not require enlarging. Vessels of the St. Lawrence Seaway class would have access to all the ports in the projected area.

Each lock will be provided with approach walls and a highway bridge. The gates will be sector type operating on vertical hinges. Safety fenders will be installed on each side of the gates. Stop-log gains or recesses will be provided during the construction for any emergency dewatering or repairs.

The additional construction cost necessary for the larger locks would be beyond the normal concept of providing equivalent replacement facilities and the resulting incremental cost of the larger locks would not be chargeable to the overall cost of the project. The requirements of future navigation cannot be evaluated until the cost of tidal power has been determined and the industrial potential has been evaluated.

(l) Materials for Construction: Power auger borings were taken in the fall of 1957 in areas where geological reconnaissance has indicated materials suitable for concrete aggregates and for embankment fill. Faces and pits were opened at several potential sites for embankment fill materials, and representative samples were obtained. The information obtained from the analysis and tests will enable a more accurate determination of the cost of the various structures.

The anaylsis of the core samples taken for foundation investigations are also being studied in connection with the materials for construction as it is intended to use the excavated materials for embankment dams and cofferdams wherever possible.

(m) Embankment Dams and Cofferdams: Typical cross-sections of tidal barriers are being studied in order to arrive at the most feasible section, considering location of materials, tidal currents, maximum size of rock available, equipment required, methods and sequence of construction. The problem of closure is receiving special consideration including the use of models.

A roadway will be provided on all sections of the embankment barriers, and bridges will be provided at each lock. During the 1935-36 construction period, embankment dams were built between Pleasant Point on the Maine mainland and Carlow Island, and between Carlow Island and Moose Island. Both of these structures now carry a branch railroad line.

When the project is built, the total length of embankment dams will be more than seven miles and will be in depths of water up to 300 feet. The top of the embankment dams will be 60 feet in width and will be 20 feet above mean sea level. The side slopes in general will be 1 on 1.75.

With the two-pool system, the high pool will be generally at or higher than the ocean at all times and always higher than the low pool, and the ocean will be generally at or higher than the low pool at all times, so that the head through any section of the barriers will be for the most part in the same direction. Therefore, consideration has been given to embankment dams of two general types—with an impervious core blanketed with quarried stone on each side or with quarried stone blanketed with impervious fill on the pressure. side only. Studies are being made of each type taking into consideration relative quantities, costs, and ease of placing.

Cofferdams will be required in the construction of the various structures. These cofferdams will consist of rock and earth fill and of the design similar to the èmbankment barriers. It is intended to re-use the cofferdam material for the embankment dams.

(n) Model Studies: Hydraulic model tests were conducted in 1935 on the 30 x 30 foot Venturi gate proposed by Cooper to determine the coefficient of discharge. Variation in the gate type, entrance and exit shapes, and sill elevation were tested to determine the gate with the maximum efficiency.

As a result of the model studies the gate selected is that shown in (Fig. 4.)

A model study is being made to determine the most economical method of constructing the embankment barriers. Particular emphasis is being placed on construction by end dumping methods, effect of wave action on slope materials, and method of closure.

A single model of the entire project built on a scale sufficiently large to provide useful information would not be economical.

(o) Transmission Study: A review of the existing transmission facilities in Maine and New Brunswick has been made. Studies are now being carried out to determine the future requirements and costs of the facilities required to deliver the energy output from the tidal project to existing and potential load centres.

During 1955 in New Brunswick, energy requirements were 423 million kwh. By 1980 it is estimated that the requirement will increase to 2,647 million kwh., an increase of over 600 per cent. In Maine the energy requirement is expected to increase from the 1955 figure of 2,417 to 7,160 million kwh., a predicted increase of almost 300 per cent. The largest utility system in Maine, the Central Maine Power Company, supplies 70 per cent of the power load in Maine. In New Brunswick, the New Brunswick Power Commission, a publicly-owned company, serves most of the province. The systems in each country are interconnected at the international boundary, and energy is exchanged between New Brunswick and Maine.

Transmission lines are being studied for the distribution of energy from the project throughout the State of Maine under four different conditions:

(1) The tidal project alone with a local load.

(2) The tidal project alone without a local load.

(3) The tidal project and River Hydro with a local load.

(4) The tidal project and River Hydro without a local load.

The estimated capital costs for transmission lines in Maine vary between $12 million for (1) and $40 million for (4). In New Brunswick the costs will be considerably lower as the area covered by the existing network borders on the project area, and plans are already under way to increase the voltage level of sections of the system.

(p) Pumped Storage Study: Investigations have been carried out for three possible pumped storage sites in the project area. These include Haycock Harbour, Calais, and Digdeguash River. The required foundation explorations and topographic mapping for these sites has been completed. These have indicated that the Digdeguash River site is the best and more detailed study is being given to this project so that a comparison can be made of it with alternate steam or hydro plants.

The Digdeguash River, in New Brunswick, has a drainage area of some 200 square miles and the damsite and reservoir area are located at its outlet into the northerly end of Passamaquoddy Bay. Preliminary plans are for a high-level reservoir providing approximately 100 feet of head. The reservoir will be fed by the river as well as by pumping.

Water will be pumped up into the reservoir during periods when the supply of energy from the tidal project exceeds demand, by a combined pumping and generating station consisting of 4 or 5 pump-generator units, operated with power from the tidal plant. This stored water would be used to generate power through the same units to firm up the tidal output.

(q) Period of Construction Study: Construction has been scheduled for a six year period. This period is sufficient for completion of the entire project, including the auxiliary plant and transmission lines.

Because of the international aspect and the physical nature of the project, it is probable that the construction would be carried out by a series of separate contracts.

The powerhouse constitutes the largest single major construction item and will take five years to complete. The auxiliary power unit, whether steam, pumped storage or river hydro, would be started at the same time and would be completed within three years. This schedule would permit the new capacity to go into production gradually as the demand of the power market increased. The construction of the gates, locks, and embankment barriers will be coordinated to permit maximum re-use of cofferdam materials and to permit bypassing of some of the ebb and flow currents through the gates during the final closure of the embankment dams.

(r) Fisheries Investigation: Fisheries investigations are being conducted by the International Passamaquoddy

(Continued on page 84)

The two official languages used at the World Power Conference Sectional Meeting were English and French, and a simultaneous translation service was available to delegates who attended the sessions.
Unlike some of the permanently-installed systems, the present method, which can transmit on six separate channels, may be set up in any room. It operates on the principle of a closed-circuit radio station, with individual transistor receivers and earphone set for each user. Shown with one of the sets is V. O. Marquez, deputy chairman of the sub-committee on interpretation and recording.

WORLD POWER CONFERENCE CANADIAN SECTIONAL MEETING

Montreal, September 1958

FOUNDED IN 1924 in Great Britain to further international co-operation between engineers, scientists, administrators, and economists in the various fields of power and fuel technology, there have been five full World Power Conferences plus twelve sectional meetings at which particular aspects of the objective program have been discussed.

The most recent of these sectional meetings was the first to be held in Canada, when some 1300 delegates from 61 different countries met to consider the theme 'Economic trends in the production, transportation, and utilization of fuel and energy'.

For nine sessions on various aspects of production, three on transportation, and four sessions on utilization, some 147 papers had been pre-printed and distributed to delegates in the two official languages, English and French, together with a general report summarizing each section. At the sessions, many delegates presented prepared discussion of particular items, and there was much spontaneous discussion from the floor. The subject of nuclear energy aroused so much interest that a special additional session was arranged, under the chairmanship of Sir Christopher Hinton, chairman of the Central Electricity Generating Board, Great Britain, who is responsible for the nuclear energy generating program in that country.

The question was inevitably asked 'what was the outstanding result of this meeting?' Just as inevitably, considering the size and scope of the event, there was no simple answer to the question. There was, however, a central theme running through much of the general discussion about specific papers and fields of interest, which perhaps indicates that the purpose of the World Power Conference was largely fulfilled. The theme can be based on the expression 'it all depends . . .'.

More specifically, the contributions of individual delegates and countries showed what most of the world leaders in the development of power and energy sources are thinking and doing, but, more importantly, the exchange of views helped to clear some misconceptions that may arise when comparing achievements in different parts of the world. What is sound practice in one country may appear quite impractical in another, but the meeting certainly achieved a great measure of success if it furthered the idea of thinking beyond the immediate technical problems involved.

In general it was agreed that engineering techniques, and therefore the work of engineers, tended to run along similar lines. On the other hand, economic and political pressures distort the implications of these techniques. The commercial production of electric power from nuclear energy is being developed rapidly in the United Kingdom because it is becoming more difficult and more expensive to produce the right kind of coal, whereas in the United States, for example, there are ample economic resources of fossil fuels and considerable undeveloped hydraulic resources. At the same time, there is much scope in the U.S.A. for widespread experimental and development work in the field of nuclear energy. A good example of political influence is the closing of the Suez canal, which almost within a few hours affected the level of petroleum prices all over the world and thus altered the economics of power production from this source.

The economic and technical aspects of power cannot be separated. There is a prospective world shortage of power, particularly when the future growth of 'underdeveloped' countries is considered, and it was suggested that the leading countries should concentrate on investigating the most efficient and economical means of developing their own resources, with the inference that the technical knowledge gained could eventually be applied to develop other areas, but in relation to their own particular economic conditions.

THE TECHNICAL SESSIONS

A very brief summary is all that can be given here of the large amount of material presented at the technical sessions. The individual papers, general reports, oral discussions, and reports of the general proceedings are to be published later as a bound volume of Transactions. A complete set of papers and general reports is available for reference in the library of the Institute.

THERMAL ENERGY

Generation, Conventional Fuels (System Planning)

Various papers in the discussion contributed data useful in considering the extension of standardizing of large steam turbines.

In general, present standards for steam generating units for 100 Mw. and under have resulted in reduced cost, earlier delivery, better availability and interchangeability of spare parts. Recent addition of the 150 Mw. standard seems to require modification of the steam temperature conditions as none are being ordered to the existing standard.

In the U.S.A. there is a feeling that the existing preferred standards should be extended to units larger than the 150 Mw. now standardized and for higher pressures and temperatures.

It was suggested that a 200 Mw. size standard be added in view of the large number of units of this size being ordered.

However, some objections have been made by some manufacturers to addition of higher size standards because improvements presently being made in the design of turbines could, within a relatively short time, make any standard adopted now unattractive in the new future.

Useful information from the Soviet Union on this matter indicated that 200 Mw. units are being made, and that for the next five years 300 Mw. will be widely employed. These will be 3000 r.p.m. single-shaft machines. When 600 Mw. units are adopted it is planned to have them built as two shaft units.

For European standardization, the International Electric-technical Commission accepted standards up to 100 Mw. at Munich in 1956, these of course applying to 50-cycle units.

The second topic for discussion was the increased useage of low grade fuels: one contribution pointed out that there are abundant deposits of lignite in Western Canada and that considerable interest is developing in its use. Its characteristics have to be considered. It is a successful fuel if proper care is taken of its peculiarities. In the United States the use of lignite and brown coal is apparently not a pressing matter as there is a variety of other grades of coal easily available. Lignites and brown coals are being used extensively and successfully for power production in Eastern Europe.

The third topic to be discussed is that of increasing the practice of using exhaust and extration steam for industrial purposes and district heating.

In the Soviet Union a balance is struck between the energy production capabilities of an area and the industrial potential of the area. Thereby an optimum economic relationship is present. This method of planning seems well worthy of careful consideration.

The dual supply of electric energy and steam from electric plants is important in other respects. In common with other systems supplying metropolitan areas, the Consolidated Edison System of New York City is experiencing a greater rate of load growth in the summer than in the winter due primarily to the impact of commercial air conditioning requirements, so that the annual peak loads have shifted from the winter to the summer season. In many instances, it has been found to be more economical to utilize steam instead of electric drive

Senior officials of the World Power Conference shown here, from left, are: G. A. Hathaway, vice-president; Sir Harold Hartley, honorary president; Maj. Gen. H. A. Young, vice-president; Franz Holzinger, president; Sir Vincent de Ferranti, chairman; and C. H. Gray, secretary.

for the air conditioning of buildings adjacent to steam supply mains.

In Belgium, as elsewhere, the two main factors considered in planning the combined supply of heat and electrical energy are the low load factor of the heating load and the relatively low density of that load, which involves extensive piping systems with high capital costs.

The last topic for discussion was the combination of the heat cycles of gas turbines and steam turbines to obtain the more efficient use of fuel used in power production.

It was reported from the U.S.A. that the main objection to the use of gas turbines on utility systems there is the small capacity of the gas units; and that, moreover, the gas turbine has not yet been properly developed for use with coal as fuel. However, one point is obvious and that is that the gas turbine has a distinct advantage, a peaking and or emergent unit easily adaptable to remote control and where fuel costs are of secondary importance and the reduction of spinning reserve of major importance.

A discussion from Switzerland points out that in comparing the combined gas turbine—steam cycle with the conventional steam cycle it is important to take into account the fact that the combustion cycle sacrifices to some extend the gains inherent in regenerative feed heating.

Discussion from France states that the combined cycle makes for gains in specific heat consumptions without going to excessive pressures and temperatures in steam units.

The free-piston gas generators are an admirable source of pressure in these cycles, being easy to regulate as they work on a substantially steady load. They give a considerable gain in output and a flat efficiency curve without involving serious trouble in operation.

Another discusion from France states that combined cycles seem to offer the best way of reducing heat losses to a steam turbine condenser. Many combinations exist. Free piston gassifiers are of great benefit and aid in achieving these results. Generally, it was felt that combined cycles reduce heat losses and should therefore be studied intensely.

A. S. Pavlenko, who was leader of the delegation of engineers and scientists from the U.S.S.R., is here seen addressing one of the technical sessions. Mr. Pavlenko later presented the Canadian National Committee with a set of three films dealing with Soviet power developments.

THERMAL ENERGY
Oil, Gaseous Fuels

The papers offered in this session dealt with the general energy supply and requirements situation, exploring the subjects of reserves, exploration, drilling, marketing and the production of synthetic gas from coal.

A major theme was the current and future pattern of fuel and energy demand to be met from oil and gaseous fuels.

The discussion at this session covered trends in future prices of natural gas and one contributor discussed trends in the delivered cost of gas in the U.S., pointing out the shift which has taken place in the share of the delivered price attributable to the field price of the product.

Another contribution called attention to the lack of reliable cost information and the inherent difficulties in allocating separate costs to oil, gas and other hydrocarbon production. It was believed that the difficulties involved are a challenge to the industry and governments concerned and that greater efforts should be made to maintain accurate statistical and cost records.

Two contributors quoted estimates of reserves and one of them stressed the importance of such estimates in future planning. The importance and value of such estimates was discounted by one contributor who suggested that they have little meaning and might even be considered as dangerous.

THERMAL ENERGY GENERATION, CONVENTIONAL FUELS (DESIGN AND OPERATION)

Six papers had been accepted in this Section and sent to all delegates prior to the opening session.

The paper by Messrs. Sporn and Fiala aroused extremely wide interest. This reported on the first nine months operation of the world's first major steam generating unit at Philo Plant in Ohio, U.S.A., of 110,000 kw. capacity, which operates at the supercritical steam pressure condition of 4,500 psi, 1150° F. with double reheat at 1,050° F. The steam is produced in a "once through" steam generator, in which the conventional steam drum is not required. Despite initial "teething" troubles on some of the ancillary equipment, the main components of steam generator, and turbo-generator have performed satisfactorily and enabled a new high in thermal efficiencies to be established.

However while the technical problems can be said to have been solved, there was a general feeling that such plant is probably not yet an economic proposition, due to the high capital costs involved in construction. However most speakers considered that not many years would elapse before large supercritical units would be an economic solution, for increasing power capacity on large networks.

Further papers were considered which dealt with the problems of using low grade fuels in steam power plants. Two Belgian authors had presented a paper dealing with the handling, separation and drying of slurries, prior to use in the steam boiler furnace. A Russian speaker discussed the problem of burning anthracite dross as it was tackled by the Soviet Union. A French speaker discussed the difficulties related to using low grade fuels with very high ash content and which are having to be burnt in ever increasing proportions in his country.

A paper presented from Czechoslovakia dealt with economic solutions of combined electric power generation and district heating schemes, brought forward several speakers who discussed the great economies that could be achieved provided that high load factors (upward of 50%) existed on the heating load system. This conclusion was claimed to be still valid, despite the important advances achieved in the efficiency of generation made by very high pressure condensing steam units.

The problems, inherent in choice of location of steam power stations, were dealt with by an Italian speaker, covering widely different geographical conditions which exist in his country.

Speakers from France and Italy reported on the progress made in their respective countries using conventional fuels for the production of steam and electric power.

The concluding speaker foresaw that in his country, the U.S.A., some 150 million kw. of new plant capacity would have to be installed in the next ten years; and that by 1968 he anticipated that supercritical conditions would be common practice together with fully automatic operation of such steam power stations.

THERMAL ENERGY—COAL

In the opening ceremony, Sir Harold Hartley, remarked: "Never before has there been available so wide a choice of sources of energy, suitable for use in varying circumstances". Coal is our oldest and most widely employed source of energy and, as the better and more accessible deposits are worked out, the problems encountered in its economic applications become greater and more numerous.

It was pointed out that high moisture content is no longer a serious problem, if the coal is burned in pulverized form and provided that a high air preheat is employed. With certain lignites, adequate ventilation is necessary to avoid overheating of the coal in storage. Underground wetting methods may result in the fine coal being too wet to screen at the pit heads, but this difficulty was not regarded too seriously.

Several speakers remarked on the steadily increasing percentages of ash (in some cases, up to 60%) which necessitate the use of coal in the pulverized form, preferably in large boiler furnaces. The fusion temperature of the ash largely determines the method of its disposal, either dry or in the form of slag, and so influences the design of the furnaces themselves. Suitable provision must also be made for the removal of ash and dust, both from the heating surfaces and from the gases entering the chimney. The various air pollution control acts specifically limit the amount of dust and gas that may be omitted into the atmosphere and these laws are becoming increasingly stringent. For the purpose of limiting these undesirable emissions, the use in series, of cyclones and electrostatic precipitators, having efficiencies up to 97 per cent, is now standard practice.

There is a definite general tendency toward the increased use of fine coals and this indicates the desirability of avoiding transportation difficulties and, at the same time, reducing costs, by generating electrical energy at, or near, the pit head. This tendency implies also the desirability of locating industries and power consuming communities near to the coal fields but, however desirable this may be theoretically, it is not always feasible in practice, because these communities require supplies other than power and, moreover, the water resources available are sometimes inadequate or unsuitable. In such cases the use of jet condensers and indirect air cooling, was suggested.

In Great Britain, the amount of large sized coal used has decreased by 23 per cent, since 1950 and that of small coal has increased by 32 per cent in the same time. Domestic heating by means of coal fell by 17.8 per cent, between 1921 and 1956.

Canada has large coal reserves located in the East and West respectively, but the area of maximum consumption is in the centre of the Dominion. As a consequence of this, Nova Scotia, recently, had a stockpile of 1,400,000 tons and a serious unemployment problem involving 10,000 miners. A new government freight subvention has resulted in the potential sale of some 500,000 tons, but this is a palliative, rather than a cure. It is hoped that the St. Lawrence Seaway will help to relieve this situation by reducing transportation costs.

The situation in the U.S.S.R. in connection with the transportation problems and the use of lower grades of coal is of a similar nature to that described by other speakers. In all cases, the economic radius of transportation evidently increases with the quality of the coal. It is claimed that the U.S.S.R. has successfully surmounted the difficulties met with in pulverizing anthracite dross.

Centralization and Methods of Control

The logical applications of the principles enumerated above suggest the advisability of employing large units and this, in its turn, implies a considerable degree of centralization and the controls associated therewith. Not only are more capital funds made available, but they can be applied to the best advantage. Planning on a large scale is facilitated, the best technical services can be obtained, more standardization becomes possible and further advantages accrue from the centralization of labour negotiations and from a monopolistic market.

Mining Operations

The general tendency toward increased mechanization and a greater amount of fine coal that results from it, was discussed in detail as far as it applies to British mines. With room and pillar mechanization, the output per man-shift increases fairly steadily with the seam thickness up to and exceeding 7 feet but, with longwall mechanization, there is a steady increase up to a thickness of 3 feet and beyond that the output remains steady, or decreases slightly, as the thickness increases. The problems associated with seams thinner than 3 feet are low output, short faces, high costs, the use of small machines and greater difficulties with faults. There is also more dirt and less room for its disposal.

With seams thicker than 6 feet, strata control is more difficult, accidents from falls are both more frequent and more serious and the roof supports are heavy to handle.

The limiting depth for roof and pillar working is considered to be 1500 feet, but longwall operation is not seriously affected by depth, provided that the face is kept moving.

Obviously, conditions such as heat, gas and dust become more serious as the depth increases. Roadway conditions also are adversely affected and costs are increased. Their seams are affected economically, to a greater extent than thick seams.

Comprcssed Air and Electricity for Underground Operations

The overall efficiency of a compressed air system varies in practice from 5 to 15 per cent, as compared with 60 per cent for electrical machines. It should be noted here, by way of comparison that, in one paper, a much lower figure is given for compressed air efficiency.

Compressed air operation is evidently preferable from the standpoint of safety in cases where gasey seams are encountered, but some accidents have occurred with these systems. Methane drainage is widely practised in Britain and has been generally beneficial. The use of electricity makes it possible to supply power conveniently to the larger and more powerful machines that are now being installed and the dust problem is reduced. Compressed air operation is declining in British mines but, nevertheless, there are some operations in which the use of compressed air is almost unavoidable.

Mr. Lorimy also favours the use of electricitv and gives some representative figures from French practice, which indicate its superiority, provided that suitable precautions are taken.

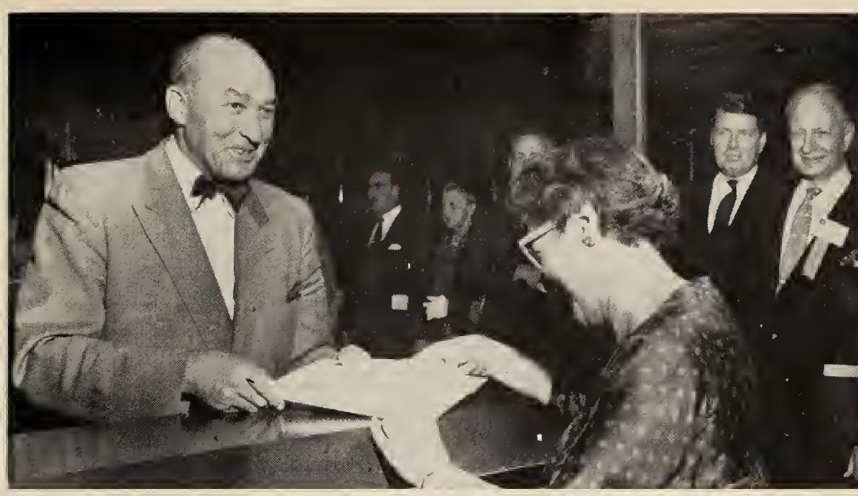
Other Applications

The use of small sized coals for producing gas, or for the liquefaction of coal, was suggested. This would not onlv reduce the drain on our liquid fuel resources, but would provide an outlet for low grade coals which might be displaced by a wider application of atomic power.

PRODUCTION—THERMAL ENERGY

Nuclear Energy and Nuclear Fuel

The world is entering a new phase in the development of nuclear power for central station applications. The early excitement and interest in a wide variety of possible types of reactors appears to be subsiding and is being replaced by sober concentration on a few. The major competitive types are the gas-cooled graphite reactor and water moderated reactors, but there is a growing universal interest in heavy water moderation. An important aspect of this new phase in nuclear power development is that



Although the World Power Conference was not an E.I.C. meeting, nearly all the members of the Canadian National Committee are also members of the Institute. Members of E.I.C. headquarters staff were present to help with registration, reception, information, and the internal post office for delegates. Dr. L. Austin Wright, HON. M.E.I.C. (extreme right), general consultant, E.I.C., who was chairman of the registration and reception committee, watches Maj. Gen. H. A. Young, M.E.I.C., chairman of the Canadian National Committee, at the registration desk.

in recent years several experimental power stations have gone into service around the world and designers are looking to the performance of these plants to provide a firm foundation for advances in design and to point the way to economies in construction. This is already bearing fruit in the United Kingdom, where the latest gas-cooled graphite designs enjoy the benefit of the pioneering experience of Calder Hall.

The United States has the largest and most varied experience with reactors. Nine civilian power reactors have produced electricitv, including Shippingport with 60,000 k.w. output. Many designers consider that enrichment can be used to lower capital costs appreciably, e.g. by permitting a larger ratio of sheath to fuel and therefore higher specific powers. The annual fixed charges are so high for private financing that the capital savings may outweigh the extra fuel costs for enrichment and it is questioned whether natural uranium reactors can become important in the United States except through government financing.

The discussion at the main session and at the additional session was very extensive, and cannot be dealt with in full here. However, the subjects discussed included the availability of nuclear fuels, various aspects of reactor design, and the economics of power production from nuclear energy sources.

In recent years it had been considered that the technical development of nuclear power might be restricted by a lack of economically-available fuels (uranium and thorium). Now the position had reversed, and the state of technical development was tending to restrict the market for the now abundantly available mineral fuels.

There were considerable differences of opinion on the economics of nuclear power production, but it was largely agreed that many of these differences were due to the varying approaches made in different countries to such subjects as capital costs, amortization, fuel costs, and so on.

The subject of nuclear power in Canada is discussed more fully in a paper on page 63 of this issue of the *Journal*.

HYDRAULIC ENGINEERING—SYSTEM PLANNING

This section discussed 13 papers, three submitted by Canada, one by Austria, one by Great Britain, one by Italy, one by Poland, one by Spain, one by Soviet Union, two by United States, and two by Yugoslavia.

The papers covered many features of hydraulic production and emphasized the importance of correct technical and economic planning of the facilities of various kinds, so that the least cost to the consumer of electricity will result.

The four points suggested for discussion by the General Reporter, Dr. G. R. Lord, brought forth discussions which occupied the whole of the allotted time for this meeting. Point No. 1 for discussion was intended to be provocative, and achieved the desired result, although there was no unanimity among those who discussed the order of development of hydraulic sites.

A number of the speakers in this discussion covered various aspects of the planning for pumped storage, which has become recently attractive to system planners in widely separated areas. It was pointed out by one speaker from Great Britain that there were features unique to each pumped storage development. His interesting discussion outlined some of the factors which were considered in a proposed pumped storage development in Scotland, and gave the conclusions they had reached. They had found use of a digital computer of great help to them in reducing the time which would otherwise be required to do laborious calculations. This is just another example of the value of this very versatile tool that can be used where engineers are making a comparison of alternative facilities, to determine which is the most economic. These computers are becoming available in ever increasing number, and have proved of immense value in relieving engineers of the necessity of making time consuming routine calculations, so that their time can be more profitably spent on other matters requiring their special knowledge and experience.

Other matters receiving the attention of the speakers at this session were:

(1) The proportion and function of hydraulic, thermal, and nuclear plants in an overall system plan where each of these types was to be used. One speaker announced what he considered to be a radical suggestion for a mixed highly economical steam stations operated continuously to carry base loads with a series of hydro electric storage plants with sufficient added capacity to carry variable and peak loads. If conditions were right, this had been proved in at least one case of which he had knowledge, to result in most economical operation.

(2) The advantage of studying the development of all the energy resources of a region to arrive at the most economic overall plan was stressed by several speakers. Their very interesting discussions outlined how each had attacked the problem giving proper weight to the features peculiar to his own region, and the form of the planning and the order of development which resulted.

(3) One speaker emphasized the importance of transmission costs where the power was generated remote from the load. In cases of this kind, the transmission cost might be a controlling factor.

HYDRAULIC ENERGY—DESIGN AND OPERATION

Of the seven papers, five dealt directly with details of construction and manufacture of hydraulic turbines and of pumps for storing water for use in hydraulic turbines. One paper described a large pumped storage scheme for developing power at periods of peak demand using water stored during off-peak periods. One paper was an analysis of a scheme to make available tidal energy on a firm basis, utilizing a design of pump turbine which can act as a pump, a turbine, or a sluice in either direction. The proposed scheme would enable dependence on some tidal power for peak periods no matter what time of day the demand were experienced.

During the discussion of the papers, evidence was presented of successful operation in France of two experimental designs of turbines for tidal schemes. It appears that France is much nearer to an economical solution of the problem of obtaining power from the tides than we have been heretofore.

The seven papers reported work done in six countries. A seventh country was heard from during the discussion, in a report on very large units being built in Sweden.

The discussion brought out that differences in techniques in America and Europe may be due largely to the different requirements of the economies of these areas.

Discussion of the papers was under four headings:

(1) Adjustable blade turbines and pumps — The outstanding contribution under this heading was the description of the development of the Deriaz pump-turbine in Great Britain — an adjustable blade diagonal flow turbine and/or pump.

(2.) Fixed blade turbines and pumps — Possibly the most newsworthy paper in this category was a description from Switzerland of successful operation of high head multistage pumps in reverse, producing power as turbines.

(3.) Bulb or tubular turbines — The report from France, mentioned above, kindled much interest in this subject. A Swiss report added to the information on various design schemes for tubular turbines, such as might be applied in small streams with small available heads.

(4.) The use of new alloys — In this category mention was made of the use of high tensile steel for the stressed plate steel parts of hydro developments, and of the use of stainless steel to reduce maintenance problems.

HYDRAULIC ENERGY—GENERAL

N. S. Lalander (Sweden) observed that the questions recommended for discussion are not amenable to definite answers. For instance, the economic limit of development of hydro resources is generally determined by the production costs of hydro power as compared with thermal power. Monetary comparisons are insufficient: the special merits of the production sources must be compared.

The economic limit of hydro development, based on cost comparison with thermal power, changes from time to time. The first evaluation of the economic limit of development for Swedish water power was figured at 32.5 x 10° kwh per year in 1923. Successive re-evaluations have raised this figure to 80 x 10° kwh per year from a gross of 200 x 10° kwh. Only 29 x 10° has been so far developed.

The relative economic value of winter energy in Sweden is placed at roughly twice the value of summer energy, due to relatively good regulation possibilities.

The Norwegian, Finnish and Swedish systems were expected to be interconnected, establishing a major Scandinavian power pool. Factors underlying this are the relatively radically reduced costs of necessary interconnections and the differences in storage possibilities in the three countries.

Mr. Adams (United States) noted—

(1) Only under most unusual circumstances is it feasible to develop hydroelectric plants for utilization in a purely hydroelectric system.

(2) The fullest and best use of hydro resources require that they be operated in combination with thermal plants.

(3) Some hydro sites can only be economically developed when they can be tied into a large system.

With reference to the subject of developing power from tidal waters, an article on the engineering aspects of the Passamaquoddy tidal power project, Bay of Fundy, appears in this issue of the Journal (page 67).

(4) Long-range planning is necessary for the proper design of hydro projects to ensure maximum utilization of the potential of each site, with system development.

However, (1) and (2) above are open to question in many areas, with attractive hydro resources but uneconomic fossil fuels.

G. Bardon (France) compared observations bearing on the relative values of the types of energy, i.e., peak, base, winter, summer, day or night. The comparison shows the following:

Base hydroelectric, 6500 hours' use	1
Hydroelectric energy from stations with reservoirs providing weekly storage	1.5
Energy from alpine reservoirs with seasonal storage	2.5 to 2.7
Peak energy, about 1000 hours' use	3 to 3.5

Mr. Bardon further noted the value of hydroelectric developments with small reservoirs providing daily or weekly storage, the increasing value of seasonal storage and improved utilization of water, as well as the reliability of hydro power for less densely developed areas.

J. Tissier (France) discussed the basis on which Electricité de France compares a hydroelectric and a thermal development providing the same service; that is, in a dry period, the capacity available on peak and the energy productibility on winter days. He also drew attention to the necessity of making this comparison over the lives of the two types of plant: 30 years for thermal plant; 40 years for the equipment and 100 years for major civil works in hydroelectric developments.

J. K. Hunter (Great Britain) stressed the significance of pumped storage to the United Kingdom program of some 5000 to 6000 Mw. of nuclear plant by 1965 in combination with larger and larger thermal units. He drew attention to the possibility of pumped storage based on sea water and noted the several problems which might arise therefrom. These are:

(1) Effect of salt spray blown from the reservoir onto adjacent farm land.

(2) Contamination of local wells and surface streams from deep seepage of salt water through the rock formation underlying the reservoir.

(3) The possibility of chemical reaction between the salt water and the surface deposits forming the floor of the reservoir with increased permeability, as possible with certain types of clay.

O. G. Gimstedt (Sweden) observed that redevelopment of Swedish waterpowers began at a slow rate about 1935, with about 10 per cent of the approximately 1000 Mw. installed by 1930 now replaced. A further 15 per cent will be replaced during the next 10 years. Redevelopment frequently involves several stations being replaced by one, using larger dams and longer tailrace tunnels, with higher head and higher water usage.

The stations which have been replaced have had an operating life of 30 to 60 years, with an average of 45 years.

A criterion proposed is that replacement should occur when the loss occasioned by shutting down an existing plant is offset by possibility of redevelopment of the head more cheaply than undeveloped waterpower elsewhere.

Dr. C. Marcello (Italy) drew attention to the factors influencing the relative economic values of the several types of hydroelectric energy and concluded:

(1) Peak energy is worth three times base energy;

(2) Day energy is worth two times night energy;

(3) Winter energy is worth three times summer energy;

(4) Seasonal storage energy is forth four times run-of-river energy, at least for Italy and some other areas.

Dr. Marcello noted that new construction, under execution or planned, would increase developed waterpower to about two-thirds of that now considered possible. As regards intensification of thermal plant construction, he considered it would increase the possibilities for attractive hydroelectric development.

W. A. Dexheimer (United States), in discussing the relative values of energy, described the Bureau of Reclamation's proposal concerning the sale of peak capacity. He noted that, because of the multiple-purpose characteristics of the Missouri River developments — navigation, irrigation and power — seasonal firm power is sold at standard firm power rates.

Mr. Campbell (United States), in discussing country-wide power pool, stated that this is not yet the case in his country. However, there were several extremely large regional pools. He noted advantages of pool operation as:

(1) Savings in capital expenditures

(2) Operating economies

(3) Improved service reliability.

I. V. Komzin (U.S.S.R.) briefly described the notable Kuybishev. He noted an interesting feature — the provision of outlets, above the draft tubes, enabling a 30 per cent reduction in the length of spillway facilities.

I. N. Ozerov (U.S.S.R.) reviewed the factors generally dictating the development of hydro systems and the impact that thermal stations might have in his country. In listing the items bearing upon regional hydro developments — uniformity of run-off, storage, possibilities, etc., Ozerov emphasized the advantages to be obtained, when feasible from the consolidation of separate individual systems.

Dr. C. Semenza (Italy) drew attention to the significance of model tests on high dams and other hydraulic structures and, particularly, to the outstanding work in this respect accomplished at Bergamo. He noted that the best scheme does not necessarily give the maximum output for a project. In addition, Dr. Semenza remarked on the importance of storage reservoirs, pumped storage and underground plants in the modern Italian power economy.

Dr. O. Vas (Austria) gave an interesting treatment of Austrian experience in evaluating the relative value of the several forms of hydroelectric energy, based on the wholesale tariff used by the network for power sales to the provincial distribution companies and a few large industrial consumers.

He noted the practice of the German-Italian-Austrian regional group, which places the following relative values on power interchanges between the three countries:

(1) Winter (November to February)	
peak hours	4
off-peak hours	2
(2) Summer (May to August)	
peak hours	2
off-peak hours	1
(3) Transition months	
peak hours	3
off-peak hours	1.5

OTHER SOURCES – PRODUCTION

Two papers were presented — one on geothermal power sources and one on solar energy utilization in North America.

Professor Tomasi Sais of Spain proposed a novel hydraulic machine for the utilization of thermal or solar energy and developed a mathematical theory. Regrettably, time did not permit a full description of the proposal. Didier Olivier-Martin described a method of extracting water from steam by means of a turbine designed in France associated with a natural uranium air cooled reactor.

Sir John Hacking discussed the utilization of wet steam and stated that the problem has been solved in New Zealand by deriving dry steam from wet steam by flashing or separation. Professor Alcutt discussed the use of solar energy for house heating and described some solar installations. Dr. Parker suggested that we are too pessimistic regarding the exhaustion of fossil fuels and believed that the rate of increased consumption currently forecast is unduly high.

TRANSPORTATION— ELECTRIC TRANSMISSION

The rapidly rising cost of right-of-way is of paramount importance in determining the transmission voltage and the number of circuits, and is of greatest interest where transmission lines must be located through cultivated and urban areas. One contributor stated that the necessity of installinga limited number of overhead lines and the large bulk of power to be transmitted dictated the use of transmission lines at 275 kv. on double circuit towers.

Sincere cooperation in the operation of interconnected systems can result in delivering cheaper power to the consumer. The operation of this system illustrates that through a common need national boundaries become of secondary importance.

The superimposing of higher voltages on existing transmission lines and electrical systems in their present form, or with some modification, is extremely interesting as a solution in producing economies in electrical transportation. Years of operating experience have shown that in some transmission lines unnecessarily high overload factors were incorporated, and on this basis it is possible to super-impose higher electrical loads. Many recent lines are designed to take advantage of this saving in capital investment. One speaker from Sweden, noted however, that although it is possible to theoretically produce a saving by superimposing 500 kv. or 650 kv. on the existing 400 kv. Swedish system, its extent is such that the savings would not be achieved in practice.

Studies of the economies of fuel versus electrical transportation indicate in general that it is more economical to locate the thermal plant adjacent to the source of fuel and to transport the electrical energy to the area of utilization. One contributor observed that in Britain the transportation of electricity is cheaper than the transportation of the coal by rail above a critical distance of approximately 50 to 70 miles, and that this is directly opposite to the situation in the United States, and again a French contributor reported that in France a specific study indicated that it was preferable to transport the coal. From this we deduce that local problems and the national economy must be very carefully considered in any study of this vital problem.

There is an increasing awareness of the possibility of economies in the transmission of electrical energy by a direct current system. Although much of the work on d-c transmission is in the study and research stage, the existing installations have provided much useful knowledge. Further studies and investigations are required due to the increasing demand for the economic transportation of large blocks of electrical energy over long distances and for submarine cables. This is a subject where all countries and organizations can co-operate by pooling knowledge and experience to produce economies in electrical transmission for the benefit of all.

The difficulties inherent in attempting to make economic comparisons of the complex problems involved in the transportation of electrical energy were well expressed by an English contributor. The technical aspects must be carefully evaluated against the economic considerations which can only be applied as they refer to the situation in the immediate vicinity.

Through design, research and economic studies, the future in the economical transmission of electrical energy is in the use of much higher a-c voltages than presently being used, the greater application of d-c transmission, and the greater use of interconnected systems.

The effect of diminishing reserves, higher priority uses and increasing costs will make the use of gas and oil untenable for mass production of electric energy in future years. Furthermore, energy production by atomic fuels is not expected to be low in cost in the near future, so it seems likely that coal fuels will be used to supply most of the United States' additional energy requirements for some time. It is also felt that voltages in excess of 500 kv. are desirable and that it is important to develop more economical transmission line designs.

A contributor from U.S.S.R. noted that for the Soviet Union, with its large territory, the establishment of a united power system must be implemented by the creation and uniting of power systems within economic and geographical regions. A united power system for the European part of the Soviet Union and Siberia is being established, and the final aim is a united system for the Soviet Union.

TRANSPORTATION — RAIL, WATER, ETC.

Five papers were received for this session. From a review of these emerged the close relationship which exists between transportation agencies and the power industry. Each is vitally dependent upon the other both for technically efficient operation and, more importantly, lowest cost operation.

There was no prepared paper on the role of highway transportation in the movement of fuel products, but during the discussion direct reference was made to the growing importance of short haul coal movement in the United Kingdom where currently 20% of coal for steam power plants moves by road transport.

The same is true in a number of other countries. It is also recognized that in the movement of petroleum products road transport, due to its extreme flexibility, has a competitive advantage in the short haul field inasmuch as many of the consumers of gas and oil are located along the road itself. Road transport, therefore, while less important as a carrier of fuels, than either railways or water carriers, does make a contribution in the transportation of fuels for power and allied uses, which should not be overlooked.

No paper considered the relationship between the location of power generating plants and transportation costs. This too is a matter of growing importance in that generating plants today have, within limits, the alternative of locating either in the consumer market and transporting fuel to the plant or building at the mine site and transmitting power to the consuming centres. Trends in transportation charges are of particular interest to the Power Industry and this subject was referred to in its relation to the various types of fuel. Liquid fuels are found to be in a particularly favourable position in this regard. The quite different and complex position where transportation by rail is involved was dealt with by two contributors to the discussion.

From the U.S.A. there was an interesting contribution showing the trend toward increase of movement of fuel by water carriers.

It was clear that in respect of both rail and water transportation economies in cost and efficiency were being realized through technological developments.

The striking efficiency of transportation in the international movement of fuels is amply attested to by the remarkable extension of the international market for fuel products since the late 30's. At a time when world production of fuels are at a peak an ever increasing proportion is entering the international market — some 20% in 1957 compared to less than 15% in 1937. Then too there has been an even more striking growth in the length of transportation haul — an increase of 50% over the same period, from 4,000 to 6,000 miles bringing virtually every country within the economic range of world fuel resources. The importance of this to under-developed countries is profound as ample supplies of reasonable rates is basic to improved standards of living.

Regarding the relationship between transportation rates and power costs, the importance of transportation costs of moving fuel should not be exaggerated. For example, fuel frequently moved thousands of miles to consuming markets without seriously affecting power costs. In Canadian railway operations, great efforts were being made to reduce operating costs; the average annual reduction in railway costs was approximately 2%. All forms of transportation are complementary rather than competitive insofar as the transportation requirements of fuel are concerned. Frequently railways cannot provide a complete service as is also the case of water carriers.

TRANSPORTATION—PIPELINE

The need for pipeline transportation for oil and gas has been obvious for a long time, but due to the geographical relationship between source and consuming centre the economic possibilities with their potential risks are not always easy to assess and great care must be taken in the evaluation of each project having regard to the large investment which is involved.

In this session there was no obvious common theme expressed in the papers presented and this is perhaps a reflection of the individual character of each project.

International pipelines might conceivably play an important role in developing cooperation between countries in the course of meeting mutual needs.

The economics of pipeline transportation in Poland was the subject of one paper and one of the main problems touched upon was the lack of heavy concentration of demand as a factor contributing to high production costs.

A French contributor amplified reference to underground storage of gas in France. The importance of this was not merely the obvious advantage of looking after fluctuating consumption but also its value in matching the delivery capability of the wells to the capacity of the gas treatment plants since the fixed charges associated with the latter represent a large component of operating costs.

The value of computers in determining optimum operating conditions was dealt with in the course of the discussion, and the elimination of human error, and the increased speed of proper reaction to changing conditions, in the interest of maximum economy in operation was of great value.

UTILIZATION OF ENERGY
Industry and Commerce

In this session all contributors stressed the importance of energy as an essential factor influencing economic growth.

In some cases this matter was dealt with in general terms, whereas in others the treatment was quite specific, attention being focussed either on efficiency of use or on the availability of different types of fuel and the effect of this on the pattern, past, present and future, of individualism in the various countries in respect of their power problems.

A contributor from France outlined various aspects of the overall problem in a country facing the need for more energy — on the one hand more energy in its various primary forms and secondly better utilization. In France the replacement of obsolete thermal stations had increased available energy from coal by a portion of 2 or 3. A Central Committee of energy utilization studies such problems. A contribution from Japan described load factor improvement by the production of such storable products as calcium carbide from otherwise surplus hydro power, and a paper from Sweden referred to the use of electrical energy in the melting of iron sponge.

Though there were disclosed numerous similarities in the use patterns of different countries, the manner in which they were supplied appears generally to be very fluid. Industrial and commercial requirements are growing more rapidly than the national average while residential and transportation usage is increasing less rapidly. The data from such widely diverse countries as Canada and India seems to confirm this view.

UTILIZATION OF ENERGY
Farm and Residential

The ten papers submitted to this section fell roughly into two categories. First, the historical development of energy use in specific areas, and the impact of this development on living conditions and productivity; and second, the description of a particular use or development in a particular area.

Electrical energy was emphasized in most papers, though some mention was made of the use of solid, liquid, and gaseous fuels for heat and combustion engines.

Papers discussing applications covered such subjects as space heating, irrigation and drainage, and rural electric distribution system design.

UTILIZATION OF ENERGY
Transportation

The papers in this group dealt with a comparison of various fuels in the transportation field, and discussed the factors which make a change in type of fuel necessary or desirable.

The motive power used for railroad operation depends on several economic factors, particularly the fuel costs, which may amount to between 20% and 50% of total annual costs.

Conversion to diesel operation is almost complete in the United States, with Canadian railroads now in the final stages of a similar conversion. In Europe there has been some conversion to diesel locomotives, but there is a greater tendency towards electrification.

It is possible that the gas turbine or free-piston gas turbine unit may become attractive, particularly as they can use cheaper fuels than the conventional diesel engine. However, it was considered unlikely that the nuclear-energy powered unit would be considered as practical for a long time. Rather, attention might be paid to the use of large nuclear power plants, linked in a common system, to provide electrical power for railroad systems, particularly where these operated over great distances or in areas in which such power was not available from conventional sources.

International Passamaquoddy Tidal Power Project

(continued from page 74)

Fisheries Board to evaluate the effect that the tidal project will have on the fishing industry in the area. This Board is responsible directly to the International Joint Commission and will report separately from the Engineering Board. Close liaison exists between the two boards. The Fisheries Board consists of Canadian and a United States sections and is assisted by federal, state and provincial agencies.

The investigations being conducted by this board include fish catch statistics, biology, habits, environment, under present conditions and forecasts of the effect on the fish life in the area of the proposed structures.

Estimates of the monetary value of any damage or benefits to the fishing industry in the area, attributable to the project, will be used by the Engineering Board in its estimate of the cost of the tidal project.

(s) Economic Study: Economic surveys are being carried out separately for the State of Maine and for the Province of New Brunswick to determine all possible uses for the new power which would become available when the tidal project is built, and to determine benefits to the industrial and economical development of the state and province. Emphasis is being given to a study of possible new industries which might locate in the project area, particularly industries which can make use of a varying supply of power.

CONCLUSION

The decision to build the Passamaquoddy Tidal Power Project will be taken by the Governments of the United States and Canada, and this decision will be based on the results of the present investigations. The final reports from the Engineering and Fisheries Boards, to be the International Joint Commission, are scheduled for completion by October 1959. The Commission, after reviewing the findings of the Boards, will make its recommendation to the Governments of the United States and Canada.

The long debated question of the economic feasibility of harnessing the tides of the Passamaquoddy region will be answered soon after October 1st, 1959, and forty years of speculation based on incomplete information will be ended.

TRANSACTIONS

OF THE ENGINEERING INSTITUTE OF CANADA

The fourth issue of Transactions in the present series, (Vol. 2 No. 3) will be mainly the proceedings of the Conference on the Bearing Strength of Ice. This Conference was held in April 1958 under the auspices of the Division of Building Research of the National Research Council.

Titles of the articles in this issue will be as follows:

Ice Landings, C. H. Duff.
The Preparation of Ice Landings by Pulp and Paper Companies in Eastern Canada, L. B. Rose and C. R. Silversides. Preliminary Measurements of the Strength of Melting Lake Ice, D. F. Barnes. Recommended Standards for Small-Scale Ice Strength Tests, T. R. Butkovich. Preliminary Results and Review of Sea Ice Elasticity and Related Studies, D. L. Anderson. Deflections of Plates on Elastic Foundation, L. W. Gold, L. D. Black, F. Trofimenkoff and D. Matz. Relative Strengths of Plates on Elastic Foundation, L. D. Black. The Theory of a Narrow Infinite Wedge on an Elastic Foundation, D. E. Nevel. Discussion of papers.

The fourth issue will be distributed to members during the next month. Publication date of September, announced in the September issue of the Journal, has been delayed.

Transactions can be mailed to non-members of the E.I.C. on request, at the cost of $1.00 per copy. Subscriptions to Transactions can be arranged through E.I.C. Headquarters.

INTERNATIONAL NEWS

INTERNATIONAL CONFERENCE ON THE PEACEFUL USES OF ATOMIC ENERGY

THE SECOND United Nations International Conference on the Peaceful Uses of Atomic Energy was held, 1st to 13th September, in Geneva. A brief summary of the main features of the conference is given below.

On 22nd September, the General Conference of the International Atomic Energy Agency (IAEA) opened its second session in Vienna, Austria, and elected Dr. Tjondronegoro Sudjarwo (Indonesia) as president. The IAEA is an intergovernmental organization under the aegis of the United Nations, with a permanent scientific staff. It investigates and co-ordinates many phases of the use of nuclear energy either as a direct service to individual nations or as a general service to all nations. The session benefited from the experience recently gained at Geneva.

The Geneva Conference

This year, 48 governments and six intergovernmental agencies submitted 2135 papers, compared with 1076 in 1955. Of the 6300 participants, 2700 were members of government delegations from 69 countries (1428 official delegates in 1955).

A scientific exhibition held as part of the conference was seen by some 100,000 visitors. It included displays set up by 20 governments and two organizations in a special temporary structure with 8,000 square metres of floor space.

FUSION INVESTIGATIONS

In his closing address to the conference, the President, Francis Perrin, French High Commissioner for Atomic Energy, stressed the importance of "unreserved disclosure, in the most important fields," that occurred during the session. In the field of controlled fusion, he said, research now seemed "to be entirely devoid of secrecy."

Thermonuclear reactions — or at least experiments aimed at obtaining enough knowledge of fully ionized gases (or plasmas) at high temperatures so that controlled fusion can be achieved in the future — were a topic of major interest at the conference. Complex devices being used in these studies occupied a large part of the governmental exhibits, and six sessions of the conference were devoted to theoretical or experimental work in this field.

In all this work, it is evident that two major approaches have been followed in all the countries doing research. First is the "pinch effect" in which a large current through a gas causes magnetic fields that constrict it, raise its temperature, and turn it into a plasma. In this approach, the problem is to prevent the pinch from destroying itself, and machines with complicated electromagnetic systems have been developed.

In the second, magnetic mirrors can be used to contain a plasma which has been pre-heated and whose temperature is then increased by collisions of the plasma particles within the magnetic fields.

Although temperatures of over a million degrees have been reported for both approaches, no one has yet been able to claim with certainty that thermonuclear reactions have been achieved. However, improved measurement techniques are providing more and more information about what happens in a plasma, and speakers expressed confidence that thermonuclear reactions would be achieved in the near future.

Actual production of sustained controlled thermonuclear reactions that yield more power than is needed to run the machines producing them lies much further in the future, most experts at the conference agreed. No estimates of the time needed have been shorter than 10 years, and some have been as high as 50.

As for production of usable amounts of power, all opinions indicate that this is far in the future and that fission will be the only source of nuclear energy for many years to come.

FISSION REACTORS PLANNED

Development of large power stations with a wide variety of reactor designs was described in sessions on fission reactors.

Reports indicated that power stations now operating in the USSR, the United Kingdom, and the United States had been "well-behaved," with less difficulty than anticipated at the 1955 conference, as Sir John Cockcroft noted in his summary of the session.

For the future, plans were outlined for large nuclear plants in Belgium, Canada, Czechoslovakia, France, Italy, Switzerland, the USSR, the United Kingdom, and the United States. They will include, for example, a 500,000-kilowatt station at Hinkley Point (UK); a 180,000-kw. station south of Chicago (USA), and a 600,000-kw. station in Siberia informally described at a press conference.

Reviewing reactor designs presented, Sir John noted that graphite-moderated and heavy-water-moderated reactors would have the lowest fuel costs. Boiling-water reactors seemed to be growing in favour because of small size and comparative simplicity; the organic-moderated reactor was attractive because of its non-corrosive, non-radioactive coolant; high-temperature gas-cooled reactors using ceramic fuels might prove important for propulsion as well as land use; and experiments with fluid-fueled reactors and sodium-cooled types were providing important information.

As a means of using the world's supply of fissionable materials to best advantage, several speakers advocated fast breeder reactors. Power breeders under construction in the USSR, UK and USA were described.

Development of methods to utilize the plutonium formed as a by-product in most uranium reactors was described as another means of conserving nuclear fuel. Thorium may well be coming into use by the late 1960's, and plans for the first large-scale power plant to use thorium (in the USA) were cited.

Estimates of the world's uranium reserves were two to four times higher than those presented in 1955. High-grade uranium reserves might total some 10,000,000 tons, and world thorium reserves seem likely to be at least 500,000 tons.

New developments in the complex process of separating fissionable uranium-235 from the more abundant U-238 were described by a number of countries. They compared, for example, the gaseous diffusion process, separation by "nozzle" equipment, and centrifugal separation techniques.

USE OF ISOTOPES

In sessions reviewing applications of isotopes, reports described use of tritium (radioactive hydrogen) as a new tool in biological and physiological research. It is a "soft beta emitter" with a half-life of 12½ days. When injected into living processes it can be assimilated in the cells, and its presence recorded photographically. Accounts were given of tritium investigations on the nucleic acids.

Reports on the use of radioactive chemicals in the treatment of disease indicated that the outstanding advantage still remains the use of radioactive iodine which lodges in the thyroid and produces internal radiation for the treatment of that gland; other radioactive elements do not lodge with the same precision in the appropriate organs or with the same measurable results, and it was emphasized that this was a question of refinement of techniques.

The detection and treatment of brain tumors was also reviewed. Here the search is for materials which will concentrate in those tissues of the brain about which the diagnostician is seeking information and, when irradiated from an external source, will give off rays showing the exact location of the tumor or lesion.

Radioisotopes in medicine are no longer novelties, although Dr. R. H. Chamberlain, of Pennsylvania University, warned against indulging in their use merely because they are fashionable. They have now become precision instruments. For example, as described at the Conference, it is now possible to take "slow-motion pictures" of living processes by injecting radioistopes into experimental animals, instantly deep-freezing them in liquid nitrogen at fixed intervals and thus obtaining photographic records of each stage of the process.

WASTE DISPOSAL PROBLEM

The disposal of wastes from present peaceful uses of atomic energy did not constitute a danger, speakers agreed. However, when fission reactors come into widespread use throughout the world, their radioactive "sewage" might produce a dumping problem. The Chairman of the session on that topic, Alexander Goldberg (Israel), commented that tombs of radioactive waste were becoming as elaborate and as expensive as those of the mummies of ancient kings.

Confidence was expressed that methods now being developed for the solid containment of dangerous atomic by-products (in glass, in concrete, and in beads) for burial could be safe and effective. A Canadian report estimated that the cost of storing wastes in glass would be an unimportant percentage of the price of commercial electricity.

Concern was expressed about the possible large-scale dumping of nuclear wastes in the seas, by speakers from the USSR and the United States, but the consensus was that disposal up to now had been within safety limits.

FUNDAMENTAL PHYSICS

In fundamental physics, highlight of the conference was the presentation by scientists from CERN (European Center for Nuclear Research) of experimental results confirming the direct decay of the pi meson into an electron. This reaction had been predicted theoretically 23 years ago, but it was not until now that the theory could be substantiated.

Almost the entire range of fundamental physics, ranging from "strange particles" to theories of interactions within the nucleus of the atom, was considered at various sessions. In his summary, Sir John Cockcroft spoke, for example, of the "enormous amount of new data" from cosmic ray workers, and a "wealth of new knowledge" produced by atom-smashing accelerators.

GENERAL

The Conference included general sessions on comprehensive subjects, technical sessions or more detailed topics, informal meetings of scientists on problems of special current interest, evening lectures open to the public, and a series of films, as well as the scientific exhibition.

The 2,135 papers came from the following 48 governments and six organizations: Argentina, Australia, Austria, Belgium, Brazil, Burma, Byelorussia, Canada, Chile, China, Cuba, Czechoslovakia, Denmark, Finland, France, German Federal Republic, Greece, Hungary, India, Iraq, Ireland, Israel, Italy, Japan, Mexico, Netherlands, New Zealand, Norway, Pakistan, Philippines, Poland, Portugal, Romania, Spain, Sweden, Switzerland, Thailand, Turkey, Ukraine, Union of South Africa, USSR, United Arab Republic, United Kingdom, United States, Uruguay, Venezuela, Vietnam, Yugoslavia; United Nations, International Atomic Energy Agency, International Labor Organization, World Health Organization, International Bank for Reconstruction and Development, World Meteorological Organization.

Speakers presented 711 of the papers orally, individually or in panel discussions, and the others will appear in the printed proceedings.

Exhibits were provided by Argentina, Belgium, Canada, Czechoslovakia, Denmark, France, the German Federal Republic, Hungary, India, Italy, Japan, Norway, Spain, Sweden, Switzerland, Union of South Africa, USSR, United Kingdom, United States, Venezuela, CERN, and the Joint Institute for Nuclear Research at Dubna, USSR.

The formal conference proceedings, together with the press briefings, were recorded on 21 million feet of tape for later use and reference.

In addition, the full 1958 Conference Proceedings will be published in 33 volumes, compared with the 16 volumes required for the 1955 conference. The first one or two volumes will go on sale in November, and publication is expected to be completed by mid-1959.

The conference was planned by the UN's seven-nation Advisory Committee on the Peaceful Uses of Atomic Energy, which is composed of scientists named by the governments of Brazil, Canada, France, India, the USSR, the United Kingdom and the United States, with Secretary-General Dag Hammarskjold presiding.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Seaway Progress

A ceremony was held on September 5 at the international power-house where it crosses the international boundary, to dedicate the new hydro-electric plant, and to mark its official opening. Premier Leslie Frost of Ontario and Governor Averill Harriman of New York State jointly pressed a switch to start eight generators delivering power on a commercial basis, and to illuminate huge figures of "Uncle Sam" and a Canadian "Mountie".

A crowd of some 1,200 Canadians and Americans heard addresses by Ontario Hydro chairman, James Duncan, New York State Power Authority chairman, Robert Moses, and former New York Governor, Thomas E. Dewey.

Weather during August was favourable, though with many contracts completed or nearing completion the total force employed was reduced to an average of some 10,000 persons during the month. Early in September, five units on the Canadian side of the power-house and six units on the American side were in operation intermittently, supplying secondary power. Installation of the remaining units was progressing, with expectation that one new unit on each half of the power-house would be readied for operation about every six weeks.

Progress by Ontario Hydro

Placing of concrete on the Canadian half of the power-house had reached about 98½ per cent of completion, with some 15,000 cubic yards yet to pour in various places. Dredging was continued on upstream channels at two sections. Dredging of the tailrace on the Canadian side will not be commenced until next year. Average employment for month of August was 2,200 persons.

Progress by NYSPA

Placing of concrete on the American half of the power-house stood at about 98 per cent of completion with some 20,000 cubic yards still to place in various locations. Work was proceeding on building a cofferdam for excavation of the tailrace area. The first half of this cofferdam will be enclosed and ready for pumping by mid-September. Two dredges were working on the south Cornwall channel.

On the Long Sault dam, the last of the concrete was being placed in the tunnels through the spillway. Twelve of the gantry-operated gates and six of the hoist-operated gates were completed and in service. Average employment during the month of August was 2,500 persons, down 300 from the previous month.

Progress by SLSDC

With lock approaches completed and the two American locks operating satisfactorily, dredging continued downstream and near the new high-level highway bridge. On the bridge, erection of steel was completed for the main suspension span and a start had been made on placing concrete on the roadway deck. Employment during the month of August had dropped to about 400 persons.

Progress by SLSA

By the end of August, water had been let in over the entire length of the seaway navigation channel between Montreal harbour and Lake St. Louis. All concrete had been placed on all Canadian locks with exception of short lengths of the upper approach wall to the lower Beauharnois lock and lower approach wall to the upper Beauharnois lock.

At the St. Lambert and Côte Ste. Catherine locks, gates were installed but not tested, while installation of gate machinery was proceeding. On the two Beauharnois locks gates were in position but installation of gate machinery had not proceeded very far. There still remained considerable excavation of the channel to complete between the two Beauharnois locks, while above the upper lock and below the lower lock preparations were underway to permit sinking in place of seven and twelve precast concrete cribs respectively in the channel upstream and in the basin below in Lake St. Louis. Target date for completion of all four locks is the end of November.

On the Welland canal, excavation had been completed between locks 1 and 4. There was still some work proceeding at Port Colborne, Port Weller, Thorold and in the Welland area.

Bridges

Only work remaining at end of August on the Jacques Cartier bridge was to pour concrete around the permanent piers supporting the span over the seaway channel. The National Harbours Board will call for tenders in September for an additional traffic lane to ease congestion on the bridge.

At Victoria bridge, the lift span over the St. Lambert lock had been completed except for electrical installations. The roadbed for the highway diversion on the upstream side was expected to be in place by March 1959, but trains will continue to use the straight course across the bridge and will wait while the lift is up until 1960, at which time the steel work for the rail part of the diversion will be completed.

At the Mercier highway bridge the four-lane section leading to the south shore was completed and traffic was running over one of the three high-level approaches. Cars were using the 'east abutment' which carries traffic towards Laprairie. Traffic to Malone and Valleyfield was also using this approach until the first of two approaches for these routes is finished by end of October. The third approach will be a two-lane ramp leading to Valleyfield which will not be completed until February. The Quebec Roads Department was building half a mile of permanent highway leading to Laprairie from the south approach to the Mercier bridge.

At the CPR-NYC Caughnawaga rail bridge the new lift span was in service across the seaway channel.

Employment on all phases of the Canadian navigation project during the month of August averaged 5,300 persons.

Other Seaway News

The City of Cornwall, as part of a master plan to serve the needs of industry, has planned a harbour for ocean vessels on the east side of the city. A total of 11,500 feet of wharfage will provide berths for 15 ships at one time. There will be offloading and storage facilities for bulk shipments on Pilon Island which will be connected with the mainland by a lift-bridge causeway. The harbour is planned for eventual handling of 4 million tons of freight yearly. The city has set aside 300 acres of serviced land with a further 900 acres reserved.

Missiles for Canadian Defence

"Although the *Arrow* aircraft and the *Iroquois* engine appear now to be likely to be better than any alternatives expected to be ready by 1961, it is questionable whether in any event their margin of superiority is worth the very high cost of producing them by reason of the relatively small numbers likely to be required", Prime Minister Diefenbaker announced on September 23, 1958.

These and other reasons prompted the decision against putting the Canadian supersonic interceptor CF-105 into production. The *Bomarc* guided missile will be introduced into the Canadian air defence system.

The *Bomarc* is a long-range anti-aircraft missile guided from the ground. The control system is the S A G E (semi-automatic ground environment).

The Avro Arrow project began in 1953. Subsequent missile developments alter the conditions anticipated when the aircraft would come into use in the 1960's. The conclusion is that manned aircraft, however outstanding, will be less effective in meeting the conditions than previously expected.

Related decisions reported by the Prime Minister are these:

Two Canadian bases for firing the *Bomarc* missiles will be established in the northern Ontario and Quebec areas.

Pinetree radar control system will be augmented by several large stations and a number of small intervening stations.

SAGE electronic control and computing equipment will be installed into the Canadian air defence system.

Missile and aircraft defence will be on an integrated North American basis under NORAD operational control.

The *Arrow* aircraft and *Iroquois* engine development program will continue until next March, when the situation will be reviewed. (One hundred *Arrows* are to be built, according to a news report.)

Development programs for the *Astra* flight and fire control system, and the *Sparrow* air to air missile being developed for the *Arrow* were cancelled. Modification of the *Arrow* during its continued development will permit the use of a system and weapon already in production.

Canadian work in the design, development and production of defence equipment will have to be closely integrated with the major programs of the U.S.

Negotiations are under way for Canadian industry to share in the production programs for the missiles, associated equipment and electronic computers.

Ontario Highway Program

Extensive additions being planned for Ontario's highway program were announced by the Premier in August.

An expenditure of some $100 million is proposed, in addition to the record program already under way.

The policy of the Government was then announced as follows:

1. To co-operate with the State of New York and the State of Michigan in building international bridges and approaches at Queenston and Sault Ste. Marie on which tolls will be charged.
2. To proceed with a new entrance to the Niagara Parks System particularly from Queenston to Niagara Falls.
3. To erect skyways at three points on the Welland Canal—at Homer, near St. Catharines, and in the Welland and Port Colborne areas. These skyways will be tolled.
4. To complete the Causeway over Rainy Lake, east of Fort Frances, and extend Highway 120 westward from Atikokan. The causeway will be tolled. These roads will give further access to the Quetico Park area and will link the Trans-Canada Highway with the Mississippi Parkway now under development in the U.S.
5. To construct the Chedoke Expressway in Hamilton as a provincial project which will greatly relieve traffic conditions in that area.
6. To extend the road from Port Colborne to Welland on through Fonthill to St. Catharines to connect with the Queen Elizabeth Way.
7. To rush Highway 401 through to completion ahead of schedule as well as the Ontario Section of the Trans-Canada Highway.

Tolling of certain roads is a new policy, it was reported, a new method of financing these extraordinary works. Where tolls are charged on skyways, the province will maintain and improve existing facilities and at Burlington a new low-level, toll-free bridge is to be constructed.

Completion and formal opening of the Burlington Bay Skyway was expected in the late fall.

Study of Rivers

Canadian scientists are cooperating in a world study which may reveal the part rivers play in the incessant disintegration of the continents.

Scientists estimate that every second over 250 million gallons of fresh water flow from the 65 rivers under study on six continents, carrying with it, in addition to silt and suspended material, an undetermined quantity of dissolved solids such as salts and other minerals. It is these soluble solids, estimated to be pouring into the ocean at the rate of 450,000 tons an hour, that Canadian and world scientists will study.

The Industrial Minerals Division, Mines and Technical Surveys, is undertaking Canada's share of the fundamental research program. Five sampling stations are operating at suitable sites near the mouths of the Fraser, Mackenzie, Churchill, Nelson and St. Lawrence rivers.

The International Association of Scientific Hydrology organized the world run-off program in which over thirty countries are participating.

Development of Education in Engineering at the University of Alberta

A Report on Growth in the Engineering Faculties in Canada

Ninth article of a series

The Faculty of Engineering at the University of Alberta offers a four-year undergraduate course leading to the B.Sc. degree in chemical, civil, electrical, metallurgical, mining, and petroleum engineering. Degree courses in engineering physics and engineering geology are offered to students with high academic records, and a combined course leading to the degree of B.A., B.Sc. may be arranged. Graduate work is offered leading to the M.Sc. and under some circumstances to the Ph.D. degree.

Physical Plant

The physical expansion of engineering facilities has followed the rapid increase in trained engineering personnel required by an expanding industrial economy. In September 1953, the four-storey, brickfaced, reinforced concrete engineering building was opened, which provided a gross area of 68,000 sq. ft. of laboratory, research, and classroom space.

There have since been continual improvements in use of physical plant, as well as additions to and alterations of facilities.

The establishment of the degree of metallurgical engineering required the installation of carefully designed teaching and research laboratory facilities and an addition to the building this summer allows approximately 1.600 sq. ft. expansion for the metallurgical section.

Student enrolment is necessitating the growth of the physical plant and is resulting in improved facilities for departments that provide basic courses for engineering.

Three new projects that are in the design stage with construction anticipated to begin during the fall of 1958 are: (a) the Physical Education Center which will provide offices, lecture rooms and gymnasia space for the School of Physical Education. Incorporated with this project will be a swimming pool and rink that will be equipped with an all-purpose floor and have an artificial ice plant. The estimated cost of this project is $2,-600,000. (b) The Physics, Mathematics, Chemistry Center is the major project under design and will consist of a six-storey building for the Mathematics and Physics Departments, and a five-storey building for the Chemistry Department. The two buildings are to be joined at the lower level and a lecture wing containing 14 tiered lecture theatres will be shared. These departments provide service courses for the Engineering Faculty. The Center will have a gross area of 300,000 sq. ft. and an estimated cost of $7,000,000. (c) the $2,750,000 addition to the Medical Building will consist of a seven-storey building having a gross area of 130,000 square feet.

Courses and Curricula

The addition and revision of courses has followed the advance of engineering knowledge. The traditional courses in civil, chemical, electrical and mining engineering had not sufficiently covered the specialized requirements of modern developments. The growth of the petro-chemical industry necessitated the establishment of a degree course in petroleum engineering in 1948.

In 1956 a degree course in physical metallurgy was established which deals with the properties, structure, and fabrication of metals and alloys. Emphasis is placed upon the recent advances in structural metallurgy.

In 1957 first year engineering program was offered at the Calgary Branch of the University of Alberta. A new campus site has been obtained at Calgary and Stage 1 of the building program will provide facilities for 150 first year students and 100 second year students.

Students are showing an increased interest in the engineering-physics pattern and courses are available in the field of interest of the student and programs in the fields of aeronautics or fluid mechanics, atomic or nuclear physics, electronics, and geophysics, have been arranged.

The faculty has embarked on a revision of the engineering curricula to enable recent developments in engineering to be included in a four-year program. The courses are being studied to eliminate unnecessary duplication of content, to introduce new material and, if necessary to adjust the lecture hours. Changes have been introduced into first and second year programs and a review of the third and fourth year programs is anticipated.

The first year engineering term is being lengthened by approximately two weeks. The basic changes in first-year engineering are an increase in the hours of the chemistry course; combining of drawing and descriptive geometry into a single course and extending the surveying course from half-term to full-term. Survey field work in the second year program will be replaced by four weeks of survey field work at the end of the first year. The faculty is also proposing that a three-hour English course be introduced into the first-year.

The changes in second year involve the introduction of a new course entitled "General Astronomy" which will make the student aware of the problems of the modern age, the problems of map making and map usage, and space exploration.

Special courses that have been introduced into second year are: (a) Graphics 2, which is taken by civil engineering students, will be a continuation of the first year drawing and descriptive geometry course with extension to other aspects of civil engineering. (b) A quantitative analysis and a physical chemistry course will be given to chemical, petroleum and metallurgical engineering students. (c) Electrical engineering students will take a course in the principles of circuitry which will illustrate types of circuits; Ohm's and Kirchoff's Laws; the effect of inductance, resistance, and capacitance, and general solutions of networks.

The purpose of these courses is to permit a more rapid advancement of the student in his area of study during third and fourth year.

Graduate Studies and Research

For the past six years the Department of Mining and Metallurgy has carried out a research project on heavy media concentration (hydrocyclone concentration) which has been sponsored by the Atomic Energy Control Board and Eldorado Mining and Refining Company Limited. A research project in hydro-metallurgy, sponsored by these same organizations, has just begun, and deals with the application of activated carbon to uranium recovery from leach liquors.

In physical metallurgy, research projects are sponsored by the Defence Research Board, Consolidated Mining and Smelting Company and International Nickel Company. These research projects have led to an active research section comprising five masters students, a research associate and a post-doctorate N.R.C. fellow.

The research projects in physical metallurgy are generally concerned with the constitution of alloys and its relationship to their mechanical properties.

Equipment bought from various research funds and university funds in extraction metallurgy include special heavy media and flotation equipment, analytical equipment, microscopes and grinding equipment; in physical metallurgy, x-ray diffraction, high frequency generator, hot stage microscope, mechanical testing equipment, arc melting unit.

In mining, the Department is co-operating with the Fuels Division of the Department of Mines and Technical Surveys on a field research project dealing with outbursts in coal mines in Alberta.

In 1957 a program involving post-graduate work in highway engineering and research projects in co-operation with the Department of Highways of Alberta, Alberta Research Council, and the highway industries was begun. This program includes traffic and safety engineering, advanced soil mechanics and soil testing, design and control of asphalt and concrete pavements, and river hydraulics. Three annual $2,000 scholarships for this program are provided by Westeel Products Ltd., Union Tractor Ltd., and Standard Gravel and Surfacing of Canada Ltd.

In 1957 there were twenty-five M.Sc. candidates in civil engineering and in 1958 a Ph.D. candidate will study in the field of hydraulics and hydrology.

A research program in concrete and concrete materials was undertaken on the properties of aggregates in the Province and a range of concrete mixes was developed suitable for major types of construction in the Province. Subsequently the work was extended into the field of durability of concrete to stand severe exposure conditions. Pioneer work on the usefulness of air entraining agents in concrete was undertaken. The Department recently started a long range investigation on light weight concrete.

In co-operation with the Division of Building Research of N.R.C., a comprehensive study of foundation conditions in the Edmonton area was undertaken. This established the existence of highly plastic preconsolidated clays which are capable of exerting substantial swelling pressures if overburden pressure is removed and if free water is available to the soil.

In recent years, graduate work in chemical engineering has been primarily concerned with fluid flow, the utilization of natural gas, and the phase behavior of hydrocarbon systems.

The work on fluid flow has been related to studies of the characteristics of two-phase flow in pipes and on the rheology of non-Newtonian fluid systems. Two phase flow studies have been made for the air-water system flowing vertically, and for oil-water and clay-water systems flowing horizontally. This work has largely been sponsored by the National Research Council of Canada. Extensive work has been done on the flow characteristics of several Alberta crude oils, initially under the sponsorship of the Interprovincial Pipeline Company and more recently of the National Research Council. A great deal of work relating to the viscosimetry of non-Newtonian fluid systems in general has been done.

The work on the utilization of natural gas has been carried out jointly by the Department and the Research Council of Alberta. Attention has been focused on the utilization of methane, propane, and butane. Studies were initiated in 1949 on the production of carbon black from methane by the Pidgeon Process, and on the production of organic chemicals from the partial oxidation of butane. More recently studies have been focused on optimum equipment and conditions for the production of unsaturated hydrocarbons from propane and butane.

Studies on the phase behavior of hydrocarbon systems was initiated in 1955 with an investigation of the phase behavior of natural gas containing relatively high concentrations of hydrogen sulphide and carbon dimide. At the present time the volumetric behavior of the same system is being studied. Work is also being done on the hydrate forming conditions in mixtures of saturated and unsaturated hydrocarbons. The studies are sponsored by N.R.C.

In order to understand and solve many of the problems of primary and secondary petroleum production from a reservoir, a program in fundamental petroleum research was initiated in the Department of Chemical and Petroleum Engineering. This project includes the examination and study of the fundamental concepts and physical principles underlying the mechanics of oil production. Work has been started on two phases of this project; 1. miscible fluid displacement and 2. the effect of initial rock conditions on the ultimate recovery of oil by gas or water drive.

The work is at present in its infancy and has primarily been concerned with literature studies and construction and development of equipment.

The work is under the sponsorship of the petroleum industry, University, and Research Council of Alberta.

Graduate student enrolment in the department has increased from one in 1947 to about twenty-four at the present time. Of these, two are working toward a Ph.D. degree. In the same period about twenty-five master's degrees have been awarded.

Graduate courses in the Department of Electrical Engineering may be arranged in the fields of high frequency communications, V.H.F. and U.H.F. communications, microwave equipment, modern power transmission engineering, corona phenomena and precision instruments. Four masters candidates were registered last year.

An electronic analogue computer has been built for studies in servomechanism circuits and a new course entitled "Principles of Servo-Mechanisms" has been introduced.

Modern equipment for study of recent developments in communications and electronics has been purchased and electric dynamometer equipment has been added to the power laboratory. The range of the impulse generator has been extended to 400,000 volts.

Other Facilities

At present a degree course in mechanical engineering is not offered but basic courses in thermodynamics, machine design, and the performance and testing of equipment are given by the mechanical engineering staff.

Engineering and Science Building, University of Sherbrooke.

Facilities are available for the performance testing of gasoline and diesel engines, steam engines and small steam turbines, air compressors, fans, and refrigeration units.

Recent equipment additions are a 4-cylinder model 180 G. L. Waukesha gasoline industrial engine, a gas fired superheater and a model 1551A sound level meter. An Orenda jet engine to be used for demonstration purposes has been donated by the Royal Canadian Air Force.

Through the generosity of the English Electric Co. and the Provincial Department of Public Works, an English Electric Model 27 Gas Turbine and Alternator is being provided for student testing. This 2,200 K.W. unit complete with regenerator, waste heat boiler, and educational panel is being housed in a specially designed, acoustic treated building.

An L.P.G. 30 digital computer has been purchased for the university and is available for use to interested departments.

Engineering Education Progress at the University of Sherbrooke

The Faculty of Science of the University of Sherbrooke traces its origin to 1951 when the Catholic School Commission of Sherbrooke undertook to create a first year of Engineering at the Ecole Superieure de Sherbrooke, directed by the Brothers of the Sacred Heart. This was the logical continuation of a 13th grade (scientific) known as Senior Matriculation, which had already been given since 1945.

In September of 1954, year of the foundation of the University of Sherbrooke, its second year of Engineering was inaugurated. 1956 and 1957 saw the addition of the third and fourth years. The program for the Fifth year is now complete and has started this fall (1958). The first convocation will be held in the spring of 1959.

Curriculum

The curriculum, leading to the degree of bachelor in applied sciences, consists of a five-year course. The first three years are mainly devoted to basic chemistry, physics and mathematics. With the third and fourth year, which are common to all branches, begins the study of engineering topics: hydraulics, machine design, thermodynamics, strength of materials, electrical engineering, geology. The student may choose one of the three following options in his fifth year: Civil, Mechanical and Electrical. The curriculum is perhaps not quite as specialized as that offered by other universities. A survey of the regional employers seems to indicate that a broad scientific training was more desirable at the present time. The course has been approved by the Board of Examiners of the Corporation of Professional Engineers of the Province of Quebec.

Physical Facilities

The grounds of the university's campus are situated 3 miles southwest of down-town Sherbrooke and

Strength of materials laboratory, Sherbrooke: a flexure test with universal testing machine.

Electrical engineering laboratory, Sherbrooke: study of wave shape of an a-c generator.

cover an area of around 500 acres. A grant from the Quebec Provincial Government permitted construction in 1956 of the Engineering Building, the first building to be erected on the new university's campus. A fund-raising campaign is in progress for the university. It seeks $4 million with which to build an adjunct to its present Engineering and Science Building at a cost of $1.25 million; four other buildings and campus services plus landscaping make up the objective. Long-range plans call for still more buildings, further extensions of engineering, science and the other faculties, to create a major university.

Distribution of space to various departments, Engineering building.

	sq. ft.
Chemistry lab.	3,000
Physics lab.	3,300
Hydraulics lab.	3,200
Strength of Materials lab.	2,500
Electrical Engineering lab.	2,400
Biology lab.	1,100
Electronics lab.	1,600
Thermodynamics lab.	2,700
Soil Mechanics lab.	1,300
Mineralogy	1,100
Cafeteria	2,500
Library	3,600
Classrooms	11,000
Drafting room	3,600
Auditorium	4,500

Present premises are designed to hold some 450 students. Registration stood at 250 during the year 1957-58. It is expected that the fall enrolment will boost that figure to over 300. Provisions have been made for expansion and it is expected that still more facilities will have to be provided within ten years.

Essex College, Windsor, Offers Engineering Education

To report the progress of engineering education at Essex College, of Assumption University, Windsor, Ont., the *Journal* abstracts here a recent brochure of the College, which is available from the registrar.

Essex College was incorporated by the Province of Ontario in 1954, as a non-denominational college with the power to provide training in the sciences and other fields of higher education. It was affiliated with Assumption University of Windsor.

In a legal sense, Essex College is a corporation whose membership is composed of distinguished leaders of local industry and business. It is governed by a board of directors which plays an active role in planning and guiding the College's progress, particularly in the financial and physical aspects.

The faculty, within its departments and committees which enjoy representation on the University Senate and other governing bodies, charts the academic course of the College. Its primary responsibility is to instruct the students in the principles and concepts which give the graduate professional competence combined with a sense of humanistic values which extend beyond specialized interests.

Essex College is on the Assumption University campus, close to the Detroit River. Dillon Hall (the Arts building) and Essex College are situated near the new University Library which will be completed this fall. The University Union, proposed for 1959, will occupy a central position on the campus. To the south is St Denis Hall, one of the largest gymnasiums in Canada. The historic buildings housing residences, administration, and chapel are on the west side of the campus.

Applied Sciences, Business Administration and Fine Arts buildings are scheduled for construction at a later date. There is also an Engineering Building in the plans.

Development of Engineering

For more than 25 years, Assumption has been teaching two years of pre-engineering beyond Grade XII. When Essex College affiliated in 1956, it assumed the responsibility of instruction in this field. A special committee of the board of directors was set up to establish whether or not the University might establish a complete accredited program leading to the bachelor degree in four branches, chemical, civil, electrical, and mechanical engineering.

The committee conducted surveys among industrial corporations to determine the demand for engineering graduates in the next five years and among high-school students to determine the potential enrolment. The Committee then recommended that in 1957 Essex College should offer the first full year of the full program. Second, third and fourth years would be added in consecutive years.

Several types of plans, including the co-operative and the quarter system, were considered, but the final decision strongly favoured the conventional four - year - beyond - Grade-XIII Canadian type of plan. The surveys conducted among industrial leaders and potential students indicated that this plan best serves the needs of that area and that province. The concentrated period of instruction makes possible the integration of the program with established courses. The long summer vacation period enables the students to gain practical experience and to support themselves financially, and gives the staff an opportunity to pursue study and research programs.

The engineering development committees are continuing their meetings in a constant effort to improve and modernize the plans from year to year. Courses in other branches of engineering will be offered as the demand for them becomes apparent.

The Curriculum

The curriculum is the result of extensive planning in consultation with engineering educators in Canada and the United States. It combines the recommendations made by the American Society for Engineering Education for a "broad base" of studies in the arts and social sciences with the high level of technical content so necessary for accreditation and for the professional competence of the graduate.

A feature of the engineering curriculum at Essex is its arrangement in a manner which facilitates the transfer to other science and arts programs without loss of a year.

The first year is common to all courses, containing: an introduction to philosophy; communication skills; chemistry and qualitative analysis; differential and integral calculus; algebra, geometry, and trigonometry; mechanics, heat and sound; electricity and magnetism; engineering mechanics; drawing and descriptive geometry; surveying.

In the four separate courses, second year, there is a common program in the philosophy of science, ethics or theology, intermediate calculus and differential equations, strength of materials. The rest of each course is concerned with the science of electrical, civil, chemical or mechanical engineering. The third and fourth years will advance the student to technical competence, while also offering work in history, social philosophy, humanities, law and economics.

Essex College's academic policy is based on the concept that every graduate should have a solid grasp of the humanities as well as of the techniques of his profession. This policy was outlined by W. H. Arison, chairman of the Board of Directors.

The foremost objective of the College is to attain the highest academic standards possible. This involves the acquisition and development of top-grade instructional staff and the provision of the necessary physical facilities for study and for research. Because pure and applied science teaching of the highest type thrives best when it is intimately associated with creative work, original research is encouraged and supported.

Dr. F. A. De Marco, chairman of the Staff Committee, describes the Essex attitude in these words: "We are primarily concerned with the individual. When classes become so large that a close student-professor relationship is impossible, the quality of instruction is bound to be inferior. At Essex College we are designing our classrooms, laboratories, and methods of instruction to allow for maximum contact between the individual student and the members of the faculty".

Changes in Engineering Curriculum Ecole Polytechnique, Montreal

L'Ecole Polytechnique, which is the faculty of engineering of the University of Montreal (see first article of this series, *Engineering Journal,* January 1958, Page 89) has been offering since last January to its third year engineering students a new curriculum leading to the full specialization course. The fields of engineering offered to them are eight in number: civil, mechanical, electrical, mining, metallurgical and geological, and also engineering physics.

Although the university has for many years been operating with departments assigned to each of these fields, except engineering physics, the degree was of a semi-specialized character. The optional courses which are still in effect for the graduates of next year, have been split into the corresponding specialized branches of engineering, thereby allowing the granting of the fully specialized degree.

The engineering physics course is being introduced for the first time. At the bachelor's degree level, it will give emphasis to subjects related to electronics and will include a first course in atomic physics and nuclear engineering.

General training in the field of applied science was the chosen method of Ecole Polytechnique up to 1941. Then the curriculum leading to the bachelor's degree was common to all students. The first degrees of the semi-specialized course were granted in 1943. There has been constant evolution and changes, as introduced, generally increased the content of the specialized subjects.

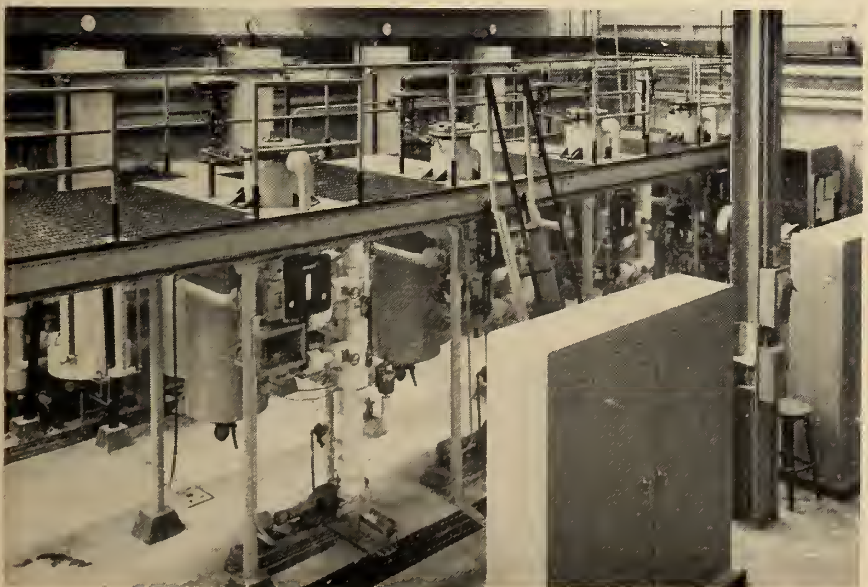
In establishing the fully specialized degree Ecole Polytechnique does not, according to Dean Henri Gaudefroy, reject the principle which has served as a guide in the past. The curriculum has practically been left unchanged in the first years of the course, where the fundamental sciences are taught. Of the total time in the five-year course, 41 per cent is still assigned to the basic science subjects; 21 per cent of the time is spent at the level of the straight engineering courses on applied science subjects not related to the specialized field, and 30 per cent is fully spent in specialized topics; the balance of 8 per cent is used to cover humanistic and social sciences.

New Building Occupied This Fall

Ecole Polytechnique is occupying its new quarters which provide approximately twice as much space as the old location. This permits a very timely expansion of the facilities, which will allow the introduction of new subjects.

This expansion will mainly take place at the level of the last two years of the course, and also at the graduate level leading to the degrees of master and doctor of applied science.

Chemical pulping laboratory, Pulp and Paper Research Institute



Pulp and Paper Research Centre

Effective partnership of industry, government and university is demonstrated by the existence of the new laboratory of the Pulp and Paper Research Institute of Canada. (illustrated in *Engineering Journal,* September 1958, Page 112).

In the new building at Point Claire, Que., the Institute will continue its function as a fundamental research centre for Canada's pulp and paper industry.

It stimulates and assists in the post-graduate training of McGill University students who are working toward higher degrees in science and engineering, those particularly whose theses deal with subjects of interest to the industry.

The institute's research operations may reach into any aspect of the process of converting cellulosic plant materials into pulp and paper and other products.

The new laboratories were built and equipped to the Institute's specifications by the Federal Government at a cost of two and a quarter million dollars. Some of the furnishings and about half a million dollars' worth of apparatus and equipment were provided by the industry.

Canadian Pipeline Projects

Westcoast Transmission Company Limited

The extension of Westcoast Transmission Company Limited's natural gas gathering system northwest of Fort St. John has been completed ahead of schedule. Testing of the 84-mile extension, which roughly follows the route of the Alaska Highway, was finished August 16, and it will go into operation in September. More than 300 men, 90 per cent of them Canadians, were employed on the project at peak periods.

When 21 new gas wells are all tied late in 1958, an estimated 80 million cubic feet a day more gas from B.C. fields will be delivered to the McMahon Plant at Taylor, which processes the sour gas into motor fuels, sulphur and residue pipeline gas. Ultimately, the extension will add 150 million c.f.d. to the gathering system's capacity.

First shipment of several carloads of sulphur was shipped from Taylor, B.C. on August 4 to three paper mills on the Pacific coast of B.C. Supplier was Jefferson Lake Petrochemicals of Canada Ltd., from its new $2¼ million plant which processes 425 tons of sulphur daily from Westcoast's gas processing plant at Taylor. This company plans other sulphur manufacturing plants at Calgary and Coleman for exports to Australia, Japan, Korea and India.

Inland Natural Gas: A contract was signed late in August between Consolidated Mining and Smelting Co. and Inland, for five million cubic feet of natural gas daily for the Company's Trail, B.C., smelter. There will be cuts in consumption of fuel oil, coal and coke but the use of these fuels will be continued in many phases. Installation of mains has started and consumption should commence in October.

Alberta Gas Trunk Line: Construction was completed during August on the Company's 1958 program of extensions and new laterals, including the 145 miles of 24-inch line from the Pincher Creek Field to junction with 34-inch main line near Princess, Alberta.

Canadian Western Natural Gas: Progress on the $2.8 million 58-mile 16-inch gas pipeline from the Carbon field to Calgary had reached the halfway mark by mid-August. The $220,000 gathering system soon to be started will furnish a supplementary supply of 150 MMcfd to the Calgary distribution system.

Trans Canada Pipelines

Construction of the final link of the Trans Canada Pipeline from Lakehead to Toronto was reported to be on schedule at the end of August, to meet the November 1 completion date.

Trans Canada reported at end of August that construction crews on the 853-mile link between Kapuskasing and Toronto were entering the most difficult stages through rock and tough muskeg country. Special methods had to be devised by contractors for overcoming what sometimes appeared to be bottomless mire. Nevertheless on both this section and on the Northern Ontario Pipeline Crown Corporation section from Port Arthur to Kapuskasing, all right-of-way had been cleared and graded and 75 per cent of the pipe had been strung or further processed. As sections are completed east from Port Arthur and north from Toronto the line is being tested.

Winnipeg Central Gas: It appeared by late August that Winnipeg and Central Gas, the existing distributor in Winnipeg, would accept the cut in rates recommended by the Natural Gas Enquiry Commission, of 90 cents per thousand feet average, a reduction from current rate of $1.01 per Mcfd. The utility has about 13,000 residential space heating customers. The report had suggested it should base its expansion program on a build-up of 56,000 such customers by 1962.

Northern Ontario Natural Gas Co. By late August, the Company's $15 million pipeline and distribution program for 1958 had reached the halfway mark, with construction proceeding on schedule. Completion of the big construction job which will bring gas to homes and factories in 32 northern Ontario communities was scheduled for completion by mid-September. Gas will be available to customers in most areas not later than mid-October. Three firms are working on 14 spreads in different sections of the franchise area. Installation of distribution systems was in progress in 17 communities, and starts on 12 other towns were scheduled to begin in late August.

Construction was also proceeding satisfactorily on the 32-mile Timmins lateral and on the 88-mile Sudbury lateral. On the latter, a drilling rig was boring two holes simultaneously through rock, which will be filled with blasting powder and detonated to blast a four-foot pipeline trench 88 miles long from North Bay to Sudbury.

Swan Hills Crude Oil Pipeline: Construction for the 125-mile 10-inch $6.5 million oil pipeline from the Swan Hills field to Edmonton has been awarded by Federated Pipelines to two companies. The northern 40 miles to Fort Assiniboine will be built by Mannix Ltd., while the southern 85 miles will be built by Fulton Bannister, Ltd. Construction was commenced in mid-August with target date for completion November 1. Ultimate maximum capacity will be 40,000 barrels a day. Pipe will be supplied by Alberta Phoenix Tube and Pipe, Ltd.

Extension of Imperial Oil Pipeline Approved: The House of Commons on August 26 approved a bill authorizing extension across Canada of an Imperial Oil franchise held by Stanmount Pipe Line Co., a wholly owned subsidiary. The franchise formerly covered only the provinces of Saskatchewan, Manitoba and Ontario.

What Goes On

Why Build Now?

An editorial under the above title to appear in *Bridge Briefs*, a publication of Dominion Bridge Company Limited, says that savings can be made by going ahead now with plans for new plants or extensions to old plants, new office buildings, new process developments.

"A new boom within a reasonably short period" is to be expected, at which time capacity may be insufficient, the editorial warns. Meanwhile, in general terms, it reports, construction costs are down, and there are these hidden items in favour of building now:

Labour is more productive, and is in adequate supply. Construction materials are plentiful. Contracting firms, are ready to swing into action, at the lowest price consistent with staying in business. Work goes ahead faster, with consequent saving of time and of money both in interest charges and in earlier availability of facilities. Borrowing to finance new construction is cheaper and easier. The machinery market is in a more fluid condition.

The fear of building now might well be exchanged for a greater fear of not building now, say Dominion Bridge.

The company is itself continuing its 20-million expansion and improvement program started two years ago.

Winter Construction

Representatives of the Canadian construction industry attending the National Winter Employment Conference in July, made recommendations to increase employment in the 1958-59 winter season.

Attention was given to incentives, with these and other recommendations:

That the Federal Government offer the incentive of accelerated depreciation (capital cost allowances) to encourage capital investment in winter months.

That the Government use means in the residential construction field such as: increase in number of builder loans to winter builders; removal of restrictions against direct mortgage lending by C.M.H.C. on rental housing projects; and study of increased mortgage valuations and decreased interest rates for winter-build units.

That study be given to expansion of operations of the Industrial Development Bank to make capital investment funds more readily available for wintertime expansion of plant facilities.

The construction industry is capable and ready to work year-round, said A. Turner Bone, past president of C.C.A. recently. It successfully carries out construction under very severe weather conditions at very low temperatures, particularly on the prairies and in the Arctic.

To keep construction going during the four months of winter, timing of the start of the building operation is the most important factor in providing reasonable costs to owners as well as maximum employment.

Port of Toronto

There will be another terminal at the Port of Toronto, to be known as Terminal No. 17. The Chairman of the Port Authority announced this at the formal opening of Terminal No. 15 in May.

This will be the third terminal built for the direct overseas trade during the last four years.

The Mineral Industry

The value of mineral production in Canada in 1957 was more than $2.133 million, according to a bulletin prepared by the Department of Mines and Technical Surveys, for the Brussels Fair exhibit. This figure is exclusive of aluminum, made from imported ore. From domestic resources, 24 metals, 27 industrial minerals, and 3 fuels were produced in commercial quantities, many of them primarily for export to world markets.

Less than half of Canada's 3.8 million square miles has been prospected in any detail, and much of the remainer is known to be favourable for the occurrence of metals, minerals and fuels.

Building Research Notes

Reports from the Building Research Division, of National Research Council, during the past several months recount various activities.

Study of wind action. The Division began a study of the action of wind on structures, with the aim of making the formulation of design wind load requirements more rational and precise and of indicating what further research would be most fruitful.

Working in co-operation with the Meteorological Branch of the Department of Transport, the Division is studying the questions of better statistical interpretation of the prescribed wind velocity, associating it with a certain probability of occurrence; the significance of action of gusts as related to size of structure; variation of wind velocity with height and topographic characteristics; wind velocity in city or countryside.

Studies of damage have already been undertaken. The Division also welcomes advice of unusual damage to structures, attributable to wind.

Loading tests on house roof frames. The Division announced completion of test work on a project it has been conducting for 2½ years. These tests were to determine the strength and deflection characteristics of a number of conventional roof framing systems and trussed rafter constructions.

From these a number of truss designs were developed using either eastern spruce or Douglas fir lumber. The designs, together with designs produced by the Forest Products Laboratories of Canada, have been distributed by Central Mortgage and Housing Corporation.

Building Code Use. The Division reported that 364 municipalities in Canada are using the National Building Code. A report on use of the Code is available from the Secretary of the Associate Committee on the National Building Code, N.R.C.

Fire Research Building. The Division announced the opening in October of the new fire research building of the N.R.C.

The building contains two large furnaces for standard tests and research on the fire resistance properties of walls up to 12 feet square and floors up to 12 by 15 feet, together with the necessary ancillary equipment.

The opening followed a special two-day conference on Fire Prevention and Fire Research.

Pressure Pipe Plant

Anthes Imperial opened a new pressure pipe plant in Calgary, May 30.

It provides highly mechanized facilities for the production of centrifugally spun cast iron pressure pipe.

This product, used for water distribution, and also suitable for gas distribution, takes an important place in current Western Canada expansion, according to commentators on the event.

The company provides products for the petroleum, mining and construction industries, and engineering specialty products.

Calgary Herald, May 30, 1958

New Brunswick Industries

Concrete Plant. The official opening of the new push-button pre-mix concrete plant of Jos. A. Likely, Ltd., at East Saint John, N.B., was celebrated during the summer.

The plant, the first of its kind east of Montreal, is arranged so that one man at a control panel directs mixing from start to finish. Aggregates, water and additives are selected automatically.

This is the latest addition to the product line of the Likely company, a business founded in 1876 to be the agent for several New Brunswick lumber mills.

Wire Mill in Lancaster. Western Wire and Cable Co. Ltd., has a new manufacturing plant at Lancaster, N.B.

The new plant will produce a wide range of industrial and commercial electric wires for both power and communications.

Fifth Convention of the Pan-American Union of Engineers' Associations

Accentuating the harmony which can exist among independent countries, the Union of Pan-American Engineering Associations, commonly known as UPADI, met at the Queen Elizabeth Hotel, Montreal, September 2-6, 1958, in a climate of international co-operation for the common good.

Seventeen countries were represented at the Montreal meeting, fifth in a series held over the past nine years, at Havana, New Orleans, Sao Paulo, and Mexico City. The last of these in 1956, had directed the activities of the past two years towards co-ordination of efforts throughout the Americas, technical standardization, and the promotion of a Pan-American study of the teaching of engineering. It was the hope that a proposal would be adopted at UPADI V to hold the first Pan-American Congress of Schools of Engineering at the next meeting in 1960, in Argentina.

Luis Giannattasio, Uruguay, president, and Walter S. Hill, secretary, presented a summary of the action taken since the Mexico meeting.

UPADI was founded for the promotion of scientific and technological progress of its associates and of mankind. Concerning itself with the intellectual and practical pursuits of the engineers of the Americas, it promotes and co-ordinates periodic Pan-American engineering congresses, conventions and exhibitions, and promotes personal contacts between the engineers of different countries. It encourages individual or group visits to member countries and to other places of interest, the interchange of professors, lecturers, engineers and engineering students, among the universities, schools and engineering associations, and closer technical relations among the American countries.

These delegates spoke on behalf of their countries and organizations at the opening session of UPADI. Left to right: F. Saturnino de Brito, Brazil; Luis Giannattasio, Uruguay, president of UPADI; Albert Deschamps, Canada, vice-president, E.I.C.; Sarto Fournier, mayor of Montreal; Dr. Irving Tait, Canada, chairman of the UPADI committee of E.I.C.; Enoch Needles, U.S.A., representative of the Engineers' Joint Council.

Dr. Luis Giannattasio, president of UPADI

Because of its own similar objectives the Engineering Institute now has friendly and co-operative relations with many societies and is a member of UPADI. The Institute council and members counted it a particular privilege to welcome the fifth convention to Canada. Vice-President Albert Deschamps made the first expression of welcome, on behalf of President K. F. Tupper. President Tupper participated in later sessions of the UPADI meeting.

The Honorable Sidney Smith, Secretary of State for External Affairs, in an address of welcome to the group said, "Engineering has been an essential factor in the growth of all American lands and it remains the symbol of their present achievement. "Not only," he said, speaking of UPADI, "Do you contribute to a high degree to better economic and technical relations between the countries of this hemisphere, but you establish as well a pattern of international co-operation which could be applied to many troubled areas around the world in order to strengthen the cause of peace."

At a civic reception given by the mayor and city council of Montreal, in the Hall of Honour at City Hall, Mayor Sarto Fournier, after extending the welcome of the City, made reference to the profession of engineering and its great contribution to the welfare of the peoples of the world.

The program included on September 2, the election and installation of three board members to replace outgoing members from Argentina, Brazil and the United States.

Resolutions committees were appointed on the subjects of administration, legislation, public relations, technical matters, budget, and teaching of engineering.

Administration Committee: A. Deschamps, Canada; W. Wisely, U.S.A.; M. T. Puente, Cuba; J. J. Gomensoro, Chile; H. de Almeida, Brazil; L. Balcazar Padilla, Mexico; M. A. Gonzilez, Venezuela. I. Vejo Rodriguez, Uruguay, spokesman.

Legislation Committee: F. Krug, Canada; G. Browne, U.S.A.; L. M. Alfonso, Cuba; R. Penades, Uruguay; B. Malta Marques, Brazil; M. A. Mantilla, Mexico; J. Taccani, Uruguay; S. De Brito Filho, of Brazil, spokesman.

Public Relations: Luis Giorgi of Uruguay, spokesman; Irving Tait, Canada; G. Hathaway, U.S.A.; R. Ondart, Argentina; J. L. Salcines, Cuba; H. Zaidan, Brazil; E. Ortega, Puerto Rico; H. Cassaigne, Mexico, and M. Villard, Haiti.

Technical Committee: C. C. Southmayd, Canada; A. Queirolo, Uruguay; R. T. Painter, U.S.A.; A. De Neymet, Mexico; R. Garcia Bango, Cuba; A. Van Langendonck, Brazil; E. Olivera Junior, Brazil, and J. Abella, Uruguay, P. Diaz Filippi, Uruguay, spokesman.

Budget Committee: spokesman, James Todd, U.S.A.; S. E. Reimel, U.S.A.; Q. Fernandez, Cuba; P. Leite Mascarenhas, Brazil; G. Padilla, Puerto Rico, and G. Sedes, of Mexico.

Engineering Education Committee: Ralph A. Morgen, U.S.A., chairman; H. G. Conn, Canada; H. Gaudefroy, Canada; L. Johnson, U.S.A.; I. Aviles, Mexico; J. Menendes, Cuba; R. Arrocha, Venezuela; M. Font, Puerto Rico; O. Castanhede, Brazil; L. Giannattasio, Uruguay; R. Ondart, Argentina; H. Tippenhauer, Haiti; and R. Penades, Uruguay.

Committee meetings continued from Tuesday, September 2, for three more days with the result that 46 resolutions were presented to the plenary session on Saturday by a co-ordinating committee.

At the formal opening on Wednesday there were talks by North, Central and South American and Carribean delegates. There was a report on the Conference of Engineering Societies of Western Europe and the United States (EUSEC), and one on the Federation of Commonwealth Societies.

The conference on engineering education continued on September 4.

The plenary session of the convention held September 6 was devoted almost wholly to the resolutions.

Joint participation in a number of functions was enjoyed by the ladies. Special events were also arranged for the ladies, including a scenic trip to the Laurentian mountains, north of Montreal, and a bus tour of points of interest in Montreal.

Resolutions of the Convention

Among the main resolutions proposed by the Co-ordination Committee to the 5th Convention of UPADI were proposals urging:—

- UPADI representation at the Organization of American States, in Washington, D.C.;
- regional centres for scientific investigation and specialized technology especially in Latin America;
- a program of scholarships, and the determining of special fields of engineering and applied sciences most necessary for each country;
- establishing of technical attaches in various embassies;
- preparation and distribution of technical publications;
- UPADI represenatives on various boards at proceedings involving adjudication of bids for great engineering works;

Above: Secretary of State for External Affairs, the Honorable Sidney Smith, extended Canada's welcome.

Below left: Ralph A. Morgan, of the Purdue Research Foundation, Purdue University, Layfayette, Indiana, and Hugh G. Conn, dean of the faculty of applied science, Queen's University, Kingston, Ont., who were among the four speakers in the conference on Engineering Education.

The other speakers, not shown, were Professor Octavio Cantahede, Brazil, and Rodolfo Felix Valdes, of Mexico.

Presentation of the flag of the Commonwealth of Puerto Rico to the E.I.C. by E. Ortega. Left to right: (first gentleman unidentified), A. Deschamps, Montreal, vice-president, E.I.C.; P. W. Gooch, chairman, Montreal Branch, E.I.C.; and Mr. Ortega.

• use of the decimal metric system in countries not now using it;
• a dictionary of technical terms in the four languages spoken in America;
• participation by member countries of UPADI in the International Association for the Exchange of Students for Technical Experience;
• maintenance of the Committee on Engineering Education so that it may continue the work it is doing and cooperate in the preparation of the first pan-American congress with the Board and the member in whose country the Congress will be held.

President Giannattasio's Talk

Speaking to all those gathered at the UPADI conference, Dr. Luis Giannattasio of Uruguay, president of the board of directors of UPADI said that the conference provided the means for studying, maintaining and perfecting professional abilities to serve the people of this hemisphere.

He referred to UPADI as an organization of enormous spiritual significance. Since 1949 four memorable meetings had taken place, and UPADI is making it possible he said, to establish close bonds between the various associations of engineers. A common Code of Professional Ethics for all engineers of America has been worked out, many aspirations formulated, coordination of conventions has been achieved, and techniques special to America have been considered by the Pan-American Committee of Technical Standards which began functioning in 1956, under the Brazilian Association of Technical Standards. UPADI's representation of the engineers viewpoints at meetings organized by the Organization of American States, will have important effects, he said.

Fundamental concern of UPADI, and the tone of its meetings, Mr. Giannattasio asserted, has been to point out the need to augment engineer training. Certain personal conditions must be cultivated by the engineer if he is to fulfill his transcendental functions in today's world. This is to be achieved, he said, through the various engineering faculties and associations.

