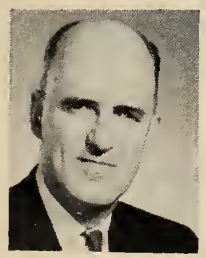
MEET THE AUTHORS

R. G. Griffith, M.E.I.C. Chief engineer of the Canadian Overseas Telecommunication Corporation, Montreal. Graduated from the Institution of Electrical Engineers in Britain in 1924; he joined All America Cables Inc. the same year, and was made development engineer in 1927; transferred to Creed & Co. in 1929, becoming assistant chief engineer, 1935; later joined Cable and Wireless Ltd., London, and was appointed chief engineer, London Communication Centre, in 1946; he came to Canada in 1951, joining the COTC as chief engineer in May, 1954. During the Second World War Mr. Griffith was seconded to the British Foreign Office and took charge of special secret telegraph machine cypher development; he has some 60 patents relating to telecommunications. *(Recent Expansion of Canadian Overseas Telecommunication Facilities.)*

J. N. Ford, M.E.I.C. (left, below). Manager of operations, Canadian Utilities Limited, Edmonton. Graduated in electrical engineering from University of Alberta in 1934; before joining Canadian Utilities Limited as chief electrical engineer in 1951 was employed in Saskatchewan, Alberta and Newfoundland in the field of electrical transmission and distribution engineering; member of Association of Professional Engineers of Alberta, Canadian Electrical Association, and Northwest Electric Light and Power Association. *(Battle River Steam Station.)*



W. I. McFarland, M.E.I.C. (right, above). Partner, Haddin, Davis & Brown Limited, Calgary. Graduated in electrical engineering from the University of Alberta in 1929; took portion of student training course with Canadian Westinghouse from graduation to 1930; from that date to the end of 1935 was assistant to the electrical engineer at Beauharnois during construction of the first power development at that site; from 1936 to December 1952 he was with the City of Edmonton in various positions: electrical engineer with light and power department, electrical engineer with power plant and water treatment plant department, electrical engineer and assistant superintendent of transit system, superintendent of power plant and water treatment plant department. *(Battle River Steam Station.)*

R. J. Kennedy, M.E.I.C. Associate professor of civil engineering, Queen's University, Kingston; attended Queen's University 1937/1941 (medal in civil engineering); RCE, Canada, England, N.W. Europe, 1941/1946 (awarded Military Cross at Arnhem); on staff at Queen's University 1946/1948; student at State University of Iowa 1948/1949 (J. Waldo Smith Hydraulic Fellowship of ASCE); Queen's University staff 1949 to date; supervisor, Pulp and Paper Research Institute of Canada, for project RC-12 since 1952. *(Forces Involved in Pulpwood Holding Grounds.)*

H. R. L. Streight. Principal chemical engineer, Du Pont Company of Canada (1956) Limited. Attended the University of British Columbia (B.A. and later M.A.); proceeded to England on an 1851 Exhibition scholarship, attended Birmingham and Oxford Universities (Ph.D., Birmingham). Spent some time with Imperial Chemical Industries in England; transferred to Canadian Industries Limited in 1937 and on its division into two companies in 1954 became a member of Du Pont of Canada's engineering department; he is a former director of The Chemical Institute of Canada; past chairman, chemical engineering subject division, C.I.C.; ex-member of the editorial board of *Chemistry in Canada*, and current member of the editorial board of *Canadian Journal of Chemical Engineering*. He will be conference chairman of the April, 1958, combined meeting in Montreal of the American Institute of Chemical Engineers and Chemical Institute of Canada. *(Air Pollution Control at a Nylon Intermediates Plant.)*

COVER PICTURE

The cover picture this month symbolizes a subject that is very much to the forefront in the daily news and in technical discussion. It is a view of a missile undergoing the low-temperature tests which form part of the customary rigorous testing program.

Recent Expansion of Canadian Overseas Telecommunication Facilities

R. G. Griffith, M.E.I.C.

Chief Engineer, Canadian Overseas Telecommunication Corporation.

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June, 1957.

IN THIS PRESENT day world, in which electronics, automation and nuclear science are an every day topic, we rarely pause to remember that it is but a few centuries back when the only means known to man of signalling the approach of an invader was by bonfires, and that it took centuries to develop from this form of communication to the semaphore, such as was used to signal the defeat of Napoleon at Waterloo. Also, that it required nearly the passage of another quarter century before the electric telegraphy was born. It is a startling fact that it is only little more than a 100 years since the first telegraph cable was laid in the sea.

During the last half of the 19th century, and the beginning of the 20th century, most of the world's submarine telegraph cables were laid, among the most noteworthy of these being the first trans-Atlantic telegraph cable, laid between Newfoundland and the British Isles in 1858; the second being the longest submarine cable in the world, involving a distance of 3,460 nautical miles, between Vancouver Island and Fanning Island, which was laid in 1902 as a joint enterprise by Canada, New Zealand, Australia and Great Britain.

At the beginning of the 20th century, radio telegraphy enters the historic picture, and reference must be made to the night of December 12th/13th, 1901, when on Signal Hill, Newfoundland, Marconi heard radio signals that had traversed the Atlantic. By 1926, with the construction of what was then termed the short wave beam radio stations at Yamachiche and Drummondville, in Quebec Province, radio communication took a great step forward.

Although numerous technical improvements have been made, both in respect of cable and radio, overseas telephone and telegraph technique, equipment and plant, which in the aggregate represent substantial progress, no further startling advance in the long distance overseas telecommunication field was made until the laying of the first Transatlantic telephone cable, which was completed in the fall of 1956. The successful completion of the installation of this first cable marks an important era in overseas telecommunications. It is even more interesting because this epoch-making advance comes into phase with the rapid development of Canada, which demands the improved inter-Continental telephone facilities that can now be made available, and it is worthy of note that with practically every leading step in the development of trans-oceanic telecommunications, Canada has been well in the picture.

Co-ordinated with the provision of the first Transatlantic telephone cable, increased communication facilities have been provided for operation between Canada and Australasia and the Far East. The main object of this paper is to survey these new facilities and to extemporise on the possible trend of future development.

In 1950 the Canadian Government established a Crown Company to provide and co-ordinate Canadian overseas telecommunication facilities. The nucleus of this Crown Company was that part of the global communication system of Cable and Wireless Limited, existing within Canadian boundaries, and this paper sets out to present a picture of the expansion of these Canadian facilities, effected during the last few years. It also indicates that, owing to the fact that at present the Commonwealth network passes through the Suez Canal area and other troublesome spots, the future might find Canada playing a much greater part in Commonwealth telecommunications. The paper also briefly refers to future trends in the development of trans-oceanic submarine telephone cables.

The First Transatlantic Telephone Cable

The first Transatlantic telephone cable has been the subject matter of a number of previous papers; even so, it is considered appropriate to include reference to salient points likely to be of general interest.

The Atlantic telephone cable project was the outcome of a joint enterprise by the American Telephone and Telegraph Company, the British Post Office, and the Canadian Overseas Telecommunication Corporation, the conditions of which partnership were embodied in a tri-partite agreement which was signed on November 27th, 1953. The cable system was to provide a two directional transmission bandwidth of 26 kc/s. for Canadian, and 118 kc/s. for American circuits. The agreement also provided for the Eastern Telephone and Telegraph Company of Canada to take over the

American Telephone and Telegraph interests in the Canadian section of the system.

This undertaking to lay a Transatlantic telephone cable across the sea involving the placing in deep water of more than one hundred repeaters, was a very bold venture; however the successful completion of the project was a very reasonable expectation, for considerable wealth of experience and "know-how" had been collected over many years in submarine cable practice, electronic repeater technique, and with methods of the manufacturing of substantially trouble-free components.

The decision to lay a telephone cable across the Atlantic immediately raised a number of matters that had to be correlated in order to arrive at the first stage of system planning, most important of which was the decision as to the actual cable route. The route was finally selected as shown in Fig. 1, which is north of the many telegraph submarine cables, which have been laid during the past 100 years.

Owing to the combining of American and British technical philosophy within the one system, the Sydney Mines/Clarenville section conforms to British practice and is therefore a single cable having two-directional repeaters, whereas the Clarenville/Oban section in accordance with American practice comprises two separate cables using unidirectional repeaters.

Most submarine cable interruptions are man-made, either by trawling gear, ships' anchors, or are caused by a cable repair ship cutting into a cable in error. Consequently, going north of the area containing the existing submarine telegraph cables was the best way to avoid erroneous interruption by cable repair ships. Trawling is rarely carried out at depths greater than 250 fathoms, and therefore the danger from this interference usually concerns the approach to the shore, and the cable reached its point of landing in the deepest water available. Trawling is a real menace to submarine cables, and the cable ship Monarch, whilst laying the Transatlantic telephone cable off the Newfoundland coast, passed through a fleet of trawlers at work, and excitement prevailed on board when one trawler came unpleasantly near the cable being paid over the stern.

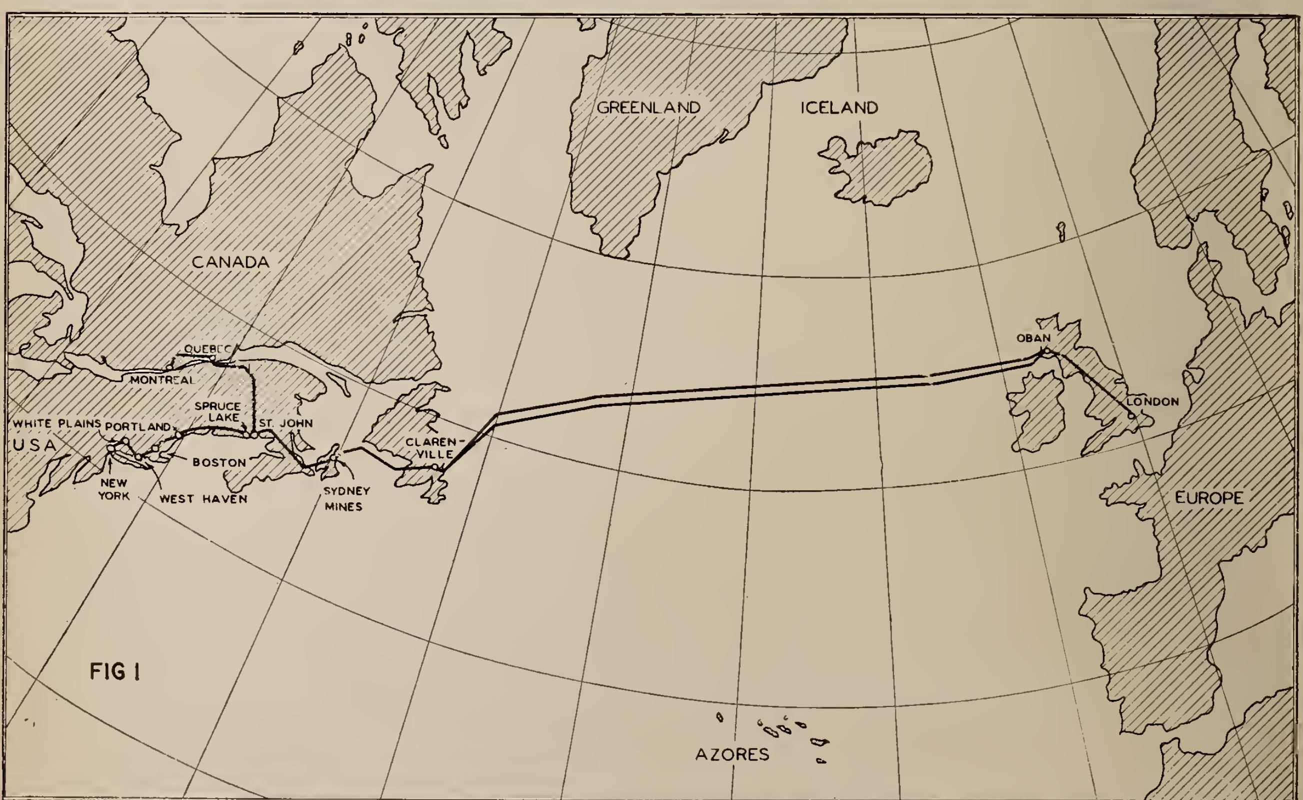
The type of cable employed for the Atlantic telephone is a polyethylene insulated coaxial cable, having a 0.620 inch diameter and a characteristic impedance of 50 ohms. The construction of the cable is shown in Fig. 2. The shore ends are heavily armoured with low carbon steel wire, whereas the deep sea type cable is armoured with much lighter gauge high tensile steel wire, this being done to improve the weight strength ratio of the cable, which is so important in respect of laying in very deep water. The attenuation characteristics of the cable are shown in the curve Fig. 3.

In order to avoid even small deviations from the design transmission objective, exceptional care was taken in the manufacture of the cable, automatic control being employed to retain the diameter to within 0.002 inch; at the same time the control of capacity and concentricity of the cable were maintained within very close limits.

Cable Power Supply

The maximum voltage that can be employed on the cable is at present limited by the voltage to ground, that can be impressed on the components of the repeater. Naturally, the voltage stress is a maximum on the repeater closest to the shore, for normally, power is fed at both ends of the cable, and therefore the repeaters near the centre are not very far removed from ground potential. It was determined from elaborate tests

Fig. 1. Route of the first transatlantic submarine telephone cable system.



that to ensure a minimum life of 20 years for the repeaters, the maximum working voltage impressed on its components, to ground, by the cable power supply, should not exceed 2,500 volts.

The Initial Number of Repeaters

The maximum number of repeaters to be employed in a cable initially, is determined by the voltage drop necessary to activate a repeater, together with the voltage dropped in to the surface of deep water. Consequently, the two ends of the cable when brought to the surface may be miles apart. Since to join these together necessitates the addition of a substantial length of cable, it is necessary to insert a repeater, for otherwise the attenuation of the repaired section of the cable would be substantially increased, which would lower the performance of the cable as a whole.

Therefore, it was imperative to been devoted to the design and manufacture of electronic components of low fault liability, within a given life period. With improvements of design, manufacture and materials, steady progress has led to the present fairly well developed state of the art. Even so, extraordinary precaution was taken in the production of all components used in the repeaters of the Atlantic cable. All the internal metal parts and component casing are gold plated to prevent crystalline whisker growth

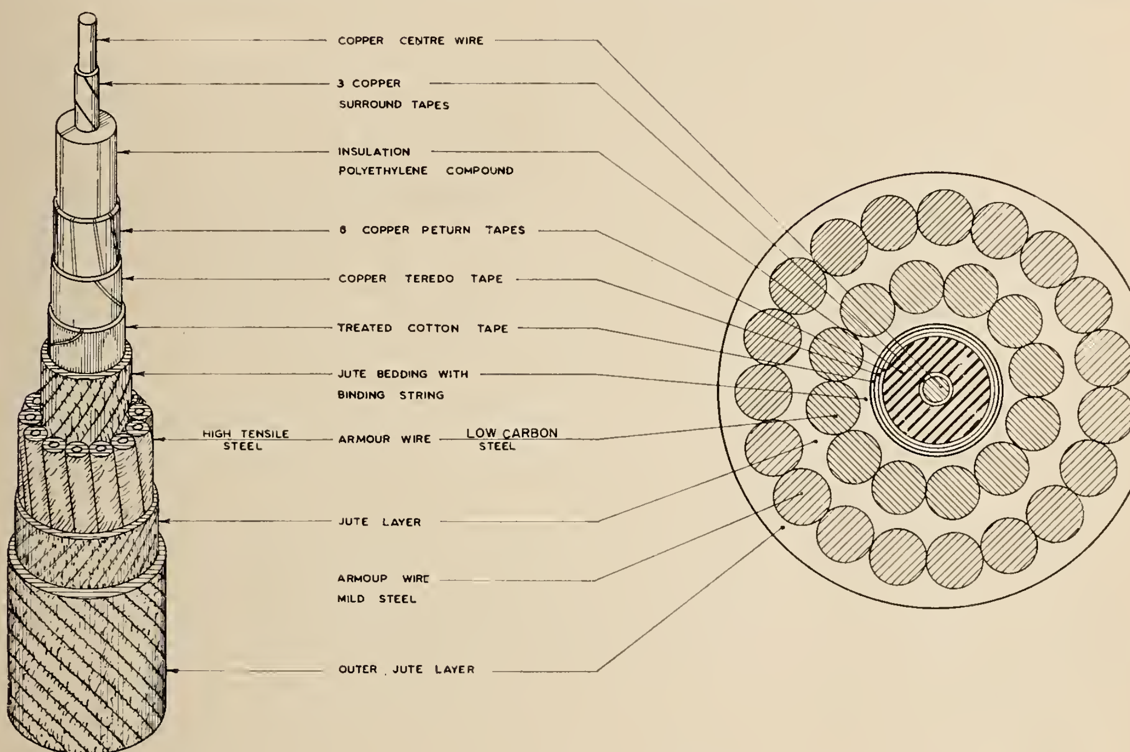


Fig. 2. Structural features of the deep-water type of cable.

the cable itself. The American flexible unidirectional repeater requires approximately 60 volts to energize it, whereas the British rigid type two-directional repeater requires 135 volts. The number of repeaters initially inserted in the cable must be less than the maximum permissible, especially is this so when a large part of the cable is laid in deep water. Fig. 4 shows the depth of the sea bed on the Atlantic telephone cable route.

The replacement of a repeater in deep water, or even the repair of a broken cable, necessitates the addition of a repeater, with a consequent increase in supply voltage to the cable. This will be readily understood when it is realized that, if not already broken, the cable has to be cut by the grapple before it can be lifted allow for at least four deep sea interruptions during the life of the cable.

Repeater Gain

Both the American and British type repeaters are designed to provide approximately 60 db gain at the high frequency end of the bandwidth concerned, and naturally the spacing of the repeaters had to be arranged so that this attenuation was not exceeded. Fig. 5 shows the gain of the two types of repeaters employed.

Component Fault Liability

Before contemplating laying 118 repeaters on the sea bed, the question as to repeater reliability received the utmost consideration. Naturally, the production of reliable repeaters was not a case of starting from scratch; years of untold effort have taking place.

The general principles of manufacture followed in respect of the Transatlantic telephone cable repeaters were as follows:—

(*a*) To use components of proven reliability, even though their use might not be in accordance with the latest technique.

(*b*) To use the best possible materials.

(*c*) Excessive precaution during manufacture of internal repeater parts and assemblies to exclude dust and direct contact with the human hand.

(*d*) Accelerated life testing where possible.

(*e*) Three months' testing of all finished repeaters before consignment for insertion in the cable.

As a result, the 118 repeaters employed were manufactured and laid successfully with one exception. Some minutes after the final splice was made on the Clarenville/Sydney Mines cable section, transmission became interrupted and the cable went dead. The fault was quickly located to the last repeater placed in the sea at the Sydney Mines end. This component had been joined to the cable and tested with Clarenville prior to making the final splice. Fortunately, the repeater was in shallow water and was quickly pulled aboard and replaced. Upon retrieving the faulty repeater, it was found to be in perfect working order, but on further inspection at the works, the trouble was located to a small capacitor inside of which was found a very minute ball of solder, which had moved during the laying of the repeater to cause the $50,000 piece of equipment to become useless. As a result, all capacitors to be inserted in the submerged repeaters are now inspected by X-ray before being used.

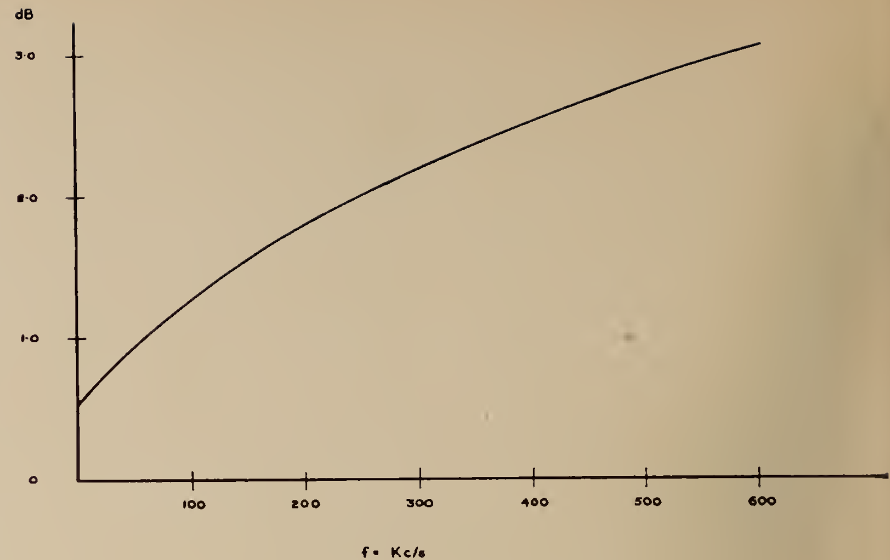

Fig. 3. Cable attenuation per nautical mile.

Cable Laying

The laying of a submarine telephone cable embraces all the difficulties encountered in laying a telegraph cable but in addition there exists the hazards associated with laying the repeaters. The American unidirectional repeater being flexible has the form of a larger diameter cable, and therefore is much easier to handle. This type of repeater can be laid without stopping the cable ship. However, it required the use of 6 to 7 feet diameter sheaves, which are larger than had been used previously, and the cable ship Monarch had to be modified accordingly.

The British type repeaters are rigid and, with existing cable ship facilities, getting them overboard in such a manner that no damage occurs to them, or the cable, is quite a task and necessitates the ship being stopped; consequently, they can, at present, only be laid in comparatively shallow waters. These rigid repeaters are fitted with supervisory devices so that the plane of the repeater during its passage to the sea bed can be observed. Also, any rotational movement on its main axis is similarly observed. The records obtained are very interesting, and show that the movement of the repeater is most disturbed, and that it rotates sometimes at considerable speed during its underwater journey to the sea bed.

Locating Faulty Repeaters

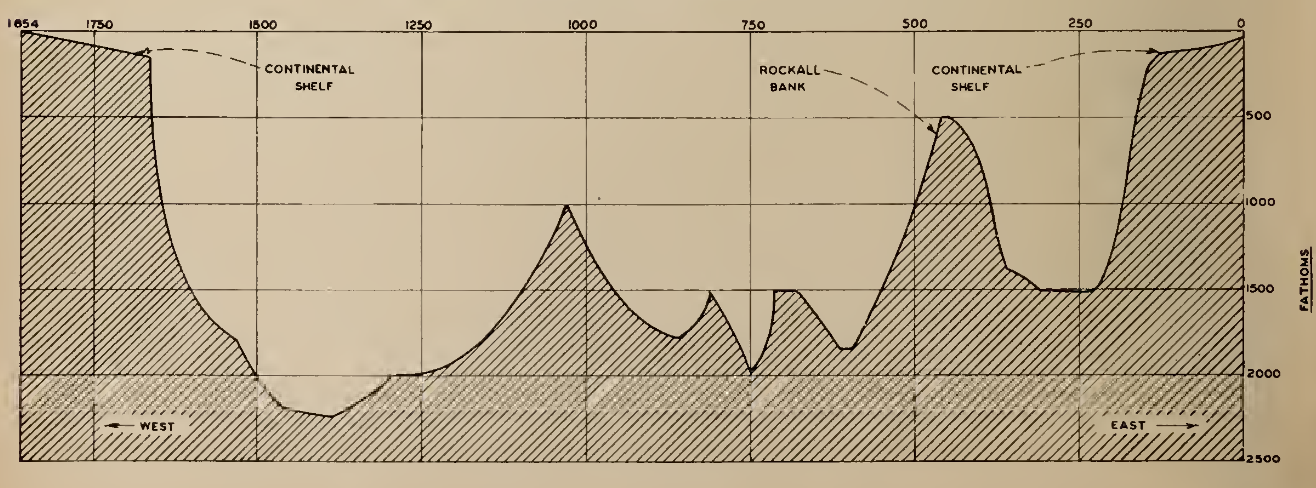
The means provided for testing is different for the unidirectional and two-way repeaters. The unidirectional repeater is arranged so that noise, outside the circuit band, passes through a crystal controlled filter, the output of which is then fed through the amplifier to the cable. The frequencies of these crystal-controlled filters are at 100 c./s. spacing for the various repeaters. By observing this narrow band at the terminal, the general condition of the repeater can be determined fairly well.

One of the tests applied to the rigid two-way repeater is to send from the terminal a test frequency which is selected and frequency doubled by a particular repeater and sent back to the testing terminal. Observing the returned transmission permits a reasonable assessment of the working of the repeater to be made.

Economic Considerations

Before the project was approved, it was concluded that the cost of providing the Transatlantic telephone cable was a sound investment in relation to its estimated earning power. The cost of the Atlantic telephone cable system, although not yet known

Fig. 4. Profile of ocean depths between Clarenville and Oban.



with absolute accuracy, is likely to be in the neighbourhood of $42,000,000. Consequently, it is a fair assumption that the cost of one Transatlantic telephone circuit, including its extension to the terminals of the Trans-Atlantic cable system, will involve a minimum capital investment of $1,250,000.

The interest on this investment, together with the maintenance charges, and profit, is estimated to be something of the order of $300,000 per annum, to which has to be added the out payment in respect of inland connections charges likely to approximate $70,000 per annum. This means that approximately 16,000 six-minute calls at $4.00 per minute would have to be carried annually on each circuit. From this it will be seen that it would have been uneconomical to have provided the cable, involving the cost of $42,000,000 giving less than 36 telephone circuits, if restricted to telephone service. However, owing to other earnings of the system, a considerably lighter traffic load can obtain with the profit objective being achieved.

A certain degree of economic relief was provided on the section between Clarenville and Sydney Mines, for by the addition of only two repeaters, the bandwidth was increased to provide 60 telephone circuits, and so 24 telephone circuits were made available on this section for domestic use; therefore this section is economically superior to the actual Atlantic section. The Transatlantic telephone cable system extends from Sydney Mines to Spruce Lake, N.B., in the form of a microwave section operating in the 4000 Mc/s. band. It is at Spruce Lake that the Canadian and American Transatlantic circuits separate into different routes, one going to Montreal and the other to New York.

Co-Ordinated Effort of Provision

The laying of the Transatlantic telephone cable represents a noteworthy engineering accomplishment, for to achieve its success, meant very close co-ordination between administrations having considerably different technical philosophy. Nevertheless, by frequent joint technical discussions, procedure was defined and provision scheduled. The result was a credit to all participants, for the work was kept ahead of the programme, and the cable was brought into service nearly three months before the date scheduled.

Performance Objective of the Montreal/London Telephone Circuits

The transmission objectives of the system were required to conform to the CCIF recommendations. The net loss objective between Montreal and London four wire test point was set at 0.5 db. The two wire termination loss at London is 3.5 db. which includes a 3 db. pad. The Montreal termination loss is 2 db. which includes a 2 db. pad, so that the overall net loss is 6 db. between the two wire switching points of Montreal and London overseas switchboards. The somewhat stringent overall tolerance on these objectives was set for the system at 0.75 db. deviation. Bearing in mind the number of different sections with their different systems of operation made this deviation objective an exacting requirement which, to all practical purpose, is being maintained.

Frequency Characteristics

The CCIF recommendation for frequency response for telephone channels is shown in Fig. 6, upon which has been plotted the performance of the Montreal/London channels, all of which fall inside the shaded area. Although the CCIF recommendations were accepted as a reasonable standard for the Transatlantic telephone cable system, it was considered to be below the objective desired.

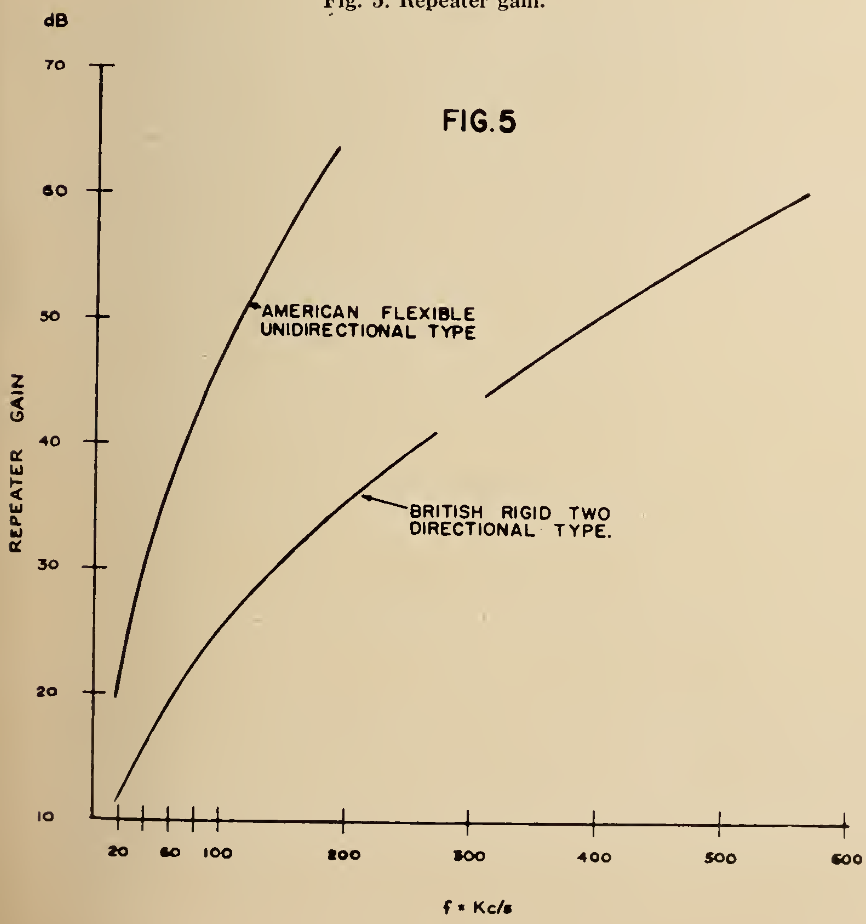
Programme Circuits

The cable terminal includes special equipment to establish "music" quality circuits, providing a bandwidth of either 6.4 or 10.4 kc/s., which utilizes two or three 4 kc/s. channels respectively. The excellent frequency performance of 6.4 kc/s. programme circuit is shown in Fig. 7.

Group Reference Pilots

The 36 telephone circuits of the cable are arranged in three standard groups of 12 circuits and each group contains a group reference pilot, located between the sixth and seventh channel, having a frequency of 84.08 kc/s. This pilot is injected at the two terminals of the system at 21 db. below the zero level reference point, and its received level is recorded at intermediate control stations as well as at the terminals. With this pilot, Montreal and London terminals produce a continuous record of the performance of the Canada/United

Fig. 5. Repeater gain.



Kingdom split group of the Transatlantic telephone cable system. The use of a systems group reference pilot has been introduced comparatively recently, and it has proved to be of great value in respect of maintenance.

Cable Bandwidth Assignment

It may be of interest to know the use of the transmission frequency bandwidth of the cable; this is given in Table No. I. When formulating this assignment, considerable caution was taken and it is not surprising that there appears further usable space available within the guard band of the two-directional section, and possibly at both the low and high end outside the band at present used. Tests are now in progress to determine what additional circuit capacity can be made available.

Canada/United Kingdom Circuits

As mentioned earlier, the Transatlantic telephone cable provides a two-way frequency bandwidth of 26 kc/s. for Canada/U.K. circuits. Six and one half 4 kc/s. voice circuits are obtained, and Fig. 8 is a systems schematic showing the appearance of these circuits throughout the system. Between Montreal and Sydney Mines, the 6½ circuits are contained within a group band which also includes the systems omnibus telephone order wire, and the systems telegraph order wire. The frequency characteristic of the 26 kc/s. band at various stations of the system is shown in Fig. 9, and these conditions are maintained in most cases to within a deviation of less than 0.5 db. The Transatlantic telephone cable system Canadian terminal is in Montreal and Fig. 10 is a photograph of the Montreal overseas test position; Fig. 11 is the telegraph test position which together form the Montreal system control centre.

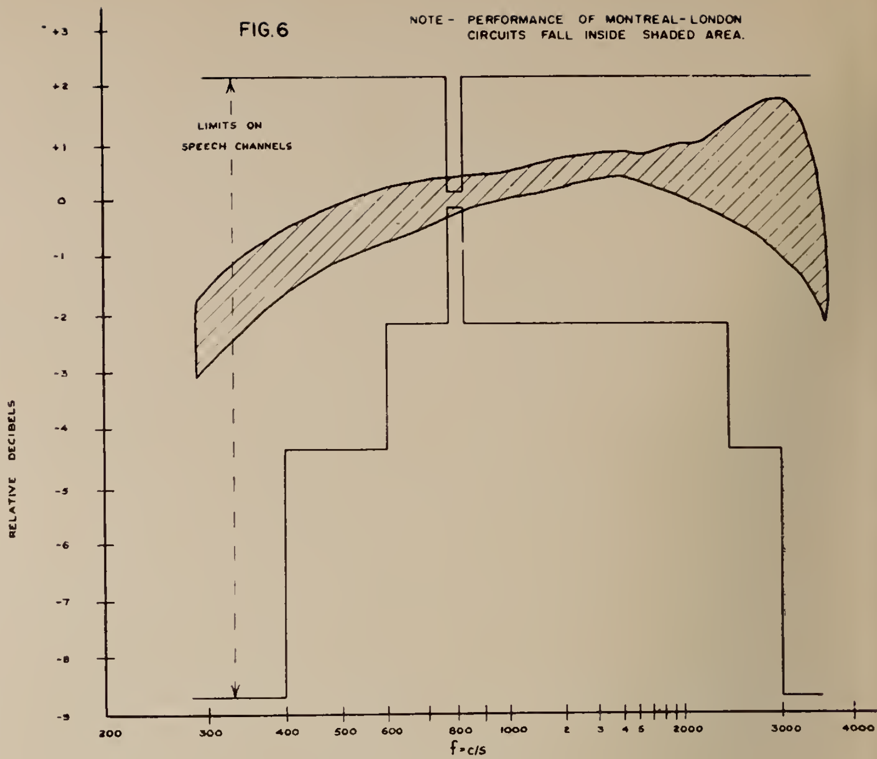


Fig. 6. CCIF voice channel frequency objective.

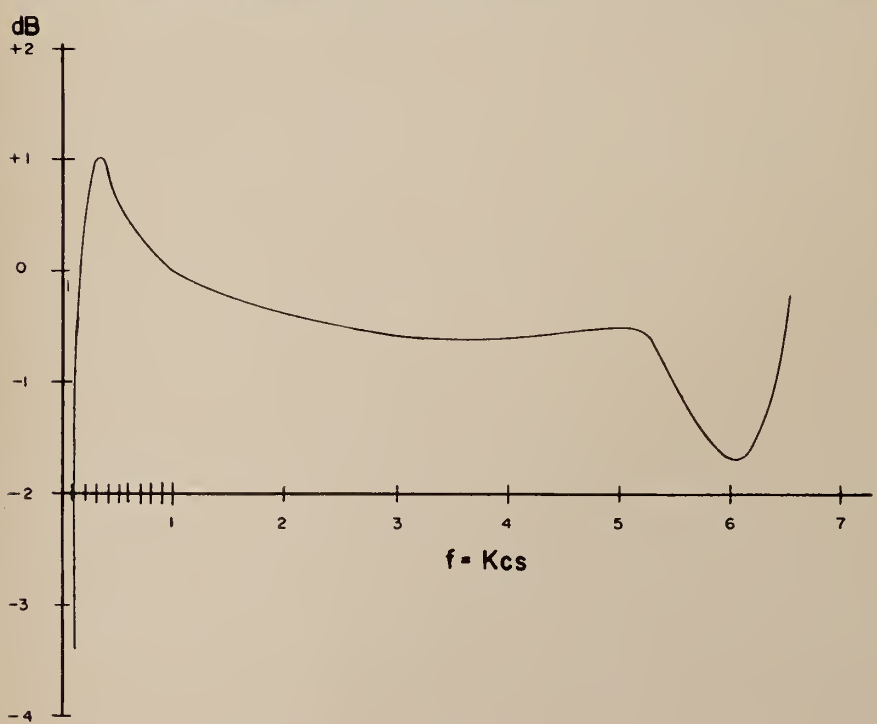

Fig. 7. Frequency characteristic 6.4 kc./s. music-in-band circuit, London to Montreal.

Transatlantic Telephone Traffic

In 1955, the Canadian Transatlantic telephone facilities comprised one full time and one part time radio telephone circuit, whereas at present, six cable and up to four radio channels are made available for public service at all times; except that the radio channels are not used unless they are "merit" 4, i.e., of very good commercial quality. Various estimates were made as to when the six Canadian Transatlantic cable telephone circuits would be fully loaded. Actually, the six circuits have been, more or less, fully taken up since the cable was brought into service on September 25th, 1956. Fig. 12 shows the growth of Transatlantic telephone traffic during recent years, and gives a fair indication of the manner in which the future demand will increase. The forecast for 1957 is very conservative and is likely to be exceeded considerably.

Additional Telephone Circuit Provision

The overload traffic condition, that so frequently obtains on the Transatlantic telephone circuits, indicates the immediate need for increased circuit capacitv, and raises the question as to the relative importance of quality of service in relation to availability of service. Naturally, by the use of conventional 4 kc/s. channel splitting equipment, the six Atlantic circuits, which provide a normal speech band 300/3,400 c.p.s., could be converted into 12, each having approximately 300/1800 c.p.s. speech band. This reduction in speech bandwidth is very undesirable, especially in regard to the extension of such circuits over a lengthy domestic network, but it has been suggested that this is preferable to prolonged delay in obtaining call connection.

Research has shown that by the use of improved filter design, the channel guard band can be reduced to 100 c.p.s. Thus, by an additional stage of modulation two circuits can be derived from a 4 kc. spaced channel, each having a 1.9 kc. usable bandwidth, to provide a speech

bandwidth of 300/2200 c.p.s., which would be a fair quality voice circuit, and it is reasonable to suppose that the improved service would justify splitting the channels in this manner. It was concluded during recent technical discussions that 3 kc. channels separated by latest type filters will provide 300/3200 c.p.s. voice channels, and this appears to offer the correct solution to the problem of providing additional circuit capacity; consequently, the 4 kc. channels of the first Transatlantic cable may ultimately be replaced by 3 kc. channels. To do so, the appearance of the pilots in the cable groups would have to be modified. It would require considerable time to develop all the new filters, so that the use of the channel splitting equipment, first referred to, appears the short term solution.

Automatic Trunk Time Sharing

Whilst on this problem of maximum utilization of expensive bandwidth, it is of interest to note that over a four wire section of a telephone circuit, only one direction is in use at any one time, that is presuming one party is listening. In addition to this, the circuit over which the actual speech is passing has a substantial factor of idle time. The existence of this idle circuit time has led to the development of various methods of automatic sharing of trunk circuit time. Such methods, to justify their use, necessitate the availability of a minimum number of trunks. To describe the system very briefly: for example, 36 four wire circuits across the Atlantic could be arranged to enable, say, 72 or even more telephone conversations to take place over the 36 Atlantic circuits apparently at the same time. The system operates so that when a predetermined traffic load condition exists, the trunk sharing automatically comes into service. At the commencement of speech, following a predetermined pause, an idle trunk is seized via which the speech passes to the distant end, preceded by an indicator. This indicator directs the speech to the correct circuit extension, and in this manner, during a normal call, a person might have spoken over the entire 36 trunk circuits. To avoid clipping of the speech, delay lines of a few milli-seconds will be required at each end in both directions. It is arranged so that the trunk sharing does not operate until the connected circuits approach the number of trunks available.

This equipment is likely to be very costly, and may involve considerable fault preventive maintenance, but neither of these two factors should prove very objectionable, because the additional circuit capacity provided by this means over such costly media, as the Transatlantic telephone cable system, is of great traffic value and, consequently, there is every possibility that automatic distribution of trunk circuit time will become a normal method of expanding the use of such expensive trunk line facilities.

Telegraph Channels

The Canadian circuits of the Transatlantic telephone cable system, that is the six and a half voice circuits, provided on the 26 kc/s. bandwidth, are obtained by splitting cable group number one in the middle of the sixth channel, so that the Canadian bandwidth is 60/86 kc/s. and the remaining 86/108 kc/s. is for American circuits. The six Canadian telephone circuits utilized 60/84 kc. and the 84/86 kc/s. band accommodates eleven frequency modulated voice frequency telegraph channels plus one pilot.

The FMVFCT equipment provides 120 c.p.s. spaced channels, having a modulation deviation of 30 c.p.s. Test on these telegraph channels between Montreal and London show the distortion, at 50 baud keying, to be less than 4 per cent, and at 80 baud keying, distortion is about 10 per cent. As there is a great demand for telegraph channels in excess of those available, arrangements are being made to fit synchronous time division equipment to each channel, so that by suppressing the start and stop pulses over the cable, two 50 baud teleprinter circuits can be provided on each of the eleven telegraph circuits. The conservation of bandwidth in this manner on transoceanic circuits is a well worth while objective, especially in view of the rebirth of telegraphy, which is now taking place.

Also the use of narrow band frequency diplexing is being investigated, the object of which is to provide two circuits on a 120 c.p.s. spaced channel system. The diplex keying uses a four position frequency shift code, and a total deviation, from the mean channel carrier, of less than ± 30 c.p.s.

Consequently, it is reasonable to predict that, by combining time division multiplexing with the diplex, four teleprinter circuits can be provided on each of the eleven 120 c.p.s. spaced channels without increasing the transmission power, so increasing the Transatlantic telegraph channels to 44.

The ability to provide 96 standard speed teleprinter circuits on one 4 kc/s. speech channel in this manner is of considerable importance, and should engage the attention of telecommunication engineers.

Telex

Telex is the international term for a public switching system which provides teleprinter subscriber-to-subscriber connection. Such overseas service was provided in Canada by the establishment of a Telex switchboard in Montreal, which enables any of the Canadian Telex subscribers to obtain immediate connection with Telex subscribers of other countries. This Telex service has been discovered by industry, commerce, allied services, and Government departments as an extremely important and useful medium of communication, the phenomenal growth of which is shown on Fig. 13.

Since the service can be given without attention at the distant station, lack of co-ordination of business hours, which so often restricts the use of the telephone between countries, is not a real hindrance in the case of Telex. Further, the message to be sent can be prepared and checked before the call is made and so permits full utilization of the charged "call" time. The growth in the use of international Telex has, during recent years, been amazing, and there is no doubt that this service will develop very rapidly in Canada. Fig. 14 shows the Montreal Overseas Telex switchboard.

It would appear that telegraphy in this new form, will prove a great competitor to the telephone, in respect of overseas service, not only for the reasons given previously, but because Telex, or rather telegraphy, is the most accurate means of telecommunication; it is also the most economical of bandwidth. Telegraphy permits a substantial degree of signal prediction and error detection at the distant end. For example, by using a seven unit telegraph code, arranged so that the elements of each combination comprise three of one condition of modulation and four of the other condition, most errors, due to the transmission path, can readily be detected. Consequently, if a code combination is received without this ratio being recorded, the receiving equipment automatically detects an error and arrests printing, and then signals the sending end to effect automatic retransmission of the failed signal, and all thereafter. In this manner, in spite of mutilation to the transmission, a clean, accurate, printed message results. This automatic detection of received failures in transmission gives a means of supervising the entire transmission path, which is a very important facility and which may prove very necessary when lengthy telex circuits are set up, including microwave system, long carrier links etc., upon which hits or short interruptions obtained, such as would result in failures on unprotected teleprinter operation. Automatic repetition equipment has recently been brought into service on the Canada/Australia radio circuits with very successful results.

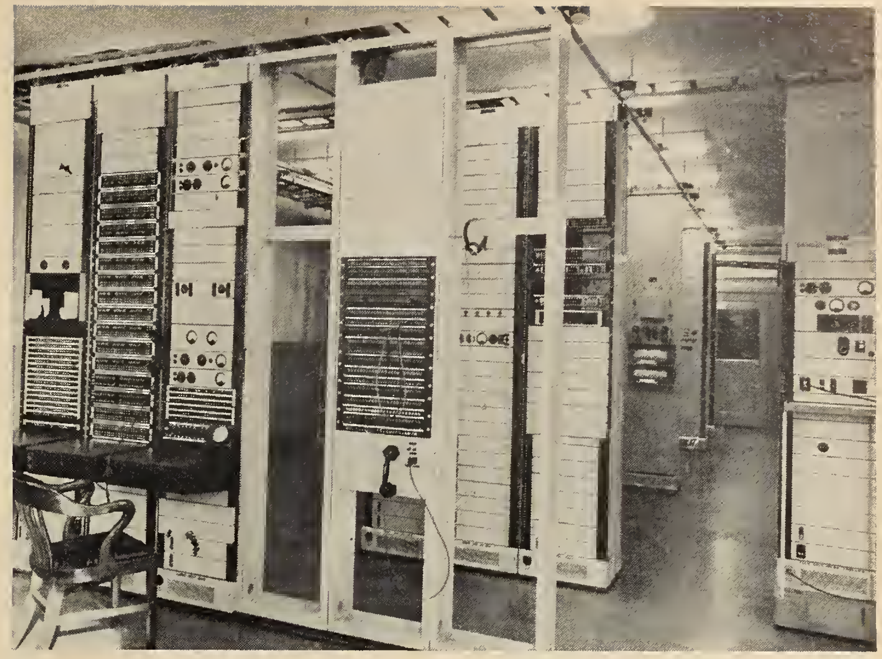

Fig. 10. Montreal overseas telephone test position.

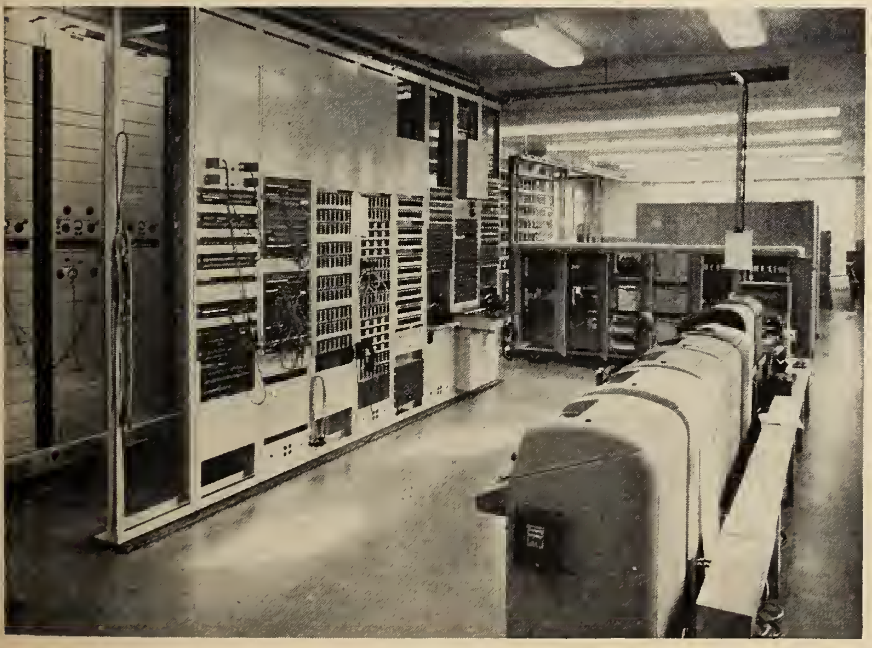
Canada/Australia Telecommunication Development

Until the opening of the new radio stations in the Vancouver area in November last year, the public telecommunication facilities, between Canada and Australia, were limited to the two pacific telegraph cables and one radio telegraph circuit, the latter operating directly with the Montreal area radio stations. No public telephone service operated direct to Australia. The provision of the radio stations on the west coast was with the main object of providing direct radio telephone service, and telegraph circuits for covering interruption of the Pacific submarine telegraph cables, and at the same, to accommodate future expansion of telegraph facilities to Australia, New Zealand, and countries in the Far East. The reason why this was not done by expansion of the Montreal area radio facilities was due to the superior ionospheric path conditions existing between Australasia and Canada from the west coast.

Fig. 11. Montreal overseas telegraph test position.



New Vancouver Area Facilities

These new overseas telecommunication facilities on the west coast comprise a central telegraph office in Vancouver city, which connects with the Montreal terminal by Trans-Canada telegraph channels, and also with the cable station at Bamfield, located on the west coast of Vancouver Island. This is where the Pacific telegraph cables leave Canada for Australia and New Zealand. The Vancouver telegraph office also connects with the radio receiving station at Ladner, about 20 miles to the south. The Ladner receiving station remotely controls the radio transmitting station at Cloverdale, Fig. 15, which is about 20 miles distant.

Figure 16 is a block schematic diagram showing the Ladner and Cloverdale arrangement which, the author understands, embraces the largest radio transmitting station to be operated entirely unattended. The advantages of single sideband operation for telephony are well known, but an additional merit of such method of operation on busy routes is found in the application of independent sideband working which provides up to four telephone channels on one transmitter—two on each of the upper and lower sidebands. A sideband of 6.00 kc/s. wide is used which, by means of equipment, displaces one voice channel, so that two 3 kc/s. telephone circuits are established on one sideband, each providing a nominal 200/2950 c.p.s. voice channel. Thus the overall band width for the four channels is 12 kc/s. This method of operation has the advantage that interference can obtain in part of the band without necessarily preventing the operation of circuits in the other part. It is this flexibility which makes ISB such an excellent method of operating in crowded parts of the radio spectrum.

Cloverdale Radio Transmitting Station

As a consequence, the Cloverdale transmitting station was equipped with three ISB transmitters, each giving a peak power of 30 kw. on telephony. A 5 kw. DSB transmitter was also provided for service development purposes. The transmitting station, as mentioned previously, is controlled from Ladner, and a 6000 megacycle microwave system connects the two stations and provides 18 telephone channels, one of which is being used to provide multichannel voice frequency circuits necessary to establish remote control. Although recordings of the field strength indicate very frequent sharp fading on the micro radio path, the out-of-service time is extremely small. Fig. 17 is a photograph of the Cloverdale transmitter hall.

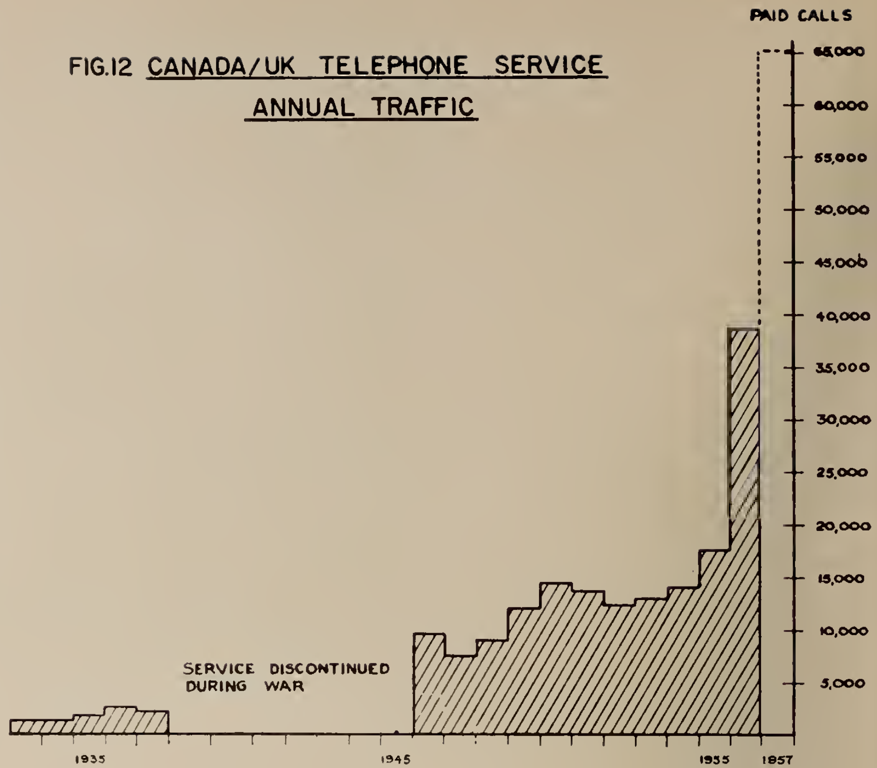


Fig. 12 (above). Canada/U.K. telephone service, annual traffic.

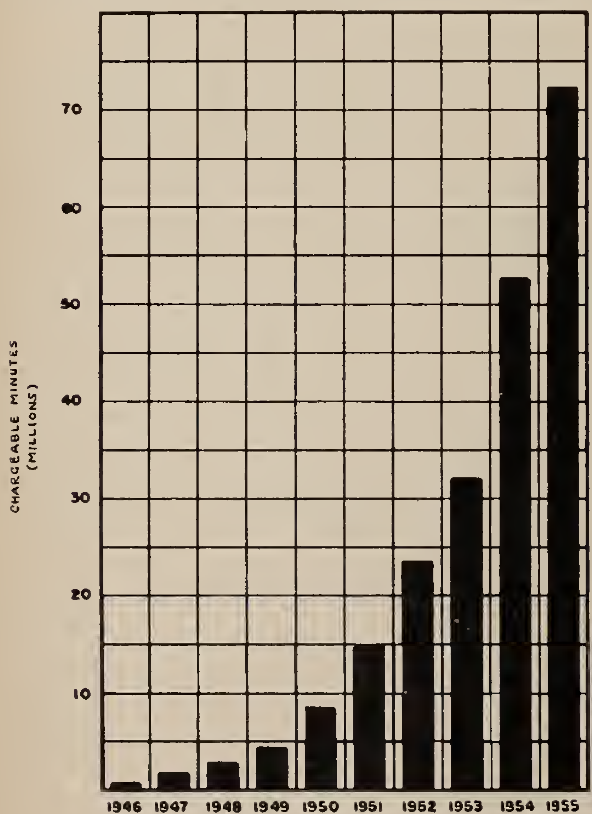

Fig. 13. International Telex traffic: chargeable minutes (extracted from I.T.U. Journal).

The ISB transmitters were specifically designed for remote operation, being equipped with some 15 motorized tuning units. Fig. 18 is a photograph of the transmitter with the air tight doors removed. Separate associated crystal drive units are employed each comprising 6 crystal drive outputs which, by insertion of a suitable crystal, enable the transmitter to be adjusted for operation on any desired frequency within the range 4 to 27 Mc./s.

Another piece of associated equipment is the Independent Sideband Drive, which embraces two balanced modulators providing for two modulating inputs of 100/6000 c.p.s. In this equipment the unwanted sidebands are suppressed, and the wanted upper sideband and a lower sideband are combined with a low level 3.1 mc/s. pilot carrier, which feeds into the frequency changing stage of the transmitter to drive a substantially linear amplifier.

Monitoring facilities are provided to enable intermodulation distortion, carrier level, and other measurements, to be made at all salient points of the equipment. Multichannel voice frequency telegraph channel equipment, having three 1000 c.p.s. spaced channels, each employing frequency shift keying with a ± 200 c.p.s. deviation, is employed on any of the voice circuits, the three voice mean frequency carriers employed being 600, 1600, and 2600 c.p.s. This arrangement permits narrow band receivers to be used for recording the channels separately. Each of these telegraph channels can be keyed up to 120 bauds.

Rhombic antennae are employed at the transmitting station because of their directive quality of propagation, their better efficiency over a relatively large frequency band, and because of their simplicity of construction. This choice meant different antennae for Australia and New Zealand, even though their bearing differs by only 20°. At the receiving station, horizontal array of dipole (HAD) antennae are used in spaced diversity, the HAD being employed because of its broader major lobe pattern which accommodates for variation in azimuthal arrival angle, which means that one antenna can cover the 20° difference in bearing angle of the Australian and New Zealand routes.

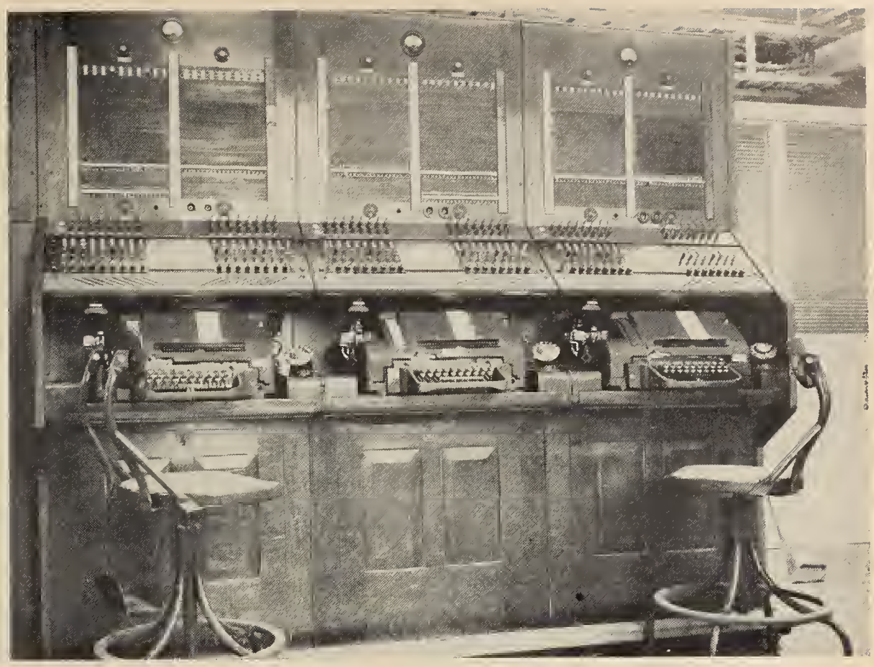

Fig. 14. Montreal overseas Telex switchboard.

Ladner Radio Receiving Station

This station is equipped with the latest ISB receivers, Fig. 19, which have automatically synchronized carrier generating equipment. They provide two outputs upper and lower sideband each of 100/6000 c.p.s., and when four channels are provided, each output passes to the channel restoring equipment, each of which provide two 200/2950 c.p.s. outputs. For connection with the public telephone system, the received circuits are fed via a constant volume amplifier (Vogad) to a telephone terminal which, in a conventional manner, provides for two or four wire connection. To provide for improved secrecy on the radio path the incoming speech on the line side of the terminal is divided into five separate sections of the speech band. These sections are permutated in a time sequence so that the resultant modulation of the transmitter is unintelligible. Naturally, the reverse translation has to take place at the distant end. This five band privacy equipment, such as it is called, has a cycle of 36 different combinations which are switched automatically at a predetermined interval of 4 to 20 seconds, and although not providing for absolute secrecy, offers substantially greater protection than the methods of inversion, previously employed. Means are provided for measuring the circuit delay time to permit correct synchronization between the two ends of the circuit.

Fig. 15. Cloverdale transmitting station.

Telegraph Receivers

The telegraph receivers provided for receiving the FSK transmission on a channel of the three multichannel system, previously referred to, are of a design employing triple superheterodynes with crystal filters on the second IF stage, providing bandwidths of 0.5, 1.0 and 2.0 kc/s. In this manner, a very narrow band receiver is provided having automatic frequency regulation operating under the control of either the mark or space frequency. They cover a range from 3.0 to 27.5 mc/s. in four bands having crystal control of six spot frequencies.

Remote Control

The system of remote control of the Cloverdale transmitting station employs FM telegraph circuits between the two stations. By dialling a predetermined sequence from a control panel at Ladner, any switching function desired to be performed at the transmitting station is selected; indication is displayed at Ladner, by automatic transmission from Cloverdale, as to the actual function selected. Should it not indicate the desired switching, it is cleared, and a second attempt made. Providing the indication is correct, an operate key is depressed at Ladner, following which the required switching is then automatically performed at Cloverdale. The transmitter monitors are fed back to Ladner so that the actual performance of the transmitter can be observed. To prevent fortuitous operation of the remote control, it is arranged to monitor the telegraph channels used for the operation of the remote control equipment, so that should the telegraph channel on encouraged a desire to improve telephone and telegraph facilities between Australia and the United Kingdom, which has, up to the present, been largely dependent on direct radio circuits—entirely so in the case of telephony.

Considerable effort has been made in the past to improve this very troublesome direct radio path by tralia passes through the Suez Canal area, which circuits may be taken from British control. Consequently, a route to Australia and New Zealand, via Canada, is becoming more important each day. It is desired to establish through telephone facilities between the United Kingdom and Australia via the Transatlantic telephone cable, Trans-Canada facilities

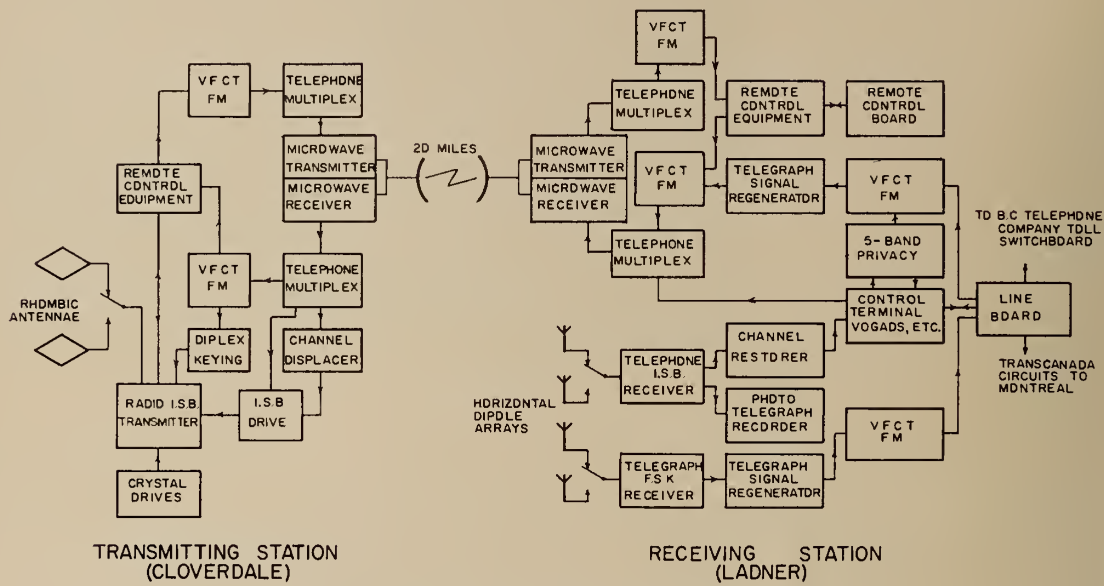

Fig. 16. Schematic of the Vancouver area radio stations.

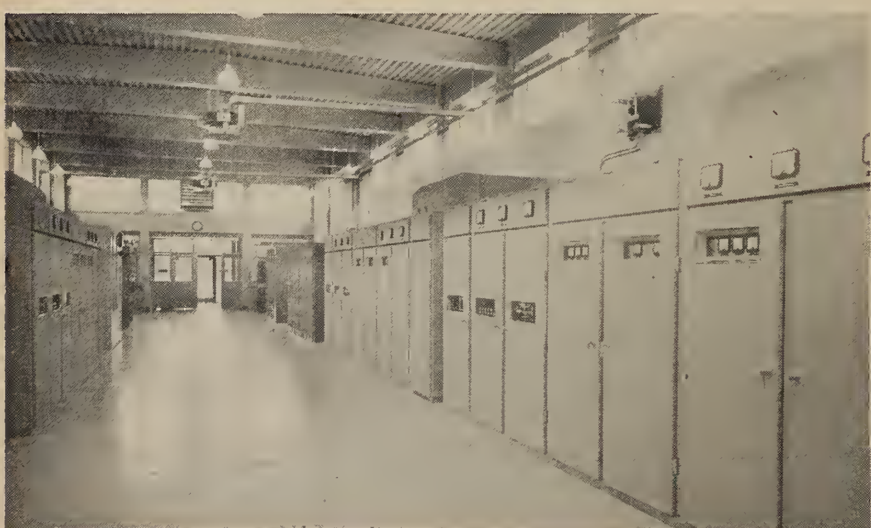
the microwave be troubled with noise or interruption, an alarm is given and the remote control equipment is made inoperative.

Interconnection of Australasia With Europe Via Canada

These recent expansions of Canadian telecommunications both across the Pacific and the Atlantic, have establishing radio relay stations at Barbados, Ascension, and at Colombo, in Ceylon. Even so, radio communication between Australia and the United Kingdom is invariably interrupted for some hours each day, and at some times for days on end; therefore, a better route has considerable attraction. Also, the main route of the telegraph cable circuits to Australia and radio from Vancouver. Also, it is required to extend this service via London to other countries. This means that circuits of from 6 to 8 thousand miles in length would be connected with the Australia/Vancouver radio route, which adds more than another 6000 miles to the circuit, and therefore the "via net loss" and noise must be kept within limits if useful facilities are to be provided. Even with the use of companders and Vogad equipment, the present circuit performance does not come within the desired standard, but there is every reason to state that, before very long, good telephone service will obtain over these phenomenally long circuits, which will prove of great importance to the Commonwealth nations.

Fig. 17. Transmitter hall at Cloverdale.



Future Trends in Overseas Telecommunications

It would seem that the usefulness of radio for transoceanic communication has reached its peak—that owing to crowding in the HF spectrum, the value of the submarine cable, for bridging the oceans, is finding favour. The cable referred to is of coaxial construction employing, as may be necessary, submerged repeaters. In fact, we are on the threshhold of the development of a global wideband submarine cable network.

Naturally, no technical paper would be complete without some reference to transistors or television, and this will be no exception. As is well known, there is no fundamental technical difficulty in providing wideband trans-oceanic cables; the difficulties encountered are in the practical execution, for if the repeater spacing is made six to eight miles apart, a bandwidth suitable to accommodate television in one direction could be provided in a cable. However, this would mean over 300 repeaters in a trans-Atlantic cable section. Assuming the use of the existing design of submerged repeaters, the use of 300 repeaters would necessitate the cable being powered by more than 20,000 volts, and the application of this high voltage—even though it was applied half at either end—would, at the present time, be impracticable.

Consequently, the avenue of development of wideband long haul ocean telephone cables does appear to await the provision of a suitable, very low voltage tube or a transistor of proven integrity, and when this point is attained, the author suggests that laying unidirectional cables may be reverted to as general practice, and that in all probability, the repeaters may become very much a part of the manufacture of the cable. However, it is a reasonable assumption to conclude that the transistorized cable is some years away, and the immediate line of action is to devise all possible means to ensure the maximum use of the bandwidth that can be provided by a cable conforming to present technique.

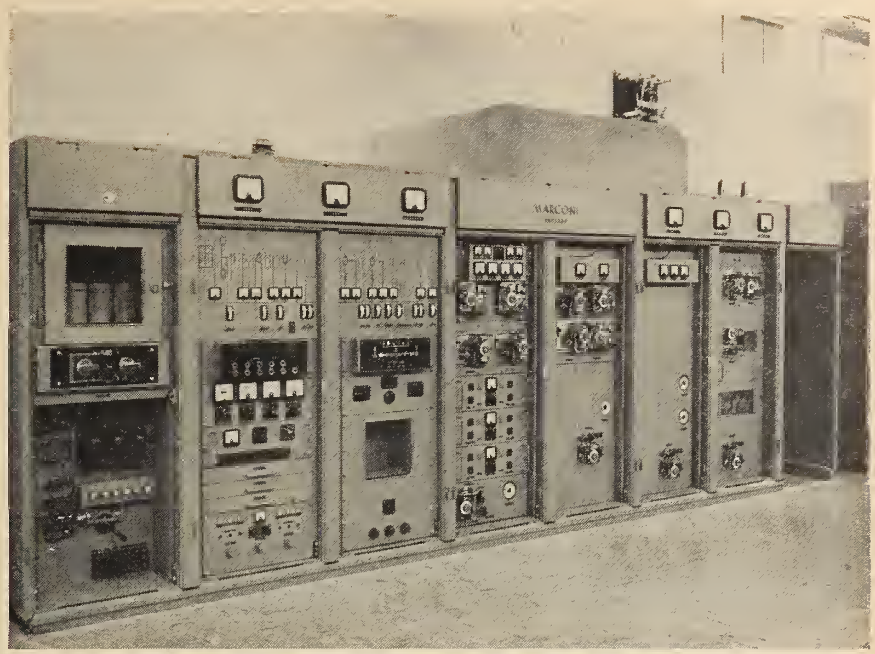


Fig. 18. One of Cloverdale SSB 30 kw. transmitters.

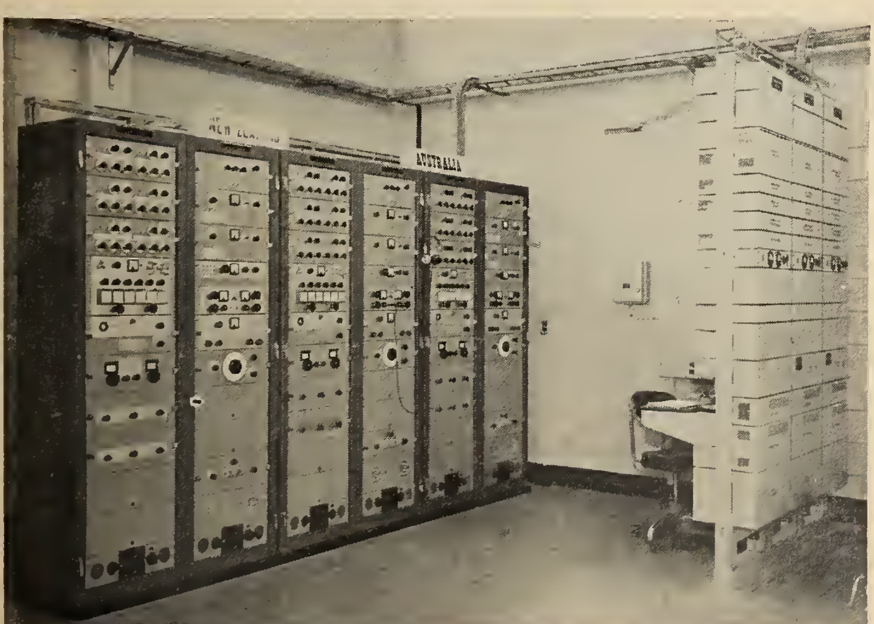
New Type Cable (Fig. 20)

Proceeding in this direction, the British have proposed to abandon outside armouring of the deep sea cable and employ a cable having a stranded high tensile steel central support wire located inside a tubular centre conductor. The central stranded support cable is constructed with reversed helix lay which eliminates practically all tendency for the cable to twist, which at present obtains under the tension of laying, and which naturally occurs in the reverse direction when the cable passes out of tension. Consequently, this twisting of the cable can be seriously troublesome, either during laying or when recovering cable from deep sea, being most active either at the point where the cable reaches the sea bed or on the ship's deck.

Another feature of this new type cable is found in the fact that the outside covering is polythene and is practically impervious to deterioration. This is an essential difference to the existing external armoured cables which, although having a heavy external serving of bitumized jute, after the passage of time the armouring corrodes, and the position is ultimately reached when the cable cannot support its own weight when being lifted from the sea bed for repair. When this stage is reached, there is no alternative but to abandon the cable. This condition should not obtain with the new type cable; in any event, its life should prove to be many times that of existing cables.

Another feature of the new cable is its weight strength ratio. The new cable, as will be seen from the table (Fig. 20), gives a greater margin of strength. This is a very important feature as it obviously will permit cable laying to be carried out in rougher weather than can be done with the conventional submarine cable. Naturally, these advantages, combined with the fact that the new design of

Fig. 19. ISB receivers at Ladner.



cable is relatively cheaper, and which also permits a cable to be provided having much less attenuation than could be obtained with a conventional cable at similar cost, makes its use most attractive. Also, it must not be overlooked that, since the new type cable is so much lighter, the handling on the cable ship during loading or laying is that much easier, which must help to reduce the cost of laying the cable. All in all, this new type cable would appear to indicate that its use will be favoured in future ocean cables for the deep sea sections.

There are one or two difficult problems associated with the use of this new type cable, one being the jointing of the central steel support cable, and another is the joining of this new type cable to externally armoured cable, which must be used in shallow water. Various methods of satisfying these and other requirements are now being investigated and the position looks promising.

Whilst we are forced to use thermionic tubes in the submerged repeaters, it would seem most likely that the rigid two-directional repeater may come into general use. This is primarily because of the high cost of cable and the need to employ many more repeaters when unidirectional cables are provided. This presents a problem, because cable laying ships at present are not designed to provide for the laying of cable with repeaters, except those that are flexible and can pass over the bow or stern sheaves. Laying the rigid type repeaters is done without great difficulty in shallow water, because the weight of the suspended cable in the sea from the ship can be handled with reasonable precautions being taken; even so, it necessitates stopping the cable ship. The whole crux of the problem is to get the repeater from the ship in such a manner that the strain due to the suspended cable is taken through the length of the repeater in a steady gradual manner, as it is fed from the ship into the sea. Methods have been conceived how this might be done, and it is proposed to carry out tests in the very near future. The real answer is to build new cable ships specially designed for the laying of rigid repeaters.

Conclusion

It is envisaged that the future holds very little prospect for the provision of many new HF international radio circuits, but one can predict that it will see the laying of a large number of trans-oceanic coaxial cables with submerged repeaters, which, during the early phase of the era, will most probably tend towards the single two-directional cables with rigid repeaters, using a light weight type cable for the deep sea section. Later, when the transistors replace the thermionic tube, this trend may change by a reversion to unidirectional cables.

In the telegraph telecommunications field, it is considered reasonable to suggest that telex will continue to grow and the public telegraph services may cease to operate as a sep-

Battle River Steam Station

J. N. Ford, M.E.I.C.
Manager of Operations, Canadian Utilities Limited, Edmonton, Alta.

W. I. McFarland, M.E.I.C.
Partner in Haddin, Davis & Brown Limited, Calgary, Alta.

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June 1957.

In Alberta, as in other parts of our Dominion, kilowatt hour requirements have been increasing at a rapid rate. In this particular section of Alberta the kilowatt hour consumption has been increasing 15 per cent per year while peak load demands have been going up 12 per cent per year. When one considers that a 12 per cent annual increase in peak load means doubling peak load figures every 6½ years, and when it is necessary to place orders for generating equipment two to three years ahead of the commissioning date, it is most important for electric utilities to make a forecast of load requirements well into the future. The study of these forecast data made it clear that we would require additional generating facilities by 1956. Since facilities at existing plant sites limited the plant output, a new site was required to offer facilities capable of producing 120 Megawatts or better.

After considering numerous possibilities, it was decided to locate on the Battle River, south of the town of Forestburg. Coal was already being strip-mined by two coal companies near the selected site, one on each side of the river. The coal reserves were therefore known, and with more than one coal company operating in the area the benefit of competition could be reaped in so far as price is concerned.

Water could be supplied from the Battle River by constructing an earth-filled dam across the valley to create a reservoir. Contours indicated the man-made lake would be 10 miles long and ½ mile wide.

In addition to providing the essentials, fuel and water, for the proposed plant, the location was ideal geographically, being about midway between our two existing steam plants and at the load centre of the two areas to be supplied, the Vegreville and Drumheller districts. This planning made necessary the construction of a 138 kv. transmission line to connect the Battle River and Vermilion stations and also two 69 kv. lines to tie the Drumheller plant to the system.

Having established the reasons for constructing the plant at its present location, let us now consider the mechanical features of the Battle River station.

Forecasts of power requirements in Alberta indicated that, by 1956, new generating capacity would be needed on a site with a potential of 120 Mw. or more. The paper describes the background of the plant, its design, and equipment.

The Coal Supply

The American Society of Testing Materials classification of the coal is sub-bituminous Class C. It is found in the Edmonton formation. Cover varies, but a typical section in an existing mine shows thirty feet of clay and soft shale, six feet of coal, fifteen inches of soapstone clay, fifteen inches of bone, eighteen inches of coal and one repetition of the soapstone, bone and coal layers. The drainage conditions are good and the deposit is favourable for open pit mining operations. Operations of the mines are seasonal. The market covers a portion of Central Alberta where gas has not taken over, and extends into Saskatchewan and Manitoba. There is a market for much of the slack coal in Saskatchewan. Freight charges necessitate slack being sold for a low price at the tipple.

Typical analyses of the coal from this area are shown in Table I. These analyses are taken from the 1953 edition of Analysis Directory of Canadian Coals, published by the Department of Mines and Technical Surveys, Mines Branch, Fuels Division, Ottawa.

It will be noted from the analysis that the coal is high in moisture, but low in ash, sulphur and heating value. The coal slakes in storage. It can be stored in large outdoor stock piles if crushed and well compacted.

Coal from this area had never been used in pulverized fuel furnaces. Our company has, however, been pulverizing sub-bituminous Class B coal in Drumheller since 1947. In order to obtain some preliminary information on the performance of the coal from the plant area several carloads of slack coal were shipped to Drumheller for experimental firing. An average analysis from samples on these shipments was as shown in Table II.

This analysis was used in asking for tenders on the coal firing equipment.

Long term contracts were signed with the two large mines operating in the area for the supply of the plant requirements. These contracts provided a basis for calculating the price of coal, either slack or mine run. A base price was set with a formula for adjustment according to changes in equipment and labour costs. The price was based on delivery by truck to the receiving hopper at the plant.

Fig. 1. Battle River station, located on Battle River south of Forestburg, Alta.

The contracts also protected the Utility Company if the mines should cease operation. The Utility Company could take over operations under such circumstances.

In the early stages of the contract slack coal will make up a good proportion of the plant requirements. As the load grows a larger proportion of mine run will be required. However, the favorable price on mine run coal will make the fuel costs very moderate at all times.

Selection of Unit Size

The selection of the size of turbogenerator is always one of the first items to be settled in a power plant development. This selection is governed by the size of the system into which the unit is to be connected, and the expected growth of the system. The ability of the system to supply its load requirements with one unit out of service must be considered.

Referring to the line diagram of the system (Fig. 2) it will be seen that the Battle River station is located approximately midway between generating stations at Drumheller and Vermilion. The system is interconnected with the Calgary Power system at Drumheller, Holden, and Wainwright. These inter-connections will be strengthened over the next few years to minimize the seriousness of a shutdown in the Battle River station. Since fuel at Battle River was to be somewhat cheaper than at Drumheller and Vermilion it was desirable to install a unit which could carry a high proportion of the total load on the system. A unit of 30,000 kw. was decided on, as this size seemed adequate to meet these conditions for several years. It practically doubled the capacity of the system and could generate a large percentage of the energy requirements of the system until a second unit would be required for capacity. The actual machine purchased has a maximum capacity of 32,000 kw. if the power factor is kept up to 90 per cent.

Power shortage due to an outage of the 32,000 kw. unit during peak load periods can be supplemented from other sources; i.e., existing plants plus interconnections. The reliability of modern boilers and turbines coupled with planned maintenance has reduced the likelihood of outages, and it is believed that reliable service can be offered from this single unit plant. Although some early consideration was given to a 15,000 kw. initial installation, such a unit would have required bolstering with added capacity within a very short time, and the use of several small machines would have resulted in higher building costs and a complicated operating procedure.

Selection of Steam Generating Unit

Having decided on an installation approximating 30,000 kw., the next consideration was given to the size of steam generating unit and method of firing. It is obvious with coal at 8,300 B.t.u./lb. the quantity to be burned will be about 50 per cent greater than with 12,000 B.t.u. coal. This influences the type of firing.

Several methods of firing are available, such as travelling grate, stoker, spreader stoker, pulverized fuel, and cyclone firing. If a single unit were decided on, it would be out of the

range of the travelling grate and spreader stoker, leaving only the cyclone furnace and pulverized fuel as possibilities. In fact, no design of a cyclone furnace had at that time been completed for such a small unit, so the choice really was between a single pulverized unit, and two units of pulverized fuel, spreader or travelling grate stoker.

The company had considerable experience with pulverized fuel at Drumheller and were satisfied with this type of firing. The travelling grate and spreader stoker have moving parts within the furnace and some relatively minor breakages may require two or three days shutdown in order to cool the furnace, complete the repair, and place the unit back in service.

There is a tendency to consider the steam generating unit as more subject to outages than the turbo-generator. The record of availability of modern pulverized steam generating units, however, compares favourably with that of the turbo-generator.

With these considerations it was decided to specify a single pulverized fuel unit. Tenders were called on the steam generator including pulverizers, fans and air heater.

Bidders were asked to supply 3 mills of such capacity that 2 mills could carry 80 per cent of the boiler capacity. The boiler capacity was selected liberally (350,000 lb./hr.) to provide for heating of incoming air and other possible auxiliary uses. It is therefore probable that full load could be carried on the turbo-generator with only 2 mills operating.

Steam Conditions

There was no existing plant at the proposed site of the Battle River station, and therefore there was no requirement to match existing steam conditions. The Drumheller steam conditions were 400 lb. and 825° F. total temperature. It was desirable to select a standard steam condition and, with the size of the unit, two conditions were compared, i.e., 600 lb. at 825° F. and 850 lb. at 900° F. For the expected load conditions there was actually little to choose between the two conditions. The choice was made in favour of 600 lb. at 825° F. largely because it was a smaller jump from the pressures and temperatures to which the staff had been accustomed.

Selection of the size of unit (both turbo-generator and steam generator), selection of method of firing, and selection of steam conditions are the major decisions affecting the design and economy of the plant and selections of auxiliary items, though important, have less effect on the economy of the plant design.

Tests of Coal

Since the Battle River coal had never been burned in pulverized form, several carloads were shipped to Drumheller and burned in the power plant furnaces there. It was hoped to learn something from these tests as to the mill sizes required, temperatures of air to the mills required, fineness for good burning, and any other information which might help design satisfactory equipment for the new plant. These tests were supervised by engineers from Combustion Engineering-Superheater Ltd. who supplied the Drumheller equipment.

In general the tests indicated that the coal was easily burned even if the fineness out of the mill did not meet the requirements necessary for Drumheller coal. Unburned carbon loss, even with coal coarser than 60 per cent through a 200 mesh, was below 0.6 per cent.

Power requirements for the mill increased and mill capacity was found to drop off rapidly if the moisture content of the coal was not reduced below 17 per cent. Little improvement resulted from lowering the moisture below 15 per cent. High mill inlet temperatures were found necessary to accomplish the required drying. It was indicated that temperatures above 600° would be desirable. Temperatures above 800° appeared to add little to the mill performance.

Grindability index was determined as 29. Some compensation for low grindability is obtained from the free burning characteristics of the coal. However, the power requirements for grinding are high, and large mills are required.

The information obtained from these tests was helpful to bidders in electing mill sizes.

Steam Generating Unit

The steam generating unit purchased was a two-drum bent-tube boiler with water-cooled furnace, pendant superheater, tangential burners and tubular air heater. This contract included all draught equipment and ducting from the inlet to the F.D. fan to the louvres on the discharge of the I.D. fans. Mechanical type dust collectors were included.

Some design figures on the unit are listed below.

Heating surface (boiler)	18,400 sq. ft.
Heating surface (furnace)	10,173 sq. ft.
Heating surface (air heater)	82,100 sq. ft.
Full load combustion rate	21,750 Btu/hr./cu. ft.
Air to F. D. fans	368,000 lb./hour
Air to F. D. fans	94,000 c.f.m.
Gas to I.D. fans	194,000 c.f.m.

The unit was provided with eight air-operated, steam blowing, long retractable soot blowers with automatic sequential control. Provisions were made for future installation of wall blowers if these should prove necessary.

Since high temperatures were required at the mills, a very large air heater was supplied with the intention of getting 600° F. air from the heater. Later this design was modified with primary air being taken through additional air heater space to give a full load primary air temperature of 680° F. The air heater is installed outdoors with one side sealed to the plant to form part of the plant wall. Regenerative air heaters were considered and were competitive. If the boiler had been larger no doubt regenerative heaters would have been chosen. It was, however, decided to use the tubular heater because of the absence of moving parts.

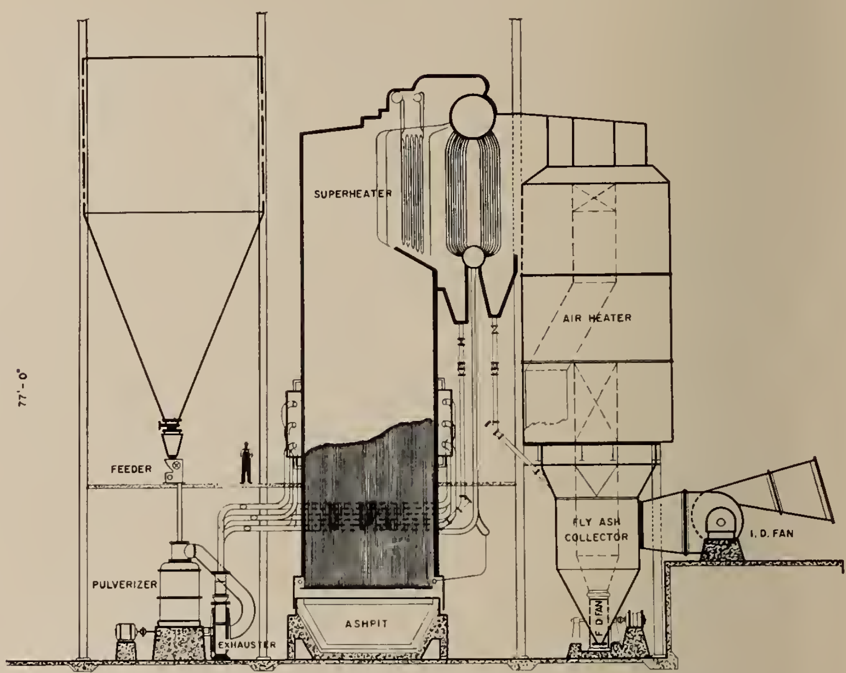

Fig. 3. Steam generator; 350,000 pounds per hour.

The large quantities of air required for the furnace cannot be satisfactorily drawn from the plant during cold weather. If this were attempted the plant would be too cold for the operators and there would be freezing troubles. It is necessary therefore in winter to draw some or all of the combustion air directly from outdoors to the F.D. fan. If this cold air were supplied to the air heater there would be cold areas in the heater in which the gases would be cooled below the dew-point, and corrosion and plugging of tubes would result. Although this condition would be much worse in high sulphur coals, it would to a lesser degree prevail in any plant. A number of ways have been tried to eliminate excessively low temperatures in the air heaters. The incoming air can be heated by steam coils, a portion of the gas can be recirculated, or cold air could be by-passed around the heater. The third method is cheap but results in low air temperatures to the burners and a drop in efficiency. The second method requires modification to the fan inlets for proportioning the admission of gas, requires more fan power, and limits the heating at light loads. The first method adds some draught loss.

At Battle River steam coils were installed to heat the incoming air. The proportion of air to be taken from the plant is determined by manually set dampers in the louvres between the F.D. fan room and the plant and in the outdoor inlet to the fan room. A by-pass damper, which is thermostatically controlled to by-pass air around the heater regulates the air temperature. Control is normally set for 80° F. air to the F.D. fan. Steam to these heating coils is taken from the saturated header and reduced to 200 lb. pressure. Condensate from these heaters is discharged through continuous discharge thermostatic traps to the surge tank in the feed heating system.

Two F.D. and two I.D. fans were called for. The unit is not beyond the capacity of single fans but two fans were specified as some measure of protection against outages. Probably 70 per cent of the turbine load could be carried with one fan out of service. The addition of two fans does complicate automatic control. The F.D. fans have inlet vane control. The I.D. fans have hydraulic couplings and outlet vane control. The latter are located outdoors. Water-cooled sleeve bearings were specified for the fans.

An electrically operated relief valve was installed on the superheater header which is set lower than the main relief valves. This valve takes care of many of the rises in pressure which would normally result in operation of the main relief valves. Since it can be isolated by a gate valve, it can be reseated without taking the boiler out of service. This feature would eliminate some boiler shutdowns resulting from leakage of the main relief valves.

With tilting burners provided, it was not considered necessary to provide dampers in the superheater section or any attemperator control for maintaining accurate superheat temperatures. At very light loads, some falling off in temperature would be expected, but otherwise sufficient range was expected in the burner tilt.

Combustion Equipment

The steam generator is equipped with three tilting burners in each corner of the furnace. One oil torch was supplied for each corner of sufficient capacity to generate 75,000 lb. of steam per hour. Other torches can be added later if it is ever desirable to go completely to oil firing. One coal burner in each corner is supplied from each mill. Some control of steam temperature can be obtained at light loads by selecting the burners to be used. The upper level of burner will naturally give the higher gas temperature through the superheater. This is in addition to the burner tilt control.

Since the coal flame becomes unstable at very light loads, small oil torches (side igniters) can be turned on which play a small oil spray on the coal stream and help to maintain a flame which might otherwise be snuffed out. The igniters are also used to light off the coal when the boiler is being brought into service. Igniters are turned on or off from the boiler control desk.

As stated three mills were called for. The mills supplied are Raymond bowl mills, size 533A, each capable of pulverizing 22,000 lb. per hour of coal with 25 per cent moisture, and 35 grindability index to a fineness of 55 per cent through a 200 mesh screen. These mills are fitted with an integral exhauster which draws the coal-air mixture out of the mill and blows it into the furnace. With one burner in each corner of the furnace, the coal is aimed at the tangent of an imaginary circle in the furnace resulting in high turbulence, which is necessary for proper contact between the oxygen in the air and the carbon in the coal. The mill is under a vacuum which helps to prevent escape of dust.