Exploring another fundamental aspect of UPADI, Dr. Giannattasio urged that a greater number of young people be educated in science and technology. "In an age when the greater part of the work and responsibility of modern civilization, falls on the engineer and the investigator, training in the humanities must not be sacrificed," he said. "The principal problem of education is one of enabling men to organize and control the environment, to guide its evolution, to reduce sacrifice, to distribute the benefits of progress with justice.

Engineering Education Conference

Engineering Education in Canada

Discussing Engineering education in Canada, Dr. H. G. Conn pointed out that the strength of the engineering faculties in Canada lay in the fact that the schools are not identical. There are those schools which encourage a scientifically oriented curriculum and others which aim to produce a good solid practicing type of engineer, the "traditional engineer," a good balance of "know how, know why." But, according to Professor Conn, "most schools steer a wobbly path between these two."

He added, "the difference between the products of these two schools is frequently much more imaginary than real, the difference existing more in the minds and ambitions of the respective staffs than in fact." "There is, however," he added, "a general drift toward the scientifically oriented curriculum."

Most engineering schools plan to double available space by 1965, Dr. Conn reported. This brings out the need of having by that time a sufficient and a mature staff, whose "aging process must start now."

Dr. Conn cited the 5-year program as an answer to the present crowded curriculum of studies. Or another alternative is a fifth year, normally at an M.Sc. level, designed around research work or advanced study, for the best students.

Research in a university is necessary, "a whole field of thought above and beyond the details of day-to-day teaching." A gradual improvement in the salary differential between industry and university helps to attract and hold staff, from whose work constructive thought is stimulated.

"There is far too little real research being carried out at the universities," said Dr. Conn. This is being corrected gradually.

The large engineering schools are losing staff to the smaller schools, which until recently were "feeders" for the upper years of the larger schools. Several of these are now offering degree courses. Dr. Conn said, "Some question the wisdom of establishing new facilities at the present time, although few will argue against expanding existing facilities. It would be unfortunate if available teachers and money were spread unnecessarily thin in an attempt to meet a demand from industry for more engineers, unless of course, the demand is a real one. Although no one will question that there is and always will be a need for good quality creative engineers, there is some cause to doubt that there will continue to be a need for engineers to be employed on other than engineering work, work that could be done equally well by competent technicians, if they were available in much larger numbers than at present. While thinking along these lines it must be recognized that many employers prefer to engage engineers on work which is not strictly engineering, but which requires an engineering or analytical approach."

Dr. Conn concluded with a remark on the recommended practice for engineering students spending summer intervals working in an engineering atmosphere.

(continued on page 130)

A plaque commemorating the Montreal meeting of the Fifth UPADI Convention was presented to Dr. Tupper, president of the E.I.C., by Dr. Luis Giannattasio.

Confederation

Since the annual meeting of the Institute last May, considerable progress has been made towards Confederation.

At that time the plenary meeting of Council, on the recommendation of the Institute's Committee on Confederation, approved of certain clauses of a report submitted by the joint-sub-committee, as a "guide to further action." The meeting requested that the joint committee "continue its work" to the end that a report be prepared for the consideration and the balloting of the membership.

The Institute's committee has worked throughout the summer studying the problems and developing the suggestions contained in the report of the sub-committee. The result of this was the preparation of a long report which summarized the situation and extended the thinking farther into the future. This report was for the consideration of the Institute's officers and the members of the committee.

Subsequent to the study of the report by the Institute a meeting was arranged in Ottawa in August with the executive group of the Canadian Council committee. This was attended on behalf of the Institute by I. R. Tait, Montreal, chairman of the E.I.C. Committee, T. Foulkes, Ottawa, vice-chairman, and L. Austin Wright, Montreal, a member of the committee, and on behalf of the Canadian Council by John Fox, Toronto, chairman, Herb Smith, Toronto, and Guillaume Piette of Quebec.

This meeting lasted from nine in the morning until four thirty in the afternoon, and advanced the negotiations substantially. Several points already discussed were elaborated and classified, and many new angles of the proposals were developed and agreed upon. As well several points had to be left over for further study and discussion at a later meeting.

To summarize the action it can be reported that Dr. Tait has held three meetings of his group and has met twice with the Canadian Council group since the annual meeting. That is a lot of work and a lot of sacrifice of summer holiday time, by a group of voluntary workers.

Dr. Tait has enlarged his committee by the appointment of C. M. Anson, of Sydney, N.S., Leo Roy and Austin Wright of Montreal.

The closer one is to this matter the more clearly he sees the seriousness of it, the complications and the difficulties. Some members of the Institute have expressed concern at the length of time being taken, but to all those who have been working close to the problem it does not seem possible to move any faster. The situation is much more complicated than it would seem to one who has not studied it carefully. It is a serious matter of tremendous importance to the organizations concerned, and mistakes must not be made—not even to save time.

Sure progress is being made, piece by piece, and it is hoped that within a reasonable period of time a proposition that will really mean something will be available to the Councils of both organizations for their study and decision.

In the meantime, Dr. Tait proposes to report to each meeting of Council, and *The Engineering Journal* will present these reports to the entire membership, month by month.

IAESTE News

Duplication of requests has occurred in the matter of placement of mining students from the United Kingdom in summer vacation jobs in Canada through IAESTE. The Canadian Institute of Mining and Metallurgy and the Canadian Metal Mining Association, and IAESTE (Canada), will in future be able to avoid duplication of the requests for employment with which they have to deal.

After consideration by the professional institutions involved and by IAESTE in Great Britain, it has been agreed that all applications should be channelled through a single source. The source selected is IAESTE.

Any company wishing to receive students from a particular university or college would do so by advising IAESTE (Canada), accordingly. Offers may also be reserved for students to be nominated by professors abroad having specific contacts in Canada.

Addresses to be used are: In Canada—IAESTE Committee, c/o The Engineering Institute of Canada, 2050 Mansfield Street, Montreal; in the United Kingdom—The Executive Secretary of IAESTE (GB), 178 Queens' Gate, South Kensington, London, S.W. 7.

Canadian mining and metal industries are invited to advise the Canadian IAESTE committee in the autumn, of the numbers of mining, metallurgy and any other students they are prepared to receive from the United Kingdom the following summer. This information, once relayed to the committee in Great Britain, will facilitate selection of students from the universities. When necessary, the committee will also act in collaboration with the Institution of Mining and Metallurgy in London. Canadian industries receiving direct applications from individuals in Great Britain need only pass these on to the Canadian IAESTE secretary without comment.

DID YOU KNOW THAT

350 employers used the Employment Service of the E.I.C. in 1957 to obtain engineering personnel. Fifteen hundred engineers visited the department.

The Pines, Digby, N.S.

The Conference Committee: front row, Mrs. Myra Lusby, ladies committee, G. H. Dunphy, general chairman, H. W. Doane, Jr., secretary; back row, W. J. Phillips, L. F. Kirkpatrick, vice-chairman, F. C. O'Neill, entertainment and sports, W. T. Windeler, registration, G. F. Vail, papers and speakers, H. A. Marshall, publicity. G. N. Haliburton, finance, was absent when the picture was taken.

Maritime Professional Engineers Conference

Branch chairman were out in full force. In this group, front, C. Trenholm, Moncton, President K. F. Tupper, General Secretary Garnet T. Page, and J. Wilson, Sackville; back row, C. W. Henry, St. John's, H. M. W. Townsend, Saint John, J. A. McLaren, E.I.C., Toronto, J. F. Clarke, North Nova Scotia, C. W. Currie, P.E.I., J. D. Kline, Halifax.

The ladies shown enjoying the morning sun are Mrs. J. F. Callahan, Mrs. F. G. Murphy, Mrs. F. C. O'Neill, Mrs. J. B. Dicks, Mrs. G. E. Franklyn, Mrs. J. A. G. Brown and Mrs. J. A. Marshall.

ENGINEERS in record numbers registered at Digby, N.S., for the Maritime Professional Engineers' Conference, held at The Pines, September 2, 3, 4, 5, 1958.

This response to the efforts of the organizing committee prompted the conference chairman Gordon H. Dunphy to comment that it is apparent that recognition of the calibre of the Maritime Convention is spreading, resulting in many delegates from outside the Atlantic Provinces taking an interest. The engineers' wives obviously favour this meeting, for there were many there with their husbands.

The maritime meetings, held every second year, have been pleasant and profitable in the past as they alternate between St. Andrew's, N.B., and Digby. This year's meeting was hugely successful, with representation from as far afield as Toronto and Hamilton. Gordon Dunphy's request that the delegates enjoy themselves to the utmost met no opposition.

The fine attendance, beautiful weather, excellent technical papers, and exceptional entertainment were the main elements of success.

The *Eager Beaver*, official journal of the meeting suggested other particular elements, such as the Early Bird Breakfast, the Maripenco Club, golf tournament, dancing, etc.

The Maritime hosts were, of course, the Associations of Professional Engineers of Newfoundland, Prince Edward Island, New Brunswick, and Nova Scotia, and the eleven Maritime Branches of the Engineering Institute.

They welcomed representatives of the Association of Professional Engineers of Ontario, C. T. Carson and J. H. Fox, president and past-president; of the Corporation of Professional Engineers of Quebec, Guillaume Piette, President, and Pierre

At the first luncheon, J. D. Kline, Halifax branch chairman, presented souvenir trays to Dr. K. F. Tupper and Mr. D. O. Turnbull of the Canadian Council. Both were speakers at this luncheon.

Bournival, general secretary; of the Canadian Council of Professional Engineers, D. O. Turnbull, vice-president and L. M. Nadeau, secretary-treasurer.

President K. F. Tupper of the E.I.C. was present with General-Secretary Garnet T. Page. They expressed the Institute's great interest in such co-operative regional meetings, of which the Maritime Conference has a very long record of achievement. Other Institute staff members were on hand to help, including John A. McLaren, the eastern field secretary.

The technical part of the program, consisted of papers as follows:
"Canada's Progress Toward Economic Nuclear Power", by J. L. Olsen.
"The Shippegan Island and Campebellton Bridges".
"Engineering Management of an Advanced Weapon System", by C. V. Lindow.
"Industrial Application of Computers", by Admiral G. L. Shephens.

Presiding at and taking active parts in professional sessions and luncheon and dinner meetings were officers of the Maritime Associations and the E.I.C. Branches. The first luncheon featured greetings by a representative of His Worship G. R. Turnbull, Mayor of Digby, by D. O. Turnbull of the Canadian Council, and Dr. Kenneth F. Tupper.

The dinner speaker on Wednesday was Hon. R. A. Donahoe, Q.C., Attorney General of Nova Scotia. J. S. Richardson, of Montreal gave a luncheon address on the refreshing subject of "Old Inns of England". Speaker at the banquet on Thursday evening, September 4, was Dr. Will R. Bird of Halifax.

The proceedings were the best possible argument in favour of the next conference, scheduled for 1960 at St. Andrew's, N.B.

Everyone made the Early Bird's Breakfast but a few just barely. Below, General Secretary Garnet Page and 299 others made the Early Bird's Breakfast.

Above, a group of M.P.E.C. enthusiasts: Dr. K. F. Tupper, Dr. J. Hoogstraten, of N.S.T.C., Dr. J. B. Stirling and Dr. I. P. McNab, past presidents.

Some conference committee members in action; H. C. Rounsefell, F. C. O'Neill, L. F. Kirkpatrick, G. H. Dunphy, Mrs. Dunphy and Mrs. T. Lusby.

Nominees for Office

Engineering Institute of Canada

The report of the Nominating Committee, as accepted by Council at the meeting held on September 2nd, 1958, is published for the information of all corporate members as required by Sections 19 and 40 of the by-laws:

Vice-Presidents	
*Zone A (Western Provinces)	C. V. Antenbring, Winnipeg, Man.
*Zone B (Province of Ontario)	R. B. Chandler, Port Arthur, Ont.
*Zone C (Province of Quebec)	F. L. Lawton, Montreal, Que.
Councillors	
†Yukon	N. Gritzuk
†Vancouver Island	P. F. Fairfull
†Vancouver	P. N. Bland
†Central British Columbia	H. R. Hatfield
†Kootenay	A. F. Brooks
†Edmonton	S. J. Hampton
†Saskatchewan	A. H. Douglas
†Winnipeg	Stewart Barkwell
†Lakehead	D. B. McKillop
†Sudbury	F. A. Orange
†London	A. L. Furanna
†Port Hope	Harry Gadd
†Kingston	J. W. Dolphin
†Nipissing & Upper Ottawa	J. W. Millar
†Border Cities	W. G. Mitchell P. N. Brown
‡Toronto	Harvey Self
†Belleville	A. D. Janitsch
†Brockville	J. S. Waddington
†Chalk River	C. A. Crawford
‡Ottawa	Hector Chaput
§Montreal	T. N. Davidson P. W. Gooch Jacques Hurtubise
†Eastern Townships	A. S. Mitchell
†St. Maurice Valley	Viggo Jepsen
†North Shore Lower St. Lawrence	W. S. Martin
†Lower St. Lawrence	L. P. Dancose
†Saguenay	A. B. Sinclair
†Baie Comeau	Charles Miller
†Fredericton	S. B. Cassidy
†Saint John	T. C. Higginson
†Halifax	R. D. T. Wickwire
†Amherst	Lawrence L. Spurr
†Prince Edward Island	N. F. Stewart
†Corner Brook	M. C. Collins
†Newfoundland	C. H. Conroy

*One Vice-President to be elected for two years
†One councillor to be elected for two years
‡One Councillor to be elected for three years
§Three councillors to be elected for three years each

Aid for Education

A plan to provide financial assistance for full-time employees taking voluntary out-of-hours educational courses — including engineering — has been put into effect by The Bell Telephone Company of Canada.

Full-time employees—both men and women—may apply for reimbursement for courses likely to broaden their usefulness to the company, either in their present positions, or in positions that they might reasonably be expected to qualify for in the future.

Reimbursement for half the tuition cost to a maximum $150 annually, may be claimed by employees taking acceptable courses, whether the language of instruction is English or French.

The company's educational assistance plan is available to employees taking evening courses at colleges and universities, and to those attending certain evening classes at secondary or high schools. Employees without access to suitable classes, but who receive instruction by correspondence from universities or recognized correspondence schools, may also apply for assistance.

Providing they do not duplicate the courses available in the Bell company's plant schools, courses for craftsmen could include electricity, electronics, engineering or business administration. Clerks or telephone operators might be interested in shorthand and typing, or university courses in arts, science or commerce.

The plan is administered by regional interdepartmental committees, which are responsible for interpreting company policy. The advice of supervisors is taken into consideration in each case, since they are in a position to know whether the required time will interfere with the job, whether the employee is likely to complete the course and in what way he or she may benefit.

If closely related to the job, tuition in individual subjects below junior matriculation may be acceptable. However, basic education is a personal responsibility of the individual employee.

The Bell company's offer of financial assistance toward the cost of voluntary out-of-hours educational courses is based on the fact that technical proficiency and specialized knowledge are becoming increasingly important to its employees because of the growing complexity of company operations. As a result, the plan will prove especially helpful to engineers following technical or management courses.

It is estimated that some 1,600 employees have been taking voluntary out-of-hours educational courses of various types over the past year. More than half of these employees will be covered by the new plan during the coming term.

ENGINEERING JOURNAL

July Issue, 1958

The July issue of *The Engineering Journal* is in very short supply.

We would be very grateful if any members not wishing to retain their copies would send them to The Librarian at Headquarters.

UN Conference on Atomic Energy

Canada's delegation to the Second United Nations International Conference on the Peaceful Uses of Atomic Energy, Geneva, Switzerland, September 1-13, 1958, was headed by Dr. W. B. Lewis, vice-president, research and development, Atomic Energy of Canada Limited. His associates were Dr. A. R. Gordon, of A.E.C.L. and University of Toronto; R. E. Barrett, of Eldorado Mining and Refining Limited; Dr. H. G. Thode, of National Research Council and McMaster University; and M. H. Wershof, Canadian delegate to U.N., Geneva. The delegation included 65 advisers from private industry, universities, government departments and Atomic Energy of Canada Limited.

Canadians submitted 47 scientific papers to the meeting of some 5,000 scientists from 80 countries. The Canadian papers covered such topics as the atomic energy program, the NRU Reactor, types of ores in the various uranium mining regions, uses of radioactive isotopes, cancer therapy, health and safetv in the operation of atomic installations and disposal of fission products.

Canada's exhibit at the conference covered the full range of atomic energy developments in this country from the uranium industry through fundamental and applied research to radioactive isotopes. There is a model of the NPD (Nuclear Power Demonstration) our first atomic power station, with fifteen models of atomic power reactors, cancer treatment machines, a uranium mine mill and the research reactors at Chalk River.

The most important result of the first Conference, held in 1955, was the very open exchange of information, said the conference secretary-general, Sigvard Ekland, in *United Nations Review*, July 1958. English, French, Spanish and Russian versions of the proceedings were published, which are now generally considered to be an encyclopedia in this field.

This year's second conference was held at the request of the Secretary-General of UN, on the recommendation of his Advisory Committee on Atomic Energy. The member states and the specialized agencies of UN were invited to participate, with the result that during March, April and May, this year, 2,409 abstracts of papers were received by the conference secretariat. The twenty-one scientific secretaries assisting in the scrutiny of abstracts included Canadians Thomas Church, of Atomic Energy of Canada Limited, Chalk River, and Dr. Harold Copp, Prof. of Physiology of University of British Columbia.

The program contained this year the general sessions and five parallel series of sessions. The general sessions covered such topics as the future of nuclear power, experience with nuclear power plants, the possibility of controlled fusion, progress in the use of isotopes, recent developments in fundamental physics and international collaboration in the field of atomic energy. The five technical series of sessions dealt with (1) physics, (2) reactors, (3) chemistry, (4) isotopes and radiological protection, and (5) raw materials and metallurgy. The total number of sessions were 77 as compared with 55 in 1955.

The proceedings of the second Conference will be published in English, during the early part of 1959, with abbreviated versions in Russian, Spanish and French. The proceedings are estimated to consist of 33 volumes.

Annual Meeting 1959

ENGINEERING INSTITUTE OF CANADA

Toronto

Royal York Hotel

June 8, 9, 10

Members are invited to submit papers for the meeting to the Committee on Technical Operations. Full information appeared on Page 113 of the September issue of the *Journal.*

Authors were asked to observe these deadlines: November 1, 1958, receipt of title of paper and name of author; December 1, receipt of abstract; February 1, 1959; receipt of manuscript.

Four of Canada's five official representatives to the Second United Nations International Conference on the Peaceful Uses of Atomic Energy, 1958. Left to right are: R. E. Barrett, Ottawa, Dr. A. R. Gordon, Toronto, Dr. W. B. Lewis, Chalk River, leader of the delegation, and Dr. H. G. Thode, Hamilton, Ont. The other representative is M. H. Wershof, member of Board of Governors, International Atomic Energy Agency, Vienna, and Canadian Representative to UN, Geneva.

Student delegates to the annual meeting of the Institute last May at Quebec City were: Donald J. Thomson and W. M. Calderwood of U.B.C.; R. W. Pollock, Alberta; W. A. Neff and T. W. B. MacFarlane, Saskatchewan; Ken A. Bailey and B. K. Laxdal, Manitoba; W. J. Simpson and R. B. Schaeff, Toronto; David R. Durnford, Western Ontario; Andrew M. McMahon and John E. Vollmer, Queen's; P. V. Glasheen, R.M.C.; Philippe Lemay, Ottawa; Andre Rinfret, Ecole Polytechnique; George M. Desjardins, McGill; Gilles G. Henault, Sherbrooke; Michel Chamberland and Gaston Asselin, Laval; Hans Foerstel, New Brunswick; and John Jay, N.S.T.C. Photographed with the students were: Henry P. Gatin of E.I.C. Headquarters, C. G. Southmayd, Montreal, chairman of the Conference, and Miss Gillian Clover of Headquarters.

Hoosac Tunnel

Robert F. Legget, M.E.I.C., supplied this picture of the Hoosac Tunnel, the construction of which is recorded in "Daylight Through the Mountain", published last year by the E.I.C.

The tunnel, he reports, is in very good shape but one of the two tracks has been removed due to decrease in traffic and the necessity of obtaining extra headroom for the single remaining track in order to accommodate the "piggy back" traffic which the Boston and Maine Railroad are now developing.

The strange cover over the portal is a metal casing in which slides a metal door which is dropped to close off the tunnel during the winter when the weather is extremely cold.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of Council held on September 2.

Members: D. Biggar, Kingston; H. R. Bryett, Vancouver; H. S. Chapman. Calgary; D. Gunasekera, Ceylon; L. G. Harmsworth, Toronto; A. P. Humble, Ottawa; N. H. Kearns, Copper Cliff; P. J. Killaby, Toronto; D. S. McIntosh, Calgary; C. E. Michener, Toronto; R. C. Monaghan, Hamilton; H. J. Mutz, Copper Cliff; S. Persson, Toronto; C. Pozsonyi, Montreal; O. B. Schier, New York; D. A. N. Scott, South Africa; H. Skantze, Arvida: R. W. Smith, Toronto; K. B. Snaggs, Trindad, B.W.I.; C. J. Stewart, Toronto; S. G. Wickham, Montreal; A. H. Wilson, Chalk River.

Juniors: M. M. Abbas, Ottawa; J. R. Ariss, London; R. C. Freeman, London; J. Huva, Quebec; D. R. Parkes, Victoria; D. R. Peach, Shawinigan; G. J. Trausch, Quebec; G. T. Trotter, Toronto; D. R. Van Sickle, Houston, Texas.

Affiliate: W. H. Taylor, Calgary.

Junior to Member: A. G. Fletcher, Vancouver; M. R. Kent, Ottawa; J. Klimovich, Vancouver; R. E. Manning, Toronto; J. C. Stevens, Victoria; E. H. Talbot, Vancouver.

Student to Junior: J. R. Dean, Fredericton; W. R. Sexsmith, Shawinigan.

STUDENTS ADMITTED

McGill University: C. Giannakakis. J. K. Nixon. **University of Alberta:** P. J. Kostiw. **University of Toronto:** R. D. Thibodeau. **University of B.C.:** L. H. Nohr. **University of London:** N. R. Spencer. **University of Toronto:** M. G. Masuda, B.A.Sc. (elec.), 1958. **University of Sask.:** S. J. Yaki, B.E. (mech.), 1958. **Queen's Univ.:** V. Olsevskis, B.Sc. (chem.) 1958. **McGill University:** C. Cote, B.E. (civil), 1958.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members: R. K. Ulveland, G. L. Ward; **Junior:** G. R Ursenbach; **Student to Junior:** N. M. Boyd.

SASKATCHEWAN

Members: J. D. S. Brookes. J. W. Harding, R. J. Fleming, D. B. Phillips, J. D. Fowler. **Junior:** R. A. Fox. **Junior to Member:** J. M. Crawford, E. G. E. Wurts. **Student to Junior:** A. A. Gorkoff.

NOVA SCOTIA

Junior to Member: J. H. Boyce, R. L. McCarther, M. R. Leybourne, J. P. Livingston.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Frank P. Vaughan, M.E.I.C., of Saint John, N.B., retired consulting electrical engineer and contractor of radio pioneering fame, died at his home in Saint John on August 8, 1958.

Born at Liverpool, England, on June 3, 1874, Mr. Vaughan attended Regent College, Southport, England. Later he acquired engineering skills at the Massachusetts Institute of Technology.

On the threshold on his career in 1891, at Vancouver, he worked with a telephone corporation, through which he was connected with several British Columbian interests. Four years later, established in Eastern Canada he worked with Canadian and American companies at Yarmouth, N.S., Saint John, N.B., Boston and Schenectady, N.Y. He settled at Saint John in 1902 and opened a private practice as electrical engineer and contractor. The Vaughan Electric Company Limited came into being in 1906.

In 1904 he was granted a licence for experimental wireless telegraphy, and was in four years able to project his voice a distance of three miles by wireless telephone, thus contributing to his renown in wireless telegraphy, telephony and high potential high frequency currents. These creative stages of wireless communications arrested widespread attention among scientific writers. The first radio broadcasting station in New Brunswick was designed, built and put into operation by him in 1923. This was station 9-B1.

For long and faithful service to his profession, the University of New Brunswick in 1922 conferred on him an honorary M.Sc. degree.

Mr. Vaughan held office in the Institute as branch chairman at Saint John in 1921. Four years later he was councillor representing that branch.

Mr. Vaughan became a member of the E.I.C. in 1919 as an Associate Member, became a Member in 1920 and attained Life Membership in 1942.

Late in life, after retirement, he devoted a great portion of his time to art. He developed an unusual skill in the use of colored pencils, producing effects that were difficult to distinguish from oil painting. His favorite subjects were animals and birds. All his pictures were remarkable for their life-like portrayal and for the third dimension that appeared in them all.

He did some work in oils and water colours as well, but his colored pencil "paintings" were his greatest achievement. The Institute is fortunate in having several of his finest works on the walls at Headquarters.

It is men like Mr. Vaughan who give life and purpose to a learned society. He participated in all activities at the branch, provincial and national levels. He presented papers, he held office, he worked for the Institute, and for other organizations as well in which he found interest.

Many circles, including engineering, have been greatly enriched by the support and loyalty of this great man. A true gentleman, he attained distinction but without vainglory in his greatest field of interest—engineering. The profession could do with more like him.

Dr. P. L. Pratley, M.E.I.C., consulting engineer of Montreal, died in that city on August 1, 1958.

Philip Louis Pratley was born at Liverpool, England, on December 4, 1884, and studied at the University of Liverpool, gaining a B.Sc. degree, in 1904, a B.Eng., degree in 1905, M.Eng., 1908, and an D.Eng., in 1939.

He moved to Canada in 1905 and worked with the Quebec Bridge Board of Engineers, Department of Railways and Canals. Later he gave extensive service to the St. Lawrence Bridge Company of Montreal, the Dominion Bridge Company Limited, the Grand Trunk Railway System and its subsidiaries. Dr. Pratley was associated with the Dominion government, various provincial governments, cities and municipalities throughout the country, by railways and industrial corporations, by private companies and general contractors. He also collaborated as Canadian consultant with different American engineering firms on international bridges.

At the time of his death he was consulting engineer for the new Champlain bridge at Nun's Island, Montreal.

Lately he was called in on the collapse of the Second Narrows Bridge, Vancouver.

Dr. Pratley gave many years service to the E.I.C. He was a member of the council representing the Montreal Branch from 1927 to 1934, was elected E.I.C. treasurer in 1933, and became a vice-president in 1935 and 1936.

In addition to his service on the Council Dr. Pratley was Canadian member of Council for the Institution of Civil Engineers of London.

Twice a winner of Institute awards, these were the Gzowski Medal, in 1935, and the Duggan Medal. He was its first recipient in 1937.

Dr. Pratley joined the Institute as a Student in 1907, transferred to Associate Member in 1909, and to Member in 1917. He became a Life Member in 1946, Honorary Member in 1958.

Seldom has the profession of engineering in Canada suffered the loss that it experienced recently with the death of Dr. Pratley.

Dr. Pratley's mark on the engineering profession in Canada is deep and impressive for two things. Firstly, his outstanding technical ability and secondly, his equally outstanding character. Few engineers have ever enjoyed the high reputation that came to Dr. Pratley because of this combination of sterling qualities.

He was a man who was interested not only in his work but in the welfare of his profession as well. He devouted many years of interest to the affairs of the Engineering Institute in serving the society in many capacities and contributing many papers to the meetings and to the Engineering Journal.

It is a great thing for a profession that it can find within its ranks outstanding gentlemen of great competence who are indeed "a decoration to the house". The profession has been greatly enriched by Dr. Pratley's achievements in all the fields in which he has shown an interest.

P. C. Kirkpatrick, M.E.I.C., of Montreal who died on June 30, 1958. An obituary item appeared in the September issue of the *Journal.*

James Forgie, M.E.I.C., consulting engineer, pioneer and expert on subaqueous tunnel design and construction practise, died on August 13, 1958, in New York City, at the age of 90.

Mr. Forgie was born in Scotland. After graduating from Gordon's College, Aberdeen he began his professional engineering career in London. He was associated

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

BRITISH COLUMBIA

THE SIXTEENTH ANNUAL CONVENTION of the Municipal Engineers' Division of the Association of Professional Engineers of B.C., which concluded its three day session in Prince George on September 20 attracted 260 d legates and their wives. Final day was devoted to field trips of engineering interest in the community, including the water treatment plant, the new earth resevoir and waterworks pump house, and the municipal land assembly project which will provide 177 large lots, completely serviced with underground lighting and telephone connections, sewers and all facilities at a purchase price of $1800 per lot.

Bold New Look

A highlight of the business session was a paper on "Labour Relations and the Municipal Engineer" by G. A. Wilkinson, (of Vancouver), vice-president, Marwell Construction Company and noted provincial labour relations authority. A former member of the Vancouver Trades and Labour Council, he has also served on the Labour Relations Board of the province.

Mr. Wilkinson called for a "bold new look" to establish industrial peace, and expressed the opinion that strikes have long since outlived their usefulness as an instrument for attaining union objectives. He advocated rescinding or amending the obsolete Trade Union Act of 1907 and bringing labour relations procedures up-to-date in order to fit the changed conditions which have brought organized labour to a position of power and responsibility in the economic welfare of society. He warned against placing full blame for labour troubles entirely on the unions, at the same time as he described the results of irresponsible tactics of some sections of organized labour.

He stated that "our Number One problem is communication, coupled with education" to insure that all sections of the public, including labour, are aware of what these labour disputes are costing us, and that they are no longer arguments between employers and employees, but are everybody's business. He cited a recent case where the votes of 16 individuals in Vancouver gave a union the right to tie up every construction job throughout the province. "How silly can we get?" he asked.

Reviews Wenner-Gren Project

At the annual banquet the Hon. Ray Williston, Minister of Lands and Forests, reported on progress to date of the vast Wenner-Gren project in the Rocky Mountain Trench of northern B.C. Engineering data obtained at a cost of $8 to $10 million is being turned over to the government, and will be of immense value "whether or not" the main project of the mono-rail railway is carried out to completion, the Minister said. Among the several subsidiary developments under consideration is a four million horsepower hydro-electric development north of Prince George. This enormous new power potential, the Minister said, has already put Canada in a much stronger bargaining position with the United States in the development of Columbia River power.

Elected to the executive of the Municipal Engineers' Division of the Association of Professional Engineers of B.C., at their annual meeting in Prince George, September 18 to 20, were, left to right, (standing), S. Lefeaux, P.Eng., J. A. Merchant, P.Eng., registrar of the A.P.E.B.C.; A. S. G. Musgrave, P.Eng., and G. O. White, P.Eng. Seated are Ron Cameron, P.Eng., G. Q. Lake, P.Eng., G. Meckling, P.Eng., and G. P. Harford, P.Eng.

North West Highway System Paper

Another interesting paper on the "Northwest Highway System" was presented jointly by Lt. Col. D. M. C. Saunders, M.E.I.C., of the Royal Canadian Engineers, and Mr. B. A. Yates, M.E.I.C., both of Whitehorse. They reported in detail on the Canadian Army's stewardship of the 1221 miles of the Alaska Highway from Dawson Creek to the Alaska border. Along this vast and isolated stretch the Canadian Army is responsible not only for road maintenance and repair, but for the public utilities, the sewerage and waterworks and power facilities along the route. Some idea of the difficulties and variations existing in different localities is the cost of supplying water, which ranges from $3.58 per thousand cubic feet at Muskwa on Mile 259 to 15c per thousand at Whitehorse. The paper went into specific detail about techniques developed under special conditions of climate and terrain for highway maintenance and public utilities. For this reason it was perhaps the most interesting and novel of all the business sessions at the convention.

Lagooning Method of Sewage Disposal

The "Lagooning" method of sewage disposal, which is both inexpensive and effective for smaller communities, was outlined by R. Bowering, P.Eng., director of public health engineering of the Department of Health and Welfare, Victoria. Seven B.C. communities are already using this method with good results, Mr. Bowering stated. According to climactic conditions the sewage is effectively disposed of with a three to five foot depth of shallow pond which provides one acre of area to approximately 200 population on the system. When properly constructed, or where suitable natural ponds exist, the necessary depth is maintained entirely by the influx of waste, and very little attention is required. Because of the absence of odour they may be located as close as 500 feet away from public travel and there is no unsightly matter on the surface, although Mr. Bowering recommended that they should be screened from public view.

Contracts Discussed

A. J. MacDonald, P.Eng., gas distribution manager of the B.C. Electric Company, Abbotsford, outlined the advantages of forms of contracts developed with great economy and satisfaction for projects involving the installation of natural gas mains. After progressive experience with various forms of low-bid and negotiated contracts, he advocates a unit-cost plus fixed fee arrangement which could be adapted, with modifications, to municipal engineering requirements. By working toward an elimination of risk plus an established profit for the contractor, Mr. Macdonald found that costs declined steadily and sharply as contractors became familiar with the work to be done. Comparative savings, within the course of one year, amounted to nearly 50 per cent in some instances. He concluded that the most advantageous form of contract, which could be adapted to apply to certain forms of maintenance as well as new construction, is a continuing contract with an incentive factor that reimburses the contractor for all his expenses and adds a fixed fee per unit of work to cover overhead and profit.

Asks Careful Work Scheduling

George Wallach, of the regional National Unemployment Commission in Vancouver, told delegates that very serious employment problems are anticipated this winter. He made a plea for municipal authorities throughout the province to schedule works and purchases so as to provide as much additional work as possible during the normally slack season.

He reported that Vancouver had already decided to provide $4,000,000 for special projects this winter, and announced a national "Plan Now" campaign, starting in November, to stimulate both private and public employers to spread work over the winter months. Among his concrete suggestions were the elimination of overtime and "moonlighting" (the holding of two jobs by one man), winter schedules of public works, and acceleration of purchasing programmes to stimulate employment in the supplying industries.

Talk on Soil Conditions

M. C. Nesbitt, P.Eng., regional construction engineer for the Department of Highways at Prince George, spoke on soil conditions and treatment in connection with the new stretch of paved highway between Prince George and Quesnel.

Charles Broadbridge of Vancouver, showed coloured slides of the new Deas Island tunnel in Vancouver, and C. E. Leonoff, P.Eng., told about the "Construction of an Earth Water Storage Reservoir for the City of Prince George" for which his firm, Ripley and Associates, had been the consulting engineers.

Executive Elected

New executive of the Municipal Engineers' Division for 1958-59 are: G. Q. Lake, P.Eng., Burnaby; Stuart Lefeaux, P.Eng., Vancouver Parks Board; George Meckling, P.Eng., North Vancouver District; Ronald Cameron, P.Eng., Richmond; G. O. White, P.Eng., Oak Bay, Vancouver Island; and G. P. Harford, P.Eng., who has resigned as city engineer of Prince George to take up his post in the planning division of the Vancouver City engineering department. Honorary secretary is A. S. G. Musgrave, P.Eng., founder of the Municipal Engineers' Division and former municipal engineer of Oak Bay. Secretary-Treasurer is J. A. Merchant, P.Eng., Registrar of the Association of Professional Engineers of B.C.

ONTARIO

Engineers in the News

George W. Vosper, P.ENG., who is on the teaching staff of the department of mechanical engineering, Royal Military College, Kingston, Ont., has recently been elected a director of the Eastern Ontario Development Association. Last year Mr. Vosper was on the executive of Zone 2 of this body and he is presently serving, also, his second year both as alderman of the City of Kingston and a director of the Kingston Chamber of Commerce. As a matter of interest, both aldermen representing Mr. Vosper's ward are professional engineers — his fellow-alderman being Col. L. F. Grant, P.ENG.,

Robert Wilson Higgs, P.ENG., recently completed post-graduate studies at Cornell University and received the degree of Master of Science in Transportation on an International Road Educational Foundation fellowship awarded through the Canadian Good Roads Association. He is returning to Ottawa to resume employment with the highways division, Department of Public Works of Canada.

Malcolm M. Turnbull, P.ENG., has been appointed city engineer and commissioner of works of the City of Belleville, Ont.

Before accepting the appointment in Belleville he was engineer of streets and sanitation in Ottawa.

Professional Engineers Wives Association

The winter and spring activities of the Professional Engineers' Wives Association concluded with a buffet at the Savarin, Toronto. This Association originated with the wives of the graduating classes of 1950 and 1951 of the University of Toronto and later graduating classes have since joined. Last year the membership was extended to wives of all graduate engineers from any accredited university.

The group has given enthusiastic support to the raising of funds to provide a bursary to an engineering student. In addition to a $500 bursary, funds were raised to make a loan available to fourth year students.

Mrs. H. R. Fielding succeeds Mrs. L. W. Alexander as president and the executive includes: Mrs. B. G. De Graaf, vice-president; Mrs. R. P. Sloan, secretary; Mrs. E. J. Bartley, treasurer; Mrs. L. W. Alexander, auditor; Mrs. G. R. Truewin; Mrs. J. M. Clarke; Mrs. K. H. Sharpe; Mrs. M. A. Couse; Mrs. W. D. Bonisteel; Mrs. H. V. Ivers; and Mrs. R. H. Andrews.

George R. Mills, P.ENG., of Ethyl Corporation of Canada Ltd., has been promoted to the position of operations superintendent at its Sarnia, Ont., plant. A 1957 graduate in engineering from the University of British Columbia, Mr. Mills joined Ethyl of Canada in 1955 after varied experience in the chemical and petro-chemical field.

Barry E. Smith, P.ENG., has accepted a position with the Corporation of the City of Oshawa, Ont. He was formerly with the consulting firm of Marshall, Macklin Monaghan Ltd., Don Mills, Ont.

R. J. Thomas, P.ENG., has left for Sarawak where he has accepted a position with the public works department of Sarawak as an executive engineer. He will be located at Kuching, Sarawak.

V. B. Schneider, P.ENG., has moved from Lively to Ottawa, Ont., where he has joined the mineral resources division of the Department of Lands and Technical Surveys of Canada. Prior to this change, Mr. Schneider was associated with the International Nickel Company of Canada Ltd., at Copper Cliff.

A. J. G. Leighton, P.ENG., is leaving the Hydro-Electric Power Commission of Ontario, where he has held the position of manager of the Whitedog and Caribou Falls construction projects, to accept the position of program control engineer with the British Columbia Power Commission, Victoria, B.C.

Harold Evans, P.ENG., has left the Canadian General Electric Co. Ltd., Peterborough, Ont., and has moved to Montreal, Que., where he is employed by the Montreal Engineering Company.

Thomas Thompson, P.ENG., has left Toronto and is now located in Rugby, England, where he is presently with the English Electric Co. Ltd.

Walter N. Button, P.ENG., who has been project approvals engineer with the Frequency Standardization Program of Ontario Hydro, has been transferred from St. Carthanines to Cornwall, Ont., where he is with the H.E.P.C. operations divisions at the Robert H. Saunders Generating Station.

W. J. Notley, P.ENG., of the engineering department of Canadian National Railways, has been transferred from Montreal to the Toronto offices.

Donald L. Melick, P.ENG., of the Bell Telephone Company of Canada, is Toronto area plant personnel supervisor and is located at 393 University Ave., Toronto.

Management Training Course

Of 122 enrolled in the August 1958 Management Training Course of the University of Western Ontario School of Business Administration, at least 18 are professional engineers with companies or utilities in Ontario or Quebec. Of these, over half are Ontario professional engineers and include D. M. Alloway, P.Eng., Oshawa; J. S. Crerar, P.Eng., Alex De Maio, P.Eng., E. R. Gill, P.Eng., and Gordon Macivor, P.Eng., of Toronto; H. R. D. Graham, P.Eng., North Bay; B. R. Lewis, P.Eng., Hamilton; T. N. McLenaghen, P.Eng., Iroquois Falls; V. M. Norwood, P.Eng., Corunna; and J. W. Thomson, P.Eng., Timmins.

Alexander Watson P.ENG., of the Department of Transport of Canada, has been promoted director of ship construction and supply. Mr. Watson has been with the Department for over 20 years and prior to his recent promotion was associate director of marine services.

Fred R. Dorward, P.ENG., has joined Angus Butler & Associates Ltd., Edmonton, Alta., as head of the electrical department of this firm of consulting engineers. He was formerly with Crowther MacKay & Associates Ltd.

M. R. Laundry, P.ENG., is now with Orenda Engines Ltd., Malton, Ontario, as a mechanical engineer. He was formerly employed with L. H. Schwindt & Co. Ltd., at Burlington, Ont.

D. R. McAuley, P.ENG., of Ottawa, Ontario is a defence production officer in the electronics branch of the Department of Defence Production.

Col. R. H. Ramsay, P.ENG., has been appointeed Commandant of the RCEME School at Kingston, Ont. His appointment and promotion to the rank of colonel took effect on August 18, 1958.

Col. Ramsay, who graduated from McGill in 1940, has been deputy director (production) in the Directorate of Electrical and Mechanical Engineer for the past year.

OBITUARIES *(Continued from page 105)*

with the outstanding United Kingdom firms of Sir Benjamin Baker and Company, and Sir Basil Mott and Hay. Mr. Forgie took part in building tunnels for the London Underground before the turn of the century. In 1902 the Pennsylvania Railroad invited Mr. Forgie to New York to provide advice on the design and construction of tunnels under the East and Hudson rivers. Completed in 1910 these tunnels became the models for subsequent shield-driven tunnels in the U.S.A.

Shortly after this Mr. Forgie became a partner in the consulting firm of Jacobs and Davies, which was handling work on the Hudson and Manhattan Railway tubes. Then he began a consulting practice of his own in 1914, which he continued actively until a few years ago. Among his clients were the Port of New York Authority, Pennsylvania Railroad, Mexican Light and Power Company and many other utilities. His last major work was for the Pennsylvania Railroad on its tunnel under the city of Baltimore.

Mr. Forgie was also an expert witness and an arbitrator in many cases of litigation relating to tunnels.

A member of the Institution of Civil Engineers (Great Britain), Mr. Forgie was a recipient of that society's Telford Gold Medal, given for distinguished service to civil engineering.

Mr. Forgie joined the Engineering Institute in 1910 as an Associate Member, attained Life Membership in 1947.

Lieutenant Colonal Blair Ripley, C.B.E., D.S.O., M.E.I.C., consulting engineer at Oak Bay Victoria, B.C., died on July 5, 1958.

Blair Ripley was born at Oxford, N.S., on August 29, 1880. He had his education through private tuition and began his engineering career in 1897 with the Great Falls and Canada Railway and the Canadian North-West Irrigation Company. Around the turn of the century he was an assistant engineer with the G. F. and C. Railway, and during the next few years was an engineer of construction on the St. Mary's River Rly, now the C.P.R., and resident engineer of construction on the Grand Trunk Pacific Railway, C.N.R., resident engineer on viaduct construction at McLeod, Alta., and Outlook, Sask. Swinging back into Eastern Canada he was an assistant engineer with the Dominion Atlantic Railway in Nova Scotia, 1910-1912. He was an engineer of grade separation for the C.P.R. at Toronto, 1912-1915. As the commanding officer he recruited and took the First Canadian Railway Construction battalion overseas in 1916. He was awarded the C.B.E., the D.S.O., and gained mention in despatches three times for his part in the hostilities. Lt.-Col. Ripley was district engineer, Ontario district, for the C.P.R., at Toronto from 1919 to 1938 and then took over the post of engineer, maintenance of way, Eastern lines, until 1943. In 1944 he was named special engineering representative for the Toronto Terminals Railway Company.

Colonel Ripley moved to Victoria in 1945 and opened a consulting engineering practice at that time.

He joined the Institute as an Associate Member in 1907, transferred to Member in 1913, and attained Life Membership in 1943.

W. S. Wilson, M.E.I.C., chief engineer of the Dominion Steel and Coal Corporation, Limited, died at Sydney, N.S., on September 9, 1958.

Born on January 15, 1894, in Frodingham, Lincolnshire, England, Mr. Wilson came to Canada as a young man. In May, 1911 he began work with the Dominion Iron and Steel Company as a foundry helper. The following year he became a tracer and eventually a draftsman in the mechanical department sketch room.

Mr. Wilson occupied the posts of draftsman, checker, squad foreman, assistant chief draftsman, and technical engineer between the years 1917 to 1919. After a year as engineer in charge of the economy department of the Dominion Coal Company, he returned to the Dominion Iron and Steel Company in 1920 as a technical engineer. In 1930 he was named to the post of chief engineer for the company.

His final appointment as chief engineer for the Corporation was made in 1936. Mr. Wilson served under six consecutive Dosco presidents.

He also played a prominent part as consulting engineer in the promotion of the Canso Crossing project.

Mr. Wilson joined the Engineering Institute of Canada in 1921 as an Associate Member, transferred to Member in 1940 and attained Life Membership in 1957.

George Nixon Hatfield, M.E.I.C., retired street engineer with the City of Saint John, N.B., died on July 3, 1958 in that city.

Born at Saint John on May 1, 1880 Mr. Hatfield attended high school in that locality and studied engineering with the International School of Correspondence. In 1910 he accepted the post of assistant engineer with the City of Saint John. Two years later he served in the public works department, and spent some time as a road engineer with the municipal body. In 1946 he retired from active professional life.

Mr. Hatfield joined the Engineering Institute as Student Member in 1909, transferred to Associate Member in 1915, and became a Member in 1940. He attained Life Membership in 1950.

Cecil W. Fowlie, M.E.I.C., of Halifax, a member of the Federal Department of Public Works, died on July 17, 1958.

Cecil Winston Fowlie was born on August 1, 1902 at Orillia, Ontario. He had his early schooling there and then went on to Queen's University, Kingston to study engineering. In 1930 he graduated with a B.Sc. degree in civil engineering. For a number of years unable to practice due to personal affairs, he began as a field engineer in 1936 with a mining firm, later worked with the Verita Porcupine Gold Mines, the Makbodas Mining Company, Faymar Gold Mines, Hoyle Gold Mines, as an assistant engineer, between 1937 and 1943. He joined the Department of National Defence, Army, in 1943, becoming Chief Works officer and assistant to the command engineer officer. He was appointed a Member of the British Empire, in 1946. Discharged from military service in 1947, he joined the Department of Public Works at that time.

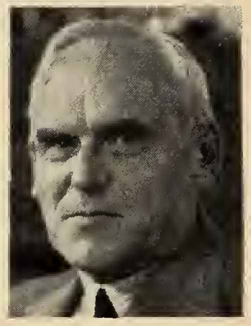
Mr. Fowlie joined the Engineering Institute as a Member in 1949.

Personals

News of the Personal Activities of Members of the Institute

R. Yuill, M.E.I.C.

R. E. Tweeddale, M.E.I.C



Rt. Hon. C. D. Howe, HON. M.E.I.C.

Rt. Hon. C. D. Howe, Hon. M.E.I.C., (B.Sc., M.I.T., 1907), formerly Minister of Trade and Commerce, member of the federal cabinet from 1935 to 1957, founder of the firm of C. D. Howe and Company at Port Arthur, was among those who received honorary degrees at Mount Allison University, Sackville, N.S., at the Centenary Convocation held August 16th, 1958. Rt. Hon. Howe was conferred an honorary doctor of laws degree in recognition of services to the state.

Russell Yuill, M.B.E., M.E.I.C., (Mount Allison; B.Sc., civil, McGill, 1915), recently retired port manager of Saint John, N.B., National Harbours Board, was conferred an honorary doctor of laws degree at Mount Allison University, Sackville, N.S., on August 16, 1958. The award was made in recognition of the part former students have played and are playing in the life of Mount Allison University.

R. E. Tweeddale, M.E.I.C., (B.Sc., elec., New Brunswick, 1935), chief engineer of the New Brunswick Electric Power Commission since 1957, has been appointed general manager of the Commission. Provision for the appointment of a general manager was made during the last session of the Legislature by amendment to the Electric Power Act. Mr. Tweeddale will however retain his responsibilities as chief engineer in addition to the top executive office.

S. G. Gamble, M.E.I.C., (R.M.C., 1932; B.Eng., civil McGill, 1933), chief topographical engineer, surveys and mapping branch, Department of Mines and Surveys, Government of Canada, has been named director of the Branch. Mr. Gamble joined the Topographical Survey of the federal government in 1946, took over the air surveys section of the Survey in 1949.

Gilbert Proulx, M.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1941), general-superintendent of Saguenay Electric Company at Chicoutimi, Que., from 1950 to 1956, has been named president of the firm. For the past few years Mr. Proulx has been administrator of the Aluminum Company of Canada Limited, Chutes-des-Passes power project.

Gaston Dufour, M.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1937), has been named vice-president and general manager of the Saguenay Electric Company. He was formerly works manager of the Aluminum Company of Canada smelter at Isle Maligne, Que. He has been associated with Alcan in the Saguenay since 1940.

J. N. Ford, M.E.I.C., (B.Sc., elec., Alberta, 1934), of Canadian Utilities Limited, Edmonton, Alta., manager of operations with the organization since 1956, has been named general manager of the electric utility company. Mr. Ford had early experience with Calgary Power Company and in 1951 gained the appointment of chief electrical engineer with his present employer.

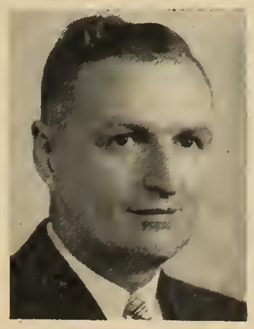
G. G. Henderson, M.E.I.C., (B.Sc., civil, Toronto, 1924), has recently been appointed general sales manager of the Canadian Bridge division of the Dominion Steel and Coal Corporation Limited. Mr. Henderson joined Canadian Bridge in 1924 and has served the company in various senior executive capacities since that time. Active in the affairs of the E.I.C., he has held office both as chairman and councillor of the Border Cities Branch.

F. J. Pollock, M.E.I.C., (B.Sc., civil, Toronto, 1922), has recently been appointed industrial and public relations manager for the Canadian Bridge division of the Dominion Steel and Coal Corporation Limited. He has been associated with the firm in various senior executive posts, most recently as operations manager.

W. R. Mitchell, M.E.I.C., (B.Sc., civil, Manitoba, 1934), contracting engineer for the Canadian Bridge division of the

F. J. Pollock, M.E.I.C.

W. R. Mitchell, M.E.I.C.



D. Scouler, Jr. M.E.I.C.

G. G. Henderson, M.E.I.C

S. G. Gamble, M.E.I.C.

Dominion Steel and Coal Corporation has been appointed chief engineer of Canadian Bridge. Mr. Mitchell joined the firm in 1940 as draftsman and design engineer and served as chief contracting engineer prior to his promotion as chief engineer.

Mr. Mitchell was elected chairman of the Border Cities Branch of the Institute in 1952, became a councillor representing the Branch in 1955.

Daniel Scouler, Jr., M.E.I.C., (B.Sc., mech., Nova Scotia Technical College, 1948), chief plant engineer for the Steel Fabrication and Manufacturing division of Dominion Steel and Coal Corporation Limited, has been appointed general manager of the Canadian Bridge division. He was formerly plant engineer for Halifax Shipyards and assistant chief engineer for Dosco.

Dr. Lyle G. Torey, M.B.E., M.E.I.C., (B.Sc., London, 1927; Ph.D., London, 1944), consulting engineer of Vancouver and Ottawa, has been retained in connection with an extensive radar air survey project of 200,000 kilometers, by the Canadian-owned Spartan Air Service Ltd., in the Zambezi Valley, Mozambique, P.E.A.

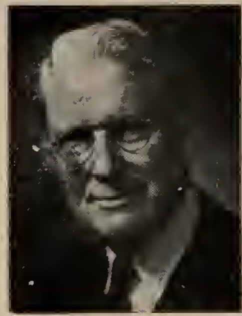
John William Southin, M.E.I.C., formerly resident engineer and resident manager, Sandwell and Company Limited, Pakistan is project engineer with Sandwell and Company Limited, Vancouver.

R. E. Crysler, M.E.I.C., (B.A.Sc., civil, Toronto, 1949), of the firm of H. A. Babcock and Company Limited, Toronto has been named a director in the organization. Mr. Crysler has had extensive experience in structural designing and municipal engineering works. He was in 1956 associated with W. S. Atkins & Associates Ltd., Toronto as a design engineer.

F. R. Murray, M.E.I.C., (B.Sc., Glasgow, civil, 1923), has been appointed Quebec sales manager for the Canadian Bridge Company and Truscon Steel, at Montreal. The announcement was made by the Dominion Steel and Coal Corporation.

Roy F. E. Bunston, M.E.I.C., (B.Sc., Queen's, 1942), has been named industrial products manager for the firm of Burndy Canada Ltd. Associated with the company since the formation of the Canadian company ten years ago, he concludes six successful years as president of Bunston Ltd., agents in B.C. and Alberta for Burndy and other electrical manufacturers.

J. E. Margison, M.E.I.C



O. Margison, M.E.I.C.

J. G. Beresford, M.E.I.C

Douglas Parent, M.E.I.C., (B Sc., mining, New Mexico, 1934), formerly manager of the Eastern Metals Corporation Limited, St. Fabien de Panet Co. Montmagny Co., Que., is general manager of the T.A.M. Company Ltd., Nigeria, West Africa. Mr. Parent has been engaged in mining projects in the province of Quebec for a number of years.

Arthur W. Harrington, M.E.I.C., (C.E., Cornell, 1909), of Ithaca, New York, has retired after more than 42 years of federal service. Mr. Harrington was, since 1921, district engineer for surface water, in charge of hydraulic and hydrologic investigational work in the State of New York for the U.S. Geological Survey, Department of the Interior.

Dr. David Silverman, M.E.I.C., (B.Sc., elec., Paris, 1935), formerly development engineer, Radio Engineering Products, Granby, Que., has taken over as senior design engineer with Henry J. Kaiser (Canada) Ltd., Montreal.

F. E. Hogg, M.E.I.C., (metall., Colorado School of Mines, 1937), assistant general technical superintendent of the Arvida works, Aluminum Company of Canada, Arvida, Que., has been named staff metallurgist with the general technical department, fabrication division of the organization at Kingston.

Mr. Hogg was secretary-treasurer of the Saguenay Branch in 1949, 1950 and 1951.

John G. Beresford, M.E.I.C., newly appointed manager of the Toronto apparatus factory, Linde Air Products Company, Division of Union Carbide Canada Limited, Toronto whose photo appears above. A "Personal" appeared in the September issue.

Col. K. H. McKibbon, M.E.I.C., (B.Sc., mech., Queen's, 1938), has taken over the post of officer in charge of administration, 4th Canadian Infantry Brigade Group, Soest, Germany. Formerly he was director of quartermaster operations and planning, army headquarters, Ottawa.

J. E. Margison, M.E.I.C., (B.A.Sc., chem., Toronto, 1942), and **Arthur G. Keith**, B.Arch., M.R.A.I.C., of Toronto, have formed a partnership for the practice of consulting engineering and architecture. Mr. Margison held industrial engineering posts with Shawinigan Chemicals Limited, Dominion Tar and Chemical Company Limited, and Merck and Company Limited. He was a director of the firm of A. D. Margison and Associates Limited. He will specialize in operations and cost reduction analysis for manufacturing firms.

Mr. Keith has served as chief architect of the Toronto Transit Commission and more recently was a director of the firm of A. D. Margison and Associates Ltd. He is colonel of the 2nd Field Engineering Regiment.

O. Margison, M.E.I.C., (B.A.Sc., civil, Toronto, 1916), formerly president of A. D. Margison and Associates Limited, has been retained as a consulting engineer with the new firm.

Professor J. W. Brooks, M.E.I.C., (B.Sc., civil, Queen's, 1939), associate professor of civil engineering, Queen's University, and a member of the faculty since 1947, left Kingston, Ont., with his family in August to accept an appointment at Ankara, Turkey. Granted a leave of absence from Queen's University, Professor Brooks has been commissioned by the United Nations Educational, Scientific and Cultural Organization to assist in

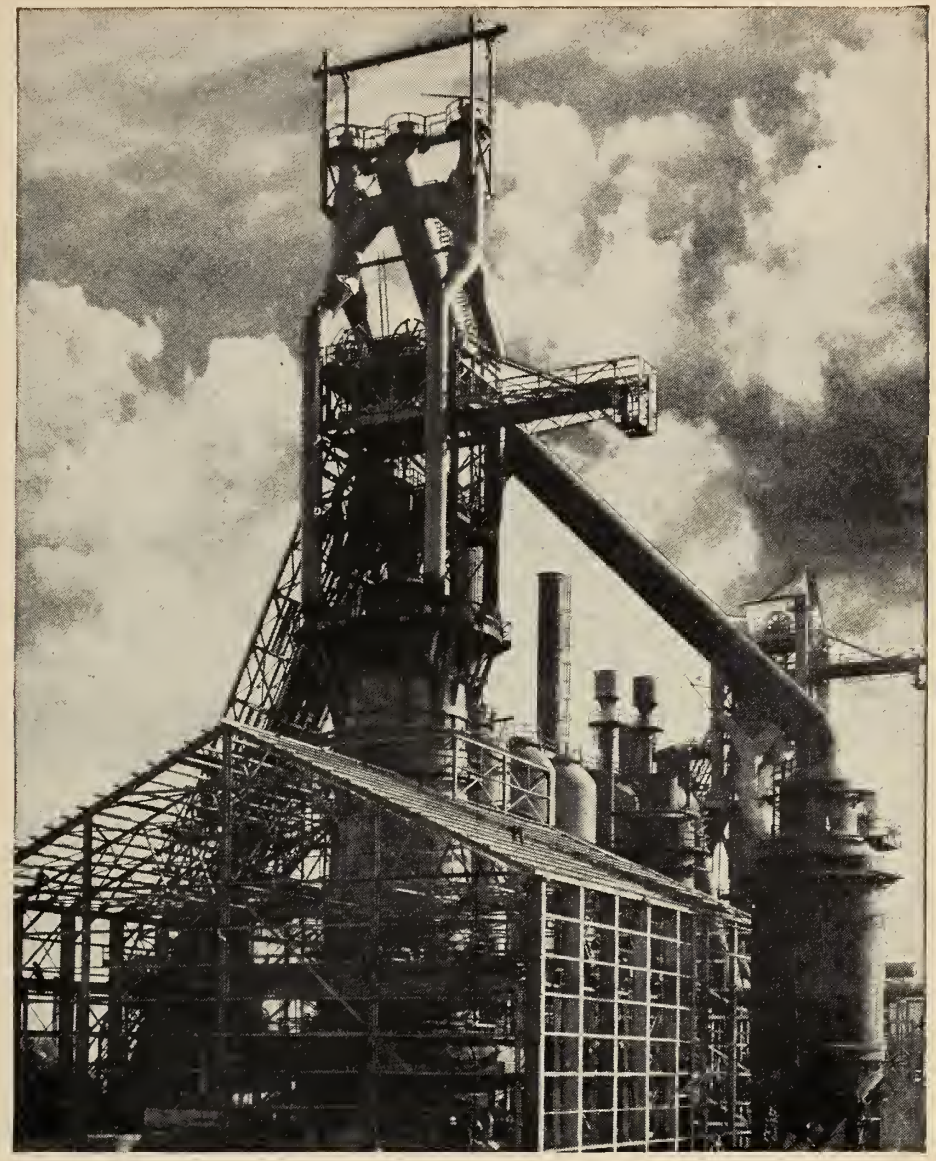
Bouquets and Blast Furnaces



The "Bouquet"

A major job, recently completed by Dominion Bridge for Dofasco's expansion programme, drew this letter: "The writer wishes . . . to thank and compliment you and your organization for the very fine manner in which the recent steel construction contract was handled . . . and delivered to us on the date asked for . . ."

The Blast Furnace

Dofasco's number two blast furnace, at Hamilton, shown above, included the uptakes, downcomer, and other intricate steelwork fabricated by Dominion Bridge.

Long experience, modern methods and continuous research are behind every job carrying the slogan—Platework by Dominion Bridge.

the Maritime and Newfoundland areas of the firm as district engineer, Moncton office. He had earlier professional experience with the New Brunswick International Paper Company in 1946, following R.C.E.M.E. service in World War II.

E. B. Broadhurst, M.E.I.C., formerly assistant to the chief engineer, Consolidated Mining and Smelting Company, at Kimberley, has accepted an appointment as superintendent of the engineering department, with Cominco.

Mr. Broadhurst was secretary of the Kootenay Branch E.I.C. in 1947-48, and chairman in 1955.

Major James H. MacLean, M.E.I.C., (B.A.Sc., mech., Toronto, 1941; M.A.Sc., Toronto, 1949), officer in charge of 200 workshops R.C.E.M.E., Halifax, N.S., has taken over the post of Army Development Establishment resident officer, Canadian Arsenals Limited, Small Arms Division, Long Branch, Ont.

Edward T. Kirkpatrick, M.E.I.C., (B.A.Sc., mech., British Columbia, 1947), has left the Carnegie Institute of Technology, Pittsburgh, Penn, and has become associated with the University of Pittsburgh, mechanical engineering department at Pittsburgh.

Albert R. Goddard, M.E.I.C., (B.Sc., civil, Manitoba, 1939), has transferred his services from the City of Winnipeg to the legal surveys branch of the Department of Mines and Resources, Ottawa. He was employed as a calculator and draughtsman in the Manitoba city.

J. W. Mason, M.E.I.C., (B.A.Sc., mech., Toronto, 1949), has accepted work as head of the turbine ship section, engineering department, H.M.C. Dockyard, Halifax. Previously he was engineer officer with H.M.C.S., Ottawa.

Harold C. Shannon, M.E.I.C., (B.Sc., civil, Alberta, 1947), of Imperial Oil Limited was recently transferred from the Edmonton to the Regina refinery and has been promoted to mechanical superintendent. Formerly assistant mechanical superintendent, he will within a short time proceed to Ioco refinery, Ioco, B.C. as mechanical superintendent.

Captain K. L. F. Coupland, M.E.I.C., (B.Sc., mech., Queen's, 1948), recently returned to Canada from Great Britain.

Now stationed at Calgary, Captain Coupland is second-in-command with No. 1 Infantry Workshop, R.C.E.M.E., which unit has recently relocated from Kingston, Ont.

W. D. Mackinnon, M.E.I.C., (B.Sc., civil, Manitoba, 1941), of Port Arthur, Ont., is chairman of the Lakehead Branch of the Institute. Mr. Mackinnon is a member of the Lakehead Technical Institute, Port Arthur, Ont. Early in his career he was associated with the water resources branch, Province of Manitoba, and the C. D. Howe Company of Port Arthur.

D. W. Harvey, M.E.I.C., (B.Sc., civil, Alberta, 1951), has left the post of project engineer and estimator with Walsh-Canadian Construction in order to accept employment with the Canadian National Railways as a construction engineer at St. Bruno, Que.

Robert E. Johnson, M.E.I.C., (B.A.Sc., civil, Manitoba, 1947), has transferred

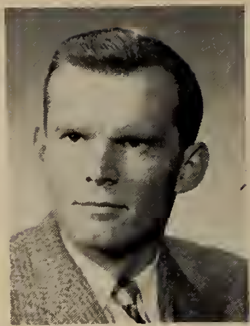
W. D. Mackinnon, M.E.I.C.

his services from Ontario to British Columbia. In his new professional association, he is project engineer with the British Columbia Power Commission at Victoria, B.C. Previously he was hydraulic model engineer with the Hydro-Electric Power Commission of Ontario, at the Islington Hydraulic Laboratory.

W. A. McLaughlin, M.E.I.C., (B.Sc., civil, Saskatchewan, 1951; M.S.C.E., Purdue, 1958), division engineer with the Saskatchewan Department of Highways in charge of all construction within the Tisdale division, has been promoted to senior traffic engineer with the Saskatchewan Department of Highways at Regina, Sask.

J. P. Walsh, M.E.I.C., (B.Sc., civil, Alberta, 1951), has moved from Alberta to the Northwest Territories. Mr. Walsh who was a district construction engineer with Mobil Oil of Canada, Drayton Valley, Alta., in his northern location is area engineer with the Department of Public Works of Canada, highway division.

Eric C. Scott, J.R.E.I.C., (B.A.Sc., civil, Toronto, 1949), has accepted the appointment as engineering officer with the Industrial Development Bank at head office, Montreal. Mr. Scott was formerly staple fibre plant supervisor with the Canadian Industries Limited "Terelene" plant, at Millhaven, Ont.



E. C. Scott, JR.E.I.C

C. V. Davies, JR.E.I.C.

J. A. Dubuc, JR.E.I.C.

Jacques A. Dubuc, J.R.E.I.C., (B.Eng., elec., McGill, 1953), of James H. Wilson Limited, Montreal has left his post as chief engineer to become manager of the newly formed equipment division of the firm at Roxboro, Que. Mr. Dubuc was vice-chairman of the junior section, Montreal Branch E.I.C. in 1958.

C. V. Davies, JR.E.I.C., (B.Sc., civil, Queen's, 1947), erection engineer for the Canadian Bridge division of the Dominion Steel and Coal Corporation Limited, has been appointed assistant general manager of that division. With Canadian Bridge since his graduation he served as a design engineer and assistant engineer of erection before being promoted to erection manager.

R. R. Ritchie, JR.E.I.C., (B.Sc., elec., New Brunswick, 1947), of Fredericton, N.B., is president of the Maritime Design Consultants Ltd., in that city. He formerly held the post of vice-president of C. W. Ritchie and Sons Ltd., at Fredericton from 1956 to 1958. Earlier in his career he gained experience with the Montreal Engineering Company Ltd., Montreal and with Calgary Power Limited, Calgary.

N. P. Wallace, JR.E.I.C., (B.Eng., mech., Nova Scotia Technical College, 1949), has been named to the post of industrial engineer with the Dominion Steel and Coal Corporation.

Ian Broadbent, JR.E.I.C., (B.Eng., civil, McGill, 1952), of Montreal, has been

• PERSONALS

named executive engineer with the Dominion Steel and Coal Corporation, Montreal. Mr. Broadbent has served Dosco for a number of years.

Eric Mercer, J.R.E.I.C., (B.Eng., civil, N.S.T.C., 1952), resident engineer on water and sewage installation at Windsor, Nfld., has accepted an appointment as local government engineer, Department of Municipal Affairs and Supply, Nfld.

Eric G. Hale, J.R.E.I.C., (B.Sc., mech., Saskatchewan, 1948), of Timber Preservers Limited, Toronto, has been transferred to New Westminister, B.C. as chief estimator for the organization. While in Eastern Canada, Mr. Hale was manager of the Toronto office of the firm.

Arthur de Breyne, J.R.E.I.C., (B.Eng., mech., McGill, 1949), a member of the firm of The Ventilating and Blow Pipe Company Limited, St. Lambert, Que., since 1950 is secretary-treasurer and engineer of the organization.

He is 1958-59 president of the Montreal Chapter of the American Society of Heating and Air Conditioning Engineers.

Stanley Nowak, J.R.E.I.C., (B.Eng., elec., McGill, 1950), of the Falconbridge Nickel Mines, Onaping, Ont., has been promoted from assistant chief electrician to chief electrician.

W. G. Lancaster, J.R.E.I.C., (B.A.Sc., mech., U.B.C., 1950), has transferred his services from the Ford Motor Company of Canada, Windsor, Ont., to the Dominion Bridge Company in Calgary. Formerly employed as a field engineer his present work is that of mechanical design engineer.

Marcel Bourque, J.R.E.I.C., (B.Eng., civil, McGill, 1951), an associate of the Sherbrooke, Que., firm of Cote-Lemieux-Carigan and Bourque, consulting engineers, and in addition to this professional association, Mr. Bourque now represents the office in the new firm of Cartier Cote Piette.

Donald J. Ross, J.R.E.I.C., (B.Sc., civil, McGill, 1951), formerly field engineer with Interprovincial Pipe Line Company, Sarnia, Ont., has been transferred to head office of the firm at Edmonton, on completion of work in Ontario. He was engaged in building an electrical pump station to move crude oil from Sarnia to Clarkson and Port Credit refineries.

E. Lundy Pearson, J.R.E.I.C., (B.Sc., mech., Manitoba, 1953), and former Athlone Fellow, 1954-1956, has been transferred from sales development office of Canadian Industries Limited in Montreal, to the mechanical development ammunition division at Brownsburg, Que. with the duties of project engineer.

William A. Johnson, J.R.E.I.C., (B.Sc., C.E., Manitoba, 1952), of the firm of C. A. Pitts General Contractors Limited, project engineer at the Laurie River Power Development, #2 in Northern Manitoba, has taken over the duties of job superintendent on highway construction for the company at Magpie, Ont.

William D. West, J.R.E.I.C., (B.Sc., elec., Queen's, 1955), formerly a lieutenant (L) Royal Canadian Navy, electrical officer of Helicopter Anti-Submarine Squadron Fifty, is now engineer with R.C.A. Victor general service department, Montreal.

C. K. A. Stieda, J.R.E.I.C., (B.Sc., civil, Manitoba, 1955; M.Sc., Alberta, 1958), assistant to the building superintendent, University of Alberta, has taken on the duties of forestry officer with the Forests Products Laboratory timber mechanics section, Ottawa. His work involves research into wood structures.

John E. Thomlinson, J.R.E.I.C., (B.A.Sc., elec., Toronto, 1955), of the Hydro-Electric Power Commission of Ontario, formerly assistant to the area manager, Norwood R.O.A., has become assistant manager, Peterborough R.O.A., at Peterborough, Ont.

T. J. McDonald, S.E.I.C., (B.E., elec., N.S.T.C., 1958), has accepted a post with the Northern Electric Company Limited, engineering department, in Montreal.

John Alexander Watson, S.E.I.C., (B.A.Sc., civil, U.B.C., 1958), has accepted work as a transitman for the Canadian Pacific Railway Company at Medicine Hat, Alta.

Kelvin Bellis, S.E.I.C., (B.A.Sc., mech., Western Ontario, 1958), has found employment with the Pratt and Whitney Aircraft Company, Longueuil, Que. Presently taking part in a training program, his work will be that of design engineer.

C. L. Papenhuyzen, S.E.I.C., (B.Eng., mech., McGill, 1957), test course engineer with Canadian General Electric Company Limited, Peterborough, Ont., has taken over the post of plant engineer with Asten-Hill Limited, Valleyfield, Que.

Clement Crepin, S.E.I.C., (B.Sc., mech., Laval, 1958), has found employment with the Canadian Westinghouse Company Limited, at Hamilton, Ont.

F. W. Meyers, S.E.I.C., (B.Sc., elec., Queen's, 1955), formerly communications officer, R.C.A.F. Station Falconbridge, Ont., has taken over the post of Station Telecommunications officer, R.C.A.F. Station, Foymount, Ont.

Fernand Leduc, S.E.I.C., (B.Sc., A., mining, Montreal, 1958), is at present in the employ of the City of Montreal, waterworks department.

...ys a big part in St. Lawrence Power Project

For the St. Lawrence Power Project English Electric are supplying

. . . for the Generating Station—

all sixteen of the 75,000 H.P. turbines that will provide the whole of Canada's share of the power from this international project.

also the control metering and relaying equipment. This equipment located in the main control room, and other parts throughout the powerhouse will form the 'nerve centre' of the whole station, and will control the main functions of normal operations. English Electric relays are used extensively to protect against, or warn of, abnormal conditions.

. . . for the Transformer Station—

two 115,000 KVA auto transformers, and six 46 Kv, 1000 MVA outdoor oil circuit breakers.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings

HAMILTON

W. A. H. Filer, JR.E.I.C., *Sec.-Treas.*

THE PROFESSIONAL DEVELOPMENT program registration night held September 17, opened another season of the largest P.D. program in operation in Canada.

J. A. Walsworth, JR.E.I.C., director of the four year P.D.P., first organized in 1951, had this to say as an opening remark: "Possibly the greatest failing of the Canadian professional engineer is his lack of pride in himself and his chosen profession. For too many years in the past the engineer has been interested in mending only his own personal fence and has said in effect, 'to hell' with the rest of society." Mr. Walsworth said that the most important fact to bear in mind, however, was that the P.D.P. has the objective of developing the engineer to better fit him for the responsibilities of his profession. These, he said, were: to expand and develop his fund of knowledge for his own betterment; to better understand and handle the problems that arise in day to day work for his employer; guarantee that an engineering theory will not be permitted to develop into a monster. An attempt is made, he said, to cover these points in the four-year program. Sufficient emphasis had not yet been given to the last point, however, which relates the matter of responsibility to the engineering profession in assisting in its expansion and growth.

New Plans Outlined

Mr. Walsworth outlined new plans which had been put into effect in aiding the development of the engineer. An Engineers Reading List prepared by the 1957 directorate is available.

A personal self-appraisal form has top priority in P.D.P. plans. It is hoped the forms will be available this year. A "Big Brother" movement has been planned with the idea of advising and encouraging these young men on a personal basis. This is to be executed with the help of the alumni group of 150 men and will be carried out at McMaster University.

Counselling will be carried on in the high schools, as in other years on a personal basis.

The objective of the P.D.P., as outlined in Article 2 of the constitution of the organization, he said, was the development of engineers through a comprehensive program of study, lectures and discussions; thereby better fitting them for the responsibilities of their profession. The means, he said, were as follows: by instruction in non-technical subjects through lectures, discussion periods, group presentations and case studies; by obtaining recognized authorities in non-technical fields to present these topics; by stressing individual participation in organizing and operating the program and in discussion periods; by providing a place where individuals may meet and become acquainted with their professional contemporaries.

Mr. Walsworth also urged flexibility in the program, urging members to suggest changes deemed necessary.

Industry, he said, had indicated a great interest in the program in supplying speakers and in showing interest in their own members who took part in the program.

Program Directors and Guests

Members of the executive of the program who will direct the operations of the program are: immediate past director, Ken Crean; secretary, Jim Nisbet; treasurer and caretaker-chairman gr. 1, Ed. Borza; chairman gr. 2, Doug Pearson; chairman gr. 3, John Bailey; and chairman gr. 4, Bob Payton.

Mr. Walsworth introduced two men who, he said, were outstanding and had been greatly instrumental in bringing the program to its present successful state. They were the first director and E.I.C. representative on the E.C.P.D. training committee, G. L. Schneider, and W. A. H. Filer, past director and chairman of the P.D.P. National Co-ordinating committee. Also present for the registration night was W. Lardner, director of P.D.P. in Toronto and representatives from interested engineering groups. Colonel T. N. Medland, executive director of the Association of Professional Engineers of Ontario was among the guests. Others were R. C. Mitchell, Hamilton Branch chairman, E.I.C., H. P. Gatin, director of membership service, E.I.C. headquarters, Montreal, and J. A. MacLaren, Eastern field secretary, E.I.C., Toronto.

LONDON

W. C. Sinkins, JR.E.I.C., *Sec.-Treas.*

G. W. Chorley, M.E.I.C., *Branch News Correspondent*

A PANEL DISCUSSION on "London's Water Supply" heard at the London Branch meeting held September 16 was very well attended. Speakers were A. Furanna, assistant general manager, Public Utilities Commission; L. Johnson, sec.-treas., Upper Thames River Conservation Authority; and W. McNaughton, assistant engineer, U.T.R.C.A.

Opening the discussion, Mr. Johnson described the work done by the Upper Thames River Conservation Authority in conservation, flood control, water supply and control of pollution. Future plans for the north branch of the Thames call for dams at Wildwood and Glengowan. Dams for the south branch will be located at Woodstock, Cedar Creek and Thamesford. With these dams it will be possible to increase the minimum flow through London from 20 million g.p.d. to 180 million g.p.d.

Mr. McNaughton, who operates the dam at Fanshawe, north of London, described the operation of the dam for flood control purposes.

Third member of the panel, A. Furanna, outlined the history of water supply developments in recent years in London. Referring to the 1954 engineers report, Mr. Furanna pointed out that it recommended using, a) deep well water b) surface water at Fanshawe and c) Great Lakes water, in that order of preference. At the present time, water is being pumped out of Fanshawe Lake into natural kettles. It is being recovered from nearby deep wells at the rate of 4 to 5 million g.p.d. A proposed filtration plant at Fanshawe for 6 million g.p.d. is at present held up by lack of approval from the Ontario Water Resources Committee. This approval is being withheld

subject to the City of London improving its sewage disposal facilities. Mr. Furanna went on to explain what work had been done investigating pipe lines from either Lake Huron or Lake Erie.

Considerable discussion ensued on the sources of water supply for London. Mr. Miller, ex-city engineer, St. Thomas, Ont., described his experience with surface water in the last thirty-eight years. Speaking out strongly in favour of using surface water for London, E. V. Buchanan said, "London needs a pipeline as much as Egypt needs another pyramid!"

MONTREAL

G. M. Boissoneult, JR.E.I.C., *Sec.-Treas.*

J. Turner Bone, JR.E.I.C., *Entertainment Committee Chairman*

THE FOURTEENTH ANNUAL DANCE for the Junior Section of the Montreal Branch of the Engineering Institute will be held at the Windsor Hotel, Montreal, Friday, November 7.

Due to the large turn-out last year, the entertainment committee has secured more spacious accommodations so that there will be more room to dance. Both the ballroom and the Rose room have been reserved for this popular event. Members are urged to attend.

The Annual Spring cocktail party, 1958, was held at the Berkeley Hotel, Montreal, early in the month of June. This event was a success although space permitted a larger attendance. It is hoped that in 1959 more of the young juniors of the section will participate in the event.

NORTHERN NEW BRUNSWICK

S. K. Henry, JR.E.I.C., *Sec.-Treas., and Branch News Reporter*

THE SIXTH ANNUAL DINNER meeting of the Branch was held at the Country Club at Dalhousie on June 6. Fifty-five members and guests including the ladies attended. Cocktails, a lobster and turkey dinner preceded a short business meeting.

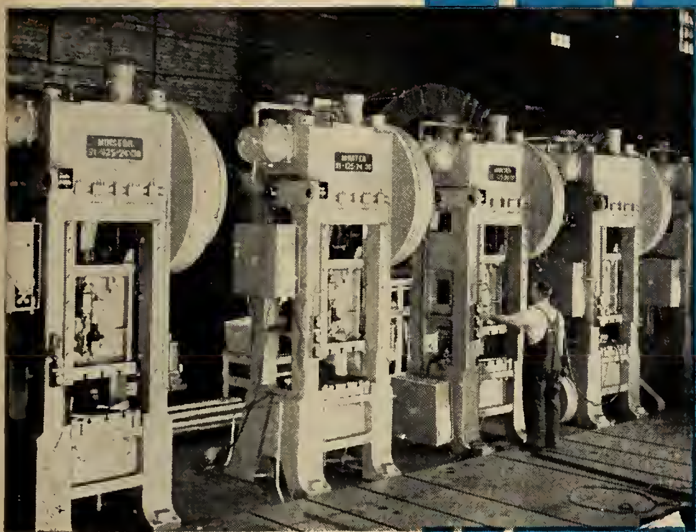
Elected chairman was D. C. MacCallum, vice-chairman, J. A. Mersereau; and secretary-treas., S. K. Henry. Executive members are K. A. W. MacDonald, T. H. McSorley, of Restigouche Co.; Peter Dallien, P. J. Delicaet, Gloucester Co.; and F. B. Ervine of Northumberland Co.

Outgoing chairman L. L. Marshall thanked the retiring executive for their co-operation and the members for their interest in the events of the year. D. C. MacCallum was then introduced and took the chair.

Regional Meteorologist Speaks

E. A. Barks, regional meteorologist of the Atlantic Provinces outlined the de-

- for metals processing
- for the mining industry
- for pulp and paper mills
- for the steel industry



Five 125-ton Minster Presses for an Ontario steel processing company are re-checked before shipment from Canada Iron's shops.

HAVE YOU CONSIDERED *the machinery building ability of* CANADA IRON?

In Trois Rivières and in Toronto, Canada Iron operates plants for building machinery from a single, small unit to a battery of presses (as illustrated). Year in, year out, these plants are producing machinery for every type of industry from the Atlantic to the Pacific.

An experienced Engineering Staff is at your service. Make a point to bring your problems, or your blueprints, to Canada Iron.

Canada Iron
MACHINERY
CANADA IRON FOUNDRIES, LIMITED

Sales Offices Montreal: 921 Sun Life Building, UNiversity 6-7841 • Toronto: 169 Eastern Avenue, EMpire 3-8801 velopment of weather forecasting in which he covered the growth and scope of the weather services of Canada. He pointed out that weather forecasting on an organized basis was started about 100 years ago, with the aid of the telegraph. In the past years aviation forecasting has become the most important weather service. Mr. Barks emphasized the fact that weather forecasting is a service and expands according to the needs and demands of the country.

Dancing was enjoyed at the close of the sixth annual dinner meeting.

TORONTO

D. S. Moyer, JR.E.I.C., *Sec.-Treas.*

G. F. R. Norton, JR.E.I.C., *Branch News Reporter*

A PLANT VISIT to Avro Aircraft Limited at Malton, Ont., arranged by I. S. Gauley, chairman of the Junior activities' committees, concluded the spring program of the Toronto Branch of the E.I.C. Although an attendance of 200 was anticipated, all tickets were disposed of on the day they were issued. As a result Avro increased reception facilities and accommodated nearly 300 members of the branch.

In the well-filled company cafeteria, R. Adey, chief administrative engineer, briefly outlined some of the achievements of Avro since taking over from Victory Aircraft in 1946. These included producing the first Jetliner in North America; design and production of the CF-100 interceptor now employed in the R.C.A.F., Belgian and NATO forces, and more recently producing the already famous supersonic interceptor, the Avro Arrow. He emphasized that the Arrow was an integral part of a weapon system designed to receive attack information, despatch and control the Arrow to repel the attack, then return it to base and restore it to readiness for further study.

The introduction to the reason for the Arrow was followed by a film. This showed how the problem of flutter of various components had been studied and conquered using models under test in the wind tunnel of the National Research Council. Then the production departments were visited. These included detail and assembly shops, the flight line, the repair and overhaul line, and the final assembly line. Probably the most impressive single operation was skin milling, that is, the routing of wing surfaces with integral stiffeners out of great slabs of aluminum alloy.

After the visit to the production departments, the film of the first flight of the Arrow was shown. Then followed coffee and questions. It was pointed out that 17,000 drawings were required for the 38,000 parts of the aircraft, and that the initial drawing releases were for production tooling.

● BRANCH NEWS

At the end of a three-hour visit the Branch was able to compliment Avro on their remarkable achievements of forward thought and action in the field of aircraft production, and to thank them for their exceptional hospitality.

WINNIPEG

Professional Engineers' Wives Association

The Professional Engineers' Wives Association completed its eighteenth year in Winnipeg with a high record of membership, achievement, activity and general sense of friendship.

The highlight of each session is the visit of the wife of the president of the E.I.C. In April, members enjoyed a coffee party to meet Mrs. C. M. Anson, and later in the day the executive and committee held a sherry party and dinner at the Winnipeg Winter Club.

The fall membership rally tea, Christmas shower tea for tubercular patients, a dessert party, a tea meeting with a speaker, and the very successful money-making coffee party held at the Hudson's Bay Company's Beaver Hall, rounded out the season with regular business meetings, after luncheon and guest speakers. Get-acquainted evenings have been held for three seasons and this year were arranged for member-interests. Eight members opened their homes for bridge, music, games and crafts in March.

Two bursaries of $100.00, sponsored by the group, for engineering students in the University of Manitoba may receive some change in form and amount of cash given. One bursary is self-supporting at the present time.

The members feel a real sense of pride in the organization for it is recognized in Winnipeg for its purpose and good program and is now affiliated with the Winnipeg Council of Women and the Canadian Association of Consumers.

UPADI Convention *(continued from page 98)*

Status of Engineering in the U.S.A.

Ralph A. Morgen of Purdue Research Foundation, Purdue University, Lafayette, Indiana, reported to UPADI that there are 221 institutions of higher learning offering engineering degrees in the U.S., and it is expected that the total enrolment this fall will be in excess of 300,000.

Slightly more than half of these institutions are publicly controlled institutions. The shift from predominantly privately supported engineering education to a majority support by public institutions and the tremendous growth in the need for graduate education in engineering are two of the major factors in the status of engineering education in the U.S.A.

Of the 221 institutions which offer undergraduate engineering degrees at the bachelor's level, 153 have one or more accredited programs. Those offering advanced degrees are virtually the same as those with accredited programs. This is significant in Mr. Morgen's opinion.

Prior to the Wickenden reports of the 1920's an engineer was thought of as a high-grade technician. The reports recommended that a liberal amount of study in the humanities be included in engineering education; this was a first step in making engineering a broad professional subject. But the question still remains unanswered; "how much theory and how much practice, in how much time, can be included in any engineering curriculum?

The next logical step after the Wickenden Reports was a concerted program of accreditation for all engineering curricula. The registration laws also called for proper classification. The engineering societies co-operating, E.C.P.D., the Engineers' Council for Professional Development was established in 1932. One of the aims of E.C.P.D. was to provide criteria for colleges of engineering to insure graduates with sound educational foundation," developed into the accreditation program of E.C.P.D. Accreditation was to be by specific curricula rather than by accreditation of an engineering college as a whole. The American Society of Engineering Education made a study for E.C.P.D., and the Society's committee on the Evaluation of Engineering Education issued a report in 1955. Recommendations made included strengthening the basic sciences; identification and inclusion of six engineering sciences; integrated study of engineering analysis, design and engineering systems; the inclusion of elective subjects to develop the special talents of individual students, to provide flexibility; strengthening of humanistic and social sciences in the curriculum; development of the oral, written and graphic communication of ideas; encouragement of experiments; strengthening of graduate programs to provide a specially qualified faculty, to attract students of superior ability, and furnish adequate financial and administrative support; positive steps to insure the maintenance of faculties with the intellectual capacity as well as scholarly attainments.

(Continued on page 132)

• UPADI CONVENTION

(Continued from page 130)

Mr. Morgen listed three "inescapable conclusions," regarding the course of engineering education in the U.S.A.; 1) Technological progress and increasing education in the U.S.A.; larger percentages of technically trained and engineering-trained employees; larger output by universities will be required. 2) The quickening pace of technical development has resulted in an increase in research and development effort, and the need for men educated to master's level for development and higher level design work. 3) Need for 1000 engineering teachers a year for the next ten years, the majority with a doctorate in engineering. Industry requires the same number of Ph.D.'s in engineering per year. Doctorates are now granted to about 600 a year, and only ten per cent select university positions.

Engineering Education in Brazil

Professor Octavio Cantahede of Brazil said that teaching at the higher levels in Brazil is orientated and controlled by the government, through the Ministry of Education and Culture.

Between 1930 and 1957, the number of schools of engineering, architecture, and chemistry increased by 100%, but facilities are still inadequate, he said. Today, 25 schools, scattered over the different states, serve a student population of 10,000. Of this number, 2,000 graduate in engineering and architecture.

The setting up of schools specializing in aeronautical problems and aircraft construction, new courses in electronics, telecommunications, naval construction and others all bear witness to the degree in which Brazilian teaching processes and education are advancing with the times. Methods for the better orientation of the technological instruction problems are being studied, he said.

Due to immense industrialization in Brazil there is a growing need for engineering technicians as well as for engineers. Present ratio of technicians to engineers is 0.8 to 1; engineers to labourers, about 4 to 1000.

A vast program for enlargement and improvement of educational facilities was drawn up in 1957 by the Ministry of Culture and Education. Covering primary, secondary, professional and rural teaching, the plan will encompass the entire educational system and will be interwoven in the Law of Directives and Bases of Brazilian education. Two special steps were taken in regard to engineering education: the establishment of diverse technological institutes; and the enlargement of engineering schools.

Notable among other measures under study is the project establishing the National Bank of Education, S/A, which will attend entirely to the problem of finance. This solution would bring to an end one of the greatest problems of Brazilian educational authorities.

Engineering Education in Mexico

Rodolfo Felix Valdes, of the National School of Engineers, National University of Mexico, spoke on Engineering Education in Mexico. He said that the rapid progress of present day development in Mexico requires the availability of well-trained engineers, capable of assuming very important duties. Mr. Valdes reported the plan which was accepted by the First National Congress of Engineering Schools and Faculties, held in Monterrey, in April, 1958.

Prime considerations in the teaching of engineering in Mexico are: the plan of study, co-ordination of courses, the problem of enrolment; and the numbers who drop out of school. Two classes of subjects are: basic or preparatory courses; and professional courses. Two years are devoted to the study of basic subjects generally. Three years are considered necessary for the study of professional courses, with a program adjusted according to the development of the geographic region in which a student has the most probability of practising his profession, and at the same time providing a sufficiently broad background to enable him to practice in other regions and in other branches of engineering.

The regional needs and academic problems are related and the co-operation of the professors indispensible.

Also recommended is the provision of facilities allowing teachers to gain master's and doctor's degrees and by personal research and progress, help their students.

Mexico has enrolment problems, such as crowding in schools in the capital city, while local schools are uncrowded; and also the problem of too large a percentage of students dropping out of university. Both of these difficulties should be studied.

News of Other Societies

National Nothern Development Meeting

The National Northern Development Conference, sponsored by the Edmonton Chamber of Commerce and the Alberta and Northwest Chamber of Mines and Resources was held at Edmonton, September 17-19, 1958.

General chairman of the event was E. K. Cumming, of Cumming Galbraith and Company. Welcome to the delegates to the convention was expressed by C. W. Carry, president of the Edmonton Chamber of Commerce.

Also at the opening session there were greetings from W. V. Wilkin, president of the Alberta and Northwest Chamber of Mines and Resources.

The program consisted of four panel discussions, as follows:

Potential Northern Development—an inventory of present and potential development of northern Canada as related to the further economic development of North America.

Teamwork for development—an outline of the parts to be played by government, industry and finance, in the development of Northern Canada.

Planning Northern Development — the necessity of replanning the orderly development of the north.

Living in the North—the problems of northern living and their solution.

During the proceedings a joint luncheon was held with the Edmonton Rotary Club and addressed by guest speaker G. L. McMahon, Calgary, president of Pacific Petroleums Ltd.

At a banquet provided by the Province of Alberta, the Hon. E. C. Manning, premier of the Province of Alberta was guest speaker.

On the closing day of the proccedings, His Worship Mayor William Hawrelak was guest speaker at a noon luncheon. The City of Edmonton played host on this occasion.

Concluding the conference, delegates took part in the post conference air tour to the Yukon and Alaska with stop-overs at Whitehorse, Y.T., Fairbanks and Anchorage, Alaska.

C. C. A. Housing Conference

The Canadian Construction Association housing conference held in June in Ottawa, laid emphasis on ways and means of increasing the opportunities of improved housing for the under-5,000-a-year income group. It was a follow-up of a preliminary conference last November. Representative of the E.I.C. was J. H. Irvine, of Ottawa.

Recent developments relating to the low rental housing were reviewed. A paper was presented on "The Overall Cost of Housing" by R. F. Legget. The lower-cost housing market, and the necessary factors for a lower-cost, long-term housing program, were discussed by the delegates.

The opinion emerged that factors of land cost and availability were in general more of a problem than actual construction costs and, at the time, the availability of mortgage funds. Higher housing densities in land-poor metropolitan areas were desirable in many areas because of the relative shortage of serviced land and the problems of urban sprawl.

Resolutions was adopted urging that the Federal Government give consideration to altering its policy whereby agency loans for low-cost rental units had been discontinued, and recommending N.H.A. financial assistance for the installation feeder water-mains and trunk sewers on low-cost housing areas.

Among other conclusions and recommendations agreed upon were the following:

The outlook for large housing programs was encouraging, with three million units needed in the next decade or two. There were examples whereby conventional methods can produce a three-bedroom house for persons with incomes as low as $300 a month in areas with moderate land costs. Technically, Canadian methods compared favourably with those of other countries.

Society of Chemical Industry

Approximately 44 leaders of the chemical industries of Great Britain, the United States and Canada converged on eastern Canada for the annual general meeting of the Society of Chemical Industry and a program of visits and plant tours to major centres in Quebec and Ontario, September 11-23, 1958.

The president of the Society of Chemical Industry is H. Greville Smith, president of Canadian Industries Limited. He is the first Canadian to hold this position in the past twenty years, while Dr. R. S. Jane, president of Shawinigan Chemicals Limited, is president of the Canadian section.

Sessions of the annual conference were held at Montreal on September 14 and 15, and in Toronto, September 17 and 18. Preceding and following the sessions, visits and plant tours were made to seven cities, including Quebec City, Shawinigan, Sarnia, Niagara Falls, and Ottawa.

The Messel Medal of the Society for the first time presented to a Canadian, was awarded to the Rt. Hon. C. D. Howe. It was given for meritorius distinction in science, industry, or public affairs.

The U.S. section of the society presented its chemical industry medal to Fred J. Emmerich, past-chairman of the board of Allied Chemical Corporation. The medal was awarded for conspicuous services to applied chemistry.

NOTICES

Canadian Lecturer

The honour of giving the British Commonwealth Lecture in 1958, one of the annual highlights of the Royal Aeronautical Society, went to James C. Floyd, vice-president, Engineering, Avro Aircraft Limited, Malton, Ontario, on October 9. In accepting the Society's invitation to address the most famous aeronautical personalities in Commonwealth aviation, Mr. Floyd has joined an impressive role of speakers, including the Duke of Edinburgh, the 1954 speaker.

Coal Research Conference

The tenth annual conference of the Dominion-Provincial Committee on Coal Research was held September 1 and 2, 1958, at the Algonquin Hotel at St. Andrews, N.B.

As has been the custom in the past the Coal Research group meets just prior to the Mines Ministers' Conference which this years was held at the Algonquin Hotel also, September 3 to 5, 1958.

The Committee on Coal Research tries at its annual meeting to bring forward items of interest, both to producers and users of coal throughout Canada.

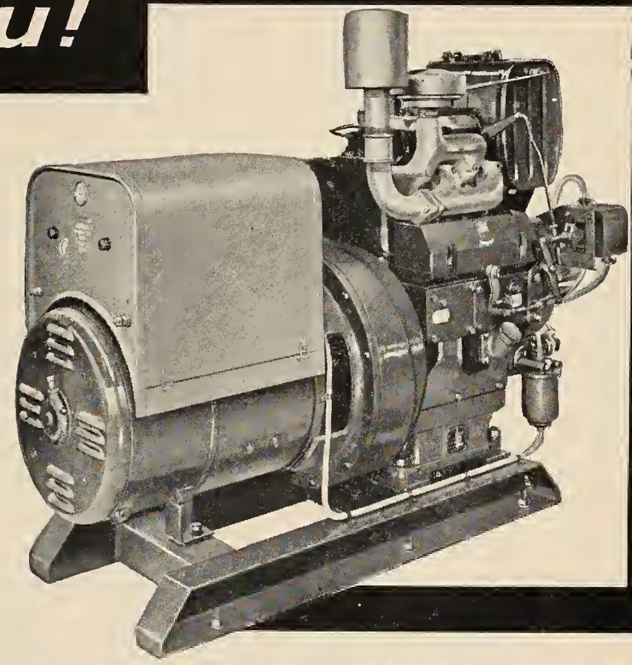
OFFICERS

A.S.M.E. Election

Glenn B. Warren, vice-president and consulting engineer of the turbine division, General Electric Company, has been elected president of The American Society of Mechanical Engineers for a one-year term. Mr. Warren has been active in turbine generator design, development and manufacture, particularly for electric power generation, throughout his engineering career. General manager of General Electric's turbine division from 1949-1957, Mr. Warren is now responsible for formulating and establishing long-range engineering and products plans for the division.

Here's POWER for you!

RUSTON



GENERATING SETS
3·5 kW upwards

THE TOUGHEST, LONGEST-LASTING DIESEL SETS THIS SIDE OF ANYWHERE!

You don't know these Rustons? It's time you did. Time you had a real good look at them. Time you got the facts on what they can give you in the way of really reliable power. On what they can **save** you in the way of fuel costs, maintenance costs, replacement costs. Time you brought yourself up-to-date, on the toughest, longest-lasting diesel sets yet produced.

Here's your chance to do that. Clip this coupon and mail it — today — to your nearest Ruston Agent.

C.I.C. Appointment

T. H. G. Michael, general manager and secretary of The Chemical Institute of Canada has announced the appointment of D. W. Emmerson, as editor of the news-technical journal, Chemistry in Canada.

Calendar

Chemical Institute of Canada

"Canada's Export Trade in Chemicals" will be the theme of the Chemical Institute of Canada Chemical Economics Division meeting on November 18, 1958 at the Sheraton-Mount Royal Hotel, Montreal.

The opportunities in the export field and the experience of Canadian companies active in it will be examined in detail at this full-day session.

The opening address by the chairman and founder of the Division, Rhys D. Bevan, will set the stage for panel discussions between government and industry experts.

The broad aspects of international trade and the factors influencing chemical export opportunities will be handled by a panel including members of the Trade Commissioner Service and International Trade Relations Branch of the Department of Trade and Commerce. The British Commonwealth, Latin America and the Far East will be the main target areas for this panel. Senior executives of Canadian chemical companies will present case histories of their operations in the export field to demonstrate the opportunities and pitfalls. An important feature of this meeting will be the dinner address by A. A. Thornbrough, president, Massey-Ferguson Limited.

Those interested should contact J. R. Charlton, Canadian Curtiss-Wright Limited, 1980 Sherbrooke St. W., Montreal.

Public Works Congress

Public Works and Municipal Services Congress and Exhibition. Olympia, London, England, Nov. 10-15, 1958.

The Society of the Plastics Industry, Inc.

Eighth National Plastics Exposition. International Amphitheatre, Chicago, Ill., Nov. 17-21. Concurrently, the National Plastics Conference, Hotel Morrison.

Operations Research Society of America

Fourteenth National Meeting, Saint Louis, Mo. Oct. 23-24, 1958. Statler Hotel.

Society for Experimental Stress Analysis

1958 Annual Meeting. Sheraton-Ten-Eyck Hotel, Albany, New York.

American Society of Civil Engineers

Conference on Electrical Computation, Kansas City, Mo., Nov. 20-21, 1958.

Steel Founders' Society of America

Thirteenth Technical and Operating Conference. Carter Hotel, Cleveland, Ohio, Nov. 10-12, 1958.

National Association of Corrosion Engineers

Western Region Meeting. Los Angeles, Nov. 17-19, 1958.

The Society of the Plastics Industry, Inc.

Eighth National Plastics Exposition, Annual Plastics Conference. International Amphitheatre, Chicago, Ill.

Institute of Traffic Engineers

Twenty-Eighth Annual Meeting. Deavuille Hotel, Miami Beach, Florida, Nov. 11-13, 1958.

Electronic Engineering Association and Office Appliance and Business Equipment Trades Association.

Computer Exhibition and Business Symposium, Olympia, London, Nov. 28 to Dec. 4, 1958, under the Patronage of H.R.H. the Duke of Edinburgh. Immediately preceding this event, an associated scientific symposium organized by the National Physical Laboratory, Teddington, Middlesex, Nov. 24-27, 1958.

LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

ELECTRIC CRANES, 3RD ED.

This edition has been completely re-written to include all the progress made in mechanical handling and electric cranes since the last edition was published in 1922. Its publication will be warmly welcomed by all those interested in mechanical handling and the design, construction and application of electric cranes.

New subjects covered include photo elastic methods of stress analysis; the use of recording strain gauges; the use of influence lines in determining the effect of moving loads, etc.

Included in this complete survey are chapters dealing with crane types; framed structures; compression members; ropes; gears and gearing; transmissions; motor characteristics and control; standardization; cargo handling, etc. There are useful bibliographies at the end of each chapter. (H. H. Broughton. London, Spon, Toronto, Van Nostrand, 1958. 511p., $21.00.)

*THE FUTURE SUPPLY OF OIL AND GAS

In place of the traditional forecast techniques such as the proved reserve concept, the author utilizes economic, technological, and geological variables to determine the future availability of oil and gas in the United States and the adjacent continental shelf through the period ending 1975. (B. C. Netschert. Baltimore, Johns Hopkins Press, Toronto, Burns and MacEachern, 1958. 134p., $4.00.)

SOLAR ENERGY

An elementary treatment of the subject commencing with a discussion of the nature of solar energy. The uses of solar energy described include water heaters, heat pumps, space heating, controlled photosynthesis, furnaces and steam boilers, cookers and water distillers, electric generators. A final chapter discusses power which might be obtained from the wind and the sea. (F. M. Branley. Toronto, Ambassador, 1957. 117p., $3.50.)

*ANALYTICAL MECHANICS FOR ENGINEERS, 5TH ED.

A standard text on the subject, covering statics, kinematics, kinetics, and various special topics. This edition includes new material on vector analysis; the equilibrium of bodies, making use of the concepts of virtual work; the equilibrium of force systems, utilizing a general coplanar force system; and the use of the inertia-force method in kinetics (F. B. Seely and others. New York, Wiley, 1958. 475p., $7.25.)

FUNDAMENTALS OF HYDRO— AND AEROMECHANICS

A reprint of an Engineering Societies Monograph first published in 1934, this standard work covers the statics and kinematics of liquids and gases, and the dynamics of non-viscous fluids. It is based on a series of lectures given by Professor L. Prandtl. (O. G. Tietjens. Toronto, McClelland and Stewart, 1957. 270p., $2.05.)

TABLES FOR THE DESIGN OF FACTORIAL EXPERIMENTS

Published in Japan, with a new title page inserted by the United States publisher, Dover publications, this book contains tables for designing factorial experiments and covers Latin squares and cubes, factorial design, fractional replication in factorial design, factorial designs with split-plot confounding, factorial designs confounded in quasi-Latin squares, lattice designs, balanced incomplete block designs, and Youden's squares. The authors have used the standard notation system, and where they have introduced their own symbols, an explanation has been added. The authors are well known in the fields of mathematics and statistics. (Tosio Kitagawa and Michiwo Mitome. Toronto, McClelland and Stewart, c.1953. irreg. paging, $8.80.)

*MATHEMATICAL FOUNDATIONS OF INFORMATION THEORY

Two papers translated from Russian. The first develops the concept of entropy in probability theory as a measure of the uncertainty of a finite "scheme", and discusses a simple application to coding theory. The second gives a complete detailed proof of both Shannon theorems, assuming any ergodic source and any stationary channel with a finite memory. (A. I. Khinchin. New York, Dover, Toronto, McClelland and Stewart, 1957. 120p., $1.35.)

THE CONDUCT OF MEETINGS

The Secretary of the Toronto Board of Trade has compiled a handy guide to correct procedure at meetings, which will be of benefit both to chairmen and others attending meetings.

The first part discusses the different functions of a business meeting: preparation for it; opening the meeting and order of business; resolutions; minutes; committees, etc. The second part illustrates with examples the points covered in the first part. (G. H. Stanford. Toronto, Oxford, 1958. 88p., $2.50.)

*GAS TURBINE MATERIALS

Intended to bridge the gap between the metallurgical textbooks and those on gas turbine design, this volume provides a

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m. — 5 p.m.; Saturday: 9 a.m. — 12 noon.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

survey of high-temperature materials chiefly in the field of metallic alloys. Their development is outlined, the behaviour of metals under stress and temperature is discussed, followed by the application of high temperature materials. The influence of fuel and of performance requirements on operating conditions is dealt with, and the final chapter takes up the manufacture of gas turbine components. (G. Lucas and J. F. Pollock. London, Temple Press, 1957. 163p., 25s.)

*MOTION AND TIME STUDY

Presents the fundamentals of methods, time study, and wage payment with a view to providing substantial savings in labor and materials. In addition to proven techniques of work measurement, the author outlines the controls made possible once fair time standards have been developed. This edition gives increased emphasis to work sampling, indirect labor standards, curve plotting, and maintenance of standards. (B. W. Niebel. Homewood, Ill., Richard D. Irwin, 1958. 494p., $8.70.)

NUCLEAR ENGINEERING MONOGRAPHS
1. ELEMENTARY NUCLEAR PHYSICS
2. NUCLEAR REACTOR THEORY
3. REACTOR HEAT TRANSFER

A new series of booklets on nuclear engineering, written in England, and intended for university students, and those working in the field.

The first monograph explains for non-physicists the basic nuclear physics of reactors, and discusses in an elementary manner nuclear theory, radioactivity, nuclear reactions, fission, and radiation measurements.

The physics of reactor design are outlined in the second monograph which commences with an account of neutron behaviour in reactors. It is shown how theories of slowing down and diffusion of neutrons can be applied to determine the behaviour of neutrons in a reactor lattice. Also discussed are the changes in reactor properties due to temperature and neutron irradiation, and the various reactor types and the ways in which they can be fuelled.

The third monograph deals with the important subject of heat transfer from the fuel elements to the coolant. The topics covered are: the fundamentals of convective heat transfer; the application of heat-transfer principles to reactor design; various aspects of reactor heat transfer.

All the monographs are written by specialists in the field. The three volumes still to be published will cover nuclear reactor shielding, nuclear reactor control and instrumentation and steam cycles for nuclear power plants. (General ed. W. K. Mansfield. New York, Simmons-Boardman, 1958. v.1, v.3, $2.75 ea., v.2, $2.95.)

*ZONE MELTING

Covers the theory and practice of zone melting. Included is a description of how to build and operate zone refiners; a complete set of computed zone refining curves showing impurity concentrations throughout an ingot as a function of the number of passes; a discussion of continuous multistage techniques; and information on solidification methods for growing and controlling properties of semi-conducting crystals. (W. G. Pfann. New York, Wiley, 1958. 236p., $7.50.)

THE ROLLING OF METALS, V. 1

Adapted from a series of articles which appeared in the periodical Sheet Metal Industries, this work is concerned solely with the rolling of flat products. It covers such topics as forward slip, flow of material, yield stress, friction, factors influencing rolling load, theories of rolling applicable to thin sheet and strip, and the calculation of the rolling load. There is a classified bibliography of over twenty pages. (L. R. Underwood. London, Chapman and Hall, Toronto, Ryerson, 1950. 344p., $9.00.)

CONDUCTANCE CURVE DESIGN MANUAL

This manual explains the use of conductance curves in circuit designing, and is based on a technique originated by the author for designing electronic circuits. The first of the three main sections of the book gives a brief explanation of the special curves and their application in typical R-C amplifier designs. The second section contains tables useful in making tube substitutions, and in selecting tubes for given applications. The last section gives a special set of curves arranged to make tube circuit design easier. (K. A. Pullen. New York, Rider, 1958. 114p., $4.25.)

PHYSICS AND MATHEMATICS IN ELECTRICAL COMMUNICATION

Intended for all those interested in physics, mathematics and electrical engineering, and their inter-relation, this is a clearly written book, illustrated with many graphs. It covers conic section curves, circles, ellipses, parabolas, and hyperbolas; exponentials; alternating current; and electrical oscillations.

The book is an explicit explanation of what happens in electrical circuits containing resistance, inductance and capacitance. (J. O. Perrine. New York, Rider, 1958. 261p., $7.50.)

LINEAR PROGRAMMING AND ECONOMIC ANALYSIS

The aim of this study is to show the relationship of linear programming to standard economic analysis. It is intended primarily for economists needing a broad introduction to the theory of linear programming, and for those interested in managerial economics.

Some of the topics covered include: basic concepts; the valuation problem; linear-programming analysis of the firm; nonlinear-programming; the statistical Leontief system; elements of game

● LIBRARY NOTES

theory; interrelations between linear programming and game theory. There is a useful bibliography. (R. Dorfman and others. Toronto, McGraw-Hill, 1958. 525p., $11.50.)

*ASME HANDBOOK: METALS ENGINEERING — PROCESSES

Gives information on the various processes by which metals are converted into the finished product. Among the manufacturing methods included are the heat treatment of steel, casting, hot working, cold working, powder metallurgy, welding and cutting, machining, finishing, and electroforming. For each method the basic physical characteristics to be considered are given along with its advantages and disadvantages. Also presented are data on the suitability of various metals for each process and the tolerances on size and surface finish obtainable. One of a series of four volumes sponsored by the American Society of Mechanical Engineers. (Ed. by R. W. Bolz. Toronto, McGraw-Hill, 1958. 428p., $16.20.)

*NONLINEAR CONTROL SYSTEMS

Treats the nonlinear phenomena arising in the area of control systems. Topics discussed include the rise of techniques for linear systems with time varying parameters for determining the response of control systems; nonlinear systems excited by random input signals; reduction of statistical problems to differential equation form; and application of switching circuits in control systems. The approach to the subject is expedited by the use of the concepts and terminology of automatic-control theory rather than those of classical mechanics. (R. L. Cosgriff, Toronto, McGraw-Hill, 1958. 328p., $10.80.)

METAL INDUSTRY HANDBOOK AND DIRECTORY, 1958

The first section of this useful handbook contains a wealth of information on the properties of metals and alloys, the second section consists of general data and tables, including temperatures required for various purposes, hardness tables, tables of gauges, prices of metals over the last 28 years, etc. The third section contains information on electroplating and allied processes, while the last section, in which the pages are green, is a directory. In addition to a buyers' guide, this section contains a list of trade names, and information on British metal and allied trades associations and societies.

This is a British publication appearing annually. (London, Iliffe, Toronto, British Book Service, 1958. 544p., $3.50.)

SPINNING TOPS AND GYROSCOPIC MOTION

In this reprint of a work first published some 50 years ago under the title of Spinning Tops, the author explains on an elementary level the importance of studying the behaviour of spinning tops

and gyroscopes. Some of the topics covered include quasi-rigidy in flexible and fluid bodies, and its nature; the reasons for the fall of a gyrostat and the rise of a top; the effect of climatic conditions on the earth's precessional movement; the effect of internal fluidity on rotating bodies. (John Perry. Toronto, McClelland and Stewart, 1957. 102p., $1.10.)

*BIBLIOGRAPHIC SURVEY OF CORROSION, 1954-1955

A thorough review of corrosion literature for the period covered. Substantial abstracts of papers cited are arranged in eight major divisions: general, testing, characteristic corrosion phenomena, corrosive environments, preventive measures, materials of construction, equipment, and industries. Author and subject indexes are included. (Houston, National Association of Corrosion Engineers, 1958. 468p., $20.00.)

*CONCRETE TECHNOLOGY, VOL. 1: PROPERTIES OF MATERIALS

This volume deals with the following aspects: kinds of cement and their properties; additives; concrete aggregates; lightweight concrete; concrete mix design and quality control; properties of cements and concrete; deterioration of concrete and its resistance to chemical attack. There are bibliographies at the end of each chapter. (D. F. Orchard. London, Contractor's Record, 1958. 348p., 45/-.)

SAFETY TECHNIQUES FOR RADIOACTIVE TRACERS

The widespread use of radioactive material in laboratories, even in the very small quantities required in tracer investigations, means that adequate precautions must be taken to safeguard health. This little book explains the various types of radiation which may be encountered in the laboratory, the safety techniques to be adopted in working with radioactive material, the disposal of radioactive waste, laboratory administration and recommendations for safe working. The appendices include a table of isotopes showing their toxicity, diagrams of protective equipment, maximum permissible quantity of radiation, etc. (J. C. Boursnell. Toronto, Macmillan, 1958. 68p., $1.30.)

D-C CIRCUIT ANALYSIS

One of the most fundamental aspects of electricity is covered in this book which stresses the basic concepts: charge, electric current and potential difference, resistance and conductance, resistance factors, resistivity, conductivity, simple and combination d-c circuits, Kirchhoff's laws and Thévenin's theorem. (Alexander Schure. N.Y., Rider, 1958. 72p., $1.35.)

NUCLEAR ENERGY

Another in Rider's Basic Science Series, this volume explains the structure and uses of the atom. The first chapter discusses the electron, the proton, alpha, beta and gamma rays, the Bohr atom model, the structure of the nucleus, and isotopes. The second chapter discusses the sources and applications of nuclear energy, and the tools of the nuclear physicist. The last chapter discusses more advanced theories of atomic structure based on quantum considerations and wave mechanics. (Alexander Efron. New York, Rider, 1958. 63p., $1.25.)

MECHANICS

The author has commenced this basic text with a discussion of vectors which is used as a base for later discussion of moments, torques and kinematics. Succeeding chapters cover dynamics, work, energy and power. (Alexander Efron. N.Y., Rider, 1958. 112p., $1.50.)

*SWITCHING CIRCUITS AND LOGICAL DESIGN

Presents the fundamentals and applications of switching theory. Among the various aspects discussed are switching algebra; switching components and their characteristics, including relays and high speed components; contact networks; gate circuits; and switching aspects of codes. Although the book does not deal specifically with computing machines, the switching theory discussed is funda-

mental to their design. (S. H. Caldwell. New York, Wiley, 1958. 686p., $14.00.)

ELEMENTARY PARTICLE ACCELERATORS

A Supplement to the Soviet Journal of Atomic Energy now published in English translation, this volume contains previously unpublished reports.

"The reports published in this collection should be useful for specialists working with cyclic or linear elementary-particle accelerators—". Ed. (New York, Consultants Bureau, 1958. 66p., $15.00.)

NUCLEAR REACTORS IN LIGHT NUCLEI

Another Supplement to the Soviet Journal of Atomic Energy translated into English, containing ten reports of work carried out in the USSR in 1951-1955 on nuclear reactors. (New York, Consultants Bureau, 1958. 73p., $15.00.)

AN INTRODUCTION TO FOURIER ANALYSIS AND GENERALISED FUNCTIONS

Based on an undergraduate course, this volume covers the principal results concerning Fourier transforms and Fourier series, and serves as an introduction to the theory of generalized functions. Detailed mathematical knowledge is not required for an understanding of the book, although a general knowledge of mathematical proof is assumed in the reader. (M. J. Lighthill. Toronto, Macmillan, 1958. 79p., $3.00.)

*APPLIED MATHEMATICS FOR ENGINEERS AND PHYSICISTS, 2ND ED.

Covers a wide range of topics in advanced fields of calculus. The chapters on matrix algebra, Fourier methods, variational methods, Laplace transforms, and nonlinear differential equations have been considerably expanded in this edition. A new section on Cartesian tensors has been added to the chapter on vector analysis. New illustrations have been added, and the number of problems doubled. (L. A. Pipes. Toronto, McGraw-Hill, 1958. 723p., $10.50.)

*THEORY OF STRUCTURAL ANALYSIS AND DESIGN

Aspects of structural analysis included are lateral and out-of-plane loading, curved girders, and space frames. Secondary stresses and participation stresses, including the effect of gussets are discussed, and extensive curves are given for stiffness and carry-over factors. A particular feature is the extensive treatment of arches, including continuous arches and arches with stiff ties, with extensive influence lines and tables for both vertical and horizontal loading. (J. Michalos. New York, Ronald, 1958. 552p., $12.00.)

*HEAT TRANSFER AND FLUID MECHANICS INSTITUTE, 1958. PREPRINTS OF PAPERS

Papers covering such areas as aerothermodynamics, fluid dynamics, dynamics of reactive fluids, heat transfer, magnetohydrodynamics, and hypersonics. The total of twenty-one papers provides an up-to-date review of advances in important sectors of the field. (Stanford, University Press, 1958. 264p., $8.50.)

*THE GYROSCOPE

A study of the mathematical and mechanical aspects of the gyroscope. Following a discussion of the theory, specific applications are discussed, including vehicles and rotating bodies, direction indicating and steering, stabilizing, and astronomy. Vector methods are used throughout in the solution of problems. (J. B. Scarborough. New York, Interscience, 1958. 257 p., $6.50.)

*ENGINEERING ECONOMY, 3RD ED.

Deals with the various stages of planning from the inception of an idea to its development and design phases, including the design and operation of a factory to produce the product. This edition brings cost data up to date and introduces new operations research procedures, particularly the concept of "models" and "criteria". The effect of state and federal taxes on engineering projects is treated for the first time. (C. E. Bullinger. Toronto, McGraw-Hill, 1958. 379p., $8.40.)

*ANNUAL REPORT ON THE PROGRESS OF RUBBER TECHNOLOGY, VOL. 21, 1957

A series of papers surveying developments within the field of rubber technology, including compounding ingredients, fibers and fabrics, tires, belting, hose and tubing, cable and electrical insulation, footwear, surgical goods, cellular and hard rubber, flooring, machinery and appliances, and roads. (Ed. by T. J. Drakeley. Cambridge, W. Heffer and Sons Ltd., for the Institution of the Rubber Industry, 1957. 134p., 25/-.)

*FINITE QUEUING TABLES

Provides tables useful in the solution of queuing problems such as communication channel requirements for finite populations, machine loading determinations, and estimating equipment and manpower requirements. A preface gives information and examples illustrating the use of the tables in specific applications. The second volume in the series "Publications in Operations Research" sponsored by the Operations Research Society of America. (L. G. Peck and R. N. Hazelwood. New York, Wiley, 1958. 210p., $8.50.)

*RIGID FRAME FORMULAS

Covers all single-span types of rigid frames. The formulas for the bending moments and reactions on rigid frames of a number of different types, and many loading conditions can be used to secure results rapidly by the direct substitution of numerical values. The Mohr equation, aided by the diagrams in the book, provides a rapid method for computing displacements of rigid frame structures. Eleven new frame shapes are dealt with in this edition. (A. Kleinlogel. New York, Ungar, 1958. 460p., $14.50.)

*RECENT ADVANCES IN THE ENGINEERING SCIENCES: THEIR IMPACT ON ENGINEERING EDUCATION

Surveys the educational implications of a number of expanding areas including automation and automatic control; operations research and systems engineering; thermodynamics; mass, momentum and heat transfer; nuclear engineering; solid

state physics and engineering materials, computer development and applications. The book is a report of the proceedings of the Conference on Science and Technology for Deans of Engineering, held at Purdue University in September 1957. (Toronto, McGraw-Hill, 1958. 257p., $5.70.)

*ELECTRICAL ENGINEERING PRACTICE, VOL. 1, 6TH ED.

A review of current British practice to appear in three volumes. The first part of volume I deals with definitions, materials, and measurements, the second part with the generation and sale of electrical energy, and the third part with the transmission and control of electricity, including switchgear and protection of circuits. (J. W. Meares and R. E. Neale. Toronto, Ryerson, 1958. 716p., $12.00.)

*CIRCUIT ANALYSIS OF TRANSMISSION LINES

An analytical approach to transmission lines with special attention given to radio frequencies and measurements. Simple transients, including application of transient operational methods, are discussed, as are matching devices and the design of resonators and transmission cavities. Also discussed are the standing wave ratio and the principles and applications of the Smith chart. (J. L. Stewart. New York, Wiley, 1958. 186p., $5.50.)

*PRINCIPLES OF NOISE

Covers such areas as probability, stationary random processes, physical sources of noise, equivalent noise generators, noise factor, measurement of a direct voltage, Gaussian random processes, the detection of alternating waveforms, and target noise. (J. J. Freeman. New York, Wiley, 1958. 299p., $9.25.)

*THE EFFECTS OF RADIATION ON MATERIALS

Theories and concepts of radiation effects, radiation sources, and measurements of radiation are presented, as are the known effects of radiation on the physical, metallurgical, mechanical, corrosion and electrical properties of materials. Among the materials dealt with are metals, alloys, inorganic dielectrics, semiconductors, organic and polymeric materials, and materials for nuclear reactor components. Comprises papers delivered at the Colloquium on the Effects of Radiation on Materials at Johns Hopkins University in 1957. (Edited by J. J. Harwood and others. New York, Reinhold, 1958. 355p., $10.50.)

*PERFORMANCE OF METAL CUTTING TOOLS

The author has gathered together information on the mechanical and physical performance of metal-cutting tools. Aspects discussed include the theory of continuous type chip formation, tool life, and surface finish. There is a bibliography of

158 references. (R. Tourret. Toronto, Butterworth, 1958. 184p., $10.00.)

*AUTOMATIC PROCESS CONTROL

Automatic control principles are presented with emphasis on block diagrams and frequency techniques in process control. Beginning with process and controller characteristics, the book continues with the closed loop in automatic control, measuring and controlling elements, process instrumentation, sinusoidal analysis, and stability analysis. (D. P. Eckman. New York, Wiley, 1958. 368p., $9.00.)

*AUTOMATIC CONTROL: PRINCIPLES AND PRACTICE

The first part of the book is concerned with the dynamic behavior of control systems, including static requirements and adjustments for peak performance. This is followed by a detailed description of electrical and mechanical components such as measuring elements, controllers, and control valves. Various control systems and their specific applications are then described. The approach is in terms of practical concepts rather than in mathematical terms. (W. G. Holzbock. New York, Reinhold, 1958. 258p., $7.50.)

*AIRCRAFT AND MISSILE PROPULSION. VOL. 1: THERMODYNAMICS OF FLUID FLOW AND APPLICATION TO PROPULSION ENGINES

This volume, the first in a three volume work, covers the following areas: fundamental principles of thermodynamics; general characteristics of propulsion systems; thermodynamics of compressible fluid flow; flow through nozzles; flow through diffusers. A large number of illustrative problems are completely worked out. (M. J. Zucrow. New York, Wiley, 1958. 538p., $11.50.)

*A COMPREHENSIVE BIBLIOGRAPHY ON OPERATIONS RESEARCH

A listing of 3000 books, articles, reports and proceedings intended for operations researchers. Material closely related to this field is included. An alphabetical index to all of the citations is followed by bibliographies dealing with special fields of interest such as sequencing, theory, site location, layout, etc. The main bibliography covers references through 1956; a supplement contains titles published in 1957. (By the Operations Research Group, Case Institute of Technology. New York, Wiley, 1958. 188p., $6.50.)

*MATERIALS AND METHODS OF ARCHITECTURAL CONSTRUCTION, 3RD. ED.

A completely rewritten edition of a standard work. Modern design formulas and current working unit stresses are presented and explained. Among the many new areas discussed are tilt-up, lift-slab, lamella, and stressed skin construction; air-entraining cement; modular coordination; aluminum alloys and monel metal; tempered plate glass and plexiglass; flat-plate design; and the slab-band system. (H. Parker and others. New York, Wiley, 1958. 724p., $12.00.)

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Champlain Oil Company — J. C. Clapinson has been elected president of Champlain Oil Products, Limited. He succeeds R. L. Dunsmore, M.E.I.C., who is retiring as president, but will continue to be a director of the organization.

B. F. Goodrich—I. G. Needles has recently been elected chairman of the board of B. F. Goodrich Canada Ltd., Kitchener, Ont.; also elected was R. V. Yohe as president and chief executive of the company.

Controllers Institute—N. J. Brown, comptroller, The Steel Company of Canada Ltd., has been elected president of the Hamilton Control of the Controllers Institute of America. J. G. Sheppard, secretary and comptroller, Dominion Foundries & Steel Ltd., is the new treasurer of the group, and J. A. Durfey, treasurer, Bridge & Tank Co. of Canada, Limited, has been selected a director.

Mannix Co. Ltd.—The following executive appointments were announced recently by Mannix Co. Ltd.: T. C. Oxman, vice-president and manager of operations; E. P. Lougheed, vice-president of administration and a director, continuing as general counsel; C. P. Baker, manager of the general contracts division.

R. V. Yohe

George Kent (Canada) Ltd.—P. Hooper has been appointed sales manager for George Kent (Canada) Ltd., Toronto, and B. Kipling is now projects manager, in charge of planning and development. Also announced is the appointment of two additional sales representatives: M. Stretton, covering the Toronto and Hamilton area, and D. Tizard, who will be responsible for the London, Windsor, Sarnia district.

Northern Ontario Natural Gas Co. — Announcement has been made of the appointment of K. J. Edleman as residential and commercial sales manager of Northern Ontario Natural Gas Company Limited, Toronto.

R. H. Nichols — It has been announced by R. H. Nichols Limited that A. W. Bleue, formerly sales manager, has been appointed to represent the company in the West; he will be located at 624 Vancouver Block, 736 Granville St., Vancouver 2, B.C.

Sun Oil Company — R. D. McCleary and C. E. Scott have been appointed industrial products department representatives for Sun Oil Company Ltd., Toronto; they will be active in the Ontario sales territories. Also announced is the appointment of G. L. Harrison as industrial products department representative; his sales territory will include Quebec and Eastern Ontario.

Leland Electric — D. W. Richardson has been made assistant general sales manager of Leland Electric Canada Limited, Guelph, Ont.

Linde Air Products — The appointment of R. H. Rastorp as assistant manager, advertising and sales promotion department, Linde Air Products Company, division of Union Carbide Canada Limited, has been announced recently. Mr. Rastorp will be responsible for the overall operation of the department.

W. M. de Carteret

Franki Fellowship Award — Franki of Canada Limited have announced the award of the Franki Fellowship Award to Michael A. Hargraft, B.A.Sc., University of Toronto. The Franki Fellowship is awarded every second year to a student graduate in science, engineering or agriculture who has made a special study in soil mechanics.

Dominion Engineering — P. D. Mosher has been appointed sales engineer for the paper machinery division of Dominion Engineering Works Limited. He will assist J. B. Stirling, JR.E.I.C., sales engineer, in serving all the paper mills in eastern Canada including the Quebec City area.

Neptune Meters — Neptune Meters Limited have announced the appointment of W. M. de Carteret as branch manager of their Calgary office.

Imperial Oil—V. Taylor, formerly man-

• BRIEFS

ager of Imperial Oil Limited's producing operations in western Canada, has been appointed a director of the company.

Bechtel Corporation — W. K. Davis has been elected a vice-president of Bechtel Corporation, responsible for advanced engineering projects in the nuclear field.

Quebec Iron and Titanium — The appointment of J. M. Herndon as assistant general manager of Quebec Iron and Titanium Corporation has recently been announced.

New Vice-President — Announcement has been made of the appointment of R. A. Wykes as vice-president and managing director of the Taylor Woodrow Group (Canada), replacing R. Hirst.

Canadian Line Materials — J. W. MacLea, formerly manager of sales promotion of Canadian Line Materials Limited, Toronto, has recently been appointed sales manager for the company.

Saguenay Electric Company — The following executive appointments have recently been announced by the Saguenay Electric Company: P. Tellier has been appointed executive vice-president; G. Dufour, M.E.I.C.,, has been named vice-president and general manager; P. Beaulieu, treasurer, and G. Proulx, M.E.I.C., have been made vice-presidents of the organization.

News of Business and Industry

Continuation of Consulting Practice — Mr. H. H. L. Pratley, M.E.I.C., has announced that he will continue to carry on in Montreal, in his own name, the practice of his late father Dr. P. L. Pratley, M.E.I.C., who was so well-known as a member of the Institute and to Canadian engineers generally.

Plant Extension — Peacock Brothers Limited are undertaking an extension of one of their plants in order to consolidate and expand their valve manufacturing facilities. The plant is located at 161 Stirling Avenue, LaSalle, Que., and the extension, when completed next summer, will be five times the size of the existing plant.

New Location — Ontario General Contractors Association have recently announced their new location at 57 Bloor Street West, Toronto, Ont. Tel. No.: WAlnut 1-0122.

Arctic Aerial Survey — Two high-altitude long-range photographic B-17's are being serviced and overhauled for The Photographic Survey Corporation at Oshawa Airport near Toronto. They are to play a key role in the Canadian government's $6.3 million Arctic Islands aerial survey. This survey starts this spring and is expected to take four to six summer seasons to complete. The B-17's have been fitted by Field Aviation Company Limited, a PSC associate, with special equipment including long-range tanks to enable them to remain airborne over the Arctic upwards of 15 hours.

Safety Award—The Canadian Kellogg Company, Ltd. has recently been awarded the B.C. Centennial Safety Award Certificate, commending the company for completing 16,573 man-days free of accident in one month during the construction of the British American Oil Company's new Port Moody refinery. Kellogg's safety record was achieved during the peak period of construction. The vast amount of work accomplished during this time has helped speed the job to the point where it is several weeks ahead of contract schedule. Construction will be completed early this fall, almost exactly one year from the date when initial foundation work was begun.

Bathurst Acquisition — Bathurst Power & Paper Company Limited has announced that its subsidiary Bathurst Containers Limited has entered the western Canadian market through the acquisition of the assets and undertakings of Norwood Box Co. Ltd., St. Boniface, Manitoba. Norwood Box Co. Ltd. has been engaged in the manufacture and sales of corrugated and solid fibre shipping containers. The purchase of Norwood assets represents a significant addition to the converting facilities of Bathurst Containers Limited already operating in five plants strategically located throughout Ontario and Quebec.

Union Carbide New Division — Announcement of the formation of a new division of Union Carbide Canada Limited was made recently. The new division, known as Haynes Alloys Company, will handle all sales in Canada of Haynes Stellite Company, Division of Union Carbide Corporation. The products marketed by the new division will include more than 100 different special alloys, castings, and fabricated products. Consideration will be given to the installation of production facilities in Canada when the market warrants. Office and warehouse location of Haynes Alloys Company, Division of Union Carbide Canada Limited, is at 805 Davenport Road, Toronto.

Ames Canadian Office—Announcement has been made by The B. C. Ames Company, of Waltham, Mass., of the opening of a Canadian office at 45 Oriole Parkway, Toronto 7. A representative stock of the complete range of Ames micrometer dial gauges and dial indicators, and replacement parts will be carried, and complete engineering and servicing facilities available. The sales and service staff will be under the management of J. A. Morrison.

• BRIEFS

Canadian Agent—Frommelt Industries of Dubuque, Iowa, makers of the Car-Dox snug fit dock covers have appointed Horsfall Engineering, 2696 St. Clair Ave. West, Toronto, as their sole Canadian agent.

Loading Dock—An unusual loading dock, located a quarter of a mile from shore, will be built at Ogden Point, Ont. The St. Lawrence Cement Company, of Clarkson, Ont., has awarded a contract to Dravo of Canada Limited, Toronto, for construction of the 480-foot-long cellular steel sheet pile dock. Included in the contract also are a quarry stone causeway and a 700-foot-long trestle to carry a belt conveying system. The dock, one of the few of its type on Lake Ontario, will be used for loading quarried limestone on ships bound from Ogden Point, near Colborne, about 100 miles east of Toronto, to St. Lawrence Cement's Clarkson plant. Locating the dock 1300 feet from shore in water 32 feet deep eliminates the necessity for dredging a harbour to accommodate the draft of lake freighters. Officials of St. Lawrence Cement expect to use the dock 12 months a year. They intend to start shipping early in the summer of 1959.

Canadian Valves Representatives—Announcement has been made of the appointment of the J. B. Morrison Machinery Co. Ltd., 45 Oriole Parkway, Toronto 7, as exclusive Canadian representatives for Valcor Engineering Corp., Kenilworth, N.J. Morrison will stock and service the complete range of industrial solenoid valves manufactured by Valcor, and complete engineering services will be available.

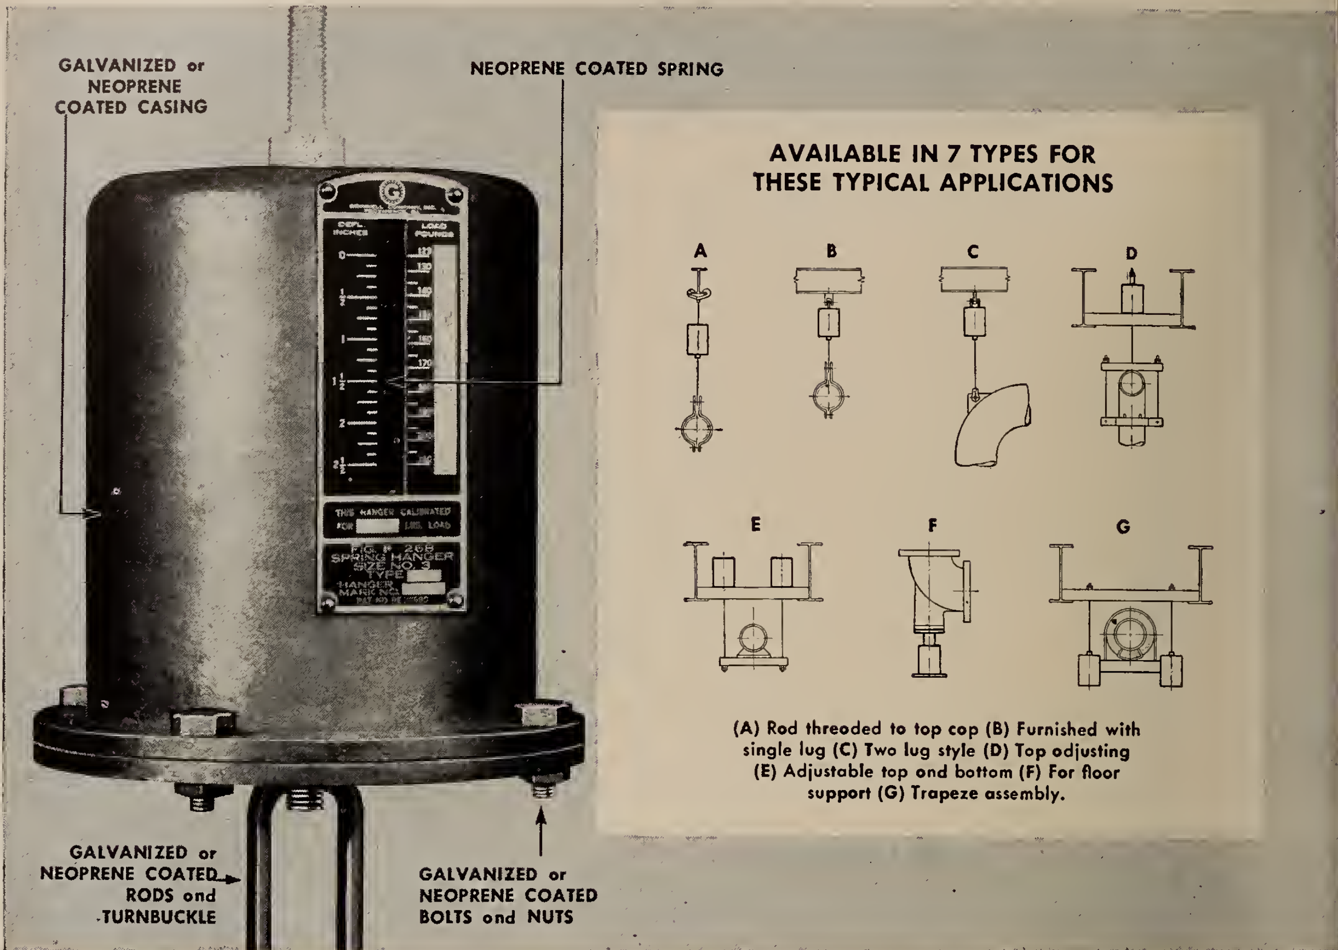
Westinghouse Contract—The Canadian Westinghouse Company has been awarded a contract by the Quebec Hydro-Electric Commission for four 76,800 h.p. generators for the third section of the Beauharnois power development now under construction near Montreal. The four generating units and six identical machines already on order will practically complete the new generating station. Beauharnois Three will be interconnected with Hydro-Quebec's overall system and the new power will serve the Metropolitan District of Montreal. The first power-producing generator is expected to go into service early next year.

Dental Building—Being built by The Foundation Company of Ontario Limited, the new $6,000,000 dental building for the University of Toronto will be one of the most modern dental teaching units in the world. It also represents the first major academic construction project to be undertaken in the University's expansion plans, estimated to cost $50,000,000.

Canadian Plant — Cleaver-Brooks Company, Milwaukee, Wisconsin, manufacturers of packaged boilers for industrial, institutional and commercial applications, plans to build a new plant in Stratford,

corrosion-resistant, weather-resistant

GRINNELL VARIABLE SPRING HANGERS



In addition to their proven corrosion and weather resistance, these spring hangers offer other features.

- Maximum variation in supporting force for standard spring models per ½" of deflection is 10½% of rated capacity — in all sizes.
- Precompression (a patented feature) assures operation of spring within its proper working range, as well as saving valuable erection time. Reduced over-all height saves space.
- 21 sizes available from stock for load ranges from 50 lbs. to 28,200 lbs.
- Available in 3 spring lengths for maximum travel of 1¼, 2½, and 5 inches.
- Installation simplified by integral load scale and travel indicators.
- All-steel welded construction meets pressure piping code.

For hanger installations which are subject to highly corrosive industrial conditions — or where exposed to severe weather, Grinnell makes available two distinct lines of pre-engineered spring hangers.

These hangers are the result of extensive experimentation with various coatings for Grinnell's standard pre-engineered spring hangers. In addition to providing flexibility in pipe suspension, they provide versatility of application through their corrosion-resistant characteristics.

1. NEOPRENE COATED – for highly corrosive conditions, such as those found in chemical plants and refineries. All parts of the hanger are neoprene coated to protect the base metal from a wide range of corrosives. The flex life of the spring is unaffected by the neoprene . . . the coating resists cracking or flaking over a wide temperature range.

2. GALVANIZED – for outdoor installations, where weather conditions are severe. All parts of the hanger are galvanized except the spring, which is neoprene coated to avoid alterations of temper, hydrogen embrittlement and decreased flex-life of the spring – usual hazards to springs from the galvanizing process. Write for further details.

GRINNELL

CANADA'S #1 SUPPLIER OF PIPE HANGERS AND SUPPORTS

Grinnell Company of Canada Ltd. • Edmonton • Montreal • Toronto • Vancouver • Winnipeg • Distributors in Principal Cities

pipe fittings • welding fittings • pipe hangers • valves • Grinnell-Saunders diaphragm valves • pipe prefabricated piping • heating specialties • water works supplies • Grinnell automatic fire protection systems

• BRIEFS

)nt. The firm plans to spend about 900,000 on its Stratford development. This includes a 25,000 sq. ft. production ind test center slated for occupancy ate this year. Initial production is set or early 1959. This marks the first ime that an American manufacturer of his type equipment has built a Canadian lant.

Canadian Agents—As the result of the ecent tour of Canada by J. G. Gershon, ales director of Rocol, Ltd., Swillington, ear Leeds, England, manufacturers of pecialized molybdenized and other ubricants, the following Rocol agents ave been appointed: British Columbia: nternational Agencies and Machinery Co., Ltd., 2315 Cambie St., Vancouver, 3.C.; all Canada, except British Columbia: W. R. Watkins Co. Ltd., 41 Kipling ve. South, Toronto 18.

New Address—Edgar A. Cross & Associtates, consulting engineers, have announced that their new address is 2510 Yonge treet, Toronto 12, Tel. No.: HUdson -1139.

Exclusive Representative—Abitibi Co., Montreal, are the exclusive representaives for the Tarrant hydraulic slide rule, pecially designed for calculations of flow hrough pipes and circular sewers and in pen channels. The formulæ chosen have een selected from the many exponential ormulæ in general use for such calculaions.

New Affiliate—The Sandwell Organizaion, professional engineering and mangement service, have announced estabishment of a new affiliate, Sandwell Inernational, Inc., with offices in Portland, Dregon. The organization has eight other ffiliates in Canada and abroad. Offices vill be located in the Public Service uilding, Portland. M. R. Oberdorfer, vho has been with Sandwell since 1956, nd formerly was president of St. Helens Pulp and Paper Co., will serve as esident representative.

Construction of $1,000,000 Building — Construction of a new two-storey building by Canadian Kodak Co., Limited at a cost of more than $1,000,000 has been announced. When ready for use in the summer of 1959, the building will house all finishing operations in the production of photographic paper. This new project will complete an extensive five-year, $5,000,000 expansion of Canadian Kodak's photographic paper manufacturing facilities, the company states. It is also part of the company's continuing program of investment in additions, improvements and replacements for plant processes and equipment.

New Pipe Mill — The Steel Company of Canada Limited has started preparations for a new pipe mill on a new site located twenty-five miles east of Montreal at Contrecoeur, P.Q. The new plant will be the initial installation of a 700 acre property acquired by the company during the last year or so. Stelco has estimated the cost to run to some $10,000,000, and it will be the most modern type of continuous butt-weld mill; it is being designed to produce diameters ⅜" to 4" inclusive, in single and double random lengths up to 50 feet.

Contract with Norway — Aluminium Limited, Montreal, recently stated that one of its trading subsidiaries has concluded a new contract in Oslo, Norway, with the largest Norwegian aluminum producer, calling for the delivery during the next 20 years of a total quantity of about 4,400,000 short tons of alumina. It is expected that the major portion of the alumina, which is the principal raw material in refining aluminium, will be supplied by Aluminium Limited's producing company in Jamaica, West Indies.

Change of Location — Canadian General Electric Company Limited has recently announced that the marketing operation of the small appliance department will be located at the small appliance plant at 80 Bradford Street, Barrie, Ont. The Ontario district sales office for the department will remain at 214 King Street West, Toronto.

New Equipment and Developments

New Diesel Engine—A General Motors our-cylinder, two-cycle diesel, rated at 53 h.p. at 2,200 r.p.m. and a high torque f 385 ft. lbs. at 1,600 r.p.m. is one of everal installed in company buses which ave completed 275,000 miles or more vithout any major repair, it was recently tated by General Motors Diesel Limited, London, Ont. Purchased in 1954 with 15 thers, the engine is being stripped down or routine overhaul. General Motors tate that in all probability the engine vould only need rings, pistons and leeves. The crankshaft has been measured and magnafluxed and found to be perfectly straight, without cracks, and journals and throws show no wear or taper. When re-assembled the engine should be good for another 300,000 miles or more.

AC/DC Engine Driven Heliwelder—Air Reduction Canada Limited announces the new 300 amps. AC/DC engine driven Heliwelder for field operation where the welding of structural members of aluminum or magnesium is necessary. In addition, the flip of a switch provides AC or DC straight or reverse polarity welding current with or without high

• BRIEFS

frequency stabilizer. This machine provides 115 volt, 1kw. DC auxiliary power for the operation of electric tools and lights while welding or 115/230 volt, 10kw. single phase 60 cycle power when operated as a power plant only. Complete with automatic inert gas control panel and post flow timer the rated machine output is 65 to 400 amps. AC, 75 to 350 amps. DC and 35 to 375 amps. AC or DC for Heliwelding with maximum OCV of 80 AC - 72 DC.

Dustless Stoper — Canadian Ingersoll-Rand Co. Ltd., Montreal, have announced a new rock drill known as the "Vacujet" dustless stoper which sucks all dust and cuttings down through the drill, then discharges them under pressure through a long hose to a container. The new stoper, described in Ingersoll-Rand's flier Form 4195, works as follows: Vacuum is developed by an ejector jet incorporated into the back-head of the drill. This vacuum draws the cuttings down through the drill steel and the drill. When the dust and cuttings reach the jet, they are caught in the jet air stream and pushed under pressure through a hose to a tank or bag 25 feet or more away from the drill. The manufacturer stresses that the stoper is a completely new drill and not merely a modification.

The Hypsometer Statoscope—Canadian Applied Research Limited, Toronto have announced the design of a height deviation indicator which is said to supply the operator and the pilot with height deviation information with an accuracy of ±5 feet. Known as the "hypsometer statoscope" the design of the new survey instrument is based on the hypsometer circuitry used in C.A.R.L.'s airborne profile recorder, Mk 5.

World's Largest Spray Dryer—In a million-dollar expansion program which will double the waste sulphite liquor capacity at the Quebec plant of Lignosol Chemicals, Ltd., the Canadian company will install the world's largest spray dryer for the production of by-products from waste sulphite liquor. The dryer, which will be engineered and constructed by Bowen Engineering Inc. of North Branch, New Jersey, will be capable of producing 100,000 lb. of spray-dried product daily. A Bowen-patented design allows introduction of cooling air into the drying chamber to cool the product before it leaves the unit.

Photocell Tracer—The "Linde" photocell tracer, a new and versatile photoelectric tracing device designed for attachment to oxy-acetylene shape-cutting machines, has been introduced by Linde Air Products Company, Division of Union Carbide Canada Limited. Sold under the trade mark "L-P-T", this new unit incorporates a recently developed Canadian Westinghouse Company electronic circuit. It automatically traces from a simple pencil or ink line drawing, a great advantage over most existing photoelectric tracing devices which will only follow the edge of a wide line or silhouette. Superceding the older type strip and magnetic drive heads used on shape cutting machines, the "L-P-T" photocell tracer eliminates the necessity of making costly strip or magnetic templates. In many shops, the saving on templates alone could amortize the cost of this new tracer in less than a year.

Screw Type Compressor—The first range of large, two-stage screw type compressors, will be introduced into Canada by Atlas Copco Canada Ltd. The new compressor, which is described as being similar to a roots blower but with a screw twist in its rotors, was developed after ten years of intensive work by the Swedish Rotormachinery Company on an invention patented in 1934 by Professor A. Lysholm. The large capacity machines will be manufactured and sold by Atlas Copco in three models with capacities of 6,700, 10,000 and 19,500 c.f.m free air delivery. The company states that a great deal of the development work on the new compressor centered on investigations of the most suitable rotor profile. The design employed is in the form of circular arcs providing advantages both from mechanical and manufacturing point of view. Because the rotor surfaces are in rolling rather than sliding relationship to each other, they will not damage each other in the event of damage to the timing gears which would lead to a failure to maintain rotor positions.

Open-Type Motor Applications — Canadian Allis-Chalmers Limited, Montreal, have declared that increasing open-type motor application areas at extensive cost reduction are today's improved insulations. Previously, many application required motors with expensive protective enclosures; now, open motors with protection built right into the insulation, are available with the resultant savings of millions of dollars to users. A major factor in this evolution is an all-silicone-rubber insulating system for form-wound stator coils in large motors. Another is epoxy-encapsulated coil structures for field windings of large synchronous motor rotors and for stators of smaller frame motors with random or mush-wound coils. Allis-Chalmers utilizes both in its Super-Seal line of open motors. Silco-Flex silicone-rubber insulation and epoxy resins are the foundation stones of the new line.

Vinyl-Modified Silicone Gums — Two vinyl-modified silicone gums designed for use in the formulation of Class 500 or extreme low temperature service silicone rubber compounds have been added to the standard product line of chemical

Correction

On page 206 of the September 1958 issue, reference was made to equipment manufactured by Ruston & Hornsby Ltd. Inadvertently, the name "Ruston" was misspelled "Rushton".

• BRIEFS

materials section, Canadian General Electric Company Limited. SE-54 is the only low shrinkage, extreme low temperature reactive silicone gum now on the market, the company declares. SE-53, is a standard shrinkage polymer. Because these gums are vinyl-modified, ultimate physical properties of the compounds based on them can be obtained with curing cycles shorter than normally required. Other features are the realization of excellent compression set properties without the use of toxic additives, and reduced levels of curing agents.

Publications

Steel Plate for Hydro-Power — Horton Steel Works Limited have recently issued an illustrated brochure on steel plate engineering, fabrication and erection for Hydro Power. Copies of the brochure are available from Horton Steel Works Limited, 25 Adelaide Street West, Toronto.

Iata Airlines—Fifty thousand copies of the first comprehensive collection of the insignia and aircraft liveries of the major scheduled airlines are shortly to be distributed to many parts of the world. Published by the BP Aviation Service, the "BP Book of IATA Airlines" shows the principal aircraft operated, distinctive markings, and the company symbols of 81 airlines which are members of the International Air Transport Association. The booklet gives a brief history of each company in English, German, French and Spanish.

Rod-and-tube Thermostat—Rod-and-tube type steam thermostats for use in commercial appliances are described in a new four-page bulletin published by Robertshaw-Fulton Controls Company, Toronto.

Crane Iron Body Valves—Crane Limited, Montreal, have recently published a pamphlet entitled "Crane Iron Body Valves and their end Connections." The pamphlet provides a quick reference for all personnel responsible for determining valve selection, and contains information on the popular valve sizes and types manufactured by Crane factories.

Lightning Arresters—Northern Electric Company Limited, Montreal, has published a 20-page well-illustrated bulletin dealing with the Slater-Hubbard lightning arresters. The design, construction and application of the various types of autogap arresters are fully described.

Regulator Catalogue—Oxweld industrial gas regulators are described and illustrated in a twenty-page catalogue available free from Linde Air Products Company, Division of Union Carbide Canada Limited, 40 St. Clair Ave. E., Toronto. This comprehensive catalogue includes complete specifications and ordering information on 47 Oxweld regulators available for use with all industrial gases. Inlet and outlet connections are listed according to the American Standards of the Compressed Gas Association.

Comparison of Furnaces—Bulletin GER-1479, published by Canadian General Electric Company compares costs, efficiencies and heat losses of the two types of furnaces used to strand anneal wire continuously. The 8-page publication discusses data collected on the two furnaces over a one month test period in the United States and contains pictures, graphs, curves and formulas.

New Air Starting Motor—Canadian Ingersoll-Rand Company announces a new 20 page bulletin, Form 5094D, describing its complete line of air starting motors for starting Diesel, gasoline and natural gas engines. The new bulletin contains detailed specifications and mounting dimensions on the 34 models in the company's line. Approximately 500 popular engines by 25 engine manufacturers are listed, with the proper air starting motor shown for each engine. In addition, easy to follow instructions are included for selecting the correct air starting motors for unlisted engines.

Watertight Masonry—A 6-page bulletin issued by The Master Builders Co. discusses the important elements involved in the design and specification of watertight masonry. Citing good workmanship and lack of cracks between brick and mortar as the principal pre-requisites to watertight masonry, the bulletin outlines six important considerations to be given in designing watertight masonry walls.

Packaged Air Conditioners—Complete physical data for all units and all major components of new model packaged air conditioners is included in a new, 20-page, illustrated catalogue published by American-Standard Products (Canada) Limited, Canadian Sirocco Products, 310 Ellis Street East, Windsor, Ont. The catalogue, bulletin 6125, superseding 5125, is 8½ in. x 11 in. and describes fully all six models in the line of packaged commercial air conditioning units available through Canadian Sirocco. The six blowers range in size from three to 20-ton capacities.

Aluminum Railings — The Aluminum Company of Canada, Ltd. has issued a 30-page book entitled "Alcan Aluminum Railings for Bridges and Highways." It introduces a complete line of aluminum bridge and highway railing components, including nine railing designs. The book is illustrated with detailed drawings and specifications are included. A copy may be obtained from the Aluminum Company of Canada, Ltd., 1700 Sun Life Building, Montreal, Que.

ENGINEERING NOTES FROM BRITAIN

Computer-Controlled Flame Cutting. The cutting of steel plates by means of an oxygen flame is a process now commonly used in industry. Where plates of rectangular shape are required, this can be done without difficulty on an automatic machine that is set and then left to operate by itself. But where irregular shapes are needed—as is frequently the case in shipbuilding and other industries—it is necessary to make a full-scale template and then cut the plate by hand, which is not always very accurate.

The making of templates and hand control for the profiling of curved edges can now, however, be eliminated by a computer-controlled flame-cutter which has been developed by British Oxygen Gases Ltd., of Cleveland Row, London, S.W.1., in conjunction with Ferranti Ltd., of Chadderton, Lancashire, England.

This machine is designed to follow instructions fed to it from a magnetic tape, and it is claimed that it can cut a plate of any shape under automatic control from start to finish. It has been estimated that this new technique will save as much as 40 per cent of the present cost of profiling plates, as computer-controlled cutting eliminates many of the conventional stages between drawing board and cutting machine.

The machine receives its instructions from the magnetic tape and operation thereafter is entirely automatic as to shape, correction of error and monitoring.

Speeding Welding Time On Big Jobs. Increased production of welded cylindrical vessels with a wide range of sizes is now being obtained at the works, at Barrow-in-Furness, England, of Vickers-Armstrongs (Engineers) Ltd., with the aid of a high-lift boom and traversing roller bed installation. The equipment is being used for the welding of rotary kilns, storage tanks, high pressure and low pressure heaters, rotary coolers, and for other cylindrical fabrications.

The high-lift boom equipment consists basically of a boom of 17 feet six inches in length, one end of which is mounted so that the height of the boom above the roller bed is variable to accommodate vessels of varying diameters. At the other end of the boom is a Fusarc automatic welding head, made by Quasi-Arc Ltd., of Bilston, Staffordshire, England.

Provision is made for the operator and his equipment to be carried at the end of the boom. In the case of internal welds on small diameters, the operator is carried prone. The roller bed can support, turn and traverse a weight of up to 48 tons, and is adjustable to accommodate vessels with diameters ranging from two feet to 15 feet.

Both longitudinal and circumferential welds may be carried out by moving the workpiece while the welding head remains stationary. All motions of the roller bed, as well as all welding conditions, can be controlled by the operator at the welding head. Power is supplied by a 1,000 ampere generator, and continuous covered electrode type is used, at currents up to 750 amp. for internal welding and 900 ampere for external welding.

Automatic Trolley Control System. Applications of electronic control to machine tools, mechanical handling, and automatic weighing devices, have now advanced a stage further with the introduction of a new wire guidance system for the automatic control of powered trolleys and trucks in factories and warehouses.

The method employed is a system of magnetic induction. A wire is laid — or buried — over the desired route and a current passed through the wire sets up a magnetic field which is detected by sensing coils mounted on the front of the trolley.

Stopping and starting from one or more remote control points is provided; several trolleys may be operated independently over the same route with facilities for automatically selecting branch routes, and automatic stopping controls are fitted which operate either if the trolley's path is obstructed or if a failure occurs in the guidance system.

The new system, which has been developed by E.M.I. Electronics Ltd., of Hayes, Middlesex, England, can be used by a variety of undertakings for the mechanical handling of material where previously it has not been economically justifiable.

Automated Production Of Concrete. Continuous 300 feet lengths of pre-stressed concrete beams are now being manufactured in England. The total number of men required to operate the machine is four and they produce one-third of a mile of beam per shift. The process makes moulds superfluous: the concrete is extruded from a travelling machine on to flat beds. When the beam has been cured it is automatically fed to a saw table which cuts off the required lengths. Beams, for floors or roofs or for any other purpose to which pre-stressed concrete can be put, can be cut in lengths up to 30 feet.

The beams are formed on a flat concrete bed over which the casting machine travels suspended from a gantry driven by an electric motor. The moulding section moves in short steps of about 18 inches metering out the correct amount of concrete from an overhead hopper, which is kept supplied from a mixer by monorail truck. The moulding section is moved by compressed air. As the concrete is poured it is vibrated between side plates which, with the concrete bed, act as a forme.

The layout of the casting shop, which has been designed by Richard Lees Ltd., of Mugginton, Derbyshire, England, allows for the travelling moulding gantry to straddle three parallel beds at the same time, one bed casting, one curing and the third being cleared and cut for length. The time cycle is four hours.

Glass Used As Heating Element. Normally, electric heating elements are constructed with resistance wire and their application is confined to the production of heat for use by radiation from a glowing element. A problem arises however when there is a need to spread the heat which has been generated, and a method of transferring the heat becomes necessary. This can be done by direct radiation as in the case of a fire, by induced air currents as in conventors, by fan-produced air currents, or transfer media such as oil and water. All these methods have the one common drawback in that there is a loss of heating efficiency to a varying extent.

Now there is a new product, Mhoglas, made by Hunting Mhoglas Ltd., of Luton, England, which it is claimed overcomes this efficiency loss and offers exactly the advantage which wire heaters lack. The material is made by a process which makes glass fabric electrically conducting. This is because, as the element itself is in sheet form, the whole of which heats evenly, the heat generated is also in sheet form.

Among the wide varieties of use to which Mhoglas may be put are heated panels, skirting boards, floors, tables and walls. It has also been used in tests with great success in solving aircraft de-icing problems, and in the plastics industry.

One important claim for the new material is that it cannot cause a burn if touched, a great safety point in any form of panel heating. The normal running temperature is that of hot, though not boiling water.

● NOTES FROM BRITAIN

New Test-House For The Conway Pod. Those airlines which have specified the Rolls-Royce Conway by-pass engine for their Boeing 707 airliners will have a complete Rolls-Royce power plant — engine, accessories, thrust reverser, noise suppressor and the pod which houses them all. In order to test the complete pod as a unit, Rolls-Royce Ltd. has constructed a special test-house at the Flight Test Establishment at Hucknall, England, and has already carried out more than 200 hours' running with the Conway pod exactly as it will be installed in the aircraft except that until recently the thrust reverser and noise suppressor were not fitted.

The test-bed was developed jointly by Rolls-Royce and Heenan and Froude Ltd., and is equipped to measure both forward and reverse thrust. The power-plant is suspended from a bridge-type cradle by an actual Boeing strut, and through this strut all engine controls and instrumentation, starter and other air feeds are led exactly as in the aircraft.

This in itself has been a difficult task, for in addition to the normal services, the strut has also had to contain the leads from more than 60 pressure tappings and a similar number of temperature indicators used in engine development runs. In all there are nearly 3,000 electrical leads passing through the strut.

The test cradle is suspended on four vertical spring plates and is restrained by electric load cells from which thrust measurements are obtained. By mechanically loading the craddle against the load cells it is possible to read both forward and reverse thrust.

The load cells used on this installation have been developed by Davey and United to the requirements of Rolls-Royce. The load cell system has been chosen principally on account of the accuracy of measurement it permits without interference from ambient temperature variations. The total movement of the engine cradle over the whole power range from 10,000 pounds reverse thrust to 20,000 pounds forward thrust is only 0.006 inches which virtually eliminates inaccuracies arising from varying positions of the cradle suspension, ambient temperature interference is diminished by surrounding the cells with an oil jacket and a water jacket, and such variations as remain can be compensated in the load cell circuit.

As a result an accuracy of 0.1 per cent is attained over the full scale of —10,000 pounds to 20,000 pounds thrust, and an error of less than ten pounds thrust is guaranteed when extended scale readings are taken.

Mechanical Slipway For Tankers. A new mechanical method has just been designed for overhauling large tankers without the use of elaborate dry-docking facilities. It consists of a slipway equipped with a series of flange-wheel carriages fitted with keel blocks, which runs down from the shore on to a thick concrete runway beneath the water. A tanker coming into "dock" for a refit is brought on to the slipway in much the same manner as an airliner coming in to land.

A series of buoys or siting poles are located in the water so as to form a plainly visible "run-in" on to the slipway. The tanker arrives at high tide and is anchored to the correct buoy. As the tide recedes, the tanker slowly lowers on to the keel blocks below. When completely bedded down, it is hauled up the slipway on the carriages.

The motive power is supplied by electric motors which are located in pits well above high water level. The use of the slipway is restricted to tankers of up to 50,000 tons displacement. This mechanical slipway has been developed by Mitchell Engineering Ltd., of Bedford Square, London, W.C.1.

THE PRIME MINISTER

VICTORIA

I am grateful for this opportunity to pay tribute, perhaps all too infrequently paid, to the professional engineers of Canada, particularly those whose work has been closely connected with British Columbia's development during the past 100 years.

I am proud, too, that the Engineering Institute of Canada, the largest and oldest association of engineers, has seen fit to devote this issue of its official organ, the Engineering Journal, to the Province of British Columbia.

We forget sometimes that a large part of the real work and the enormous responsibility for the physical development of a country or a province is borne by the engineer. In both government and private industry others may set the policy but the engineer conceives and builds the bridges, the railways, the highways, the pipelines, the hydro-electric dams, the transmission lines, the buildings and the industrial plants. Without his skill we would live primitive lives, without his knowledge we would stand still and without his advice we would founder.

Over the past century British Columbia has been a particular challenge. Beneath its rugged crust, along its rivers and on its surface are untold resources, but only through the engineer's skill have these become available to us.

If we appear sometimes to forget the contribution made by the professional engineer, it is not because we do not appreciate it, but perhaps because the high standard of performance through the years has made us take it for granted. And we know that much of the present and future physical development of British Columbia is in his skilled hands.

Perhaps the words of Historian Judge Howay in describing the work of the Royal Engineers on the original Cariboo Highway nearly 100 years ago would not be out of place here and, indeed, could be applied to anyone of the many great engineering projects today. He said "This road was the pride of British Columbia, and a source of wonder and admiration to its visitors, who were loud in their expression of surprise at the daring conception and skillful execution of the work".

Prime Minister of British Columbia

BRITISH COLUMBIA

AN HISTORICAL SKETCH

R. H. Roy *Provincial Archives, Victoria, B.C.*

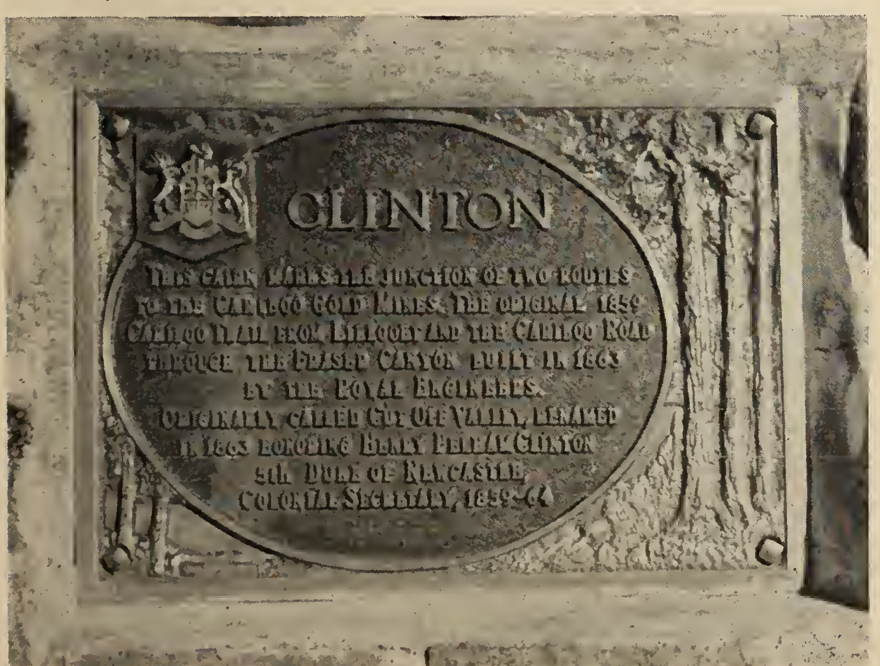
THIS YEAR British Columbia is celebrating its one hundredth birthday. The date for this centenary is based on an event which took place at Fort Langley, B.C., on November 19th, 1858. At this Hudson's Bay Company post on the bank of the Fraser River were gathered a handful of men who, at the command of Queen Victoria, proclaimed the mainland to be a Crown Colony of Great Britain, giving it equal status with Vancouver Island, its colonial senior by nine years.

This event took place in what was one of the most isolated colonies of the British Empire. To the west the nearest colony was Hong Kong, some 6,500 miles away. To the east, across 2,000 miles of mountain and prairie, were the older Canadian colonies. Between the capital of British Columbia and London, the heart of the Empire, were 14,500 miles and months of sailing time.

The geographic isolation of British Columbia accounts for the fact that it was not until the middle of the previous century that any serious attempt was made to discover and chart the northern Pacific coast of the continent. Similarly, while time and distance were factors militating against discovery by sea, the great mountain ranges of the Rockies and Selkirks served as a barrier to the early penetration of the area by land.

Russia and Spain, both operating from ports opening upon the Pacific, were the first to send their ships along the Pacific Coast. In 1725 Vitus Bering, a Dane in the service of Czar Peter the Great, started on the first of two great expeditions which took him across Russia to Kamchatka. One of his tasks was to determine the eastern boundaries of the Czar's domain, and in so doing to find out, once and for all, whether a land bridge existed between Russia and North America. Bering, after skirting the Alaskan coast during his second expedition, perished when returning to his base at Petropavlovsk in 1741. It was his Lieutenant, Chirikoff, and those who came later, who established Russia's claim to Alaska.

Where the Cariboo Trail and the Cariboo Road meet: The Cariboo Road monument at Clinton, B.C.



An important result of these Russian explorations was the discovery of a hitherto unknown fur-bearing animal—the sea-otter. Pelts from this animal claimed a very high price in China, and as a result a lucrative maritime fur trade was established by the Russians from bases in Alaska.

Far to the south were the Spanish possessions in Mexico and Lower California which had been conquered during the 16th century. Although claiming the entire Pacific Coast by authority of the papal bull of 1493, Spain had been content to exploit the riches she had uncovered in the southern latitudes, and for decades had taken no serious steps to explore and settle the lands north of California. News of the Russian advances, however, coupled with the defeat of France in North America, resulted in a reawakening of Spanish interest in the Pacific.

The voyage of exploration by Don Juan Perez in 1774 represented the first move of Spain's new policy of expansion into the north Pacific. Operating from the Mexican port of San Blas, Perez was followed by other Spanish explorers such as Martinez, Heceta and Quadra. The contributions of these voyages to the knowledge of the northern Pacific, however, were limited, and it was not until the advent of Captain James Cook and Captain George Vancouver that a true outline of the islands and mainland coast of British Columbia emerged.

Although Great Britain's entry into the northern Pacific had been late, she came as the foremost maritime power in the world. Her ships were large, well-equipped, and captained by men whose ability and navigational skill were unmatched. Foremost among these was Captain

James Cook, an officer of the Royal Navy who had gained renown for his two famous expeditions in the South Pacific. In 1776, Cook was sent on a scientific and exploratory mission to the western coast of North America to discover, if possible, the long-sought Northwest Passage—the fabled waterway which supposedly connected the Atlantic and Pacific Oceans.

After voyaging around the Cape, Captain Cook, in *H.M.S. Resolution,* arrived off the coast of Oregon in March, 1778, and proceeded northward. Adverse winds and storms prevented his entering the Juan de Fuca Strait, but at Nootka Sound, on the western coast of Vancouver Island, Cook anchored his ship and became the first European to set foot on what is now British Columbia. Incidentally, while repairing his ships at Nootka, he was also the first to make use of the excellent timber for new spars and masts.

Although he sailed farther north, charting the outline of the coast to Bering Strait, Cook did not discover the Fraser or Columbia Rivers nor did he know that Vancouver Island was not part of the mainland. Cook's voyage, however, did reveal the commercial potentialities of the sea-otter trade with China, and when his journals were published in 1784, following the end of hostilities in Europe and North America, both British and American ships set out for the Pacific Coast to engage in this lucrative trade.

The maritime fur traders, as they were called, played an important part in the history of British Columbia. One of these men, the American sea captain Robert Gray, was to achieve fame as the discoverer of the Columbia River, an action which was to establish the claim of the United States to that part of the coast. Another, a British subject, Captain John Meares, was the first to build a ship —the *North West America*—in British Columbia.

The activity of the maritime fur traders was rudely interrupted in 1789 when Captain Martinez, of the Spanish Navy, arrived at Nootka to proclaim and enforce Spain's claim to the area. This proclamation, accompanied by the seizure of Captain Meares' vessels, resulted in a controversy between Great Britain and Spain which led both nations to the brink of war. Open hostilities were avoided when Spain, lacking the strength to enforce national aspirations, signed the Nootka Sound Convention in 1790, a step described as "the first express renunciation of Spain's ancient claim to exclusive sovereignty, navigation, commerce, and fisheries on the Pacific Coast of America".

In the following year the British government sent Captain George Vancouver, R.N., to continue and further the task of exploring and mapping the coast undertaken by Captain Cook, and also to accept the surrender of the lands and districts seized by the Spanish. It was Vancouver who, by his patience, determination and navigational skill, became the first to circumnavigate Vancouver Island and who, upon his return home in 1795, brought with him accurate charts which showed in detail the islands and coastline of Canada's Pacific Coast. Vancouver's discoveries exploded the myth of a North-West Passage, a myth which evaporated as did the former Spanish pretensions to sovereignty in the North Pacific.

So far we have dealt with the approach to British Columbia by sea. Yet it was only three or four weeks after Vancouver had sailed through Fitzhugh Sound in 1793 that, a few miles up a neighboring sound, Alexander MacKenzie completed the first journey made by a European across the continent.

The discovery of British Columbia by land was directly connected with the fur trade which, after 1760, fell from the French into the hands of the British. By this time the Hudson's Bay Company had been in existence for almost a century. The company had done comparatively little, however, to explore into the heart of the continent, a passive attitude which it was forced to abandon with the coming of "the pedlars". This was the derisive name given by the Hudson's Bay Company men to those independent fur traders from Britain's colonies bordering the Atlantic, who stepped in to exploit the fur trade in the area formerly held by the French. Within a few years the "pedlars" were to band together into loose organizations which, in turn, amalgamated in more permanent form as the North West Company.

From 1785 until 1821, the North West Company was to provide the Hudson's Bay Company with the most aggressive competition it was to experience in its entire history. Basically, it was a period when both companies, but especially the Nor'Westers, pushed farther and farther west in order to open the new, beaver-rich lands which awaited exploitation. No longer would the white men remain in their forts awaiting for the India[illegible] hundreds of miles to the tra[illegible] posts around Hudson's Bay and [illegible] Great Lakes. Instead the traders, [illegible] canoe and on foot, travelled into the wilderness bringing their goods to the Indians and reaped their rewards by hard work and shrewd bargaining. The Hudson's Bay Company had the advantage of a royal charter, strong financial resources and a sea route from London to its posts around the bay. To offset these advantages the North West Company, with its profit-sharing organization, depended upon

A Cariboo freight wagon leaving Ashcroft, B.C.

Barkerville—Main Street before the fire of September, 1868.

its business efficiency, its energetic, hard-driving partners, and the flexibility of operations it enjoyed.

It was the Nor'Westers who first entered British Columbia by the overland routes. Alexander MacKenzie, a partner in the North West Company, penetrated the mountain barrier by way of the Peace and Pine Rivers and, after weeks of toil and danger, this hardy Scotsman and his companions reached the Pacific near present-day Bella Coola in July, 1793. Their voyage by canoe and by foot is a saga by itself, and there are few knighthoods which have been won at such great risk and under such adverse conditions as that granted MacKenzie for his exploits.

The journey of MacKenzie to the Pacific Coast, although important historically, was unsatisfactory as a transportation route for the fur trade. Preliminary steps to undertake a new attempt were taken twelve years later by Simon Fraser. After establishing several trading posts in the Upper Peace River country—or New Caledonia, as he called it—Fraser, thinking he was on the northern reaches of the Columbia River, set out down the rushing, turbulent river which now bears his name. Fraser's amazing voyage down this waterway to the ocean was completed on July 2nd, 1808. Yet once more, despite his feats of endurance and leadership, this journey was a commercial failure. The river was not the Columbia, and further, it was obvious that the roaring currents, whirlpools and rapids of the Fraser River would not serve as a water highway for the fur trade.

While Fraser was exploring and penetrating the northern routes into British Columbia, David Thompson, also a North West Company fur trader, was making his way slowly and methodically into southern British Columbia. Thompson, famed as a cartographer as well as an explorer, was the first to travel the length of the Columbia River and to establish the first feasible route for the Nor'-Westers from the Pacific to the Great Lakes.

For over a decade, the North West Company dominated the fur trade on the Pacific slope, establishing numerous posts over a vast area. Although tapping rich beaver territories, the long, expensive journey back to the Great Lakes, together with the vicissitudes brought on by the keen competition of the Hudson's Bay Company, resulted in the amalgamation of the two competitors under the name of the Hudson's Bay Company in 1821.

Seven, or approximately half, of the posts mentioned above were located south of the present-day international border. West of the Rockies, the United States and Great Britain, by mutual agreement, jointly occupied the territory commonly called Old Oregon. The main events of British Columbia's history from 1821 until 1846 took place in this area, and revolved around the inability of the British fur trading company to stem the tide of American immigration into the rich farming country of Washington and Oregon.

It seems almost ironical that it was the hospitality offered the early American pioneers by Dr. John McLoughlin, the Chief Factor for the Hudson's Bay Company, west of the Rockies, which resulted indirectly in the success of the settlement of the Oregon country. This success in turn brought hundreds and then thousands of Americans over the Oregon Trail, and with them came the demand that this new land should throw off its dual sovereignty and be incorporated into the United States. The British hope of establishing the border along the Columbia River faded in proportion to American immigration, and in 1846 the boundary line was continued along the 49th parallel to the Pacific Ocean.

Sir George Simpson, who controlled the Canadian activities of the H.B.C., had foreseen this turn of events and, in order to provide an alternate headquarters for the fur trade on the Pacific, he ordered the construction of Fort Victoria on the southern tip of Vancouver Island. The location for this new post, the future capital of the province, was selected by James Douglas, who succeeded McLoughlin as Chief Factor in 1846.

Oregon, as we have seen, was lost by the failure of the British to settle there, and not unexpectedly there were many in Great Britain who had complained that the Hudson's Bay Company charter was in effect a major obstacle to the settlement and development of the Canadian West. When the company's licence had been renewed in 1838, a clause was inserted whereby the British Government retained the right to establish a colony within the company's territories to exclusive trade. Following the boundary treaty, therefore, Vancouver Island was proclaimed a Crown Colony and Richard Blanshard was commissioned its Governor in 1849.

Unfortunately, owing to the reticence of the Hudson's Bay Company as the colonizing agent, the geographic isolation from Great Britain, and the lure of California gold, few settlers came to Vancouver Island. As late as 1858, Fort Victoria was a small sleepy village of about 600 souls, the greater number of whom were present or past servants of the Hudson's Bay Company.

The discovery of gold on the Fraser River in that year brought about profound changes. When word of the gold strike reached San Francisco, the news spread like wildfire. During the Spring and Summer of 1858, some 25,000 Americans streamed into the Colony, eager to make their fortune, and caring little whether they did so under the Stars and Stripes or the Union Jack. This inundation of American gold miners swamped the small British population and there were fears that, unless prompt measures were taken, British Columbia might be annexed to the United States.

James Douglas, at this time Governor of Vancouver Island and Chief Factor for the Hudson's Bay Company, possessed those qualities of decisive action and firmness which quickly made it apparent to the gold miners that they were on British soil and subject to British laws and justice. Although his legal authority was limited to Vancouver Island, the British Government, informed of the situation, appointed Douglas governor of the mainland area also when it was proclaimed a Crown Colony at Fort Langley on November 19th, 1858.

To strengthen Douglas' hand, as well as to assist the new colony, the British Government sent out a small force of Royal Engineers under Colonel R. C. Moody. These men, many of whom remained in the colony when the force returned home in 1863, played a more important part in the development of British Columbia than their numbers might indicate. As surveyors, road and bridge builders, printers, town planners, et cetera, they performed the work which, in later years, would be undertaken by several governmental departments.

With the Royal Engineers based at New Westminster, and ships of the Royal Navy stationed at Esquimalt, Douglas had at his command the means of enforcing British rule in the colony should it be necessary. Yet these forces were never called upon to quell any serious disturbance, and part of the credit for enforcing British law in the colony is due to the colony's Chief Justice, Matthew Baillie Begbie. Begbie, sometimes called "the Hanging Judge", meted out justice with a swift and sure hand in the remotest parts of the gold fields, treating Canadians, British, Americans and Indians without fear or favour. The tales about him are legend, but there is no doubt that he demanded and received a respect for British law and justice which kept lawlessness in the colony at a minimum.

For the next decade both colonies depended almost entirely on gold mining as their chief source of revenue. From the Fraser the miners probed to the north and east, periodically making new strikes, and with each major strike setting off a new "gold rush". The later strikes were made in the interior of the mainland, and brought with them a demand for suitable transportation routes to the gold fields. The famous Cariboo Road to Barkerville, constructed through part of the colony's most rugged territory, was an example of the difficulties faced and overcome by the miners. In time almost every type of transport was used, and miners travelled on foot, on horseback, by ox- and mule-train, by stagecoach, by river paddle-wheelers, and even some by camel. The history of transportation in British Columbia is an epic in itself.

By the mid-sixties British Columbia was beginning to feel a recession as the peak of the gold rush period passed and miners left by the hundreds to prospect elsewhere for that elusive precious metal. Many remained, however, not as miners but as farmers and ranchers who were attracted by the rich valley lands in the interior.

A river boat at Emory's Bar near Yale, B.C.

The recession brought about the end of dual colonial government. In order to lessen the cost of administering two contiguous colonies, both were united under the name of British Columbia on November 19, 1866, with its capital first in New Westminster and then Victoria.

In the following year two events took place which were to shape the future political path of the colony. In 1867 the United States bought Alaska from Russia, thus placing the colony in a situation where it was exposed to the full blast of Americans' cry of "Manifest Destiny" and possible annexation. In the same year the eastern provinces confederated to form the Dominion of Canada, a new nation whose founders were already thinking in terms of a nation which would stretch from sea to sea.

Of the three choices open to the colony — annexation, confederation, of remaining a Crown Colony— British Columbia decided to pick the middle path, especially as confederation would bring with it the long-sought railway connection with the east. On July 20, 1871, the colony became the sixth province of the new Dominion.

The potential wealth of the new province was immense, but before its natural resources could be exploited it was essential to construct a network of roads and railroads throughout the province in order to transport the lumber, ores, agricultural produce, et cetera, to the markets of the world. It was not until 1885 that the Canadian Pacific Railway was completed from the Atlantic to the Pacific when the last spike was driven at Craigellachie.

The advent of the railroad, and especially the numerous branch lines constructed during the latter part of the last century, brought a surge of life to the economic development of the province. Villages grew into towns, heavy machinery was brought in to develop and increase the mining industry, settlers arrived to take up land throughout the province, and British Columbia, once a remote part of the British Empire, entered a new era of progress.

ONE HUNDRED YEARS OF ENGINEERING

Early in 1958 the Vancouver Branch of E.I.C. sponsored, in conjunction with the University of British Columbia, a competition for essays on an engineering subject. The first prize was awarded to **Gerald Gatz**, *Engineering I, U.B.C., for his essay, "One Hundred Years of Engineering in British Columbia". The text of this interesting contribution from an engineering student is published here.*

WITH THE cry of gold echoing across the western frontier in 1858, the watersheds seethed, not only with glistening torrents, but with humanity as well. A letter to James Douglas, Chief Factor of the Hudson's Bay Company and future Governor of the Colony of British Columbia, was to indicate the beginning of engineering in this province. Sir Edward Bulwer-Lytton, England's Secretary of State for the Colonies, wrote that he was sending an officer of Royal Engineers and a company of 150 men.

> It will devolve upon them (he wrote) to survey those parts of the country which may be most suitable for settlement, to mark out allotments of land for public purposes, to suggest a site for the seat of Government, to point out where roads should be made, and to render you such assistance as may be in their power . . .

In October 1858, Lytton wrote again to Douglas saying why Engineers had been chosen.

> The superior intelligence and discipline of this force, which afford ground for expecting that they will be far less likely than ordinary soldiers of the line to yield to the temptation to desertion offered by the goldfields, and their capacity at once to provide for themselves in a country without habitation, appear to me to render them especially suited for this duty; whilst their services as pioneers in the work of civilisation, in opening up the resources of the country, by the construction of roads and bridges, in laying the foundations of a future city or seaport, and in carrying out the numerous engineering works which in the earlier stages of colonisation are so essential to the progress and welfare of the community, they will . . . establish themselves in the popular good-will of the emigrants by the civil benefits it will be in the regular nature of their occupation to confer.

Lytton made a good choice. In the short period of five years, the accomplishments of this little band of men were staggering.

This detachment of Royal Engineers was a versatile body. They were not long at sea before editions of *The Emigrant Soldiers' Gazette and Cape Horn Chronicle* were distributed throughout the vessel—"published at the Editor's Office, Starboard Front Cabin, *Thames City.*" The spirited paper contained good poetry, short stories, puzzles and items of interest to all on board. The publication was later undertaken by John Robson of New Westminster.

On land, the corps' industriousness created a swirl of activity. Organization, construction, expansion, these were not dreams; they were facts! The new capital of New Westminster was laid out; wagon roads appeared; the towns of Hope and Yale were surveyed; sites at Clinton and Quesnel were cleared; and by 1860, mills were seen on the lower Fraser. The birth of British Columbia's valuable lumber trade took place. Fort Victoria, on the nearby Colony of Vancouver Island, would not be outdone. Here it was that the Phoenix Brewing Company first laid foundation. Shipbuilding was taking place at Esquimalt.

One finds that most of the important tasks in the colony were performed by the Engineers. They published the first maps; they established a systematic meteorological service; they erected the first churches; they helped locate the forty-ninth parallel. They built the first mint. The Royal Columbian Hospital owes its existence to this force. If for no other reason, the people of this province became indebted to them when their Colonel, Richard C. Moody, set aside, as a military reserve, what was to become known as Stanley Park.

In 1865, two years after the dispersion of the Royal Engineers, the Cariboo wagon road was completed. This was the year that the news of Lincoln's assassination buzzed across the territory. Telegraph poles were becoming familiar sights along the right of way. In six more years the colonists on the Pacific Slope would begin a lonesome vigil for a through railroad from the East.

Eight years of waiting, then old mining camps, camps that had been stilled by the swift depletion of surface gold, sprang to life again. Railroad men appeared. Through the Fraser Canyon, fills and cuts were made, tunnels bored. Bridge and trestle came into view. "No such mountain work had ever been attempted in Canada before," said H. J. Cambie, one of the engineers. Near Revelstoke, at Craigellachie, on November 7, 1885, east met west, and the last spike was driven.

At the turn of the century, the rush to the Klondike indicated a need for improved communication. Telegraph lines reached Dawson Creek. This success was in keeping with the times, for Vancouver Island was now linked to Australia by trans-oceanic cable. Rail development again demanded public attention. Two years before the first World War, plans

The Consolidated Mining and Smelting Company's smelter and metallurgical works at Trail, as it appeared in 1949. *Provincial Archives*

were laid for the Pacific Great Eastern to link Squamish, Quesnel and Prince George. The Kettle Valley line of the Canadian Pacific Railway was conceived. This line is now famous for its high trestles through the Coquihalla Pass, masterpieces of engineering.

By 1927, highway construction had replaced railroad building. The Cariboo Highway, completed by the Provincial Government, is only one example of work done at this time. The old Colonial government's wagon road, started by the Royal Engineers, had been destroyed during the period of railway construction, and a new highway to the interior was necessary.

The completion of the Panama Canal stimulated industry, but only by the tireless efforts of science and engineering were new processes introduced. When the Provincial Engineering Acts were passed in the year 1920, tighter control was gained on design and function of engineering operations. Safer and more efficient methods were imminent. A far greater degree of protection to public and to industry was in prospect.

Hydro-electric stations were feeding "white-coal" to the greedy mines and mills. During this era, "Knewstubb of Nechako", chief hydraulic engineer of the Department of Lands, discovered the vast power potential of the chain of lakes at the source of the Nechako River. He envisioned a 2,850 foot drop to the sea by great amounts of water diverted through the Coast Range. Twenty years would pass before the Aluminum Company of Canada would begin to harness this large resource. Knewstubb's discovery will ultimately become one of the world's largest privately - financed power projects, producing close to two million horsepower.

Wartime demands once again directed intensive research efforts. At Trail, the Consolidated Mining and Smelting Company's scientists and engineers worked around the clock improving metallurgical processes. New industries appeared on the horizon almost overnight. Old ones expanded. Shipbuilding received a boost. Petroleum refining obtained prominence. British Columbia airports demanded prestige. At the end of the conflict, engineers did not become idle. New consumer goods had to go on the market.

With the view of making more and cheaper electricity available, the British Columbia Power Commission was organized in 1945. The John Hart project at Campbell River was soon developed. Conductors, supported by steel towers one-sixth of a mile apart, transmitted energy southward as far as Victoria.

Private enterprise felt no restraint. Projects of the British Columbia Electric Company are known the world over. The Bridge River development is one of the most recent and most gigantic. Its power capacity made practical the erecting of one of the world's longest overhead cable-crossings, on the Powell River transmission line, a 10,100 foot span over Jervis Inlet. The unique submarine cable, now supplying 12,000 kilowatts at 130,000 volts to Vancouver Island, was so large an undertaking that British Insulated Callender's Cables Limited, of Manchester, had to rebuild part of their factory in order to produce continuous lengths up to seventeen miles. According to Thomas Ingledow, vice-president and executive engineer for the British Columbia Electric Company, "It is a milestone in the history of engineering." The investment that this company has made in developing water power is again indicated by the Cheakamus development, designed as the world's largest remotely-controlled hydro-electric plant — 140,000 kilowatts "put on the line" in 1957. The confidence that this company has in the economy of the province is signified by a proposed 1958 budget of $98,600,000, designed for construction and improvements. For communication, the B.C. Electric turns to the British Columbia Telephone Company for a subscription of over 1000 locals.

Tremendous advances in the field of communications is evidenced by the micro-wave radio relay network now being installed for the Northwest Telephone Company. From reports, this company's mountain cable car was as thrilling to build as it is to ride.

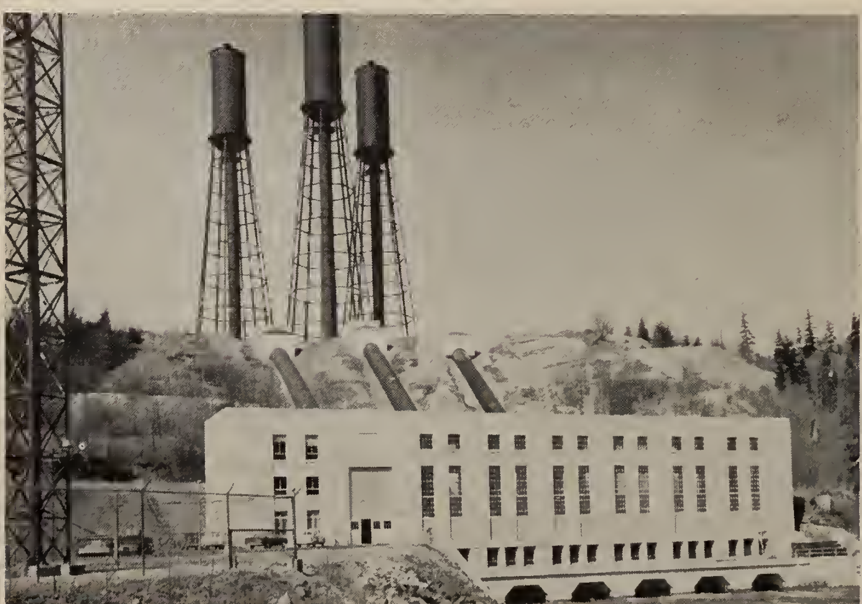
Projects like the Deas Island tunnel, the completion of the Pacific Great Eastern Railway from Squamish to Vancouver and from Quesnel to Prince George, the Upper Levels Highway from West Vancouver to Horseshoe Bay, are part of our daily conversations. The Granville Street and Oak Street bridges are no less to be admired than the Lions Gate, an engineering wonder of twenty years ago.

The controversial Rocky Mountain Trench concept could develop four million horsepower, say engineers of the British Thompson-Houston Company. Whether or not this dream will develop to its conceived conclusion remains to be seen.

Regardless, the province's industries will continue to utilize the abilities of many engineers graduating from the University of British Columbia's engineering faculties. Might it be said of them in years to come, as it has been said of engineers in the past,

> They have made their mark, and it will be seen by future generations, whether in throwing a pathway across a foaming torrent or in cutting a highway through the towering mountains of everlasting rock.

The John Hart Power Plant, Campbell River, B.C.



ENGINEERING BRITISH COLUMBIA'S FORESTS

R. G. McKee

IN THIS, British Columbia's Centennial Year, there is a general sense and appreciation of history and its significance abroad in the land.

As more and more of this Province's past unrolls, via all types of communication media, the place of the forests and their impact on and control of the social and economic development of Canada's third largest province, becomes increasingly noticeable. No one group, however, is more intimately involved in this pattern of evolution than is the Provincial Forest Service, charged as it is with the administration, in the general public interest, of the most vital single natural resource in British Columbia—its 200,000 square miles of forest land.

British Columbia had a rough and rowdy birth. Yet, coincidental with the influx of the rough gold-seeking transient population, were the true settlers who had made the tortuous trip around the Horn to carve a new and better life in this forbidding land. It was this group, whose efforts gradually began to turn the tide towards stability and respectability and the development of one of the world's most spectacular industries.

Far back in British Columbia's forest history, it is recorded that it was Captain James Cook, who became B.C.'s first white-skinned logger, as a result of his decision to refit his two ships *Resolution* and *Discovery* in the shelter of Nootka Sound, on the West Coast of Vancouver Island, in March, 1778. Cook's seamen went ashore and for four weeks busied themselves fashioning and fitting new spars and masts. Subsequently, it became common practice through the years for many of the trading and exploration ships operating in what are now British Columbia waters to refit in a similar manner.

None of these uses of Douglas fir was, in a true sense, a commercial use. However, this was soon to come.

In the words of the Honourable Gordon McG. Sloan, when Chief Justice of British Columbia and acting as Royal Commissioner on Forestry in 1956 ". . . the earliest explorers and pioneer settlers found in this Province vast and seemingly limitless forested areas, in greater part composed of tall and lordly trees . . . The first reported commerce in timber was in 1788. In that year Captain John Meares loaded a vessel with furs and a deck-load of spars for the China trade."

Although these and other historical events are interesting, they bear little real relationship to the sequence of forest administration development which started, in a small way, to take shape about 1865.

This was the year before the Mainland of B.C. and Vancouver Island joined together to become the Crown Colony of British Columbia. Prior to this period, forest lands were widely regarded in the public mind as of little or no value, possibly because there appeared to be so much of it. Timber lands could be acquired by outright purchase and Crown grant in the same way as any other Crown Land, and for the same price. The land was the thing—the timber, a bit of a hindrance.

However, the Land Ordinance of

*An article prepared by the Public Information & Education Division, B.C. Forest Service. Provided through the courtesy of R. G. McKee, Deputy Minister, B.C. Forest Service.

1865, introduced for the first time the system of selling timber cutting rights on Crown land without alienating the land itself. This was the important precedent that has established an over-all public control over the vast majority of forest land in British Columbia that obtains to the present day when some 92 per cent of productive forest acreage is held by the Crown. It was, of course, also the first step towards placing almost the entire responsibility for managing the forests on the shoulders of the Crown.

The intent behind this move was undoubtedly to gain Crown Revenue and promote the establishment of a forest industry, but it was not accepted without question.

To quote again from Hon. Mr. Sloan's Royal Commission Report:

"In the following years, cutting rights took various forms and were subject to varied conditions. It was an uneven and somewhat complex development, motivated by conditions thought impelling at the time these various forms of tenure were devised. To conclude that the earlier settlers, who had a hand in framing the forest laws and policies of those days, were, in so doing, deliberately thinking in terms of generations ahead is, I think, with respect, to attribute to them an unwarranted prescience. Early administrations were, in my view, motivated by the immediate objectives important to the era in which they lived. They were confronted with the critical necessity of obtaining Crown revenue and of finding means to encourage the utilization of forest products. The developing pattern of Crown ownership was the consequential result and not the design of their pioneering policies."

—and thus, the early stage was set.

It is interesting to note that the next major developments in forest administration in the province arose out of public horror over forest-fire losses. Early in this century, the province suffered from a terrible scourge of forest fires, not uncommonly of incendiary origin. The matter finally came to a head in 1909 when the city of Fernie, B.C., was wiped out by a forest fire. This resulted in the appointment of the first Royal Commission on Forestry in this province under the Hon. F. J. Fulton. A year later the Commission reported, and one of their principal recommendations resulted in the enactment of the "Forest Act", which in turn provided for establishment of the Provincial Forest Branch of the Department of Lands in 1912.

The original Forest Branch was primarily a fire-fighting agency with a modicum of staff and even less in the way of funds. It also had the responsibility of disposing of Crown timber through timber sales and collecting the Stumpage and Royalty fees for the Crown.

As is so often the case, when wise and dedicated men are needed, they seem to appear. Fortunately for British Columbia's future development, they appeared at this juncture and it was not too many years before their counsel on the wider implications of forest administration and conservation began to become manifest through law.

This trend towards greater understanding and appreciation of the absolutely vital role of the forests in British Columbia's daily economic life was underlined by a second Royal Commission in 1945. This has been followed by the 1956 Royal Commission, both under the Hon. Gordon McG. Sloan, now Forestry Advisor to the Government of British Columbia.

These Commissions, plus periodic heavy fire seasons and the passage of the industry from oxen to horsepower, through steam power to the present-day Diesel, with a parallel expansion of world export trade, brings us through economic depressions and booms, and two World Wars, to the massive but diversified and vastly complicated economic structure that constitutes the forest industry of today.

The giant that is the forest industry in 1958 is worthy of consideration if one is to gain any kind of a true appreciation of the administrative problems of the Forest Service. Firstly, it is a giant with a dual personality divided roughly into a massive, more or less, rigid Coastal industry accounting for approximately 65 per cent of the total annual cut, and the smaller, more fluid, somewhat seasonal Interior industry. Some 70,000 persons are directly employed in the forest industries of the Province and 40 cents of every dollar in circulation within the Province has its origin in the forests. Of Canada's total net value of forest industry production, 66 per cent originates in British Columbia. Over 60 per cent of all lumber produced in Canada comes from this Province. The annual cut in B.C. amounts to 5.6 billion board feet and the estimated value of production has averaged over $500,000,000 per year for the last decade with a peak yearly value of $631,000,000, in 1955.

The administrator is concerned not only with the maintenance of the industry in a vigorous and healthy state, but must also be keenly aware of the effect such a massive industry has had, is having, and is likely to have on the welfare of the prime resource itself.

It is generally agreed that this

Portable Spar Tree used in coastal B.C. operations is now being widely used. Goose-neck loader lifts logs on to trucks after they are yarded in by spar tree.

Province is richly endowed with some of the finest large forests in the British Commonwealth. Latest survey and inventory figures gathered over the past 7 years assisted in part by the Federal Government under the terms of the "Canada Forestry Act", provide the basis for a comprehensive assessment of the dimensions of this resource.

The following are some of these facts:—there are 118 million acres of commercial forest in British Columbia carrying 306 billion cubic feet of sound wood; the net annual growth amounts to 2.3 billion cubic feet; 2.2 billion cubic feet are lost each year through fire, insects, disease, and other factors.

These gross figures give an idea of the size of the problem, but not of the complexity of management.

A loaded truck leaving the 260,000-acre Willow River sustained yield unit over a forest development road. *B.C. Forest Service*

A resource is only a resource when it can be utilized to the benefit of man. So, in the matter of forest management, one must consider the key factor of accessibility. An accessible forest is considered to be one that can be harvested commercially at a fair profit at any particular time. This means that accessibility is not only related to topography and physical availability of markets, but also to the market prices themselves.

It stands to reason that when log and lumber prices are good, the operators can afford to go further from the market for their raw products, which has the effect of increasing the accessible wood supply. As the market drops generally, or in connection with specific species, the periphery of accessible supplies is automatically reduced. Thus, the operator is forced to return to those areas where logging has been going on for many years. Sometimes he finds insufficient timber available to support this investment. Sometimes he finds just sufficient to keep in business in the hopes that the market will improve and allow him to venture further afield. In this latter case, which was becoming more and more common a decade ago, increasing pressure is brought to bear on a small proportion of the productive forest area. Regional overcutting can easily develop under such circumstances and the annual harvest greatly exceed the ability of the forest estate to produce. This is one of the administrator's greatest problems and has brought about the spectacular shift from a straight cut-it-where-you-can-and-get-out philosophy, to a point where almost 50 per cent of British Columbia's annual forest harvest originates on land operated under some system of sustained-yield forestry.

Table I. Estimated Value of Production, Including Loading and Freight within the Province, 1948–57

Product	1948	1949	1950	1951	1952	1953	1954	1955	1956	1957	Ten-year Average, 1948–57

In addition to 694,119 tons of pulp manufactured into paper in the Province, 605,984 tons were shipped out of the Province during the year.

This then, the story of sustained-yield forestry and the attempts to overcome the imbalance problems with their regional overcuts while other good forest stands remain untouched, is the forest story of the Centennial Year in British Columbia.

There are four principal vehicles by which forests in British Columbia may come under sustained-yield management designed to ensure the continuance of a regular forest harvest from such areas forever. The largest acreage is managed by the Forest Service as "sustained-yield units". Second is the programme of co-operative management, whereby an operator accepts the responsibility of managing specified Crown lands in conjunction with his own holdings. The owner of forest land is also encouraged to practice sustained-yield forestry through tax concessions under the "Taxation Act". Finally, are the farm woodlots which are designed to provide employment for the farmer and his equipment in off-seasons.

Although each of these four types have different administrative techniques and mechanics, they all have a common goal—the securing of the forest crop for the future and the resultant increase in permancy to the industry as a whole and dependent communities in particular.

Probably the fundamental difference between the types of sustained-yield operations is that tree farm licences, tree farms, and farm woodlots, are operated by private companies or citizens under Forest Service supervision, while the sustained-yield units are planned and developed by the Forest Service, and the timber put up for competitive bid at public auction.

As at 31 December, 1957, there were 58 sustained-yield units covering 29,277,000 acres of productive forest land with an annual allowable cut of 334,440,000 cubic feet; twenty-three tree farm licences covering 4,858,000 acres with an annual cut of 191,272,000 cubic feet; a total of 70 tree farms and farm woodlots with a combined productive area of 541,800 acres yielding 26,608,000 cubic feet per year. In all, over 34,000,000 acres of productive forest land were under sustained yield management capable of producing a continual crop of 551,000,000 cubic feet per year—about 50 per cent of the current provincial cut. These totals have increased somewhat in the interim.

The tree farm licensee is required to manage both his own and the Crown land allotted in accordance with the principles of sustained-yield, and no other reason or object is considered sufficiently important to warrant the issuance of a licence. At any time the licensee can lose his deposit or even his licence and investment if it can be shown the operation as carried out is breaching the contract provisions.

The sustained-yield units have precisely the same objective as the tree farm licence but, where the latter is managed by a company, the former is managed by the Forest Service.

A method of log transportation on the B.C. coast is by self-dumping barges. By flooding tanks on one side, the barges heel over and dump their load.

A sustained-yield unit is a manufacturing plant producing wood in the form of trees. One of the first things the administrator has to determine is the amount of wood that will be produced annually in perpetuity. This is the annual allowable cut and before it can be calculated, as complete a picture as possible of the resources must be available. Then the forest manager must decide on the method of harvesting and type of management; e.g., what stands are to be managed as uneven-aged or as even-aged and what stands are to be clean-cut or partially cut?

On the Coast, most forests are managed as even-aged stands and are logged on a clear-cut basis. The formula most commonly used on the Coast is one proposed by Mr. E. Hanzlick which states that if the old growth timber is divided by the number of years it takes the timber to reach to maturity and added to that the growth per acre multiplied by the number of acres of immature growing stock, the answer is the annual allowable cut. Yet this answer, based as it is on present-day standards of utilization, is constantly subject to change. Indeed, as forest management becomes more intensive and widespread throughout the Province and as utilization standards increase as a result of products research and improved machinery, the annual allowable cut in any managed area should change in order to maintain maximum utilization of the resource.

Annual allowable cut is also further complicated by the effects of forest fires, disease, and insect attacks, and the rate of natural regeneration.

When it is considered that this type

Table III. Number of Acres Managed and Operated under Approved Working Plans, 1948-57

of close control is now required over some 35,000,000 acres, the magnitude of the administrator's task can be imagined.

Every facility of the Forest Service is committed to a greater or lesser extent to make this sustained-yield programme work. The Research, Working Plans, Management, Protection, Reforestation Divisions and, to possibly the most spectacular extent, the Engineering Services Division, continuously labour to make B.C.'s forest future secure.

The engineers have come into their own in the planning and execution of the details that are involved in forest management and possibly more than any other profession personify the "new look" in British Columbia's forests.

With the advent to sustained-yield forest management, access roads became one of the first and primary concerns of forest administration. The Government has, therefore, undertaken the construction of forest development roads in the sustained-yield units to facilitate sound forest management practice in these areas and to make large tracts of inaccessible timber available for operators.

One task of the Engineering Services Division is to locate, design, and supervise the construction or construct these forest development roads. In addition to the access road programme, the Division supplies a large part of the engineering knowledge required for numerous phases of Forest Service administration. It works in close co-operation with the Timber Management Division, for instance, in locating roads for large timber sales. Other forest engineering problems on timber sales are investigated for Management Division and District personnel. The "Design" section assists with the design and construction of buildings and structures requiring engineering as well as architectural knowledge. Construction crews of the Division, under the direction of the engineers, from time to time perform a variety of tasks for the Districts and other Divisions ranging from the driving of a few foundation piles to a water system involving a small dam and a complicated distribution system. Forest development roads vary from public highways for a number of reasons.

(1) They are constructed for the purpose of making an area accessible for the management of the forest, not for the public to travel between localities. The traffic is largely of a specialized nature concerned with the utilization, protection, improvement or general administration of the forest. The volume of traffic can be calculated from known factors, particularly the annual field of forest products.

(2) They are designed and located to various standards according to the volume of timber and the quality of the site in each part of the forest and in conjunction with the most efficient utilization plan. By contrast the location and standard of a public road is determined largely by the position and size of settlements and the shortest route between them.

(3) They are designed as haul roads (adverse grades are designed on the basis of hauling cost and construction cost).

(4) They are designed for use by experienced truck drivers (minimum width and visibility as determined from construction costs and the traffic volume).

(5) They are constructed as permanent roads for a definite traffic volume which will increase very little. The roads will not be reconstructed every 20 or 30 years as are public highways where the traffic volume increases steadily and reconstruction is necessary.

(6) The standard of road is determined from the calculated traffic volume and hauling cost so as to give the lowest transportation cost for the forest product (that is the smallest sum of amortization charge, maintenance cost and hauling cost).

(7) The capital cost is amortized over an economic period comparable to that used by industry to determine the feasibility of each project; based on the average utilization costs for the region.

(8) The amortization charge is computed on the unit of measurement of the forest products to be hauled, and must not exceed the average cost per unit on local timber sales, that is, the cost in private competitive business practice. It is possible to construct permanent roads, on which forest products can be hauled more cheaply for the same cost that some operators are now building poor temporary roads.

(9) The cost of the road to the Crown will be repaid by the increased value of the timber.

Since 1950, the Engineering Services Division has completed construction of well over 153 miles of development road, has located another 350 miles and carried out reconnaissance on 700 miles of possible routes.

All this engineering of British Columbia's forests is directed towards correcting an historic imbalance and unhealthy concentration of industry in the easily accessible areas. The small and medium sized operator now gets a chance to find and log new timber supplies by using Government-constructed access roads.

No one with any understanding of the situation could possibly say that the sustained yield job is finished in B.C. It is far from finished. As a matter of fact it will probably never be finished — it is a continuous job. Nonetheless in the past 10 years, more, far more has been done towards securing the forest future of the Province than in the previous century. If we can continue towards our goal over the next decade without too many setbacks, one of the prime forest areas of the western world will have been converted to one massive sustained-yield unit for the betterment of industry and the nation as a whole.

THE MINERAL INDUSTRY AND B.C.

Dr. Hartley Sargent *

THE PRESENT year is the 100th anniversary of the establishment of the mainland colony named British Columbia, in 1858. Administrative needs arising from a great rush for placer gold occasioned the establishment of the colony. The colony of Vancouver Island, created in 1849 continued its separate existence. The gold rush and its consequences resulted in the union of the two colonies in 1866, the extension of the area to that of the present province, and in 1871 the entrance of British Columbia into confederation as a province of the Dominion of Canada.

Before the gold rush, the area had a history of exploration and fur trade and on Vancouver Island and near Fort Langley of some agricultural and commercial developments. This background of experience in a rugged and difficult country cannot be overlooked in considering the era of expansion that began with the gold rush. The early history of these developments is reviewed on pages 00 to 00.

The Treaty of Washington, in 1846, settled the boundary as the 49th parallel on the mainland, thus giving to the United States much of the Columbia River including the part that had been most useful to the fur brigades. Although the right to navigate the river was preserved to the Hudson's Bay Company, that right was not exercised for long. War between the United States and the Indians in 1848 forced the Company to find an alternative route to its interior posts, and to transfer its main depot and headquarters to Victoria which had been established in 1843 in anticipation of the boundary settlement. The Fraser Canyon route between the newly established Fort Yale and the interior was attempted in 1848. Fort Yale was abandoned in 1849, and a less difficult route was adopted from Fort Hope through the Cascade Mountains to Fort Thompson (Kamloops). When thirst for placer gold brought thousands of eager adventurers into the area in 1858, knowledge won in 50 years of supplying interior trading posts was available to prospectors and administrators.

Lower Tunnel Georgia Mine, Rossland, B.C., before 1897.

*Chief of the Mineralogical Branch, British Columbia Department of Mines.

The twenty years preceding the gold rush saw the beginning of agriculture near Fort Langley and Victoria, the establishment of a fishing industry that shipped dried salmon up the coast and as far as the Hawaiian Islands, the beginning of coal mining* with shipments from Nanaimo to San Francisco and short lived efforts at lode-gold mining on Moresby Island in the Queen Charlotte Group. The development of commerce in the coastal area was in marked contrast with the activities in New Caledonia, where horse and canoe transportation limited activities to satisfying the most pressing needs of the fur trade, and serves to emphasize the importance of transportation then and now in British Columbia.

It is curious that in a period of some forty years in which much of the country had been traversed by fur traders no search seems to have been made for placer gold, and that within ten years of the gold rush in California, a gold rush was on in British Columbia. Possibly the recovery of a small quantity of gold on the Moresby Island in 1851, and the discovery of a small gold bearing vein there in 1852 drew attention to possibilities in British Columbia. Probably the first discovery of placer gold in British Columbia was made in 1855 on the Columbia River just north of the 49th parallel. In 1856 discoveries were reported near Fort Hope and on the Thompson River, and these precipitated the first and greatest gold rush. Because of increasing interest noted in placer gold in 1857, James Douglas, Governor of Vancouver Island and head of the Hudson's Bay Company on the Pacific Coast, anticipated a rush the following year, and assumed authority to regulate mining activities on the mainland. An inrush of gold seekers from Puget Sound began early in 1858. Others came by ship from California in thousands. By the end of July 15,000 people and perhaps some thousands more had entered the area in which the total white population had numbered a few hundred.

The gold seekers made their way from Esquimalt via Victoria to the mainland and up the Fraser River to Yale by boats they had built, or by ship as far as the river mouth, and by two American river boats authorized by Douglas to operate on the River.

After a disappointing period while workable gravels were limited by highwater, the bars exposed by falling water were worked and yielded fine gold in quantity sufficient to maintain interest and encourage search for other diggings. Bar after bar was found to pay and the miners pushed up the forbidding river at an amazing rate. The fact that some had

*Traffic in coal began in 1835, with coal recovered from the beach at Suquash on the northeast coast of Vancouver Island but it was not until 1852 at Nanaimo that a viable coal mining industry was established.

reached the Chilcotin River by July suggests that they had by-passed the canyons and reached the river upstream from the Thompson. By May 1859 the Quesnel River was reached and miners following up that river found it more rewarding than the Fraser. Keithley Creek, a tributary of the Quesnel, was found in 1860 and the search was carried over the divide and past the head of Cunningham Creek to Antler Creek. In 1861 Williams Creek, the most fabulous in the Cariboo, was discovered. The richness of that area caused a revival of the Cariboo rush, drawing miners from competing areas in British Columbia and from far parts of the world. Shallow diggings on upper Williams Creek were followed by deep diggings lower on the creek, the first successful shaft being sunk by Billy Barker for whom Barkerville was named.

We cannot trace the course of placer mining including frequent short lived booms or rushes in which easily won gold was worked out in many parts of the province, leaving deeper ground to be worked by those who could find the money necessary for costly hydraulic installations and poorer shallow ground to be worked by patient Chinese miners. In one hundred years placer mining has recovered gold valued at almost $96,000,000 of which almost a half was recovered in the first 25 years. Placer mining played a part in the development of British Columbia of which the importance cannot be approximated by taking the value of the gold recovered. In a year it increased the white population of British Columbia from a few hundred to more than 15,000 and in a few years forced the construction of roads and trails and on inland waters the construction of steamers, in feverish haste, in contrast with the leisurely fur trade that in 50 years had gained much knowledge of the country but had left it almost unchanged except for the establishment of scattered posts, and the beginnings of settlement on Vancouver Island and the lower Fraser.

Provincial Archives.

The Victoria shaft and ore bins of the Granby Company, Phoenix, (1907).

The hope of quick wealth and the high unit value of the product encouraged men to undertake placer mining in spite of the lack of transportation facilities necessary for almost any other activity. Consequently although many lode discoveries were made in the years following the early placer mining boom, substantial lode mining did not develop until facilities had been established to permit bringing in machinery required by mines and smelters to convey ore from the mines to smelters, to transport the necessary supplies, including coke required in large volume by the smelters and finally to ship matte or metal for further processing or to its ultimate market.

The Heinze Smelter on the Columbia River at Trail Creek (1896).

Provincial Archives.

Lode mining developed rapidly in the era of railway building and in turn stimulated the construction of branch railway lines. Kimberley, Nelson, Trail, Rossland, Grand Forks, Greenwood and small communities in the southern interior were established because of the opening of gold-copper, and silver-lead mines in the southern interior, and of smelters to treat their ores. The need of the smelters for coke and of the railroads for steam coal caused the opening of the Crowsnest Pass coalfield and the establishment of Fernie. Development of copper mines at Britannia, on Texada Island, Vancouver Island, and at Anyox, and the gold mines at Surf Inlet and Portland Canal followed the developments in the southern interior.

In the thirty years preceding World War I, lode metal production yielded gold, silver, copper, and lead in substantial volume; during the War production of zinc became important and subsequently other metals, either prime- or by-products, have been added to the list which also includes, or has included, iron, mercury, tungsten, antimony, bismuth, cadmium indium and tin. Much of the lead, zinc, silver, bismuth, and cadmium is refined at the Trail smelter of the Consolidated Mining and Smelting Company. Tin, copper, and iron, as ores and concentrates are exported to foreign smelters. Copper has been of great importance since early in the lode-mining history. Shutdowns in 1957 and early in 1958 have reduced the output of copper to the lowest level in sixty years. However, important supplies of copper ore have been indicated by work on recent discoveries and on deposits known for many years, and exploratory work is continuing.

Provincial Archives.

Placer miners on Williams Creek (1863).

Production of structural materials, mainly for the British Columbia market, includes,— cement, limestone, clay products, sand, gravel, and rock, with a combined value of more than $25,000,000 in 1957. The industrial minerals group includes half a dozen products but more than 85 per cent of the total value is in sulphur and asbestos. Until late in 1957 sulphur recovery was entirely a by-product of lode-metal mining. The sulphur has mainly been used in British Columbia in the production of fertilizer, chemical wood-pulp and in other chemical processes. Late in 1957 a large additional source of sulphur became available from the absorption plant at Taylor that removes sulphur from natural gas preparatory to shipment through the main pipeline. Asbestos production began in 1952 and reached a value of more than $9,000,000 for the year 1957. The asbestos comes from the McDame Creek area, not far from the Yukon boundary. Because of its high quality it commands a price that permits bearing the high transportation costs necessitated by the remote source and distant markets.

Coal production has been mainly from Vancouver Island and the Crowsnest Pass areas. The latter area, in the southeastern corner of the Province, has by far the largest deposits, and produces the best source of coking coal.

Monitors in a hydraulic placer pit, Atlin (1941).

B.C. Dept. of Mines.

Exploration continues to indicate increasing supplies of petroleum and natural gas in northeastern British Columbia. By the end of 1957, 22 oil wells and 130 gas wells had been completed. In the period 1942-1957 308 wells were drilled, of them 152 or almost 50 per cent, were completed as oil or gas wells.