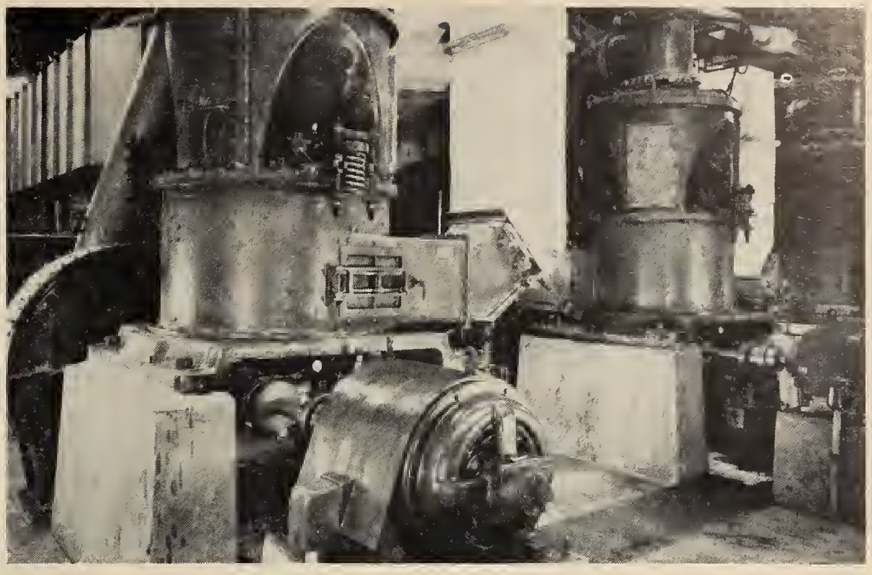

Fig. 4. Raymond ball-mill pulverizer; 22,000 pounds of coal per hour.

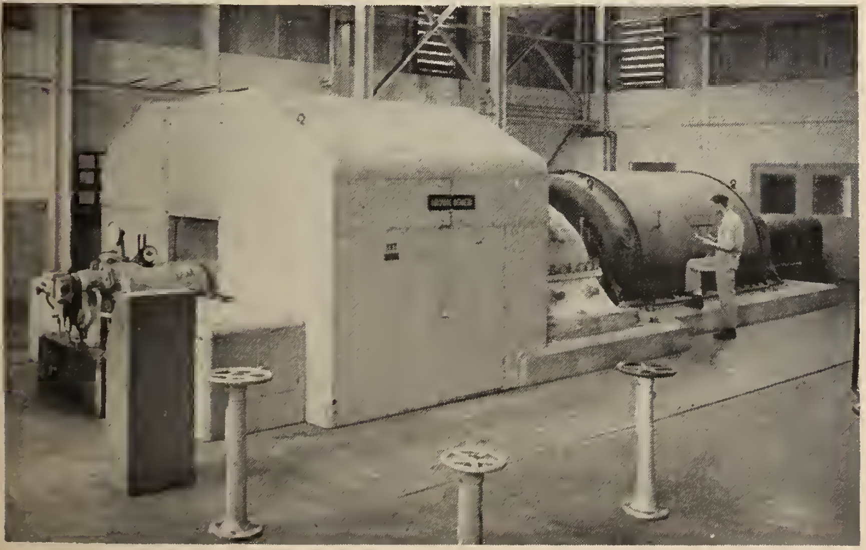
Coal is fed to the pulverizer from a feeder placed on the operating floor above the pulverizers. Coal is measured by pockets in the rotating wheel of the feeder. The rate of feed is then determined by the speed at which the feeder rotates.

In the operation of a pulverizer the coal remains in the mill until it is fine enough to be borne out by the air stream. With the coal at Battle River it is necessary to dry the coal considerably in the mill and high air temperatures are required — in the order of 680°.

The coal burns in suspension in the furnace, being mixed with additional (secondary) air which is admitted around the burner. The proportioning of coal to air is done automatically by the combustion control equipment. The combustion arrangement is standard except for the special provisions to get high air temperatures to the mills.

When the gas leaves the air heater, the induced draught fans deliver it to the chimney which is located a short distance from the plant. An insulated steel breeching connects the I.D. fan discharge to the chimney.

Fig. 5. Turbo-generator; 32,000 kilowatts.



Chimney

The chimney has an inside diameter of nine feet at the top, 15 feet at the bottom, and is 180 feet high. Radial brick was selected though concrete was competitive. The chimney was lined with radial brick for about 40 feet of its length. The design of the chimney was selected to give sufficient draught to overcome chimney losses at full load.

The Turbo-Generator

The turbo-generator installed at Battle River was manufactured in Switzerland. Nominally rated at 30,000 kw. at 80 per cent power factor, it has a capability of 32,000 kw. with power factor not less than 90 percent. The short circuit ratio of the alternator is 0.7.

The turbine is single cylinder with impulse followed by reaction blading. It has four bleed points for feedwater heating. It was designed for 28.5 in. vacuum. Since fuel is cheap and condensing water ultimately limited, it did not appear economical to go to higher vacuum for greater efficiency.

The turbine is connected by solid coupling with a 35,300 kva. air-cooled alternator. A direct connected exciter with pilot exciter is used. Hydrogen cooling was not specified for the generator, though American practice would favour such cooling for a 30,000 kw. unit. For European machines the extra efficiency from hydrogen cooling would not have shown an operating saving with the low priced fuel. Following the underlying principle of keeping the plant as simple as possible it was decided to specify only air cooling.

The turbine exhausts into a two-pass divided surface condenser with a cooling surface of 26,800 sq. ft. The tubes are of Admiralty metal and are 1 in. in diameter. The tube plates are of steel. This latter selection was made after some hesitation but it is not expected that cooling water conditions will result in tube plate corrosion.

Condensing water requirements with water at 70°F. are 27,000 Imperial gallons per minute. This drops to 15,000 gallons per minute in winter with cooling water at 40°F.

Steam is brought to stop valves on both sides of the turbine. Stop valves are followed by governing valves which control the admission of steam to the turbine. For light loads partial admission of steam is used, with additional nozzle sections being brought in as the load increases. Governing is effected by oil under pressure with action initiated from a flyball governor. Normal oil pressure is maintained by direct gear-driven oil pump. An emergency electrically driven pump will take over in case of a dangerous drop in oil pressure or during start-up and shutdown procedures. A steam driven oil pump is also available.

Special protective features incorporated in the unit are, centrifugal type of over-speed tripping device, low vacuum load rejection and trip, and axial displacement alarm and trip. All the emergency tripping devices act through a valve which releases control oil pressures under the stop valves causing them to shut instantly. If for any reason the vacuum should fall below 25 in. of Hg the load rejection device will allow a certain leakage of oil out of the governing system permitting the governing valves to move towards the closed position, thus reducing the load carried by the machine. Should the vacuum continue to decrease to a dangerous point, the low vacuum actuates the emergency shutdown device and causes a complete shutdown of the machine. The turbine cannot be restarted until the trip is reset and the normal starting procedure is followed.

The axial displacement alarm warns of axial movement of the shaft within narrow limits. If the movement exceeds these limits the second stage of the protective equipment will initiate a complete shutdown.

The normal governor of steam turbine has about 5 per cent droop in the speed characteristic from zero to full load. That is, if the governor is adjusted at full load to 3600 rpm and full load was slowly applied without adjusting the governor, the speed would drop about 5 per cent. This assumes the unit is not connected to an electrical system. Normally the operator would correct this droop by ad-

justing the governor setting. This droop is desirable in order that machines may be operated in parallel without one or the other machine attempting to grab all the load on the system. With a steam unit connected in a system with a large hydro unit, there is a tendency for steam units to be more sensitive to load changes and they may become overloaded. A device has been added to the Battle River unit which will permit adjustment of the drooping characteristic even when the machine is in operation. This device will permit adjusting the droop to as high as 20 per cent. This is a recent development which, it is expected, will assist in the operation of this station while paralleled with the Calgary Power system.

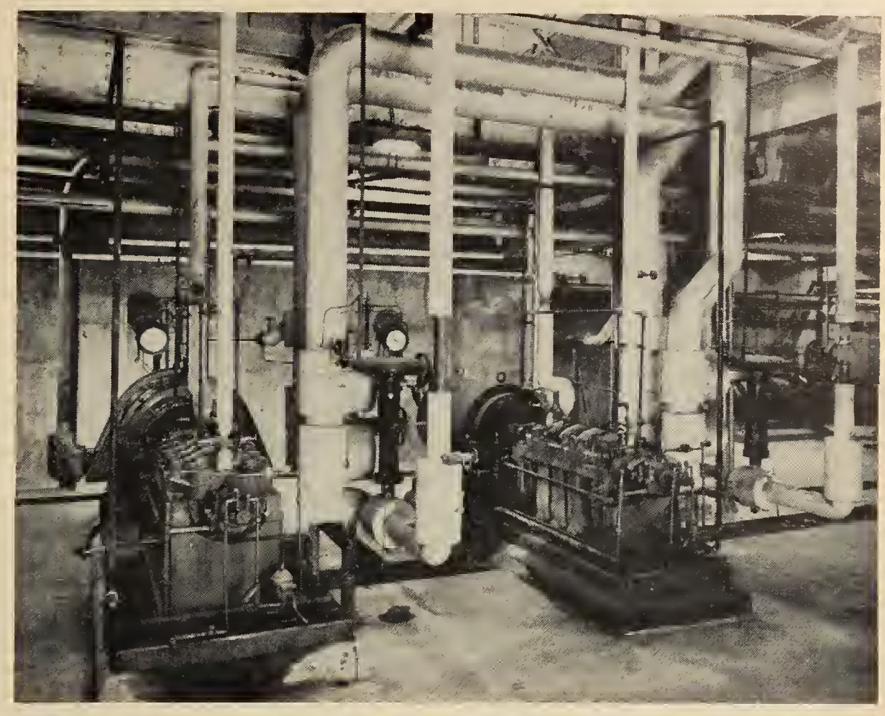

Fig. 7. Boiler feed pumps; 600 h.p.

Feed Heating and Make-up

The feed heating system was included as part of the turbine supply. It is a four-stage system with two low pressure and two high pressure heaters. Condensate from the condenser is pumped by the extraction pump through the two L.P. heaters and sprayed into a surge tank located near the top of the boiler plant. This surge tank is vented back to the condenser and the surge tank acts as a deaerator though most of the deaeration takes place in the condenser. Water from the surge tank returns to the boiler feed pump where it is pumped through the high pressure heaters and into the boiler drum. The final feedwater temperature is 360° F. at full load.

Raw water for "make-up" is first treated in a hot lime-zeolite process softener. It then goes into a storage tank or into the evaporator. There are a number of processes to choose from for treatment of boiler feedwater make-up. The water can be conditioned by evaporation alone; by demineralization alone; or by acid zeolite, split stream, or hot lime-zeolite with or without evaporation. Economically for this station the choice lay between the hot lime-zeolite process or no pre-treatment ahead of the evaporators. On a future installation further study will be given to the possible elimination of the evaporators.

The make-up water is drawn from the storage pond in the Battle River. The analysis of this water will vary from season to season. Two analyses are given in Table III to give some indication of the range in quality.

A probable analysis after treatment is as shown in Table IV (based on an average raw water).

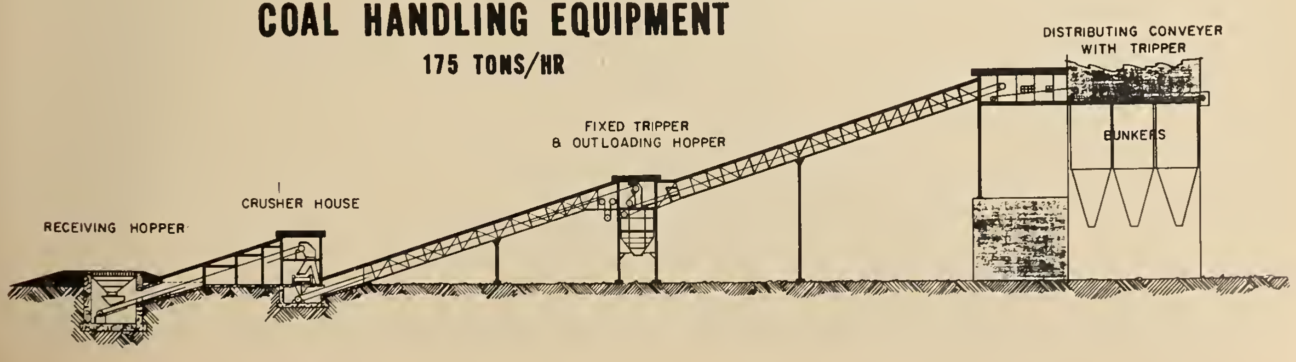
Chemical costs for pre-treatment of water are in the order of 4 cents/1000 gallons.

Steam for the evaporators is taken from the second bleed point on the turbine. This same bleed point serves the first high pressure heater. The evaporated make-up enters the second low pressure heater and along with condensed steam cascades back to the first low pressure heater. It is then passed back to the condenser at very light loads or is picked up by the drip pump at heavier loads and introduced into the feedwater line on its way to the surge tank.

The level in the surge tank is float controlled. If it reaches the top limit an electric valve is opened permitting condensate to go back into the storage tank. If the low limit is reached another valve is opened which permits water from the storage tank to be drawn back into the condenser.

The evaporators are single effect. Cupro-nickel tubes were used as it was felt that copper tubes might not resist corrosion from the high pH water reaching the evaporator. The pH of the make-up water would be of the order of 10.2 to maximum 12.

Fig. 8. Coal handling equipment; 175 tons per hour.



Provisions were made for the feeding of such other chemicals as are necessary for delivering a satisfactory water into the boiler drum.

Boiler Feed Pumps

Selection of boiler feed pumps involves size and number of units, type of drive and control.

In Battle River it was decided to use two 100 per cent capacity pumps. It was first intended to use one pump with direct constant speed motor drive and one turbine driven pump. A hydraulic coupling was considered for the motor driven pump but the coupling did not show fuel savings sufficient to justify its cost. It was attractive from its operating characteristics but it was finally rejected. The turbine drive was finally rejected also mainly because the turbine manufacturer did not wish to handle the large quantity of exhaust steam from the turbine in his feed heaters, and the losses resulting if steam were exhausted into the condenser would have been large. The result was that two direct connected motor driven pumps were purchased. The motors are 600 h.p. and are two of the larger auxiliary motors in the plant.

Condensing Water

The Battle River is a very small river in which the flow may vary from zero to perhaps 5000 c.f.s. during floods. In order to be assured of water at low flows a dam was constructed across the river and a storage pond created.

A pumping plant was constructed beside the cooling pond. Two vertical mixed flow pumps were installed, one of 27,500 I.g.m. capacity and one of 13,000 I.g.m. capacity. The smaller pump was designed to provide cooling water for full load conditions during winter while the larger one was designed to provide full load summer requirements with the water at 70° F.

The large pump is driven by a 700 h.p. motor and the smaller one by a 350 h.p. motor. Both are full voltage starting.

Revolving screens are installed in each pump intake well.

The pump station is remotely operated from the control desk in the power plant. Alarms will indicate high bearing temperatures on the motors, or low water on the downstream side of the screens. In the latter case the operator can start up the screens and turn on the screen wash water.

Fig. 9. Ash handling equipment and chimney.

The pumping plant is about 600 feet from the power plant. Forty-two inch steel pipe carries the water to the condenser. Wood stave pipe was used for the discharge from the condenser to carry the water beyond the power plant grounds. From there a steel flume conducts the water about 3000 feet upstream at which point it returns to the storage pond. At periods of low flow evaporation will aid in maintaining a reasonable cooling water temperature.

Coal Handling

As previously stated coal will be delivered to the plant by truck. The coal may be anything from pea slack to mine run. Slack coal will be delivered at the Battle River site at the rate it is produced at the mines. This may be faster than the plant is consuming the coal. In such cases, the coal will have to be stocked.

Various types of trucks will be used by the coal truckers to deliver their coal, including end dump trucks and large centre dump coal haulers. Coal will be reclaimed from the stock pile by tractor-hauled scraper. The receiving hopper is required to accommodate both mine run and slack coal and all of the various vehicles mentioned. The major vehicle considered during design provides for driving this hauler across the hopper and dumping any coal up to 16 in. size into the centre strip of the hopper. End dump trucks back on to the hopper and dump into the centre strip. It was found desirable to place vibrators on the receiving hoppers to ensure free flow of coal during extreme weather conditions.

Because of the length of hopper required to accommodate a 40-ton hauler, the receiving hopper was constructed as a double hopper. Reciprocating feeders move the coal from the bottom of these two hoppers on to a 42 in. belt which raises the coal to a crusher at ground level. The receiving hopper, crusher, and weigh scales are all close together at ground level. This arrangement was intended to save man-power in operation.

The crusher supplied was a double-rotor ring-type Knittel crusher with each rotor driven by a 50 h.p. motor. Coal from the crusher is hoisted by a 24 in. belt to the top of the plant where it is discharged into travelling tripper for distribution into the bunkers.

For stocking out coal a fixed tripper is placed part way up the hoisting conveyor, and by manipulation of a flop gate coal can be diverted into the stocking out hopper. From there it can be hauled to the stock pile.

The coal handling system was designed for 175 tons per hour. This would handle the coal for a continuous load of 60,000 kw. in less than eight hours. Further capacity could be obtained by higher belt speeds. but it will also probably be necessary to take delivery over longer periods than 8 hours in order to accommodate the mines. The coal is crushed to 1 in. minus.

For stocking, compacting and reclaiming coal, three pieces of equipment were purchased. These were a D7 tractor, a front end loader, and a seventeen yard scraper. The tractor does most of the compacting. Reclaiming can be done by tractor and scraper or by front end loader and truck. Run of mine coal will be crushed before stock piling.

Ash Handling

The ash handling system is of the vacuum type. Sluicing was considered but since there was sale possible for the ash, it was decided to use the dry removal system. A system for handling 12 tons/hour was installed, with a steam exhauster for producing the vacuum. The evacuating equipment was placed outside on top of a 100-ton glazed tile storage silo.

The system works on the intermittent principle. An air washer is used in the discharge from the ejector. Selection of steam exhauster over a Rootes blower for producing vacuum was based strictly on price. Live steam at 600 lb. and 825° F. is used.

A dustless unloader was installed for tranferring ash from the hopper to the truck. Sufficient water is added in the unloader to prevent the dust from rising from the ash.

Provision is made for keeping the coarse ash from the furnace bottom separate from the fly ash in the collector. The silo is partitioned and a remote operated gate permits directing the ash into the proper compartment of the silo. At the time this was planned, it appeared there would be a market for fly ash but possibly none for the coarse ash.

Control Equipment

The control is largely pneumatically operated. Combustion control operations are initiated by a pressure sensitive relay acted on by the main steam pressure. A drop in steam pressure is converted into a change in control air pressure which starts the

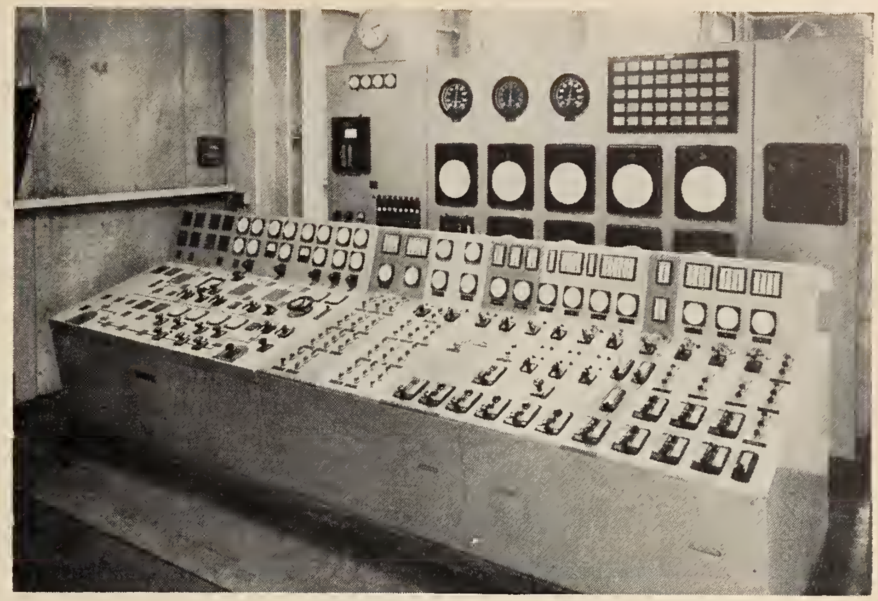


Fig. 10. Substation turbine generator boiler control equipment.

necessary corrective steps in order to restore the steam pressure to normal. To produce more steam, more coal and air must be fed into the boiler so the control pressure changes are transmitted to the fan dampers, the hydraulic couplings, the exhauster dampers and coal feeders in order to bring about the increased heat production. Corrective influences are fed into the control system to maintain the proper coal/air ratio for good combustion.

The controllers performing the actual moving of dampers, valves, etc. are pneumatically operated cylinders with suitable linkage to produce the desired movement.

Since the mills are started by the operator, the boiler may be operating with one, two or three mills at one time. It is impossible to cover the full range of boiler load under these conditions and reduction from full load to quarter load requires taking off two mills. In order that the load may not go beyond the limits of the mills in service, limiting relays are a part of the control equipment. These are set to cover the limit which the automatic control can handle for the number of mills in service. For example, if three mills were in service the low limit on the control might be set at 150,000 lb. of steam per hour. If the steam requirements fell below that it would still not be safe to cut the coal and air supply below a certain point. Thus more heat would be supplied than required. The pressure would rise and would eventually open the safety valve. By this time the operator could take off one mill and reset his load limiting relays. This may seem undesirable, but it is a safe arrangement whereas cutting the load on three mills to a dangerous point would snuff out the fires and might result in an explosion.

Automatic control of the steam temperature within the limits of the equipment is provided by converting the change in steam temperature to a change in control air pressure to produce a change in the burner tilt. The change in air flow is used to anticipate a probable change in steam temperature and thus initiates the corrective action as early as possible.

Feedwater is controlled by similar equipment which receives indications from steam flow, feedwater flow and drum water level. The control attempts to keep steam and water flow even, but drum level acts as a corrective influence to restore any departure from normal level. The actual control of the flow of feedwater is by regulating valve. Where hydraulic couplings are used on feed pump drive, the setting of the coupling is altered to change the rate of flow.

The control switches for the pneumatic control system and for the various electrical switches are installed on a control desk mounted between the boiler and turbine on the operating floor. Indicating instruments occupy a portion of this desk. A vertical panel in front of the desk contains some of the larger indicating instruments and the graphic instruments. From this point the operator can control all the normal operation of the boiler, turbine and plant auxiliaries.

Forces Involved in Pulpwood Holding Grounds

I. Transverse Holding Grounds without Piers

R. J. Kennedy, M.E.I.C.

Associate Professor of Civil Engineering, Queen's University, and Supervisor, Project RC-12, Pulp and Paper Research Institute of Canada.

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June 1957

The pulpwood holding ground is the link between cheap river transport of pulpwood and the mill yard, but very little has been known of the forces which its structures should be designed to resist. The Pulp and Paper Research Institute was asked by the industry to investigate the problem and this report covers the first phase of the project.

A survey of field installations and practice in eastern Canada was made. The objectives of the study were then defined, and a combined laboratory and field investigation begun. Methods of calculating the total force exerted by the water on the wood in a transverse holding ground, and the division of that force between the shores and the boom system, have been developed. The rather complex solution is presented in nomographic form and a typical design problem is worked out. Finally, in Appendix 2, the force measured on a large holding ground in 1956 is compared with that calculated from the nomograph for the same conditions; the agreement is within seven per cent.

SINCE THE days of squared timber rafts, Canadian forest products have been floated to market with the force of gravity supplying much of the necessary power. Most of the vast quantity of pulpwood produced in Canada today proceeds down creeks and rivers and is held for a time in pulpwood holding grounds, a single one of which may contain millions of dollars worth of wood. Very large sums of money are spent on the construction and maintenance of the booms, piers and anchors of these holding grounds; but comparatively little is known of the forces, caused by the flow of wind and water past stationary pulpwood, which these structures must resist. Occasionally, under severe conditions, structures fail, resulting in the escape of quantities of valuable wood. On the other hand, many structures are built so that they possess strength far in excess of that required for a reasonable factor of safety. With this in mind, the pulp and paper industry asked the Pulp and Paper Research Institute of Canada to investigate the whole question of pulpwood holding grounds, and in May, 1952, a Steering Group met and laid out a preliminary programme. A three-man team was formed and commenced working on the problem under the guidance of the Steering Group.

The first steps taken by the project team were to conduct a literature survey and to send out questionnaires requesting basic data on holding grounds. When the information received had been organized, a field inspection of about forty holding grounds in eastern Canada was made.

It became apparent that river holding grounds are of two main types:

(*a*) Transverse — with a boom stretched across the river at a sharp angle to the current.

(*b*) Parallel—with the boom nearly parallel to the main current and the banks, usually to permit navigation.

Illustrations of these two types are given in Figure 1.

In addition, there are lake holding grounds and holding grounds in tidal waters, each with their own characteristics.

The function of each type of holding ground is the same—to hold wood stationary against the forces exerted by water and wind. The design of safe and economical holding grounds requires a knowledge of the magnitude of the forces which will act on the booms, piers, ties and anchors. The present study is concerned with the determination of these design forces for given physical conditions.

River holding grounds, which outnumber all others, are mainly affected by water flow. The forces caused by wind are independent, and may be added vectorially to those caused by water. The investigation of wind forces was, therefore, postponed until a later stage.

Considering only the action of the water, there are three basic factors governing the magnitude of the downstream thrust, T_1, which is imposed upon the jam of pulpwood. These are:

(*a*) the quantity of wood held,

(*b*) the maximum stream flow,

(*c*) the physical characteristics of the stream.

All of these may be measured or estimated with some degree of accuracy, and the first part of the problem involves the discovery of the relation between T_1 and these factors.

The total downstream thrust imposed upon the wood by the water is then transmitted to, and ultimately resisted by, the shores and various structures of the holding ground. The second part of the problem is the determination of the ratio in which T_1 is divided among these resisting elements.

Because the measurement of pertinent variables at full scale is difficult and their manipulation usually impossible, it was decided to use scale models, which could be controlled easily, to determine relationships over a wide range of conditions. The results (suitably corrected for scale) could then be spot-checked by field measurements on actual holding grounds.

Since the transverse holding ground without piers in a straight stretch of river promised to exhibit the simplest relationships among the variables involved, it was chosen as the subject of the first stage of this study and of this report.

Analysis of Forces on a Transverse Holding Ground

Pulpwood floating into a holding ground is stopped by the boom. At first, succeeding sticks tend to build back one layer deep. Then some are forced under at the upstream edge of the jam and these roll and tumble along the undersurface of the floating logs until they come to rest in a hole or crevice. As more wood arrives, the downstream thrust increases. The jam buckles and consolidates, becoming even deeper, and pushes against the boom system and shores.

A search of the literature concerned with pulpwood holding grounds revealed several equations dealing with the forces on booms and piers. All contained empirical coefficients and none seemed to be generally applicable. It was therefore necessary to analyze the forces in the system in order to determine what measurable quantities could be used to define them.

While the total force exerted on a pulpwood jam by water is dependent upon the three general factors mentioned, quantity of wood, stream flow and physical characteristics of the stream, the problem cannot be studied on this basis because the factors are not simple independent variables. There is, for instance, no single measurement which will describe the width, depth, roughness and alignment of a stream. A more detailed approach relating *independent* variables to the force T_1 must be used.

The probable maximum discharge for a given stream may be determined from flow records and hydrologic studies. After detailed surveys have been made, the surface velocity and the mean velocity of the stream corresponding to this maximum discharge may be calculated. Assuming that a relation exists between the surface velocity and the depth to which wood of *given characteristics* will jam, then it should be possible to predict the depth of the jam. As the approximate quantity of wood and the width of the stream are known, the length of the jam which is to be held can be estimated closely. This brings us to the point where we have available for use the measurements shown in Fig. 2, in which

h_1 and h_2 = the depth of water in feet at sections 1 and 2
V_1 and V_2 = the mean velocity in feet per second at sections 1 and 2
V_s = the surface velocity in feet per second
d = the mean depth of the jam below the surface of the water in feet
L = the length of the jam in feet.
b = the width of the stream in feet

If a simple boom is placed across this straight uniform reach of a stream and pulpwood floated down, a jam of length, L, and depth, d, will form. If the stream bed is considered to be horizontal and frictionless, we may expect that the depth of water h_2 will be greater than h_1 in order to provide the force necessary to drive the water past the rough underside of the jam.

If the section surrounded by the heavy black line (Fig. 2) is taken as a free body, one foot in width, then the horizontal forces acting on it are:

F_1—the hydrostatic force at 1
F_2—the hydrostatic force at 2
F_3—the force exerted on the boom by its ties
F_4—the reaction to the force required to change the momentum of the water between 2 and 1

Since the free body is stationary these forces must be in equilibrium.

$$F_2 - F_1 - F_4 = F_3 \qquad \ldots\ldots(I)$$

F_3 is the external force necessary to hold the pulpwood jam stationary, and its evaluation is the first step in the overall problem.

Taking the weight of water as w pounds per cubic foot and $h_2 - h_1$ as Δh, then

$$F_1 = \left(\frac{w}{2}\right) h_1^2$$

$$F_2 = \frac{w}{2}(h_1 + \Delta h)^2$$

$$F_3 = \frac{w}{2}[(h_1 + \Delta h)^2 - h_1^2] - F_4 \qquad (II)$$

$$F_4 = h_1 V_1 \frac{w}{g}(V_2 - V_1)$$

where g is acceleration caused by the force of gravity.

Fig. 1.

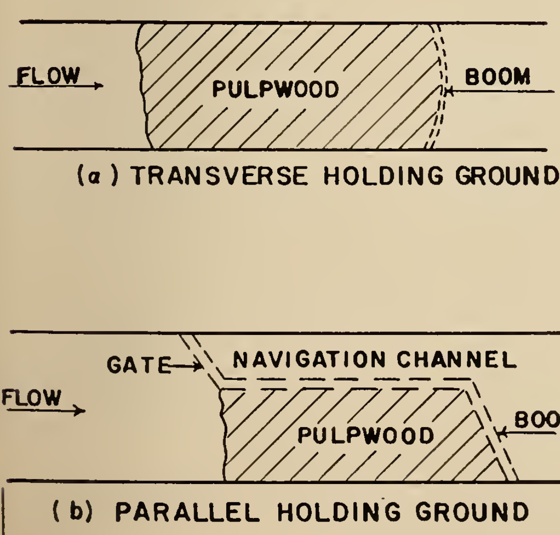

Fig. 2. Transverse holding ground

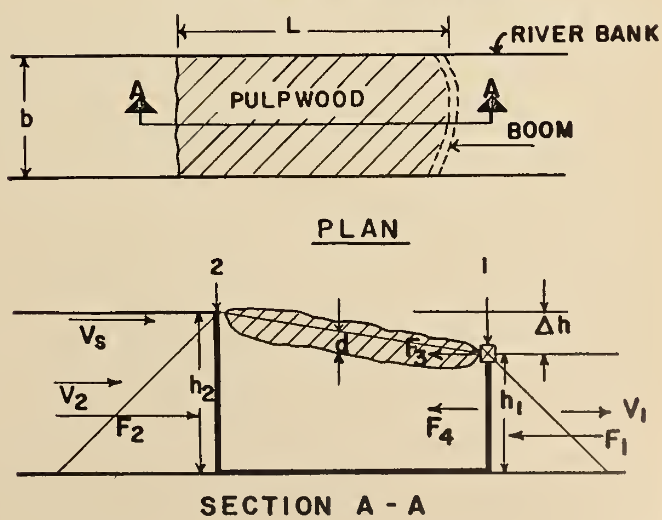

Though F_4 may be evaluated as above, it is not necessary to do so in the final development because it is possible to eliminate it completely at a later stage.

At this point, for a stream with frictionless shores, F_3 is equal to T_1, the downstream thrust, and may be calculated, provided h_1, V_1 and Δh (the head of water backed up by the jam) can be measured or otherwise determined.

Plan of Attack

It was necessary to evaluate the dependent variable F_3 in terms of the independent variables such as the depth of the water, velocity, etc. Because F_3 is a force with the dimension of pounds, it would not fit into the type of plot desired. Also, even in the analytical development it proved more convenient to use the quantity Δh ($h_2 - h_1$ for a frictionless river bottom, and which is directly related to F_3 in equation (II)) instead, as an intermediate dependent variable. Since at that time no analytical method of evaluating Δh in terms of the independent variables was known to be applicable, the project team went ahead on the basis of scale model experiments. It seemed that Δh was probably a function of h_1, V_s, L and d. There was a possibility that d was dependent on V_s, but it was decided to treat it as an independent variable until more information was available.

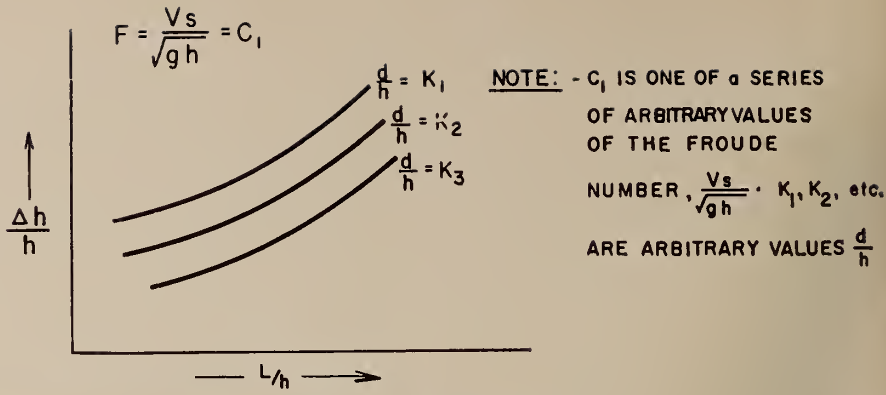

Fig. 3. Proposed Δh plot.

Fig. 4. Model jam and laboratory jam depth gauge.

Fig. 5. Tension test bar and strain indicator.

If $\Delta h = f(h_1, V_s, L, d)$ ......(III)

then these five variables may be grouped into four dimensionless ratios. The most promising arrangement appeared to be

$$\Delta h/h = f_1(d/h, L/h, V_s/\sqrt{gh}) \quad ..\text{(IV)}$$

The parameter $V_s/\sqrt{gh}$ is a form of the Froude number.

It was hoped that the parameters could be plotted on a series of charts of the type shown in Fig. 3. A separate chart for each value of F would be required.

Since full scale field tests are difficult to conduct and very expensive, the plan called for extensive use of scale model tests in the laboratory to build up these curves. The independent variables h_1, V_s, d and L were to be controlled by the operator, and the dependent variable Δh measured. Though not necessary for the analysis so far developed, the force on the boom, F_3, was measured also. When frictionless shores were used, T_1 was equal to F_3, and it was possible to check the accuracy of the measurement by means of equation (II). When ordinary shores were used, comparison of the computed T_1 and the measured F_3 provided useful data for the study of the division of force between boom and shores.

Method of Attack

Since this paper is intended primarily to delineate the problems faced and to present results obtained from the first phase of the work, the actual procedure is given here only in outline with a few details of some unusual features.

The first model work was done at the National Research Council Hydraulic Laboratory in Ottawa. After preliminary trials in an available two foot wide flume, a scale of 1 : 20 was selected and a new four foot wide flume was designed and constructed. The scale of 1 : 20 was chosen because it was believed to be the smallest at which surface tension did not seriously affect the behaviour of the model logs, and the smaller the scale the wider the range of conditions that could be investigated without making the apparatus excessively large. The model logs themselves after much trial and error, were made from oak dowel stock manufactured with dull cutter knives. The resulting "logs". 0.4 in. by 2.4 in. representing 8 in. by 4.0 ft. sticks in the field, were about as rough as pulpwood with the bark on. After they had been soaked in spar varnish and dried they had approximately the same density as green spruce. The varnish made them sufficiently impervious to retain this density for several weeks of intermittent soaking and drying.

Standard laboratory practice was used to control the water levels and discharge. Because of the very flat water surface slopes encountered, it was necessary to develop gauges and techniques capable of measuring differential levels to 0.001 inch. Since the bottom of the flume was horizontal and smooth, but not frictionless, the differential heads measured had to be adjusted to eliminate the effect of the natural slope of running water in order to get the Δh required for plotting.

A cantilever beam, with SR-4 strain gauges as measuring elements, was developed to measure the pull of the jam. The measurement of the total force acting on the jam required that friction between the flume walls and the wood be eliminated. This was accomplished by isolating the jam from the flume with floating walls which were supported by almost frictionless rollers. Both the boom and the floating walls were attached to the force measuring apparatus.

The glass walled plywood flume which was built at NRC was 4 feet wide by 24 feet long; a later flume, used at Queen's University, was 6 feet wide and about the same length. Both had accurately levelled rails on top. The depth of the jam was measured by means of a horizontal arm supported from a carriage which travelled on these rails, as shown in Fig. 4. The current velocity was measured by means of Bentzel tubes or cube-tipped pitot tubes, also supported from the carriage.

The measurement of the same variables in the field was much more difficult. The force on the boom was measured by tension test bars placed between boomsticks and in all the supporting wire rope and chain guys to piers and shore anchors. These bars, developed at the Institute, consisted of suitably machined 65 ST aluminum bars to which SR-4 strain gauges had been bonded as measuring elements. Two layers of rubber were vulcanized onto the bars to provide waterproofing and shock resistance. Electronic recording equipment was used to provide a continuous record of the loads on the various parts of the boom.

The depth of pulpwood jams in the field had been estimated many times, but few records could be found of actual measurements. A jam depth gauge (Fig. 6) was developed to make this measurement, and later a technique for making a representative survey was worked out.

The velocity downstream of the boom could be estimated easily by using a standard current meter, but the velocity underneath a heavy jam required a special instrument which could be poked down through small openings. The cube-

Fig. 6. (top) Jam depth gauge

Fig. 7. Water level recorder.

tipped pitot tube, which gives almost twice the differential that a simple pitot tube supplies, proved satisfactory. However, for light jams, where holes could be found, the current meter was preferred. The positions at which various readings were taken and a map of the holding ground were obtained from a stadia survey. In many instances the men on the jam taking measurements encountered soft areas which would not support them, and light boards had to be used in the manner of skis.

The water levels and differential heads were obtained from direct reading water level recorders mounted on portable stilling wells, as shown in Fig. 7. An accurate level survey was required to tie in the readings of these recorders.

Depth of Jam

The deeper the jam of pulpwood, the greater is the force exerted on it by flowing water. The shallower the stream, the larger is this increase in force with depth of jam. It was necessary, therefore, to determine as early as possible the depth to which a jam would form under particular conditions.

In hydraulic model work it is often impossible to keep all the variables in the proper ratio. When this is the case, the practice is to keep the most important variables in the correct ratio, and to allow those judged to be of lesser importance to assume other values. The results obtained may not be quantitative where the secondary variables have a large effect.

As the water in a stream is forced past a pulpwood jam by gravity, conditions in the model and prototype may be expected to be similar when the Froude numbers are the same. In all model tests the velocities were adjusted so that the Froude number would be identical with that of the corresponding field condition.

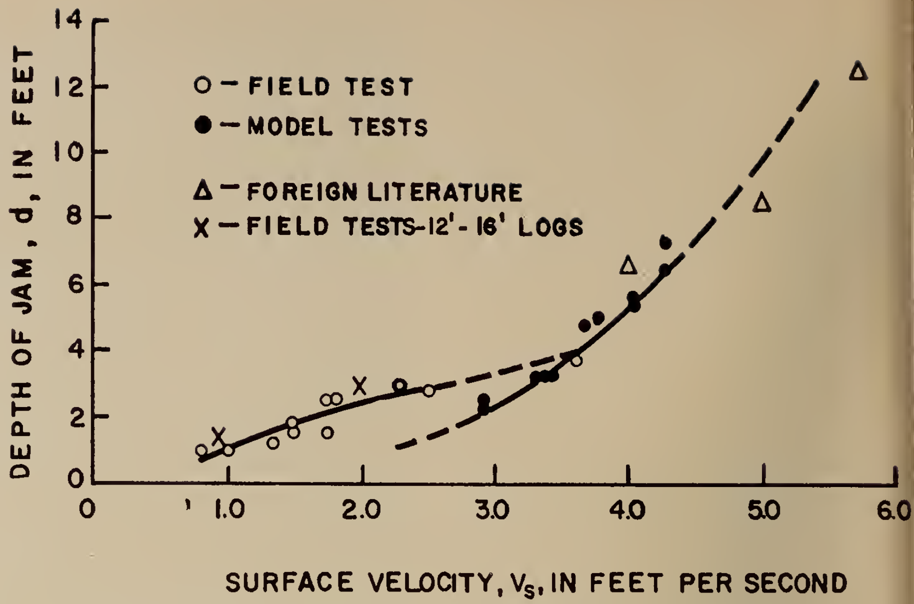

Fig. 8. Surface velocity *v*. depth of jam (when jam is forming).

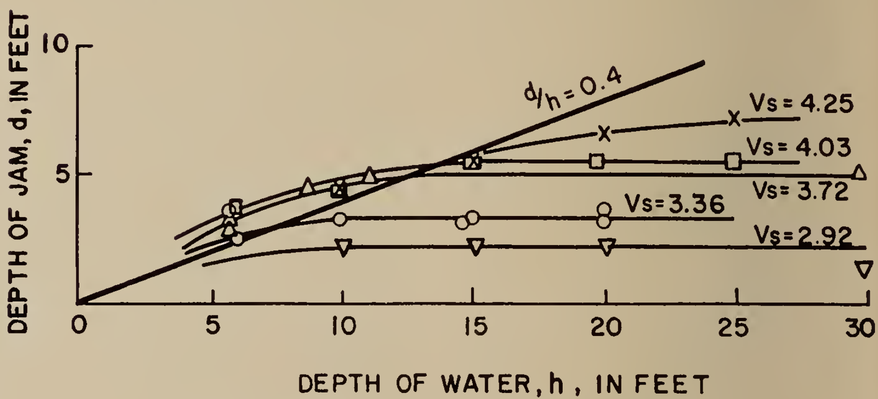

Fig. 9. Limit of d/h under normal conditions.

Figure 8 shows that model and field test results agree for velocities above about 3.5 feet per second. For lower velocities the field jams are relatively deeper. Apparently the consolidation or buckling which occurs in long field jams is not present to the same degree in short model jams. For higher velocities, something approaching full consolidation occurs in the model and the depths of model and field jams correspond. Twelve and sixteen foot wood may form even deeper jams than four foot wood, as is indicated by the points shown on Fig. 8.

The laboratory tests also showed that there is a maximum depth of jam for a given depth of water (Fig. 9).

When the obstruction ratio, d/h, exceeded about 0.4, the velocity underneath the jam became great enough to scour away wood. Then the depth of jam indicated in Fig. 8 for a given velocity could not be obtained. No field verification of this phenomenon was obtained, and indeed there are records of field jams that went right to the bottom of the stream. These must have occurred where long logs wedged themselves between the river bottom and the jam, or in some other unusual circumstances. It would be dangerous to attempt to hold four foot wood in a swift, shallow stream by means of a conventional boom, as the loss of wood under the boom might be large.

On the basis of Fig. 8, the depth of jam could be regarded as being dependent on the surface velocity and the term d/h could be eliminated from the analysis. However, if this were done, the final results would be applicable only to the case where the jam is formed at the maximum velocity. This is the most severe condition and the one for which structures should be designed: but the wood usually arrives in the holding ground before the velocity has reached its peak, and for verification of the development it is necessary to be able to calculate the forces corresponding to actual field conditions at the time a measurement is made. In addition, it appears that wood of unusually high density forms exceptionally deep jams and that twelve and sixteen foot long wood forms deeper and rougher jams than four foot wood.

Because the d required for verification computations does not often correspond to that for maximum velocity, and because in design computations the engineer may wish to increase the d obtained from Fig. 8 to allow for the effect of longer or denser wood, it was decided to continue to handle the depth of jam as an independent variable.

Model Limitations

The model logs did not jam properly at the very low velocities required for small Froude numbers in the flume. In addition, since L was limited by the length of the flume, large L/h values could not be obtained. If h was reduced the critical d/h ratio was soon reached. As the work progressed, it became clear that a huge flume would be needed to produce the points necessary to define the remainder of the curves.

As an alternative, a study of methods of computing the friction drag of the water on the bottom of a pulpwood jam was made. Results from laboratory tests and from some field tests on rafts of pulpwood towed at a uniform rate in deep water were now available. Analysis of these results showed that the force calculated from a form of the Karman-Prandtl equation for velocity distribution near rough boundaries could be used to indicate the friction drag with acceptable accuracy.

Extension of Analysis

The most convenient form of the Karman-Prandtl equation for this purpose is given below:

$$Fo = \frac{V_y{}^2 wL}{g[5.75 \log y/k + 8.5]^2} \quad \ldots . (V)$$

where

Fo is the friction force on the under side of the jam in pounds per foot of width.

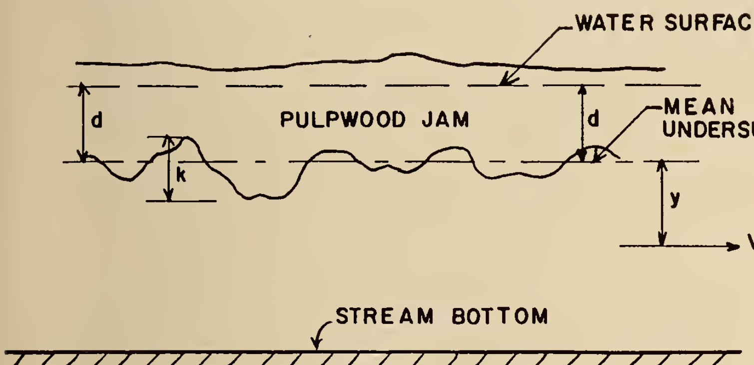

Fig. 10. Jam depth and roughness.

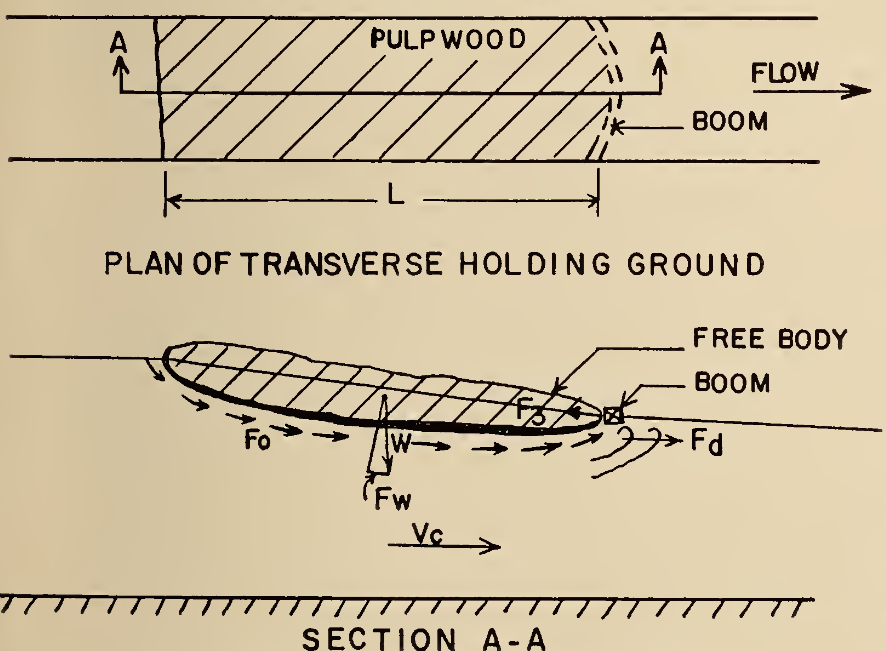

Fig. 11. Longitudinal cross-section with jam as free body.

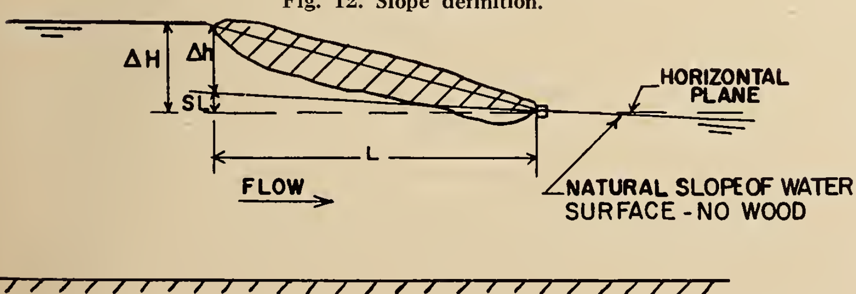
Fig. 12. Slope definition.



V_y is the velocity at a distance y feet below the mean undersurface of the jam—feet per second.

w is the specific weight of water—pounds per cubic foot.

g is the acceleration due to gravity—feet per second per second.

L is the length of the jam—feet.

k is the absolute roughness of the under side of the jam—feet. (See Fig. 10.)

Measurements in both laboratory and field clearly showed that flow through a jam with obstruction ratio less than 0.4 was negligible.

Equation (V) and the information about flow through the jam made it possible to extend the original analysis and compute F_3. The change in the analysis is illustrated by Fig. 11, which is similar to Fig. 2 except that this time the jam only is taken as a free body.

In Fig. 11:

F_3 is the force on the boom in pounds per foot width.

F_d is the form drag of the body of the jam in pounds per foot width.

F_0 is the friction drag in pounds per foot width.

F_w is the component of the weight of the stationary mass which acts downstream because of the slope of the water surface, in pounds per foot width.

W is the weight of the mass of wood and water which is held motionless in pounds per foot width

$$F_3 = F_0 + F_w + F_d \quad \ldots . (VI)$$

This equation gives the value of the total downstream force since the shores are still assumed to be frictionless. The solution of two of the terms is particularly awkward. F_0, the friction on the underside of the jam, is computed from equation (V) and must usually be worked in steps like the standard step solution for a backwater curve. In addition, the probable velocity distribution in the water under the jam and the roughness of the underside of the jam must be estimated. F_w, the weight component, can be obtained only after Δh is determined by trial and error. Under these circumstances it was thought best to prepare curves from which the solution for given conditions could be read (Fig. 13). It was hoped that the d/h band for each Froude number would be narrow and that the roughness dimension k, which is to a great extent dependent on the depth of the jam, need not appear as an independent variable. Eventually it became clear that a considerable band of d/h values must be covered and that, consequently, the variation of k/h was significant. The points for Fig. 13 were computed with regular increments in the value of d/h and k/h, but the resulting plot was so complex that interpolation to find $\Delta h/h$ for a given set of conditions was very difficult. Finally, Professor F. M. Wood, of Queen's University, reworked the computed points of Fig. 13 into the nomographic form shown in Fig. 14. From this chart Δh may be obtained and substituted in equation (II) to calculate the downstream thrust for most conditions.

It should be noted that equation (VI) is complete in itself and may be solved for any given conditions. The Δh concept is retained and Fig. 14 presented only because the time required for the solution of most problems is thereby reduced from hours to minutes.

The Δh/h Curves

The method of calculating Δh follows

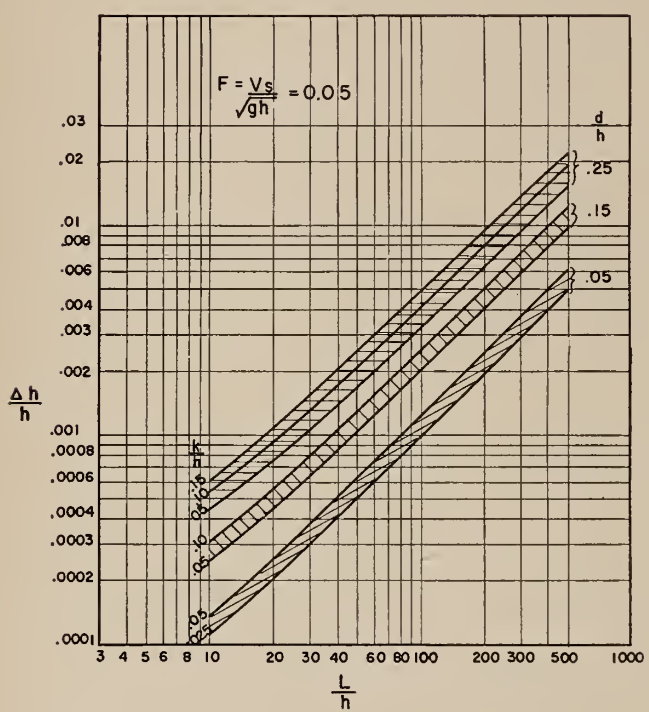


Fig. 13(a). Δh curves.

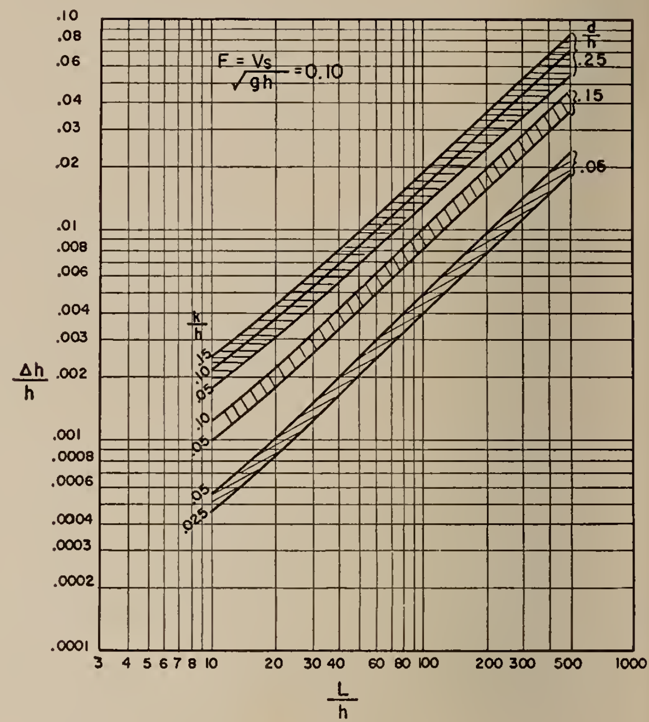

Fig. 13(b). Δh curves.

Fig. 13(c). Δh curves.

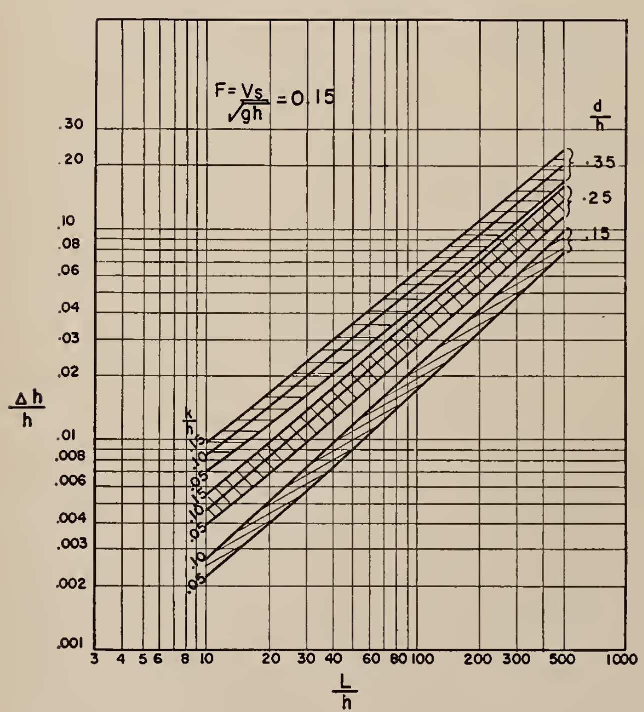

Fig. 13(d). Δh curves.

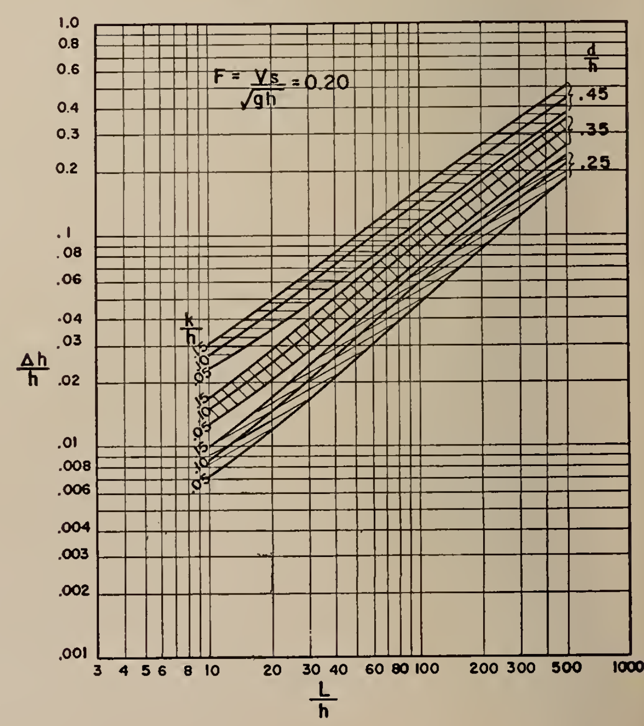


from equations (I), (V) and (VI).

$$F_3 = F_2 - F_1 - F_4$$
$$= F_0 + F_w + F_d \text{ (I) and (VI)}$$

$$F_2 - F_1 = \frac{w}{2}\left[(h_1 + \Delta h)^2 - h_1^2\right]$$

$$= \frac{w}{2}(2h_1 + \Delta h)\Delta h$$

Then

$$\frac{w}{2}(2h_1 + \Delta h)\Delta h$$
$$= F_0 + F_w + F_d + F_4,$$

and

$$\Delta h = \frac{F_0 + F_w + F_d + F_4}{\frac{w}{2}(2h_1 + \Delta h)} \quad \text{..(VII)}$$

Equation (VII) must be solved by trial and error to obtain Δh. The eventual goal is the determination of F_3, which may be calculated from equation (II) when Δh is known. If F_4, the momentum term, is arbitrarily dropped from equation (VII) and equation (II) it may be shown that the final value of F_3 is not affected except by a very small change in F_w which is induced by the slight change in Δh. This effect was found to be negligible and in the work which follows F_4 has been eliminated.

Equations (II) and (VII) now become:

$$F_3 = \frac{w}{2}(2h_1 + \Delta h)\Delta h \quad \text{....(II')}$$

$$\Delta h = \frac{F_0 + F_w + F_d}{\frac{w}{2}(2h_1 + \Delta h)} \quad \text{....(VII')}$$

To evaluate Δh for given conditions from equation (VII') we must first compute, F_0, F_w and F_d. F_0 is obtained from equation (V) using jam roughness indicated in Fig. 15 and a velocity distribution as measured between the bottom of the jam and stream beds where Manning's 'n' had a value close to 0.04. The proper choice of coefficients is difficult unless the operator has had some field experience.

F_w is obtained from the equation $F_w = W(\tan\theta)$, where $\tan\theta = \Delta H/L$ (Fig. 12) and $\Delta H = \Delta h + SL$. S is the natural slope of the water surface which can be found from Manning's equation:

$$S = \frac{V^2 n^2}{(1.49)^2 r^{4/3}}$$

r is the hydraulic radius of the stream.
n is Manning's 'n', assumed in these calculations to have a value of 0.04.

Because the unknown Δh appears in the expression for F_w, a trial and error solution is indicated. This would be very laborious for a single point, but the number of tries can be reduced to a minimum when working out continuous curves on a systematic basis. Using the previous points as a guide a value of Δh is assumed, the natural slope of the stream surface, S, is computed, and ΔH is equal to Δh plus SL. The natural velocity distribution in the vertical plane will be affected by the jam of wood and the SL term slightly increased, but this correction is small and has not been incorporated into this solution.

Since the flow of water through the jam is negligible, and d represents the mean depth of jam below the water surface, the weight of the motionless mass of wood and water is equal to the weight of the layer of water d feet deep by L feet long:

Thus, $F_w = 62.4(d)L(\Delta H/L)$
$= 62.4(d)\Delta H$

The form drag per foot width of stream is

$$F_d = C_d \frac{w}{g} d V_c^2$$

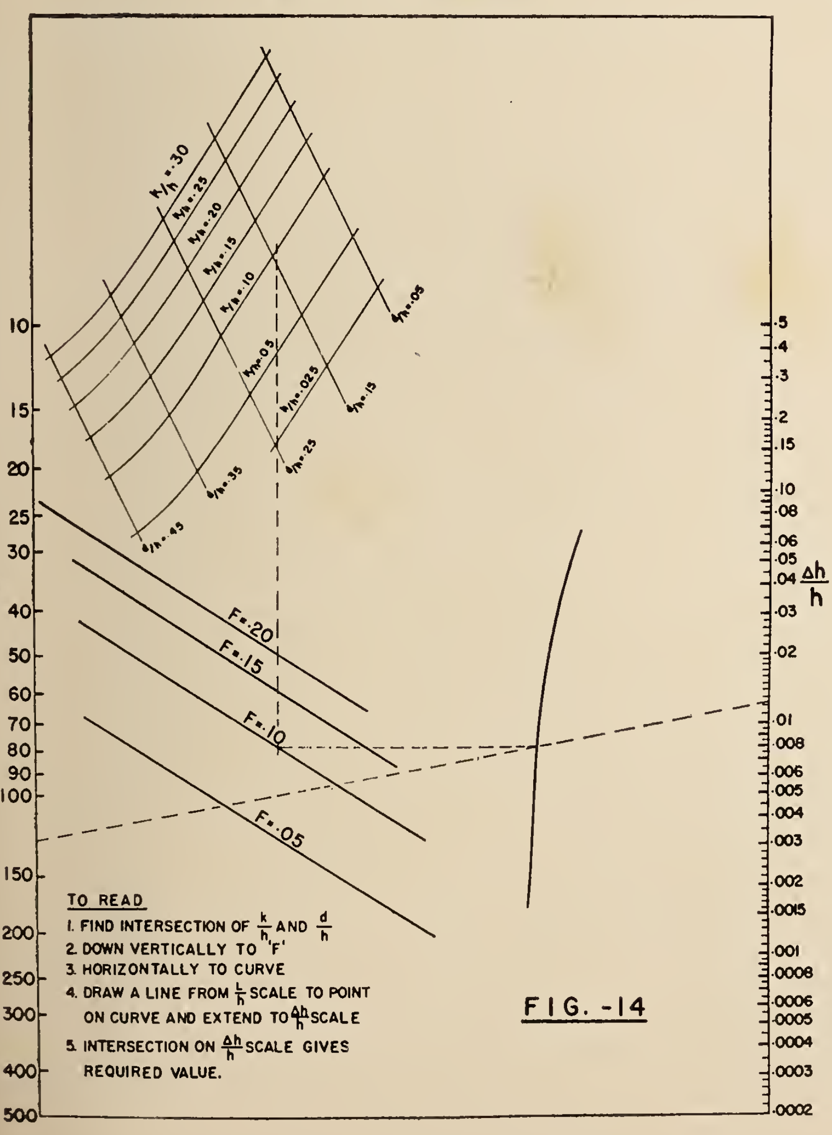
where

C_d is the coefficient of drag.
V_c is the average current velocity under the jam in the vicinity of the boom—feet per second.
d the depth of the jam in feet.

When the above figures have been obtained, Δh is calculated from equation (VII'). If it does not check with the assumed value, a new estimate is made and the solution repeated.

Figure 13 shows the Δh curves produced by plotting values obtained from this solution. These curves are of the type expected (see Fig. 3), but because the inclusion of the k/h lines made it difficult to interpolate and read the maximum value of $\Delta h/h$ for a given holding ground, the nomographic curves of Fig. 14 were developed. To use Fig. 14, the water velocity, depth of stream, length and depth of jam, and the roughness of the underside must be known. The probable depth may be obtained from Fig. 8, and Fig. 15 may be used as a guide in estimating the roughness.

Fig. 14. Δh/h nomograph.



Since the roughness, k, is the distance from the outside of the protuberances on the underside of the jam to the bottom of the openings between the logs (see Fig. 10), it cannot be measured accurately. Figure 15 was built up from field measurements and confirmed as far as possible by laboratory experiment and calculations.

Verification of the Δh/h Nomograph (Fig. 14)

The plan was to verify the $\Delta h/h$ curves by means of laboratory and field measurements. Since interpolation on the final version of Fig. 13 is difficult, a chart (Fig. 16) showing the correlation of $\Delta h/h$ as measured and as read from Fig. 14 was constructed. Considering the difficulty of measuring the variables concerned, the correlation is satisfactory.

When $\Delta h/h$ has been obtained, F_3, the force on the boom *for frictionless shores*, may be calculated from equation (II′). This is equal to the downstream thrust of the water on the wood, T_1, and is the solution to the first part of the problem.

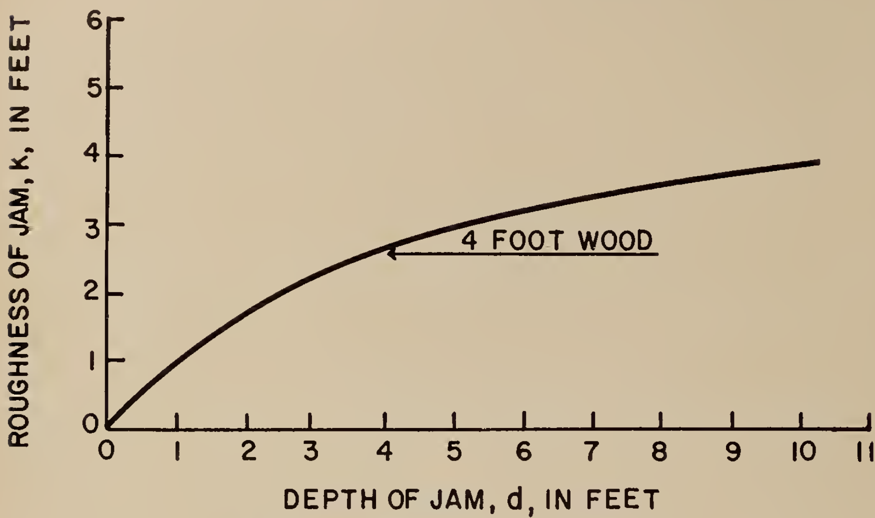


Fig. 15. Roughness of jam v. depth of jam.

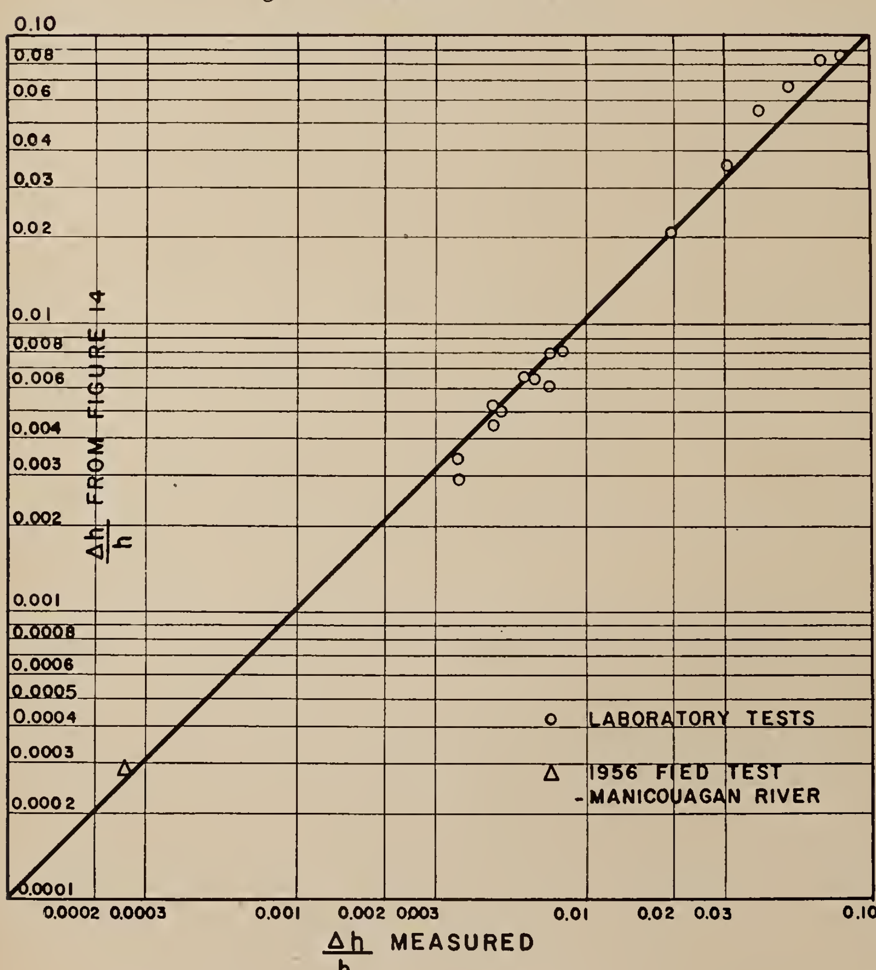
Fig. 16. Correlation curve for Δh/h.



Shores Which Develop Friction

The downstream thrust, T_1, is not all transmitted to the boom system: much of it is absorbed directly by the shores. It was necessary to discover how much of this thrust is taken by the shores under given conditions. A mathematical solution based on the analogy between pulpwood in a river and granular material contained between two parallel walls was worked out. It was subsequently discovered that Janssen had developed the same solution in connection with the design of grain elevators.*

If in Fig. 17:

P is the force with which the jam upstream is pressing against the jam downstream in a direction parallel with the current in pounds per foot width of stream;

f_0 is the drag of the current on the undersurface of the jam—pounds per square foot:

k_0 is the coefficient of lateral thrust;

μ is the sliding coefficient of wood against wood;

Then

$$Pb - (P + dP)b + bf_0(dL) - 2\mu k_0 P(dL) = 0$$

and

$$-b(dP) + (bf_0 - 2\mu k_0 P)(dL) = 0$$

$$\frac{dP}{f_0 - 2\mu \dfrac{k_0 P}{b}} = dL$$

Solving

$$P = \frac{bf_0}{2\mu k_0}\left(1 - e^{-2\mu k_0 (L/b)}\right) \quad \text{..(VIII)}$$

First attempts to check equation (VIII) by model test were unsuccessful. Finally it became apparent that the ratio of the stream width, b, to the log length, l, (b/l), has a pronounced effect. When b/l is greater than 30, the jam seems to behave in accordance with equation (VIII). For lower values of b/l the percentage of force transmitted directly to the shores increases as b/l decreases.

A series of laboratory tests showed that the value of $2\mu k_0$ was approximately 0.4. Substituting this value in

---

*The Design of Walls, Bins and Grain Elevators, M. S. Ketchum, McGraw-Hill, 1907.

equation (VIII) and dividing by f_0bL, the total downstream thrust in length L, gives the proportion of the total force transmitted to the boom.

The percentage of the total force on the boom is

$$\frac{100P}{f_0L} = \frac{100b}{0.4}\left[1 - e^{-0.4(L/b)}\right] \quad \text{.. (IX)}$$

This equation is plotted in Fig. 18. The points shown are from laboratory tests. No check could be made at higher values of L/b because L could not be increased and when b was decreased the b/l ratio dropped below 30 and the mass no longer behaved as granular material. Tests run at b/l values below 30 produced points which fell below the curve, and thus it is believed that the curve is a satisfactory basis for design. It may be shown that after the length of jam becomes equal to 6 times the width of river, 90% or more of the additional force is transmitted directly to the shores. Therefore, if a boom system can retain a jam of length equal to 6 times the width it is probably adequate for any longer jam.

Application of Results

The curves presented may be used to calculate the probable maximum load on a boom in a simple transverse holding ground on a straight stretch of river. The procedure is illustrated by the following example:

Consider a proposed holding ground where the depth of water, h, is 20 feet and the width of channel, b, is 400 feet. The maximum surface velocity, V_s, is 2.5 feet per second and the quantity of wood is such that the length of jam, L, is 2,500 feet. What will be the load on the boom system?

Assuming that in the worst case the wood will arrive when V_s is a maximum, then

(*a*) depth of jam will be 2.7 feet for V_s of 2.5 feet per second from Fig. 8.

The roughness, k, will be 2.2 feet from Fig. 15.

(*b*) The Froude number

$$F = V_s/\sqrt{gh} = 2.5/\sqrt{32(20)} = .099$$
$$L/h = 2500/20 = 125$$
$$d/h = 2.7/20 = 0.135$$
$$k/h = 2.2/20 = 0.11$$

For these values Fig. 14 gives

$$\Delta h/h = 0.0124$$

and then

$$\Delta h = 0.0124\ (20) = 0.248 \text{ feet.}$$

(*c*) The total downstream thrust

$$F_3 = \frac{w}{2}(h_1 + \Delta h)^2 - \frac{w}{2}h_1^2 \quad \text{..(II')}$$

$$= \frac{w}{2}\Delta h(2h_1 + \Delta h)$$

$$= \frac{62.4}{2}(0.248)(40 + .23)$$

$$= 312 \text{ pounds per foot width.}$$

(*d*) $$L/b = \frac{2500}{400} = 6.25.$$

Figure 18 shows that for this L/b ratio about 38 per cent of the total force is transmitted to the boom. The remaining 62 per cent is taken directly by the shores.

The probable maximum load on the boom system will be 0.38 (312) = 119 pounds per foot width of stream or a total load of 119 (400) = 47,600 pounds. The boom may be designed to withstand this force with a suitable factor of safety.

Continuation of Investigation

When this project was begun it was hoped that it would produce methods of calculating:

(*a*) The total force acting on a transverse holding ground.

(*b*) The division of this force among boom, piers and shores.

(*c*) The effect of wind on floating pulpwood.

(*d*) The forces on parallel holding grounds.

(*e*) The forces on tidal holding grounds.

The work done until Autumn 1954 has been detailed above. Since then studies of the division of force between piers and booms, and the effect of wind on floating pulpwood have been proceeding. Results of these continuing studies will be reported at a later date.

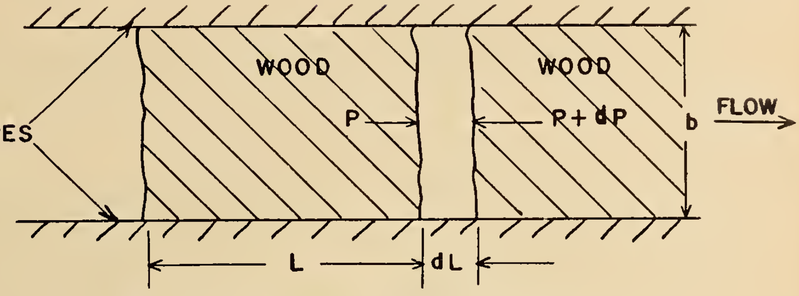


Fig. 17. Wood confined between parallel shores.

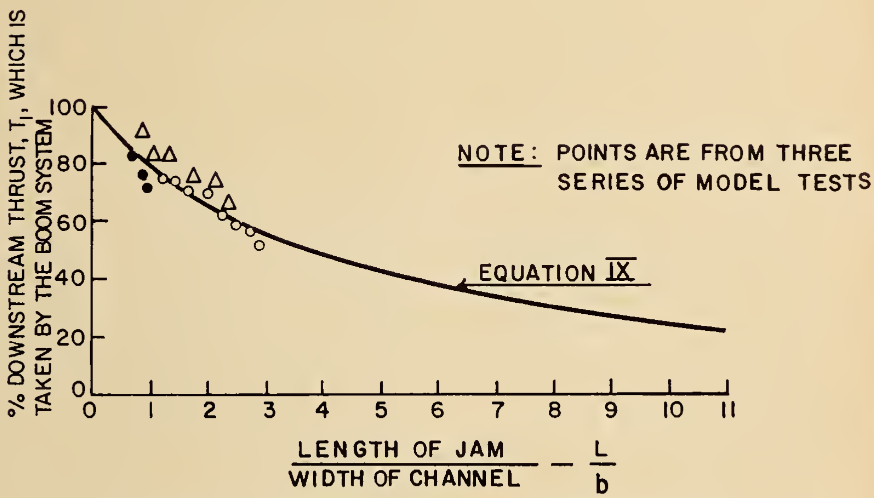

Fig. 18. Division of force between boom and shore.

APPENDIX I—LIST OF SYMBOLS

b	width of stream in feet.
C_1, C_2, C_3	assumed constants.
C_d	the coefficient of drag of an immersed body.
d	the mean depth of jam below the surface of the water in feet.
e	base of Napierian logarithm—2.718.
f	mathematical function.
f_0	friction of running water on underside of jam in pounds per sq. ft.
F	the Froude number $= \frac{V_s}{\sqrt{gh}}$
F_0	the force exerted by the friction of the water against the underside of jam in pounds per foot width of river.
F_1	the hydrostatic force at section 1 in pounds.

F_2 the hydrostatic force at section 2 in pounds.

F_3 the force necessary to hold the boom stationary in pounds.

F_4 the reaction to the force necessary to change the momentum of the water flowing under the jam in pounds.

F_w the component of the weight of the stationary mass of wood and water which acts downstream because of the slope of the water surface in pounds.

g the acceleration due to gravity—32 feet per second per second.

h the depth at the section indicated by subscript in feet.

Δh the differential head necessary to force water past the jam when the shores are assumed to be frictionless in feet.

ΔH $\Delta h + SL$ in feet.

k the absolute roughness of the bottom of the jam in feet.

k_0 the coefficient of lateral thrust—the ratio of the lateral thrust per foot length to the downstream thrust per foot width.

l the length of a pulpwood stick in feet.

L the length of the jam in feet.

P the force with which the jam is pushing downstream in pounds per foot width of river.

q discharge per unit width in cubic feet per second.

r the hydraulic radius of the river in feet.

S the slope of the water surface when no jam of wood is present.

V the mean velocity in feet per second at the section indicated by the subscript.

V_c the mean velocity under the jam.

V_m the mean velocity over a reach or length of river.

V_s the surface velocity.

V_y the velocity at a point y feet from the boundary.

w the weight of water in pounds per cubic foot.

W the weight of the stationary mass of wood and water in pounds per foot width of river.

μ the sliding coefficient of wood against wood.

θ the angle subtended by mean water surface and the horizontal.

y the distance in feet from the mean undersurface of jam to a point at which the velocity is V_y.

APPENDIX II—1956 FIELD CHECK ON METHOD OF CALCULATING FORCES ON PULPWOOD HOLDING GROUNDS

On June 8th measurements taken between 8 a.m. and 11 a.m. indicated that the forces noted below were acting on the Manicouagan holding ground of the Quebec North Shore Paper Company.

Pier No. 7
East cable—3580 pounds
West cable—3000 pounds.
Bulkhead—3060 pounds.

Pier No. 8
East cable—3000 pounds
West cable—2560 pounds
Bulkhead—1950 pounds

Pier No. 7 was resisting a total force of 9640 pounds and Pier No. 8 a force of 7510 pounds. Forces on the individual bulkheads changed considerably during the test, while the sum of the two changed through a smaller range.

The piers are 200 feet apart and the center line of the row of piers makes an angle of about 60° with the direction of the current. Thus, two piers support about 400 cos 30°, or a 350 foot width of jam measured in a direction at right angles to the current. The total thrust of this width of jam was 9640 + 7510, or 17,150 pounds. The average thrust per foot width was 17,150/350, or 49 pounds.

The holding ground contained about 45,000 cords of wood jammed two feet deep for 1500 feet upstream of Piers 7 and 8. The river discharge was 150,000 cubic feet per second and a 12 m.p.h. wind was blowing almost directly downstream. The current velocity at a depth of 10 feet was 1.4 feet per second and the average velocity about 1.6 feet per second.

Calculation of Force using Δh/h Curves

The Manicouagan holding ground is very wide—about 3000 feet at the boom. It was assumed that none of the thrust originating towards the centre of the river would be transferred to the shores by the action of the jam itself.

The 12 miles per hour wind flowing over a jam of the roughness measured was calculated to cause a downstream thrust of 8.3 pounds per foot width (this development is not covered in the present article). The remaining measured force, 49 pounds less 8.3 pounds, or 40.7 pounds per foot width, may be attributed to the thrust of the water.

Available data:

V_m = 1.6 feet per second
h = 50 feet
d = 2 feet
L = 1500 feet

If the wood had not been there the surface velocity V_s would have been, by calculation, 1.85 feet per second. If the wood had arrived in the holding ground with this current the jam would have been more than 2 feet deep. It actually had arrived in slack water and the consolidated jam measured slightly less than 2 feet deep. The roughness, k, was 1.75 feet.

$$F = \frac{1.85}{\sqrt{32(50)}} = 0.046$$

$$k/h = \frac{1.75}{50} = 0.035$$

$$d/h = \frac{2.0}{50} = 0.04$$

$$L/h = \frac{1500}{50} = 30$$

From Fig. 14, $\Delta h/h$ is found to be .00028

$$\Delta h = h(.00028) = 50(.00028)$$

$$= 0.014 \text{ feet}$$

$$F_3 = \frac{w}{2}(\Delta h)(2h_1 + \Delta h)$$

$$= 31.2\ (.014)\ 100.014$$

$$= 43.6 \text{ pounds per foot.}$$

This compares closely with the measured thrust of 40.7 pounds per foot.

Air Pollution Control at A Nylon Intermediates Plant

H. R. L. Streight

Principle Chemical Engineer, Du Pont Company of Canada (1956) Limited

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June, 1957

An extensive pollution control program was started during the design of the organic chemical plant, built in an agricultural and recreational community at Maitland, Ontario. Air pollution was reduced by designing the boiler house stacks for adequate dispersion of flue gases and by developing and installing an absorption system for almost complete removal of oxides of nitrogen in effluent gases. Atmospheric surveys, made before and after operation began, showed the low and safe concentrations of potential contaminants.

MODERN scientific methods have been employed to control within acceptable limits atmospheric and aqueous pollution from a plant, designed and operated by Du Pont of Canada, for the manufacture of nylon intermediates, the basic chemicals for making nylon. The Company is anxious to prevent or minimize pollution that may result from the operation of the new organic chemical plant.

The location of the plant is shown in Figure 1.

The 1500 acre site is on the St. Lawrence River, 7.3 miles northeast of Brockville (12,000 population), 4.5 miles southwest of Prescott (3,500 population), and 3.8 miles from Ogdensburg, N.Y. The Montreal — Toronto highway crosses the property near the river and the Canadian National Railways line divides the property about two thirds of a mile behind the highway. In topography, the land rises gently from the river and is essentially flat or slightly rolling. The surrounding area has a number of cottages and motels alongside the river, with orchards on the sides and bushland north of the railway. Recreational activities include boating, sailing, and fishing.

The processes used for the production of nylon intermediates are based on complex organic reactions and are large consumers of steam and other services. In the manufacture of the raw material, nitric acid, and the intermediates considerable quantities of solid and liquid by-products and off-gases are formed and this necessitates careful planning and treatment to effect safe and economic means of disposal acceptable to the community. The main by-products are essentially fly ash from the boiler house and organic liquors and tars which were to be burnt in an open incinerator; the off-gases contained oxides of nitrogen from several process buildings and sulphur dioxide from the boiler house.

The policy adopted was to design and operate the plant so that the quantity and concentration of any contaminant would not approach a level which might cause a nuisance or damage to persons, property or vegetation in the community.

Successful control measures cannot be instituted without a comprehensive knowledge of the amounts of pollutants emitted from all major sources in relation to the concentrations found in the air. Three general methods are available for determining the effectiveness of diffusion in dispersing gaseous and particulate contaminant.

(1) Calculate the rate of dispersion and maximum ground concentration.

(2) Make an atmospheric survey.

(3) Test dispersion in a wind tunnel, using a model of the building releasing an effluent gas.

The programme by which this policy was put into effect at Maitland comprised the following steps:

(1) Design features.

(2) Atmospheric surveys.

(3) Garden plots.

(4) Development of a method for reducing the concentration of a contaminant.

The number and height of the stacks on the boiler house were based on the calculated rate of dispersion of sulphur dioxide and particulate matter. The two atmospheric surveys, made before and after the plant operated, gave useful information on the concentrations of potential pollutants, any subsequent increases from the nylon intermediates plant and boiler house, and ground concentrations of contaminants which could be compared with the values calculated for dispersion from the stacks of the boiler house. Early signs of damage could be obtained from an inspection of garden plots planted with sensitive flowers and vegetables which are more readily affected by fumes than individuals. The toxic concentration of a pollutant from the incinerator used to burn organic wastes would be shown by the plants in a nearby garden plot and by apples on the trees, 200 to 300 feet away. A study showed that the oxides of nitrogen leaving the nitric acid and nylon intermediates plants could be reduced by absorption in an alkaline solution. The results of pilot-plant tests were successfully applied in the design and operation of a large fume absorption system. The efficiency of operation was so improved in the field that the treated off-gases left in an almost colourless condition. During operation, source - control methods included good combustion, proper maintenance, and good housekeeping.

The proposed methods of treating off-gases and by-product waste streams were discussed with consultants who have a wide knowledge of air pollution. During the design, Dr. Morris Katz, an international authority on air pollution, was retained as a consultant to advise on the dispersion of the combustion products and the design of the boiler house stacks. The Ontario Research Foundation undertook the comprehensive atmospheric surveys which extended over a period of 25 months. Dr. Katz furnished the list of flowers and vegetables to be planted in the garden plots and subsequently examined their condition as well as that of apple trees within the property.

The experience gained in each air pollution problem has convinced us that air pollution from a complex organic chemical plant can be controlled.

Threshold Limits

For every chemical contaminant there is a threshold limit or maximum ground concentration that acts as a guide in the control of health hazards to persons and of damage to vegetation. The threshold limit varies widely for each compound and should be regarded as a line between safe and dangerous concentrations. In many cases, reliable information is still lacking and authoritative opinion is conflicting.

For Persons. The threshold limits shown in Table I represent average concentrations of substances in the air to which workers may be repeatedly exposed for a continuous number of days without having their health adversely affected.[1] A selection has been made of gases and vapours encountered in the manufacture of nylon intermediates or produced in a boiler house.

Table I.—Threshold and Fatal Concentrations for Persons

		Max. Conc. p.p.m.	Fatal Conc. p.p.m.
Ammonia	raw material	100	2,500
Carbon dioxide	ex boiler house	5,000	
Carbon monoxide	ex boiler house	100	2,000
Cyclohexane	raw material	400	
Cyclohexanol	int. product	100	
Cyclohexanone	int. product	100	
Nitrogen dioxide	waste gas	5*	100–150
Sulphur dioxide	waste gas	10	50–250

* 10 parts per million are permissible for 8 hours/day, 5 days/week[2]

For Animals and Insects. The effect of pollutants on animals and insects is much less than on plants. For instance, air contaminants which damaged alfalfa by 25 per cent did not affect the cattle consuming it.[3]

For Vegetation. There are many sources of information on threshold limits for flowering and crop plants, fruit and conifer trees; references should be consulted to determine the influence of a number of variables which alter the fumigation limit for a specific plant i.e. age, environment and duration. The effects of potential Maitland pollutants, sulphur dioxide (SO_2), oxides of nitrogen and ammonia, on vegetation are described.

(a) Sulphur dioxide. Usually SO_2 is given first consideration as it is present in a greater amount than other air pollutants. Acute injury to vegetation usually presents a typical and easily recognized pattern of collapsed areas in leaves and is caused by the entrance of SO_2 through any open stomata of the leaves. Most plants close their stomata at night, although those of alfalfa, potato and certain other plants remain open. Environment which opens the stomata can favour injury by SO_2; this includes a temperature above 5 deg. C., adequate supply of moisture to the roots, a high light intensity and a high relative humidity [4-6]. For instance, the relative resistance to injury increases tenfold as the relattive humidity decreases from 100 to 0 per cent.[7]

Plant species vary in their susceptibility when exposed to known concentrations of SO_2. Alfalfa is among a list of the most sensitive plants and is marked by 0.4 p.p.m. after 7 hours exposure. Exhaustive tests have been made on more than 300 species and varieties of plants under controlled conditions of fumigation and the results expressed on a basis of alfalfa or barley, taken as 1.0 p.p.m. SO_2 at 100 per cent relative humidity.[5] The ratings of susceptibility of the plants used in our garden tests and of surrounding trees are in Table 11.[7]

Table II.—SO_2 Threshold Limits for Vegetation

Plant	Form as Planted	Basis (Alfalfa = 1.0)
Dahlia	bulb	1.5–2.0
Carrot	seed	1.5
Lettuce	seed	1.2
Cosmos	plant	1.1
Petunia	plant	1.0–1.2
Zinnia	plant	1.0–1.2
Gladiolus	bulb	2.6
Tomato	plant	1.3–1.7
Daffodil	bulb	—
Tree		
Apple		1.8
Maple		3.3
Plum		2.5
Pine		7.5–15

In general, SO_2 may be toxic to sensitive plants at a concentration greater than 0.4 p.p.m. during the growing season when the conditions for rapid absorption are at a maximum during a long period of exposure. Low concentrations of SO_2, 0.20 p.p.m. or less, have no influence on plant life as shown in a detailed study on crop plants and conifers.[4] Plants have a marked ability to recover from the effects of SO_2.

(b) Oxides of Nitrogen. Injury to vegetation near large nitric acid plants has been noticed. Brown margins, brown to black spots on the leaves and a bright yellow tint on the needle tips of conifers indicate the damage caused by concentrations of 25 p.p.m. of nitrogen dioxide.[7]

(c) NH_3. Ammonia is a gas of intermediate toxicity and will brown the leaves of plants. The threshold limit of sensitive plants (sunflower, tomato, etc.) has been given as 8 p.p.m. over a 5 hour period, 17

p.p.m. over a 4 hour period and up to 40 p.p.m. over a 1 hour period.[6]

Accepted Threshold Limits

The permissible ground concentration of any pollutant should not affect the health of individuals or damage the growth and appearance of neighboring vegetation. As the threshold limits are not in complete accord, the values in Table III provided by our consultants were accepted for pollution control at Maitland Works.

Stacks for Boiler House

The volume of gases leaving the boiler house is large as the chemical plant has an annual coal consumption of 60,000 tons/year. With the prevailing SW wind and under conditions of temperature inversion, the maximum concentration of SO_2 may occur at a distance beyond the eastern boundary of the property, 6,600 feet from the boiler house. Likewise the emission of dust and fly ash is important as the coal contains 8-10 per cent ash.