Oil production began in 1956 and has gone to the X.L. Refinery of Dawson Creek. Gas production also began in 1956 to serve the village of Fort St. John. Construction of the Westcoast Transmission Company 30 inch pipeline to convey gas to southern British Columbia and to the international boundary was started late in 1955 and completed in 1957. The local gathering lines, and the absorption plant and sulphur recovery plant at Taylor came into use late in 1957. These facilities are now recovering liquid fractions and about 150 tons of sulphur a day in preparing gas. In British Columbia gas is supplied to the Vancouver area, Williams Lake, Kamloops, the Okanagan Valley, Trail and Nelson and also the Power Commission generating station at Prince George.

In 100 years British Columbia has produced minerals with a gross value of three billion nine hundred million dollars. By 1957 the list of products included a dozen metals, nine industrial minerals a dozen structural materials and three fuels. For the past ten years, the annual value has averaged $162,000,000 and it is apparent that despite reduced prices for important metals, and reduced output of several items, the accumulated gross value of mineral output will have passed the four billion dollar mark before the end of the centenary year.

HIGHWAYS IN BRITISH COLUMBIA

T. Miard M.E.I.C. Deputy Minister

BRITISH COLUMBIA has progressed far in its highway development since the day shortly after World War One, when an engineer said "We are now building roads 14 ft. wide—wide enough for this generation ,and the next!" Eight-lane divided highways are being designed and tenders will be called soon for the first stages of these multilane roads.

The Province has a difficult topography, in that it is crossed from north to south by all the mountain ranges of the Western Cordillera, while the majority of traffic wishes to move in an east and west direction. There are three main east-west routes. The Southern Trans Provincial Highway, which is close to the 49th parallel, and extends from Hope to the Crows Nest Pass. The Trans-Canada Highway which follows the Fraser River from Vancouver to Lytton, then east to Rogers Pass and the Kicking Horse Pass. The Northern Trans-Provincial Highway will cross the Province from Prince Rupert to Prince George, thence to McBride and the Yellowhead Pass.

A pioneer route from Kamloops up the North Thompson to the Yellowhead route is gradually being modernized.

The Province has a main north-south route, through the Okanagan to cross the Trans Canada at Kamloops, on to Cache Creek and north through the Cariboo to Prince George. The route continues north on the Hart Highway to join the Alaska Highway at Dawson Creek, and a new road is being constructed to replace the present route from Dawson Creek to the Alberta border.

This year Kitimat received its first road access and the first highway access to Squamish on Howe Sound was opened.

In the 1957-58 fiscal year, 247 miles of highway were constructed by contract and almost 24 million cubic yards of material were moved, including four million yards of rock. This was an increase over the previous year's total of 15.6 million, and the 6.7 million moved in 1955-56.

The B.C. Department of Highways, with headquarters at Victoria, divides the Province into four regions with a regional headquarters in each. These regions are divided into districts with thirty district offices. Duties are divided among the following headquarters' branches:

Location and design; construction (including paving); bridge; research and development (including traffic and testing); specifications and statistics; right-of-way; ferries; equipment; special projects.

The old Alexandria Suspension Bridge at Spuzzam.

Location and Design

The Location and Design Branch is responsible for reconnaissance, location survey and design for all major roads, and has done nearly all the Department's highway design, including major freeways under construction, or to be built in the immediate future.

It is interesting to note that in the last three or four years "800 miles" of topographic maps from aerial photographs have been used for location and design of highways. The larger portion of this mapping has been of the reconnaissance type with scales of 1″ = 1000′ or 1″ = 500′ with contour intervals at 20 ft. or 25 ft. A considerable amount of 1″ = 200′ and 1″ = 100′ 5-ft.-contour mapping has been used for location purposes. Fifty-eight miles of four-lane freeway have been designed on aerial mapping at a scale of 1″ = 100′ with 5-ft. contours, or 1″ = 50′ with 2-ft. contours. Considerable use is made of mosaics, photo lay-downs, and soils interpretation from aerial photos.

Construction and Paving

Thirty-four road contracts are in progress this year. At the end of the year, with the exception of 10 miles, the formidable Fraser Canyon will have been conquered by a Trans Canada standard highway. Of interest are two tunnels, 740 ft. and 950 ft. long, with an I.R. 17′1 from the springing line 8′9 above grade. They are lined with concrete and the roof sections are grouted.

The standard two-lane road section has a 24 ft. pavement with 10 ft. or 12 ft. shoulders.

One throughway currently being designed provides for an eight-lane divided roadway, while several sections of four-lane divided or separated highway are under construction.

On the Trans Canada the minimum thickness of base-course is 12 inches (6 in. of 2 in. crush and 6. in. of ¾ in. crush).

Paving is usually covered by a separate contract, but some current grading contracts require that the contractor pulvi-mix or road-mix the top of the base course, to prevent loss of gravel and to provide a smooth dust-free surface until paving is done.

The Department also operates two pulvi-mixing crews.

Paving on Trans Canada is designed to result in a 3-inch compacted thickness. On certain other highways a 2½-inch compacted pavement is laid.

The Department maintains a field laboratory on every paving project to design and control the mix, using the Marshall method.

The density is checked by core-drilling and this has resulted in extending the type of weather under which paving may be permitted. Satisfactory pavements have been obtained at temperatures as low as 26° F., and also in light rains.

Considerable success has been obtained with a new technique for seal-coating, using a lab design (based on the size of aggregate) for the amount of asphalt applied. A change in the gradation specifications permits adjustment for any size of aggregate.

Bridges

The topography of British Columbia produces turbulent and tremendous streams and rivers, and bridge crossings are a major problem.

A program was commenced about twelve years ago to replace all major bridges with permanent structures.

The Department, for economy purposes, uses a standard steel through truss for spans from 150 ft. to 250 ft. It also has standard steel beam concrete deck spans up to 70 ft in length.

The Department designed the first prestressed concrete bridge in Canada for the crossing of Mosquito Creek in North Vancouver. It also designed one of the first solid-slab post tensioned, prestressed, concrete spans for the Royal Avenue overpass in New Westminster.

Major bridges of interest in British Columbia include the Rock Creek Bridge, designed by the Department, a continuous cantilever of total length 938 ft., with the roadway 300 ft. above the creek.

The Agassiz-Rosedale Bridge, a major crossing of the Fraser, 6,127 ft. long, which cost 4.5 million dollars.

The Nine Mile Canyon Bridge, a 3-hinged arch of overall length 786 ft. with arch span 480 ft., height above the creek 360 ft.; opened 1958; cost 1.2 million dollars.

The Nelson Toll Bridge, designed by A. B. Sanderson Company, has a length of 2,062 ft., the two main piers being in water 80 ft. deep. The cost was 3.75 million dollars.

The Kelowna Toll Bridge, designed by Swan, Wooster and Partners, comprised of 2100 ft. of floating pontoon bridge, two articulated steel trusses 175 ft. long and a 260 ft. steel lift span; total length of approach causeways 1500 ft. The cost 7.3 million dollars.

The Hope-Princeton Highway, Skagit Bluffs.

The Oak Street Toll Bridge, designed by Phillips and Barratt, a four-lane high level roadway over the North Arm of the Fraser River, with connections at the south end to the Sea Island (Vancouver) Airport, and to the new freeway to the United States Border.

The Bridge Department has designed 10 ft. x 20 ft. rigid frame reinforced concrete culverts for use under deep fills 100 ft. or higher.

British Columbia is a Province of forests, and treated timber is being used for bridges built on secondary roads. Pioneering is being done on glulam construction.

Deas Island Tunnel

The outstanding feat in highway work in British Columbia this year is the construction of the Deas Tunnel, a 4-lane traffic artery under the south or main ship channel of the Fraser River.

Six reinforced concrete tunnel elements, each 344 ft. long, 78 ft. wide and 24 ft. high were constructed in a drydock, sealed and floated out, and lowered into a dredged trench.

The ramp to ramp length is 4,360 feet and the portal to portal distance 2,155 ft.

Ferries

Due to the number of large rivers and lakes, on many highways it has been necessary to carry traffic over the water by ferry. Many of the Coastal Islands, particularly in the Gulf of Georgia, are attractive residential and resort areas, and traffic is ferried to most of them.

Many of the operations are extensive. The ferry across Okanagan Lake, which was replaced by a mile-long causeway and bridge on July 19th, operated three ferries continuously of 30-38 car capacity.

The largest Government-owned ferry is the M. V. *Anscomb*, which carries forty cars on its 5½ mile run across Kootenay Lake. It is a conventional ferry, while its sister-ship the 36-car M.V. *Balfour* is a barge-type, powered by "outboard" type motors.

On the inland lakes and rivers, the Department operates seven Government-owned toll ferries, 33 free ferries, two chartered ferries, and one aerial ferry to carry cars across the Fraser Canyon at North Bay. On salt water, eight out of nine ferries operated are chartered.

The Toll authority has called for tenders for two sea-going ferries to operate between the Saanish Peninsula on Vancouver Island and the

Mainland. Each will carry 108 cars, and will be 330 ft. long with a 74 ft. beam and will be propelled by two 3,000 b.h.p. engines at 18 knots.

Materials Testing

The Testing Branch has advanced from its origin in 1948 to become a large and important factor in the Department. Its functions include soil analysis, materials testing, design of road subgrade, design of pavement thickness, control of land slides, which are large and numerous in both the mountainous and flat areas, deep soil investigation, establishing the bearing capacity of soils for bridge foundations, design of concrete mixes, interpretation of aerial photos, interpretation of geological investigations and investigation of granular deposits.

Current research on pavement includes Benkelman beam tests at all seasons, plate bearing, soil and pavement tests.

Temperature and moisture profiles are being studied to investigate the relationship of soil type, moisture, frost penetrations, and spring thaw loss of bearing strength.

The southern part of the Province is predominantly granular, and glacial tills; the central part is lake silts and varved clays, while the northern part is heavy clays.

Problems arise with slides, soft subgrades not preconsolidated, and extremely low strength silts. Some bridge foundations are difficult, due to the great depths of soft clays in the Fraser Valley and the western fiords.

Most of the gravels are excellent, except in the northern part of the Province where lake deposits have covered natural ones and where, ironically, gravel is most needed.

Traffic Branch

The Traffic Branch directs all traffic, origin and destination surveys; predicts traffic requirements, assists in design of freeways, designs and directs all traffic control devices and intersection illumination. It operates 13 permanent weigh scales (four continuously) and two roving scale patrols, bridge traffic patrols, the Department sign shop and the striping units.

The senior traffic engineer acts on planning committees and safety committees.

Right-of-Way

The Department's Right-of-Way Branch assesses all properties required, makes title searches, negotiates the purchase and arranges disposal of surplus property. Formerly, right-of-way purchases were a small portion of a

Road construction near Alexandria Bridge (October 1957).

project cost, but in the case of freeways in the rich farmlands of the Fraser Delta, and in urban residential, commercial and industrial land, the cost of right-of-way may amount to 40% of the grading cost.

Classification of Roads

A large part of British Columbia is unorganized, and there the Department of Highways is responsible for all roads and streets, including construction and maintenance.

In the Municipalities, with the exception of the Cities of Vancouver, Victoria and New Westminster, through provincial highways are classified as arterial, and the Department assumes the full cost of them from curb to curb. Certain other through roads, or by-passes, may be classified as secondary. These are operated by the Municipality, but the Province pays 50% of construction costs and 40% of maintenance costs on a preapproved budget.

Maintenance

Maintenance is a continuing chore in British Columbia. The heavy rains are damaging to gravel road surfaces, and to shoulders and slopes of all roads. Extreme runoffs on the coast in the fall, and in the interior in the spring, require constant protection of roads and bridges. Severe frost and icing conditions, and heavy snowfalls require expenditures for snow removal and sanding as high as 3.5 million dollars in a single winter season.

The district crews are well equipped for both summer and winter maintenance, and for construction undertaken on a day-labour basis. Since the war, 4110 miles of road have been constructed or improved by District Forces.

The inventory includes 59 large tractors (D7 and larger); 83 small tractors; 61 tractor loaders; 53 power shovels; 614 dump trucks; 255 power graders; 170 sanders; 9 rotary tractor-mounted snow-plows and 12 snow plow trucks (plows are available for most of the larger trucks also); 39 tar kettles; 9 pulvi-mixers; 48 rollers; and 7 gravel-crushing plants.

Conclusion

Traffic is continually increasing in British Columbia. The motor vehicle registration has more than tripled since 1946, when 147,196 autos and commercial vehicles were listed. On January 31st, 1958, this figure had grown to 478,490.

The Pattullo Bridge (a 4-lane structure carrying the present Trans-Canada traffic into New Westminster) has recorded a volume of 53,983 for one day, with hourly volumes in one direction of 2700.

New areas are being developed, such as Kitimat, and the far north. Routes into Vancouver are becoming congested. The incidence of heavy axle loads is mounting. A continuing but rewarding task faces British Columbia's highway builders.

Summary of British Columbia Highways 31st July, 1958

	miles
Paved	3,520
Surface-treated	176
Base-processed	143
Gravelled	9,842
Dirt	7,653
Undeveloped, or cleared only	1,670
Total	23,004

PLANNING

THE KEY TO FUTURE POWER DEVELOPMENT

BRITISH Columbia's electrical power requirements today (July, 1958) are a little over 2 million kilowatts. Fifty years from now they will be close to 50 million.

British Columbia grew during the century following the advent of those who came to seek their individual fortunes. Many of them remained, pooled their resources and formed communities. These communities needed energy on a basis much larger than that of the prospector. Not until recent years has much thought been given to looking more than a few years into the future to see what energy needs might be.

The next 50 years will be within the life span of many of today's younger generation, who will be able to see the progress of long-range planning—that is, if long-range planning is adopted.

This sort of planning was actually started 15 years ago. The government set up a Rural Electrification Committee in 1943 to "report upon the extent and condition of electrical service in the Province of British Columbia with particular reference to the service in rural communities." Its findings include the following[1]:

> There is a close inter-dependent relationship between rural electrification and the central station industry established to supply cities, towns and villages.
>
> The large number of small separate organizations supplying electricity in the Province is a serious obstacle to a sound industry and extension of service.
>
> In the opinion of the Committee, a major reorganization of the central station industry is necessary not only that service may be extended in the rural areas but also that rates and service in towns, villages, and areas at present served may be improved.
>
> In the reorganization as many as possible of the present supply systems should be combined under one control which should have sufficient capital to carry out an extensive construction programme and to carry on the operation of the combined systems until they become self-sustaining.

These recommendations were without limitation, as was also the legislation which was enacted to put them into effect.

The intent of this report has been carried out under the Power Act, administered by the British Columbia Power Commission, by extending electrical service throughout the towns, villages and sparsely settled areas of the province, outside the metropolitan areas.

Now is the time to plan for B.C.'s growing requirements for electrical energy by extending the plan, which has already proved so successful.

Future Power Requirements

Figure 1 shows the province's estimated power requirements over the next 50 years—1958 to 2008.

The curve on the chart is based on an increase in demand of 6 per cent compounded annually with a base figure at the year 1975 somewhat lower than the province's estimate as submitted to the Royal Commission on Canada's Economic Prospects.

For the past several years, B.C.'s annual rate of growth in electric power requirements has averaged about 13 per cent, well above the national average of about 7 per cent. It is not expected that the rate of increase of 13 per cent will be sustained.

The 6 per cent rate is quite conservative compared to world averages. In the Gordon Commission's report "Canada's Energy Prospects," Dr. John Davis commented that[2]:

> In most countries (and regardless of their degree of industrialization) the demand for electricity will continue to rise at a long-run average rate approximating 7 per cent per annum; there is no statistical basis for the contention that, as power consumption increases, the rate at which it does so tends to decline.

Dr. Davis also said that the annual rates of growth in demand do not differ markedly between the economies which are now beginning and those, like Norway and Canada, which already use electricity intensively. In other words, we can expect our use of electricity to continue rising to match the trend of rising living standards and further advances in automation.

An official of the Tennessee Valley Authority recently said that average residential use, now 6,500 kwh. per year (almost double the Canadian average), may be 40,000 kwh. per year 25 years from now. This means that one would use as much electricity in a month as now in a year.

World consumption of primary energy has increased recently by 2½ per cent a year, while the consumption of electricity has increased by over 8 per cent a year.[3] Primary energy means the result of the first conversion of a raw material or resource into a form that can be employed in doing useful work. Examples are the conversion of water power into electricity, coal into steam, natural gas or oil into the mechanical force of a reciprocating engine. And so half the primary energy may be utilized as electricity by 1975. What may it be by the year 2008?

In Canada, electricity accounted for 15 per cent of total energy consumption in 1926; it was 24 per cent in 1955.[2] This trend would have been higher but for the huge energy source in Canada's oil and natural gas. The oil and gas industries have moved into the field of basic energy supply, and also provided raw materials for the multiplicity of synthetics, such as nylon and plastics. In the next century, people may say ". . . in the last century they actually used to burn oil.[4]"

Oil will continue to be faced with increasing demands, particularly in transportation. Perhaps before long the world will welcome the replacement of some of the uses for oil by nuclear energy, so that oil, a depleting resource, may assume a greater role as a source of raw materials.

Population

Increase in population alone is an important factor in the future growth and demand for electricity. Figure 2 is the curve of population in British Columbia projected to the year 2008. This was based partly on the prediction made for the Gordon Commission, but more directly on a study made by the B.C. Research Council[5] in which B.C.'s population was estimated to 1975.

The rate of increase in B.C. has been higher than for each of the other provinces and is assumed to continue so, even after 1975, at a rate slightly

---

Based on an address by C. W. Nash, M.E.I.C., Director of Load Development, B.C. Power Commission, to Hope and District Board of Trade, July, 1958 under 3 per cent per annum. This should be reasonable, keeping in mind undeveloped potential in raw materials, energy resources, seaports for rail and water trade, and the fact that B.C. is one part of the world that is becoming more and more attractive to live in. Some hold the opinion that the rate of population increase, and also the rate of increase in electrical demand, will share a marked decline after the next 20 or 30 years. This is unlikely in B.C. and there is every reason to assume that the growth of population in this province will reach a total of 8½ million persons by the end of the next half century.

This expanding population will continually increase the domestic market at the same time as we endeavour to improve our competitive position in world markets.

Per capita use of electricity

Figure 3 shows the relationship between the demand for electricity and population. Dividing one into the other gives the future trend of electricity demand *per capita.* This indicates an average demand of 5.6 kilowatts *per capita* by the end of this half century.

There are other ways of estimating this figure, but this gives us a comparison with estimates made by others. The Hydro-Electric Power Commission of Ontario made estimates of *per capita* increase of electrical demand for the Gordon Commission in 1956.[6] The results ranged from a long-term rate of growth of 4.85 per cent, based on population and capital projections, to zero, based on an assumption that there might be no future growth at all. The figure 4.85 per cent growth rate, presented in Ontario Hydro's graphic illustration, is the figure to be compared with the mean growth rate indicated by Fig. 3 (something less than 2½ per cent).

This comparison shows no extravagance in our estimate of future demands, rather, a possible underestimate.

Sources of Power Supply

Whatever the load growth, it must be met by some method or combination of methods. No one plan can be formulated now and be expected to hold good over the next century. But plans must be formulated on a long-range basis in the light of today's conditions and tomorrow's forecasts. They can then be continually brought up to date on actual experience.

How demand will be met depends upon the type of loads on the line, and on their individual and group characteristics. These include daily and annual load factors and the effects of different loads on system diversity. For example, a sawmill operating three shifts a day with a certain maximum load has three times as high a load factor as when it operates only one shift with the same maximum load. A pulp mill, or electrochemical plant which operates continuously seven days a week, has a much higher load factor than a sawmill. Diversity is the effect of a mill's maximum electrical demand being considerably less than the arithmetic sum of all the individual motor loads, because they are not all fully on the same time.

These factors, collectively, influence the type of operation of the generating plants supplying the load or system, and hence influence the selection of the type of power plant.

The types of power which may be employed to meet the growth are hydro, thermal (that is, the use of fuel such as coal, oil or gas to produce heat), or nuclear. As well as load factor and diversity, other factors influencing the selection of one or other, or all of these types are: capital cost, fuel cost, heat rate, transmission cost. The energy picture is essentially dynamic, varying constantly with time and economics. In one locality a hydro plant may be the best selection to supply a load, whereas in another a thermal plant may be the best choice to serve exactly the same kind of load.

In other words, no single, all-embracive formula can be established. Power systems must be tailor-made and custom-built.

The best overall answer is the system that will provide the greatest benefit to the most people for the longest time. The relative importance of the various means of generating power in B.C. is indicated by Table I, which shows recent proportions between hydro and thermal energy.

Top to bottom: Fig. 1, 2, 3.

(in kwh x 1000)

	Canada kwh	% Total Energy	British Columbia kwh	% Total Energy
Hydro	81,408,254	92.6	9,350,558	92.9
Thermal	6,530,677	7.4	719,778	7.1

Thermal

Coal is not a major source of energy in B.C., accounting for only about 15 per cent based on conversion to merchanical energy, and half that used is imported.[8] The railroads indicate the principal means if transportation which becomes a real factor in the delivered cost of fuel, if it is to be used in power plants remote from the coal fields. Consequently, transportation affects the final price of electrical energy. A coal-fired steam plant's economy is usually best when the plant can be situated right in the coal field and the coal can be mined at a low cost. The future of coal-produced power will depend on relative costs of alternative sources, and on the feasibility of power transfer by transmission line compared to coal transfer by rail.

A coal-fired power station depends upon the ability of utilities on industries to obtain coal supplies throughout the useful life of the plant at costs close to those which are at present operative. The problem of supplying large volumes of fuel is staggering when compared to present production. For example, to supply fuel to a 500,000 kilowatt generating station, coal output in the province would have to be doubled, added to which is the long-term upward trend in fuel prices. Since coal costs at load centres make competition with hydro and gas difficult today, one cannot expect coal to play a major part in power production in British Columbia in the future.

Sources of gas and oil are not great in B.C. itself although proven reserves are increasing. Unfortunately, most of them are in the far north-east corner of the province. The pipeline is the principal means of transporting both these types of energy from their sources to the load centres. A pipeline has a high capital cost and must be operated at high load factor to be economical.

Several small power generating stations are now operating on gas from the pipeline system, and a large station of 900,000 kilowatt capacity is now under construction on the lower mainland. This is expected to use 144 million cubic feet of natural gas a day at 70 per cent load factor.

If a subsequent gas-fuelled generating station were planned at a capacity of, say, 500,000 kilowatts, another 80 million cubic feet of gas per day would be required. This amount of gas could not be supplied from domestic sources without a second pipeline. Its effect on cost is easy to see.

It is unlikely that a new pipeline could be built for the same unit cost as the present one. The rise in labour and material costs would rule otherwise. Costs of drilling for new gas reserves are going up and the contracts for supply to the pipeline are likely to be at higher prices than those in the past. This is a case where large consumption is more expensive than small consumption because of the additional collecting systems required to gather the gas to the point of delivery to the pipeline.[9]

Therefore, we must expect future gas contracts to be at higher prices than those at present, with the result that the cost of the electrical output of gas-fuelled generating plants must rise. In point of fact, it is historically true that the cost trend of thermal fuels always rises; it does not go down.

On the other hand, continued improvements in thermal efficiency will offset the rapid increases in fuel costs which appear certain to take place in the next decade. Such improvements, however, are becoming more difficult to attain, both technically and economically. There are many indications that advances in technology are tending to lag behind the present inflation of costs of labour and materials.[10] But costs must be competitive to start with and this is difficult unless a generating plant can be located at a coal field or near the source of oil or gas. This is not usually near the load centre, particularly in British Columbia today, and present favourable gas contracts are not likely to be duplicated in the future.

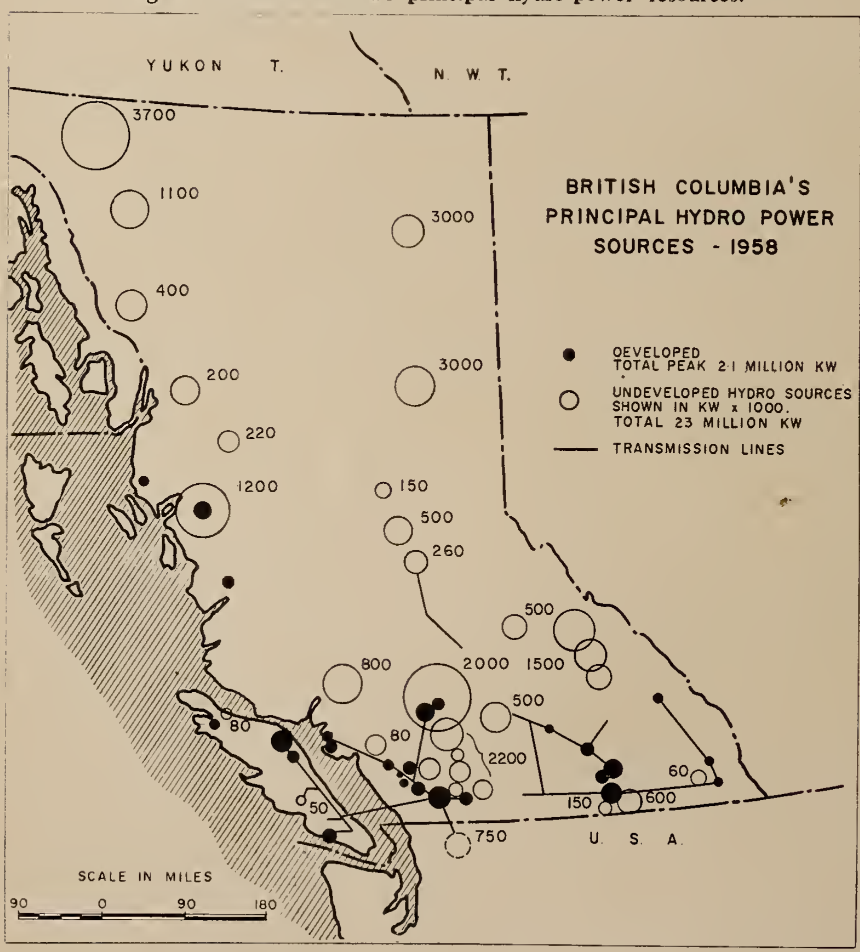
Hydro

B.C.'s principal hydro resources are shown on Fig. 4. The building of large thermal plants on both the mainland and Vancouver Island may appear to indicate that we have run out of hydro already, and yet the undeveloped capacity totals some 23 million kilowatts compared to a little over 2 million developed today (in round figures).

Figures could vary depending upon the type of power developed — whether for base load or peaking operation.

The unsolved problems of the coexistence of fish and dams have delayed a number of hydro projects capable of producing low-cost power. The unresolved international problems on the Columbia River have so far precluded the development of

Fig. 4. British Columbia's principal hydro-power resources.



power in Canada and the division of downstream benefits between ourselves and the United States.

But these are not the only reasons for delay. If, instead of various areas of the province being under different authorities for power supply, there had been overall integrated system planning and control during past years, the present situation could have been quite different. It might not have been necessary to build large gas-burning generating plants on the mainland and an oil-burning plant on the Island —while large hydro sources still await markets and development.

The very large hydro potentials in the northern part of the province are not yet developed because the market is not there. As long as the load centres are in the southern part, the economics of power transmission rule against the northern developments in the near future, particularly as long as hydro power is available closer to the load.

Even if there were no more hydro potential in this lower part of B.C., it is unlikely that transmission of power from the far northern sources could compete with thermal generated power today, or perhaps even with nuclear power 20 years from now. However, one must assume that the demand for that northern power will exist, and that it will be developed for use in the northern regions, or for transmission south, or both, according to the economics of power supply at the time.

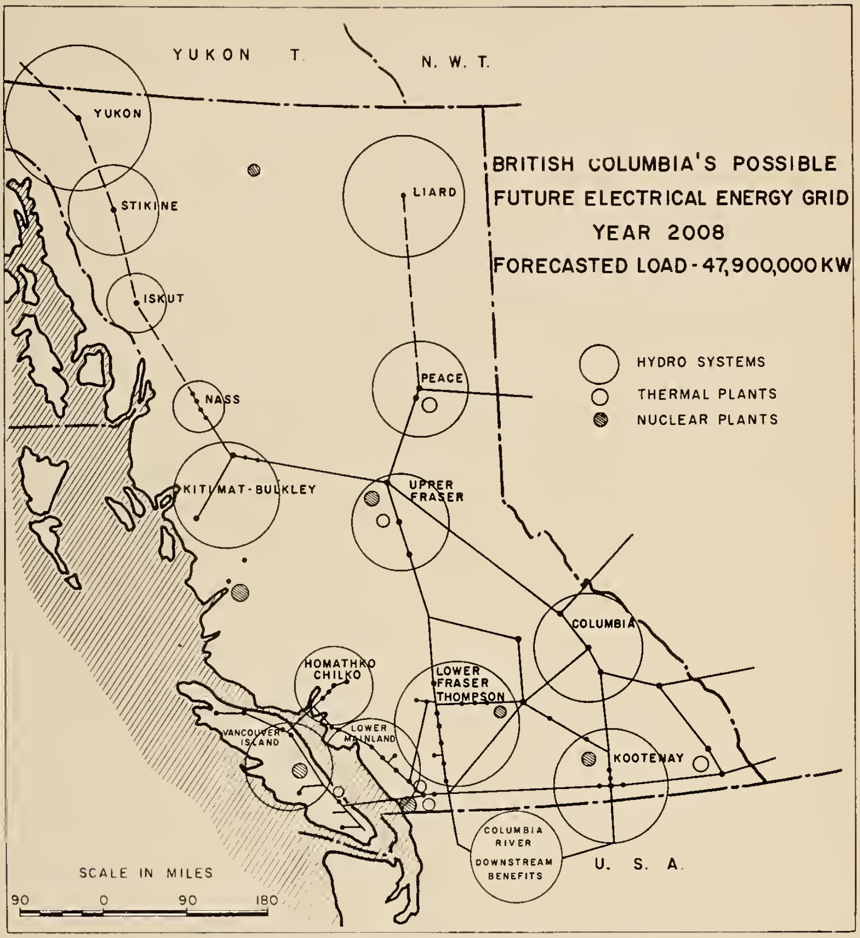


Fig. 5. Possible future electrical energy grid.

Nuclear

What will be the role of nuclear power in British Columbia? B.C. should be the last province in Canada to develop nuclear power on a large scale.

Nuclear plants should be operated on base load because of high capital cost. Nuclear plants are not adaptable to quick on and off operation for peak loads. Only large-scale plants can be expected to reach a unit cost level competitive with conventional types of thermal power, and then only after much more development work over a period of years.

A large nuclear plant should be installed only on a large integrated system where the capacity of the plant will be a relatively small percentage of total load. At the present stage of development, nuclear plants are faced with operating difficulties resulting in extended shutdowns for one reason or another. A large utility system could not chop off a portion of its otherwise continuous power supply while waiting for radioactive dust to be mopped up in a shutdown plant, unless its capacity could be picked up by other plants on the transmission network.

The cost of nuclear produced power is not expected to be competitive with hydro or conventional thermal power in British Columbia for many years yet. Britain is planning large nuclear installations because of the scarcity and high cost of other types of power. A cost equivalent of about 12 mills per kilowatthour may be competitive in Britain, but it certainly isn't here. Also, the planned installations are a much

Fig. 6. Earliest of B.C.'s large hydro developments was the West Kootenay Light and Power Company plant at Lower Connington, built in 1897. (Provincial Archives)

Fig. 7. Strathcona development of the B.C. Power Commission is the third dam and generating station on Campbell River system, central Vancouver Island. White arrow shows semi-outdoor type station; black arrow shows gate structure on spillway.

smaller percentage of the total load on the British transmission grid than they would be in British Columbia where we have not yet got a grid.

From this, it appears that nuclear plants should first become of value in supplying large quantities of electricity to meet the base load of a large transmission network. They are not immediately suited to the needs of small networks or to intermittent loads.[11]

Application of Sources to Meet the Demand

The long-range problem is to meet the demand for electricity from available sources to obtain the best results. The important thing is that all sources be considered in the light of long-range planning for optimum benefit. Such planning must take into account all energy sources, the economics of their conversion into electricity, the transportation of fuel or transmission of power, and the relation of power to other resources.

Over the next 50 years, additions will be made to power supplies until the province is served by a high voltage transmission grid that may look something like Fig. 5. The map shows the power system as it might look in the year 2008.

All the principal hydro sources would have been developed, and those in the southern two-thirds of the province at least would have been joined by a network of high-voltage transmission lines. If planning and its implementation are to be effective, it is obvious that future main transmission lines should be designed and built for the high voltages (in some cases, probably 500,000 volts) that will be required for future operation on an integrated system.

The large sources in the northern regions may or may not be physically joined, depending upon markets and the economics of transmission. There are still many problems to be solved before long-distance power transmission becomes practical. These include the electrical stability and the physical reliability of a long line, and the economics of transmission cost related to power delivered. Dotted lines are drawn on the map to the Yukon, Liard, Stikine and other northern sources because of their remoteness, and to indicate that it is possible that these might first be developed as power sources for heavy electricity-consuming industries. Any acceleration of growth in these areas, however, could materially alter the schedule of additions as shown.

Thermal plants are shown. These may have been on the system for some years, going through the transition to nuclear supply. They may still be operating on the fossil fuels of coal, oil or gas, according to their function for base load, peaking, or stand-by supply, according to the economics of fuel supply, and to the relative efficiency and reliability of nuclear power.

Indicated are nuclear plants introduced at major load centres such as Vancouver, Kamloops, Trail, Prince George, Nanaimo, to carry the base load on the network. The already existing hydro plants may then be converted progressively from base load to peaking operation. The full, system-wide advantages of this will be possible, of course, only if the hydro resources have been developed according to plan.

Peaking Capacity

Consider what this means. Take, for example, a hydro plant designed and built for base load operation. It must average out the minimum and maximum water flows of the river by storage dams and control works so as to produce a constant amount of power throughout the year. Its generating capacity is matched to that constant average. If a nuclear source takes over the base load, the hydro plant's generating capacity can then be upgraded for use as a peaking plant. This means that it can take care of the fluctuations in the hour to hour, or season to season demand by the installation of additional generators, using the same amount of water over shorter periods. There may be little or no additional investment in storage or control works. Thus the unit cost per kilowatt of hydro capacity can be materially reduced. To put it another way, the value of hydro power on a transmission system will increase when nuclear power can handle base loads economically.

If the John Hart Plant on the Campbell River, for example, can be regarded as having a capacity of 120,000 kilowatts for base load operation, it could produce 200,000 kilowatts or more as a peaking plant. This would be accomplished by a greater capacity in generators operating for a few hours at a time to handle the peak loads. Apply this same principle to the province's future hydro potential of 23 million kilowatts and, depending upon design load factor, the capacity could be upgraded to 30, or perhaps 40 million kilowatts for peaking purposes as nuclear power moves in on the base load.

The best economic advantage of this feature will be obtained by the construction of hydro plants at the earliest date consistent with system requirements. The earlier the development, the lower the unit cost on a rising trend of construction costs.

One or two nuclear plants are shown not connected to the network to illustrate the possible economic use of small-scale, higher-cost nuclear plants in isolated, industrial centres such as Ocean Falls or Cassiar. These are used for illustration only, but are the sort of places where nuclear supply may be economically feasible sooner than elsewhere because of the cost of other fuels or of power transmission.

Development of Conflicting Resources

Comprehensive development must take into account resources whose interests conflict. If problems of fish and power can be solved by the decade 1968-78, then the Fraser may be developed for joint resource use. If they still are unsolved it may be necessary to compromise by building the Moran Dam sometime during 1968-78. This would affect only a minor portion of B.C.'s salmon production. Development of the Lower Fraser and the Thompson could then be deferred until the next decade.

If it were still impossible to develop the Lower Fraser and Thompson in order to take advantage of some of the cheapest power sources in the country, the schedule would involve a large increase in thermal or nuclear supply.

It is heartening to note a new desire on both sides of the fish and power question to co-operate in research to achieve the best results in joint resource use.

There are other factors besides fish and power affecting your hydro resources. Great importance should be attached to problems of flood control, navigation, erosion, irrigation, pollution, and just ordinary water supply.

Islands have been cut in half and carried downstream as silt by unregulated river flow. Timber purchased by lumber companies has become a dead loss when it was uprooted by the Fraser. Farmland has disappeared and roads have been washed away. Sand bars have built up in the navigation channel of a relatively new bridge and the river is moving closer each year to the approach foundations. One third of the tax bill in some areas goes for nothing more than to keep the river out of the streets and basements.

If co-ordinated and comprehensive resource development would solve many problems on one river, consider the advantages of one authority to deal with power matters on all hydro resources.

Output to be Matched to Demand

The scheduling of additional sources of supply will depend to a large extent on how plant output can be matched to market demand. This matching must be in both quantity and price.

B.C. is now at the stage of its development when it needs low-cost power. Small projects are expensive; large projects have capacity that will not be used all at once. The large ones may be developed in stages with regard to generating capacity, but heavy initial investment may be required for storage dams and other works that are common to the complete development. It may take some years before the total output of a large project is needed by the B.C. power market, because the capacity of the project may be a very large percentage of the capacity installed in B.C. today. This will not be the case a few decades from now when a one million kilowatt addition may be sufficient to meet only about one year's growth.

This suggests that planning takes into consideration financing, marketing and authority.

Financing

An offer of federal assistance in financing has already been made. The availability of low-interest money is an important factor in resource development involving investments that are large in proportion to present population and demand, but which are perfectly reasonable in the light of anticipated growth.

The cost of money alone can represent more than half of the final marketing price of the power. Electric utility investment is high per unit of power or per customer; the ability to finance at as low an interest rate as possible is, therefore, significant.

Marketing

The initial marketing of the output of a large project must be part of the planning. In an economy where power demand is growing, additional capacity must always be installed somewhat in excess of immediate demand. Small projects are relatively expensive, and desirable, large, low unit cost projects may have surplus capacity for some years before being fully utilized. Revenues are needed as soon as the investment is made in order to discharge debt obligations.

Two sources of revenue are possible apart from the already established and growing demand. One is from large power consuming industries, and the other is from temporary, recoverable export. Both of these have their problems.

Industrial Sales

There are a few industries to whom electrical energy at low price is important. It is regarded almost as a raw material. The availability of such power can be a major factor in influencing the location of these industries. It might be thought wise to offer a block of power that would otherwise be surplus to initial requirements at a low price to induce establishment of load and bring in immediate revenue.

Planning must take this into account because the overall benefit to the country's economy of a large consumer of low-priced power that employs relatively few persons is sometimes debatable. If this power is in an area that is growing and that will need it for expansion within a comparatively short period, then the wisdom of such disposals of power should be carefully considered.

This is no problem in remote locations where the power potential may not become a factor on a transmission grid for many years. Alcan, at Kitimat, is an example. Even this power source may some day become part of a provincial grid.

Export of Power

The other means of disposing of initial surplus is, of course, by export contract. It must immediately be recognized that any surplus capacity is only temporary. This country will eventually need all the power that can be produced. Therefore, any contract made with another country must be safeguarded to allow the recovery by B.C. of its power output when needed.

The development of large-scale projects would be facilitated by assured revenues during the initial years of operation if satisfactory export contracts were possible. This is still an unresolved question. The problem is to write an export contract to ensure that the purchaser makes adequate arrangements to supply his own growing loads when the supplier needs the power.

The future will emphasize more than ever that energy is interprovincial and international, that energy agreements must transcend political boundaries.

(References on page 73)

INDUSTRY

COMMUNICATIONS - COMMERCE

THE ECONOMY of British Columbia has largely been dependent on the natural resources of the province, particularly in the field of wood products. For example, statistics for the value of manufacturing production by industrial groups for the year 1956 show that the value of wood products and paper products accounted for some 43.5 per cent of shipments worth nearly $1,905 million. However, in recent years there has been a tendency to greater diversification of industry, not unaccompanied by various labour problems.

Backing all this development of industry there is naturally a considerable growth in the supply of electrical and thermal energy. Current developments in the production of electrical energy have been discussed in the October issue of the *Engineering Journal*, and the planning of future requirements is dealt with in an article on page 64 of this issue. Although British Columbia has some indigenous resources of coal, petroleum, and natural gas, and considerable effort is being made to find more of these resources within the province, far more of these thermal fuels are available in the neighbouring province of Alberta. Whatever the original source, transport by rail, road, and pipeline has to be developed to meet the needs of industry.

Natural Gas

The distribution of natural gas has in itself become a major industry. The largest undertaking has been that of the Westcoast Transmission Company Limited with the installation of a 30-inch pipeline to serve the interior and lower mainland areas of British Columbia as well as the northwestern part of the United States. Initial capacity of the pipeline was 400 million cubic feet of gas a day, but this was to be expanded to a throughput of 660 million cu. ft. a day by the addition of a booster pumping station at a cost of an additional $70 million above the original $155 million invested in the project. Further expansions are under way.

New Products

Among the recent new products and industries are aluminum (the Kitimat development), asbestos, and the aforementioned natural gas. Shipyards, iron and steel processing, food and other consumer goods producers have all been active.

Capital investment in industrial projects has been exceptionally high in recent years, and the industrial and commercial construction fields have been correspondingly vigorous.

Nearly 1500-million dollars of private and public capital were invested during 1957. Much of this expenditure went into engineering construction, particularly into the fields of electrical power, thermal fuels, and highway construction.

Labour Problems

A prominent member of the construction industry in British Columbia, who is also associated with national construction interests, has recently expressed concern about the labour situation in the province. Some of his views are quoted here.

The construction industry, which is basic to the establishment or expansion of all other industries, serves as a good illustration of the difficulties encountered. Largely because of a crash programme during recent years, abuses by management and labour became quite common. This was greatly aggravated by a few large contractors coming in from the outside, unaware and totally unappreciative of local B.C. conditions. Such contractors, operating on huge budgets and unlimited financing, gave concessions in wages, fringe benefits and working conditions, without regard for the effect such "give-aways" would have on local economy. To justify their position, they would say that in view of the huge sums of money required to finance the particular project (none of which would be productive until the plant actually started producing) it was far better to give way on such matters as unrealistic wages and working conditions than to face high interest charges for long periods of time if completion of the project were delayed by manpower shortages and/or industrial disputes. The result of such thinking is now all too apparent. Even union representatives admit that some of the concessions given were far out of line with the economy. However, such wages and conditions were used at the bargaining table as "established practices", and consequently local contractors were forced to negotiate on such a basis.

British Columbia has long enjoyed two outstanding natural advantages for industrial development, an adequate supply of hydro-electric power and ready access to tidewater and competitive shipping rates. In view of recent nation-wide developments, these factors should be re-assessed. The construction and operation of Trans-Canada Pipe Lines, for instance, puts huge power potential into areas which have never previously enjoyed such prospects. The power transmitted by this organization is available to investors without the necessity of building expensive hydro projects, a gas trunk line being relatively inexpensive to construct and maintain. Again, there is the effect on world shipping lanes of the St. Lawrence seaway project. More than one-third of Canada will literally be at or near deep-sea shipping, with all the implications that such a low-cost form of transportation carries. To say that industry *must* come to British Columbia is to cherish a myth, and investors are showing just how big a myth such thinking implies. Alberta changed its economy almost overnight from agricultural to industrial, Saskatchewan is fast following suit, and Manitoba can be expected to do likewise.

Speaking of major problems in British Columbia, it is pointed out that fringe benefits must be re-examined, productivity must be re-established, and there must be an immediate end to the wildcat walk-outs and jurisdictional disputes which have disrupted the construction industry in B.C. for the past few years. It is stated that the unions will oppose any move to reduce their "hard-won gains", but they are also going to have to consider whether it is really to their advantage to have the highest wages and best conditions embodied in their union agreements, with no one working to enjoy them. Management must become more cost-conscious, re-assert its authority, and strive for greater efficiency at all levels.

While the consumer price index increased 66.8% during the period 1945 to 1958, the lowest wage increase in the basic building trades was 126.9%, and the highest was 174.7%. Again, while the consumer price index increased 25.1% during the period 1949-58, the lowest wage increase in these particular trades over the same period was 63.6% and the highest was 77.3%.

In the case of operating engineers and teamsters, where no full degree of organization was experienced previous to 1951, figures for the period 1951 to 1958 indicate that, while during this period the consumer price index increased 10%, wage increases in the various categories involved were all in excess of 63%.

Taking into consideration fringe benefits, which range from a basic minimum of 25c per hour to over $1.00 per hour, the figures for percentage wage increases would be much higher.

British Columbia is the only province in Canada where province-wide agreements are in effect between the general contractors and the building trades unions, and the commentator points out that the contractor employer has become the greatest organizer for the trade unions, due to the union shop clause embodied in the agreements.

There are many issues which must be resolved, but there are four factors which would undoubtedly help the situation and which could be embarked on immediately. They are:

(1) To establish a uniform expiry date for all construction trades union agreements.

(2) To establish two-year agreements. (Such two-year stipulations can always contain a clause to protect the members in case of a world-wide situation which could cause drastic inflation.)

(3) To make a joint request to the Provincial Government urging fair and equitable amendments to the Trade Union Act. Such amendments to provide adequate protection to unions from unscrupulous anti-union employers, while protecting fair employers from irresponsible picket lines.

(4) To establish local unions in key centres of the Province with a view to eliminating costly transportation and travel-time stipulations.

The opinion is further developed that the idea that we can develop our natural resources by allowing rigid control of building tradesmen from Vancouver is dangerous and unworkable. If a union is certified on a province-wide basis, the onus should be on the union to supply workmen from the closest urban centre—not necessarily from Vancouver. The Provincial Council of Carpenters has recognized this principle by the establishment of some thirty-eight local unions serving the province, thus eliminating to a considerable degree excessive transportation and travel-time costs on jobs far removed from Vancouver.

Management recognizes the immense contribution organized labour has made to the general social and economic betterment and some union leaders recognize the improvement in management's thinking about the welfare of employees. The unions, however, have shown little appreciation of the responsibilities management undertakes when starting a construction project.

Both labour and management face a colossal task, not only in ironing out the present difficulties, but in planning the future—to build hydro plants, pulp mills, pipe lines, oil refineries, bridges, highways, railroads and the many diversified projects which the construction industry undertakes.

The construction industry is basic to the establishment and expansion of all industries. Shown below is an example of some of the difficulties encountered.

Capital Investment

Residential building material costs in 1957 advanced one-sixth of one per per cent from the 1956 average. Non-residential building materials costs rose 1.7 per cent. The greater use of steel and other fabricated metal products which increased in price over 1956 explains the higher rise in costs for this branch of construction.

Employment in the construction industry reached an all-time high in 1957. The estimated average number of workers stood at 78,000, an increase of 8.4 per cent from 1956. At the same time, however, there was a surplus of construction labour throughout the year in most areas of the province, owing largely to the substantial increase in the labour force over the preceding year. Also since some of the larger engineering projects were in the final stages of construction during the year, their labour content was relatively low. Average wages of salaried and hourly paid workers in the construction industry rose to $87.00 per week from $81.13 in 1956. This represents a gain of 7.2 per cent in one year.

Capital expenditures may be divided into two groups—new capital investment and repair expenditures; and each of these may be subdivided in turn into 'construction' and 'machinery and equipment.' The trend towards a higher proportion of expenditures accounted for by new investments continued in 1957. In 1955 new investment in building and machinery was 75 per cent of the total expenditures; it was 80 per cent in 1956 and an estimated 82 per cent in 1957. The percentage allocated to repair expenditures diminished accordingly from 25 per cent in 1955 to 20 per cent in 1956 and to 18 per cent in 1957. But, the usual proportion between building expenditures and expenditures on machinery and equipment was maintained at about 63 per cent for building and 37 per cent for machinery and equipment.

Construction

The total value of construction (new and repair) put in place during the year was estimated at 898 million dollars, up eight per cent from the previous year. Most of this increase was due to the higher value of engineering construction carried out in 1957. Its proportion in total value of construction is about 53 per cent, while in 1956 it was 50 per cent, and 39 per cent a year earlier. Housebuilding declined about 17 per cent from the 1956 value to an estimated total of 168 million dollars, but increases in industrial, commercial, and institutional construction made up for this drop. The total value of building construction in 1957 is estimated at 420 million dollars.

A measure of overall building construction in the organized areas of the province (cities, district municipalities, villages, and regulated areas) is provided by the value of building permits issued. The total for 1957 should reach 245 million dollars, which represents a slight decline from last year's total of $247,096,000. Generally, less building has been done in the established commercial and industrial centres during 1957 than in former years, and more has been done in the suburbs and in newly developing parts of the province. Some of the estimated values of building permits for 1957 are given below (with 1956 figures in parentheses):

Vancouver City, 55 million dollars (64.7 million); Burnaby, 22 million dollars (14.4 million); Surrey, 18.5 million dollars (13.0 million); Delta, 3¾ million dollars (3.4 million); North Vancouver District, 7¾ million dollars (11.5 million); Victoria, 5.5 million dollars (6.7 million); Nelson, 2.5 million dollars (800,000); Prince George, 3.4 million dollars (5 million in 1956 and only 2.8 million in 1955); Prince Rupert, 2¼ million dollars (700,000); Kelowna, 1.5 million dollars (2.2 million); and Kamloops, 1.3 million dollars (2.6 million).

Residential building was at a lower level than a year ago, and there was a general tendency towards a balance between starts and completions, a feature not observed in the past years of considerable expansion in the housebuilding industry.

The total number of houses started this year is estimated at about fifteen per cent less than in 1956, and the number of completions is estimated at a level four to five per cent lower. Lessened activity in the housebuilding industry was reflected in the longer average time that houses were under construction. In 1956 the average number of months was 7.4, while in 1957 it was estimated to be 7.9 months.

Engineering Construction

The total value of engineering construction put in place during 1957 is estimated at 477 million dollars. This is 57 million dollars more than the 420 million dollars spent on engineering projects in 1956. Installations of gas and oil facilities estimated at 125 million dollars contributed the largest single item to this total. Next in estimated value of construction was the road, highway, and airodrome group — 97 million dollars. Construction expenditures on electric power facilities followed closely at 93 million dollars.

Among larger industrial projects in the engineering construction group were the British Columbia Electric Company's thermo-electric plant at Port Mann (11 million dollars) and the Bridge River hydro-electric installation (43 million dollars); the natural gas pipeline in the Interior (75 million dollars); a steel casting mill at Port Coquitlam (1¼ million dollars); electric transmission systems in the Interior (2 million dollars); an aluminum manufacturing plant in Richmond (1 million dollars); and a copper mill at New Westminster (8 million dollars).

Industrial Building Outlook for 1958

A number of building projects were to be carried out or started in 1958. Among the largest are: the B.C. Power Commission's Ash River plant ($10,000,000) and a new hydro-electric development near Alert Bay on Vancouver Island expected to cost around $12,000,000. A transmission line will be constructed from Vernon to Kamloops which will more than triple the available power in the Kamloops area (cost—$1,500,000). A new plywood plant is scheduled for Princeton ($2,500,000); a chemical plant in Vancouver (Pennsalt Chemicals (Canada) Ltd. took an option on a property and they propose to spend $10,000,000); and a wire and cable plant will be constructed at Langley ($1,000,000).

SUBMARINE POWER CABLE

In the October issue of the *Engineering Journal* the general progress of power developments in British Columbia was discussed, and reference was made to the problem of supplying power from the large potential sources of the mainland to the industrial centres of Vancouver Island, which itself has limited resources of electrical power.

This problem was solved on the basis of an original suggestion by Mr. T. Ingledow, M.E.I.C., then chief engineer of the B.C. Electric Company Limited, to use submarine power cables for the crossing of the several stretches of sea between the mainland and the Island. The engineering problems involved were considerable and their resolution plays an important part in the general development of industry in the province.

In brief, the power link involved the laying of lengths of 138,000-volt cable, the first complete link being officially inaugurated in September 1956. A second circuit in this link was put into commission in July 1958. Some of the technical details are given below.

The total length of the link is comparatively short, less than fifty miles, but includes a number of sea crossings, the major one, across the Strait of Georgia being approximately fourteen miles across with a maximum depth of 100 fathoms.

From a preliminary approach to the British Insulated Callender's Cables Group in 1952 regarding the feasibility of such a scheme, positive proposals resulted in the award in February 1954 of an order for the supply and installation of some 91 miles of high-voltage single-core submarine cable.

On the mainland of British Columbia, high voltage power is transmitted at 230kv., whereas on Vancouver Island it is transmitted at 132kv. It was decided that the power to be carried by the cable link, 120Mva., should be transformed down from 230kv. to 138kv. on the mainland and fed to the link at this latter voltage.

The most desirable form of cable was one that could be made in one continuous length without any joints. Obviously, to produce a cable of this type would create manufacturing problems of a very difficult nature besides requiring much special plant. The most satisfactory solution to these problems was to use the single-core gas-filled pre-impregnated paper-insulated type of cable. The use of pre-impregnated paper overcomes the difficulties incurred in tank impregnating very long lengths.

At the maximum depth at which the cable would be laid the external pressure on the cable would be as great as 280 lb./sq. inch. The gas pressure decided upon for this cable was 300 lb./sq. inch.

As finally produced, the 0.35 sq. inch conductor consisted of a central spiral steel duct, over which were applied two layers of copper wires and a conducting screen of three impregnated metallized paper tapes. Pre-impregnated paper tapes were applied over the metallized paper screen to form the dielectric, which is itself screened with copper tape. The lead-alloy sheath, extruded to a shrink fit over this core, is reinforced against the internal gas pressure by three layers of tin coated bronze tape, all applied in the same direction. Between this tape and the jute yarn bedding for the armouring is a protective sheath of vulcanized rubber, capable of withstanding the highest lead sheath voltages liable to occur in service. The cable is armoured with a single layer of galvanized steel wire, applied in a direction opposite to that of the reinforcing tapes to balance torsional forces. The armour is served with two layers of compound jute yarn and the cable has an overall diameter of approximately four inches.

It was decided to manufacture the cable in three distinct operations: stranding, insulating and lead sheathing and, finally, reinforcing, armouring and coiling down.

A completely new cable factory unit was laid out at Trafford Park, Manchester, adjacent to the Manchester Ship Canal, giving the advantage of deep-water berthing facilities. In-line production was most suitable for the manufacture of long, continuous lengths of cable and this necessitated not only many new items of plant but also the considerable modification of standard plant to adapt it for this specialized method of manufacture before being installed in the new unit.

The scheme decided upon by the British Columbia Electric Company was for a.c. power at 60 c/s. to be transformed from 230kv. to 138kv. at Arnott Sub-Station in the Delta area of the mainland of British Columbia. Thence, via an overhead route on wooden poles, the power would be carried to a point at Tsawwassen Beach, just west of Point Roberts. From here, there would be a submarine cable crossing across the Strait of Georgia to Galiano Island. An overhead line, on steel towers would then continue the transmission across Galiano Island, an intervening channel and Parker Island. There would then be a second submarine cable link to a point on Saltspring Island and finally an overhead line across the island and another channel to Vancouver Island, there to be linked, at Stratford Sub-Station, with the main Vancouver Island 132kv. transmission system. In all, the length of line from Arnott to Stratford is approximately forty-eight miles.

Thus two submarine cable crossings were necessary, the longer one, of approximately sixteen miles, crossing the Strait of Georgia from the mainland near Point Roberts to Galiano Island, and the shorter, of three miles, crossing Trincomali Channel from Parker Island to Saltspring Island. The other water crossings incurred were quite short and were to consist of overhead spans of four-conductor lines.

Cable laying of this kind resolves itself into two distinct parts: laying across the central channel and landing the shore ends. Laying across the channel is carried out by paying the cable out from the moving ship. A method of laying was evolved whereby tension was applied to the cable according to a previously calculated schedule depending on the depth at the point of laying. This schedule was based on a nominal laying speed of three knots.

Cable laying from the 4600-ton *Ocean Layer* started on 18 July, 1956 and continued throughout the following four weeks. For the whole of this period the weather was favourable.

After laying the fourth short length, the cableship and two shore-laying scows moved into Georgia Strait to lay five sixteen-mile lengths. A mile off Galiano Island, the sea bed rises rapidly from 100 fathoms to only forty fathoms, but this did not cause any difficulty. While the laying was in progress, work on the shore ends was proceeding.

Immediately after each cable had been laid, a high voltage d.c. test was carried out on the cable at atmospheric pressure. The cables were then moved into their final positions in the chases and the ends terminated in sealing ends. They were then gassed and the official high voltage acceptance test carried out, together with other electrical tests and a pneumatic test to ensure gas tightness. To prevent damage to the cables, malleable iron protectors were fitted to the cable at the shore end of the concrete chases to below low water mark at the three deep water landings. At the Tsawwassen Beach landing, the protectors were fitted for a short distance from the tunnel entrance, the remainder of the shoreward end of the cable being buried in trenches.

INTERNATIONAL NEWS

The Development of Peat Resources in Ireland

Irish Peat Board

THE NATURAL fuel resources of Ireland consist of a small amount of coal of an anthractic character occurring in very thin seams and a substantial amount of potential fuel in the form of peat bogs.

Peat is a combustible material formed by the humification of such plants as mosses, rushes, grasses, algae, tree debris, etc., under conditions in which the land is of such a nature that large quantities of water can accumulate and are prevented from evaporating rapidly. In such water-logged conditions the rapid multiplication, growth and decay of vegetation takes place. The overlying water cuts off oxygen and a slow carbonisation or humification of the constituents of the plants occurs which forms peat layer on top of layer. Depressions and scars, resulting from the Glacial Period, provided suitable depositing grounds for many peat areas in Ireland.

These bogs occupy approximately 3,000,000 acres of land or roughly one-seventh of the total land area of Ireland. With the establishment of an independent Irish State and the necessity to develop national resources in the interests of national economy, a programme for the development of the bog lands was initiated.

The major physical characteristic of bog deposits which presents difficulties to their utilization is their high moisture content, ranging from 90% to 95%. An intensive drainage programme is necessary before any winning of peat may be undertaken.

Bord Na Mona or the Irish Peat Board which is the authority responsible in Ireland for the development of the bogs, has developed and adapted machinery to meet such conditions and allow almost full mechanical drainage work. Where general bearing pressures for tractors and machinery may be of the order 6 to 10 lbs. per sq. inch it is necessary in the drainage of bogs to provide machinery with a bearing pressure of approximately 1 lb. per sq. inch. The drainage of the bogs results in the moisture content being lowered by approximately 5% and the period required for drainage varies, depending on local topographical and meterorological conditions, from 3 to 6 years.

There are two methods of production at present employed in Ireland, i.e., the sod peat process and the milled peat process. Sod peat which, when dry, is a densely compacted peat of approximately 30% moisture content and in size approximately 12-by 3-by 3-inches is cut by 40-ton electrically powered excavating machines which excavate the peat from near-vertical face banks or trenches of about 12 ft. deep. The raw peat passes through a macerator in the machine and is spread to dry on the bog in sod form. The machine cuts a mixture of the various layers making up the bog. The maceration process causes high shrinkage on drying and results in a dense product. The peat lying for a period of 3 to 6 weeks when it is lifted into small piles mechanically. After a subsequent drying period it is turned and finally collected into storage ricks. From the ricks the peat is conveyed by narrow gauge railway to the railhead for despatch to the consumer. Sod peat is used in the generation of electricity and by domestic and industrial consumers. It may also be used in the production of activated carbon. The calorific value of sod peat at 30% moisture content averages approximately 6,100 B.t.u. per lb.

Machine peat has a high volatile content with an ignition temperature lower than any other solid fuel. It is a non-caking fuel and has a low combustion temperature and a low ash content, and is a most suitable fuel for use in steam boilers, low pressure central heating systems and in ovens, kilns and drying plant.

Milled peat winning consists of milling the surface of the bog over its entire area by a tractor drawn rotating drum on which small cutting blades or pins are fixed. The depth of each cut is about ½ in. and the cut peat is left drying on the bog surface in very small pieces which will dry quickly. To accelerate the drying, harrows are driven over the bog which turn the peat, aerate it and leave it in small corrugations. Some hours later a special type tractor with an angle dozer blade scrapes the loose dry peat into ridges in the centre of each milled peat field. Later a special half track vehicle known as the harvesting machine picks up these ridges and builds a large rick from every ten small ridges. At this stage the peat has dried to about 50-55% moisture content. To achieve a maximum output these operations must be repeated as often during the season as drying conditions permit. In this method of production all operations are completely mechanised. The milled peat process has many advantages over the sod peat process and will figure very largely in future peat development plans in Ireland. This peat, having such a high moisture content must be burned near the bog in electricity generating plants, or converted into briquettes. The economics of milled peat firing for electricity generation have been very satisfactorily demonstrated and, in fact, the electricity generated from milled peat is the cheapest generated in Ireland from fuel. The calorific value of milled peat is 3,500 B.t.u.'s per lb.

Peat briquettes, which are made from milled peat, are used by industrial and domestic consumers. The milled peat is converted into briquettes following screening, thermal drying and pressing. The moisture content of the briquettes is approximately 12% and the calorific value 8,000 B.t.u. per lb.

A further product from the Irish bogs is Peat Moss, which has numerous applications in agriculture and horticulture, and is widely used as a soil conditioner. A considerable export market has been developed for Peat Moss and expansion in production is now envisaged.

Peat is an organic substance and almost anything that can be made from organic substances can theoretically be made from peat, but as it is a low grade product, it is an expensive basis from which to work. Some such products are peat chemical fertilizer mixtures, nitrogenous fertilizers, complete gasification leading to synthetic oil products including rubbers and waxes, partial gasification leading to town gas and coke production and the production of industrial alcohols, sugars, acids and soaps. Most of these products, however, are very doubtful economic propositions and, in some instances, would be economical only in large scale plants.

The peat industry in Ireland has become one of our leading industries. Approximately 100,000 acres of bog land on which 7,000 men are employed are being developed for an ultimate production of 3½ million tons of peat fuel annually. When these bog lands have been cut away, the land will be reclaimable for agricultural production or for afforestation. Experiments are at present being carried out by the appropriate Irish authorities and when large scale areas are available for reclamation the results of these experiments will have indicated most suitable uses for the land so recovered.

Electricity Generation from Peat

GENERATING STATIONS designed to burn peat are included in the post-war construction programme for generating stations in Ireland. Planning included seven sod peat stations of which six are in commission and four milled peat stations, the first of which was commissioned in 1957.

The combined capacity of the peat-fired stations in commission is 145 Mw. or 22.3% of the present total generating capacity of 650 Mw. New plant under construction or on order will increase the capacity of the peat-fired stations to 285 Mw. and the number of units generated from peat to 1350 million per year. The stations are constructed and operated by the Electricity Supply Board.

The capacity of each station is based on the size of the neighbouring peat reserves. Under Irish climatic conditions the average annual peat production is in the region of 30 tons per acre for sod peat and 100 tons per acre for milled peat. Stations are planned on the basis of a 25-year life.

The peat is produced and delivered to the stations by a separate semi-state organisation, *Bord na Mona.* Since 1951 the policy for large-scale peat developments in Ireland has been towards the production of milled peat because of its lower seasonal labour content and its cheaper cost on a calorific basis.

Peat is geologically a young fuel and in its natural state contains approximately 93% water, half of which can be removed by drainage. The physical and chemical properties of peat vary appreciably from one area to another and over the depth of any individual bog. The moisture content of sod peat after air-drying is approximately 35% while that of milled peat is in the region of 55%.

Sod peat is excavated from vertical face banks and spread to dry on the bog as lumps or sods. The excavation machine in this way cuts a mixture of the various peat layers which makes up the bog and gives a fairly uniform product. The average size of the sods as received at the generating station is 8 in x 3 in x 3 in.

Disc ditcher machine excavating bog drain to a depth of 4′ 6″ and spreading spoil to the adjoining areas.

Winning of milled peat on the other hand consists of cutting the horizontal surface of the bog over its entire area by a high-speed rotating drum on which small cutting blades or pins are fixed. This operation and subsequent harvesting give a granular fuel of which approximately 75% passes through a ¼ in. sieve. There is no mixing of the various layers of peat and milled peat has, therefore, larger variations in moisture content and in quality. Its high moisture content and low bulk density make it an expensive fuel to transport and economic utilization is limited to a radius of a few miles from the production area.

The price paid for peat as delivered to the station is varied with moisture content.

The basic price for sod peat is related to 30% moisture, 4% hydrogen and an anhydrous calorific value of 9800 B.t.u./lb. The price paid for the peat as delivered varies in the ratio of its nett calorific value to that of the standard peat. The average basic price for sod peat is 52/6d. per ton. The average fuel consumption is 2.65 lbs. peat/kwh. exported giving a corresponding fuel cost of 0.75 pence. The auxiliary load in the station is normally 5.9%. The moisture content varies appreciably but averages in the region of 32%.

In the case of milled peat the basic price is 23/6d per ton related to 55% moisture. The initial period of operation for the milled peat station in commission shows an average fuel consumption of 4.8 lbs. peat/kwr. exported and a corresponding fuel price of 0.6 pence. As this period includes an appreciable amount of irregular running due to commissioning, these figures for milled peat are somewhat above normal. The present indication is that the figures for normal operation will be in the region of 4.4 lbs. peat and 0.56 pence/kwh. exported. The average load for station auxiliaries is 8.7%.

Peat as a fuel is characterized mainly by its high volatile and low bulk density. Anhydrous peat has a volatile content of approximately 70% while the ash averages 2%. The ash has a low melting point. On a thermal basis the bulk of sod peat is approximately four times that of coal. Anhydrous peat is a highly reactive fuel

*Thanks are due to The Electricity Supply Board of Ireland for the above information.

and when heated does not form a coke but a soft friable char.

As received at the generating stations in either sod or milled form, peat has wide fluctuations in moisture content, density and sizing not encountered to the same extent in the other low-rank or low-grade fuels. It is these variations and their combinations which present the major problems in peat combustion. Seasonal variations in moisture contents give a range of 500-700 B.t.u./lb. for sod peat and 2500-5000 B.t.u./lb. for milled peat. These variations necessitate what might be called a stabilization zone external to the combustion chambers so that the fuel may reach the ignition zone in a reasonably uniform condition.

The largest sod peat boiler installed has a capacity of 220,000 lb./hr. which represents the maximum capacity for this type of boiler because of stoker limitations. Before reaching the stoker the peat passes through a drying shaft where pre-heated air at a maximum temperature of 450°F. is introduced. The depth of the fuel bed depends on the quality of the peat and can be varied from 12 in. to 30 in. The peat is delivered to the station by rail and the wagons are lifted by crane to bunker level.

Experience at the sod peat stations has emphasised the necessity for a long flame path and for shielding the stoker from the radiant heat of the combustion chamber. The flame path in the latest boiler installed is in the region of 40 ft. In the annual maintenance bill stokers constitute the largest single item. This high cost is due to the heavy loads imposed by peat, the small cover of ash on the stoker and the fact that less primary air is required than with the lower volatile fuels.

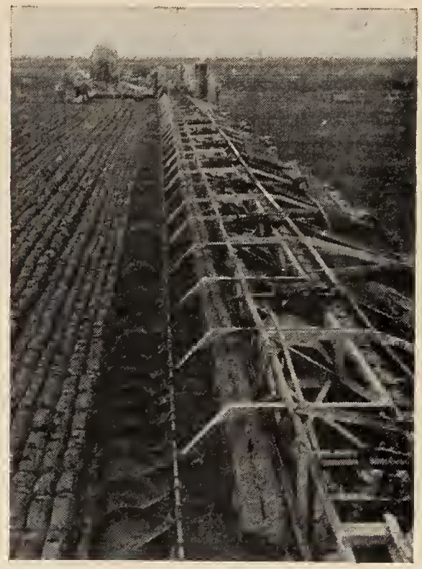
Milled peat has not previously been used on any comparable scale outside Russia for power production and many of the early considerations were, therefore, of a fundamental nature.

The method of drying and grinding of the peat prior to firing is based on the Kraemer mill system used extensively with brown coal. The wide variation in the moisture content of milled peat complicates the drying and gas circuits. The volume of combustion gases at a given load may vary over a range of 1.5 to 1 due to moisture variation and gas recirculation has been provided to stabilize heat transfer to the boiler heating surfaces. Provision has been made for supplying to the mills hot gas from the combustion chamber; cold gas from the flue circuit and preheated air. The mixture depends on the peat quality being fired.

Each of the milled peat boilers has a capacity of 220,000 lb. steam per hr. and the technique of corner firing has been adopted. The moisture content of the peat entering the burners is in the region of 15 to 30% and the temperature of the mixture approximately 200 to 250°F.

The milled peat is delivered to the stations by rail and is then handled by belt conveyors. Special attention was required in the design of bunkers to prevent blockage of the peat at the bunker outlets.

It is not possible at this stage to write in any conclusive way about experience at the milled peat stations as the optimum compromise between operating variables and boiler availability will require more prolonged study. Early experience has, however, shown that the ventilating effect of the mills and an adequately high gas temperature for drying are of primary importance.



Sod peat excavator spreader arm with cutting discs.

SOUTH AFRICAN RAILWAYS

The Government-run South African Railways who have a monopoly in the Union, are busy implementing a great scheme for increased electrification of many of its lines.

Total cost of the scheme will be approximately $100 million. South Africa already has one of the most extensive networks in the Commonwealth, and the largest one in Africa.

In the Orange Free State work is well under way on the 121-mile Vereeniging-Kroonstad section. This project is expected to be completed by June, 1959. The only electrified line in the province at present is a twenty-mile-stretch in the Eastern Free State, on the Durban line to Harrismith.

The programme in Natal has reached an advanced stage and the end of 1958 should see the completion of the work. When that is done, Natal will have 400 route miles of electrified lines.

In the Cape Province, a distance of 210 miles is being electrified. The most important section still to be done is the main line between Touws River and Beaufort West — 179 miles. This is the longest single stretch of electrification ever to be undertaken by the South African Railways and will take nearly four years. When the programme for the Cape has been completed, the total route mileage under electrification will be 435.

A total of 302 miles is being electrified in the Transvaal. All the electrification projects in the Pretoria area should be completed during this year. When all programmes are completed, there will be electrified double lines from Broodsnyersplaas in the Eastern Transvaal to Kroonstad in the Orange Free State, a distance of 220 miles. The line from Johannesburg to Kroonstad will also be electrified.

NEW AIRCRAFT FROM SWEDEN

STOCKHOLM — Parallel with the quantity production of the first version of Sweden's highly supersonic single-seat all-weather jet fighter and attack aircraft Saab-35 "Draken" a new version intended also for export is being developed at the Saab Aircraft Company, it was announced last week.

The new Draken aircraft will be equipped with a more powerful Rolls-Royce engine of undisclosed thrust. This engine and other improvements will make possible a top speed in excess of Mach 2 while the initial rate of climb will be about 820 ft. per second. The flying range and the service ceiling will also be increased.

The aircraft is to be equipped with Saab's new collision-course gunsight and air-to-air rockets. It is also designed to carry heavy ground attack armament, a fact which might be of considerable importance to possible foreign purchasers, it is said.

In September this year a Draken aircraft was the highlight of a big international air display held at the Basle-Mülhausen airport, Switzerland. Subsequently the aircraft was submitted to a two weeks' thorough evaluation by the Swiss Air Force at Emmen near Lucern. The practical tests carried out showed that the Swedish aircraft was able to operate from Alpine airfields and, in spite of its high top speed, also in narrow valleys. Following these tests the Draken was decorated with the Swiss Air Force's unique "Alpine Badge".

GEOTHERMAL ENERGY

In the first few thousands of feet of the earth's crust, the temperature increases with increasing depth below the surface, and it is supposed that heat is generated by radioactivity of the silicic rock which forms this crust. For most non-volcanic regions the thermal gradient lies between 6° F. and 30° F. per 1,000 ft., depending largely on the heat conductivity of the various layers of rock. In spite of these quite large differences of gradient the rate of outward flow of terrestial heat is fairly uniform, averaging about 0.0135 Btu/sq.ft./hr. and, in general, deviating by no more than 40 per cent from this value.

The total flow of heat at the earth's surface is equivalent to nearly 2 x 10^{14} kwh. representing a continuous power output of about 2 x 10^{10} kw. However, use of the energy at the moment is limited to a small fraction of that at volcanic regions where thermal gradients are relatively high and where the heat is more readily available, or to a few non-volcanic areas where the phenomena of natural steam and hot water geysers occur.

In volcanic regions, fissures up to 20 miles in depth may occur in the earth's crust, so that rock in a fluid state (magma) having an initial temperature around 2,000° F. may force itself to the surface. Magma which does not actually erupt, and which becomes trapped again below the surface, will heat the adjacent crust and give rise to temperature gradients, in the first few kilometres, perhaps three or more times as high as normal. Secondary fissures tend to channel the ground water to considerable depths; the temperature of the water is raised through contact with the hot rock and it then returns to the surface. Convection, together with the pressure of water above, tends to maintain the circulation. Water may re-enter the atmosphere either as steam in various states of saturation, or simply as hot water, depending to a large extent, on the quantities of cooler water picked up during the vertical motion. It is this steam or hot water which can be used to meet local requirements for heating or power.

This phenomenon also occurs in certain non-volcanic areas but the primary cause is not definitely known. One of the most noted regions is that at Larderello near Florence in Italy, and it is here that the major progress in the utilization of geothermal energy for the production of electricity has so far been made. In 1954 the installed capacity there was 274 Mw., producing some 2 x 10^6 Mwh. annually. Further development up to 428 Mw. is foreseen. As a result of experience simple power units of 3,500 kw. capacity have been designed. These operate from the steam at its exit point from the ground and exhaust into atmosphere. While not highly efficient in the use of steam, they can be built for low capital cost. Larger, more efficient machines, incorporating equipment for the recovery of chemicals from the steam, have been built in sizes up to 25 Mw.

The steam fields of Iceland, which are of volcanic origin, have yet to be seriously exploited. The rate at which heat is dissipated from these fields is estimated to be some 10^{10} Btu/hr., which is equivalent to a continuous power of nearly 3,000 Mw. Iceland has also many hot springs which are used as the source of domestic and greenhouse heating in Reykjavik and surrounding areas. A central heating system utilizing the natural hot water, which is piped over a distance of 10 miles from its source, supplies 32,000 of the inhabitants and many of the industrial and office buildings with water at about 170° F. It is planned to extend the hot water supply to the whole of the city and to more distant communities.

In New Zealand, where the thermal area covers about 3,000 square miles, exploitation of the Wairakei-Rotorua springs will, by the end of this year, add 70 Mw. of installed power to the main electricity supply. Drilling has been carried out, under difficult conditions caused by the permeable sub-surface rocks, to a maximum depth of 3,360 ft., and tests have shown the source to be capable of easily supporting 150 Mw. of plant. The second phase of the program will carry this out. Total power potential of the region is estimated at 475 Mw. An advantage of the steam here is that it is not charged with chemicals as at Sarderello.

In 1942 a small test plant of 112 kw. rating was operated for a short time in Japan. Continued borings have been successful in proving the wide availability of the source. A 3,000 Mw. power station is planned for the near future.

In the Belgian Congo a 275 kw. plant taking its power from a single hot water spring, has been in operation for many years. Other plants which are projected are for 100 Mw. in California, 50 Mw. in Chile, and two 25 Mw. experimental units in Mexico. There is also an important hydrothermal area in Alaska which has not yet been exploited.

REACTOR IN FRANCE

A GIANT GLOBE is now being constructed near Chinon in the Loire Valley and is intended as a shielded enclosure for a power reactor built by Electricité de France for producing electric power. The globe will have a diameter of 180 feet and is designed to resist an internal pressure of 24 lbs. per square inch. The thickness of the steel plates varies from 25 to 32 inches at the top to 1-3/16 inches at the bottom of the globe. The plates were cold rolled by a completely new process from steel with the relatively high impact strength of 22 ft-lb at 14° F. The average dimensions of the plates are 11 ft 6 inches wide by 30 ft long.

A particular feature of the design is the complete absence of any internal structural members or exterior supports. Upon completion, it will be the largest self-supporting globe ever built, although in actual diameter it will be only the third largest in the world. The base part of the sphere is set in a concrete foundation and a special arrangement at ground level has been provided to eleminate the bending stresses due to the concrete bed and the temperature gradient.

The free-carrying plates will be assembled before erection in sections of three at a time and welded by automatic welding machines. Construction welds will be made with low hydrogen electrodes and all welds will be x-rayed. The specifications prescribe extremely close tolerances.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Project

Although power was being delivered by eleven generators from the international power-house at Barnhart Island at the end of September, contracts amounting to some $60 million remained to be completed on the entire power project in the international section, with some 4,000 persons still on the payrolls.

Progress by Ontario Hydro

Concrete on the Canadian half of the power-house was all placed with exception of a few 'filling' pours. All of the original downstream cofferdam caissons had been removed. Dredging of the tailrace was deferred until the spring of 1959. Five units were in operation and a sixth almost ready. Installation of remaining units was progressing. Gibson tests for turbine efficiency were being carried out. Employment stood at some 1,700 persons at month-end.

Progress by NYSPA

Several small pours of concrete remained to complete at the end of September on the American half of the international power-house. Tailrace excavation was proceeding within the first tailrace cofferdam, which enclosed about a fourth of the tailrace area. No efficiency tests on turbines had been commenced, but six units were operating, with a seventh almost ready.

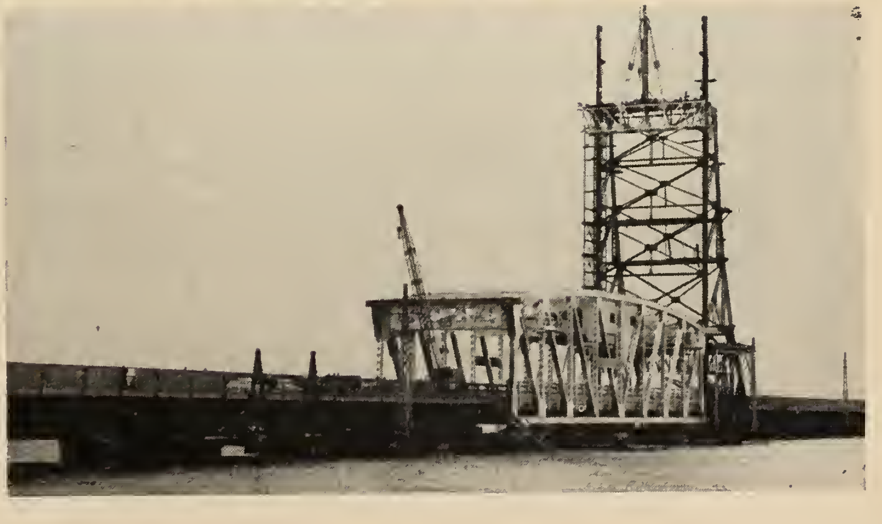
On the Long Sault dam, all tunnels through the dam had been plugged and only small pours of concrete on parapets and bridge walls remained to be completed. Temporary sluice gates in front of the tunnels were being removed, and installation of permanent hoists was proceeding. About half the river-flow was passing through the power-houses. Employment stood at about 2,300 at month-end.

Sweeping the beds of the upstream navigation channels by a barge with a dragging beam continued, to determine spots where the channels lacked 27 ft. depth. It is expected full depth will be attained throughout before freeze-up, though all channels may not be completed to full width.

Progress by SLSDC

With employment down to about 400 persons, some dredging was be-

The new lift span for the Valleyfield bridge was floated into position by Quebec Hydro workers, and installed by Dominion Structural Steel Limited with minimum interruption of traffic. Two lift towers will lift the span 115 feet over the seaway's Beauharnois canal. (Please see Progress by SLSA).



ing continued in the south Cornwall channel. Full width and depth was expected to be attained by freeze-up. On the north Cornwall (Canadian) channel for reducing velocity, dry excavation at some points continued.

The floating lock-gate for the two American locks, damaged last summer at the manufacturer's plant, was still under repair, but delivery was expected by February. On the international high-level highway bridge at Cornwall steel erection was completed, leaving only paving of deck on main span and small pours on approaches to complete. The bridge is expected to be open for traffic early in December.

Progress by SLSA

Bridges: With Jacques Cartier and Caughnawaga bridges virtually completed, bridge work was concentrated on Victoria and Mercier bridges during August. At Victoria bridge on the upstream rail diversion, all piers were in place from the end of the rail embankment at Riverside Drive in St. Lambert to the crossing of the St. Lambert lock. Steel was erected for the rail-highway lift bridge bridge over the existing lock and over the space left for the future twin lock when required. Erection of the lift tower was proceeding. The bridge approach-span over the drainage canal was erected.

At the Mercier bridge, steel erection was completed and concrete deck placed for the northbound lane of the Malone highway approach. On the southbound lane, steel was erected for eight spans on the south end and the deck was being formed for placing concrete. The highway approach from Laprairie to the bridge was carrying traffic.

Early in October a 212-ft., 1,500-ton rail-highway lift span, assembled a mile east of the upstream entrance to the Beauharnois Canal, was loaded on two scows and towed by three tugs to the site of the Valleyfield rail-highway bridge crossing the canal. After one existing span had been removed and stored on pile supports, the new lift span was raised by pumping out the scows and let down to exact position on the bridge piers. With one tower already erected, the second tower and electrical installation will be completed by year-end.

A similar operation was carried out in mid-October for another 212 ft. rail lift span, which will be towed 8 miles down the canal to the existing NYC-St. Louis rail bridge over the canal. The lift towers also will be erected at this site by January.

With work valued at some $35 million including channels, locks and bridges, remaining to complete at the end of September, total employment remained at close to 4,000 persons.

At the St. Lambert lock, paving and fill for approach roads in the area was under way, and clean-up operations were started. A start on similar work would be made at the end of October in the area around the Côte St. Catherine lock, where installation of electrical machinery for the gates and painting of gates continued.

At the lower Beauharnois lock very little concrete remained to place, but considerable finishing and repairs remained to do on approach walls and lock floor. Mitre gates were in position and aligned but not yet set. Dredging continued in preparation for sinking cribs in November at outlet end on Lake St. Louis. A start had been made on roads and paving in the area.

At the upper Beauharnois lock, the guard cribs at the upstream entrance were expected to be placed in October. There still remained some 10,000 cubic yards of rock to remove from the channel bottom between the upper and lower locks. Roads and paving in the area were expected to be completed by year-end. Installation of gates was completed up to prestressing of diagonals and electrical machinery was being installed.

Dredging, though somewhat behind schedule in some places, was proceeding satisfactorily, with the target being to complete a 'minimum channel' by the end of 1958. 'Sweeping' the channels, with scows dragging the riverbed with beams, was proceeding satisfactorily in Lakes St. Louis and St. Francis and along the Beauharnois canal.

The building in Cornwall to house the staff of the St. Lawrence Seaway Authority, under construction during the past two years, was completed in August. Some of the staff moved in during September.

Lakehead Ports

Now that the Federal Government is to participate in seaway harbour developments at the Lakehead, hopes have risen that Port Arthur and Fort William will get new general cargo terminal facilities to handle ocean tonnage. Cost of the terminal is placed at $4 million with completion likely within three years.

The Lakehead is currently equipped with a dozen general cargo sheds with total capacity of some 70,000 tons, sufficient to handle the half million tons of bulk cargo yearly, more than Toronto and Hamilton combined. A five-man harbour commission, with three members government-appointed and one from each of the Lakehead cities, will administer the two ports as one. Currently, dredging of the harbour to seaway standard depth of 27 ft. is under way at both ports.

The Bow River Irrigation Plan

Alberta's $6 million Bow River Irrigation Development, scheduled for completion in November, will serve 50,000 acres of irrigable land in the Lomond-Travers-Enchant areas, fifty miles north of Lethbridge. This is the second system in Alberta to be constructed and supervised solely by the Water Resources Branch of the Provincial Department of Agriculture. Engineers of the Water Resources Branch and P.F.R.A. officials have worked in close co-operation.

The water for the development was taken from a main P.F.R.A. canal running from the Travers Reservoir to Hays. This water is originally diverted from the Bow River near Carsland into Lake McGregor and the adjoining Travers reservoir.

The main canal is 30 mi. long, has a carrying capacity of 1,150 cu. ft. per second. The irrigation water is fed to 7 distributory channels totalling 375 mi. in length. A 30-mi. trunk drain canal leads back to the Bow River.

The irrigated land for the most part will produce feed for cattle and specialized grass seed, it is expected. Alfalfa, tame hay, irrigated pasture land and other specialized crops, will take up a large percentage of irrigated deeded lands.

The Bow River's "Parshall" flume was designed to measure the amount of water going through the main canal by means of automatic instruments. All other structures in the project are calibrated to permit measurement of the flow of water. A radio control communications system aids the management and control of the new irrigation system.

Laval Looks Forward to New Engineering and Science Buildings

At Laval University, the need for considerable expansion of the physical facilities available in the Science and Engineering departments has grown rapidly over the last decade. The two present buildings, erected in 1925 and 1939, were intended to house at most one half of the present student body of over 900.

New space must be made available to ease the present paralyzing pressure and to take care of increasing enrolments for some years to come, Dean of Science Cyrias Ouellet has reported. This would permit long-delayed improvements in laboratory teaching as well as increasing activities in various fields of research. Plans are now being drawn for two new buildings and it is hoped that construction will begin sometime during 1959.

The science faculty has, over the last 20 years, organized courses in several branches of engineering. As the engineering departments came to life one after another, the same original facilities for teaching in the basic subjects continued to be used and thus, the engineering departments have remained closely linked with the science departments under a single academic structure. The first two years are common to all categories of students. The new buildings are being designed so as to make the retention of this closely knit academic structure possible without making it a physical necessity. A balance is sought between the economical advantages of sharing common services and the academic desirability of a reasonable physical segregation at the departmental level and also between the two main groups of disciplines: the engineering subjects and the pure sciences.

The project calls for two interconnected buildings of roughly equal sizes, one for science and one for engineering. These two buildings are to be located in the Cite Universitaire, in the neighbourhood of the new medical building, the forestry building and also of the Science Service laboratories now under construction. The total floor area is estimated at about 600,000 square feet. It is expected that this space will eventually accommodate some 2,000 students and a considerably increased number of research workers.

These two units, linked by a short tunnel, will share a common auditorium, main library, administration space, central workshop and some other services. One unit will house the science departments and also most of the lecture rooms used by the students of the first two years. The other unit will house the engineering departments. Each department, while sharing some of the space available in one of the main blocks, will extend into a wing of its own, behind which ground will be provided for eventual expansion.

In the case of the engineering departments these wings will be high, single-storied structures, permitting installation of heavy equipment and leaving possibilities for vertical and horizontal subdivision. Much of the space will consist of relatively large areas inside which movable partitions will permit reallotment according to a standardized modulus. In each department, facilities for research and advanced undergraduate teaching will, where feasible, be grouped in the same region and sheltered from the more busier areas.

A Report on Growth in the Engineering Faculties in Canada

Eleventh article of a series

Nova Scotia Technical College Anticipates Future Requirements

Engineering education in Nova Scotia takes a different pattern from the rest of Canada.

The province is served by four universities,—Acadia, Dalhousie, St. Francis Xavier, and St. Mary's. The present system is really a heritage from the past, in which the first three years of engineering training was taken at the various "Associated Universities" and the last two years given at the Nova Scotia Technical College, which was established for this purpose in 1907. In addition to the Nova Scotian universities mentioned, Memorial University of Newfoundland, Mount Allison University, and the University of New Brunswick, are included in the group known as the "Associated Universities". Entrance to the three-year course in engineering at these universities is based on junior matriculation.

The Nova Scotia Technical College therefore gives undergraduate instruction only in the fourth and fifth years of the five-year course, and deals only with the more senior aspects of engineering education. There are at present 26 members on the teaching staff, ranking from assistant professor upward, and the current registration is 300 students. The small campus of approximately eight acres is situated in the heart of Halifax, and includes the electrical, mining, mechanical, civil, and administration buildings.

Within the last few years the curriculum has been reshaped to conform with the modern requirements in educating engineers whose careers extend some forty years into the future. The emphasis has been placed firmly on the fundamentals of the physical and applied sciences, with a reduction in the proportion of time allotted to the study of current practice. This is regarded as the appropriate method of educating for the coming era of burgeoning technical activity, President J. Hoogstraten reports.

Students with exceptional talent are admitted to the honours course in which additional work in a major advanced study is undertaken. The purpose of this opportunity is to enable the exceptional man to secure a broader and deeper knowledge of some portion of the field.

A new $800,000 building is now being planned by C. A. Fowler and Company, architects. These plans currently envisage a lecture room and draughting room wing attached to the south end of the present Macdonald Building, reaching towards Barrington Street and terminating with an administration and library wing parallel to the Macdonald Building. A laboratory wing extends southward, generally in line with the existing Macdonald Building. The open areaways under the lecture-draughting room wing, and also at the north end of the administration wing, will lend a feeling of spaciousness on a crowded campus. It has been decided, as a matter of policy, that no classes shall exceed 40 students in number, and classrooms and draughting rooms are planned to accommodate these numbers. The lab wing will house a new mechanical laboratory, and all electrical engineering laboratories will be re-established here. It is expected that further building will be necessary in 1965.

The Alumni Association is presently engaged in raising $300,000 for the erection of a gymnasium and auditorium. It is expected that construction will begin about 1960.

Calgary Campus Planned

Tentative plans for the proposed campus for the University of Alberta to be located in Calgary were presented to the Council of the City of Calgary in October. The plans were outlined by representatives from the Department of Public Works and the Board of Governors of the University of Alberta.

The site which is located west of 16 Street N.W. and south of the old Banff Trail, provided by the City of Calgary, comprises approximately 312 acres.

Initial plans call for the erection of an Arts and Education Building and a Science and Engineering Building to be in service for the fall term of 1960. Subsequent buildings will proceed as student population and student requirements expand.

Commencement of construction is now awaiting the provision of sewer and water mains by the City of Calgary. It is anticipated that construction of the first two buildings will start in the spring of 1959.

Canadian Pipeline Projects

Westcoast Transmission

The $7 million extension of Westcoast's natural gas gathering system northwest of Fort St. John was completed in mid-September and went into operation later in the month. The 84-mile extension, roughly following the Alaska Highway, will tie in 21 more gas wells and add 80 million c.f.d. for delivery to the processing plant at Taylor, B.C. Ultimately the extension will add 150 million c.f.d. to the gathering system's capacity. More than 300 men, 90 per cent of them Canadians, were employed at peak periods, nearly half the pipe used was of Canadian manufacture and cost over $1 million. The balance came from Kaiser Steel Corporation.

Alberta Gas Trunkline: BA Oil formally opened two major plants costing a total of $50 million in mid-October. The Pincher Creek gas-processing plant, which commenced delivery of gas at end of September, was dedicated October 15, while the Port Moody refinery near Vancouver was ready for public opening October 17. Completion of the Pincher Creek recycling plant makes British American the largest supplier of natural gas to the Trans Canada pipeline. It will have a daily initial production capacity of 13,700 gallons of propane, 20,000 gallons of butane, 450 long tons of sulphur, and will deliver 70 million c.f.d. of gas the first year of production.

Canadian Western Natural Gas: Reflecting the vast expansion of the Company's services throughout southern Alberta, an official estimate predicts CWNG will be serving 82,750 customers by end of 1959, compared with 24,300 twenty years previously. This year the towns of Enchant and Vauxhall were added to the system. Next year, Carmanguay Champion, Kirkaldy, Barons and Vulcan will be served.

Sask. Power Corporation: Early in September S.P.C. dedicated its 90-mile, 14-inch trunk pipeline carrying 383 billion cubic feet or more yearly from the Hatton-Many Islands field on the Alberta-Saskatchewan border. The line extends to S.P.C.'s Success-Moose Jaw system. Some 211 billion cubic feet per year in the Many Island field were dedicated to this line.

Construction was nearing completion early in September in southeastern Saskatchewan on the natural gas conservation plant of Steelman Gas Ltd. The plant is the first in the province designed to produce sulphur from gas, and the first to produce liquid propane from casinghead gas. Total expenditures to end of August were $7.1 million, well within budget estimates. Underground storage for propane in salt wells at Melville is provided by two storage wells and a brine disposal well. International Sulphur Co. will purchase the sulphur with a floor price of $19 a ton. Plant is designed

A few of the 24 large tanks which give the B-A Pincher Creek plant a storage capacity of 336,000 gallons of LPG products and 24,000 barrels of condensate.

to produce 25 MMc.f.d. with ultimate expansion to 45 MMc.f.d.

Trans Canada Pipelines

Trans Canada, already serving the Lakehead area, expects to be delivering over 130 billion feet yearly by the fifth year of operation. Ontario uses about 14 per cent of the country's energy, of which 91 per cent is imported at present. The rapid growth of Ontario's gas market is largely responsible for an unexpected need for expanded delivery facilities by 1961/62. Trans Canada sees a need to double capacity by that time.

At the end of September construction of the entire mileage between Lakehead and Toronto on both the Northern Ontario Pipeline Crown Corporation section of 367 miles between Port Arthur and Kapuskasing and the wholy owned 486-mile Trans Canada section between Kapuskasing and Maple near Toronto.

Final tie-in welds had been made on all 1958 mainline construction except for the loop sections and some of the river crossings. It was expected pigging, purging and pressure testing would be finished ahead of the scheduled completion date of November 1st. The year's program also included five compressor stations.

Northern Ontario Natural Gas expects deliveries by end of 1958 to reach 72 million c.f.d. and by end of 1959 up to 103 million c.f.d., nearly its Trans Canada contract maximum. The company, and its affiliate Twin City Gas, will serve 34 communities on the 1,100-mile route of Trans Canada east of the Manitoba boundary with some 800 miles of distribution mains and service lines and 180 miles of laterals and intercity connections, costing $22 million. They have already contracted to supply 60 per cent of industry's total fuel needs in the franchise areas. Three Lakehead mills of the Abitibi Power and Paper Co. have been converted to natural gas. Combined consumption could reach 7.7 million c.f.d. Northern Ont. Natural Gas and Twin City now hold long term contracts for nearly 60 million c.f.d. to eleven miles between Kenora and Orillia.

Two Export Applications Temporarily Rejected: The Alberta Conservation Board rejected late in September applications for two companies wishing to export gas to Pacific States, namely Alberta Southern and Westcoast Transmission. The former had asked a permit to export 4.2 trillion feet the next 25 years, while the latter had sought permission to export 1.3 trillion feet.

Pointing out that of the 23 trillion c.f. of gas reserves, only 4.1 trillion feet was surplus to present and future Alberta needs, the Board suggested the two applicants scale down their demands by about 25 per cent. They were told their applications would be reconsidered at new hearings before the end of the year.

B-A Port Moody Refinery

Port Moody, B.C. is the site of the British American Oil Company Limited's largest refinery. The $25 million installation, which covers a 380-acre area, will have a 20,000 barrel per day capacity of petroleum products. Two miles of 12-inch pipe line connect the Burnaby, B.C. terminus of the Trans-Mountain pipeline and the new refinery. Trans-Mountain supplies crude oil from Alberta oilfields. Ultimately these lines will be capable of supplying the refinery with 80,000 barrels of crude per day.

The Port Moody location offers the proximity of the market centre of metropolitan Vancouver, as well as favourable taxation rates, it is reported. The company intends production of a full range of petroleum products, high octane gasolines, stove oil, diesel oil, and others.

The Port Moody plant is supplied with the most modern of equipment.

An alkylation unit which produces a material expressly designed to raise the octane of gasoline is part of the new refinery. Liquid gases, such as propylene, butylene and amylenes, produced in the refinery are combined with isobutanes to produce an alkylation reaction and are processed with sulphuric acid. A motor alkylate is produced and is finally blended with gasoline, resulting in a higher octane rating.

B.A.'s first middle distillate unit has been set up at Port Moody. A cobalt molybdate catalyst promotes the reaction of sulphur with hydrogen. About 75 per cent of the sulphur content of the feed stock is eliminated. This results in superior burning and heating characteristics.

One of the two great steam producing boilers is of the carbon-monoxide type, capable of producing 85,000 lbs. of steam an hour. About 30 per cent of its fuel is waste gases from the catalytic cracker.

Automatic gauging equipment maintains a constant check on the level and temperatures of the big tanks. Workers at Port Moody simply dial the number of a particular tank to obtain this information from electronic equipment which covers the entire refinery.

A new development is the automatic blending equipment on process units. All-electronic instrumentation is used to blend gasolines.

For its largest refinery, B.A. has

B-A Refinery, Port Moody, B.C.

provided a maximum of fire protection. A fire truck is provided which can carry 1,000 gallons of foam and is capable of refilling during pumping. It can discharge 9 streams of foam, and four streams of cooling water.

The refinery also maintains a double source of electric power from the B.C. Electric Company's 60-kv. main transmission line nearby. An automatic throw-over switch gear can draw power from the second line, if necessary, without interrupting plant operations.

Montreal-Laurentian Autoroute

The Montreal-Laurentian Autoroute, construction of which began in August 1957, is expected to open in November 1959 for the full 29-mile route. A 9-mile section will be opened to traffic during November this year — the stretch between Cremazie Blvd. in Montreal and Ste. Rose, Que. Two thousand men were employed on the project during October.

The Autoroute will link Montreal's Metropolitan Boulevard, running east to west across the island, with the provincial dual highway, one mile north of the City of St. Jerome, Que. Motorists will be able to travel at a rate of 70 miles an hour, travelling the full distance in about half an hour. Ernest Gohier described the project at the Canadian Good Roads Association annual meeting in October, 1958. He is the chairman of the Montreal-Laurentian Autoroute Board, a Provincial authority.

Right of way is 200 ft. wide for the first three miles, and 300 ft. for the rest of the way. At the full clover leaves or interchanges the width is 1,200 ft.

Three traffic lanes in each direction are separated by a 40 ft. or a 100 ft. mall. The four outside lanes are 12 ft. wide; the two passing lanes 13 ft. wide. Acceleration and deceleration lanes are 12 ft. across, and vary from 1,000 to 1,200 ft. in length to permit perfect weaving of traffic.

The two main bridges, one over Rivière des Prairies, 1,850 ft. long, and one over Thousand Island River, 3,300 ft. long, are 92 ft. wide. They have steel superstructures resting on concrete abutments and piers, with reinforced concrete slabs 8 inches thick. Four shorter bridges of the same type cross the North River.

Forty underpasses and overpasses are built of reinforced concrete. Composite structures of steel and concrete are used at four railway crossings.

Bridges, underpasses and overpasses are built to H-40 standard. Each has 6 lanes. Fourteen interchanges serve the already settled communities along the route.

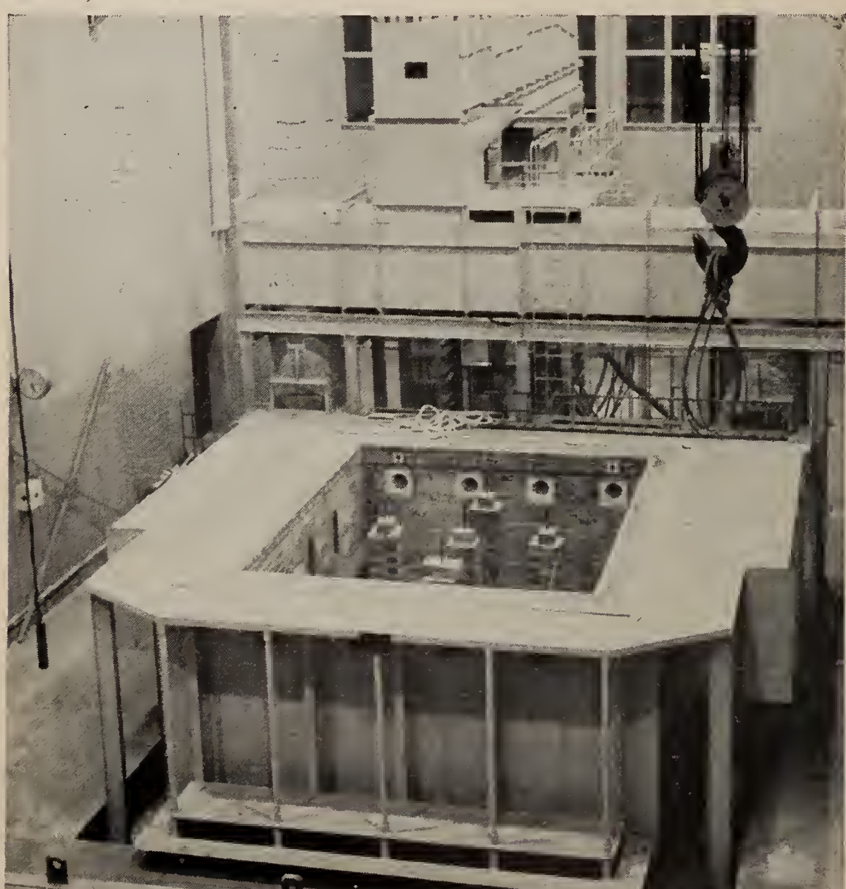
Three toll gates, each with 12 paying booths, are planned for minimum interruption of traffic.

The profile of the autoroute shows a maximum grade of 3 per cent (at loops, 5 per cent). Maximum degree of curvature is 2 degrees and 30 min.

Pavement on the Autoroute consists of a uniform 8-inch thick reinforced concrete slab. Transversal expansion joints are provided every 200 ft. and paved contracting joints every 40 ft. Clover-leaf loops are surfaced with a 300-lb. hot asphalt concrete pavement.

Designed for an axle load of 28,000 lbs., the roadway structure is composed of a compacted sub-grade; 4 inches of filter-type sand and stone cushion; 8 inches of crushed compacted stone; two inches of sand or ¾ of an in. of run-of crusher stone for the fine grading; and 8 in. uniform reinforced concrete slab.

Furnace laboratory in the Fire Research Building of the Division of Building Research, National Research Council.

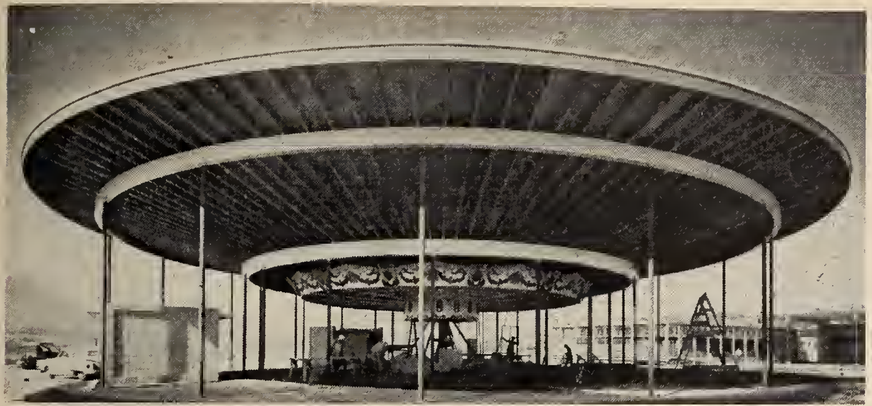


Fire Research

The fire research laboratory of the National Research Council, dedicated on October 3, covers an area of 20,000 sq. ft. Of a total volume of 550,000 cu. ft., nearly one half consists of a 40-ft. high laboratory housing two large furnaces.

One of these, used for research into the fire resistance of wall structures, will accommodate panels 14 ft. by 14 ft.; the other is a floor furnace accommodating floor structures 12 ft. by 15 ft. In both furnaces the specimens can be loaded to maximum working capacities prior to the application of heat in accordance with either ASTM or BSI standard test procedures. There are also chemical and physical laboratories, a special room for carrying out model burns, and space for research into the hydraulic aspects of fire fighting and fire prevention.

The proceedings of a two-day conference which preceded the official opening of the fire building, will be published by the Division of Building Research.



Carousel at P.N.E. Grounds, Vancouver.

Engineered Timber in Construction

Special fabricating techniques employing B.C. timber, used on a $1 million project in British Columbia saved approximately five weeks construction time, it is claimed. Prefabricated piece by piece away from the building site, the largest roller coaster in Canada and a giant carousel were completed for the Pacific National Exhibition Grounds by Timber Preservers Limited, during the past summer. The architect was Douglas Miller of Vancouver.

The roller coaster, using approximately 256,000 f.b.m. of lumber has more than one-half mile of track and will rise to a height of 72 ft. at its highest point. It consists of 284 bents of 10 ft. spacing, with the bents preframed and bored, using 4 in. by 6 in. structural Pacific Coast Douglas fir braces. The structure, designed to withstand wind velocities in excess of 90 miles per hour, specified the use of pressure-creosoted Douglas fir piling together with 12 in. by 12 in. caps.

Speeds up to 60 m.p.h. can be attained on the 45° angle runs. Bracing of the structure, running parallel to the ground is spaced at 5 ft., is overlapped and fastened with spiral nails. The track consists of 8 layers of wood and cross ties. Many structural members were pressure treated with Wolman salts for increased strength.

The carousel which has an outside roof diameter of 102 ft., was also constructed by the preframing and prefabricating technique. The roof is formed from large pie-shaped arched sections of plywood, 25 ft. long. The method used was to erect a false stage to support the carousel centre steel ring to a height greater than the centre glued laminated ring. The inner glued laminated timber ring carries vertical roof loads, whereas the horizontal thrust from the inner portions of the roof is contained by a welded steel plate ring precision fitted around the inner glulam ring of 29 ft. radius.

Other structures include a whip building, scooter building, a concession building and covered midway. They employ plywood boxed beams and structural laminated members, in combination with other materials.

The drive-in restaurant building was designed with glulam beams radiating from the centre steel column. All the posts supporting the roof and floor are run down to concrete bearing walls or pedestals. The novel Douglas fir plywood gussets within the posts were designed to allow greater cantilever without increasing the size of the glulam beam. The plywood itself provides lateral stability. The entrance walls are of rough stone.

In one structure glulam trusses salvaged from a bridge project were used again as a building material.

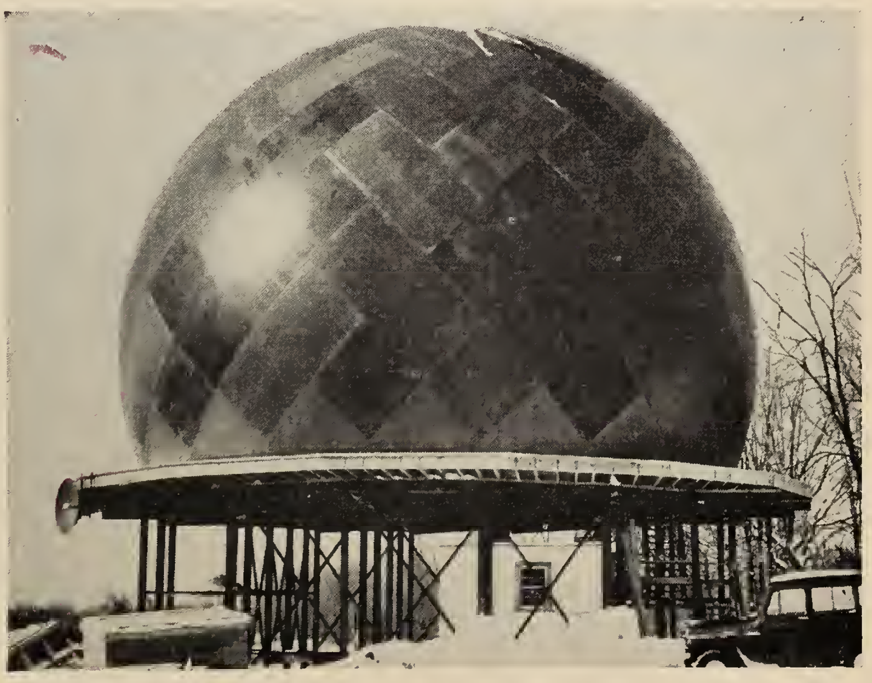
Epoxy Radome

A ground-based reinforced epoxy radome has been designed, built and erected by Long Sault Woodcraft, Ltd., St. Andrews East, Quebec. It stands 40 ft. high and weighs 9,000 lb. It has a 50 ft. base diameter and 55 ft. equatorial diameter. The prototype radome, which was built under contract to Rome Air Development Center, U.S. Air Force, Rome, New York, was assembled earlier this year. Other units of the same size are under way, but Long Sault engineers say that the stressed laminated skin type of construction makes possible even larger ones — of 100 ft. and even 200 ft. in diameter.

The lightweight rectangular panels of the radome are designed so that the entire unit can be knocked down and shipped in a single aircraft. It is fire- and weather-resistant, and can withstand winds greater than 150 m.p.h. at sub-zero temperatures. Six men can erect the radome in only 1½ working days.

It consists of 156 individual contoured panels, the largest near the equator weighing 100 lb. and measuring 6 by 12 ft., and the smallest near the pole being 3 by 5 ft. A panel is made by preparing two skins, each consisting of two plies of glass cloth reinforced with a formulation of Epon* 828 (Shell Oil Company of

Ground based reinforced epoxy radome, built in Quebec



Canada, Limited) and a curing agent. A one inch paper honey-comb core is then bonded between the two skins. A sheet of Dynel fabric on the outer surface of each panel provides not only fire resistance, but also an additional reinforcing layer for improved weather resistance.

From a structural point of view, design of the radome is that of a sphere in which loads are carried uniformly throughout the structure.

Joints are arranged to cross the surface at 45 degrees rather than vertically or horizontally. This means that panel joints do not interfere with either search or height finder radar sets. Surface of the radome is entirely spherical rather than faceted. The individual panels are attached to each other by 1,500 cam-actuated locks closed by a ¾ turn.

Saskatchewan Research Council

The Saskatchewan Research Council, moving into recently completed laboratories on the University of Saskatchewan campus, can apply itself to still wider interests. In its ten-year history it has worked on research and investigation in the physical sciences, pure and applied, aimed primarily at improving the provincial economy. These aims have been implemented mainly by research at the University, sponsored by the Council through grants to the University and scholarships to graduate students. Since 1955 a Technical Information Service has been available to industry. In 1956, T. E. Warren became director of the Council.

There are six divisions: the physics division, headed by Dr. T. P. Pepper; chemistry, Dr. E. J. Wiggins; engineering division, W. H. W. Husband; geological division, Dr. J. R. Smith; technical information, I. S. Evans; and a biology section.

Notable projects are:

A Lignite project: studying the carbonization of lignite, which is produced in Saskatchewan to the extent of two million tons annually. Work on the efficient use of lignite was sponsored by the Saskatchewan Power Corporation.

Carbon dating: Improved method of measurement of age of materials by a carbon 14 apparatus.

Rape seed oil: development of a lubricant from rape seed would provide an alternative crop for Saskatchewan farms.

Building and highway foundation problems: Long term savings are attributable to this project, which studied methods of building foundations on clay.

Thirty-six projects now being sponsored by S.R.C. are discovering new methods, new materials and new markets.

What Goes On

Export Credits Insurance Corp.

Five new members have been appointed to the Advisory Council of the Export Credits Insurance Corporation, a Crown Company which insures exporters against non-payment by foreign buyers.

Those just appointed are: Hon J. V. Clyne, chairman of the Board, MacMillan & Bloedel Limited, Vancouver; H. G. De Young, president, Atlas Steels Limited, Welland; Raymond Dupuis, president, Dupuis Freres Limited, Montreal; A. C. McKim, president, Merck & Co. Limited, Montreal, and F. G. Rutley, chairman of the Board, The Foundation Company of Canada Limited, Montreal.

They serve with others remaining on the Council: Hon. Hector Authier, Amos, Que.; R. B. Buckerfield, Vancouver; James S. Duncan, Toronto; Raymond Garneau, Quebec; H. G. Hesler, Montreal, George W. Robertson, Regina, Sask.; Fletcher S. Smith, Halifax, James Stewart, Toronto; K. F. Wadsworth, Toronto; F. Homer Zwicker, Lunenburg, N.S.

New Brunswick Industry

Many of the items imported for the Atlantic Provinces market could economically be produced there. However, the low volume of that market is a deterrent.

At the same time, manufacturers, through changing conditions or for other reasons, periodically find their plants with surplus production capacity.

The New Brunswick government advises the relating of these two circumstances, as a way to open opportunities for expanded business. The method would be a working arrangement with another manufacturer to make his products with existing facilities, to cater to the limited markets. Overhead savings, elimination of tariffs or transportation charges could

Wolverine Tube plant, Calumet Hecla of Canada Ltd., London, Ont.

place such products in a preferred competitive position.

The Department of Industry and Development, New Brunswick, is exploring the potential with provincial manufacturers and with those presently exporting to the area or to Canada.

Canada's Exports

"Canada's exports to date have shown strong resistance to the downward tendencies in world trade at large", it was reported by John H. English, Deputy Minister of Trade and Commerce, in September. There was a more than two-fold increase in one of Canada's new exports — uranium, he said. Other items had been sold abroad in substantially larger amounts this year, such as aircraft and farm implements.

It was evident that many Canadian industries were successfully weathering the competition from imports, Mr. English said. He mentioned particularly the iron and steel industry where operations had at no time fallen below 72 per cent of capacity.

Efficient Productivity

Speaking at the annual meeting of the Canadian Chamber of Commerce, in October, in Montreal, retiring president R. C. Pybus, M.E.I.C., of Vancouver, said "It is my belief and it is the thinking of our Canadian Chamber of Commerce that efficient productivity is the key to our continuing prosperity and our defence against the cost price squeeze. We must increase our engineering skills, our research and technological developments. We must increase efficiency in management and in Government, and create a desire for the worker to be interested and industrious in his or her work.

"It will require cooperation between labour leaders and management and a realization that labour, management, government and capital are as a team which must work and pull together for our economic welfare and in the interest of all, which is indeed enlightened self-interest."

Western Copper Mills Ltd.

By means of a recently concluded agreement between Western Copper Mills Ltd., Harrisons & Crosfield (Canada) Ltd., and Harrisons & Crosfield (America) Inc., there will be world-wide sales representation for the products of Western's mill now nearing completion on Annacis Island in the Vancouver area.

Harrison's president said that sales will be made through established Harrisons offices in Canada and the United States.

Construction of Western's fully integrated copper alloy tube, rod and bar mill, covering nearly five acres, is to be completed late this year. It is equipped to produce up to 3 million pounds of copper water tube, copper and brass pipe, refrigeration tube, automotive tube, condenser tube, electrical bus conductors and brass rod per month.

Wolverine Tube Plant

Full operation of the tube-producing facilities at Calumet & Hecla of Canada, Limited, Wolverine Tube Division plant at London, Ont., was announced in September by D. D. C. McGeachy, M.E.I.C., vice president and general manager of the Company.

The plant, a source of non-ferrous seamless tubing, since its first shipment in April has approached the 1,500,000 pound mark. With full production, the planned production of 1 million pounds per month may be exceeded.

Some features of the industrial development are:

- Architectural design uses colour scheme to unify separate buildings
- The dominant building, the 820 ft. x 140 ft. tube mill, has 85,000 sq. ft. of manufacturing space, providing a clear height of 29 feet to the underside of the 100-foot span steel trusses. The mill building is free of columns.
- The mill includes a casting shop of 12,000 sq. ft., where raw metal and scrap are melted and poured into billets.
- The service area and boiler house running parallel and adiacent to the mill, contains electrical and millwright maintenance shop, tool shop, supply crib, engineering office, physical and chemical testing laboratorv. The area totals 24,000 sq. ft., including 7,000 sq. ft. for the boiler house.
- The administration building, and the gatehouse and personnel building are parts of the scheme.
- Pump house is provided, where 500,000 gallons of water are treated for industrial re-use.
- Each building can be enlarged in a pre-determined direction, according to a plan.
- Duplicate 3-phase, 60 cycle, 27.6 kv., three wire electric power services are obtained from the Ontario H.E.P.C. and terminate at the outdoor plant substation.
- Two 100-hp. boilers take care of the steam and hot water requirements of the plant. They are of the packaged four-pass forced draft type, each rated at 500 sq. ft. of heating surface, 3,345,000 B.t.u. per hour output, and 3,450 lb. of steam per hour.
- Production is essentially a cold drawing or cold working process, with modifications for brass tube working.
- Statistical quality control is used for all operations.

Automobile of the Future

The "new and different car" of the future was described by Gordon E. Grundy, president of Studebaker-Packard recently. It will be a car that is amply big enough for passenger comfort, but not excessively large; that has all the power needed for every sensible motoring demand, but not more; its basic design incorporates simplicity and elegance, but avoids superficial ornamentation.

Mr. Grundy said that his company is in process of tooling up for production run of a new type of car combining the best qualities of European and North American cars.

Ferranti Business Transactor

Ferranti-Packard Electric Limited, entertaining A.I.E.E. delegates to the Toronto plant, demonstrated the company's business-transactor, adaptable to reservation systems or inventory control where points of input are physically or geographically separated.

In the power transformer division, automatic core steel handling equipment was demonstrated. Five-ton rolls of sheet steel were seen being slit lengthwise while running at 200 feet per minute, and then the strips cut to length with an accuracy of ±.002 in., in a continuous operation. The machine stacked the cut material readv for assembly into "boltless" transformer cores.

Refining Unit for Yukon

The Yukon Territories will benefit by a $1 million refining unit when Alaska-Yukon Refiners and Distributors Limited, a Canadian company with headquarters at Edmonton, constructs the installation at Haines Junction, Y.T. The engineering design and construction will be the responsibility of the Fluor Corporation of Canada Limited.

The refining unit, a new industry, represents a forward step in the territorial development program. The Haines River plant will be a products treating and separation plant capable of handling a through-put of 3,000 barrels of oil dailv, and will produce asphalt of several grades as well as stove, diesel and bunker fuels for distribution in the Yukon and Alaska regions.

The acquisition earlier this year of one of the Canol pipelines used in World War II, from the United States, and the imminent turnover to the Yukon of the remaining ones transfer of which is being negotiated, will aid the distribution of petroleum products in the remote northern area.

CONFEDERATION — A Progress Report

The chairman of the E.I.C. Committee on Confederation, Dr. Irving R. Tait, presented the following report to Council at its meeting on Saturday, October 25, 1958.

"Since the last report, presented to the September meeting of Council, the Institute panel of the sub-committee has met three times, and the whole sub-committee has met twice. Mr. Foulkes, vice-chairman of the Institute panel, came from Ottawa to Montreal for two of these meetings.

"The sub-committee reached accord on all points, and are now submitting their report and recommendations to all members of the joint committee. It is planned when all committee members have approved, it will be submitted to the Council of the Institute and to the Canadian Council.

"The sub-committee report recommends unanimously that the two bodies take the action necessary to bring about Confederation. The next steps are clearly defined. The first step is to have the councils send the proposal to all members with a ballot asking their approval of the overall general plan, and their authority to set up a provisional council. This provisional council will then proceed to set out the final details for Confederation including the necessary by-laws.

"The second step recommended is that the final proposals of the provisional council be sent to all members with a ballot asking for their approval. If the ballot is favourable Confederation will be inaugurated as soon as the necessary arrangements can be completed."

Council discussed this report on Confederation at great length and expressed its appreciation and pleasure at the considerable progress that had already been made.

Several councillors inquired when the ballot of all members, referred to in the report, might be held. Dr. Tait replied that, if nothing unforeseen happens, the first vote mentioned in his report would probably be held during the first half of 1959.

Meeting of Western Councillors, at Calgary, October, 1958

The first trial meeting of Councillors in Zone A (the Western Provinces) was held in Edmonton in March 1958, and was so successful that it was decided to continue the experiment this year. The councillors are constituted as an Advisory Committee of Council as a whole on matters affecting the Western Branches.

Accordingly, a meeting was called for the forenoon of Saturday October 18 in the Palliser Hotel, Calgary. Present were the late S. C. Montgomery, vice-president, in the chair, and Councillors F. M. Cazalet, Vancouver, D. Cramer, Lethbridge, P. F. Fairfull, Victoria, W. K. Gwyer, Kootenay, N. M. Hall, Winnipeg, W. F. Hayes, Saskatchewan, R. N. McManus, Edmonton, P. M. Sauder, Association of Professional Engineers of Alberta, and T. D. Stanley, Calgary; Past-Councillors J. B. Mantle, Saskatoon, and W. A. Smith, Calgary. Also present were F. L. Perry and O. O. Junker, chairman and secretary of the Calgary Branch. The Western Field Secretary, A. C. M. Davy acted as secretary.

The meeting lasted for about four hours, following which a reception was held by the Calgary Branch for the visitors.

Among the interesting topics on the agenda was the proposal to hold a two-day Regional Technical Meeting next October, in Banff. Professor Mantle, chairman of a committee set up in March to study the possibility of holding such a meeting, reported that the replies to a questionnaire sent out by him to the Branches showed sufficient interest to justify proceeding with the project. Further information, notices and so on will be forthcoming as plans develop. Chairman of the Conference Committee is W. Smith.

Confederation, of course, came in for its usual lively discussion, but in view of the existence of the two committees working in Montreal, no formal steps were taken.

Altogether, the meeting was very successful. It was the general opinion that these meetings have great usefulness in drawing together the widely scattered membership in Zone A. Perhaps they do more good by strengthening the loose-knit ties of the membership than by any formalized passing of resolutions.

The whole event was saddened by the tragic and sudden death of the Vice-President S. C. Montgomery who collapsed while driving his car in downtown Calgary on the Monday morning after the meeting.

ECPD Annual Meeting

The twenty-sixth annual meeting of the Engineers' Council for Professional Development was held in St. Louis, Missouri, on October 9 and 10, 1958. The Institute was represented by several members, including two of the three Canadian members of the Council, i.e., W. S. Wilson of Toronto, and G. R. Henderson of Sarnia.

The Institute took a special part in two of the three panel discussions. A group of five from Ontario gave a detailed account of how the Professional Development Program is carried out in Canada. This activity was set up originally by Colonel L. F. Grant, HON. M.E.I.C. and has gone on to success after success. It developed originally from the ECPD program "The First Five Years", but so far as is known no comparable development has taken place in the United States.

The Canadians made an excellent showing under the chairmanship of George L. Schneider, of Hamilton.

The other demonstrators were: J. J. Durand, Toronto, *Development and Objectives;* Jack Walsworth, Jr.E.I.C., Hamilton, *Organization of a Typical Program;* W. J. O'Reilly, Jr.E.I.C., Niagara Falls, *Program Content;* Wm. E. Lardner, Jr.E.I.C., Toronto, *Publicity and Participation.*

The other panel discussion was based on finding a new and "exclusive" word for the profession to replace "engineer". This was an activity of the Committee on Recognition. Panel members were — P. L. Alger, chairman, Ethics Committee, consulting engineer, General Electric Company, Schenectady; L. G. Smith, Guidance Committee, Baltimore Gas and Electric Company, Baltimore; L. Austin Wright, general consultant, The Engineering Institute of Canada; with George H. O'Sullivan presiding, vice-president, J. G. White Engineering Corporation, New York.

This was a most interesting session. After the three panel members had spoken there was a wide discussion from the floor. The outcome was that the audience voted to have the committee continue its work in the hope that a better word would be found.

Another interesting discussion took place at the meeting of the Council, relative to a definition of engineering submitted by the Recognition Committee. Finally the definition was approved and accepted. It is as follows: "Engineering is the (learned) profession in which a knowledge of the mathematical and natural sciences gained by study, experience and practice is applied with judgement to develop ways to utilize economically the materials and forces of nature for the progressive well being of mankind".

A very useful "show" was staged by the Education and Accreditation Committee. With W. L. Everitt, dean of engineering, University of Illinois, presiding, a "mock" accrediting session was demonstrated. Participants were Norman A. Hall, professor of mechanical engineering, Yale, R. G. Folsom, president, Rensselaer Polytechnic Institute, and J. Henry Rushton, professor of chemical engineering, Purdue University. In three acts they showed how accrediting is actually carried out by the committee.

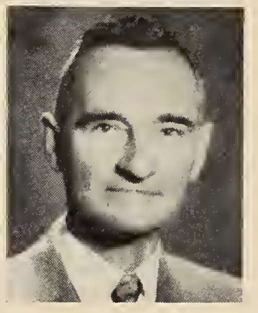
Special speakers for luncheons and dinners were the Hon. Raymond R. Tucker, Mayor of St. Louis, G. A. Hawkins, dean of engineering, Purdue University, Curtis L. Wilson, dean of engineering, Missouri School of Mines and Metallurgy, and Dr. George E. Mowrer, director of guidance, St. Louis Public Schools.

Another matter of interest to the Institute is that ECPD would welcome an invitation to hold their meeting in Canada about 1960 or 1961.

The newly elected officers are: president, W. L. Everitt, dean of engineering, University of Illinois; vice-president, W. L. McCabe, dean of engineering, Polytechnic Institute of Brooklyn.

The Institute's representatives on committees are: Guidance, D. A. Young; Education and Accreditation, C. H. R. Campling; Ethics, J. E. L. Roy; Recognition, Guy Savard and J. C. H. Dessaulles; Information, Garnet T. Page; Planning, L. Austin Wright; Student Development, (under consideration by the Student Development Committee).

Honorary Member



Dr. Armand C. Crepeau, Hon. M.E.I.C.

Dr. Crepeau's photograph was not available for the September issue, Page 118, where the award of E.I.C. honorary memberships in 1958 was reported.

Distinguished Visitors

It is a pleasure to report on two important personalities who were in Montreal during the recent World Power Conference — namely Mr. and Mrs. D. P. R. Cassad of Byramji Town, Nagpur, India.

Mr. Cassad is president of The Institution of Engineers (India) and was their delegate to the Conference of Engineering Institutions of the British Commonwealth held last spring in Australia. Thus it was that Messrs. Anson, Tait and Wright had had the earlier opportunity of meeting him and Mrs. Cassad and of appreciating their outstanding qualifications.

Mr. Cassad is managing director of a group of industrial enterprises in his country. It is interesting to note that in each instance Mrs. Cassad is the president or chairman of the company.

Mrs. Cassad is also a great worker in charity affairs. She is a councillor of Nagpur and is chairman of the municipal committee that deals with all these matters. In Canada, as in Australia, her first interest was to see how Canada handled its federated charities, in particular the care and instruction of the blind, and the care of needy children.

The Institute marked the occasion of the presence of these distinguished people in Montreal in several ways. A luncheon in honour of Mr. Cassad and presided over by our president was given at the University Club, and on another day a luncheon in honour of Mrs. Cassad, and presided over by Mrs. Tupper, was held at the club.

The party was met at the airport and conducted to the hotel by Dr. and Mrs. I. R. Tait and Dr. and Mrs. L. Austin Wright.

The Cassad's were accompanied by two other distinguished visitors from India — Mr. and Mrs. E. A. Nadirshah of Bombay. They were included in all the arrangements that were made for the Cassad's.

It was a pleasant experience to assist in entertaining these charming and important people. Recognition should be made of the important part played in these affairs by Dr. I. R. Tait and Mrs. Tait.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at the meeting of Council on October 25, 1958:

Members: A. C. R. Albery, London, Eng.; S. G. Barber, Don Mills; H. R. Bohne, Whitehorse; A. F. Branscombe, Montreal; R. J. Braun, Montreal; E. L. Brown, La Tuque; D. E. Coates, Peterborough; A. P. den Engelsen, Montreal; W. H. Edwards, Hamilton; L. V. Frampton, Montreal; P. Gavrin, Montreal; J. A. King, Montreal; R. N. Knapp-Fisher, Weyburn; L. J. Nadeau, Montreal; M. A. Notte, Montreal; J. Pawliw, Peterborough; P. Queneau, New York; T. A. Redmond, Montreal; D. P. Reid, Toronto; R. Scott, Montreal; E. S. Spencer, Toronto; S. A. Stannard, Lauzon.

Juniors: C. V. Aquilina, Montreal; W. G. Brusey, Toronto; F. G. Elkins, Montreal; L. R. Gjertsen, Port Alice; W. Hickinbotham, Orillia; S. A. Kawai, Montreal; P. T. Koltai, Montreal; F. de P. Linares-Gasol, Toronto; J. B. Lowery, Calgary; J. D. Nicholson, Montreal; J. P. Richards, Toronto; S. W. Shishakly, Montreal; P. F. Welling, Hamilton.

Affiliates: T. K. Stephens, Montreal; J. B. Wheeler, Vancouver.

Junior to Member: O. D. Bobyn, Agincourt; K. R. Bullock, Brockville; P. J. Harris, Montreal; N. W. E. Lee, Toronto; C. O. Lockhart, Moncton; J. A. Michell, Hamilton; D. S. Moyer, Toronto; S. Nixon, Trail.

Student to Junior: G. J. Arvisais, Shearwater.

STUDENTS ADMITTED

Royal Military College: A. F. J. Cardin; D. F. Dance; J. G. Delisle; J. G. L. Despatis; J. G. R. Doucet; L. A. Hamilton; W. H. Hatfield; G. W. Hollingshead; N. W. Johnstone; J. S. Klenavic; G. Y. Lafond; N. R. Lee; J. W. Logie; T. H. Marshall; J. A. McCulooch; B. M. Moore; R. Perreault; J. M. R. Prefontaine; S. C. Ross; M. J. M. Ruel; W. H. Sheridan; R. W. Shurb; R. B. Smale; D. B. Smith; V. J. Sokolosky; J. G. Watson; D. E. Weese; B. H. Wilkerson.

University of Toronto: R. Abel; L. P. Drimmel; B. D. Simpkins; K. W. Sparks; E. Suyama; R. K. Watson; W. M. Zacharkiw.

McGill University: M. D. French; D. Gottesman; A. J. MacDowell; M. Papadopol; M. R. Shirlaw; T. P. S. Toor.

University of Manitoba: R. J. M. Bevis; K. A. Biccum; R. W. Glasman; C. D. Holmes; P. J. Keough; C. G. Kunze.

Dalhousie University: I. M. Fraser; D. E. Teed.

Queen's University: J. J. R. Nicholls.

Mount Allison University: J. A. Spargo.

Nova Scotia Technical College: A. D. MacDonald; C. R. Kennedy.

University of Detroit: R. K. Simpson.

C.P.E.Q. Student: K. A. Scholz.

Applications Through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members: L. R. Clark; F. H. McHenry; B. C. Millar; F. J. Ronicker; J. Werner.

Junior: L. R. Thompson.

Junior to Member: D. E. Bateman; J. W. Meagher; N. J. Oneschuk.

SASKATCHEWAN

Members: J. I. Daniels; M. G. Jacoby; M. A. McNichol; T. E. W. Nind; L. P. Williams.

Juniors: L. C. Cole; A. Shklanka; R. W. Stark.

Junior to Member: M. M. Muth; L. A. Parker; P. W. Wright; H. N. Yeomans, L. S. Dillon; C. Zeglinski.

Student to Junior: M. Cherney; H. Schmidt.

NEW BRUNSWICK

Junior to Member: R. B. Brenan.

DID YOU KNOW THAT

The Engineering Institute is the oldest engineering society in Canada, established February 24, 1887, incorporated by the Dominion Act, June 23, 1887, as The Canadian Society of Civil Engineers.

New Periodical Index

Repeated enquiries by the Toronto Public Library have revealed the important role which business and technical periodicals published in Canada are playing in the economic advance of this country and abroad. At the moment a cumulative index to the articles and information appearing in many of these periodicals does not exist.

The Toronto Public Libraries, in consultation with the Canadian Library Association, propose at this time that a further specialized index to other business and technical periodicals be started.

The Toronto Public Libraries will issue in 1959 a bi-monthly index to the articles appearing in the periodicals listed below, and provide an annual cumulation of this index if sufficient orders are received to warrant the cost of publication and distribution.

The index will be prepared by the staff of the Hallam Room of Business and Technology at the Toronto Public Library, and will incorporate the material which is prepared at the present time for users of this section of the Reference Library.

The following Canadian periodicals will be indexed:

Bank of Montreal, Business Review
Bank of Nova Scotia, Monthly Review
C.I.L. Oval
Canada Lumberman
Canadian Bank of Commerce, Monthly Commercial Letter
Canadian Machinery & Manufacturing News
Canadian Mining & Metallurgical Bulletin
Canadian Office
Canadian Oil & Gas Industries
Canadian Personnel & Industrial Relations Journal
Canadian Power Engineer
Canadian Purchasor
Canadian Shipping & Marine Engineering News
Canadian Textile Journal
Canadian Transportation
Chemistry in Canada
Engineering & Contract Record
Engineering Journal
Food in Canada
Imperial Oil Review
Imperial Oilways
Marketing
Modern Power & Engineering
Municipal Utilities
Municipal World
Office Equipment and Methods
Oil in Canada
Plant Administration
Pulp and Paper Magazine of Canada
Trade and Commerce

Businesses, librarians, and individuals are asked to indicate their willingness to subscribe at a cost of $20.00 a year.

Further information may be secured by writing to: Publication Section, Toronto Public Libraries, Toronto 2-B, Canada.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Charles Douglas Norton, M.E.I.C., retired engineer of the firm of Aerocrete Construction Limited, Montreal, died in that city on July 16, 1958.

Mr. Norton was born at London, England, on December 19, 1882. He attended the London Polytechnic before moving to Canada in 1901, at the age of nineteen. Mr. Norton lived and worked on different projects in Northern Quebec and Ontario during his first twenty years in Canada. At the outset of his career he gained experience on construction work with the Canadian Pacific Railway. Within a short time he had also worked for the firms of J. S. Metcalfe Company, the Algoma Central Railway, Canadian Northern Railway, and the Mackenzie Mann Company. In 1917 he began an association of several years duration with various mining companies, among them the Canadian Copper Company, British American Nickel, and the Riorden Company.

Moving permanently to Montreal in 1922, he was with the C.P.R. for some time. In the late twenties he began an association with the Fraser Brace Engineering Company Ltd., which was to be renewed in 1940. During the depression years of the nineteen thirties he was with Canadian Industries Limited, the firms of Hans Lunberg, John Stadler, and the Shawinigan Engineering Company Limited. Immediately prior to joining Aerocrete Construction Limited in 1947 he was employed with the Montreal Locomotive Works and the Aluminum Company of Canada. When the Aerocrete company began extensions to the plant it fell to Mr. Norton to take charge of the design of buildings and equipment. At the conclusion of this work he was engaged in the development of new products and continued in this work until the time of his retirement in 1955.

Mr. Norton joined the Institute in 1907, as a Student, transferred to Associate Member in 1915, and to Member in 1940. Mr. Norton attained Life Membership in the Engineering Institute of Canada in 1952.

John Alexander MacGillivray, M.E.I.C., construction engineer with the Ontario Water Resources Commission, died at Willowdale, Ont., on August 23, 1958.

Born at New Glasgow, N.S. on January 7, 1889, he studied engineering for two years at Dalhousie University.

His varied career began in Nova Scotia. It included railroad construction, the duties of construction superintendent on the Halifax reservoir and in 1910 entailed a move to Manitoba to work on the original construction of the Pointe du Bois power plant on the Winnipeg River. Assistant bridge engineer for the Manitoba Good Roads board in 1917 and 1918, he moved on to become resident engineer at Great Falls, Pointe du Bois extension, and the Slave Falls hydro-electric power developments. These projects were on the Winnipeg River, connected with the Abitibi River power plant of the Hollinger Gold Mines.

At a later period he was assistant superintendent and engineer for the greater Winnipeg Sanitary District.

In 1948 he became resident engineer for the Hydro-Electric Power Commission of Ontario at their Des Joachims and later at La Cave, Otto Holden generating stations, on the Ottawa River and the Pine Portage power plant extension on the Nipigon River.

Mr. MacGillivray joined the E.I.C. as a Junior in 1917, became an Associate Member in 1919, Member in 1940 and Life Member in 1957.

Alvin Lawrence Kenneth Malcolm, M.E.I.C., retired field engineer on power development for the Hydro-Electric Power Commission of Ontario, died at Peterborough, Ont., on July 11, 1958.

Born at Galt, Ont., on August 6, 1884, Mr. Malcolm had his early education at Dickson School and the Galt Collegiate Institute. As a 1909 honour graduate from the faculty of applied science and engineering at the University of Toronto Mr. Malcolm joined the consulting engineering firm of Smith, Kerry and Chace, Toronto and worked at Cambellford, Ont. on the Northumberland pulp mill. After two years of work for this firm as an inspector, he returned to the district as assistant engineer on the initial development at Healey Falls, Ont. Later he transferred his services to the Riordon Paper Company, Hawkesbury, Ont., and engaged in preliminary surveys and estimates on the Rouge and Quinze River developments.

In 1916 he accepted an appointment with the Federal Department of the Interior, water power branch, to investigate Bow River, Alta., power possibilities and level regulation on the Lake of the Woods, Ont. About the same time Mr. Malcolm was employed with the Hon. T. A. Low, Renfrew, Ont., in charge of the construction on the control dam and dredging outlet at Golden Lake. The project was taken over by the Ontario Hydro-Electric Commission in 1917 and with the transfer Mr. Malcolm joined the staff of the Commission. This was the beginning of his residency in charge of a long series of power developments throughout the province. During the early years of the 1930's he was engaged in carrying out major maintenance projects. The impact of World War II on the power situation was reflected in the rapid increase in the capacity and number of power projects, involving work at DeCew Falls, Barrett Chute, on the Madawaska, and Des Joachims. Consultant on miscellaneous reports and inspection work at head office in 1949, he was loaned to Defence Construction (1951) Limited, Ottawa, as project Engineer on defence projects in Ontario and Edmonton, two years later after his retirement from the Commission he was retained as consulting project engineer pending completion of these assignments. On many of the Commission's developments Mr. Malcolm served in the dual capacity of resident engineer and construction superintendent.

From his part in the development of power for one of the foremost public utilities in the Dominion, Mr. Malcolm has left a mark of lasting significance in the growth of our country.

He joined the E.I.C. as an Associate member in 1921, transferred to Member in 1940 and to Life Member in 1955.

K. W. Bash, M.E.I.C., of Toronto died recently.

Kenower Weimer Bash, was born at Huntington, Indiana, U.S.A., on June 21, 1887. He was awarded a B.Sc. degree in civil engineering from the University of Michigan in 1909. His first professional appointment was with the Canadian Bridge Company, Walkerville, Ont., as draftsman. He worked as engineer and manager of the Maritime Bridge Company Ltd., a subsidiary of the Canadian Bridge Company, 1912-1914, and two years later became engineer, of the Lewis-Hall Iron Works, at Detroit, Mich., and sales and designing engineer of the Whitehead and Kales Iron Works, Detroit. Mr. Bash took charge of the construction department of the Christman Burke Company, Detroit, in 1919, became manager and partner in 1930. After the difficult years of the

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

Professional Conduct Post Created

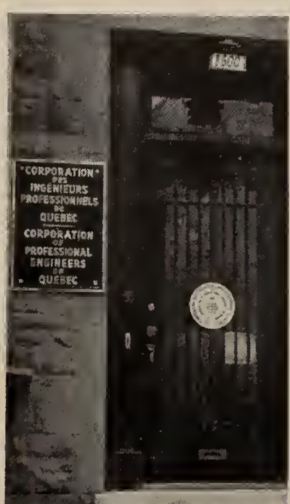
J. P. Dagenais, P. ENG., 36, has been appointed Professional Conduct Officer of the Corporation of Professional Engineers of Quebec, a headquarters post created to better investigate and control unethical or illegal practice of engineering. Mr. Dagenais was formerly combustion sales engineer with the Dominion Bridge Company Ltd., Montreal.

Thoughtful Gift to Corporation

Thanks to the generosity of past-president G. Lorne Wiggs, P.Eng., and that of the Crane Company of Canada Limited, an enamel plaque reproducing in colour the official crest of the Corporation of Professional Engineers of Quebec now adorns the front door of the professional headquarters. The plaque and the name-plate at left, identify in a very dignified manner the home of the Corporation.

American Plans Harmful

Engineering plans and specifications originating in the United States enter into Canada duty-free, unless they pertain to the construction of buildings, in which case they are considered architectural, and are dutiable. Duty on engineering plans was eliminated some years ago with the establishment of Tariff Item 180e. Previously, they had been subject to an import duty of some 20 per cent of the value of the plans.



New plaque improves doorway at C.P.E.Q. headquarters

At various times, representations have been made to have this tariff reimposed, as it was felt that Canadian engineers were not adequately protected. After carrying this item on its agenda for many years, the Canadian Council of Professional Engineers came to the conclusion that it would be necessary to demonstrate that some harm was caused to Canadian industries or to Canadian engineers before any representations to have this duty reimposed could be warranted.

J. P. Dagenais, P.Eng.

Consequently, all members of the Corporation were invited to forward their comments to Leopold M. Nadeau, P.-Eng., secretary-treasurer of the Canadian Council of Professional Engineers. Mr. Nadeau was particularly interested in obtaining actual cases of plans being imported into Canada and causing prejudice to engineers or the Canadian industries and public.

Consulting Engineers' Agreement Forms

Standard forms of agreement between consulting engineers and clients were approved by Council in the summer of 1958 and have since been released, under copyright form, for distribution to the members of the Corporation who are in private practice.

These carefully drafted forms were prepared by members of the committee on consulting practice, but the yeoman's service of Past-President G. Lorne Wiggs, P.Eng., chairman of the committee, deserves special acknowledgment and thanks.

There are three sets of forms: one for architects, and two for ordinary clients; one based on a percentage fee and the other based on a time basis fee, available at a cost of 25 cents.

ALBERTA

(Taken from "The Alberta Professional Engineer," bulletin of the Association of Professional Engineers of Alberta, September 1958 issue)

"The Engineer and His Profession"

A completely new information booklet published by the Association will shortly be coming off the press. This publication entitled "The Engineer and His Profession" has been designed to provide both members and prospective members with a concise account of the aims, purposes and activities of the Association and the Profession of Engineering.

With the extensive expansion of Association membership and activity during recent years, the present information booklet no longer provides an adequate picture of Association affairs. The new publication will supply members with a medium which they can use effectively in promoting the work of the Association. By distribution of the booklet to prospective members, the Association hopes to encourage membership.

"The Engineer and His Profession" represents a two-year task undertaken by the Public Relations committee through a sub-committee headed by Walter Balke. The firm of McConnell, Eastman & Co., our public relations counsel, has organized the information into an attractive format.

Highlights from Council

Council unanimously approved the sponsorship of a Gold Medal in Metallurgical Engineering to be made available in the spring of 1959. Beginning this term the University of Alberta will offer a degree course in metallurgical engineering. The Association will now sponsor a total of seven Gold Medals yearly in the various branches of Engineering.

Mr. L. A. Thorssen, a past president of the Association, and an active committee member, was appointed Association representative on the engineering faculty council, University of Alberta, for 1958-59.

A report was presented on an industrial survey being conducted by the Department of Industries and Labour. The Association co-operated with the Department in preparing data for initiating the survey. The results of the survey should prove helpful in completing a long-term Association plan, as well as in giving an accurate picture of science and applied science personnel employed by the industry in the Province.

ONTARIO

Report on Salaries

(Taken from "The Professional Engineer", the bulletin of the Association of Professional Engineers of Ontario, by T. C. Keefer, field secretary of the A.P.E.O. The article was entitled "A Report on Salaries of Professional Engineers by Levels of Responsibility")

This new report on salaries contained in a booklet mailed to A.P.E.O. members supersedes the "Schedule of Salaries" which was last published in June 1957.

Instead of the former grade definitions, a series of job levels has been defined in the new booklet. The "level descriptions" are more explicit than the old "definitions of grades." Instead of a single salary figure recommended for each grade of the old schedule, representing "equitable remuneration for one performing adequately the duties of that grade", the new booklet reports the median, middle 50 per cent spread, and middle 80 per cent spread of actual salaries paid on July 1, 1958. No recommendations are contained in the new publication. It is, instead, a factual report of salaries paid to 6309 professional engineers by 92 industrial and other organizations in Ontario and Quebec, on July 1, 1958.

While this number of engineers represents more than 25 per cent of the total membership of the Association and the Quebec Corporation, the salary figures reported are believed to be much more representative than indicated by the size of the sample, for this reason.

The organizations participating in the survey were asked to identify professional engineers in their employ who were performing precisely the work specified in a number of job descriptions supplied in a "reporting manual" at the beginning of the survey. They were asked to report the salaries paid all the engineers doing this work, whose positions in addition matched the appropriate responsibility level, but they were also asked to exclude ruthlessly from their reports the salaries of men whose jobs did not meet these two requirements. In respect of each job, therefore, something approaching a "saturation" sample was obtained from all the organizations in the survey.

Since the job descriptions form a series of "bench marks" throughout the hierarchy of engineering, each related to its own level of responsibility, there is no doubt that the process of ranking by job level, which the approach outlined in this new publication involves, can provide professional engineers and their employers with accurate and meaningful information concerning "going rates" for a great variety of engineering positions.

Copies of the job descriptions used in the survey were available upon request.

Most important and perhaps least apparent among the differences between the old publication and the new, is the fact that whereas the former was a compendium of salary information built up by the engineering profession in Canada from its own resources, the latter is the culmination of a co-operative effort extending over the last five years between the Association and industry.

The ninety-two organizations that have engaged with the Association and the Corporation in this work have shown a sincere desire to assist the engineering profession in improving the techniques of salary surveys to a point where these can be entrusted entirely to the professional bodies. It is considered desirable by all concerned that engineers should be given, by their professional governing bodies, the same basic data that is used by their own employers in establishing proper salaries. It is believed that a professional relationship between engineers and their employers is most likely to develop and flourish when the only concern of both parties in the matter of remuneration is likely to be the correctness or otherwise of a man's assignment to a given level of responsibility and his performance within that level in terms of productivity. This is a new departure in industrial relations. It opens new vistas to us all in the matter of professional recognition.

(Continued on page 138)

OBITUARIES *(continued from page 91)*

early thirties he became general superintendent for the Foundation Company of Canada at its Baie Comeau, Que. development in 1936.

He was secretary and manager of the Foundation Company of Ontario, 1938, and superintendent of the building equipment and repair department for Loblaw Grocers Company Ltd., in 1940. Loaned to Wartime Housing Limited, at the request of Federal authorities in World War II, he was assistant to the managing director in charge of construction, later became acting general manager of Wartime Housing Ltd.

Mr. Bash joined the E.I.C. as a Member in 1944.

Jerzy Paszkiewicz, M.E.I.C., structural engineer with the Foundation of Canada Engineering Corporation, Montreal, died in that city on September 6, 1958.

Born in Russia on January 22, 1912, Mr. Paszkiewicz entered the Technical University of Lwow and graduated in 1939 after a period of training at a military officers' school. After World War II, then resident in London, England, he studied civil engineering at Polish University College, London. In 1950 he was awarded an engineering diploma from that institution. He served the firm of J. D. and D. M. Watson, chartered civil engineers, of London, England, as an assistant engineer for a period of six years before moving to Canada in 1956. Mr. Paszkiewicz was in Great Britain engaged in a variety of schemes of sewerage, sewage purification and water supply.

He joined the E.I.C. as a Member on March 1, 1958.

Pierre-Michel Larouche, JR.E.I.C., of the Saguenay Electric Company, Chicoutimi, Que., head of substations and generating stations departments, died on September 17, 1958, after a few months illness at the age of thirty-five.

Mr. Larouche was born at St. Georges de Champlain, Que., on September 29, 1923. While very young he moved with his family to Chicoutimi, Que., attended primary schools and the Chicoutimi Seminary from which institution he graduated with a B.A. degree in 1945. Five years later he was awarded a B.A.Sc., degree in electrical engineering at Laval University. Mr. Larouche worked with the Saguenay Electric Company from the time of his graduation in 1950 until the date of his untimely death.

Mr. Larouche joined the E.I.C. as a student member in 1949, transferred to Junior in 1952.

Jean Valiquet, S.E.I.C., of Ottawa, athlete and engineer, died in a Montreal hospital on December 31, 1957, following a long illness.

Joseph Georges Jean Valiquet was born at Rimouski, Que., on May 11, 1935. He received his elementary education at Garneau School, Ottawa, and later attended the University of Ottawa and McGill University. He was awarded a bachelor of science degree from the University of Ottawa in 1955 and in 1957 graduated in civil engineering with a B.Eng. degree.

As best French Canadian athlete in Eastern Ontario and Quebec, he was in 1953 awarded the Gil O. Julien trophy. The following year Mr. Valiquet was named best athlete at the University of Ottawa.

After his untimely death former classmates turned over to the school a trophy commemorating the champion athlete. Noted as a Canadian tennis-player, he was captain and top scorer of the University inter-collegiate football team, and was outstanding in baseball, softball, rugby, swimming, skiing and badminton.

He joined the E.I.C. as a Student Member in 1954.

Personals

News of the Personal Activities of Members of the Institute

J. H. Mowbray Jones, M.E.I.C., (B.A.Sc. mech., Toronto, 1927), president of the Mersey Paper Company Ltd., Liverpool, N.S., has been named president of Bowater's Newfoundland Pulp and Paper Mills Ltd., Corner Brook, Nfld. Although five hundred miles and a province apart, these separate companies are members of the world-wide Bowater organization. Mr. Jones joined the Mersey Paper Company Ltd., thirty years ago as a resident engineer. He assumed the presidency, while remaining as general manager in July 1958.

R. A. Emerson, M.E.I.C., (B.Sc., civil, Manitoba, 1930), has been named vice-president of the Canadian Pacific Railway Company at Montreal. A third generation C.P.R. employee he has held the office of vice-president of operation and maintenance since 1955.

Mr. Emerson held a number of different appointments with the company in Western Canada from 1935 until his transfer to Montreal in 1948. Since that time he has performed the duties of engineer of track, assistant chief engineer, 1950, and chief engineer, in 1951.

A. G. Asplin, M.E.I.C., (B.Eng., civil, McGill, 1938), of Horton's Steel Works Limited, has been named general manager of the organization. Formerly manager of operations at Fort Erie, Ontario, Mr. Asplin continues as vice-president and director of Horton Steel and brings to his new post 19 years service with the company.

Mr. Asplin is a past chairman of the Niagara Peninsula Branch of the E.I.C., 1949.

R. A. Emerson, M.E.I.C.

R. R. Moffatt, M.E.I.C.

J. H. Mowbray Jones, M.E.I.C.

W. D. Hurst, M.E.I.C., (B.Sc., civil, Manitoba, 1930; C. E., Virginia Polytechnic Institute, 1931), City Engineer of Winnipeg, has been elected president of the 4,000 member American Public Works Association. Mr. Hurst, who has served on the board of directors of the A.P.W.A. since 1955, is the first Canadian to hold this office.

Fraser H. Fargey, M.E.I.C., (B.Sc., elec., Manitoba, 1934), of Brown Boveri (Canada) Limited, was recently named vice-president in charge of sales and secretary of the company. Last year Mr. Forgey became vice-president and sales manager of the organization. He joined Brown Boveri in 1950.

Air Vice Marshal Max M. Hendrick, M.E.I.C. (B.A.sc., mech., Toronto, 1932), Air Member for Technical Services R.-C.A.F., has been named chairman of the Canadian Joint Staff, Washington. As Air Member for Technical Services, Air Vice Marshal Hendrick had responsibility for the design and development of all Air Force equipment and facilities.

R. R. Moffatt, M.E.I.C., formerly superintendent, heavy mills department, Dominion Steel and Coal Corporation Ltd., Sydney, N.S. was recently appointed rolling mill consultant, Dominion Steel and Coal Corporation.

Maurice D'Amours, M.E.I.C., (B.A.Sc., elec., Laval, 1945), of the Quebec Power Company, has been named to the post of general superintendent of the firm. In 1954 Mr. D'Amours took over the duties of superintendent of operations, electrical division, following service in the company dating to his graduation.

Gordon D. Campbell, M.E.I.C., (M.Sc., civil, Man., 1951; Ph.D., Purdue, 1956), has been appointed a director of tech-

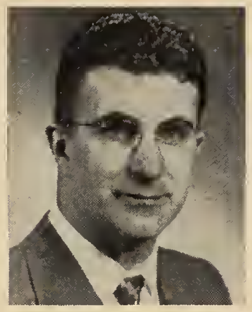
nical services to the staff of the Canadian Good Roads Association. Dr. Campbell was formerly the C.G.R.A. engineer-observer on the $12,000,000 Test Road, constructed in 1956 by the American Association of State Highway officials and the Highway Research Board, at Ottawa, Ill.

Guy Savard, M.E.I.C. (Royal Military College, Kingston, 1937; welding, Ecole Superieure de Soudure Autogene, France, 19), of the Canadian Liquid Air Company Ltd., manager of the technical development department of the firm, has been promoted to manager of the Montreal branch.

Robert S. Morrow, M.E.I.C., (B.Eng., mech., Mount Allison, N.S.T.C., 1950), of the power shovel department, the Maritime Steel and Foundries Limited, New Glasgow, N.S., previously a member of the Branch executive has been elected chairman of the North Nova Scotia Branch of the E.I.C. He has been associated with his present employer since the time of his graduation.

J. E. Pickering, M.E.I.C., (B.Sc., mech., Sask., 1946), has left the services of the Du Pont Company of Canada (1956) Ltd., to join the firm of Babcock, Wilcox and Goldie McCulloch Ltd., Montreal.

R. L. Payer, M.E.I.C.



W. A. Corbett, M.E.I.C.

R. S. Morrow, M.E.I.C.

His new responsibilities are those of sales engineer for the provinces of Quebec, New Brunswick, Prince Edward Island and Newfoundland.

R. Leo Payer, M.E.I.C., (B.Sc., elec., New Brunswick, 1948; M.Sc., elec., 1953), has been appointed manager, electrical apparatus division. Mr. Payer will retain active management of the preformed products division.

William A. Corbett, M.E.I.C. (B.Sc., civil, Man., 1950), of Winnipeg, has been named chief engineer for the consulting engineering firm of Haddin, Davis and Brown (Manitoba) Ltd. Mr. Corbett has had experience in the fields of municipal and structural engineering.

J. E. Pickering, M.E.I.C.

J. C. Kingston, M.E.I.C., (E.M., mining, Colorado School of Mines, 1935), of the St. Lawrence Seaway Authority has joined the Canadian General Electric

Company Ltd., civilian atomic power department, Deep River, Ont. While associated with the Seaway Mr. Kingston's work was that of concrete control engineer. His present duties are those of resident manager, N.P.D. - 2 project.

J. C. Kingston, M.E.I.C.

Major Jack Adams, M.E.I.C.

Major E. C. Ilott, M.E.I.C.

Major E. C. Ilott, M.E.I.C., (B.Sc., elec., London, 1941), has been posted from Fort Churchill, Man., to Winnipeg. While in the North Major Ilott was commanding officer of the No. 18 Company, R.C.E.M.E. At Winnipeg he is deputy command electrical and mechanical engineer of the Prairie Command.

Major **Jack Adams**, M.E.I.C., (B.Sc., mech., Sask., 1944), has been posted from Ottawa to Center Line, Michigan, U.S.A. as Canadian Army Liaison Officer at the Detroit Arsenal. While serving at Canadian Army headquarters Major Adams was chief test officer, vehicle experimental and proving establishment, department of National Defence.

W. Ralph Lewis, M.E.I.C. (BA.Sc. elec., Toronto, 1947), of the electrical engineering department, Dominion Steel and Coal Corporation Ltd. was recently appointed electrical engineer, Contrecoeur project, Dominion Steel and Coal Corporation, in Montreal.

Stanislaw A. Janusz, M.E.I.C., (diploma, mech., Polish University College, London, 1948), has transferred his services as design engineer from the Canadian Westinghouse Company Ltd., motor generating division, Hamilton, Ont., to the atomic energy division of the organization, also at Hamilton.

Correction:
W. F. Allen, M.E.I.C. It was stated in the September issue of the *Journal*, Personals section, that Mr. Allen was employed with the firm of Sherwood Properties Ltd., at Toronto. Mr. Allen has been living in Edmonton, since May 1957, and is chief engineer with the latter firm, earlier known under the name of A. L. Trowbridge & Associates.

George P. Cote, M.E.I.C., (B.A., St. Charles Borromee Seminary; B. Eng., mech., McGill, 1949), has been elected chairman of the Eastern Townships Branch of the E.I.C., for the 1958-1959 term of office.

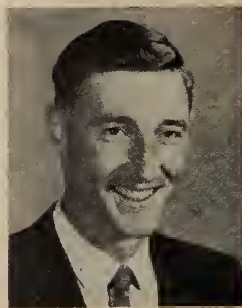
Mr. Cote joined the firm af A. R. Wilson Ltd., Sherbrooke, Que., on graduation. Associated with this firm as vice-president for eight years, he founded

G. P. Cote, M.E.I.C.

with two other engineers the consulting firm of Cote, Leclair and Langlois in 1957. He was vice-chairman of the Branch in 1957.

D. T. Austin, JR.E.I.C., (B.Sc., Queen's 1948, M.Sc., metall., Queen's 1949), chief metallurgist at the Arvida works, Arvida, Que., for the Aluminum Company of Canada, was recently named technical director of the Kingston works of the organization.

H. E. T. North, JR.E.I.C. (B.Sc., Queen's, 1955; D.C. Ae., College of Aeronautics, U.K., 1957), has accepted employment as a sales engineer, with Canadian Pratt and Whitney Aircraft, Ltd., at Montreal. Mr. North recently returned from an Athlone Fellowship in Great Britain.



H. N. Yeomans, JR.E.I.C.

D. C. MacCallum, M.E.I.C.

J. P. Woods, M.E.I.C.

Hugh N. Yeomans, JR.E.I.C. (B.Sc. Civil, Manitoba, 1950), has been appointed senior roads engineer with Underwood, McLellan and Associates Ltd., Saskatoon, Sask. Mr. Yeomans previously served as assistant supervising engineer, highways division, Department of Public Works, Edmonton, Alta.

D. C. MacCallum, M.E.I.C., (B.E., mech., Nova Scotia Technical College, 1949), is the 1958-1959 chairman of the Northern New Brunswick Branch of the E.I.C. Mr. MacCallum, a mill engineer with the New Brunswick International Paper Company at Dalhousie, N.B., has been associated with the organization since his graduation.

Mr. MacCallum was a member of the Branch executive in 1957.

D. T. Austin, JR.E.I.C.

H. E. T. North, JR.E.I.C.

J. R. MacKay, JR.E.I.C.

J. P. Woods, M.E.I.C., (B.Eng., mech., Nova Scotia Technical College, 1942), is chairman of the St. Maurice Valley Branch of the Institute. Mr. Woods is assistant general superintendent of the Laurentide division of the Consolidated Paper Corporation. He was formerly steam plant superintendent and assistant steam plant superintendent.

John R. MacKay, JR.E.I.C., (B.Eng., mech., McGill, 1951), of the Dominion Bridge Company Ltd., Montreal, has been appointed combustion sales engineer for the Eastern division of the firm. Mr. MacKay was previously with the boiler sales department.

Jean Louis Desautels, JR.E.I.C. (B.A.Sc., mech., Toronto, 1951), has returned to Canada from France. Associated with the firm of Defence Construction (1951) Limited, No. 2 (F) Wing, R.C.A.F., Grostenquin (Moselle) France for some time he now serves the Ottawa office of the organization.

R. Bradley, M.E.I.C., (B.Eng. Mech. Nova Scotia Technical College, 1948), formerly assistant master mechanic, heavy mills department, Dominion Iron and Steel Company Ltd., Sydney, was recently appointed assistant superintendent in the same department.

L. J. Bandiera, JR.E.I.C., (B.Sc., Sir George Williams 1949; civil, Queen's, 1951), who has been associated with the Aluminum Company of Canada, Ltd., since 1951, was transferred from Montreal general engineering department to

L. J. Bandiera, JR.E.I.C.

call an Imperial man

their Kitimat works engineering department in May 1958. Mr. Bandiera was recently appointed to the post of works engineer for the Kitimat works.

John B. Rea, JR.E.I.C., (B.A.Sc. mech., Toronto 1950), mechanical superintendent of Sprostons (Jamaica) Limited, Kingston, Jamaica, has returned to Canada. He has rejoined the Ford Motor Company of Canada Ltd. at Oakville, Ont. and is temporarily connected with the technical service department. Mr. Rea was earlier associated with the Ford Company in Canada.

J. B. Rea, JR.E.I.C.

Louis Chaumette, S.E.I.C. (Queen's), and Hubert Pilon, S.E.I.C., (B.A.Sc., mech. & elec., Ecole Polytechnique 1958), have been awarded prizes of $150.00 each in the eighth annual Canadian Construction Association competition for theses on construction subjects. Two prizes were awarded because of the excellence of the theses submitted among entries from senior students at seven Canadian universities. Mr. Chaumette's paper was entitled "Serre Poncon Dam," and Mr. Pilon's, "Preparation des Agregats, Bersimis II."

K. E. Plumb, S.E.I.C., (B.A.Sc. mech., Toronto, 1957), of Toronto has left the services of the Canadian Ingersoll-Rand Company Ltd., to join the Toronto Star Limited. In his new work Mr. Plumb is employed with the research and engineering department.

T. A. Brzustowski, S.E.I.C. (B.A.Sc., eng. physics, Toronto, 1958), has been awarded the Air Reduction Company Fellowship in aerochemistry. He is a graduate student in aeronautical engineering, with the Jet propulsion option, at the Forrestal Research Centre, Princeton University, Princeton, N.J. He was an engineer-in-training at Orenda Engines Limited, Malton, Ont., before winning the fellowship.

J. J. Wallace, S.E.I.C. (B.Eng., civil, McGill 1957), formerly with International Nickel Company, Copper Cliff, Ont., has accepted employment with the highways division of the Department of Public Works of Canada, at Edmonton.

BAIE COMEAU

Norman Lapierre, JR.E.I.C., *Secretary*

G. W. Scott, M.E.I.C.,
Branch News Reporter

A FIELD VISIT to Labrieville, Que., at the invitation of Hydro-Quebec on Friday and Saturday, September 26, 27, began the 1958-1959 winter season of the Baie Comeau Branch.

This was a highly successful and enjoyable outing. Some 142 members and guests attended from Baie Comeau and these were later joined by 9 Labrieville members together with representatives of Hydro-Quebec and construction staff engaged on the Bersimis 1 and Bersimis 2 projects.

The Baie Comeau Party left at mid-day on Friday, 26th September, arriving at Bersimis 2 construction site about 4 p.m. Here work on the various dam sections and 800,000 h.p. power house of the Bersimis 2 Project was in progress. Good weather provided an excellent opportunity for inspection by the visitors.

The tour of the Bersimis 2 construction site was completed by 6 p.m., and thereafter the party went on to Labrieville where the evening's arrangements took the form of a cocktail party, dinner and dance. Brief speeches at the dinner included those of V. M. Wallingford, Branch chairman; J. O. Parker, Hydro-Quebec project coordinator; and J. H. Huggard, resident engineer. A most enjoyable dance followed the dinner.

On Saturday morning, September 27, a conducted tour was made of the Bersimis 1 power station. The eight generators involved in this 1,200,000 h.p. installation are the most powerful of their kind in the world; and although construction was largely complete, it was possible to examine both generators and turbines at various stages of construction. Following the Power House visit a twenty-three mile trip by road was made to the Stage I Desroches and Bersimis dams.

Lunch at Labrieville, as the guests of Quebec-Hydro, terminated the official arrangements and the visitors returned home during the afternoon. The Baie Comeau Branch is much indebted to Quebec-Hydro for this their first field outing and in particular to Mr. J. O. Parker and Mr. J. H. Huggard and their staffs for their hospitality.

A field trip to the Bersimis No. 1 & 2 Power Stations, took Baie Comeau Branch members to Labrieville, Que., on Sept. 26, 27. The four photos here provide a glimpse of the tour. Left: view inside the Bersimis 2 Power station; centre: entrance to the power house, power project No. 2; V. M. Wallingford, chairman of the Baie Comeau Branch; bottom: Baie Comeau visitors viewing the tunnel intake to the Bersimis 2 Power House.

A PLANT TOUR of the Hinde and Dauche Paper Company at Trenton, Ontario, marked the opening meeting of the season on October 6. Mr. George Boyce, resident manager, briefly described manufacturing processes. Most of the wood used to make cardboard for corrugated boxes is obtained nearby. About 20 per cent of the pulp used consists of scrap paper. The process resembled more an "art" than a "science". It is, however, checked constantly by the chief chemist, Bill Sherisky and assistant, R. Mason.

The tour divided in groups, was conducted by members of the staff of the Hinde and Dauche firm. They were: John Thilson, superintendent, George Bar, boss machine tender, Bob Lane, assistant master mechanic, Howard Langdon, accountant, Frank McCormack, pay master, Bill Sherisky and R. Mason.

In presenting the thanks of the visiting group, to Mr. Boyce, Branch chairman, T. E. Flinn, pointed out that it was very heartening to find a place of interest so close to home.

in the Program, "Organization and Function of Government, is also discussed in five lectures. The series for the 1959 session will be published later. Under consideration for the new year are such topics as Canadian culture, music appreciation, and financial control, to mention a few. The ACE - PD program is arranged each year under the sponsorship of the E.I.C. in co-operation with the Canadian Institute of Mining and Metallurgy, and the Alberta Society of Petroleum Geologists. The 1957-1958 program enrollment totalled more than four hundred persons, with an average of two hundred per meeting in attendance. Fees for each course is $5.00 or $15.00 for all the courses in the later 1958 and early 1959 session. Courses will consist of four or more subjects with five speakers for each topic. The 1959 session will open with a social evening, cocktails, dinner and a speaker. Audience participation is planned at all other meetings. Cheques for participants in the Professional Development course are payable to V. Horte, treasurer, ACE - PD program, 401 Natural Gas Building, Calgary.

Annual Barbecue Held

The third annual barbecue of the Calgary Branch was held on September 19 at Colpitt's Ranch and provided the kick-off social event of the fall season. Despite the uncertainties of rapidly changing weather conditions, more than 200 intrepid members and guests were rewarded for a gamble by a clear evening and an unlimited feast of beef, spare-ribs and chicken. An able committee headed by "Nip" Guest provided an excellent evening of fellowship, community song and dancing.

THE COMMONWEALTH CONFERENCE of Engineers in Australia was discussed by C. M. Anson, immediate past-president, E.I.C., and vice-president and general manager of the Dominion Iron and Steel Company at a meeting held at Sydney September 25.

Mr. Anson used coloured slides to illustrate his account of places visited not only in Australia, but enroute. He described living conditions in Australia, power plant constructional projects, the construction of reservoirs and other related endeavours.

Second item of interest on the program was a group of slides showing the Ripple Rock explosion in British Columbia, observed by Mr. Anson as he returned to Canada.

M. Anson was introduced by M. R. Chappele, building contractor of Sydney, and thanked by Bruce Rossettie, President of the Sydney Engineering and Dry Dock Company.

Three retiring professional engineers, J. E. Underwood, R. A. McLellan, and Dean I. M. Fraser, were honored at a reception given by the Saskatoon section, Saskatchewan Branch, on September 23. They are: back row, l. to r.: W. G. McKay, O. L. Symes, G. O. Handegord, A. Michalenko, R. Peterson, A. F. G. Carroll, R. E. Ludwig. Middle row: C. R. Forsberg, W. E. Lovell, J. A. Wedgwood, A. H. Douglas, W. R. Staples, R. B. Torchinsky, and J. B. Mantle. Front row: H. M. Weir, and the three honored guests, R. A. McLellan, J. E. Underwood, and Dean I. M. Fraser; A. A. Murphy, and E. K. Phillips. *(See page 116 for report.)*

CENTRAL BRITISH COLUMBIA

SOIL MECHANICS, with special reference to landslides, was the subject of a paper delivered before the Central British Columbia Branch at its September 26th meeting.

The paper covered a short history of development of study of soil mechanics and a review of books. Particular reference in the talk was made to the "Drynock Slide" which has been a source of trouble to Canadian Pacific Railway since 1894. The slide, a few miles west of Spence's Bridge in the Thompson Canyon must be stabilized to enable completion of Trans Canada Highway. It is estimated some 18,000,000 cubic yards is moving in a "flow" slide. The methods of measuring and controlling to be used were discussed.

Reports were submitted on the erection of memorial cairns at Vernon, Kelowna, Oliver, Penticton and Revelstoke with plaques drawing attention to pioneer engineers and their work. These projects are being handled by local engineers.

The pioneers to be so honoured are: F. H. Latimer, designer of the South Okanagan Land Project Irrigation, Oliver, B.C.; A. H. McCulloch, chief engineer, construction of Kettle Valley, Railway, Penticton; F. B. Groves, designer of major irrigation works at Kelowna; A. E. Ashcroft, designer of the Vernon Irrigation System, Vernon; Major A. B. Rogers, engineer in charge of construction of the C.P.R. through the Rocky mountains, 1880-1885, at Revelstoke. This work is to be completed in 1958 as a part of the Centennial Year of the province of British Columbia.

COMMUNICATIONS IN NEWFOUNDLAND was the subject of a talk given by F. J. Lounder, plant supervisor for C.N.T., St. John's, Nfld., at the September 24 meeting of the Branch.

Particular reference was made to the microwave system extending from coast to coast in Canada, the Newfoundland portion of which it is expected will be in operation by mid-1959. This will connect Newfoundland with the television network of the C.B.C., and with the existing Telex system of the mainland.

Mr. Lounder also mentioned the con-

siderable expansion of C.N.T. facilities connecting this province with the rest of Canada since the 1949 confederation of Newfoundland with Canada.

CANADIAN ARSENALS were discussed by Lt.-Col. Serge Stucken, director of Engineering Services, Canadian Arsenals Ltd., before an audience of 70 persons attending the first fall meeting of the Ottawa Branch held at the Chateau Laurier on September 18.

Lt.-Col. Stucken was introduced by John P. Sterling, chief engineer, Defence Construction Ltd. Lt.-Col. Stucken said that research on guided missiles is so expensive that Canada has not embarked extensively in that direction, but has kept up with research in other forms of conventional armament.

During the Korean War, he explained, Canadian Arsenals, with ten plants in Ontario and Quebec, was one of the largest employers of labor in Canada. In 1945, he said, Canadian government Second World War arsenals were grouped together in a Crown company under the name of Canadian Arsenals Ltd.

Colonel Stucken emphasized the fact that the purpose of the company was to supplement Canadian industrial capacity in the armament field.

A number of colored slides illustrating the specialized techniques which require a maximum of precision in operations and used by the Crown company in its work, were shown.

Hector Chaput, Branch chairman, presided at the meeting.

THE ANNUAL GOLF TOURNAMENT organized by the Junior Section for the entire Montreal Branch membership, was held on September 6, at the St. John Golf Club.

There were 101 participants in the tournament. Sixty-one players stayed for the dinner. La Cite de St. Jean graciously offered the wine served during the meal.

Approximately sixty prizes were contributed by various industrial and professional firms interested in the engineering profession. Bertrand Bouchard, won the Layton trophy and the first prize with a low gross score of 77. The other first ten prize winners are the following: 2nd), Robert Payette, 79, gross; 3rd), Dick Middleton, 71.5, net; 4th), Marcel Delage, 83, gross; 5th),

Introducing the new lightweight champion...

NEW ATLAS COPCO VT4 PORTABLE

— lightest, most compact 150 cfm portable
— 100% air-cooled compressor and diesel engine unit.

Superbly engineered throughout, the VT4 weighs only 2310 lbs., equivalent to 15.4 lbs. for every cubic foot of free air delivered. Lighter and more compact than most 125 cfm portables, the VT4 produces 150 cfm at 100 psi (guaranteed). All components are job-tested, including the enlarged annular valves and new-type cylinder heads which assure top performance at high speeds. 100% air-cooling eliminates overheating, antifreeze, cooling system maintenance and slow warm-up periods (so damaging to internal combustion engines). The VT4 is easily maintained—the housing, for instance, can be removed in a few minutes to expose the compressor and diesel engine. This remarkable compressor also has torsion-bar suspension, built-in lifting eye, time recorder and oversized oilbath filter for maximum protection against dust and sand. Atlas Copco maintains 24-hour service across Canada. *Write for further information.*

THE TELEPHONE INDUSTRY was a subject of discussion by Roy C. Henderson, supervisor of the engineering personnel at the Bell Telephone Company of Canada, in a talk entitled, "A Forward Look in the Telephone Industry."

In outlining the elements of telephone systems he explained that the binary counting system is used in place of the decimal system in telephone work. This makes it convenient to use these bistable devices such as relays in counting and recording telephone numbers. Permanent memories are produced by photographed recorded binary information. Temporary memory devices are in the form of magnetic core lattices. The use of silicon and germanium transistors enables the electronic circuits necessary in telephone work to operate without vacuum tubes with the result that components and the buildings to house them can be much smaller than would be required if tubes were needed. Mr. Henderson described the construction of the Trans-Atlantic telephone cable and explained how the one cable carries telephone conversation controlled channels and telegraph channels. Repeater amplifiers are installed every 37 miles along the cable as it passes under the ocean. Photo-transistors are used in long distance switching equipment which are now in use in Toronto and will eventually be here in Peterborough to permit dialing any number on the continent, from any phone. Photo-transistors are used in selecting the proper route for each call while the number is being dialed. The Telephone Company is installing new equipment in areas where either the old equipment was worn out or where new facilities are required. The crossbar equipment being installed in some areas this year is new, but it is already becoming obsolete with the advent of new electronic switching telephone exchange equipment. New telephone cables that can be either buried or installed on poles are now available. The presently familiar bell in each telephone will be eventually replaced by the tone sounded through the telephone receiver. This allows eliminating the bells and magnets in each telephone set. Small personal radio receivers are being developed to permit all persons to be called by central transmitter whenever they are wanted on the telephone. These are called Page Masters. Bell laboratories have recently developed solar cells to power telephone apparatus from the energy in sunlight. The operation of a transistor radio using the energy of the light from an ordinary electric lamp instead of from conventional batteries was demonstrated. A model of a picture phone was also shown.

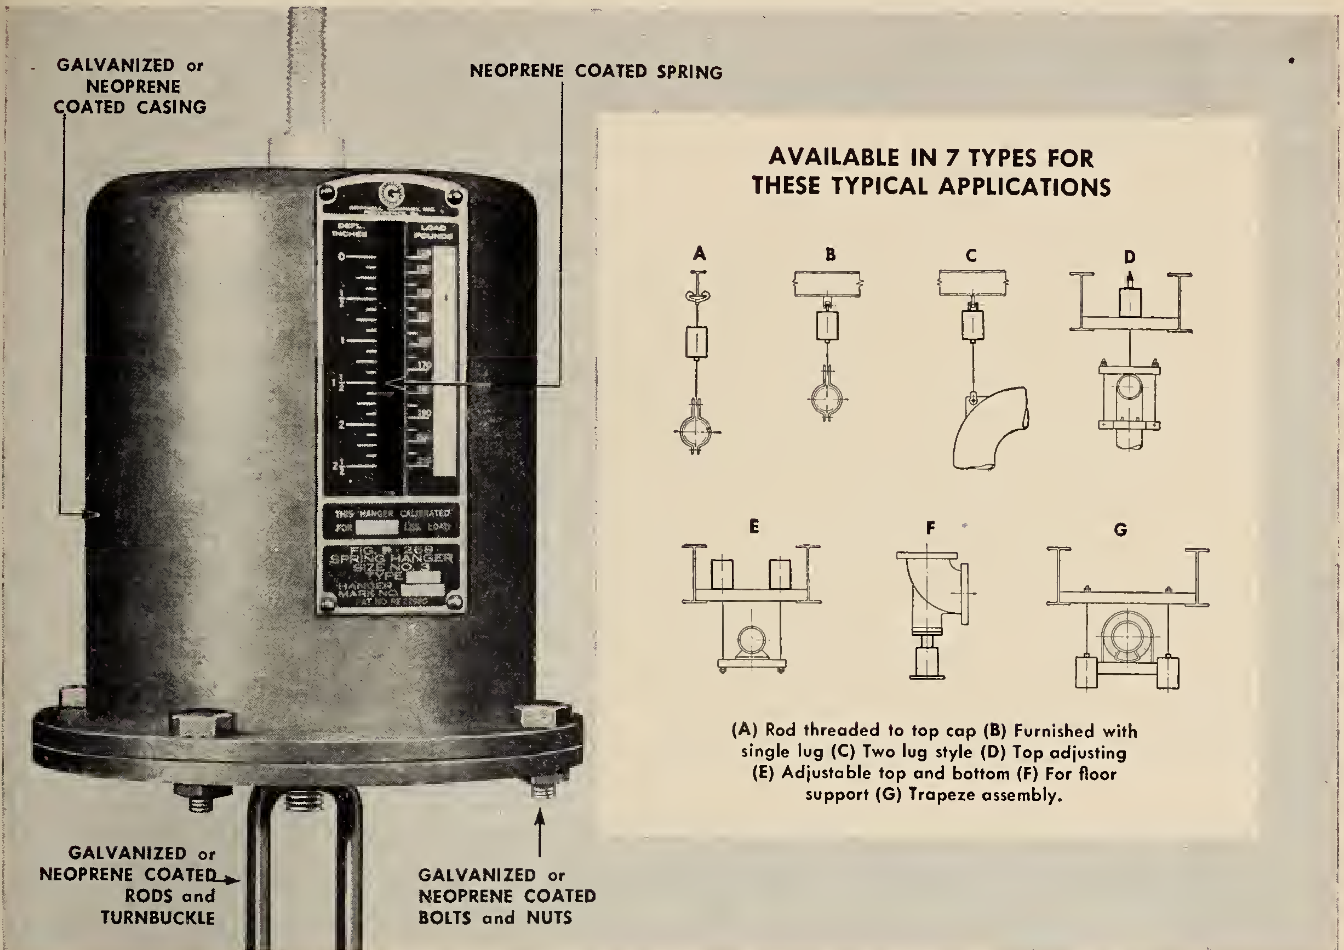
INDUSTRIAL SAFETY PROGRAMS, and the progress being made in this field of endeavor was traced by Glen Griffin, director of the National Safety Council, Chicago, Ill., at a recent meeting. In his talk entitled "The Role of the Engineer in Industrial Safety Programs", Mr. Griffin said that efforts were first made to improve working conditions in the plant, to concentrate first on machine guarding, and to rectify other unsatisfactory plant conditions. The present need, he said, emphasizes safe working conditions and the training of personnel in safe working methods. Accidents result from deficiencies in both of these factors, he added.

corrosion-resistant, weather-resistant

GRINNELL VARIABLE SPRING HANGERS



(A) Rod threaded to top cap (B) Furnished with single lug (C) Two lug style (D) Top adjusting (E) Adjustable top and bottom (F) For floor support (G) Trapeze assembly.

In addition to their proven corrosion and weather resistance, these spring hangers offer other features.

- Maximum variation in supporting force for standard spring models per ½" of deflection is 10½% of rated capacity — in all sizes.
- Precompression (a patented feature) assures operation of spring within its proper working range, as well as saving valuable erection time. Reduced over-all height saves space.
- 21 sizes available from stock for load ranges from 50 lbs. to 28,200 lbs.
- Available in 3 spring lengths for maximum travel of 1¼, 2½, and 5 inches.
- Installation simplified by integral load scale and travel indicators.
- All-steel welded construction meets pressure piping code.

For hanger installations which are subject to highly corrosive industrial conditions — or where exposed to severe weather, Grinnell makes available two distinct lines of pre-engineered spring hangers.

These hangers are the result of extensive experimentation with various coatings for Grinnell's standard pre-engineered spring hangers. In addition to providing flexibility in pipe suspension, they provide versatility of application through their corrosion-resistant characteristics.

1. NEOPRENE COATED — for highly corrosive conditions, such as those found in chemical plants and refineries. All parts of the hanger are neoprene coated to protect the base metal from a wide range of corrosives. The flex life of the spring is unaffected by the neoprene . . . the coating resists cracking or flaking over a wide temperature range.

2. GALVANIZED — for outdoor installations, where weather conditions are severe. All parts of the hanger are galvanized except the spring, which is neoprene coated to avoid alterations of temper, hydrogen embrittlement and decreased flex-life of the spring — usual hazards to springs from the galvanizing process. Write for further details.

BRANCH NEWS

To improve the effectiveness of safety programs engineers would do well to assist the vast majority of safety department personnel who are not engineers, Mr. Griffin indicated. Advice on technical matters and the formulation of new safety standards were fields in which engineers could be of considerable help.

In analysis of accidents, and near accidents, the important thing was to establish the cause and to take preventive steps, rather than to point the finger of blame at an individual. Immediate action on safety recommendations is essential. Mr. Griffin was introduced by William Schofield.

Professional Development Course

The Canadian economy in 1958 will be evaluated by the Sarnia Branch this season in an eight-lecture series, from October 2 to November 20. Purpose is to give members an opportunity to become acquainted with certain vital aspects of our Canadian economy. Cost of the course to members is $8.00, for non-members, $12.00. Maximum enrollment was set a fifty.

Featuring top speakers drawn from the ranks of various university department and national interests, the lectures are: The Economics of Full Employment; Wage Policy and Full Employment; Canadian Trade Relations; Dominion-Provincial Financial Relationships; Transportation; the St. Lawrence Seaway; and the Economics of the Canadian Chemical Industry.

THREE BRANCH MEMBERS were honored at a reception given by the Saskatoon section of the Saskatchewan Branch, Sept. 23, marking their resignation from the consulting engineering and educational fields after many years of service. The three gentlemen, J. F. Underwood, and R. A. McLellan of the firm of Underwood, McLellan and Associates, and Dean I. M. Fraser, retiring dean of the college of engineering, University of Saskatchewan were presented with gifts from the Branch.

A review of the careers of the three long-time engineers was presented during the evening.

Dr. B. W. Currie, head of the physics department at the University of Saskatchewan, gave a short talk on experiences gained in Moscow while attending an IGY conference. He cited a number of humorous incidents which befell him behind the Iron Curtain, and entertained the group with his outlook on Russian life.

TORONTO

D. S. Moyer, JR.E.I.C., *Sec.-Treas.*

Sherman Gauley, JR.E.I.C.,
Branch News Reporter

THE ENGINEERING ASPECT of the operation of Orenda Engines Ltd., Malton, Ont., was outlined interestingly by several company spokesmen as an introduction to a plant tour enjoyed by the Toronto Branch, September 25. They were S. L. Britton, chief administrative engineer; C. B. Wrong, chief aerodynamics engineer; D. E. Cram, chief mechanical development engineer, and P. K. Peterson, chief equipment engineer. F. L. Frame performed the duties of host.

In the initial stages the design is controlled by many parameters; some of which are: designed thrust, mass flow, engine diameter, weight, maximum altitude, maximum inlet temperature. From the first design proposal, charges are dictated by practical problems such as machining and materials. Finally the first experimental engine is built.

The work of a development department is to produce failures. The experimental engine is tested in component form, such as a complete compressor, and later as a complete engine. As weaknesses are found in the design, development and design departments work closely together to find the best re-design. The cycle of design, manufacture, test, re-design goes on until the complete engine reaches a satisfactory state of reliability.

● BRANCH NEWS

The equipment needed for testing is very complex and costly. An example is the purchase of the world war II munitions plant at Nobel, Ont., for use as a test facility. The steam turbine was used as a source of shaft h.p. to drive compressor units on test.

To date Orenda has designed three turbo-jet engines. The Chinook, with a 3,000 lbs. thrust, was an experimental engine. The Orenda is an engine of approximately 7,500 lbs. thrust. Over 4,000 have been produced. The Iroquois has a 20,000-lb. thrust without after burner, a higher thrust per lb. of weight than any other known engine. In recent tests in the U.S.A. it produced the highest thrust and ran at the highest inlet temperature recorded on this continent.

GEOFFREY F. KENNEDY, M.A., M.I., MECH., M.I., E.E., senior partner of Kennedy and Donkin, consulting engineers, London, England, an outstanding authority in the field of thermal and hydro-electric power stations discussed the famous Owen Falls development in Uganda at the September 25 meeting of the Branch. The particularly well-presented address was followed by a film depicting the construction of the dam and powerhouse.

Annual Ladies' Night

The annual "ladies' night", of the Vancouver Branch was celebrated on October 3, at a dinner-dance, held at the Waldorf Hotel. The Polynesian setting supplied the theme to the whole mood of the evening. Each lady received a beautiful orchid corsage and the dinner jackets of the men were adorned with leis. Even the door prize was a Hawaiian grass skirt and hat.

Wives Association Program—1958

The Engineers' Wives Association of Vancouver and Lower Mainland, British Columbia, have announced the events scheduled for the 1958-1959 season, in a neat black and white printed folder. Membership in the organization is open to the wife or widow of a member, junior, student or affiliate of the E.I.C., and/or The Association of Professional Engineers of British Columbia. Annual fee for membership is $2.00, payable to Mrs. J. J. Kaller, 3862 W. 41st Ave., Vancouver.

First item on the program was a membership tea, at the University Club of Vancouver, on September 25. On October 23, and November 20, a dinner, for husbands and wives at the Delmar, Granville St., with Dr. Desmond Kidd, guest speaker, and, last event of the year, a bridge and tea. Early in 1959, Mrs. Ellen Harris will give an illustrated talk on "A Visit to Japan", in the B.C. Electric Bldg., January 22. On February 20, a dinner dance has been arranged at the Thunderbird Room, North Vancouver. Luncheon at Leon's Cabaret Co. Ltd., with a millinery demonstration by Miss Mollie Entwhistel of Mayfair Hat Shoppe will take place on March 26. A theatre party, April 30, to the Waltz of the Toreadors, at the Vancouver Little Theatre Association. Closing the events for the summer, the annual meeting and luncheon, on May 21. Mrs. A. Peebles will weigh "Comparisons and Contracts: Canada and Europe."

The Engineers' Wives Association officers are as follows: Honorary president, Mrs. J. N. Finlayson; president, Mrs. A. Peebles; vice-president, Mrs. E. S. Pretious; recording secretary, Mrs. T. A. McLaren; corresponding secretary, Mrs. F. G. Pearce; treasurer, Mrs. J. J. Kaller; program, Mrs. L. T. Postle; social, Mrs. K. E. Patrick; membership, Mrs. H. Lillie; hospitality, Mrs. C. D. Bailey; press and publicity, Mrs. D. K. Bannerman; ways and means, Mrs. A. A. Wilson.

News of Other Societies

CGRA Meets at Montreal

The Canadian Good Roads Association held its 39th annual meeting September 30-October 3, 1958 at the Queen Elizabeth Hotel, Montreal, and delegates were welcomed by Lt-Governor Onesime Gagnon, Hon. Antonio Talbot, Quebec Minister of Roads, and His Worship the Hon. Sarto Fournier, Mayor of Montreal. J. T. Douglas, Saskatchewan's Minister of Highways and Transportation was elected president of the Association for 1958/59.

Looking ahead, members foresaw greater use of electronic equipment for computations in road design work and traffic surveys; a trend to much larger and heavier equipment for construction, with giant units up to 34-cubic yard capacity; foam plastic as a base course material, replacing crushed stone and gravel; and plastic membranes for highway subgrades.

The first day's morning session on Tuesday was devoted to presentation of the annual presidential review by the Hon. Hugh Flemming, premier of New Brunswick and president of the Association. He predicted annual expenditures of $2.2 billion on Canada's roads and streets by the year 1973, twice the current total government outlay of $1 billion; and the accompanying increased problems of engineering and administration. He stressed the need for imagination and boldness in dealing with these problems on the part of all those connected with the highway industry.

Mr. Flemming said increased road use and vehicular speeds were "inevitable". He emphasized the need for research in the development of new design criteria and construction materials to accommodate this growing traffic volume and speed.

"The road ahead", the CGRA president said, "points to a bright, challenging and interesting future for all of the people in the highway industry".

Members of the board of directors, the president and first vice-president, Canadian Good Roads Association, appointed at the 39th annual meeting, Montreal, September 29—October 3. Left to right, (front): Norman H. Bell, Hon. F. M. Cass, Minister of Highways, Ontario, first vice-president, C.G.R.A.; Hon. J. T. Douglas, Minister of Highways and Transportation, Saskatchewan, president of C.G.R.A.; Hon. Antonio Talbot, Minister of Roads, Quebec; and A. C. Knight. (back): C. W. Gilchrist, managing director, C.G.R.A.; Frank N. McCallum, Canadian Trucking Association, L. E. Sawyer, R. H. Whiteside, W. B. Flora, A. W. Clark, and J. H. L. Ross.

Roads Roundup

Newfoundland: In the first afternoon session delegates heard reports from each of the ten provinces on construction progress for the year. Deputy Minister C. A. Knight of Newfoundland reported a four-year program for roads other than Trans-Canada had been announced last March, to cost 56 million, and called for 1,200 miles of new construction, 1,700 miles of reconstruction and 600 miles of paving on provincial roads. Contracts had been awarded for 45 miles.

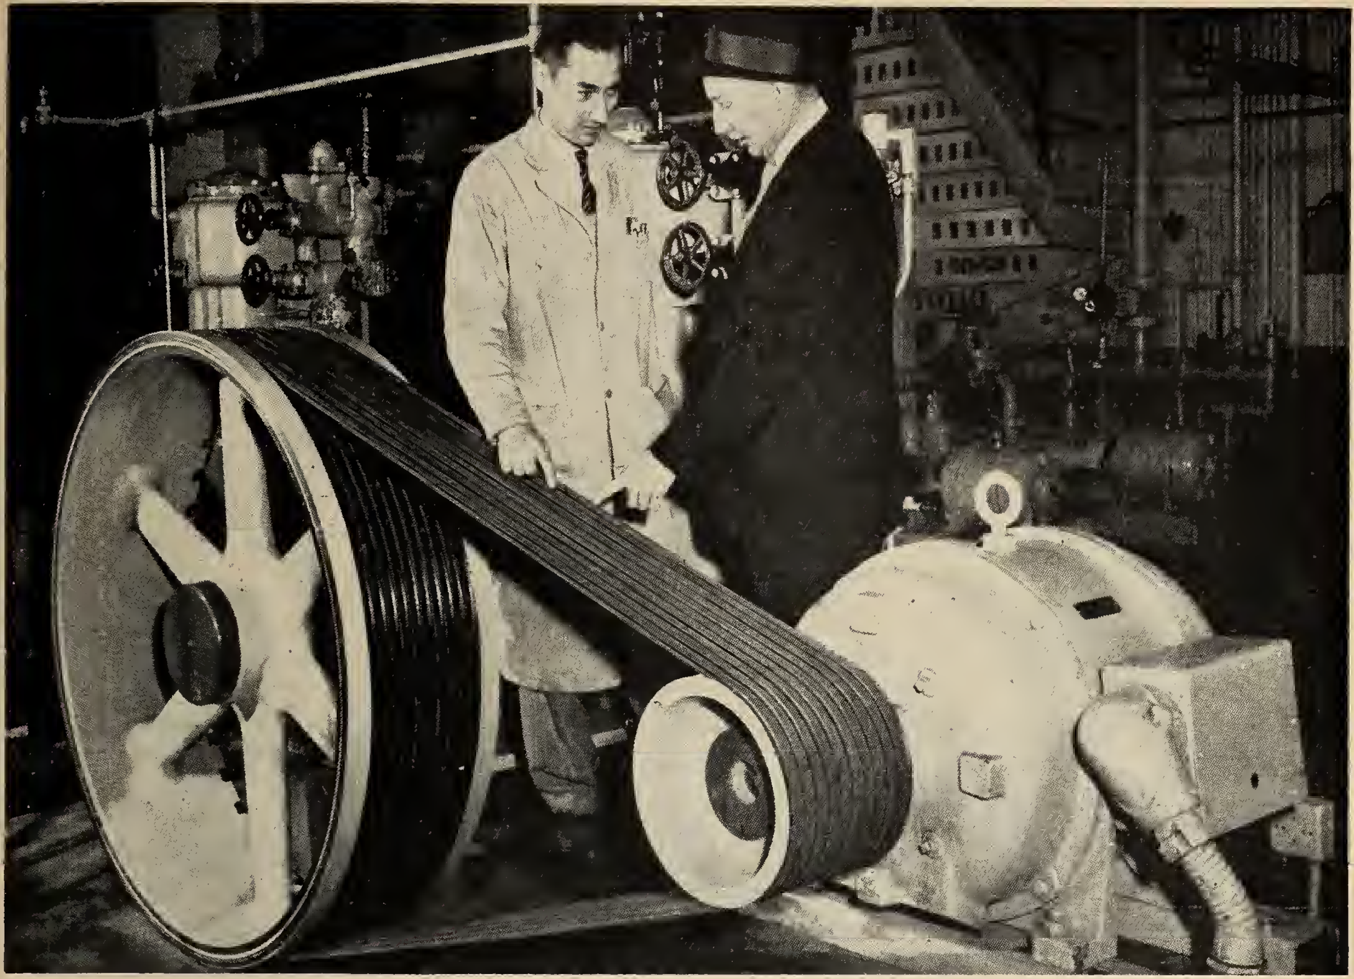
This year expenditure on the Trans-Canada would approach $7½ million, he said, bringing completion of 260 miles of grading and 50 miles of paving out of the province's share of 570 miles of T.C.H. With the opening of the bridge over the Exploits River and completion through Terranova Park early next year, it would be possible to drive from end to end of the province without need of ferries.

Nova Scotia: Highways Deputy Minister, J. L. Wickwire of Nova Scotia reported his province was carrying out its greatest program since 1937, with $20 million earmarked for new road construction and $13 million for maintenance. Work to be done during the year included 78 miles of paving on primary highways, 222 miles paving on secondary highways, and re-paving, 48 miles. Some 285 miles would be prepared for paving. Bridges completed or under construction would total over 200, including 50 of from medium to large size.

Grading and base course for the 10 mile trunk artery to Dartmouth Airport at Halifax was nearing completion, he stated, while the $1 million dam over the Annapolis River was being built. Tenders had been called for a $7 million high level bridge and causeway over the Big Bras d'Or Channel, while a $1 million grade separation at Halifax would be in use by November. Twenty miles of circumferential limited-access highway to serve the Halifax Dartmouth suburban area, to cost $4 million, were being planned.

New Brunswick: Richard Palmer, Deputy Minister of Public Works for New Brunswick, said his province was investing $23½ million on roads and streets in 1958, the largest program in its history. With the $9.9 million from revenue account the total budget for the year would amount to $33.4 million.

In a concentrated effort to complete New Brunswick's unpaved sections of the Trans Canada, $14½ million was being spent this year, said Mr. Palmer. The Province's largest bridge undertaking this year had been the 3,600 ft.



INSTALLED IN 1952—STILL SAVING MONEY

...thanks to Goodyear's 3-fold service

At Sicks Edmonton Brewery Ltd., a set of 10 Goodyear V-belts has been delivering power to an ammonia compressor every working day for 6 years. Even now Goodyear maintains a keen interest in this installation. Periodically the Goodyear Representative "drops in" to inspect the belts and to talk over operating efficiency with the maintenance engineer. Such "follow-up" is but one part of Goodyear's 3-fold Service which consists of:

1. Analyzing and counselling on projects in the blueprint stage.
2. Recommending belting and hose that will improve operation of existing equipment.
3. Making periodic examinations to assure continuous low-cost performance.

3-fold service is a tradition with Goodyear that dates back more than 50 years. The range of Goodyear made-in-Canada industrial rubber products is continuously growing . . . and equally important . . . Goodyear is always prepared to "back" each product with on-the-spot service.

For assistance on any problem pertaining to industrial rubber products, contact the Goodyear Representative at . . . Moncton, Saint John, Quebec City, Montreal, Toronto, London, Windsor, Winnipeg, Regina, Saskatoon, Calgary, Edmonton, Vancouver, or Head Office . . . New Toronto.

INDUSTRIAL RUBBER PRODUCTS ENGINEERED FOR THE JOB

GOODYEAR

THE GREATEST NAME IN RUBBER

Fredericton T.C.H. structure to be finished next year at a cost of some $6 million.

Grading and gravelling contracts for the year would cover 300 miles, seal coating 600 miles, new pavements, 39 miles, and re-capping and reconditioning, 60 miles, he said. Quebec and New Brunswick jointly are building a $5 million bridge near Campbellton, and a N.B.-Maine and Ottawa joint project would see a $1 million bridge at Campbellton-Lubec.

Prince Edward Island: Deputy Minister of Highways R. G. White of Prince Edward Island told the meeting that $17 million had been budgeted by his province for 1958. The province's 75 mile section of the Trans Canada Highway was only seven miles short of completion. The West River Causeway 1,800 feet long was completed this year. At year-end, P.E.I. would have a total of 3,200 miles, 500 of which were paved.

He reported good progress on planning for the proposed $50 million causeway linking the province to the mainland, which would require some 40 million tons of rock and would take some three to five years to complete. Such a causeway, he said, would mean great savings in transporting marketable goods to and from the island.

Quebec: Arthur Branchaud, chief engineer, Quebec Department of Roads, reported a budget exceeding $100 million has been set in 1958 for the fourth year in succession. With $160 million voted, this was exclusive of a further $22 million for bridges and $30 million for the Laurentian Autoroute, the largest in the province's history. This amounted to $20 more per motor vehicle than the province collected in gasoline taxes, registrations and license fees.

In a summary of current construction projects, he referred to the paving of a 22-mile stretch of highway 58 north of Mont Laurier. Completion of this highway would allow motorists to travel 1,100 miles across the province, from the tip of Gaspé to the Ontario border east of Rouyn, without encountering a single mile of gravel road, he stated. Other major projects included the 560-mile belt-road of the Gaspé Peninsula which will be completed this year, and the linking of Quebec City with the Seven Islands - Baie Comeau extension of Highway 15. Only a gap of 26 miles remains in this $25 million highway project.

Ontario: W. J. Fulton, Ontario's Deputy Minister of Highways, reported his province was in the fourth year of a program which would result in modernization of its entire system of King's Highways by 1970. This year Ontario would spend more than $253 million on its provincial highway system and on subsidies to municipal roads and street authorities, compared with $212.8 million last year. Some 289 capital contracts were scheduled for letting this year, involving 504 miles of grading, 310 miles of paving and 135 structures. The trend of prices paid in the current year had been sharply downward, and the program for the year was well up to schedule.

During the 1958 construction year the Burlington Bay Skyway and another 50 miles on dual-lane controlled access Highway 401 would be completed. Good progress had been made on making the Queen Elizabeth Way Canada's first dual-lane highway. Work had continued on the Ontario section of the Trans Canada, while the Queensway section through Ottawa had shown good progress. Work had also started on the Rainy Lake Causeway east of Fort Frances and eventually the present gap between Fort Frances and Atikokan on Highway 120 would be closed and would then connect the head of the lakes with the proposed Mississippi Parkway.

Authority had been received to accelerate the present program for secondary highways still further, he stated. An additional program had been announced of special large projects which the province will either undertake itself or in co-operation with other highway authorities, in the case of international bridges. This special program could involve an expenditure of $100 million over the next five years and it had been decided to charge nominal tolls on a very few large and expensive bridges. Tolls would first go into effect on the Burlington Bay Skyway, to be officially opened on October 30.

Manitoba: Manitoba's Deputy Highway's Minister, George Collins, reported weather excellent for construction. With a surplus of earth moving equipment, prices had been bid down at least 25 per cent below the 1956 level. Paving and structural prices had remained steady. With a 1958 budget of $35.6 million, the season's program comprised 374 miles of grading, 698 miles of gravelling, 184 miles of base stabilization, 136 miles of prime treatment and calcium chloride, 136 miles of seal coating, 289 miles of bituminous material, and 17 miles of concrete paving.

Manitoba had reached agreement with Ottawa early this summer, in respect to general locations of the joint Northern Development Road Program. Four contracts would be let by October 30th on the route from Simonhouse to the new International Nickel development in the north-west part of the province within the Precambrian Shield, and involved rock equipment and considerable muskeg removal equipment, he stated.

The international connection to the North Dakota portion of the Interstate Highway System was being made at the border towns of Emerson, Manitoba and Pembina, North Dakota. The Trans-Canada would be completed this season, except for a portion of the Metropolitan-Winnipeg Perimeter Route.

Saskatchewan: Saskatchewan's Deputy Minister of Highways, L. T. Holmes, reported excellent weather, no shortages of materials or labor and bid prices somewhat lower than recently. Provision for provincial roads had amounted to $34 million including help for municipalities and northern development. Funds for provincial highways at $25 million were about 11% higher than for 1957. Some 3600 miles of the Municipal Road Grid system would be completed by year-end.

Two large paving contracts would be completed this season on the northern trans-provincial route, he stated, replacing existing surface treatments, and paving had been commenced on the last primary gravel link into the south-central part of the province between Assiniboia and Moose Jaw. The Department was moving into the north-eastern part of the province where there were no cities. This involved paving and dust-control work on highways Nos. 6 and 14. The Roads to Resources program in Saskatchewan was being handled jointly by the Department of National Resources and the Department of Highways, he said. The DNR was working on two roads, one from the Town of Hudson Bay, via the Carrot River to the Manitoba border, destined for The Pas, Manitoba. The other connection to highway No. 55, east of Prince Albert, runs via Nipawin Provincial Park to Flin Flon, Manitoba. The Province had been allocated responsibility for a road into the far north originating on the provincial highway system at La Ronge with a probable destination of Uranium City, and work was now under way.

Alberta: A. M. Paull, chief engineer, Alberta Department of Highways, reported his province had set a budget of $60 million in 1958, divided as follows: Trans Canada Highway $4.8 million; other new roads $30.8 million; bridges, $10.1 million; maintenance $4 million; new district roads, $9 million and for location and surveys $0.62 million.

On the T.C.H., 3.7 miles of grading, 6.25 miles base course, 6.7 miles of concrete paving and 58.7 miles of plant mix surface course would be built. On other new roads there would be 225 miles of grading; 275 miles of sealcoat and 300 miles of gravel surfacing. Bridges would include 10 major, and 24 lesser structures, and replacement of 180 shorter spans.

By year-end, the TCH would be completed except for three miles, he said, while the province would have 132 miles of four lane highways completed. The new Peace River Bridge at Dunvegan would have piers and abutments completed ready for steel erection. It was expected to be open in the fall of 1960. Construction would commence on three bridges at Morrin, Drumheller and Sundre. Two other bridges near Taber and Bonnyville would be commenced.

British Columbia: Deputy Minister H. T. Miard of British Columbia's High-

Here's Why Ciment Fondu

is industry's most versatile cement!

because the same cement makes

CONCRETE IN HOURS—NOT DAYS (using ordinary aggregate)	Mature concrete at unequalled speed. The maximum waiting time is 24 hours.
CORROSION-RESISTANT CONCRETE (using ordinary inert aggregate)	Concrete highly resistant to chemical attack.
REFRACTORY CONCRETE (using firebrick aggregate)	The most adaptable refractory known.
INSULATING CONCRETE (using light-weight aggregate)	Jointless castable insulation suitable for high temperatures.
COLD WEATHER CONCRETE	Hardens satisfactorily in temperatures well below zero.

FOR SUPER-DUTY REFRACTORY CONCRETE OR CASTABLE MIXES
SECAR 250 White Calcium-Aluminate Cement can be used for service temperatures from 2450°F. to 3300°F.
Over 70% Al_2O_3
Iron Compounds & Silica less than 1%.

CIMENT FONDU ALUMINOUS CEMENT

ways Department reported. Thirty-four contracts were in progress, 18 of them on the Trans Canada; 53 bridges were under construction. The $20 million Deas Island Tunnel under the Fraser River, and one bridge, were being built by the Toll Authority. Of the total 533 miles of Trans Canada Highway through the province only 63 miles would not be complete or under contract by year's end.

Construction continued on southern trans-provincial by-passes, the Cariboo highway (nearly completed) and the northern transprovincial, he reported. New roads opened in 1958 included the 24 mile Lakelse-Kitimat Highway — The Horseshoe Britannia Beach 21 mile road to Squamish Valley and Garibaldi Park, and the new Elko-Roosville Highway, 23 miles long. The paving program for the year included 120 miles of plant-mix, 42 miles of road mix and 88 miles of sealcoat. Three notable bridges, two of them toll structures, had been opened since the last association meeting.

Federal Highway Program: G. B. Williams, chief engineer, Development Engineering Branch, Federal Public Works, reporting on the Federal highway program, stated federal highway expenditure for the current year was estimated at $115.7 million, of which Public Works was concerned with $83 million exclusive of $15 million for grade separation and $10 million for some 1500 miles of the Northwest Highway System including the Alcan Highway.

Total estimated value of approved Trans Canada Highway projects was $429 million, of which the Federal share was some $256 million, he said. Total length of the T.C.H. including National Park sections is 4,470 miles. At the end of July 2,607 miles had been graded, 1,878 miles had been paved and 255 structures had been completed. There was an additional 1,200 miles of paved road along the route not to T.C.H. standard, which provinces may wish to leave in its present condition.

Through Banff and Yoho National Parks the T.C.H. was complete to the bituminous stage; through Glacier and Revelstoke Parks on the Roger's Pass Route, brushing was practically completed, but it was doubtful if the grading schedule set for the fall of 1959 would be met, he observed. In addition, on behalf of Dept. of Northern Affairs and National Resources, Public Works was undertaking a program of reconstruction of major National Parks highways.

Northern Affairs and National Resources assumes the Federal responsibility for the new Roads to Resources Program, for which Ottawa provides 1½ million per year to each, to be matched on a 50/50 basis by provinces for development of roads, said Mr. Williams. This is a five year program which, if all provinces participate, will call for a federal outlay of $75 million.

Already under construction in the NWT was an extension to the Mackenzie Highway from Alexandra Falls via Fort Rae to Yellowknife and a bridge crossing over the Kakisa River, he reported. Three ferries on major river crossings on the existing Whitehorse-Dawson Road would be replaced with 700 ft. structures.

Addresses and Panel Discussions

On Wednesday morning two addresses were presented relating to construction and maintenance, followed by a panel discussion on specifications, while two addresses were heard on safety education. At the afternoon session two papers were given on soils and materials, followed by a panel discussion on soil compaction. An evening session was devoted to a symposium on frost action, with three papers.

On Thursday morning at a session devoted to roadbuilder's activities, five addresses were presented from regional Road Builder's Associations. In the afternoon session five papers relating to traffic and operations were read, while elsewhere the subject of economics, finance and administration was discussed with presentation of three papers relating to statistics, land acquisition and liquidated damages.

Recalling that the Romans brought their peace and law to the known world by a system of roads, J. B. McGeachy, associate editor of the Financial Post, guest speaker at the Wednesday luncheon, told delegates "the world's greatest headache today is that there is no road between the United States and China by land, air, sea, radio or telepathy . . . It would be a great help to peace if there were such a road now safe, smooth and free, from Paris to Peking . . . There is no peace now without tolerance and no tolerance without roads."

The annual banquet took place on Thursday evening, with the Rt. Hon. John G. Diefenbaker, Prime Minister, as guest speaker. He told delegates and guests that "nothing can help redress the imbalance of northern development Canada has with her neighbouring Arctic communities, more than the construction of roads. A lack of transportation there, more than climate, is the major obstacle to the region's development."

"Alaska is now a state", he said. "Greenland, under Denmark's guidance, is a generation or two ahead of us in development. In Russia, cities of 50,000 persons or more are situated inside the Arctic circle. With its minerals, forests, tourist attractions and strategic position in defence, Canada's great northland is no longer a forbidding land of ice. We want to see a redress of our failure in the past to recognize the north. Canada will spend $100 million on roads in the two territories over the next six or seven years, which will in the forseeable future have provincial status," he added.

H. R. Hawthorne, chairman of the President's Award Committee, presented the President's Medal at the banquet for the best technical paper contributed at the 39th Convention to David L. Townsend, associate professor of engineering at Queen's University, Kingston. His paper, "The Performance and Efficiency of Standard Compacting Equipment" was presented during the panel discussion on soil compaction.

Canadian Chamber of Commerce

Some 700 delegates attended the 29th annual meeting of the Canadian Chamber of Commerce, in Montreal, October 6-7-8, 1958. Discussions developing the theme "Blueprint for Progress" were

A. C. Ashforth

led by R. C. Pybus, M.E.I.C., of Vancouver, who was completing a year in the office of president of the Canadian Chamber.

Delegates represented business and community affairs of wide variety in all parts of the country. The three-day program of the "parliament of business" included plenary sessions on labour-management relations, freedom, foreign trade, and the role of the community Chamber in preparing for tomorrow.

New officers were elected during the meeting. The Canadian Chamber will be led in 1958-59 by Albert C. Ashforth, who assumed the office of president. He is president of the Toronto-Dominion Bank, a resident of Toronto. First and second national vice-presidents are: W. A. Scammell Case, Saint John, N.B., and Herbert Gordon Love, Calgary, Alberta.

The Rt. Hon. The Earl of Home, London, England, Secretary of State for Commonwealth Relations, was the speaker at the annual dinner. He reviewed Commonwealth relations and talked about the general areas of agreement demonstrated by the recent Commonwealth conference in Montreal.

With the recognition of the concept of freedom as a commonly held philosophy, the Montreal conference, he said, found three further objectives attainable. Material betterment could be brought about through this partnership by various means; education would be advanced by current and future plans for study of educational needs; "interdependence"

was the goal, the "secret of progress to be found in constructive co-operation".

Policy of the C.C.C.

In a day of discussion, a series of policy declarations and resolutions of the Canadian Chamber was made ready for presentation to the annual meeting. These resolutions, all national in character and on such subjects as low cost housing, tourism, railway level crossing safety, tarriff rates, government spending, northern development, etc., numbered about 40. They are to form a submission to the Federal Government.

A few of the resolutions are abstracted very briefly, as follows:—

Education: Recommendations favoured active and constructive interest in education on the part of members; establishment of scholarships and endowments, and research programs; co-operation in vocational guidance; encouragement for able students to continue on to higher education.

Automation: Declaration stated that automation is part of the continuing industrial evolution, and an aid to improved productivity; stress was laid on importance of education designed to meet the need for different skills, and more engineers and technicians; gradual utilization of automation would permit retraining or redeployment of the work force.

Material resources: Conservation of soil, water, and forest resources was declared essential; government support was recommended for irrigation schemes which are feasible and economically sound; co-operation of industry, commerce and agriculture was advocated.

Natural resources: Members urged to promote and support federal, provincial and business policies leading to: (1) the properly integrated development of Canada's natural resources in the national interest; (2) resource management that will ensure maintenance and expansion of renewable resources; (3) fiscal and taxation policies consistent with good resource management; and (4) education on conservation and efficient utilization.

Defence: recommendations urged maintenance of defence efforts; re-examination of defence program in view of more expensive weapons of the future; organization of some part of armed forces to assist the civil population to survive a nuclear attack; development of a disaster organization; co-operation with the United States in scientific planning and defence programming and standardization in the production of military equipment.

National highway program: resolutions urged that government of Canada make federal appropriations to provinces for improvement and construction of highways of national significance; that the government sponsor inter-provincial liaison and planning for construction of inter-provincial, development and other highways of national importance.