Recent advances have made it possible to design boiler installations which will give emissions that do not constitute a nuisance. The combustion of coal releases SO_2, finely divided particulates, and a dustfall of soot and fly ash. Dispersion from a stack depends on many factors which were considered during design. In a light wind, the plume from a stack will gradually rise and flow downwind until dispersion is complete while in a strong wind, gust or unstable atmosphere such as vertical convection, the flue gas will be brought to the ground before the gases have completely dispersed. During a period of calm, temperature inversion or if the stack is not sufficiently above the level of a nearby building, the exit gases can reach the ground in high concentrations. In all cases, level ground is assumed for steady and uniform dispersion.

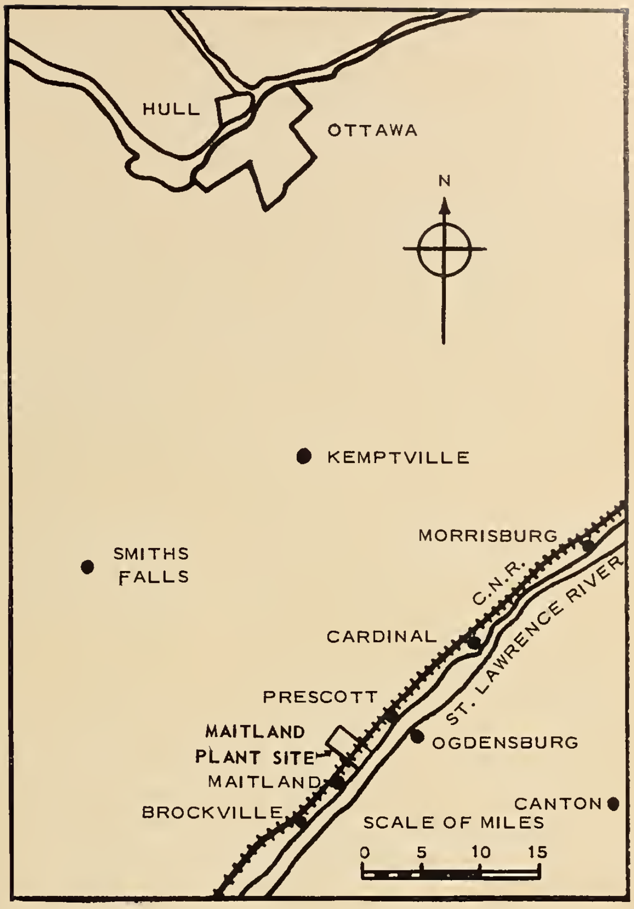

Fig. 1. Location of Maitland plant.

The most useful relationships for predicting atmospheric diffusion are those of Bosanquet et al.[8, 9] and of Sutton.[10] The formulas contain turbulence parameters or eddy-diffusion coefficients that are functions of atmospheric stability and turbulence. The actual stack height is increased to an "effective stack height" which is the sum of the stack height, the rise caused by the velocity of the stack gases and the rise attributable to the density difference between the stack gases and the atmosphere. The effective height should be sufficient to stop downwash in the vicinity of the stack.

The design of the Maitland stacks the addition of 29 per cent excess air was based on the coal consumption, the 1.5 to 3 per cent sulphur and 8 to 10 per cent ash contents of the coal, and release of 90 per cent of the sulphur in the ash to the atmosphere as SO_2. As at least 85 per cent of the ash was to be removed from the flue gas by dust collectors, it was estimated that the ash emitted to the atmosphere would be 110 lb./hr. per boiler of which 70 lb./hr. would be greater than 10 microns in size. Using Sutton's formula, calculations were made on the dispersion of SO_2 from 1 and 3 stacks and for low and high concentrations of sulphur in the coal.

To effect the desired reduction in the pollution level, one of two alternatives could be adopted: a single 250-ft. high stack or the selected three 125-ft. stacks, i.e. one per boiler. The maximum SO_2 ground concentrations shown in Table IV were calculated for burning 8440 lb./hr. of

Table III.—Accepted Threshold Limits

Contaminant	Permissible Ground Concentration p.p.m.	Critical Ground Concentration p.p.m.	Duration of Exposure
Sulphur dioxide	1.0	1.0	1 hour
	0.5	—	up to 8 hr./day
	0.25	0.3	prolonged
Nitrogen dioxide	—	10	up to 8 hr./day
Ammonia	—	8	up to 5 hr.

Table IV.—Maximum SO_2 Ground Concentrations from Stacks

Wind Velocity miles/hour	Meteorological Condition	Effective Height ft.	Sutton max. conc. SO_2 p.p.m.
2.2	strong inversion	988	0.036
4.4	strong inversion	487	0.075
6.6	mild inversion	318	0.117
11.0	isothermal	198	0.181
15.4	adiabatic	154	0.214

coal containing 1.75 per cent sulphur and dispersion of flue gases from a 125-ft. high, 6-ft. diameter stack per boiler. Emission from the boiler plant is treated as a continuous point source.

There should be no damage to vegetation as the maximum SO_2 concentration is below 0.3 p.p.m., the value accepted for the growing season. The sulphur content of the coal could be increased to 3.0 per cent during the non-growing season with the maximum SO_2 concentration remaining below the level of 0.5 p.p.m.

If the three stacks are discharging at the same time, the distance from the points of emission at which the three plumes unite downwind was estimated to be not less than about 500 feet, the stacks being 38-ft. apart. This distance would increase under temperature inversion or conditions of low turbulence as the plumes would rise to a greater height above the stacks. Again if the plumes of the three stacks were to join and form a continuous line source, the gas would not disperse as rapidly and the maximum SO_2 ground concentrations would be higher and vary from 0.5 to 1.1 p.p.m. except under certain meteorological conditions when the three plumes would rise and join farther from the source. The dustfall would also increase. The rate of dispersion of suspended particulate matter and dustfalls (light and heavy particles respectively) from the stacks were estimated to be low, 0.15 to 0.53 milligrams/cubic metre and 1 to 2.7 tons/(square mile) (month) and would not be a nuisance.

Comparison of Empirical and Field Concentrations

The verification of the theoretical diffusion formulas by field tests is of great interest to consultants on air contamination. Only a few correlations between calculated and actual ground concentrations have been reported, largely because of the difficulties encountered. For instance a large number of analyses for SO_2 have to be made at various distances from the stack and detailed meteorological information is required on wind, temperature, rainfall, etc. For tall smelter stacks, agreement was only found between Sutton's calculated SO_2 ground level concentrations and field tests provided the value of the turbulence parameter was reduced from 0.3 to 0[11]. For an 80-ft. stack, average concentrations for 30-min. or longer were about half the values predicted by Bosanquet and by Sutton.[12] The Sutton values were much higher near the stack.

The 12-month atmospheric survey made after the nylon intermediates plant commenced operation adds further knowledge on the accuracy of predicting maximum ground concentrations. The maximum average SO_2 concentrations recorded during the winter lie below the range calculated for continuous point and line sources. According to field tests, the SO_2 never exceeded 0.20 p.p.m. for an hour or more although peak values up to 0.32 p.p.m. were found during shorter periods of time and lower values (average 0.06 p.p.m.) were found over a 5-hour period. A comparison of calculated values and field results indicate that the former are approximately twice the actual values found in the survey.

Likewise the calculated values of suspended particulates or dust concentrations to be expected under varying meteorological conditions indicated maximum values of 0.15 to 0.53 mg./cu.m. The maximum concentrations found by analyses, 0.090 and 0.119 mg./cu.m. were below the calculated values. A comparison of empirical and field values indicated that the former can be approximately three time the latter.

How does the SO_2 level vary with distance from the source? Based on Bosanquet's equation[8] the SO_2 ground level concentration may be predicted at distances downwind from any stack both for low, average and high turbulence. It is of considerable interest to compare the calculated values with those found in the atmospheric survey. Accordingly the SO_2 ground concentrations were estimated for average turbulence and distances up to 4500-ft. away from the stacks of the boiler house and shown as a curve in Fig. 2. The averages of numerous SO_2 analyses determined during downwind conditions are marked as points on this figure. As each sample was collected over a period of time and under varying meteorological conditions, the analyses are best compared with the values for average turbulence.

The measured SO_2 ground concentration, at a distance downwind from the stack, was found to be about one half to two thirds of the calculated value except near the peak concentration shown in Fig. 2.

Atmospheric Surveys

The ground level concentration of contaminants is now recognized as a controlling factor in appraising the potential contamination of the atmosphere by a new plant. In an atmospheric survey it is usual to measure the ground concentrations of SO_2, suspended particulate matter (dust) and deposited matter (dustfall) arising from the steam plant; organic aerosols from combustion might be increased by losses of organic materials from the process buildings. To avoid nuisance or damage, no contaminants should exceed a threshold limit. Sulphur dioxide is usually given first consideration as it is present in a greater amount than any other contaminant and a small amount can be quickly determined by simple and well-developed methods. A valuable index of pollution is the concentration of suspended matter i.e. small particles of complex composition which are not more than 10 microns in size. Aerosol contaminants give another guide to pollution as all combustion processes produce small liquid and solid particulates 0.1 to 10 microns in size; the size range of tobacco smoke, ammonium chloride and fog are approximately 0.01-0.15, 0.1-2 and 1-40 microns in diameter.[7] Dustfall is a valuable indication of the amount of fly ash and consists of particles larger than 20 to 40 microns which settle readily and can be collected and measured in dustfall containers. Dustfall is two to three times as great in the winter as the summer,

Table V.—Dustfall in Various Locations

Area	tons/(square mile) (month) Variation [20]	Av. [21]
Heavy to medium	65–100	92
Medium or moderate	50–65	54
Low	35–50	40
Residential (Canada)	11–30	20
Rural (Canada)	3–11	—
Ocean	0.35	—

Table VI.—Comparison of SO_2 Concentrations (parts per billion)

Winter Values	Maitland				McGregor	Leicester (30 mi. away)
Wind Direction	NE	SE	SW	NW		
SO_2	3	0.1	5	1	6.1	3

owing to additional heating, and varies on location as in Table V.

An atmospheric survey was made before the plant commenced operation to determine whether the air in this area conformed to "clean country air" or was more polluted and could be classified as "suburban air". It was possible that air contaminants came from the C.N.R. locomotives and the ships in the St. Lawrence River which are nearer than the two neighboring centres of population, Brockville and Prescott-Ogdensburg. Brockville has a round-house in the railway yards and a number of medium-sized industries, Prescott has fewer industries and Ogdensburg has a paper mill. The nature, distribution and dispersion of contaminants in an urban area has been reviewed by Dr. Katz.[14]

The first survey, October 1952 to May 1953, was called the "blank run" as the values could be compared with others found in the second survey, October 1953 to October 1954, named the "operating period", conducted a few months after the plant started. The surveys established the contaminant levels and determined if the operation of the nylon intermediates plant added to the pollutants which were found and recorded in a new area.

A large number of tests must be made to obtain reliable average readings as the following meteorological conditions can affect the results.

(1) Inversion over a smoke plume —an upper stable area prevents movement of the air below and smoke will rapidly descend.

(2) Sudden increase of turbulence near the ground — the smoke will drift downwards and reach the ground in maximum concentration under the plume. This generally occurs about one half hour after sunrise in the summer.

(3) Velocity of wind — a high speed improves dispersion and reduces the ground level concentration.

(4) Direction of wind — the degree of pollution will vary with changes in the direction of the wind, an occurence that may take place slowly or quickly.

(5) Temperature of atmosphere —a large temperature differential in the air and above the ground level will reduce pollution. This occurs often in the winter. The movement of a cold front and passage of cold air into a warm region will act in this manner and reduce pollution.

(6) Precipitation — rain, snow and hail will reduce a pollution level.

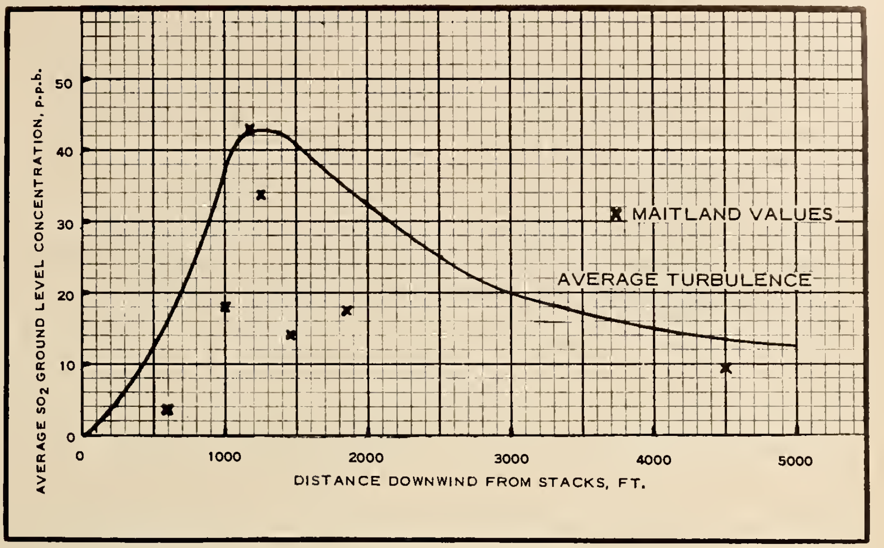

Fig. 2. Variation of average SO_2 ground concentration with distance from stacks.

Accordingly an analysis of meteorological information is necessary as a background for an intelligent interpretation of the results of an atmospheric survey. Temperature, barometric pressure, humidity, hours of sunshine, inches of rain, and wind speed and direction were recorded. The distribution of the wind, blowing in each direction of the compass is normally shown as a wind rose which is very useful in locating the source of a contaminant. The 1954 wind rose at Maitland is given in Fig. 3 and the wind velocities in Fig. 4.

At Maitland the prevailing wind direction is SW and the highest recorded wind speed is 73 miles hour.

The SO_2 measurements were made with a Thomas autometer, suspended particulates (commonly called dust) and organic aerosols were collected in dust and aerosol samplers; the dust was trapped on filter paper and the organic aerosols on silica gel. Four dustfall collectors of the Detroit type, as shown in Fig. 5, were used throughout the investigation.

The collectors are a development of the Harvard wind-tunnel experiments and have been used in the Detroit-Windsor Pollution Survey by the International Joint Commission. The dustfall varies according to the type of collector (Detroit, Toronto, Pittsburgh, and British Standard); a Toronto value should be multiplied by 1.82 to equal the Detroit value.[20] McKinnon Industries Ltd., St. Catharines, Ont., kindly lent a testing station, the dust samplers and autometer. In the second survey, the McKinnon station was used as well as a new mobile testing laboratory which was moved as a trailer from one location to another.

The meteorological factors were determined by the following standard instruments:

Casella sunshine recorder, rainfall recorder and barograph.

Bendix-Friex hygrothermograph for temperature and humidity, aerovane and recorders for wind speed and direction.

All instruments were calibrated before and after a survey.

The locations of the dust cans, McKinnon stationary testing station and garden plots are shown in Fig. 6. They were placed 1200 to 3200 feet from the boiler house stacks.

1. Blank Run

(a) SO_2. To assess the degree of pollution around Maitland, the determined mean concentrations were compared with values reported for rural areas, at McGregor which is 15 miles south of Windsor, Ont.[15] and at a location 30 miles from the city of Leicester, England.[16] Figures are in Table VI.

The average SO_2 concentration is similar to clean suburban air, found 10 to 20 miles from a large city.

The pollution pattern shows the effects of Brockville and Ogdensburg as well as indicating low but important pollution from an unknown NW source, perhaps from Ottawa and Hull which are 50 miles from the plant.

An examination of the SO_2 analyses showed a standard diurnal variation i.e. well defined peak concentrations at 10—noon and in the late evening, the actual time depending on the month. There is a monthly variation in SO_2, the mean concentration increasing from 2.4 to 5 p.p.b. between October and February and decreasing to 0.5 p.p.b. in May.

(b) Aerosols. The mean concentrations of suspended particulates (dust) are comparable to those reported at McGregor[15] and higher than reported near Leicester,[16] the value recorded for a residential area in Cincinnati is also higher[17] (Table VII).

The Maitland concentrations are higher than normal for a rural area, the highest level coming from the NE, Ogdensburg. The concentration was similar during an 8, 16, 24, or 32 hour collection period, with a monthly maximum in November and minimum in February.

The concentration of organic aerosols is usually of the same order of magnitude as the suspended solids and as the mean is only 56 per cent of the suspended matter, the latter must arise more from a mechanical source than from combustion which is the usual source of aerosols.

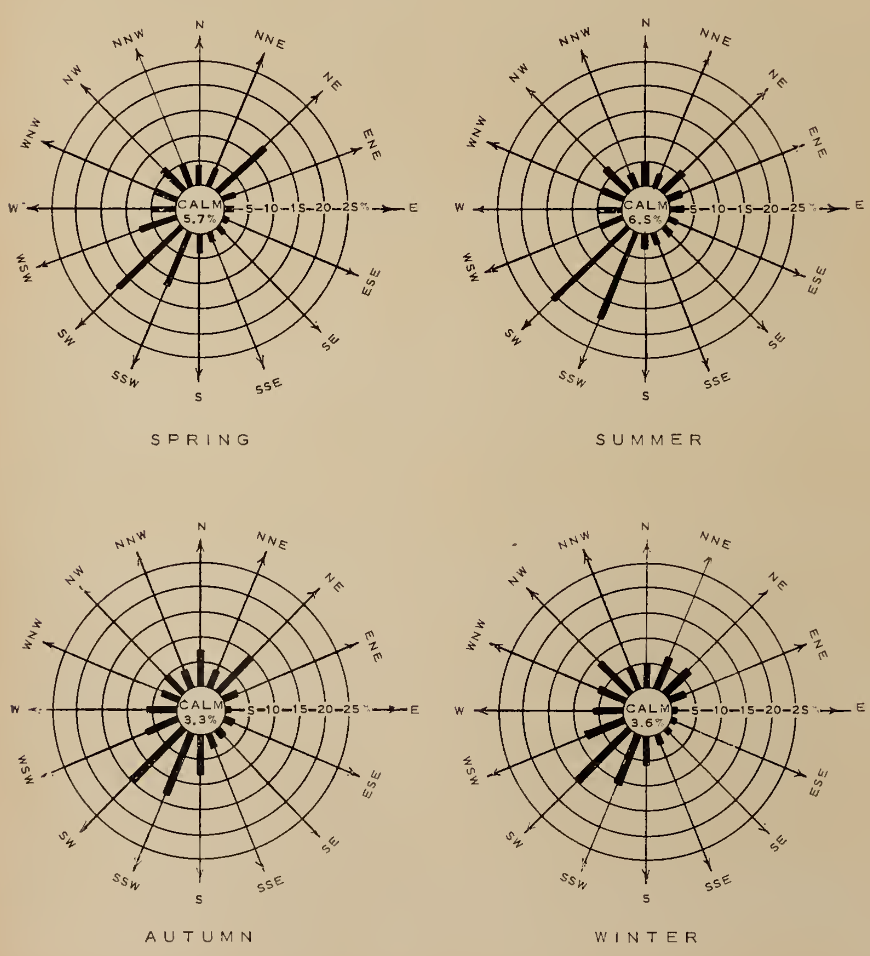
(c) Dustfall. The dustfall at Maitland is similar in value to that found near Toronto[18] and is lower than recorded in the city of Toronto[18] and in a semi-rural area near Windsor.[14] (Table VIII).

2. *Operating Period*

(a) SO_2. The maximum pollution caused by SO_2 occurred with winds clearly showing the boiler house stacks as a source; all concentrations were below the threshold limit. As in the blank run, the occurrence of SO_2 pollution was noticed with NE winds.

The monthly variation of SO_2 differed in the blank and operating periods, possibly caused by heavy snowstorms or other meteorological conditions. The daily diurnal variations in SO_2 concentrations are shown in Fig. 7; values given for Leicester, Los Angeles, and St. Louis are plotted on this figure as the maximum concentration was said to depend on location.[7] The Maitland values are comparable with Leicester and Los Angeles.

Fig. 3. Wind rose at Maitland works, 1954.



A number of tests were made in the mobile trailer, up to 4,400-ft. NE of the plant. The average concentration of SO_2 in SW winds, downwind from the plant, was reduced by 1/2 to 2/3 of the value at 1200-ft. This information indicates the degree of dispersion in a distance equivalent to 35 actual stack heights. The SO_2 frequency and average concentration were similar at various locations on the plant-site, the highest values coming from winds passing over the boiler house.

(b) Aerosols. The average dust concentration, through the winter months shows a decline from November to a low in January and February followed by a steady rise until May. The mean dust concentration is similar for the blank and operating periods. (Table IX).

The organic aerosol concentrations were satisfactory although in March the values were high, exceeding 0.15 mg./cu.m. This corresponded to a period when operating conditions at the incinerator were particularly bad, the fumes from the incinerator being carried towards the sampling point. Better control of the incinerator was achieved late in March and the organic aerosol levels returned to normal. The average concentration in the summer did not differ from values taken during a plant shut-down, namely 0.05 mg./cu.m. It appears that in the summer months the contribution of the plant to suspended particulate matter is relatively slight.

(c) Dustfall. Comparable pickups were obtained from the four dust collectors. A comparison of compositions obtained in the blank run and in the operating period is shown in Table X.

The water-soluble dustfall was considerably higher in the operating period, possibly owing to a large fall of snow — the values agreed within 80 per cent by eliminating the month of February 1954, when two-thirds of the total precipitation fell in one snow-storm. The chloride content of the dustfall was reduced by precipitation. The lower sulphate content indicates that some of the sulphate in the blank run might have come from a source (possibly ground dust) other than fly ash.

3. *Summary of Two Atmospheric Surveys*

(a) As shown in Table XI, average concentrations of SO_2, dust, and organic aerosols were lower in the operating period than in the blank run, possibly owing to changes in meteorological conditions, although the

dustfall was increased during the operating period.

(b) The SO_2 levels at varying distances downwind from the plant showed that the maximum levels were lower than calculated for dispersion from the boiler house stacks and were safe for persons and vegetation.

(c) The suspended particulate matter is below the level calculated for dispersion from the boiler house stack and is comparable to an area of low pollution.

(d) The organic aerosols are well below the damaging limit, 0.04 vs. 0.35 mg./cu.m.

(e) The dustfall was increased after the plant started and is characteristic of an area of low concentration.

Garden Plots

As shown in Table II, sensitive plants will be damaged by a low concentration of SO_2. Accordingly consultants on pollution have suggested that garden plots be suitably placed and examined to observe if one or more plants are marked by an excessive emission of fume. In 1953 and each subsequent year, four garden plots were laid out in the positions marked on Fig. 6, each plot being downwind from an area having an effluent. The plots were prepared each spring for planting and after fertilization were stocked in an identical manner with a selection of sensitive flowers and vegetables. In the spring of 1954, an additional plot, containing gladioli, zinnias and petunias, was placed in front of the administration building.

Plants in all plots, except No. 2, remained healthy. The 1954 inspection showed slight gas damage in No. 2 plot, downwind from the incinerator, especially to the leaves of gladioli. Apple trees within 200-300 feet of the incinerator were also damaged in the growing season. The period of damage coincided with poor burning conditions in the incinerator and after correction the plants in No. 2 showed steady recovery during the summer. Again in 1956, slight damage was shown on the gladioli, zinnias, petunias and tomato plants in the plot near the incinerator but since the removal of the incinerator there has been no deposit of soot on the flowers or leaves of garden plots as noticed in former seasons when the incinerator was operating. The apple crop was also excellent.

It is proposed to continue with garden plots and to examine susceptible plants each year. Damage from contaminants leaving the nylon intermediates and other chemical plants to be operated at Maitland Works can be quickly seen. The wind direction and velocity will continue to be recorded so an immediate check can be made for the source of any pollution that might arise despite the safeguards.

Incinerator

The organic residues and tars from the nylon intermediates plant were burnt in an open-pit incinerator, situated some distance behind the process buildings. Every attempt was made to accomplish complete combustion with a minimum discharge of

solids, noxious gases or odour. In practice, some nuisance within the plant site was created by the fumes during adverse weather conditions.

Immediately a study was started to determine if the organic wastes could be disposed of more efficiently. It was found to be economic to recover the bulk of the heat of combustion by burning the wastes in a suitable burner under a conventional boiler in the boiler house. Over a given feed range, the designed burner was satisfactory for lighting the coal fire when steam and atomized oil were used with the organic wastes. Below the minimum rate the organic wastes caused pulsation and made it difficult to control a constant rate of burning, while above the maximum rate an unstable flame occurred.

In 1956, the incinerator was removed and organic wastes were disposed of on a continuous basis while tars were fed intermittently. Under controlled burning, combustion appears to be complete and the appearance of the stack is normal i.e. no additional colour or odour.

Fume Abatement System

The reddish-brown appearance of the emissions from a number of vent stacks in the nylon intermediates area and from the nitric acid plant would appear unsightly as well as being a nuisance owing to their corrosive nature. This colour is caused by nitrogen dioxide (NO_2) which with nitric oxide (NO) accounts for 0.12 to 49 weight per cent in individual emissions. The question of reducing the oxides of nitrogen to a safe limit was carefully examined during the design of the nylon intermediates plant and as a result of a literature search, what appeared to be the most effective process for reducing the colour was investigated in a pilot plant. Based on the results of tests covering the absorption of NO and NO_2 in an alkaline solution, a full scale plant was designed, erected and operated.

The fume abatement unit consists of a piping system for collecting the low pressure fumes from tanks and process equipment in process buildings and delivering them to a blower and then to an absorber which also receives high pressure reaction off-gases from the nylon intermediates and nitric acid plants. Dilute caustic solution is circulated through the large absorber, 8-ft. in diameter with 41-ft. 6-in. of dumped 2-in. ring packing. In performance, the colour of the effluent gases was considerably reduced. Later a waste liquor containing dilute ammonia and caustic, was tested and it was found that a heavy white plume containing finely dispersed ammonium salt particles was discharged from the absorber. The solid particles were very small, about 0.1 to 10 microns in diameter, and they required a suitable scrubber for their removal. A wet scrubber of the Venturi type, was considered most suitable for removing the fine particles.[19] This scrubber consists of a Venturi throat through which the gases pass at high velocity and at the same time come in intimate contact with water which is widely dispersed in small droplets after it enters the throat. A pilot Venturi scrubber was tested and the results showed that the bulk of the white fume could be removed. A Venturi scrubber, with attached separator to collect the liquor, was installed and successfully operated. The effectiveness of the Venturi scrubber was quickly demonstrated when water was added — then the white discharge leaving the clean up unit was rapidly reduced in volume and density. A year after first adding ammonia liquor, a careful examination was made of the entire fume abatement system to be certain that solid ammonium nitrite, an unstable compound formed in the absorber, was not deposited on the equipment. Ammonium nitrite, in the solid state but not in dilute solutions, will quickly decompose and detonate. As the examination did not reveal the presence of any solid ammonium nitrite, this equipment should continue to run in a safe manner. As safety is such an important word in the Company, periodic inspections will be made of the new removal unit.

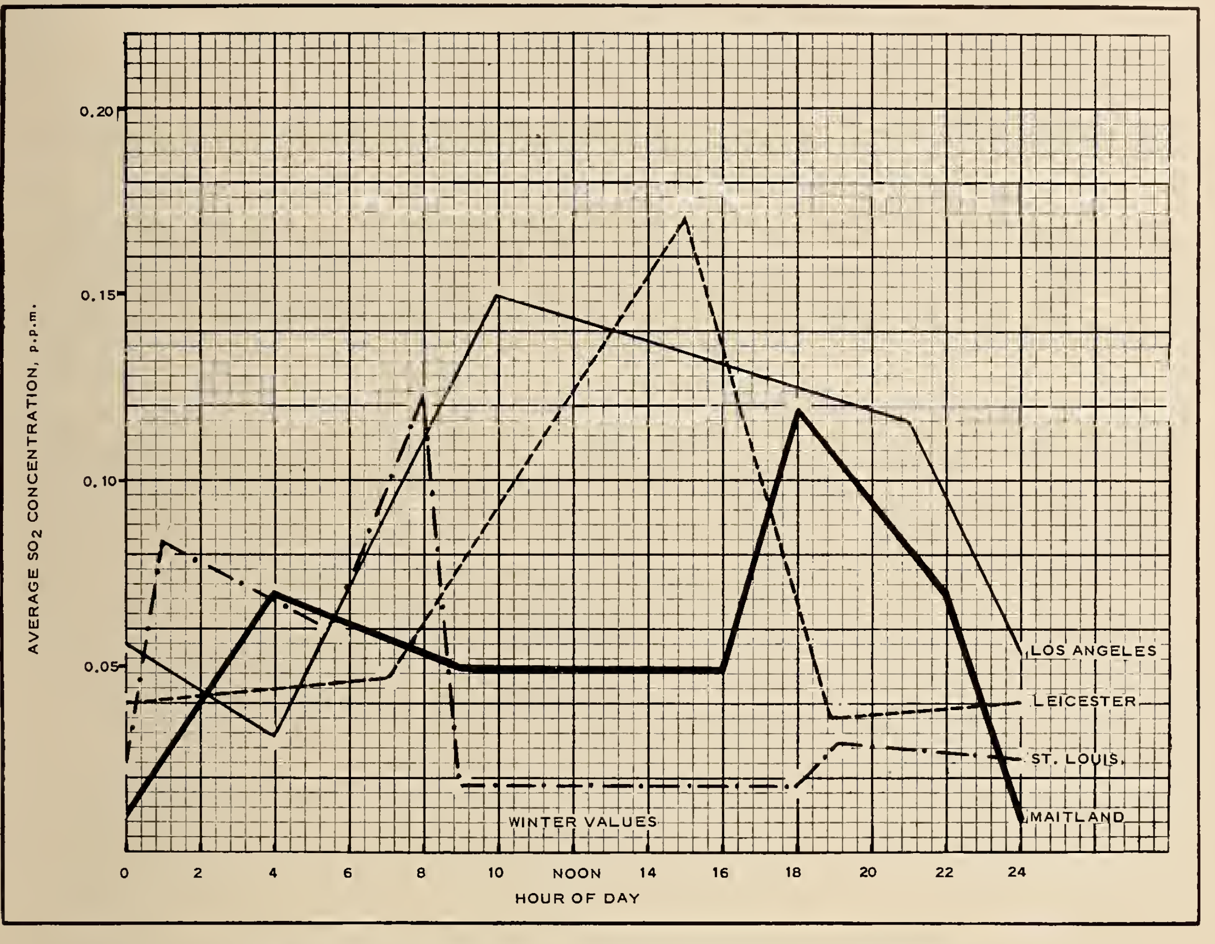

Fig. 7. Diurnal variation in SO_2 concentrations for various locations.

This seems to be the first fume abatement system used in Canada for the reduction and near elimination of oxides of nitrogen from effluent gases leaving a nitric acid plant. Details of the experimental tests, design of the equipment, and its operation were given at the 1957 Annual Conference of the Chemical Institute of Canada.

Conclusions

The steps taken by the Company have shown that each contaminant is released at such a controlled rate that the maximum ground level concentration is below the toxic or threshold limit to individuals and vegetation. The two atmospheric surveys showed only an increase in dustfall, not of SO_2, suspended particulates or organic aerosols. The estimated maximum SO_2 ground concentrations, at various distances downwind from the source, were within the limits set by empirical equations. Occasional and objectionable fumes from the incinerator were eliminated by burning the organic wastes in the boiler house. Perhaps the most interesting story associated with pollution control at Maitland is that of the reduction of the oxides of nitrogen and elimination of the brownish-red colour from the fumes leaving the nitric acid and nylon intermediates plants. This process could be applied to other nitric acid plants.

The success of pollution control is indicated by the establishment of a recreational area on the St. Lawrence River by the employees, on a site which is both downwind and downstream from the plant.

Conversion Factors

The following are the useful conversion factors for units employed in atmospheric pollution:

1 microgram /cu.m. $\times$ 0.36	= 1 grain /cu. ft.
1 milligram /cu.m. $\times$ 357	= 1 grain /cu. ft.
1 micron $\times$ 3.9×10^{-5}	= 1 inch
1 part per million $\times$ 10^{4}	= 1 per cent.
1 ton /stack day $\times$ 83.3	= 1 lb. /hr.
1 metre /second $\times$ 2.2	= 1 mile /hr.

Canadian Overseas Telecommunication Facilities

(Continued from page 48)

arate system, such service being provided by utilization of the telex network. The consequent possible existence of carrier systems, microwave, and scatter links in a telex connection, should tend to force the use of telegraph transmission providing for automatic repetition of transmission when a "hit", "fade", interruption or noise causes a mutilation of the transmission. Therefore, from the foregoing, it can be stated that the future of overseas telecommunications would appear to offer great interest to the engineer, and it will require substantial effort, and what might be called original thinking, by our engineers, if Canada is going to make its full contribution to future development of its overseas telecommunication services.

Battle River Steam Station

(Continued from page 57)

This does not include such special functions as ash removal, soot blowing or coal handling.

An interesting added feature is a television camera which views the flame in the furnace through a window in the top of the the boiler. The monitor is mounted on the vertical panel in front of the operator. In this monitor, the operator can view the torches lighting up in the corners of the boiler, and can see the flame conditions in the furnace. Besides being a very attractive item for visitors, it also is a valuable instrument for the operator.

The Future

The ultimate capacity of the Battle River station will be decided by the cooling water requirements, which places the limit at 120 Mw. if conventional steam installations are made throughout. This could be bettered if higher pressures and temperatures with reheat are adopted for the steam conditions of future installations, as this would reduce cooling water requirements per megawatt.

Again looking into the future, it appears that a second unit will be required at Battle River by the fall of 1962. Although the second 30 Mw. unit will undoubtedly be of conventional steam plant design, we are most interested in the development of a gas turbine using coal for fuel. It is not beyond the realms of possibility that the third installation at Battle River will be such a unit. As water cooling requirements for the gas turbine are small, such an installation would greatly increase the potential capacity of the Battle River station. We have been asked many times if we are considering atomic power. It is our belief that Alberta Utilities will not be interested in this new development for some time, in view of the abundance of coal and natural gas available for fuel at reasonable rates in our province.

DISCUSSION

of Technical Papers and Other Articles

AIR POLLUTION CONTROL AT NYLON INTERMEDIATES PLANT

H. R. L. Streight

The Engineering Journal, 1958, January, p. 69

Canadian Journal of Chemical Engineering.

E. B. Lusby*, M.E.I.C.

We have been privileged to hear Dr. Streight's paper on the control of air pollution at the Maitland plant of the Du Pont Company.

The approach to the problem of another industry starting operations in any area has been well described with figures showing the air pollutants before and after operations. It seems that pre-operations surveys are necessary as a guide in the design of new process equipment so that good neighbourliness is maintained with the former residents. It has been brought out however that sometimes lower figures for pollutants are obtained in the survey made after the operations have started than what was obtained in the pre-operations survey. Those contemplating the installation of new processes would have to keep this point in mind. It was also noted that the necessity of better design for incinerators was stressed and this can be an inspiration to all chemical plant designers.

Of particular interest was the application of garden plots at the Maitland plant. The location of these plots is important and it was brought out that such plots are a very effective and economical method for detecting and thus maintaining control of air pollutants. Dr. Streight and his company are to be complimented for their contribution to this important subject.

I would like to ask Dr. Streight a question . . . It was noted that the oxides of nitrogen that are evolved could be reduced by absorbing in an alkaline solution; could this be explained further and could Dr. Streight tell us the disposition of the solution?

Author's Reply

In reply to Mr. Lusby's question, a fume abatement system is operating at Maitland Works to reduce the oxides of nitrogen leaving the nitric acid and nylon intermediates plants to a value less than the threshold limits for human beings or sensitive plants. The design, operation and performance of the equipment were given in a paper entitled "Reduction of Oxides of Nitrogen in Vent Gases" at the 1957 Annual Conference of the Chemical Institute of Canada — this paper is being published in the *Canadian Journal of Chemical Engineering.*

Briefly, the vent gases are scrubbed in a large packed absorber with a dilute ammonia-caustic soda solution and cleaned in a following Venturi scrubber. An almost colourless effluent gas passes to atmosphere. 97% of the oxides of nitrogen are removed in the absorber and Venturi scrubber. The solutions containing ammonium nitrate and nitrite are sent to the St. Lawrence River and are of benefit to the health of aquatic life.

BATTLE RIVER STEAM STATION

The Engineering Journal, 1958, Jan., p. 49

J. N. Ford, M.E.I.C. and W. I. McFarland, M.E.I.C.

E. B. Campbell†, M.E.I.C.

With the tremendous expansion of thermal electric generating capacity presently underway in Canada it is gratifying to those of us associated with the utility industry to see an ever increasing interest in this field of engineering by the Engineering Institute of Canada. I am sure that future annual meetings will hear more about thermal power generation and its associated problems.

We have heard a very interesting description of another of Canada's new thermal generating stations. It is interesting to note that because of the tremendous rate of load growth this utility has considered it to be economic and expedient to install in one unit capacity equivalent to the total capacity previously installed on that part of their system.

It is only recently that much attention has been paid to the burning of Western Canadian coals in pulverized form and very little information or experience is presently available on the problems associated with these fuels or their pulverizing and burning characteristics.

However, from preliminary information available, it appears that the various western coals which are similar in analysis do differ greatly in the fineness to which they must be pulverized for satisfactory combustion and low carbon loss, the primary air temperature required for satisfactory drying in the mills, and the coal/air mixture temperature necessary at the burners. In addition, these coals appear to differ greatly in their effect on steam temperature. It is very difficult, if not impossible, to predict the behaviour of these coals from standard laboratory test methods which have been established from, and are applicable to, other fuels which differ greatly in analysis from the Western Canadian coals. This indicates an urgent need for numerous full scale tests on existing pulverized fuel installations to provide the necessary design data for the many large plants presently in the planning stage by utilities in Western Canada. It is imperative that all test data and conclusions be distributed as widely as possible and be made available to all interested parties, both utilities and manufacturers.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

LUBRICATION WITH MOLYBDENUM DISULPHIDE FORMED FROM THE GAS PHASE

F. P. Bowden and G. W. Rowe, *The Engineer.* v. 204 n. 5311, Nov. 8, 1957.

Lubrication of surfaces at high temperatures is becoming of increasing importance, and since the conventional liquid lubricants break down at temperatures of a few hundred degrees centigrade, use is made of solid lubricants such as graphite, molybdenum disulphide and other lamellar solids. Firm attachment of solid films of these substances to the surface is important and if formed by chemical reaction this attachment can be improved. When the surface is heated in an appropriate gaseous atmosphere this is accomplished. Lubrication from the gas phase has the additional advantage that the film can be reformed in operation if the parts are surrounded by the gas.

It has been shown that if molybdenum disulphide is rubbed on to steel surfaces a thin film is produced which has good lubricating properties which continue up to reasonably high temperatures, and also that sintered molybdenum forms a low-friction coating when heated in hydrogen sulphide gas. Recent experiments have been made with pure molybdenum, initially heated to 1400° C. in a high vacuum to remove surface contamination. After cooling to room temperature the surfaces had a high coefficient of friction between them, $\mu = 2.0$, which rose with temperature until complete seizure occurred at 110° C. Purified H_2S gas was admitted at a low pressure (0.01 to 0.1 atmos.) and at room temperature. It was immediately absorbed on to the surface, reducing the friction to $\mu = 0.9$. When heated in the gas, chemical reaction took place and the friction between the surfaces fell to $\mu = 0.2$ at 800°-900° C. Specimens cooled after 20 minutes of heating in H_2S at 850° C were covered with a thick purple film of molybdenum disulphide which gave good lubrication. The film was stable and gave low friction in vacuum up to 800° C but above 900° C the film decomposed and friction rose rapidly. If the H_2S gas atmosphere is maintained the worn films can continuously be repaired during the sliding process.

An attempt was made to lubricate steel surfaces in this way. Molybdenum disulphide rubbed on to steel gave a fairly low friction, $\mu = 0.4$ *in vacuo*, and protected the surfaces from seizure up to 700° C - 800° C but the friction was high, $\mu = 1.5$ to 2. When the molybdenum coating was applied to the steel by a sputtering process it spalled off when heated in H_2S gas, due to the formation of iron sulphide within the discontinuous molybdenum layer, and friction coefficients were high. However, the application first of a protective nickel coating on top of a flash of copper to the steel specimens before applying the sputtered molybdenum permitted the formation of MoS_2 without chemical attack on the substrate metal and resulted in low friction coefficient.

These observations have provided further evidence that films formed by heating molybdenum in hydrogen sulphide as in carbon disulphide vapour can give low friction at high temperatures even *in vacuo*. If destroyed during rubbing the films are readily reformed in the hydrogen sulphide gas, so that in this atmosphere the surfaces will continue to give a low friction. In this manner a gas may act as an effective lubricant if it reacts with the surface to form a compound of appropriate structure.

WHAT'S IN THE LITERATURE (THE IMPORTANCE OF DOCUMENTATION)

F. T. Sisco, *Metal Progress*, v. 72 n. 4, Oct. 1957.

The tremendous massing of technical and scientific literature which is going on at an ever-increasing rate presents a very serious economic and often ethical problem. Searching of the literature is now so costly in the use of time of qualified people that it is frequently cheaper (for many small scale research problems) to get a direct answer by laboratory research than to find out whether someone has recorded his findings.

In 1952 the Library of Congress received nearly 40,000 scientific and technical journals and other serial publications which contained approximately 1,500,000 papers, applying only to engineering and science. While books can be excellently indexed and classified, periodical literature has not been so treated because of the diversity of publications and the great magnitude of the job. To conserve the time needed for literature perusal many excellent abstracting services have developed but although abstracts are valuable time-savers they have many faults. There is too much duplication, too much of a time lag between publication of the paper and the appearance of the abstract, much bad indexing and confused and uncertain terminology, and there are too many omissions. The free world prepares in the average year about 300,000 abstracts and the Soviet Union about 400,000 but duplication in this total amount is serious and only about one quarter of the available engineering and scientific literature is abstracted in any one year.

The output of technical literature has increased at a startling rate. The major American engineering societies publish in an average year about five times the number of technical papers published 20 years ago. In 1956, *Engineering Index* prepared 27,000 abstracts in all fields of engineering.

A threefold attack on the problem is needed. First, the development of a logical and uniform system of indexing based on semantic principles;

second, a logical system of classifying technical papers or abstracts which will permit them to be coded effectively and rapidly; and lastly the development of some system, preferably by the use of machines, which will rapidly locate and retrieve the coded literature.

The Society for Metals has initiated some studies and research projects dealing with metallurgical abstracts in an attempt to solve the problem as outlined above. They hope that it will spur other organizations in the engineering field to action in finding an answer to what is now one of the most pressing problems — making the literature readily available. Its solution will eliminate the economic factor of high cost and waste of manpower in repeating work which has already been done but which cannot be found, and the ethical question of reporting as new and original, data which should be credited to a previous investigator.

VACUUM METALLURGY

R. C. Bertossa, *Mechanical Engineering*, v. 79 n. 11, Nov. 1957.

Materials capable of withstanding high temperatures and corrosive environments are in demand in the petroleum industry and in the aircraft, missile and atomic energy fields. Titanium, zirconium, tantalum, columbium, and molybdenum all have exceptional properties which make them desirable for use in newly developed processes and industrial equipment where requirements are too severe for ordinary metals and alloys. However they have one common undesirable characteristic in that they are easily embrittled at elevated temperatures by contact with even small quantities of atmospheric gases such as oxygen and nitrogen, and also hydrogen. Rapid deterioration through oxidation also occurs at high temperatures.

The use of vacuum techniques in melting, heat-treating, joining and cladding not only protects against contaminating gases, but also promotes the removal of gases and other impurities from metals previously contaminated. This is termed "out gassing". Oxidation-resistant claddings are being developed for metals such as molybdenum, tungsten, tantalum, columbium and others in order that they may have protection in high-temperature service while their exceptional high-strength properties are utilized. Vacuum cladding appears to present the greatest potential for solution of this problem. It is used for producing high-strength clad plates for subsequent fabrication into pressure vessels which are subjected to corrosive conditions at high temperatures e.g. 1/16 in. of fine silver integrally and continuously vacuum bonded to 1 in. of austenitic stainless steel. There are large vessels now in chemical, petroleum, and paper-pulping service fabricated by vacuum cladding stainless steels, monel, nickel, and inconel on inexpensive low and medium-carbon steel plates. Vacuum brazing techniques are used to produce light-weight honey-comb sections of great rigidity and strength from thin stainless sheets for the aircraft industry.

Many advantages are obtained from the use of vacuum-metallurgical techniques. High vacuum effectively excludes atmospheric gases during the time the metal is at elevated temperatures. It can actually break down and remove oxide films previously built up on certain metals, cleaning and de-oxidizing the surfaces, Many non-metallic, some metallic, and most gaseous impurities are scavenged from metals, upon both vacuum melting and heating under vacuum without melting. In brazing of metals, vacuum techniques exclude oxidation from the interfaces, allowing uniform and complete bonding without fluxes. Vacuum can be used also to exert very high uniform pressures on the bonding interfaces, bringing them into intimate contact and thus insuring a uniform cross section of bond and highest strength of joint with a minimum of brazing alloy. In all operations, vacuum methods produce products which are bright and clean and, in many cases, need no further finishing. The metals produced by ordinary production practices normally contain defects such as segregations of nonmetallics, voids, entrapped hydrogen and other gases. When these defects and impurities have been removed by vacuum-melting or heat-treating, these common metals and alloys show remarkable increases in strength and other desirable properties for an increase in cost of only a few cents per pound.

On the other hand vacuum-metallurgical processes are more difficult to carry out, the equipment is intricate and skilled, meticulous operators are required to produce, heat-treat, join, and decontaminate the metals. However these particular problems are being resolved rapidly and many commercial processes are operating.

THE FIRE RESISTANCE OF PRESTRESSED CONCRETE

A. W. Hill and L. A. Ashton, *Civil Engineering*, v. 52 n. 617, Nov. 1957.

Fire resistance tests in Great Britain are carried out at the laboratories of the Joint Fire Research Organization, at Boreham Wood, where facilities exist for testing walls, floors, columns and beams up to 24 ft. span. Fire resistance is a measure of the ability of a constructional element to withstand heating of a specified intensity while performing its normal functions, so restricting the spread of fire in a building for a definite time. Fires of varying severity can be represented by tests of different duration, since a relation has been established between the amount of heat liberated by complete combustion of the contents of a compartment of a building and the corresponding test period. Observations are made continuously throughout the test to determine when the first critical point is reached, denoting failure of the specimen to act as a barrier to spread of fire.

In structural elements such as floors or walls which form the boundaries of a compartment of a building, failure may occur in three ways: (a) by heat conduction sufficient to ignite flammable material in contact with the surface remote from the fire; (b) by the formation of cracks and holes which will allow flames and hot gases to pass from one side of the element to the other; (c) by collapse. Beams and columns have only a load-bearing function in a building and their fire-resistance is given by the time from the start of the test in which failure by collapse occurs. The fire resistance of an element of structure is the time from the start of the test to the occurrence of failure as judged by any of the above conditions, and is generally given to the next lower of one of the following periods; ½ hour, 1 hour 2 hours, 4 hours, 6 hours.

Investigations in Great Britain so far have been confined to beams and floor members. Prestressed concrete members of a given type, span and load-bearing capacity, are likely to have a lower fire resistance than their equivalents in normal reinforced concrete for three reasons:

(1) prestressed concrete members have a smaller section and therefore less heat capacity;

(2) cold-drawn steel wire used for prestressing is more susceptible to high temperatures than mild steel, and it usually carries a stress which is a higher proportion of its ultimate strength than that in mild steel;

(3) continuity, which is more common with reinforced concrete, has a marked effect on fire resistance.

In assessing the fire resistance of prestressed concrete it can be assumed, as the result of experience in fire tests, that collapse due to failure of the steel is imminent when the temperature of the wires has reached 400° C. At this temperature the strength of the high-tensile steel is reduced to one half that at normal temperatures. By comparison, mild steel loses half its strength at a temperature between 500-600° C., and fracture at normal working stresses does not occur until in the region of 600° C.

In normal practice the high-tensile steel in prestressed concrete can often be given additional cover, as compared with reinforced concrete, without loss of economy, so that the inferior temperature-strength characteristics of high-tensile steel wires can be offset to some extent. With reinforced concrete the steel, to be most effective for strength requirement, has to be located as near the tension face as possible, and in such a position would be affected relatively quickly by fire. With prestressed concrete the wires are not so near the surface exposed to fire, and are often spread over the section. Provided, therefore, that adequate protection is offered by in-situ concrete, hollow tiles, etc., the strength of a prestressed member even with losses in the extreme wires, may diminish at a slower rate than expected. Additional fire resistance can be obtained by the use of protective coatings which reduce heat transmission to the wires and prevent spalling of the concrete as long as they remain in place.

At 150° C the tensile strength of high-tensile wires usually shows a slight increase but not as much as with mild steel. This characteristic is of less importance in the fire resistance of prestressed concrete and its subsequent residual strength than the effect of heat on the tension in the steel. The modulus of elasticity decreases by 6 per cent at 200° C. and by about 20 per cent at 300° C., which reduces the tension in the wires, while further reduction with rise of temperature is caused from relaxation of the steel due to creep. In addition it has been shown that the longitudinal expansion of hard-drawn wire is not linearly proportional to temperature and not recoverable for temperatures above 150° C., and this would cause a further loss of tension in the steel.

When steel in a loaded prestressed concrete beam is heated to between 200° and 300° C. an appreciable deformation can be expected, and on cooling the loss of prestress may be considerable although the recovery of strength of the high-tensile steel wire may be complete for temperatures up to 300° C. and considerable up to 400° C. Thus the behaviour of a prestressed beam which remains intact after damage by fire is less likely to be severely affected by a fall in strength than by loss of prestress due to reduction of tension in the steel.

Tests made to date have indicated the following tentative conclusions:

(1) Explosive spalling of unprotected beams, having no part of the section less than 2 in., is unlikely.

(2) Failure of a beam can be regarded as imminent when the mean cable temperature at any section reaches 400° C.

(3) A fire resistance of one hour can be obtained with a concrete cover to the cable of 1½ in., a fire resistance of two hours with a concrete cover of not less than 2½ in., and of four hours with a cover of at least 4 in. In order to obtain the four hour period it is necessary to incorporate mesh reinforcement round the prestressing steel to retain the cover in place.

(4) Collapse is likely to be gradual. Warning of failure is given by the development of a marked sag, which may increase visibly just before the end.

(5) There is little difference in performance between beams of rectangular section and beams of I-section designed for the same load and having the same cover to the cable.

(6) A beam longitudinally restrained may have a lower fire resistance than when simply supported.

(7) Even after a heating of about one half of that necessary to cause collapse, a beam will show an appreciable loss of prestress on cooling. A marked permanent deflection will be present after removal of the imposed load, but the ultimate strength may still be a high proportion of its original value.

(8) Protection may also be afforded by the addition of surface finishes adequately fixed to the concrete. Thicknesses of surface finishes to give an increase in fire resistance of about two hours are:

(a) 1 in. of vermiculite concrete slabs placed as a lining to the mould;

(b) 7/8 in. vermiculite gypsum plaster;

(c) ¾ in. sprayed asbestos.

BRITISH MOTOR TRANSPORT INDUSTRY

The Overseas Engineer, v. 31 n. 359, Nov. 1957.

The motor industry has contributed substantially to the overall growth in the British economy in recent years. In 1956 the output of cars, commercial vehicles and tractors was more than twice as great as that in 1938 (1,115,000 units compared to 455,000 units). As judged by the index of industrial production the motor industry's share is from 5 to 6 per cent.

Although there are some 50 companies engaged in the manufacture of vehicles and tractors, the five largest make about 90 per cent of the output of the industry. The "Big Five" producers (B.M.C., Ford, Rootes, Standard and Vauxhall) all make passenger cars and commercial vehicles, and B.M.C., Ford, and Standard are also in the tractor field. Of the 45 or so smaller concerns in the industry, 20 make passenger cars, 20 commercial vehicles, and the remainder specialize in battery electric vehicles. The automotive interests of the 20 smaller car manufacturers are mainly concentrated on the production of sports and large luxury cars. The 20 commercial vehicle makers outside the "Big Five" make the bulk of the heavy trucks and almost all the buses and coaches produced in the U.K. These are mainly non-mass-production items because of small volume output and large range of models.

The 50 vehicle and tractor manufacturers obtain their raw materials, accessories and components from about 4,000 separate suppliers so that the industry employs about 450,000 to 500,000 persons, of whom about one half are working directly for vehicle manufacturers.

The most striking development in the industry during the post-war period has been the expansion of exports from a pre-war level of some 110,000 units to 556,000 in 1956. This 5 to 6 fold increase compares with an approximate doubling in volume of total U.K. exports over the same period. Total automotive products now account for 12-13 per cent of U.K. exports compared with 4 per cent in 1938. Of the 9.5 million vehicles produced in 1946-56 over 55 per cent were exported.

Commonwealth markets have been growing comparatively slowly due to the number of vehicles in use being high in proportion to population or due to low income levels of the people. By contrast the West European market has been growing rapidly and steadily and is likely to continue doing so with the gradual coming into force of the Common Market and (perhaps) the European Free Trade Area. The U.K. makers' share in this market has declined substantially from the (admittedly exceptionally high) levels of a few years ago, due primarily to the efforts of the German motor industry. Germany is, by far, the strongest competitor to the U.K. in world markets and in 1956 U.K. vehicle exports at 461,136 were slightly exceeded by German exports, 484,598. German cars are very competitive both as regards product and price and the German industry has concentrated production on far fewer models and paid special attention to the servicing and spares availability in foreign markets.

It seems likely that the German and U.K. shares in world markets may further increase, and that the share in world vehicle exports of the United States and France will decline. The American industry is unlikely to be able to compete both because of the dollar shortage and especially because American design trends are more and more out of line with requirements in most other countries. The French industry's export prospects are not very good because of high unit costs of production.

The U.K. domestic market, long protected by high tariffs, has formed the base of the industry's expansion in recent years. The coming into force of the Free Trade Area is not likely to seriously affect conditions because of the difficulties facing foreign manufacturers in rivalling the local industry's servicing and spares facilities in its home market.

EARTHQUAKE RESISTANT CONSTRUCTION IN MEXICO CITY

J. H. Thornley and Pedro Albin, *Civil Engineering*, v. 27 n. 11, Nov. 1957

A survey of forty-seven buildings, by detailed examination after the recent earthquake of July 28, 1957, has led to some conclusions regarding earthquake resistant construction.

A common theory, heretofore, has been based upon resonant vibration, that is, if the frequency of vibration of a building comes into consonance with that of a shock, a build-up may result, which will wreck the best designed and most stoutly built structure. In the study of the damaged buildings a considerable uniformity was found in the location of maximum damage. It occurred in most cases between the third and fifth floors. The structural types of these buildings, their heights, and their space layouts varied through a wide range. There seems to be no observable relationship between the extent of damage and either the building height or structural type. The one factor which is consistent with the effects is that of type of foundation. The natural frequencies of all these buildings must vary widely yet the dissimilarity of frequencies does not seem to override the effect of the type of foundation.

Five main types were present, plain concrete raft, compensated concrete raft, mat on sectional wood piles (obsolete), mat on concrete piles, and mat hung from concrete piles by yokes and screws. All buildings resting on and locked to a concrete mat supported on attached long concrete piles driven to point bearing on the cemented sand stratum came through the quake practically unscathed. Soil waves due to earthquakes are the result of vibrations presumably active at great depths. The actual movement of large volumes, of soil is probably a surface phenomenon and may partly explain the failure of raft foundations without piles and the tilting of some buildings.

Some conclusions reached are:

(1) If a pile foundation is used, the piles should be battered (at least in three directions). It should be rigidly connected to the superstructure so that its damping effect on the shock waves can be fully developed.

(2) All secondary internal structural members, particularly curtain walls, should be designed to act as internal bracing for the main structural skeleton both in bending and in shear. Curtain walls should be of concrete diagonally braced, so that they can act as stiffeners to the main structural members. Diagonal bracing members will provide the cheapest and most effective safety feature. Wherever possible the connections between columns and beams should be knee-braced.

(3) In at least five instances, severe damage was suffered by adjacent buildings where each possessed a separate wall which adjoined the wall of its neighbour, instead of both sharing a mutual party wall. One wall in some cases acted as a battering ram buffeting the other. The walls of adjacent buildings should be tied rigidly together, or a protective space of two or more feet should be left between adjoining high buildings.

PAPERS OF THE INSTITUTION OF ELECTRICAL ENGINEERS

The Design of the Control Unit of an Electronic Digital Computer. M. V. Wilkes, W. Renwick, and D. J. Wheeler (2365)

The function of the control unit of an electronic digital computer is to provide the sequences of pulses, which, when applied to the store, arithmetic unit and other units of the machine, cause the orders of the programme to be executed. The paper discusses a number of related ways in which a systematic and flexible design for a control unit may be achieved. In one group of systems the order code is determined by the arrangement of diodes in a diode matrix, and in another by the appropriate threading of wires through a matrix of ferrite cores. The first part of the paper is concerned with logical design, and the second part with the practical design of a system using a ferrite matrix.

A Decimal Adder Using a Stored Addition Table. M. A. MacLean and D. Aspinall. (2389)

A serial decimal adder is described which accepts numbers in binary-coded form. The binary digits, which are handled in parallel, are decoded into a set of pulses which actuate a built-in addition table storing all the possible sums. A special form of number representation has enabled the adder to be constructed more economically than would otherwise have been the case, while the advantages of this type of adder have been retained.

The circuits use square-loop magnetic cores for all logical functions and junction transistors as pulse amplifiers.

INTERNATIONAL NEWS

The Soviet Union and the I.G.Y.

A VAST AMOUNT of work is being done by many nations all over the world during the International Geophysical Year (I.G.Y.), but nothing has aroused so much public comment as the launchings by the Soviet Union of the two Earth satellites known as Sputnik I and Sputnik II, which are part of the Soviet contribution to I.G.Y.

The first satellite, launched on 4 October 1957, was a 22.8 in. diameter sphere weighing 184 lb. It was made of aluminum alloy, highly polished, and filled with nitrogen. Coded signals were transmitted at 20.005 Mc/s. and 40.002 Mc/s. and were received up to 10,000 km.; four rod antennas, 7.9 to 8.5 ft. long, projected outside the spherical body. The initial time to complete one orbit of the Earth was about 96 minutes, the highest point reached (the apogee) being about 621 miles.

The second satellite, launched on 3 November, was a much larger and more complex unit, of which a diagram is shown here. The payload of Sputnik II was just over 1120 lb. and the orbit even more extensive than that of the smaller satellite; the apogee at the start of flight was about 1000 miles, but the orbit period was not very much greater at 103.7 minutes. Equipment carried included instruments for the investigation of cosmic radiation, and the ultra-violet and x-ray regions of the solar spectrum; an hermetically sealed chamber with a dog inside; radio telemetering equipment for relaying the results of measurements to the ground; transmitters and batteries.

It was estimated that Sputnik I would continue to travel around the Earth until about the end of 1957, but that the larger satellite should have a longer life because of its greater distance from the retarding effects of the upper atmosphere.

Scientific Observations

In addition to the existing observatories in the Soviet Union, a large network of optical and radio observing stations has been organized in various other territories from which information is sent to Soviet scientists. Many observations are also being made in other parts of the world.

Measurements of the intensity of the field of radio signals received from the satellites were made by continuous automatic recorders and by individual records made at definite intervals. The results have contributed to the knowledge of the absorption of radio waves in the ionosphere, including the areas which lie above the maximum ionization of the main ionospheric layer F_2 and are therefore inaccessible to ordinary measurements from the Earth's surface. Signals on the 15 metre band were received at distances far exceeding those determined by direct observation — up to 5, 7, and even over 10 miles. It is expected that the final analysis of data from the radio observations will bring further useful information about the ionization of the upper areas of the ionosphere and the absorption and propagation of radio waves therein.

A further field of observation is the investigation of ultra-violet radiation from the Sun, which is largely absorbed by the earth's atmosphere. Some observations have been made from high-altitude rockets, but the satellite is the first means of making prolonged observations under favourable conditions. Instruments for the observation of cosmic radiation (two counters mounted with axes relatively perpendicular) gave useful information on the intensity and distribution of this radiation.

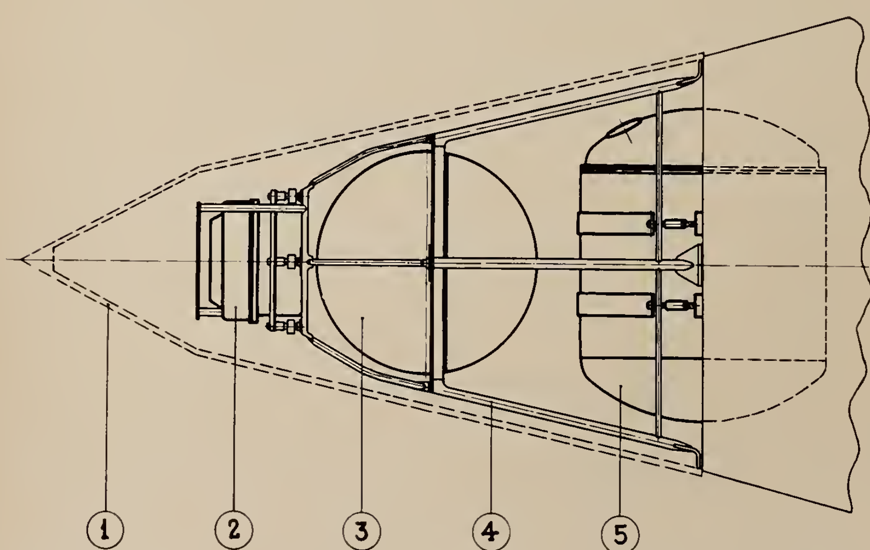

Diagram of the layout of equipment in Sputnik II. (1) Protective cone, discarded after satellite is on orbit. (2) Instruments for measuring ultra-violet and x-radiation from the Sun. (3) Sphere, resembling Sputnik I, containing instruments and radio transmitters. (4) Framework. (5) Chamber containing the test animal.

Biological Observations

Test animals, particularly dogs, have been used by Soviet scientists for several years to obtain data on physiological phenomena during short rocket flights up to altitudes between about 60 and 120 miles. The husky dog that travelled in Sputnik II was pre-conditioned to remain calm under the abnormal conditions of its flight so that necessary scientific measurements could be made. It is stated that the condition of the dog, Laika, remained "satisfactory" through the violent acceleration and subsequent protracted state of "zero-g" (or loss of the Earth's gravitational effect); observations were made for several days.

Future Projects

It is visualized that a manned expedition to the Moon will be achieved between 1960 and 1965, and to Venus and Mars by 1962-1967. Soviet scientific reports indicate that techniques are already well advanced towards this end.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

St. Lawrence Seaway and Power Projects

Progress by Ontario Hydro

Favourable weather for construction work prevailed throughout the month of November and good progress was made in all sections of the project. The work force at the end of the month totalled 4,450 persons.

Installation of generators in Ontario Hydro's half of the International power-house got underway in full scale manner during November, as technicians from the two major suppliers, Canadian General Electric and Canadian Westinghouse, arrived on the scene. Stator sections were placed in generator pits for units 1, 2, and 3, while work also was in progress on winding of the stator for No. 1 unit. Stacking of No. 3 rotor also was commenced.

Meanwhile, in turbine erection, the speed ring was placed for the sixteenth and last unit. Turbine units Nos. 1 and 3 were readied for installation of the runners. The guide vanes for turbine units No. 2 and 4 were in place and the outer head cover had been installed in No. 2 unit.

Concrete placing had been in progress throughout the month over the entire power-house structure. Construction of the transformer pocket walls was well underway with two completed. At month end, the total concrete placed amounted to 45,000 cubic yards. Excavation of earth and rock in the tailrace area continued with the total excavation for the power-house area amounting to 1,737,500 cubic yards. All the upstream main grout curtain had been completed.

Work on Cornwall dike was finished by month end. Trimming and placing of rip rap on the upstream face and granular material on the downstream face, were carried out. A total of 5,000,000 yards of compacted glacial till and 300,000 cubic yards of rip rap had been put into the dike.

Channel improvement work continued with few interruptions throughout the month. Two dredges were working in Chimney Island channel and making favourable progress. In the Galop Island reach, a dredge was working each end of the Galop cut. Two other dredges were operating in the channel for Lotus Island. At Iroquois Point, most of the perimeter cofferdam had been removed. Dry excavation was nearly completed at Point Three Points.

All house moving along the north shore of the river to be flooded for the power development, was completed during the month of November. Final house moving operations also were completed in Morrisburg in the month, marking the clean-up of this extensive program to transport more than 530 homes to new sites.

Progress by NYSPA

During November, five construction contracts were virtually completed, one for rehabilitation of the Massena-Taylorville transmission line, one for clearing the sites of the Barnhart - Plattsburgh transmission project facilities, one for the bridges on state highway route 345 and Franklin Road in Waddington and two for relocation of state highway routes 37 and 37B and relocation of River Road on each side of Massena intake. Concrete placement for all project structures now exceeds 1,916,000 cubic yards or 93 per cent of the total requirement. Excavation exceeds 48 million cubic yards or 88 percent of the required total. Employment averaged 4,990 for the month.

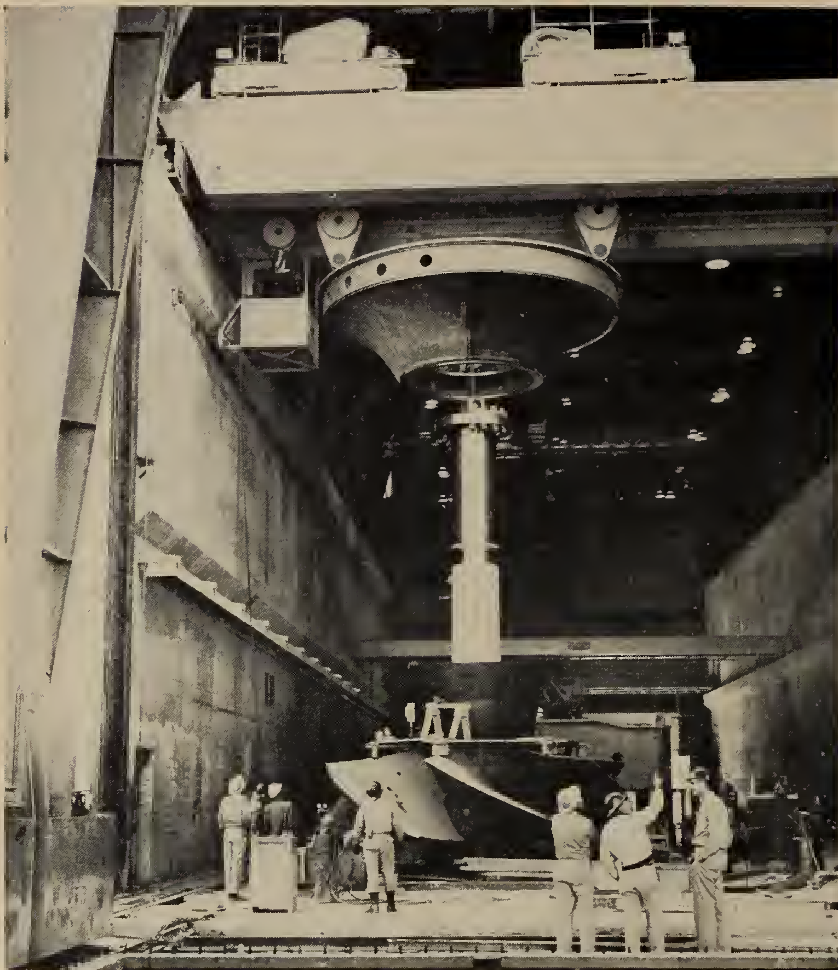
Concrete placement at the Barnhart Island power-house continued on schedule. During November 49,000 cubic yards were placed, bringing the total to date to 921,000 cubic yards or 95 percent of the required total, within the cofferdam. Excavation in the tailrace was in progress. Installation of electrical facilities in the power plant and switchyard was progressing. Stringing of seaway feeder conductors across river was completed.

At Long Sault dam, placement of 16,400 cubic yards of concrete during the month brought the total to date to 587,500 cubic yards, thus completing stage II concrete placement for the spillway section, the spillway apron, the roadway and the upstream crane girders. The temporary vehicular tunnels through blocks NB7 and NB9 were plugged. Final excavation and general clean-up of the stage II area was in progress.

At Iroquois dam, removal of stage II cofferdams and clean-up of the construction area continued. At Massena intake, pressure testing of the permanent Alcoa and Massena water supply lines was completed.

Channel improvement work at Sparrowhawk Point, Toussaints Island, Point Three Points and at Ogden Island continued. Channel improvements on the entire project were 93 per cent completed. Relocation of Norwood and St. Lawrence Railroad facilities continued on schedule.

Good progress was being made on construction of the Barnhart-Plattsburgh transmission project. Foundation work was in progress on the Plattsburgh substation and on the footings for the transmission line towers for the Reynolds power supply and the Barnhart-Adirondack transmission line north extension.



St. Lawrence Power Dam. An intermediate headcover is lowered over the main shaft into position in the runner assembly for Unit 32.

Progress by SLSA

Though employment on locks for the Canadian seaway operations, was somewhat reduced in November, due to the closing down of some concrete placing operations, increase in employment on bridge erection and lock gate installations, and favourable weather, prevented any sharp curtailment.

Water was let in at the Iroquois lock and the operation of the lock was tested by allowing vessels to pass through it on October 22. Navigation was closed for the season on December 7.

At the upper Beauharnois lock, 12,000 yards of earth and 41,000 yard of rock were excavated in November, bringing totals to 544,000 yards and 1,100,000 yards, respectively. By the end of the month, 180,000 cubic yards of concrete or 65 per cent of the total had been placed. The upper gate section was completed and about half of the lock chamber walls built to full height.

At the lower Beauharnois lock, with little excavation remaining to complete, some 220,000 cubic yards of concrete had been placed to month end, or about 75 per cent of the total. Some 30,000 yards were placed during November, practically completing the chamber section and bringing the lower gate structure to 80 per cent of completion. Concrete placing operations would soon be closed down for the winter.

On the Cote Ste. Catherine lock, with some 95 per cent of the concrete placed, mixing and placing from the central plant had been suspended, with completion to be carried out where necessary by ready-mix concrete. Preparations were under way for machinery and gate installation.

With 98 per cent of concrete for the St. Lambert lock placed by end of November, the balance would be supplied by ready-mix. Some 168,000 yards were excavated during November. With the erection tower and guy derrick in place, erection of the lift-span for Victoria bridge was commencing. The derrick was being set up for installation of lock gates and some of the gate machinery was being installed.

Elsewhere on bridges, jacking continued on the Jacques Cartier bridge with between 6 and 10 feet of the lift completed to date. A start had been made on erection of the lift span on the CPR-New York Central rail bridge at Caughnawaga, while at the south end of the Mercier bridge a start had been made on some of the roadway spans between the bridge piers. Excavation was under way for the Valleyfield bridge over the Beauharnois canal.

On the four piers for the Nuns Island Bridge awarded to Atlas Construction Company by National Harbours Board last summer, two were completed and the remaining two at the river's edge were well advanced to some 18 feet below final elevation.

It was announced during the month that Charles Gavsie, president of the Canadian Seaway Authority, would resign his position to resume practice of the legal profession in Montreal.

Progress by SLSDC

By end of November, progress on navigation channels and locks on the American side was tapering off as contracts were completed or nearing completion. Labour force had fallen to about 1,700 persons. At Eisenhower lock installation of mitre gates was proceeding, while the upstream emergency flap gate was installed. The project was 85 per cent complete with only machinery installation and access roads remaining to complete.

At the Grasse River lock installation of both mitre gates was nearing completion. With 90 per cent of the project done, work remaining was mostly excavation and cleanup.

On the Long Sault channel mainland section only some 400,000 cubic yards of excavation remained to complete the work. The project had reached 98 per cent of completion, with everything west of the Eisenhower lock practically finished.

Dredging was under way for three sections of the south Cornwall channel with a little more than a third of the yardage completed.

Testing of Iroquois Lock

Testing the machinery that will operate the Iroquois lock, first navigation structure to be completed on the seaway, has been going forward daily at this most westerly of the seven new seaway locks.

Due to the control of the St. Lawrence above and below Iroquois lock which will go into force in 1959, the Iroquois lock will operate at a head of from six feet to around one foot, the latter figure being achieved by gradually raising the water from the new levels over a period of several years. (Water level in the power pool will be initially 238 feet above sea level, while that in the river upstream of the Iroquois lock and dam will be from 244 to 248 feet above sea level.)

For the first two months of the 1958 season, however, the sector gates have been designed for and will probably operate against a head of 22 feet of water—believed to be the highest head of free-flowing water against which such gates operate anywhere in North America. For the Iroquois control dam will hold the waters leading upstream to Lake Ontario to a level of a little over 240 feet above sea level and the water downstream before the flooding stand at approximately 220 feet above sea level.

When the present stage of testing has been completed, the stop-logs will be removed by the stiff-leg derricks which stand permanently at each end of the lock. Then 20 million gallons of water will flow into the chamber.

Turbo Generator Installed at Halifax

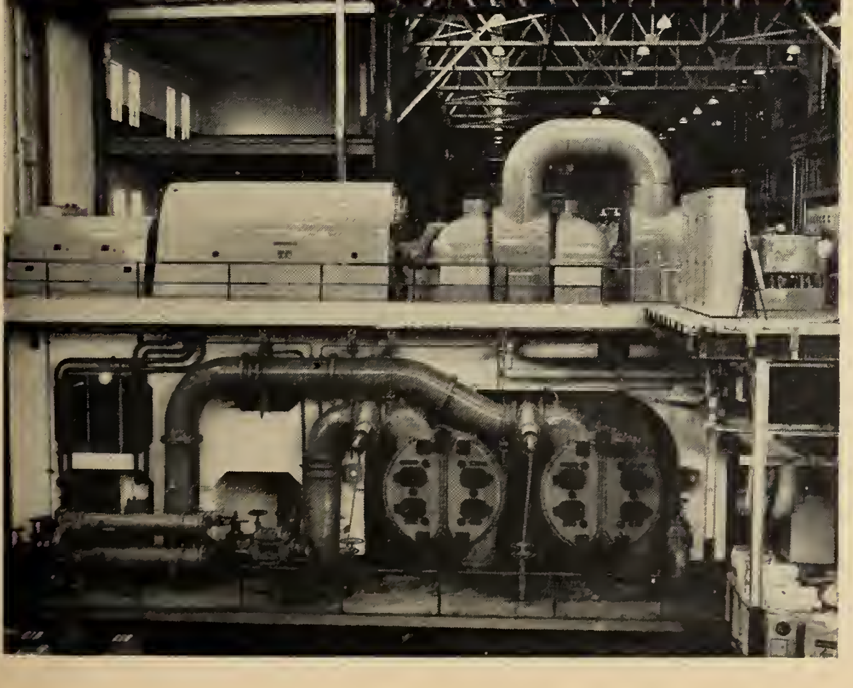
A 67-000-horsepower turbo generator installed at the Water Street thermal generating station of the Nova Scotia Light and Power Company Limited was commissioned on October 4, 1957.

Another 50,000-kilowatt turbo generator will be installed in 1959, to complete the development at the Water Street site. Planning is well advanced for the development of a new site at Tufts Cove, on the Dartmouth side of the harbour, which will have an ultimate capacity of approximately 500,000 kilowatts. During the next five years the Company plans to spend $40 million for new generating and distribution equipment. These plans were disclosed by the president of the Company, J. C. MacKeen, at the ceremonies opening the new plant.

He also talked of co-operative action of principal power utilities in the Maritime Region on the problems of electrical supply, including an interprovincial transmission grid. This cooperation is encouraged by the Power Committee of the Atlantic Provinces Economic Council.

The effect of the new plant is that after peak demand has been met this winter, there will be more than 30,000 kilowatts available for new industry and further demands, Mr. MacKean said.

Plant No. 6 at Water Street, Halifax.



It provides another market for Nova Scotia coal.

The building is supported on steel bearing piles, penetrating through overburden to solid rock. It is of a height equivalent to a 12-storey building and has structural steel frame.

The coal handling system is designed to unload the fuel mechanically from rail cars, crush it at the rate of 200 tons per hour, and transfer it by conveyor to the bunkers.

The cyclone fired steam generating unit is the first one of its type installed in Canada. It was developed by Babcock Wilcox Company to burn low grade bituminous coals which normally have a high content of low fusing temperature ash. It is also suitable for burning alternate fuels or fuel combinations.

The unit has a steam capacity of 450,000 lb. per hour continuous, or 500,000 lb. per hour on peaks. The operating steam conditions at the superheater outlet are 925 p.s.i.g. and 915° F. At maximum continuous rating the unit consumes 21.4 tons of coal per hour at an efficiency of 90.06 per cent. Running at full load the boiler will burn 513.6 tons of coal or 70.8 gallons of Bunker "C" fuel oil per day.

The instrument panels for both the new No. 6 plant and the future No. 7 plant are located together on the operating floor. The boiler control system is of the pneumatic type, manufactured by the Bailey Meter Company.

The No. 6 turbo-generator consists of a 49.5-Mw., 3,600-r.p.m. turbine, driving a 40/45/49.5 Mw., 13.2-Kv., 60-cycle, 0.85 p.f. hydrogen-cooled generator with gear driven exciter and pilot exciter, connected to a 60-Mva, 69/1.32-Kv., main step-up transformer and a 5-Mva., 13.2/2.3-Kv. auxiliary transformer. This equipment is operated as a unit. The generator is controlled from the control room.

The station service system used here has been designed so that the station may be operated on either the "parallel plant" or the "unit plant" idea. The No. 6 unit will operate as a unit plant at least until the commissioning of No. 7 boiler, that is it will supply power for its own auxiliaries directly from the generator terminals. Two voltages are used for the supply to the station, 2,300 volts for large motors and 575 volts for small motors, lighting transformers, etc.

New Building for Ecole Polytechnique, Montreal

The expansion program of Polytechnique, is the result of many years of effort. Back in 1948, at the time the institution was celebrating the 75th anniversary of its foundation, there was published a study of future enrolments which sounded the alarm. The next few years rapidly showed that the estimates of 1948 were so definitely on the conservative side that, in 1952 a second and more serious alarm was sounded. The evidence was received with sympathy everywhere and the case was settled generously in an announcement made in June 1954 by the Honorable Maurice Duplessis, Prime Minister of the Province. With the guarantee of a first grant of 6 to 7 million dollars, * the board of governors launched the project based on preliminary building studies already made in 1952. The program as defined three years ago is now on schedule and staff and students will be installed in their new quarters during the summer of 1958.

The new, modern building is erected on the campus of the Université de Montréal, located on the north slope of the Mount Royal, overlooking north west Montreal and suburbs. The structure provides about 500,000 square feet of floor space and has a volume close to 7,500,000 cubic feet. It more than doubles the dimensions of the existing facilities on Saint Denis Street in downtown Montreal. Its completion by 1958 will greatly relieve the situation experienced in 1956, whereby 900 students were accommodated within the same facilities available ten years ago to 375 students. Last fall, again, every available square inch was very precious as the enrolment reached close to 1,000.

The building has the form of an H with a double crossarm, the north leg having a length of 460 feet and the south, 570. The width of the structure is 290 feet except in the center axis where it reaches over 400 feet. The front wing accommodates the administration, the library, the students quarters and most of the lecture and draughting rooms. The other wings accommodate the other departments, useful space distribution being as shown in the accompanying table.

The building is erected on a slope and is generally four storeys high with intermediate sections at five and six storeys. Vertical circulation is assured by three passenger elevators, two freight elevators and one

*Since that time, the provincial government has passed legislation bringing the amount to $9,500,000.

Distribution of Space to Departments

Strength of Materials	19,000 sq. ft.
Mechanical Engineering including the Heating Plant	34,000 sq. ft.
Hydraulics	33,000 sq. ft.
Public Works Laboratory	18,000 sq. ft.
Metallurgy including ore dressing	24,000 sq. ft.
Electrical Engineering	45,000 sq. ft.
Physics	30,000 sq. ft.
Chemical Engineering & Chemistry	60,000 sq. ft.
Geology and Mining	34,000 sq. ft.
Library	26,000 sq. ft.
Administration	15,000 sq. ft.
Classrooms	90,000 sq. ft.

escalator, which serves the front wing, originating near the students' entrance in their own quarters and locker room.

The architectural treatment is very simple and follows the modern trend. The material used is a very light beige brick, similar to that used in the university's main building but, while the university's appearance has a tendency to show the vertical structure, the new building adopts the more up-to-date concept of horizontal geometric lines. This has the advantage of almost unlimited possibilities in window space and provides very adequate natural lighting of the interior.

The front wing is the only one treated in a special manner, with suspended ceilings and plaster finish walls. The other wings which contain the laboratory facilities are provided with the bare haydite cement block and no treated ceiling, thus leaving the services uncovered and assuring easy access to them for maintenance and possible changes. The only permanent partitions are those of the main circulation halls and corridors; all other haydite block divisions, containing no electrical wiring or other services, are easily movable and provide excellent flexibility in case of necessary changes in space distribution and utilization. Except in certain locations when special material is required, the floor is finished in terrazo in the halls; the concrete floor in the laboratories is specially treated with a hardener for ease in upkeep and to prevent dust formation. Sound-absorbing tile floor covering is provided in the lecture rooms, the library and administration offices. The structure is in reinforced concrete throughout, 4 ft. x 8 ft. veneer having been used on concrete forms to assure smoother finish on uncovered ceilings, columns and walls.

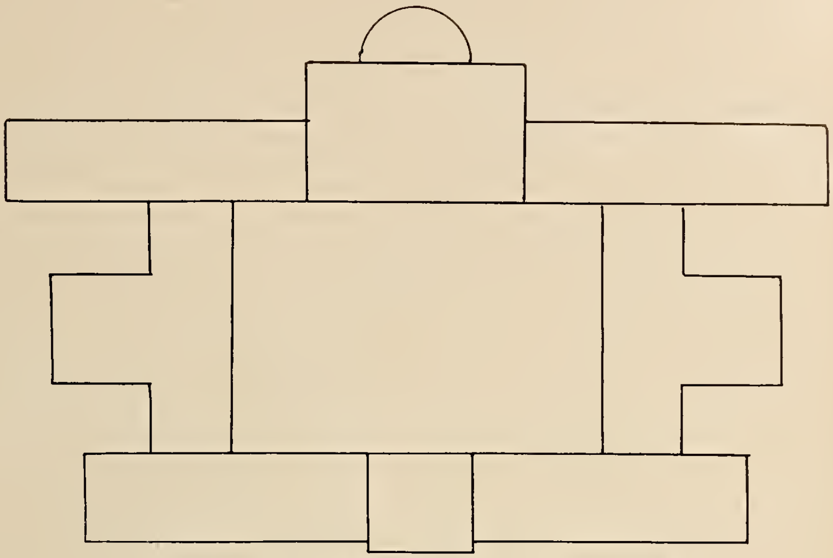
The foundation of the building is on rock of volcanic origin, unfortunately of inconsistent properties. Excavation for the laying of foundation required the removal of 125,000 cu. yd. of material, 60 per cent of which had to be blasted. About 25,000 cu. yd. of concrete have been poured to complete the structure. The building required 1,200,000 bricks and 500,000 blocks of various filling material. Stonework which lies at the bottom of the outside wall around the building covers an area of 24,000 sq. ft. The size of the roof is close to 115,000 sq. ft. and the building has 2,700 windows.

The team responsible to the board of governors for the execution of the project includes the following: the architect: Gaston Gagnier; the consulting engineers: Lalonde and Valois, for the reinforced concrete, P. P. Vinet, for heating, ventilation and other mechanical services, F. Leblanc, for the design of the electrical equipment, and the office of Lalonde, Girouard and Letendre, for the designs related to grounds, roads and accesses. The contract was let to Quemont Construction, owned by a Polytechnique graduate, Arthur Laplante. The resident engineer, supervising on behalf of Polytechnique is Roland Bureau, who will act as superintendent of buildings and grounds after the completion of the project.

The building is not designed for future extensions. It is estimated that 1,800 students will be very easily accommodated in it, which, based on the experience on the present site, probably means quite a few more. Whenever space becomes a problem again, it is estimated that the solution will lie in a separate building for one or more of the departments, thus allowing expansion of the remaining ones within the actual structure.

No one will dare to prophesy the future but, in view of present population estimates and trends in the orientation of the younger students in the high schools and classical colleges, it is expected that the enrolment of 1,800 will be reached very easily before the next ten years. It is felt in many quarters that this is still a conservative forecast.

The engineering profession is happy to see that this very important project is nearing completion. Engineering is becoming ever more popular among the students in the French high schools and classical colleges. The major industrial developments in Eastern Canada catch the eye and the mind of young French Canadians as they never did before. This, coupled with the normal increase in the school age population will soon result in a much greater participation of French Canada in national economic development. The new facilities of Ecole Polytechnique come at a good time to cater to the coming generation, which rightly sees the opportunities where they lie.



Plan of new building erected by Ecole Polytechnique.

The Journal Reports Growth in Engineering Faculties in Canada

This article is the first of a series intended to give an account of the physical development of the engineering faculties, so necessary to face the increase in enrolment and to supply industry with technical personnel.

Canadian Pipeline Projects

Alberta Gas Trunk Line

General manager J. K. Horton announced at end of October that in the event of Alberta and Southern obtaining necessary permits to export Alberta gas to California, the Alberta section of the line will be built and operated by Alberta Gas Trunk Line, subject to approval of the Minister of Mines and Minerals.

Canadian Western Natural Gas

Permission was granted early in December by the Alberta Government on recommendation of the Alberta Conservation Boards to Northwestern Utilities for a $3.5 million project to transport gas from the Pembina oil field to Edmonton. Alberta and Southern Gas Co. has contracted 80 per cent of all the gas in the Pembina area. The project involves a 72-mile pipeline and a gathering system.

Plans for a $9.5 million project to develop gas reserves in the Carbon area 55 miles northeast of Calgary as a source of winter peak day deliverability are announced by Vice-President B. F. Willson. Gas reserves of more than 200 billion cubic feet are to be acquired and additional wells will be drilled. A 16-inch pipeline ultimately capable of delivering 150 million cubic feet daily to the Calgary area will be built in 1958.

Trans Canada Pipelines

Seven spreads will go to work on the 1958 Trans Canada program for the 486 miles of 30-inch line from Kapuskasing to Toronto. Tenders are expected to close in December. Full winter operations are planned in clearing, brushing, and riprapping. Spreads will be as follows: No. 8 from Kapuskasing River 82 miles to Potter; No. 9 covers 83 miles, Potter to Kirkland Lake; No. 10 is 83 miles, Kirkland Lake to Rib Lake; Spread 11 is 47 miles, mostly in rock, Rib Lake to Tilden Lake; Spread 12 continues in rock and then in sand and clay 62 miles to South River; Spread 13 is 63 miles from South River to Bracebridge; Spread 14 covers 92 miles, Bracebridge to Maple, where the mainline feeds into the Niagara loop and the Toronto-Montreal line. Some deliveries of pipe had started by mid-November, and with adequate supplies of steel plate to mills, orders will be filled promptly.

All three spreads on the 20-inch Toronto-Montreal section of Trans Canada had welded out by the end of November. The line is being pigged and purged, with testing expected to be completed by mid-December. The dual 10,000-foot crossing of the Lake of Two Mountains above Oka was completed early in November. Trans Canada expects to be delivering gas to Montreal before the end of 1957, using a supply of borrowed gas from Union Gas Co. The 12-inch lateral to Ottawa is completed, as well as a lateral to Lindsay and purging and testing of both will be completed in December.

Northern Ontario Pipeline Crown Corporation

Work was still in progress at end of November on two spreads. Houston on spread D, ending at Port Arthur, welded and doped out early in November and at month end completed tie-ins and backfill. Dutton Williams on spread A, ending 3 miles east of Kenora, welded out and doped out on November 24 with final tie-ins expected before month-end. Morrison-Shivers on Spread B east of Vermilion Bay was still not finished with pipelaying but hoped to complete before winter shutdown. Majestic-Nelen Ltd. finished its rock ditch late in November and would weld and dope out before month end. Pigging, purging and testing will proceed in hopes of having gas at Lakehead before year-end. Crossing of the Winnipeg river at Kenora still remains a bottleneck and completion this year depends on weather, though delivery to Kenora appears possible.

Union Gas Co. of Canada

Welland Tubes Ltd. had completed its order for 20,000 lengths of big-inch steel pipe by the end of November. The pipe is being useful in the Company's 142-mile gas pipeline from Dawn Township to Hamilton and Streetsville.

Winnipeg & Central Gas Co.

Claims by the Winnipeg and Central Gas Co. that it has exclusive natural gas distribution rights in greater Winnipeg will be tested soon before the Municipal and Public Utility Board. The board will be asked by the suburb of St. James to confirm a franchise granted to a competitive company by St. James city council. If this franchise is confirmed it would mean Great Northern Gas Utilities Limited had made a good bid to move into the Winnipeg market. Offering lower consumer rates than Winnipeg and Central, Great Northern would pick up a number of other suburban franchises.

A third bid for the market has been made by Great Plains Gas Co., offering a rate of 71 cents per thousand feet compared with 81 cents offered by Great Northern and $1.03 by Winnipeg and Central.

Qubec Natural Gas Corporation

The $6 million natural gas conversion program will begin in Montreal in January 1958 when gas is scheduled to be available. The cost will be amortized over 12½ years. Conversion is slated to take 20 weeks and to employ some 500 men. Involved are gas appliances for almost 250,000 customers.

President Maurice Forget stated in late November that the conversion would be followed by a longer range plan to extend lines into areas not now served, at a possible cost of $30 million. Natural gas will be available on a loan basis from Union Gas.

Sales of manufactured gas in 1951, as revealed by the last census of housing, revealed that cooking was by gas in 185,000 of Montreal's 246,000 households. Sales of manufactured gas in 1956 by Hydro Quebec were 8½ billion cubic feet. This was 465 B.t.u. gas. Converting it to natural gas leaves volume at about four billion cubic feet. With the expansion now planned Forget expects total by 1962 to amount to 40 billion cubic feet yearly, a ten-fold increase. Of this, residential use may account for 12 billion, while large industrial use may amount to another 24 billion feet in firm and interruptible services.

U.S. Demands Action Soon on Gas Issue

Federal Power Commission Examiner Francis Hall, hearing the Tennessee Midwestern case at Washington, dismissed a motion early in Deceber to kill the hearings made on the grounds that appointment of Canada's Royal Commission (The Borden Commission) on Energy indicates a lengthy delay at best before export premission can be given by the Diefenbaker government. He warned that "failure of Canadian Authorities to act timely and definitively may very well cause the FPC to consider that the Midwestern and Tennessee applications have reached the end of the road". He noted, however, that the Diefenbaker government had not specifically rejected a promise of an export license made by former Trade and Commerce Minister C. D. Howe.

With many searching questions arising in Parliament in the wake of the recent Diefenbaker announcement on gas policy, key Canadian gas authorities are making strong recommendations. The main one is that the Borden Commission be required to swing its investigation onto the gas phase of its study at once, and come up with as early an interim recommendation on gas export as possible.

Indignation at the long delay in natural gas development imposed by Ottawa's declaration on export permits has erupted in the form of public statements by three leading oil and pipeline executives. They all covered the same theme: that natural gas in Western Canada is in surplus supply, that export is the only solution, and that idle capital invested in capped gas reserves is a strong deterrent to further exploration and development. But the surplus problem must be impressed on governments as well as being told to public audiences.

Dominion Bridge Anniversary

The Dominion Bridge Company on November 20 celebrated the 75th anniversary of its founding in 1882 at Lachine, Quebec. The company is now engaged in a $20 million expansion program designed to increase its capacity by 40 per cent in 1960.

Since 1883, when the first plant was built with a production capacity of 1,000 tons of finished steel per month, the company has grown to one of 9,000 employees and 7,779 shareholders with 14 plants across the country.

Typical of the development of Canada is the changing nature of the work undertaken by this completely Canadian company. In 1900, for example, 90 per cent of its work was in the building of bridges. Today, bridge construction represents a comparatively small proportion of the annual output. In addition to supplying the steel framework for structures of all kinds, the company designs and builds gate equipment for hydro-electric power developments, cranes and other handling equipment; huge vessels and other equipment for the pulp and paper, chemical, oil and mining industries, and a wide range of boilers. It also operates eleven steel warehouses and steel mill.

The national scope of this company is illustrated by the Lion's Gate Bridge in Vancouver, and the Angus L. MacDonald Bridge in Halifax; by the Sun Life Building in Montreal, the Chateau Laurier in Ottawa, the Royal York in Toronto, and the new Winnipeg Post Office, for all of which Dominion Bridge supplied and erected the steelwork. Today there are many all-welded buildings and bridges in Canada testifying to the Company's pioneer development of electric arc welding and other aspects of steel fabrication.

Three New Branch Railways

Three branch railways were completed in 1957 and are being operated by CNR into mining areas in New Brunswick, Quebec and Manitoba.

Beattyville-Chibougamau

The 161-mile CNR line from Beattyville to Chibougamau, recently completed, is part of a larger project to serve the 300 square miles of the Chibougamau area in Northern Quebec.

The completed railway, branching from the C.N.R.'s northern transcontinental line, will be 294 miles long terminating at St. Felicien in the Lake St. John area. The St. Felicien-Chibougamau section is now under construction.

The route, planned in 1953, crosses bushland, muskeg, forest, and a number of fast-flowing rivers. Construction began in November 1954.

By the fall of 1955 the line had been almost completely cleared, with grading well advanced. Work on bridges was well ahead, and the major construction problem of spanning the Bell River had been overcome. Here the first cantilever structure ever built by C.N.R. engineers was constructed. There are ten bridges on the line.

In March 1957, ore was first carried over the completed line to the Noranda smelter, but consolidation was necessary at spring break-up. Ballast lifts were used to remedy frost action and settlement in muskeg areas.

The line was inspected and approved for freight and passenger traffic in October 1957. General supervision of construction was in the hands of the chief engineer of CNR's central region, W. E. Griffiths. Construction work in the field was supervised by the chief engineer of construction, central region, G. H. Workman, and was the direct responsibility of the regional construction engineer, R. E. Oldham. The bridges were designed by the system bridge engineer, T. H. Jenkins, M.E.I.C., and their construction was supervised by the regional bridge engineer, E. J. Napier.

Heath Steele-Bartibog

In 1955 Heath Steele Mines Limited started construction of a concentrating mill to commence development of major base metal deposits in northwestern New Brunswick, and entered into negotiations with Canadian National Railways, who agreed to construct a railway to serve the area.

Survey parties began working in February 1956 on the line, 22.9 miles from Bartibog to the Heath Steele property. They were aided by aerial photographs and maps furnished by the New Brunswick government. Swamp land, heavily forested flat land, a number of deep ravines and broken, rocky ground were encountered in the relatively short distance.

Construction of the sub-grade was undertaken by Modern Construction Co. Ltd., Moncton, in September 1956.

Tractors and earth moving machinery cut through 325 acres of forest. Bulldozers, scrapers, shovels and carryalls moved 22 million cubic feet of rock and earth to form out the roadbed. Twenty-seven million feet of earth were excavated to make the cuts. Many of the cuts were blasted through igneous rock, and some of them are 50 feet in height.

The Little Tomogonops River was diverted to flow through two 12-feet diameter pipes, 200 feet long. Above the pipes, a gorge 60 feet high and 300 feet wide was filled with 500,000 cubic yards of earth, topped with special ballast, to form the roadbed at this location.

In charge of the work in its various phases were D. W. Blair, M.E.I.C., regional chief engineer, R. K. Delong, engineer of construction, and M. J. Nickerson, JR.E.I.C., resident engineer of Canadian National Railways.

Sipiwesk-Moak Lake

Operations began in October 1957 over a 32-mile line from Sipiwesk on the Hudson Bay Railway to the International Nickel Company's base metal development at Moak Lake, Manitoba. The line was built by INCO, and is being operated by the Canadian National Railways.

● **DISCUSSION** *(continued from page 79)*

BATTLE RIVER STEAM STATION: *The Engineering Journal*, January 1958.

The Saskatchewan Power Corporation recently completed a series of tests with Drumheller and Saskatchewan lignite coal on a boiler at the A.L. Cole Station, Saskatoon, similar to the one Mr. Ford has just described.

This boiler and fuel firing equipment were not designed for lignite and it was therefore expected that the capacity would be limited because of the lower heating value and higher moisture content of this fuel. The maximum load attainable on lignite was about two-thirds of boiler rating and surprisingly, this limit was imposed because of high steam temperature and not because of difficulties with the fuel firing equipment. There was, however, some difficulty with plugging of the dust collector.

The most striking result of the test was the effect of lignite coal on the performance of the superheater. At a steam flow of 225,000 pounds per hour the temperature rise of the steam through the convection super-heater was 315° F on lignite and only 250° F on Drumheller. This higher steam temperature on lignite occurred in spite of the fact that the tangential burners were tilted down from the horizontal 25° on lignite and only 5° on Drumheller. Although there is a higher mass flow through the boiler on lignite this does not completely explain the higher rate of heat transfer to the convection superheater and no complete and satisfactory explanation for this difference has yet been proposed.

It is planned in the near future to run a similar set of tests on this boiler with Forestburg and Wabamun coal and the results of all of these tests will be reported to the industry in due course.

Canadian Utilities Limited are to be complimented on their pioneering installation at Drumheller which was the first modern pulverized fuel plant in Western Canada. Much valuable information has been gained from experimentation and test on this installation which has been very valuable to other utilities planning to burn Drumheller coal.

I understand that in preparation for the design of the Battle River boiler, Canadian Utilities ran a series of tests on their Drumheller installations with Forestburg coal. I would like to ask Mr. Ford to comment briefly on the differences they discovered between the pulverizing and burning characteristics of Forestburg and Drumheller coal and also if the results attained in the tangentially fired unit at Battle River have been in line with expectations resulting from tests on the horizontally fired units at Drumheller.

The Author

In reply to Mr. Campbell's question, the tests made with the Forestburg coal at our Drumheller plant were made to study its pulverizing characteristics rather than how it burned. Our pulverizers at the Forestburg plant operated satisfactorily when the primary air temperature required for drying was correct.

I quite agree with Mr. Campbell that Western Canadian coals should be analysed very carefully as to burning characteristics, even though they may be similar in every other respect, when a thermal plant is being planned.

Southern Ontario Regional Conference

15 March, 1958

Royal Connaught Hotel, Hamilton, Ontario

Participating Branches

Border Cities Hamilton Kitchener London
Niagara Peninsula Sarnia Toronto

The Program Will Include

Noon Luncheon Reception and Cocktails
Technical Papers Dinner and Guest Speaker
Dance (dress optional)
***For the Ladies:* Special noon luncheon and afternoon program**

FURTHER DETAILS WILL BE GIVEN IN THE FEBRUARY ISSUE

News of the Institute and the Profession

COMMENT
CORRESPONDENCE
ELECTIONS
AND TRANSFERS

The 49th Branch

At Baie Comeau, Que., on the night of Friday, December 6, President Anson officially inaugurated another branch of the Institute, the occasion being marked by the presentation of the charter at a large gathering of citizens of that Lower St. Lawrence industrial centre.

Canada's steady march toward geographic and industrial expansion is shown very markedly in this area. For many years Baie Comeau has been famous as a paper town, but within the last two years new industry has sprung up there to increase greatly the social and industrial activity. The Canadian British Aluminum Company Limited is the giant newcomer which has gone out into rough new terrain to set up industrial buildings, roads, services and town sites, to transform the area from rock and forest into a new self supporting municipality. Naturally such a development would bring to this distant shore a host of engineers and other technical personnel. Fifty-one persons signed the petition for a charter.

For the Institute to establish a branch there is to follow the long established policy of going forward with the frontiers of industrial expansion. Branches in Newfoundland, at Seven Islands further down the St. Lawrence, and at Whitehorse in the Yukon, are further examples of the Institute's policy of advancing with the profession and with Canada.

V. M. Wallingford is Chairman

The first chairman of the new branch is V. M. Wallingford of the Canadian British Aluminum Company, and to him must go much of the credit for the new unit within the E.I.C. He has been a member of the Institute since 1944, but most of this time has been spent at centres where there was no branch. The other officers of the branch are:

Secretary, Norman Lapierre; Treasurer, T. G. Rust; Executive Committee, Peter Suttie, G. Scott and J. M. Pope.

The inaugural function was in the form of a banquet at the delightful Manoir Comeau. There were 115 in attendance. The mayor of Baie Comeau, J. A. Duchesneau, welcomed the visitors and expressed his satisfaction in seeing an engineering society established within the community. The president was accompanied by Mrs. Anson, past vice-president R. L. Dunsmore and the general secretary.

Greetings from Other Branches

B. M. Monaghan, chairman of the branch at Seven Islands, was present to wish the new branch success, and to make a presentation to the new chairman on behalf of his, the parent, branch.

The banquet was followed by a dance which provided a happy conclusion to an important and pleasant development in local affairs.

The presidential party was shown over the territory and was duly impressed. The C.B.A. Company have done a remarkable piece of work in building a town and a plant in about a year and a half. Current was turned on in one row of pots, for the first time, on Saturday, December 7. This was not an official opening, but it was even more important, for it was a real test of the equipment, the materials and the engineering — and it was successful. Arrangements have been made for a paper on the plant to be presented to the Institute.

It was surprising to see the great expansion in and around Baie Comeau. The new town for C.B.A.—Baie Comeau Nord—and the new town of Hautrive, along with the original Baie Comeau, are expected to have 25,000 people by 1965. That is a measure of Canada's expansion, in all of which the Institute is privileged to participate.

The Angus Medal

The Robert W. Angus Medal will be awarded by the Engineering Institute for the best paper each year on a mechanical engineering subject, the first award to be made at the 1958 annual meeting in Quebec.

The medal is so named to honour the achievements of Robert W. Angus, HON. M.E.I.C., emeritus professor of mechanical engineering at the University of Toronto. Professor Angus, now in his 84th year, is residing in Toronto after a long and distinguished career.

The Council of the Institute will administer the award, which has been made possible through the generosity of two members of the Institute, brothers, H. G. Thompson of Brockville, and W. L. Thompson, of Toronto. They are both mechanical engineers, and both former pupils of Professor Angus. There is also another bond — Prof. Angus and the Thompsons spent their school days in London, Ontario.

The conditions of the award of the Angus Medal, as they appear below, provide that there will now be a means of acknowledging the best Canadian contributions to the literature of mechanical engineering. That this event should be associated with the name of the well known Toronto professor will be thought appropriate by a great number of engineers and particularly by former University of

NOTE: Please let the Editor know if you did not receive your regular *Journal* in December, a copy will then be sent to you.

Toronto students.

Professor Angus received his primary education in London, Ontario, and later completed his academic training with a B.A.Sc. degree from the University of Toronto in 1896. He was engaged in the establishment of mechanical engineering as a separate department of that university, became its lecturer in 1900 and its first professor in 1906. He retained this position until he retired in 1944.

Always conscious of the liaison that must be maintained between class room and industry, Robert Angus devoted much of his life to consulting work. The most recent consulting job was the design of a 15 mgd. filtration plant for New Toronto, finished in 1953.

His work has been recognized by the distinction of election to Honorary Membership in the Engineering Institute of Canada in 1937, in the American Society of Mechanical Engineers in 1940, and in the American Water Works Association in 1945. He is also a member of the Institution of Mechanical Engineers. He was active in promoting the Association of Professional Engineers of Ontario, and was its president in 1936.

Professor Angus is the author of numerous papers and articles, and has made a definite contribution to the literature on water hammer, on which subject he has also done considerable consulting work.

Conditions of the Award

1. Competition for the medal shall be open to any corporate member of The Engineering Institute of Canada, The Institution of Mechanical Engineers or The American Society of Mechanical Engineers, who is resident in Canada at the time the paper is presented.

2. Award shall be made not oftener than once a year, and the medal year shall be the year ended June last previous to the year in which the award is made.

3. The medal shall be presented at annual meetings of the Engineering Institute of Canada.

4. A committee of five shall judge the papers entered for competition, all of whom shall be members of The Engineering Institute of Canada, and shall be appointed by the Council of the Institute.

5. All papers presented shall be the work of the author and shall have been presented at a meeting of The Engineering Institute of Canada as well as published in the literature of the society. To be eligible no paper shall have been made public previously or contributed to any other society in whole or in part prior to its presentation before a meeting of The Engineering Institute of Canada.

6. In the event of the committee not considering a paper in any one year of sufficient merit, no award shall be made; but in the following year or years, it shall be in the power of the committee to award the accumulated medals to the authors of different papers which may be deemed of sufficient merit.

Nominees for Office

A list of nominees for office, as reported by the Nominating Committee, appeared on Page 1492 of the October, 1957, issue of the *Journal*. Since that time the committee has reported the selection for president as follows:

President . . . . Kenneth Franklin Tupper . . . . Toronto, Ont.

This Journal is Different

There are a number of improvements and new features in the January issue.

These added services are largely the result of the Publication Committee and the staff considering the many valuable suggestions received from readers in response to the Reader Survey which has been conducted every month during the past year.

Some of the measures adopted will enable the *Journal* to be even more complete in its editorial coverage, while others will facilitate reference to the *Journal* or will put into effect improvements in publishing practice. They should result in convenience, simplicity, and more varied and improved editorial material.

- The pages of each issue of the 1958 volume will be numbered consecutively from the first to the last page, each issue commencing on Page 1. The two sets of numbers distinguishing editorial and advertising pages will be discontinued.
- The number of each issue (1 to 12) will be prominently shown on the spine of the book.
- The Contents Page will be Page 3 in every issue. This will be good news for the many readers requesting this change. The Contents Page has also been redesigned.
- The new Page 5, "Meet the Authors" is an innovation—a page devoted to notes on the people who contribute papers. This page also includes the "Cover Picture" description.
- There is a new "International Section" in which technological developments in other countries of interest to Canadian engineers will be reviewed. One country at a time will be featured, commencing with the U.S.S.R. in this issue.
- A timely series describing expansion of teaching facilities for the engineering faculties at the Canadian universities also begins this month.
- An item of briefs, "Did You Know?" in the Month to Month Section, may help to recall some facts about the accomplishments and operation of The Engineering Institute.

President and Mrs. C. M. Anson visited Sherbrooke on November 25. This picture taken at a Branch meeting shows, left to right, Mrs. Gaetan Cote, Mrs. George Cote, Mrs. Mawhood, Mrs. Dick, Mrs. Dunsmore, Mrs. Anson, Mrs. Masse; George Cote, R. L. Dunsmore, Gaetan Cote, L. Austin Wright, Mr. Anson, Branch Chairman R. D. Mawhood, Vice-President G. M. Dick, Jacques Lemieux, Gaston Masse.

THIRTY-FIVE YEARS AGO

Comment on the Journal of January, 1923

Almost half of the January 1923 issue was devoted to publication of three papers: Electric Furnaces For Heat Treatment of Steel, by A. W. Lamont, A.M.E.I.C., of Canadian Westinghouse Co. Ltd.; Power Factor, Its Physical Meaning and Commercial Application, by W. G. H. Cam, E.E., A.M.E,I.C., of the Canada Cement Co. Ltd.; and The Inspection of Ferrous Materials, by E. A. Allcut, Associate Professor of Thermodynamics, University of Toronto. These papers, particularly the one on Power Factor, are valuable papers for the young engineers.

A dozen pages were devoted to Branch News. The London Branch recorded an address on Town Planning and proposed legislation in relation to it, presented by J. Clark Keith, A.M.E.I.C., secretary-treasurer of the Border Cities Branch, who pointed out town planning was 'a firm base for building a healthy, happy community.

The Fuel Situation was the subject of a symposium, in Ottawa with interesting addresses by B. F. Haanel, M.E.I.C., of the Department of Mines; G. Gordon Gale, M.E.I.C., of Hull Electric; George Mountain, M.E.I.C., chief engineer of the Railway Commission, and Hon. D. D. MacKenzie, solicitor general. Dr. Charles Camsell, deputy minister of mines, reviewed the coal situation.

The Kingston Branch recorded a discussion on Meteorology and Weather Forecasting, including an address on the subject by Dr. A. L. Clark, HON. M.E.I.C., dean of the Faculty of Science, Queen's University. Captain Donnelly presented a paper at another meeting on the releasing of the steamer *Rapids Prince* from the rocks of the Lachine Rapids in the St. Lawrence River,

Members of the Hamilton Branch welcomed Professor Lester Willis Gill, M.E.I.C., recently appointed principal of the new technical school at Hamilton, who had served during World War I as director of education for the Khaki College under Colonel Tory On his return from overseas, Prof. Gill had been given the office of director of technical education for the Dominion Government.

A number of interesting papers and addresses were reported by the Winnipeg Branch for December 1922, subjects being Relativity; An Electric Furnace for Heat Treatment of Moving Parts of C.N.R. Locomotives; The Economics of Rate Making as Applied to a Public Utility; and a report by Harold Edwards, A.M.E.I.C., on behalf of the Committee on Foundations.

The Niagara Branch reported on an inspection trip over the Niagara Falls Power Company's plant at Niagara Falls, N.Y., and the intake works of the Queenston Chippawa power development, which was followed by a dinner at the Clifton Inn and an address on the Near East by Mr. D. A. Andrus.

November meetings of the Saskatchewan Branch had been devoted to addresses and discussions of The Clay Products of Saskatchewan; and Town Planning in its Relation to the Engineering Profession.

The Vancouver Branch reported on its November general meeting, at the new auditorium of the Vancouver Board of Trade. An innovation had been the introduction of a speaker outside of the Engineering Profession, Dr. R. H. Mullin, director of laboratories, Vancouver General Hospital, whose subject was Sanitary Water Supplies.

The Toronto Branch reported well attended weekly meetings during November, one of which was taken up with discussion of the report of the Committee on Policy, as formulated at the meeting at Montreal in April 11, 1922. Addresses at other meetings included one by R. C. Harris, commissioner of works, City of Toronto, on The Local Improvement Act; Purification of Public Water Supplies, by Norman J. Howard, chemist and bacteriologist at the Toronto Filtration Plant; and a discussion of the Institute's Report of the Committee on Classification and Remuneration.

In the Maritimes, Dr. Bigelow, dean of the Faculty of Science, Mount Allison, addressed the Moncton Branch on The Place of Research in the Development of Canadian Industries. The annual meeting of the Cape Breton Branch was addressed by J. G. H. Purves, M.E.I.C., on the subject of Abnormal Friction Losses in a 12-inch Water Main. At the monthly meeting for December the Saint John Branch heard a paper entitled A Fundamental Plant Study of Saint John by W. R. Pearce, M.E.I.C., chief Engineer, New Brunswick Telephone Company. Members of the Halifax Branch heard J. A. Wilson, A.M.E.I.C., secretary of the Dominion Air Board, on the subject of Aviation in Canada.

James Watt International Medal

The Council of the Institution of Mechanical Engineers, London, issued last fall the brochure containing a record of the proceedings in May 1957 of the presentation of the James Watt International Medal to Professor Dr. Ing. Walther Bauersfeld, of Germany.

The award was made in recognition of Professor Bauersfeld's great work as a scientist, as an inventor and as a successful organizer, particularly in the application of precision engineering in the field of optics.

Sir Ewart Smith, vice-president, made the citation, summarized below:

Walther Bauersfeld was born in Berlin in 1879, and studied mechanical engineering at the Technische Hoshschule, Berlin-Charlottenburg. He worked as an assistant to the professor of mechanical engineering and hydraulic prime movers from 1903 to 1905. In the latter year he joined the firm of Carl Zeiss, Jena, as design engineer, and has served continuously with this organization up to the present time.

Throughout this long industrial career, he has maintained a close interest in technological education.

Walther Bauersfeld has had a profound influence on many branches of engineering as a result of his scientific work, technical inventions, and practical design. These include major improvements to water turbines of the Kaplan type. He has contributed to the developments of gearing, of sliding ball bearings, and of precision bearings having minimal friction. He invented the Phantophos lamp and has been responsible for many inventions in the field of ancillary lens systems, projection and stereophotographic plotting. He has also done much to improve the mechanical development of the microscope. He has also been largely responsible for the development and design of the modern projection planetarium.

As an industrial organizer and leader, he has further developed the pioneering work of Professor Ernst Abbe, who founded the Zeiss Trust in 1896.

As chairman of the Foundation, Dr. Bauersfeld rebuilt the Zeiss organization in Western Germany (the works at Jena had been dismantled by the Russians in 1946). At Stuttgart he collected the nucleus of key staff and skilled workmen from Jena, believing that it is people, and not equipment, who are crucial in any undertaking. By 1951, the Zeiss-Werke was again established.

Did You Know That . . .

The Engineering Institute has co-operative agreements with eighteen societies, including the American Society of Mechanical Engineers, The American Society of Civil Engineers, and the leading institutions throughout the British Commonwealth.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council held at Saint John, N.B., on November 23, 1957.

Members: A. H. C. Carson, Baie Comeau; J. C. Cherna, Montreal; T. M. Claughton, Montreal; D. C. Cullingham, Temiskaming; L. E. Fischer, Seven Islands; R. Folli, St. Johns; G. M. Goodreid, North Bay; R. W. Griffiths, Hamilton; D. L. Halsall, Seneca Falls, N.Y.; T. Henry, Calgary; N. Holloway, Montreal; E. Holzl, Montreal; E. C. Hopkinson, Tulsa, Okla.; H. R. Jenkins, Baie Comeau, Quebec; E. J. Kane, Quebec; B. A. Kelly, Baie Comeau; R. W. Kirkland, Seven Islands; A. R. G. Leckie, Calgary; V. S. G. Lewis, Kingston; J. A. Little, Seven Islands; Y. Liu, Toronto; R. L. MacIntosh, Quebec; D. W. R. McKinley, Ottawa; C. E. McManus, Montreal; L. A. Madonna, Ottawa; W. S. Martin, Seven Islands; J. Negro-Morel, Baie Comeau; C. J. B. Newton, Montreal; J. L. Nyke, Montreal; J. T. Power, Thicket Portage; C. M. Rodkiewicz, Toronto; T. G. Rust, Baie Comeau; M. R. Scriven, Montreal; J. N. Seguire, Shawinigan South; S. I. Simon, Montreal; K. Tammik, Montreal; W. M. Taylor, Montreal; J. B. Tee, Dundas; R. A. Temple, Toronto; G. Trepanier, Baie Comeau; W. W. Walker, Toronto; W. G. Ward, Peterborough; A. G. White, St. Catharines.

Juniors: W. E. Desbarats, Montreal; F. E. Estabrook, Calgary; D. G. Hubley, St. John's; J. A. Karnas, Montreal; S. S. Kathuria, Hamilton; G. Kepes, Arvida; L. H. Lafontaine, Montreal; J. A. G. McGurhill, Ottawa; L. A. Quinn, Isle Maligne; R. G. T. Wilson, Baie Comeau.

Junior to Member: W. F. Allen, Edmonton; J. B. Bowron, Calgary; F. S. R. Flewelling, St. Catharines; F. L. Kahn, Toronto; H. T. Kane, Quebec; J. A. Kane, Quebec; E. O. LaFontaine, Windsor; E. Maltz, Regina; H. Reicher, Toronto; C. H. Smith, Calgary; C. M. Williams, Grand'Mere; B. E. Wilson, Toronto; L. A. Zalkind, Toronto.

Student to Junior: H. A. Dalkie, Winnipeg.

Affiliate: C. F. Baxter, Copper Cliff; R. Betley, Brockville.

STUDENTS ADMITTED:

University of New Brunswick: A. M. Adams, K. F. Agnew, L. S. Armstrong, G. A. Arseneault, B. B. Barnes, L. J. Barrett, W. F. Barrett, E. M. Barrie, J. A. P. Belyea, D. B. Betts, W. Bodzian, J. L. J. Dalhousie University: V. D. Conrad, F. Cordeau, D. M. Lewis, W. A. Massey, R. B. McIsaac.

Acadia University: D. G. Killen, D. Reardon, R. B. Rogers, D. R. Smith.

Queen's University: W. G. B. Armstrong, J. E. Gaylord, H. P. Russell, R. J. Salvas.

Mount Allison University: N. F. MacLeod, D. A. Roy.

McGill University: B. R. Walsh.

University of Manitoba: I. Shore.
Sir George Williams College: A. H. Kursell.

University of Sherbrooke: J. B. Hamel.

Imperial College: B. W. D. Sarjeant.

University College: M. S. Cunningham.

C.P.E.Q. Students: J. S. Crispin, R. M. Gifford, D. V. Doran-Veevers.

A.P.E.Ont. Student: F. G. J. Legros.

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Members: F. Blackburn, W. D. Storey, A. E. Van Clieaf, N. W. Polak; **Junior:** F. K. Szojka.

SASKATCHEWAN

Member: G. W. Moore; **Junior to Member:** J. L. Labossiere.

NOVA SCOTIA

Junior to Member: D. F. Oakley, J. V. Palmer.

NEW BRUNSWICK

Member: H. Knell; **Junior to Member:** R. E. Haines.

QUEBEC

Member: R. G. Fuller.

THE ENGINEERING INSTITUTE OF CANADA

MEMBERS OF COUNCIL – 1957

President
C. M. Anson, Sydney, N.S.

Past-Presidents

*D. M. Stephens, Winnipeg
†R. E. Heartz, Montreal
‡V. A. McKillop, London

Vice-Presidents

†A. Deschamps, Montreal, Que.
†S. C. Montgomery, Trail, B.C.
*G. M. Dick, Sherbrooke, Que.
†W. J. Ripley, Sudbury, Ont.
*H. W. L. Doane, Halifax, N.S.
*H. R. Sills, Peterborough, Ont.

Councillors

§M. L. Baker, Halifax, N.S.
*H. C. Bates, Orillia, Ont.
†A. G. Baxter, Amherst, N.S.
*A. J. Bonney, Peterborough, Ont.
†Roger Brais, Montreal, Que.
‡J. H. Budden, Montreal, Que.

General Secretary
L. Austin Wright, Montreal

Treasurer
O. M. Solandt, Montreal

Deputy General Secretary
Garnet T. Page, Montreal

Assistant General Secretary
H. P. Gatin, Montreal

Assistant General Secretary
E. C. Luke, Montreal

Eastern Field Secretary
J. H. McLaren, 160 Eglinton Ave E., Toronto 12

Western Field Secretary
A. C. M. Davy, 1370 Minto Crescent, Vancouver

COMMITTEES

Admissions
Roger Brais, chairman; W. H. Gauvin, D. H. Hobbs, J. H. R. Dansereau, R. J. Harvey.

Board of Examiners
J. L. deStein, chairman; John M. Cape, J. Hurtubise.

Canadian Standards Association (Technical Council)
P. L. Pratley—Institute Representative.

Finance
A. Deschamps, chairman; R. L. Dunsmore, R. A. Emerson, R. G. Ferrabee, J. M. Breen, O. M. Solandt, R. L. Weldon.

Canadian Chamber of Commerce
F. G. Rutley—Institute representative on National Board of Directors.

Legislation
C. G. Kingsmill, chairman; D. C. MacCallum, J. B. Stirling.

Library and House
C. E. Frost chairman; L. A. Duchastel, W. D. Kirk, E. D. Gray-Donald, W. C. M. Luscombe.

Membership
R. H. Self, chairman.

Publication
H. A. Mullins, chairman; J. A. Audet, William Bruce, W. H. Gauvin, B. D. McDermott.

Papers
J. H. Budden, chairman; D. H. Hobbs, H. L. Johnston, M. McMurray, W. B. Pennock, E. R. Smallhorn, H. S. Van Patter, L. P. Bonneau, R. Boucher.

Prairie Water Problems
G. A. Gaherty, chairman; P. M. Sauder, vice-chairman; T. D. Stanley, secretary; C. S. Clendening, D. W. Hays, B. Russell, T. H. Hogg, G. L. MacKenzie, J. H. McLean, J. M. Wardle.

Policy
R. L. Dunsmore, chairman; B. G. Ballard, A. Deschamps, I. P. Macnab, D. M. Stephens, R. L. Hearn, R. E. Heartz, J. B. Stirling, W. G. Swan, I. R. Tait.

Professional Interests
E. B. Jubien, chairman; G. A. Gaherty, vice-chairman; W. E. Brown, G. J. Currie, W. G. Swan, H. L. Branchaud, E. K. Phillips, I. R. Tait.

Property
F. G. Rutley, chairman; A. Deschamps, V. B. King, C. N. Murray, R. C. Pybus.

Student Policy
C. G. Southmayd, chairman; R. E. Jamieson, J. Dubuc, E. J. Muszinski, J. F. Riel, A. Pakalnins.

Technical Operations
F. L. Lawton, chairman; B. G. Ballard, W. H. Paterson, C. E. Frost, D. L. Rigsby, R. M. Hardy, S. Sillitoe, A. R. Harrington, E. R. Smallhorn.

OFFICERS OF THE BRANCHES

AMHERST

Chairman, J. W. Wilson; *Vice-Chair.,* D. J. Rockwell; *Executive,* F. C. Wightman, L. E. Burrill, R. G. Baxter.
Sec.-Treas., G. R. Pond, 7 Victoria Street West, Amherst, N.S.

BAIE COMEAU

Chairman, V. M. Wallingford; *Executive,* Peter Suttie, G. Scott, J. M. Pope; *Treasurer,* T. G. Rust.
Secretary, Norman Lapierre, P.O Box 1583, Baie Comeau, Que.

BELLEVILLE

Chairman, J. A. Grant; *Vice-Chair.,* A. E. Argue; *Executive,* T. E. Flinn, B. D. Pullen, H. T. Floyd, W. C. Benger, T. J. McQuaid, W. L. Canniff.
Sec.-Treas., E. T. Hilbig, 67 Bertram Blvd., Belleville, Ont.

BORDER CITIES

Chairman, C. Maurice Armstrong; *Vice-Chair.,* J. E. Dykeman; *Executive,* R. H. Darke F. P. Mascarin, A. W. Malmberg; *Treasurer,* E. R. Carpenter.
Secretary, J. M. Reid, 1511 York Street, Windsor, Ont.

BROCKVILLE

Chairman, W. N. Simmons; *Vice-chair.,* D. C. Turner; *Executive,* R. B. McRuer, W. E. Morden, F. E. Trewartha, K. R. Bullock, J. F. Preston.
Sec.-Treas., G. R. Bowcs, c/o Du Pont of Canada, Maitland, Ont.

CALGARY

Chairman, A. W. Howard; *Executive,* K. L. Broe, W. J. McGill, R. S. White, J. L. Mitchell; *Treasurer,* R. G. Price.
Secretary, O. O. Junker, c/o Cumming, Galbraith Limited 1510a - 1st St., S.W., Calgary, Alta.

CAPE BRETON

Chairman, W. A. MacDonald; *Vice-Chair.,* V. Palmer; *Executive,* D. Wilson, H. Aspinall, R. Bradley, G. W. Ross, J. Richard, F. MacDonald, H. Maitland; *Treas.,* C. A. Campbell.
Secretary, W. A. Dodson, 201 Columbia St., Sydney, N.S.

CENTRAL BRITISH COLUMBIA

Chairman, H. D. DeBeck; *Vice-Chair.,* A. Provenzano; *Exec.,* F. E. Gayfer, P. Tasie, J. W. Nelson.
Sec.-Treas., W. J. M. Owen, 634 Eckhardt Ave., W., Penticton, B.C.

CORNER BROOK

Chairman, Milton G. Green; *Vice-Chair.,* E. J. Leja; *Treasurer,* W. S. Read; *Secretary,* Eric R. Skanes, c/o Bowater's Engineering Dept., Corner Brook, Nfld.

CORNWALL

Chairman, W. Rothwell; *Executive,* D. Burnham, V. Harrison, G. Biard, J. Moriarty, J. Pescod, L. Snelgrove.
Sec.-Treas., D. W. C. McEwan, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.

EASTERN TOWNSHIPS

Hon. Chair., A. C. Crepeau; *Chairman,* R. D. Mawhood; *Vice-Chair.,* G. P. Cote; *Executive,* J. P. Champagne, J. E. Freeman, C. D. McKinney, E. T. Harbert, M. Lafreniere, G. B. Moffat; *Treas.,* A. S. Mitchell.
Secretary, Jean Bourassa, 450 Belvedere St., S., Sherbrooke, Que.

EDMONTON

Chairman, S. J. Hampton; *Vice-Chair.,* T. H. Newton; *Executive,* R. H. Cronkhite, D. H. Sands, G. Ross, S. R. Sinclair, H. Hole, R. H. Gardener, R. H. Nicolson, J. Longworth.
Sec.-Treas., G. Hodge, 10615-146th St., Edmonton, Alta.

FREDERICTON

Chairman, R. P. Lynch; *Vice-Chair.,* O. I. Logue; *Executive,* J. J. Gorman, W. L. Barrett, L. W. Smith, F. J. Abbass, R. S. Shephard, L. W. Bailey; *Treasurer,* R. D. Neal.
Secretary, A. M. Stevens, Box 62, Marysville, N.B.

HALIFAX

Chairman, R. D. T. Wickwire; *Vice-Chair.,* J. D. Kline; *Exec.,* M. C. Sutherland-Brown, G. H. Dunphy, P. M. Lane, A. H. MacKinnon, W. J. Phillips, G. F. Vail, B. N. Cain, J. E. Clarke, L. D. Hopkins, J. W. Powers.
Sec-Treas., J. E. Reardon, P.O. Box 33, Halifax.

HAMILTON

Chairman, D. B. Annan; *Vice-Chair.,* R. C. Mitchell; *Executive,* R. H. Stevenson, H. E. Seeley, H. E. Archibald, E. R. Bushfield.
Sec.-Treas., W. A. H. Filer, 2 Maple Ave., Hamilton, Ont.

HURONIA

Chairman, R. MacKay; *Vice-Chair.,* L. G. McNeice; *Executive,* S. R. Walkinshaw, J. Richardson, C. Campbell, D. M. Harris, J. L. Armstrong, B. C. Lamble, J. E. Sears.
Sec.-Treas., L. Morgante, 36 Borland St. W., Orillia, Ont.

KINGSTON

Chairman, J. W. Dolphin; *Vice-Chair.,* R. B. Wotherspoon; *Exec.,* W. M. Campbell, D. C. MacPherson, W. B. Rice.
Secretary, D. I. Ourom, 991 Princess St., Kingston.

KITCHENER

Chairman, J. F. Runge; *Executive,* B. Nichols, R. Senyshen, R. Blezard, C. Leicht.
Sec.-Treas., A. H. Austin, c/o Armco Drainage & Metal Products of Canada Ltd., Box 300, Guelph, Ont.

KOOTENAY

Chairman, W. G. Small; *Vice-Chair.,* J. T. Higgins; *Executive,* R. F. Bailey, D. J. Turland, D. Danyluk, W. V. Nicholson, E. Rohatynski; *Treasurer,* J. I. McClelland.
Secretary, J. L. P. Limbert, 649 Forrest Drive, Trail, B.C.

LAKEHEAD

Chairman, V. B. Cook; *Vice-Chair.,* W. D. MacKinnon; *Exec.,* W. H. Bulger, P. W. Pinn, J. W. Lukey, J. E. Rymes, G. S. C. Smith, G. A. Walker, J. H. Hargrave, A. T. Sherrett; *Sec.-Treas.,* C. M. Cotton, 320 North Syndicate Ave., Suite 2, Fort William, Ont.

LETHBRIDGE

Chairman, A. J. Branch; *Vice-Chair.,* J. R. Milne; *Executive,* P. A. Harding, A. A. Kenwood, W. B. Thomson.
Sec.-Treas., R. D. Hall, Utility Engineer, City Hall, Lethbridge, Alta.

LONDON

Chairman, D. J. Matthews; *Vice-Chair.,* R. W. McMeakin; *Executive,* H. Osborne, R. Fuller, G. Hayman, S. Lauchland, H. Martin, R. Smith, W. Sinkins.
Sec.-Treas., G. W. Chorley, c/o M. M. Dillon & Co. Ltd., P.O. Box 1026, London, Ont.

LOWER ST. LAWRENCE

Chairman, Jean R. Menard; Vice-Chair., M. Lanouette; *Executive,* T. Bernier, R. Joncas, A. Leroux, G. Santerre.
Sec.-Treas., Claude St. Hilaire, 10 Rue St. Jean, Rimouski, Que.

MONCTON

Chairman, G. E. Franklin; *Vice-Chair.,* C. L. Trenholm; *Executive,* H. S. McCleave, L. McIsaac, G. A. Peck, C. E. Spear, W. M. Steeves.
Sec.-Treas., V. C. Blackett, 97 MacBeath Avenue, Moncton, N.B.

MONTREAL

Chairman, J. E. Leo Roy; *Vice-Chair.,* R. F. Shaw; *Executive,* C. A. Colpitts, J. O. McCutcheon, H. Audet, R. A. Phillips, L. M. Nadeau, L. Nenniger.
Sec.-Treas., G. M. Boissonneault, Shawinigan Water and Power Co., P.O. Box 6072, Room 809, Montreal, Que.

NEWFOUNDLAND

Chairman, G. E. Knight; *Vice-Chair.,* C. W. Henry; *Executive,* R. P. Hunt, A. H. McKinnon, D. S. Templeton, G. N. Cater, R. W. Myers, R. F. Martin.
Sec.-Treas., R. L. Smyth, c/o Imperial Oil Limited, Centre Building, St. John's, Nfld.

OFFICERS OF THE BRANCHES

NIAGARA PENINSULA

Chairman, E. C. Little; *Vice-Chair.*, D. A. Barnum; *Executive*, H. J. Saaltink, G. N. Cotton, H. C. L. Joe, D. O. Ramsdale, W. D. Tanner, G. E. Griffiths, C. A. MacDonald.
Sec.-Treas., Malcolm Stevenson, Box 196, Fonthill, Ont.

NIPISSING AND UPPER OTTAWA

Chairman, J. F. Chantler; *Vice-Chair.*, J. S. Cooper; *Executive*, E. A. Watson, R. S. MacLennan, J. Crothers, J. Warburton, P. Rebin, H. Staniforth.
Sec.-Treas., R. A. Booy, Box 1, Temiskaming, Que.

NORTH EASTERN ONTARIO

Chairman, A. A. Kidd; *Vice-Chair.*, J. S. Whyte; *Executive*, C. McIntyre, J. Blakeman, J. N. Greggain, J. Shipman, M. McLean, W. Swann, G. Flett.
Sec.-Treas., J. S. Busby, c/o C.N.R., Cochrane, Ont.

NORTHERN NEW BRUNSWICK

Chairman, L. L. Marshall; *Vice-Chair.*, D. C. MacCallum; *Executive*, Stewart Henry, A. R. Bonnell, J. A. Mesereau, C. K. Steeves, Martin Cyr, R. A. Cameron.
Sec.-Treas., G. P. Milton, P.O. Box 637, Bathurst, N.B.

NORTH NOVA SCOTIA

Chairman, D. J. MacNeil; *Vice-Chair.*, W. I. Fisher; *Exec.*, C. McGibbon, M. Wolfe, Rev. W. Fogerty, J. K. Godfrey.
Sec.-Treas., D. G. Dunbar, Pictou County Power Board, New Glasgow, N.S.

NORTH SHORE LOWER ST. LAWRENCE

Chairman, B. M. Monaghan; *Executive*, R. W. Kenway, M. Michaud, M. Storrier.
Sec.-Treas., L. E. Fisher, Iron Ore Company of Canada, Dock Terminal, Sept-Iles, Que.

OTTAWA

Chairman, Col. W. A. Capelle; *Vice-Chair.*, H. Chaput; *Executive*, T. M. Patterson, R. C. Silver, A. H. Graves, G. C. McRostie, J. P. Stirling, S. G. Frost; *Treasurer*, H. C. Brown.
Secretary, W. V. Morris, 2078 Knightsbridge Road, Ottawa.

PETERBOROUGH

Chairman, W. H. Ackhurst; *Executive*, I. N. MacKay, E. Oliver, F. R. Pope, R. A. Blount, L. E. Marian.
Sec.-Treas., D. B. Chase, Canadian General Electric Company, Waddell House, Monaghan Rd., Peterborough, Ont.

PORT HOPE

Hon. Chair., J. G. G. Kerry; *Chairman*, A. F. Alexander; *Vice-Chair.*, T. F. Kennedy; *Executive*, R. Waterfall, D. A. Runciman, J. L. Sylvester.
Sec.-Treas., J. A. Pollock, 8 Shortt St., R.R. 3, Port Hope, Ont.

PRINCE EDWARD ISLAND

Chairman, N. F. Stewart; *Vice-Chair.*, C. W. Currie; *Exec.*, R. D. Donnelly, J. D. MacDonald, L. A. Coles, G. Milligan.
Sec.-Treas., C. F. Buckingham, 46 Green St., Charlottetown.

QUEBEC

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Bruce Gilbert Dixon, M.E.I.C., retired diking commissioner with the Province of British Columbia, Victoria, B.C., died at New Westminster, B.C., in November, 1957.

Bruce Dixon was a maritimer, born at Hopewell Cape, N.B., on September 28, 1889. Awarded a B.Sc. degree in civil engineering at the University of New Brunswick in 1912 he undertook the post of chief of a hydrographic survey party on the Pitt and Fraser rivers in British Columbia at the outset of his career. Transitman on the revision of the location of the Pacific Great Eastern Railway in B.C. in 1913, he was in charge of highway location and construction of trails and bridges for the Strathcona Park Development on Vancouver Island.

With the advent of World War I Mr. Dixon offered his services to the Imperial Munitions Board where he was engaged in the testing of ammunition in 1915. For the remainder of the war he was involved in active service overseas with the Royal Canadian Artillery.

In 1919 Mr. Dixon joined the staff of the Taylor Engineering Company, taking charge of the construction of pipe lines and storage basins for the Alice Arm, B.C., hydro-electric installation.

Early in 1921 named inspector of dikes he became diking commissioner for Coquitlam, Pitt Meadows, Matsqui, and Maple Ridge, beginning more than thirty years service with the Province of British Columbia.

In 1948, following the flooding of the Fraser Valley, Mr. Dixon was named to the Fraser Valley Diking Board and was called to the post of diking commissioner for the Province. He was a member of the Federal-Provincial Board set up to study the overall problem of flood control in the Fraser Valley.

Mr. Dixon joined the Institute as a Junior Member in 1914 and transferred to Associate Member in 1923. He was named a Member in 1940.

Harry Stewart Van Scoyoc, M.E.I.C., retired advertising manager of the Canada Cement Company Limited, Montreal, died November 15, 1957 in that city.

Mr. Van Scoyoc was born on June 27, 1881 at Canaan, Pennsylvania. Awarded a B.Sc. degree in civil engineering at the University of Pennsylvania in 1907 his first professional responsibility was with the city of Altvona, Pa., as assistant engineer on road construction.

Mr. Van Scoyoc moved to Canada in 1912 to undertake the post of inspecting engineer assisting in the construction of concrete work throughout Canada. Thus began his long association with the Canada Cement Company Limited, Montreal.

During World War I Mr. Van Scoyoc was sent on loan to the Toronto and Hamilton Highway Commission as chief engineer during the construction of one of Canada's first major highways.

In 1918 he took over the post of consulting engineer of the Toronto, Hamilton highway Commission. At that time he was also named manager of publicity for the Canada Cement Company Limited, Montreal.

Named manager of the advertising and technical departments in 1931 he con-

H. S. Van Scoyoc, M.E.I.C.

tinued to hold office as such until his retirement in 1946.

For many years Mr. Van Scoyoc took an active part in advertising and sales organizations. In 1924 he was chosen to represent Canada at the world convention of the Associated Advertising Clubs of the World in London, England.

Mr. Van Scoyoc joined the Institute as an Associate Member in 1915, transferred to Member in 1921. He attained Life Membership in 1951.

William Jamieson, M.E.I.C., retired engineer, for many years associated with the Powell River Pulp and Paper Company, Powell River, B.C., died on June 21, 1957, in that city.

Born at Liverpool, England, on February 17, 1875, Mr. Jamieson obtained an engineering diploma at Liverpool University in 1895. One of his first posts was that of assistant engineer of the sewerage department of the Liverpool Corporation. In 1900 he served with British troops in South Africa then engaged in winning the Boer War.

He became resident engineer for the British Electric Traction Company Limited, at Worchester on his return to England, in 1901. Three years later he was construction engineer on bridge building and tramways over the Forth and Clyde Canal in Scotland.

In Shanghai in 1905 Mr. Jamieson was employed as superintendent engineer and agent on the construction of tramways.

He left the Orient in 1910 to join the engineering staff of the Kettle River Valley Railway as a waterworks engineer and superintendent of the district of North Vancouver.

During the thirteen years that followed he handled a number of appointments in the interior of B.C.

In 1924 began his long-term career with the Powell River Pulp and Paper Company. His first commission was concerned with the extension of Powell Lake Dam. For many years he served as a field engineer.

Mr. Jamieson retired in 1949. Nevertheless, he was able to continue his contribution to engineering in some measure, as consulting engineer for the Powell River Company and several other adjoining concerns.

Mr. Jamieson joined the Institute as a Member in 1925. He attained Life Membership in 1925.

John Stuart Slater, M.E.I.C., general manager of Pembina Pipeline Limited, died in Calgary, Alta., on October 20, 1957.

Born at Winnipeg on December 9, 1916, he moved to Vancouver at an early age. He attended Magee High School, in Vancouver. In 1944 he was awarded a B.A.Sc. degree in civil engineering at the University of British Columbia.

Beginning his graduate career as an assistant engineer with the Department of Public Works of Canada at New Westminster he gained experience with a number of firms in British Columbia before accepting the post of chief engineer for the Pembina Pipe Line Company Limited, Edmonton, in 1954.

During that period Mr. Slater was associated with the Western Bridge and Steel Fabricators, Vancouver, as an assistant engineer in 1946; the following year transferring his services to Bloedel, Stewart and Welch, Bloedel, B.C., in the same capacity. In 1948 named civil designer with the B.C. Electric Company at Vancouver, he remained there until 1951. Field engineer with Morrison Knudson Company of Canada Limited, Vancouver, later that year, he was associated with Canadian Bechtel Limited, Kamloops in 1953 and with B. D. Bohne and J. L. Miller Limited, consulting engineers, Vancouver.

Mr. Slater joined the Institute as a Student in 1943; became a Junior in 1946; and transferred to Member in 1951.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

In a Nutshell

Quebec City and region members established a local chapter of the Corporation on December 6 when Council held its regular monthly meeting in Quebec City.

The president, **C. A. Peachey, P.Eng.**, has visited most of the Corporation regions; the tour, started in Rimouski in early autumn, took the president and some of the councillors as well as the general secretary **Pierre Bournival, P.-Eng.**, to the Northwestern, St. Maurice Valley, Lake St. John and Quebec regions. Members from the Eastern Townships and the Ottawa Valley will greet the president early in February.

W. W. Beaton, P.Eng., mining consultant of Noranda, Que., replaces Lucien Béliveau, P.Eng., as regional representative of the Northwestern region. A graduate of Queen's University (B.Sc. mining and metallurgy '26), Mr. Beaton is a member of the Corporation, the A.P.E.O., the C.I.M.M., the Canadian Legion, R.C.A.F. Associated, the Prospectors Association and is also Past-President of the Northwestern Quebec Branch of the Boy Scouts.

The Lake St. John members have recently elected **F. A. Brown, P.Eng.**, as their regional representative. Mr. Brown graduated from Queen's University in 1947 (B.Sc., electrical) and has been employed since that time by the Aluminum Company of Canada; he is presently assistant general superintendent, electrical division, Arvida Works. Mr. Brown replaced F. A. Dagg, P.Eng., as Lake St. John representative.

W. W. Beaton, P.Eng.

F. A. Brown, P.Eng.

Laval Faculty of Science has scored another first: creation of a Student Section of the Corporation. Promotion of professionalism will be its main concern.

ONTARIO

(Taken from The Professional Engineer, Journal of the Association of Professional Engineers of the Province of Ontario.)

Association Takes Stand

The Association's submission to the Gordon Commission, which was also forwarded to the Provincial Government, contained this paragraph — "The engineering profession is affected by the shortage that presently exists for all types of trained technicians. It is suggested that study should be given to the expansion of such senior technical schools as Ryerson Institute of Technology. There is a definite need for this type of senior technical school. It is, however, considered that rigid control of the curricula of such schools should be maintained to ensure that the graduates will be well-trained technicians rather than borderline engineers."

Retirement Plan Launched

The first group retirement savings plan for professional engineers in Canada has been launched by the Association of Professional Engineers of Ontario.

The plan consists of two methods of participation: purchase of a guaranteed insured annuity underwritten by North American Life Assurance Company; or purchase of common stock through the Chartered Trust Company. There is also a combination of both methods available. Minimum annual payment to the Plan is $200.00.

Under the common stock investment plan, members' savings are invested by the Chartered Trust Company. Members are allotted a number of units and each year receive a statement indicating the number of units standing to their credit.

ALBERTA

(An editorial taken from "The Alberta Professional Engineer", November 1957 issue by E. K. Cumming, chairman of the editorial committee.)

Confederation

The majority of the members of this Association and their fellow engineers throughout Canada are anxiously awaiting news of Confederation. In the June issue of the Professional Engineer it was reported that Canadian Council had adopted a plan which had been referred to Council of the Engineering Institute for the Annual meeting in June.

The E.I.C. Council, unable to adopt the plan in principle, referred it to their Committee for consideration. Arrangements for committees of Canadian Council and the E.I.C. to meet were delayed by vacations and the absence of J. Herbert Smith, chairman of the Canadian Council committee and originator of the idea.

Recently Mr. Smith was made president of his company and has found it necessary to resign as chairman of the committee, although he will continue as a member. The chairmanship has been given to John Fox, current president of the Association of Professional Engineers of Ontario. Arrangements are now being made for a meeting of the joint committee in early 1958.

There will be few engineers, if any, who will not welcome Confederation, and the end of their "split-personality". Such a change does not come easily. Only as a result of careful, sincere diagnosis and prescription will the patient develop a strong single personality. This important task lies with the able members of the joint committee who must not be forced to a hasty decision. On the other hand damage may be done by procrastination.

In any event it would be most ill-advised for either personality to attempt to proceed in its own way.

Personals

News of the Personal Activities of Members of the Institute

Rt. Honourable C. D. Howe, HON. M.E.I.C., was recently elected a director of Dominion Tar and Chemical Company, Limited.

D. S. Abbott, M.E.I.C., (B.Sc., mechanical, Queen's, 1930) of Howard Smith Paper Mills Limited, largest fine paper producer in the Commonwealth, has been elected president of the organization.

His career with the organization dates to the closing years of World War II. As manager of the plastics division of the company he devoted a number of years to the production of Arborite.

Since 1948 a member of the executive, Mr. Abbott was in 1954 appointed president of the Alliance Paper Mills and the Don Valley Paper Company. He was named president of Arborite in 1952. He is president of all Howard Smith subsidiary companies and a director of Consoweld Corporation and Continental-Diamond Fibre Company.

F. F. Fulton, M.E.I.C., (engineering diploma, Mount Allison University; B.Sc., electric, McGill, 1928) has been named general manager of the telephone contract division of Northern Electric Company Limited at Montreal.

Mr. Fulton joined Northern Electric in 1928 devoting the early part of his career to the field of electronics. He was appointed chief engineer of the electronics division in 1946. Within the last few years he has become assistant to the vice-president and managing director, and then general manager of the sales division.

R. N. Fournier, M.E.I.C.

A. B. Hunt, M.E.I.C.

Air Commodore V. H. Patriarche, M.E.I.C., (B.Sc., Manitoba, 1929) at Ottawa has received a posting to London, England where he will serve the Canadian Joint Staff. He was named chief of training at Air Force Headquarters, Ottawa.

R. N. Fournier, M.E.I.C., (engineering physics, Saskatchewan, 1937), has been appointed general manager of the wholesale department of the Canadian General Electric Company Limited, at the company's head office in Toronto. Mr. Fournier has held key managerial assignments in many of Canada's major marketing areas. In 1955 he was named manager of the Mid-West district in Winnipeg and held this position until his recent appointment.

F. F. Fulton, M.E.I.C.

D. S. Abbott, M.E.I.C.

Douglas C. Borden, M.E.I.C., (B.Sc., civil, McGill, 1924) of Montreal has been promoted to planning manager, communications equipment division with Northern Electric Company Limited, Montreal.

With the company for a number of years his most recent appointment was that of organization planning manager of the general sales division.

A. B. Hunt, M.E.I.C., (B.A.Sc., Toronto, 1928) formerly general manager of the telephone contract division of Northern Electric Company Limited, Montreal, has been appointed general manager, research and development for the organization.

During 1954-55 Mr. Hunt served as director of the electronics branch of the Department of Defence production.

E. H. Tovee, M.E.I.C., (B.A.Sc., electrical, Toronto, 1934) has been appointed director of quality control for the Canadian Westinghouse Company, Hamilton, Ont.

Mr. Tovee joined the firm in 1935. He has since 1953 co-ordinated the work of cost improvement teams throughout Westinghouse operating divisions.

W. D. Hurst, M.E.I.C., (B.Sc. civil, Manitoba, 1930; C.E., Virginia Polytechnic Institute, 1931) city engineer of

Photograph courtesy of Pirelli Cables, Conduits, Limited.

PERSONALS

Winnipeg and chairman of Commissioners of the Greater Winnipeg Water and Sanitary Districts was elected vice-president of the American Public Works Association at its annual meeting in Philadelphia on September 23.

Mr. Hurst's election culminated terms of service on the directorate of the Association as director-at-large, and as director of region 6. This consists of the American States of Iowa, Kansas, Minnesota, Nebraska, Missouri, North and South Dakota, and the Province of Manitoba.

J. Edward Goodman, M.E.I.C., (B.Sc., civil, Queen's, 1931) of Toronto, president of the J. E. Goodman Sales Limited, of Toronto has received the appointment of vice-president of Serviced Products (Canada) Limited. Mr. Goodman has an engineering background which includes thirty years' experience as project manager in road and heavy construction.

J. N. Cram, M.E.I.C., (B.Sc., chemical, Saskatchewan, 1937; B.Eng., mechanical, Nova Scotia Technical College, 1950) has transferred his engineering services from Toronto to Delora, Ont. Appointed manager of the Delora Smelting and Refining Company Limited, Mr. Cram was formerly associated with the Toronto firm of Crowthers Manufacturing Limited as sales manager.

Joseph A. D'Angelo, M.E.I.C., (B.Sc., electrical, 1946; B. Comm., Manitoba, 1957) has been appointed by Chrysler Corporation, Detroit, Michigan, as comptroller of the Joseph Campan Engine plant. More recently he was budget manager of the corporation's engine division.

W. H. Berry, M.E.I.C., (Birmingham, National Certificate, Central Technical College, 1938) has left his post as resident engineer for the British Malayan Petroleum Company Limited in Borneo to take up work for Shell Oil Company Limited at Maracaibo, Venezuela.

Mr. Berry has been employed in the British East Indies for several years. In 1952 he served as resident engineer for United British Oilfields of Trinidad Limited.

R. Walker, M.E.I.C., has moved to Western Canada to take over the post of chief electrical engineer with Associated Engineering Services Limited at Edmonton. Mr. Walker was formerly resident construction engineer with J. T. Donald & Co. (1956) Ltd., Montreal.

C. L. Cosser, M.E.I.C., (B.Sc., electrical, Cape Town, 1932) has left Montreal and is at work with an engineering concern in Southern Rhodesia. The firm, J. E. Stone and Company Limited is located at Salisbury.

Keeping in circulation?

We may not have the circulation problems of this young swain, but we too must keep our address book up-to-date. Your name is in it.

Once every year, the auditor from Canadian Circulations Audit Board Inc. checks our address records. If he checks your name, he will want proof of the business you are in, and that your address is correct. The proof may be a letter from you, or it may be a listing of your name in a directory, or it may be a salesman's report after calling upon you.

The auditor's most recent check of our circulation, summarized your name and others on our lists in this manner:

THE ENGINEERING JOURNAL

is a member of

CCAB CANADIAN CIRCULATIONS AUDIT BOARD INC.

• PERSONALS

While in Montreal Mr. Cosser was employed with Northern Electric Company.

Commander W. B. Christie, M.E.I.C., (B.Eng., electrical, Nova Scotia Technical College, 1950) who was stationed in Great Britain for four years has held the post of assistant E.E.C. in C., at Naval Service headquarters, Ottawa since his return to Canada a number of months ago.

In Great Britain, Cmdr. Christie was acting electrical representative for the Royal Canadian Navy on the construction of the aircraft carrier, H.M.C.S. Bonaventure. He served as deputy electrical officer after the commissioning of the vessel.

J. F. Curran, M.E.I.C.

R. S. Cornell, M.E.I.C.

Richard S. Cornell, M.E.I.C., (B.Eng., chemical, McGill, 1949) who has for the past three years served the firm of Peacock Brothers Limited, as manager, pulp and paper division, has accepted the appointment of chief engineer with the chemical engineering company, Separator Engineering Limited, at Montreal. He has been elected a director in the firm.

Mr. Cornell was for three years associated with the Chemipulp Process Limited, pulp mill engineers.

John F. Curran, M.E.I.C., (B.Eng., civil, National University of Ireland) who came to Canada in 1951 has for a number of months held the responsibility of assistant Commissioner of Works for the City of Sarnia, Ont.

He was formerly with the Toronto consulting engineering firm of James F. MacLaren Associates.

Ronald B. Leeming, M.E.I.C., (Higher Nat. Certificate, Great Britain) has transferred from Vancouver to Montreal. He has accepted an engineering appointment with the Montreal Engineering Company Limited. Although Mr. Leeming was associated with this company previously, his address since 1956 has been c/o Sandwell and Company Limited, in the West Coast city.

Douglas O. Blake, M.E.I.C., (Higher National Certificate, 1946) until recently chief engineer of the Defence Research Laboratories, at Downsview, Ont., has moved to Montreal in order to accept a new appointment. The post he now fills is that of chief experimental engineer for Canadian Pratt and Whitney Aircraft Company Limited.

Major R. W. Potts, M.E.I.C., (B.Sc., civil, Saskatchewan, 1947) attending the Army Staff College at Camberley, Surrey, England, for the past year has been posted to Halifax, N.S., as D.A.A.G., manning, at Eastern Command headquarters.

Erik Hoel, M.E.I.C., (M.Sc., mechanical Technical University of Norway, 1947) has severed his connections with engineering in Toronto and is employed with Williams Brothers Sudamericana Limited, at Bogota, Colombia, S.A.

Mr. Hoel was formerly vice-president and manager of Dahl Brothers (Canada) Limited, in Toronto.

William Frederick Hull, M.E.I.C., (B.A.Sc., civil, Toronto, 1949) carrying on his engineering career in Africa for several years, has left Southern Rhodesia. His headquarters now in Capetown, South Africa, he is general manager of R. H. Morris, (Pty) Limited, building and civil engineering contractors. Mr. Hull was general manager with the firm of Laing and Roberts (Rhodesia) Limited while in Bulawayo, Rhodesia.

Boris Nebesar, M.E.I.C., (chemical, Prague, 1950) has left his employment at Sudbury, Ont., where he was with

• PERSONALS

the International Nickel Company and has accepted an appointment with the Northern Electric Company Limited at Montreal. His post is that of associate chemical engineer.

Gerald Malo, M.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1948) has gained a Quebec City appointment as assistant to the district engineer, department of roads, Province of Quebec.

Mr. Malo formerly worked as division engineer for the Province of Quebec, Department of Roads, Cookshire, Que.

J. T. Kokotailo, M.E.I.C., (B.Sc., electrical, Alberta, 1949) has left Toronto where he was manager, industrial wiring & maintenance, with Magnetic Electric Company and has joined the staff of the Province of Saskatchewan as chief electrical inspector, Department of Labour, electrical inspection and licensing branch.

D. H. Pugsley, M.E.I.C., (B.Sc., mechanical, Saskatchewan, 1948) of the McColl Frontenac Oil Company Limited now holds the post of zone manager at the Lethbridge, Alta., office of the organization.

K. Madsen, M.E.I.C., (B.Sc., civil, Alberta, 1950) has joined the firm of Brown and Root Limited, at Calgary, Alta. His previous appointments have included work with the firm of H. G. Acres and Company Limited, Niagara Falls, Ont., and with the Provincial Institute of Technology and Art, Calgary.

R. N. Walker, M.E.I.C., (B.Sc., civil, Witwatersrand, Johannesburg 1950) has moved from Regina to Saskatoon, Sask., in order to accept an appointment as design engineer with the consulting engineering firm of Underwood, McLellan and Associates Limited. He formerly worked in the city engineers' department at the provincial capital.

G. L. Wilson, M.E.I.C., (B.A.Sc., civil, Toronto, 1951) has left Sudbury, Ont., where he was a director in the firm of E. M. Powell & Assoc. Ltd. He is presently carrying out engineering duties with Sprostons (Jamaica) Limited, a subsidiary of the Aluminum Company of Canada Limited in Kingston, Jamaica, B.W.I.

D. Segal, M.E.I.C., (B.A.Sc., civil, Toronto, 1953) has been transferred from St. John's, Newfoundland to Montreal, with The Warnock Hersey Company Limited. In Newfoundland Mr. Segal filled the post of branch manager for the organization.

D. T. Vanstone, JR.E.I.C., (B.Sc., chem., Queen's, 1951), has been transferred by his company, Du Pont Company of Canada (1956) Ltd., from the company's technical service group in Kingston to their sales development group at their

• PERSONALS

Montreal head office. Both of these positions are in Du Pont's textile fibres division. In Montreal, Mr. Vanstone will be working as a senior sales development representative on industrial applications of nylon and acrylic fibres.

J. C. Allen, JR.E.I.C., (B.Eng., mech., McGill, 1949), is presently employed as engineer with RCA Victor Company Limited, Montreal, He was formerly methods engineer with Northern Electric Company Ltd.

Jean Paul Cote, JR.E.I.C., (B.A.Sc., electrical, Laval, 1951) whose former employer was Pirelli Cables and Conduits Ltd., St. Jean, Que., is now with Canada Wire and Cables, Leaside, Ont.

Peter W. Brown, JR.E.I.C., (B.Sc., mechanical, Saskatchewan, 1954) is no longer with the Bailey Meter Co. Ltd., but has taken up duties in the office of the engineer-in-chief Naval Technical Services, Department of National Defence. Ottawa, Ont.

W. J. McNicol, JR.E.I.C., (B.A.Sc., mechanical, U.B.C., 1950) is appointed assistant Ontario district manager of the Canadian Westinghouse Company Ltd. He was formerly sales manager, for the company's motor-generator division at Hamilton.

K. M. McMillan, JR.E.I.C., (B.Sc., civil, Alberta, 1953) is presently employed as field operations manager, Pembina Pipe Line Ltd., Edmonton, Alberta. He was formerly with the Texaco Exploration Company.

Donald E. Lee, JR.E.I.C., (B.Sc., chemical, Alberta, 1956) is a research engineer in the research and development department of the Eldorado Mining and Refining Ltd., Eldorado, Sask.

David M. Derworiz, JR.E.I.C., (B.Sc., Mechanical, Sask., May 1955), who was employed for 2 years with Polymer Corporation Ltd., Sarnia, Ont., is now an inspection engineer for the McColl-Frontenac Oil Co. Ltd., Montreal.

M. C. Wolfe, JR.E.I.C., (B.Eng., mechanical, N.S.T.C, 1950) is chief engineer, Trenton Steel Division, Dominion Steel & Coal Corporation, Ltd, Trenton, N.S.

Arthur J. Shama, JR.E.I.C., (B.Eng., civil, McGill, 1948) is division engineer, Quebec Division, for Canadian Petrofina Limited, Montreal, Que. He was earlier a construction supervisor in Toronto.

R. N. Smith, JR.E.I.C., (B.A.Sc., electrical, U.B.C., 1951) is employed in the applied science division of International Business Machines Co. Ltd., Toronto.

Bruce Alexander, JR.E.I.C., (B.Sc., civil, Alberta 1955) has for some time been engaged in work as a designer for the

• PERSONALS

firm of Wallace and Carruthers and Associates at Don Mills, Ont.

Prior to that time Mr. Alexander gained experience in working as a site engineer on the DEW Line.

G. W. T. Richardson, JR.E.I.C., (B.A.Sc., mechanical, Toronto, 1948) has been appointed superintendent of electrode production and plant maintenance at the Welland, Ont., plant of the Electro Metallurgical Company, division of Union Carbide Canada Limited.

Mr. Richardson's association with the Electro Metallurgical Company dates to his graduation. Previously he held the appointment of assistant superintendent of maintenance and services.

Joseph H. Amblard, JR.E.I.C., (B.Sc., Engineering and Business Administration, Massachusetts Institute of Technology, 1951) sales engineer for Process Steam Specialties Inc., Montreal, since 1953, now heads his own company, Associated Instrumentation & Controls Ltd., Montreal, as president.

J. C. Hungate, JR.E.I.C., (B.Eng., elec., McGill, 1951) is maintenance superintendent for Canada Iron Foundries at Three Rivers, Que.

E. J. Woods, JR.E.I.C., (B.A.Sc., electrical, British Columbia, 1947) previously works engineer at the James Island, B.C. explosives plant and Canadian Industries Limited, has now assumed duties as plant engineer at Lenkurt Electric Company in San Carlos, California.

Arthur P. Earle, JR.E.I.C., (B.Eng., electrical, McGill, 1949) is presently employed by The Shawinigan Water and Power Company, Montreal, as cost control engineer, production and plant department.

Olivier Y. Barde, JR.E.I.C., (engineering diploma, civil, Swiss Federal Institute of Technology, 1948) has severed his connections with C. D. Howe and Associates Limited and has joined the Montreal firm of Miron, Sterling and Walsh.

J. D. Sikal, JR.E.I.C., (B.Sc., civil, Alberta, 1949) is employed as a site engineer for the Bell Telephone Company of Canada at Schefferville, Que. Earlier this year he was located at Dawson Creek, B.C.

G. C. Willeumier, JR.E.I.C., (civil, Technical University of Delft, Holland, 1949) has accepted a position with C.B.A. Engineering Limited at Vancouver, B.C.

For the past few years Mr. Willeumier has been employed in Montreal with the firms of Beauchemin and Hurter, surveying and designing, and with H. S. Pratley, consulting engineers, both of Montreal.

J. S. Baldwin, JR.E.I.C., (B.Sc., chemical, Saskatchewan, 1951) is now employed by the Boeing Airplane Company, Seattle, Wash., as a liaison planning engineer. He was formerly associated with the Canadian Arsenals Limited, as a supervisor, propellants department, Valleyfield, Que.

F. C. Bertrand, JR.E.I.C., (B. Eng., mechanical, McGill, 1953) is working for the Canada Iron Foundries Limited, Three Rivers, Que. He was formerly associated with the Anglo-Canadian Pulp and Paper Mills as a maintenance engineer.

Robert Boisvert, JR.E.I.C., (B.Eng., mechanical, McGill, 1952) has transferred his services from the Fluor Corporation Limited, Toronto, as project engineer to the Moulton Company Limited, Montreal.

E. N. Yaramy, JR.E.I.C., (B.Sc., mechanical, Queen's, 1954) who has been with Taylor Instrument Company Limited since his graduation has recently been transferred from Montreal to Toronto.

F. R. Long, JR.E.I.C., (B.Sc., mechanical New Brunswick, 1955), design engineer with Canadian International Paper Company Limited, in Dalhousie, N.B., has now joined Racey MacCallum & Assocates, at Montreal, Que.

G. M. Ross, JR.E.I.C., (B.Eng., electrical McGill, 1955) is presently employed as engineer in the Microwave Group of Standard Telephones & Cables Manufacturing Company (Canada) Ltd., Montreal, Que.

J. A. Pickard, S.E.I.C., (B.Sc., mech., Queen's, 1957) is employed as design engineer, in the design engineering department of the E. B. Eddy Company Ltd., Hull, Que.

R. Lapinas, S.E.I.C., (B.Eng., civil, McGill, 1957) is assistant concrete engineer, with the technical control division of the Mount Royal Paving and Supplies Limited, at Montreal.

Louis Pertus, S.E.I.C., (B.Sc., civil, New Brunswick, 1957) has joined the Department of Transport, Montreal airport, as district construction engineer.

L. R. McCartney, S.E.I.C., (B.Sc., civil, Queen's, 1957), is assistant city engineer for the City of Guelph, Ontario.

G. T. Dewhurst, S.E.I.C., (B.Eng., mechanical, Saskatchewan, 1957), is application engineer with Honeywell Controls Limited, Calgary, Alberta.

Louis E. Deveau, S.E.I.C., (B.Eng., mechanical, Nova Scotia Technical School, 1956) is employed with the Moncton Foundry and Machine Company Limited, Moncton, N.B., and is engaged in the work of designing and estimating for the firm.

NEWS OF THE BRANCHES

Activities of the Forty-Nine Branches of the Institute and abstracts of the papers presented at their meetings

BELLEVILLE

E. T. Hilbig, JR.E.I.C., *Sec.-Treas.*

T. E. Flynn,
Branch News Reporter

On Monday, November 11, 1957, the Belleville Branch held a joint meeting with the Bay of Quinte Section of the I.R.E. in Belleville. Chairmanship of the meeting was shared by Mr. John Grant of the E.I.C. and Mr. Ryan of the I.R.E.

After matters of routine business were completed by the joint chairmen, Mr. Grant introduced Mr. Robert Tanner of the Northern Electric Company, guest speaker.

Mr. Tanner received his bachelor's degree in science and post-graduate degree at London University. He worked for the British Broadcasting Corporation, served in the British Army during World War II and in 1947 came to Canada to work for the Northern Electric Co. He is in charge of the development engineering department at the Northern Electric Co. in Belleville. He is engaged on the acoustical problems involved in the design of public buildings.

Acoustics Ancient Problem

Mr. Tanner stated that the study of architectural acoustics dates to ancient times. He cited the design of the Greek theatres as quite an acoustical achievement. During the last 50 or 60 years, there has been intensive study in this field and nowadays the acoustical characteristics of a building can be predicted quite accurately.

Mr. Tanner stated that the best acoustical design for a building does not usually satisfy the architect. Therefore, one can never achieve a perfect acoustical design. As in many other fields, a compromise must be reached.

Mr. Tanner said that the design of the permanent Stratford Shakespearean Theatre, Stratford, Ont., was begun in December, 1955. The acoustics of the building was one of the matters to which thought was first given. This theatre had developed a type of actor who had proved very popular with the public. It was desired to incorporate in the permanent building many of the features of the temporary tent theatre. However, the permanent building required the installation of a balcony and this, in turn, required that the ceiling should be higher.

The theatre is circular in design with the centre of the stage at the centre of the circle. The design of the rear wall behind the actors was the first problem encountered. This wall was constructed of open surface texture concrete blocks covered by perforated steel painted blue.

DEEP RIVER, ONT.: Formation of a Branch of the E.I.C., to serve Deep River, Ont., was the subject of discussion when Colonel L. F. Grant, field secretary of the E.I.C., and thirty professional engineers of the area gathered at a dinner meeting on November 14 in the Ontario town. Top photo; l. to r. are: standing, H. F. Pragnell, H. Chaput, Col. Grant; J. S. Flavelle, W. G. Allen. Seated: B. P. Scull, W. E. Erlehach and E. A. Moore. Lower photo shows (back) D. M. Hayter, P. G. Ashbaugh, J. B. Gordon, F. A. McIntosh, W. Arasuk; (front row) R. O. Sochaski, C. E. L. Hunt, A. E. Hart, E. W. Fee, and J. G. Melvin.

● BRANCH NEWS

This wall has a zigzag form, and besides having a pleasant appearance, it was found to diffuse sound adequately.

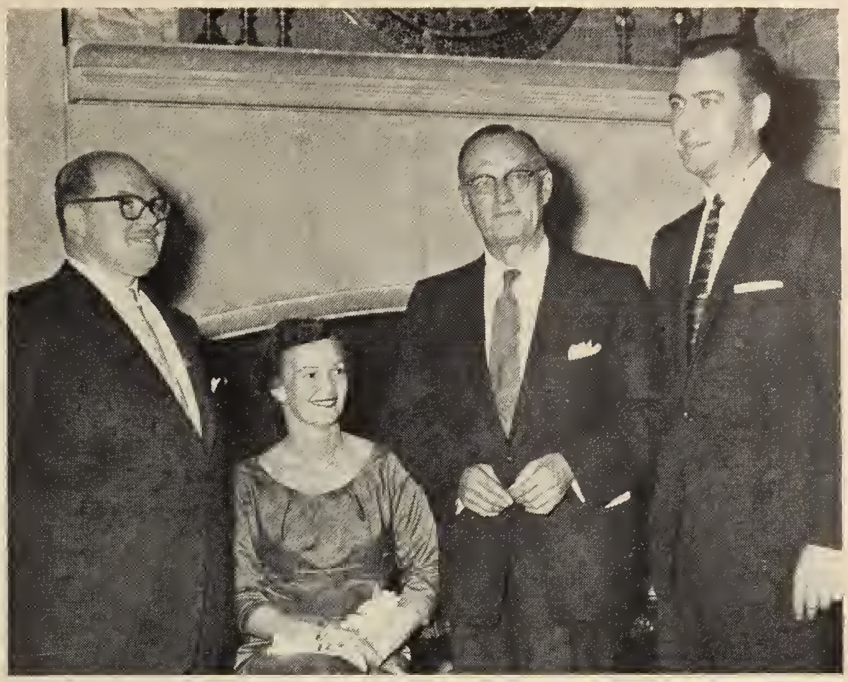
The design of the ceiling was problem No. 2. Due to the layout of the theatre, an actor has his back to part of the audience at times. The problem in designing the ceiling was to secure the reflection of his voice back to the audience behind him with the shortest possible time delay.

As the audience itself is an important factor acoustically, the padded chairs in the theatre were designed to have an absorption factor as near as possible to that of a human being.

Mr. Tanner stated that one of the most difficult problems he faced was the calculation of the volume of the theatre. This was made difficult by its unusual design. The volume is about 300,000 cu. ft. and there are 2200 seats.

It was desired to install an orchestra pit, but instead of placing the orchestra in the usual position between the actors and the audience, it was placed underneath the ceiling behind the stage balcony.

Mr. Tanner stated that the whole building was constructed in 10 months. Measurement of reverberation times using a revolver and tape recorder gave



BORDER CITIES: The President Visits Windsor, Ont. C. M. Anson, president of the E.I.C. was guest speaker and guest of honour at the dinner-dance, October 25, at Essex Golf Club, Windsor, Ont. With Mr. Anson are: (l. to r.), Dr. G. T. Page, deputy general secretary, E.I.C., Mrs. P. N. Brown, president of the Women's Auxiliary to the Institute, Windsor; C. M. Anson; and P. N. Brown, Branch chairman. During the afternoon preceding the dance Mr. Anson and Dr. Page met with the Branch executive for an informal discussion of current Institute activities.

results very close to the design calculations.

After a question and answer period, Mr. Ryan of the I.R.E. thanked the speaker and the meeting adjourned for refreshments.

HAMILTON

W. A. H. Filer, JR.E.I.C., *Sec.-Treas.*

J. R. Currie, M.E.I.C., *Branch News Editor*

THE NOVEMBER MEETING of the Branch was held November 14 at the Westdale Hotel. One hundred and fifty members heard Alfred Hedefine, introduced by W. A. Whetan, deliver a talk on the proposed Eastern and Western Expressway connections for the City of Hamilton. Mr. Hedefine is a partner in the consulting firm of Parsons, Brinckerhoff, Hall, & Macdonald, of New York which firm, together with C. C. Parker & Associates Ltd. of Hamilton, have been engaged by the City of Hamilton to work out the solution to the traffic problems at the eastern and western entrances to the city.

Mr. Hedefine pointed out that the two basic problems in the consideration of this study were, that Hamilton is located on the main traffic routes between Toronto and Buffalo to the east, and Toronto and Detroit to the west, and secondly, that owing to the geography of the area, the traffic in the west must pass through a built up area. Coloured slides were shown illustrating many of the proposals considered.

In connection with the Eastern Expressway connections, Mr. Hedefine proposed the building of what he termed The Red Hill Creek Expressway which would be an internal connection within the city with three interchanges, the principal ones to be Woodward Avenue and Beach Road. This expressway would connect to the present interchange at Burlington Street which is now under construction. Several studies of the proposed interchanges at Beach Road and Burlington Street were presented.

Two or three possible solutions to the Western connections were studied, taking into account the geographical conditions and the future port expansion. Studies were presented showing the two types of road bed proposed, either concrete highway or flexible pavement construction.

In response to questions from the floor, Mr. Hedefine estimated that the Eastern connections might cost approximately $12,000,000.00, the Western connections $18,000,000.00 based on today's costs. As the Burlington Skyway is now under construction, Mr. Hedefine thought that the Eastern connections were the more urgent necessity at the present time.

LETHBRIDGE

R. D. Hall, JR.E.I.C., *Sec.-Treas.*

R. F. Smith, JR.E.I.C., *Branch News Editor*

THE ANNUAL JOINT MEETING of the Association of Professional Engineers and the Lethbridge Branch of the Institute was held October 19. Fifty members attended.

Presided over jointly by Dr. J. C. Sproule, president of the A.P.E.A. and J. R. Milne, chairman of the Lethbridge Branch, E.I.C., among those attending the meeting were J. F. McDougall, Edmonton, registrar for the A.P.E.A.; A. E. McDonald, Edmonton, executive secretary of the A.P.E.A.; Commodore A. C. M. Davy, Vancouver, Western Field Secretary for the E.I.C.; and J. Hanna, Calgary, alderman and engineer.

J. C. Dale Guest Speaker

J. C. Dale, of Edmonton, president and general manager of Canadian Utilities Limited and president of the Canadian Electrical Association, in dealing with the vast potential of Canada's Northland, the problems and necessity of developing it, told the assembly, "Some day we are going to need, and need des-

perately, what the North has to offer." He warned, "We should at least now begin to try to solve the problems which must be solved before we can take what is being held in trust for our use."

Mr. Dale stated that the Yukon consists largely of the North land extension of the Cordilleras and their flanks. The eastern two-thirds of the main land of the North West Territories and much of the Arctic Island are the great metal bearing regions of the North American continent.

The geology of the North promises a wide range of mineral resources. Mr. Dale explained that an assortment has already been located. These included gold, silver, lead, coal, zinc, cadmium, copper, tungsten, platinum, antimony, nickel, radium and asbestos. All of these minerals have been produced. Examples of others known to exist are tin, iron, gypsum, monozite, molybdenum, arsenic, fluorite, and bismuth.

Stumbling Block

The greatest stumbling block to northern development at present, he felt, is the high cost of transportation.

It may be possible, he said, for thermo-electric plants to supply the power necessary to mining industries, due to the existence of oil, gas, and coal for diesel, gas turbine, or steam turbine plants.

Mr. Dale went on to explain that nuclear power plants are frequently considered the answer to the problem of the supply of energy in areas deficient in fuel and hydro power.

Mr. Dale concluded his remarks with the statement that, "the Northland's storehouse of mineral wealth can make an important contribution to the world's energy supply through its supply of uranium and oil. The hydro-electric potential of such areas as the upper waters of the Yukon, the recently announced Wenner-Gren Rocky Mountain trench scheme and the Hamilton River, Grand Falls site, each in the order of 4,000,000 horsepower are available for projects of the magnitude of Kitimat and greater." He stipulated, however, that, "The wealth remains a potential. Exploitation will not be without difficulty, successful development will depend largely on ingenuity, resourcefulness and the technical ability of those accepting the challenge. The challenge offered is of particular interest to engineers.

PETERBOROUGH

D. B. Chase, JR.E.I.C., *Sec.-Treas.*

V. Aare, M.E.I.C., *Publicity Chairman*

FIRST FALL MEETING was held at the Peterborough Armouries on September 25, 1957 with the double purpose of spotlighting engineers and engineering in the army, and combining it with a Ladies' Night program.

A reception in the Officers Mess was followed by a talk on "Engineers and the Army of Today," by Major W. Reid, chief instructor, R.C.E.M.E. School, Kingston, Ont., who demonstrated with the help of statistics the importance of engineers in a modern army designed for atomic warfare.

An inspection of the technical equipment at the armouries preceded a pipe band display and a dismissal parade of the 28th Technical Squadron, R.C.E.M.E. Major T. E. Duffield, officer commanding the Squadron who was host for the evening was responsible for the interesting program.

F. R. Pope and W. C. Durant, presented golf prizes to the winners of the Peterborough district E.I.C., and professional engineers Golf Tournament held in August. The "R. L. Dobbin Trophy", donated by R. L. Dobbin, past president of the E.I.C. was won by V. A. Taylor. A picture recording this event appeared in the December issue of the *Journal*, page 1870.

Greetings were sent to R. L. Dobbin, confined to hospital recovering from a heart attack, and unable to present the trophy as originally planned.

Attended by 70 couples, the evening ended with dancing and lunch provided by Mrs. H. R. Sills, and other members of the E.I.C. ladies' Auxilliary.

The Branch was honoured by the visit on October 21, of President C. M. Anson and General Secretary Dr. L. Austin Wright who spent a busy day in Peterborough.

At a Branch executive meeting which included the Belleville and Huronia Branches 15 items ranging from membership to confederation were discussed.

The president's party then toured the Peterborough works of the Canadian General Electric Company. Guides were W. H. Ackhurst, Branch chairman; H. R. Sills, E.I.C. vice-president; and W. G. Ward, general manager, apparatus department, of C.G.E.

A dinner meeting, attended by 70 members was arranged for the evening. Mr. Anson's talk, "The Engineer in Management," concerned with engineers, industrial organization and labour relations, drew great interest.

The monthly technical meeting of the Branch attended by 50 members took place November 5, 1957.

H. Lloyd Johnston, chief engineer of Du Pont Company of Canada, guest speaker, gave a talk on "Evaluating Performance in an Engineering Department." He outlined the different methods used to evaluate engineering work. The performance cannot be measured with direct production as it is the case with shop labour. Consequently the methods used are often quite complicated. Mr. Johnston reviewed his own method which is a combination of several others commonly used in the industry.

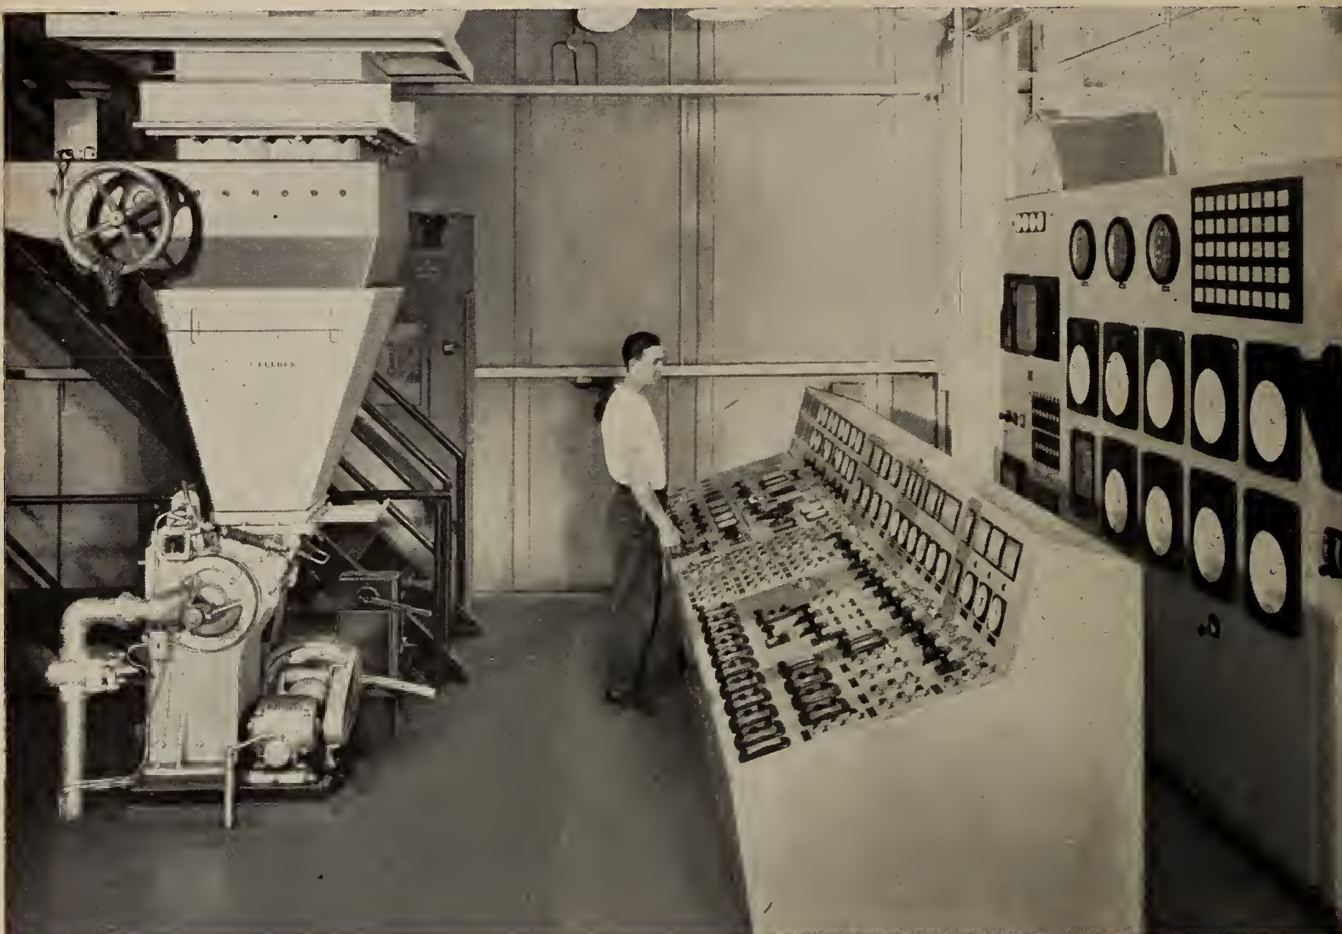
As the majority of engineers resident in Peterborough are associated with large engineering departments, the meeting was of great interest to them.

SASKATCHEWAN

R. Bing-Wo, M.E.I.C., *Sec.-Treas.*

THE SASKATOON SECTION of the Branch held a dinner meeting on November 15. Forty-five members, turned out for the event which included an address read by Dr. J. D. Mollard of J. D. Mollard

BAILEY Mini-line Controls



at Canadian Utilities Limited
Battle River Station near Forestburg, Alta.

- Functional Operation of Alberta's pulverized coal-fired power plant.
- Mini-line Indicators co-ordinate data as it happens; round Recorders give load trend information.
- Automatic Combustion Control, Steam Temperature Control and Feedwater Controls maintain peak performance and efficiency with Reliability and Safety.

Bailey Meter Company Limited

HEAD OFFICE: 1980 CLAREMONT AVE., MONTREAL
ENGINEERS AT YOUR SERVICE FROM COAST TO COAST

and Associates Limited, Regina, on photo interpretation.

Dealing specifically with "Air Surveys Knowledge of Natural Resources," Dr. Millard stressed the urgent need for studies of the resources of the earth to meet the ever increasing demands of world population. Perhaps unique in Canada in his photo interpretation of aerial studies, Dr. Mollard outlined phases of this work which vary from gravel searches in the construction of railroads, highways, and for construction generally to the latest development of petroleum searches. This is done through a study of cracks in the earth's crust.

Professor B. B. Torchinsky expressed the thanks of the Section for the informative talk.