Ontario Industrial Development Conference

Premier Leslie M. Frost of Ontario addressed a luncheon in Toronto on October 2nd of special interest to over 1,000 municipal officials, business and industrial leaders attending the Ontario Industrial Development Conference. This event, sponsored by the Government's Trade and Industry Branch provided the first opportunity for representatives of municipal government, industrial commissions and planning boards in Ontario to meet with key business executives on such a large scale. The primary purpose was to share specialized knowledge and thinking in relation to industrial development.

Under the chairmanship of Ontario's Director of Trade and Industry, A. V. Crate, this symposium heard opinions from leading Canadian businessmen. Themes of their addresses were as follows:

Herbert Smith, president, Canadian General Electric Company: the need of Canadian industry to develop and manufacture new products suited specifically to Canadian market, and what expanding industry requires from municipalities.

Crawford Gordon, president, A. V. Roe Canada Limited: necessity for Canadian manufacturers to develop their own resources and "brain work" in the area of design research and engineering.

Chairman of Canada's Royal Commission on Economic Prospects, Walter L. Gordon, president of J. D. Woods & Gordon Limited: 'observations and elaboration on specific facets of the Canadian economy related directly to industrial development as revealed through the work of the Royal Commission. Canada's Deputy Minister of Trade and Commerce, John H. English: the outlook, present and future, for industry in Canada and particularly in Ontario.

John S. Proctor, president, Imperial Bank of Canada: the means and problems involved in financing industrial growth.

Mayor Michael Patrick of Windsor, Ontario: local programs to encourage and assist in the expansion of existing industry and in the attraction of new industry.

Eric Beecroft, director, Community Planning Association of Canada: basic community planning and zoning requirements of industry and municipalities.

Stuart D. Armour, Economic adviser, Steel Company of Canada Limited: what government should do for business.

Dr. Edward G. Pleva, University of Western Ontario: transportation requirements of industry, and significance of existing systems of transportation, including the St. Lawrence Seaway.

O. W. Titus, president, Canada Wire and Cable Company Limited: economic and municipal factors to industrial decentralization in Ontario.

Professor Charles E. Hendry, director, School of Social Work, University of Toronto: the impact of modern industry on labour and its families, automation and future social dangers.

Officers

A.S.C.E. Election

Francis S. Friel, of Philadelphia was elected president of the American Society of Civil Engineers at its annual convention on October 15. The new president of the 41,000 member society said that there are many problems ahead for the engineering profession. He cited the need for greater understanding in the fields of guided missile research, traffic and highway engineering, water supply, flood control. Mr. Friel also stated that the social and political implications of all engineering works must be considered as well as the problem of construction.

Human Factors Society of America

Renato Contini, senior research scientist and research coordinator at New York University, college of engineering research division has been elected the first president of the Human Factors Society of America to serve a one-year term. It is an organization of research scientists from government agencies, industrial firms, and educational institutions. It is concerned with the many problems inherent in the man-machine systems. It strives to bring about the best merging of human capacity and machine capacity within the framework of engineering limitations and equipment functions.

Awards

Dr. Frank K. Schoenfeld, vice-president, research, the B.F. Goodrich Company, has been named a recipient of the Industrial Research Institute Medal for 1959. The medal, awarded annually since 1945 honors "outstanding accomplishment in leadership in or management of industrial research which contributes broadly to the development of industry or the public welfare.

Calendar

Illinois Institute of Technology

Industrial Management Engineering Conference, Illinois Institute of Technology, chemical engineering building, 10 W. 33rd Street, Chicago 16, Ill., Feb. 5-6, 1959.

Canadian Construction Association

Meeting, Queen Elizabeth Hotel, Montreal, Jan. 18, 1959.

Institute of the Aeronautical Sciences

Twenty-seventh annual meeting, Sheraton-Astor Hotel, New York. Honors night dinner, January 27, 1958.

Riches from the Untamed Mountains

This is the Rocky Mountain Rift, 500 miles North of Vancouver. With BTH acting as electrical advisers, ambitious plans are in hand to develop this remote, virgin territory for its raw materials and power resources. Present schemes envisage the possibility of the world's largest man-made lake, taking 7 years to fill, and having a hydro-power potential of some 4,000,000 h.p.

To tame these mountains calls for endeavour and hardship in one of the greatest modern pioneering jobs. BTH are proud to be numbered among the pioneers.

Recent BTH Contributions to Canada's Industrial Growth

* Toronto's modern subway has 140 railcars fitted with BTH traction control equipment.
* Generating equipment of 25,000 kW for the Ford Motor Company of Canada.
* 230,000-volt, 7,500 MVA lenticular circuit breakers for the B.C. Electric Company.
* The largest blast furnace blower of its kind, for the Algoma Steel Corporation.
* Mercury-arc rectifiers, transformers and switchgear for the Canadian British Aluminium Company's Baiecomeau Smelting Plant.

EXPERIENCE BACKED BY IMMENSE RESOURCES

In many parts of the world BTH equipment is fulfilling electrical needs efficiently and dependably. The BTH Canadian Company is backed by the resources of the progressive parent company in Britain.

B T-H **looks ahead with Canada**

Power Generation · Transformers · Switchgear · Electric Drives for Industry, Agriculture, and Mining · Fractional-Horsepower Motors · Electronic Controls · Electric and Diesel-Electric Locomotives · Marine Radar · Aircraft Electrical Installations

LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*CONFERENCE ON EXTREMELY HIGH TEMPERATURES

Represents a summary of the knowledge underlying commercial or usable thermonuclear reactions. Particular emphasis is placed on high temperatures as they relate to the propulsion fields. Covers the production of extremely high temperatures, methods of temperature measurement such as optical radiation, plasma analysis, and applications. The conference, held in 1958, was sponsored by the Electronics Research Directorate, Air Force Cambridge Research Center. (Ed. by H. Fischer and L. C. Mansur. New York, Wiley, 1958. 258p., $9.75.)

*SCIENTIFIC PROGRAMMING IN BUSINESS AND INDUSTRY

The author attempts to present the technique of scientific programming in terms of a mathematical language and understandable by businessmen. An extensive review of the fundamentals of linear programming is given, including the simplex method, the dual theorem, geometry, convex and dynamic programming, and the elements of the theory of games. Specific applications discussed are transportation allocation and production and inventory control. (A. Vazsonyi. New York, Wiley, 1958. 474p., $13.50.)

*LANDING GEAR DESIGN

Throughout the book particular attention is given to practical design advice. It begins with chapters on the purpose and arrangement of landing gear, problems of energy absorption, tires, wheels, and brakes. The general layout and detail design of landing gear are described with information provided on shock absorbers, retraction and stressing. The concluding chapter deals with unorthodox landing gear. This is another in the series of text-books published under the authority of the Royal Aeronautical Society (H. G. Conway. Toronto, Ryerson, 1958. 342p., $11.25.)

ORAL COMMUNICATION OF TECHNICAL INFORMATION

Written to provide a practical guide to effective speaking for technical personnel. The book covers organization of material, composition, delivery of formal and impromptu speeches, and the use of mechanical aids such as recordings and slides. In addition special sections are devoted to presiding at meetings, presenting science to the layman and giving technical legal testimony. (R. S. Casey. New York, Reinhold, 1958. 199p., $4.50.)

*BETRIEBSSICHERE GLEITLAGER

Intended as a manual on the safe and efficient operation of journal bearings, this book covers practical bearing design, lubricants and the basic laws of lubricating films, bearing capacity, heat transmission and operating temperatures, and bearing materials. There is a separate chapter on thrust bearings. The practical aspect of the book is exemplified by the extensive use of tables and graphs for the presentation of technical data. (Georg Vogelpohl. Berlin, Springer-Verlag, 1958. 315p., 46.50 DM.)

*KERBSPANNUNGSLEHRE, 2ND ED.

This thorough development of notch stress theory is devoted to the problem of precise determination of strength and stresses in structural parts. In addition to the technical data interspersed in the text a number of loose folded graphs and diagrams are provided in a pocket at the back for easy use. (H. Neuber. Berlin, Springer-Verlag, 1958. 226p., 36 DM.)

*ZAHNRADER, VOL. II: STIRN- UND KEGELRADER MIT SCHRAGEN ZAHNEN SCHRAUBGETRIEBE

This second volume of a treatise on gear design contains three main sections. The first section deals with spur and bevel gears having helical teeth; the second, with worm gears; the third provides a brief treatment of the measurement of gear characteristics. This new edition covers the developments of the past 20 years and the standards introduced in that period. (A. Schiebel. 4th ed. rev. by W. Lindner. Berlin, Springer-Verlag, 1957. 132p., 21 DM.)

ANALYSIS AND CONTROL OF NONLINEAR SYSTEMS

Developed in a graduate course, this book is intended to provide an account of the available techniques for the analysis and control of nonlinear physical systems. It presents both analytical and topological methods of solving nonlinear differential equations, covering both mechanical vibrations and electric oscillations. Third- and higher-order nonlinear differential equations are thoroughly treated. The author has developed a new approach, based on his method of space trajectory in n dimensions, which extends the phase-plane method to the phase-space.

There is a bibliography of 735 items covering the years 1860 to 1957. (By Y. H. Ku. New York, Ronald, 1958. 360p., $10.00.)

ENGINEERING SURVEYS: ELEMENTARY AND APPLIED, 2ND ED. ENLARGED.

In this new edition of a well-known text-book for undergraduates, the material has been revised and modified where necessary, particularly the chapter on photogrammetry, and the bibliographies have been brought up to date. Sections have also been added on construction problems, modern instruments, and measurements and errors.

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m. — 5 p.m.; Saturday: 9 a.m. — 12 noon.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

• LIBRARY NOTES

The first eighteen chapters, the Elementary section, are also available in a separate publication. (H. Rubey, G. E. Lommel and M. W. Todd. Galt, Brett-Macmillan, 1958. 916p., $6.75).

MULTIPLE PURPOSE RIVER DEVELOPMENT

The development of water resources involves many disciplines in addition to engineering. This volume provides an economic view of the subject, and a framework for the economic analysis of river system development. The authors consider the conditions required to achieve economic efficiency in water development, and analyse the differences in the pattern of income distribution arising from different policies.

In the second part of the book, case studies of Hells Canyon, the Alabama-Coosa River, and the Willamette River are used to illustrate the economic analysis, and the problem of achieving economically efficient river-basin development. (J. V. Krutilla and O. Eckstein. Baltimore, John Hopkins, 1958. 301p., $6.25).

ELEMENTARY ENGINEERING SCIENCE, 4TH ED.

An elementary textbook brought up to date and largely rewritten, this fourth edition covers the Mechanics, Heat and Electricity sections in Science of the English General Certificate of Education. The M.K.S. system of units has been used throughout, and chapters have been added on velocity and acceleration, expansion of solids, liquids and gases, primary and secondary cells, and the magnetic circuit. Many worked examples, and problems and answers are included. (A. Morley and E. Hughes. Toronto, Longmans Green, 1957. 381p., $2.10).

SPACE FLIGHT AND SATELLITE VEHICLES

Intended for the reader with some basic scientific knowledge, this volume presents a survey of past developments, and an assessment of the future of interplanetary flight. The authors consider the basic principles and methods of achieving space flight, the position in 1957, the prospects for the immediate future, and the uses of satellites. A brief excursion into the far future is also made. Bibliographies are included. (R. B. Beard and A. C. Rotherham. Toronto, British Book Service, 1957. 150p., $3.50.).

PROBLEMS IN ELECTRONICS WITH SOLUTIONS

The problems in this volume cover most of the undergraduate syllabus in electronics, and should prove useful to both lecturers and students. The 282 problems are divided into twenty-three chapters covering circuits, valves, amplifiers, oscillators, modulation, photoelectricity, transmission lines, etc.

The answers are given with the problems, and the solutions are given separately. (F. A. Benson. London, Spon, 1958. 219p., 36/–.).

IMPEDANCE MATCHING

A basic treatment of this important topic intended for design engineers, technicians and students. It covers impedance matching and power transfer, impedance matching devices, and impedance matching at audio frequencies, at radio frequencies and in transistor circuits. (Ed. by A. Schure. New York, Rider, 1958. 119p., $2.90.).

DOCK AND HARBOUR ENGINEERING VOL. 1: THE DESIGN OF DOCKS

The first volume of this set deals specifically with the design of docks. Beginning with the general principles of design and with descriptions of typical dock layouts, it continues with dock and wharf walls; entrances and locks; graving docks, floating docks, and slipways; lock gates and caissons. This work is a revision of two earlier works by Brysson Cunningham entitled "Dock Engineering" and "Harbour Engineering". It is fully illustrated, references are listed after each chapter, and there is a detailed index. (H. F. Cornick. London, Griffin, 1958. 316p., £5.5s.).

COAL AND STEEL IN WESTERN EUROPE

A history of the iron and steel industry in Western Europe, and its relation to the coal mining industry, covering the last two hundred and fifty years.

The first part of the book covers the origins of the modern industry in the eighteenth century when there were many small ironworks and the mining of coal was beginning to be of importance. In the second part the growth of the industries in the nineteenth century is traced in Belgium, France, Lorraine, Luxembourg, the Saar and Germany. The third part shows how in more recent times the production of iron and steel has become concentrated in a small number of very large works owned by a few companies, centred in the European Coal and Steel Community.

The authors, a geographer and an economist, have drawn on many original sources in the preparation of this most useful and readable survey. (N. J. G. Pounds and W. N. Parker. Toronto, British Book Service, 1957. 381p., $9.00.).

GEOGRAPHY AND PLANNING

Although applying particularly to the United Kingdom, this book will prove interesting to all those interested in regional planning and the optimum use of all available land. The author, a Reader in economic geography, discusses the geographical basis of planning, considering physical features, climate and weather, rural and land use, town growth, problems connected with industrial location. A useful bibliography is included. (T. W. Freeman. New York, Rinehart, 1958. 191p., $1.50.).

THREE DIMENSIONAL DYNAMICS: A VECTORIAL TREATMENT

Intended for honour students in mathematics, this volume presents a vectorial treatment of the three-dimensional motion of a particle and a rigid body. Tensors are omitted as they are not considered vital to the study. Among the topics covered are vector algebra; motion of a particle; kinematical motion of a rigid body; theory of rotating axes; moments of inertia; equations of motion of a rigid body; Euler's equations; precessional and impulsive motion. Three dimensional statics are covered in an appendix. (C. E. Easthope. Toronto, Butterworth, 1958. 277p., $7.80.).

AUSTRALIAN RAINFALL AND RUN-OFF

This first report prepared by the Stormwater Standards Committee of the Institution of Engineers, Australia, which was established in 1950, presents information on the intensity, frequency and duration of rainfall in Australia. In the second part of the report methods are given for flood estimation, and for the design of urban drainage. These are considered under the headings of urban storm drainage systems; flat areas, such as aerodromes; minor and major structures of rural catchments. The book is well illustrated with many graphs, tables and maps, and there is a useful bibliography on drainage and floods. (Institution of Engineers, Australia, Stormwater Standards Committee. Sydney, The Institution, 1958. irreg. paging, mimeog., £A2.10.0.).

*INTANGIBLE REWARDS FOR ENGINEERS AND SCIENTISTS, ADMINISTRATION OF SALARIES

Two surveys devoted to the needs, goals, and job satisfaction of engineers and scientists. Specific aspects investigated are job activities, actions of immediate supervisors, salaries, intangible rewards, working relations with associates, company assistance to professional development, attitudes towards collective bargaining, and the administration of technical programs. The surveys are Reports numbers 8 and 9 of The University of Michigan Bureau of Industrial Relations. (J. W. Riegel. Ann Arbor, Bureau of Industrial Relations, University of Michigan, 1958. 1st report 105p., $3.50. 2nd report 84p., $2.50. Bound tog. $6.00.).

LIGHT VISIBLE AND INVISIBLE

In this volume translated from the German, the author sums up modern knowledge of the nature and behaviour of light, and shows how the knowledge has been obtained, and how it is used. He explains how visible and invisible light makes photographs in the dark, weighs and measures stars, opens doors, and cooks food. He explains infrared photography, ultra-violet rays, the telescope, the microscope, x-rays, why the sky is blue, and the colour vision of bees. There are many illustrations. (Eduard Ruechardt. Ann Arbor, Univ. of Michigan Press, Toronto, Ambassador, 1958. 201p., $6.00.).

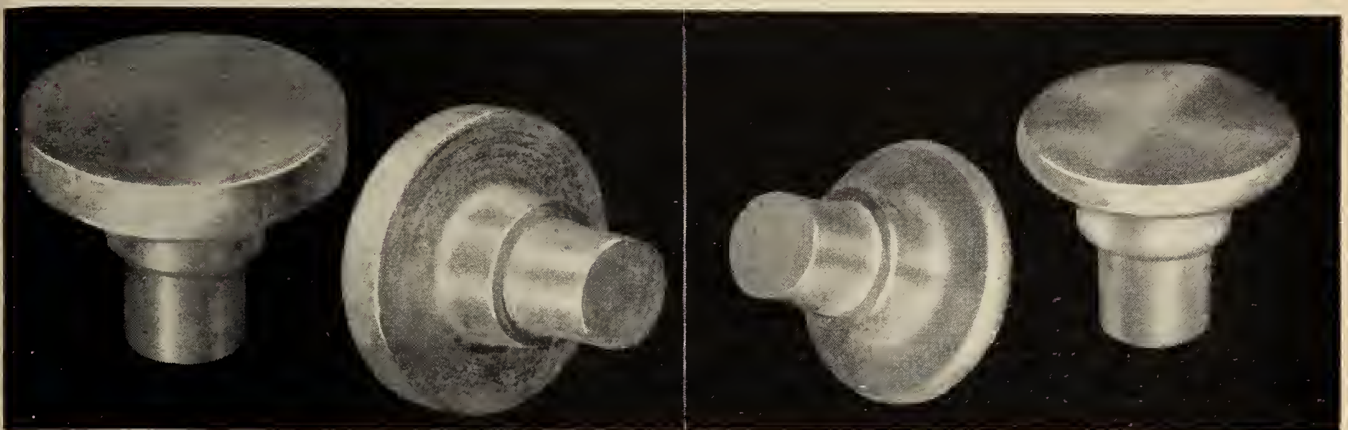
TROUBLE-FREE HYDRAULICS

A practical book for those concerned with the efficient running of hydraulic

TO SAVE ON **FASTENERS**

Standardize your Specials

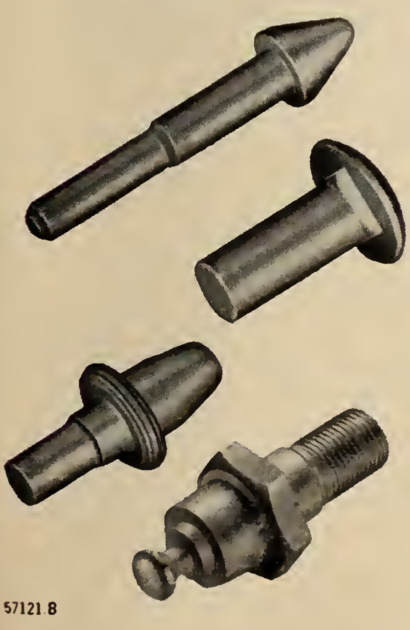
THROUGH STELCO COLD HEADING



Machined "Special" . . . slightly redesigned as a Cold Headed "Standard"

The simple Flat Head Shoulder Rivet shown on the left above (enlarged), was slightly amended as seen on the right, to permit production by cold heading instead of by machining. The elimination of scrap loss, combined with increased speed of production, brought a saving of 80% to the purchaser.

Pictured below are several other "specials" standardized by Stelco with considerable cost reduction.



57121.B

Result - 80% Savings!

Stelco's modern bolt-making facilities, plus the services of Specialty Fastener Representatives, offer you three ways to save on "special" fasteners —

FIRST — Many types of contoured parts can be produced by cold heading more economically than by machining. Not all savings are as impressive as the one illustrated above, but *cost reductions in the region of 40% are not uncommon* and are often accompanied by minor redesigning which adds to the strength of the part. Secondary operations, such as thread rolling or cutting, knurling, extruding, flattening, piercing, drilling, broaching, and bending are also provided for in Stelco's facilities.

SECOND — Stelco will carry as stock items your long-run repetitive "specials" — giving you a ready source of supply and the benefit of large-quantity prices.

THIRD — Your "special" requirement might already be in stock as a Stelco "Standard" — or possibly an existing "special" could meet your needs. In either case you would realise a saving.

Why not ask Stelco's Engineers to examine *your* "specials"? If they are adaptable to production by the cold heading process your cost reductions will be substantial. Any Stelco Sales Office is at your service.

THE STEEL COMPANY OF CANADA, LIMITED

Executive Offices: Hamilton and Montreal

Sales Offices: Halifax, Saint John, Montreal, Ottawa, Toronto, Hamilton, London, Windsor, Winnipeg, Edmonton, Vancouver. J. C. Pratt & Co. Limited, St. John's, Newfoundland.

machinery, it commences with an introduction to the hydraulic system and the problem of systematic maintenance. Other chapters cover pipework and oil-tanks; hydraulic fluids; hydraulic seals; the diagnosis and cure of faults. Much of the material is presented in tubular form, and a set of fault-finding charts is included. (Toronto, Longmans, Green, 1958. 124p., $3.60.).

MANUAL OF SCIENTIFIC RUSSIAN

The author has had considerable experience in teaching Russian to scientists, and has based this manual on the experience he has gained. The emphasis throughout is on scientific vocabulary and texts, and on the written rather than the spoken word. The Manual can be used both as a textbook and as a reference book on the structure of the Russian language. (T. F. Magner. Minneapolis, Burgess, 1958. 101p., $4.60.).

CANADIAN TRADE INDEX 1958

Invaluable to purchasing agents, businessmen, and anyone wanting to obtain a product from a Canadian source, this 1958 edition of the Canadian Trade Index lists the names and addresses of over 10,000 Canadian manufacturers and their products. The larger part of the book is, as usual, a classified directory, with a French glossary. (Toronto, Canadian Manufacturers' Association, 1958. 1083p., $10.00.).

TRAFFIC DESIGN OF PARKING GARAGES, REV. ED.

The changes and advances in parking garages since this book was first published ten years ago have led to its publication in this revised edition. The factors influencing design which are discussed include method of operation, parking demand, peak loads, daily loads, seasonal variations, etc., garage location, delivery time, traffic, etc. Various types of floor design and layout and ramp design, are considered as are mechanical garages and various miscellaneous features such as heating and operational techniques. With the present emphasis on off-street parking in our cities, this should prove a most useful book. (E. R. Ricker. Saugatuck, Conn., Eno Foundation, 1957. 168p.)

*CONFORMAL TRANSFORMATIONS IN ELECTRICAL ENGINEERING

Preliminary material on the elements of field theory and of complex numbers is followed by transformations in the order of increasing complexity. The second half of the book deals with transformations involving elliptic functions. Emphasis is placed on the application of transformations to engineering problems. (W. J. Gibbs. Toronto, Ryerson, 1958. 219p., $9.00.)

*PRE-STRESSED CONCRETE: THEORY AND DESIGN

Divided into three parts, the first of which deals with the theory underlying prestressed concrete. Part two covers the design of simply supported beams. Part three gives an introduction to the specialized types of prestressed structures such as composite construction, statically determinate structures, indeterminate structures, liquid-retaining structures, and domes and shells. (R. H. Evans and E. W. Bennett. Toronto, Ryerson, 1958. 294p., $12.00.)

PHOTOSENSITORS

The author has coined the word "photosensitor" to denote any type of photoelectric element, that is for vacuous or gas-filled photo-cells, photo-e.m.f. cells, photolytic cells, and light sensitive resistors. In this treatise the various types of photocell and their applications to industry are discussed.

The first part of the book describes the characteristics of photosensitors, their associated circuits and optical equipment, while the second part examines their application in protective devices, colorimetry, counting devices, door openers, synchronizers, timing devices, etc. There are also chapters on relays and installation and maintenance. A lengthy bibliography and list of patents are included. (W. Summer. Toronto, Ryerson, 1957. 675p., $21.00.)

SALES AND ENGINEERING REPRESENTATION

The sales and engineering representative is becoming increasingly important in modern industrial marketing. This volume discusses the origin of sales and engineering representation, its functions, advantages and disadvantages, the people working in the field, the qualities necessary for success, and the future of the field. It considers ways of getting started, relations with clients, salesmanship, and agency policy. A biblography adds to the usefulness of this interesting and informative book (L. O. Thayer and G. E. Harris. Toronto, McGraw-Hill, 1958. 210p., $6.90.)

*THE SOLID STATE FOR ENGINEERS

Intended to acquaint engineers with the basic principles underlying the behavior of solid materials. Aspects discussed are crystallography; thermodynamic stability of solid structures and rates of change between states; types of solids: metallic, ionic, covalent and molecular; elastic and plastic deformation; mechanical properties of solids; electron and zone theories; electronic conduction, semi-conduction, and insulation phenomena; optical properties of solids. (M. J. Sinnott. New York, Wiley, 1958. 522p., $12.50.)

*MEDICAL ELECTRICAL EQUIPMENT

An introductory section on the uses of electricity in hospitals and the safeguards necessary is followed by sections on various types of equipment, including shadowless light fittings for the operating theatre, emergency lighting systems, x-ray apparatus, radioisotope diagnostic instruments, surgical diathermy, endoscopes, electrocardiographs, electroencephalographs, respiratory and suction apparatus, incubators, and sterilizers. The book concludes with a discussion of small electric motors used in medical equipment. (Edited by R. E. Molloy. New York, Philosophical Library, 1958. 312p., $15.00.)

*MICROWAVE TRANSMISSION DESIGN DATA

Preliminary material is given on general transmission line theory and on coaxial lines and flexible cables. This is followed by a discussion of wave guides with particular emphasis on practical structures and components; dielectric materials and their properties at microwave frequencies; cavity resonators. A reprint of a book

that has been unavailable for some time. (T. Moreno. New York, Dover, Toronto, McClelland and Stewart, 1958. 248p., $1.50.)

*PUMPS, FANS, AND COMPRESSORS

A discussion of the phenomena of flow and of energy transformations is presented prior to the problem of design and construction which comprises the main portion of the volume. Rather than relying on mathematical formulae the authors have stressed experimental results as a basis for the calculation of dimensions for centrifugal and axial-flow fans, pumps, and compressors for various operational requirements. Translated from the original French edition published in 1953. (A. de Kovats and G. Desmur, Glasgow, Blackie, 1958. 327p., 45/—.)

*FEEDBACK THEORY AND ITS APPLICATIONS

Presents methods of linear and non-linear system analysis. The book begins with a discussion of the properties of feedback, particularly with reference to negative feedback and to stability. It continues with applications of the theory of electronic circuits such as the d.c. coupled virtual earth amplifier, the synthesis of stabilizing networks, and to servomechanism. Additional chapters are devoted to non-linear analytical techniques, control systems employing on-off elements and electronic analogue simulators. (P. H. Hammond. Toronto, British Book Service, 1958. 348p., $7.50.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Atomic Energy

The A.B.C. of atomic energy, by Sir C. Hinton. London, B.B.C., 1958.

Bridges

Studies in composite design of steel beam and concrete bridge decks. U.S., Highway Research Board, 1958. (Bul. 174).

Cement and Concrete

Cement and concrete, 1958. (ASTM S.T.P. No. 205).

Danish National Institute of Building Research, Committee on alkali reactions in concrete. Progress reports:
F 1, 2 & 3: The alkali content of Danish cements, by E. V. Meyer; A new Danish alkali-resistant cement, by E. V. Meyer; Methods for the determination of alkalis in aggregate and concrete, by J. Andersen and L. Ditlevsen.
I 1: Investigations of Danish aggregates at the building research station Garston, England, by F. E. Jones.

Electrical engineering

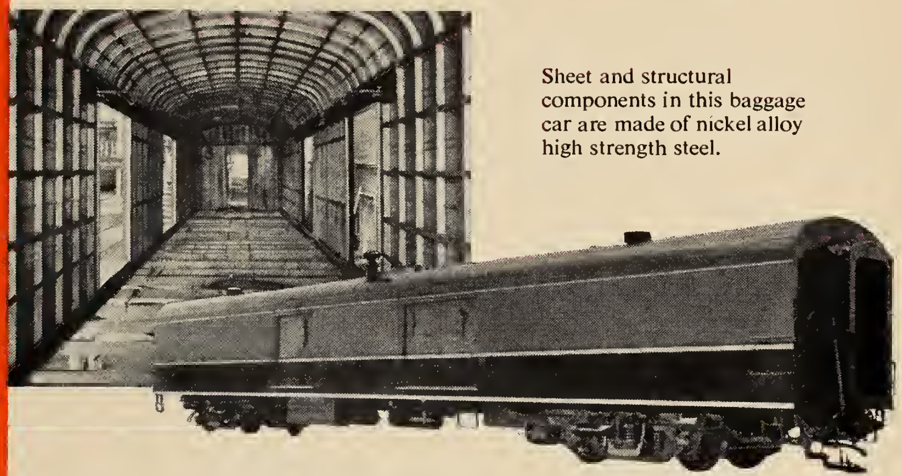
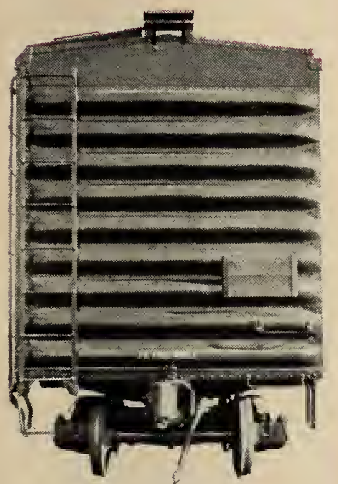
nickel-copper high strength low alloy steels reduce railroad maintenance costs!



Sheet and structural components in this baggage car are made of nickel alloy high strength steel.



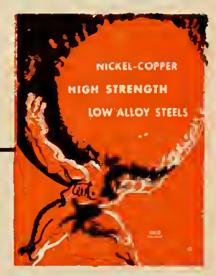
Box cars made of nickel alloy high strength steel.

Covered hopper cars produced with nickel alloy high strength steel plate.

Nickel-copper high strength low alloy steels are providing greater strength, wear and corrosion resistance for hopper cars, baggage cars, box cars and refrigerator cars on railroads. With a yield strength of 50,000 psi. minimum, the high tensile steel plate gives up to 50% longer service life than carbon steel sheets formerly used. Maintenance costs are reduced and out-of-service time cut. In many instances weight savings with the improved ratio of dead weight to payload permit more economical operation.

The same nickel alloy high strength steels that are proving themselves so successfully on railroads give similar results in a host of other applications—mine dump cars, truck hoists and bodies, tank trucks, dump trucks and car carrying trucks . . . bus bodies, barges and bridges . . . shovels, snow plows and cement mixers . . . farm equipment.

Mail the coupon below for a free copy of the booklet entitled "Nickel-Copper High Strength Low Alloy Steels", containing complete information and suggested applications.



Canadian producers of nickel alloy high strength steels:

ALGOMA STEEL CORPORATION LIMITED, Sault Ste. Marie, Ontario.

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Union Carbide — F. P. Wilson, vice-president of Union Carbide Canada Limited, Toronto, has recently been elected to the board of directors of the organization. Also announced was the appointment of R. G. Leckey as manager of public relations.

Shell Oil Company — Appointment of C. A. Foster Jr. as vice-president, marketing, of Shell Oil Company of Canada Limited, has been announced. He succeeds A. L. Wilson, who has been chosen to carry out a special assignment, reporting directly to the president.

Brown Boveri — W. A. Thomann, formerly with Brown Boveri, Switzerland (a parent organization of the Canadian company), has been appointed president and director of Brown Boveri (Canada) Limited, Montreal. Further executive appointments are: C. H. Wich, executive vice-president and works manager; F. H. Fargey, M.E.I.C., vice-president in charge of sales, and secretary of the company; G. R. Labelle, treasurer and assistant-secretary.

W. A. Thomann

Canadian Broomwade — J. Dyson-Gregory has been appointed president of Canadian Broomwade Limited, Toronto. H. D. Broom, C. Broom Smith and J. Lawton Clay have been appointed directors of the company.

Peacock Brothers — B. P. Emo has been appointed manager of Peacock Brothers Limited's Toronto office. R. C. Cook succeeds Mr. Emo as Montreal branch manager.

RCA Victor Company — P. J. Casello, president of RCA Victor Company, Ltd., Canada, has been appointed executive vice-president, consumer products, Radio Corporation of America.

Phillips Wires and Cables — Due to divisional changes at Phillips Electrical Company Limited, the following appointments have been made: C. Sherman, formerly development manager, has been appointed to the new position of chief technical officer. J. E. Thomas has been named manager of the Brockville division; J. S. Waddington, M.E.I.C., becomes manager of the Montreal division. E. G. Purdy will continue as head of the Vancouver division. All three divisions will be administered from the company's head office in Brockville, Ont.

J. H. Lock & Sons — As a result of the death of R. H. Lock, the following appointments have recently taken place at J. H. Lock & Sons Ltd.: J. M. Lock has become president and general manager. C. L. Torry has been elected a director and has become vice-president; he will also continue as manager of the refrigeration and air conditioning division. H. B. Douse, secretary-treasurer, has assumed the additional position of assistant general manager. K. Davis, manager of the company's steel fabricating division.

B. P. Emo

Canadian British Aluminium Co. — The following appointments have recently been announced by the Canadian British Aluminium Company Limited, Montreal: G. Diamand, secretary and controller, succeeding the late C. W. Leslie; H. L. Murray, assistant secretary.

Canadian Aero Service — J. W. Strath has been appointed sales manager of the enlarged sales staff of Canadian Aero Service Limited, Ottawa.

York-Shipley of Canada — Announcement has been made of the appointment of R. D. Whiteman as sales manager of York-Shipley of Canada, with headquarters in Toronto.

Flintkote Company of Canada — The appointment of A. E. Field as sales manager, paving materials division of the Flintkote Company of Canada Limited, Toronto has been announced.

Brown Boggs Appointments — W. A. Dawson, M.E.I.C., has been appointed assistant sales manager of Brown Boggs Foundry and Machinery Co. Ltd. J. J. Brown, grandson of the late J. M. Brown, one of the founders of the company, has joined the sales department.

• BRIEFS

La Salle Builders Supply — Announcement has been made of the appointment of H. R. Dorion as sales manager of La Salle Builders Supply Ltd., Montreal.

National Adhesives — M. Archambault has been appointed supervisor—technical service for the Montreal division of National Adhesives (Canada) Ltd. A. Tate has been named supervisor—technical market development for the Toronto division of the firm.

Canadian Johns-Manville — Canadian Johns-Manville Co. Limited, Port Credit, Ont. has announced the appointment of J. F. Small as company representative for friction materials and industrial products.

Ensio, Whiton & Associates — R. A. Elliott, has joined Ensio, Whiton & Associates Limited, Toronto mine, mill and smelter engineers. He will deal with problems connected with consulting work in the field of mineral beneficiation.

News of Business and Industry

Disher Steel Rexdale Plant — Disher Steel Division of Dominion Structural Steel Limited, Montreal, officially opened recently their new offices and structural steel fabricating plants in Rexdale, Metropolitan Toronto. Some 300 visitors toured the spacious twin bays of the fabricating plant, each 500 ft. x 80 ft., where structural steel is fabricated by the most modern equipment. The plant layout is designed for efficient step-by-step processing of structural steel components. Four giant Taymar cranes, products of Dominion Structural Steel Limited, two of 15-ton capacity and two of 10-ton capacity, speed transfer of the steel units through the plant and to outside storage yards. On the second floor service area of the plant, visitors viewed modern production scheduling and payroll offices, and had a panoramic view of the work area below. A separate building is equipped for reinforcing rod fabrication.

Canadian Distributors — Julie Research Laboratories, Inc., New York, have announced that their products will be marketed exclusively in Canada by Philips Electronics Industries Ltd., 116 Vanderhoof Ave., Toronto, Ont. Julie Research Laboratories are manufacturers of precision laboratory equipment of very high accuracies, and precision encapsulated resistors to .01% over military temperature ranges.

New Nitrile-Silicone Rubber — A new kind of rubber was recently discovered by Canadian General Electric Company Limited, (research), combining oil resistance with the ability to maintain strength and usefulness at temperatures ranging from a sub-arctic 100 degrees below zero (F.) to the 500-plus degrees required for modern jet aircraft. Nitrile silicone rubber was described as "a major advance in chemistry that will offer industry — particularly the automotive and aircraft industries a unique combination of important properties never before available in a single material". The announcement was made by Dr. G. Suits and Dr. E. Reed. They described how basic research in chemistry performed at the General Electric Research Laboratory in Schenectady has been developed into an industrial process at the silicone plant in Waterford, N.Y. At a recent demonstration, representatives of the press saw samples of nitrile silicone rubber remain calmly impervious when immersed in hot jet fuels that caused ordinary rubber materials to writhe, curl, and swell into ugly shapes much larger than their original size.

Atlas Copco Contract — Atlas Copco Canada Ltd., Montreal, has recently announced that it has been awarded a contract to supply all the air compressors, rock drills and other pneumatic equipment which will be used in driving the Italian side of a major highway tunnel linking Italy and France through the 15,771-foot-high Mont Blanc in the Alps. This new project is regarded as one of the construction industry's greatest challenges and has been in the planning stage for years. Running approximately 7½ miles through Mont Blanc, the tunnel is scheduled for completion in 1961 at a total cost of about $16,200,000. The 29½-foot-tall horseshoe tube will have a tunnel area of 785 sq. ft. Road width will be about 23 feet. The supply contract was signed by Atlas Copco Italia S. p. A. with Societie Italiana per Condotte Dacqua, the civil engineering firm responsible for driving the Italian section of the new tunnel.

Hydro-Electric Generating Station — The Shawinigan Water and Power Company's new Beaumont hydro-electric generating station has recently been inaugurated at a ceremony at the site. The new plant, Shawinigan's seventh development on the St. Maurice river, is located approximately 10 miles north of La Tuque. When all six of Beaumont's generating units are in operation next year, the plant will have an installed capacity of 246,200 kilowatts, increasing the total capacity of the Shawinigan system to more than 1,500,000 kilowatts. The Beaumont plant was designed and built by The Shawinigan Engineering Company Limited, wholly-owned subsidiary of Shawinigan Water and Power.

Peacock Brothers Expansion — Construction of an extension to Peacock Brothers Limited's Highlands Works plant in LaSalle, Que., has recently been started. Completion is scheduled for mid-summer of 1959. This extension will actually be five times the size of the existing plant, bringing the total area to about 70,000 sq. ft., and will allow Peacock Brothers to consolidate and expand the manufacture of their Rockwell-Nordstrom lubricated plug valves in one location. These valves are now produced both at Highland and at the company's main plant, also in LaSalle. The move will, at the same time, enable the company to devote the manufacturing facilities of the main plant to the production of their other lines of engineering and industrial equipment. The new building will comprise three bays of steel frame construction. The walls will consist of masonry, continuous aluminum sash and corrugated asbestos siding. Care has been given to the general appearance and the building has been designed so that it will not clash with the adjoining residential area.

New Location — The Northern Electric Company Limited, Montreal, have recently announced the head office of the company will be located in The Northern Building, 1600 Dorchester Street West, Montreal.

Change of Address — Brunner & Lay (Canada) Ltd. have recently announced their new address at 2280 - 43rd Ave., Lachine, Que.

Public Works Contracts Awarded — Contracts involving expenditures totalling $7,253,452.56 were awarded by the Federal Department of Public Works during the month of February, 1958. The amount for new works in building construction and harbours and rivers engineering was $6,753,397.56; for the repair and maintenance of existing structures $25,055.00; and for the extension of the Mackenzie Highway $475,000.00.

Contract awards and tender calls issued during April involved a total estimated expenditure of approximately $52,075,000. Projects were being pressed forward by the Department in practically every part of the country. At St. John's, Nfld., for instance, consulting engineers engaged by the Department had undertaken surveys and the practical work of preparing contract plans and specifications for an estimated $12,000,000 harbour development to be completed over the next two or three years.

During the month of May, 1958, expenditures totalling $9,104,953.52 were awarded in contracts by the Department. The amount of new works in building construction and harbours and rivers engineering was $3,532,887.05; for repair and maintenance of existing structures $468,851.47; for the extension of highways $3,075,422.00; and for dredging $2,027,793.00.

During June, 1958, the Public Works Department awarded $12,211,291.98 in contracts. The amount for new works in building construction and harbours and rivers engineering was $10,238,097.02; for the repair and maintenance of existing structures $853,718.50; for bridge and highway construction $682,658.96; and for dredging $436,817.50.

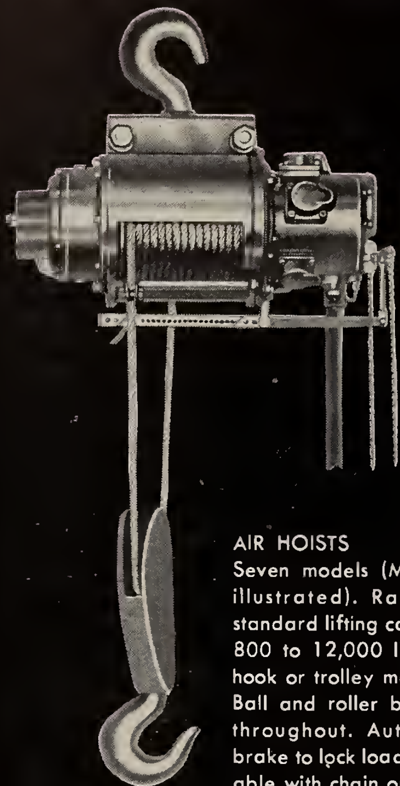
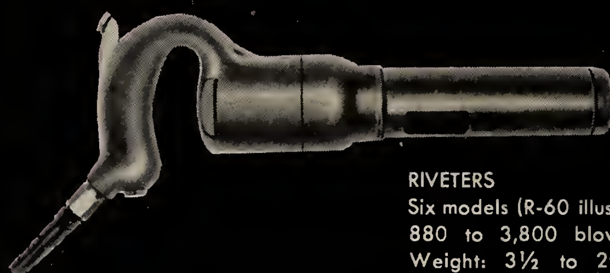
Air Tools proved most efficient and economical in FORD Study

In a Study of High Frequency Electric Versus Air Tools by the American Ford Motor Company, air tools proved to be "...most efficient and economical on an overall basis..." Actual use demonstrated that there is practically no limit to the adaptability of air tools. Averaging 50% lighter and being much cooler in operation than similar electrical tools, they increased operator efficiency. The Ford Study also revealed that an average ratio of 7 out of 10 operators questioned *preferred* to use air tools.



AIR HOISTS
Seven models (MLT-51K illustrated). Range of standard lifting capacity: 800 to 12,000 lbs. with hook or trolley mounting. Ball and roller bearings throughout. Automatic brake to lock load. Available with chain or cable.

STRAIGHT GRINDERS
Fifteen models (LSR-11 illustrated). Range: 2,600 to 65,000 r.p.m. Weight: 1¼ to 16¾ lbs. Designed for use with all types of wheels, mounted points and rotary files. Frictionless governor positively prevents overspeeding.



RIVETERS
Six models (R-60 illustrated). Range: 880 to 3,800 blows per minute. Weight: 3½ to 29½ lbs. Rivet Capacity: ⅛" to 1½". Lower weight and air consumption. Finer control with spring loaded poppet-type throttle valves.

Atlas Copco Air Tools, being basically simpler in design, have established a world-wide reputation for efficiency and economy in every type of application. Maintenance costs are reduced because there are fewer replacement parts. Working parts are made from special Swedish alloy steels, precision finished to the finest tolerances. Atlas Copco maintains prompt service across Canada.

Write for further information.

METAL DRILLS
Model LBB-41 illustrated. High capacity—no load speed approximately 1,300 r.p.m. Low air consumption. Light weight (8 lbs) Increased strength, less friction and wear due to the use of simple spur-gearing running in ball bearings.

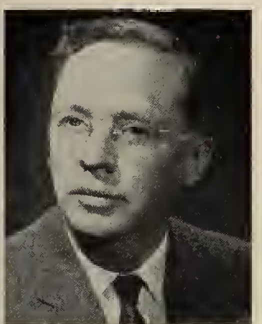
MEET THE AUTHORS

Hugh G. Conn, M.E.I.C., Dean, faculty of applied science, and Head, department of mechanical engineering, Queen's Uni-



versity, Kingston, Ont. *(Engineering Education in Canada).*

With a background of service in industry and the army, H. G. Conn was educated at Queen's University from which he graduated with a B.Sc. degree in mechanical engineering in 1931.

In 1932 he joined the firm of Procter and Gamble Company Limited, at Hamilton, returning to Queen's University as a lecturer in the mechanical engineering department in 1937.

Dean Conn served with the Royal Canadian Electrical and Mechanical Engineers from 1939 until the end of the war, returning to Canada in 1945.

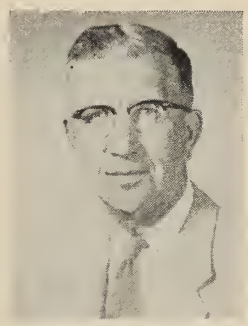
He completed work for an M.S. degree at the University of Michigan in 1946. That fall he was appointed head of the department of mechanical engineering at Queen's; he became dean of the faculty of applied science in 1955.

He was elected vice-president of Zone B of the Engineering Institute, representing the Province of Ontario in 1958, following service as a councillor, Kingston Branch, E.I.C., 1955.

He is chairman of the Canadition Advisory Committee of the Institution of Mechanical Engineers (London).

H. C. Gunning, M.E.I.C., Consulting Geologist, Anglo-American Corporation of South Africa, Salisbury, Rhodesia. *(Trends in Engineering Education).*

Dean Gunning graduated from the University of British Columbia in 1923 with a B.A.Sc. degree in geological



engineering. Later, he attended the Massachussettes Institute of Technology, obtaining a S.M. degree in 1926, and a Ph.D. in mining geology in 1929.

He was associated with Geological Survey of Canada as geologist from 1928 to 1939. That same year he joined the staff of the University of British Columbia as professor, department of geology and geography. Named department head in 1949, he was appointed dean of the faculty of applied science in 1953.

Apart from his contribution to the field of education, he has been active as a consulting geologist for various mining companies. Among them are the International Pacific Sockeye Salmon Commission, and Mannix Co. Ltd.

He is a Fellow of the Geological Society of America and of the Royal Society of Canada. He was a member of the National Committee on the Removal of Ripple Rock, and the National Advisory Committee on Research of Geological Sciences.

R. E. Chamberlain, M.E.I.C., Project Engineer, Dominion Bridge Company Limited, Montreal. *(Modification of the Jacques Cartier Bridge for the St. Lawrence Seaway).*

Educated in Montreal, he graduated from McGill University in 1951 with a B.Eng. degree. After further studies at the University of Birmingham, England, he obtained a Ph.D. in 1953. On returning to Canada, he joined the staff of Dominion Bridge Company. He had

worked for the organization as a student, during summer months. In 1954-1955 he was engaged on the Jacques Cartier Bridge project under the direction of the late Dr. P. L. Pratley, Montreal consulting engineer.

Since 1956 he has been at work on the project for Dominion Bridge.

COVER PICTURE

Practical training is one of the most important elements in preparing technical specialists in Canada. The importance of higher education in a young and progressive country such as ours cannot be overrated and it is through such education that great strides will be made toward scientific, technical and cultural progress for the benefit of all Canadians.

Our cover picture shows students at work in the Chemistry Laboratory at the University of Toronto.

M. M. Dillon & Co. Ltd.
London, Ont.
Type of Structure :
Office Building
General Contractor :
Pigott Construction Co. Ltd.
Hamilton, Ontario
Number of Caissons :
180
Working Loads :
90 tons

TYPICAL BORING LOG

The Problem

While the original intention was to construct this building upon spread footings, excavation revealed a water problem more serious than was expected, together with a much lower safe bearing capacity than soil tests had indicated.

A tight construction schedule was endangered.

The Solution

The decision was made to use 180 Standard Franki caissons loaded up to 90 tons each. They were to transmit the building loads through the troublesome silt layers to a strong sand stratum at 23′ depth.

The Results

Within one week of this decision, two modern, hydraulically operated Franki caisson-driving rigs were on the site and erected — even before excavation was completed.

Within less than 4 weeks of the decision to use Franki, and after only 12 driving days, the caisson work was completed.

A positive, sound foundation. Minimum dislocation of the construction schedule.

FOREWORD

ENGINEERING EDUCATION

WE ARE NOW WITNESSING in Canada a period of rapid growth in the field of engineering education, and particularly a growth in the number of engineering colleges which teach engineering. I am pleased to see these new colleges begin this work. It is only the arrival of these schools which will arrest the growth of the older teaching institutions, some of which are admittedly already too large for the good of their students.

One wonders whether engineering students in Canada receive the real benefits of a university education. In a recent visit to the U.S.S.R., when I had an opportunity to take a quick look at their engineering schools, the thing that struck me first was the fact that their institutes of engineering are separate autonomous colleges, operating under the Ministry of Higher Education and are not physically located near nor academically attached to the universities.

It seems to me that Canadian universities will have to make a very deliberate effort if they are to prevent their faculties of engineering operating in such a fashion that the engineering student will derive no benefit from the other faculties on the campus.

The hazard is a multiple one. Curricula can come too completely under the control of the enthusiastic engineering teachers. The students can sit in classes only with other engineering students. Unless dormitory accommodation on a university wide basis is provided the engineering student can live only with other engineering students and miss one of the most enriching experiences of a lifetime.

It is difficult to change customs which have become firmly established. Newer institutions should be vigilant in watching over and shaping the pattern of their growth. In this way they stand a good chance of producing not just embryo engineers but university graduates with an engineering education.

It has always alarmed me a bit that young men seeking a university education should be so sensitive to job opportunities of the moment, and so unaware of the possibility of getting an education which will last them the whole of their working lives. The comparatively rapid swing of enrollment from one course to another and the quick rise and fall in engineering enrollment with economic changes are evidence of this.

This is something which all engineering counsellors can keep in mind. Whether anything can also be done about it in the offices of university registrars and directors of admissions one does not know. There is a limit to which responsible adults can go in trying to guide young people.

PRESIDENT
The Engineering Institute of Canada

ENGINEERING EDUCATION IN CANADA

H. G. Conn, M.E.I.C.

MOST professional schools in Canada, including the engineering schools, have developed as a Faculty affiliated with a well-established Liberal Arts College or university, whose prime function is to "educate" or to create an atmosphere where true learning is made somewhat less difficult. Thus it is natural, that as the professional schools began to grow, they set themselves high standards of education, as well as of training. This was undoubtedly influenced by the fact that in any engineering course a considerable part of the teaching in the early years is by professors in the sciences, familiar with high quality research and with the teaching of basic fundamentals. Since the engineer must first be a useful citizen, it is essential that he have as liberal an education as possible, consistent with the technical requirements of his profession.

How do we attempt to do this?

It is fortunate that in Canada we have a fairly uniform primary and secondary school education system, administered by the provincial governments. Each university requires that a candidate pass the provincial examinations in mathematics, physics, chemistry, a language, and an option, with some minimum standing, the minimum varying with each university. Some universities, which receive their major financial support from provincial funds, are obliged to accept all candidates who meet their minimum requirements, while other schools supported by private funds may restrict enrolment at their own discretion.

In Canada there is a continual turmoil over the apparently ever-changing quality of the students coming to university. There are those who are convinced beyond any shadow of a doubt, that the oncoming generation is the poorest trained lot to date and that they are getting worse. When one realizes that more and more is being crammed into curricula, and more and more is expected of the student, and in spite of this the failure rate is not increasing, it is difficult to justify the statement that the students are not as well prepared for university life today as they were many years ago.

This defence of the high school graduate must not be a substitute for a determined effort to choose more wisely those to be admitted. If restricted enrolment is inevitable, the restriction should be because of a lack of people who will benefit from a university education, rather than due to a lack of space or facilities. All schools are seriously concerned with the problem of the selection of the proper candidates.

Let us assume that a boy has set his heart on engineering, has done well on the required high school examinations and has been fortunate enough to be selected as a candidate at a university. One of his first problems will be that of financing. If the boy will be livng away from home, and by far the majority do live away from home, he must figure on $1200-$1500 per year to cover fees, board and room, and general expenses. During the three summers he can save a clear $300-$700 per summer or even more, depending on the particular job and its location, with respect to sources of spending. Some boys who spend their summers in remote places do very well financially.

Most engineering schools have a very liberal scholarship program for the top students. Other students may be helped by bursuries. There are, however, many students who are not brilliant enough to win scholarships and whose parents are not poor enough to entitle them to bursuries, who must fend for themselves. Some loan funds are available for students who find themselves embarassed by an unforeseen need for funds. The loans normally allowed are not large and preference is given to students in the upper years, who have established some confidence that they will graduate.

The school term in Canada is fairly uniform at approximately seven and one half months at school and four and one half months at work. The cooperative program has just recently been started in one of our schools, but it is too early to comment on it.

As one studies the various curricula across Canada a pattern quickly appears. The first year, although not always common to all branches is weighted heavily with mathematics, physics and chemistry. In addition some professional subjects are included, such as surveying, drawing, etc. Almost all schools attempt in various ways to include as much of the humanities as time will permit. Much of the academic work in the first year is a continuation of the work of the high school, but the student is introduced to the wonders, newness and challenge of calculus, dances, freedom of study habits, football, new concepts in physics and chemistry, a rather rigourous social life, and last, and far from least, the panic, despair, and elation associated with writing examinations and watching for the results.

1957	219	508	409	375	57	59	43	90	97	1,853

**The Engineering Journal* (Revised 31 Dec., 1957).

When examinations are through and all the sums have been made, a very consistent 20% to 25% of the first year have dropped by the wayside. Some of these will return and finally graduate, while others will find use for their talents in other fields.

The second year is a particularly dangerous year. The 75% who have passed their year are now confident that they have the ability to succeed, some without too much effort, and settle back to obtain a well-rounded "education" of which their academic work assumes too small a portion. Their degree is still three years in the future, some of their enthusiasm has waned and temptations are many. The work in the second year is heavy and the professors grind on relentlessly. The result is that another 20% to 25% drop by the wayside, as a result of what is called the "sophomore complex" or the "second year slump". The work of this year is also concentrated on fundamentals, mathematics, physics, chemistry, and some more of the humanities.

In the third and fourth years the students come to grips with their professional courses, their interest rises, the poorer students have been eliminated, and convocation day is now on the horizon. The result is a raising of spirits and a lowering of failure rates.

In preparing the work to be covered in a four year engineering course, some schools lean toward the scientifically oriented curriculum, intent on producing only high quality scientific engineers, leaving to others to deal with what has been established as a "traditional" engineer, a good balance of "know how" and "know why".

Other schools set their sights to help the good solid practicing type of engineer, knowing that a world full of thinkers only would result in a dull and unprogressive state of affairs.

But most schools steer a wobbly path between these two, veering one way and then the other, depending upon economic conditions, the influence of industry, the alumni, and the personnel of a teaching staff. The oscillations of expressed objectives seem to be timed to the frequency at which Sputniks are sent careening into space.

In the minds of some there is a lack of appreciation of the fact that to be a good doer you must also be a good thinker, and that there is not a fine line separating these two species.

The difference between the products of these two schools is frequently much more imaginary than real, the difference existing more in the minds and ambitions of the respective staffs, than in fact.

There is, however, a general drift toward the scientifically oriented curriculum.

I suppose it is as true in other countries as it is in Canada, that in a few years a large wave of people of university age will be upon us. Even with no increase in the percentage seeking admission to universities, and with no increase in the percentage of these who will be wishing to study engineering, facilities and staff will be inadequate to meet the problem. Most engineering schools in Canada have plans for the doubling of space by 1965. We have heard much about the spending of many millions of dollars on buildings and equipment but have heard very little about the spending of even small portions of this amount *now* for the provision of the necessary staff. There are very few serious space problems that a few million dollars cannot solve. Buildings can be built and equipped well within a two year period. The solution of staff problems is not so easy. It is not sufficient to "buy" a technically competent engineer from industry. He must first have a desire to teach and not merely to circulate in an academic atmosphere associating with and showing an interest in, only those who are equally qualified. He must have a longing to discover new things through research and to talk about his work with the students. If he lives his subject the students cannot help but learn since there is nothing more contagious than enthusiasm.

Buildings and equipment are usually at their best the first day they are used. Not so with staff. A certain aging process is required before a teacher is effective. If the staff of 1965 is to be a mature one, the aging process must start now.

Not only are buildings and equipment over-crowded, but curricula are also feeling the effect of having more

and more added. The reasons for a crowded curriculum are obvious. With tremendous strides in scientific development and the associated responsibility that new discoveries be used for and not against mankind, it is natural that more and more must be placed before the student. The only difficulty in adding some new topic to a curriculum comes when you must say what shall be eliminated. Most schools now work on a thirty to thirty-five contact hour per week basis. If you add twenty-five to thirty study hours per week to this the week is as full of formal education as is wise.

One answer to the crowded curriculum is a five year program. There is some feeling in Canada that the five year program must come, but as yet the feeling has not gathered enough momentum to make a move in this direction a practical one. When such a move is made it must be made by all schools and the objective must be clearly stated, either to allow for the introduction of more material into the course or to cling to the teaching of the existing fundamentals but use the additional time to study these fundamentals more thoroughly. The success of a scientific engineer after graduation is more closely related to the thoroughness of his understanding of the basic fundamentals than his knowledge of facts. The practicing engineer must also have available many facts as well as being able to apply the fundamentals. However, the facts can be gathered more effectively after graduation on the job where they have more meaning and where there is some justification for trying to remember them.

And now a word about the role that research plays in Engineering Education in Canada. It is a generally accepted fact that salaries in industry exceed those at a university. While the difference was rather pronounced in the past, there has been a gradual improvement in the situation. One must look at the overall picture to discover the compensations that make it possible to attract and to hold able staff. One of the significant features of work at a university is the freedom to seek a path of one's own choosing and to follow it, or any of the side-roads that may develop, with no justification required, other than that something new is learned and that constructive thought is stimulated. Thus it is only natural that many engineering professors become engaged in what is called research or development. This is no place to argue about the differences between fundamental research, research, development, or technical investigations. In this context I am speaking of the whole field of thought and endeavor above and beyond the details of day-to-day teaching.

While universities have made and will continue to make an important contribution as a result of their research, they cannot hope to compete with government bodies, or the research divisions of industry, insofar as quantity of research is concerned. With limited funds and facilities what is the justification of research work being done in an engineering school?

Table IV. Estimated Number of Engineers in Canada, 1953 (including 1953 graduates)

Aeronautical	400
Agricultural	260
Chemical	3,200
Civil	8,500
Electrical	6,900
Engineering Physics (including physics)	2,400
Forest Engineering (including forestry)	1,950
Geological Engineering (including geology)	1,400
Mechanical	7,200
Metallurgical	1,100
Mining	2,800
Total	36,110

Note:—This is quite near the *best estimate* of this figure give by the Bureau of Technical Personnel as 35,738.

Source: Federal Department of Labour, Economics and Research Branch.

Most of my colleagues will agree that without this research work the staff and the work they do become stagnant and uninspiring, teaching becomes a mechanical process, creativity dies, first class students become numb, and talents are misused.

Even though the students do not take an active part in research work, they do, however, rub shoulders with the graduates and staff, who become involved with and have an enthusiastic interest in some particular investigation. Such work in a department opens doors to the more inquisitive, and attracts to further study students who would otherwise follow the path of the crowd.

I think that a critical examination of the Canadian engineering picture would reveal that there is far too little real research being carried out at the universities. This is gradually being corrected as young recent graduates find their way to positions on the staffs of engineering departments and bring with them their new Masters or Doctors degrees, and particularly their new ideas and the result of recent learning at other institutions.

The position of Junior Colleges or "feeder" schools has been an important one in Canada. These are schools who are in a position to give the maths, physics and chemistry, and some other subjects equivalent to the first year or two at a university, but who do not have the facilities for the professional work in the upper years. Each such school usually patterns its course after the first year or two of a particular university, so that their students may enter the upper years with as little difficulty as possible. With much overcrowding in

TRENDS IN ENGINEERING EDUCATION

H. C. Gunning, M.E.I.C.

BEFORE discussing general trends in engineering education and the relation of these to the business activities of engineers, it will be wise to recall some of the fundamental factors that influence the design of any engineering curriculum. These influences exist because we are dealing with the education of professionals who, in common with members of other learned professions, have legal rights and responsibilities that have been granted to them by the public through their elected parliamentary representatives. In Canada these rights and responsibilities are set forth in provincial "Acts Respecting the Practice of Professional Engineering" and the regulations or by-laws that accompany those acts. The acts and by-laws are administered by provincial Associations of Professional Engineers. Much of the detail of administration is performed by the councils of the associations which consist entirely of professional engineers who served voluntarily and without remuneration.

Accreditation of Engineers and Engineering Curricula

Possession of a university degree in engineering or applied science does not confer upon the holder the right to practise as a professional engineer. The power to confer that right rests in the hands of the Association. The British Columbia Act stipulates that an applicant for membership in the Association must submit satisfactory evidence that "he has graduated in applied science or engineering from an institute of learning approved by the Council *in a course approved by the Council*". Courses prescribed by a university faculty are not automatically accredited by Council. Council also has the right to demand evidence of satisfactory engineering experience and of good character and repute. In British Columbia at present the period of experience after graduation is a minimum of two years. A satisfactory "thesis" or engineering report is an additional requirement for registration. The activities of the provincial associations are coordinated by a Dominion Council on which each association has one representative.

Professional Responsibilities

The concept of a profession has been established in the public mind largely by the professions of theology, law, and medicine. These were the fields of professional study in the universities after their establishment in Western Europe early in the 12th and 13th centuries. By their competence, integrity, and service to mankind these professions won prerogatives that are the basis of all true professions as we know them today. A great American educator and scientist has phrased it as follows: "There has been no true profession that has not with dignity and authority advised and counselled the people, that has not guarded the Commonweal. For a true profession exists only as the people allow it to maintain its prerogatives by reason of confidence in its integrity and belief in its general beneficence".

Competence, integrity, and public service—these are the cornerstones of professional ethics. Public service includes protection of the public, and in particular, protection of the public in professional activities. All three attributes should be instilled in the student by any professional curriculum. But without the first, competence, no person can fulfil his professional obligations. Consequently, professional competence must be a primary goal of all professional curricula. "The most ardent advocate of a wider education would be displeased if our bridges collapsed, our electric light failed, our drinking water became polluted or our oysters became radio-active."[1]

Modern Trends in Engineering Education

The general trend in engineering education today is toward more emphasis on skill in the basic sciences —mathematics, physics and chemistry; less specialization in engineering techniques, especially those that can be acquired during professional experience; and increasing breadth of training in English, history, economics, and human relations in general. The objective is to provide a broad training in engineering and the related sciences, an acceptable minimum of specialization in any particular branch of engineering and a maximum of acquaintance with the resources of the humanities and the social sciences. It is thought that the last will benefit the student as a professional, as a citizen, and as an individual.

The attainment of these ideals is not easy, but much progress has been made in the past ten years or so. I hardly need to mention to this audience the additional demands on the curriculum that have been made by spectacular recent advances in the basic sciences of engineering. We are faced with the necessity of greatly increased instruction in nuclear physics, at the junior and senior level, and with the necessity of supplying recruits for nuclear engineering from almost all branches of engineering. Several schools have felt it necessary to establish departments of nuclear engineering at the undergraduate and post-graduate level. Organic chemistry has not been, in the past, a part of the training of engineers except those in chemical engineering. The rapid growth of industries based on synthetics has made it apparent that organic chemistry should be included in the training of other engineers who have to work in these industries or use the new materials. The application of analogue and digital computors and the expanding application of electronics and servomechanisms mean that greater facility in higher mathematics is a necessity for many engineers. The tremendous importance of geophysics in the development and exploitation of our mineral resources and in other engineering operations means either that engineering physicists and electrical engineers should have a better training in earth science or geologists and mining engineers should have more

1 R. P. Linstead; "The Future of Imperial College"; 1955.

physics and mathematics. Physical metallurgy has become in recent years almost a new discipline demanding greatly increased knowledge of metal physics and metal chemistry, of X-rays, radio-activity, and other things. A host of complex, intricate machines have, almost overnight, graduated from the research laboratories to become the ordinary tools of the engineer. The engineering curricula are being adjusted every year to include a wider range of science as well as more advanced training in several sciences. At the same time there are pressing needs for other adjustments and improvements. Many of the old requirements remain. The slide rule and the draughting board are still with us.

Administrative Obligations in Industry

I have read the suggestion, made in all seriousness, that engineers should be used only in design and research. Operations should be left to the technicians—of whom in Canada we have too few and for the training of whom our facilities are woefully inadequate. Management should be left to the non-technologist. A recent reply to this attitude is: "With a technology whose complexity is increasing at a geometrical rate, amateur judgments and cut-and-try methods, however well-intentioned, simply will not do. The skills and training of the engineer are needed just as much in the direction (management) of industry as they are in technical operations." Another article, in advocating the necessity of technologists in management and the need for considering this in their academic training, lists a few of the highly competent technologists who have been responsible for much of the spectacular industrial growth on this continent: Westinghouse and Swope in the electrical industry; Sloan and Chrysler in the automobile industry; Thomson, Dodge and Budd in the railroads. We could add many Canadians in these and other industries. Figures I have seen indicate that about 60 per cent of engineers are seriously involved in industrial or professional management fifteen years after they graduate. Therefore our basic assumption is that the curriculum must include as much as possible of the general education that is helpful and important in management. It is also assumed that if the young engineer cannot, for the first few years, make a success of the practice of his own profession, he is not likely to assume a supervisory or managerial position in technologic operations. It is to be hoped that management will see that the abilities or skills of competent engineers will not be wasted unnecessarily in the management of non-technical operations.

General Education of Engineers

The attempts to satisfy the need for general education in the engineering curriculum vary with each academic institution. I would be surprised if you found in any institution unanimity of opinion either in the engineering faculty or in the faculty of arts and science. Many institutions, including The University of British Columbia, have doubled or tripled the time devoted to general education within the past ten or fifteen years. I should say at the start that none of the programmes I have heard of include specific training for business or management as such, except in the case of a few special "hybrid" courses such as "Engineering and Business". It should also be clearly understood at this point that the dollar or the pound sterling is one of the basic factors of all engineering training; that all engineers (well, nearly all) are given courses in things like industrial engineering or engineering economics and that it is thought they are trained to be cost-conscious. It is said that the obligation of an engineer is to do things better at less cost. If this were not so, with our wage structure for labour progressing upward as it has, I suspect that there would be no profit from which to pay wages, and we should be in a very unhappy position. This kind of training is part of the orthodox curriculum and I am considering now only the new needs and the new trends.

I will consider two major approaches to the broadening of general education: one is voluntary, the other compulsory.

The first may be represented by the recent trend at Imperial College in London. It has been discussed in the inaugural address "The Future of Imperial College" by the new Rector, Dr. R. P. Linstead, and he has generously supplied me with some additional detailed information, as follows:

"Since 1952 the College hours have been adjusted on Tuesdays and Thursdays throughout the Autumn and Spring terms. This enables us to have a break of two hours at lunch-time. General Studies take place from 1:30 to 2:30 p.m. On any one day there is a choice of two or three talks. The speakers are visitors distinguished in a very wide variety of fields. The talks are informal, and it is left to the speaker to allot as much time as he likes to discussion. Attendance at the talks is voluntary, and no register is kept; the numbers attending vary a good deal, from a maximum of about 200 to a minimum of about 40 for any one talk. The speakers are unpaid, only their out-of-pocket expenses being met by the College.

"Week-end discussion groups meet twice a term. They were started in 1950 by my predecessor, who gave them the name of 'Touchstone Week-Ends'. They are held at the College Field Station at Sunninghill, Berks, some twenty miles from London. A topic is chosen for discussion, and a distinguished speaker is invited to introduce it. About thirty staff and students travel to Silwood Park on the Saturday afternoon, and are joined at Silwood by some of the staff and students who work there. After tea the guest speaker introduces his subject, and this is followed by a general discussion. After dinner the party usually splits into two or three groups to discuss questions subsidiary to the main topic. Sunday morning is free; the party reassembles after lunch, the spokesmen of the groups report their findings and the guest speaker sums up the discussion. The party returns to London in the early evening. Some recent topics were: 'The Changing Concepts of Psychological Medicine', introduced by Dr. E. B. Strauss, Physician for Psychological Medicine, St. Bartholomew's Hospital; 'Telepathy', introduced by Dr. S. G. Soal, Senior Lecturer in Mathematics at Queen Mary College; 'The Artist and the Material World', introduced by Mr. Basil Taylor, Librarian of the Royal College of Art, and well-known critic and broadcaster.

"Some titles of The General Studies addresses at the noon meetings are as follows: 'World Unity and World History', Professor Arnold Toynbee; 'Walking in the Alps' (with slides), Hubert Walker; 'The Enjoyment of Music', Antony Hopkins; 'Sources of the Russian Revolution', Professor G. H. N. Seton-Watson; 'The Impact of the Oil Industry on the Persian Gulf Shiekhdoms', Sir Rupert Hay; 'The Americans—How did they get that way', Professor Arthur Newell; 'Philosophy: (II) Existentialism—A Modern Revolt Against Science', H. J. Blackham; 'Anthropology and Problems of Industrial Organization in Western Societies (I)', J. A. Barnes."

The other approach may be illustrated by efforts that are being made in many American schools with pressure and a great deal of good work by The American Society for Engineering Education.[2] It should be noted that the minimum length of the engineering course in the United States is four years after the equivalent of a good Canadian junior matriculation whereas in Canada it is four years after senior matriculation. On the other hand, each year in the United States' colleges is a little longer than ours. Canadian students, almost without exception, gain very valuable technical experience for four months each summer.

The general A.S.E.E. programme calls for a minimum of 20 per cent of the engineering curriculum being devoted to general studies, distributed if possible more or less evenly throughout the four years. There is difference of opinion as to whether the general courses should be specially tailored for engineers or whether they should be regular courses offered by the liberal arts faculty. On the whole, the former seems to be favoured in most good schools. One of the most emphatic recommendations is that *humanistic-social studies must be distinguished from business training* and that the latter must not count as part of the general programme. The titles of some of the "tailored" courses will give you some idea of the content: History of Western Civilization; Foundations of Western Civilization; The Background of Western Civilization I, II, III, IV; Introduction to the Humanities; Economic Analysis and Contemporary Problems I and II; and Public Affairs. History, Economics, and English occupy the prominent roles but Philosophy and Psychology are admissible. It is claimed that some thirty reputable schools have proven that this kind of training can be included in the curriculum without endangering the professional competence of the students. Several have attained the 20 per cent ratio. Stanford, California Institute of Technology, Michigan State, Massachusetts Institute of Technology, North Carolina State, Case Institute, and Clarkson College are among the prominent examples.

Most Canadian universities keep in close touch with American trends and benefit by them and by the British developments. At present I judge that we, as is the case in other things, have adopted a course intermediate between the two extremes. At The University of British Columbia, nearly all engineers now take every year at least one course that qualifies as general studies in the American pattern. There is also a good deal of the voluntary approach, for which the students get no official academic credit.

I would not leave the issue without affirming that many engineering educators believe that administrative ability and business acumen are among the human qualities that can be classed as "gifts"; that for those who have the gift much can be gained by practical experience, personal and post-graduate study; and that the approach that is developed by good training in the solution of scientific and particularly of engineering problems should be very helpful to the young man who may later find himself drafted into business and administration. Many professional engineers take post-graduate courses or degrees in Commerce or Business Administration and it is important that first-class training of this kind should be available.

2 "General Education in Engineering"; The American Society for Engineering Education, 1956.

Engineering Education . . .

(Continued from page 40)

the early years the universities have been anxious to make arrangements with well-established Junior Colleges to admit students direct to the second or third year. This enabled them to offset to some extent the drop in class numbers due to normal wastage.

However, the picture is changing. As the demand by industry for engineers became more pressing and as hopes for money for the training of larger numbers of engineers became more promising, these schools developed their facilities to the point where many of them are now offering courses leading to the engineering degree. Such schools as Carleton University, McMaster University, University of Western Ontario, University of Ottawa, University of Sherbrooke, and Essex College, are at various stages of offering the degree in some branches of engineering. Those responsible for such details as finding staff have a particularly difficult piece of work ahead of them and the established schools must look forward to contributing staff if the work of the next schools is to be integrated properly with the balance of our Engineering Education system. No one likes to lose a valued staff member, but there is some consolation in having had one of your colleagues chosen to take part in the development of such an important undertaking.

Some question the wisdom of establishing new facilities at the present time, although few will argue against expanding exisiting facilities. It would be unfortunate if available teachers and money were spread unnecessarily thin in an attempt to meet a demand from industry for more engineers, unless, of course, the demand is a real one. Although no one will question that there is and always will be a need for good quality creative engineers, there is some cause to doubt that there will continue to be a need for engineers to be employed on other than engineering work, work that could be done equally well by competent technicians, *if they were available in much larger numbers than at present.* While thinking along these lines it must be recognized that many employers prefer to engage engineers on work which is not strictly engineering, but which requires an engineering or analytical approach.

Earlier I referred to there being approximately four and one-half months each summer, during which the students can earn a considerable sum of money with which to finance the next year. Most students are required to spend their summers at some work associated with their profession, in order that their school work will have more meaning, and so that they may more intelligently choose a field in which to work after graduation. It is more important that the student work in an engineering atmosphere, even though his task may be that of a labourer, than to have what appears to be a highly skilled job, but without the opportunity to look around to see what other people are doing and to talk with engineers and others about their problems.

Knowing that statistics are frequently misleading and present only a quantitative picture of the problem, I have refrained from quoting figures in this talk. There is, however, an appendix available, setting out certain data which may be compared with similar data gathered from other sources.

an artist's impression—before and after modification.

MODIFICATIONS TO THE JACQUES CARTIER BRIDGE

Ross E. Chamberlain, M.E.I.C.

THE Jacques Cartier bridge, which links the Island of Montreal with the south shore of the St. Lawrence River, consists of three main sections. The north approach passes over part of the City of Montreal and is about 1,950 ft. long. The 1,937 ft. main cantilever structure is a familiar landmark to most Canadians. It crosses the Montreal Harbour with a clearance of 155 ft. The third section of the bridge is the 4,930 ft. south approach which passes over St. Helen's Island and crosses the portion of the St. Lawrence River between that island and the south shore. Fig. 1.)

When the bridge was built, about thirty years ago, most proposals for a St. Lawrence Seaway envisioned a channel on the north side of St. Helen's Island. If this were the case, the main cantilever span would have provided ample ship clearance. The congested Montreal Harbour on the north side of St. Helen's Island, and other factors, forced the final Seaway planners to locate the channel close to the south shore. Consequently, it became necessary to alter the portion of the Jacques Cartier bridge which lies south of St. Helen's Island.

This section of the bridge consists of a series of simple deck truss spans. The trusses are 40 ft. apart and support floorbeams which rest on, and cantilever over, the top chords every 24 ft. 6 in. The concrete deck is supported on longitudinal stringers. The original roadway was 37 ft. wide and placed centrally on the bridge. On each side of the roadway was a lane to be used for tramway lines and then a 5 ft. sidewalk. In 1955 a concrete deck was placed on the downstream tramway lane making the overall width of roadway 48 ft.

The first three spans from the south shore are 122 ft. 6 in. long with trusses 13 ft. deep. Spans, 4, 5, 6 and 7 are 147 ft. long and the trusses are 25 ft. deep. All spans are completely independent except that at pier 3, span 3 rests on a post from the first bottom chord panel point of span 4, thus at this pier there is only one floorbeam and one pair of pier members.

Spans 8 and 9 are 196 ft. long with trusses 30 ft. deep, while the spans north of pier 9 are 245 ft. long and are supported by 35 ft. deep trusses. The depth changes at piers 7 and 9 are allowed for by 5 ft. high concrete pedestals on the pier tops which support the pier members of the shallower spans. The total dead weight of one span varies from 680 tons for a 122 ft. 6 in. span to 1330 tons for the 245 ft. spans; 56% of this weight was on the downstream side due to the unbalanced roadway deck. The total dead weight of

The Jacques Cartier Bridge, which crosses the St. Lawrence River at Montreal, had to be modified to give the 120 ft. vertical clearance required for the St. Lawrence Seaway. This necessitated an increase of 83 ft. in the original clearance, with a minimum of interference to the bridge traffic, and absolute safety to the public who traverse this bridge to the extent of some 35,000 vehicles per day. This paper describes the two methods used to attain these results. The roadway profile was changed by physically jacking the bridge spans and building up the piers by varying amounts to increase the clearance by 50 ft. The remaining 33 ft. was gained by replacing one of the original deck truss spans with a new through truss span.

bridge lifted totalled some 14,000 tons.

From south to north the original roadway profile was up at 3.08% until pier 7 where the grade flattened to 1.01%, which was then constant to St. Helen's Island.

As it was desirable to keep the Seaway channel close to the south shore, it was designed to pass under span 10, the first 245 ft. span. This would provide the required lateral clearance for the Seaway channel.

The St. Lawrence Seaway clearance requirement of 120 ft. above high water level meant that the clearance under span 10 had to be increased by 83 ft. This clearance increase was obtained by two methods. The roadway profile was changed by jacking to increase the span 10 clearance by 50 ft., while the remaining 33 ft. was gained by replacing the deck span by a through truss span. (Fig. 2)

Roadway Profile Changes

As the elevation of the roadway on the tenth span was to be increased by about 50 ft., and, as the final roadway elevations should be the same at piers 9 and 10, it was decided to increase the elevation at pier 9 by 50.52 ft. and at pier 10 by 48.00 ft. (Fig. 3). A line joining the centre line of pier 14 at the original elevation and pier 10 centre line at the new elevation has a grade of only 3.80%. As a result, the centre line of pier 14 was chosen as the point of intersection between the old and new profile lines. A parabolic vertical easement curve 199 ft. long, placed symmetrically about the centre line of pier 14, was introduced.

South of pier 9, a maximum grade of 4.20% was specified. This is slightly less than the grade prevailing on either side of the main cantilever span.

This necessitated raising the roadway elevation at the south abutment by 26.83 ft. Since this abutment could not sustain the pressure of added fill, the bridge was extended by a new 65 ft. girder span and a new abutment. The old abutment was altered to act as a pier while still serving to retain the original fill.

A most important requirement of this contract was that the bridge remain in use for the duration of the work with an absolute minimum of interruption of traffic. It must be appreciated that this bridge, which constitutes a vital link in Montreal's traffic arteries, carries some 35,000 vehicles each day. In the interests of safety there was no alternative to stopping traffic for occasional short periods while certain delicate operations were in progress, and while the new tenth span was moved into place. Except in the latter case, all such interruptions were confined between the hours of 1 a.m. and 5 a.m.

One of the first operations necessary to maintain traffic flow while constructing the new south abutment, constructing the 65 ft. span, increasing the height of the old abutment, and placing the fill, was the provision of suitable traffic detours. For this purpose, diversions were constructed on both sides of the main bridge at the south end.

Temporary Diversions

The layout of the detour routes was governed by the south shore fill design, the traffic flow, and the work that had to be done while the diversions were in use. (Figs. 1 and 4.)

The space between the upstream and downstream diversion roads was designed to contain the additional 26 ft. of fill with side slopes of 1½ to 1. This placed the two routes on new fill either side of the old roadway with about 160 ft. clear between them. The Bailey bridges, and the portion of the temporary fill roads approaching them, were at the same elevation as the original bridge roadway.

Fig. 2 Aerial view of the Jacques Cartier Bridge—showing some work in progress on the south shore.

Fig. 1 Before and after view of bridge over channel.

Since 1955 the Jacques Cartier Bridge traffic has been travelling over a four lane roadway. With this in mind, it was decided to use four separate Bailey bridge lanes for the diversion, two on the upstream side for southbound traffic, and two on the downstream side for northbound traffic. In spite of a speed restriction on the diversions, they did not retard traffic flow more than the normal restrictions caused by bridge entries, exits and toll collections. The general design of the diversion layout was governed by the fact that the traffic had to be returned to the main bridge route after the alterations to the south end were completed, and before the roadway elevations at the turnouts could be altered. This meant that spans 1 and 2 must be jacked so that span 1 would reach its final elevation at the old abutment.

The reasons for adoption of a temporary grade of 7.51% on spans 1 and 2, meeting a reverse grade of 4.20% at the old abutment, need some explanation. Since the north end of span 3 is supported on the south end of span 4, which prevented any appreciable rotation at this point, the choice lay between temporary Bailey bridge routes 310 ft. long from span 3, or 580 ft. long from span 5. The latter, naturally, would have resulted in more moderate grades. The facts that re-routing of traffic from the turnoffs to the original bridge would take place in summer, that the steep grade could be rapidly reduced by the jacking of spans once the turnoffs were abandoned, and the obvious economy of the shorter routes, dictated their use. This reasoning was subsequently justified by the minor inconvenience to traffic during the relatively short period during which this condition existed.

Each of the two diversions consisted of duplicate Bailey bridge spans of 80 ft. triple-single and 110 ft. triple-double construction. These were supported on steel pile foundations at the South end and elsewhere on steel bents and towers anchored to concrete piers founded on rock (Fig. 5). All spans were designed to carry H20-S16 loading and provision was made for differential movements due to temperature between the bridge spans and the diversion structures. Generous turnoff curves from the bridge proper were established. Prominent warning signs, illuminated by night, were placed at intervals of 700 ft. and 100 ft. from the southbound turnoff.

The responsibility for maintenance of the steelwork and roadway was that of the Contractor, while policing, snow removal, and sanding was the responsibility of the National Harbours Board, who operate the bridge on behalf of the Dominion Government.

Southbound traffic was first switched to the southbound turnoff, after which the main bridge roadway was temporarily reduced to three lanes while the precast slabs of the recently added downstream lane were removed to allow completion of the northbound turnoff. During the seven months, from January to August 1957, that these diversions were in operation, when some 7,000,000 vehicles were handled, not one accident of a serious nature occurred. This speaks well for the planning of the engineer and cooperation of the National Harbours Board and the contractor in carrying out this phase of the work.

New and Old Abutments and 65 ft. Span

The new abutment, 68 ft. south of the old abutment, is the concrete gravity type. It retains fill which is 26 ft. higher than the old roadway, with a backwall 77 ft. wide. The wing walls are parallel to the bridge centre line and are about 40 ft. long. The abutment is supported on a spread footing on the old fill about 5 ft. below the original surface (Fig. 6).

The old abutment backwall was increased in height by 20 ft. 8⅞ in. to become the northern bridge seat for the 65 ft. span. This wall increase was 4 ft. thick and 77 ft. long. This new wall was dowelled to the old backwall with ⅞ in. diameter rods at 2 ft. centres 4 in. inside the north and south faces of the wall.

The original abutment bridge seat was 47 ft. wide and extended 4 ft. 4 in. out from the backwall face. As stage one jacking progressed, two pilasters were constructed to include the jacking blocks. They are anchored to the abutment backwall face with dowels and are 4 ft. 4 in. thick. Each pilaster is 12 ft. wide and they are placed 23 ft. apart between inner faces.

The 65 ft. deck plate girder span consists of eleven 5 ft. ½ in. deep riveted plate girders. These girders are tied together with top and bottom lateral angle bracing. Shims are placed between the shoe plates and girders in varying thicknesses to give the roadway crown of 2 in. The roadway is 60 ft. 2¼ in. wide and consists of an 8½ in. reinforced concrete slab. There is a 5 ft. sidewalk on each side of the roadway.

After the two abutments were completed, the 65 ft. span erected, and stage one jacking completed, the fill behind the new abutment was placed. On this fill, an exit route and an entrance route were paved up to the new abutment. In early August 1957, northbound traffic was again routed over the main bridge. While southbound traffic was still being diverted, the northbound turnoff was disconnected from span 3 and the bridge restored to its full four lane width by replacement of precast slabs. Southbound traffic was then routed over the bridge proper. At this time all traffic was moving over an unfavourable grade condition. Moving to the north, the profile was up at 4.20% over the fill and 65 ft. span, then with practically no easement, it turned down at 7.5% over the first two spans, then up again at the original 3.08% grade over pier 2.

As soon as possible, the upstream turnoff connection to span 3 was removed to free the span for jacking. Jacking then started immediately on piers 1, 2 and 3. Four weeks after the traffic was back on the main bridge, pier 2 had been increased in height by 7 ft. 8 in. and piers 1 and 3 about 4 ft. This relieved the unfavourable grade condition to the extent that the grades were now plus 4.20%, minus 4.4%, and plus 0.3% respectively.

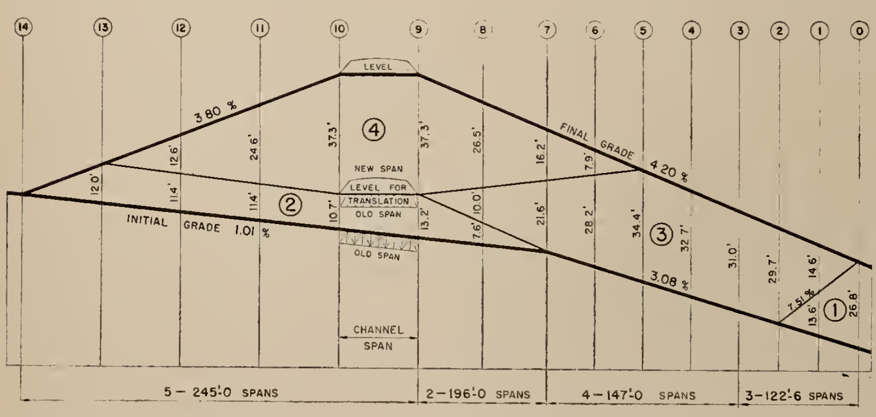
Jacking

The physical jacking of the bridge was divided into four main stages, as shown by Fig. 3. Stage one, as described before, was completed while traffic was on the temporary diversions. This stage consisted of jacking on abutment 0 and pier 1 only, and rotating about pier 2. The roadway at abutment 0 was lifted by 26.83 ft. to final elevation while pier 1 was lifted by 13.6 ft.

The second jacking stage was completed while the new span 10 was being erected. This stage was designed to bring span 10 to a level position for translation and to include enough work to keep jacking crews busy during the summer of 1957.

These four distinct jacking stages were designed so that not more than eight piers would be involved during any one stage in order to reduce the number of hydraulic jacks, pumps and hydraulic control systems needed. Confining the jacking to as few piers as possible during the winter

Fig. 3



PROFILE SHOWING FOUR MAIN JACKING STAGES months also reduced the heating problems connected with cold weather concrete pouring.

In order to discuss the jacking of thes pans, it is first necessary to describe the construction of the bridge with regard to bearings and jacking provision (Fig. 7). Each of the spans is supported by two Warren trusses at 40 ft. centres. The trusses rest on cast steel pier members at each end. These are either fixed bearings or contain expansion rollers. The top surface of each pier member is a convex spherical surface of 3 ft. radius, which fits into a concave surface of a dish plate riveted to the under side of the bottom chord. The positioning of the concave spherical surface on the dish plate is such that the spherical centre is vertically below the truss working point, or intersection point of the truss member centre lines. In this position the thrust from the pier member passes through the working point. This theoretical position will obviously change with variations in the roadway grade.

At each end of each span a heavy plate girder, known as a jacking girder, spans the 40 ft. between the truss end posts. The web of each girder is perpendicular to the truss chords. The jacking girder is stiffened and a bearing plate is riveted on the bottom flange 4 ft. inside the truss centre line. This serves as the jacking point.

The jacking girders were designed to support the dead load of the original bridge, with a three lane concrete roadway, allowing the usual 50% overstress for jacking. The roadway widening lane on the downstream side increased the dead load by 22% which necessitated the reinforcement of the jacking girders. It was not practical to reinforce for the added dead load plus live load at normal unit stresses. For this reason, traffic had to be stopped briefly during the night for these operations while the load was supported by jacks under jacking girders.

Heavy platforms were built around the circumference of each pier. These were suspended by wire rope from the bridge structure so that they would move up with the jacking. The height of the platform floor was adjusted to suit both concrete forming and jacking operations. A catwalk was constructed on the bottom lateral bracing for the full length of the working area to give access to each pier.

Fig. 4 Aerial view of Bailey bridges, new abutment, 65-ft. span and stage one jacking.

Besides structural strength considerations, one of the biggest problems during the jacking programme was geometrical control and planning for each lift. The basic lift was a height increase of 6 in. on all the jacks on one pier. To maintain roadway continuity, both spans resting on any one pier had to be lifted simultaneously. For stability reasons, a span could not be jacked at both ends at the same time. During a lift at one end of a span, the span rotated about the centre of the bearing sphere at the far end. In these deck spans, the height of roadway surface above the centre of rotation varies from 19% to 25% of the span length. For this reason, a 6 in. vertical lift at one end of a span moved the roadway deck longitudinally by about 1¼ in. The roadway expansion gap above the pier where jacking occurred opened by about 2½ in. while the gaps over the adjacent piers closed by about 1¼ in.

The theoretical roadway gaps on this section of the Jacques Cartier Bridge vary from 2¼ to 3¼ in. but over the years these roadway gaps have drastically reduced due to concrete slab elongation. In order to restore the total summation of gaps to the original figure, a total of 18 ins. of roadway had to be removed. This was done by cutting the deck slabs and roadway stringer extensions over several piers. To gain additional roadway clearance in certain regions while jacking, 1 ft. 2 in. of roadway was removed over pier 2 and replaced later. At pier 14, 1 ft. 5 in. of roadway was removed permanently during the easement construction so that the large rotation of span 14 could be made without risking a poor position of the span 14 pier members on pier 14. The length of the new span 10 was made to suit these various changes and the new length of roadway profile.

As the roadway gaps were opened by cutting, or as they varied by jacking rotations, traffic was carried on steel plates over the gaps or on timber fillers. These fillers consisted of 14 by 14 timbers spanning from the end floorbeam of one span to the end floorbeam of the other. Above these timbers were laid transverse 4 x 14's on edge filling the gap.

Each span lift of 6 in. was carefully planned in a particular order. This order was designed to prevent jamming of the spans at the roadway gaps, to reduce the number of longitudinal shifts of spans for geometrical changes, to give the most economical cycle of jacking, concrete pouring, and concrete curing, and to maintain good profile grades. The theoretical position of each span, both horizontally and vertically, was calculated for each jacking cycle. These geometrical calculations generally gave positions which were very close to those found in practice. In a few cases, however, the longitudinal position of a span did not conform to calculations. In such cases, the positions were surveyed and a new set of geometry was calculated for further operations from this base geometry. In cases where the jacking cycles could not be made to avoid jamming of the spans a longitudinal shift of a span was called for. The fixed end bearings were placed on a nest of cold rolled steel rollers between steel plates and the span moved longitudinally by hydraulic jacks. Where geometry calculations showed positions where the pier member thrust shifted too far away from the truss working point, the dish plates were changed. The moment of pier member reaction multiplied by the truss working point offset, after some rotation around the spherical bearing, was distributed to the truss bottom chord, end diagonal, and end vertical, in proportion to their rigidities. The secondary stress caused by this moment was allowed to reach 30% of the allowable before changing dish plates.

In the final position, each bearing point had new dish plates fitted to suit the theoretical permanent case. The dish and disc assemblies over pier 3 between span 3 and span 4 could not be removed as there is no jacking girder on the north end of span 3. As a result, the end posts and end diagonals of span 3 at pier 3 were reinforced.

As previously explained, the jacking cycles at pier 3 had to be such that spans 3 and 4 were kept very nearly in a straight line. The last panel of stringers for both spans rest on a common floorbeam. If the spans were too low at pier 3, the stringer ends would jam, while if too high, the sliding stringers would move off the floorbeam.

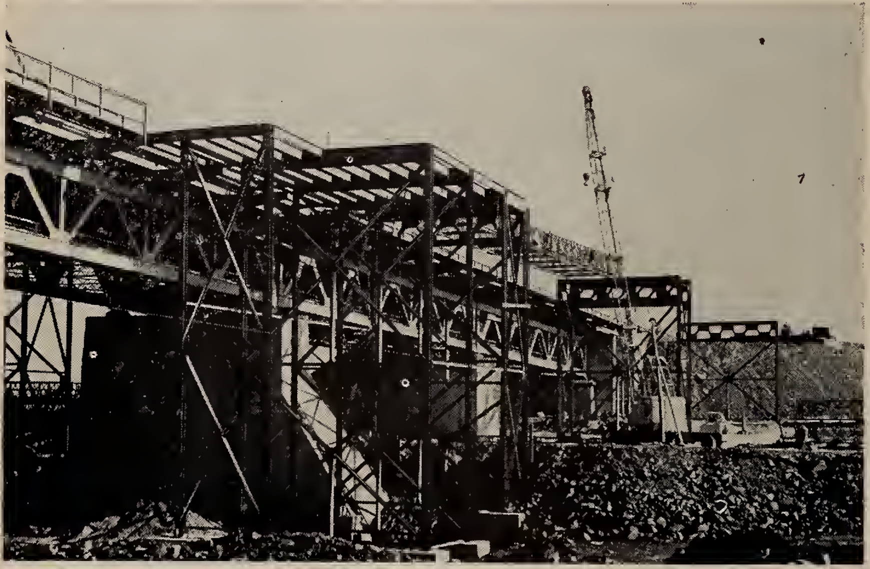
The jacking problem was somewhat complicated by the fact that the Bell Telephone Co. of Canada, and the Quebec Hydro-Electric Commission both have cable ducts on the bridge located just below the deck slab. Longitudinal geometry changes due to jacking necessitated continual moving and adjusting of the cables. Both organizations had men on hand throughout the jacking operations. As the 120,000-volt gas-filled electrical cables are very delicate, a catwalk was provided for the full length of the job beside the Quebec Hydro duct, giving access to every foot of cable. Both sets of cables come on the bridge from the ground at pier 1. Cable slack was stored at pier 1 to accommodate the additional height of the pier and the additional length of the new profile. Some of this slack was moved along the bridge as necessary.

The main jacking was done by using "climbing jacks" as shown in Fig. 8. These climbing jacks, 4 ft. 7½ in. high, replaced the pier members, which were about 2 ft. high, and it was therefore necessary to raise each span before they could be installed.

The preliminary jacking was done by lifting the spans with low height jacks under the jacking girders (Fig. 9). Usually two low-height jacks of about 200-ton capacity each were used under each jacking point. With various bridge grades the jack thrust must pass into the jacking girder in the plane of its web. The jacks were therefore set on two circular bevel plates and by rotating one bevel plate relative to the other, the grade of jack base could be adjusted to that of the span to be jacked. This method of jacking resulted in a slight horizontal thrust on the span. If the far end of a span being lifted was the expansion end, the longtitudinal movement was prevented by blocking and tying to the next span.

To avoid inconvenience to the travelling public, all preliminary jacking was done between 1 a.m. and 5 a.m. on Tuesdays to Fridays inclusive. During these hours traffic was stopped and the ends of the two spans on a particular pier, with all four pier members attached, were lifted. Aluminum shims, on account of their lightness, were used to follow up the span under the pier members. After about 10 minutes of jacking had elapsed, the spans were landed on the shims and traffic was allowed to resume. This process was repeated until the pile of ¾ in. aluminum shims could be replaced by a layer of 6 in. precast concrete blocks.

Fig. 5 Supporting steel for Bailey bridges and turnoff.



For the latter stages of the preliminary jacking, special hydraulic equipment which also formed the power portion of the climbing jacks was utilized. When the spans over a pier had been lifted high enough to receive a climbing jack, traffic was stopped between the hours of 1 a.m. and 4 a.m. The spans were then raised on the jacking girders by the special jacks and the retaining nuts locked. Pier members and supporting concrete blocks were then completely removed and the 4 ft. 7 in. high climbing jacks were put in their place (Fig. 10).

The heavy hydraulic equipment consisted of eighteen 500-long-ton jacks, twelve 400 long ton jacks, eight 4-cylinder electrically-powered pumping units, and sixteen hydraulic panels, each to control two jacks. The 500 ton jacks are 3 ft. 2½ in. long when closed and 22½ in. diameter, while the 400 ton jacks measure 3 ft. 1 in. by 20 in. They are double acting, that is, the rams are retractable under power. The rams are threaded for a retaining nut, designed to support the load when locked in any position. The jacks have an 8 in. stroke and operate under a hydraulic pressure of 5,600 p.s.i.

The pumping unit is designed with four cylinders on a single shaft driven by a 6 h.p. electric motor. Each of the four cylinders powered one of the four jacks on a pier. Thus with constant displacement, regardless of load, all four jacks on the pier raised at very closely the same speed.

The control panels provided each jack with a complete set of independent controls and relief valves. Oil from the pump passed through the panels on its way to and from the jacks. A control valve for each jack could be set in any one of four positions. The load could be held in any position with the oil returning to the pump sump. The load could be raised or lowered under control, or the jack could be put into a powered fleet to retract the ram. It was impossible to put the control lever to "Fast Return" while the jack was carrying load. Each jack was protected by relief valves for both main ram and annulus pressures, and the main ram pressure could be read at any time. The main ram line could be throttled for setting relief valves. A metering valve was in the circuit to control the speed of lowering under load, while a reflux valve prevented the ram falling by its own weight.

The "climbing jack" Fig. 8) consisted essentially of two parts, a heavy steel weldment, and a hydraulic jack with a steel base plate on its ram. The steel weldments were 4 ft. 7½ in. high, 5 ft. 5 in. long, in a direction perpendicular to the bridge axis, and 2 ft. 7 in. long in a direction parallel to the bridge axis. Each consisted of two side plates cut in the shape of an inverted U. These side plates were spaced 22¾ in. apart inside and were in a plane perpendicular to the bridge axis. On top of these two plates was a horizontal cap plate which supported the bridge bearing. On the bottom of the side plate legs were two horizontal bearing plates 16 in. wide by 2 ft. 7 in. long with a 2 ft. 9 in. space between them. Between the two side plates and perpendicular to them were two diaphragm plates 22¾ in. wide. These diaphragm plates ran from the centre of each base plate to points 22¾ in. apart on the underside of the cap plate.

The bridge bearing consisted of 6 in. diameter half round on the cap plate with its axis horizontal and perpendicular to the bridge axis. A special bearing plate rested on the half round. This plate had a 6 in. diameter cylindrical concavity in its underside and a 3 ft. radius spherical surface on top. The spherical surface matched the spherical cut of the bridge dish plate and allowed small lateral rotations for bearing adjustment. The 6 in. diameter bearing allowed very free rotation with the jacking and thus reduced the friction moments on the pile of concrete jacking blocks.

The space between the two diaphragms and side plates contained the cylinder of a hydraulic jack with its ram downwards. The base plate on the jack ram was 2 ft. 2 in. wide and 2 ft. 7 in. long and fitted between the two base plates on the weldment. When the jack was fully closed, its foot was 1 in. above the two weldment feet. By adjusting filler plates, every climbing jack weldment could accommodate either size of hydraulic jack. While in operation the hydraulic jack was firmly held in the weldment. The space inside the U shape of the side plates was such that when the outer feet were on 12 in. of blocking, the hydraulic jacks could be lowered by 12 in. and removed. Fifty climbing jack frames were made and placed under the structure at all points to be jacked while the thirty hydraulic jacks were moved from pier to pier for the four jacking stages.

Fig. 6 South bound Bailey bridge route, 65-ft. span and addition to old abutment.

As the climbing jack weldments actually became the bridge pier members for the length of the job, some were constructed with sliding Lubrite plates and used as expansion pier members. The sliding feet were made so that by tightening a screw at either end of the foot, the bearing could be locked in any position.

A stability strut connected each of the weldment feet to the bottom chord of the span at the first panel point. These were designed to stabilize the climbing jack in the longitudinal direction for expansion, contraction and traction. They were telescopic and could be locked to any length to suit the span grade.

Four types of climbing jack frames were made, heavy or light, and sliding or fixed. The heavy climbing jacks were designed to support 1,200 kips and the light ones were for 800 kips. The frames were designed to support these loads assuming a simple span between the two outside block piles.

The side plates and cap plates were made of U.S. Steel Co. grade T.1. steel using a design stress of 54,000 lb./sq.in. The diaphragms were made of A.S.T.M. grade A-373 steel, and the half round bearing of S.A.E. 1060 steel. All other portions of the weldments were of A.S.T.M. grade A-7 structural steel.

The choice of T.1 steel was based on several considerations. Its high strength, a guaranteed yield point of 90,000 lb./sq.in. and ultimate strength of 105,000 lb./sq.in., reduced the weight of a climbing jack frame by about 35% or about 1½ tons on a heavy type frame. This of course meant easier handling. This high strength also reduced the depth of the side plates at mid span which allowed the hydraulic jack to be removed while the frame was resting on two block layers instead of three. This meant better stability for a jack frame while the jacking work was proceeding at another section of the bridge. The side plates used were either 1¾ in. or 2½ in. thick. If the side plate depths were kept the same, the carbon structural steel design would require side plates more than 6 in. thick.

As these jacks supported the full weight of the bridge during the winter months, the low temperature notch toughness of T.1 steel was a desirable quality.

During fabrication of the climbing jack weldments, cracking difficulties were encountered when stress relieving at 1,150° F. before machining. The cracks appeared at the junction of weld and parent metal in many of the T.1 joints. No cracks appeared in the frames which were not stress relieved. The cracked frames were repaired and all were used without stress relieving.

The jacks were welded with a mild steel electrode (E 7016) except for joints of T.1 to T.1 where a high strength alloy electrode (E 11016) was used. Extreme care was taken to have smooth surfaces on all regions of high stress.

When the spans over a particular pier were to be jacked 6 inches, the procedure was as follows: If the far end of either span was resting on a sliding climbing jack, the sliding feet were locked to give longitudinal stability during the lift. All stability struts on both spans were loosened by about ⅛ in. to accommodate the length changes to be caused by rotation of the spans. The roadway gaps were checked for longitudinal clearance and the filler timber was adjusted, if necessary. Hydraulic pressure was simultaneously applied to the main rams of the four hydraulic jacks forcing the jack cylinders, the climbing jack frames, and the span ends upwards. The speed of travel was about 6 in. in 15 minutes. As the spans moved up, the jack travels were checked to keep the spans level laterally and the roadway slabs of the two spans at the same level. As the jack ram became exposed, the retaining nut was turned up against the jack cylinder, thus any possible hydraulic failure could not drop the span. As jacking progressed, aluminum shims were placed as a precaution under the outer feet to guard against lateral instability. The stability struts, although slack by a small amount, guarded the longitudinal stability. When 6 inches of the ¾ in. aluminum shims had been placed under the outer feet, they were replaced by 6 in. thick concrete blocks. These blocks were first placed under the feet closest to the bridge centre line during which time the outer shims were in position to resist any lateral forces on the ends of the spans. The outer blocks were then placed with the same safety. As the hydraulic jack centre of the climbing jack was stable by itself, the shims were really an extra safety device.

When all blocks were in place, the jack ram retaining nut was screwed down and the bridge lowered until the load was transferred to the jack frame. The ram and central foot was then lifted hydraulically and a 6 in. concrete block was placed under the base plate. Thus the spans had been lifted 6 in. and the jacks were in readiness for the next jacking cycle.

After the lift, the stability struts were locked at their new length, the sliding feet released, and the roadway gaps checked. Jacking operations then proceeded on another pier.

The precast concrete jacking blocks were of two sizes. The ones for the outer feet were 20 in. x 35 in. x 6 in., while those under the central feet were 28 in. x 35 in. x 6 in. They were designed for a vertical compressive stress of 1,200 p.s.i. The additional stressing from horizontal forces was low.

The blocks were made of 5,000 lb. concrete, reinforced with a cage of 4 in. x 4 in. No. 4 gauge welded wire fabric 1 in. inside all faces. They were cast, with hooks projecting from the edges to bond them to the pier mass, in machined steel forms. Accuracy was necessary because of high surface pressures, and all bearing surfaces were accurate to within 1/64th in. and the block thicknesses to within 1/32nd in.

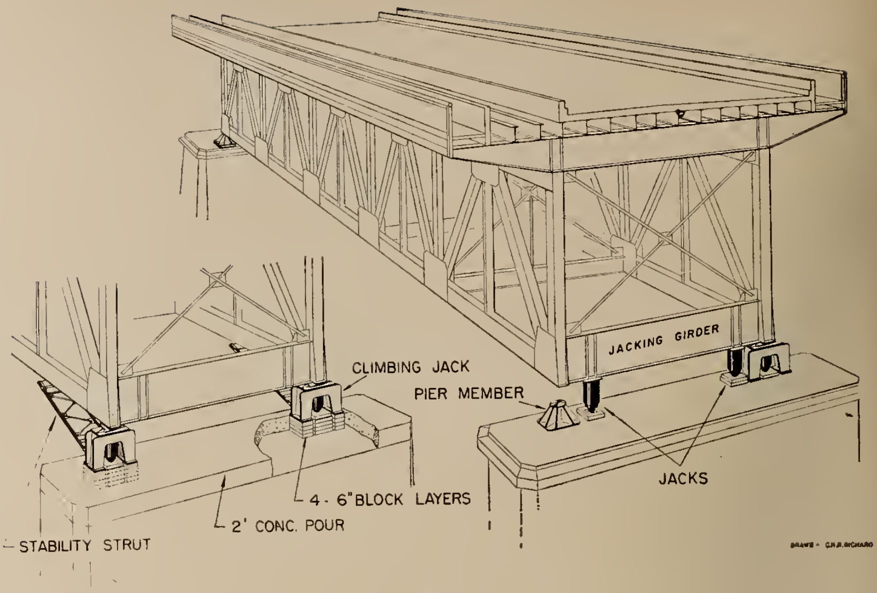


Fig. 7

When the spans over a pier had been lifted by 2 ft., that is, four layers of 6 in. jacking blocks had been placed under all the climbing jacks on the pier, a course of main pier concrete was poured around the jacking blocks casting them permanently in place (Fig. 7.) All the jacking blocks were tied together by reinforcing rods laid in the block anchor hooks and the main pour of 3,500 lb. concrete was reinforced by horizontal ⅝ in. rods at 8 in. centres near the pier faces.