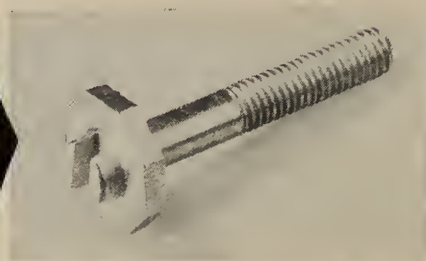
On tour of Canadian General Electric Company Limited's Peterborough, Ont., Works, members of the presidential party observe the rotor spider of one of the generators used in the construction of the St. Lawrence Power project. L. to r. are: E. L. Cavana; Dr. G. T. Page, deputy general secretary of the Institute; H. C. Bates; W. H. Ackhurst, Branch chairman; C. M. Anson, E.I.C. president; W. G. Ward; H. R. Sills, a vice-president of the Institute, and Dr. L. A. Wright, general secretary of the Institute.

Two (or more) for the price of one!

Here's PROOF of savings . . .

by STELCO COLD HEADING

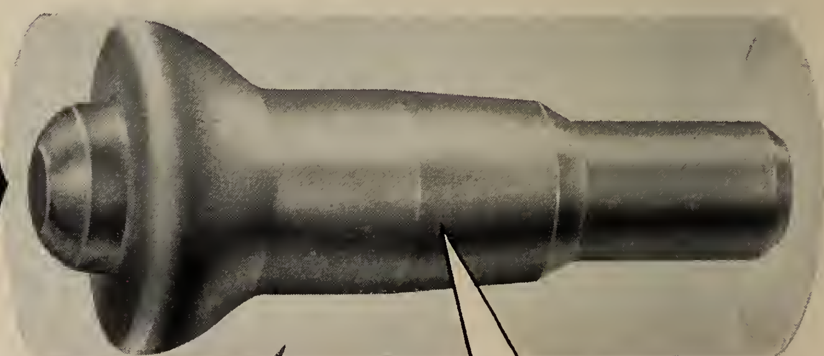
Manufacturer 'A' saves 50% (approx.) on overall cost



Enlarged view of part previously produced by machining.

Part as now produced by STELCO Cold Heading at half the cost.

Manufacturer 'B' uses 63.5% less material



Material blank previously used for machining (actual length 2¼") .550 lbs.

Finished part, cold headed by STELCO. Material used .200 lbs.

Any part that can be machined from rod stock is potentially suited to production by cold heading. This technique offers speed of production* without scrap loss — and therefore low unit costs. Costs remain attractively low even when one or more secondary operations is required. In addition, cold working increases the tensile strength of the metal, and produces an excellent surface finish.

Quality of cold headed products is high, because metals must be resistant to cracking and free from defects to be satisfactorily upset or extruded cold.

Stelco's Engineers can tell you quickly whether *your* fasteners or contoured parts can be made by cold heading. If so, the savings are likely to be considerable. Send in your specifications with a drawing and an idea of the application, and you will receive prompt attention.

Any Stelco Sales Office is at your service.

THE STEEL COMPANY OF CANADA, LIMITED

Chairman W. G. McKay reported on the activities of the provincial Association. His talk included an outline of the proposal that the annual meeting be held February 22, in Saskatoon.

Mr. McKay also announced that one copy of the E.I.C. publication, "Daylight Through the Mountain," had been presented to the City of Saskatoon Public Library on behalf of the Saskatoon Section.

Professor J. B. Mantle, E.I.C. Councillor, provided a report and summarized various items from the minutes of the previous meeting. Part of his remarks were concerned with the announcement that a Canadian Engineering Council has been formed. Service rendered by engineers elected to the Council was outlined.

It was reported that Professional Development Courses are underway in the city. Chairman S. J. Warder is in charge.

YORKTON SECTION

D. Matheson, M.E.I.C., *Sec.-Treas.*

The Yorkton Section of the Saskatchewan Branch E.I.C. was formed on November 8, 1957. Promoted through the efforts of J. B. Sveinbjornson, M.E.I.C., city engineer, a group of engineers assembled at the Yorkton Hotel to consider formation of the group. Those present were: I. B. Sveinbjornson, R. Brown, D. Matheson, W. Riddell, H. Hansen of the Kamsack area, E. Staible, and J. Ayles. Visitors attending this unique meeting were W. G. McKay, of the Saskatoon Section, John Mantle, Councillor, Saskatchewan Branch, A. Sherrett and F. W. Catterall, of the Saskatoon Section.

Chairman of the new section I. B. Sveinbjornson; vice-chairman, R. Brown; D. Matheson, secretary-treasurer.

Addresses were read by W. G. McKay and J. Mantle. A program of activities was discussed and regular meetings planned to occur alternate Friday evenings. Institute-Association affairs were a feature in the discussion.

The meeting adjourned with an expression of appreciation to all who assisted in the formation of the Yorkton Section.

SUDBURY

M. D. Head, M.E.I.C., *Publicity Committee*

The November dinner meeting of the Sudbury branch of the Engineering Institute of Canada was held at the Sudbury Granite Club on November 14. Forty one members and guests attended. R. C. Crawford introduced W. Moore of the Meehanite Metal Corporation who presented an informative film on casting design and foundry practice and discussed these subjects. He stressed the need for close liaison between the design engineer, the pattern maker and the foundryman. Most metals contract on solidification and cooling, resulting in residual casting stresses. Shrink defects may occur if the design does not provide for the location of feeder heads to offset liquid shrinkage. The most common casting defects are "hot spots", or points of interruption of free cooling. It is therefore desirable to strive for a casting design that will permit uniform cooling. When possible, thickness of all sections should be equalised, and abrupt section changes should be avoided.

Mr. Moore continued by referring to the outstanding versatility of iron castings. Compositions and textures can be modified to provide tensile strengths comparable to alloy steels as well as superior machinability and freedom from notch sensitivity. The type of structure required can usually be obtained by suitable choice of graphite content, dependent on the cooling rate of the casting, and the allowable range of cooling rates can be widened by the use of suitable alloys.

In a question period at the end of his talk, W. Moore discussed the production and qualities of nodular irons, the relationship between test section chill values and casting section, and other topics of interest.

Specify... **J-M Asbestos Wick** **J-M Asbestos Rope**

Wherever you need general utility packings that are easy to handle, highly heat resistant

Throughout the iron and steel industries, the list of uses for Johns-Manville Asbestos Wick and Rope is constantly growing. These soft, resilient, heat-resisting materials are widely employed for general packing, gasketing and caulking applications.

In coke ovens, both are used to caulk around the doors to prevent the escape of gases. Asbestos Rope (Style 4200) also serves as expansion joint material in the brickwork.

Only a few of the many applications for Asbestos Wick (Style 4202) can be given here. It seals hot metal in the ingot mould, around the top and between the mould and the stool. It gives protection from burning to water hoses that cool Open Hearth doors. It serves as a seal between the cope and drag on moulding flasks. It is used to wipe excess coating from wires after passing through the galvanizing bath.

Styles 4200 and 4202 are made from pure asbestos fibre carefully controlled for quality at Johns-Manville's own mine and mill (largest in the world). Asbestos Rope is formed by twisting together two or more strands of Wick to obtain the desired thickness. For further information, call your local J-M distributor or write Canadian Johns-Manville, 565 Lakeshore Road E., Port Credit, Ontario. Dept. IA.

members heard Dr. Donald B. Keyes reminisce upon the painful lessons learned in 19 years as a professor in the faculty of chemical engineering, University of Illinois. Dr. Keyes was introduced by Dr. A. E. R. Watson of the Ontario Research Foundation.

For the benefit of those who have gone through the learning process themselves, Dr. Keyes enumerated certain fundamental facts relative to the process of teaching at a university level known to most professors. A professor must of course educate himself, otherwise how would he become a professor? The teacher must reach the individual, and not treat a class of students as a class. This is the costly way to do the best teaching, because it means there must be more good teachers to reach every individual. The large university is, according to Dr. Keyes, an educational foundry or factory; the small liberal arts college is best for carrying out this idea of the teacher reaching every student.

Dr. Keyes emphasized the fact that the success of any student after he leaves college depends on his knowledge and interest in many fields outside the engineering sciences. The major problems which will confront him will never lie in his specialist field.

Some of the difficulties which had to be overcome in developing his course in chemical engineering at the University of Illinois were related by Dr. Keyes.

Dr. Keyes wound up his talk by citing five points on the better utilization of engineers which have been developed by skilled psychologists:

1. The engineer should be treated as an individual and not on a class basis.
2. Pay and fringe benefits should be adequate, but not more than adequate.
3. Men who are scientists and engineers should be given a challenge somewhat beyond the level of their capacity.
4. Scientists and engineers work best when they have the utmost freedom to solve a problem.
5. Scientists and engineers, when they have solved a problem should be rewarded. This is not necessarily a monetary reward.

Arrangements for the meeting were directed by Douglas Abbey.

Metropolitan Government

F. G. Gardiner, chairman of the Toronto Metropolitan Area Council on November 7 addressed 125 members of the E.I.C. and the A.I.E.E., Toronto Branches.

Mr. Gardiner was introduced by Eric Hardy, director of municipal research, who gave a short resume of his career in municipal affairs, clarifying the fact that in the position of chairman of Metro-Toronto Mr. Gardiner was not popularly elected, but elected indirectly.

Mr. Gardiner remarked that his generation had seen more changes technically than any other, and that the phenomenon of suburbanization is one of the more amazing of these changes.

The population of Toronto has remained static at about 700,000, while the suburbs surrounding the city have jumped from 145,000 to 800,000 between 1945 and 1957. At present the Metro form of government might be thought of as "Balkanized", he felt. It consists of 1 city, 4 towns and 5 organized townships, which at times conduct their affairs as independent entities in so far as the good of the whole may be concerned.

At the end of World War II a sudden rush to the country was felt. The problems which developed were a consequence of the desire of the new inhabitants to have all the advantages of the country, as well as urban amenities.

All the services have to be supplied eventually Mr. Gardiner explained. This takes time and inevitably leaves a backlog of unfinished business, which irks the suburbanite. Although the metro services and the suburban services are behind, the backlog has been reduced.

Lessons have been learned. Enactment of legislation accomplishes nothing, but it does provide a vehicle. With the legislation available the next thing to do is take one step at a time, and to work with patience and persistence and perserverance. The progress made in the Metro Toronto plan has been better than expected.

The membership of metro council is equally divided between the city and the suburbs. Mr. Gardiner expressed pleasure that the council have adopted a broader, metro viewpoint. The expenditures made in Metro Toronto are investments to attract industry so that care may be given residential development. There is no difference between operating a business and operating Metro. Any business must attract customers, he felt.

At present the greatest problem is borrowing money, Taxes at present are not sufficient to pay for the services.

Traffic a Problem

Traffic is an urgent problem. Toronto has to move some 450,000 vehicles in the area plus 100,000 from outside the area each day. Statistics were quoted to show the importance of the automobile industry to the Canadian economy. A little reflection will demonstrate its importance, he said. If the automobile were not driven, the economy would suffer. On the other hand, public transport is needed, but quicker and better service will not be obtained by abusing the driver of an automobile. Mr. Gardiner reviewed some attempts which have been made to cope with the public transport problem. The Boston subway system was not correctly situated because no one foresaw the tremendous increase in the use of the automobile. Los Angeles is without public transportation. Parking is therefore very difficult, strangling east-west communication in the city. Chicago's Congress Street combination of rapid transit and freeway look like a promising solution. This is being tried on a small scale in the west end of Metro Toronto. As a consequence of these past errors and future uncertainties, Mr. Gardiner emphasized the need for assurance that the proposed east-west subway will serve the best interests of the community.

As to federal-provincial-municipal relations Mr. Gardiner called for a more equitable share of taxes to be returned to the cities. For example, Toronto metro area provides about 27% of the federal income taxes and succession duties, while Ontario yields about 50% of the total.

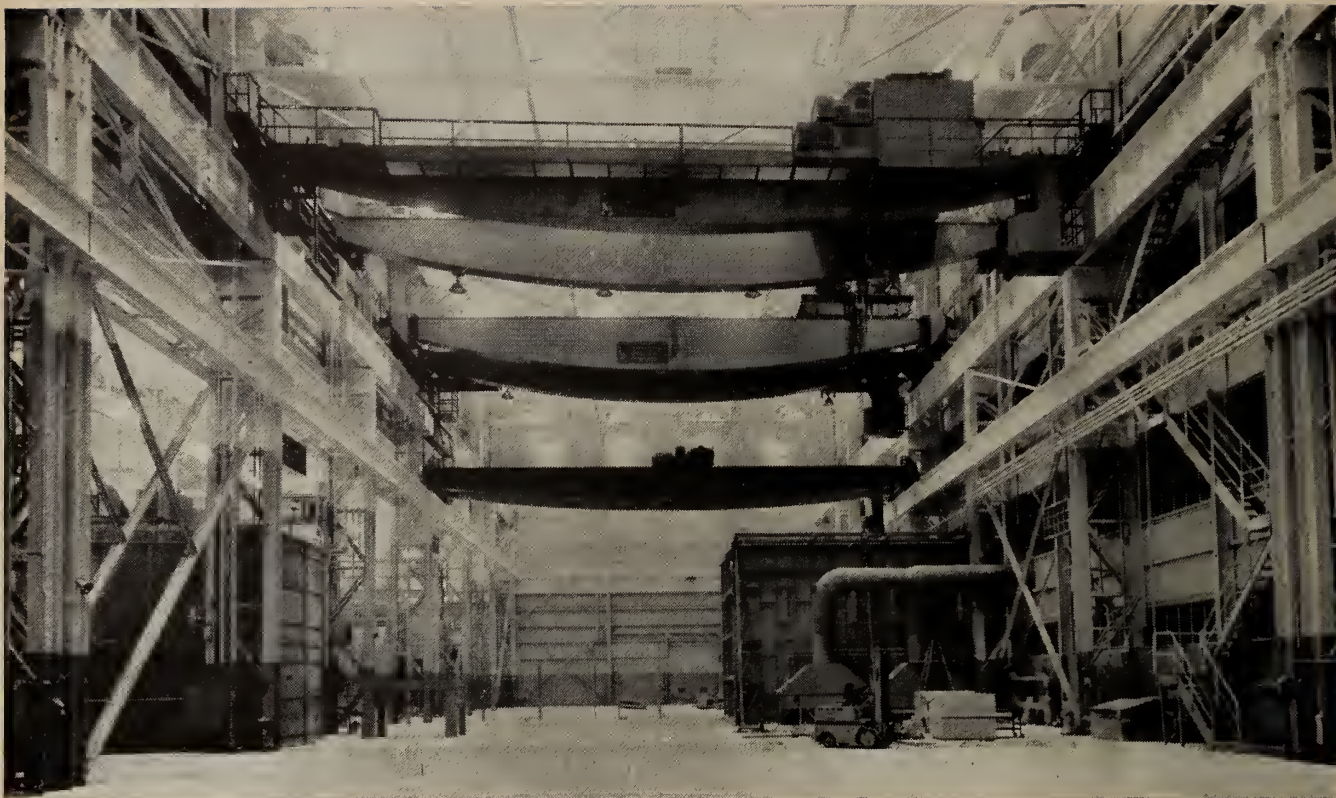
Future Annual Meetings

E.I.C., 1958

Quebec, Chateau Frontenac, May 21, 22, 23

1959

Toronto, Royal York Hotel, June 8, 9, 10



In closing, Mr. Gardiner pointed out that opportunities in Metro Toronto were matchless for those who have the courage and the strength to seize them.

Joint Committee Meeting

Members of the joint committee of the E.I.C. and the Institution of Electrical Engineers met on November 12, 1957 for a visit to the R. L. Hearn Steam-Generating Station of the Ontario Hydro Electric Power Commission.

Initial installation at this station was four 100 MW turbo-alternator units with the last unit commissioned in June 1953.

Four additional 200 MW units are to be added to make an ultimate installed capacity of 1200 MW.

This is the largest steam generating station in Canada. When the four new units are finally commissioned it will rank among the largest in North America.

VANCOUVER

A. D. Cronk, JR.E.I.C., *Secretary*

R. C. McMordie, chief engineer of the B.C. Power Commission addressed the Vancouver Branch of the E.I.C. on the question of "Meeting the Load Growth of the B.C. Power Commission," at a meeting held November 27.

From the initial installed capacity of 4200 k.w. and gross assets totalling $2,400,000 the B.C. Power Commission's plant increased to the present 331,000 k.w. installed generating capacity and 152,000,000 worth of assets since its inception in 1945.

In spite of its growth the B.C. Power Commission is so far still a small enterprise as compared to the eldest provincially owned public power utility. Ontario Hydro has 2 billion dollars worth of assets.

In the early days many small distribution systems in existence were unable to supply satisfactory services at reasonable rates. Such a need still exists today in spite of the spectacular growth of the B.C. Power Commission.

Mr. McMordie said that the operations of the B.C. Power Commission are not subsidized. Sole source of revenue is from the sale of the electrical energy.

He pointed out that through the efforts of the Commission, less densely populated parts of B.C. now have electrical service stimulating industrial and commercial growth.

Illustrating the company's power with a break-down Mr. McMordie said that the Commission's plant consists of six hydro-electric plants, totalling 239,000 kw.; one gas turbine plant, totalling 20,000 kw.; and 23 diesel electric plants, totalling 72,000 kw. Requirements for 1970 are expected to total 850,000 kw.

Mr. McMordie elaborated in considerable detail regarding the Homathko-Chilco scheme capable of providing 30,000 kw. of continuous firm power. If the full yield of Chilco Lake were used, that total would become 1,020,000 kw., he said.

Second well-attended meeting of the season was held recently when K. McKenzie and R. N. McLellan discussed the suspension type of river pipeline crossings.

Mr. McLellan covered very thoroughly the subject of mechanics of suspension while Mr. McKenzie presented the problems of anchorages, foundations and towers. Slides were shown.

WINNIPEG

C. S. Landon, M.E.I.C., *Sec.-Treas.*

Members of the Electrical Section heard an interesting paper entitled "Higher Utilization Voltage" delivered by Mr. S. Collins of the Canadian Westinghouse Co. Ltd. on November 7, 1957.

Mr. Collins stated that "The electric utility industry is faced today with the dilemma of reconciling three basic facts". His paper was built around these headings:

1. One hundred and twenty volt lamps and miscellaneous appliances by the millions sold over the counter every year—maintained by "do-it-yourself" home owners.
2. The 120/240 volt single phase distribution system has inherent economic limitations.
3. Central air conditioners and heat pumps are becoming more popular and their integral hp motors practically demand three phase service.

W. R. C. Taylor, M.E.I.C., presented a most interesting paper to the Branch on the subject of structural precast and prestressed concrete on November 21.

Mr. Taylor dealt at length with the advantages to be derived from the use of precast and prestressed concrete, enumerating some of the disadvantages.

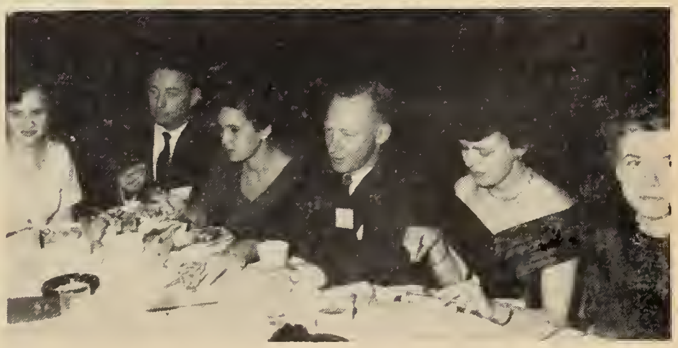
The lecture was illustrated by a series of slides and coloured films in which were shown many of the projects undertaken by Mr. Taylor's company and the differing methods of construction employed was shown.

Electrical Section Dance

The Electrical Section annual dinner and dance was held in the Marlborough Hotel, November 15, 1957. Attendance at this year's function was reduced considerably from previous years. However, the ensuing informality was enjoyed.

The 1957 edition of the dance served as a commemoration of the 50th anniversary of the founding of the Winnipeg Branch of the E.I.C. Dr. C. S. Landon spoke on behalf of the Branch.

The Toronto Branch enjoyed a Ladies' Night on November 15, 1957 at the Boulevard Club, Toronto. Of the 315 assembled members and guests, a few are shown here. At lower left (beginning second from left) are: E. R. Davis, Toronto Branch chairman; Mrs. Roy Brown and Roy Brown, chairman of the Toronto Branch A.I.E.E. The gentleman at the extreme left was not identified.
The photo at lower right shows Gordon Norton, and guests during the dinner.



News of Other Societies

Mining and Metallurgical Congress

The Sixth Commonwealth Mining and Metallurgical Congress, 1957, having taken the form of an extensive tour of Canada, concluded in Halifax in October. The Canadian Institute of Mining and Metallurgy was host for the sixth Congress, whose nearly 500 registered delegates represented 35 countries.

The seventh congress will be in 1961, in South Africa.

Dr. R. W. Diamond, M.E.I.C., of Trail B.C., president of the Sixth Congress, in his official address, discussed generally the non-ferrous metal business, and particularly the shortage of engineers and scientists in the mineral industries.

The C.I.M. reported the Sixth Congress in September, October and November issues of the *Canadian Mining and Metallurgical Bulletin*, publishing Dr. Diamond's address in full.

The tour was reported to be a success. An impressive array of mineral developments was offered for inspection. Various rail and air tours leaving Vancouver September 11, permitted inspection of mining at Trail and Kimberly, coal mining operations in the Crow's Nest Pass area, a chemical metallurgical plant at Fort Saskatchewan and various petrochemical plants in the vicinity of Edmonton. A group inspected shaft sinking practices for potash mining at Unity, Sask. A northern aerial tour visited Kitimat, Whitehorse, Mayo, Dawson, Yellowknife, Uranium City, Flin Flon, Lynn Lake.

From Winnipeg the party proceeded through Steep Rock, Sudbury, Sault Ste. Marie, Blind River, and the gold mining fields of northern Ontario. There were visits to Timmins, Kirkland Lake, Noranda-Rouyn, and the Val d'Or-Malartic areas. In Toronto, Hamilton and Niagara Falls the industrial areas of Ontario were seen.

The delegates were entertained in Ottawa, Montreal and Quebec City. They toured the St. Lawrence Seaway, and travelled in parties to Asbestos, Thetford Mines, and Knob Lake. From Moncton, one group flew to Newfoundland to study operations at Wabana and Buchans. Mining developments in New Brunswick were observed, and mining and industrial plants of the Sydney and Halifax area.

To commemorate the Sixth Congress a series of volumes devoted to various phases of the exploration, development, production, and beneficiation of Canadian mineral resources have been prepared by the Technical Division of C.I.M. Information about these volumes appears on Page 536 of the *Canadian Mining and Metallurgical Bulletin*, September, 1957.

Housing Conference

A two-day top level conference held November 14-15, 1957 at Ottawa and sponsored by the Canadian Construction Association discussed ways and means of increasing the opportunities of home ownership among those earning less than $5000 a year.

Honourable Howard Green, Federal Minister of Public Works, guest speaker, said that the special interest of the Federal Government in low-cost homes was the reason for the introduction of the $150 million agency loan program last August.

From statements made, and conclusions reached at the conference it was concluded the present main housing lack was in the lower cost field.

The present relative shortage of investment funds was such that in general the easing of down payments and other financial arrangements making more people eligible for N.H.A. loans would not lead to an appreciable increase in the number of units built.

Unless public funds in some form are again made available to supplement private resources it is indicated that housing starts in 1958 will be less than achieved in 1957.

The construction industry is technically capable of producing low-cost homes. The main reasons why more low-cost homes are not being built are largely factors beyond the industry's control—marketability of low-cost units and availability of serviced land, etc.

Delegates were of the opinion that the land cost and availability factors were in general more of a problem than actual construction costs. Land prices for N.H.A. housing doubled, 1951-56, whereas the construction cost per square foot increased by only a fifth. In most large cities the relative shortage of serviced land and the problems of "urban sprawl" meant that greater emphasis would have to be given to apartment blocks, row housing and semi-detached houses than had been the case in recent years.

One of the main problems in connection with the servicing of land is the provision of feeder watermains and trunk sewers. A resolution was adopted advocating that the National Housing Act be amended so as to provide for the financing of these facilities in lower cost housing areas and make them available to builders.

The Canadian Construction Association was requested to sponsor another similar conference next spring.

CALENDAR

American Concrete Institute

The Annual Convention of the American Concrete Institute will be held February 24-27, 1958 at the Morrison Hotel, Chicago. The fifty-fourth meeting of the A.C.I. will encompass many varied discussions on the technical aspects of concrete and concrete construction.

Address of the Institute is: P.O. Box 4754, Redford Station, Detroit 19, Michigan.

Welding Conference

The Fourth Annual Midwest Welding Conference will be held in Chicago on January 29 and 30, 1958. The conference will be held in the Illinois Technical Chemistry Building, 3255 Dearborn Street, Chicago.

Inquiries concerning the conference should be sent to the conference chairamn, Harry Schwartzbart, Supervisor of Welding Research, Armour Research Foundation, 10 W. 35th St., Chicago, 16.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

AIRCRAFT HYDRAULICS: V. 2 COMPONENT DESIGN

The second of a series of textbooks on aircraft hydraulics sponsored by the Royal Aeronautical Society, this volume deals with component design including seals, pumps and motors, jacks, selectors, valves, piping and servo-controls. The authors of the different chapters are all experts in their own fields. There are many illustrations.

The first volume covered hydraulic systems, fluids, hydraulic theory, general system problems and circuits, and system installation and testing. The third volume will cover the design of landing gear. (Ed. by H. G. Conway. Toronto, Ryerson, 1957. 198p., $9.00.)

*BANDSTRASSEN IM BAUBETRIEB

Conveyor belt lines in the construction industry are treated in this practical text book. Part 1 describes the equipment in detail and covers its selection and use, including supporting structures, drives, and auxiliary equipment. Part 2 deals with the cost aspects; dimensioning the plant, cost of equipment, cost of operation; and maintenance costs. The information given is based on extensive practical experience. (H. Eckert. Berlin, Springer-Verlag, 1957. 201p., DM 37.50).

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

LIBRARY HOURS

Monday to Friday

9 a.m. — 5 p.m.

Saturday

9 a.m. — 12 noon

*CATALYSIS IN PRACTICE

Seven papers by practicing engineers for practicing engineers make up this small volume. Presented in simple, direct language the papers describe how to select a suitable catalyst for a proposed process, the commercial preparation of industrial catalysts, fixed bed moving bed catalyst systems, the economics of catalyst use, operating problems, and trends and prospects in catalysis. A handy guide for anyone concerned with the chemical process industries. The papers were originally presented at a conference sponsored by the American Institute of Chemical Engineers, Philadelphia-Wilmington Section and the University of Pennsylvania School of Chemical Engineering. (C. H. Collier. New York, Reinhold, 1957. 153p., $3.95)

THE EARTH CHANGERS

The story of the United States heavy construction industry in the twentieth century, from the building of the Hoover Dam to the present, this book is concerned chiefly with the Utah Construction Company, Morrison-Knudsen, Bechtel, Kaiser, and Perini-Walsh.

It is an exciting history of the building of dams, bridges, tunnels and roads, and of the men who built them, both in the United States and abroad. (N. C. Wilson and F. J. Taylor. Toronto, Doubleday, 1957. 312p., $5.75.)

EFFECTIVE INDUSTRIAL MANAGEMENT

Intended to be used as a textbook in an introductory course in industrial engineering and management, this book not only describes the functions and duties of management, but also emphasizes the basic procedures involved. The author has tried to show the advantages and limitations of current managerial techniques, policies and practices, and how these may be changed when necessary.

Among the topics covered are: the growth of modern management; accounting fundamentals, business finance, etc.; plant location; product development; methods analysis and work measurement; plant layout; materials handling; purchasing and inventory; production and quality control; and labour.

Bibliographies are included at the end of each chapter of this book which should prove useful both to students and to those wishing to obtain a general picture of the field of management. (J. L. Lundy. Toronto, Brett-Macmillan, 1957. 588p., $6.90.)

*ENGINEERING METALLURGY

This is a concise, up-to-date, and authoritative presentation of the essentials of the subject, useful to all engineers, student and practicing. Produced by a group of 40 professors actually engaged in teaching metallurgy, the book deals in chapters 1 through 6 with general principles as related to engineering, 7 through 10 with nonferrous metals, and 11 through 20 with iron and steel. Machinability, corrosion, and the effects of temperature are covered in the last three chapters. The text is liberally illustrated with photographs and drawings, and sets of exercises and problems are provided at the end of each chapter. (By the Committee on Metallurgy. Toronto, Pitman, 1957. 516p., $7.50.)

ENGINEERING SURVEYS: ELEMENTARY
ENGINEERING SURVEYS: ELEMENTARY AND APPLIED

The first of these volume is intended for an elementary course in surveying and the second, combined, volume for more advanced students.

The first eighteen chapters are included in both books and cover measurement of distance; compass surveying; leveling; the transit; instruments; observations for meridian; stadia surveying; topography; triangulation; land, area, route and city surveys, and the organization of surveys.

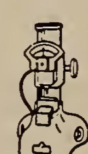
Part two, found only in the second volume deals with such topics as horizontal and vertical control; engineering astronomy; topography; photogrammetry; map projection; hydrographic surveying; legal principles of boundary surveying; city planning, underground and construction surveys.

Both volumes contain mathematical and other tables. These are, of course, well-known texts, this being a 1955 print-

Full complement of small diameter rollers insures maximum number of contact lines in load zone for high radial capacity in minimum space.

Mounted without races between hardened shaft and hardened housing (RC-60 recommended), Torrington Needle Rollers allow largest possible shaft diameters.

Carefully hardened, ground and lapped high carbon chrome steel makes each Torrington Needle Roller a precision part for long life performance.



Close tolerances are assured by stringent quality controls. Standard OD tolerance is .0002", but Torrington Needle Rollers can be supplied with tolerance of .00005". Tolerance on length depends on end shape.

Fine finish reduces friction to a minimum. Torrington Needle Rollers are usually polished to 4-6 rms, but finishes as fine as 1-3 are available on special order.

Now you can get highest capacity at lowest cost with Torrington Needle Rollers

A hardened shaft, a hardened housing, and precision Torrington Needle Rollers provide the most economical, highest capacity antifriction assembly you can obtain.

Six roller end shapes permit design flexibility whether the requirement be maximum effective roller length, proper fillet clearances or greater lip retainment. Torrington Needle Rollers are available in a complete line meeting SAE and AFBMA specifications. Torrington standards for material, heat treat, tolerance and finish of Needle Rollers are the highest in the industry.

Operating results with Needle Rollers depend on careful design of mating parts. Torrington's Engineering Department, with extensive experience in Needle Roller application, will be glad to give you technical advice on your needs. *The Torrington Company Limited,* 925 Millwood Road, Toronto 17, Ont.

ing of the latest edition. (Harry Rubey, G. E. Lommel and M. W. Todd. Toronto, Brett-Macmillan, 1955. 2vols $5.00 and $7.00.)

ENGINEERING THERMODYNAMICS, WORK AND HEAT TRANSFER

Intended for students up to the standard of a British honours degree this volume covers the fundamentals of applied thermodynamics.

The first part of the book deals with the principles of thermodynamics without referring to the behaviour of particular substances. Part 2 deals with the properties of fluids, and applies the principles already discussed to open and closed systems. This section also covers gas and vapour mixtures and combustion processes. The third and fourth parts cover work and heat transfer. Worked examples and problems are included and there is a list of references for further study.

The authors are lecturers in mechanical engineering at the University of Bristol. (G. F. C. Rogers and Y. R. Mayhew, Toronto, Longmans Green, 1957. 619p., $9.00.)

FRANCE EXPORTATION: FRENCH DIRECTORY FOR INTERNATIONAL TRADE

A trade directory with a difference, this volume, the French "Annuaire Bleu", not only lists manufacturers and producers of various products, but also gives a brief description of each industry and locates the main centres of the industry on a map of France.

The industries covered are: food and agriculture; wine; construction; pottery and glass; leather; textiles; clothing; chemical and pharmaceutical; mining; iron and steel; mechanical engineering; precision and optical instruments; electrical; automobile; aeronautical; paper; perfume; jewellery. There are also sections on insurance and banking; travel and the tourist trade, and foreign trade.

Invaluable for those interested in purchasing anything from France. (Paris, Centre d'Expansion Francaise, 1957. 623p.)

FRICTION, LUBRICANTS AND CUTTING FLUIDS

A chapter reprinted from Modern Workshop Technology, this useful monograph covers the theory of lubrication; types of lubricants, their care, handling and properties; lubrication of machine tools; and cutting fluids. There is a list of references for further reading. (I. S. Morton and A. L. H. Perry. London, Cleaver-Hume Press, 1957. 41p., 3/6.)

HIGH FIDELITY SIMPLIFIED, 3RD ED.

Written primarily for the amateur enthusiast this volume contains all the information required for the installation and operation of a high fidelity set. The theory behind high fidelity reproduction is explained, and the various parts of the set are covered, including the loudspeaker, the amplifier, the record player and the tuner. Tape recorders are also discussed.

The text of this third edition has been revised, mention of older models removed, and new ones included. (H. D. Weiler. New York, Rider, Toronto, Pointon, 1957. 202p., $2.50.)

IDEAS, INVENTIONS AND PATENTS; HOW TO DEVELOP AND PROTECT THEM

The author's main purpose in writing this book was to help engineers, scientists and management to obtain a better understanding of patents. He points out that much information on current technological developments can be gained from patent literature, and that more use could be made of it.

He explains the principles underlying patents in all fields of engineering, outlining exactly what patents are and their purpose, and what inventions are patentable. He discusses the records which should be kept for patent protection, and the important role played by the patent attorney. Also covered are the steps which must be taken before a patent can be granted; the procedure followed by the patent office; interference; licenses, assignments and shop-rights; understanding patent claims and infringements; trade secrets and confidential disclosures; designs, copyrights and trademarks. The Appendix includes representative forms of an approved engineers' agreement to assign inventions, a form of assignment and copies of the necessary formal papers.

The author, a graduate electrical engineer, is a practicing patent attorney. (R. A. Buckles. New York, Wiley, 1957. 270p., $5.95.)

METALS AND MEN: THE STORY OF CANADIAN MINING

Already well-known for his books about Canada, Mr. LeBourdais here turns his attention to the fascinating and often exciting story of Canadian mining.

As the author points out in his foreword "Canadian mining has advanced across the continent against the sun in a series of booms." He begins his story with the gold rush into the Cariboo a hundred years ago, and follows the eastward course of mining development to the latest expansion into New Quebec and Labrador.

All the names which have meant so much in Canada's development are here, the Klondike, Sudbury, Cobalt, Porcupine, Kirkland Lake, Rouyn, Noranda, Haileybury, Falconbridge, Asbestos, Steep Rock, Knob Lake and Elorado. The emphasis throughout is on discovery and development, on the men who did the prospecting and on those who had the vision, and the money, to bring the finds into production. There are many photographs in black and white and colour, as well as some excellent maps.

Mr. LeBourdais has spent many years collecting the material for this book, and has himself visited many of the mines of which he writes. (D. M. LeBourdais. Toronto, McClelland and Stewart, 1957. 416p., $8.50.)

MINERALS: CANADA AND THE WORLD

The remarkable growth of the Canadian mineral industry in the last thirty years is shown in this publication which deals with some thirty-five metals, non-metals and mineral fuels produced in this country. During this period the value of the Canadian mineral production rose from $240 million to over $2 billion.

For each mineral information is given on Canadian and world production, Canadian exports and the imports of other countries. The material is presented in the form of Canadian and world maps, graphs and charts, and the location of Canadian producers and potential production is shown.

The maps, charts, etc. have been prepared from official statistics which are reproduced in a supplementary volume. (Canada, Dept. of Mines and Technical Surveys. Ottawa, Queen's Printer, 1957. 2 vols., spiral binding, $1.00. Mines Branch report No. 860.)

NATIONAL DIRECTORY OF THE CANADIAN PULP AND PAPER INDUSTRIES

The main part of this Directory is devoted to a listing of Canadian pulp and paper companies arranged by province. The information given for each company includes: location of head office and mills; rail and steamship connections; officers; chief personnel; timber supply; production; specialties; equipment; power supply.

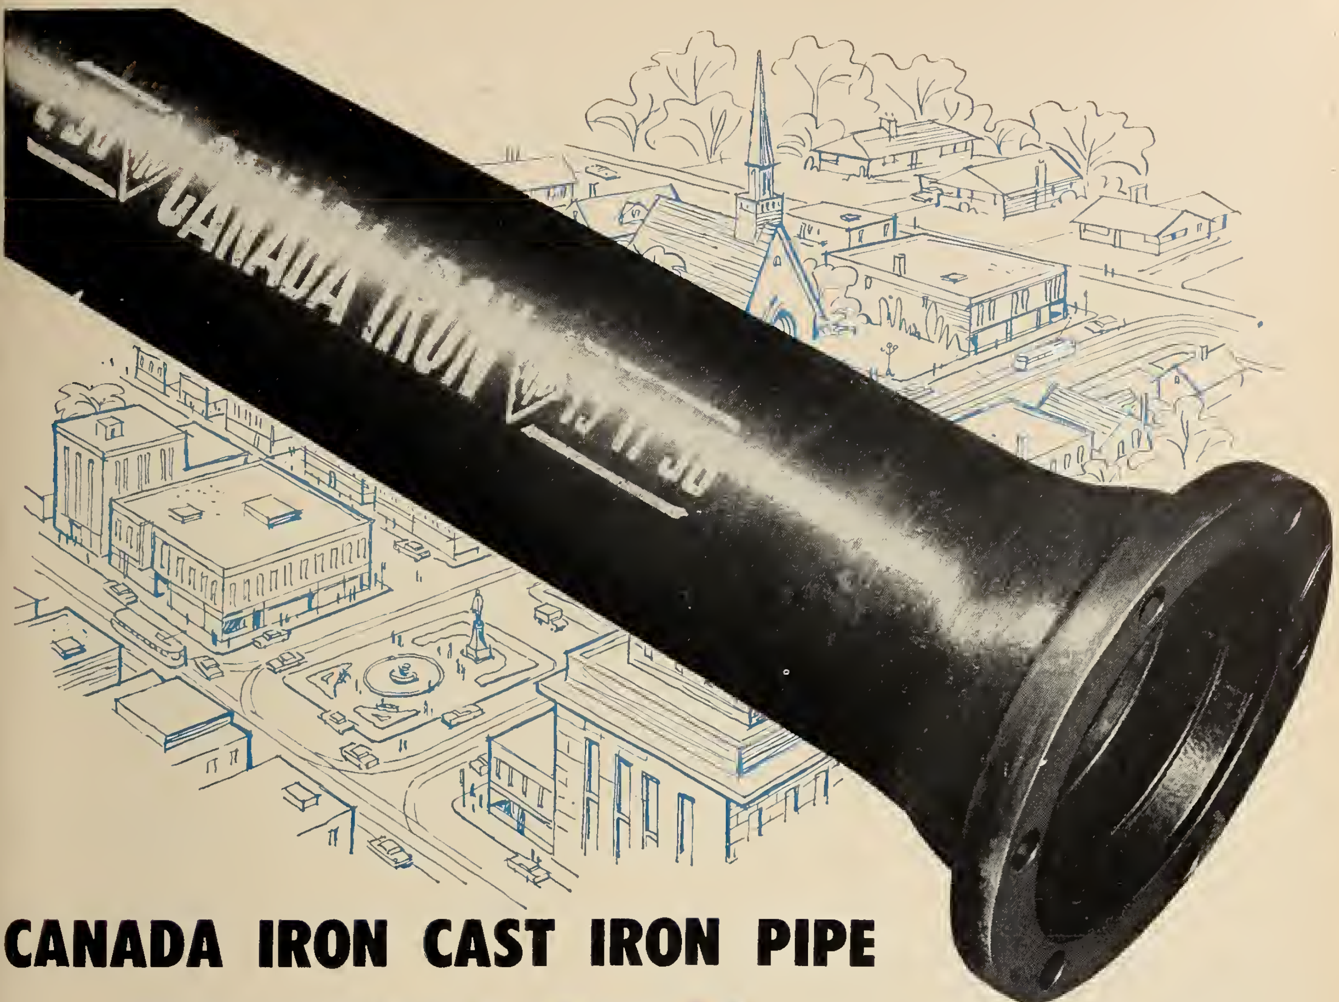
Preliminary figures are given for 1956 production and exports, and there are surveys of the pulp and paper, paper box and bag and roofing paper industries in 1955. There are lists of converters of paper, pulp and paper distributors, paper merchants, pulp and paper mills classified by product; manufacturers of paper products, and organizations connected with the industry.

This is a most useful publication. (Ed. by J. N. Stephenson. Gardenvale, National Business Publications, 1957. 534p., $5.00.)

PROFILE OF THE ENGINEER

The first in a series of projected reports of a "Comprehensive Study of Research Relating to the Engineer" undertaken by Deutsch and Shea, the purpose of this Profile is to examine the personality traits, interests, intelligence and abilities of engineers. The report is based on various earlier studies made of engineers and their profession, and these are listed in the bibliographies for those who wish to pursue the analysis further, or from a different angle.

The general conclusion, our readers will be pleased to learn, is that engineers are above-average in intelligence, and take an all-absorbing interest in their work. They tend, however, to have rather narrow fields of interest, and to be tense and unstable. This we are sure,



CANADA IRON CAST IRON PIPE

THE LOGICAL CHOICE *for municipalities*

First consider the immediate savings:

FAST DELIVERY:
No hold-ups at commencement or during the project.

TWO PLANTS TO SERVE YOU:
Toronto and Trois Rivières.

DELIVERY FROM STOCK:
Large supplies of pipe—and literally thousands of standard fittings (from 4″ to 24″) are stocked at these plants.

PRE-TESTED PIPE:
Every length of Canada Iron's Cast Iron Pipe is inspected and tested before shipping.

EASY TO LAY:
Canada Iron's Cast Iron Pipe with either the Mechanical Joint or the new Tyton Joint is simple and easy to lay. They cut installation time to a minimum.

EXTRA SERVICE:
Canada Iron's Pipe Service Manager is ready to assist municipalities and contractors with any installation problems.

Then consider these long term savings:

STRENGTH:
Canada Iron's Cast Iron Pipe is designed to take the loads of modern traffic, to resist heavy fill, soil disturbances and abnormal pressures.

LONG LIFE:
Cast Iron Pipe has proved conclusively, that it will last indefinitely. The oldest cast iron water main in North America, laid in Montreal in 1816, is still in service today.

TROUBLE FREE SERVICE:
Because of its strength, its long life and its flexible, bottle-tight joints, Canada Iron's Cast Iron Pipe needs no maintenance.

That is why more and more Waterworks Engineers agree that Canada Iron's Cast Iron Pipe is the *only logical choice.*

• LIBRARY NOTES

will be a hotly debated point, as will be many of the other findings.

The series was undertaken because of the growing importance of engineering in today's society, and the need to know something of the men who design and run the machines which form the basis of that society.

This should prove a most popular report. (Deutsch and Shea. New York, Industrial Relations News, 1957. 3 parts.)

THE PROTEROZOIC IN CANADA

Proterozoic rocks include those Precambrian which are the least deformed and metamorphosed, and the Proterozoic time produced in Canada much of great interest to geologists and of great economic importance. It is probable that at that period were formed the iron deposits of the Lake Superior district, the Michigan copper deposits, the Sudbury nickel-copper-platinum deposits, Cobalt silver and the uranium deposits, of the Canadian Shield. This period was also responsible for the Sullivan zinc-lead-silver deposits.

Many of these areas have been studied intensively, and the findings are summarized in this volume.

The first papers cover the Proterozoic in Canada, and its dating, and the forms of life found in that era. The second and largest group of papers deals with the Proterozoic rocks in the Canadian Shield, each paper covering one particular area. The remaining papers discuss the various other areas in Canada where these rocks are found.

This symposium and an earlier one on the Grenville Problem present the views of active workers in the Precambrian. (Ed. by J. E. Gill. Toronto, University Press, 1957. 191p., $5.95. Royal Society of Canada Special Publication no. 2.)

*ROADS, RAILS AND WATERWAYS

This non-technical account of the activities of the Engineer Department of the United States War Department in the exploration of the country and in the construction of roads, waterways, lighthouses and other public works from 1815 to the Civil War will interest students of economic and military history and the history of transportation. Extensive bibliographical references are included. (F. G. Hill. Norman, University of Oklahoma Press, Toronto, Burns and MacEachran, 1957. 248p., $5.25.)

*ROUTE-MAPPING AND POSITION-LOCATING IN UNEXPLORED REGIONS

Ground route-mapping as distinguished from that making full use of photogrammetry is the main subject of this book. The two principle parts of the book are given over to a method of route-mapping and to position-finding and altitude measurements. The third part takes account of photography as an aid in route-mapping and topographical surveys. Each part has its own author, who is an expert in his field. (W. Filchner, E. Przybyllok and T. Hagen. New York, Academic Press, 1957. 288p., $9.00.)

*SIXTH SYMPOSIUM (INTERNATIONAL) ON COMBUSTION

This sixth symposium was held at Yale University in August 1956, and was sponsored by the Combustion Institute. The principle subjects covered in this collection of 129 papers are: structure and propagation of laminar flames; structure and properties of turbulent flames; high speed reactions; flame stabilization in fast streams; instability in combustion chambers; combustion of solid fuels; combustion of explosives and solid propellants; evaporation and combustion of droplets and sprays; experimental and analytical techniques; and applications. The volume as a whole is an important source of information on recent advances in the combustion field. (New York, Reinhold, 1957. 943p., $28.00.)

SOLAR CONTROL AND SHADING DEVICES

Although there is a tendency to think that solar control is a problem which has only to be faced in hot climates, this is incorrect for, as the authors point out,

Sheldon

"PEASE-ANTHONY"

P. A. VENTURI SCRUBBERS

Air Pollution Problems are present in many phases of chemical and industrial processes.

P. A. Venturi Scrubbers provide the solution for high efficiency collection of sub-micron particles at low capital cost.

Removal efficiencies of up to 99+% have been obtained on many difficult gas cleaning problems.

Special materials are available for corrosive applications.

Gas temperatures in the range of 1800° F. also may be successfully cleaned of fume and dust by application of Venturi Scrubber equipment.

For information on P. A. Venturi Scrubbers as applied to your air pollution problems call our nearest office.

MEMBER CANADIAN BOILER SOCIETY

TORONTO MONTREAL OTTAWA LONDON HAMILTON

CANADIAN LICENSEE FOR PEASE ANTHONY EQUIPMENT the real idea behind solar control is to let the sun's heat energy into buildings in cool weather, and exclude it in hot.

The authors, who are at present teaching and doing research at Princeton School of Architecture, have had much experience in designing apartment houses, hotels, factories, exhibition buildings, etc.

The first part of the book deals with the role of shading devices as architectural elements and the technical considerations in the design of solar protection, including such factors as climate, the movement of the earth, solar and standard time, shading effects of trees, buildings, etc.

The practical application of shading methods is discussed, and a final section contains over one hundred examples of buildings by many different architects in all parts of the world where solar control devices have been incorporated. The photographs, as might be expected, are excellent, and there is a list of references for further reading. (A. and V. G. Olgyay. Princeton, University Press, Toronto, Saunders, 1957. 201p., $14.40.)

THE STATESMAN'S YEAR-BOOK, 1957

This "statistical and historical annual of the states of the world" contains a wealth of information, obtained in many cases from official sources. The first section deals with the United Nations and other international organizations.

Other sections cover the British Commonwealth, country by country, the United States, and other countries of the world. The information given for each country includes type of government, constitution, area, population, religion, education, justice, social welfare, finance, national defence, commerce, communications, national income, banking, and diplomatic representatives. For each country a list of reference books is given.

This is a most useful volume. Most of the information it contains is correct to the end of 1956, although some of the statistics are for 1955 or earlier. (Ed. by S. H. Steinberg. Toronto, Macmillan, 1957. 1638p., $8.50.)

STEREOPHONIC SOUND

All hi-fi enthusiasts, and those interested in the mechanics behind the vast quantities of sound heard in movie houses these days, will welcome the advent of this book which explains the theory of stereophonic sound, which, incidentally, was first demonstrated in 1881.

It covers such systems as binaural, two and three-channel stereophonic, stereosonic, and coded-stereophonic and also their use with radio, disc recordings, tape, etc. Also discussed are the systems available, and those likely to become available. (N. H. Crowhurst. New York, Rider, Toronto, Pointon, 1957. 118p., $2.25.)

• LIBRARY NOTES

***SYMPOSIUM ON FULL SCALE TESTS ON HOUSE STRUCTURES**

The included papers cover tests on houses built of plywood stressed-cover panels, on prefabricated buildings, and on pre-cast multi-story flat construction. There is also a report on a structural test of a house under simulated wind and snow loads. (Philadelphia, American Society for Testing Materials, 1957. 60p., $2.50. (ASTM stp. no. 210.))

SYMPOSIUM ON INTERNAL COMBUSTION ENGINE VALVES

The fourteen papers in this volume are all by members of the firm of Thompson Products Inc., and were originally read at technical meetings or appeared in industrial publications, and are now unavailable elsewhere. The papers deal with the internal combustion engine valve, and all those interested in the subject will appreciate the generosity of the firm in making these papers available. (Cleveland, Thompson Products, Inc., 1957. 216p.)

***SYMOPSIUM ON RADIATION EFFECTS ON MATERIALS, V.1**

The first of a series of symposiums on this subject, sponsored jointly by ASTM and the Atomic Industrial Forum. The sixteen papers included deal with theory, radiation facilities and mechanics of testing, and with experimental work both on fuel and graphite materials and structural materials. Radiation effects on plastics, organic materials, plain-carbon steels, and copper-iron alloys are discussed. (Philadelphia, American Society for Testing Materials, 1957. 190p., $4.75. (ASTM stp. no. 208.))

***SYMPOSIUM ON: SEISMIC AND SHOCK LOADING, GLUED, LAMINATED AND OTHER CONSTRUCTIONS**

Three of the papers in this combined publication deal with building design for lateral forces and with the results of laboratory tests on full-size wooden structural elements particularly with reference to lateral shock resistance. The other five papers report on the development of glued-laminated, stressed-skin, and sandwich constructions with wood as the material. Technical information is also included on factors affecting the characteristics and properties of wood. (Philadelphia, American Society for Testing Materials, 1957. 85p., $2.75. (ASTM stp. no. 209.))

***SYMPOSIUM ON STRUCTURAL SANDWICH CONSTRUCTIONS, 1956**

This symposium includes two papers on adhesive bonds, including metal-to-metal and metal-to-resin adhesion, and two papers on high-temperature testing. Other papers deal with sandwich in the design of helicopters, materials for architectural panels, non-destructive testing of sandwich structures, and shear strength of aluminum honeycomb. (Philadelphia, American Society for Testing Materials, 1957. 103p., $2.75. (ASTM stp. no. 201.))

***SYMPOSIUM ON VAPOR PHASE OXIDATION OF GASOLINE, 1956**

Four papers as follows: Fuel factors influencing deposits in intake portio nof fuel systems of gasoline engines; Induction system gum: Engine versus bench test; Test method for studying the effect of fuel composition upon intake valve deposit forming characteristics; Effects of inhibition and envronment on the induction system oxidation of gasoline. (Philadelphia, American Society for Testing Materials, 1957. 68p., $2.50. (A.S.T.M. stp. no. 202))

THERMODYNAMICS OF HEAT-POWER SYSTEMS

The author has arranged this treatment of thermodynamics in the way in which he has taught the subject for the last twenty years, the basic concept being that of thermodynamics as the study of energy from source to utilization. He has emphasized general ideas rather than technical explanations, mathematical derivations, etc., which he believes are better covered in the classroom. He has included references for further reading, both for those wishing to examine the subject from a different point of view, and for those wishing to go more deeply into any topic.

The first two sections of the book discuss energy sources, and the major forms of stored energy—atomic, molecular and mechanical. Following this is a discussion of the liberation of energy, and a detailed coverage of energy in transition, that is, heat and work. The next three chapters present energy equations for nonflow and flow processes, and flow-to-nonflow processes. The final sections deal with the transportation of energy in gases, vapours and gas-vapour mixtures, and with its utilization in the different heat-power systems. (F. W. Hutchinson. Cambridge, Addison-Wesley, Toronto, Allen, 1957. 490 p. $8.50.)

*TELECOMMUNICATIONS

The main emphasis in this comprehensive, introductory textbook is on the basic principles of communication engineering in modern practice, and although intended for engineering students, the text should be of interest to practising engineers who are interested in the field.

Following a brief historical introduction, the author covers such topics as networks, circuit, transmission lines, attenuators and filters, valves, amplifiers, modulation, microphones, telephony, telegraphy, radio wave propagation, etc. References for further reading and problems taken from University of London and other examination papers are included.

The author is a lecturer in electrical engineering at the University of London. (W. Fraser. London, MacDonald, 1957. 772p., £3.5.0.)

SOVIET EDUCATION FOR SCIENCE AND TECHNOLOGY

With the interest in Soviet technology and education at an all-time high, the publication of this report will be of interest to many people. The book is the outcome of a project begun by the M.I.T. Center for International Studies in 1953 as part of its study of Soviet society. The author is on the staff of the Center.

In this book Mr. Korol examines in a general outline the Soviet educational system from elementary to graduate schools, and then considers in greater detail training in physics and mechanical engineering. Some references are made to the American system, but this is not intended to be a comparative study.

In the first chapter the general organization of education through the secondary level is outlined, and the alternatives to academic training mentioned. The next two chapters discuss the ten-year school, the equivalent of elementary and high school, its curriculum, intruction, textbooks and examinations. This is followed by a chapter on technical schools.

The greater part of the book is devoted to higher education, at both the undergraduate and graduate levels, with the curricula in physics and a typical major in mechanical engineering given in full, compared with their nearest equivalents at M.I.T.

In a final chapter the author presents his own opinions of Soviet education and American education. This is a most timely and thought-provoking report. (A. G. Korol. New York, Wiley, 1957. 513p., $8.50.)

URANIUM IN SOUTH AFRICA 1946-1956

This is the record of the development of the production of uranium in South Africa. It is the story of an industry which has had a phenomenal growth from its beginnings in 1946 to the present when some twenty million tons of gold ore residues are processed each year.

The Symposium at which these thirty papers were presented was organized by five South African Societies: South African Institute of Mining and Metallurgy; South African Chemical Institute; Institution of Chemical Engineers, South African Branch; Geological Society of South Africa; South African Institution of Mechanical Engineers. The societies are to be congratulated on organizing and publishing this Symposium.

There is an historical review of the developments leading to the construction of plants for the recovery of uranium from ore residues, and other topics covered include the occurrence and origin of gold and radio-active minerals in the Witwatersrand System; the determination of uranium; design and construction of uranium plants; leaching and ion exchange processes used; and other subjects related to the recovery of uranium.

Canada, the United States, and the United Kingdom all assisted in the development of this industry, although the majority of technical personnel were South Africans. Actual production began in 1953. (Johannesburg, South African Institute of Mechanical Engineers, 1957. 2 vols., $20.00.)

URBAN MOTORWAYS

"Traffic stagnation threatens most major cities in the world."

This volume reports the proceedings of the London International Conference which was organized by the British Road Federation in 1956 to discuss the problem as it applied to Britain, to see how the provision of urban motorways might help the situation, and to learn the steps being taken in other countries where the problem is being met.

Engineers from some thirty-two countries attended the conference which was called at the time a "Highway UNO" The various sessions discussed: the definition of an urban motorway and its value; the need for them in Great Britain and other countries; their economic justification; design aspects. One session was devoted to an open discussion, when comments were made by engineers from various countries illustrating their experiences.

This book is praactically a "must" for all those concerned with the urban traffic problem. (London, British Road Federation, 1957. 245p., £5.5.0.)

● BRIEFS

sales manager for controls and safety heads, Toronto area, for Black, Sivalls & Bryson Ltd.

Norton Company — The following appointments have been announced by the Norton Company of Canada Limited: G. W. Watts, manager, sales engineering; T. O. Charles, formerly Montreal district manager, to be general sales manager with headquarters in Hamilton Ontario; Robert E. Yule, JR.E.I.C., who was formerly district representative resident in Peterborough, Ontario, has been appointed Montreal district manager, with offices at 4920 Western Ave., Montreal; William D. Braun, formerly district representative in Toronto, has been appointed district representative Eastern and Northern Ontario with headquarters in Peterborough.

Canadian General Electric—I. A. Mayson has been appointed manager—marketing, electronic equipment and tube department, Canadian General Electric Company Limited, and G. S. MacDonell has been made manager—marketing, lamp department.

Canada — U. S. Chemical Engineering Conference

More than 750 engineers and executives are expected to attend a Canada-United States chemical engineering conference to be held in Montreal 20-23 April, 1958. The meeting is sponsored jointly by the American Institute of Chemical Engineers and the Chemical Institute of Canada, Chemical Engineering Division.

In addition to some 40 technical papers, to be delivered in a number of symposia on some of the latest developments and problems in industry, the program includes:

- A review of the European chemical industry by speakers from the Soviet Union, the United Kingdom, France, West Germany and Italy.
- A panel discussion on chemical engineering education in Canada and the U.S. with Dr. Walter G. Whitman of M.I.T. as moderator and three university professors representing each country.
- A panel discussion on the relationships between investors and the chemical industry management with Dr. C. F. Prutton, executive vice-president, Food Machinery and Chemical Corp., New York, as moderator and two industry executives representing each country.

Luncheon speakers include Lester B. Pearson, former Canadian external affairs minister and 1957 Nobel Prize winner, and W. M. V. Ash, president, Shell Oil Company of Canada. Plant visits arranged include an aerial tour of the St. Lawrence Seaway project, visits to the Industrial Cellulose Research Division of the Canadian International Paper Company at Hawkesbury, Ont.; Du Pont of Canada's integrated data processing centre in Montreal; the new Canadian Petrofina refinery in Montreal East; Quebec Iron and Titanium Company, Sorel, Que.; Canadian Titanium Pigment Company, Varennes, Que.; and the new facilities of the Pulp and Paper Research Institute of Canada, Pointe Claire, Que.

The technical symposia, each of four papers, include:

Statistics in Chemical Engineering (Dr. J. C. Whitwell, Princeton, chairman);

Chemical Engineering Problems in Heavy Water Reactors (Drs. D. Stewart, Atomic Energy Commission, Washington, and W. M. Campbell, Atomic Energy Commission of Canada, Chalk River, Ont., co-chairman).

Chemical Engineering in Mineral Processing (Dr. F. A. Forward, University of British Columbia);

High Temperature Materials for Jets and Rockets (Dr. C. J. Marcel, New York University);

Fluid Mechanics (two sessions — Drs. S. G. Mason and W. H. Gauvin, McGill and the Pulp and Paper Research Institute);

Noise in the Chemical Industry (Dr. G. Thiessen, National Research Council, Ottawa);

Future Sources of Energy (Dr. J. W. Hodgins, McMaster Univ.);

Chemical Engineering in the Pulp and Paper Industry (Dr. L. R. Thiesmeyer, Pulp and Paper Research Institute);

Modern Engineering Construction Techniques (S. A. Guerrieri, Lummus Company, New York).

In addition, there will be two sessions of general technical papers, one under the chairmanship of Dr. H. G. Donnelly, of Wayne State Univ., Detroit, and the other under Dr. K. O. Beatty, Jr., North Carolina State College, Raleigh, N.C., in which representatives of both industry and education will participate.

The two sessions of general technical papers will include topics ranging from "High purity tonnage oxygen for the steel industry" and "Operational control of continuous distillation plants", to "Turbulent heat transfer to Newtonian fluids of high Prandtl number".

Participants in the program come from 24 different universities in Canada and the U.S., and 30 different companies and research agencies. Universities represented are: British Columbia, Alberta, Toronto, McMaster, McGill, Laval, Queen's, Moscow, Frankfurt, M.I.T., Princeton, Delaware, Buffalo, New York, Cincinnati, Wayne, Illinois Institute of Technology, Purdue, Wisconsin, Southern Methodist, North Carolina State, West Virginia, Michigan, and California.

Companies represented include Etablissements Kuhlmann, of Paris; Farbwerke Hoechst, of Frankfurt, West Germany; Shell Oil; Imperial Chemical Industries Limited, Great Britain; American Cynamid; E. I. du Pont de Nemours and Company; Shawinigan Chemicals; Canadian Industries Limited; Du Pont of Canada; Consolidated Mining and Smelting; International Nickel Company of Canada; Columbia Cellulose; Carbide Chemical Company; L'Aire Liquide; Sherritt Gordon; Haveg Industries; Titanium Metals Corp.; Food Machinery and Chemical Corp.; Rysdon Products; Lockheed Aircraft; Lummus Company; Computer Usage Company; Fluor Corporation; Combustion Engineering; Foster Wheeler Corp.; Dow Chemical; Ohio Oil Company; Antibiotics S.A.; American Standard (Atomic Energy Division); and Kaiser Engineers.

Members of the National Research Council, the Pulp and Paper Research Institute of Canada, the Atomic Energy Commission of Canada, the U.S. Atomic Energy Commission, and the Battelle Memorial Institute are prominent on the program.

ANNUAL DINNER - DANCE

Senior Section, Montreal Branch
Windsor Hotel, Montreal

21 February 1958

Dinner 7.30 p.m. — **Tickets $5.00 a person**
Dance (two orchestras) — **$5.00 a couple**

MEET THE AUTHORS

Capital Press Service

C. R. Crocker, M.E.I.C. Senior Research Officer, National Research Council, Ottawa. *(Winter Construction).* Graduated from University of New Brunswick with degrees in electrical and civil engineering; worked with the New Brunswick Department of Highways and Federal Department of Mines and Resources. Served for five years overseas with the Royal Canadian Artillery; awarded the Distinguished Service Order. Joined the National Research Council in 1946, and in 1950 went to Division of Building Research; now head of the building practice (construction section).

J. T. Madill, M.E.I.C. Manager — Power Operations, B.C., Aluminum Company of Canada Limited, Kitimat, B.C. *(Installation and Operating Experiences with Kemano 2500-foot Head Impulse Turbines).* Graduated in electrical engineering from the University of Alberta in 1939 (B.Sc.), and in electrical engineering from the graduate school of M.I.T. in 1940 (M.Sc.). From 1941 until 1950 Mr. Madill was associated with the engineering, operating and maintenance of the Aluminum Company of Canada's 2½ million h.p. Saguenay system in the Province of Quebec. From 1950 until 1952 he was in the general purchasing department in Montreal supervising all electrical buying. In 1953 he was made manager of power operations for Alcan in B.C. As manager, power operations, B.C. he is responsible for Kemano, the reservoir operation, power transmission, Kitimat distribution, meteorological and hydrographic stations and records, and for the engineering of the Kemano expansion.

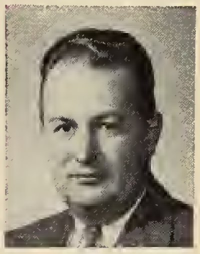
F. P. Gordon, JR.E.I.C. Assistant Superintendent — Power House and Transmission Lines, Aluminum Company of Canada Limited, Kemano. (Co-author, *Kemano Turbines.*) Joined the R.A.F. in 1939, leaving the service in 1945 as a Flight Engineer, after which he attended the University of British Columbia graduating in 1950 with a B.Sc. in mechanical engineering. He worked for Vancouver Iron Works Ltd. in their hydraulic turbine business and supervised the installation of the first Kemano turbines while with this company; he joined Alcan in 1954 as master mechanic for the Kemano power station.

H. F. Moore, Esso Research and Engineering Company, Linden, N.J. *(Automatic Computing for Process-Unit Operating Guides.)* Has been associated with oil refining since graduating from the University of Illinois in electrical engineering in 1928; his first job was with Lago Oil & Transport Company in Aruba, Netherlands West Indies. In 1934 Mr. Moore transferred to the central engineering organization of the Standard Oil Co. (N.J.) now part of Esso Research & Engineering Company; here his work has been in procurement, application, process design and engineering development, with the field of instruments, automatic control and analyzers always represented.

Four co-authors, Messrs. M. A. Scheil, G. E. Fratcher, S. L. Henry, and E. H. Uecker, all of the A. O. Smith Corporation, Milwaukee, Wis., contributed to the paper *Manufacture and Metallurgy of Flash-Welded Line Pipe.*

M. A. Scheil, Director, Metallurgical Research. Graduated from University of Wisconsin, (B.S. Chem. Eng. 1927, M.S. Metallurgy 1930). Mr. Scheil joined Gisholt Machine Company, Madison, Wis., as metallurgical chemist, 1927; in 1929 he joined A. O. Smith Corporation, Milwaukee, as metallurgist, became metallurgical engineer, in 1932, and has been director of metallurgical research since 1940. He is a prominent member of many technical societies, and active on several advisory committees on metallurgy.

G. E. Fratcher, Director of Engrg., Tubular and Process Div. Graduated from Marquette University (B. Mech. Eng. 1936) and joined A. O. Smith Corporation, Milwaukee, as design engineer; in 1944 he became chief product engineer, vessel division, in 1949 manager of research pressure vessel and tubular goods, in 1952 chief engineer of process equipment division and consulting engineer on tubular products, and has been in his present position since 1955.



G. E. Fratcher

S. L. Henry

E. H. Uecker

S. L. Henry, Asst. Dir., Metallurgical Research. Graduated from the University of North Dakota (B.S., Mech. Eng. 1934, post graduate study in metallurgy, 1936). Mr. Henry was instructor in mechanical engineering at the University of North Dakota, 1935-1936; was employed as metallurgical engineer at Fairbanks Morse & Co., 1936-1942; he joined A. O. Smith Corporation as metallurgical engineer in 1942, and in 1946 was appointed to his present position.

E. H. Uecker, Dir. of Quality in Oil Field Products and Ordnance. Mr. Uecker's training included courses in business, chemistry, and engineering and metallurgy. After employment with A. F. Westphal and Witmor and Gibbons between 1924 and 1926, he joined A. O. Smith Corporation in 1926 and was engaged on manufacturing, engineering and inspection. He became quality control supervisor in 1932 and in 1941 his present appointment was made.

COVER PICTURE

The forthcoming Southern Ontario Regional Conference will be held not far from the new Burlington Beach Skyway, which will eliminate a serious restriction in traffic on the Queen Elizabeth Highway near Hamilton, Ont. The cover picture shows part of the recently completed centre span which crosses the ship channel into Hamilton harbour.

Winter Construction

C. R. Crocker, M.E.I.C.

Associate Research Officer, National Research Council, Ottawa, Ont.

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June 1957

WINTERS IN CANADA are praised by many and cursed by many more. The severity of the weather varies from the mild damp regions of the Pacific coast to the harsh cold plains of the Prairie Provinces. But all regions in Canada have one thing in common—unemployment during the winter months. The construction industry is no exception to this general situation; in fact, the seasonal variation in employment in construction is greater than in any other major industry.

For Canada as a whole employment reaches a peak around the beginning of September, holds at a fairly high level through the fall, and then starts going downhill. This decline continues until about April when the seasonal upturn begins. What are the reasons for this annual variation in employment? The weather is, of course, one of the important factors. The Canadian farmer with the best will in the world cannot plant seed in February; Canadian seamen cannot sail the Great Lakes in mid-winter. There is another reason, however, for seasonal unemployment and that is customs and traditions like buying gifts at Christmas or new clothes at Easter (which is reflected in high employment in the retail trades) or starting to build a new house in the spring.

The most serious result of seasonal unemployment is the waste of manpower involved. Man-hours not used can never be regained. It is estimated that there are 250,000 Canadians seasonally unemployed each winter even in years of generally high employment. It is impossible to assess the actual cost of reduced output during the winter months, but in lost wages alone the figure would be many millions of dollars. Another important consideration is the annual cost of helping to maintain workers and their families who lost their jobs during the winter. In the months from December 1954 to April 1955 about $162,000,000 was paid out in unemployment insurance benefits, a large part of it to those seasonally unemployed. Unemployment affects all, because idle workers are not productive workers, and the loss in wages and purchasing power of those who are seasonally unemployed is felt by everyone.

Seasonal unemployment in the construction industry has been a national problem for only a relatively short time. Not long ago most construction work closed down in November and remained closed until April. Unemployment was not a serious problem because the good construction worker in summer became the top bush worker in winter. The construction industry has, however, undergone a "mechanical revolution" resulting in the development of many specialists to keep pace with the introduction of machines. These skilled men no longer find it easy to get another job when a construction project closes. In February 1957, 75,000 skilled construction workers were seeking employment. In fact, one-third of all unemployed at that time were skilled or unskilled construction workers. The profound effect of unemployment in the construction industry on the national economy is clearly evident.

The Federal Government has been vitally concerned with seasonal unemployment and in the past few years has been studying the problem in co-operation with employer and labour groups and with provincial governments. One of the results of the study made by the National Employment Committee was a recommendation to the Government that it should undertake a study of ways and means whereby the awarding of government contracts might be better timed to offset as much as possible the seasonal variations in construction activities.

In September 1955 in an address delivered before the Union of Nova Scotia Municipalities, the Minister of Public Works, the Honourable Robert Winters, announced the details of a Cabinet directive relating to winter construction. This directive ordered four specific steps to be taken in so far as they were practicable. These were:

(1) Government departments and agencies were to arrange their construction programs so that plans and specifications, tender calls, contract awards, and the various stages of actual construction would be timed to provide the maximum amount of winter work for the construction trades;

(2) alterations and repairs on buildings, houses and equipment owned by government agencies were to be planned so as to be carried out as far as practicable during the winter months;

(3) procurement programs were to be arranged where practicable to create the maximum amount of winter employment; and

(4) with the objective of keeping increased winter employment in mind, each department and agency concerned should, if necessary, adapt its financial arrangements, staffs, and other related matters in such a manner as to give effect to this directive.

Federal departments and agencies, although they spend sums running into hundreds of millions of dollars annually in the construction field, cannot alone solve the unemployment problem. The example already set by the Federal Government, if followed by governments at all levels and by private enterprise could really result in great progress.

In recognition of this fact, a Joint Committee on Wintertime Construction was formed in 1955 under the sponsorship of the Canadian Construction Association. This Committee represented the Canadian Chamber of Commerce, the Canadian Manufacturers' Association, the National House Builders Association, the Engineering Institute of Canada, the Royal Architectural Institute of Canada, the Canadian and Catholic Confederation of Labour, the Canadian Labour Congress, the Canadian Legion, as well as the sponsoring agency. In addition, representatives of the Federal Department of Labour and the National Research Council were associated with this Committee. The main work of this Committee to date has been to promote winter construction among its own member organizations by giving wide publicity to the advantages of maintaining a high level of employment throughout the year.

The Division of Building Research of the National Research Council has prepared a bulletin outlining techniques for winter construction[1] and a translation of a Swedish document on this same subject.[2] A study has been made of winter construction projects and some specific aspects of construction in winter, notably masonry construction, are being investigated. The study of construction techniques in other countries has been of particular interest particularly in the Scandinavian countries and in the U.S.S.R. where climatic conditions are similar in many respects.

In the translation of the Swedish bulletin on winter construction, the statement appears that state control of the building activity was enacted in order to spread work over the whole year by specifying times at which construction is to start, thus counteracting any unequal burden on the labour market. Details of this system were provided by Mr. Gil Schonning of the Department of Labour on his return from a visit to Scandinavian countries.[3]

In Norway and Sweden two major seasonal industries, construction and farming, dominate summer activity and two, forestry and fishing, are most active in the winter months. Although forestry and fishing always absorbed a sizable portion of the workers released from other seasonally fluctuating industries, statistics show that before the second World War winter unemployment was fairly high in both countries. During the postwar period, industrial expansion tended to outstrip available manpower resources and this led to inflationary pressures that have been reflected in the wage-price spiral of these countries. The high and rising

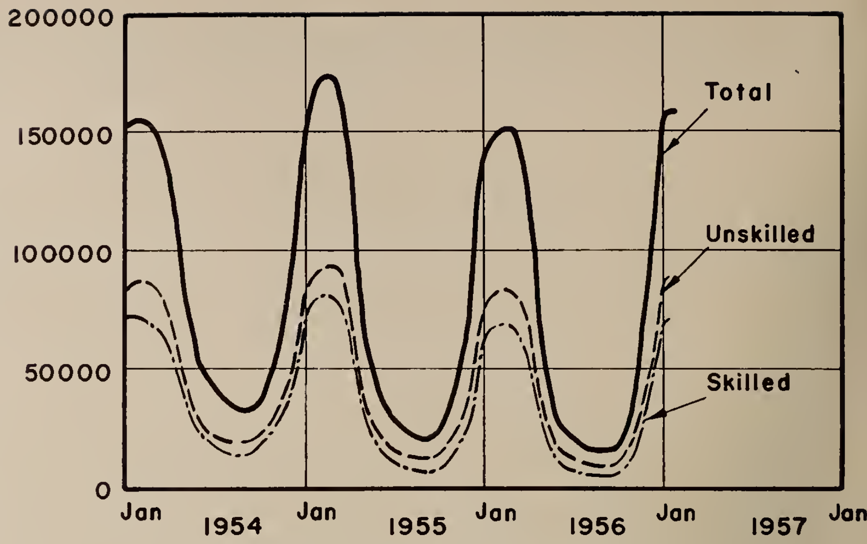

Fig. 1. Unemployment in the construction industry.

level of investment for expansion of industrial capacity and services created a fast-growing construction industry somewhat out of proportion to the size of the countries. The inflationary burst of the construction industry in the summer added force to the already strong pressures on manpower and material generated by the rest of the economy. It was the development of these conditions that prompted Norway and Sweden to bring the construction industry under control.

The main technique introduced by the state with a view to stabilizing employment was the "permit" system. Permits to start work are now a prerequisite to almost all types of construction in Norway and Sweden. The immediate purpose of this scheme was to reduce summer activity and so reduce pressures on the manpower resources; a secondary aim was to stabilize employment in the building industry throughout the year. It was considered that when contractors had sufficient experience with planning year-round work, most of them would accept this new pattern of work as normal, even in the absence of control.

Building permits are issued by government agencies at the state, regional, or local level. Before authorization to begin building is granted, the contractor is required to show a time-table for the building, indicating the duration of work at each stage. If, on examination of the labour markets, the agency finds that sufficient tradesmen are not available for the work, or finds any other justifiable reasons for not allowing construction to proceed, it is empowered to withhold the granting of a permit to begin work. The agency is also authorized to interrupt work if the construction, in the judgment of the agency, should warrant it.

The permit system does not force a contractor to build in the winter, but it may prevent him from building in the summer thus meeting the immediate objective. Both Norway and Sweden have, however, announced national policies respecting year-round activity in construction. Thus a contractor who is granted a permit to build and then lays off large numbers of workers when winter sets in may find that the state agencies are unable to supply him with labour in the following spring and summer.

Apart from the direct approach through the permit system, the governments of the Scandinavian countries assist the construction industry both with respect to long-term capacity growth and to seasonal stability. Systematic planning seems to be the key factor in the attempts to level out construction employment. To assist the contractor in planning year-round work tripartite boards have been established at local, regional, and national levels with representation from the building unions, the contractor, and the state. Although the main function of these boards is to prevent undue pressures on the local labour markets, they also form the main pipeline of communication from research institutions to contractors, and to the public, on new techniques and information about materials.

Research appears to receive strong emphasis in the Scandinavian countries. At present, work is being done by agencies associated with the Ministries of Labour and Housing to determine which construction activities can only be done in summer and which can be done in winter. For example, a study is being conducted in Norway with a view to providing a list of road building and railway maintenance operations that could be done in the winter but that are now being done in the summer.

To utilize more fully the scarce manpower resources, various devices were introduced to stimulate greater labour mobility. The state undertook to cover workers' expenses of moving from place to place and to provide them with accommodation. An educational program was established designed to make the public and the builders aware of the problems and possibilities of winter construction and to disseminate information from research organizations and professional people in the industry. It was found that published information was not widely read by those for whom it was intended and that a more direct approach through short courses and visits to construction sites was more effective.

A study made by the research department of the Swedish Building Trade Unions indicated that it is almost impossible to reduce the summer to winter decline in employment to less than 10 per cent. The problem of additional costs of winter construction has also been studied. It is admitted that a project carried out during the winter months will sometimes cost more, depending on the duration of the project. If it lasted for a year, little or no extra cost might accrue from carrying the project through without interruption. If it was begun in the fall and finished in the spring some extra costs were undoubtedly incurred. It was considered, however, that such matters could not be considered of any significance in comparison with what might happen to wages and prices if the volume of extra work now carried out in the winter were dumped on the already scarce resources available in the summer.

The climate of much of Scandinavia is similar to parts of Canada and it is not strange therefore to find that winter construction techniques are also similar. The requirements for winter concreting are much the same in both countries. Calcium chloride may be used in quantities up to 2 per cent by weight of the cement, forms are insulated to retain the heat in the concrete, and the concrete is heated when the temperature falls below 25°F. The ideal temperature for the concrete during the first three days is considered to be in the range 60°-68°F.

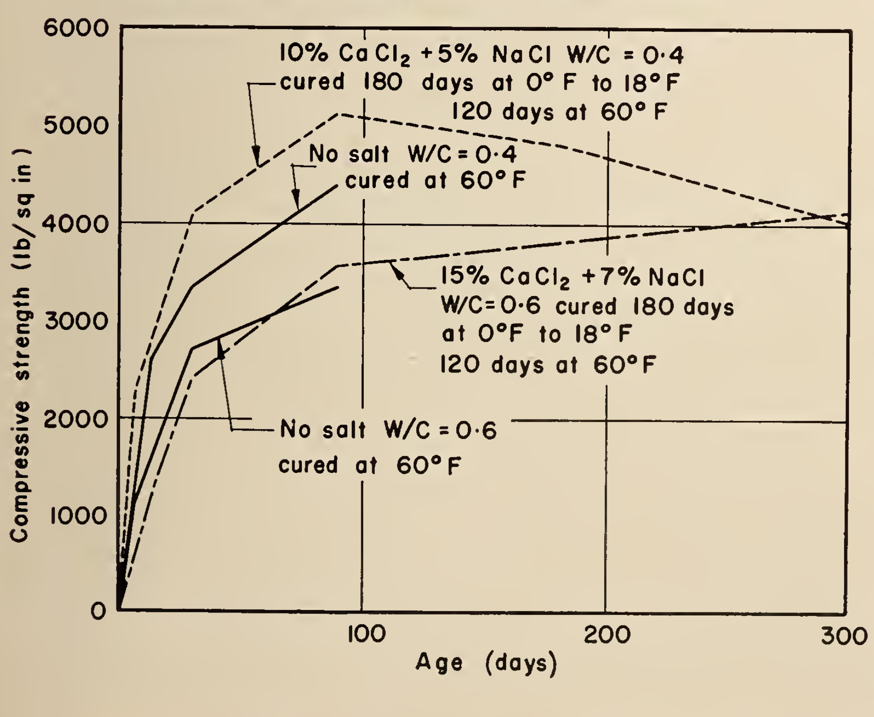
Owing to the fact that parts of Canada are subjected to extreme cold, concreting is done at much lower temperatures here than is normally the case in Scandinavia. For example, in Sweden it is considered possible to place concrete at temperatures down to 5°F., with protection, but contractors in Stockholm do not normally place concrete at this temperature. During the international symposium on winter concreting held in Copenhagen in February 1956, a visit was to be made to construction sites to see ready-mixed concrete being placed. The trip was called off, however, because the weather was too cold, the temperature being about 10°F., although by Canadian standards this is not low.

In the field of masonry construction, the requirements are less rigid than in Canada. Masonry work is allowed to proceed in Sweden and Norway at temperatures down to 14°F., when dry brick and warm mortar are used. In Finland, the minimum temperature for masonry construction is 21°F. and in Denmark 18°F. In all these countries, the work must be covered at the end of each working day to ensure that the walls are protected from rain or snow. Where night temperatures fall below 14°F., the walls are covered with reed mats. In Canada the requirements are that when the temperature falls below 40°F., the materials shall be heated to 40°F., and the masonry kept at 40°F., for 48 hours after being laid up.[4,5,6]

Precast cellular concretes are widely used in the Scandinavian countries where they were developed. These materials are often used as an outside facing for the load-bearing reinforced monolithic concrete used in residential and commercial buildings. By this method the concrete is not directly exposed to the elements. In coastal regions in Sweden and in most of Norway, the high incidence of wind-driven rains makes it necessary to place the insulating cellular concrete on the inside. In most of these areas, however, prefabricated concrete wall panels are used.

Prefabricated concrete wall, floor and roof panels as well as beams and columns are widely used, particularly in the northern parts of Scandinavia. In winter, particularly, this technique assumes great importance since most of the concreting can be carried out under shelter, the joints involving only a small volume of concrete. The joints are made by welding the reinforcement and covering it with concrete. The concrete is protected by small portable insulated

Fig. 2. Compressive strength of "cold concrete" cylinders.



shelters heated in many cases by light bulbs.

Sliding forms are also used on many multi-story buildings. The concrete is insulated by a layer of cellular concrete on the surface. This is considered a good method for winter concreting since the fresh concrete is protected from exposure and the enclosure is easy to heat. It is often used in conjunction with prefabricated floor elements.

Although there is a great deal of work being done in Europe to investigate many aspects of winter construction, the practical application of the work lags far behind these theoretical studies. This is partly due to lack of equipment and an apparent unwillingness on the part of labour to carry on under severe winter conditions. Certainly in Canada winter work goes on in greater relative volume under conditions more severe than those generally experienced in Europe.

No mention has yet been made of winter construction in the U.S.S.R. Practice in that country is of particular interest since the weather conditions in many parts of Russia can be duplicated in Canada. Many new and interesting techniques have been developed in the U.S.S.R. in an attempt to bring the volume and cost of winter construction to the same level as summer construction. Two of the more interesting developments—the use of cold concrete and the curing of concrete—will be described.

"Cold concreting" is the name which has been given to the Russian technique of using large quantities of calcium and sodium chloride in concrete placed in below-freezing weather. Calcium chloride, in quantities up to 2 per cent by weight of cement, has been widely used for years as an accelerator to increase the early strength of concrete placed in cold weather. In such cases, the anti-freeze property of the salt solution is ignored since the freezing point is lowered by only a few degrees. In the U.S.S.R., however, the chloride salts are used as an anti-freeze.

The amount of salt used is high, the maximum recommended being 20 per cent salt by weight of the water for use where minimum temperatures do not exceed —5°F. The ratio of calcium chloride to sodium chloride in the admixture depends on the air temperatures during curing and the time that the concrete can be left in the forms. But equal parts of NaCl and $CaCl_2$ are used where air temperatures are between +5°F. and —5°F.

The compressive strength of concrete made with large additions of chloride salts is high, and at temperatures between 0°F. and 18°F., design strengths are obtained in about 90 days. Where $CaCl_2$ alone or a mixture of salts high in $CaCl_2$ is used, quick setting and high early strength result. Later the rate of development of compressive strength slows down and in some cases an actual loss of strength occurs. When NaCl alone is used, the development of strength is slow at an early age, but at 270 to 300 days, the compressive strength exceeds that of the concrete with $CaCl_2$. Temperature has a marked effect on strength development, and if the air temperature is above freezing, very high strengths are recorded after only a few days.

The impermeability of cold concrete is higher than ordinary concrete, but its durability, as measured by resistance to freeze-thaw cycling, is low. Rapid corrosion of reinforcement occurs unless the concrete is dense and provides a cover of more than 1 inch. Well-graded high-quality aggregates are essential for reinforced concrete and the water-cement ratio should not exceed 0.5. Even then reinforced concrete should not be exposed to humidities in excess of 60 per cent.

Since 1952, when cold concrete was first used, until January 1956, 200,000 cubic yards had been placed in the U.S.S.R. It is used for retaining walls, canal structures, secondary roads, and building and machinery foundations. Concrete with large salt additions is not recommended, however, for the following conditions:

(*a*) reinforced concrete in areas where relative humidity exceeds 60 per cent;

(*b*) reinforced concrete subjected to alternate wetting and drying cycles;

(*c*) reinforced concrete where thorough compaction is difficult;

(*d*) reinforced concrete where cover is less than 1 inch;

(*e*) prestressed concrete;

(*f*) structures where good appearance is an essential requirement; and

(*g*) in massive structures with low surface area.

The properties of cold concrete as given above are all based on Russian reports.[7] There appears to be little information from other countries on concrete containing a high percentage of salts although at the recent annual meeting in Dallas of the American Concrete Institute it was reported that an American investigation had confirmed the low resistance of such concrete to freeze-thaw cycling.

Fig. 3. Winter construction in Edmonton.
Photograph: Goertz Studios

In the U.S.S.R., as in Canada, there has been great activity in hydro-electric power development. Since much of the concrete for the hydraulic structures must be placed during the winter months, a system has been developed for heating the surfaces of the concrete by electricity. Electrodes of ¼ inch to ⅜ inch round steel are placed at intervals of 8 to 12 inches on the inside of the forms and on adjacent concrete surfaces. The electrodes are heated by low voltage (50 to 90 volts) alternating current. The approximate time for electric heating is set as follows: for an air temperature of 15°F., 8 hours; for —5°F., 16 to 24 hours; for —20°F., 32 to 40 hours. Electricity is supplied by portable 50-kilowatt three-phase oil transformers and the consumption at —20°F., is 6 kilowatts per square yard of exposed surface.

The advantage of this system is that it permits the placing of concrete with a temperature of 40°F., without the danger of freezing at the edges and it does not require a heated structure around the concrete during the curing period. The top surfaces of the concrete blocks are not electrically heated but are covered and insulated. Unheated shelters are erected over the blocks only during prolonged periods at temperatures below 0°F.

In spite of the development of new materials and techniques of winter concreting, prefabrication is still widely used by Russian contractors. Residential, commercial, and many industrial buildings, are constructed the year round of prefabricated floor, wall, and roof panels, beams and columns. Most of these components are made of factory produced concrete which in winter can be placed and cured under optimum temperature conditions. The parts are erected by large cranes and the connections between components are made by welding the reinforcement and grouting the joints. High early strength concrete is often used and where necessary small portable heated shelters are used.

Although concrete is the chief material used in prefabricated components for buildings, brick masonry is also prefabricated into wall panels and columns, and lifted into place after curing by means of mobile cranes. In winter, the brick masonry is generally prepared in heated enclosures or protected by electrical heating. In some cases, however, the masonry is allowed to freeze as quickly as possible and the blocks develop sufficient strength by freezing to permit transporting them to the construction site and lifting them into position. Blocks prepared at freezing temperatures become fit for transportation within a few hours if the temperature is very low or within 10 to 15 hours at temperatures just below the freezing point. The blocks are placed on a thin layer of warm mortar which may have "anti-freeze" agents incorporated in the mix. These chemical admixtures are always used when it is known that the temperature will fluctuate around the freezing point or when a sudden thaw can be expected. Walls erected with frozen masonry blocks lose considerable strength when they thaw and some settlement occurs, often as much as 0.015 foot per foot in height. As the mortar hardens at temperatures above freezing, the walls gradually acquire the necessary strength and stability.

The details given above should not leave the impression that the Russians have developed new techniques which permit full-scale winter construction without the protection required in Canada. The quantity of "cold concrete" used to date is very small in terms of any large construction job. Electric heating of concrete is chiefly confined to some hydro-electric projects and the technique of freezing masonry blocks is still under study. Although the records show that much experimental work is in progress to improve these methods, they do indicate that something more can be done about cold weather construction. At the same time, it must be kept in mind that the laws of nature have not been repealed, and it is still as necessary as ever to recognize the hazards of winter construction.

Turning now to winter construction in Canada, there seems to be little doubt that this country leads the world in *per capita* volume of winter work. A study of practices in other parts of the world show that, with the possible exception of the U.S.S.R. and the United States, no country normally carries on winter construction under such severe weather as is experienced in the Prairies in winter. This is partly due to the climate of other countries since the U.S.S.R. and North-western United States are the only areas where similar climatic conditions to those of Canada exist. Even in Canada, however, there are great variations in winter construction activity depending on local conditions. During the winter 1956/57, for example, a great deal of winter construction work was carried out in the Prairie Provinces. Contractors and engineers in this part of Canada face the most severe winter conditions in the country, although it must be admitted that in the Far North the severe weather lasts for a longer period. Western builders, while naturally proud of their ability to cope with the existing conditions, look with envy on contractors in other parts of Canada where weather conditions make winter construction more attractive. They are naturally surprised to find that most construction jobs in Vancouver were shut down for six weeks because of the severe local weather—snow on the ground and temperatures down to +10°F., to +20°F. This would almost indicate that local custom often decides what can be done in winter in any given area.

Fig. 4. Laminated wood arch enclosure.
Photograph: Brian Akins, "Techniques of Winter Construction"

Canadian contractors have developed some ingenious methods of combating winter weather. Many types of hoarding are used including movable enclosed platforms suspended from outriggers on the roof of the building and laminated arch structures made from 1 x 4 lumber, reinforced kraft paper and polythene film. This latter type of enclosure was very successfully used with the lift-slab type of construction at the Winnipeg General Hospital.

The use of the lift-slab method of construction seems to be well suited to winter work. The floor and roof slabs, since they are all placed at ground level, can be protected by low cost structures which require little headroom and are easy to heat. When the slabs are cured they can be hoisted into place in temperatures as low as —20°F. Once the slabs are in place, the sides of the structure can be enclosed with canvas or polythene permitting work to continue without interruption.

Prefabricated wall, floor and roof panels are being specified on an increasing number of construction jobs in Canada, but in spite of the obvious advantages for winter work, the potential of this method of construction has not been fully exploited. Since these panels can be fabricated under controlled conditions, the weather at the site would have little effect on building progress. The use of prefabricated wall panels, in conjunction with the lift-slab method of construction, would seem to remove most of the difficulties of winter construction in many types of buildings.

It would be well to look briefly at some specific winter jobs in the various categories of construction to see what can be done. These may not be typical examples but they do show that "where there's a will, there's a way".

Ottawa house builder, Heinz Kroeger, found a circus tent the answer to his winter construction problem. The excavation was made in early February and the tent erected over the excavation. Four blower-type heaters maintained a temperature of 38° to 40°F., under the tent even when the outside temperature dropped to —20°F. Meanwhile, the foundation walls were placed, the frame erected, roof installed, brick veneer, stucco and plaster applied and even some outside painting was completed. Four weeks from the time the excavation was started, the tent was stripped and moved to a second house. The total extra cost was estimated by the builder at $300 to $500 but the advantages of continued work the year round were considered to be worth a great deal more.

In Winnipeg, the contract for a new bank building was awarded on 1 December 1955. The date of occupancy was set by the bank officials to be 15 March 1956. Thus, it was necessary to construct this building in its entirety during a period when very severe weather conditions are normal. By careful planning, the building was completed at an estimated additional cost of hoarding and heating of $500, or 1¼ per cent of the completed building cost.

In Hull, Quebec, two almost identical school buildings were erected by the same contractor, Mr. Raymond Brunet, one in summer and one in winter. The additional cost of the winter job was $4,800 or ¾ of 1 per cent of the total building cost. In addition, by starting in the late fall, the school was finished four months ahead of the original schedule.

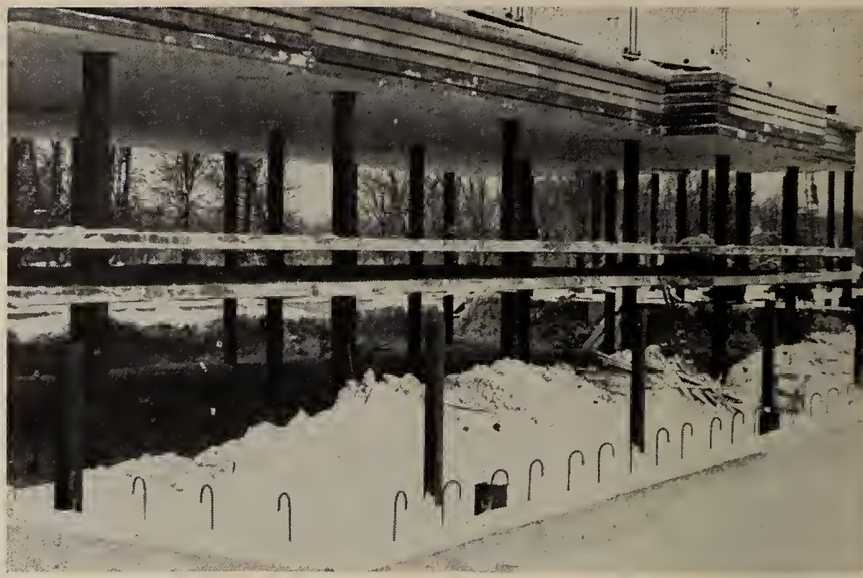


Fig. 5. Winter erection of a lift slab apartment block.
Photograph: Brian Akins, "Techniques of Winter Construction"

Many more examples could be given to show that all phases of construction, even excavation and outside painting, can be done in winter. There is always, however, an additional direct cost of winter construction since it is just not possible to enclose and heat a structure without incurring some expense. In addition, ready mix concrete costs more in winter and this can be a substantial item in some types of buildings. There are, however, many immediate compensations such as retention of skilled labour, good materials delivery, availability of subtrades, reduction in overhead, and early completion. Another factor that is not generally considered is the reduced labour costs of winter construction. Since 1934 there has been a steady increase in wages in the construction industry which, since the end of the second World War, has amounted to just under 8 per cent per year on the average. Material costs have also risen, although not to the same extent. That this factor may compensate for the added cost of winter construction is seen in cases where alternate tenders are called in the fall, one for an immediate start and the other for a spring start. In many such cases, the bids are the same.

Since it has been shown that winter construction is possible in Canada, and at an acceptable cost, what can be done to reduce unemployment in the construction industry during the winter months? The answer seems to be in convincing the owner that the quality of winter work is as high as summer work and that the additional direct cost is offset by many factors of which early occupancy and lower labour costs are but two. The Engineering Institute of Canada and the Royal Architectural Institute of Canada can do a great deal to promote winter construction, but only when the members of the two professional bodies are themselves convinced that it can be done and done properly. Whether this is the case can only be judged by the statements issued at the request of the Joint Committee on Wintertime Construction.

The E.I.C. stated: "Engineering projects are not shut down in winter when the cost of shutdown, including the interest on funds invested, exceeds the extra cost involved in winter construction.

"While there are exceptions, the quality of construction work carried out in winter in Canada need not suffer provided planning, supervision, and control of work is done by qualified engineers."

The statement of the R.A.I.C. read in part:

"It is felt that generally speaking wintertime construction is feasible provided that proper precautions are taken. It is recommended that before any decisions are made the proposals should be discussed with the architects of the buildings in the light of all circumstances such as climate, type of construction, site conditions, materials, costs, etc."

Contrast this with a statement made in the findings of a committee established by President Hoover in 1921 to study and report on seasonal operation in construction. It states: "Summarizing the question of winter construction it may be stated without fear of contradiction that both from an engineering and quality standpoint any type of modern building construction can be accomplished, and most classes of engineering construction fully as well, in the winter months as at other seasons, if the proper protection during the progress of certain parts of the work is provided."

In the meantime, much valuable work is being done by local committees across the country, particularly in regard to the timing of maintenance work. This effort has been very successful and may well establish a permanent pattern. In addition, the trade journals are giving much publicity to winter construction programs and the techniques developed by individual builders to meet the challenge of local conditions.

The Division of Building Research, besides issuing several bulletins on winter construction, is making studies of specific problems such as the use of masonry construction in winter. This study was started as the result of a request from a builder who pointed out the difficulties of complying with the existing regulations regarding the protection of masonry during cold weather. Investigation has shown that the existing regulations are based on the results of work done between 1923 and 1935, to determine the effect of low temperatures on concrete. The need for laboratory work to determine the effect of low temperatures not on concrete or on mortar, but on the combination of mortar and brick, is clearly indicated. This presents such a complex problem, however, that only after years of work will the answer be found.

In the meantime, where the regulations do not apply or where inspection is lax, brick masonry is being erected in winter under extremely adverse conditions with no apparent ill effects. There does seem to be some hope for the relaxation of existing requirements at least for non-load-bearing walls, but if such a change is to come soon it will probably be based on current practice in this and other countries rather than on laboratory investigations. In Europe, masonry construction is permitted at lower temperatures than in Canada and it may be possible to use the experience gained in these countries to adopt a more realistic approach to this problem.

Winter construction in Canada is now a well established practice and each year more and more people enjoy year-round employment in this great Canadian industry. There are still, however, great numbers of skilled and unskilled construction workers seeking employment during winter months. It is to the advantage of all Canadians to make every effort to ensure that seasonal unemployment is kept to a minimum. In the construction industry this should mean keeping the summer to winter decline to 10 per cent. That this can be done is shown by the fact that during the past five years 45 per cent of all construction work carried out by Defence Construction Limited was put in place each year in the six months between November and April.

One out of every five dollars spent in Canada today on end goods and services is spent on construction. This country cannot afford to shut down or even to slow down appreciably so vital an industry as construction. The so-called "construction season" is a term that should soon be out-dated. Canada must build the year round.

Read at a meeting of the Vancouver Branch of the Engineering Institute of Canada, 24th October, 1956

The Kitimat, B.C., smelter of the Aluminum Company of Canada is supplied with electrical power from the powerhouse at Kemano, B.C. This paper describes the installation of the first three vertical impulse turbines in the Kemano station, and gives some details of operating experience and test results.

THIS PAPER describes the installation of the initial three 150,000 h.p. 4-nozzle vertical impulse turbines in the Kemano power station of the Aluminum Company of Canada, Ltd., and includes some operating experience and test results.

The turbines are 4-jet vertical impulse machines operating under a net head of 2,500 ft. and producing 150,000 h.p. at 327 r.p.m. The manifold inlet diameter is 60 inches; the jet diameter approximately 8½ inches. Runner pitch circles vary from 132 in. to 134⅝ in. The turbines were manufactured by Canadian Allis Chalmers, Ltd., Vancouver Iron Works Ltd., and Dominion Engineering Co. Ltd.

The water supply for the Kemano power station is obtained from a chain of lakes forming a reservoir in Tweedsmuir Park on the east side of the Coast Range. From an elevation of 2,800 ft. at Tahtsa Lake the water passes through a 10 mile tunnel to a point about 2,600 ft. above the powerhouse then drops through eleven-foot diameter penstocks to discharge at elevation 210 feet before release into the Kemano River.

Turbine installation starts with the bottom pour of concrete, including support pedestals for pit liner bottom (Fig. 1). In addition to the visible pads anchor, eyes were also set in the concrete to provide a solid tie-down for the bottom plate. The bottom plate (Fig. 2) made up of five sections of ½ in. plate, was reinforced with 8 in. wide flange I-beams which were spaced approximately on 3-1/3 ft. centres running parallel to the longitudinal centreline of the powerhouse, and which rested on jacks on the support rods. Turnbuckles fastened between pad eyes on these beams and the anchor eyes provided the necessary anchorage; 1¼ in. pipe jacks were added, wherever required, to make local adjustments. Further anchorage and adjustment was obtained by use of turnbuckles and pipe jacks between the plate edge and the pit walls. Once in place the sections were welded, followed by a further adjustment check and correction where required. Fig. 2 shows the bottom plate in position at elevation 184 with the first course in place. One-inch turnbuckles and tie rods can be seen attached between liner and pit wall. The centre shoring ring originally provided as a steel set for tunnel work was supported on 4 in. x 6 in. posts and braced

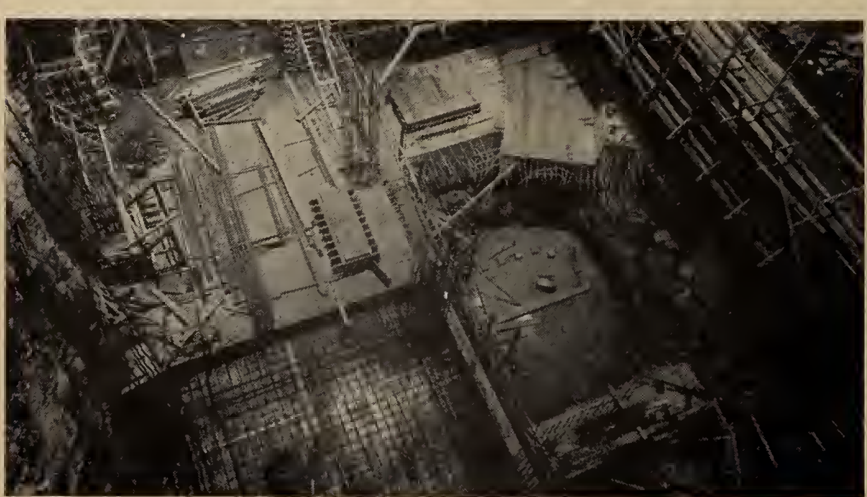

Fig. 1. Lower concrete showing support pedestals for pit liner bottom.

against the liner wall. A 4 in. pipe was welded across the 16 foot discharge opening to hold it to the correct width. This pit liner is 26 ft. 3 in. in diameter.

The second course, in two sections identical to the first, was butted to the first course and braced in place. The third course was added in a similar manner (Fig. 3) but, since it formed the cover for the discharge opening, it was the first completely circular course.

Runner removal platform beams were added when the course was in place (Fig. 4). These are two 18 in. W.F.I.-beams, which protrude through the liner and which are stiffened by two short beams at either end, braced against the liner wall. Grating was later added in front of the door and along the outside of each main beam to provide a walkway to facilitate inspection. With this course in place and all necessary drain lines installed, preparations began for prepakting to the 205 elevation.

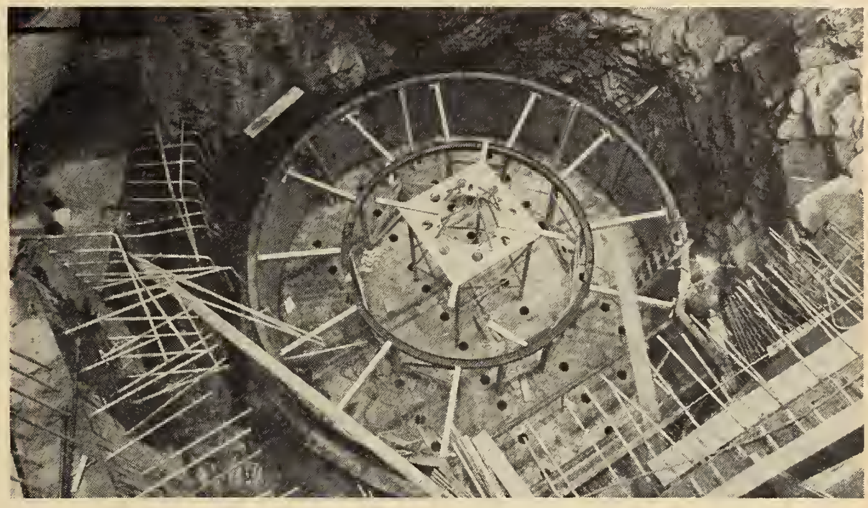
Prepakting differs from conventional concrete roughly in that aggregate is placed in the void first and a grouting mixture pumped into it through piping suitably located before the aggregate was added. There was no floating or lifting action noticed on the bottom section and no distortion in the liner walls. Some hollow spots were found but were mainly very shallow. As the grout is pumped into place it rises in "cones" about the pipes and drives ahead of it a considerable amount of water which must be removed. When the surface starts to flood, the area between the pipes is probed and grout pumped in until the space between the cones has been filled.

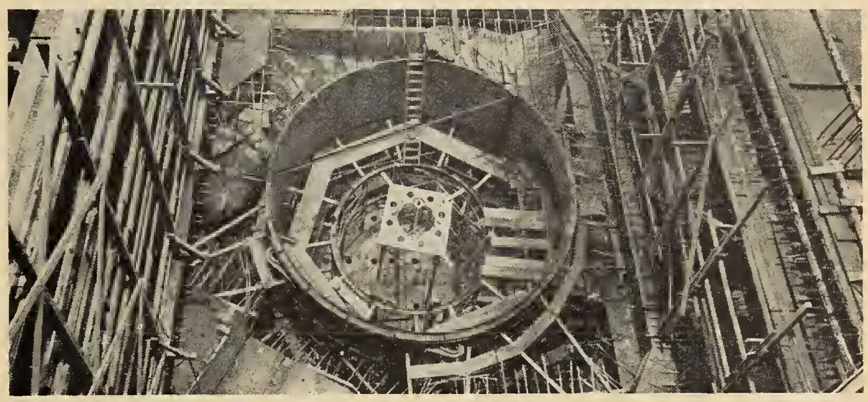
Basically, the erecting procedure for all unit pit liners was the same as the above.

The shapes varied considerably; two are more or less circular, while one could be classed as octagonal. The circular shaped liners were easiest to erect and align. Welding of the joints was a considerable job on all three. It was felt that the welding could be reduced considerably since, in many cases, seal passes could replace a full weld.

The handling problem was affected by the weight and shape of the course sections. In unit 2 they were small and light, being made of ⅜ in. plate averaging 6 feet in height and 8 feet in length. These sections were easily handled by a jury rig, permitting assembly to a greater height before shoring was added and alignment corrected. In unit 3 the sections were very heavy, being made of 1 in. plate with 10 in. channel stiffeners. Because of the size and weight of the sections considerable effort was expended, manoeuvring them into position. However, this provides a very substantial pit line, which, from an operating point of view, is a real advantage.

Scroll case sections (Fig. 5) were





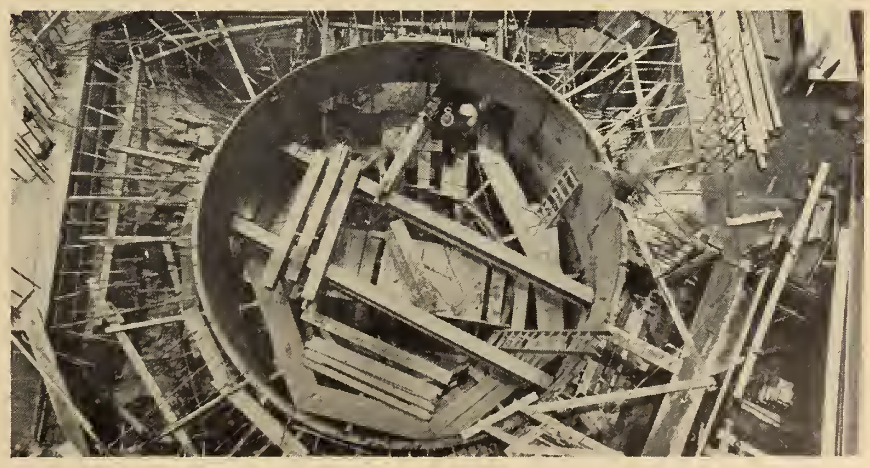


Fig. 2. Bottom plate and lowest pit wall plates.

Fig. 4. Runner removal beams in place.

Fig. 5. Scroll case section.

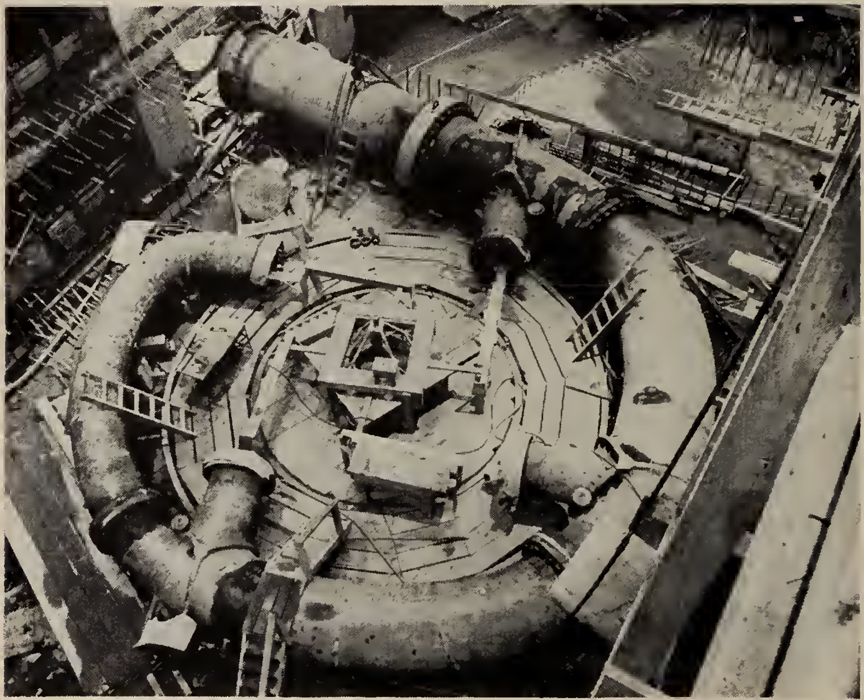

Fig. 6. Scroll case bolted together.

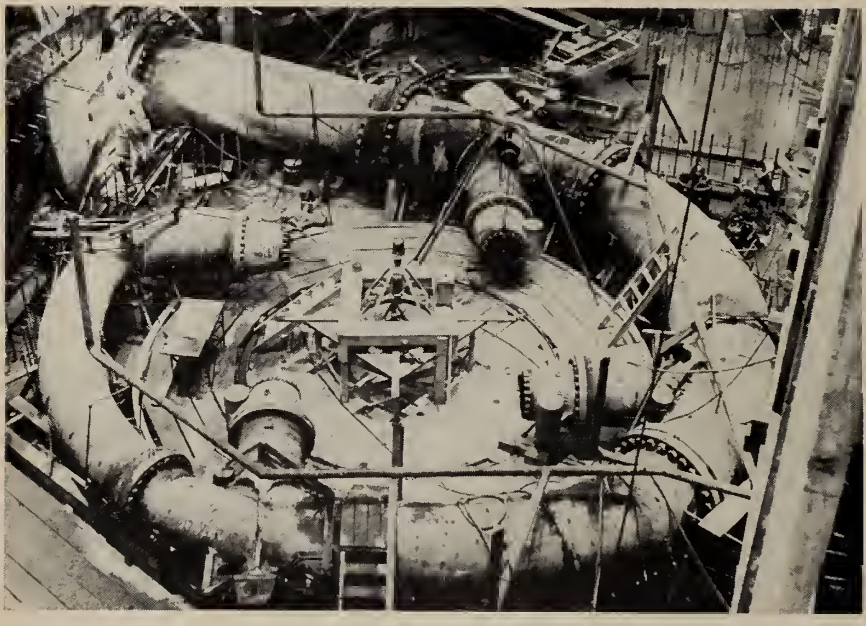

Fig. 7. Test heads installed.

brought in on a heavy trailer unit through the tailrace and up unit 4 discharge which had been filled in and graded to provide a roadway to the 205 elevation. The tailrace was used as a main supply tunnel all through the final excavation and construction.

In unit 2 there were five flanged sections including the inlet section. The heaviest piece weighed about 34 tons. Except for the inlet section connection to No. 1 nozzle body all joints were bolted and dowelled with a "dutchman" or spacer plate between, which had been grooved to take a ¼ in. diameter neoprene gasket.

The inlet section bolted directly to No. 1 nozzle body without dowelling; the flange was grooved for a ¼ in. gasket.

With the sections roughly aligned, bolting proceeded (Fig. 6) until all joints were secure and the bolts stretched approximately 0.001 in./in. of grip. Repeat checks were made on nozzle alignment to keep them within reasonable limits during the operation. Tie downs were attached plus extra turnbuckles to permit lengthwise adjustment of the sections. Nozzle alignment was obtained as follows.

From the arms of the centring stand, supported on the runner removal platform, piano wire, 0.016 in. dia., was strung through the centre of each nozzle to a centring plate located snugly in the bore of each needle gland at the servomotor end of the nozzle where it was securely fastened. The opposite end ran over a grooved pulley on the arm and was held taut with a 30 lb. weight. The pulley was adjusted for height and distance from centre so that the wire at the pulley lay on the tangent point between nozzle centre line and runner pitch circle. The casing was then manoeuvred until each servo centre plate centre was on elevation and the wire was central in each nozzle. During this process the upstream flange of the inlet section was kept in its proper location. The result put the nozzle centre lines within the tolerance required by the manufacturer of $\pm 1/8$ in. horizontally and $\pm 1/16$ in. vertically.

On completion of the alignment, test heads were attached (Fig. 7) as well as all piping which would be subjected to full penstock pressure. A pressure test was made by means of a hand pump at 1850 p.s.i. for two hours. To check movement of the scroll case during the test, dial indicators were set up at the test head behind No. 2 nozzle and at No. 4 nozzle. Though the casing did move under pressure, an alignment check made afterwards showed that it returned to its previous position. The specification that all joints be drop tight was adhered to and attained in all cases.

After alignment was completed, the remainder of the pit liner, plus baffle plates and air vent piping, was installed and the pit cover set in place. This cover (Fig. 8) came in sections consisting of an inner ring or wheel pit cover, which bolted to an outer or foundation ring, to which I-beam channels were welded, which in turn carried the segmental cover plates welded to the bottom of the beams. These parts were assembled beforehand and the assembly installed as a unit on the top course of the liner (Fig. 9). Final alignment and attachment of this cover came after all welding was completed on the liner and the prepakt elevation was raised to cover the scroll case and secure the cover adjusting anchors at elevation 214.

Unit 1 scroll case installation was the same as for unit 2. There were ten flanged and bolted sections including the inlet section; no dutchmen were used. The flanges were grooved to take a ⅜ in. dia. rubber gasket as a seal. Bolting procedures varied a little in that the stretch of 0.001 in./inch of grip was applied in two stages. The second stretch was applied after the pressure test as a check to ensure that all bolts were secure.

With the cover in place on unit 2 the rockshaft bearing supports were installed and mandrels were fitted to replace the rockshafts which had been delayed. Preparations were then made for concreting to the 218 elevation (Fig. 10). Meanwhile, needle stems, needles, nozzle tips, and needle servomotor installation had begun.

The assembly of the pit liners continued after the tests and the pit cover was placed. The next stage of prepakting brought the level to 214 elevation. The final setting of the cover was then completed, pipe supports were placed under it to prevent any sag during concreting and the level raised to the 217 elevation (Fig. 11, unit 1).

The wheel pit cover was dowelled in place and the bearing support fitted. The remaining work consisted of

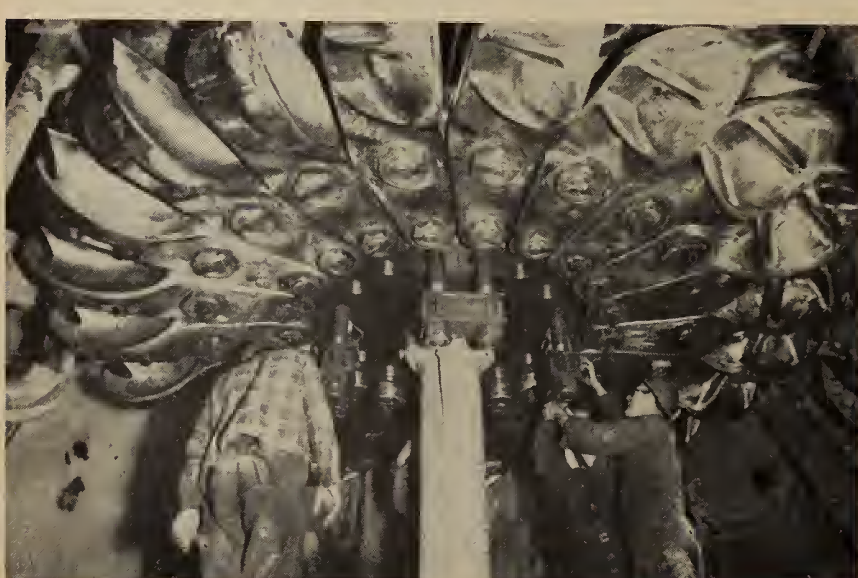

Fig. 15. Turbine No. 2 runner lifted into position.

completing the nozzle assemblies, installing the rockshafts, deflectors, linkage and servomotor, as well as setting the governors, pressure tanks and restoring cable piping. Briefly, the needle assembly consists of needle, servomotor, needle stem, needle tip and back, which are connected together to form a unit. The nozzle tip containing the needle seat is bolted to the nozzle body and provides a vertical bearing housing to guide the lower end of the rockshaft to which the deflector is keyed. Support for the needle stems, which vary in length from 12-18 feet, is obtained by guide bushings located in the nozzle body and at the servomotor end. Fig. 12 shows a needle guide barrel being installed in unit 1.

The turbine shafts were lowered into position. No. 1 turbine shaft was lowered on to a plate disc supported by four 2½ in. bolts from the pit cover and was then levelled and centred so that the generator erection could proceed. No. 2 turbine shaft was supported in its bearing and was coupled up with temporary bolts to the rotor which was installed immediately after. Reaming of the coupling bolt holes proceeded immediately (Fig. 13).

The next major items to be installed were the runners for all three units and the turbine shaft for unit 3. Unit 3 runner (Fig. 14) was made up of an integrally cast 13 per cent chrome bucket ring having 23 buckets and supported by a two-piece disc which clamped to it; the weight was approximately 22 tons. It was installed from the top and supported on special turn buckles attached to the pit cover. The inner cover was then lowered into position, the turbine shaft placed on the runner and bolted up, and the shaft and runner assembly weight then transferred to a support stand on the cover.

Unit 2 runner (Fig. 15) was a cast steel bolted-bucket type having 22 buckets; it weighed approximately 30 tons. Unit 1 runner was a forged plate steel integrally welded 24-bucket wheel which weighed approximately 24 tons (Fig. 16). These two runners were installed from below by means of a special car and hydraulic jacking unit. Figs. 15, 16, 17, and 18, though they show two different runners, depict the method of installation. The lift from car to shaft coupling takes approximately 10 min. at 1800 p.s.i.

Turbine erection at this point was complete except for governor checks.

Operation

From an operating point of view, the turbines behaved most satisfactorily in all but one respect, and all delivered more than 150,000 h.p. To determine accurately the turbine discharge and efficiency, Gibson tests were conducted on all three by the firm of Norman R. Gibson, consulting engineers, of Niagara Falls, N.Y. The piezometer sections for these tests had been included in the design and installed in consultation with Dr. Gibson's firm. Table I and Fig. 21 give the essential data from this test work and these are the final and official figures. It will be seen that all units show a high efficiency over the range 90,000 to 150,000 h.p. and all produce in excess of 150,000 h.p. Since all units were tested by the same engineers, using the same equipment and instruments and identical test sections, it is considered that these results, relatively, are highly accurate. Incidentally, deceleration tests had been conducted previously on each generator, so the turbine output was accurately determined in all cases.

In the case of two turbine runners, cavitation of the back of the tip of the bucket splitters occurred. The condition in Fig. 19 was found after only a couple of weeks' operation, and that in Fig. 20 after about a month. This problem was attacked in both cases from two points of view: first, change and improvement in bucket contour in the critical area, to eliminate as far as possible the cavitation; and second, metallurgically to improve the material.

Table I. — Kemano Turbines Gibson Test Results

Unit No.	*Av. Eff. % 90,000–150,000 h.p.*	*Max. Eff. %*	*Max. Output h.p.*	*Max. Discharge c.f.s.*
1	91.0	91.4	156,000	607.5
2	90.6	91.4	157,700	620.7
3	90.5	90.9	154,300	607.0

The metallurgical story is an interesting one. The objective was to produce an 18-8 alloy tip on all buckets. This was attempted by straight build-up, and by welding on 18-8 prefabricated tips. In either case a layer of 25-20 alloy was laid down on the carbon steel of the bucket. Serious cracks developed and almost simultaneously both manufacturers, and Alcan through the Ontario Research Foundation, concluded that the 25-20 was causing the trouble as it is liable to hot-cracking, especially when deposited on carbon steel. A charge to 29-9 removed this difficulty and permitted the sound attachment or build-up of 18-8 or 19-9 tips.

Constant work on improvement of contour has lengthened the inspection and maintenance interval considerably from that experienced initially and, though not completely solved, this problem is well under control.

From the excellent experience with the 13 per cent chrome runner at Kemano, from a survey of European experience and practice, and from general metallurgical research all turbine manufacturers now conclude that this is the material to use for impulse runners for such high head service. Incidentally, at Kemano the water is carrying no foreign material at all, and all nozzles, throat rings, and needles are in excellent condition.

The 13 per cent chrome is a very difficult material to weld. It requires a preheat to about 600°F. and stress relieving afterwards, for major repairs so if hydraulic contours are not correct, repairs can be more difficult than with other materials.

Large 13 per cent chrome steel castings are difficult to obtain. The sources at the present time are all in Europe.

Little is known of the fatigue behaviour of 13 per cent chrome, at low stress levels, under 10,000 p.s.i., after a great number of cycles. A Kemano turbine, with an availability factor of 94 per cent runs approximately 55 million stress cycles in one month. Ordinary fatigue testing usually does not even approach this figure.

Thus certain interesting questions arise, which are being investigated by Alcan in cooperation with other organizations. In time, there may be an interesting story to tell here.

Automatic Computing for Process-Unit Operating Guides

H. F. Moore,

Esso Research & Engineering Company, Linden, New Jersey

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June 1957

The use of computers in military applications suggests a similar computer use to optimize process operations. At present, the central office type of computer is used by the oil industry to establish running plans for process units and refineries. The extension of computer use to continuous service directly on a unit is a large step that will require considerable development. In this situation it is shown that fairly simple computers may be used directly on the operating unit to compute important operating variables that cannot be measured directly but which can be computed from other measurements — an example is furnace efficiency. Eleven such "operating guides," for fluid catalytic-cracking plants, are discussed, for which two installations are under way.

FOR SOME TIME there has been considerable discussion in technical circles about the possible use of computers to optimize oil-processing operations. This discussion is a logical outgrowth of computer success on complex military jobs such as anti-aircraft-gun control against fast-moving targets, the guiding of missiles, and the recently publicized computer system[1] that would analyze all pertinent facts in the event of enemy air attack (location and speed of enemy planes, weather data, and so on) and compute the optimum defence moves.

Considerable thought is being given to such possibilities. The intricate, large-scale, central-office-type computer is already being used in the oil industry to determine how best to run individual processing units and complete refineries, when major cost factors change. Extension of such computing to continuous service at a process unit is a very broad step. The purpose of this paper is to discuss a shorter, concrete step in this direction that is now being taken, based on oil-industry experience with automatic log-sheet printers and data-handling equipment.

Automatic Log-Sheet Printers

An automatic log-sheet printer, or "logger" as it is now termed, does automatically what the house-man of an operating crew does manually — it records a line of data on a log sheet at regular intervals, usually every one or two hours. Starting with the signals from the regular process thermocouples (for temperatures), flow-rate transmitters and pressure transmitters (pneumatic or electric type), it operates one or more electric typewriters that print out the numbers on the prepared log sheet.

A logger has many individual components that are similar to and no more complicated than conventional oil-refinery instruments: Stepping switches, pressure switches and voltage dividers. The tying together of the components into the logger results in a device which is not difficult to understand, but which does require service personnel who are specifically trained in its maintenance. Available reports on oil-industry logger installations indicate that most, if not all of them, have been installed on an exploratory basis to investigate their values and their possibilities.

Very little has been seen in the technical press about the results obtained from the refinery installations. Informal contacts and discussions indicate that many of the loggers are giving poor results. Analysis of the problems and the underlying reasons for them will make interesting reading. At the same time, it is known that good results have been obtained with other refinery installations, such that it can be said that a properly engineered, installed and serviced installation should give a service factor well over 95 per cent. Service factors over 99 per cent have been demonstrated for long periods.

Most of the incentives for automatic loggers have been intangible[2], covering such items as *(a)* obtaining data during plant upsets, *(b)* obtaining more accurate data, and *(c)* allowing accounting changes. The loggers that have worked well should now allow these intangibles to be confirmed[3]. However, for the cases studied the intangibles are elusive. This, coupled with the difficulties encountered, cast doubt on the future of loggers for process units (their future on tank farm, pilot plants and testing operations seems brighter). Something more seems needed. This something may be the extension of the logger into computing.

What is There to Compute?

Most of the refining-industry loggers have involved some computing. The orifice meter flow integrators for example, handle the equation.

$$Q = C\int_0^t \sqrt{p-p_0}\ dt$$

where

Q - quantity flow in time t, such as barrels/day

C - meter factor, based on orifice area, discharge coefficient, differential range, and so on.

p - air-pressure signal from flow transmitter.

p_0 - air-pressure signal from flow transmitter for 0 flow.

t - desired time interval, commonly 24 hr.

Compensation for pressure and temperature changes for compressible fluid flow has been included on many jobs, and a few also have included adding up all the product meters and comparing the total with the feed meter, thus giving a material balance.

Such computing is more or less accessory to the log sheet, and is little or no different from what a good operator frequently did manually. It does, however, show what might be done and opens the door to a next possible step.

Operating Guides

Often there are important variables which cannot be measured directly, but which are computed easily from measurements that are made directly. Furnace efficiency is an example common to most process units. On a fluid catalytic cracker an important example is catalyst circulation rate. Although not measurable by any normal means, it is easily computed from a heat-balance equation. To generalize, most of the guides to operation that would be computed by a process engineer (1) during plant start-up, (2) to analyze an operating difficulty or (3) to compare with design figures, can be handled by a relatively simple computer. A general name of "operating guides" is commonly used for such variables.

By using a process-unit computer with a logger, such operating guides can be made available to the non-technical operating staff on a routine basis, being printed on the log sheet with the other logged quantities. Inasmuch as cycle time has little influence on complexity of the equipment, and thus little influence on its cost, a shorter or longer printout cycle can be used for the operating guides if desirable.

Two operating-guides computer installations are under way for affiliates of the author's employing company on fluid-catalytic-cracking units. One will use digital computing equipment. The other will use electronic analog equipment, keeping all values as voltages up to the time the typewriter prints them in digits on the log sheet. One will compute eleven operating guides, the other a few additional. The number of guides to be computed had a small effect on computer cost, as it was determined that after three or four computations were included, the cost of additional related computations that could use portions of previous computations, was minor. Thus, it was possible to cover considerable extra ground for slight added cost.

Operating-Guide Calculation Examples

Two examples of the types of calculations involved in computing operating guides are given, one being quite simple and the second more complex. These two illustrate the possibilities of this technique, using relatively simple computing equipment.

Heat Duty of a Pumparound Circuit

A pumparound circuit is typified by a heat-removal circuit on a fractionation tower; a hot stream is withdrawn from the tower, pumped through heat exchangers and perhaps a water cooler, and returned to the tower. The quantity of liquid is not changed.

The equation for heat duty is of the form: Duty = flow rate x spec. heat x (temp. out - temp. in) x constant.

Catalyst Circulation Rate, in a Fluidized-Solids Circulation System

In this type of circuit the catalyst picks up heat in a regenerator, where carbon is burned off, and gives up heat in the reactor to maintain an endothermic reaction. The calculation is of the heat-balance type. The equation is of the form shown here.

$$\text{Cat. Circ. rate} = \frac{K_1(CO_2\text{ rate}) + K_2(\text{CO rate}) + K_3(\text{air rate}) + K_4(\text{flue-gas rate}) \times (\%CO_2 + O_2 + \%CO/2) - K_5(\text{air rate})\ (\Delta t_1)}{\Delta t_2 \times \text{spec. heat}}$$

$$= (\text{Btu/hr.})/(\text{deg. F. Btu/lb. deg. F.}) = \text{lb./hr.}$$

In this calculation the CO_2 rate, CO rate, air rate, and flue-gas rate are separately calculated and held in storage for use in computing two or more of the operating guides.

Value of Operating Guides

The two installations referred to are exploratory. Experience with them should establish two points: (1) Are present-day computers practicable for use on refinery-process units, and (2) what is the value to refinery operators of having frequent computations made for them of important operating variables and information not otherwise measureable?

On the first point, experience with the better logger installations indicates that with suitable design, installation and servicing, a service factor over 95 per cent is attainable. The character of the computing equipment being added to the logger equipment is not expected to change this figure. It should be noted, however, that this is much too low a service factor for important closed-loop automatic control. Distinct improvement in dependability is needed to make the use of computers in closed-loop control attractive for long-term continuous operation such as is common for oil-processing units.

On the second point, the value of operating guides to operators is a matter of opinion today. The possibility of using such information to (1) improve plant operation, (2) reduce severe upsets and (3) to recover from upsets sooner is sufficient to justify such exploratory installations. It does not require too spectacular an improvement in the operation of a process unit that is upgrading the value of its feed stream $20,000 per day (not an unusual figure in the petroleum industry) to justify an expenditure of $20,000. It is necessary, however, to demonstrate at least two things: (1) that the equipment will continue to work without the need for what has been called "resident experts," and (2) that the improvement is "real", and not so small as to be masked by normal everyday variations.

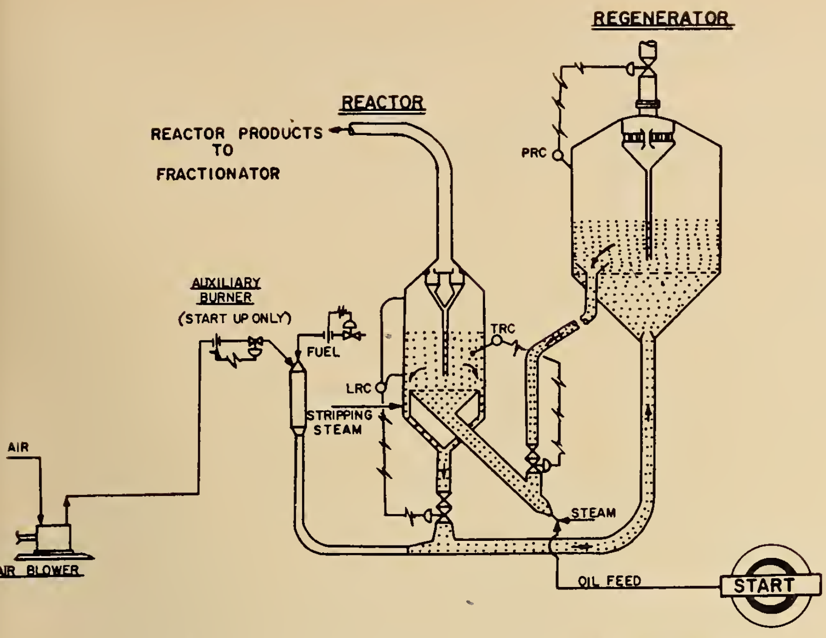
The Operating Guides

The eleven operating guides for one of the cat-cracker installations are:

(1) *Carbon burning rate,* lb/hr. This computed variable tells the operator how much carbon, which is deposited on the catalyst during the cracking reaction in the reactor, is being burned off in the regenerator.

(2) *Catalyst circulation rate.* This has been discussed.

(3) *Catalyst to oil ratio.* This is the weight ratio between catalyst circu-



Type of process unit to which automatic computing is being applied.

lation rate and oil-feed rate to the reactor.

(4) *Ratio, weight of oil fed to reactor per unit time, to weight of catalyst in the reactor.* This is a measure of contact time between oil and catalyst.

(5) *Per cent conversion of heavy feed oil to gasoline.* The feed stream is measured directly. The gasoline material is computed from several flow measurements on product and intermediate streams.

(6) *Amount of hydrogen in coke.* This is a measure of the efficiency of the stripper at the bottom of the reactor, where the oil is stripped from the coked catalyst as it is moved from the reactor to the regenerator.

(7) *Total carbon make — per cent of feed.* This is an important variable that is a measure of the effectiveness of the cracking reacton. The goal is to produce a maximum of cracked material with a minimum of carbon.

(8) *Heat duty of fractionator top pumparound stream.* This has been discussed.

(9) *Heat duty of fractionator mid-pumparound stream.* Similar to 8.

(10) *Regenerator superficial velocity.* This is a measure of velocity of gases through the regenerator.

(11) *Reactor superficial velocity.* Same as 10; for the reactor vessel.

Manufacture and Metallurgy of Flash-Welded Line Pipe

M. A. Scheil, *Director of Metallurgical Research*
G. E. Fratcher, *Director of Engineering, Tubular & Process Division*
S. L. Henry, *Asst. Director, Metallurgical Research*

Contributed by the ASME Petroleum Division for presentation at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June 1957

THE BEGINNING of resistance welding by the flash-welding process dates back to 1886, but it was not until after 1917 that it began to be developed into a practical welding method. The American Welding Society[1] defines flash-welding as a resistance-welding process wherein coalescence is produced simultaneously over the entire area of abutting surfaces by the heat obtained from resistance to the flow of electric current between the two surfaces, and by the application of pressure after heating is substantially completed. Flashing and upsetting are accompanied by expulsion of metal from the joint. The process found an increasing number of applications in the middle twenties and was well adapted for the fabrication of many articles. The process was rapidly expanded during World War II so that very critical structural forms for aircraft could be flash-welded. These included landing gears and hollow steel propeller blades.[2]

A very large production item for the company was the manufacture of 500, 1000, and 2000-lb. bomb casings from flash-welded pipe. This one item involved over 3954 miles of flash-welding medium-manganese steel of about 0.25 per cent carbon. The successful heat-treatment of these bombs to minimum mechanical properties of 70,000 p.s.i. yield strength and 105,000 p.s.i. tensile strength is further testimony to the distinct advantage of the flash-weld; namely, that by reason of its nature, no chemical composition change takes place between the weld and its parent metal and the properties that result from heat-treatment of the structure are therefore always similar. This fact has resulted in many specification bodies for our government facilities permitting 100 per cent joint efficiency for heat-treated flash-welds.

Flash-welding is used to join other metals or combination of metals which include stainless steels, copper-bearing alloys, aluminum alloys, and titanium.

This is the first of three companion papers by the same authors covering the general subject 'The Metallurgy and Cold-Temperature Testing of Flash-Welded X52 Pipe'. The other two papers, dealing respectively with Brittle Fracture in Steel, and Low Temperature Burst Tests, both related to flash-welded line pipe, will be published in the March issue of the Engineering Journal.

An outstanding example of the integrity of flash-welding is the flash-welded oil-well drill stem, fabricated by joining forged alloy-steel tool joints to drill pipe. This drill stem, working sometimes to depths below 20,000 ft., is subjected to high tensile and torsional stress, impact and abrasion. Economic success is borne out by the fact that over 50 per cent of the drill stem in service today is flash-welded.[3]

In 1926 the authors' company became interested in flash-welding as a means of joining steel. At that time the word "automation" was known only to the Greeks, but visions of this new concept already were being manifest in industries whose products were capable of being mass produced. By using new designs, we adapted the flash-welding process for making casing couplings, and the process fitted in very well with the mass produced article.

A year later the company became interested in the manufacture of large-diameter pipe. Before 1927, the total producing capacity for large-diameter pipe in the United States was about 3 miles per day. The demand for this product was growing rapidly with the oil and gas industries and in 1927 the company entered this field and by September of the same year a pipe mill was in production which had a capacity of 4 miles per day. The pipe was fabricated from a flat plate 30 ft. long which was formed to a tubular shape and then shielded-metal-arc welded. Within a year, more improvements were made and the capacity was increased to 9 miles a day. But this was not enough and in 1928 a new mill was designed to make large-diameter pipe in 40-ft. lengths. In designing the mill it was apparent that the arc-welding process was not adaptable to the economical operation planned. Since casing couplings could be easily flash-welded, there was no reason why a 40-ft. pipe section could not be welded except for the electrical power requirements. With some development work and experience, flash welders were designed and made to weld a 40-ft. length of pipe up to ⅝-in. wall thickness. To do this the electrical capacity of the flash welder had to be 6000 kva. and capable of delivering over 1,000,000 amp. to the flashing edges of the pipe.

The success of this operation was such that in the early part of 1930, all of the pipe arc-welding operations were discontinued. Since the beginning of flash-welded pipemaking the pipe-mill capacity has increased so that about 400 miles of pipe of sizes 8⅝ to 30-in. diam. can be made per month in the original plant. In addition a new plant was completed in Houston in 1950 which has a productive capacity of 200 miles per month with provisions for sizes up to 36 in. diam.

No history of a process would be complete without some facts and figures. As we often say, "the record speaks for itself." Flash-welded tanks of gauges 0.088 to 0.110 in. of mild steel for our glass-lined water heaters are a sizable item and have amounted to 2700 miles of flash welds.

We are rightly proud of the service record established over 30 years by the 42,000-odd miles of pipe laid to date, the greatest percentage of which is 20 in. and larger thin-wall pipe for high-pressure trunk-line service. Fig. 1 is a bar graph of the total mileage for the different sizes produced through 1956.

We can add a substantial tonnage to the foregoing for high-strength oil-well casing and other tubular products made by flash-welding which gives us an extensive and varied experience that justifies confidence in the safety, reliability, and economy of flash-welded line pipe.

Process of Line-Pipe Manufacture

Pipe manufacture begins in the

Fig. 1 (left). Line pipe production — miles of pipe of each size produced from 1927 through 1956.

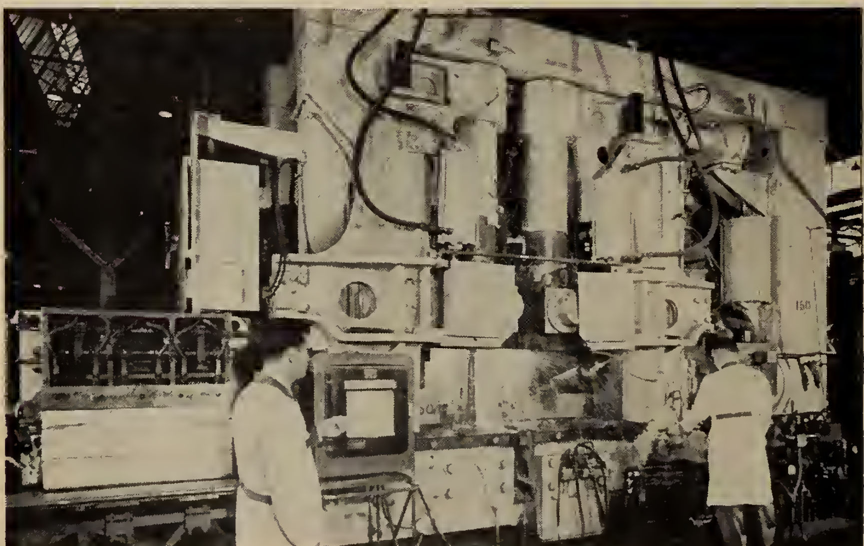

Fig. 6. Fifty-square-inch flash-welder for research welding.

laboratories of the research and engineering building with facilities for investigating every facet of line-pipe manufacture and end use. A few of our laboratories are regularly used to maintain quality and uniformity of line pipe. Fig. 2 shows the research and engineering building.

A view of the spectrographic and analytical chemical laboratories is shown in Figs. 3 and 4. Residual elements are periodically determined for the many sources of steel.

Another important research apparatus shown in Fig. 5 is the vacuum-fusion equipment for gas analysis and the fractional vacuum-fusion analysis of oxides in steel. The analysis from this equipment tells us about the deoxidation products remaining in the steel and is a valuable tool in evaluating the metallurigical behaviour of our materials.*

An experimental flash welder equipped with ultrasensitive electronic controls and variable pressures for burn off and bump is used in a continuous study of flash-welding research. Fig. 6 is one of these machines designed for 5-sq.-in. welding capacity with 2500 kva. power capacity.

The welding research laboratories together with metallurgical research are two of the oldest in our company. Their facilities encompass a complete laboratory for manufacture and testing of covered-metallic-arc-welding electrodes, all types of welding machines for automatic fusion welding in gas-protected atmospheres and the metallurgical testing equipment necessary to study and evaluate the processes.

Fig. 7 is a polariscope used to study and rate stresses in plastic models. Next to the Brinell hardness tester we consider this equipment and its value to engineers in design as one of the most valuable tools in our laboratories.

Fig. 8 is a corner of the research welding electrode laboratory. In earlier days this laboratory produced the first coated electrodes used to weld line pipe in the field and has contributed much to the recent developments.[4]

Figs. 9 and 10 show some of the mechanical testing equipment used

*An excellent discussion to A. B. Wilder's paper (reference (5) of the bibliography of the second companion paper) on the effect of deoxidation and its influence on the toughness and ductility of steel is given by A. Hurtgen, Henry Vogt Machine Company, and G. H. Enzian, Jones & Laughlin Steel Corporation.

to determine accurately the stress-strain characteristics of steel. The Instron testing machine in Fig. 9 has low load ranges of testing with maximum capacity of 10,000 lb. and a minimum full-scale load of 20 grams. The wide range of loads is facilitated by changing its strain-gauge-type load cells. Its electronic-amplifying system permits the selection of several load ranges within one load cell.

The selsyn-controlled mechanical-drive system moves the crosshead at a maximum of 20 in. per min. and a minimum rate of 0.02 in. per min. The recorder chart can be driven by time, microformer, extensometer or by a strain gauge mounted on the specimen, making it a complete X-Y recorder. Various controls permit automatic cycling, by load or deflection, and zero suppression.

The elevated temperature-stress rupture equipment shown in Fig. 10 is used entirely in this laboratory to study the long-time strength and ductility characteristics of weldments above room temperature. There has been very little work of this nature reported in the literature.

Fig. 11 shows some of the larger fatigue testing equipment used to test welded structures in vibration. The setup shown is that used to test a flash-welded propeller blade for the B-36 airplane.

measurements to evaluate structures from an engineering viewpoint.

In studying the efficiency of reinforcements for branch-line connections in co-operation with a large distributor of natural gas, we recently conducted a study of several engineering designs with the use of strain gauges to record the stress pattern while the welded structures were pressurized. Fig. 12 shows a typical setup for strain-gauge study and Fig. 13 shows the results obtained in calculating to stress, the readings obtained from strain-gauge study. Fig. 14 shows the burst test which indicates failure at the location of highest stress predicted from the strain-gauge survey.[6]

The actual operations involved in the manufacture of flash-welded line pipe are best illustrated in the schematic outline of Fig. 15.

Fig. 16 shows the acid cleaning of the plate steel in controlled baths: first, a pickling with inhibited acid to rot the mill scale, then a water rinse, then a neutralizing in an alkaline bath, followed by a hot water rinse. This assures a clean surface for inspection of the pipe.

Fig. 17 shows the cleaned, inspected plate being simultaneously flattened and scarfed.

Fig. 18 shows the forming operations which require three separate presses. The sketch in Fig. 18 shows each forming shape from flat plate to round pipe. Figs. 19 and 20 show forming equipment at our Houston plant. The press shown in Fig. 20 is 16,000 tons capacity for closing the pipe to a round. Fig. 21 shows two flash welders at our Houston plant and Fig. 22 shows the three flash welders at Milwaukee plant. The entire 40-ft. length of pipe is flash-welded simultaneously and the operation being largely automatic, uniformity of the weld is assured.

The welding process produces an upset on the inside and outside surfaces of the pipe and in the next operation this flash is removed by a series of cutting tools from both the inside and outside as in Fig. 23.

Fig. 24 shows the end facing after expanding.

Internal expanding offers three advantages for the pipe: *(a)* The internal expansion provides a test of the weld, *(b)*, it increases the yield strength of the pipe in the hoop direction, and *(c)*, it produces uniformity of physical dimensions by accurate straightness and roundness.

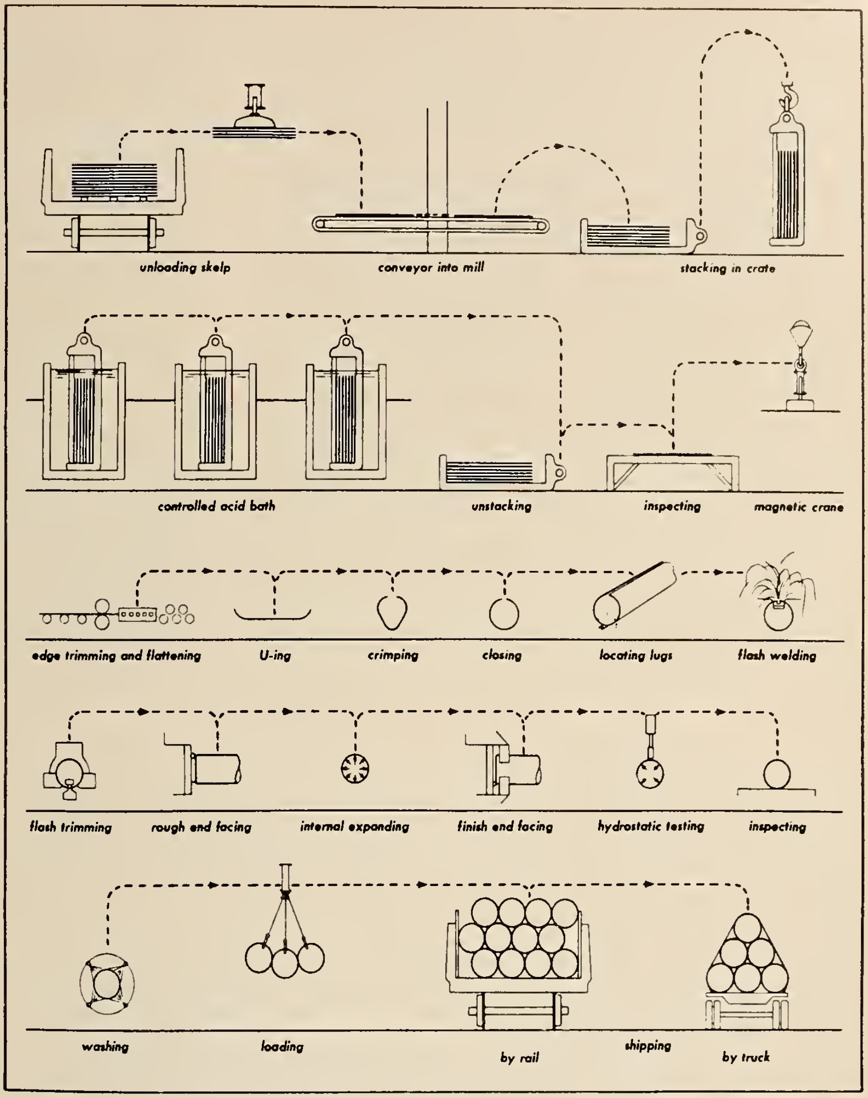

Fig. 15. Line-pipe production flow chart.

Fig. 16. Pickling operation on line-pipe skelp assures clean surfaces with no hidden defects for line-pipe manufacturing.

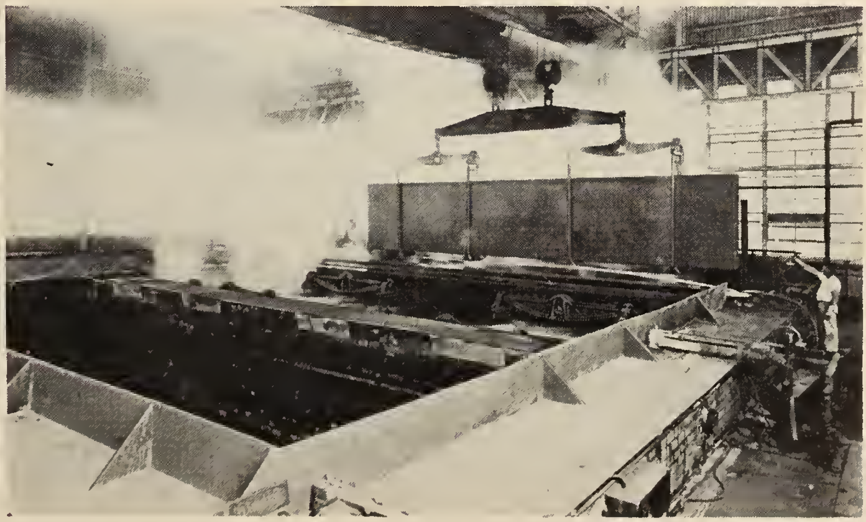

Fig. 25 shows the latest development of internal expansion of large-diameter pipe by means of a special expanding tool. Expansion by this process assures uniform inside diameter throughout the length of the pipe without any scratching, gouging, or maltreatment of the ID surface. After internal sizing, the pipe is faced on both ends, Fig. 26, to the bevel or contour of API Standard 5L or 5LX and then moves into the final testing machine.

The final hydrostatic test, shown in Fig. 27, is performed at a pressure of at least 90 per cent of the specified minimum yield strength for 20-in-OD and over line pipe, or as may be called for by API specifications. While under full test pressure, repeated blows are struck directly on the weld by 6½-lb. hammers placed at 2-ft. intervals along the weld area. Following the hammer test, the pressure is reduced 50 per cent while the inspector examines the entire length for leakage before certifying the soundness of the weld.

Inspection follows hydrostatic test where the inside and outside surfaces and dimensions are checked carefully. Fig. 28 is a view of the inspection area. The weight and length are recorded.

Final cleaning of the pipe is through a washing machine which uses hot alkali solution to remove any grease that may have accumulated during manufacture. The size, length, and weight are paint stenciled on the pipe and at this point the pipe is given a final visual inspection by company inspectors and by the customers' representative.

Fig. 17. Continuous operation of flattening plate and machine scarfing of edges for welding.

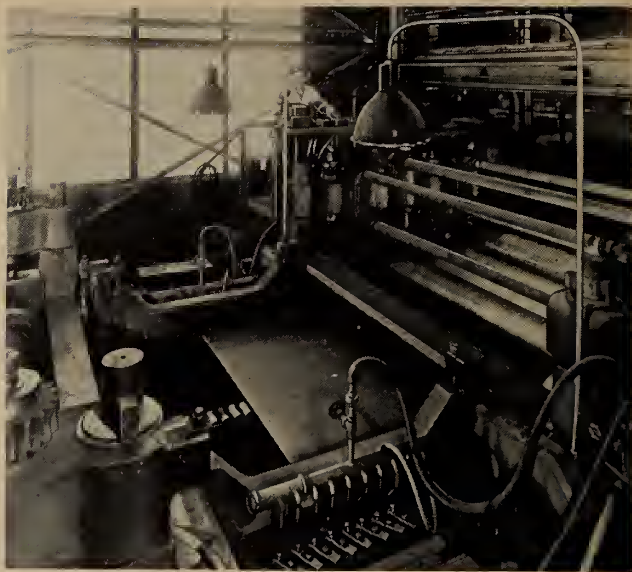

Fig. 18 (below). Forming operations for line pipe U, crimp, and closing prior to flash-welding.

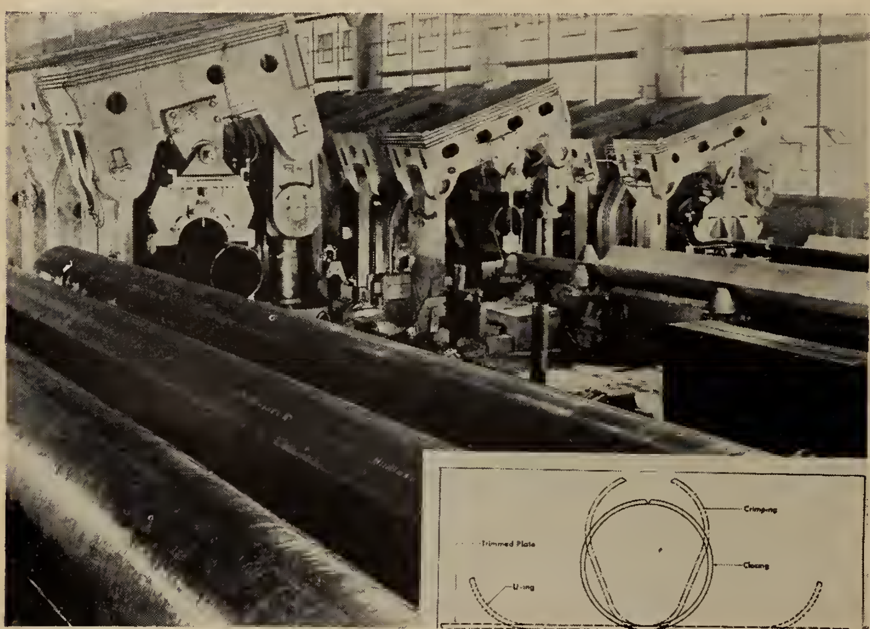

The finished pipe is conveyed on to a loading platform and deposited in a gondola car according to procedures that have been worked out from experience. Fig. 29 shows diagrams for loading 16 to 30-in-diam pipe. For a more detailed description of large-diameter line-pipe manufacture the reader is referred to recent articles by W. C. Hoppe.[7,8]

Bending in the Field

With the advent of high-strength line pipe in 1941, cold instead of hot bending was developed as a means of retaining the high-strength properties imparted through cold-working. Three general techniques now account for virtually all field bending — cold wrinkle bending, cold bending in a bending block, and the more recent cold-stretch bending. All three bending methods have been tested extensively and used on thousands of miles of line pipe, to the complete satisfaction of the operators. Figs. 30 and 31 show two views of cold field bending.

Layer-Wrapped Pipe

For high-pressure submerged applications such as river crossings and offshore high-pressure gas lines, our layer-wrapped pipe is now being used to meet problems occasioned by abnormal operating pressures and conditions.

Layer-wrapped pipe is pipe that has been strengthened by adding an outer layer of steel. It provides the heavier wall thickness needed to resist higher pressures and, where used for river crossings, it provides additional, uniformly distributed weight which reduces buoyancy.

Fig. 32 shows several sections of wrapped pipe for a submerged, high-pressure 20-in-diam line from offshore gas wells.

Metallurgy of the Flash Weld

The literature pertaining to the metallurgy and mechanical properties of flash-welded joints in steel and alloys of iron are of rather recent origin and the reader is referred to one of the more up-to-date articles by Dr. Hans Kilger and Prof. E. Nippes at Rensselaer Polytechnic Institute.[9]

For the purposes of this paper we will mention only some of the fundamentals of metallurgy in flash-welding semi-killed medium manganese, 0.20 to 0.30 per cent carbon steels

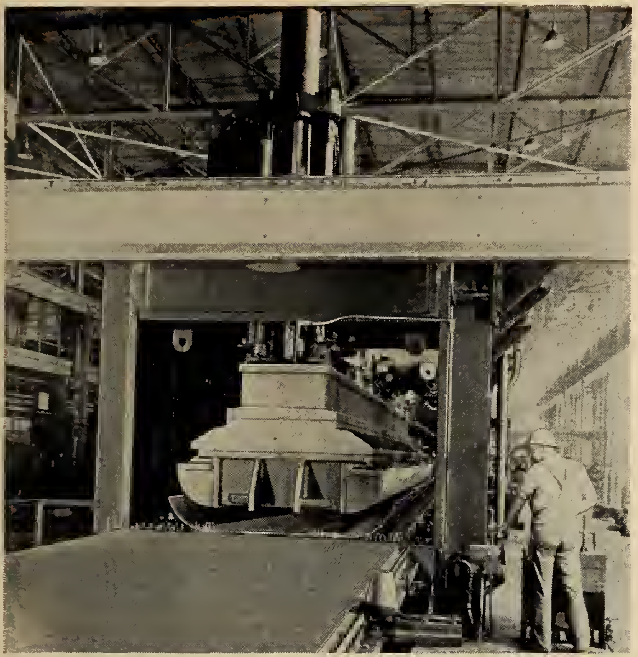

Fig. 19. Initial forming press for line pipe at Houston plant.

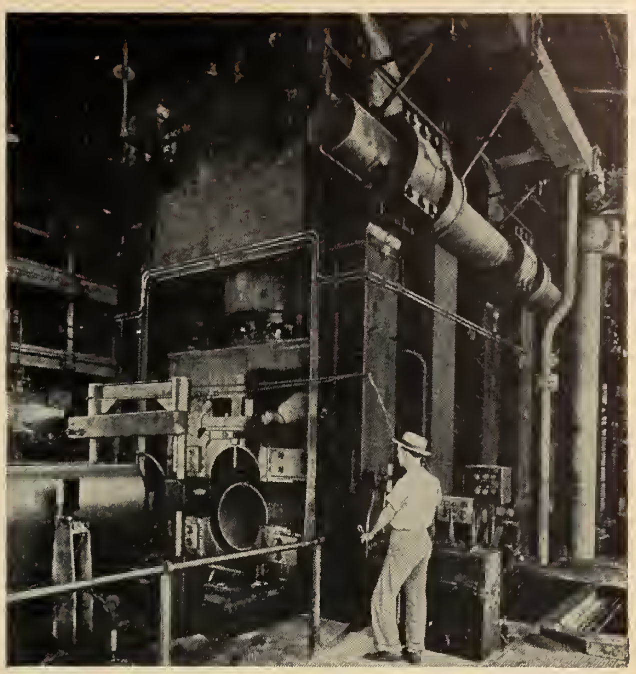

Fig. 20. 16,000-ton closing press for line pipe at Houston plant.

which are of the type generally in use for expanded 5LX Grade X52 steel line pipe.

In the manufacture of a flash-welded joint the edges to be joined are brought to a semi-liquid state by a flashing action caused by the passage of electrical energy between the contacting surfaces. Just before the current is cut off the two edges are bumped together automatically, thus making the weld. By this process a predetermined amount of metal together with the oxides formed by heating are squeezed out, resulting in a clean, sound, and strong union.

Fig. 33 shows a polished cross section of the as-welded condition of a line pipe weld as we produce it. The structure is brought out by a light etching of the polished surface.

The photograph shows a graduation of heat into both sides of the parent metal. It is observed that the grain size is slightly coarser near the center of the weld and blends with

weld zone* shown in Fig. 35 indicates very little change in hardness and therefore no decrease or increase in the tensile strength of the metal after the flash-welding process.

The rapid cooling of the flash-weld zone produces a normalized grain structure with no change in tensile strength but with an increase in the yield-strength property. This increase in yield strength in the flash-weld zone is best illustrated by the results of strain measurements on a 40-ft. length of flash-welded and trimmed 30-in. x 0.375-in. line pipe made during internal mechanical sizing to 1¼ per cent circumferential expansion:

(1) Circumferential permanent expansion of the stock was uniform varying from 1.14 to 1.40 per cent. The average of nine strain-gauge readings along the length of pipe was 1.27 per cent.

(2) Longitudinal permanent contraction of the stock varied from 0.24 to 0.38 per cent. Shortening of 30-in-OD line pipe after cold internal mechanical sizing on a 40-ft. length is about 2¼ in.

the parent metal out to the contact saddles where the water-cooled electrical contacts together with the mechanical contacts actuate the pipe during flashing and the welding bump.

Both surfaces of the weld show a flash of hot extruded metal.

During the flash-trimming operation, the weld flash is removed from both the inside and outside simultaneously to within 1/16 in. or less of the pipe surface. The finished trimmed flash-weld, now ready for service, appears as in Fig. 34.

A hardness survey across the flash-

*The weld zone in a flash-weld is defined as the material which has been heated above the transformation temperature.

(3) The weld area of a cold expanded pipe is under residual compression in the longitudinal direction because of the relatively greater yield strength of the flash-weld zone. The residual compression stress in the weld zone is 30,000-35,000 p.s.i. in the longitudinal direction. This could be considered to be a built-in safety factor against fatigue damage in service as well as shock or pulsating loading.

(4) The combination of the forging action and controlled normalizing heat-treatment obtained from the simultaneous heating and automatic welding of the 40-ft. pipe welds in our flash-welding process improves the toughness characteristics of the steel in the weld zone over that of the parent metal.

As an example of this effect the Charpy vee-notch-energy values are compared in Table I at different temperatures. The data shown are an average of three Charpy tests at each location and temperature.

From the data it will be observed that the weld zone has a transition temperature at 10 ft-lb energy* of minus 50°F. whereas the parent metal has a transition temperature of +32°F. This improvement of the weld-zone notch toughness, over the parent metal is not due entirely to the normalizing heat-treatment, as we have determined that under the best heat-treated conditions, it is not possible to bring the parent metal to a state of notch toughness, as determined by Charpy impact data, to duplicate the properties in the weld zone. The observed improvement then must be due to a combination of high-velocity hot-forging impact followed by controlled rapid cooling which prevents a coarse "blocky" ferrite structure formation.

treatment purposely given to bring out the flow pattern, by etching, of the metal after the welding bump.

It will be observed that the direction of metal fibre or flow, so important to the strength of forgings, is gradually and uniformly turned about 90 deg. This flow pattern is evidence of a high-velocity hot forging impact causing the removal of any impurities at the semi-liquid surfaces of the 40-ft. length which are brought together simultaneously and automatically.

It will be observed from Table II that controlled cold expansion by mechanical internal sizing in small amounts is beneficial to the mechanical properties of the steel and the flash weld.

It has been our experience with over 42,000 miles of flash-welded line pipe in service, that the metallurgical properties of a simultaneously flash-welded tubular product of steel can be likened to high-quality closed die forgings. Every closed die forging has a flash line to permit the hot steel to fill the die cavity properly and as a result flow lines are generated in the extruded metal. Superior advantages for flash-welded tubes over hollow-forged or pierced cylinders are evident in a comparison of the surface condition. The skelp used for the flash-welded tube must first be rolled to proper width and length from its billet or slab and in this process the cross rolling benefits the mechanical properties in the transverse direction.

For example, taking the data of the Armour Research Foundation[10] report on welded X52 grade steel line pipe and averaging the 2/3 standard Charpy vee-notch data at 80°F. for the longitudinal and transverse direction on 53 heats of expanded line pipe resulted in the evaluation given in Table III for X52 grade steel.

Fig. 30. On-the-spot cold field bending of 26-in.-OD line pipe.

Since flash-welded line pipe is made from carbon-steel plate (skelp) purchased to rigid specifications the steel possesses the desirable surface smoothness and density characteristic of rolling, and both inside and outside surfaces can be inspected thoroughly for flaws and imperfections before manufacture into line pipe.

Metallurgical Analysis of Expanded Flash-Welded Line Pipe (24 in. x 0.344 in.) in Service 25 Years

An opportunity was provided recently to examine a piece of 24-in. x 0.344-in. flash-welded line pipe manufactured in 1930. The pipe had been joined in the field with oxyacetylene welds at the girth seams. Internal sizing had been performed with hydrostatic pressure. The average carbon analysis was 0.23 per cent, the average manganese was 0.61 per cent. Average transverse strip tensile across the weld and stock averaged 47,733 p.s.i. yield strength at approximately ½ per cent stretch and the ultimate tensile strength averaged 68,640 p.s.i. The average elongation was 19.29 per cent. The results of several burst tests averaged 46,160 p.s.i. at yield and 63,820 p.s.i. ultimate tensile strength. These tests were performed when the pipe was fabricated in 1930. The pipe was manufactured to minimum properties of 60,000 p.s.i. tensile strength and 30,000 p.s.i. yield strength.

After approximately 25 years of service this pipe was removed and retested by the customer. One of the line pipes was field tested to a pressure of 1700 p.s.i., which corresponds

Fig. 31. Tough bend requirement met with 26-in-OD line pipe.

Fig. 32. Installation of wrapped pipe for submerged, high-pressure line.

Fig. 33. Etched structure of an as-welded line-pipe flash-weld.

Fig. 34. Trimmed flash weld of a line pipe.

to a circumferential stress of 60,000 p.s.i., or the minimum guaranteed ultimate tensile strength of the steel, "as fabricated". One reason for the work being done was to prove or counteract rumors that pipe which had been cold internal expanded and which had been in service for a long period of time becomes brittle and dangerous for future use.

It is not the purpose here to discuss the quality of the welding, which, it was evident, was far inferior to anything produced at the present time, in the matter of field girth seams, and it is not the purpose here to detract by reason of this evidence any demand for the highest quality field welding demanded today for pipe-lines.

However, the authors believe it would be of interest to review Table IV showing the mechanical properties that were determined after 25 years of service on this 1930 vintage expanded 24-in. x 0.344-in. wall flash-welded line pipe.

Based on a 10-ft.-lb. value of the ½ standard Charpy vee-notch bar a transition temperature of approximately +50 deg. F. is obtained. The grain size of the material based on the ASTM carburizing test was found to be 5-7 and would be classed fine grained.

As a result of these tests, it was concluded that the material did not embrittle or deteriorate in mechanical strength properties in the 25 years of service.

DISCUSSION

of Technical Papers and Other Articles

WILL ULTIMATE STRENGTH DESIGN OF REINFORCED CONCRETE BEAMS SIMPLIFY STRESS CALCULATIONS?

E. M. Rensaa, M.E.I.C., *The Engineering Journal*, 1957, June, 805

J. G. MacGregor.* S.E.I.C.

Mr. Rensaa's recent paper on ultimate strength design served the very necessary purpose of pointing out some of the major limitations of this method of design. I would like to discuss this paper and its relation to the appropriate sections of the most recent reinforced concrete design codes of the U.S.A.[1] and Britain.[2]

Basically, the question is whether to accept the ultimate strength design method at this time. Mr. Rensaa believes that it may be too early to do this now and he questions several of the assumptions made in deriving the basic design equations. On the other hand, the proponents of ultimate strength design feel that the inaccuracies still remaining in their method are small compared to those introduced by the straight-line theory in use today. In passing, let me quote a distinguished engineer on this subject. "In the field of structural design the effort to get intelligence through standardization has been carried pretty far. In reinforced concrete, for example, it has been necessary to set up elaborate standards. Out of this work came a narrowly circumscribed standardization of procedures which is called the theory of reinforced concrete and to which unfortunate students are exposed. Few will question that the standardized theory of reinforced concrete is perhaps as complicated a bit of nonsense as has been conceived by the human mind . . ."[3]

Balanced Design

Perhaps Mr. Rensaa's chief point in criticizing ultimate strength design is that a "balanced design" beam is undesirable. As he states, such a beam is difficult to construct and is directly affected by accidental differences in concrete strength which might occur in the field. The strength of such a beam is greatly affected by the exact shape of the stress block which will occur in the beam at failure and the failure of this type of beam is sudden and violent, often completely destroying the beam.

While the above are all valid criticisms of any design procedure *allowing balanced or over-reinforced beams,* they are not valid criticisms of the appendix to the A.C.I. Code or to the Load Factor Design Section of the British Standard Code of Practice. The former[4] specifically limits the amount of tension reinforcement allowed in a beam to a percentage which "is about 0.9 of that required to develop the full compressive strength of the section,"[5] and the latter limits the depth of the compression block which can be considered effective.[6] Both these codes, therefore, do not allow balanced or over-reinforced beams.

The Effect of the Shape of the Stress Block

Before the turn of the century, reinforced concrete design formulas were based on ultimate strength concepts. The straight line theory became generally accepted about 1900 since it was mathematically simple and, on the basis of tests available at that time, it appeared to give a reasonable factor of safety. Since that time, as the author stated, many different stress blocks have been proposed. These have been of four general types: rectangular, triangular, trapezoidal and parabolic, all of which were recognized as being approximations to the true shape. The constants involved in defining these stress blocks, however, were derived on the basis of rigorous laboratory experiments. The A.S.C.E.-A.C.I. Ultimate Strength Design Joint Committee Report compares the calculated values of ultimate moment from three of these stress blocks to the actual strengths of seventy-seven singly reinforced test-beams (Table 4 of Appendix A). A similar study was made comparing formula 2 of the committee report (Formula A1 of the A.C.I. Code) and the straight line theory formulas for 299 singly reinforced test beams (Table 1 of Appendix A). The results of these comparisons are tabulated in Table A below.

Table A — A Comparison of Various Methods of Computing Ultimate Strength

Method of Computation	*Test/Calculated Values of Ultimate Moment*			
	Mean	*Standard Deviation*	*Maximum*	*Minimum*
Parabolic Stress Block......	1.09	0.14	1.52	0.81
Trapezoidal Stress Block.....	1.04	0.13	1.39	0.74
Rectangular Stress Block....	1.08	0.14	1.52	0.74
Formula 2 of U.S.D. Report..	1.09	0.14	1.65	0.87
Straight-Line..............	1.30	0.32	2.60	0.92

From the first comparison it can be seen that there is little actual difference between the ultimate moments computed using each of three different stress blocks. The second comparison, however, shows that much more difference exists between the straight-line theory and the more accurate ultimate strength formulas. This latter difference can be attributed to the fundamental differences between the straight-line theory and modern ultimate strength theories.

*Graduate Student and Research Assistant University of Illinois, Urbana, Illinois

Other Applications

Up to now, this discussion has been limited to rectangular beams, conventionally reinforced in tension only. For this type of beam, the final proportions are very little affected by the design method used since the most economical steel percentages are approximately equal to the straight-line theory "balanced" steel percentage. For other types of beams, however, the straight-line theory tends to fall down.

This is true of prestressed concrete beams where the high steel strengths and the lack of a well defined yield point stress make it necessary to use an ultimate strength design procedure to determine the actual factor of safety of a beam. Indeed, much of the recent research regarding the ultimate strength of concrete beams has been done in connection with prestressed concrete.

Similarly, the straight-line theory fails to predict accurately the ultimate strength of beams with compression reinforcing. This was borne out in tests run at the University of Illinois.[7] A straight-line analysis of these beams yielded values for the ratio of test strength to calculated strength ranging from 1.12 to 1.43 and averaging 1.22. For the same beams the A.C.I. ultimate strength analysis yielded a range of 0.96 to 1.08 and an average of 1.03. The reason for this close agreement is that the ultimate strength design methods, as set forth in the building codes previously referred to, closely express the actual behavior of beams with compression reinforcing. The same is also true for T-beams.

Another field where ultimate strength design is superior to the straight-line theory is the design of eccentrically loaded columns. The present design method, for e/t less than 2/3, assumes that the column does not crack until e/t equals 2/3. This approach was first proposed by Prof. Richart[8] who felt that the errors involved in this approximate method were not serious for e/t values less than about 0.5. For columns with greater eccentricities, design is presently based on a straight-line procedure. In Tables 2 and 3 in Appendix A of the A.S.C.E.-A.C.I. report, the actual test results for 184 columns are compared to ultimate loads computed using the 1951 A.C.I. code formulas and the proposed ultimate strength formulas. It should be noted that the empirical nature of the A.C.I. design method makes it impossible to directly compute the maximum capacity of the section. For this reason, the A.C.I. design load is compared directly to the ultimate load and therefore the ratio of strengths includes the safety factor. The mean ratio of test strength to A.C.I. strength (e.g. the mean safety factor) is 3.18, standard deviation is 0.61, with a range of 4.65 to 0.85. The ultimate strength method, on the other hand, attempts to directly predict the ultimate strength and for the A.S.C.E.-A.C.I. Report formulas the mean ratio of test to computed ultimate strength was 0.98, standard deviation 0.094 and range 1.32 to 0.72. To this ultimate strength a safety factor desirable to the designer must be applied.

So far we have discussed only the accuracy and adequacy of the ultimate strength formulas. Equally important to the safety of the finished structure are the load factors applied. While the design equations are based on over half a century of research and thought, the problem of load factors has generally been ignored. It appears that more thought and research into this phase of design is necessary before the Ultimate Strength design method is entirely perfected.

Conclusion

While the writer believes that some parts of the ultimate strength design codes have to be revised in the next few years, it is evident that there are several definite advantages to using ultimate strength design for proportioning flexural members.

The Author

The discussion by Mr. J. G. McGregor Jr., E.I.C., is of interest because it represents the general opinion of those who have been converted to believe in the efficacy of the ultimate load design method. His final conclusion, however, contains the statement of belief that "some parts of the ultimate strength design codes have to be revised in the next few years". The author certainly agrees with that opinion.

Mr. McGregor quotes a statement made by Hardy Cross to the effect that the usual theory of reinforced concrete is more or less nonsense. It is unfortunate that an engineer of the standing of Hardy Cross should make such a rash and unfounded remark. Such a statement is apt to mislead students and young engineers into believing that the present theory of reinforced concrete, which has been built up by a large number of able men, ought to be scrapped. As far as standardization is concerned, the greatest attempt in that direction is really the ultimate strength design method which its proponents are trying to make universally applicable. Reinforced concrete happens to be a composite material which needs special treatment of different parts and functions of structural elements. A thorough knowledge of basic facts is therefore necessary even if this involves elaborations. It is unfortunate that the attempt to simplify has in time led American text book writers to cut out basic explanations to a very large extent. The result has been a too literal belief in approximate formulae. When it was then found that these had limited applicability, some engineers reached the conclusion that the whole theory was wrong and should be abandoned.

I think it is incorrect to say that "before the turn of the century, reinforced concrete design formulas were based on ultimate strength concepts". This is hardly true if meant to indicate the use of a stress distribution different from the straight line one. There was no mathematical reinforced concrete theory before the work of Koenen was published in 1886 and his was of the straight line triangular type. Other engineers who during the next fourteen years until the turn of the century continued the development of the mathematical theory also based their work on straight line stress distribution. It is true that they found very early that this did not give a correct picture of concrete stresses at ultimate loads, but the present concept of ultimate stress design never made any headway. The reason for this was the necessity in most cases to calculate the stresses for conditions of use. The author does not think that this reason has been made obsolete by any later developments.

It is correct that for tied reinforced concrete columns, the ultimate strength design is the best. This is not the case, however, for spirally reinforced concrete columns. It is possible to design such a column so that it will be shortened by loading as much as 3%. This would mean that a column 100 in. high could be compressed 3 in. The shell would have cracked long before this and the column and supported structure would certainly be in a precarious condition. We should in this case again have been forced to limit our load on basis of conditions of use instead of on ultimate load capacity.

The author had purposely limited the scope of his paper to the discussion of ordinary beams. Discussion of columns would require a rather long paper.

SHEAR, DIAGONAL TENSION AND BOND STRESSES IN REINFORCED CONCRETE BEAMS

E. M. Rensaa, M.E.I.C., *The Engineering Journal,* 1957, October, p. 1464.

I. F. Morrison*

Under the heading, Shear at Points of Contraflexure, on page 1467, the author states, "The ordinary formula for shear in a reinforced concrete beam $v = \frac{V}{bjd}$ is based on the assumption that the concrete below the neutral axis is unable to take tension . . .". And further on, "The term jd, therefore, has no definite value . . ." The writer does not agree with these statements.

If one goes back to the derivation of the usual formula, it will be found that, regardless of the shape of the stress-solid assumed for the compression area and for the tension area of the cross-section of the beam, there will always be some distance from the neutral axis to the centroid of that portion of the stress-solid above an assumed horizontal section on which the longitudinal shearing stress is to be computed. As different horizontal sections are selected, the longitudinal stress varies from zero at the top of the beam to some maximum value and then decreases to zero at the bottom. The value of jd, when placed in the usual formula, gives this maximum value of v. It is the distance from the tension reinforcement to the centroid of the stress solid above the section of maximum shearing stress.

The value of V represents the $\frac{dM}{dx}$ i.e. the rate of change of bending moment along the axis of the beam. So that, although the moment is zero at a point of inflexion, this fact does not enter into the derivation of the usual formula for the maximum longitudinal shearing stress.

*Professor Emeritus of Applied Mechanics, University of Alberta, Edmonton.

It will be recalled that shearing stresses are always in pairs at right angles to each other and, therefore, the vertical shearing stress is equal in value to the longitudinal. There is always a neutral axis, although it may not lie within the cross-section.

In respect of a cracked section assuming the crack to be vertical, there can be of course no vertical or longitudinal stress at the end of the crack. But above this point there will be a shearing stress which varies in value to a maximum at some point and then decreases to zero at the top of the beam. Where the computed maximum value will occur would depend on the shape of the stress solid-assumed. Under any circumstances, however, there will be a definite factor such as jd in the formula which will yield the maximum value of v.

In this case, there will be also a compressive stress where the value of v becomes a maximum and since it is the tension stress on the concrete, which arises from the shearing stresses, which is important, the Mohr's circle should be plotted to determine the value of it. If it be excessive, then suitable reinforcement should be provided. Incidentally, this same point arises in the theory of prestressed concrete beams which benefit considerably in reduction of the tension stress on the concrete due to the combination of the shearing stresses with the compressive stresses in the concrete caused by the prestressing.

In the last paragraph on page 1467, the author claims that it is necessary to use the formula for homogeneous sections in order to find the actual shearing stresses. If this means the formula for unreinforced rectangular sections, then it is not correct for concrete sections reinforced top and bottom. The transformed section should be used. It will be noted that the formula for the unreinforced section can be written $v = \frac{V}{b\ .67d}$, so that here in effect the definite value of j is 0.67. For the transformed section, j will have a different and larger value. The shear stress distribution curve is, of course, parabolic between the reinforcements. At the reinforcement, a discontinuity occurs and part of the shear is transposed into bond stress along the reinforcement. The curve then goes to zero at the free surfaces of the beam.

The Author

The author's statement in his paper that the usual shearing stress formula for reinforced concrete does not apply at points of contraflexure seems to be difficult to accept by some engineers. It is, therefore, of value that this statement has been questioned by Professor Morrison because it gives an opportunity to explain this fact in more detail and to show that it is correct.

When calculating the stresses in a reinforced concrete section, it is usual to designate the condition before there is any cracking as "Case 1". When a crack forms and only a part of the concrete section is effective, the condition is designated as "Case II". The usual shearing stress formula for reinforced concrete with its corresponding stress diagram is based on the conditions of Case II. This assumes cracks to be perpendicular to the axis of the member and that there will be an uncracked portion from the neutral axis to the compression side of the beam.

In order to follow the action of the stressing of the member, it is necessary to start with Case 1. We know that concrete has its greatest weakness in tension and when it cracks it will be along a line perpendicular to the principal tensile stresses. This cracking line is never vertical at a point of a beam acted on by transverse forces in a location where there is little or no bending moment. The assumption of vertical cracking at such a point to suit our usual shear stress formula is therefore not in order. Furthermore, since the tensile stresses perpendicular to a diagonal line will extend from top to bottom of the beam and will be of greatest magnitude near midheight, we cannot generally figure on the crack stopping before it has passed through the complete section. From the above two considerations, it should be clear that the assumptions of Case II do not hold at points of contraflexure. In fact, there is no Case II in the accepted sense of the term but only Case 1 and a second condition with complete cracking where the reinforcing steel must carry the full shear. Unless this fact is understood, the most important point in the paper has been missed. The use of a formula with its stress diagram in a place where it does not apply is, therefore, quite misleading. Although it is hardly necessary to write any more about this case it might be worth showing how ridiculous a condition it might lead to if we accepted the formula for general use. Assume a section just to the left of the point of contraflexure with negative moment. There should then be a vertical crack from the top of beam to the neutral axis. On the right side of the point of contraflexure with positive bending moment the crack would be from the bottom of beam to the neutral axis. Assuming the formula to hold from both sides to the point of contraflexure the two sections could be moved infinitely close together with the result that there was a vertical crack clear through the beam. This would certainly be an easy way of explaining the weakness at a point of contraflexure but it would have nothing in common with facts.

That the usual shear formula does not give correct values of maximum shearing stresses where there is little bending is not a new discovery. A two page discussion about this matter (not especially referring to points of contraflexure) may be found on pages 340 - 341 (Wirkliche Schubspannungen) in the book by Rudolf Saliger[1].

Regarding the use of the fundamental shearing stress formula for the uncracked condition, Case 1, the author is quite aware that the transformed section should be used if the object is to calculate the exact shear stress distribution. That the steel will have some modifying effect has also been mentioned in the article. This effect will be to cut "notches" into the upper and lower limits of the diagram about similar to those for a flanged beam. The knowledge of the exact stress distribution along an inclined section would, of course, have some academic value. However, this is rather unimportant for the main purpose of the paper. The important fact is that the sum of vertical shearing stresses at a section must be equal to the external shear and that the shearing stress is greatest at about the middle height of beam and decreases in some kind of order to zero at both top and bottom of beam.

If we want to give a designation of the internal lever arm, some other term than jd should be used because this designation assumes the lever arm to be measured from the reinforcing steel. Such an assumption is generally not in accordance with the starting or terminal points for the internal lever arm in an uncracked section. Anyhow, the cause of failure at a point of contraflexure is not caused by internal shearing stresses but is rather due to diagonal tension where the central portion of beams is "hung onto" the cantilevered beam end. There is considerable similarity between this case and the case of a reinforced concrete member subject to direct tension. Before cracking, concrete carries most of the tensile force, while the steel must take the complete tension after the concrete has cracked. It is in reality a mistake to think that concrete can take no tension. If that was the case concrete would be completely useless as a construction material. The stability of continuous slabs for instance, is secured by the diagonal tension in most cases being so low that it can be safely carried by the concrete.