Plywood forms were cantilevered from the last pour and during each pour form, anchors were cast in place ready for the next course of concrete. Before each pour, the forms were lifted and adjusted for the pier batter. During winter months the top sections of the pier were covered by heated plywood enclosures.

As the weight of the bridge was always carried by the piles of precast concrete blocking, the mass concrete surrounding the blocks did not have to be fully cured before further jacking.

Renewed jacking was permitted when the following conditions had been met: (1) The last pour had reached a strength of 1,500 p.s.i. or had cured for 48 hours. (2) The second to last pour had reached a strength of 1,500 p.s.i. (3) During winter months the pour becoming exposed below the heated enclosure had reached 2,500 p.s.i.

A Schmidt impact hammer was used for determining concrete strengths.

The final shape of piers was such that the pier tops were the same size as originally. The pier shaft batter was generally the same as the original 1 in 24. The original piers had to be thickened by about 1 ft. 6 in. on all faces. This was done the year before jacking work was started. This cladding concrete was bonded to the original pier by ¾ in. diameter dowels at 2 ft. centres, both horizontally and vertically, and reinforced with welded wire fabric.

Piers 12 and 13 were not increased in height by enough to merit thickening, but the original shafts were extended at the old batter. Four feet below the final cap, the shafts were enlarged to give pier tops of the same dimensions as the original ones.

To accommodate the new through span over the channel, with trusses 66 ft. 0 in. centre to centre, piers 9 and 10 had to be greatly enlarged. The tops of the original piers were 10 ft. by 50 ft. and were enlarged to 18 ft. by 84 ft. at the same elevation. After the spans were lifted to final elevation, tall pedestals were constructed on the upstream and downstream ends of piers 9 and 10 to support the through span trusses. The deck span trusses of spans 9 and 11 rest on these piers between the two pedestals.

Pedestals were originally provided to make up the differences in truss depths on piers 7 and 9. These differences were maintained during jacking operations by jacking the shallow spans from the pedestals and pouring courses of concrete on the pedestals each time a pier pour was made.

When the bridge over a particular pier had reached final elevation, the elevation of the top of the last block layer was found. The surrounding pier concrete was brought accurately to this level around the blocks. From this elevation and the required final pier top elevation, the capping block thickness could be calculated. These capping blocks, or bridge seat blocks, were a little larger than the pier member bearing area and about 18 in. thick. The block reinforcing protruded from the sides and was welded to the main pier cap reinforcing.

When the four capping blocks for a pier had been made and cured, a date for placing them was set, and the traffic was stopped during the night. The spans were supported on the jacking girders while the climbing jacks were removed. Two additional layers of jacking blocks were laid on soft grout over the old jacking blocks and surrounding pier concrete. The capping blocks were then put in place. The pier members were positioned and the spans lowered on to them. The last concrete pour was made flush with the top of capping blocks thus completing the pier.

Pier Fourteen Easement

The 199 ft. long parabolic vertical curve centred on pier 14 was designed to smooth the 4.81% grade change between the old 1.01% grade to the north and the new 3.80% grade to the south. The first construction operation was to deck a length of the upstream tramway lane with precast concrete slabs. This provided a temporary fifth lane so that further work on a lane of the main bridge roadway would still leave open four lanes for traffic. The easement construction work was done one lane at a time. The traffic was diverted from the lane and the roadway concrete slab was removed. The stringers were lifted and stools or fillers placed above the floorbeams and under the stringers to give the proper vertical curve.

The new deck consists of precast concrete slabs about 12 ft. by 6 ft. with the 6 ft. dimension being in the direction of the traffic. Steel anchor plates, cast in the underside of the slabs, were welded to the stringer top flanges. The roadway was then finished with an asphalt wearing surface.

Span No. 10

As mentioned before, the clearance increase was gained partly by changing the roadway profile, and partly by replacing the tenth deck span by a through span (Fig. 2.) The new through span is 248 ft. 0 in. long with trusses 66 ft. 0 in., centre to centre. The main trusses are eight panel, 40 ft. 0 in. deep, polygonal chord, Warren trusses with verticals (Fig. 11). The structure supports a 60 ft. 2¼ in. roadway between the trusses and two 5 ft. 1½ in. sidewalks outside the trusses. The deck is constructed with a 230 ft. vertical curve which serves as an easement between the final 4.20% and 3.80% grades. The floorbeams are Pratt trusses and vary in depth from 7 ft. 0 in. to 9 ft. 7-13/16 in. to suit the easement curve. The stringers are at 8 ft. 0 in. centres and span 31 ft. 0 in. They are 32 in. deep castellated beams made from 24 in. wide flange shapes.

Across the stringer top flanges are 10 in. I-crossbeams at 4 ft. 5⅛ in. centres. These crossbeams rest on various thicknesses of fills to follow the easement curve between floorbeams. The crossbeams are straight and the roadway crown is made in the 7 in. reinforced concrete slab.

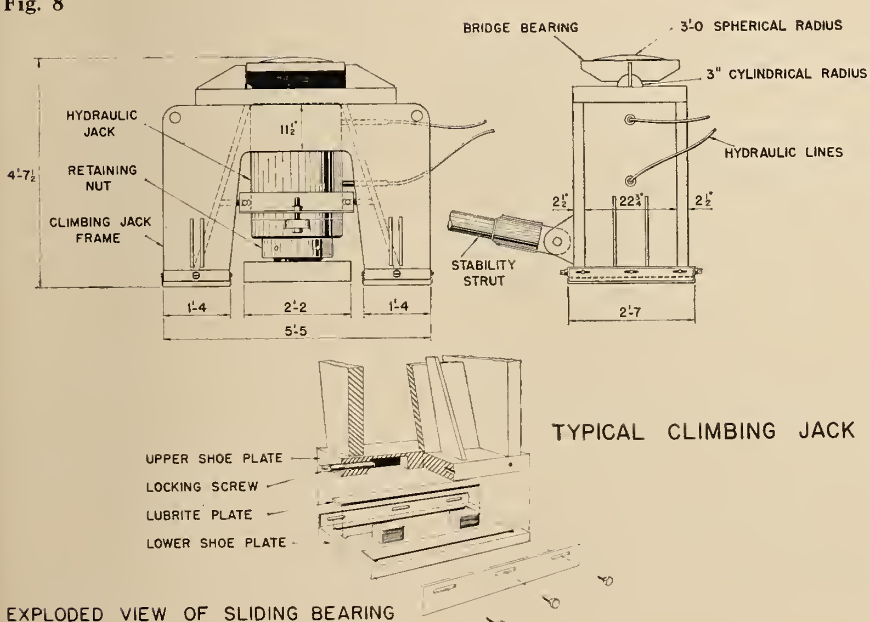
The end floorbeams are designed as jacking girders with jacking points 5 ft. 0 in. inside the truss. On each stringer line, there is a stringer extension bracket from the end floorbeam. These brackets were left off until the completion of jacking to give clearance for rotations and translation.

The span was designed to C.S.A. Specification S6 — 1952, except that the compression allowable was 20,000 - 70 l/r but not exceeding 18,000 lb./sq.in. The live load was two standard twenty-ton trucks and sixteen-ton trailers per lane spaced 48 ft. centre to centre. The live load stress for four trucks abreast was reduced to 83% while the other reductions were as per the C.S.A. specifications. All steel was medium carbon C.S.A.-G40.4.

In order to minimize interference with traffic, it was decided to erect the new span on falsework upstream of the bridge, tie the new and old spans together and roll them laterally, placing the new span on the bridge centreline and the old one on the downstream side. To conduct this translation of two spans at one time, it was necessary to have a common runway for new and old spans. To suit the old span, the runways were 245 ft.0 in. centre to centre and 45 ft. below the roadway surface. This required the provision of temporary steel legs on the ends of the new through span 35 ft. high and sloped to reduce the span length by 1 ft. 6 in. at each end. (Fig. 11).

These steel erection legs consisted essentially of main posts from the end truss working points to the runway bearings, bracing posts from the first interior truss panel points to the bearings, posts from the jacking points 5 ft. 0 in. inside and parallel to the main posts, and heavy bracing in the plane of the main and jacking posts. This bracing was designed for lateral wind and a portion of the dead

Fig. 8



and live load while the span was supported on the jacking point at runway level.

As the original truss depths changed over pier 9, there were 5 ft. high concrete pedestals under the bearings of span 9. The new span temporary legs at pier 9 were therefore made with a 5 ft. bottom section which was removable after translation. All four bearings on the piers were thereby brought to a common elevation for jacking after translation.

Translation runways were constructed upstream and downstream of piers 9 and 10. The runway centrelines were perpendicular to the bridge centreline and passed through the span 10 bearing points on both piers. The total length of upstream and downstream runway and the section over the pier top was about 220 ft.

During the channel construction, pier guard walls had been built from channel bottom around the foundation of piers 9 and 10. The top of the pier guards is 53 ft. above channel bottom. These pier guards were used where possible to support translation runway falsework.

Each runway consisted of seven rails at 6½ in. centres. The top of rail was 100 ft. above channel bottom and 45 ft below roadway surface. The rails were supported by either the pier top or four parallel steel beams. The beams were supported by 43 ft. high timber bents which rested on either the pier guards, pile foundations behind the pier guards, or 53 ft. high structural steel from the channel bottom. The runways were designed for a 400-ton concentration at any point.

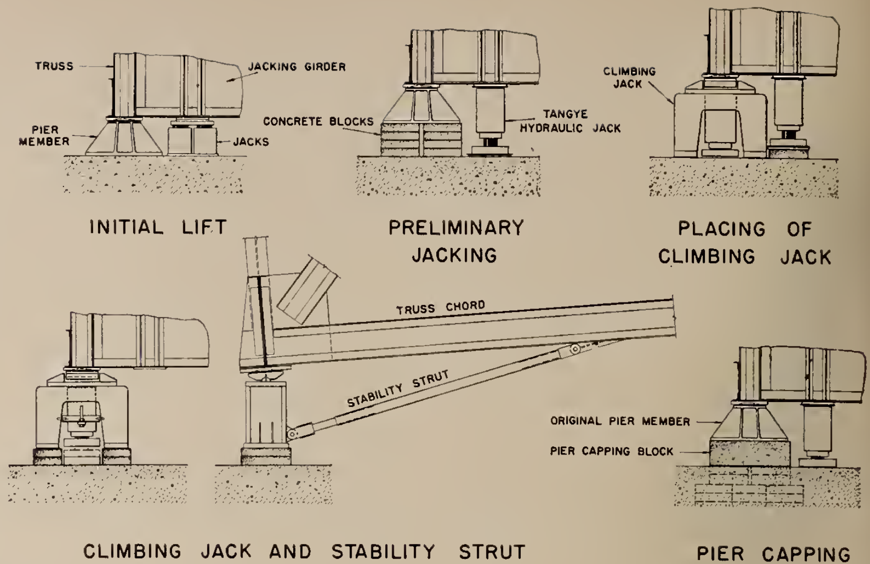


Fig. 9

During erection of the new span, the temporary legs and span ends were supported by the upstream runways. The interior panel points of the span were supported by timber falsework from the channel bottom. The erection falsework was 137 ft. high and was constructed in four tiers. (Fig. 12). The tier height was such that the top three tiers could later be used for falsework to dismantle the old span.

The bents for erection and runway falsework were fabricated during the winter of 1956/57 and erected by mobile crane during the spring and summer of 1957.

Fig. 10 Climbing jacks in place under the bridge trusses.

The new span and leg steel was erected with a 20-ton stiff leg traveller operating at the span deck level. The traveller was first erected by a mobile crane on falsework 90 ft. high located just south of pier 9 and upstream of the main bridge. After erecting the legs at pier 9 and the first floor panel, the traveller proceeded northward erecting the floor steel, bottom chords, and verticals of span 10. After reaching pier 10 runway, it moved back across the span and on to the traveller erection falsework erecting the top chords, diagonals, top laterals and portals (Fig. 13). When the steel erection was complete, the intermediate erection falsework was removed and the span was left supported on the two runways. The traveller was then dismantled and the traveller erection falsework transferred for use in the downstream runway.

The reinforced concrete roadway slab was formed, poured, and cured while the span was in this position. With the slab cured, the span was ready to receive traffic immediately after being moved into place.

The maintenance of electrical power and telephone service during the translation of the spans presented a problem which was worked out with the Quebec Hydro-Electric Commission and The Bell Telephone Company of Canada. In both cases, new lines had to be spliced into the circuits which ran from the top chord ducts to the bottom chord on spans adjacent to span 10. These temporary lines passed through ducts in piers 9 and 10 and across the Seaway channel below the spans being moved.

The telephone lines were more flexible and less likely to be damaged by movement and so were carried on wire ropes strung between the two piers. The Bell Telephone Company was able to store enough slack at piers 9 and 10 so that the final jacking elevation could be reached by the new span before splicing in the permanent cables on top chord ducts.

The electrical cables had to be placed on a steady platform as excessive movement might be harmful. In this case a double-single Bailey bridge supported on a steel bent at mid-channel carried the cables from pier 9 to pier 10. Immediately after translation, the cables were placed in the new span ducts and spliced into the main line.

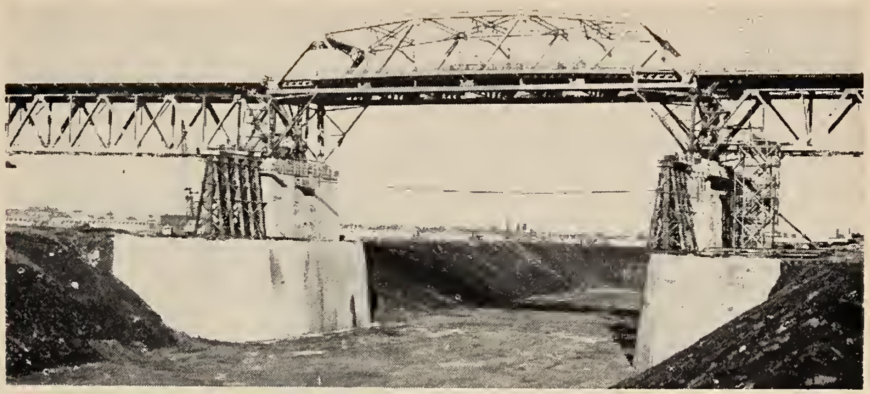

Fig. 11 New span in place on erection legs after removing old span and channel falsework.

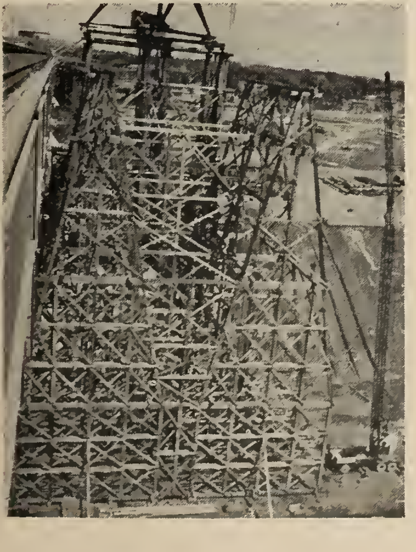
During the translation, each of the two spans was carried on four roller trucks. The new span was constructed directly on its trucks. The old span, however, had to be supported on the jacking girders while the climbing jacks were replaced by piles of concrete jacking blocks, a heavy steel plate, seven parallel runway rails, and the roller trucks. Each roller truck contained forty-two 6 in. diameter steel rollers with bronze bushings running on 2½ in. cold-rolled steel axles. The axles were bored for greasing. During translation, the rails themselves were greased to minimize friction in the case of a seized roller. On the top surface of the trucks, were horizontal tongue plates which transmitted the pulling force into the truck and also on through to the trucks behind. The top surface of the tongue plate carried a spherical bearing for the span. Between the tongue plate and the roller truck were bronze plates to allow movement caused by span expansion and contraction and mal-alignment of the runways and span during translation. The two spans were tied together by heavy steel tie plates between the tongue plates.

The moving force was supplied by two horizontal hydraulic jacks, one jack at the downstream end of each runway (Fig. 14). Each 300-ton double-acting, 4 ft. runout jack was powered by all eight cylinders of two pumping units and one control panel of the vertical jacking equipment. A stand-by diesel generator was ready in case of power failure. With this hydraulic system, each jack had a capacity of 250 tons with a power stroke speed of about 10 in. per minute and fleet stroke speed of 24 in. per minute.

Fig. 12 Span 10 erection falsework.



The completed span.

During the power stroke each jack pushed on a cross-head which pulled a chain of links on either side of the jack cylinder. These links were 3 ft. 10 in. centre to centre of pins and connected the cross-heads to the downstream trucks on the old span.

The pumping units, control panels, and translation control centre were located on the downstream sidewalk of the old span. During every jack stroke, the movement of each jack was measured by a gauge at the jack ram. These readings were relayed to the control centre by telephone. The movements of each jack were recorded by moving pointers on scales for the benefit of the control engineer. As speed correction became necessary, the control engineer contacted either jack control panel by telephone. The roller trucks were inspected regularly and their condition reported to the control centre by telephone. When the jacks had reached the end of their stroke, a link and pin was removed from each chain and the jacks were fleeted so that the next link could be connected to the cross-head and another stroke started.

Traffic was stopped at 5 a.m. on Sunday, 20th October, 1957, and the roadway gap plates were removed. When this was done, the spans were started along the runways and were essentially in final position by 9.30 a.m. The spans were then accurately aligned and gap plates were placed across the joints over piers 9 and 10. Traffic was back to normal before 11 a.m.

During the operation a total load of 3,100 tons was moved 78 ft. (Fig. 15). Throughout the movement, the overall friction effects as found from the hydraulic pressures, was always below 10% of the moving load. No difficulties with alignment of trucks, spans or jacks or from falsework settlement were experienced.

Because of the dangers of ice and high water during the winter months, the St. Lawrence Seaway Authority had to start flooding the channel by December 1st. It was therefore necessary to remove the old span, all falsework, and the electrical cable Bailey bridge before this date. After the translation, the old span was blocked on falsework which had been transferred from the upstream side of the bridge and erected from the channel bottom. The concrete deck was first cut into sections about 4 ft. by 8 ft. with concrete saws and pavement breakers. The sections were lowered by crane to avoid damaging the falsework below.

After all slab had been removed, the twenty-ton stiff-leg traveller was erected on the span at the north end by means of a mobile crane. It backed to the south dismantling all the steelwork as it went. Connection rivets were cut out and all pieces were salvaged for possible re-sale. When the traveller reached the south end of the span, it was removed and the rest of the steel was cut into pieces small enough to be handled by crane from the ground. A traveller falsework was not used in this case as its cost was high compared with the loss of a few pieces from the old span.

The falsework and the Bailey bridge with its steel bent were removed and the channel cleared for flooding. The anchor bolts were cut off flush with the concrete base pads which were left in place as they had been poured flush with the channel bottom.

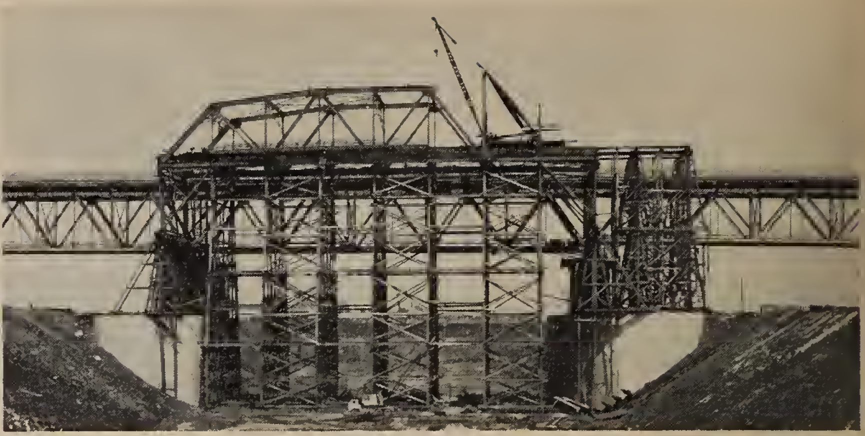


Fig. 13 Erection of new span 10.

After final jacking of the new span 10, which completed all jacking operations, the concrete pier pedestals were cast around the temporary steel erection legs and the exposed steel bracing was removed. The permanent span pier members were already in place as the top sections of the erection legs. While the sliding type climbing jacks at pier 10 were free for temperature expansion and contraction, the pier 9 pedestals were completed and the roller pier members at that pier released. Then the pier 10 pedestals were poured. This construction method left one end of the span free for expansion at all times.

The St. Lawrence Seaway as a whole has been a most interesting engineering challenge and each section has presented its own particular problems. In the case of the Jacques Cartier Bridge modification there was, at times, some unavoidable inconvenience to the travelling public, as well as several novel problems to be solved. Solution of these problems for the successful completion of the work and reduction of interference with traffic to a minimum was only made possible by the excellent cooperation of all parties concerned. Chief credit must be given to the late Dr. P. L. Pratley, HON. M.E.I.C., who designed the orignal bridge and who also acted as consulting engineer to both the National Harbours Board and the St. Lawrence Seaway Authority in its modification.

Jacques Cartier Bridge is maintained and operated by the National Harbours Board on behalf of the Dominion Government, control being vested in Major Guy Beaudet, Port Manager, at Montreal.

INTERNATIONAL NEWS

TRAINING OF ENGINEERING PERSONNEL IN THE SOVIET UNION

The Soviet higher educational system is coping successfully with the task of training specialists of various types, but the biggest achievements have been registered in the training of engineering personnel.

In the USSR training for a higher technical education begins in the secondary school. The curricula of the Soviet secondary school are designed to give the pupil a general education of quite a high level.

The secondary school strives to foster in the children love not only for the humanities, but also for the natural and exact sciences, for engineering professions, for work in industry. Polytechnical training has been introduced for this purpose in many schools, where, together with the study of theoretical subjects, the pupils work in school shops, visit industrial establishments, get to know production and acquire some work skills. This is also facilitated by school circles of natural and exact sciences and also Olympiads arranged regularly in mathematics, physics, chemistry, biology, and other subjects.

The result of all this is that, in the USSR, engineering higher educational establishments have no difficulty in getting full enrolments.

In Soviet institutes, as a rule, there are three to four applicants for each vacancy. Those wishing to enter a technical institute have to pass competitive examinations in the Russian language, mathematics, physics, chemistry, and a foreign language. Those who reveal a higher level of knowledge are enrolled as first-year students. Knowledge is the only criterion for admission to a university or institute. True, some preference in enrolment is given to young people who have worked for two or three years after graduation from high school. But this by no means precludes the possibility of entering an engineering institute immediately after graduation.

Having young people who are sufficiently trained to continue studies and to master scientific and technical knowledge the Soviet state had to provide the conditions necessary for study. A wide network of technical higher educational establishments has been set up by the Soviet Government in a brief period.

The Soviet higher technical school system is represented in the main by two types—polytechnical and branch institutes. Polytechnical institutes hold an important place in the system of technical higher education. These are establishments with many departments which graduate specialists for a wide range of industries and in different specialties.

For example, the Leningrad Polytechnical Institute, one of the largest of its type, has nine departments: metallurgical, mechanical and engineering, electro-mechanical, power engineering, physical and mechanical, hydro-technical, radio engineering, and others. Each department unites related specialties. For example, the radio engineering department has the following specialties: radio-physics, industrial electronics, dielectrics, and semi-conductors. The metallurgical department trains engineers who specialize in the metallurgy of ferrous and non-ferrous metals, metallography, metal casting, pressure treatment of metals, etc.

Altogether this institute is training 10,500 regular students and over 600 evening students in 42 different specialties. The institute has a faculty of 870 professors and instructors. It has more than 200 laboratories equipped with the latest instruments which makes possible not only laboratory studies but also large scale research conducted by the faculty and the students.

Similar in structure are the other polytechnical institutes: Urals (13 departments, 36 specialties); Kharkov (15 departments and 38 specialties); Kaunas (7 departments, 18 specialties). In 1957 the Soviet Union had 29 polytechnical institutes with a total enrolment of over 195,000 students.

Another type of technical higher educational establishment is the branch institutes which usually train specialists for a definite branch of industry. Among them are metallurgical, mining, building, chemical, technological, and transport.

Mining institutes are very widespread in the USSR. The training of mining engineers has increased scores of times as compared with the pre-revolutionary years. Oil institutes and departments prepare specialists in the extraction and refining of oil and natural gas. Many institutes graduate metallurgical engineers. Some of them have arisen together with large metallurgical plants; for example, the Siberian and Magnitogorsk metallurgical institutes. Such educational establishments have been set up in Central Asia, the Caucasus, and other metallurgical centres of the Soviet Union.

Almost each Soviet technical institute is training mechanical engineers for different industries. In addition, there are a number of specialized engineering institutes. Up to forty institutes graduate electrical engineers, electrical mechanical engineers, thermal engineers, and radio engineers.

Soviet technical institutes also provide engineering personnel for the chemical, timber, paper, light, and food industries, and for the rail, river, and air transport services.

The number of specialties and departments in branch institutes is usually smaller than in polytechnical institutes. The Dniepropetrovsk Mining Institute which trains coal mining engineers has four departments: geological prospecting, mining, mining mechanical engineering, and colliery construction. The 3,800 students are trained in ten specialties. The Novosibirsk Construction Institute has five departments and seven specialties.

There are also a number of institutes in an intermediary position. The Moscow Power Institute, for example, while nominally being a branch institute, actually has ten departments and trains engineers of 26 specialties. The Bauman Higher Technical School of Moscow is closer to a polytechnical institute in its structure.

The number of technical institutes in the USSR, their nature and particularly their structure reflect the achieved level, needs and prospects of Soviet industrial development.

Instead of the sixteen technical institutes with a total enrolment of 22,000 students in 1914, Russia now has 200 such institutes with a student body of 785,000.

The graduation of engineers of all specialties is growing at a mounting rate. While in old Russia, 1,500 to 2,000 engineers were graduated annually, in the USSR about 30,000 engineers completed their studies annually before the war. In the first post-war (Fourth) Five-Year-Plan period (1946-50) 134,000 engineers were graduated and in the Fifth five-year period (1951-55) the number reached 258,000.

ISRAEL

THE TECHNION, Israel Institute of Technology, is a fully developed institute of university rank, offering undergraduate courses in engineering, architecture and the exact sciences, leading to the Bachelor's degree, and research facilities in basic and applied postgraduate studies leading to Masters' and Doctors' degrees. It also provides technical services and advice to Government and public bodies, as well as to Israel's industry and agriculture. The Technion was recognized by the first convention of the International Association of Universities, of which it has been a full member since 1951.

The Technion is an independent institution administered by a Board of Governors through an Executive Council. The supreme academic authority is the Senate, composed of the President, Vice-Presidents, full-time Professors and the Director of the Library. In the academic year 1956/57, the teaching and research staff numbered 440, and the student body 1980, including 220 students of the Evening Technion, as well as 150 postgraduate students.

Applicants for admission to the Technion must have a valid Matriculation certificate and must pass entrance examinations.

Faculties and Departments:

Studies are conducted within the framework of six Faculties and four Departments. With a few exceptions, the course of study is four years. During the first two years, students are offered general instruction in the basic sciences (mathematics, physics, chemistry and mechanics), as well as in technical drawing and selected fundamentals of engineering, on the level required for the advanced courses and according to the special needs of the Faculty, Option or Department. On reaching the advanced stage of undergraduate studies, the student is allowed to choose one of the options of specialisation offered, in accordance with his personal field of interest.

Faculty of Civil Engineering:

The general curriculum of the Faculty comprises Strength of Materials, Theory of Structures and Structural Design, Bridge Engineering, Soil Engineering, Building Materials, Hydraulics and Hydraulic Engineering, Sanitary Engineering, Surveying and Communications Engineering. Options offered are Structural Engineering, (advanced courses in Structural Design and Engineering), Hydraulic Engineering (advanced courses in Applied Hydraulics, Sanitary Engineering, Maritime Structures, Hydrology and Soil Science) and Public Works (advanced courses in Highway, Railway and Airfield Engineering). Laboratory facilities are available in Building Materials, Hydraulics, Soil Mechanics, Technical Climatology and Highway Engineering.

Faculty of Architecture:

The activities of the Faculty comprise the teaching of design in all its implications, ranging over the entire background of daily life (from objects for daily use to buildings and town and regional planning), adapted to the particular geographical, socioeconomic, technical and cultural requirements of the country. Options offered are Architecture and Town Planning. A Centre of Industrial Design, under the auspices of local and foreign bodies, was established recently within the Faculty.

Faculty of Mechanical Engineering:

Options offered are General Mechanical Engineering (advanced courses in Machine Tool Design, Lifting Machinery, Textile Technology, Industrial Machinery and Precision Manufacture), Power and Heat (advanced courses in Applied Thermodynamics and Design of Power Machinery) and Industrial Engineering (advanced courses in Organizational Methods, Costing and Budgeting, Production Planning and Economics). Laboratory facilities are available in Machine Tools, Metrology, Metallography, Industrial Research and Power and Heat Machinery.

Faculty of Electrical Engineering:

The general curriculum of the Faculty comprises Electrodynamic Fields, Electric Circuits, Electrical Machinery, Electrical Measurements, Fundamentals of Electronics and Production Engineering. Options offered are Electric Power Engineering, and Electronics and Telecommunications. Laboratory facilities are available in Electrical Machinery, Electrical Measurements and Electronics. A third option, Control and Servomechanisms, to include courses in Automatic Control and Servomechanisms, Network Synthesis and Computing Machines (including fields other than Electrical Engineering) is under way.

Faculty of Science:

Graduates of this Faculty are trained for scientific and research careers in academic institutions and industrial and Government laboratories, as well as educational careers in secondary and vocational schools. The Faculty also instructs students of other Faculties and Departments in the exact sciences. Options offered are Mathematics, Physics and Chemistry. Laboratory facilities are available in Physics, Inorganic, Organic, Analytical and Physical Chemistry, Mechanics and Rheology, and Solar Radiation.

Faculty of Chemical Technology:

Options offered are Industrial Chemistry and Chemical Engineering (including elective courses in Petrochemistry), High Polymer Technology and Advanced Chemical Engineering) and Food Technology and Biotechnology. Laboratory and pilot-plant facilities are available in Technical Analysis, Unit Processes, Industrial Control, High Polymers, Food Technology, Food Analysis and Quality Control and Industrial Microbiology.

Department of Agricultural Engineering:

Options offered are Soil and Water Conservation and Agricultural Structures (including Settlement Planning), and Farm Machinery. One term is devoted to courses in fundamentals of agriculture (Horticulture, Soil Science, Field Crops, Dairy Husbandry etc.) provided by the Faculty of Agriculture of the Hebrew University at Rechovoth.

Department of Aeronautical Engineering:

The curriculum is intended to provide a general theoretical and experimental background, with specialisation provided at the practical training or postgraduate stage. Laboratory facilities are available in Supersonics and General Aerodynamics, and Aircraft Structures and Materials.

Library:

The Technion Library serves as the main centre for technical information in Israel. It contains 55,000 volumes in the pure sciences, social sciences, engineering, chemical technology and architecture.

GERMANY

The Centenary of Structural Chemistry

Everybody is familiar with the structural formulae of organic chemistry, in particular the hexagonal benzene ring. Modern chemistry would never have been possible without these formulae. Yet structural chemistry is only 100 years old. In May 1858 a German chemical magazine published an article entitled "On the Constitution and the Metamorphoses of Chemical Compounds and the Chemical Nature of Carbon". Universities in Germany and elsewhere will commemorate this paper and its author when celebrating the anniversary this year. The author's name was Dr. August Kekulé von Stradonitz. His statue adorns the University of Bonn, where he lived and taught for a long time. Every chemical text-book in the world mentions his name.

Kekulé von Stradonitz came from a family of Hessian civil servants, but took to science. He was born at Darmstadt in 1829. Young Kekulé first studied architecture, but under the influence of Liebig he turned to chemistry. He studied in Paris, in Switzerland, and in London, where Frankland's and Williamson's ideas on chemical structure obviously influenced him.

Modest Beginnings

In 1856 Kekulé became a lecturer at Heidelberg University. A lecturer was not allowed to lecture at a university college or to experiment there; he had to lecture in his private apartment and establish his private laboratory outside the university precincts. The great Robert Bunsen, presiding over Heidelberg's Department of Chemistry in 1856, would never have permited a mere lecturer to desecrate the departmental premises by his presence, and last of all young Kekulé whose theories Professor Bunsen viewed with open disfavour all his life.

Anyhow, Dr. Kekulé had to rent an apartment in the house of a flour-dealer. Kekulé made one room into a "lecture-room" and shared it with another young lecturer who later became nearly as famous. His name was Erlenmayer: his flask is a household word to chemists all over the world. Another room was made into a laboratory. Despite Bunsen's misgivings a number of other Heidelberg lecturers soon gathered round young Kekulé. They included some names that were to reach international fame: Lothar Meyer, Beilstein, Carius, Adolf Breyer. Barely two years later Kekulé was appointed professor of chemistry at the University of Ghent, Belgium. He was 29 at the time. Another two years later he was famous enough to be able to call an international chemical congress at Karlsruhe.

This congress was a necessity. It is difficult nowadays to imagine the confusion reigning in those days within the ranks of chemists over such basic terms as "atom", "molecule", or "equivalent". Kekulé wanted to end this confusion by international agreement. Most chemists believed as late as 1860 that the formula of water was HO rather than H_2O, and the difference between an atom and a molecule was far from recognized. Under Kekulé's chairmanship the great Italian scientist, Cannizzaro, was able to convince the conference that the formula of water was really H_2O, that gases generally consist of molecules having two or more atoms, and that equal volumes of all gases at identical temperatures and pressures contain equal numbers of molecules. This had been taught by his countryman, Conte Amadeo Avogadro, half a century earlier, when this gifted amateur—he was in his chief occupation Napoleon's minister of finance in the Kingdom of Lombardy—had propounded this fundamental law of chemistry as a result of his spare-time studies in natural science.

August Kekulé had announced as early as 1856 that carbon was quadrivalent and that the symbols for the atoms elements such as C, H or O, needed only to be linked by dashes to give a faithful reproduction of the chemical structure of an organic compound. The formulae used prior to this may strike us today as most curious, yet professors taught them with iron severity and students had to recite them at their exams, with the faith of religious believers. With Kekulé, modern structural chemistry began, and it has progressed with gigantic strides ever since. Kekulé announced that two or more carbon atoms may "link up, mutually saturating their units of affinity", and as he found in 1862, they might even spend two such "units of affinity" on a mutual link, which constituted the fundamental discovery of the double bond between carbon atoms, leading to the "unsaturated" compound. Nowadays we no longer speak of "units of affinity", but simply say "valencies".

The discovery of the double bond gave Kekulé the key to the formula of benzene and the "aromatic" compounds whose number has become legion since. Chemists had hotly debated this formula. Kekulé announced that six carbon atoms are linked in the shape of a hexagon in the benzene molecule, a single and a double bond alternating. He gave experimental proof of his theory. He was quick to see that none the less all six bonds are equal, and tried to explain away the resulting contradiction by maintaining that the double bonds were oscillating between the carbon atoms. This hypothesis of oscillation met with stubborn opposition. The general ring formula was readily accepted by chemists, but they never entirely swallowed oscillation. Numerous other ring formulae were proposed, including those of Dewar and by Kekulé's own disciple, Baeyer; it became evident some seventy years after that each of them contained a grain of truth though none of them was adequate as a whole.

Today we know that the carbon bonds in the benzene ring are really equal; they are "one-and-a-half" bonds. Two of their three bonding electrons are part of a single bond while the third electron belongs to the molecule as a whole. Kekulé worked with purely chemical methods and relied on the inferences derived from them. He could not possibly know about such notions of modern science as electrons, dipole moments, polarization, vibrational and rotational spectra of molecules, the Raman effect and quantum mechanics. His intuition was all the more amazing, for our present six "one-and-a-half" bonds are in many respects equivalent to his three double and three single bonds, making a total of nine links. Half a year after Kekule's death (1896), Roentgen came with his X-rays, which Max von Laue began to use for chemical structural analysis in 1912. After this, structural research gained momentum. A. v. Werner had added a chapter on inorganic structural chemistry at the turn of the century, walking in Kekulé's footsteps. Modern atomic physics showed that atoms consist of a positively charged nucleus and negative electrons enveloping it; some of these effect the chemical bond by means of electrical attraction. Two decades ago the benzene molecule had been photographed with X-ray methods, and behold, it is a hexagonal ring with six carbon atoms linked by equal bonds. Yet Kekulé's formula with its alternating single and double bonds dominates many text-books to this day because the assumption of double bonds —though they do not really exist—facilitates the understanding of the chemical reactions of benzene.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

Railway Projects

P.G.E. Inauguration

The Pacific Great Eastern Railway, a 100 per cent dieselized system, is now an 800-mile route from Vancouver to Dawson Creek and Fort St. John, close to the Alberta border in northern British Columbia. The inaugural run on the completed line took place in October. P.G.E. has pushed north from Quesnel and south from Squamish at a cost of $96 million since 1949.

Communication on the railway is by microwave. Modernization of the older parts has been accomplished. Improved service has speeded deliveries to the coast by 48 hours. Car loadings soared from 12,482 in 1951, to more than 38,809 in 1957.

An immense development in this economic area has been forecast. Timber coal, wheat, minerals, livestock, produce are actual or potential freight from the north, with the prospect of secondary industries favourable. Manufactured goods and supplies are carried north to points where population has increased by up to 170 per cent in five years.

Canadian National Railways

Montreal: North America's largest automatic freight "hump" yard, in terms of capacity, is being built by the Canadian National Railways on an 800-acre site at Cote de Liesse, Montreal, for operation by 1961.

The $28-million brain will receive and classify daily as many as 7,000 freight cars and link them into groups of cars by means of electronics, radio, television and automatic computers. The entire operation will be controlled by personnel in six towers. The "hump" will have two tracks, which will switch cars to the 84 classification tracks in the main yard.

A $3.5 million diesel repair shop went into operation at the Cote de Liesse, Montreal, yards in August, 1958.

Winnipeg: In September a 4-year project was started to provide a $24 million freight hump classification yard at Symington yards, St. Boniface, to serve the greater Winnipeg area. It will be able to receive, classify, and despatch as many as 7,000 cars a day.

Centralized traffic control is being installed; duplication of repair facilities is eliminated; new shops will handle running repairs to diesel locomotives; and shops are being extended at Transcona.

Moncton: Another hump yard, of smaller proportions is under construction at Moncton at the cost of $15 million.

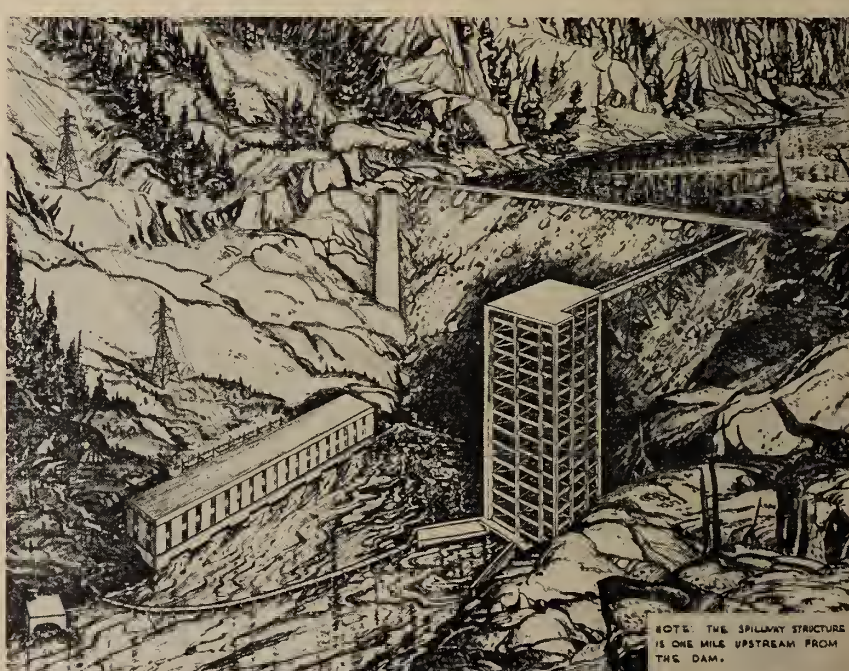
An estimated two million dollars will be spent in the Atlantic region during a two-year program to extend the centralized traffic control system westward. There are three stages: planned for completion in 1959, 1960 and 1961, the result being an automatic link from the seaboard to Montreal.

Further C.T.C. installations between Truro and Sydney, and on the other main lines in the Atlantic Provinces are also planned.

Helical Fishway

A new kind of fishway for various heights of dams has been developed jointly by Sir Alexander Gibb and Partners and Northwest Power Industries Ltd. Northwest is interested in the fishway for its proposed Nass River power project in B.C.

Rectangular or circular helical structure would be incorporated into the dam. Salmon ascend by a series of pools designed so that the lift from pool to pool is within their capacities. There are 12 travel pools in every circuit of the tower and a rest pool is provided in the centre for every circuit. The illustrated tower is 250 ft. high and has 14 circuits and a capacity of 2,700 fish per hour.



Model of Memorial University campus

Engineering at the Memorial University of Newfoundland

The Engineering Department at Memorial University College was started in 1930 with a staff of one lecturer and an enrolment of six students. The course set up then and still being given is a three year pre-engineering diploma course. From the beginning, as a University College, the institution has been an affiliated College of Nova Scotia Technical College, being represented on its Senate by the head of the Engineering Department and on its Board of Governors by the President. This affiliation still continues even though the Memorial University College was, in 1949, raised to the status of a degree granting institution under the name of the Memorial University of Newfoundland. Because of this affiliation the majority of the graduates from Memorial go on to Nova Scotia Technical College to finish their engineering degree, but they are not precluded from going elsewhere. "An increasing number are going on to McGill, and we have had students go on to Toronto, Michigan, and Massachusetts Institute of Technology to finish their engineering degree," Dean of Applied Science S. J. Carew reported.

The student enrolment in the Department of Engineering increased at a fairly even rate, with a slight peak after the war, until about five years ago when the rate of increase became rather large and the enrolment reached a peak of 154 in the year 1957-58. This same rapid rate of increase obtained in all faculties with the result that the existing facilities, although increased by the addition of temporary buildings, became rather strained and the decision was taken to make admission more selective thus keeping the total enrolment within manageable proportions. This accounts for the reduction in enrolment in the Engineering Department, which in the present year is 138.

As the student enrolment increased the staff of the department has been expanded by the addition of one new member in 1946 and another in 1954. The space allocated to the department was increased in 1954 and again in 1957. At the present moment the department has draughting accommodation for 45 students in the main laboratory, and for 35 students in the senior laboratory at one time, besides providing reading space for an additional 18 students. In the very near future a materials testing laboratory for concrete and hardness testing of metals will be in operation.

In 1956 a pre-forestry diploma course was instituted, closely geared to the requirements of the University of New Brunswick and the first diplomas were awarded in 1958. There has been a trend, since the granting of university status, for the better students to spend four years at Memorial and obtain a general B.Sc. degree as well as the engineering diploma. In this degree course a certain amount of credit is given for the purely engineering courses.

Looking to the future, the university has acquired a new site of about 100 acres and considerable work has been done in planning a completely new campus. For the first stage of the expansion — which consists of four buildings and will occupy about one sixth of the area — plans are already complete and it is hoped that construction will start in the near future.

The first of these buildings will house the administrative offices, alumni office, extension department, and the faculties of Arts and Education. The second building will house the departments of Physics, Chemistry, Biology, Geology, and Geography, as well as the Faculty of Applied Science which includes Engineering, Forestry and Household Science. Also housed in this building will be laboratories of some of the departments of Government, such as concrete testing, soils mechanics, and assay. The third building — the Library — has the usual reading rooms and library stacks. In addition the library building provides proper facilities for art exhibitions and for music appreciation. The fourth building will have a large gymnasium, which will also serve as an auditorium seating 1400, a swimming pool, squash courts, bowling alleys, a miniature rifle range and other athletic

A Report on Growth in the Engineering Faculties in Canada

Twelfth article of a series

facilities. Besides it will include offices for the U.N.T.D., the C.O.T.C. and the U.R.T.P., and a cafeteria. It is further hoped that hostels, which are included in the master plan for the new campus, will be started at the same time.

In the particular case of engineering, the department will, in the new building have facilities enabling it to handle about twice the present enrolment, as the laboratory space provided will accommodate about 150 students at one time.

The next stage of expansion envisages the faculties of Applied Science and of Education moving into new buildings, and so allowing Arts and Science to expand in the buildings of the first stage.

Acadia University

Acadia University, Wolfville, N.S., has a registration in three years of engineering totalling 139 this year.

Acadia is one of the Associated Universities giving three years of engineering studies in a program undertaken by a number of Atlantic Provinces universities. The students proceed to Nova Scotia Technical College for the last two years of engineering studies.

There is one building in the planning stage at the present time for Acadia University — a chemistry building. Souter Associates, a firm of architects located in Hamilton, Ont., are planning the building, in association with R. M. Peck, M.R.A.I.C., of Wolfville, N.S.

Saint Mary's University

By 1959 Saint Mary's University, Halifax, N.S., will increase its classroom facilities by twenty per cent. This will be made possible by allocating to the university class-room space now used by the high school. Other accommodation is being found for the high school.

Saint Mary's now has a registration of 95 in the three years of engineering. It is one of the Associated Universities, whose students traditionally proceed to Nova Scotia Technical College after completing third year.

Apart from staff increases and normal acquisition of equipment, no major addition has been made to the facilities of the engineering department.

In the next five years it is planned to erect a building to house some of the sciences and possibly engineering. This project is still in the tentative planning stage, but its need is urgent.

Expansion at the University of Western Ontario

The Department of Engineering Science was established at The University of Western Ontario in 1954, to offer a two-year course designed to prepare students for admission with advanced standing to certain engineering courses at other Canadian universities. At that time, it was thought that an expansion of the program would be considered in 1959 or 1960. The initial policy was to admit not more than 30 students to the first year.

The new department became, and still is, one of the departments of University College. The Faculty of Arts and Science consists of University College and a number of affiliated colleges. The well-known School of Business Administration was a department of University College until 1950.

A philosophy of what engineering education should be in the second half of the Twentieth Century was formulated at the University before the department was established. This was done in consultation with a small group of professional engineers and executives who acted as an advisory committee. The principles adopted were essentially the same as those proposed several years later in the Report on the Evaluation of Engineering Education (the Grinter Report) by the American Society for Engineering Education.

In 1956 the Board of Governors authorized (a) the expansion of the course to a four-year one leading to a degree, and (b) the planning of the Engineering Science Building. The following decisions were made before any plans were prepared: (a) the first-year enrolment was to be limited to 150 students, (b) all instruction in physics, chemistry, mathematics, geology, the humanities, and the social sciences would be given by the departments concerned and neither lecture-room nor laboratory accommodation would be required in the building for work in these subjects, (c) for a number of years, the Department of Physics, which had the staff and the equipment, would be responsible for the high-frequency electrical field, and (d) the laboratories in the new building would be suitable both for undergraduate work and for a modest program of staff and graduate research.

The preliminary plans were completed in May 1957, the detailed plans and specifications were completed in December 1957, and the contract was awarded and construction started in January 1958. The building will be ready for occupancy about the end of April 1959. The cost of the building, including furniture, will be about $1.40 million and the cost of laboratory equipment will be about $0.35 million.

The exterior of the building is of rough stone and matches the other buildings on the campus. There are three floors and a penthouse for the ventilating equipment and the elevator hoist.

The building contains laboratory facilities for work in mechanics of materials, soil mechanics, fluid mechanics, thermodynamics, photoelasticity, vibrations, unit operations and chemical pilot-plant studies, electric machines, and electric control systems. In addition, the building contains lecture rooms, problem or computing rooms, draughting rooms, a reading room, a conference room, a departmental office, staff offices, a shop for the fabrication of laboratory and research equipment, and considerable storage.

An Advisory Commitee on Engineering Science was appointed in 1957. This committee consists of four members of the Board of Governors, the President, the Principal of University College, about fifteen engineers who are recognized for their professional and managerial abilities, and the head of the Department of Engineering Science. The Engineering Institute of Caanda is well represented on the committee.

The departmental shop has been set up in temporary quarters and some laboratory equipment has been installed temporarily in existing buildings. More laboratory equipment will be installed temporarily during the present academic session.

During the 1958-1959 session the staff consists of a professor, two associate professors, two assistant professors, two lecturers, a secretary, and a technician. Six engineers, who are graduate students in the School of Business Administration, are part-time members of the staff.

The present first-year enrolment is 80 and the total enrolment is 155.

The development of a program in enginering education is only one phase of the expansion of the University. Since early in 1954 the following buildings have been constructed: Stevenson Hall, which contains the administrative offices of the University; Somerville House, which contains a dining hall, a snack bar, and other facilities; the Richard G. Ivey School of Business Administration Building; and the Biological and Geological Sciences Building. A men's residence, which will contain a dining hall, for 300 students will be completed in 1959.

It should be noted that graduate enginers form the largest group of students in the two-year course leading to the M.B.A. degree in the School of Business Administration. As mentioned above, six members of this group are part-time demonstrators in the Department of Engineering Science.

Engineering Science Building under construction at the University of Western Ontario.

Aid to Education

Three sources of information on aid to education are available.

Industrial Foundation on Education

A survey of higher educational institutions has recently been completed, and information from this has been published by the Industrial Foundation on Education, Toronto (170 University Ave.), under the title "The Case for Corporate Giving to Higher Education (1958 Supplement)".

This report studies the performance of business and industry in this field for the academic year ending in 1957. It is the second edition of the report.

The October 1958 news letter of the Industrial Foundation on Education, commenting on the survey, is abstracted as follows:

"The most startling information in the current report is the phenomenal increase in the amount of money given by corporations in 1957 over 1956. This increase was nearly 4½ times—increasing from 2.7 million dollars to 11.6 million dollars."

Chart No. 1 of the report indicates that between 1946 and 1957 corporate giving increased at a much more rapid rate than either university enrolment or university capital and operating costs. Enrolment increased to 1.75 times the 1946 figure and costs increased 3.37 times what they were in 1946. Over the same period corporate financial aid to universities increased by nearly eight times the amount given in 1946.

Corporate giving to universities expressed as a percentage of profits before taxes amounted to .083 per cent in 1956, and .384 per cent in 1957, or 4.6 times the 1956 percentage.

The corporate grants accounted for 9.2 per cent of the capital and operating costs of universities in 1957. This almost amounts to the Foundation's originally suggested formula for total corporation giving, that is, providing 10 per cent of corporation profits before taxes.

Nature of Expenditures Associated with Grants

In the survey, grants from two major sources were considered: those from business and industry, and those from foundations established by industrialists. Approximately 75 per cent of the total were found to originate from the former, and 25 per cent from the latter.

The analysis by type of grants shows by far the largest proportion going for capital purposes (61 per cent). Grants for operating purposes constituted 8 per cent; for research, 11 per cent; and for unrestricted and unclassified purposes, 20 per cent. The large proportion provided for capital purposes was evidently encouraged by the well managed and informative campaigns conducted by the universities during the year, and is further evidence that business responds well when the need is made known.

Distribution of Grants—by Region

Considerable variation in corporate giving expressed as a rate per student enrolled was indicated between various regions in Canada. For the two years 1956 and 1957, the giving per student in the various regions was:

	1956	*1957*
Western Canada	$26	$60
Ontario	48	148
Quebec	15	240
Maritimes	105	94

In total, the rate per student for all Canada was $38 in 1956, but rose to $149 in 1957.

Grants from Canadian and Foreign-Controlled Companies

In a News letter earlier this year, the Foundation reported that foreign-controlled companies in Canada contributed a much larger proportion of the student aid funds in this country than do Canadian-controlled companies—$687,775, or 67.1 per cent of the total compared with $337,020, or 32.9 per cent of the total by Canadian companies.

However, for the much larger amounts covering grants made directly to universities the percentages are reversed. Foreign-controlled companies in Canada contributed $3,280,441 or 30 per cent of the total, while Canadian-controlled companies contributed $7,652,947, or 70 per cent of the total corporate grants. The comprehensive total — student aid plus grants direct to universities and colleges — show Canadian-controlled firms contributing 66.8 per cent and foreign-controlled 33.2 per cent.

Dominion Bureau of Statistics

Undergraduate Awards

An important, comprehensive source of information about undergraduate scholarships and bursaries is the publication "University Entrance Awards". This is published by the Dominion Bureau of Statistics, Education Division, and sold by the Queen's Printer at cost of $1.00. The latest edition, a revision of "Reference Paper 55", brings the information up to date as of February 1958, listing awards not previously listed, and giving more complete coverage of awards by professional and service organizations and by business and industry.

The awards listed are limited to entrance scholarships and bursaries valued at $100 or more. Most of the institutions included also have various loan funds and in--course awards, details about which can be found in the calendars of the individual universities or colleges.

The information, being comprehensive, refers only in part to engineering education.

Graduate Awards

"Awards for Graduate Study and Research, 1957" is the title of a 158-page report published by the Dominion Bureau of Statistics, a revision dated December, 1956. It is available from the Queen's Printer at price of $1.00.

As in the past, awards open to Canadians from sources in Canada and abroad are included. Wherever possible, a notation has been made to indicate whether or not Canadian awards are also open to persons from outside Canada.

In this edition there is an increase in entries from outside Canada, principally from the United Kingdom and the United States.

In so far as it is available, information about part-time assistantships in the various institutions, and information on research grants, has been included.

St. Lawrence Seaway and Power Project

Early in November 1958 many signs could be observed that the construction phase of the billion dollar St. Lawrence Seaway and Power Project was nearing completion.

Though close to 7,800 persons were still employed and work costing many millions of dollars remained to complete, most of it consisted of underwater dredging and 'sweeping' of channels, steel erection, and the installation of electrical and mechanical devices required to operate lock-gates, lift spans on bridges, or of turbines and generators. Apart from the dredging which would be closed down for zero weather, most of the machinery installation would continue throughout the winter months.

On the Canadian half of the international power-house all construction cranes were dismantled, the last two cells of the cofferdam were removed, and seven units were operating. Cleaning up and sweeping of channels upstream was nearing completion as scheduled, and work would continue next summer. Employment stood at 1600 persons.

On the American half of the powerhouse 4,600 yards of rock had been removed from the tailrace. Seven units were operating and another undergoing tests. Concrete was all placed on the Long Sault dam and permanent hoist erection nearing completion. Upstream dredging of channels was completed and sweeping was continuing.

Dredging of the north Cornwall channel was shut down, but excavation to widen the channel, and removal of cofferdams would continue. The international high-level highway bridge at Cornwall was opened for traffic on December 1. Employment by NYSPA stood at some 2,300 persons, while the force employed by SLSDC stood at close to 400 persons.

Progress by SLSA

At the Beauharnois locks, rock excavation between the locks was completed while sills for the mitre gates in the upper lock were nearing completion. Water was let in to the intermediate pool. As on the St. Lambert and Cote Ste. Catherine locks, installation of machinery and testing would proceed during the winter months. Upstream and downstream cribs were in place.

On the Jacques Cartier bridge, permanent approaches at the south end were carrying traffic, with only the toll portal structure still under construction. On the Honore Mercier bridge the northbound lane of the Valleyfield approach was erected and paved but not yet opened for traffic. All lanes were expected to be opened for traffic by end of November. At the Victoria bridge, seven spans on the railway diversion on the upstream side north from St. Lambert were erected and being riveted, leaving three spans nearest to the St. Lambert lock to be erected. Work was continuing on erection of the tower for the lift bridge over the lock.

Employment by SLSA stood at approximately 3,500 persons at month-end.

The South Saskatchewan River Project

With the signing of a Federal Provincial agreement at Ottawa on July 25 between Canada and the Province of Saskatchewan, the stage was set for preliminary construction work on the South Saskatchewan River Dam. Overall cost of the project is estimated at $182 million. The Federal Government will pay $72 million towards the cost of the dam, estimated at $96 million. It will also lend Saskatchewan $12 million for its 25 per cent share of the cost of the dam. The cost of power and irrigation works, amounting to almost another $90 million, will be borne by the provincial government.

Preliminary work under way

Early in October a contract was awarded to the Evans Construction Co. for building 12 miles of access roads to the dam site at a price of $172,000. Early in November, MacNamara Ltd. was awarded a contract for processing aggregates at $812,000, and Beatty Ramsey Construction Co. was awarded a contract for headquarters services at the damsite. Tenders were asked for headquarters buildings. Further bids would be called soon for rockfill bridge abutments, piers and a bridge superstructure. Some $4.5 million was allocated by the Canadian government for the current fiscal year. Most of the bids will be asked in the spring.

A modern village, to have a population of about 200, will be laid out and built on the east bank of the South Saskatchewan river, near the site of the proposed 210 ft. high earthfill dam. It will have gravelled streets, concrete sidewalks, sewers and a water distribution system. This village will contain the offices of the P.F.R.A. engineering and construction supervisory staff, with living quarters for them and their families. No stores, service stations, churches or schools will be built. Streets and services will be completed by late December.

Geraldton in time for this year's heating season. The Company commenced service in Port Arthur, Fort William and Dryden last year.

Northwestern Utilities: Delivery of gas from the Pembina field to Edmonton started October 31, following testing of the 70-mile, 16-inch pipeline of Northwestern Utilities, Limited. This new pipeline will make it possible for gas consumers in Central Alberta to utilize gas which was formerly flared. About 50 million cubic feet of gas a day will be delivered initially, enabling Northwestern Utilities to conserve its own gas reserves for meeting severe winter demands.

Saskatchewan Power Corporation: Steelman Gas Ltd. officially opened its casinghead gas processing plant in southeastern Saskatchewan on October 30. With capacity of 30 million c.f.d. it is starting off with production of 25 million c.f.d. Gas formerly flared off as waste from more than 600 wells will be collected through the gathering system. First call on the gas will be given to cities of Estevan and Weyburn.

F. P. C. rejects Trans-Canada gas: The Federal Power Commission on October 31 rejected Midwestern Gas Transmission's application to import Canadian gas at Emerson, Manitoba. Its decision was based on the fact that Trans-Canada had not contracted for sufficient reserves to satisfy both Canadian customers and the U.S. market. Turned down also were the competing applications from Northern Natural Gas and Michigan Wisconsin Pipeline Co. But the way was left open for new applications from all three for projects "conceived realistically on the basis of natural gas needs", in the upper middle west area.

Canadian Pipeline Projects

Canadian pipeline construction in 1958 will total some 4,200 miles, — the second largest annual pipeline construction season in Canadian history. Biggest job was the Trans Canada system between Lakehead and Toronto, on which 12 spreads worked on a continuous section of 853 miles including the Crown Corporation section from Lakehead to Kapuskasing. Other natural gas mileages included: Westcoast, 200; Alberta Trunk, 237; two Alberta Utilities, 270; Saskatchewan Power Corporation, 475; Northern Ontario Natural Gas, 270; Union Gas, 400; Consumers Gas, 400; Lakehead 150; and Quebec Natural Gas, 100; for a total of 3735 miles of gas pipelines. Some 482 miles of crude oil pipelines were under construction in the prairie provinces, inclusive of 82 miles of looping on Interprovincial.

Westcoast Transmission

Westcoast Transmission and Alberta and Southern Gas Co., have announced plans for joint construction and use of single gas pipeline from the Alberta border to the B.C.-Idaho boundary. The line will be owned and operated by Alberta Natural Gas Co. Initial cost will be some $40 million. Each export company will continue to purchase gas from Alberta distributors independently from one another.

Delivery of gas from the Blueberry field in the Half-way area of northern B.C. started in mid-October through Westcoast's $7 million gathering system with initial deliveries of 15 million c.f.d. Deliveries will ultimately be stepped up to 50 million c.f.d. by 1960.

Trans Canada Pipelines

Final testing of Trans-Canada Pipe Lines' natural gas line from Alberta to Montreal was completed October 23, and approval from the Board of Transport Commissioners received. The final testing took place between Hearst and Kapuskasing. It was completed well ahead of schedule when the final weld was made near Kapuskasing October 10. Natural gas from Alberta arrived in Toronto the following day and then moved through the line to Ottawa and Montreal.

During the 1958 construction season, 5,000 men built the final 852 miles of the line, working east from Port Arthur on the Northern Ontario Pipe Line Crown Corporation section of the line, and north from Toronto on the Trans-Canada section.

Northern Ontario Natural Gas Co.: Natural gas arrived in Northern Ontario in mid-October.

Also nearing completion were two small lateral supply lines built by Northern Ontario Natural Gas to carry gas from the Trans-Canada line to Timmins and to Sudbury.

The Company holds a contract to supply an initial six million cubic feet of gas daily to the International Nickel Company plant in neighbouring Copper Cliff. Eleven pulp and paper mills in the area are also large users.

Northern Ontario Natural Gas will distribute natural gas in the following communities this year; Orillia, Gravenhurst, Bracebridge, Huntsville, Sturgeon Falls, Sudbury, Copper Cliff, Cobalt, Haileybury, New Liskeard, Englehart, Kirkland Lake, Porcupine, South Porcupine, Timmins, Schumacher, Ramore, Matheson, Ansonville, Iroquois Falls, Cochrane, Smooth Rock Falls Kapuskasing and Hearst. Service has been available in Kenora since last year.

Northern's affiliate, Twin City Gas Company Limited, will commence service in Red Rock, Nipigon and Geraldton in time for this year's heating season.

Design Competition

Fifteen awards totalling $44,000 are offered to engineers and engineering students in a competition open to Canadians. Sponsor is the United States Steel Export Company, 100 Church Street, New York 8, N.Y.

The competition poses the problem of designing an overpass structure in steel to carry a two-lane highway at right angles over a four-lane highway on level ground. Standards of the American Association of State Highway Officials and the U.S. Bureau of Public Roads will be regarded.

First award for engineers is $15,000; first award for an engineering student is $9,000. All entries will be judged on the basis of originality of design, utilization of the properties of steel, economy, and appearance.

Information and rules may be obtained from the Company at the above address, or from the American Institute of Steel Construction, 101 Park Avenue, New York 17, N.Y.

CONFEDERATION—A Progress Report

The Institute panel of the sub-committee on Confederation met again in Ottawa on November 4 with Messrs. Tait, Foulkes and Wright present. The proposed report of the sub-committee was completely reviewed with the object of clarifying and more clearly defining the wordings. A final version was agreed upon.

This report was sent by the Institute to the Canadian Council's panel on the sub-committee on November 7, with the request that approval or changes be indicated as soon as possible.

In response to a telephone call from your chairman on November 18, Mr. Fox stated that the report was satisfactory to the three members of his panel of the sub-committee except for one slight alteration.

As our three panel members of the sub-committee agreed with this proposed change, the alteration has been made in the report and copies have gone to all members of the Committee on Confederation on November 26. Mr. Fox planned to send copies to the members of his committee and accordingly an adequate number of copies have been sent to him at the same time as they were sent to the members of the Institute committee.

It has been agreed with Mr. Fox that replies from all members of the joint committee must be back in the hands of the chairmen by December 12, and for those who do not reply it will be assumed that they are in agreement.

It is hoped that the report will be acceptable to all committee members and that within a very short period of time it will be submitted to the two councils.

It is a matter of satisfaction to your chairman that unanimity of approval has been given by all six members of the sub-committee. This is an encouraging sign which it is hoped may indicate the reception the report will get from the two councils and eventually from the general membership.

IRVING R. TAIT, HON. M.E.I.C.
Chairman
COMMITTEE ON CONFEDERATION

1958 University Registration

Once more the Institute has completed its annual survey of registration in engineering at Canadian universities. These figures have been obtained direct from the registrars across the country, and a tabulation of them in detail is given on pages 67, 68, 69 of this issue.

Readers will interpret these results in different ways in accordance with their varying points of view. However, certain facts stand out and some editorial comment therefore seems appropriate.

Perhaps the most important figure to examine is the grand total of the enrolment. This now stands at 14,552 as compared with 14,247 a year ago. This increase, slightly over 2 per cent, is the smallest rise to be reported for quite a few years. Causes for this could be sought, but it is not considered to be too significant for the reason that new and improved university facilities on many campuses are expected to swell the total again soon.

Observers of these trends are always interested in the statistics of new freshman intakes. This year's survey discloses a sharp drop in the number of new engineering students starting their courses this year. The total new class numbers 4,572 against 5,132 last year, a decrease of 11 per cent. This does not reflect a very healthy condition for the profession. At least in part, this must be attributed to general economic conditions this year which made it difficult for engineering students to obtain proper employment during the past summer vacation. News of this undoubtedly spreads around among prospective university applicants.

The same trend is evident when one looks at the estimated number of 1959 graduates. A slight decline is expected. If students presently in their final year complete their courses, 2,104 will graduate and enter the profession next spring. This follows an estimated figure of 2,130 for 1958. If the forecast proves accurate, it will mark the first time that the size of the graduating class has fallen off since the student veterans left the scene. As mentioned above, new facilities and the influence of oncoming classes should soon boost this total again.

On the brighter side of the picture this year, readers will notice the ever-growing number of universities and colleges listed. We now have 30 educational institutions in Canada where some kind of an engineering course is offered, and 15 of these now grant degrees. It is interesting to watch the continued rapid growth of engineering education in Western Canada. This year's survey has disclosed that 30 per cent of students now enrolled in engineering are taking their courses west of the Lakehead.

An examination of the results in the different faculties shows a steadily increasing interest in the study of engineering physics, as commented on last year. Total enrolment in this branch now stands at 727 which is an increase of 12½ per cent over 1957. The Sputnik age is certainly having its effect on young minds in their choice of studies. A close observation of the table of courses will show that aeronautical engineering has disappeared from the list. This has been a part of the training offered at the University of Toronto for many years. The explanation lies in the fact that these aeronautical students now take their instruction under the course in engineering physics, up to B.A.Sc. degree. Aeronautical engineering as such is now shown as a post-graduate course.

ASME-E.I.C. Conference on Engineering Education

"How Should Industry Aid Engineering Education?" This was the theme of the third biennial engineering education conference, sponsored jointly by the American Society of Mechanical Engineers and the Engineering Institute of Canada, held at the University of Michigan at Ann Arbor, October 15 and 16, 1958.

Attendance was by invitation, and invitations were sent to equal numbers of educators and industrialists. One hundred and seventeen delegates attended the conference, of which 33 came from Canada. Eleven Canadian universities were represented, from Halifax to Edmonton.

In order to provide the greatest possible freedom of expression and discussion, the presiding chairman, E. W. Allardt, vice-president, Region V, ASME, requested at the opening session that the conference be "off the record". The conference was divided into three sessions which took the form of panel presentations followed by general discussion. Dr. Harlan H. Hatcher, President, University of Michigan, welcomed the delegates at the opening luncheon.

The speaker at the dinner following the opening day's sessions was Dr. C. M. Anson, immediate past president of the Engineering Institute. He began his remarks by asking, "Should industry aid engineering education?" He said, "Industry needs engineers today; it will need them in greater numbers tomorrow. There lies the answer then to my first question. Industry not only should, it must aid engineering education." He went on to discuss the evolution of engineering education and pointed out some of the things he found deficient in the present system. He emphasized the importance of training in labour relations.

At the closing luncheon, Dr. K. F. Tupper, president of the Engineering Institute of Canada, related some of the things he had seen during a trip, just completed, to the Union of Soviet Socialist Republics. He described briefly the methods of engineering education in Russia and mentioned some of the construction projects he had seen during this short but crowded visit.

The first panel presentation was on the topic, "The Philosophy of Co-operation Between Industry and Higher Education". The moderator was Richard G. Folsom, president of Rensselaer Polytechnic Institute, who introduced the panelists. These were: Ira Needles, Chairman of the Board, B. F. Goodrich Rubber Co. of Canada; Raymond O. Darling, assistant to the director of educational relations, General Motors Corporation, Detroit, and Eugene H. Case, director of college and university relations, Deere & Co., Moline, Illinois.

Mr. Needles described the work he is now doing in developing engineering courses on a co-operative basis with industry at Waterloo College. He indicated several ways in which industry could aid education, including grants for specific activities, scholarships and gifts of equipment. Both Messrs. Darling and Case mentioned that competitors in industry had access to the same raw materials, to the same technology and to the same markets. The only difference lay in people and in the direction of their activities, hence the need and the obligation for industry to assist education. Money alone was not enough. The following guiding principles in developing programs of assistance were enumerated:

1. All programs of assistance to education should be evaluated in the light of demonstrated need on the part of the educators.
2. Avoid becoming involved in educational matters which are strictly the property of educators, such as the development of teaching methods.
3. All classroom aids should be field tested before being made available to educators and students.

The following ways of aiding education were also suggested by one of the panelists:

1. Through the printed and spoken word and day to day actions, place an emphasis on increasing the respect of the public for learning and the teaching profession.
2. Provide scholarships, not for the students but for the faculty.
3. Encourage the participation of industry's best people in the broad aspects of the educational process.
4. Increase the recognition that everyone and every corporation has a vital interest in the advancement of our educational system and the development of the individual.

The second panel session was on the topic, "Continuing Education by Industry in Industry". The moderator was R. D. Richmond, chief engineer of special weapons, Canadair Limited. The panelists were: H. L. Shepherd, in charge of salary administration and personnel development at Canadian Westinghouse, Hamilton; John Gammell, director, graduate training program, Allis-Chalmers, Milwaukee, and Dr. Alan W. Brown, former president of Hobart College.

From left to right, at left: Panel members: Ernest T. Stewart, J. Moreau Brown, G. Ross Lord, Pierre Gendron, Alan W. Brown, John Gammell, and H. L. Shepherd.

Below: With E. W. Allardt, left, panel members R. O. Darling, Ira Needles and E. H. Case, and Moderator Richard G. Folsom, right.

The following methods were among those described for continuing education in industry; private coaching on the skills of a job, technical conferences, manager training courses, pre-management courses, recruiting and induction procedures, job rotation and special skill courses. In concluding his remarks Mr. Shepherd said: "Perhaps the greatest education of all is the engineer's growing realization of his favoured position in society and a sense of obligation to contribute realistically and well".

Mr. Gammell reported on some of the courses operated by his company, including one involving a great deal of mathematical analysis, reserved for brilliant students who expect to go into research, design or development. He also mentioned special courses arranged from time to time to take care of particular needs, using where necessary local vocational schools to do the instructing.

Dr. Brown spoke of the following: in-service education and training versus sponsorship of outside study in local institutions; the upgrading of personnel, not merely in the useful and the applied but in terms of widening of horizons and the encouragement of imagination; the use of television, whether closed or open circuit, for educational and training purposes. He expanded his remarks concerning educational television, pointing out the advantages of this method of imparting instruction. Dr. Brown is president of the Metropolitain Educational Television Association, New York.

The final session dealt with "Support by Industry of Higher Education". The moderator was J. Moreau Brown, administrator of corporate support programs, General Electric, New York. The panelists were: Dr. Pierre Gendron, dean of the faculty of pure and applied science, University of Ottawa; Dr. G. Ross Lord, head of the department of mechanical engineering, University of Toronto.

In his remarks, Dr. Gendron suggested the following ways for industry to assist education: contribution to building funds, unrestricted support for operations, undergraduate scholarship programs, research grants, consulting fees for certain staff members. He based his recommendations on the concept that "Industry has always been very farsighted in providing for future raw materials and should also be farsighted in the supply of technical personnel to work these raw materials."

Dr. Lord spoke of graduate study and research, dealing more particularly with Canadian problems. He discussed the value of graduate training and the national value of research. He suggested larger fellowships should be granted, with matching amounts to the university. He also suggested that gifts to universities should have fewer strings, with more trust in the university to use the money wisely and well.

E. T. Stewart explored the problem of selectivity in corporate giving. He said there were nearly 2,000 recognized institutions of higher learning and that it was necessary for corporations to limit their programs. He also asked if industry should limit its support to higher education. In concluding his presentation, he said: "Because of the problems of selectivity, corporations have done much experimenting in setting up their aid-to-education programs. On the whole this has been a healthy development. But time will bring more careful evaluations of existing programs to insure their worth."

The discussions which followed the panel presentations were lively and the chairman found it difficult to close off discussion. This was strong evidence indeed of the interest in engineering education on the part of educators and industrialists. Even though no resolutions were passed, the delegates left the conference with a better understanding of the problems of industry's assistance to education, and with new ideas arising from the experience of others.

The Annual Index is in this issue.

INDEX of VOLUME 41, 1958.

*In previous years some students attending University of Toronto have been shown in a course of Aeronautical Engineering. No figure is given for this year and the explanation obtained from the University Calendar 1958-59 is that students in this course up to the level of B.A.Sc. degree are registered in the course in Engineering Physics. Aeronautical Engineering as such is now shown as a course in the School of Graduate Studies.

** Students in Agricultural Engineering who will proceed to their final year in Mechanical or Civil Engineering at the University of Toronto on completion of their studies at Guelph.

***Of these 263 students 45 are expected to enter 3rd year in January 1959 and 27 more will enter 3rd year in April 1959. This is because course intakes at Waterloo are on the "quarter system".

E.C.P.D. 26th Annual Banquet. The Engineers' Council for Professional Development held its 26th annual meeting at St. Louis, Missouri, on October 8 and 9. The Engineering Institute's representative on the executive committee is W. S. Wilson, of Toronto, seated third from the right at the head table. A report of the meeting appeared in the November issue.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected:

Members: A. G. Antonopoulos, Montreal; S. I. Csibor, Montreal; H. C. Dawson, Toronto; H. J. DeSmet, Montreal; R. G. Frederick, Port Hope; H. B. Fuller, Montreal; R. C. Gunn, Toronto; R. F. Harris, London; R. A. C. Hausser, Montreal; C. T. Heeney, Ottawa; A. J. Kruysse, Montreal; M. P. Lawlor, Vancouver; W. F. McGarry, Ottawa; R. F. Marshall, Don Mills; A. G. Moffatt, Winnipeg; W. F. Moore, Arvida; J. G. Sutherland, Hamilton; D. S. Watson, Winnipeg.

Juniors: C. D. Couzens, Toronto; G. Douglas, Montreal; K. L. Smith, Deep River; N. H. Tawfik, Shawinigan.

Affiliate: J. R. Gordon, New York.

Junior to Member: H. A. Benson, Calgary; W. P. Harris, Montreal; G. C. Stewart, Victoria; R. L. Walker, Ceylon.

STUDENTS ADMITTED

Nova Scotia Technical College: P. E. Bowser, S. A. Butcher, R. O. Butler, D. J. Cameron, P. A. Clarke, H. A. Coneen, R. C. Connors, B. K. Conrad, J. R. Dick, J. H. Farrell, R. J. Fougere, D. E. Fraser, R. H. Gillis, L. D. Hicks, G. H. Keenan, D. A. Kilgour, J. R. Landsky, F. C. S. Lee, W. R. Legge,

A. H. K. Ma, J. D. MacDonald, D. J. MacDougall, D. Z. MacInnis, J. H. MacLean, J. M. MacLean, C. J. MacLellan, J. M. P. McCaffrey, C. W. McGillicuddy, J. E. J. McNeil, R. H. Montgomery, M. L. Nickerson, R. E. Nickerson, W. G. G. Nooyen, R. T. O'Dell, J. F. O'Reilly, R. E. Parker, R. H. Poitras, H. A. Sealy, R. P. Shaffelburg, S. J. Smart, R. C. S. Smith, D. J. Sperry, W. J. Stewart, J. S. Sullivan, J. W. Taylor, C. G. Wadden.

University of New Brunswick: F. J. Aucoin, D. Beardsley, W. F. Blair, R. M. Bouchard, J. P. Coombes, W. W. Colpitts, S. E. Dick, J. B. Di Diodato, S. C. Douglass, D. M. Fellows, J. B. Forrest, E. E. Gillespie, J. D. P. Graham, D. G. Hayward, D. E. Hersey, H. W. Hoyt, F. L. Le Fort, J. G. MacDonald, J. F. MacElmon, R. J. Morden, C. R. Reynolds, H. A. Savoy, F. H. Schatz, E. R. Smith, N. H. Walker, J. H. Walsh.

University of Alberta: T. W. Bahniuk, R. L. Coulman, W. A. Dalgliesh, E. Drucker, G. W. Elkington, C. R. G. Halls, C. D. D. Howard, H. Klukas, A. N. Koskowich, C. C. Louis, R. F. Lukey, R. A. MacKett, W. G. Magee, B. Mah, R. F. C. Marriott, J. R. Maze, E. M. Morrison, D. G. Pennell, K. Shimizu, V. A. Sowa, R. S. Thomson.

University of Toronto: J. L. Drolet, C. S. Halliday, R. I. Harvie, W. A. Heard, J. W. Hicks, R. C. Landsborough, M. C. Mapp, A. Mottershead, M. J. Seliga, W. B. West.

Sir George Williams College: L. Geller, N. W. Harvison, M. Konecny, J. G. Meek, J. G. Mezofenyi, N. G. Novak.

Dalhousie University: E. W. Jones, J. A. MacKenzie, R. S. Smith, R. C. Trider, K. P. Wong.

St. Dunstan's University: E. J. Arsenault, J. M. Kennedy, W. E. Power, L. J. Praught.

Royal Military College: J. A. F. L. Gagnon, W. H. Rozel.

Laval University: M. Tremblay.

University of Sherbrooke: R. G. Boily.

University of Toronto: J. R. Britton, W. K. Wells.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

Alberta

Members: H. D. Hamer-Hunt, P. Teensma.

Manitoba

Members: W. E. A. Brandford, H. O. Coish.

Nova Scotia

Members: G. A. Collins, H. H. Jones, J. C. Marsh, L. Meszaros, A. E. Steeves, G. S. Trivett, J. H. White; **Junior to Member:** A. T. Ball, G. R. Pond, J. H. Merritt.

DID YOU KNOW THAT

There are now three publications of The Engineering Institute: *The Engineering Journal*, issued monthly; *Transactions* of The Engineering Institute of Canada, issued quarterly; and *Engineering Careers in Canada*, issued yearly.

COMMITTEES

Admissions: Roger Brais, *chairman;* W. H. Gauvin, D. H. Hobbs, R. J. Harvey, D. G. Laplante.

Board of Examiners: J. L. deStein, *chairman;* J. M. Cape, J. Hurtubise.

Canadian Standards Association (Technical Council): *Institute Representative,* (to be appointed).

Finance: Albert Deschamps, *chairman;* J. M. Breen, R. L. Dunsmore, T. W. Eadie, R. A. Emerson, F. G. Ferrabee, O. M. Solandt, R. L. Weldon.

Canadian Chamber of Commerce: F. G. Rutley, *Institute Representative* on National Board of Directors.

Legislation: R. B. Winsor, *chairman;* C. G. Kingsmill, D. C. MacCallum.

Library and House: C. E. Frost, *chairman;* W. D. Kirk, E. D. Gray-Donald, W. C. M. Luscumbe.

Membership: R. H. Self, *chairman.*

Publication: H. A. Mullins, *chairman.* W. K. Bruce, W. H. Gauvin, R. E. J. Layton, D. W. R. McKinley.

Papers: J. H. Budden, *chairman;* R. Boucher, D. H. Hobbs, H. L. Johnston, M. McMurray, E. R. Smallhorn, H. S. Van Patter.

Prairie Water Problems: G. A. Gaherty, *chairman;* P. M. Sauder, *vice-chairman;* T. D. Stanley, *secretary;* C. S. Clendening, D. W. Hays, B. Russell, G. L. MacKenzie, H. J. McLean, J. M. Wardle.

Policy: Albert Deschamps, *chairman;* B. G. Ballard, R. L. Dunsmore, R. L. Hearn, R. E. Heartz, I. P. Macnab, D. M. Stephens, J. B. Stirling, W. G. Swan, I. R. Tait.

Professional Interests: E. B. Jubien *chairman;* G. A. Gaherty, *vice-chairman;* W. E. Brown, G. J. Currie, W. G. Swan, H. L. Branchaud, E. K. Phillips, I. R. Tait.

Property: F. G. Rutley, *chairman;* A. Deschamps, V. B. King, C. N. Murray, R. C. Pybus, L. Austin Wright.

Student Policy: C. G. Southmayd, *chairman;* J. Dubuc, R. E. Jamieson, E. J. Muszinski, A. Pakalnins, J. F. Riel.

Technical Operations: F. L. Lawton, *chairman;* B. G. Ballard, C. E. Frost, R. M. Hardy, A. R. Harrington, W. H. Paterson, D. L. Rigsby, S. Sillitoe, E. R. Smallhorn.

Confederation: I. R. Tait, *chairman;* L. J. Hammerschmid, *secretary;* C. M. Anson, H. W. L. Doane, T. Foulkes, H. T. Libby, J. McMillan, W. S. Wilson, L. Austin Wright, J. Leo Roy.

OFFICERS OF THE BRANCHES

AMHERST
Chairman, J. W. Wilson; *Vice-Chair.*, D. J. Rockwell; *Executive*, F. C. Wightman, L. E. Burrill, R. G. Baxter.
Sec.-Treas., G. R. Pond, 7 Victoria Street West, Amherst, N.S.

BAIE COMEAU
Chairman, V. M. Wallingford; *Executive*, Peter Suttie, G. Scott, J. M. Pope; *Treasurer*, T. G. Rust.
Secretary, Emil Bodmer, 197A Champlain Street, Baie Comeau, Que.

BELLEVILLE
Chairman, T. E. Flinn; *Vice-Chair.*, W. Benger; *Exec.*, V. L. Lewis, E. Hilbig, W. Canniff, N. Throop, D. Law.
Sec.-Treas., F. E. Moore, 71 Golfdale Blvd., Belleville, Ont.

BORDER CITIES
Chairman, C. Maurice Armstrong; *Vice-Chair.*, J. E. Dykeman; *Executive*, R. H. Darke, F. P. Mascarin, A. W. Malmberg; *Treasurer*, E. R. Carpenter.
Secretary, J. M. Reid, 1511 York Street, Windsor, Ont.

BROCKVILLE
Chairman, W. N. Simmons; *Vice-Chair.*, D. C. Turner; *Executive*, R. B. McRuer, W. E. Morden, F. E. Trewartha, K. R. Bullock, J. F. Preston.
Sec.-Treas., D. B. Ashenden, 58 Abbott Street, Brockville, Ont.

CALGARY
Chairman, F. L. Perry; *Executive*, D. F. Kobylnyk, P. S. Grant, G. A. Hutton, T. Covello; *Treasurer*, R. G. Price.
Secretary, O. O. Junker, c/o Cumming Galbraith Ltd., 1510a - 1st St. S.W., Calgary, Alta.

CAPE BRETON
Chairman, J. V. Palmer; *Vice-Chair.*, W. L. Dodson; *Executive*, G. Ross, J. R. Wallace, H. Maitland, R. Bradley, P. Terry, J. Stevens; *Treasurer*, C. A. Campbell.
Secretary, H. M. Aspinall, P.O. Box 485, Sydney, N.S.

CENTRAL BRITISH COLUMBIA
Chairman, E. R. Gayfer; *Vice-Chair.*, P. Tassie; *Executive*, R. G. Harris, D. G. Hepburn, D. Wales.
Sec.-Treas., W. J. M. Owen, 634 Eckhardt Avenue West, Penticton, B.C.

CHALK RIVER
Chairman, C. A. Crawford; *Exec.*, J. G. Melvin, C. E. L. Hunt, J. S. Flavelle.
Sec.-Treas., W. O. Findlay, P.O. Box 339, Deep River, Ont.

CORNER BROOK
Chairman, E. A. Leja; *Vice-Chair.*, K. F. St. George; *Treasurer*, W. S. Read.
Secretary, Eric R. Skanes, c/o Bowater's Engineering Dept., Corner Brook, Nfld.

CORNWALL
Chairman, W. Rothwell; *Executive*, L. H. Snelgrove, J. Moriarty, J. Pescod, M. Broadbent, M. S. Thompson, F. J. Willis.
Sec.-Treas., D. W. C. McEwan, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.

EASTERN TOWNSHIPS
Hon. Chair., A. C. Crepeau, G. M. Dick; *Chairman*, G. P. Cote; *Vice-Chair.*, J. C. Davidson; *Executive*, E. T. Harbert, M. Lafreniere, G. B. Moffat, J. M. Fletcher, M. Dufresne, J. Moreau; *Treasurer*, A. S. Mitchell.
Secretary, J. Bourassa, 1699 White Street, Sherbrooke, P.Q.

EDMONTON
Chairman, T. H. Newton; *Vice-Chair.*, S. R. Sinclair; *Executive*, I. G. Finlay, J. C. Moon, A. Sandilands, G. A. McNeill, H. Hole, R. H. Gardener, R. H. Nicolson, J. Longworth.
Sec.-Treas., G. Hodge, 10615 - 146th St., Edmonton, Alta.

FREDERICTON
Chairman, O. I. Logue; *Vice-Chair.*, William L. Barrett; *Executive*, L. W. Smith, M. P. Estey, R. C. Ballance, K. O. Bartlett, R. S. Shepherd, G. D. Reeleder. *Treasurer*, E. C. Garland.
Secretary, Robert D. Neill, 150 Miles St., Fredericton, N.B.

HALIFAX
Chairman, J. D. Kline; *Vice-Chair.*, W. J. Phillips; *Executive*, J. G. Belliveau, G. M. Haliburton, A. H. MacKinnon, K. R. Mitchell, M. C. Sutherland-Brown, J. R. Cameron, L. D. Hopkins, B. E. Langley, R. B. Killam, M. A. Marshall.
Sec.-Treas., J. E. Reardon, P.O. Box 33, Halifax, N.S.

HAMILTON
Chairman, R. C. Mitchell; *Vice-Chair.*, H. E. Seely; *Executive*, P. J. McNally, T. O. Watts, J. A. Mitchell, A. F. Barnard.
Sec.-Treas., W. A. H. Filer, 23 Maple Ave., Hamilton, Ont.

HURONIA
Chairman, H. C. Bates; *Vice-Chair.*, S. R. Walkinshaw; *Executive*, D. M. Harris, C. G. Campbell, J. L. Armstrong, J. E. Sears, J. W. Davies, R. G. Freeman.
Sec.-Treas., L. Morgante, 36 Borland Street West, Orillia, Ont.

KINGSTON
Chairman, R. B. Wotherspoon; *Vice-Chair.*, W. M. Campbell; *Executive*, D. C. MacPherson, F. M. Wood, R. J. Kennedy.
Secretary, D. I. Ourom, c/o Aluminum Company of Canada Ltd., Kingston, Ont.

KITCHENER
Chairman, C. A. Leicht; *Vice-Chair.*, W. J. Horner; *Executive*, R. Dahmer, W. Bobbie, G. Tidswell, H. Walters.
Sec.-Treas., A. H. Austin, Armco Drainage & Metal Products of Canada Ltd., Box 300, Guelph, Ont.

KOOTENAY
Chairman, J. T. Higgins; *Vice-Chair.*, D. J. Turland; *Executive*, R. F. Bailey, L. S. Piper, G. C. Rogers, E. Rohatynski, W. V. Nicholson, R. J. Portman; *Treasurer*, J. I. McClelland.
Secretary, J. L. P. Limbert, 649 Forrest Drive, Trail, B.C.

LAKEHEAD
Chairman, W. D. MacKinnon; *Vice-Chair.*, J. E. Rymes; *Executive*, G. A. Walker, J. A. Brown, L. B. Walker, J. W. Lukey, P. W. Pinn, W. H. Bulger, J. H. Hargrove.
Sec.-Treas., C. M. Cotton, 2-304 N. Syndicate Ave., Fort William, Ont.

LETHBRIDGE
Chairman, W. B. Thomson; *Executive*, G. B. Davies, R. L. Francis, J. A. Wilihan.
Sec.-Treas., R. D. Hall; Utility Engineer, City Engineer, Lethbridge, Alta.

LONDON
Chairman, R. W. McMeekin; *Vice-Chair.*, C. H. Osborne; *Executive*, G. W. Chorley, H. E. Martin, L. S. Lauchland, G. O. Hayman, G. E. Wilson.
Sec.-Treas., W. C. Sinkins, London Steel Construction Co. Ltd., P.O. Box 69, London, Ont.

LOWER ST. LAWRENCE
Chairman, L. P. Dancose; *Vice-Chair.*, A. Michaud; *Executive*, A. A. Albert, R. Boisvert, A. Leroux, F. Roy.
Sec.-Treas., Donald F. Caveen, c/o Public Works Dept. of Canada, Federal Building, Rimouski, Que.

MONCTON
Chairman, C. L. Trenholm; *Vice-Chair.*, W. M. Steeves; *Executive*, F. F. Burchell, L. F. Clifton, D. A. Foster, H. S. McCleave, C. E. Spear, R. F. Weir.
Sec.-Treas., V. C. Blackett, 97 MacBeath Avenue, Moncton, N.B.

MONTREAL
Chairman, P. W. Gooch; *Vice-Chair.*, R. A. Phillips; *Executive*, R. J. Harvey, R. J. Kane, L. L'Allier, H. Audet, C. A. Colpitts, J. O. McCutcheon.
Sec.-Treas., G. M. Boissonneault, Shawinigan Water and Power Co., P.O. Box 6072, Room 809, Montreal, Que.

NEWFOUNDLAND
Chairman, C. W. Henry; *Vice-Chair.*, A. M. Butt; *Executive*, R. P. Hunt, D. S. Templeton, G. A. Myers, H. W. Goudie, S. Miller, J. P. Pike.
Sec.-Treas., R. L. Smyth, Imperial Oil Limited, Centre Building, St. John's, Nfld.

OFFICERS OF THE BRANCHES

NIAGARA PENINSULA

Chairman, D. A. Barnum; *Vice-Chair.,* D. O. D. Ramsdale; *Exec.,* R. T. Bailey, W. D. Tanner, H. S. Lundy, W. J. Smith, W. J. O'Reilly, F. R. Denham, G. E. Griffiths.
Secretary, F. R. Denham, c/o Electro-Metallurgical Company, Welland, Ont.

NIPISSING AND UPPER OTTAWA

Chairman, J. S. Cooper; *Vice-Chair.,* J. M. Rosborough; *Executive,* J. Warburton, H. Staniforth, R. S. MacLennan, D. Catford, P. Rebin, D. W. Briden.
Sec.-Treas., D. W. Briden, 353 Worthington Street West, Apt. 12, North Bay, Ont.

NORTH EASTERN ONTARIO

Chairman, A. A. Kidd; *Vice-Chair.,* J. S. Whyte; *Executive,* C. McIntyre, J. Blakeman, J. N. Greggain, J. Shipman, M. McLean, W. Swann, G. Flett.
Acting Secretary, A. A. Kidd, P.O. Box 640, Cochrane, Ont.

NORTHERN NEW BRUNSWICK

Chairman, D. C. MacCallum; *Vice-Chair.,* J. A. Mersereau; *Executive,* K. A. W. MacDonald, T. H. McSorley, P. Dallien, P. J. Delicaet, F. B. Ervine.
Sec.-Treas., S. K. Henry, P.O. Box 269, Dalhousie, N.B.

NORTH NOVA SCOTIA

Chairman, J. E. Clarke; *Vice-Chair.,* J. K. Godfrey; *Executive,* J. L. Cavanagh, Wm. Fogarty, F. C. Morrison, J. Ferguson.
Sec.-Treas., R. S. Morrow, 151 Almont Ave., New Glasgow, N.S.

NORTH SHORE LOWER ST. LAWRENCE

Chairman, B. M. Monaghan; *Executive,* R. W. Kenway, M. Michaud, M. Storrier.
Sec.-Treas., L. E. Fisher, Iron Ore Company of Canada, Dock Terminal, Sept-Iles, Que.

OTTAWA

Chairman, Hector Chaput; *Vice-Chair.,* John S. Watt; *Executive,* A. H. Graves, T. M. Patterson, R. C. Silver, H. A. MacKenzie; *Treasurer,* Hugh C. Brown.
Sec.-Treas., W. V. Morris, Water Resources Branch, Department of Northern Affairs and National Resources, Ottawa, Ont.

PETERBOROUGH

Chairman, I. N. MacKay; *Executive,* J. L. Olsen, V. Aare, R. A. Blount, W. H. Powell, J. G. Cooper, C. W. Holman, D. J. Kawaja, P. Tuck, G. W. McPhee, E. R. Shirley.
Sec.-Treas., G. M. Locke, Civilian Atomic Power Dept., Canadian General Electric Co. Ltd., 107 Park St. N., Peterborough, Ont.

PORT HOPE

Chairman, T. F. Kennedy; *Vice-Chair.,* J. A. Pollock; *Executive,* J. L. Sylvester, D. A. Runciman, T. S. Bradfield.
Sec.-Treas., R. Waterfall, 81 Hope Street North, Port Hope, Ont.

PRINCE EDWARD ISLAND

Chairman, C. W. Currie; *Vice-Chair.,* A. Coles; *Executive,* J. D. M. MacDonald, L. E. Slaght, A. D. Cameron.
Sec.-Treas., R. D. Donnelly, P.O. Box 184, Charlottetown, P.E.I.

QUEBEC

Life Honorary Chairman, A. R. Decary; *Chairman,* Roger Desjardins; *Vice-Chair.,* P. A. Duchastel; *Executive,* Lionel Boulet, J. B. Delage, Hugh Kane, P. E. Begin, L. Joncas, Jacques Roy.
Sec.-Treas., Marc Bergeron, Concrete Repairs and Waterproofing Co., 128 Blvd. Ste. Anne, Quebec, Que.

SAGUENAY

Chairman, F. A. Brown; *Vice-Chair.,* D. W. Stairs; *Executive,* G. C. Gauthier, L. Tessier, J. J. Falardeau, H. S. Monahan, R. Thompson, S. Solinski, A. Sinclair.
Sec.-Treas., D. L. Aker, 309 Racine St., Arvida, Que.

SAINT JOHN

Chairman, H. W. M. Townshend; *Vice-Chair.,* J. W. G. Scott; *Executive,* G. C. Robinson, P. W. Hastings, K. V. Cox, G. C. Mouland.
Sec.-Treas., D. I. Higgins, 30 Elizabeth Court, Saint John, N.B.

ST. MAURICE VALLEY

Chairman, J. P. Woods; *Vice-Chair.,* W. A. Pangborn, T. W. Ross; *Treasurer,* M. G. Fraser.
Secretary, J. Carson, 568-6th Ave., Grand'Mere, Que.

SARNIA

Chairman, J. H. Douglas; *Executive,* M. Waghorne, J. Miller, A. W. Wirth, C. M. Stewart, M. Brown.
Secretary, R. F. Routledge, c/o Imperial Oil Limited, Sarnia Refinery, Sarnia, Ont.

SASKATCHEWAN

Chairman, J. C. Traynor; *Vice-Chair.,* J. B. Mantle; *Executive,* E. J. Cole, J. D. A. Mollard, M. F. Pardoe, K. W. Allcock, M. B. Pierce, B. B. Torchinsky.
Sec.-Treas., R. Bing-Wo, 2043 Cameron St., Regina, Sask.

SAULT STE. MARIE

Chairman, R. H. Tooley; *Vice-Chair.,* L. F. Mason-Tulby; *Executive,* K. I. Fletcher, K. E. Kansikas, W. H. Hogg, W. B. Sproule.
Sec.-Treas., R. L. Wimperis, c/o General Delivery, Sault Ste. Marie, Ont.

SUDBURY

Chairman, W. B. Ibbotson; *Vice-Chair.,* E. M. Powell; *Executive,* H. W. Whittles, B. Russell.
Sec.-Treas., W. J. Ripley, 14 Miller Crescent, Lockerby, Ont.

TORONTO

Chairman, R. Harvey Self; *Vice-Chair.,* A. C. Davidson; *Executive,* L. F. Bresolin, A. M. Toye, G. F. R. Norton, R. R. McLaughlin, I. S. Patterson, R. A. Rule, B. L. Farrand, Cameron MacInnis, I. S. Gauley, M. H. Pryce.
Sec.-Treas., C. L. Thompson, c/o Honeywell Controls Limited, Leaside, Toronto 17, Ont.

VANCOUVER

Chairman, W. G. Heslop; *Vice-Chair.,* C. P. Jones; *Executive,* C. H. White, J. F. Muir, E. S. Rhodes, W. J. Johnson, J. H. Swerdfeger, J. J. Kaller; *Treasurer,* R. H. Carswell.
Secretary, Ronald Clough, 1232 Dogwood Crescent, North Vancouver, B.C.

VANCOUVER ISLAND

Chairman, G. Griffiths; *Vice-Chair.,* H. Graham; *Executive,* H. T. Miard, L. C. Johnson, W. G. McIntosh, A. F. Paget.
Sec.-Treas., J. A. Cowlin, 1044 Hillside Avenue, Victoria, B.C.

WINNIPEG

Chairman, L. A. Bateman; *Vice-Chair.,* W. L. Wardrop; *Executive,* R. N. Sharpe, R. T. Harland, W. D. Hurst, T. E. Storey, J. P. C. McMath, N. Mudry, J. B. Striowski, N. S. Bubbis, N. M. Hall, H. A. Dalkie, L. E. Poyser, S. H. Eggertson, R. Barschel.
Sec.-Treas., C. S. Landon, Room 418–265 Portage Ave., Winnipeg 2, Man.

YUKON

Chairman, Lt.-Col. D. M. C. Saunders; *Treas.,* J. Scott.
Secretary, E. W. King, P.O. Box 1189, Whitehorse, Y.T.

ONTARIO DIVISION

Chairman, M. A. Montgomery; *Vice-Chair.,* H. R. Sills; *Treasurer,* G. R. Turner; *Board of Management,* P. E. Buss, H. G. Conn, E. R. Davis.
Secretary, J. G. Hall, 92 Heddington Ave., Toronto, Ont.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Fraser Sanderson Keith, M.E.I.C., retired manager of the Shawinigan Water and Power Company's Department of Development and general secretary of the Engineering Institute from 1917 to 1925, died on October 28, 1958 at Smith's Falls, Ont.

Born at Smith's Falls, Ontario, on June 8th, 1878, he attended school there, after which he went to McGill University and graduated with a B.Sc. degree in electrical engineering in 1903.

After graduation he joined the staff of McGill University for a one-year term as senior demonstrator in the electrical engineering department. Subsequently he gained a very extensive experience in editorial work with a number of well-known Canadian technical publications, *Canadian Machinery*, 1904-05-06, *Canadian Manufacturer*, 1907, *Construction*, 1917, occupying such positions as managing editor and editor.

In 1908 he went to Vancouver, and for the following six years was engaged in concrete construction and the manufacture and sale of concrete materials. Returning to Eastern Canada early in 1915, he became manager of technical publications, eastern region, with the MacLean Publishing Company, during which time he wrote a series of articles on the adoption of ingenious methods by Canadian manufacturers, in the manufacture of ammunitions, which articles were afterwards published by the Australian Government as a guide to similar production on that continent.

His association with The Engineering Institute of Canada began in 1917, on his appointment as general secretary. The Engineering Journal was designed and inaugurated in 1918 by Mr. Keith as manager and editor.

Helped by the initiative and ability of Mr. Keith, the Institute made rapid and steady progress during the period. The Institute increased its branches across Canada from nine to twenty-four and its membership from 3,100 to 5,400.

He was official Canadian delegate to the first World Power Conference in London in 1924.

Mr. Keith resigned as general secretary in 1925 to assume the post of manager of the Department of Development, Industrial and Public Relations with the Shawinigan Water and Power Company, Montreal. He retired in 1944.

Throughout his life he was active in the McGill Graduates Society. He held various offices in the organization leading to his election as president, 1943-1944. His election as a graduates' representative on the board of governors of McGill, for a three-year term, was announced in 1945. He was granted a life-membership in the Society in 1953.

Mr. Keith joined the Institute as a Student Member in 1902, became Associate Member in 1909, and a Member in 1921. In 1947 he attained Life Membership in the Institute.

D. W. Hays, M.E.I.C., a noted engineer, pioneer and authority on Western Canadian irrigation development, died on September 12, 1958, at Medicine Hat, Alta. Mr. Hays had been living in retirement in the Southern Alberta community since 1950.

David Walker Hays, for whom an Alberta community in the Vauxhall district of the province was named, in honour of his accomplishments in irrigation, was born at Bridgeport, Calif., on March 24, 1878. He attended the MacKay School of Mines, at Reno, Nevada, and received a Bachelor of Science degree at 1900. In his early graduate career Mr. Hays worked briefly with the Department of Highways, State of California, and with a U.S. geological survey as a field assistant. With the United States Reclamation Service, he was shortly thereafter engaged in the construction of irrigation works in Nevada and California, on the general investigation of five irrigation projects in those states.

On the instigation of a group of British investors he moved to Canada in 1912 to study the irrigation problems in this once-dry corner of Alberta. The firm was called the Southern Alberta Land Company.

Mr. Hays was a prominent figure in the early-day history of the old Southern Alberta Land Company which became the Canada Land and Irrigation Company. For thirty-nine years he directed the affairs of the company from his Medicine Hat headquarters.

Mr. Hays was elevated to a higher post when the Southern Alberta Land Company fused its interests with those of the Canadian Wheatlands and the Alberta Land Company to form the Canada Land Irrigation Company, with control of 530,000 acres. In 1925 he was named general manager. A quarter of a century later the Canada Land Irrigation company was sold to the Dominion, becoming the Bow River Development. Mr. Hays retired at that time, having lived to see the irrigation of 40,000 acres of land.

During his long years of public service Mr. Hays was instrumental in the establishment of the Ronalane Experimental Station brought into being by the Canada Land.

He was also called into service as a consultant on the Royal Commission on the proposed South Saskatchewan River dam, and on the Bow River development.

Mr. Hays joined the E.I.C. as a Member in 1918. He was named to Life Membership in 1949.

S. C. Montgomery, M.E.I.C., vice-president of the Engineering Institute, representing the Western Provinces for a two-year term, 1957-1959, died at Calgary on October 19. Mr. Montgomery was a maintenance engineer with the Consolidated Mining and Smelting Company, smelting and refining division, Trail, B.C.

Samuel Clifford Montgomery was born in Winnipeg on July 24, 1894, and had his schooling there. He graduated from McGill University with a B.Sc. degree in mechanical engineering in 1915.

Enlisting in the Canadian Field Artillery almost immediately, he served with the First Division in France, the Fifth Brigade, Second Division, and won the Military Cross.

After a refresher course at the Royal Technical College, Glasgow, he returned to Canada late in 1919.

Re-established in this country he began the next phase of his engineering career as a designing draughtsman with the Whalen Pulp and Paper Company in British Columbia, worked in the logging industry on Vacouver Island and in 1925 became assistant superintendent of construction and maintenance.

In 1929 he joined the Consolidated Mining and Smelting Company at Trail as a designing draughtsman, later as an assistant construction engineer on the Tadanac plants. His last professional responsibility as maintenance engineer, smelting and refining department was announced in 1948.

Mr. Montgomery joined the Engineering Institute as a Student Member in 1911, transferred to Junior status in 1920, Associate in 1929, Member in 1940. A charter member of the Kootenay Branch he was its first chairman and councillor.

F. S. Keith, M.E.I.C.

D. W. Hays, M.E.I.C.

S. C. Montgomery, M.E.I.C.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

ONTARIO

A multi-purpose education foundation has been established by the 17,000-member Association of Professional Engineers of Ontario. Known as the Ontario Professional Engineers' Foundation for Education, one of its basic purposes will be to provide financial assistance to members of the teaching profession and persons proposing to become teachers who will specialize in mathematics and science subjects.

C. T. Carson, president of the A.P.-E.O. points out that "there is a dangerous shortage of qualified maths and science teachers in this country at present". He adds that the Association hopes the establishment of such a foundation will encourage an increasing interest in these subjects by teachers. The foundation will also promote and assist the post-graduate training and education of professional engineers to enable them to achieve higher professional qualifications. The foundation will accept contributions, gifts, bequests and legacies, with gifts being deductible for income tax purposes. The foundation was approved by the Association's Executive Council as a means of augmenting the present scholarship program undertaken by the engineering body The existing program includes a $500 scholarship given in alternate years annually to the University of Toronto and Queen's University for the student entering an engineering course at either university with the highest academic standing in grade XIII. Additional annual scholarships each valued at $250.00 are awarded at both universities in the first. second and third years.

The newly-established education foundation will be administered by the Association's permanent staff which is headed by Col. T. M. Medland, executive director.

BRITISH COLUMBIA

(Taken from the B.C. Professional Engineer, October issue, by A. H. Ashworth, P.Eng., member of the editorial board.)

Unfair to Ourselves

No self respecting Professional Engineer would ever want to be accused of being a square peg in a round hole amongst his fellow members, and yet this risk is inadvertently run at times.

When the day arrives on which an engineer retires from active service, how gratifying it would be for him to be able to look back upon his term of office with an easy conscience and a realization that he took all the opportunities which arose to help make the lot of his colleagues a happier one.