The author would like to draw the attention to a printing error in the equation on page 1469 second column where the sign after T should be an equal sign instead of a minus sign. It would also have been better instead of Q to use R or V to represent the shear at the section.

There is a statement in the paper which needs some qualification. This refers to the third column on page 1465 where it is mentioned that where shear has any influence on ultimate strength this increases until web reinforcement sufficient to carry the complete shear is provided (Reference 4). Later information (2) has shown that this statement based on the work by Mörsch only applies for concrete of comparatively low strength as was generally used in the first quarter of this century. Even Mörsch found that when concrete had reached a cube strength of 225 kg. per square centimeter (approximately 2500 p.s.i. cylinder strength) web reinforcing for half the shear would give as much ultimate strength as full web reinforcing. It is rather seldom at the present time that reinforced concrete of less than 2500 p.s.i. strength is used in North America even though this is not the general case in Europe. To reinforce for the full shear, excepting where it reaches a very high intensity, seems therefore unnecessary. This statement does not apply to the vicinity of points of contraflexure where full shear reinforcing should be provided if there is any danger of failure in diagonal tension.

It is not too difficult to understand why stronger concrete will need less web reinforcing for bending-shear conditions than weak concrete would. Not only will the strength in combined compression and shear on the remaining uncracked portion be greater but the web steel will be much more effective due to a more secure anchorage in better concrete. Where bent up bars are used, the higher compressive strength at points of bends will provide more resistance to crushing, making such truss bars more effective. The author had these conditions in mind when making recommendations to the National Building Code committee. It was recommended and later tentatively adopted that only two thirds of the shear at bent sections needs to be carried by web reinforcing. This is less than provided by European practice but more than generally specified by the A.C.I. Code.

The question may properly be asked if it is necessary in all cases to provide web reinforcing at points of contraflexure. The author does not think that this is the case. We know that concrete can take some tension and that also applies when this acts in a diagonal direction. Continuous reinforced concrete slabs, for instance, have given little or no trouble at points of contraflexure because the diagonal tension in most cases will be low and on the safe side. It is clear, however, that the allowable diagonal tension should be lower at a point of contraflexure than near the face of an internal support where there is both shear and bending. It is fortunate that in most cases the shear at points of contraflexure in a uniformly loaded member complies with such a requirement. In practice it may vary somewhere between 50 and 70 per cent of the shear at the face of support. For a member of uniform cross section this automatically provides a corresponding reduction in diagonal tension. This may not be true for concentrated loading and for non uniform cross sections. The author thinks that if the maximum allowable shearing stress at face of an internal support does not exceed what is allowable for unreinforced concrete then no special web reinforcing at points of contraflexure is needed unless conditions are such that the shearing stress at this point exceeds two thirds of the allowable shearing stress. If, however, the allowable shearing stress at face of support is exceeded, web reinforcing for at least two thirds of the shear at support and for the full shear at and somewhat beyond the extreme location of points of contraflexure should be provided. This simple rule will exclude, in the majority of cases, slabs and stubby beams from the strengthened code provisions for shear. Special precautions should, however, be taken when the continuous line of beams is long or restrained from longitudinal movement and where most of the load is of a permanent nature.

While it may not be theoretically necessary with low shearing stresses to provide web reinforcing in beams, the author thinks that stirrups should be placed along the complete length of beam in any case. This should be mandatory where the beam is rectangular. Stirrups, in addition to giving more secure placing of steel, are also useful to provide resistance against splitting and as ties where the reinforcing is in compression.

A MAJOR POWER PLAN FOR YUKON RIVER WATERS IN THE CANADIAN NORTHWEST

J. M. Wardle, M.E.I.C., *The Engineering Journal*, 1957, November, p. 1638

C. C. Marshall,* M.E.I.C.

The author is to be congratulated on an admirable presentation of a most interesting project.

The general public, and perhaps many engineers, do not appreciate the tremendous amount of work that must go into the early stages of a scheme of this nature and magnitude, and how easy it is to spend a great deal of time and energy exploring blind alleys.

I have had the privilege of visiting the areas in question during the survey and of advising the author on certain aspects. I was most impressed by the way the work had been organized and carried out.

The project represents one of the few remaining great blocks of cheap power on the North American continent.

It has the great merit that it can be developed in stages. Its principal disadvantage lies in the location of the industrial area on the Taku River just within the United States border, which precludes the construction of a deepwater port in Canadian territory.

However, I am disposed to think that, in the long run, this disadvantage may prove to be a blessing in disguise. Mr. Wardle has mentioned the possibility of transmitting power to Alice Arm, where deepwater sites would be available in Canadian territory. I would like to look even further to the Lower Nass Valley from Aiyansh to the sea. Unlike so much of British Columbian territory on the coastal belt, this region is relatively flat and open and affords many square miles of area suitable for towns and industry. The imbalance of the distribution of population in B.C. is well known, and was indeed a subject discussed in the Province's recent brief presented to the Gordon Commission.

It is my view that, in the years to come, part of the solution will be in the development of the Nass Valley into a great industrial area. A certain amount of power is available locally on the Nass River itself. The question of whether it will be found best to develop this power first, or to go for the first stage of the scheme described, with an industrial area on the Taku, is one to which the answer will be worked out during the next year or two.

My point is, however, that in taking the longer view, the presence of this great block of power only 360 miles to the north of Aiyansh cannot but have a profound effect on the pattern of the Province's development.

*Chief Representative and Chief Engineer in Canada, Sir Alexander Gibb and Partners, Toronto.

Discussion from Meeting of the Institution of Civil Engineers

This paper was also presented to The Institution of Civil Engineers and was published in the Institution's *Proceedings* (vol. 7, pp. 441 - 464, July 1957) together with considerable discussion, to which the author replied.

Readers who are interested in this additional discussion should refer to the Proc. Instn. Civ. Engrs., as above, or get in touch with the library of The Engineering Institute of Canada at headquarters in Montreal.

FORCES INVOLVED IN PULPWOOD HOLDING GROUNDS

R. J. Kennedy, M.E.I.C.

The Engineering Journal, 1958, Jan., 58

G. E. LaMothe, M.E.I.C.†

As Professor Kennedy states, this is a very important subject to the pulp and paper industry; millions of dollars are tied up in structures which are often under heavy strain, the design of which up to this day has been, to say the least, haphazard.

As the author clearly shows, this is a hydraulic problem and a very abstract one at that; as he states, no single measurement will describe the condition of a boom layout.

So far, Prof. Kennedy's laboratory and field experiments have conclusively covered holding grounds where the average or surface velocities are relatively low. Under these conditions, the question of design arises.

For instance, it is to be noted that the Manicouagan site "check" (Appendix II) goes to show that the piers carry a relatively small proportion of the load in this case of low velocities. One may ask oneself this question: Were all these piers necessary, and could the load have been carried by guys anchored to the bottom, instead of piers, at a considerable saving? In other words, what conditions are required to oblige one to build piers?

This is not intended as a criticism of the Manicouagan boom layout, which was designed for absolute safety and before the mass of the information gathered by Prof. Kennedy and his associates had crystallized, but is meant to show the ramifications of the problems involved.

Many holding grounds in this country have been located where the water velocities are high (much higher than at Manicouagan) so as to fit into the mill location or for other imperative reasons.

As the industry expands or new rivers are opened, such locations will have to be used to hold wood. For instance, some present-day locations have after the jam is formed a considerable ΔH, according to the author's nomenclature.

†Chief Engineer—Woodlands, Price Brothers and Company Limited, Quebec, Que.

In one case I can recall, the ΔH was about 12 feet with an L of about ¼ mile; the SL being perhaps one foot or so, if no wood or piers had been there. This caused very heavy log jam, in some places over 15 feet thick, resting on a nest of piers which, in turn, held heavy booms tied together with chain. In this case, the piers carried the load, the boom's load being relatively insignificant after the jam was formed.

To date, these layouts have been designed by "hit or miss."

In summary, there are two types of boom layouts: one where the velocities are not too great, and the load is carried in great part by the booms - this is covered in Prof. Kennedy's paper; the other, where the velocities are so high that the load must be carried by the piers completely, or by both booms and piers.

Prof. Kennedy and his team know of this, and it is my belief that, with the information gathered to date and further laboratory and field tests, better methods than used today will be found, perhaps by exploiting more than it is today the division of force between the boom and shore, as illustrated in Figure 18 of the paper.

In concluding, one may well remember that the development of the basic hydraulic formula $V = \sqrt{2gh}$ has taken a long time to come to its present-day state, with a lot of dispute; the whole matter being of course empirical.

It is hardly a century since Francis came out with this weir formula, based on a spillway a few feet long and not two feet deep. As water demands grew, the application of this formula was extended by experiments to what it is today.

I feel that the present problem in Prof. Kennedy's able hands is of the same type, coming from the great expansion of Canada's number-one industry.

WINTER CONSTRUCTION

C. R. Crocker, M.E.I.C. *The Engineering Journal*, 1958, February, p. 43.

F. G. Rutley*, M.E.I.C.

I must agree with the author that the consulting engineer and the architect can reduce costs on winter construction if they and their clients will only watch the timing when a construction job is started. It is not economical to start a construction job in the middle of winter when everything is frozen up. Winter costs are naturally higher but they can be materially decreased with proper timing. If construction can be started in the early fall so that the contractor can get out of the ground before the really cold weather, then the contractor can handle his contract in a reasonable manner. Latterly, wage increases have come into effect in the spring and most workmen are definitely more work-conscious in the winter when there are construction men out of work. Consequently, labour costs are generally reasonable. Most of the increased cost of winter construction is due to heating, protection against the elements and the increased materials that are used up in protection and heating units and fuel.

There is another way the consulting engineer and the architect can help to decrease costs. There are more or less standard specifications on how to carry out most construction work during winter. Naturally these specifications are written for the most exacting conditions. There are many times and many occasions where the maximum winter protection is not necessary. In many cases the good judgment of the professional designer is lacking and in its stead is left an inspector who may or may not have the qualifications to judge when maximum or minimum winter protection is necessary.

AUTOMATIC COMPUTING FOR PROCESS-UNIT OPERATING GUIDES

H. F. Moore *The Engineering Journal*, 1958, February, p. 57.

K. N. Thompson†

Successful computation of guides for operating oil processing units will be a major forward step in simplifying the application of human judgment to process control. Significant gains in economy of operation should follow.

Mr. Moore emphasizes that simple, reliable data gathering and computing equipment is required. At an instrumentation session sponsored by the American Petroleum Institute's division of refining in Philadelphia May 15th, a panel discussion brought out that performance of the existing data loggers has been poor by any standards. Further study indicates that both design and maintenance failures have contributed. The possibilities of process parameter computation emphasize the need for correcting this condition. Equipment manufacturers have underrated the need for reliability, stability and longevity of components. Equipment designs must have more provisions for testing components while the equipment is operating. Both suppliers and users have underestimated the skill and training needed to adequately maintain logging and computing systems.

There is a current trend toward contracting for maintenance of data handling equipment in the same manner that business computer maintenance is handled by the manufacturer, or by a service corporation. This ties in with the "systems approach" to engineering, design, procurement, installation and maintenance of complete instrumentation and data handling facilities for process units or refineries. There are many advantages inherent in this approach. There is also a potentially serious disadvantage.

Major oil companies design their own processing facilities. As these designs become more costly and complex, the adequacy of control, especially dynamic control, becomes much more vital to successful operation. The process design groups must include people thoroughly familiar with the actual "in service" capabilities of measuring, control and computing components. Organizations which purchase instrumentation and data handling design, installation and maintenance assistance may seriously increase their problem in obtaining trained competent people for process control engineering, since they will be unable to provide detailed instrument engineering or service experience. This must be weighed against the current difficulty in obtaining skilled instrument service people through refinery labor training methods.

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

CANADIAN AVIATION INDUSTRY REVIEW

E. Hamphill, *Canadian Aviation*, v. 30 n. 12, Dec. 1957

Looking back on a course charted long before the 12 months under review, the Canadian aviation industry may well designate 1957 as a banner year. Here are the highlights.

December, 1956: The West German Republic places an order for 225 Canadair Sabre VI's, a contract representing an investment of 80 million dollars, including 400 Orenda 14 turbojet engines and spares.

January, 1957: Trans-Canada Air Lines reports its first 2 million passenger year and outlines plans for re-equipment which will make it one of the first all-turbine airlines in the world by late 1960.

February: Exactly on schedule Canadair rolls out its first CP-107 Maritime Reconnaissance version of the Bristol Britannia, the largest aircraft ever produced in Canada.

March: de Havilland Aircraft of Canada reveals details on its new twin-engined utility transport and announces that the United States Army has obtained special permission from the American Defense Department to place an evaluation order for five Caribous, off-the-drawing-board.

April: Canadair concludes extensive licensing agreements with Bristol Aircraft Ltd. of England for production and sale of Canadair modified commercial versions of the Britannia to be powered by Bristol Orion turboprop engines.

May: Canadian Pacific Air Lines inaugurates service on its precedent-setting new route to Europe linking Mexico and South America with the Iberian Peninsula through Toronto and Montreal.

June: Belgium places a 50 million dollar order for 54 Avro CF-100 Mark V's to be supplied under NATO mutual aid commitments financed by Canada and the United States.

July: Orenda Engines Ltd. unveils its Iroquois turbojet, rated by independent observers throughout the Western world as the most powerful jet engine at its stage of development.

August: Nordair Ltd., a new carrier combining the assets of Mont Laurier Aviation Ltd. and Boreal Airways, inaugurates a new service between Roberval and Frobisher Bay, establishing the first regularly scheduled air service between the Eastern Arctic and a southern base.

September: The Royal Canadian Air Force officially accepts its first CP-107 Argus from Canadair Ltd.

October: Avro Aircraft rolls out its first CF-105 Arrow all-weather supersonic interceptor, described as the ultimate in manned fighter aircraft.

November: Canadair Ltd. announces its decision to proceed with production of two prototypes of its original design for an ab initio jet basic trainer, the CL-41. Orenda Engines Ltd. reveals that the Iroquois has been run in flight in its modified B-47 test bed with completely satisfactory results.

December, 1957: Avro's Arrow will make its first flight powered by Pratt and Whitney J-75 engines.

Viewed strictly as dollars and cents and revenue miles the industry respectively maintained and surpassed records of previous years. Manufacturers' records for the year 1956 indicate sales totalling about 356 million dollars, about the same as in the previous year. During 1956 the manufacturing industry paid a record 114 million dollars in salaries and wages. For 1957, figures available at press time cover only the first six months of the year. They indicate that employment over-all will be up some 10 per cent over 1956 totals. Predicted on 1957 Canadian defence expenditures on a par with 1956 (about 240 million dollars), this year's unprecedented success in the export field should push 1957 sales above previous totals.

ALUMINUM WELDING EASY WITH LOW TEMPERATURE FLUXLESS SOLDER

S. Freedman, *Canadian Electronics Engineering*, v. 1 n. 8, Dec. 1957.

Aluminum is a metal difficult to solder or weld because it is covered by a protective oxide film which forms whenever it is exposed to air. This film will not disintegrate at temperatures less than the melting point of aluminum itself (1218 deg. F.). Unless this film can be penetrated, soldering (adhesion) or welding (fusion) is impossible.

Various blends of fluxless aluminum solder or welding rod have been developed which require application temperatures between 500 and 800 deg. F. On a research basis work is continuing to enable dropping the minimum temperature 100 to 150 degrees so that soldering irons can be used. The successful blends have been those which were high in zinc and contained up to several per cent of lead. However, zinc and lead are normally unblendable because the lead sinks to the bottom and separates the grains of zinc and makes a powder. Blending, homogenizing and cleansing the ingredient metals were necessary. This was accomplished by adding a small quantity of muriatic acid with the metals in a molten state. In order to prevent any risk of explosion, a special super-porous flour-like material with many pores per grain was developed. It was impregnated with muriatic acid to a paste consistency and introduced into the molten metal by special techniques. What would otherwise become a single instantaneous explosion is safely converted in a prolonged boiling and agitation of the molten metal, and its intensity is fully controllable. The object is to cause optimum homogenization of zinc and lead and other metals, and to lift up non-ferrous residues and impurities to the surface.

While ordinary soft solder will not adhere to aluminum, if the aluminum is first tinned with this special fluxless solder (Chemalloy) soft solder will readily adhere to it. This permits the attachment of any metal that can itself be soft-soldered. Chemalloy solder requires only 40 per cent of the aluminum damage temperature for joining and so this protects the parent metal during the heat-up process. Also the solder has an electrically balanced property which reduces corrosion and gives it dry bearing abilities to withstand friction without coolant or lubrication. It has never splattered or exploded and has shown no hazard in use as verified by thousands of trials and tests.

The techniques by which this joining material is derived can undoubtedly be used to improve other metals or metal blends so as to yield special properties. The bearing properties of Chemalloy by which it functions without lubrication and without generation of heat for appreciable periods of time seem to be due to microscopic space-separated electrical friction rather than direct full metallic contact. The bi-polar electrical properties, dry bearing properties and ability to penetrate surface oxides without flux appear to be inter-related. It holds high promise as a substitute for tin in babbit metal applications. With an increasing market the eventual price is expected to be very close to that of bulk aluminum.

UNDERGROUND GASIFICATION OF COAL

Engineering, v. 184 n. 4788, Dec. 13, 1957.

The possibility of gasifying coal was suggested in 1868 but no large-scale experiments were made until 1931, when field work, which has continued ever since, was started in Russia. In Great Britain, experiments began in 1949 and they are still in progress.

Underground gasification offers the double advantage of supplementing the power supply and of using coal seams which, because of low grade, faulting, thinness, or some other natural feature, would not be economic to work by orthodox mining methods. No solid matter is brought to the surface while the coal is being gasified and the only interference with agriculture or amenities is that caused by the shafts and pipelines all of which are small and of a temporary nature. Subsidence is relatively small. The gas produced is of low calorific value (usually less than 100 B.T.U. per cu. ft.) but it is combustible, and an obvious way to use it is in electric power generation by orthodox steam plant. It is on these lines that the present experiments are proceeding.

For some years the main experimental work was based on working from the surface, and some success was achieved with the two principal methods tried, high-pressure linkage and electro-linkage, both of which opened up passages for air and gas in the coal seam between vertical bore-holes. Linkages up to 50 yards were obtained, and on one occasion 800 tons of coal were gasified in a single trial. It was decided, however, that neither method was sufficiently reliable for commercial operation, and in 1953 the experiments were changed from the purely surface-operated kind to a type in which a certain amount of preparatory work is done by men working underground. This enabled boreholes to be put into the coal from galleries driven in the seam, and so provide a more positive means of controlling the flow of air and gas.

Given the necessary underground access to the seam, boreholes can be used in two different ways. They can be put through from one galley to another, to enable the air for combustion to go in at one end and the gas to be taken out at the other. Alternatively, they can be driven to a blind end, with no outside connection, and, the coal having been ignited at that end, air can be passed in through a core tube, and the gas drawn off in the space between the air tube and the borehole wall. Hot gases passing back along the borehole transfer much of their sensible heat to the ingoing air. It is this technique which is being used today.

Responsibility for underground gasification was taken over from the Ministry by the National Coal Board in 1956 and a 73 acre test area is located at Newman Spinney. In co-operation with the Central Electricity Authority work is now in hand for a pilot system to produce gas in sufficient quantity to generate 5 MW continuously for several years, beginning next year. This installation, about one-tenth of the size of the smallest commercial scheme, will enable further data to be accumulated for the design of a full-scale scheme. In particular, it will provide a basis for determining costs and will give technical information on plant operation.

The practicability of the blind borehole technique has been established beyond doubt, but much experimental work requires to be done to clear up various technical problems. In its essentials the blind borehole method is simple. When the borehole has been drilled to the required length an air pipe is inserted in it, together with a small pipe carrying at the inbye end an electrically-ignited firework of the flare type in a waterproof container. The ignition of the coal is by means of this firework and propane or other gas fed up the small tube for a sufficient length of time to enable the coal reaction to become established. Possible dimensions for the borehole are: length 300 ft.; diameter 12 in. air pipe dia. 4 in. Mild steel tube has been used for the air supply, but experiments are in progress with high-chromium cast-iron tube, sleeved at the forward end with refractory material to protect it against excessive temperature and corrosion. For obtaining experimental data in a single borehole trial, instruments are provided on the surface for recording temperature, calorific value, gas constituents (including moisture), specific gravity, air and gas flow, and pressure and water level in the sump.

The pilot system, on which work is now in progress, is scheduled to be producing gas by December 1958. It will consist of a number of sections or "arrays" each having an 8 ft. diameter shaft and a gallery 100 yards long, with ten boreholes 100 yards long drilled on each side from bags spaced at 10 yard intervals. Each section will thus cover an area of about 20,000 square yards of coal seam. Two arrays operated simultaneously will provide the desired gas output of about 1 million cu. ft. per hour, and at this rate of production they will have a working life of about six months. Fresh arrays will be brought into production as the original ones become exhausted. Air will be taken from a central blower house via mains up to 36 in. in diameter to the shaft tops at a maximum pressure of 10 psi and thence by ducting and manifold to the borehole air tubes. Gas mains up to 48 in. in diameter will take the gas to the power station, and a booster in the gas line will maintain a negative pressure in the galleries. Gas and air may be pre-heated with chimney heat at the power station.

UNDERWATER OIL TANKERS?

Engineering, v. 184 n. 4788, December 13, 1957.

A current research investigation sponsored by Mitchell Engineering Limited, Great Britain, if it proves fruitful, may lead to a revolutionary advance in the design of oil tankers. The possibilities of nuclear propulsion units for underwater craft have revived interest in the potentialities of high-speed submarine oil tanks and experiments are now being carried out on underwater hull forms.

It has been announced some months ago that the Japanese are well away with the design of a nuclear powered submarine tanker, but with a dead-weight of 30,000 tons and a submerged speed of 22 knots it would appear to be quite a conservative venture in comparison with the British proposal. The concept is that, given a propulsion unit independent of air supplies and capable of developing very high powers, a small fleet of large high-speed underwater tankers, with a high ratio of payload to deadweight, might well be competitive in cost with the slower conventional surface tanker. The magnitudes envisaged are of the order of 100,000 tons total weight, cruising at speed of 50 to 60 knots. By operating at depths far below the surface, wave-making resistance, which constitutes the larger part of the drag of a surface vessel can be drastically reduced, and by suitable hydro-dynamic design of the body, at high speeds an overall resistance very much lower than that of a conventional vessel can be obtained.

Eight models are being tested in a towing tank and the model data will be extrapolated to full-scale Reynolds number to provide data for a range of sizes of full-scale bodies so that the effect of size on hydrodynamic efficiency and operating economics can be assessed. A rough determination of the effect of the body shape on propeller efficiency, and hence the best combination of propeller design and hull form is also to be made for the full-scale craft. Possible alternatives for the prime mover include steam turbines supplied from a heat exchanger through which the reactor coolant flows; or possibly, the reactor may be gas-cooled and the coolant gas used directly in a closed-circuit gas-turbine; or electrical energy may be derived directly from the nuclear plant. The propellers operating at high speeds in the fully cavitating region are therefore likely to be of the narrow-blade wedge-section "supercavitation" type, giving much lower friction loss at such speeds than propellers of conventional design. Although maximum efficiency is likely to be attained by the usual pusher-type propeller this has the disadvantage of imposing compressive stresses on the shell which are undersirable due to the possibility of using a very light structure. Apart from a small space for the crew and space for the reactor block the whole vessel will comprise a liquid container. Although hydrostatic pressure at the operating depth may be ten atmospheres or more, the shaft structure would serve, in practice, only as a surface of separation of two liquids, and would be very lightly stressed. In the absence of waves there would be no back-breaking bending moments such as a surface vessel has to cater for, and the propeller loads would probably be arranged to act in tension. Tractor propellers at the nose or padded pusher propellers amid-ships are possible alternatives. Unloading of the oil cargo would be carried out underwater, taking in water as the oil was pumped out through flexible pipelines.

A yet more radical solution to the propulsion system might be to use the heat of the nuclear reaction to energise a propulsive water jet. This is not very efficient but possibly much simpler to instal than a turbine and shaft drive, and if ample power is available the low efficiency may be a small matter in comparison with mechanical complication.

It seems likely that auto-stabilization of the vessel both in roll and in pitch would be desirable, probably controlled by means of hydrovanes. Only a very small crew would be required, and, because air-conditioned living space would be severely restricted, both for structural and for air supply reasons, they would require to be specially selected and trained to withstand the psychological strain of confined living.

STRESSES ALTER HARDNESS

S. K. Setty, J. T. Lapsley and E. G. Thomsen, *Mechanical Engineering*, v. 79 n. 12, Dec. 1957.

Since hardness measurements have come into wide-spread use for production control and for predicting mechanical properties of heat-treated steels, it is important to understand errors that may be introduced by residual stresses or by stresses due to external loading. The present investigation set out to determine hardness under uniform stress as well as bending (gradient) stress, and during states of stress below and at the intantaneous yield condition of the metal.

Penetration hardness tests of the Brinell and Rockwell type give hardness numbers in terms of resistance to local plastic penetration into the test piece, by a ball or cone, at constant load. The hardness numbers therefore, must be related to that state of stress induced in the test piece under the indentor which will be just sufficient to prevent continued penetration. Hence this region of metal must be at or near the instantaneous yield condition, and any simultaneously superimposed stresses could have the effect of either increasing or retarding yielding at this point. Determination of the state of stress under the indentor which will fulfil the yield condition should reveal whether or not superimposed stresses will influence the hardness readings.

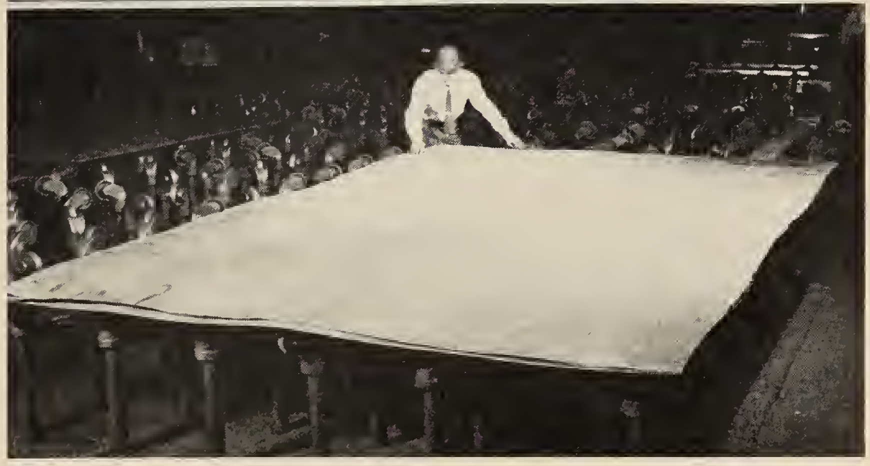
An examination of mathematical equations describing the yield condition in terms of the elastic state of stress and of maximum shear for a sphere penetrating a flat surface indicates that under constant load the final hardness must be decreased when tension stresses are present, and conversely an increase would result if compressive stresses are present. Thus materials appear to become softer under tension and harder under compression.

A series of experimental tests were carried out. Mild steel (SAE 1020) specimens were annealed and carefully machined to retain flatness and minimize machining stresses. The specimens were then loaded uniformly in a portable test fixture in axial tension and subjected to hardness measurements. It was observed that as the tensile stress increases the hardness decreases approximately linearly in the elastic region. It departs from linearity as the yield strength of the material is approached.

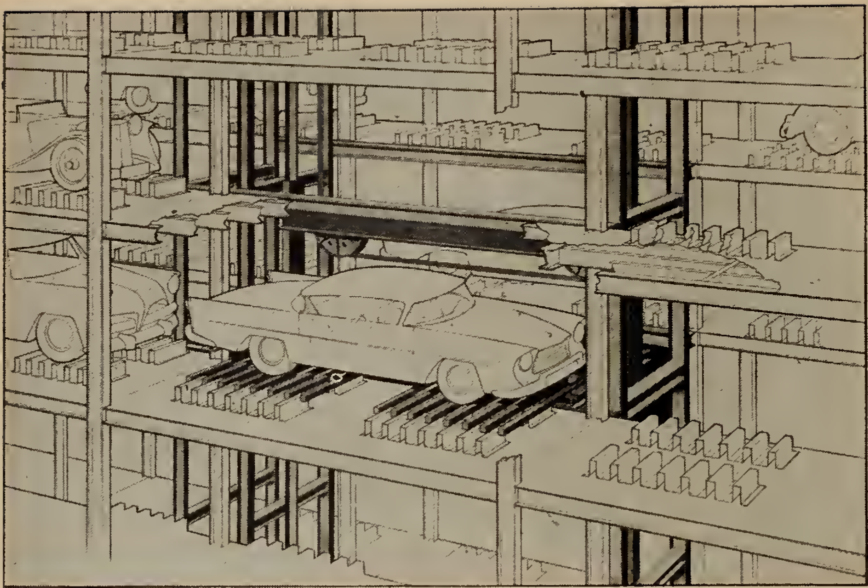
In order to test if an increase of hardness is obtained when a test specimen is under compressive loading, 2 in. dia. annealed commercially pure aluminum (1100-0) was subjected to combined compressive loading. This was accomplished by subjecting the specimen contained in a steel jacket to an axial load of approximately 80,000 p.s.i. and then releasing the axial load before making hardness tests. In this way the springback of the retaining cylinder induces biaxial compression in the test bar. The increase in hardness was relatively small indicating that compressive stresses are less effective in altering the hardness of a material than are tensile stresses.

Another series of hardness tests was run on tensile and compressive stresses induced in a bent mild steel strip. These strips were machined and then bent plastically to various radii. They were then annealed in the deformed state and descaled by an acid dip. The specimens were then mounted in a bending fixture in which bending moments could be applied until the specimens were again straight. Hardness readings were taken on both sides of the specimens. The object was to evaluate hardness changes in the presence of stress gradients but without subjecting the test section to curvature while under load. Results indicate that the decrease in hardness on the tension side is generally larger than the increase on the compression side. Also, comparison with the first tensile tests shows that the decrease in hardness due to tensile stresses when stress gradients are present is apparently smaller than it would be if uniform stresses of the same magnitude exist in the test piece.

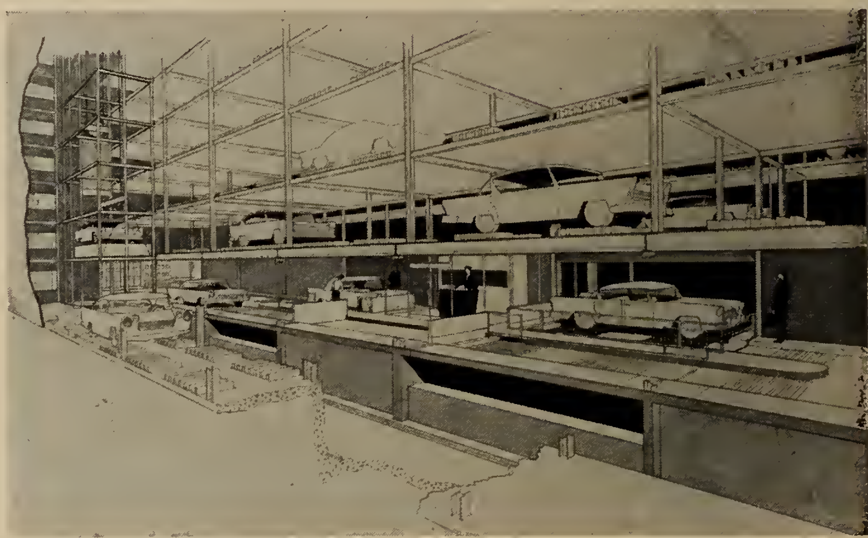
Polyethylene film is now widely used for various construction jobs. Above, it is being used in curing and protection of concrete on the New York Southern State Parkway. The film is made in Canada by Visking Ltd.



To get thin alloy steel sheets in so-far unobtainable widths, United States Steel Corporation has developed a sandwich rolling process (alloy steel between carbon steel sheets). Widths up to 90 inches have been produced, about twice that now available to aircraft fabricators, thus reducing the joins needed in assembly. The plates inside the sandwich are treated with a separating compound.



Described as the first completely automatic parking garage, a new eight-story structure being built in New York City is owned by Columbia University. Developers are Speed-Park Inc., and Otis Elevator Company are responsible for the equipment. The picture at left shows the operating principle. Below, at left are the incoming driveways from which cars are picked up by either of two travelling elevators and automatically taken to individual parking "lockers" on each of the eight floors. The process works in reverse to deliver cars to the outgoing driveways to the right of the central control panel. The single attendant acts only as cashier. Up to three cars a minute can be parked or discharged. The conveyors touch only the tires of the vehicle.



PAPERS OF THE INSTITUTION OF ELECTRICAL ENGINEERS

An Accurate Electroluminescent Graphical-Output Unit for a Digital Computer. T. Kilburn, G. R. Hoffman, and R. E. Hayes. (2241)

The paper describes a graphical-output unit fabricated from a uniform layer of electroluminescent phosphor with 512 parallel conducting strips on either side, these respective sets of strips being mutually at right angles to form a matrix of conductors. The application of a changing electric field between selected strips of both sets causes the phosphor to fluoresce at their intersection. As intersections are selected in turn a pattern can be traced out on the panel and recorded photographically. The discrimination ratio of brightness of wanted to unwanted spot positions and an improved method of biasing the matrix are considered in some detail. Other factors, such as driving-voltage frequency, waveshape and intermittent operation, are considered as they affect the discrimination ratio. Details of some prototype matrices are given, and a display indicating the resolution of such a system is shown.

Recent Developments in Medium Voltage H.B.C. Fuse Links. R. H. Dean. (2419)

The paper reports development work carried out in the investigation of fuse links of ratings up to 600 volts and 600 amp. in respect of basic problems of design when compliance with North American specifications and general circuit requirements is sought. Although this work was of a fundamental nature for universal application, it was stimulated by the publication of the Canadian Standards Association Code 106. Comparisons are made between this Canadian Code, the 'Standard for Fuses' used in the United States, and current practice in Britain, which centres on B.S. 88: 1952. Fundamental difficulties in fuse-link design are set out, leading to the choice of a design to satisfy general circuit requirements and the C.S.A. Code No. 106 in particular. Details of performance are given of the resulting range of fuse links. The results of the high-breaking-capacity tests carried out by the Canadian Standards Association are compared with the calculated figures.

Consideration is given to consistency of performance, and tests to demonstrate non-deterioration under service conditions are described.

A novel method is given for the rapid estimation of the effect of the fuse link in limiting fault power and energy admitted on severe fault conditions.

Investigations of Power Follow Current Phenomena Using a Synthetic Power Source. L. L. Alston and Prof. F. M. Bruce. (3553)

Criteria for the development of a power follow arc in a rod gap sparked over by the application of a high voltage impulse were investigated, using a synthetic power source. The latter comprised a tuned LC circuit, and could be adjusted to give a range of values for voltage, current, impedance, and frequency. The effects of these variables, and of the impulse waveform, on the development of power follow arcs in rod gaps up to 10 cm. spacing, are discussed.

INTERNATIONAL NEWS

Developments in Sweden

SOME RECENT NOTES on industrial development in Sweden.

Peak Steel Production in 1957

Sweden's steel output reached a new peak of 2,500,000 tons in 1957 and the value of exports, about $120,000,000, is the highest on record, according to Ragnar Sundén, managing director of the Swedish Iron-Masters' Association. However, the stock of orders has decreased and forecasts for 1958 are more difficult to make than in previous years.

In the period 1947-56 world production of steel rose by 80 per cent to 283 million tons, while Sweden's output was up by 100 per cent to 2.4 million tons. The largest expansion programme now under way in Sweden's steel industry is the Grängesberg Company's steel and heavy plate works at Oxelösund which, when completed by 1961, will have an output of about 300,000 tons of ships' plate.

Since 1954 Sweden's steel exports have doubled both in value and volume. The major part of exports is made up of high-quality steel for the engineering industry. Thanks to the wide geographical distribution of the quality steel exports, these are not likely to be seriously affected by a temporary business recession, while the fairly new exports of merchant iron and steel are having to face ever keener competition.

High Timber Production

With a probable total of about 1,050,000 stds., Sweden's exports of sawn and planed timber set a new post-war record in 1957, exceeding the previous peak in 1955 and being the highest since 1929, according to Knut Ronge, managing director of the Swedish Wood Exporters' Association.

This very satisfactory result, as far as quantity is concerned, has been largely due to particularly favourable circumstances. There was, for instance, considerably less competition from Finland and Canada than in previous years. Another factor favourably affecting the market was the unusually mild winter last year, which made it possible to lengthen the period in which timber could be shipped from Norrland during the winter months.

However, the economic return is generally found to be much less satisfactory. It is true that the price level remained unusually stable, but the margin of profit has been severely contracted. The costs of production have continued to rise and still further reduced the narrow margin.

Increasing Automobile Exports

Volvo, Sweden's largest automobile manufacturers, turned out 57,946 units in 1957, including 42,192 passenger cars, according to preliminary figures. The corresponding numbers for 1956 were 50,682 units and 31,260 cars. The turnover was up from Kr. 613,000,000 to Kr. 680,000,000 ($132,000,000).

Exports showed a new peak of 24,076 units, as against 16,996 in 1956. The largest increase was noted for shipments to the United States, which rose from 5,082 to 10,309 cars. Exports to Norway went up from 1,781 to 4,896 units. Denmark imported over 3,000 Volvo vehicles. Other major markets are Holland, Belgium, Greece, and South American countries.

For 1958 Volvo plans an increase in output of about 12,000 units, mainly passenger cars. Sales to the United States — so far primarily concentrated in the Pacific Coast — are likely to increase considerably also in the Middle West and the Eastern states, where it has hitherto not been possible to satisfy demand owing to shortage of cars. In Canada sales are handled by the Wenner-Gren-owned company Swedish Auto Imports, with which an agreement was signed August last. Shipment to Canada totalled about 100 units in 1957. It is expected that Canada will become an important market also for Volvo's trucks and lorries.

A record shipment of 1,000 Volvo passenger cars recently left Gothenburg on a 13,000-ton freighter specially designed to carry automobiles. The entire cargo was consigned to Los Angeles.

New Uranium and Heavy Water Plants

Sweden's atomic energy programme will receive Kr. 131,000,000 ($25,400,000) in appropriations under the 1958-59 budget estimates. Out of this sum the mixed Government-private company AB Atomenergi accounts for Kr. 112,000,000 and the Swedish State Power Board for Kr.15,000,000, while Kr.4,000,000 has been set aside for Sweden's participation in international atomic energy collaboration.

The appropriations to AB Atomenergi include funds for the continued construction of the company's research station at Studsvik, on the Baltic coast south of Stockholm, which will house the materials-testing reactor R 2 purchased in the U.S. and expected to be completed early in 1959. Work on the combined heat and power reactor R 3 at Agesta, which commenced at the end of 1957, is expected to be completed by 1960, when the reactor will supply heat and electric power to the Stockholm suburb of Farsta.

Initial funds under Atomenergi's appropriations have also been set aside for building a new and larger uranium extraction plant, a plant for plutonium production and an experimental plant for the production of heavy water.

Appropriations to the State Power Board are intended for the "Adam" atomic heating plant at Västeras, already decided on by the Riksdag, and for commencing work on the first Swedish atomic power plant, "Eve".

Water-Soluble Industrial Enamel

A water-soluble industrial enamel has been developed at the Swedish Becker paint industries. It is claimed to be the first in the world of its type to have been successfully manufactured on a large scale and has many advantages besides the one originally aimed at, of being fireproof.

Two types are a hard-finish product and a softer one which is specially adaptable for outdoor articles. The new enamel is also suitable for use as primer, having excellent adhesive and wearing properties. It is resistant to alkaline media and water after drying in a furnace.

Mixing vessels and spraying equipment can be cleaned by water, and the sediments used afresh. The same applies to losses in spray painting. Moreover, costs for ventilation and other details in the work-area equipment can be reduced, and the lack of organic thinners makes manufacture less hazardous.

(These notes are taken from information provided by the Swedish-International Press Bureau, Stockholm.)

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

The St. Lawrence Seaway and Power Project

Progress by Ontario Hydro

The month of December was generally favourable for construction work. The work force had been sharply reduced with the completion of some major contracts, and totalled 3,400 persons at year end.

A transfer from construction to operations activities was accomplished during December when the Iroquois control dam was turned over by the U.S. contractor to Ontario Hydro's regional operations staff. This staff now is operating the gates on this key structure.

Concrete placing continued over the power-house between units four and sixteen throughout December. By month end the total amount of concrete placed in the generating station was 880,000 cubic yards.

Construction of the first bank of transformer pockets was completed. Similarly concrete work for the terminal structure footings was finished ready for steel erection. Erection of the structural steel for the switchgear building was completed to unit four. The speed ring for the last turbine was installed and the pit liner was placed. On the upstream face of the power-house six headgates had been installed for units one and two. The heat pumps had been delivered and work of installing them was to commence in January.

Good progress was made on the rotors for two of the generating units. The laminations for unit one were expanded and keys driven. Technicians were ready to start installing the poles. On rotor three lamination work had been completed and ready for expansion and driving of keys. The No. 1 unit stator winding was completed and the winding for No. 3 stator was well advanced.

Work of installing the isolated phase bus for No. 1 unit commenced in December. Installing electrical starting equipment of headgate hoists for units one, two and three was begun. The erection bay and administration building had been completely closed in and work was proceeding on the interior installations.

At the St. Lawrence transformer station, the service building had been closed in with the installation of glass. The 230-kv. relay building (west) also had been closed in and work was proceeding in the interior of both buildings.

Grading proceeded in the extreme westerly section of No. 2 highway between Morrisburg and Iroquois in December but had been terminated at month end until spring. Work proceeded on several railway overpasses. Virtually all work on highway No. 31 overpass had been completed. Grading had been suspended on Carman Road, Crysler Park and Dickinson Drive overpasses.

Dredges worked until mid-December on Chimney Island, Galop Island and Cardinal contracts. All work had been suspended at Iroquois Point with the completion of the dragline excavation work. Good progress had been made on dry excavation at Point Three Points.

Opening or closing time of Iroquois lock sector gates to fill or empty the lock will be 5 minutes; its length is 768 feet; width, 80 feet; depth of water over the sills, 30 feet. It will provide access between the power pool in the International Rapids section and the stretch of river upstream leading through the Thousand Islands section to Lake Ontario. Lift of the lock will be 6 feet. ***Hans van der Aa photograph.***

The shopping centres in Morrisburg, Ingleside and Long Sault were opened in time for the Christmas trade. By year's end, all municipal services were completed for Iroquois, Morrisburg, Ingleside and Long Sault, including services, street paving and sidewalk building.

At Morrisburg the contract for the demolition of the old business section was awarded during the month. Construction of the United and Anglican Churches and manses continued in Iroquois. The building of New Iroquois town hall is now ready for the finishing work.

Progress by NYSPA

Concrete in place on all features totalled 1,917,000 cubic yards or 93 per cent of the estimated total. Excavation quantities had reached 48,800,000 cubic yards or 89 per cent of the required total. Employment averaged 2,570 for the month.

Long Sault dam cofferdam "E" was breached during December and the river again covered the Long Sault rapids area. With the breaching, stage II diversion was considered complete on December 11, 1957. Removal of Cofferdam "E" to elevation 190 was started. Removal of material from cofferdam "DD" continued.

The winter concrete placing program greatly reduced the concrete operations in December, being limited primarily to the intake structure and embedded turbine parts. All major concrete placements in the intake structure for six units were complete and the stayrings for ten of the turbines had been set. The generator rotor was placed in unit 32. Erection of structural steel in the 230-kv switchyard was 40 per cent complete.

Glass was being installed in the service building at Massena intake and interior painting was in progress. The contractor's warehouse and equipment are being removed from the site. Bricklaying, piping and electrical installations were in progress at the sewerage and water supply station at Waddington.

Channel improvements at Sparrowhawk Point, Toussaints Island, Leishman's Point and Ogden Island continued as total channel work on the project reached 94 per cent of completion.

Pole setting for seaway power facilities continued. On transmission lines between Barnhart Island and Plattsburgh, for the Reynolds power supply, and for foundations for the Barnhart-Adirondack transmission line north extension, foundations were being built, structures are being erected and conductor is being strung and sagged. Construction of the Plattsburgh substation vault walls was progressing. The contract was awarded for construction of the north extension of the Barnhart-Adirondack 230-kv transmission line.

Expediting continued on the remaining undelivered equipment to be used on the project. Eight turbines and five generators for the St. Lawrence power dam had been delivered. All other major items of equipment were being completed and shipped in accordance with the construction requirements.

Progress by SLSA

SLSA President Charles Gavsie, in a year-end progress report, announced that construction of the seaway had reached some 75 per cent of completion. The authority had awarded a total of 125 contracts, to a value of some $235 million. Twenty-nine of these had been completed. The work, he stated, was progressing satisfactorily.

Locks:

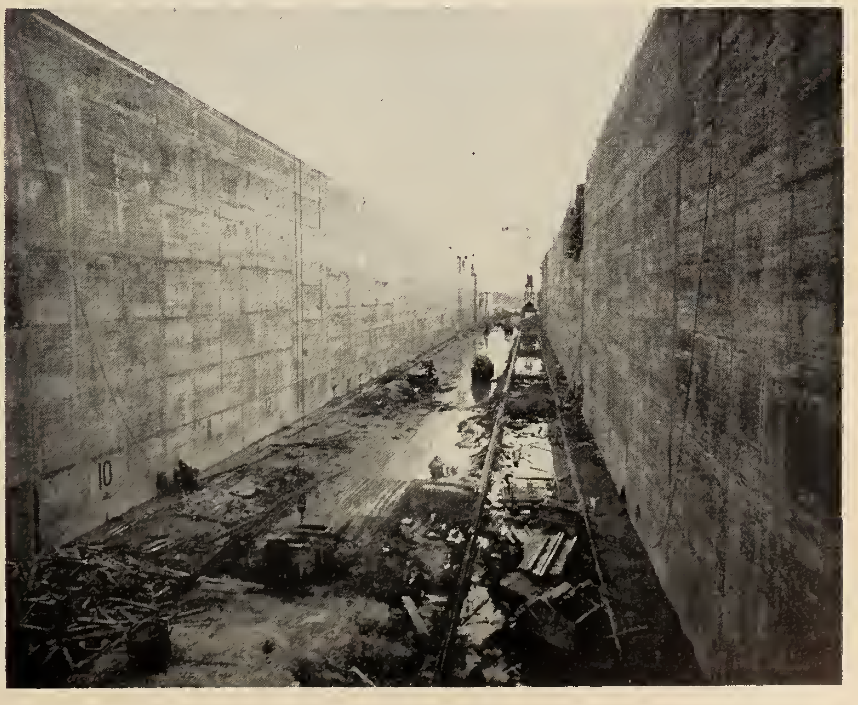
The most significant event, he said, had occurred on November 22, with the final test of Iroquois lock, most westerly of the new locks. This lock, with a six foot lift under normal seaway conditions, will provide access between the power pool in the International Rapids section and the stretch of the St. Lawrence upstream leading through the Thousand Islands section to Lake Ontario.

At St. Lambert lock, most easterly of the locks, last mass concrete was placed in December. Concrete for the main lock structure of the Cote Ste. Catherine lock was also all in place before year-end. The main lock structure of lower Beauharnois lock will be completed early in 1958 with the upper Beauharnois lock in late spring. Thus concrete work was 88 per cent complete at year-end.

Excavation and Dredging:

Contracts for dredging in Montreal Harbour, Lakes St. Louis and St. Francis, the channels at Cornwall Island and in the Thousand Islands section, and requisite reaches of the Welland ship canal must be partly suspended for the winter season. They will be resumed with the opening of the navigation season next April. Some 10.5 million cubic yards had been removed at year-end, for a completion figure at 56 per cent. Authority plans call for almost 21 miles of canal to be excavated "in the dry" and the total figure for dry excavation of all kinds is 55 million cubic yards Of this, 43.7 million

Looking down into the 80-foot-wide chamber of the Cote Ste. Catherine lock, second from seaward of seaway locks being built beside the Lachine Rapids, in the Montreal area. Locks will have a usable length of 768 feet. This is one of seven new locks for the seaway being built between Montreal and Prescott, Ont., to replace 21 on the old system. Canada is building five of the new locks. ***Hans van der Aa photograph.***



yards had been removed, or 78 per cent of the total.

Bridges:

Translation of the trans-channel span of the Jacques Cartier bridge took place in less than five hours on October 20. The southern portion of this bridge is being permanently raised to provide 120 foot overhead, clearance for shipping. The former deck-truss span was removed and a new through-truss span set in its place, thus providing 30 feet of the 80 foot increase in vertical clearance required.

New roadways and approaches on the south shore end of Honoré Mercier bridge were being constructed. For the support of these, concrete piers were built last year near Caughnawaga. Nearby work was well along for installation of two travelling lift spans for the double-track line of the Canadian Pacific Railway's Caughnawaga bridge.

At Victoria bridge, near the St. Lambert lock, the diversion of highway traffic was already accomplished. Lift spans were being installed on the main bridge for highway and rail traffic and on the diversion bridge, just upstream of the lock.

At Cote Ste. Catherine lock a service bridge of the bascule type is being built across the lock. A bridge of this type also serves to handle traffic across the lower entrance to the Iroquois lock.

The only highway tunnel under the seaway in Canada was opened to traffic in the summer of 1957. It is a four-lane tunnel, and carries highway No. 2 in two tubes under the seaway channel just upstream of the lower Beauharnois lock.

At the upstream end of the Upper Beauharnois lock, installations are being made for a swing bridge to carry the New York Central right of way over the seaway channel. Nearby, the Authority is building lift spans in two road and rail bridges crossing the Beauharnois canal. The substructure of a new bridge for highway traffic over the south channel of the St. Lawrence is also being built at Cornwall Island. The SLSDC is building the superstructure.

Operating Problems

As construction of major seaway facilities goes forward on schedule, planning for the operation and maintenance of the seaway is growing in importance as the time of opening approaches. The question of tolls, their probable quantum, method of application and collection is one which occupies much of the attention of SLSA officials.

The Canadian and U.S. entities announced last July that maximum vessel dimensions compatible with efficient operation, expeditious dispatch of traffic and with regard for the safety of navigation and property in the normal handling of seaway traffic are to be of an overall length of 715 feet and a beam of 72 feet. Ships with overall length of up to 730 feet and a beam of up to 75 feet can be accommodated subject to non-interference with other traffic.

Progress by SLSDC

With excavation for navigation channels practically completed on the American side, remaining rock removal still continued during December. All concrete had been placed in the Eisenhower and Grasse River locks. Installation of lockgates and machinery was progressing. A curved rock dike has been built downstream from the Grasse River lock to deflect water from the approach channel as it flows from Polley's Gut.

Foundations were being built for the new general motors Chevrolet plant downstream from the Reynold's metal plant site, where rapid progress was being made.

Other Seaway News

Plans are now before the government for improving four upper Lakes ports in time for the opening up of the seaway in the spring of 1959. They concern the Lakehead Cities, Sault St. Marie, Sarnia and Windsor. Biggest changes and most extensive works will be required at Port Arthur and Fort William.

The two ports chiefly affected by seaway opening are Windsor and Sarnia where new facilities will be needed from 1959. The deadline for improvements at the Lakehead and at "the Soo" comes only with the completion of dredging in the upper channels by the U.S. Corps of Engineers, scheduled for some time in 1962.

Difficulties surrounding the Lakehead improvements include — traditional rivalry between Port Arthur and Fort William; ownership by the two railways and exclusion of truck traffic; old railway terminals; existing wharves that cannot be dredged to 27 foot depth; existing ownership of the foreshore, calling for transfer of lands before new facilities can be built.

New President for SLSA

It was announced at the end of the year that Bennett John Roberts, chairman of Canada's National Harbours Board, would be the new president of Canada's Seaway Authority, replacing Charles Gavsie whose resignation was announced in October. Mr. Gavsie will resume the practice of law in Montreal.

Tolls

Eastern and midwestern U.S. interests are in a sectional conflict over tolls to be charged on the seaway. Traditional eastern seaboard opponents want the highest possible tolls to thwart traffic. New York City is not opposed to the seaway, but wants to see the project self-sustaining. Boston will object to any bargain rates. Railroads will fight against low tolls through a newly formed "National Committee for a Non-subsidized Seaway". A joint announcement by the United States and Canada on what the tolls will be is expected about March 1958.

Word from Washington late in November was that the U.S. and Canada were in agreement that there should be no tolls imposed on the seaway during 1958. It would not be fair or practical to charge tolls for an uncompleted project. 1958 would be a training period for manifest study and for recruitment of personel to serve in the collection of tolls.

Improvements at Chicago Port

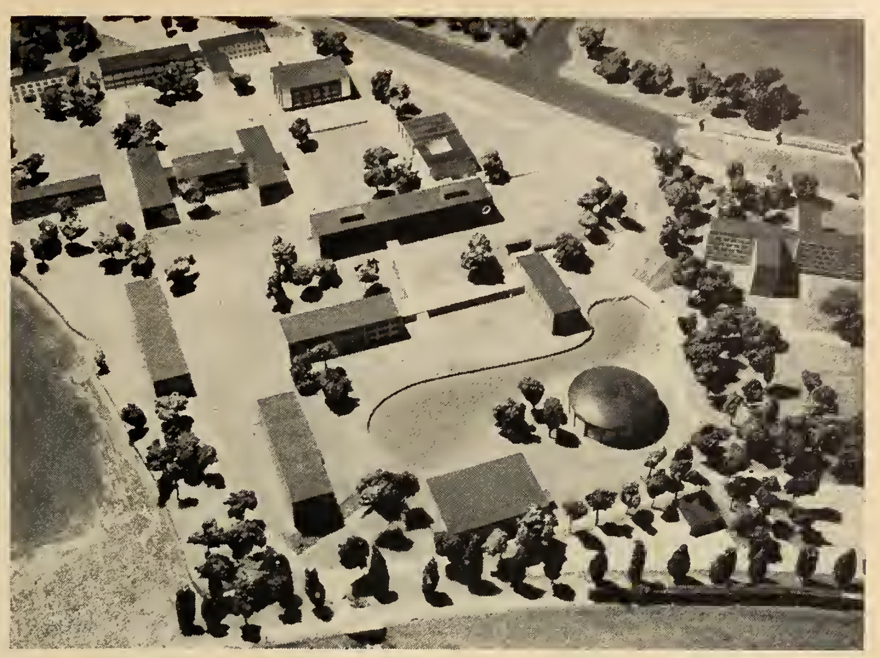
Contracts will be awarded early in 1958 for work on a $4 million improvement program at Navy Pier during the first half of 1958. Improvements will include two berths for ocean vessels south of the pier. This is the first phase of a $37 million program recommended by a marine engineering firm. The $4 million will be spent on the first two berths to give officials an idea of how much ocean traffic the new seaway is going to bring in.

SOUTHERN ONTARIO REGIONAL CONFERENCE

of seven E.I.C. Branches

See Pages 94-95 of this issue for program details

CARLETON UNIVERSITY building plan shown in architects' model (right) will develop the 130-acre Rideau River Campus to which the university will move next August. The Science Building is under construction now. It will house the engineering school and other science departments. The Library-Administration Building is under construction. The first section of the Arts Building should go to tender in a short time. These three will cost an estimated $4.5 million. A Students' Union, and an Administration Building are projected for some time in the future. These five buildings, which will make up the central court of the campus, will be the focal point. Student residences will soon be needed but are not projected for the immediate future. Carleton will spend $11 million during the next eight years for capital purposes, it is believed.



New Engineering Program at Carleton University

The *Journal* Reports Growth in Engineering Faculties in Canada

Second article of a series.

Carleton University in Ottawa established a new four-year curriculum in engineering in 1957, designed to suit the present conditions in our country and to prepare students for the assumption of increasingly important roles in society.

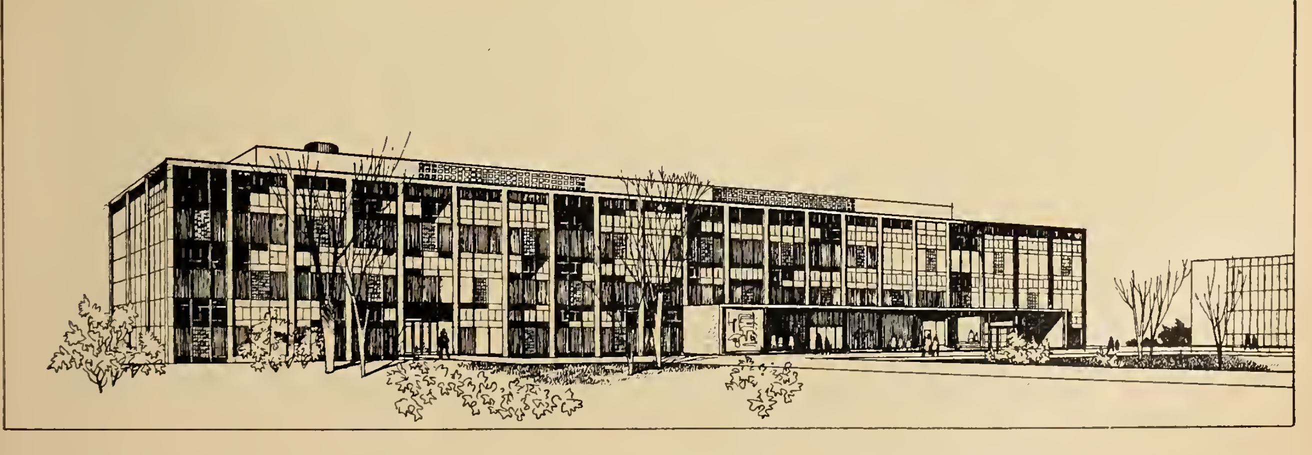
In setting up the new program, the university has established a School of Engineering under the directorship of Donald F. Coates, M.Eng. (McGill), M.A. (Oxford), P. Eng., M.E.I.C. Professor Coates went to Carleton from McGill University where in addition to his academic duties he was active as consultant on seaway, power and building projects.

The new Carleton course replaces the two-year certificate program. The university describes it as suitable for those students interested in careers in design, development, construction, production and operation in the fields of civil, mechanical and electrical engineering. It differs from many other university programs, however, in that it is less specialized. The specialization that does occur is principally in the fundamental subjects common to electrical, civil and mechanical engineering. In addition, study is required in a sequence of subjects in the humanities.

The university designed its engineering program to provide the graduate with the means for building up sound judgment as well as the basic engineering tools required for professional practice.

There are several reasons for offering a program of this sort, Professor Coates reports. Many students in their second or third years have no sound basis for choice among existing specialties, and many who graduate in one specialty find themselves practicing in another. A number of the larger companies would prefer graduates with broad fundamental

Henry Marshall Tory Building for School of Engineering and Science departments.



training. Furthermore, the increased specialization of modern engineering makes breadth of training at the undergraduate level a necessity.

Today there is also a trend to more design and project engineering being done by Canadian engineers for native enterprises. This is creating a greater demand for more highly qualified Canadian engineers. Furthermore, the rapid growth in industrialization has been accompanied by rapid change in engineering practices. Hence, in most fields engineering methods quickly become obsolete. Thus a large part of the undergraduate's time should be used in studying the fundamentals of the subject, in Professor Coates' opinion.

The engineer of today is assuming a more important role in society, and he is the individual that the community must look to for advice on technical-social matters. Consequently, it is considered important that he study the humanistic aspects of our society.

Professor Coates reported that 40 students had been enrolled for the new course by the middle of September. The first students will be graduated in 1961 with the degree of Bachelor of Engineering. Other faculty members in the School are assistant professor S. G. Tackaberry, C.B.E., B.A.Sc. (Toronto), M.E.I.C.; assistant professor E. E. Goldsmith, Dipl. Ing. (Berlin), D.I.C. (London), M.E.I.C., A.M.I.E.E.; and sessional lecturer Roderick C. McDonald, B.A.Sc. (Toronto).

An advisory council has been formed consisting of B. G. Ballard, M.E.I.C., vice-president (scientific) and director of the Division of Radio and Electrical Engineering, National Research Council; L. F. Grant, HON. M.E.I.C., field secretary, Engineering Institute of Canada; D. C. MacPhail, director of the Division of Mechanical Engineering, N.R.C.; J. H. Parkin, formerly director, now senior consultant to Division of Mechanical Engineering, N.R.C; K. F. Tupper, M.E.I.C., Ewbank and Partners, Engineering Consultants, Toronto; G. R. Turner, M.E.I.C., formerly chairman of Ottawa Branch, Engineering Institute of Canada; C. J. Mackenzie, HON. M.E.I.C., president of Atomic Energy Control Board and chancellor of Carleton University; E. W. R. Steacie, president, N.R.C.; C. T. Bissell, president, Carleton University; M. S. Macphail, associate dean, Faculty of Arts and Science, Carleton University; and Professor Coates.

Carleton University is planning to move next fall from its residential location in the Glebe area of Ottawa to a 130-acre campus about a mile and a quarter away.

Two buildings are under construction, the Henry Marshall Tory Building for science and the Library-Administration Building.

Target date for completion of the Henry Marshall Tory Building is August, 1958. It will house five science departments, including the engineering school.

The structure is being constructed on five levels, is 330 feet long and 60 feet wide, its estimated cost being $2,500,000. It is of reinforced concrete with curtain wall construction. The exterior will be of enamelled steel with large glass areas.

The building will provide accommodation for instruction and some research.

B.C. Electric Projects

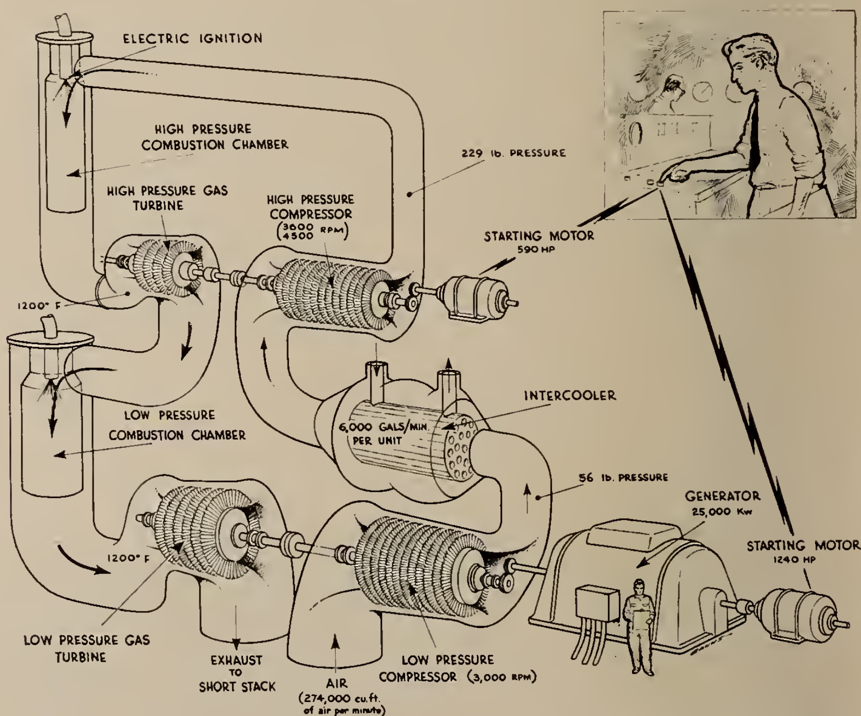
B.C. Electric's new $26 million Cheakamus hydro-electric generating project adds 190,000 horsepower to the power supply of the Lower Mainland and southern Vancouver Island.

Glacial waters were diverted westward, from the Cheakamus Canyon, at right angles into the Squamish River via a 6.7-mile tunnel under Cloudburst Mountain.

From the west portal of the tunnel, the water plunges 900 feet vertically through penstocks down the west slope of the mountain to spin two giant turbines in Cheakamus powerhouse on the Squamish River. The intake and east portal is near Garibaldi Station 22 miles north of Squamish.

Work on tunnel, dam and powerhouse was carried on simultaneously so that the whole project would interlock and be ready for service in late November 1957. The second of two generators came in line during December. More than 400 men were engaged during peak construction periods on various phases of the work.

Contracts were let during the winter of 1954-55 with Mannix-Stolte of Calgary and Oakland, California, successfully bidding as general contractor for the tunnel job. Mannix-Stolte went to work in April, 1955, assembling heavy equipment for drilling the rock face. Working around the clock, and with borings averaging about 80 feet a day, working from both ends



Cutaway drawing of the natural gas turbine generators to be installed at Port Mann, B.C., in 1958. Each unit will generate 2,000 kilowatts (4 units).

of the tunnel, on February 12, 1957 the crews met in the middle. Some 360,000 tons of rock had been cut from the depths of the mountain and at the power-house site.

Already work on the dam was well advanced by Emil Anderson and construction of the power-house and penstock foundations was underway.

The power-house, 140 by 70 feet, was contracted to Mannix-Stolte. It is as high as a six-storey building with an additional 40 feet below the ground. It is made of 6000 cubic yards of concrete reinforced with 750 tons of steel. The structure has an outside covering of corrugated asbestos. From the power-house a 14-mile transmission line carries power at 230,000 volts to Cheekeye substation, 11 miles north of Squamish.

By the end of 1957, operation of the Cheakamus plant was automatic. Its operation is remotely controlled by electric impulses from B.C. Electric's control office in Vancouver.

Canadian Westinghouse Ltd. built the two 95,000-hp. generators, the transformers, switchgear and control equipment. Westinghouse engineers report Cheakamus is the largest remotely controlled hydro-electric plant in the world, and it contains the largest remotely controlled generators.

Hydro electric generating stations at Clowhom (40,000 hp.), and at Lajoie (30,000 hp.), were also added to the system in November.

Port Mann, B.C.

The $13 million gas turbine thermal electric generating station steadily taking shape at Port Mann, B.C., will add 134,000 horsepower to B.C. Electric's generating capacity when the plant goes into service in 1958.

Structural steel for the powerhouse has been erected and work is proceeding on the roof and siding. Piledriving in the switchyard area has been completed, as have foundations for the steel towers.

Four 25,000-kilowatt turbines are on order from Brown Boveri in Switzerland and are scheduled to be delivered in time for the first unit to go into service in July and the fourth unit in November, 1958.

The station's electrical output will will be used to supplement the company's hydro-electric system during poor water years or when plants are shut down for maintenance or reconstruction.

The plant will receive natural gas at 300 pounds per square inch, through a 4-mile-long, 12-inch diameter pipeline from the main B.C. Electric gas line through the Fraser Valley, using a maximum of 40 to 44 million cubic feet a day for full operation.

Super-hot gases will be applied directly to the turbine blades of the generating units. No intervening step involving a boiler and steam will be required.

Storage facilities will be constructed to hold 3,500,000 gallons of fuel oil which will serve as stand-by fuel for the station. Foundation for the storage tank has been completed and construction of the tank has begun.

Canadian Pipeline Projects

West Coast Transmission

Westcoast's application to export gas from southwestern Alberta to the United States was being heard during November before the Alberta Conservation Board. Westcoast seeks to export 1,300 billion cubic feet, not to exceed a rate of 55 billion cubic feet per year over a 25 year period. Main opposition comes from Alberta and Southern Gas Co., which asks the Board's permission to export 450 million c.f.d. from Canadian Western Natural Gas Co. reserves, the East Calgary field and from several new Foothill discoveries, to serve San Francisco through a 1,300-mile pipeline. Hearings resumed the third week of January.

Westcoast management will move rapidly in the next two years to boost pipeline capacity to the peak permit level of 660 million c.f.d. from Peace River fields. This will call for expenditure of an estimated additional $55 million for further pumping capacity and the laying of extra gathering lines. But with expanded requirements both in B.C. and the U.S., plans are already being laid for a second 'big-inch' gas line to parallel the present one, once permits are available from Washington, Edmonton and Ottawa.

The bridge over the Little Smoky River on the Alaska Highway, which collapsed last fall, seriously hindering the transport of oil well and drilling supplies to northern B.C. gas fields, had been repaired by the Royal Canadian Engineers, Edmonton 25 Field Squadron. Replacing a ford across the river, a 46-ton 200-foot section of Bailey bridge was erected in less than four hours' time with a tractor and 47 men.

Another bridge on the highway across the Pine River north of Dawson Creek, carried away by ice early in December, was temporarily replaced at Christmas, permitting resumption of traffic.

Trans Canada Pipelines

With testing operations on Trans Canada's 34-inch line to Winnipeg fully completed, and with testing of the 85 miles of its 30-inch line to the Ontario border under way in December, gas was available to fill the Crown Pipeline's 310-mile section to Lakehead. The eastern section between Toronto and Montreal was also tested and would be ready for operation by year end or shortly afterward. Trans Canada will soon award contracts for its 491 mile stretch of 30-inch main pipeline between Kapuskasing and Toronto, scheduled for completion late in 1958.

A sixth blowout occurred on the Trans Canada pipeline on December 24, this one 30 miles east of Kenora on the Northern Ontario Pipeline Crown Corporation section. The pipe was repaired and operation resumed on December 27.

Northern Ontario Pipeline Crown Corporation

With Alberta gas available for testing the 310-mile section between the Manitoba border and Lakehead, this section was being purged and tested early in December. The unexpected long open fall weather had greatly facilitated construction and gas would be available to Lakehead cities for use this winter.

Awards of contracts for the 360-mile stretch between Lakehead and Kapuskasing were made to Nelen Ltd., Majestic Contractors, River Construction Corporation Ltd., Mannix Ltd., and Morrison-Shivers Ltd., in November. Bids averaged $10.19 per foot of pipeline, three times the average cost of $3.50 per foot for laying 24 and 20-inch pipe between Toronto and Montreal, and almost twice the $6.00 average for 34-inch pipe west of Winnipeg. The contract to Morrison-Shivers Ltd. averaged $16.03 per foot. Some of the unsuccessful bidders quoted $10 per foot higher than the award prices. The five contracts awarded total $20,827,789.

Tough ditching problems were probably the main reason for the high prices. One section passes through a 35-mile stretch of solid rock through the Precambrian Shield. This indicates that completion of the Trans Canada section between Kapuskasing and Toronto, except through the clay belt at its northern end, will also be expensive.

Pipeline News

British Columbia Electric Corp. will spend some $10.7 million in 1958 on gas trunk lines, distribution mains and gas extensions on the lower mainland and greater Victoria.

Winnipeg and Central Gas. Winnipeg city council in December turned down a C.C.F. proposal to expand the city's municipal hydro into the natural gas distribution field. But still in the air at year-end was the question of whether a second company, Great Northern Gas Utilities or Great Plains Gas Co., should also be allowed to distribute gas in the city.

Northern Ontario Natural Gas and Twin City Gas are planning expenditures of some $17 million in 1958 to bring gas to the rest of their marketing areas covering 34 communities between Kenora and Orillia, Ontario. Laying of distribution lines in Lakehead cities was nearing completion at year-end, as well as on the Kenora lateral. Work on all other municipalities will proceed in the spring, with completion scheduled for late 1958. Biggest undertaking will be the laterals from Trans Canada to Sudbury and Timmins, 82 and 31 miles long respectively.

Union Gas Co. of Canada has acquired all natural gas production and distribution properties previously operated by Dominion Natural Gas Co. of Brantford, which serves communities as far west as Leamington and Kingsville and south to St. Catharines and Port Colborne. Provincial Gas operating in Welland County and the Niagara Peninsula will in turn acquire Dominion's properties in Welland County and the Niagara Peninsula. Provincial Gas is a subsidiary of Consumers Gas Company.

Dominion Natural Gas, previously controlled by Cities Service Co. New York, owned 1266 producing gas wells and 1,750 miles of distribution lines. This deal will increase the stature of Union Gas considerably.

Union Gas is now nearing completion of the biggest expansion program in its history, including a 142-mile, 26-inch main pipeline from its Lambton County fields to Lisgar outside of Toronto where it will join up with Trans Canada. Through this artery, gas on loan from Union will supply communities east of Toronto as far as Montreal and Ottawa until arrival of Alberta gas late in 1958, to be paid back in kind over two years. Service was extended early in December to Guelph and Stratford.

Consumers Gas Co., for the third year of natural gas operation ending September 30, 1957, reports net profit 63 per cent higher than for the previous year. The company and its subsidiaries sold 14,884,000 m.c.f. of natural gas, compared with 3,584,000 m.c.f. in 1954.

Future capital expenditures could amount to $75 million over the next five years when natural gas from Alberta is available to areas not now served. Tennessee Gas meantime has agreed to allow the company to increase the flow it takes under contract to 60,700 c.f.d. Consumers plans expenditures of about $15 million during the coming year to bring gas to new municipalities in eastern and central Ontario, and for distribution in the greater Toronto marketing area.

Lakeland Natural Gas will spend $7½ million over the next five years for expansion to bring gas to 19 municipalities stretching from Port Hope to Cornwall. Installation crews have been working in Cornwall, Port Hope, Belleville and Gananoque and will have gas available to these areas by the first of January.

Quebec Natural Gas will be getting into full operation in 1958 with its huge conversion and expansion program on Montreal Island. Expenditures for 1958 are expected to reach $12 to $15 million. Conversion will begin in January 1958 and will take about 20 weeks to complete employing some 500 persons. Involved are gas appliances for almost 250,000 customers.

What Goes On

Island Airport Expansion, Toronto

First step in the program of expansion at Toronto's Island Airport was under way in November. The project is being carried out by the Federal Government under the terms of an agreement reached late in 1955, whereby the Department of Transport took over ownership at Malton Airport from the city. In exchange it agreed to provide additional facilities at the city's Island Airport which would make it one of the finest fields in Canada.

The Department of Transport had established traffic control in 1953. The following year 131,108 landings and take-offs were recorded, showing the Island Airport to be Canada's sixth busiest, though it was used largely for charter and training flights.

The Federal Government, has been operating Malton airport on the original wartime $1.00 a year agreement. Preliminary talks held between the Government and the Toronto Harbour Commission concerning the eventual disposition of the field developed the plan that the Government with its considerable investment should take over ownership as well as operation.

A new Island Airport 4,000-ft. runway, one third longer than the former one is being constructed at a different angle, to provide a clearer approach and take-off. A 36,000 square foot hangar will be provided to take care of the increased number of aircraft. Modern lighting will be provided to allow 24-hour operation of the field, if traffic warrants it. Fill, being pipelined to the airport to enlarge the field, is material removed during the dredging of the harbour western channel to post-Seaway depth.

Power Rental Regulations

Under the Water Resources Act, Alberta's new water power regulations governing the use of provincial waters for electric power generation, went into effect December 1, 1957. The new regulations follow closely those which formerly applied, especially in rental fees charged companies for the use of water. Water rentals are a form of levy based on horsepower year of electrical output, coupled with annual load factors.

Companies paid a total of approximately $100,000 in rent to the province in the last fiscal year.

CIR Reactor to India

The Canada-India Reactor, the heavy-water reactor which Canada has provided under the Colombo Plan, was shipped to India in December.

Similar in design to NRX and NRU reactors, the Canada-India reactor unit weighs 145 tons and stands 45 feet high. At the Indian reactor research centre three miles from Bombay, Foundation Company of Canada, chief contractors, with Indian help will assemble and install the reactor unit in a building now near completion. Atomic Energy of Canada Limited provided the design data and trained Indian technical personnel. Shawinigan Engineering Company of Canada were the prime contractors to supply the reactor and supervise its manufacture and installation. The hermetically sealed steel shell structure to contain the reactor is 120 feet in diameter and 135 feet high, to house a revolving crane that will remove spent fuel elements and replace them.

A little over half of the $14 million cost of CIR will be borne by Canada as a Colombo Plan contribution; India pays the balance.

Cossor (Canada) Ltd. Expands

Intended expansion of facilities or the erection of a completely new plant by Cossor (Canada) Ltd. in Halifax, has been forecast. Henry Chisholm of London, England, president of the company which works in the field of radar, communications, instruments and industrial electronics, has indicated that part of the present operations will be in new facilities within six months.

Cossor began operations in Halifax in 1948 with a working force of six persons. Personnel requirements have been as high as 315 at times of peak production, normally standing at 250. Chief among Cossor (Canada) Ltd. customers are the Department of National Defence, the Department of Transport, and the Defence Research Board. Working closely with the Royal Canadian Navy and Air Force, it operates a large research and development laboratory.

Pembina Flood Control

Initial construction began this fall on an extensive flood control program on the Pembina River, northwest of Edmonton. An Edmonton contractor completed the first diversion channel in December at a point southwest of Dapp. A series of short-cut channels is being designed by Water Resources Branch, Department of Agriculture. They will straighten out the tortuous course of the river and speed up the flow of water.

Two survey crews and an engineer spent several months last summer in preliminary survey work on the river. Their exhaustive studies laid the ground work for the construction program now begun. It is expected that tests and surveys may be finished late in 1958. Meanwhile, contracts will be let for diversion channels as engineers calculate the best location for each, and its specifications.

British Newfoundland Corporation

Work done so far on a uranium prospect 125 air miles north-east of Goose Bay, Labrador, indicates it might support a mining operation in the order of 200 tons a day, the British Newfoundland Exploration Ltd. announced in December. The find, known as Kitts prospect is on the south shore of Kaipokok Bay, between the settlements of Postville and Makkovik. A mile from the sea and at the same latitude as Knob Lake, Que., it is the first underground exploration in Labrador, and the first mining operation of any kind on the Labrador coast.

British Newfoundland Exploration Ltd., (Brinex), is a wholly-owned subsidiary of British Newfoundland Corporation Ltd. A decision to place the prospect in production would take into account the factors of methods and costs of ore extraction the extent of reserves and the marketing prospects.

British Newfoundland Corporation also reported progress in other fields. This year's extension of the original engineering studies disclosed that a development could be begun on the Hamilton River in Labrador on a scale as low as 100,000 kw. This could be accomplished by temporary diversion of the Hamilton into the Valley River. This increases flexibility and should ease the task of building up sufficient demand for power to justify construction.

The intensive investigation of the power potential in the Bay d'Espoir region of Newfoundland proper was completed during the year. The results of the survey will be available shortly. Preliminary indications are that some 350,000 horsepower at the site can be developed simply and economically in stages of 70,000 horsepower. The company is in a position to quote a price for power to consumers and to start development when justified.

Calgary Power Limited

To supply Alberta's growing power needs Calgary Power Limited in 1957 continued its program of expansion of generation, transmission and distribution facilities, and rural electrification, the company reported at year end.

More than 700 miles of transmission and distribution lines were added in 1957, half of them extensions to serve oil fields. A 69,000-volt interconnection with the City of Edmonton will replace the former 13,800 volt interconnection. One of the 138,000-volt lines between Ghost hydro plant and the East Edmonton substation is being strengthened by 60 per cent. The company's non-profit subsidiary, Farm Electric Services Limited, brought another 2,000 farms into the rural electrification program.

The Cascade plant extension, near Banff was completed in September, doubling the plant's capacity by addition of 23,000 hp. to the system. Work began on the Rundle and Spray plant extensions, (adding 40,000 hp. and 62,000 hp., respectively) to be in operation late in 1959.

Work on extension of the Wabamun steam plant was completed. The second unit will go into operation in autumn, 1958, a duplicate of the first 88,000 hp. unit installed in 1956. A third unit is scheduled for 1961. The cost of expansions at Cascade, Rundle, Spray and Wabamun is estimated at $30 million.

Public Works' Providing Employment

The Federal Department of Public Works has under way at the present time a total of 1,426 different types of projects which will cost something over $100 million to complete.

"The Federal Department of Public Works is actually setting an aggressive pace in the provision of work which is giving employment during the present winter months and continuing through the months ahead," Hon. Howard Green, Minister of Public Works stated in a December release.

"Wherever possible," the Minister went on, "inside maintenance work which might have been started or completed during the summer months was held in abeyance in order to provide additional employment through our works program during the winter months."

The Elections Act

Proposal to Amend the Canada Elections Act
(Voting at Advanced Polls)

Under this heading Bill Number 6 of the House of Commons of Canada was given its first reading on October 16, 1957. Members of the profession from coast to coast should be interested in this proposal.

The Institute's interest in the subject started with an exchange of letters early in the year with the then Prime Minister. This exchange ended in a flat denial from the Department that there was any need to extend the privileges of the Advance Poll, and that such an extension if authorized would produce unsatisfactory results.

The privilege of advance polls up to now has been limited to a very small group, "commercial travellers, fishermen, persons employed upon railways, vessels, air ships, etc., members of the reserve forces, the R.C.M.P., etc.".

It has seemed unreasonable that this privilege should be restricted to a small section of the population. If any citizen finds it impossible to be home on election day he should not be deprived of the right to vote.

The Institute was not satisfied with the reply from the Government and solicited the support of other organizations and again appealed to the Minister. Before any reconsideration of the proposal could be made the Government was out of office.

At the annual business meeting of the Institute in Banff on June 12 several members voiced their displeasure at having missed voting on June 10 because they could not use the Advance Poll. In fact it appeared that a thousand people at that meeting had been disenfranchised as far as this particular election was concerned.

The meeting instructed the general secretary to continue the efforts to have the Act changed. Accordingly a telegram was sent the same day to Mr. St. Laurent with copy to Messrs. Diefenbaker, Coldwell and Low, urging action. Herewith is the petition:—

"The Engineering Institute of Canada at its Seventy First Annual Meeting today passed unanimously the following resolution. In view of the fact that members of the profession of engineering in Canada are required on many occasions in the ordinary execution of their duties to be absent from their homes on election day it is unanimously agreed that the Federal Government be requested to so revise the Election Act that the privilege of voting at the Advance Poll be extended to engineers and others similarly situated. It is the very essence of democracy and in the best interests of Canada that no citizen be denied his fundamental right for any reason. The very existence of the Advance Poll proves the truth of these statements but it is an injustice to limit its application to so few citizens. For example here at this Banff meeting arranged five years ago there are one thousand voters all of them disenfranchised for the recent election."

The clause in the proposed amendment which is of interest to engineers, and to others as well, reads this way.

"95 — Any elector whose name appears on the list of electors prepared for a polling division comprised in an advance polling district who believes that he will for any reason be absent from and unable to vote in such a polling division on the ordinary polling day at a pending election may vote at the advance polling station established in such district if, before casting his vote, he takes and subscribes to an affidavit for voting at an advance poll, in Form No. 66, before the deputy returning officer of such district".

Of course it is impossible to tell in advance what will happen to such proposals but in view of the fact that many organizations have petitioned the Government for the change it is hoped that good results will accrue.

Among the other organizations known to the Institute to have petitioned the Government along these same lines are — The Canadian Chamber of Commerce, the Chemical Institute of Canada, and the Canadian Institute of Mining and Metallurgy.

Southern Ontario Regional Conference

Seven Institute branches will participate in the Southern Ontario Regional Conference of the E.I.C., to be held in Hamilton, Ontario on March 15, 1958. The Hamilton Branch conference committee has organized an attractive program with the full cooperation of Headquarters. For program details see pages 94 and 95 of this issue.

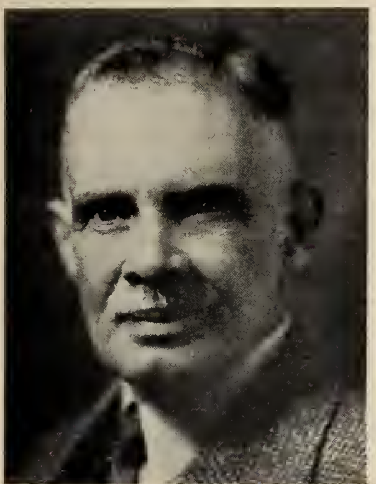
At the November meeting of Council it was agreed that some financial support be made available for the promotion of such regional meetings organized and conducted by branches of the Institute.

Grants are primarily intended to provide such services as printing, publicity, mailing, and the provision of technical papers and speakers, and branch officers have been encouraged to consider the holding of regional technical meetings in other areas.

Colonel Grant Retires

Members all over Canada will regret to hear that Past-President Leroy F. Grant, HON. M.E.I.C., who for almost eight years has been field secretary for the Institute at Toronto, has retired from that post.

There are few engineers who are so well and so favourably known across this broad Dominion as is Colonel Grant. Affectionately known by all his friends as "Leary", he has travelled Canada from coast to coast and made frequent trips to the United States in the interests of the Institute.



L. F. Grant, HON. M.E.I.C.

A chronological account of Colonel Grant's activities within the profession would not begin to tell the story of the success of his career. There are engineers whose technical achievements have been greater than his but so far as this writer knows, there are none whose personal success surpasses his.

The circumstances of Colonel Grant's assuming the office of field secretary are interesting and tell something of the man himself. After the sudden death of C. E. Sisson who was the first field secretary at Toronto, the Institute experienced difficulty in locating a successor. Colonel Grant was approached but for good and sufficient reasons declined the appointment.

However after many months had passed without finding a suitable replacement, he volunteered at considerable sacrifice, to take the post for one year pointing out that during that time he would locate a successor for himself who could carry on the good work.

As anyone who knows Colonel Grant would appreciate, it is no easy task to find a successor to him. Suggestions which were made from time time proved to be unacceptable, consequently Colonel Grant occupied the post for approximately seven and a half years.

Each year throughout that period he has suggested that the Institute retire him, but because the Institute did not wish to retire him and because he did not insist on it, he was held in the office year after year. Finally it had to be recognized that his request must be granted, and so with Colonel Grant's assistance a successor has been found and has been working with Colonel Grant through the Toronto office since the first of October.

In looking back over the record of service to the profession and to the Institute one must not overlook the work which he did in the United States through the Engineers' Council for Professional Development. For many years he was on committees there representing the Institute and for the last three years of his service was the president.

One of the great dividends the Institute has received because of this service is the establishing of the Institute in the high regard of the profession in that country and the acquiring of a great host of warm personal friends. No one but Colonel Grant could have accomplished these things so thoroughly and in so short a time.

A feature of the field secretary's work has been his interest in what he has called "the orphan groups" by which he referred to those members who were not located in the larger centres which represented the geographical centre of a branch. He visited such groups from one end of the country to the other and did much towards improving relationships between them and the Institute. In fact these meetings of his have led in many instances to formation of branch sections and even of new branches.

Professional Development

Another achievement in the life of the Institute is the program of professional development courses carried out by branches across Canada. These are definitely the product of Colonel Grant's efforts. He made the proposal in the first instance and he has fostered the efforts ever since. His imprint is clearly stamped on every meeting and every lecture of every course. Few things the Institute has done have proven as popular and as useful.

The good wishes of the members of the Institute go with Colonel Grant; all will regret the necessity of his retirement but will wish him continued good health and long life to enjoy the retirement which he has so richly deserved. His contributions to the profession cannot be counted, but in the minds of many people they are among the greatest made by any engineer in this country.

No mention is made herein of the many things Colonel Grant did for the Institute outside of his services as field secretary. That is another story; but in further recognition and appreciation of his achievements a short biographical sketch follows:

LEROY FRASER GRANT was born in Toronto; he was educated at St. Alban's School and Royal Military College, from which he graduated with honours in 1905. In 1926, while teaching at R.M.C., he received the degree of B.Sc. with honours from Queen's University.

He was appointed to the Royal Canadian Artillery in Halifax in 1905. Resigning from the Army in 1907, he worked in British Columbia for seven years, first with the Grand Trunk Pacific Railway at Prince Rupert, and later with the consulting firm Ducane, Dutcher and Company in Vancouver. At the outbreak of war in 1914, he was granted a commission as captain and adjutant in the Canadian Overseas Railway Construction Corps. Two years later he transferred to the 5th Battalion, Canadian Railway Troops as second in command with the rank of major.

After the war, Major Grant returned to British Columbia and worked until 1921 for the provincial Department of Lands and Surveys. Then he returned to Royal Military College as an instuctor in engineering. Two years later he became associate professor, an appointment he retained until 1940 when he re-entered the Canadian Army. While at R.M.C. he commanded the 32nd Field Battery, and later the 9th Brigade, Canadian Field Artillery. He was promoted to lieutenant colonel in 1937. In 1940 he was appointed general staff officer, first grade, for Military District No. 3, Kingston, remaining in that post until he retired in 1944. He then went to Queen's University as a special lecturer and was appointed associate professor of engineering in 1946. He retired in 1949.

Colonel Grant was chairman of the Kingston Branch of the Institute in 1925; secretary treasurer of that branch, 1928 to 1937; councillor, 1938, 1939, 1940; vice-president for Ontario, 1943, 1944; president, 1947. He holds the honorary degree of D.Sc., awarded by Laval University.

SOUTHERN ONTARIO
of The Engineering
Sheraton Connaught
Saturday,

SOMETHING NEW!!

This Regional Conference is the first of its kind sponsored by the E.I.C., and all Southern Ontario E.I.C. and A.P.E.O. members and their ladies are urged to attend. A special Hamilton Branch Conference Committee has made comprehensive plans and arrangements for your pleasure and convenience. The guest speakers, papers presentations, and social program will be stimulating and enjoyable for both the engineers and their ladies, and the conference will afford an opportunity to meet and mix with members from all seven Southern Ontario Branches.

11.00 a.m.	**MEZZANINE FLOOR**	**REGISTRATION** Advance registration and hotel accommodation forms will be mailed to all members
12.30 p.m.	**MAYFAIR ROOM**	**MEN'S NOON BUFFET** After registration the men are invited to assemble in the Mayfair for informal introductions and discussions prior to lunch
1.30 p.m.	**SHERATON ROOM**	**GENERAL ASSEMBLY AND WELCOME FROM THE HAMILTON BRANCH**

1.35 p.m. **SHERATON ROOM** **AFTERNOON GUEST SPEAKER**

The Impact of Television on Canadian Life — Today and Tomorrow,

J. A. Ouimet, B.ENG., D.SC., M.E.I.C., P.ENG.

Dr. Ouimet, the general manager of the Canadian Broadcasting Corporation, is a pioneer of television in Canada. He became one of the first to work in television research on leaving McGill University in 1932. In view of so long and so close an association with this medium, Dr. Ouimet's views on the impact of television will be well worth hearing.