Can every engineer honestly say to himself that he has taken each opportunity to give his fellows a helping and understanding hand? It is easy to turn a blind eye, especially if the other fellow is a new or younger person.

Medicine, not engineering, is the one profession that labours incessantly to destroy the reason for its own existence. In comparing the Medical Profession, however, we see amongst its members an admirable spirit of friendly co-operation and mutual assistance that sets them above other professions in this respect.

That luck represents a real factor in human experience is evident to us all, and he who does not expect ill-fortune as one of the ingredients of life is trying to live in a fantasy world of his own. However, bad luck can come with unnecessarily crippling force against those engineers who have to battle constantly with not only the occupational hazards of the profession but also indifference from their colleagues who may be in more secure positions.

You can't fool all the people all the time, but it isn't necessary. A majority of the people will do: and most people think that engineers all pull together and are like a great big happy family. Much patient self-inspection is indicated, for ignorance is a voluntary condition.

Each engineer, as he works away in his career, could do no harm to remember to be helpful to his fellow engineers on his way up, if only because he would meet them all again on the way down.

It is easy to look down on others; to look down on ourselves is the difficulty. Let us all, in this great profession, pause a moment to see if we are as Shakespeare describes: "As sick that surfeit with too much, as they that starve with nothing."

CANADIAN COUNCIL

(Taken from the B.C. Professional Engineer, October issue)

The Canadian Council was recently requested to express an opinion on the present employment situation in the engineering profession. In view of the absence of complete and accurate statistics it was felt that the best source of information would be the secretariats of the various provincial associations. The information obtained is summarized below.

In the less industrialized provinces, the situation appears to be somewhat balanced. No engineers are known to be unemployed and known vacancies for engineers are few or non-existent.

In the more industrialized provinces there appears to be an over-supply of engineers, the extent of which is extremely difficult to evaluate.

Although the number of known unemployed engineers appears to be relatively low, most large employers of engineers are doing their best to find employment for their engineering staff at the expense of technicians and others in order to have a trained engineering staff available when needed in the future. Some of these admit that they could function with 10 per cent less than they now have.

In addition, a large number of professional engineers are still being employed for work that could be adequately carried out by sub-professionals or technicians and are unable to find more suitable employment.

1958 graduates received mostly only one offer while several were still unemployed two months after graduation.

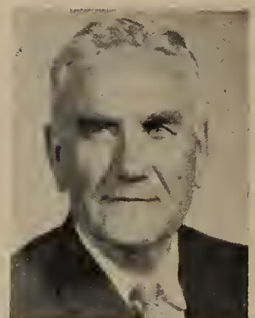
From the above, we can conclude that there is presently in Canada an over-supply of engineers which exceeds substantially the actual number of engineers known to be unemployed.

From present enrolment, it can be fairly accurately estimated that total graduations in engineering from our universities in the next four years will be 10,500 and, in view of the present over-supply, it can be safely predicted that Canada will not be faced with a critical shortage of engineers during that period even assuming a substantial improvement in economic activity.

Personals

News of the Personal Activities of Members of the Institute

L. B. Stacey, M.E.I.C.



D. A. McCuaig, M.E.I.C.

R. C. Short, M.E.I.C.

W. A. Dawson, M.E.I.C. (B. Sc., Mech., Queen's 1923), has been appointed assistant sales manager, Brown Boggs Foundry and Machine Co Ltd., Hamilton, Ont. Associated with two of Canada's leading machine tool distributors in the posts of sales engineer and branch manager since 1946, Mr. Dawson has 20 years of experience in industrial engineering and manufacturing. He is a past chairman, Hamilton Branch, E.I.C., 1953.

J. G. Little, M.E.I.C., (B.A.Sc., chem., Toronto, 1928), has recently been appointed general manager of the wire and cable division of the Northern Electric Company Limited, Montreal.

Mr. Little who has devoted his entire career to the Company, held various positions in the firm, including those of works manager, electronics division, in 1946, works manager, wire and cable division, 1950, and assistant manager of the division, 1956.

Major E. A. Marshall, M.E.I.C., M.B.E., C.D., (B.Sc., civil, Manitoba, 1936), Canadian Army retired, has accepted a position as vice-president in charge of the military pyrotechnics division of the T.W. Hand Fireworks Company Limited, with headquarters in Ottawa. Mr. Marshall formerly headed the ammunition design and development section, Canadian Army. He represented Canada at many meetings of NATO groups of experts on ammunition.

Gordon R. Henderson, M.E.I.C., (B.Sc., civil, Queen's, 1925), has been elected president and director of the Catalytic Construction of Canada Limited, at the Sarnia, Ont., headquarters of the organization. Mr. Henderson is the person originally responsible for the formation of Catalytic in Canada. He assumed the general managership of Catalytic's Canadian activities in 1951. He was appointed general manager of the Sun Oil Company Limited refinery, Sarnia, in 1953, in connection with the Catalytic organization and has held the post until the present time.

R. C. Short, M.E.I.C., (B.A.Sc., elec., Toronto, 1949), has been appointed Ontario district manager for Ferranti-Packard Electric Limited. His previous appointment was that of district manager for the Quebec division of Packard Electric Company Limited, Montreal.

D. A. McCuaig, M.E.I.C., (B.Sc., elec., Manitoba, 1923), has been named Manitoba district manager for Ferranti-Packard Limited. At an earlier date he was district manager with Ferranti, for Ontario, with headquarters in Toronto, and for Western Canada, at Winnipeg.

L. B. Stacey, M.E.I.C., (B.A.Sc., British Columbia, 1924), district manager for the Packard Electric Company Limited, Vancouver, has been named district manager, B.C., for Ferranti-Packard Limited. Mr. Stacey joined Packard Electric Company Limited in 1944.

Richard Scott, M.E.I.C., (B.A.Sc., elec., Toronto, 1941; M.Sc., Massachusetts Institute of Technology, 1948), is a senior associate of the management consulting firm of J. Edgar Dion and Company Limited, Montreal. Mr. Scott was for many years a member of the faculty of applied science and engineering, University of Toronto. Mr. Scott most recently was associated with Canadian Aviation Electronics Limited as manager, manufacturing division.

J. Homer Johnston, M.E.I.C., (B.Sc., Queen's 1910), since 1951 chief maintenance engineer for the Province of Alberta has retired. Mr. Johnston devoted his entire career to Alberta and the northern area of the country. On graduation he was appointed assistant Dominion Land Surveyor, for the Federal Government. He surveyed the Coalspur area west of Edmonton, and was, the following year, commissioned as a Dominion Land Surveyor, carrying out many surveys in the Peace River and Grande Prairie areas. In 1921 he headed an exploratory canal trip of mapping and surveying from Peace River, Alta., to Great Slave Lake, N.Y.T. He was dis-

W. A. Dawson, M.E.I.C.

R. Scott, M.E.I.C.

Major E. A. Marshall, M.E.I.C.

J. G. Little, M.E.I.C.

J. H. Johnston, M.E.I.C.

trict engineer at Peace River from 1925 to 1948, and then assistant chief maintenance engineer, at headquarters, Edmonton, until the time of his most recent posting.

Wm. A. Devereaux, M.E.I.C., (B.A.Sc., mech., Toronto, 1937), formerly district manager of the Halifax office of Bailey Meter Company Limited, in charge of sales and service work in the Atlantic provinces, is now district manager of the Winnipeg branch of the company. He is in charge of similar work for Saskatchewan, Manitoba and Northwestern Ontario.

D. L. B. Hamlin, M.E.I.C., (B.A.Sc., civil, Toronto, 1943), has been appointed to take charge of structural engineering for the firm of Margison and Keith, engineers and architects, Toronto. Mr. Hamlin was an associate of the firm of A. D. Margison and Associates, recently reorganized.

Colonel J. S. Beeman, M.E.I.C., (B.A.Sc., chem., British Columbia, 1935), has been promoted to military observer with the United Nations Military Observer Group in India and Pakistan. Col. Beeman was formerly assistant quartermaster general,

G. M. Beaumont, M.E.I.C.

T. H. Newton, M.E.I.C.

Lt.-Col. A. Mendelsohn, M.E.I.C.

at Canadian Army, western command headquarters.

Group Captain Chas. W. Crossland, M.E.I.C., (B.Sc., McGill, 1931; M.Sc., aeronautical, M.I.T., 1932), former assistant for standardization, at R.C.A.F. headquarters, Ottawa, has been named visiting assistant professor at McGill University.

Lieutenant Colonel A. Mendelsohn, M.E.I.C., (B.Eng., mech., McGill, 1939), was former commander of the R.C.E.-M.E., First Canadian Infantry Division. A new posting has named him assistant director of electrical and mechanical engineering at Canadian Army headquarters, Ottawa.

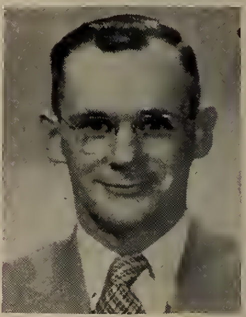
T. H. Newton, M.E.I.C., (B.Sc., civil, Alberta, 1948), of Edmonton holds the office of chairman of the E.I.C. Branch in that city. Mr. Newton has followed his engineering career with Main, Rensaa and Minsos, Edmonton, as resident engineer and as Canadian representative with the Lee Oil and Natural Gas Company, Edmonton.

C. W. Henry, M.E.I.C., (B.Sc., elec., New Brunswick, 1946), is chairman of the Newfoundland Branch of the E.I.C. for 1958. Mr. Henry is professionally associated with the Newfoundland Light and Power Company Limited at St. John's, Nfld., as a transmission and substation engineer. Early in his career he went to Maracaibo, Venezuela as assistant distribution engineer with C. A. Energia Electrica de Venezuela.

G. M. Beaumont, M.E.I.C., (B.Sc., mech., Sask., 1949), has left the consulting engineering firm of Underwood, McLellan and Associates Limited, Saskatoon and has returned to the University of Saskatchewan to study law.

Mr. Beaumont has had engineering experience as chief engineer in charge of water and sewage treatment, plant design, at a number of Western Canadian points.

Roy C. Leslie, M.E.I.C., (B.A.Sc., M.Sc., civil, Toronto 1923), of the Dominion Steel and Coal Corporation Limited, Canadian Bridge division, Toronto, has been named to a new post. Formerly district contracting engineer, the appointment is that of assistant sales manager in



C. W. Henry, M.E.I.C.

the same division of the company. He is a past secretary and chairman of the Border Cities Branch.

Professor P. S. Mani Sundaram, M.E.I.C., (B.E., civil, Madras, India, 1950; M.Eng., structural, Nova Scotia Technical College, 1958); is under the auspices of the Colombo Plan associated with the St. Lawrence Seaway Authority. Professor Sundaram is a civil engineering department head at the A.C. College of Engineering and Technology, an affiliate of the University of Madras, South India.

Prof. P. S. Mani Sundaram, M.E.I.C.

R. B. Hill, JR.E.I.C.

C. Newton Hopkins, M.E.I.C., (B.A.Sc., chem., U.B.C., 1949), who joined Hooker Chemicals, Vancouver, in 1957, has been named plant engineer with the firm. Earlier he was associated with Canadian Industries Limited in several locations in Eastern Canada. He worked in various supervisory positions in operations and maintenance.

Robert C. Sadler, M.E.I.C., (H.N.C., mech., Worcester, England, 1951), former projects engineers in the Meter division, of Ferranti-Packard Electric Ltd., Toronto, is now senior mechanical engineer, electronics department, Stromberg-Carlson, San Diego, Calif.

Active in Institute affairs while in Canada, Mr. Sadler was a publicity chairman, on the P.D.P. directorate, Toronto, 1956-57; secretary-treasurer, 1957; chairman P.D.P. National committee 1957; and E.I.C. representative from Toronto to E.C.P.D. training committee meeting in Pittsburgh last May.

W. L. Dodson, M.E.I.C., (B.E., mech., N.S.T.C., 1946), has recently been promoted from assistant superintendent to superintendent of the heavy mills department, Dominion Iron and Steel Company, at Sydney, N.S.

Major David Veitch, M.E.I.C., CD, R.C.E., (B.Sc., civil, Queen's 1948), has been posted to the Royal Canadian School of Military Engineering, at Camp Chilliwack, B.C., as officer commanding, military engineering squadron. Major Veitch was formerly Canadian Engineer Liaison Officer to the Engineer-in-Chief, the War Office, London, England.

Claude Langlois, M.E.I.C., (B.Eng., civil, McGill, 1953), is a partner in the firm of Cote, Leclair & Langlois, consulting engineers in Sherbrooke, Que. Since graduation Mr. Langlois has added to his engineering skills in gaining experience with the Montreal consulting firm of Leblanc & Montpetit, 1953-1956, and with the Donahue Electric Company, Sherbrooke, Que.

Wm. Birks, M.E.I.C., (B.Sc., mech., Queen's, 1945), has been named manager of Du Pont Company of Canada's linear polyethylene plant being built in Sarnia. He was formerly operations manager of the plastics division of the company in Montreal. Earlier he was assistant works manager in the company's Shawinigan works.

James Craig, M.E.I.C. (B.Eng., civil Liverpool 1950) of the McColl-Frontenac Oil Company Ltd., Montreal East Refinery, has transferred his services to the Warnoc Hersey Co. Ltd., St. John's, Newfoundland, as branch manager. While in Montreal, Mr. Craig was design and construction engineer for the company.

Douglas S. Laidlaw, M.E.I.C, (B.A.Sc., civil, Toronto, 1928), of Ottawa, is project engineer for the R.C.A.F. maritime development, which consists of the construction of hangars and related facilities to house the Argus at Greenwood, N.S., and Summerside, P.E.I. The design phase is nearing completion and construction is underway.

Robert B. Hill, JR.E.I.C., (B.A.Sc., engineering and business, Toronto, 1950; M. Comm., business admin., Toronto), assistant to the vice-president of operations, Canada Iron Foundries Limited, for the past two years, has accepted an appointment as chief industrial engineer, Dominion Bridge Company Limited.

R. C. Hale, JR.E.I.C., (B.Sc., civil, New Brunswick, 1956), Athlone Fellow, has returned to Canada from Great Britain. A member of the Ocean Steel and Construction Company, St. John, N.B., his work is that of project engineer. Mr. Hale spent his first year in England at the London School of Economics and Political Science where he completed a post-graduate course in business administration. During the second year of the Fellowship his headquarters were at the Cleveland Bridge and Engineering Company, London.

John D. Riddle, JR.E.I.C.

John D. Riddle, JR.E.I.C., (B.A.Sc., mech., Toronto, 1953), product engineer with the S. A. Armstrong Co. Ltd., at Toronto, has been named chief engineer with the firm of Clarke-Parry Air Conditioning Ltd., also in that city.

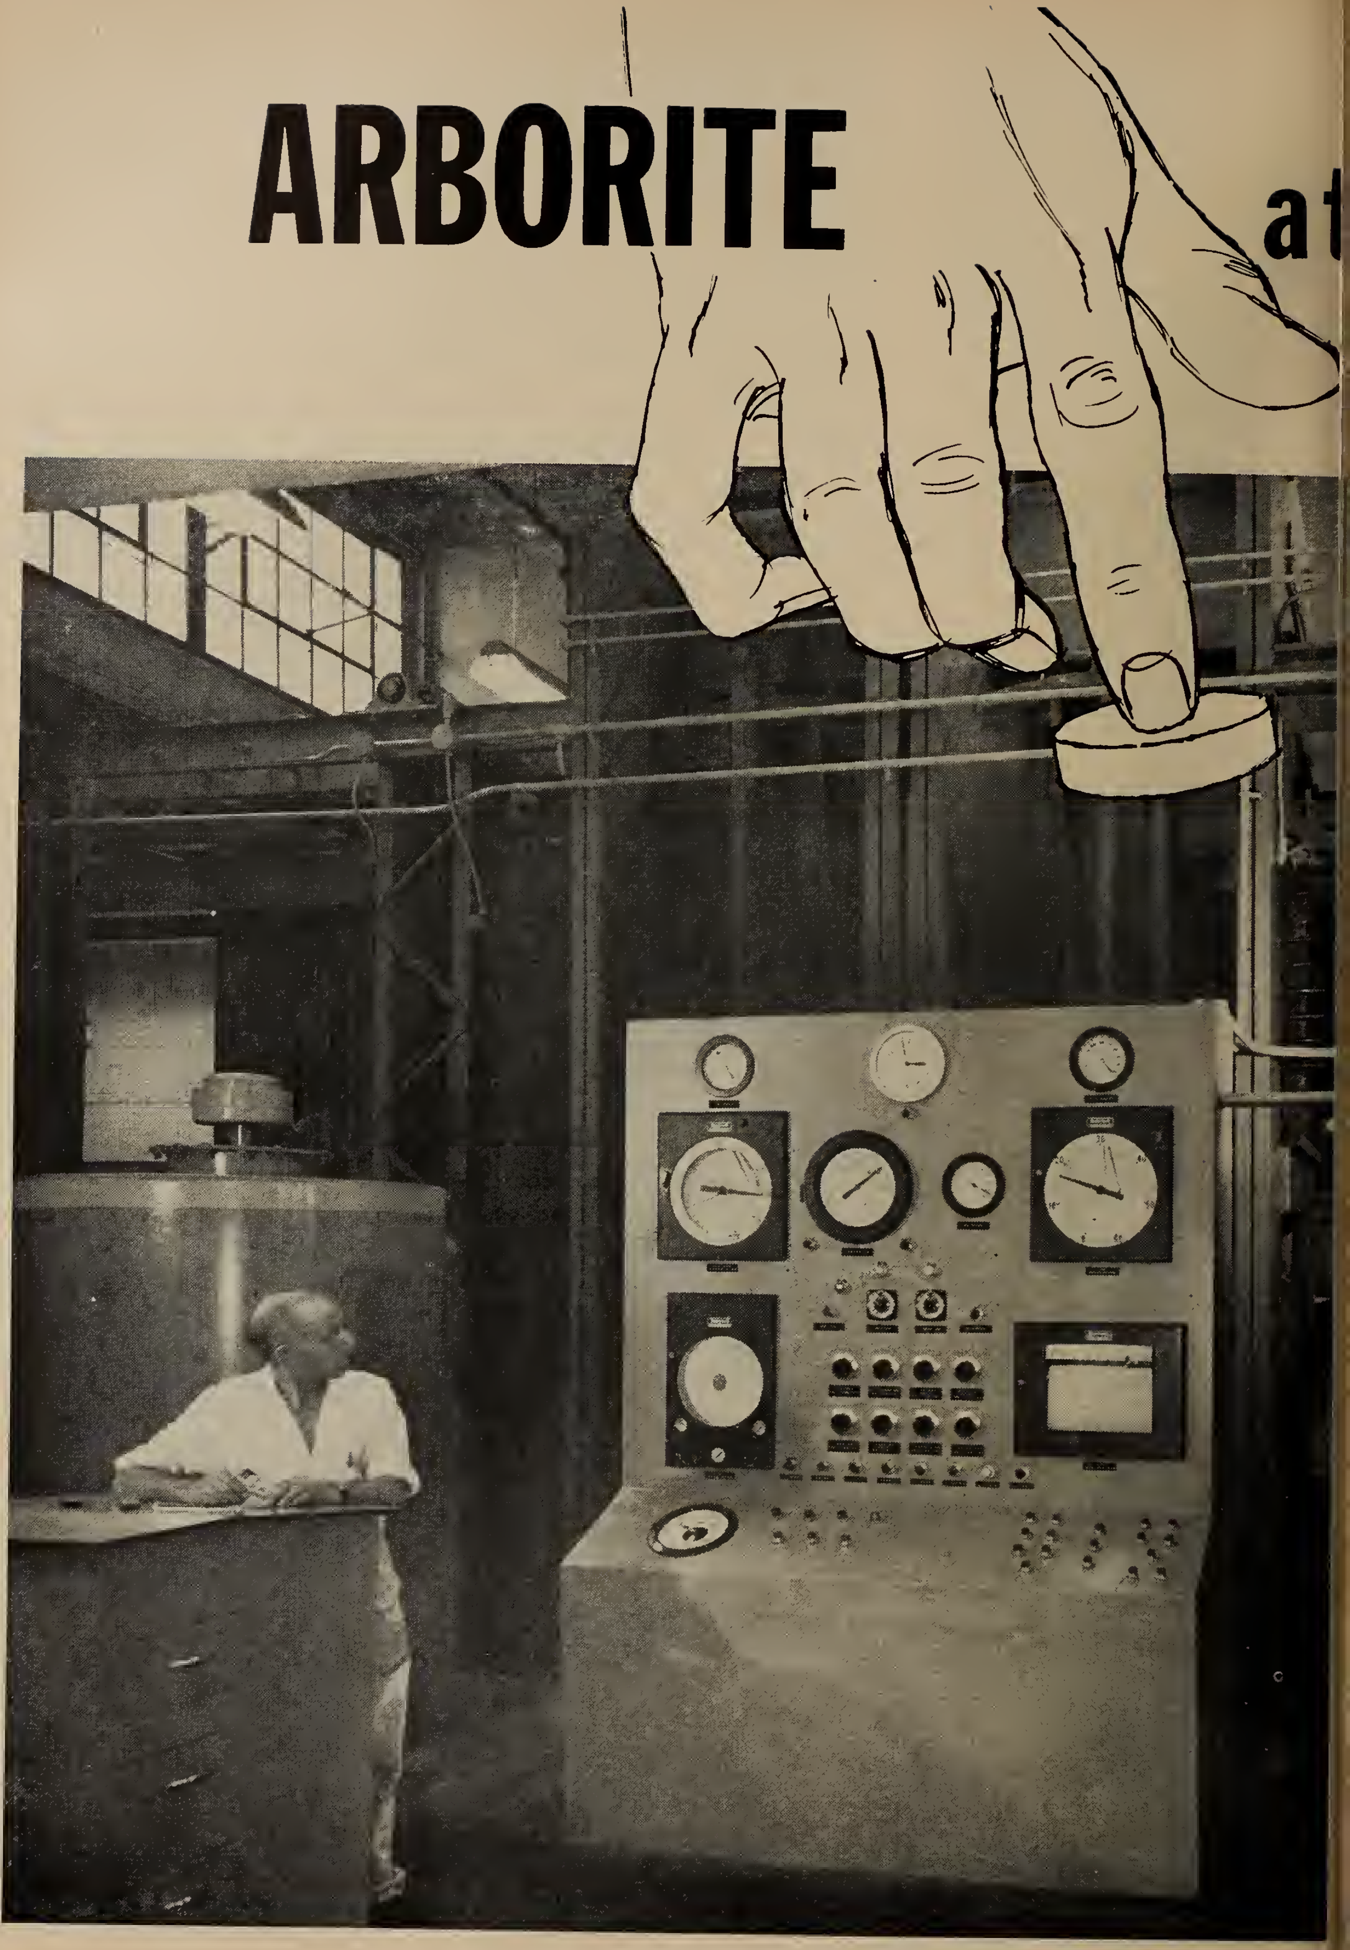
G. R. Naylor, JR.E.I.C., (B.Sc., elec., Manitoba, 1951), whose position was formerly sales engineer with Packard Electric Company Limited, Toronto, has been named co-ordinating engineer for Ferranti-Packard Electric Limited, St. Catharines, Ont. Mr. Naylor began his career with the British General Electric Company, Toronto, as junior engineer and estimator.

B. J. Armstrong, JR.E.I.C., (B.A.Sc., Engineering & Business, Toronto, 1955), has been named to represent a Canadian group in London, England. He is United Kingdom Technical representative for the Plywood Manufacturers Association of B.C. Earlier he represented the Association in Toronto.

E. R. Corneil, JR.E.I.C., (B.Sc., Mech., Queen's, 1955), is carrying on his engineering career in the field of education

B. J. Armstrong, JR.E.I.C.

ARBORITE at



• PERSONALS

as a lecturer at Queen's University, Kingston, in the Mechanical Engineering Department.

Mr. Corneil, an Athlone Fellow who recently returned to Canada, has for the past three years been following studies leading to a Ph.D. degree at Imperial College, University of London, London, England.

R. Lazar, JR.E.I.C.

Ronald Lazar, JR.E.I.C., (B.Sc., civil, Man., 1955; M.Sc. civil, Illinois 1957) a design engineer with Ammann & Whitney, consulting engineers, New York, has returned to Canada. Mr. Lazar holds the appointment of assistant professor in civil engineering, University of Manitoba.

Jean E. Villeneuve, JR.E.I.C. (B.Sc., civil, Laval, 1956), has completed studies made in Great Britain under the auspices of an Athlone Fellowship. Once again resident in Quebec City, he is employed with the St. Lawrence Construction Company Ltd.

Mr. Villeneuve was awarded a D.I.C. in concrete technology from Imperial College, London, England.

Mr. Villeneuve was president of Quebec City student branch EIC while attending Laval University.

Ralph W. Culley, S.E.I.C., (B.Sc., civil, Alberta 1958), works as a project engineer with the Department of Highways, Province of Saskatchewan, Yorkton, Sask.

Blaise Cliche, S.E.I.C., (B.A.Sc., metall., Ecole Polytechnique, 1958), is working in the Metallurgical Laboratory at Canadair Limited as Engineer "C".

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings

BELLEVILLE

F. E. Moore, M.E.I.C., *Sec.-Treas.*

D. A. Law, JR.E.I.C., *Branch News Reporter*

Baie comeau, quebec was brought to the attention of the Branch at a November 10 meeting, by Allan Hughes of the C. D. Howe Company, Montreal, who gave an interesting and informal talk on the British Aluminum Company Dock at Baie Comeau, Que. Three technical papers on the subject having appeared in the *Journal*. Mr. Hughes restricted himself to some of the more interesting highlights of the 78 million dollar project. A number of coloured slides of the project including the dock smelter and townsite, illustrated the complexity and size of the operation, and impressed the group.

Mr. Hughes was entertained at dinner by the branch chairman, T. E. Flinn and M. A. Janitsch, who introduced the speaker.

Scholarship Awards

The Scholarship award of $25 was raised to $50, half of which would go to each of the secondary schools to the grade XIII student entering engineering with the highest standing in English, mathematics and science.

J. A. Grant, past chairman of the branch made the award to Jim Green at the Quinte Secondary School on October 17, 1958. Mr. Green received a total of $3200 in scholarships and prizes. This allowed him to start on an engineering education which would have been otherwise impossible. Besides being a remarkable student, he was also a top athlete.

Thomas Benger, M.E.I.C., vice-chairman, made a presentation of a branch award at the Belleville Collegiate and Vocational Institute, October 24, 1958. The student selected, carried away approximately $1200 in scholarships and prizes.

The Border Cities Branch executive with E.I.C. headquarters visitors on the occasion of a dinner-dance, Oct. 17, 1958. Back: l. to r., J. M. Reid, F. P. Mascarin, A. Barker, R. Darke, E. Dykeman, A. Malmberg, Front: Dr. L. A. Wright, general consultant, E.I.C., Dr. K. F. Tupper, president and Dr. Garnet T. Page, general secretary of the Institute.

The new executive of the Lower St. Lawrence Branch. Back row: l. to r., Roland Boisvert, director, Donald Caveen, sec.-treas., August Albert and Fernand Roy, directors. Front: Andre Leroux, director, Jean Menard, past-president, Leon-Paul Dancose, president, and Andre O. Michaud, vice-president.

BROCKVILLE

G. R. Bowes, JR.E.I.C., *Sec.-Treas.*

W. E. Morden, M.E.I.C., *Branch News Reporter*

Water and sewage problems in Canada were considered by about 40 members at a meeting devoted to the subject on October 27. Chief spokesman was J. J. Powell of Gore and Storrie, consulting engineers, Toronto. Mr. Powell outlined water and sewage problems in the Brockville area before describing wider national aspects, in terms of the various types of installations to be found across Canada.

As far as Brockville is concerned, the central part of the town was built some 60 years ago, and the sewage system was comprised of sanitary and storm pipes of only 8-inch diameter. It is now necessary to modify the system to take care of modern day practices, as well as the expanded population. The new areas on the outskirts of Brockville are equipped with 16-inch pipe lines for the sanitary and storm sewers. Complete modification of the town will have to await an integrated system comprising new mains, water pumping station at the west end, and also a revamped sewage system.

The new pumping station to cost $1,200,000 includes a water purification plant employing micro strainers, a 30" intake, plus a new main distribution piping system for the water supply. The

micro strainers, now standard with the industry in Canada, remove all vegetation and foreign material down to a size of 35 microns.

Mr. Powell showed slides of the water and sewage systems throughout Canada, including Cornwall, Kingston, Edmonton, Toronto, Peterborough, Trenton, etc.

The speaker was introduced by Walter Ashworth, of Automatic Electric Company, Brockville.

HALIFAX

W. J. Phillips, M.E.I.C.,
Branch News Correspondent

J. E. Reardon, M.E.I.C., *Sec.-Treas.*

Sir Claude Gibb, K.B.E., F.R.S., who, on visits to Canada has been a spokesman before the Branches on several occasions, addressed the Halifax Branch on October 27. Sir Claude is professionally associated with the firm of C. A. Parsons and Company, Newcastle-on-Tyne, England. His talk, "Developments in Nuclear and Orthodox Power Stations dealt mainly with the design and construction of the Bradwell Power station with special emphasis on the reactor and other allied auxilliaries. Recent trends in large thermal plant generators such as Parson's design for a 550 MW unit was mentioned. Current trends observed in the United States as a result of a recent visit to Oak Ridge and shipping port and the difference in American and British approach to fundamental design. Films and slides were used as a visual aid to his remarks.

J. A. McLaren, Eastern field secretary, was a recent visitor to Halifax. He attended the October meeting of the Branch executive, and heard Sir Claude's talk. At Wolfville, N.S., he addressed the engineering students at Acadia University, later attended an informal supper, meeting students and senior members of the Institute residing in the area.

At Bridgewater, N.S., a similar event took place. Mr. McLaren was accompanied by members of the Halifax Branch executive and other members of the Branch on each occasion.

The 1958 Golf Tournament, Eastern Townships Branch, Sept. 27. L. to r.: G. P. Cote, Branch chairman, R. Dugre, receiving Fabi Trophy from Sam Fabi, of Fabi and Fils Ltee; G. J. Cote, R. Payette, and J. Lemieux.

HAMILTON

J. R. Currie, M.E.I.C.,
Branch News Reporter

W. A. H. Filer, JR.E.I.C., *Sec.-Treas.*

The annual engineers' ball attracted about 200 couples for a good time at Fischers' Hotel on Friday, October 10.

Mr. and Mrs. Wm. Filer entertained some of the special guests at their home before the dance. Present for the occasion were H. G. Conn, Kingston, vice-president, E.I.C., and Mrs. Conn; C. T. Carson, Windsor, president of the Association of Professional Engineers of Ontario, and Mrs. Carson; Mr. and Mrs. Eric St. John, Montreal; Mr. and Mrs. L. Jacobson, Montreal; Mr. and Mrs. E. Sillett; Mr. and Mrs. R. C. Mitchell, chairman, Hamilton section, E.I.C., Mr. and Mrs. A. C. MacDonald.

KINGSTON

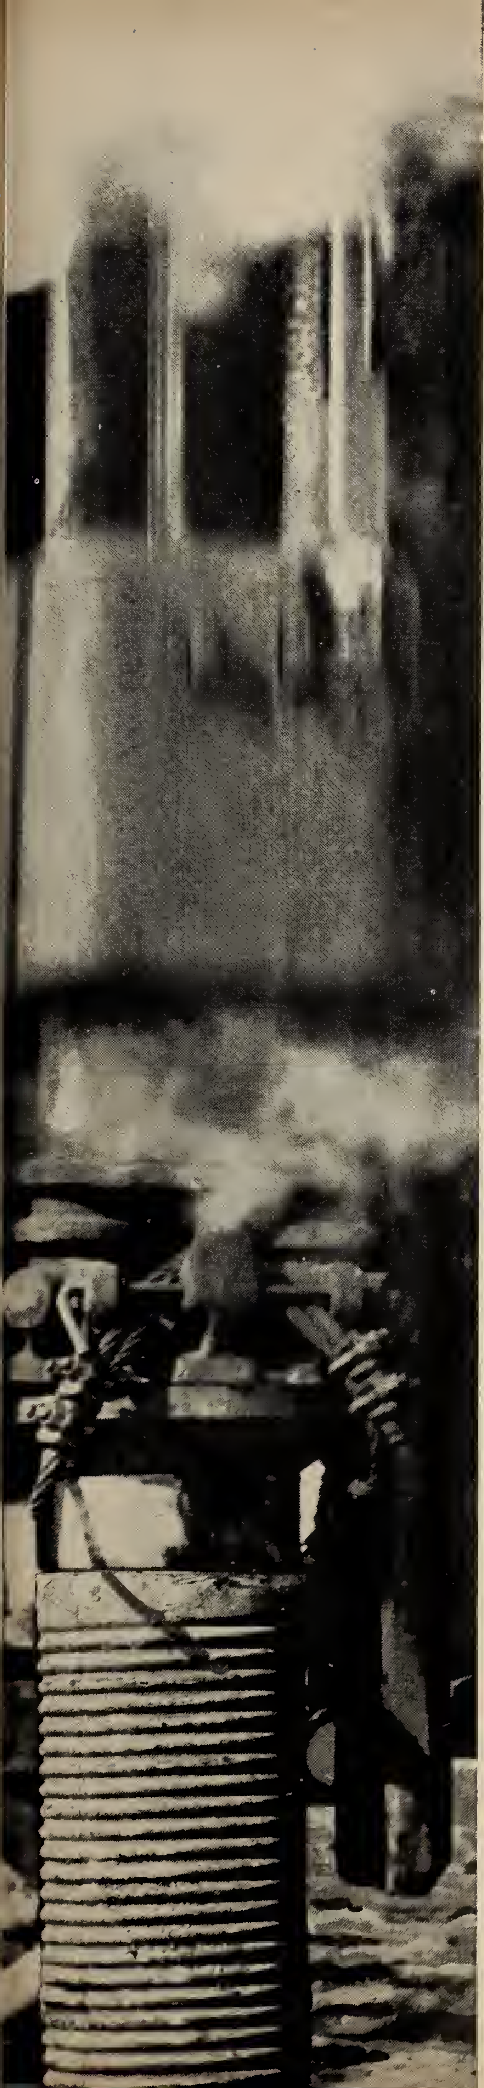
D. I. Ourom, JR.E.I.C., *Secretary and Branch News Reporter*

Dr. A. E. Berry, general manager of the Ontario Water Resources Commission outlined the functioning of the Ontario Water Resources Commission at a meeting held on September 23. He explained in some detail the reason for its existence and the service rendered to communities of all sizes. The terms of work, the matter of surveys, designs, construction and operation of water purification plants, sewerage disposal, and treatment works, which the Commission will undertake in a municipality, were put before the assembled members. The many problems confronting his department in supplying the province's growing water needs and solving pollution problems were discussed. Examples were given of work accomplished and that which remains to be done. The paper was well illustrated with slides showing the projects they have worked on to date.

Talk on Design Racing Yachts

"Some aspects of the Design of Racing Yachts," was the title of the remarks directed to Kingston members by Colonel Peter King at an October 21st meeting. Colonel King, retired head, department of mechanical engineering, Royal Military College, Kingston, is an associate professor, mechanical engineering at Queen's University.

The factors governing the design of racing yachts, the structural strength necessary to such a boat, and the form of the hull, were discussed. To give his audience some idea of the effects of wind and wave on hull and rigging, and



how to resolve this problem, Col. King outlined the structural features and consideration. Hull shapes, advantages and disadvantages of the small changes which can be made within the rules set down for racing yachts was explained. Illustration, with a model racing yacht, clarified the basic methods for transferring a selected design into the necessary transverse, longitudinal and diagonal cross sections.

Colonel King showed a number of slides of an aluminum alloy framed 28 ft. yacht which he is building, and pointed out valuable and poor design features.

After a discussion, past-president L. F. Grant discussed the recent America Cup Races at Newport, R.I. which he attended. Referring to Colonel King's paper he explained the reasons for Sceptre's defeat.

KITCHENER

John F. Runge, M.E.I.C.,
Branch News Reporter

A. H. Austin, JR.E.I.C., *Sec.-Treas.*

A FIELD TRIP to the sponge rubber division, Dominion Rubber Company, Merchants Rubber Factory, Kitchener, Ont., on October 31 was enjoyed and described as excellent by the Kitchener Branch.

The visit was made to the Koylon foam rubber plant, the most recently constructed plant in Canada devoted solely to the production of foam rubber. For this reason it has the newest and latest equipment available.

The production of foam rubber is primarily a chemical process which is dependent on mechanical processing and control equipment for effective and efficient processing.

A general talk on the foam rubber process preceded Laboratory demonstration of foam production and a tour was made of the manufacturing facilities.

KOOTENAY

G. T. J. Hughes, M.E.I.C.,
Branch News Reporter

J. L. P. Limbert, JR.E.I.C., *Secretary*

THE LATE S. C. MONTGOMERY, vice-president E.I.C., Western region, gave a brief report of Zone A activities at a recent meeting of the Branch. Under the chairmanship of J. T. Higgins, councillor W. K. Goyer presented a comprehensive report covering all aspects of the conference held in Quebec.

Mr. Higgins added an appeal to all members of the Branch to submit papers on various aspects and subjects relating to this work for inclusion in Branch programs.

European Tour

W. G. Small, past Branch chairman showed slides of his European tour of Belgium, Great Britain, France and Portugal. Highlight of the trip was an absorbing visit to the World Fair in Brussels. Mr. Small delighted the audience with his impressions of the various buildings, including the U.S.S.R. pavillion and the renowned structure, the Atomium.

A witty commentary accompanied the slide showing.

LETHBRIDGE

R. F. Smith, JR.E.I.C., *Sec.-Treas.*

G. Campbell, JR.E.I.C.,
Branch News Reporter

THE ANNUAL JOINT dinner meeting with the Association of Professional Engineers of Alberta, held October 25 drew an attendance of fifty persons.

Deputy Mayor J. Wilton extended a cordial welcome on behalf of the City to Dr. Govier, guest speaker, and A.P.E.A. president, visitors and engineers.

Dr. Govier stressed the existence of chemical and petroleum engineering, University of Alberta, and a member of the petroleum and natural gas conservation board of Alberta.

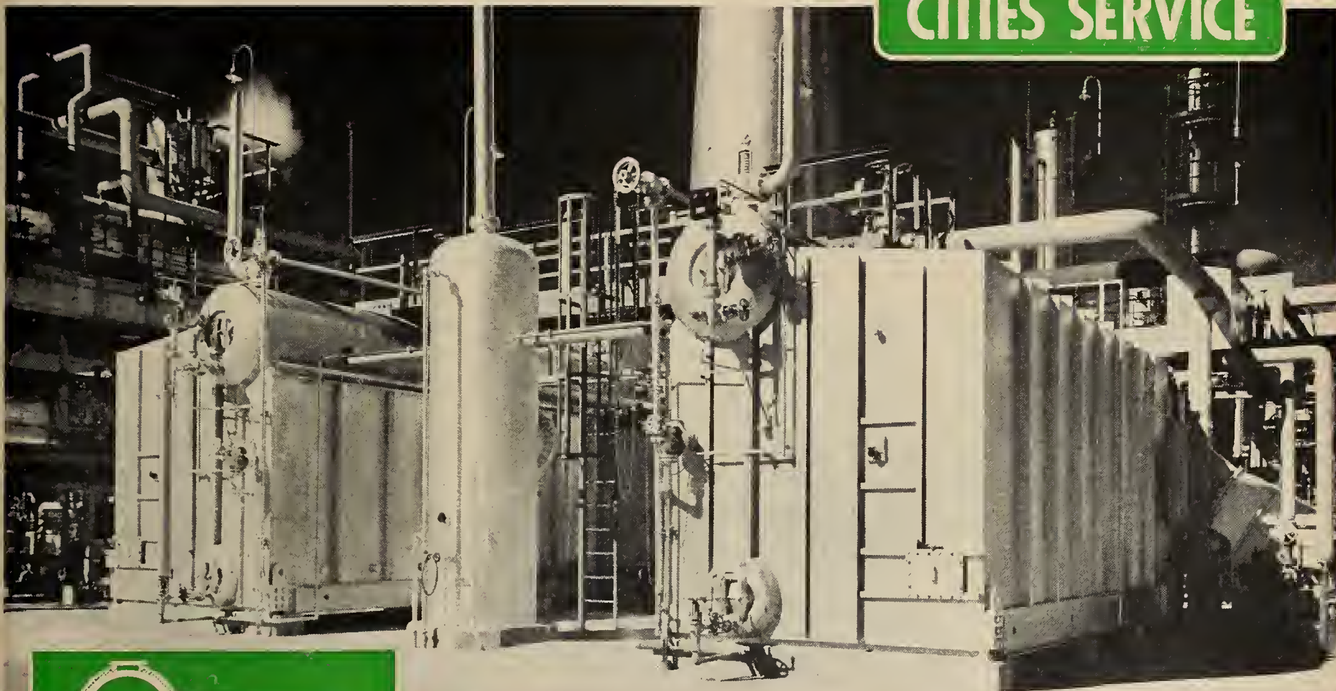
Dr. Govier is head, department of the A.P.E.A. for protection of the public, on the authority of the Alberta Legislature. Appointed for maintenance of

NEW HIGHER CAPACITY

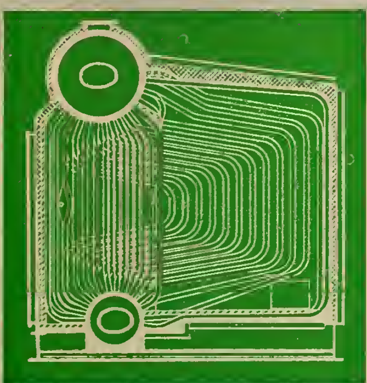
PACKAGED STEAM GENERATORS

INSTALLED AT....

CITIES SERVICE



Two AG-246 units, each capable of generating 50,000 lbs/hr sold to C. F. Braun & Co. of Canada Ltd. and installed at the new Cities Service Refinery at Trafalgar, Ontario.



FEATURES:

- Final Steam Temperatures to 840° F.
- Design Pressures to 900 psig.
- Standard Heat Recovery Arrangements Available.
- 42-inch Steam Drum.
- Two Burners.
- Automatic Controls.
- Suitable For Indoor or Outdoor Installation.
- Tangent Bare Tube Furnace Side Walls and Roof.
- Staggered Boiler Bank Tube Arrangement.
- Fully Drainable and Removable Superheater.

Series AG-200 extends economy and dependability of FW Packaged Design to over 60,000 lb/hr

To meet the needs of industrial plants for high-capacity Packaged Steam Generators, Foster Wheeler, offers units for capacities of 50,000 to 63,000 lb/hr and higher, depending on operating conditions.

A modification of the proven AG-100 design which has provided industry with reliable, economical steam in the range of 10,000 to 50,000 lb/hr, these compact, space-saving units permit more steam capacity in less space than has heretofore been possible.

Branch News Reporter

W. C. Sinkins, JR.E.I.C., *Sec.-Treas.*

An annual joint meeting of the London branches of the E.I.C. and the Association of Professional Engineers of Ontario was held on October 14, 1958. C. T. Carson, president of the latter group and a member of the E.I.C. made a presentation of certificates of registration to two professional engineers. Mr. Carson addressed the meeting on some of the activities of the Association. He explained the reasons behind the recent salary survey and subsequent "Report on Salaries" that was issued to all Professional Engineers. Mr. Carson also spoke on the subject of improving the status of professional engineers.

Gordon McHenry, P.Eng., vice-president of the Association and member of council, was introduced and spoke briefly on Association affairs. Mr. Carson was accompanied by Blake Goodings, P.Eng., field representative of the Association and J. MacLaren, P.Eng., field secretary of the Institute.

NIPISSING AND UPPER OTTAWA

R. A. Booy, JR.E.I.C., *Sec.-Treas.*

R. D. Christie, JR.E.I.C.,
Branch News Reporter

The October meeting held on October 8 featured an informal talk by V. Wolchick of Trans-Canada Pipelines. Mr. Wolchick is superintendent on the Kapuskasing-Toronto section of the line. He was very recently in charge of line location and construction on the Kapuskasing-Toronto section of the line. The route follows Highway 11 closely all the way, to provide easy access. This is considered to be the economical location, even though a cross-country route from the Lakehead to Southern Ontario would have saved several hundred miles of pipe.

An interesting feature of line location is that it is cheaper to turn the pipe and go squarely up the face of a hill than it is to run straight up a diagonal. The reasons are: easier road-building for the pipe-stringing equipment, and less danger of erosion shifting the finished line.

The line was built on contract in seven sections, with each contract sized to finish in the same time. The longest section is 92 miles, mainly through soil at the Toronto end of line, the shortest section is 43 miles through the hardrock at Temagami.

The compressor station at North Bay, currently the only station between the Lakehead and Toronto, has three gas-operated 1800 HP compressors and provisions for three more to be installed later. The compressors are reversible so that in case of a line failure in Northern Ontario, North Bay can feed Texas or Ontario gas back up the line to the point of failure. In normal operation North Bay expects to receive gas from the north at about 450 lb. pressure and raise this to 700-800 lb. output.

Construction of more compressor stations and another parallel pipeline are expected to start soon. Eventually there will be a compressor station every 80 miles along the line with all pressures monitored at North Bay.

An interesting point was brought out concerning weights used on water cross-

ings. Ordinary concrete is only 50 per cent efficient for this purpose due to its buoyancy in mud. Special concrete using iron ore aggregate, giving an efficiency of 60 per cent was used extensively. Metal weights which were used in some muskeg crossings have an efficiency of 80 per cent.

Mr. Wolchick ended his talk with a word for young engineers: Experience is far more important than education when you are looking for advancement, and you can only gain good experience by exercising patience.

NORTHERN NEW BRUNSWICK

Stewart K. Henry, JR.E.I.C., *Sec.-Treas., and Branch News Reporter*

A GENERAL MEETING was held at the Chateau Restigouche Hotel, Campbellton, N.B., October 1, attended by 17 engineers.

T. H. McSorley introduced the speaker of the evening, G. B. Lawson, who until recently was a design engineer with Fraser Company in Edmundston and is presently associated with Fraser Company sales division, Montreal. Mr. Lawson gave an interesting and aptly illustrated paper on the new Steam Plant Extension at Fraser Co.'s Edmundston mill, which produces pulp for the Fraser Company's paper mill in Madawaska, Maine. He initially traced the history of the Edmundston Steam plant to date. The latest extension, initiated in 1956, was constructed to meet the increased production capacity and additional power requirements of the mill. It centered about (1) a new Combustion Engineering H.P. boiler rated at 1250 lbs. pressure and 950°F, (2) a 12,500 Kw extraction turbine and (3) additional feedwater treatment equipment.

It was pointed out that while the Fraser Co. mills at Madawaska and Edmundston have separate power plants, they are connected by a 10,000 KW tie line and therefore it was necessary to consider the two mills jointly in setting up the latest expansion. The speaker then described the operational aspects of the re-vamped plant with the aid of a flow diagram. He stated that the prime object of the plant was to obtain the maximum amount of power at any time; to this aim the new boiler is always run at full capacity and the other two existing 600 lbs. boilers are set to take care of any fluctuations in load. The new boiler went into service on June 16, 1958 and the new turbine was expected to be in service by October 9, 1958.

The speaker was ably thanked on behalf of the Branch by A. W. Rowe. It was moved and seconded that the meeting adjourn. The meeting then retired to the Chateau Bar-B-Cue when a delicious lunch was served.

PETERBOROUGH BRANCH

G. M. Locke, JR.E.I.C., *Sec.-Treas.*

J. G. Hooper, M.E.I.C.,
Branch News Reporter

THE FIRST TECHNICAL ACTIVITY of the Branch for the fall season was a most enlightening visit to Atomic Energy of Canada Limited at Chalk River by 40 branch members on October 18.

Welcome was extended by C. A. Crawford, chairman of the Chalk River Branch of the Institute who also served as guide for one of the four tour groups. An introduction and brief illustrated address on the project preceded the tour. A fortifying lunch was served at the project cafeteria.

The groups were shown the universal cell• and the Canadair designed pool test reactor in detail and later all parts of the NRX and NRU reactor buildings. This opportunity to see these developments first-hand and to have all questions ably and graphically answered proved an ideal means of introducing most of those present to the fundamentals of atomic research and the achievements and problems in practical application of this most recent development in energy harnessing.

The attending group included a good cross-section of those members not already familiar with the work at Chalk River through their work at the Civilian Atomic Power Development at Canadian General Electric Company in Peterborough. All present were enthusiastic about

ECONOMIC NUCLEAR POWER PLANTS were to be looked for in Canada in from five to ten years time, according to J. L. Olsen, sales manager, civilian atomic power department, Canadian General Electric Company, Toronto. Sixty engineers heard the talk which dealt with Canadian Progress Toward Economic Nuclear Power, at an October 9 meeting.

Mr. Olsen said nuclear power plants could be made economic in areas where cost of other energy fuels was high, particularly coal. Ontario had been served well with cheap hydro-electric energy, but had reached its last source in the St. Lawrence Seaway. To meet its expanding needs from this type of energy it would have to go further and further north and it would become more costly. He thought Ontario would have to turn to some form of thermo-nuclear energy.

Using coal as a fuel, electric energy could be produced for two mills per kilowatt hour. Mr. Olsen said that Canadian General Electric believed, judging by development to date, that atomic power plants could be built that would produce electrical energy for a cost less than two mills per kilowatt hour.

Canada had from the start adopted the right concept for the development of nuclear energy, Mr. Olsen said. This country could produce atomic power plants more economically than any country in the world.

At Chalk River, Canadian scientists had developed production of nuclear energy using natural uranium which was mined at several places in this country and therefore relatively cheap as a fuel.

ST. MAURICE VALLEY

J. Carson, JR.E.I.C., *Secretary*

E. A. Love, JR.E.I.C.,
Branch News Reporter

CHINESE JOURNALIST and lawyer, Dr. L. E. Tsao, addressed the Branch at the October 22 meeting. Dr. Tsao's address was entitled "China and its Place in the World Today."

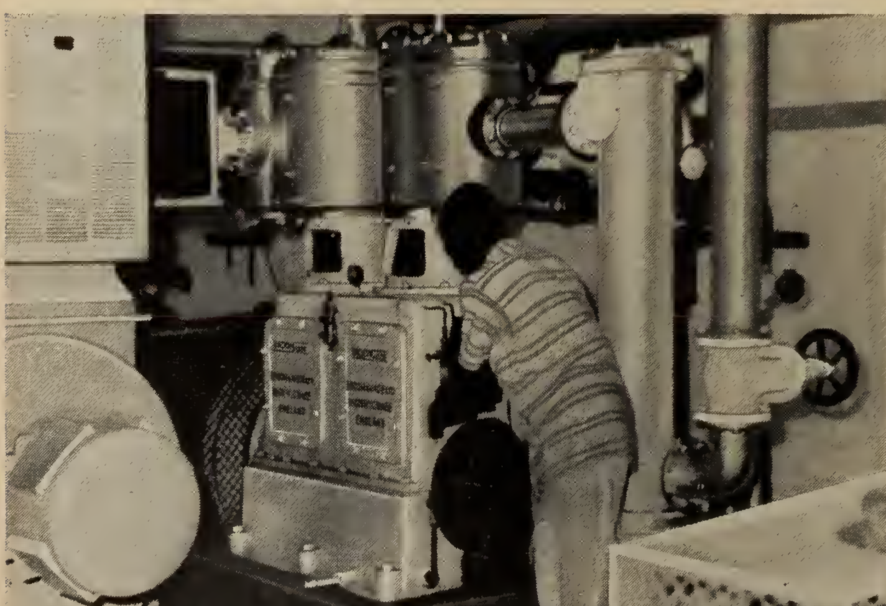
In his opening remarks Dr. Tsao pleaded the value of better understanding between East and West. He pointed out that the East had evolved a civilization based on culture, heavily laden with spiritual and artistic development, which had gone on for hundreds of years prior to contact with the West. During the last two hundred years, contact with the West had wrought abrupt changes, with Western ways more or less forced on the East. A series of wars which began in 1840, the so-called Opium Wars, wrested concession after concession from China. After years of absolute monarchy China became a constitutional monarchy under British influence; followed by the regime of Chiang Kai Shek. Both of these were of course unsuccessful legislation for China, and gave way to the experiment of Communism now being tried. Dr. Tsao explained that China is looking for an identity. The present regime will not endure, he thought, because of the need of the country to continue to grow.

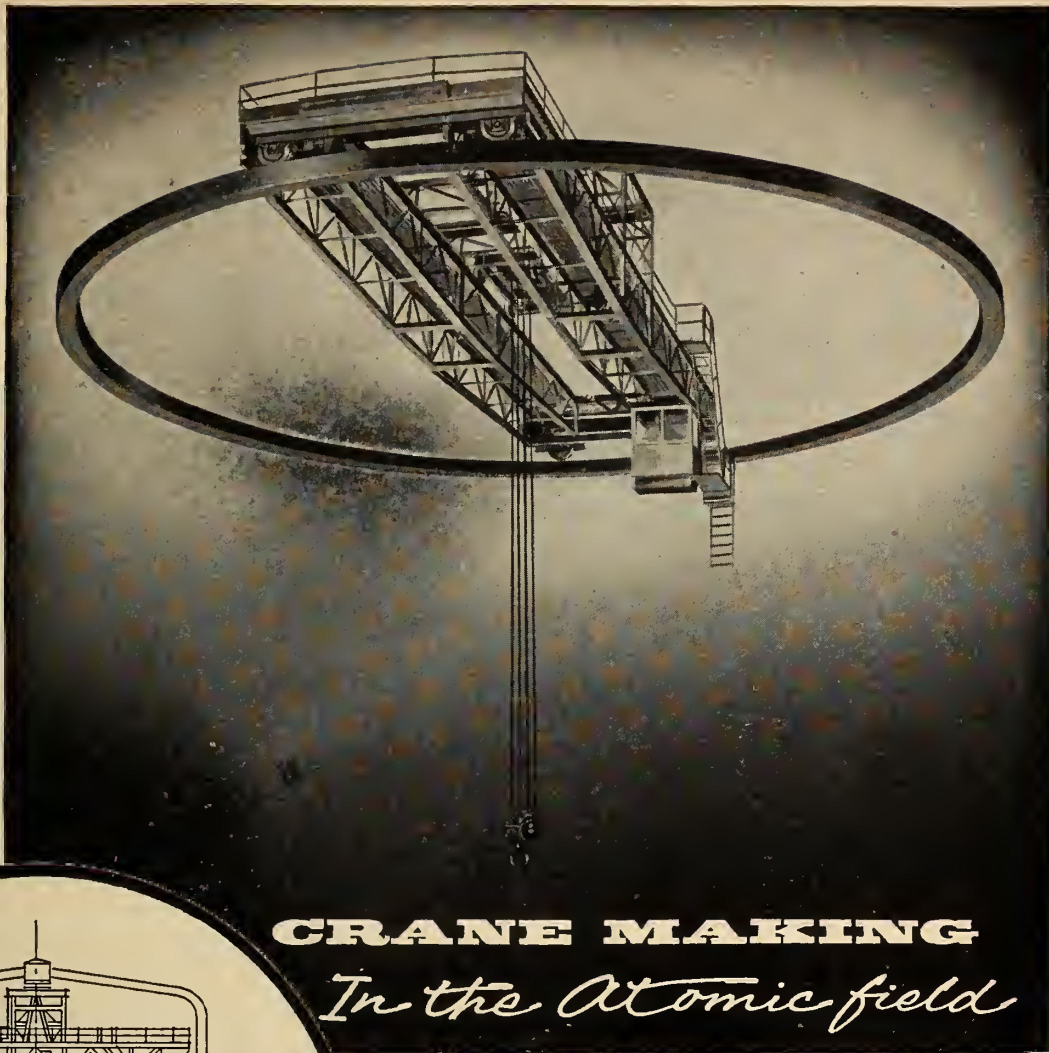
Dr. Tsao was introduced by J. V. Moreau and thanked by George Low. A very interesting question period followed.

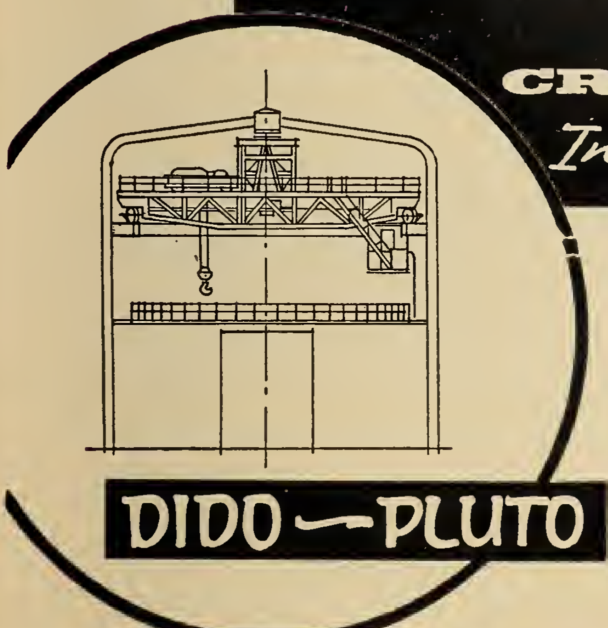
Bursary Awarded

Early this year the Thomas Berlinguet Bursary was awarded to Bernard Beland of Laval University by the St. Maurice Valley Branch in commemoration of the late Mr. Thomas Berlinguet's long association with the E.I.C. Mr. Berlinguet was the oldest member of the Institute at the time of his death at the age of 102.

The scholarship to Laval University was made out for $102. as a reminder of







In collaboration with the Ministry of Works Engineering Staff we designed and installed a special form of circular motion 20 ton Overhead Electric Travelling Crane of approximately 67 ft. span for operation in Britain's first experimental Reactor at Harwell.

In addition to this crane further circular motion units are operating in the United Kingdom in experimental Reactors at Harwell, materials testing Reactor at Dounreay and for the Australian Atomic Energy Commission Experimental Reactor at Lucas Heights Near Sydney. Other prominent cranes we have installed at Atomic Energy Projects are the Main Turbine House and Blower House cranes for Calder Hall and Chapelcross Atomic Power Stations. Currently we are engaged in the design and development of other special feature cranes in connection with British Industry in the building of Nuclear Energy Stations for the Central Electricity Authority in the United Kingdom.

the revered age of the engineer it honoured.

The presentation was made by Dr. Berlinguet, grand-son of Thomas Berlinguet.

This bursary was presented by the St. Maurice Valley Branch in accordance with the decision of the Branch last year immediately following the death of Mr. Berlinguet, to aid a deserving student from the St. Maurice Valley attending the second or third year engineering course at Laval.

SAULT STE. MARIE

R. L. Wimperis, JR.E.I.C., *Sec.-Treas.*

Two FILMS prepared by the Bell Telephone Company were on the program for the October 17 meeting of the Sault Ste. Marie Branch. One film concerned the micro-relay system which stretches across Canada from coast to coast for the T.V. network, and for long distance phone calls. The Mid-Canada Early Warning Line was the subject of the other film. Some of the construction and transportation problems involved were outlined, and the use of crawler tractor trains and helicopters was shown. Basically non-technical but well made, each film made clear the principles involved, were of general interest and can therefore be highly recommended.

Golf Tournament

Over 150 engineers and their guests turned out for the 4th Annual E.S.J.C. Golf Tournament at the Ki-8-Eb Club on Friday, August 15. Under the guidance of Match Committee chairman Wally Seline, the engineers produced some very creditable scores.

Following the tournament, a gathering of over two hundred enjoyed a buffet supper and refreshments. Charles Gagnon, president of Ki-8-Eb, welcomed all to the club and expressed the hope that the tournament would be held there again next year.

Guest speaker for the evening was Baz O'Meara, prominent sports columnist of the Montreal Star. Although he has been a newspaperman for over 30 years, this was his first trip to Three Rivers and he hoped it wouldn't be his last.

He covered many phases of sport including; baseball, football, hockey, and golf, and told the gathering some of the background of sports in Montreal and Quebec Province.

The evening concluded with the presentation of over 50 prizes to the lucky golfers. Don Peach of Shawinigan, won the John F. Wickenden, championship cup for low gross, with a score of 73. This compares with a 94 posted by Louis Boivin the first tournament winner four years ago. Mr. R. L. Bouchard captured the "Engineers' Pot" for high gross.

Riches from the Untamed Mountains

This is the Rocky Mountain Rift, 500 miles North of Vancouver. With BTH acting as electrical advisers, ambitious plans are in hand to develop this remote, virgin territory for its raw materials and power resources. Present schemes envisage the possibility of the world's largest man-made lake, taking 7 years to fill, and having a hydro-power potential of some 4,000,000 h.p.

To tame these mountains calls for endeavour and hardship in one of the greatest modern pioneering jobs. BTH are proud to be numbered among the pioneers.

Recent BTH Contributions to Canada's Industrial Growth

* Toronto's modern subway has 140 railcars fitted with BTH traction control equipment.
* Generating equipment of 25,000 kW for the Ford Motor Company of Canada.
* 230,000-volt, 7,500 MVA lenticular circuit breakers for the B.C. Electric Company.
* The largest blast furnace blower of its kind, for the Algoma Steel Corporation.
* Mercury-arc rectifiers, transformers and switchgear for the Canadian British Aluminium Company's Baiecomeau Smelting Plant.

EXPERIENCE BACKED BY IMMENSE RESOURCES

In many parts of the world BTH equipment is fulfilling electrical needs efficiently and dependably. The BTH Canadian Company is backed by the resources of the progressive parent company in Britain.

BTH **looks ahead with Canada**

News of Other Societies

American Society of Civil Engineers

The annual convention of the ASCE, was held on October 13-17, 1958 at the Hotel Statler-Hilton, New York City. Several joint sessions were held with the International Association of Bridge and Structural Engineers. Fourteen European engineers, representing eight countries, presented papers with 14 U.S. engineers at joint sessions of the society's structural, engineering mechanics and construction divisions, during the five-day program.

Prescott Bush, U.S. Senator from Connecticut and member of the Senate subcommittee on housing, guest speaker, discussed urban redevelopment. Problems related to the construction of buildings on ground with permafrost condition invoked special interest.

The Institute's award of merit went to James R. Killian, special assistant to the president of the U.S. for science and technology.

The retirement, after 28 years of service, of Walter E. Jessup, editor of Civil Engineering, the official publication of the ASCE, was announced. Succeeding him as editor of the publication of the 42,000 member society was Hal W. Hunt.

Francis S. Friel, of Philadelphia, designated as official nominee for president of the Society in 1959, took over the office from Louis R. Howson, Chicago. Two new vice-presidents and seven directors were installed.

Calendar

National Association of Corrosion Engineers
Eastern Regional Meeting, Sheraton-Mount Royal, Montreal, Jan. 12-14, 1959. Company exhibits covering all phases of products and services related to corrosion included.

Society of Automotive Engineers, Inc.
Annual Meeting and Engineering Display, Sheraton-Cadillac and Hotel Statler, Detroit, Jan. 12-16, 1959.

American Institute of Electrical Engineers
Institute of Radio Engineers, National Symposium on Reliability and Quality Control, Philadelphia, Jan. 12-14.

American Society of Heating and Air-Conditioning Engineers.
65th Annual Meeting and 14th International Exposition, Philadelphia, Jan. 26-30.

National Concrete Products Association
Tenth Anniversary Convention, Toronto, Jan. 26-28, 1959. Write: Alex Wylie, Suite 1604, 55 York Street, Toronto.

American Institute of Electrical Engineers
Winter General Meeting, New York, Feb. 1-6, 1959.

Materials Handling Analysis
Second Annual Midwest Work Course, Kansas City, Feb. 2-6, 1959. Limited enrollment of not more than 20 enrollees. For details write: Edward S. Avison, University of Kansas Extension Centre, 39th and Rainbow Blvd., Kansas City.

Society of the Plastics Industry
14th Conference of the Reinforced Plastics Division, Chicago, Ill. Feb. 3-5.

Eastern Snow Conference
1959 Meeting Commander Hotel, and MIT, Cambridge, Mass., Feb. 5-6, 1959. Write: Gordon R. Ayer, Secretary, Eastern Snow Conference, P.O. Box 948, Albany 1, N.Y.

Institute of Radio Engineers, American Institute of Electrical Engineers
Transistor and Solid State Circuits Conference, Philadelphia, Pa. Feb. 12-13.

American Institute of Mining, Metallurgical, and Petroleum Engineers Inc.
Annual Meeting, San Francisco, Cal., Feb. 15-19.

Chemical Institute of Canada
Annual Divisional Conference of the Protective Coatings Subject Division, Toronto, February 19, 1959, repeated in Montreal on Feb. 20, 1959.

Steel Founders' Society of America
57th Annual Meeting. Drake Hotel, Chicago, March 9-10, 1959.

Society of Automotive Engineers, Inc.
National Passenger Car, Body and Materials Meeting. The Sheraton-Cadillac Hotel, Detroit, Mar. 16-18, 1959.

National Association of Corrosion Engineers
The 15th Annual NACE Conference, and the 1959 Corrosion show, Chicago, March 16-20, 1959. Write: NACE, 1601 M & M Bldg., Houston 2, Texas.

American Institute of Chemical Engineers
National Meeting, Atlantic City, N.J., Mar. 16-20.

National Association of Corrosion Engineers
15th Annual Conference, Chicago, Ill. Mar. 16-20.

Institute of Radio Engineers
National Convention, New York, Mar. 23-26.

International Union of Pure and Applied Chemistry and the Chemical Society
International Conference on Co-ordination Chemistry, London, England, Apr. 6-11, 1959.

OFFICERS

Society of Naval Architects and Marine Engineers

At the annual meeting of The Society of Naval Architects and Marine Engineers, concluded on November 15, 1958, Rear Admiral Albert G. Mumma, United States Navy, was elected president of the Society for a two-year term starting on January 1, 1959. Admiral Mumma, who is chief of the Bureau of Ships, Department of the Navy, succeeds Walter L. Green, chairman of the board, American Bureau of Shipping, New York.

Plywood Manufacturers Association of British Columbia

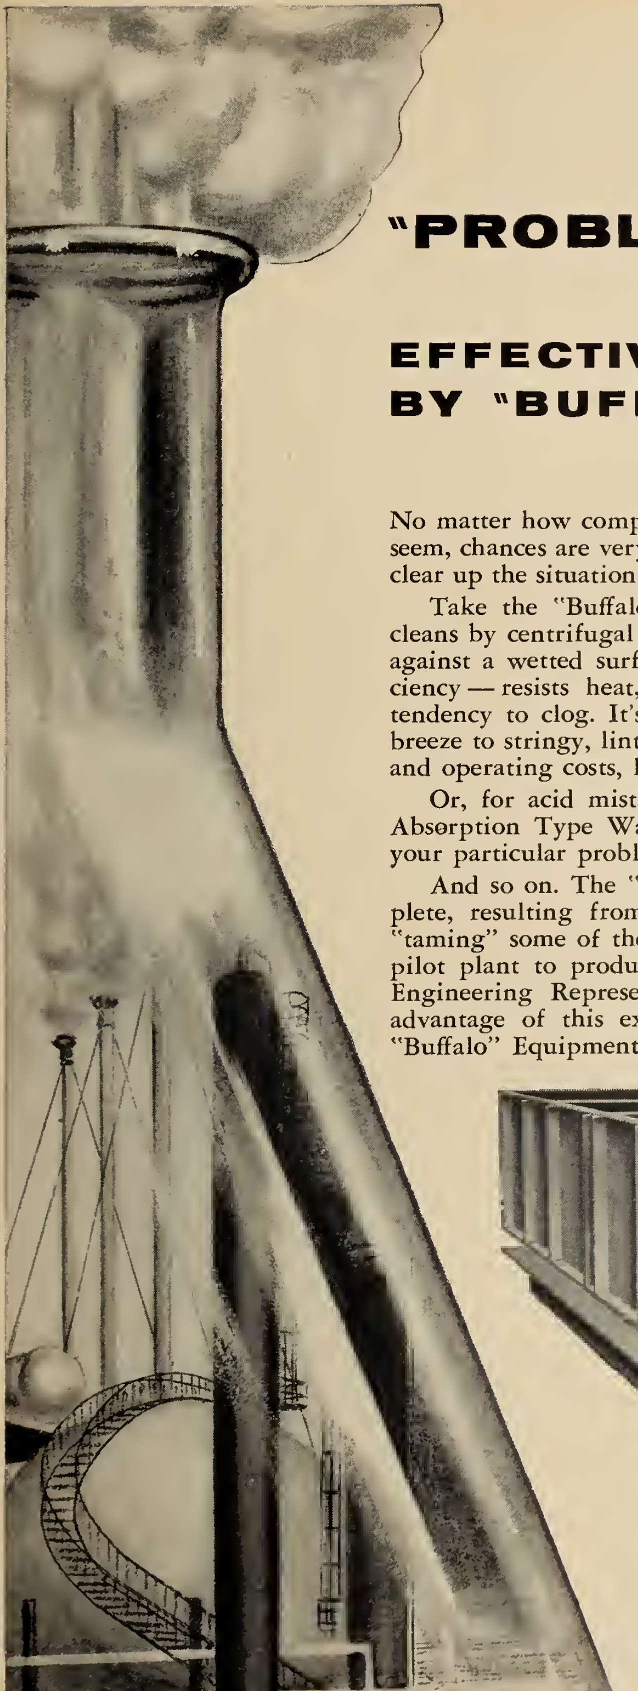
Two engineers, one an agricultural specialist, have been added to the field representative staff of the Plywood Manufacturers Association of B.C. Harvey P. Vokey, will operate the Montreal office, and G. Alexander Dring, will be stationed in London, Ont. Former London representative P. G. Willson has been moved to Toronto.

NOTICES

Safe Driving Week

Safe-Driving Week, a national campaign to impress the motorist and pedestrian with his responsibility, as an individual in preventing traffic accidents, was sponsored nationally by the Canadian Highway Safety Conference from December first to seventh, inclusive.

George B. Kenney, chairman, Canadian Highway Safety Conference called on every motorist and pedestrian to co-operate. Referring to a recent forecast of 3,400 traffic deaths in Canada in 1958 he said "more than 90 per cent of those deaths could be prevented if the individual driver and walker realized his responsibilty as an individual, in driving and walking safely.



"PROBLEM" EFFLUENTS . . .

EFFECTIVELY CONTROLLED BY "BUFFALO" EQUIPMENT

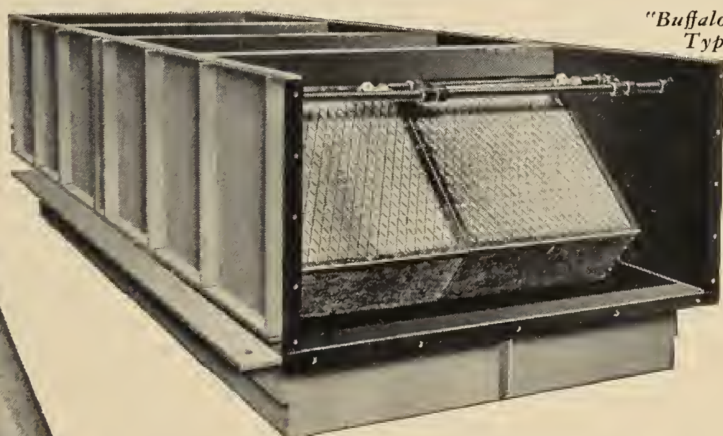
No matter how complex your air cleaning problem may seem, chances are very good that some "Buffalo" unit can clear up the situation to your complete satisfaction.

Take the "Buffalo" Hydraulic Scrubbing Tower. It cleans by centrifugal spray action, plus scrubbing action against a wetted surface — provides high collection efficiency — resists heat, corrosion and abrasion — has no tendency to clog. It's controlling everything from coke breeze to stringy, linty discharges. Maintenance is simple and operating costs, low.

Or, for acid mists, fumes and vapors, the "Buffalo" Absorption Type Washer may be the best solution for your particular problem.

And so on. The "Buffalo" line of equipment is complete, resulting from a half-century of experience in "taming" some of the toughest industrial effluents, from pilot plant to production. Write or phone the Buffalo Engineering Representative in your territory, to take advantage of this experience and the "Q" Factor* in "Buffalo" Equipment for the results you want!

"Buffalo" Hydraulic Scrubbing Tower



"Buffalo" Absorption Type Washer

**The "Q" Factor — the built-in Quality which provides trouble-free satisfaction and long life.*

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

THE STRENGTH TO MOVE A MOUNTAIN

When the two hundred thousandth ship sailed through the Panama Canal in October 1957, the author was there to help celebrate the event. This volume is the story of the building of the Canal from the first disastrous French attempt to its completion in 1914, at a total cost of over $600,000,000. It is the record of a fight against climate, disease, inefficiency and the earth itself. It makes fascinating reading. (W. Storrs Lee. New York, Putnam, 1958. 318p., $5.00.)

DIFFERENTIAL EQUATIONS

Reprinted from the 1930 edition, this volume presents a treatment of all the processes for solving differential equations that have wide applicability. It does not consider elementary or partial differential equations. (F. R. Moulton. New York, Dover, Toronto, McClelland and Stewart, 1958. 395p., $2.00.)

MATHEMATICAL TABLES, 2ND ED.

These tables of elementary and some higher mathematical functions include squares, cubes, square and cube roots, reciprocals and natural logarithms. The main part of the work consists of tables of trigonometric functions, the exponential function, and hyperbolic and bessel functions. It covers almost every function of importance in applied mechanics, engineering and the physical sciences. (H. B. Dwight. New York, Dover, Toronto, McClelland and Stewart, 1958. 217p., $1.75.)

BASICS OF DIGITAL COMPUTERS

Another in the series of "Basic" books issued by Rider, this volume covers the knowledge of electronic computers required by technicians and others in the field. The first volume reviews the development of computers, and explains the basic theory of computer arithmetic, data representation, the programme and control. The second volume discusses the elements, circuits, magnetic cores, etc., found in a computer, while the last volume considers memory, control system, input and output equipment and timing. (J. S. Murphy. New York, Rider, 1958. 3 vols., $2.50 per vol., $6.95 a set.)

ELECTROSTATICS

This volume uses a mathematical treatment in discussing the behaviour of electrical charges at rest, that is, electrostatics. The topics covered include matter and electric charges, unit systems, the nature and characteristics of the electric field, electric potential, capacitance and capacitors, and electrostatic devices and applications. (A. Schure, New York, Rider, 1958. 64p., $1.35.)

*THE ELEVATED-TEMPERATURE PROPERTIES OF WELD-DEPOSITED METAL AND WELDMENTS

Provides data for carbon, low-alloyed and austenitic steels, and for complex alloys developed for high strength at high temperatures. Among the data included are short-time tensile properties, creep and rupture strength, and chemical composition. Wherever possible the properties of the welds are related to the properties which are characteristic of the base alloys. (Philadelphia, American Society for Testing Materials, 1958. 223p., $5.50. s.t.p. no. 226.)

*SYMPOSIUM ON NONDESTRUCTIVE TESTS IN THE FIELD OF NUCLEAR ENERGY

Surveys ultrasonic, radiation, and eddy current methods and techniques. The majority of the papers included discuss applications in the inspection of castings, tubing, unclad fuel element components, and clad fuel elements. (Philadelphia, American Society for Testing Materials, 1958. 395p., $10.00. s.t.p. no. 223.)

*SYMPOSIUM ON RADIATION EFFECTS ON MATERIALS—VOLUME 2

Twelve papers dealing with the interpretation of existing code and specification values as they apply to nuclear reactor structures and components. Two deal with consideration of radiation effects in design, five with radiation facilities and techniques, and five with various materials. (Philadelphia, American Society for Testing Materials, 1958. 137p. $3.75. s.t.p. no. 220.)

TECHNIQUES OF PLANT MAINTENANCE AND ENGINEERING, 1958

This ninth volume in the series covers the proceedings of the conference held in January 1958. The majority of the 35 papers are generally applicable in all industries. Several, as well as the round table discussions, are concerned with problems in specific industries and plants. These are metal working, petroleum processing, rubber, chemical, metal fabricating, food processing, foundries, steel mills and pulp and paper mills. As usual, a wide variety of maintenance topics is discussed, and many ideas presented which are of value to maintenance engineers in both small and large plants. (New York, Clapp and Poliak, 1958. 211p., $10.00.)

HISTORY OF MATHEMATICS

Reprinted from the 1953 edition, these two volumes cover the history of mathematics from the earliest times to the end of the nineteenth centruy. The first volume is arranged chronologically by man and country, and the second by subject, discussing the evolution of the different divisions of mathematics. The author discusses all the major figures in the field, in all countries, in a most readable manner. Both volumes are generously illustrated, and there are many bibliographical references for those interested in pursuing any particular topic further. (D. E. Smith. New York, Dover, Toronto, McClelland and Stewart, 1958. 2 vols., $5.50.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m.—5 p.m.; Saturday: 9 a.m.—12 noon.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

• LIBRARY NOTES

PROCEEDINGS OF THE EIA CONFERENCE ON MAINTAINABILITY OF ELECTRONIC EQUIPMENT

At this conference sponsored by the Electronic Industries Association held in 1957, sixteen papers were presented on the subjects of maintainability concepts and requirements, and the maintainability of ground, airborne and missile equipment. The participants in the Conference were all top engineers in both the military services and industry. (New York, Engineering Publishers, Interscience, 1958. 104p., $5.00.)

THE PRINCIPLES OF TECHNICAL ELECTRICITY, 3RD ED.

Intended for students, this volume is concerned with the fundamental principles of electricity, especially with reference to its technical applications. The introductory topics discussed include electrolysis, the accumulator, electrostatics, condensers, magnetism, etc. The final chapters cover A.C. circuit theory, valves, radio circuits and the cathode-ray oscillograph. (M. Nelkon. London, Blackie, 1958. 250p., 15/-.)

*TECHNICAL EDITING

Presents the basic concepts and practices of internal communications, journal editing, book publishing, and graphic arts as related to the technical field. The papers are written by persons engaged in these activities and provide a practical approach. (Ed. by B. H. Weil. New York, Reinhold, 1958. 278p., $5.75.)

*INTRODUCTION TO NUCLEAR ENGINEERING, 2ND ED.

Major emphasis has been placed on those aspects of engineering practice unique to nuclear engineering. This edition contains two new chapters. The first deals with reactor core design and discusses burnout, hot channel factors and related problems. The second discusses thermonuclear reactions and the basic principles involved. A number of chapters have been expanded because of the declassification of literature in the field. (R. Stephenson. Toronto, McGraw-Hill, 1958. 491p., $11.40.)

ENGINEERING MATHEMATICS

An undergraduate textbook for engineers, intended to show the usefulness of mathematics and its applications in engineering. The author has developed the text from a course he gave at Iowa State College, in which differential equations and other topics were treated on the same level. The first chapter covers linear differential equations. Later chapters cover other types, the separation of variables method for solving boundary value problems, matrices and vectors, numerical methods, vector analysis and operational analysis. Many worked examples and problems and answers are included. (R. E. Gaskell. Toronto, Macmillan, 1958. 462p., $7.25.)

MECHANICS APPLIED TO ENGINEERING

Intended for those students with very little knowledge of engineering, this volume concentrates on the basic principles of mechanics, showing their application to as many fields of engineering as possible. The material is divided into statics and dynamics and there are many worked examples and problems and answers. (G. H. Ryder. London, Cleaver-Hume, 1958. 244p., 21/-.)

AIR AND WATER POLLUTION IN THE IRON AND STEEL INDUSTRY

The Proceedings of two conferences held in London in 1957 under the sponsorship of The Iron and Steel Institute. At the air pollution meeting the papers by experts from five countries covered the following topics: general and cost aspects of air pollution by the iron and steel industry; reducing air pollution from sinter plants and coke ovens; overseas experience in abating air pollution; treatment of fumes from arc furnaces; treatment of flue gases. The topics considered at the water pollution meeting were: general technical aspects of pollution of rivers; treatment of effluent from blast-furnace gas-cleaning plants and coke ovens; use of sewage effluent in steelworks, and reduction of effluent; processes for spent pickle liquor. This is a valuable contribution to the literature on this important subject. (London, Iron and Steel Institute, 1958. 259p., £4.5. Special report no. 61.)

*TOOLING FOR METAL POWDER PARTS

Stresses practical aspects of planning and tooling for structural parts such as cams, gears, and latches. Among the factors discussed are designing parts, methods of production and preparation of powders, briquetting techniques, design of briquetting tools, and the various finishing operations. The book was prepared under the direction of the American Society of Tool Engineers. (G. H. DeGroat. New York, American Society of Tool Engineers, 1958. 242p., $7.50.)

*SOUND PULSES

Describes the theory of sound pulses as based on the theory of linear partial differential equations of hyperbolic type. Aspects dealt with are the equations of motion, wavefronts and characteristics, geometrical acoustics and their application to reflection problems, and the diffraction of a pulse by a wedge, circular cylinder, sphere and other objects. (F. G. Friedlander. Toronto, Macmillan, 1958. 202p., $6.75.)

*BUILDING WITH TILT-UP, 2ND ED.

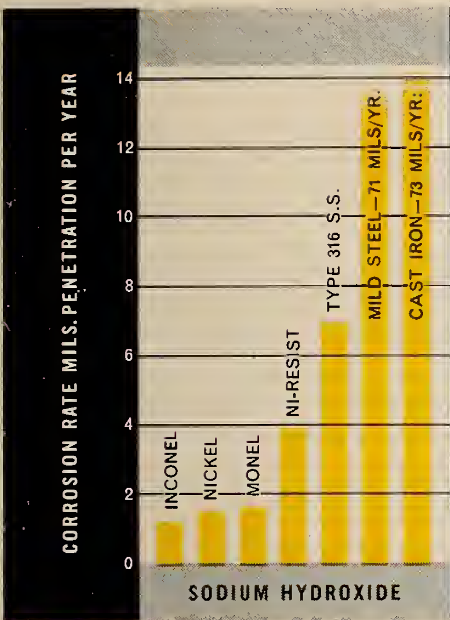
A field manual describing the various procedures utilized in this type of construction, including floor slab fabrication and crack control; wall panel fabrication; hot and cold weather concreting; wall footings and special foundations; point pick up; erection and bracing; joinery. This edition contains a special section on the custom modular framing method useful for special buildings such as schools. (F. T. Collins. San Gabriel, Calif., Know How Publications, 1958. 160p., $10.00.)

*DESIGN OF TILT-UP BUILDINGS

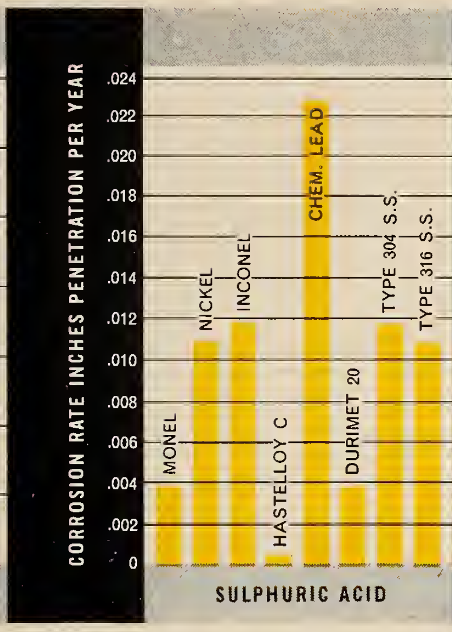
Provides the fundamental information necessary to good design practice for job

Is corrosion eating away your profits?

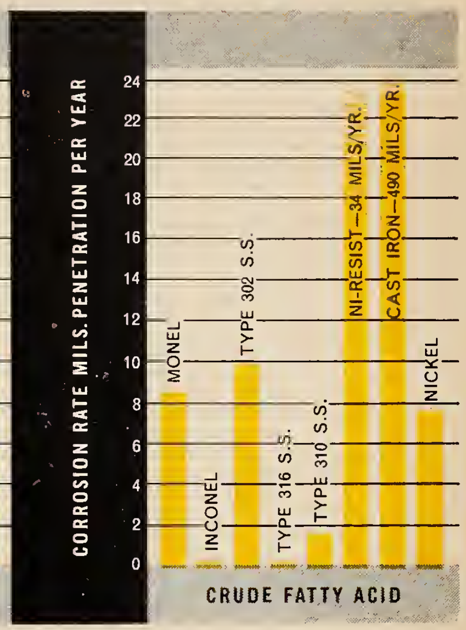
Inco Customer Service can help you!



This test was conducted in a plant manufacturing caustic soda. The test spool carrying duplicate specimens of each of the metals shown above was immersed in a solution of 75% sodium hydroxide at a temperature of 275°F. for 35 days.



Plant test in sulphation of vegetable oils with 66° Baumé sulphuric acid and an acid-to-oil ratio of 20-25% by weight at temperatures ranging from 68°F. to 140°F. for a period of 7 days.

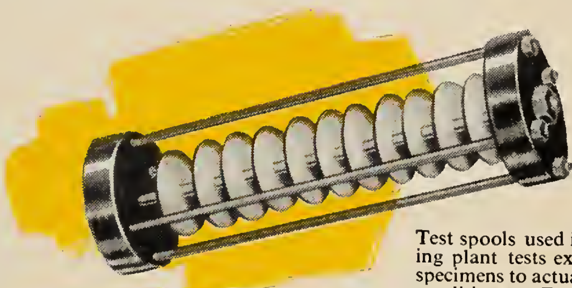


Plant test in distillation of crude fatty acid (cottonseed). Corrosion test spool was located at top of the batch still near the vapour outlet for 42 days. Temperature 480°-520°F.

The graphs above show you what can happen—and may be happening—to equipment handling acids or caustics in your plant, if you're not using the right material for the job. And they're only examples from more than 300,000 similar tests Inco has conducted in a wide range of acids, alkalies, organic compounds and other environments.

The results of these tests have been carefully documented and are available from Inco to help you select the right metal for your corrosive applications. If your corrosion problem has not been covered by these tests, Inco's research and development engineers will undertake to find a solution for you without cost. Just outline your problem on a Corrosion Data Work Sheet, also available from Inco.

Use the coupon at right to order List "B", itemizing Inco publications dealing with corrosion, and the Corrosion Data Work Sheet.



Test spools used in conducting plant tests expose metal specimens to actual corrosive conditions. Evaluation of corrosive damage is made in Inco laboratories.

site prefabrication. Gives data on lateral force resistance, roof framing, columns, wall panels, pick up analysis, concrete floor slabs, footings and foundations, and joinery. (F. T. Collins. San Gabriel, Calif., Know How Publications, 1957. 162p., $12.50.)

MANUAL OF TILT-UP CONSTRUCTION, 4TH ED.

After a brief review of the history of tilt up construction, the following topics are covered: flat cast versus thin shell construction; patents in tilt up; casting surfaces and molds; bond breaking; painting precast concrete; construction schedule; field layout; forms; panel fabrication; joinery; erection; costs; sandwich type panel construction; bibliography. (F. T. Collins. San Gabriel, Calif., The Author, 1955. 101p., $12.50.)

*INFORMATION AND COMMUNICATION PRACTICE IN INDUSTRY

Intended as a comprehensive view of the subject, this volume considers technical writing, editing, and illustrating; classification; information services and their part in internal communications; operations research; patent collections; research files; punched cards; training the literature scientist; translating; indexing and abstracting. (Ed. by T. E. R. Singer. New York, Reinhold, 1958. 304p., $8.75.)

FRASER'S CANADIAN TRADE DIRECTORY, 1958

More than 12,500 firms are included in the alphabetical listing in this 1958 edition, and their products classified under some 6,500 product headings. More than 15,000 brand and trade names and trade marks are listed, as are the Canadian representatives of over 12,000 foreign companies. The market data section contains information for companies interested in foreign trade, Canadian cities and towns with a population of over 1,500, transportation companies, utilities, banks and telephone and telegraph companies. This is an indispensable volume. (Montreal, Fraser's Trade Directories, 1958. 1872p., $10.00.)

*COMPOSITE CONSTRUCTION IN STEEL AND CONCRETE FOR BRIDGES AND BUILDINGS

The fundamentals of composite construction are given, including design equations and procedures, methods of connecting slabs to beams, and illustrative examples of design procedures. Special features include a rapid method for the composite design of beams, and design methods for the three most commonly used shear connectors; studs, flexible channels, and spirals. (I. M. Viest. Toronto, McGraw-Hill, 1958. 176p., $8.65.)

CONCRETE FOR RADIATION SHIELDING

The seven papers in this compilation previously appeared in the Journal of the American Concrete Institute. They are concerned with the use of concrete for shielding nuclear radiation, and the calculation of proportions and properties of various heavy concretes. (Detroit, American Concrete Institute. 132p., $4.00.)

GLASS-MELTING TANK FURNACES

Much research has been done in Germany in the last thirty years on the production of glass, and in this volume translated from the 1954 German edition the latest systems of operation and methods of construction of tank furnaces are discussed. The topics covered are: types of furnace; operation; construction details; heat recovery; control of gaseous flow; control equipment; heating and cooling the furnace; furnace capacity and fuel efficiency; fundamental thermal calculations; history of the tank furnace. In this translation, in addition to several minor changes, the text has been rearranged and divided into eleven chapters, the units of measurement have been changed from the C.G.S. to the F.P.S. system, and the number of references has been doubled. (Rudolf Gunther. Sheffield, Society of Glass Technology, 1958. 232p., £3.)

LES ONDES CENTIMETRIQUES

Since the advent of Radar, much research has been done in the field of very short electromagnetic waves. The majority of the texts has been written in English, this is one of the few French books on the subject. The topics covered include propagation, impedance, wave measurements, measurement of dielectric constants, high frequency generators, detectors, antennas, and application in radio astronomy. The book is intended as an undergraduate text. (G. Raoult. Paris, Masson, 1958. 401p., 6500 fr.)

INTRODUCTION A L'ANALYSE DIMENSIONNELLE ET AUX PROBLEMES DE SIMILITUDE EN MECANIQUE DES FLUIDES

The first section of this volume contains a discussion of dimensional analysis and its many applications. The second section deals with the simulation of river conditions in scale models and its attendant problems. The final section disucusses applications: study of hydraulic turbomachines, cavitation phenomena; speed of flow by a wall; and distortion in river models. R. Comolet. Paris, Masson, 1958. 116p., 1600 fr.)

C22.2 No. 97-1958: Construction and test of outdoor and submersible floodlights. $1.00.

List of approved oil-burning equipment, 5th ed., 1958.

Canadian Underwriters' Association standards. Canadian Underwriters' Association, 460 St. John St., Montreal.

No. 10. Standard for the installation, maintenance and use of portable fire extinguishers.

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Department of Defence Production — B. E. Poirier has recently been appointed executive assistant to the Hon. R. O'Hurley, minister of defence production.

Royalite Oil Company — Charles Hay, M.E.I.C., has been appointed president of Royalite Oil Company, Limited, Calgary. Following the retirement of C. U. Daniels, R. L. Thompson has been named a director. J. W. Whitaker becomes secretary, and D. J. Morrison treasurer of the company.

Canadian Westinghouse — J. D. Campbell has been elected to the newly created post of executive vice-president of the Canadian Westinghouse Company Limited, Hamilton, Ont.

Saguenay Electric — The following executive appointments have recently been announced by Saguenay Electric Company, an affiliate of Aluminum Company of Canada, Ltd.: P. Tellier has been named executive vice-president; G. Dufour, M.E.I.C., vice-president and general manager; P. Beaulieu and G. Proulx, M.E.I.C., vice-presidents.

P. Tellier

DOSCO Appointments — The Dominion Steel & Coal Corporation has announced the appointment of D. G. Scott as comptroller and A. A. Donaldson as assistant comptroller of the organization. E. L. Pursey is assistant to the vice-president, finance.

Rawhide Mfg. Co. of Canada — G. W. Barker has assumed the responsibilities of vice-president and general sales manager of the Chicago Rawhide Mfg. Co. of Canada Ltd., a division of Super Oil Seal Mfg. Co., Ltd., Brantford, Ont.

Ferranti-Packard—Ferranti-Packard Electric Limited have announced the following appointments to the newly formed marketing division of the firm. G. B. Hunnisett has been named manager, sales services. He will have co-ordinating engineers J. A. Pratt in Toronto, and G. R. Nayler, JR.E.I.C., in St. Catharines, directly assisting him. R. F. Taylor has become manager, marketing services. He will be assisted by R. J. Martin, manager, marketing research; R. M. Squires, product manager, transformers and electronics; R. T. James, product manager, metering equipment; E. A. Love, advertising manager. Headquarters for the marketing division will be in Toronto.

Also announced by Ferranti-Packard was the appointment of five district managers: J. H. McClennan, Quebec; R. C. Short, M.E.I.C., Ontario; D. A. McCuaig, M.E.I.C., Manitoba; T. C. Good, Alberta; L. B. Stacey, M.E.I.C., British Columbia.

Lenkurt Electric — C. W. Hunter has been appointed vice-president and general manager of Lenkurt Electric Co. of Canada, Ltd., Burnaby, B.C., effective January 1, 1959. He will succeed W. H. Heflin who has been named general manager of the commercial products division of Lenkurt Co., Inc., San Carlos, California.

Shawinigan Chemicals — Announcement has been made of the following appointments at Shawinigan Chemicals Limited: L. F. Fitzpatrick, sales manager, heavy chemicals division; A. E. Doig, sales manager, stainless steel and alloys division, J. P. Ogilvie, technical manager, stainless steel and alloys division.

G. B. Hunnisett

Joy Manufacturing Company — M.S. (Monte) Cranston has been appointed to the newly created post of assistant general sales manager, eastern division of Joy Manufacturing Company (Canada) Limited, Galt, Ont.; his headquarters will be in Montreal. Assisting him will be D. L. Larson.

Dominion Rubber Appointments — Dominion Rubber Company Limited, Montreal, has appointed N. W. Smith production manager of the mechanical goods division of the company. A. Beauchamp has been named factory manager to succeed Mr. Smith.

Canadian General Electric—J. R. Oakley has been appointed sales manager—semiconductor products, in Canadian General Electric Company Limited's tube section. G. E. Mean has been made application engineer.

Potter & Brumfield — A. Robinson has been made production manager of Potter & Brumfield Canada Limited, Guelph, Ont.

Honeywell Controls Limited — H. C. Sage has joined the commercial division sales of Honeywell Controls Limited, in the company's Winnipeg office.

Business News

Canadian Representative — John Hamilton is directing the activities in Canada of Simon-Carves Ltd., of Stockport, England. This company has opened offices at 670 Bayview Avenue, Toronto. In addition to representing the parent company, the following subsidiaries will also be represented; Huntingdon, Heberlein & Co. Ltd., and Chemical Engineering Wiltons Ltd.

This newly formed organization will be of particular interest to those who are concerned with colliery and mining engineering (winding and surface plant); coal preparation plants; water-tube boilers and complete power stations; sulfuric acid and other chemical plants; electro-precipitators for industrial mists and dusts; continuous sintering plants; ore preparation and concentration plants; metallurgical and chemical roasting furnaces; etc.

Permali Expansion — Permali (Canada) Limited have recently purchased the building at 137 Kipling Avenue South, Toronto, part of which they previously held under lease. Due to increased business in the fabrication of insulating components from their densified wood laminate for the heavy electrical industry, the whole building will now be used with improvements made in existing facilities. In addition, the manufacture of other insulating materials is being commenced. Permali (Canada) Limited are also sole Canadian agents for Steatite and Porcelain Products, Worcester, England.

GM Diesels for Ceylon — Ceylon was the recipient of two additional Diesel-electric locomotives recently. The two units bring to ten the number of locomotives donated to Ceylon by Canada under the Colombo Plan. Built by General Motors Diesel Limited, London, Ont., each locomotive has been named after a Canadian province by officials of the Ceylon Government Railway and each bears a designating plaque. The last two units bear the names of Prince Edward Island and Newfoundland. Known as the Model G-12, the locomotives are of a type designed by General Motors for universal application on the world's railways. They have 2-motor, three axle trucks designed for the 66-inch broad gauge track in Ceylon. These A-1-A fully flexible trucks are used to reduce axle loading.

C-I-L Sales Office — Canadian Industries Limited, Montreal, has begun construction of a new consolidated sales office at 4606-1st St. S.E., in Calgary, according to an announcement by company officials. It will be located on the same site now occupied by its consolidated warehouse. The $70,000 one-storey building will house the Calgary sales staffs of the company's paints, chemicals, explosives and ammunition divisions now located at 1029-11th Ave. W. The building contract has been awarded to the

• BRIEFS

Poole Construction Co. Ltd., of Calgary. Completion of the building is scheduled for May, 1959.

Plastics Distributor — The appointment of Plastics Maritime Limited, Halifax, as distributor for vibrin polyester resins in the Atlantic Provinces has been announced by the Naugatuck Chemicals Division of Dominion Rubber Company Limited, Montreal. Plastics Maritime Limited was incorporated in 1946 by G. L. Alguire, and since that time has expanded into the leading plastics material supply house in its region. Reinforced plastics are the fastest growing segment of the plastics industry in the Atlantic area, the company reports. In part this is due to the importance of fisheries in the Maritime economy, where reinforced plastic can play such an important role in the fabrication or covering of boats and in the manufacture of fish processing equipment. Plastics Maritime Limited will maintain distribution and service from their offices and plant at 58 Gerrish Street, Halifax, N.S.

New Division — The Bristol Aeroplane Company of Canada Limited has announced that its subsidiary, Bristol Aero Engines Limited of Montreal North, has formed an Aviation Services Division. This newly formed division is now functioning at Montreal Airport, Dorval, and is designed to perform aircraft ramp handling and maintenance services on behalf of scheduled and non-scheduled carriers.

Submarine Cable Contracts — Standard Telephones and Cables Limited of England have recently obtained two of the biggest submarine telecommunication contracts ever placed. The first — an order for 530 nautical miles of undersea cable and submerged repeaters for the Anglo-Swedish cable project — will provide the first direct telephone link between Britain and Sweden and is valued at £1¼ million. It will be the longest submarine telephone cable in Europe. The second order is for over 700 nautical miles of deep sea cable, part of a new 36 channel telephone system to be installed next year between Miami, Florida, and San Juan, Puerto Rico. Value of the contract is 2½ million dollars.

New Winnipeg Plant — Dominion Structural Steel Limited, Montreal, has begun construction of a new structural steel fabricating plant in the Winnipeg-St. Boniface area. Building and crane runway footings will be installed this fall on a 17 acre site, and construction of buildings will proceed throughout the winter and spring of 1959. The plant will be designed to permit anticipated expansion. Easy access to road and rail transportation has been arranged. Modern fabricating equipment will be included for cutting, punching, shearing, drilling, welding, rivetting, painting and erection of steel and steel products. Reinforcing steel and a wide range of warehouse stock will be available.

● BRIEFS

Quebec Distributor — Chaseside Equipment Company of Canada, Burlington, Ont. has announced the appointment of Laurion Equipment Ltd. as sole distributors for their line of tractor-shovels, dumpers and diesel power units in the province of Quebec.

Canadian Company — The formation of a Canadian company to manufacture and distribute Tapecoat protective coal tar coatings in tape form to Canadian gas, oil and industrial users has just been announced by The Tapecoat Company of Evanston, Ill. Known as The Tapecoat Company of Canada, Ltd., the new corporation has its offices and manufacturing facilities in a 5000 sq.-ft. plant at 25 Haas Road, Rexdale, Ont. J. R. Wall, formerly New York district manager for Tapecoat, is president of the Canadian corporation. Serving with him as a member of the board is A. S. Kingsmill of Tilley, Carson, McCrimmon and Wedd, solicitors of Toronto.

Public Works Contracts — Contracts involving expenditures totalling $15,086,831.31 were awarded by the Federal Department of Public Works during the month of July 1958, compared with $10,080,352.33 during the month of August 1958.

The amount for new works in building, construction and harbours and rivers engineering was $6,108,285.15 for July, and $2,429,363.07 for August; for the repair and maintenance of existing structures $975,768.70 for July, and $387,855.45 for August; for construction of Trans-Canada Highway roads through National Parks and other projects for July, $6.504,716.86 and for August $7,204,883.81; for dredging during the month of July $1,498,060.60, and during the month of August $58,250.00.

New Equipment and Developments

Twin Hoist Gantry Crane — Dominion Structural Steel Limited, Montreal, has reported that the section of Montreal's Metropolitan Boulevard Highway building project under Miron Stirling Walsh moves ahead at a rapid pace with this 12 ton Taymar Construction gantry crane. Designed and built by Dominion Structural Steel, in close co-operation with Miron Stirling Walsh, Engineers, the gantry crane has dual 6 ton hoists on a 125′ span which straddles the elevated highway. It is designed as a self-propelled machine for lifting and placing concrete and reinforcing steel from trucks under the cantilivered bridge on either or both sides of the highway. Motors for each motion draw energy from the diesel electric generator set carried on one end truck between the gantry legs, which also serve as fuel tanks. From the girder top 42′ above the rails the lifting speed is 60′ per minute for each hook. The trolleys move across the bridge at 140′ per minute, and the structure travels at 25′ per minute, reports Dominion Structural Steel.

Low-Odor, Fast-Curing Catalyst — A new catalyst for urethane polymers, N,N,N',N'-Tetramethyl-1,3-butanediamine, is available from Carbide Chemicals Company, Division of Union Carbide Canada Limited, Toronto. The new chemical is a colorless, stable fluid that is completely soluble in water and common organic solvents. This new amine is more reactive than the urethane catalysts systems commonly used, permitting faster during of urethane foams. Also, tetramethyl butanediamine is said to have an exceptionally low odor level, and yields soft, pliable foams. Tetramethyl butanediamine may also be a valuable catalyst for curing epoxy resins.

Sandvik Coromant Drill Steels — Atlas Copco Canada Limited, Montreal, has announced the introduction of Sandvik Coromant cold rolled extension drill steels for air track equipment and large-size drills. The new steels come with 1½ in. diameter in lengths of 10 and 8 ft., and with 2 in diameter in lengths of 10 and 20 ft. The company states that the new steels, designed for deeper hole drilling, feature the patented "rope thread" which simplifies uncoupling even after sustained drilling. Its rounded form is reported to reduce thread and coupling failures frequently found in reverse buttress or "saw tooth" threads. An advantage of the cold rolling process is that steels are given a tough core with hard surface, making it possible to re-thread them on ordinary metal lathes without heat treatment. A special feature of the new steel is represented by the large diameter flushing holes, which permits faster cleaning of drill holes, increases the penetration rate and gives a longer life to the steels and bits.

Space Heating — A new method of heating local, irregular or insufficiently insulated working areas has been announced by Canadian General Electric Co. Ltd., Toronto. By suspending radiant calrod panels from above, adequate warmth for complete working comfort can be radiated on to machine operators, etc. in large plants normally uneconomical to heat by usual methods. Radiant calrod panels transfer heat instantaneously, require practically no maintenance, and have relatively low operating costs. Panels are available in 6, 8, and 10 k.w. ratings, and 220, 440 or 550 volts.

Subminiature Electronic Switch — A new subminiature Haydon switch has been announced by Philips Electronics Industries Ltd., Toronto. The switch, Type 5366, is said to be qualified to MS25085 with operation up to a temperature of 400°F and a rated load of 5 amps., resistive and 3 amps. inductive. Mechanical life of 1,000,000 cycles, and 100,000 operations under rated load, are further features available. Philips Electronics state that this subminiature switch is designed to meet the strict specifications of aircraft and missile industries, requiring operation of switch assemblies under extreme temperatures.

Crane and Shovel Carrier — Sicard, Incorporated of Montreal state that a new 35 ton crane and shovel carrier has been added to the Sicard line of heavy equipment. Incorporating proven engineering advances, the Sicard model C-6435 combines welded, one-piece, torsion proof frame, low weight and complete stability. A choice of either gas or diesel engines provides traction on all wheels or on tandem wheels only. Two types of axles are available, Timken or Clark with double reduction or planetary drive. A few of the main features of this carrier are new featherweight magnesium outrigger floats; Fuller transmissions giving up to 15 speeds forward, and positive acting Bendix-Westinghouse air brakes.

Napanee Largest Press Brake — Announcement has been made of a major step forward in modern Canadian manufacturing has been taken by Napanee Iron Works, Napanee, Ont., a division of the International Equipment Co. Ltd., Montreal. Napanee reports it has recently added to its facilities the largest mechanical press brake in Canada, 1400 tons in capacity, capable of bending mild steel plate with dimensions of 1½" x 12′ or 1" x 17′. The size and capacity of the press is said to naturally lend itself to the production of custom forming of steel sections not normally produced by Canadian steel mills. Other production items would be highway safety fence, latticed bridge flooring, railway freight car doors, roofs and ends. Pressings on another components requiring high capacity forming or pressings at extreme lengths. At the present time the machine is being used for the production of nailable steel flooring which is used to replace old style wood flooring in railway freight car rolling stock, a modern answer to an old railroad problem of continuous maintenance.

TIME DEFYING STAINLESS

Canada's first major application of stainless steel curtainwall construction

At the dedication of this building, a door was opened to a new dimension in Canadian architecture. With the exterior formed entirely of prefabricated stainless curtainwall panels, here is practical proof of a metal and methods ideally suited to the rigours of our climate. All weather construction, competitive cost, lifetime freedom from corrosion and deterioration — these are but a few of the practical advantages of stainless steel, for both exterior and interior applications.

Our architectural development department is available for consultation on new and existing applications of stainless. Simply contact your nearest Atlas representative.