2.40 p.m. **SHERATON ROOM**

Engineering Applications of Reinforced Plastics

H. R. CHIPMAN, B.SC.,
Supervisor of Plastics Development,
Naugatuck Chemicals Limited, Elmira, Ontario

For some years Mr. Chipman has been responsible for Plastics development and for technical applications of reinforced polyesters. His paper will deal with the high strength, corrosion resistant, and high impact resistant properties of this new construction material.

2.40 p.m. **ORIENTAL ROOM**

Heat Wave

F. R. DENHAM, B.SC., PH.D., M.E.I.C., P.ENG.,
Electro-Metallurgical Co. of Canada Ltd., Welland, Ontario

Dr. Denham will describe a revolutionary development in heating equipment which will soon be marketed in this country. The heater, which operates on the wave principle, is self aspirating, needs no external source of power and operates at efficiencies in excess of ninety-five percent.

3.45 p.m. **SHERATON ROOM**

Rail Steel as a Medium for Reinforcing Concrete

N. A. EAGER, B.SC., M.C.E., M.E.I.C., P.ENG.,
President, Burlington Steel Company Limited, Hamilton, Ont.

A major producer of reinforcing steel, "Burlington" contributes to the research and development that has kept reinforced concrete a prime construction material. Mr. Eager's presentation will be copiously illustrated with films, one of which will show the effects of atomic blasts on different types of construction.

3.45 p.m. **ORIENTAL ROOM**

The Engineering Approach to Municipal Traffic Problems

H. F. BURNS, B.SC., M.E.I.C., P.ENG.,
Traffic Engineer, A. D. Margison and Associates Limited, Toronto, Ontario.

A director of the Canadian Section Institute of Traffic Engineers, and Chairman of the Traffic and Operations Committee, Canadian Good Roads Association, Mr. Burns is fully conversant with the urgency of present day traffic problems. He will have some interesting suggestions for their solution.

All E.I.C. and A.P.E.O. members and their

REGIONAL CONFERENCE
Institute of Canada

Hotel, Hamilton
March 15, 1958

SEVEN BRANCHES PARTICIPATING ! !

Southern Ontario has one of the heaviest concentrations of engineers in Canada with over 3300 E.I.C. members in the seven participating Branches. In addition, there are a tremendous number of A.P.E.O. members in this same area, all of which makes it ideal for a Regional Conference of this nature. The participating branches are BORDER CITIES, HAMILTON, KITCHENER, LONDON, NIAGARA PENINSULA, SARNIA, TORONTO.

6.15 p.m.	ORIENTAL ROOM	RECEPTION AND COCKTAILS AS GUESTS OF THE HAMILTON BRANCH
7.00 p.m.	CRYSTAL BALLROOM	CONFERENCE BANQUET

8.30 p.m. CRYSTAL BALLROOM — EVENING GUEST SPEAKER

Back Talk from the Rumble Seat,
J. Lance Rumble

Mr. Rumble has been employed with General Motors Corporation for the past thirty years and is presently General Manager of the Toronto Retail Truck Branch. He has given over one hundred talks per year for the past ten years which is ample testimony to his well-known humorous speaking ability.

9.30 p.m.	CRYSTAL BALLROOM	E.I.C. REGIONAL CONFERENCE BALL CHRIS LOVETT AND HIS ORCHESTRA Dress Optional

For information — contact the nearest E.I.C. Branch Executive member or R. H. Stevenson, General Chairman Conference Committee, c/o Canadian Westinghouse Co. Ltd., Sanford Ave. N., Hamilton, Ont.

For the Ladies!!

11.00 a.m.	Brittany Suite—Registration Coffee Hour
12.30 p.m.	Buses leave hotel for Canadian Westinghouse Auditorium
1.00 p.m.	Noon Buffet Luncheon
2.00 p.m.	Spring Revue

SPECIAL NOTE: — The Hamilton Branch E.I.C. Auxiliary and Wives of Professional Engineers will be hostesses to the ladies during the special afternoon program. This group has also made special arrangements to provide dressing accommodation in their homes for the visiting ladies who will not be staying overnight at the hotel. In addition, the Brittany Suite at the Sheraton Connaught will be available for the ladies throughout the Conference.

ladies are cordially invited. Plan to attend!!

Survey of Scientific and Technical Manpower

The Department of Labour of Canada is at present surveying professional men and women in scientific and technical fields. The purpose of this survey is to bring up to date records of the National Register of scientific and technical professions which have been maintained by the Department since 1942.

The current survey is part of a program in which one-third of the people in scientific and technical professions will be surveyed each year. By this means, information on scientific and technical manpower in Canada will be maintained on a current basis. Those surveyed each year are selected on a random basis thus permitting the information secured to be used as a statistical sample representing the whole group.

Thus, the analysis of Register records will provide a basic source of information on the characteristics of the supply of scientific and technical manpower, such as its age composition, its geographic location, the fields, of specialization and function within each field, education received and income earned.

The E.I.C. fully endorses the main tenance of the National Register of scientific and technical professions and the survey program being undertaken and asks that all members who have received the questionnaire form this year co-operate fully in giving prompt and accurate returns to the Department of Labour, Ottawa.

Structurals Celebrate Fiftieth Anniversary

The Institution of Structural Engineers (Great Britain) will be celebrating its fiftieth anniversary from the 7th to the 10th of October, 1958.

An invitation has been received for the Engineering Institute to be represented formally and officially at the celebrations and Council has accepted the invitation and in due course will select a delegate or delegates. Members also are invited and it is hoped many will avail themselves of the opportunity.

It would be appreciated if members of the Institute who plan to attend the conference would advise Headquarters so that an official tie-in between the delegate and the Institute can be established.

The program for the semi-centennial will cover the whole field of structural engineering under the following headings:—

1) Research, fundamental and applied
2) Single-storey structures
3) Multi-storey structures.
4) Bridges
5) Power stations (including dams)
6) Mine structures
7) Storage structures
8) Airports, docks and wharves
9) Foundations
10) Miscellaneous — any subject not covered in 1 to 9 above.

THIRTY-FIVE YEARS AGO

Comment on the Journal of February, 1923

In the February 1923 issue of the *Journal* more than half of the contents was devoted to the Report of Council for the year 1922. Council recorded a growing strength of the branches and a growing interest in branch meetings. September had seen the establishment of the Lakehead Branch embracing the cities of Fort William and Port Arthur. The financial statement showed an operating surplus. Membership totalled 5,127.

Passing of the Professional Engineers Act of Ontario in June 1922, and an amendment to the Act governing the practice of the profession in Quebec, requiring graduates of Ecole Polytechnique and McGill University to join C.P.E.Q., were recorded. Tribute was paid to Arthur T. St. Laurent, M.E.I.C., president-elect of the Institute for the year 1923.

J. G. Sullivan, M.E.I.C., in his address as retiring president, presented at Montreal in January 1923, referred to the subject of "Labour and Capital". The use of capital, he pointed out, was to make living more easy and increase the comforts of life, and no fault could be found with it. 'Labourers' included every person creating or assisting in the distribution of the world's goods.

But labour organizations did not live up to their objective of bettering the conditions of the working man in the speaker's opinion. They had created unrest, hatred and distrust in the minds of their members. Union rules restricted the kinds of work a man might do . . . The professional labour leader was the guilty party . . . The closed shop denies the brotherhood of man.

"Stop toadying to labour unions and take your employees into your confidence", he urged. A year before, at the invitation of the then Minister of Labour a meeting had been held at Ottawa of interests employing 145,000 men, all working under the Industrial Council Plan. This had been a good beginning for Canada, he declared. If engineers were to give this matter the study their personal interest in the subject deserved, the time would arrive when co-operation would take the place of hatred, distrust and discontent.

Outstanding items appearing in some fifteen pages of Branch News recorded the opening of the Longueuil plant of Armstrong Whitworth of Canada Ltd., for manufacture of pulp and paper machinery and hydraulic machinery, and placing in operation of the first unit of the Manitoba Power Company's 168,000-hp. development at Great Falls on the Winnipeg River.

At the annual banquet of the Calgary Branch, attended by 70 members and noted as the best in its history, G. W. Craig, M.E.I.C., as retiring councillor summing up the progress of the Branch during the past year, remarked each member should use the 'Code of Ethics' as a standard of guidance in his relations with those he meets in the practice of his profession.

He then quoted in part a poem by Colonel Robert Isham Randolph, M.E.I.C., a parody on Kiplings 'If' which summed up our ethics:—

If you can give yourself and all that's in you,
And make the others give their own best too,
If you can handle men of brawn and sinew,
And like the men and make them like you too;

If you can boast a college education,
Or if you have a sheepskin, can forget;

If you get a small wage for compensation,
And give a little more than what you get;
If you can meet with triumph or disaster,
And treat them without favour, nor with fear,
You'll be a real man and your own master,
But what is more, you'll be an engineer.

H.G.C.

Did You Know That . . .

There are 49 branches of the Engineering Institute. The first was formed in Toronto in 1890, the second in Cape Breton in 1905, and the latest two in Seven Islands and Baie Comeau in 1957.

Across Canada there are over 700 people serving the Institute as branch officers and members of committees. Sixty-eight councillors and six vice-presidents represent the members on the Institute Council.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee the following elections and transfers were effected at the meeting of council on December 13, 1957.

Members: A. T. Balfour, London; W. A. Dodds, Edmonton; J. M. Carbert, Trail; H. E. Farnam, Seven Islands; J. K. Kitching, Montreal; J. N. Landis, San Francisco; F. D. Ledgett, Toronto; R. R. Lee, Leamington; G. E. Midgley, Edmonton; J. R. Naismith, Toronto; G. A. Oravas, Venezuela; W. J. Shortall, Peterborough; Z. Todorski, Arvida; E. W. Vaughan, New York; E. E. Ward, Maitland; C. R. Young, Sarnia.

Juniors: D. C. Bellow, London; D. R. Gilham, Hamilton; L. L. Johnston, Belleville; M. Karpa, Hamilton; D. R. Morrison, Copper Cliff.

Junior to Member: C. B. Crawford, Ottawa; W. E. Donahoe, Fredericton; D. W. C. McEwan, Cornwall; W. E. Stone, Vancouver.

Affiliate: C. J. Robbins, Montreal.

STUDENTS ADMITTED:

McGill University: D. I. Abramovitch; C. R. Adams; N. Agensky; S. V. Allison; E. J. Altinalmazis; H. D. Alvo; V. J. Alway; J. M. Anderson; A. J. R. Armstrong; M. R. Artola; R. J. Austin; S. W. Bain; J. Baziw; N. S. Bedford; M. H. Belanger; R. C. Berry; A. E. Bethune; A. J. Birchenough; J. E. Black; W. M. Blaiklock; G. Blais; J. A. Blais; A. J. Bobkowicz; B. Bonneau; W. H. Booth; L. R. Bourassa; J. L. A. Bourbeau; D. G. Bourdon; J. E. Bradley; N. R. Breton; W. L. B. Briggs; G. R. Brighton; L. Bronstein; A. E. Brown; B. Brown; R. Brunet; S. L. Butkovic; J. W. Butler; K. K. Butler; S. Butman; J. R. Buzek; W. H. Cameron; W. R. Campbell; D. E. Cape; M. G. Cape; G. J. Carbonneau; H. Chang; W. P. Chen; P. O. Clark; M. B. Cockerline; G. J. Cohen; A. R. Copeman; D. J. Costantini; E. D. Crook; J. X. Jacques Cyr; B. Denis; G. A. Desbarats; J. G. Descary; G. F. Dionne; R. M. Dionne; A. E. Douglas; J. M. Dow; M. R. Dulepka; D. W. Dunkerley; N. L. Ede; R. D. Elliott; M. A. Faris; L. C. A. Feher; M. Fels; J. D. Finch; N. E. Florakas; A. W. Flynn; L. Frichetstun; S. R. Friedman.

L. L. Gagne; A. J. Gillies; M. Gitelman; V. Goba; L. Gordon; H. M. Gouverneur; I. Graif; M. R. Green; A. W. Greig; K. Griffiths; A. V. Grove; M. S. Guimont; C. D. Hall; D. G. Haltrecht; R. A. Hango; D. S. Harris; G. A. Helm; W. B. Horwood; D. F. J. Hudson; A. Hutchinson; W. R. Hyman; A. Ibrahim; S. C. Janco; E. C. Johns; N. R. Jones; A. J. Kibrick; L. Kostaszek; D. C. V. M. Krupka; E. Kuhnert; A. Lachapelle; J. F. P. Lalonde; K. V. Lapinas; P. R. Lavallee; W. A. Lawrence; R. G. Laxson; P. Lebeau; P. L. Leblond; J. P. Ledoux; G. H. Leduc; A. Lee; M. Leitman; A. Lenkei; D. P. L'Esperance; A. K. Leung; A. Levine; M. D. Levine; I. Lewis; B. M. Lipski; A. Litman; S. Louie; D. W. MacEwen; G. H. MacEwen; I. C. MacInnes; B. W. Mackenzie; D. J. Mactaggart; G. F. Maloney; D. W. L. Maltby; B. J. Margolese; L. Marineau; D. J. Martin; R. D. Martin; E. Master; D. G. Mathewson; S. M. Matin; E. Mazliach; W. B. McAdam; J. D. McCallum; F. T. McDonnell; G. R. McFarland; D. H. McKay; W. B. McLachlan; W. A. McLaren; P. G. McNamee; B. Meltzer; J. R. Menard; S. F. Mester; G. J. Meunier; G. H. Meuris; G. A. Milette; W. W. G. Miller; C. Mirza; H. Mitchell; D. Mongeau; O. Monkewich; I. E. Morrison; L. Najman; R. J. G. Nantel; C. W. Nelson; J. B. Nelson; J. Nev; T. M. Netterfield; H. W. H. Ng; D. K. Nimetz.

M. U. Oko; J. F. O'Rourke; R. D. O'Sullivan; S. Pandit; G. Payette; F. R. Penney; G. E. Pfaefflin; J. N. Pretty; R. Purre; H. N. O. Quao; P. Quevillon; R. A. Raimi; M. D. Rapkin; H. E. Reece; R. I. Renton; J. H. P. Richard; R. J. G. Richard; J. M. Rieffel; E. G. Riley; B. E. Riseborough; D. R. Roberts; A. H. Romano; Y. Roy; M. J. Russ; R. D. Saunders; R. R. J. Sauve; B. E. Scarvelis; E. V. Schaubel; D. J. Schurman; H. G. Scott; R. Y. Scott; V. Sefers; B. G. Sheridan; R. D. Shipton; M. H. C. Shiu; E. Shpiro; E. Silon; H. W. Silverstone; L. M. Simon; R. A. Simon; J. H. Simons; R. B. M. Smart; L. C. Smith; S. G. Smith; R. M. Smythe; G. R. Spencer; S. L. Sperber; J. A. Spotton; H. K. Stammer; G. M. Steiner; M. Stinnes; H. Suga; W. S. Szabo; A. S. Taylor; F. A. Taylor; G. Theberge; B. R. Thomas; M. Timascheff; A. J. Timleck; J. E. Tomlinson; E. A. Traynor; J. E. Udd; E. S. Uszkay; J. A. A. Vaillancourt; C. Vallerand; A. Varvaro; E. C. Venezian; M. Videtic; R. A. Wahlstrom; K. Waranica; R. O. Weir; D. E. Welch; H. A. T. Westman; J. F. Wickenden; B. J. Wiesenfeld; C. G. Williams; S. J. Windisch; D. A. Woodward; D. Zackon; B. J. Zaitlin; Z. P. Zollmann; P. J. A. Zsombor-Murray.

University of New Brunswick: R. S. Bagnall, G. L. Baker; R. J. Bell; J. R. Boissonnault; G. R. Burtt; J. R. Cushing; G. L. Gibson; A. D. Gray; L. C. Jenkinson; R. H. Kraft; G. J. J. Levesque; R. L. Mutch; I. R. G. Lowe; R. D. MacAndrew; A. E. MacDonald; C. McGraw; W. L. Mulherin; G. A. Oldham; J. H. Phillips; J. A. Saunders; D. L. Seheult; G. Singh; R. A. C. Staples; A. W. Tracey; A. Vennos; G. Mark; D. M. Margeson; W. Newman; D. H. Paterson; C. E. C. Semple; J. C. Sinclair; L. L. Wright; F. W. Young.

University of Alberta: D. G. Bacon; B. L. Bowsfield; H. T. Butchart; R. W. Culley; G. Eliasson; D. D. Farrell; J. B. Ferguson; E. P. Figol; A. E. Hanert; T. E. Kellen; S. Y. Lee; K. Lukawitsky; F. E. Magyar; G. A. Ross; G. N. Strynadka; J. R. vander Linden; R. Walker.

Acadia University: D. A. Allen; J. D. Cameron; L. R. Delaney; W. A. Gilroy; R. A. Harris; R. C. Knock; J. MacLennan;: T. S. Twells; J. K. Young.

Dalhousie University: W. D. C. Cook; J. W. Grennan; W. J. M. Meadus; N. E. Rudback; R. M. Soberman.

University of British Columbia: T. J. Babcock; G. van Dijk; L. R. Dilworth; C. A. C. Dobell; L. H. Hayton; J. L. Irvine; G. D. McLellan; H. R. T. Prudhomme; J. R. Soderberg; G. L. Stovel; A. F. Vanidour; G. H. von Dehn.

University of Toronto: T. A. Brzustowski.

Graduates: P. Moody, University of Toronto, 1957, B.A.Sc.(Civil); B. A. Oliver, University of Toronto, 1957, B.A.Sc.(Elec.).

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective:

SASKATCHEWAN

Members: J. J. Bakker; G. L. Haight; H. P. Harrison; C. J. Karasek; E. F. Mahaffy; N. W. Naimish; J. B. Renton; J. M. Schmidt; L. D. Sirett.

Juniors: M. Barabas; B. Jezzi; M. Kesmarky; D. C. Kesteven.

Student: R. J. Clarke.

Junior to Member: G. E. Baldwin; G. J. Goldsworthy; V. V. Neis.

NOVA SCOTIA

Junior to Member: J. P. Archibald; T. F. Clahane; J. D. Koppernaes; W. F. Mulhall.

NEW BRUNSWICK

Member: J. O. Dineen.

MANITOBA

Member: A. C. Warrender.

President C. M. Anson Continues His Tour of the Branches

A meeting of the policy committee in Montreal assembled (left to right) V. A. McKillop, R. L. Dunsmore, I. R. Tait, R. E. Heartz, Miss May McLaren, J. B. Stirling, D. M. Stephens, B. G. Ballard (back to camera), and A. Deschamps. ↓

At Saint John, N.B., a branch meeting marked Mr. Anson's visit. Head table guests included Mrs. Mitchell, H. W. M. Townshend, vice-chairman, Mrs. Doty, Mayor W. W. Macauley, Mrs. Donahue, Mr. Anson, J. J. Donahue, Mrs. Anson, Mayor Parker D. Mitchell of Lancaster, Mrs. Townshend, H. W. L. Doane, Mrs. Macauley, A. G. Watt and F. L. Doty.

Mr. Anson presented the E.I.C. tie clip to Life Member F. P. Vaughan (centre, right) while Vice-President H. W. L. Doane looked on. ↓

Other guests at the Saint John meetings were: L. O. Cass, Mrs. Cass, W. E. Seeley, Mrs. Sadler, R. F. Sadler, and A. E. Hanson; H. A. Whittaker, F. P. Vaughan, C. D. McAllister, Mrs. Chestnut, V. S. Chestnut, and D. M. Vye. ↑

↑ The president's visit to St. John's, Nfld., included meetings with the Branch executive, the members, and the students at Memorial University. At the University he talked with Dr. Gushue, president, (left), with H. W. L. Doane, V. A. Ainsworth, Branch chairman, F. Duffett, president of the Student Engineering Society, and Dean S. J. Carew.

The executive meeting in progress.

A group of members and guests at dinner meeting in St. John's: right to left, M. Doody, Pauline Morris, E. D. Manchul, Mrs. Manchul, Mrs. Cameron, M. Cameron, Mrs. Grant, F. Grant, Mrs. Myers and R. Myers.

At a dinner with the Halifax Branch: Mrs. Anson, the president, R. D. T. Wickwire, branch chairman, Mrs. Wickwire, I. P. Macnab, Mrs. Macnab, and J. B. Hayes.

Wickwire vs. Wickwire. Branch chairman R. D. T. Wickwire chats with L. D. Wickwire, president of A.P.E.N.S., at dinner honouring President Anson.

The Fredericton visit centered around the official opening of a new wing of the engineering building of University of New Brunswick.

The "student's table" at the branch meeting. J. Whiteley, D. Ballance, R. Lynch, M. Schofield, H. Eoekstel, J. Oudemans, A. White, S. Caughey, F. Christensen and E. Carpenter.

↑ At the head table, Mrs. E. O. Turner, Premier H. D. Flemming, Mrs. Anson, R. P. Lynch, branch chairman, President Anson, Mrs. Lynch, Dr. C. B. MacKay, president, U.N.B., and others.

↓ At another table, J. Murray, of the Alumni Association, Mrs. Weyman, C. E. Weyman, Mrs. Cuthbertson and W. B. Cuthbertson

← Students enjoy a brief chat with Mr. Anson in new lounge at U.N.B.

Dr. C. B. MacKay, U.N.B. president, Mr. Anson, and H. W. L. Doane.

W. D. G. Stratton, president of A.P.E.N.B., presented awards.

Presentation of student prize to H. N. Craig.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Walter Henderson Shillinglaw, M.E.I.C., one of the few surviving charter members of the Institute died at the age of ninety-three at his home in Brandon, Man., on November 20, 1957. Mr. Shillinglaw was a member of The Institute for fifty years.

Mr. Shillinglaw was born at Staffa, Perth County, Ontario on September 29, 1864. He attended schools in Albany, Mo., U.S.A and at Portage La Prairie and Brandon before enrolling at the University of Manitoba from which he graduated in 1886. He attended the University of Toronto School of Practical Science from 1886 to 1889, assuming private practice shortly thereafter as an architect. In 1896 he took on the additional work of city engineer. for the city of Brandon, Man. devoting himself for many years to city work. He was also responsible for the original dam on the Little Saskatchewan River.

Mr. Shillinglaw joined the Institute as a Student member in 1887; became an Associate member in 1900; and a member in 1908. He attained Life Membership in 1931.

W. H. Shillinglaw, M.E.I.C.

J. G. G. Kerry, HON. M.E.I.C., retired consulting engineer, died in his ninety-first year on November 14, 1957, at Port Hope, Ont.

Mr. Kerry was born at Montreal on August 9, 1867. Educated at McGill University, he graduated with honours with a B.A.Sc. degree in civil engineering in 1886. Following graduation Mr. Kerry spent several years in railway survey work both in Canada and the United States. He returned to Canada in 1892 in order to qualify for an M.Eng. degree at his alma mater. Subsequently he joined the teaching staff of the faculty of applied science at McGill. He remained there until 1907. Meanwhile, in 1898 Mr. Kerry had become a partner in the firm of Smith, Kerry and Chace, consulting engineers, later known as Kerry and Chace Limited. He remained a part of the company until his retirement in 1939. During a great part of his career, from 1907 until 1932 he was associated with the Temiskaming and Northern Ontario Railway as consulting engineer.

Mr. Kerry was for many years active in the construction and operation of power plants and paper mills. Construction work for which he was responsible included hydro-electric power plants, for the Nipissing Power Company, Seymour Power and Electric Company, Canada Cement Company and Hollinger Gold Mines. He was concerned with paper mill construction including plants for the Northumberland Paper and Electric Company and the Canadian Paperboard Company. Largely concerned with the pulp paper and power fields Mr. Kerry was before his retirement in 1939 elected president of Northumberland Paper and Electric Company, Seymour Electric Power Company and associated companies, the Canadian Paperboard Company and the Quinte and Trent Valley Power Company. He was also secretary of Boundary Investments Limited.

In 1946 Mr. Kerry was awarded the Gzowski Medal of the Engineering Institute, given for the best paper of the year on any subject. The winning paper was entitled, "The Winter Temperature Cycle of the St. Lawrence Waters."

Mr. Kerry was known as a teacher and consulting engineer and served his profession for more than sixty-five years.

In 1887, the year of its founding, Mr. Kerry joined the Engineering Institute as a Student member. Transferred to Associate membership in 1894, he became a full Member in 1904. He attained Life membership in 1938, and was awarded Honorary membership in 1952.

J. G. G. Kerry, HON., M.E.I.C.

His contributions to the professional life of the Institute were considered great. The Port Hope Branch of the Institute recognized this contribution in appointing him Honorary chairman on its inauguration in 1952.

James Morrow Oxley, M.E.I.C., retired architect and engineer of the firm of Chapman and Oxley, Toronto, died in that city on October 8, 1957.

James Oxley was born on September 12, 1883, at Halifax. In 1904 he enrolled at the University of Toronto where he studied applied science. Assistant engineer on construction with the Aberdeen Elevator Company, Midland, Ont., in 1905 he also worked for a short time with Canada Foundry Company before entering a partnership under the name of Oxley and Chadwick, structural designers, in Toronto, in 1907. Two years later he was named chief engineer to McGregor and McIntyre Limited, structural steel works, also in Toronto. The firm of Harkness and Oxley, consulting engineers to architects on structural design came into being in 1911. It was responsible for the John Inglis Boiler Shops; the J. F. Brown Copper and Brass Rolling Mills; the C.P.R. Building; the Dominion Bank building; the Methodist Book and Publishing House; Knox College, the R. S. Williams Building; the Veterinary College and many others.

Operations of the firm were interrupted by World War I. Mr. Oxley served overseas with the Canadian Expeditionary Force, 95th and 124th battalion, 1915-1919, attained the rank of major, and finally transferred to the 12th battalion Canadian Engineers.

Returning to this country in 1919 he became a member of the firm of Chapman, Oxley and Bishop, architects and engineers, Toronto, which association was continued throughout his entire career. Mr. Oxley was also known for his part in the design of the Royal Ontario Museum, Sunnyside amusement park, the Princes' Gates, a number of C.N.E. buildings, the new Bank of Montreal building, the Star building, Sterling tower, the National and Northern Ontario buildings and Holy Blossom Temple.

Mr. Oxley served on the National Building Code committee from 1939 to 1941.

In World War II he designed war plants for Central Aircraft and Toronto Arsenals.

Mr. Oxley was named a Fellow of the Royal Architectural Institute of Canada in 1950.

A Life member of the Institute since 1947, Mr. Oxley joined the Institute as a Student member in 1901; transferred to Associate Member in 1908. He became a Member in 1921.

Roy Talmage Steeves, M.E.I.C., architect and engineer of Fredericton, N.B., for seventeen years a member of the faculty of applied science at Acadia University died in that city on November 28, 1957.

Roy Talmage Steeves was born at Moncton, N.B. on January 17, 1897. He attended Moncton High School, New Brunswick Normal School, and served for three and a half years overseas with the Canadian Army, winning the Military Medal for bravery, before engaging in further studies. Awarded a B.A. degree in 1927 from Acadia University, he received the further qualifications of an engineering diploma and an M.Sc. degree in 1929 from that seat of learning. He also studied at the Massachusetts Institute of Technology for one year and undertook research in engineering and architecture at the Georgia Institute of Technology. Named an instructor in engineering at Acadia University in 1927 he was promoted to assistant professorship in 1933, becoming associate professor two years later. Achieving the status of a professor in 1937, his services to the university were for a time interrupted by a term of service with the R.C.A.F. As a technical officer during World War II, he saw service at No. 1 Wireless School, Montreal and as a ground instructor at Chatham, N.B. air-base. He later returned to New Brunswick as an architect and engineer for the Department of Education and introduced a school-building program. These schools are now in operation throughout the province. Due to ill-health Mr. Steeves was obliged to retire from professional endeavors in 1956.

Mr. Steeves joined the Institute as a Member in 1946.

G. Murdoch, M.E.I.C., retired consulting engineer of the St. John, N.B., firm of Murdoch-Lingley Limited died on June 29, 1957 at Saint John.

Gilbert Gray Murdoch was born in that maritime centre on October 13, 1876 and educated there. His engineering education was conducted under private tuition in the office of his father, then engineer and superintendent of water and sewage for the City of Saint John.

Obtaining a certificate early in his career as a deputy land surveyor for New Brunswick, he established himself in private practice at Saint John as early as 1895, specializing in municipal engineering.

Notable in his career, among other things is his connection with the construction of most of the water works and sewage systems in that province. He also designed and constructed many hydraulic structures for the New Brunswick Power Company. He was instrumental in the development of the Saint John Airport.

Mr. Murdoch retired from active consulting practice in 1953.

One of the incorporators in the Association of Professional Engineers of New Brunswick, he subsequently became president of the organization. He was a member of the Dominion Council from its inception in 1933, serving as one of the three representatives of the New Brunswick Association.

Mr. Murdoch was one of the wardens of Camp 9 of the Corporation of the Seven Wardens.

Active in the affairs of the Engineering Institute of Canada, he was one of the early chairmen of the Saint John Branch. He served as a councillor in 1925; and as a vice-president representing the maritime provinces in 1942-43.

Elected Life member of the Institute in 1947, Mr. Murdoch joined the organization as Student Member in 1905, transferred to Associate Member in 1911 and to Member in 1919.

Merle Franklin Ker, M.E.I.C., for thirty-five years engineer for Stamford Township, Ontario, died at Niagara Falls, Ont., on November 18, 1957.

Born there on May 23, 1894, Mr. Ker followed engineering studies at Queen's University, graduating with a B.Sc. in 1918. His studies interrupted by World War I, he served as a bombardier in the Canadian Artillery. While a student employed with the City of Niagara Falls, engineering department, and with the Hydro-Electric Power Commission of Ontario he went immediately to the staff of the latter organization on graduation, working in the laboratory department on field drafting and inspection. Mr. Ker was employed on the Sir Adam Beck No. 1 Queenston Hydro power project before his appointment as Stamford Township engineer. In 1921 he took over responsibility for all construction for the township of Stamford. He took charge not only of construction for Stamford township but also the design of waterworks, sewers and roads.

He joined the Institute as Junior Member in 1920, transferred to Associate Member in 1927 and became a Member in 1940.

Robert West Moffatt, M.E.I.C., retired professor of civil engineering, University of Manitoba, died at Selkirk, Man., on December 4, 1957.

Mr. Moffatt was born at Bognar, Ont., on September 28, 1875. After a short period spent as a school-teacher in Western Canada, Mr. Moffatt went on to further studies at the University of Toronto, school of practical science, and graduated with a B.A.Sc. degree in 1905. A short period of experience with the Canadian Westinghouse Company Limited, at Hamilton, Ontario, and with the firm of Smith, Kerry and Chace, Toronto, followed his graduation. He was also engaged as a demonstrator in civil engineering at the University of Toronto and as an instructor at the Ontario Agricultural College for several years. In 1912 Mr. Moffatt was appointed to the staff of the University of Manitoba as an instructor in civil engineering. He retired in 1944.

Mr. Moffatt joined the Institute as a Student Member in 1910; became an Associate Member in 1913 and transferred to Member in 1940. He attained Life Membership in 1946.

Review of U.S. Education Practice

An important report of United States practice in engineering education and training is available through the Engineers' Council for Professional Development. (29 West 39th St., New York 18, N.Y.)

It is a 64-page, paper bound and graphically illustrated report, containing the contributions of ECPD, the American representative to the Third Conference of Engineering Societies of Western Europe and the United States of America (EUSEC), which was held in September, 1957, in Paris. The cost of a copy of this report is $5.00.

ECPD's contribution, therefore, covering the seven subjects listed below, offers a current and comprehensive factual report of educational practice in the United States.

The seven subjects are:

1. Glossary. Including a description of the educational system, diagrams showing different routes through engineering and technological education, and a definition of terms used in education.
2. General education before, and selection for, admission to engineering schools of university level.
3. Selection for admission to engineering school.
4. Education at engineering schools of university level.
5. Practical training, before, during, and after engineering studies.
6. Criteria for professional status.
7. Post first degree education.

NEWS OF THE Associations and Corporation

Information received through co-operation of the provincial organizations.

ONTARIO

Elections for 1958

The 16,000-member Association of Professional Engineers of Ontario, on January 3, 1958 elected Charles Terry Carson of Windsor, Ont., as its 1958 president. He succeeds John H. Fox of Toronto as head of the largest professional organization of its kind in Canada.

In business life, Mr. Carson is vice-president and production manager of Hiram Walker & Sons Ltd., Walkerville, Ont. He is also chairman of the committee on engineering education at Assumption University, Windsor. The university's branch, Essex College, offers degree courses in four branches of engineering — chemical, electrical, civil, and mechanical.

Carson, a member of the Association since 1946, has served on the executive council for five years, and last year was the Association's first vice president. He is a graduate of the University of Toronto, and is also a Fellow of the Chemical Institute of Canada.

Elected first vice-president for 1958 is Andrew F. McQueen, Niagara Falls, Ont., who is president of H. G. Acres & Co. Ltd. Second vice-president is Gordon M. McHenry, London, Ont., consumer service engineer for the Ontario Hydro, London region.

Also elected were the following councillors, two for each branch, in addition to one from each branch being appointed by the Lieutenant-Governor-in-Council.

Civil branch: Tullis N. Carter, Toronto, vice president and general manager, Carter Construction Co. Ltd., and Robert A. Weir, civil engineer employed by the Ontario Department of Lands & Forests. The appointed representative is V. S. Murray, Toronto.

Chemical and metallurgical branch: Patrick E. Cavanagh, Toronto, director of engineering and metallurgy, Ontario Research Foundation, and Edmund P. Lewis, Sarnia, senior chemical engineer, Polymer Corporation Ltd. The appointee is D. S. Simmons of Toronto.

Electrical Branch: Robert L. Hicks, Toronto, engineer, distribution planning and design department, Toronto Hydro-Electric System; and John W. Holmes, Peterborough, design engineer, Canadian General Electric Company Limited. The appointee is J. Herbert Smith, Toronto, president of Canadian General Electric Company Limited.

Mechanical, aeronautical and industrial branch: Donald L. Angus of H. H. Angus & Associates Ltd., Toronto, and Lawrence C. Sentance, Hamilton, manager of the defence apparatus division, Canadian Westinghouse Co. Ltd. The appointee is Dr. G. Ross Lord, head of the mechanical engineering department, University of Toronto.

Mining branch: Marc Boyer, Ottawa, deputy minister of the Dept. of Mines & Technical Surveys; and Martin L. Urquhart, general manager, McIntyre Porcupine Mines Limited, Toronto. The appointee is Dr. G. B. Langford, Toronto, head of the department of geological sciences, University of Toronto.

Engineers in the News

E. Bonar Lindsay, P.ENG., who has been an associate of J. Edgar Dion, P.Eng., management consultant engineer in Montreal, informs us that the firm has been incorporated under the name of J. Edgar Dion & Company Ltd. Offices are located at 4643 Sherbrooke St. West, Montreal.

W. A. Martin, P.ENG., has moved from Preville, Que., to Ottawa. He has joined the Board of Transport Commissioners of Canada as senior supervisor of explosives and other hazardous materials. Mr. Martin graduated in engineering from the University of Alberta in 1947 and for the past ten years has been employed by Canadian Industries Ltd.

F. M. Schwieder, P.ENG., of Colgate-Palmolive Ltd., who has been in Switzerland for some time, has returned to Canada and is with the company at 64 Colgate Ave., Toronto.

Peter S. White, P.ENG., is now with Texas Gulf Sulphur, 170 University Ave., Toronto.

William E. Sheresky, P.ENG., has left the British American Oil Co. Ltd., with which he was employed in Toronto, and is now with Hinde & Dauch Paper Co. of Canada Ltd. in Trenton, Ont.

J. B. Harper, P.ENG., formerly a salesman with the Honeywell Controls Ltd., industrial division in the Hamilton office, has been appointed branch manager of the company's Sudbury office. Mr. Harper graduated in engineering from Queen's University, Kingston in 1954 and immediately joined the Honeywell organization.

Robert W. Higgs, P.ENG., of the Public Works Department of Canada, Ottawa, has been awarded the 1957 International Road Federation Scholarship by the scholarship committee of the Canadian Good Roads Association. A graduate in civil engineering from Queen's University in 1949. Mr. Higgs has been with the Trans-Canada Highway Division of Public Works. He will take a post-graduate course in regional planning at Cornell University.

J. Szymanowski, P.ENG., of Dominion Electric Manufacturing Co. Ltd., Toronto, has been promoted to chief engineer. The company produces high and low tension electrical distribution equipment, switchboards and similar equipment. He joined the Dominion Electric Manufacturing Company a little over five years ago.

I. C. Igimundson, P.ENG., holds the post of executive assistant with Hydro-Electric Power Commission of Ontario, administration branch. Prior to this change he was administration and service engineer in the frequency standardization division.

G. Frank Jannaway, P.ENG., of the St. Catharines Public Utilities Commission, St. Catharines, Ont., has been appointed assistant manager. Mr. Jannaway graduated from the University of Toronto in 1948 and joined the St. Catharines P.U.C. in 1950.

C. R. Stones, P.ENG., has accepted a position as chief engineer, paper division, with Price Brothers Co. Ltd., Kenogami, Que. Before joining this organization he was on the engineering staff of The Bowater Corporation of North America Ltd., in Montreal.

Kenneth J. Sewrey, P.ENG., is process engineer in the acrylic fibre section of the Maitland Works, DuPont Co. of Canada (1956) Ltd., in Maitland, Ont. He was previously with the Spruce Falls Pulp & Paper Co. Ltd. in Kapuskasing, Ont.

J. H. Stevens, P.ENG., of the Canada Wire & Cable Co. Ltd., Leaside, To-

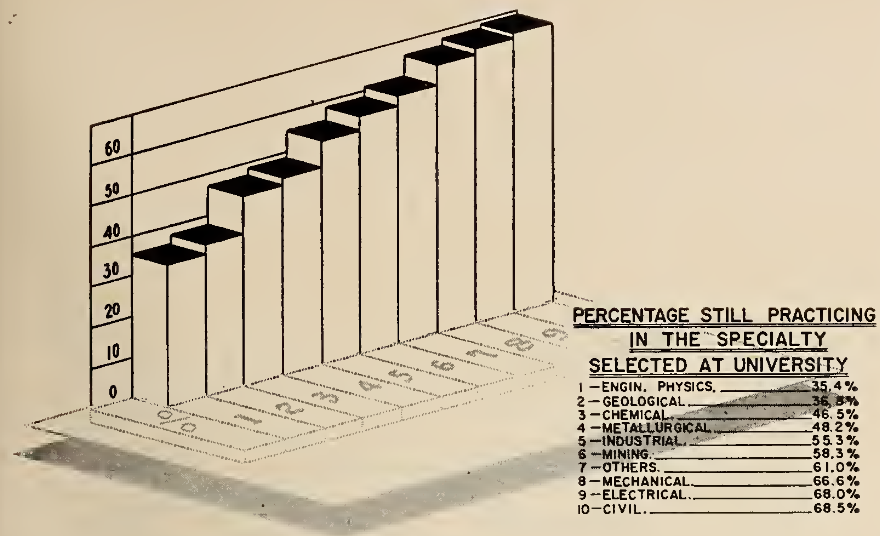

Table 1

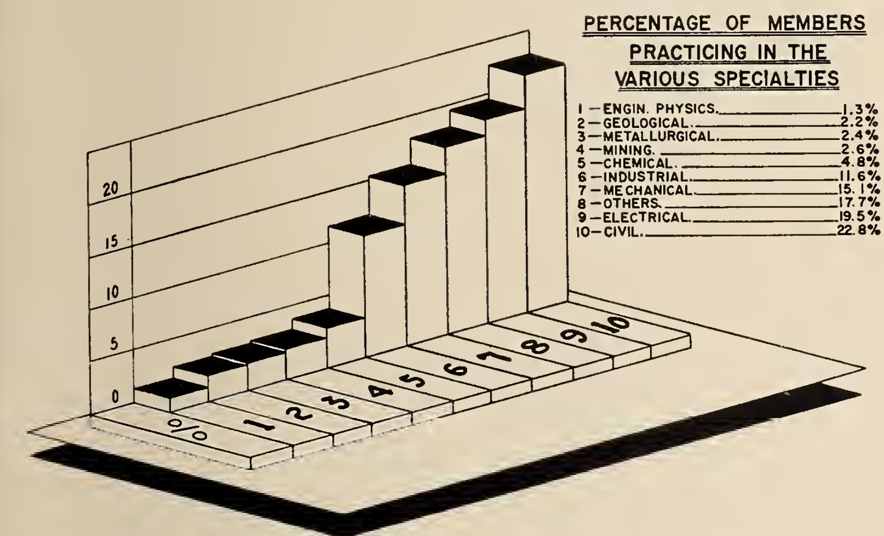

Table 2

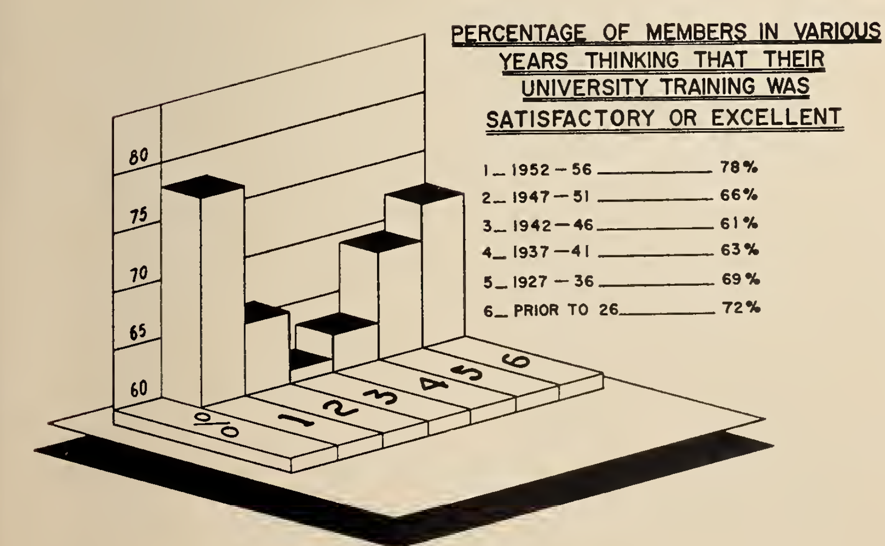

Table 3

ronto, has been appointed manager of general plant planning and engineering. Mr. Stevens graduated in mechanical engineering from Cambridge University in 1938. Ten years ago he joined Canada Wire & Cable Company.

QUEBEC

Quebec Engineers Well Pleased with Training Provided by Universities

During the course of last year, the Corporation's committee on professional training initiated a survey among engineers, employers and universities in order to find out to what extent university training fulfills the needs of the profession in private practice and industry. About one-third of the members of the Corporation have answered the questionnaire prepared for them by the committee members; questionnaires for employers are currently being prepared.

Results of the survey among engineers offer interesting information for all members of the profession, but especially for the directors of our engineering schools and universitics, because they constitute an expression of opinion that may be a useful guide in the elaboration of programs and the preparation of courses.

For many years, the deans or directors of engineering schools have discussed the relative advantages of basic general training and of strict specialization. Table 1, showing the percentage of those actually practising in the specialty they have selected at University throws additional light on the subject. Considering that some 50 per ccnt of the answers originated from graduates of the last ten years, one must expect that others will change their field of practice.

Table 2 represents the proportion of members actually practising in each of the ten specialties listed in the questionnaire. It will be seen that the greatest number of engineers are in civil engineering, and that electrical engineering occupies second place. Third, we find all other specialties not specified (aeronautical, petroleum, industrial testing, valuation, etc.) which illustrates the diversity of positions filled by engineers.

We are pleased to find that the percentage of those who have found the technical training received at the university either "satisfactory" or "excellent" —as illustrated in Table 3—increases with the more recent years of graduation. Exception must be made for the very early years of graduation, where technical knowledge has become less indispensable as the engineers involved moved towards higher administrative positions.

Answers to the questionnaire, compiled mechanically, offer numerous details which are not necessarily of general interest, but could be considered in the study of programs and the content of courses. Using the code number assigned to each university, one can find the opinion of five or ten graduating classes on the principal subjects of the curriculum. Although this may terminate examination of the situation from the point of view of our general membership, we are sure that it will initiate critical review at the university level. The Corporation of Professional Engineers of Quebec will be pleased to cooperate fully with the university representatives on this matter.

1958 Annual Meeting

The 1958 General Annual Meeting, to be held at the Sheraton-Mount-Royal Hotel in Montreal on Saturday, March 22, will be highlighted, as have been past annual meetings of the Corporation, by an Art Exhibition. The 1958 exhibition will show paintings, sculpture and ceramics by members of the Corporation.

Northern Electric Largest Employer

At year end, Northern Electric Company Limited ranked first among the larger employers of Quebec engineers; it had 273 professional engineers on its staff, an increase of 64 over last year. Bell Telephone Company which was first last year, is now in second place. Follows a list of the 27 larger employers of Quebec engineers and the number of persons authorized to practise engineering in each. Last year's figures appear in parentheses; (x) means less than 38.

Northern Electric	273	(209)
Bell Telephone	251	(244)
City of Montreal	228	(219)
Aluminum Co. of Canada	194	(172)
Hydro-Québec	157	(144)
Quebec Roads Dept.	105	(105)
Dominion Bridge	100	(78)
Shawinigan Water & Power	86	(79)
Canadair	85	(60)
Canadian Industries Ltd.	77	(64)
C.N.R.	68	(58)
Canadian General Electric	61	(58)
Consolidated Paper	60	(51)
Canadian International Paper	59	(52)
Dominion Engineering	59	(44)

Ecole Polytechnique	46	(x)
McGill University	45	(44)
Dupont	42	(x)
Quebec Public Works	39	(38)

MANITOBA

(Taken from "A Message from The President," by N. S. Bubbis, published in The Manitoba Professional Engineer, December 1957 isue)

President's Message

All of last year's committees were reappointed and have actively pursued their tasks. In addition the following new committees were established and have been working hard: plan for unity committee; certification of technicans committee; and a professional ethics committee. A special committee assisted Council with a brief submitted to the Royal Commission on Flood Cost Benefit, a joint standing committee of the Manitoba Association of architects and our Association has been set up. Another committee under the chairmanship of T. E. Storey, P.Eng., has been reviewing the Association's constitution and bylaws to determine whether any changes are required.

Another innovation this year was the meeting of Council members with engineers in Northern Manitoba held recently in Flin Flon. This was a most successful venture and is further evidence of the changes that are being brought about by the development of our Province.

Council this year also decided to establish a closer liaison with engineering students at the University and with new graduates. Early this year a letter was sent to every graduate, inviting him to join the Association as an engineer in training. This was followed by a personal appeal by the president at the Kipling Ritual. Recently a meeting with the third and fourth year engineering students, which we will hope is to become an annual event, was held at the University under the chairmanship of Dean A. E. MacDonald, P.Eng. The association of Professional Engineers of Manitoba was represented by Dr. Landon, P.Eng., chairman of the public relations committee, and President Bubbis. The objectives of the Association were outlined to the students and they were invited to become student members. The meeting was well-attended and the numerous questions which followed indicated the keen student interest. A considerable number of applications for both engineers in training and engineering pupils have since been received.

BRITISH COLUMBIA

Annual Meeting Held December 13-14

The two-day annual meeting of the Association of Professional Engineers of B.C. held December 13-14, at Vancouver, was climaxed with the decision to proceed with the purchase of a new headquarters building at a cost of approximately $90,000. It is the Baynes-Manning Construction Company office at 2210 West 12th Avenue in Vancouver.

About three years old, the building offers double the area of present Association headquarters at 1166 West Pender Street. Registrar J. A. Merchant, P.Eng., stated that the purchase would probably be completed by February.

New officers elected for the coming year were headed by mining engineer G. C. Lipsey, former vice-president and general manager of Britannia Mining & Smelting Co. Ltd., Britannia Beach. In a short address in which he accepted the office from retiring President W. O. Richmond, Mr. Lipsey announced his intention to take a year off from work and devote his full time to the Association's affairs. It will be the first time since the Association's formation in 1920 that it has been served in this way.

Other officers elected were Vice-President R. E. Wilkins, and Councillors F. A. Lazenby, F. Noakes, H. P. J. Moorhead, B. O. Brynelsen, all of Vancouver, and B. P. Sutherland, Trail, B.C.

Professor Richmond, as past president, remains on the Association Council for the coming year. The other four members of the 12-man Council will be appointed by the provincial government in the near future.

In his report on the year's activities, President Richmond drew attention to the fact that there had been, for the second consecutive year, a 20% increase in the number of membership applications received.

L. H. Cook, P. Eng., chairman of the Salary Committee, reported that a new schedule of salaries had been drawn up calling for upward revisions. This was recommended because the starting salaries of newly graduated engineers were falling behind the rising level of artisans' wages. The new scale recommends increases of approximately 11 per cent. Acceptance of the new scale has been received from the Canadian Council of Professional Engineers, who noted that by coincidence the B.C. report was almost identical to one presented at the same time by the Ontario Association.

The meeting also heard reports on the progress of the Canadian Council of Professional Engineers' committee on Confederation with the Engineering Institute of Canada and was advised that the annual meeting of the Canadian Council would be held in Vancouver May 7-9 at the Hotel Georgia. It was stated the national body expects shortly to open a full time office at Ottawa.

Hearty support was given to a public relations committee recommendation that the Association implement a plan for closer liaison with members of the high school teaching profession instructing science courses.

B.C. Minister of Industrial Development, Trade and Industry, R. W. Bonner, speaking at the Association luncheon, reported on his recent trip to Europe. He stressed the future importance of Europe as a market for B.C. and Canadian goods. With the establishment of the European common market a free trade area with a consuming population larger than the United States would be created. It would be folly not to make maximum efforts to do business with them, he noted.

Life membership medals were presented to six members. Another eight to be so honoured were unable to attend.

Announcement was made at the luncheon of the winners of a number of scholarships and book prizes.

Personals

News of the Personal Activities of Members of the Institute

Denton Massey, M.E.I.C., (B.Sc., general engineering, M.I.T., 1924), general manager of AMF Atomics (Canada) Limited, since 1956, has been elected a vice-president and director and will continue as a general manager. Mr. Massey started his business career with Massey-Harris Company Limited, working up to the position of manager of the Toronto Works. He entered public life in 1935 as a member of the Canadian Parliament, and was elected for three consecutive terms.

In recent years Mr. Massey has won recognition as an outstanding speaker on the peaceful uses of atomic energy.

Gordon B. Tebo, M.E.I.C., (B.A.Sc., elec., Toronto, 1929), has accepted an appointment with the Canadian Standards Association Testing Laboratories as manager of the laboratories. He was elected to the board of directors, C.S.A., in 1955.

Mr. Tebo's career has been linked with the Hydro-Electric Commission of Ontario for many years. He was named director of research in the latter organization in 1953. Lately he has served as director of employee relations and also as director of the organization services division.

Ignace Brouillet, M.E.I.C., (B.A.Sc., C.E., Ecole Polytechnique, 1929; D.Sc. (Hon.) Laval, 1950), of the firm of Brouillet and Carmel, consulting engineers, of Montreal, has been named a director of the Provincial Bank of Canada following recent elections.

Louis Trudel, M.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1936) manager of the public relations and advertising department of Shawinigan Water and Power Company, Montreal, has gone to Paris to attend the Quebec in Paris Exhibition, which opened January 17, closes February 28. In so doing, Mr. Trudel, onetime assistant general secretary of the Engineering Institute represents the Shawinigan Companies. Mr. Trudel was in 1955 elected president of the Montreal Branch of the Canadian Public Relations Society.

F. W. Bradshaw, M.E.I.C., (B.Sc., chemical, McGill, 1925), a member of the staff of Consolidated Paper Corporation Limited for twenty-three years, has been elected vice-president and executive assistant to the president, following a re-

Denton Massey, M.E.I.C.

cent meeting of the directors of the organization.

Mr. Bradshaw also holds office on the executive council of the Canadian Chamber of Commerce and on the Economic Development and Labour Relations Committees.

He is a past-chairman of the St. Maurice Valley Branch of the E.I.C., past councillor and chairman of the nominations committee.

He is a graduate of the Harvard Advanced Management Program.

W. J. LeClair, M.E.I.C., secretary-manager of the Canadian Lumbermen's Association has retired after twenty-two years' service with the association. In 1957 he took over the general managership of the organization.

J. R. von Renteln, M.E.I.C.

Mr. LeClair has set up a private practice as an industry consultant in Ottawa, crowning forty-six years' experience in logging, sawmilling, forest products research and marketing. His career has included 9 years practical experience in the United Kingdom, a two year period on the Continent and familiarity with Soviet and Scandinavian techniques in these fields.

Mr. LeClair was also managing editor of the publication, "Timber in Canada."

John R. von Renteln, M.E.I.C., (diploma, civil, Karlsruhe, 1927), has resigned as project engineer for the City of Kingston to act as general manager of the Overseas Instruments of Canada. He founded this firm in 1953 as sole owner for importing hydrometric, mathematical and other engineering equipment and lately established a branch in the United States.

Dr. I. R. Tait, M.E.I.C., consulting engineer at Montreal, with Canadian Industries Limited, past vice-president of the Engineering Institute of Canada, 1952-53, was named to the Council of the City of Montreal in October 1957. Appointed to office by McGill University, he represents the latter institution for 1958, 1959 and 1960.

P. L. Kuhring, M.E.I.C., of the St. Lawrence Ship Channel branch of the Department of Transport, named chief engineer in 1956, has retired after forty-five years of service.

Mr. Kuhring joined the Department of Public Works in 1913 in New Brunswick. In the following year he entered the then Department of Marine and remained with the chief engineer's branch until 1920 when he was transferred to the St. Lawrence Ship Channel. In 1944 he was appointed assistant chief engineer.

D. D. Dick, M.E.I.C., (B.Sc., civil, Alta., 1949), formerly chief civil engineer of the Power Corporation of Canada, Limited, has been appointed vice-president and general manager of Power Corporation Designers and Consultants Limited, Montreal. In his career to date Mr. Dick has been associated with the pulp and paper industry and power projects in the design, construction and maintenance of pulp and paper mills and power projects.

Power Corporation Designers and Con-

• PERSONALS

sultants Limited provides a complete engineering design and consulting service in the field of industrial and process plants, hydro-electric and steam power stations, pulp and paper mills and water treatment and sewage disposal installations.

C. R. Stones, M.E.I.C., (engineering economics, Bolton Municipal Technical College, 1929), has transferred his services from The Bowater Corporation of North America Limited, Montreal, to Price Brothers Company Limited, Kenogami, Que., where he will carry out the duties of chief engineer for the firm. Mr. Stones' association with The Bowater Corporation wa that of assistant to the manager of the engineering department.

O. J. Frisken, M.E.I.C., (B.Sc., mech., Queen's, 1929), of the De Laval Company has been appointed vice-president in charge of manufacturing. He is a director of the company and was formerly manager of manufacturing. He has been associated with the organization since 1936.

J. H. Legate, M.E.I.C., (B.A.Sc., Toronto, 1921), plant manager of the Canada Cement Company, plant No. 5, Belleville, Ont., has retired after an association of thirty-seven years in the cement

D. D. Dick, M.E.I.C.

manufacturing business. Mr. Legate became plant manager four years ago following many years as superintendent of the St. Anne plant.

Brigadier H. L. Meuser, M.E.I.C., (R.M.C., 1934; B.Sc., civil, Queen's, 1935), commander of the Northwest Highway System, Whitehorse, Y.T. since 1955, is now located at Army Headquarters, Ottawa.

E. E. Orlando, M.E.I.C., (B.Sc., elec., N.S.T.C., 1927), of Canadian Westinghouse Company Limited, Hamilton, Ont., has been named to the post of vice-president, apparatus and industrial sales. Mr. Orlando was formerly vice-president and general manager for the company's district apparatus division.

John W. Tomlinson, M.E.I.C., (B.Sc., elec., Manitoba, 1930), vice-president of the Northern Ontario Natural Gas Company Limited, Toronto, since 1956, and the Twin City Gas Limited has resigned to devote his full time to a consulting service. Mr. Tomlinson has had twenty-five years practical experience in Canadian electrical and natural gas utility engineering and management. He became assistant sales manager of Trans-Canada Pipe Lines Limited, Calgary,

E. C. Little, M.E.I.C.

Jean-Paul Drolet, M.E.I.C.

with offices in Toronto, in 1955 after a number of years experience with the Saskatchewan Power Corporation. As general manager of the Corporation he introduced natural gas to cities, towns and villages in Saskatchewan.

Jean-Paul Drolet, M.E.I.C., (B.A.Sc., mining, Laval, 1942; M.Sc., Columbia, 1947), of the Quebec Cartier Mining Company, Montreal, has received the appointment of assistant to the president. Mr. Drolet who was formerly with the Quebec Department of Mines, joined the Quebec Cartier Mining Company in 1956 as a mining engineer.

E. C. Little, M.E.I.C., (B.Sc., civil, McGill, 1915), of Fonthill, Ont., has been elected chairman of the Niagara Peninsula Branch of the Engineering Institute. A retired engineer, formerly with the Canals Branch, Ottawa, where he was engineer in charge of maintenance and operation, Mr. Little now engages in consulting engineering work and serves as engineer for the village of Fonthill.

H. W. M. Townshend, M.E.I.C., (B.Sc., marine, Durham, England, 1939), has been elected chairman of the Saint John Branch of the Institute. Mr. Townshend came to Canada in 1941. He is employed with the Saint John Dry Dock Company Limited, East Saint John, N.B.

H. W. M. Townshend, M.E.I.C.

C. G. Kemp, M.E.I.C., (mech., Technical College, Sydney, Australia, 1913), works manager with Consumers Glass Company Limited, since 1951, was recently elected a vice-president of operations for the firm. Mr. Kemp joined the company in 1934.

G. M. Dick, M.E.I.C., (B.Sc., mech., McGill, 1924), a vice-president of the Engineering Institute, residing at Sherbrooke, Que., has been named president of the St. Francis River Valley of the McGill Graduates Society. Mr. Dick is chief engineer of Canadian Ingersoll-Rand Company Limited at Sherbrooke.

W. F. Sharon, M.E.I.C., (B.Sc., civil, Queen's, 1939), has transferred his services from the Toronto firm of Sparling Tank Limited to the Mannix Company Limited at Calgary. His new post is that of executive vice-president. Mr. Sharon held the appointment of vice-president and general manager with the Sparling organization.

Roger Labonté, JR.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1955), has since September 1957 and his return to Canada from studies in Great Britain held an assistant professorship on the staff of Ecole Polytechnique, Montreal. Mr.

Labonté was awarded an Athlone Fellowship in 1955. While in Britain, he was enrolled in a public health engineering course at Imperial College of Science and Technology in London. Mr. Labonté spent his second year with the firm of Sandford Fawcett and Partners, London, a firm of sanitary engineers with branches in Canada, known as Canadian British Consulting Engineers.

T. Argyropoulos, Jr.E.I.C., (B.Eng., mech., McGill, 1951), has left Montreal in order to accept a position in Bedford, Ohio, U.S.A. Formerly with Canadair Limited he is now associated with the firm of Pescoe Products.

J. D. Lamb, Jr.E.I.C., (B.A.Sc., mech., U.B.C., 1950), has received the appointment of sales manager of the Canadian division of the Wheelabrator Corporation, located at Toronto.

J. J. Paré, Jr.E.I.C., (B.A.Sc., civil, Laval, 1955), an Athlone Fellowship winner has returned to Canada as a soils engineer with the Department of Highways, Province of Quebec, at Quebec City. While on Fellowship Mr. Paré was enrolled at the Imperial College of Science and Technology, London, Eng., as a post-graduate student of concrete technology and soil mechanics. Mr. Paré, who qualified for the diploma of the Imperial College, (D.I.C.), states that he was afforded the excellent opportunity of study with Professor Skempton, president of the International Society of Soil Mechanics and Engineering Foundation.

W. H. Potts, Jr.E.I.C., (B.Sc., civil, Queen's, 1948), formerly with the Toronto firm of Guildwood Development Limited, has accepted an appointment as project engineer with Proctor and Redfern, consulting engineers, also of Toronto.

W. E. van Steenburgh, Jr.E.I.C., (B.Sc., elec., Queen's, 1948), has changed his address from Belleville, Ont., to Ottawa. Formerly with the Ontario Hydro-Electric Commission his professional association in Ottawa is with the Organization and Methods Service.

J. T. Denley, Jr.E.I.C., (B.Sc., Alberta, 1949), is now employed as a chemical engineer by the Elk Falls Company Limited, Campbell River, B.C. He previously served H. A. Simmons Limited, consulting engineers of Vancouver, as a design engineer.

Roch Boisvert, Jr.E.I.C., (B.A.Sc., elec., Laval, 1948), has been elected chairman of the Saguenay Branch of the Engineering Institute.

A native of Thetford Mines, Que., Mr.

Roch Boisvert, Jr.E.I.C.

Boisvert has been employed with the Saguenay Electric Company at Chicoutimi, Que., as an electrical engineer since his graduation. He became a district superintendent of the company in 1950, gaining the promotion of general lines superintendent early in 1957.

G. M. Ross, Jr.E.I.C., (B.Eng., elec., McGill, 1955), who won an Athlone Fellowship in 1955 has returned to Canada. He is employed with the microwave engineering group of Standard Telephones and Cables Manufacturing Com-

• **PERSONALS**

pany (Canada) Limited, Montreal.

In England Mr. Ross was associated with Standard Telephones and Cables, Limited, in London. During this time he was able to gain experience in many branches of the telecommunications industry.

Bruce W. Brunton, JR.E.I.C., (B.Sc., civil, Manitoba, 1953) has severed his connections with the Toronto firm of Town Planning Consultants Limited, and has accepted the appointment of City Engineer for the City of Owen Sound, Ont.

L. Grant Boundy, JR.E.I.C., (B.Sc., elec., New Brunswick, 1955), of the Canadian General Electric Company Limited has been transferred from Toronto to Barrie, Ont., where he is with the small appliance department of the organization. Mr. Boundy was employed as a design engineer at Toronto.

G. M. Ross, JR.E.I.C., (B.Eng., electrical, McGill, 1955) is an engineer in the microwave group of Standard Telephones & Cables Mfg. Co. (Canada) Ltd., Montreal.

Frank S. Miller, JR.E.I.C., (B.Eng., chem., McGill, 1949) has been transferred by Scarfe & Company from Brantford, Ont., to Montreal. Formerly sales engineer, he is now branch manager for the province of Quebec.

Ronald S. Butcher, JR.E.I.C., (B.Eng., mechanical, Nova Scotia Technical College, 1954) is a design engineer for Atomic Energy of Canada Ltd., at Chalk River, Ont.

Mr. Butcher received the Athlone Fellowship in 1954.

William Taciuk, JR.E.I.C., (B.Sc., chemical 1951; B.Sc. elec. Alberta, 1954) is now employed by Imperial Oil Limited as process engineer, technical department, New Westminster, B.C.

Raymond Dumas, JR.E.I.C., (B.A.Sc., civil, Laval 1954), is now with the Standard Paper Box Company, Montreal.

He was formerly with Concrete Repairs & Waterproofing Co. Ltd., Hydro-Quebec, Labrieville, Que.,

P. F. Phelps, JR.E.I.C., (B.A.Sc., engineering and Business, Toronto, 1955) is employed by Canadian Westinghouse Company Ltd., Hamilton, as sales engineer in their power transformer sales department.

F. R. Scrase, JR.E.I.C., (B.Sc., civil, Manitoba, 1955), has been associated with Canadian National Railways for the past two and a half years at various locations as a junior assistant engineer.

Mr. Scrase has recently transferred his services to the Department of Public Works, Province of Manitoba. He is employed in the Highways Branch, Winnipeg.

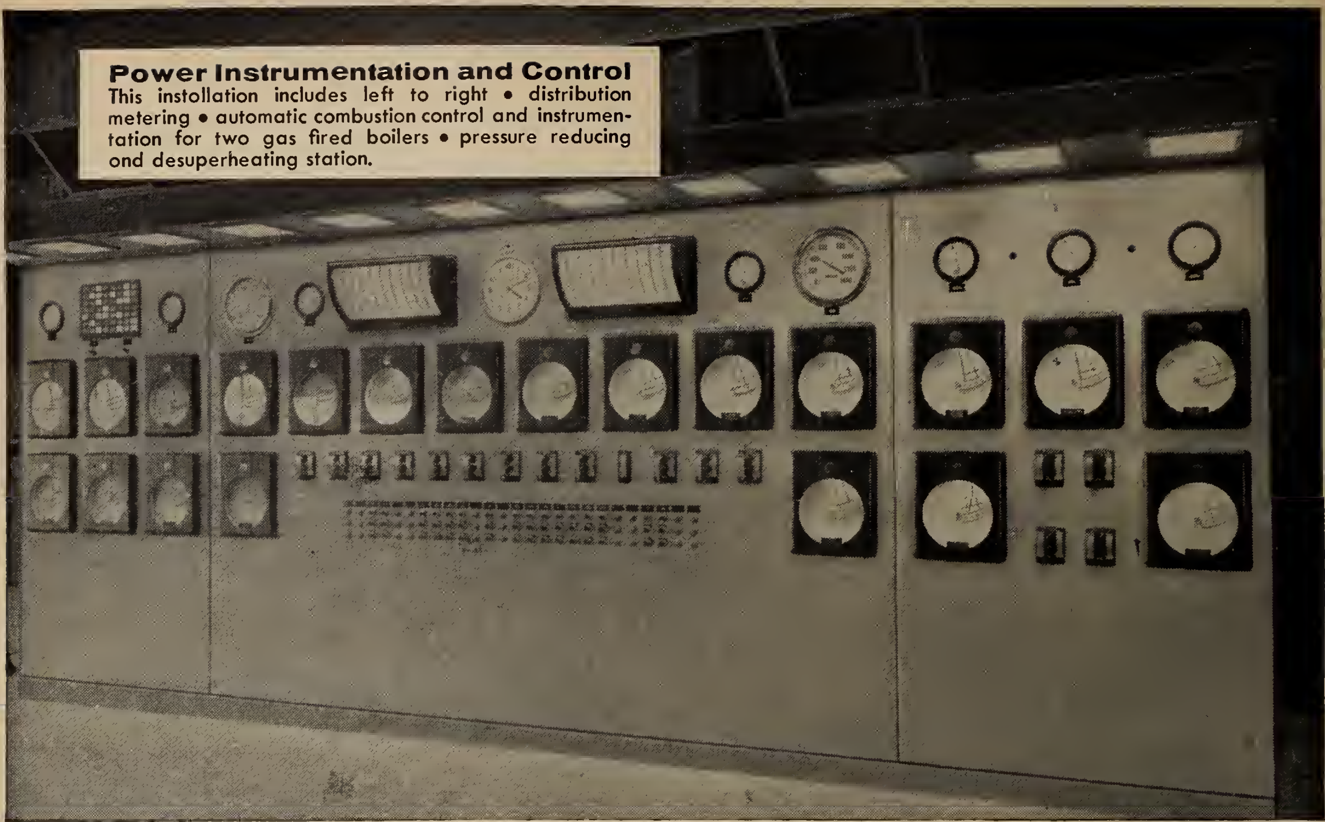
J. M. Katrusiak, JR.E.I.C., (B.Eng., civil, McGill, 1956) has left the Power Corporation of Canada Limited, Montreal, where he was employed as a design engineer and has joined the staff of Dominion Glass Company Limited, Montreal.

B. C. Doell, JR.E.I.C., (B.Sc., civil, Saskatchewan, 1953), assistant hydraulic engineer for the Department of Public Works, for Ontario, has been transferred from Fort Frances to Toronto.

D. S. Simons, JR.E.I.C., (B.Sc., electrical, Manitoba, 1949) is terminal station and transmission engineer for the Manitoba Hydro-Electric Board, Winnipeg.

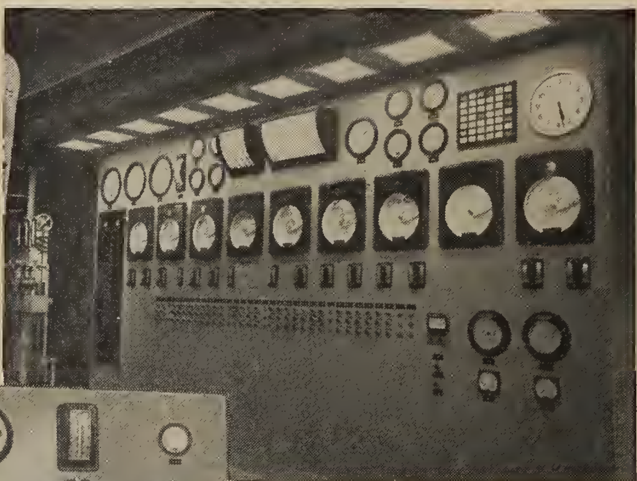
Paul R. Ukrainetz, S.E.I.C., (Sask., 1957), Athlone Fellowship winner of 1957 is living at Bristol, England, where he is undergoing practical training in aeronautical engineering with the Bristol Aircraft Company.

James Swim, S.E.I.C., (B.Sc., civil, New Brunswick, 1957), has accepted a position with the New Brunswick Telephone Company Limited, at Saint John, N.B.

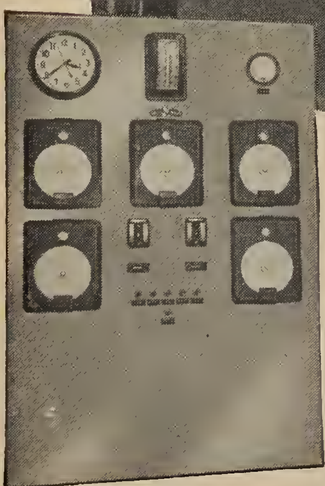


Power Instrumentation and Control
This installation includes left to right • distribution metering • automatic combustion control and instrumentation for two gas fired boilers • pressure reducing and desuperheating station.

Glimpses of Bailey at Alberta's First Pulp Mill



Black Liquor Recovery Furnace Control Includes metering and controls for • combustion • Cascode evaporators • line heaters • dissolving tank.



◀ **Lime Kiln Recording and Control** Featuring • automatic hood draft control • continuous recording of oxygen • etc.

North Western Pulp & Paper Limited, Hinton, Alta.

Now in operation and producing 430 tons of bleached sulphate pulp daily, the North Western mill is Canada's newest and Alberta's first. Consulting engineers were H. A. Simons Ltd. of Vancouver, B.C. The mill is powered entirely by natural gas, a project which required the laying of a $5 million pipeline to the company's location at Hinton, 17 miles east of the Jasper National Park.

Installations feature Bailey Plug-in Metering, Bailey MINI-LINE Control and Bailey Building Block method of approach to all metering and control installations.

Sales service offices and resident engineers are located in all major Canadian Cities. Bailey plays its part in all new development in Canada's Pulp and Paper growth.

NEWS OF THE BRANCHES

Activities of the Forty-Nine Branches of the Institute and abstracts of the papers presented at their meetings

AMHERST

G. R. Pond, JR.E.I.C., *Sec.-Treas.*

THE PRESIDENTIAL TOUR of the Amherst Branch took place on November 20, 1957. A civic welcome, extended by Councillor D. W. Tingley, was followed by a reception at which members and guests were introduced to President Anson. In the dinner address entitled, "The Engineer in Management," the president stressed the growing importance of the engineer in industrial management and labour relations. With increasing frequency the engineer is being selected to manage the many and varied components of our industrialized civilization, he said. It was therefore inevitable that the natural course of evolution should reveal the engineer as best fitted to assume the increasing responsibility of management. He has had, he added, the correct training, a training which stressed the paramount need for producing and basing decision on facts. In whatever employment he may be engaged, the engineer will find himself dealing with and directing people. This involves a knowledge of finance, governmental procedure and law. It demands adeptness in vocal communication to men in all walks of life. Thanks on behalf of the Branch was expressed by R. L. Alexander.

Vice-president of the Institute for the Atlantic provinces, H. W. L. Doane of Halifax, introduced by L. E. Burrill, produced some interesting statistics on the progress made by the Institute over the last ten-year period.

Entertainment and dancing followed the talk.

AMHERST: Assembled on the occasion of his visit to Amherst, N.S., are President Anson, Mrs. Anson, branch members and their wives. Left to right they are: Mrs. Rockwell, D. J. Rockwell; L. E. Burrill and Mrs. Burrill; D. W. Tingley, councillor and Mrs. Tingley; Mrs. Anson, President Anson; Mrs. Wilson and J. W. Wilson, Branch chairman; Mrs. Pond and Roy Pond, branch secretary; and H. W. L. Doane, vice-president of the Engineering Institute, Atlantic Region.

BELLEVILLE

T. E. Hilbig, JR.E.I.C., *Sec-Treas.*

EVALUATING PERFORMANCE in an engineering department was the subject of a talk when H. L. Johnston, chief engineer of Du Pont of Canada (1956) Limited, addressed the regular monthly meeting in December. This paper was reported in the December isssue of the Journal by the Nipissing and Upper Ottawa Branch.

In the ensuing question and discussion period it was apparent that a number of members were comparing Mr. Johnston's system of rating employees with those used by their companies.

Papers chairman, Dave Pullen listed an interesting program for the remainder of the 1957-58 season. On January 13, 1958 M. G. Townsend of The Northern Eectric Company, Montreal discussed industrial health. Dr. A. E. Berry of the Department of Public Health, Toronto, delivered a talk on water pollution and sewage disposal. It is intended that on March 10, a Branch tour of the Pryotenax Company plant at Trenton, Ontario will be made. The chemical composition of the universe will be explained by Dr. J. B. Oak, of the Department of Astronomy, University of Toronto, on April 14. Finally, the spring program will be concluded, May 12 with a film and lecture devoted to illustrating the means available for the manufacture and use of plywood.

CALGARY

O. O. Junker, M.E.I.C., *Secretary*

Fred L. Perry, M.E.I.C.,

Publicity Committee Chairman

AN OUTSTANDING AUTHORITY on atomic energy was heard by members of the Calgary Branch of the Institute on December 4, 1957. J. L. Olsen, manager of marketing research for the civilian atomic department of the Canadian General Electric Company at Peterborough, Ont., addressed the group on "A Current Review of the Atomic Power Business."

A brief explanation of the fundamentals of fissioning and nuclear power and a discussion on the uranium industry in Canada was given. Comparison between the various types and forms of reactor fuel used, as well as comparison of the various types of reactors built in Canada, the United States and Great Britain was made. Economic reasons for the courses taken were explained. Problems associated with each design were traced. Power requirement and supply in Canada and comparison with a number of foreign countries was presented. The importance of nuclear energy in Canadian planning for the future was also discussed.

The talk was accompanied by slides and various fuel samples.

A.C.E. Professional Development Program

The A.C.E. Professional Development Program initiated by the Calgary Branch of the Engineering Institute of Canada was organized under the joint sponsorship of the Alberta Society of Petroleum Geologists, the Canadian Institute of Mining and Metallurgy and the Engineering Institute of Canada. Its program was briefly reported in the November Journal. The Program, held at Calgary's modern Southern Alberta Jubilee Auditorium, began with two afternoon-dinner-evening meetings in the spring of 1957. As a result of interest displayed at that time, the program of adult education was arranged.

The purpose of the program is to assist engineers and earth scientists to broaden their knowledge and interest in matters beyond their present daily tasks; to become more interesting people who will find increased enjoyment in living and in the world around them and who will have greater potential for advancement in the professional and managerial world.

Presented on alternate weeks, for a two-hour session, the emphasis is placed on participation of members at the meetings. It is one of the aims of the program to give members an opportunity to gain experience and confidence in expressing their views in open meeting. Accordingly the speakers of the evening are asked to present the subject background in the course of one hour, followed by a short break. Meetings then reconvene for questions and discussion.

The 1958 program features such diversified matters as: government, arts and literature, human relations and finance, covered by well-known speakers throughout the province in a total of eight talks.

Fee set for the course was ten dollars with an additional charge for each dinner meeting.

Business management, government, arts and literature, and self-development comprised the subjects dealt with in the 1957 portion of the course which began during September.

TWO TECHNICAL MEETINGS both of them dinner meetings, were arranged for the Calgary Branch during the winter term. The first of these, held January 16, at the Southern Alberta Jubilee Auditorium featured two speakers. First on the program J. E. Oberholtzer, deputy minister of the Department of Industries and Labour, Edmonton, Alta., spoke on "The Present Industrial Picture in Alberta," covering development over the past ten years, and making comments on future possibilities for the province.

Following the dinner Dr. D. C. Rose gave a talk on "The International Geophysical Year" with emphasis on the part played by Canada. He gave special mention to the work of the Cosmic Ray Research Station at Sulphur Mountain, Banff, Alta.

Dr. Rose is a research officer with the National Research Council, and is chairman of the Canadian National Committee for the International Geophysical Year.

KINGSTON

D. I. OUROM, M.E.I.C., *Sec.-Treas.*

NATIONAL RESEARCH COUNCIL recently developed a machine to facilitate the

• BRANCH NEWS

production of accurate models required for tests in the Council's laboratories. The machine was described by G. J. Klein, of N.R.C., at a meeting of the Kingston Branch, held at Queen's University, January 14, 1958.

The machine was primarily designed to cut reference contours of ship models up to 25 feet long and made of wood or wax. It can also be used to cut contours of many other items, such as fan blades. It has ample rigidity and power to cut light metals. Cutter feed is controlled automatically by a 360 degree tracer system guided by a spline clamped along a contour on a master drawing. The machine manifests advanced design features of special interest to engineers.

LAKEHEAD

C. M. Cotton, JR.E.I.C., *Sec.-Treas.*

G. A. Walker, JR.E.I.C., *Publicity Committee*

A JOINT MEETING of the Lakehead Branch of the Institute with the Association of Professional Engineers of Ontario was held December 13. Fifty members heard J. H. Fox, president of the Ontario Association, discuss current problems facing the professional engineering group in Canada. Among points raised were the rating of other semi-professional groups into various classifications such as technicians and technologists. The important problem of national confederation was discussed. A working outline of the organization was presented along with some of the problems to be encountered before the organization could become a reality. Mr. Fox expressed optimism in this endeavor providing members be prepared to overlook minor personal sacrifices in realizing broad advantages to be gained.

An interesting comment in regard to the fact that presidents and vice-presidents are not voted into office, was made by Colonel Medland who said that such duties are particularly demanding and involve one-third of a man's waking hours and a great deal of travel. Presidential visits had involved 25,000 miles of travel during 1957. It could be understood, he felt, that a year's notice is necessary if one is to be prepared for such a schedule.

Mr. Fox was introduced by Branch chairman V. B. Cook, R. B. Chandler extended thanks.

An informal meeting was held following the luncheon in order that members acquaint themselves with the visiting officials.

TORONTO

D. S. Moyer, M.E.I.C., *Sec.-Treas.*

A. C. Davidson, M.E.I.C., *Branch News Reporter*

THE ENGINEERS' RESPONSIBILITY in School Planning was the subject of an address delivered by Zeph A. Marsh, director of school activities for the Minneapolis Honeywell Company to an evening meeting of the Toronto Branch, December 5.

Introduced by John Fox, president of the Association of Professional Engineers of Ontario, Mr. Marsh spoke on the more efficient construction of schools as an aid to the education field.

Giving special mention to ventilation he urged that various groups within the school system, such as teachers and students meet with those planning the design and construction of a new school in order to discuss the matter. One point which Mr. Marsh felt did not receive adequate consideration was that of ventilation.

After discussing some other mechanical details which could make for better schools Mr. Marsh gave a breakdown of the cost of education. Eighty per cent of the budget is spent on salaries. Nine per cent is used for capital investment (cost of the building) and 11 per cent is allowed for other costs. The construction of the schools should add to the efficiency of teachers and students.

THE JOINT TORONTO AREA COMMITTEE of the E.I.C., I.C.E., and the A.S.C.E. at

● BRANCH NEWS

a meeting on December 12 listened to D. A. Clough discuss the expansion of sewage disposal facilities in rapidly growing Metropolitan Toronto.

Mr. Clough began his talk by tracing the history of Metro-Toronto's population growth and the sewage disposal problem it created. He then indicated the overall plan which has been developed to satisfy the growing area. Details of some of the plants, both temporary and permanent, finished and still under construction were given. Colour slides made clear the immense amount of work which has been done.

It was felt that a citizen of Metro-Toronto would see the occasional manifestation of the construction, but would not readily grasp the picture.

President Anson's visit to the Toronto Branch at the time of the regular monthly meeting was an event of January 7, 1958. Together with the general secretary, Dr. L. A. Wright, the president attended a Branch executive meeting and dined with the executive before the regular evening meeting.

In his presidential address, delivered to the evening meeting, on the Engineer in Management, Mr. Anson outlined the ideal relationship between labour and shareholders. Mr. Anson favoured the engineer-trained manager as the man best able to serve the interests of both parties to the utmost advantage of the business partnership.

With mixed feelings, Dr. Wright who will retire shortly, referred to his twenty-two years of service and noted the material well-being which has come to the organization in that time.

A film entitled "The Four Seasons" was included in the proceedings of the event.

President Anson made an appearance on television appearing on the C.B.C. program "Tabloid".

SUDBURY

W. J. Ripley, M.E.I.C., *Sec.-Treas.*

M. D. Head, M.E.I.C.,
Publicity Committee

Sudbury district branch held a dinner meeting at the Granite Club on December 12 attended by thirty one members and guests. E. Querney introduced the speaker, L. Graham of the Northern Electric Company, who delivered an informative talk on the subject of high voltage cables. Mr. Graham traced their historical development from 1890, when a 10,000 volt cable installed by Feranti at Deptford, England, was considered hazardous and was banned by the local authorities, to the present time when 300,000 volt cables are in use, and experiments are being carried out with 800,000 volt cables in some European countries. The early cables consisted of a copper conductor surrounded by oil impregnated paper insulation. The first major design advance was made in 1914 by Hofstatter who invented shielding, that is, metallic covering outside the paper insulation to equalize voltage stresses and prevent the ionisation responsible for failure. This development permitted transmission at as high as 22,000 volts. In 1917 Emmanuell's oil filled core cable, and in 1925, Atkinson's and Fisher's inert gas filled pressure cable methods of construction further increased the allowable voltage applications. Improved methods of today for manufacture of the conductor and paper insulation, with the cable enclosed in pipe under oil pressures up to 200 p.s.i. permit operation at standard voltages of 230,000 or even 310,000.

Following his talk, Mr. Graham presented a film on the Steep Rock Dredge cable. This is a portable power line, using butyl rubber insulation, rated at 1500 volts, 500 amps., and as the speaker pointed out, hardly comparable with the high voltage cables referred to earlier. The film described the development of the Steep Rock iron ore project, which involved draining and de-silting the lake above the orebody, the manufacture of the cable and, finally, the operation of the dredge and monitors. A question period followed.

T. C. Robertson expressed the enthusiastic appreciation of the meeting.

News of Other Societies

International Labour Conference

The fortieth session of the International Labour Conference held in Geneva, Switzerland in June 1957 drew more than 900 delegates, advisors and observers from 73 member countries and 10 territories. A report of the Canadian Employers Delegation was issued late in 1957, from which the following is abstracted.

The 1958 budget of $7,972,901 was passed, supported by Canadian government and labour delegates. Canada was asked to conduct a panel on the subject of "The Role of Government in the Field of Labour-Management Relations." Speakers were G. V. Haythorne, government delegate, Claude Jodoin, worker delegate, and W. A. Campbell, employer delegate. Possibly the most heated argument before the Conference in many years took place over the question of the objections to the credentials of the government, worker and employer delegates of Hungary. Canadian Employers' delegates took an active part in these discussions.

Resolutions were accepted on the abolition of concentration camps and the deportation of national minorities, methods of wage payment, debt bondage and serfdom, abolition of anti-trade union laws, mine safety, women's work, workers' education and housing, non-metropolitan housing, hours of work, disarmament, testing of nuclear weapons, and use of nuclear energy for peaceful purposes.

There was a report of the director-general on automation and other technical development, labour and social implications.

The conference adopted a convention on forced labour and on weekly rest in commerce and offices and on discrimination in the field of employment and occupation.

Director David Morse was re-elected for another five-year term.

Eleventh Canadian Soil Mechanics Conference

Pile Foundations and Frost Action were featured at the 11th Canadian Soil Mechanics Conference, held in Ottawa, December 9 and 10. More than 200 engineers, contractors, geologists and soil scientists attended the meeting, sponsored by the Associate Committee on Soil and Snow Mechanics of the National Research Council.

The program of the first day was devoted to the subject of the bearing capacity of pile foundations and a visit to the soil mechanics laboratory of the Division of Building Research. The pile session was introduced by a paper prepared by Prof. I. F. Morrison and S. R. Sinclair of the University of Alberta. The paper reviewed was "Some Aspects of Pile Foundations".

Specifications for acceptance of wooden piles caused much interest and concern was expressed that when using crooked piles dynamic stresses during driving could exceed the ultimate strength of the outer fibres. Design considerations of lateral support for long slender piles were discussed and the question of corrosion of steel piles was raised. Attention was directed to recent work on corrosion in Norway. An interesting argument, pro and con, on the use of pile driving formulae developed. There was general agreement that the formulae were useful for determining the bearing capacity of piles in clean, granular soils and as specification for refusal.

A panel consisting of Prof. D. F. Coates, Carleton University, as moderator, Dr. G. G. Meyerhof, Nova Scotia Technical College, C. V. Antenbring, Cowin & Co., Winnipeg, E. I. Rubinsky, Raymond Concrete Pile Co., L. A. Fraikin, Franki Pile Co., and N. D. Lea, Foundation of Canada Engineering Corp. Ltd. then took up the subject.

Following a statement on "What is Pile Failure" the panelists discussed special cast-in-place piles (which are used extensively in Western Canada), the use of friction piles in soft clays, the bearing capacity of rammed-in-place concrete piles and some aspects of the National Building Code concerning the soil bearing capacity of piles. Subsequent discussion illustrated the design difficulties associated with friction piles and with establishing a satisfactory value for end bearing piles. The two main problems, of ultimate bearing capacity and settlement, were fully discussed and it was generally concluded that load tests were the best means of evaluating pile capacity.

The program on December 10 was devoted to frost action in soils. The first paper by E. Penner, Division of Building Research, summarized experimental findings on the conditions necessary for the growth of ice crystals in soil. This was followed by a description of the frost problem as it affects maintenance and operation of the Quebec North Shore & Labrador Railway by R. W. Pryer, the soils engineer of the railway. E. B. Wilkins, B.C. Department of Highways, then presented a paper on the design of flexible pavements considering the effects of seasonal variations in road bearing capacity caused by frost action.

J. J. Hamilton of the Division of Building Research, described an interesting case of severe damage to a cold storage plant caused by frost action. After 4 or 5 years of satisfactory operation the building began to heave at the centre and in less than 2 years the heave amounted to more than one foot. Temperature measurements showed that when the frost line penetrated to the footing level (and the level of fine-grained soil) the heaving became rapid. Corrective measures were explained and the plant is now back to its original level. A practical mathematical analysis of the general problem of heat flow under cold storage plants was presented by Dr. D. C. Pearce of the Division of Building Research.

Discussion on frost action covered a wide range of subjects. Much interest was shown in the relationships of loss of bearing capacity of highways to changes in density and water content of the supporting soil. The application of chemical treatment was considered at length.

The proceedings of the Conference will include summaries of the papers presented and will appear in the Technical Memorandum series of the Associate Committee on Soil and Snow Mechanics. It will be available in the spring of 1958.

Correction: An article in the November issue of the *Journal* News of Other Societies, quoted the price of three volumes on the Fourth International Convention of Soil Mechanics, obtainable from Butterworth and Company (Publishers) Ltd., London, Eng., to be $70.00. The price is however, $105.00 delivered, from Butterworth and Company (Canada) Ltd.

Canadian Management Council

The Canadian Management Council, a part of the International Committee for Scientific Management, that body concerned with the research, development and dissemination of management knowledge, known as C.I.O.S., held its annual general meeting in Montreal on October 29, 1957. C.M.C. came into being ten years ago.

• OTHER SOCIETIES

Referring to C.I.O.S. activities during the past two years president Bruce A. Hills, reported that eight papers contributed by C.M.C. were presented at the C.I.O.S. meeting in Paris in 1957. Considerable publicity has been accorded C.M.C.; the submission to the Royal Commission on Canada's Economic Prospects was favorably received in the press.

During the past year C.M.C. was consulted by the Engineering Institute of Canada relative to their management section of the Annual Meeting held at Banff in June 1957. This took the form of a panel discussion on "The Selection and Training of Second Line Executives" at which Mr. Hills took the chair. Assistance was also given to the Junior Management section of the E.I.C. in the matter of a winter seminar.

Tribute was paid to A. M. McKenzie, chairman of the Council whose death in 1956 was severely felt. Mr. MacKenzie had devoted his enthusiasm and experience to the problems affecting C.M.C., particularly its future.

The directorate of the council has been enlarged to include the president or a representative of the member societies who could take an active part in directing the affairs of C.M.C. on behalf of his association or society.

Calendar

1958 Nuclear Congress

More than thirty engineering and scientific societies are completing plans for the Fourth Nuclear Engineering and Science Conference to be held at the Chicago International Amphitheatre March 17-21, 1958. The Congress will demonstrate its progress in the uses of nuclear energy for the benefit of the Western World. For information contact: Joel Henry, Congress Manager, American Institute of Chemical Engineers, 25 West 45 Street, New York 36, N.Y.

The 1958 Nuclear Congress is an assembly of the Fourth Nuclear Engineering and Science Conference; the Fourth International Atomic Exposition; the Sixth Hot Laboratories and Equipment Conference and the National Industrial Conference Board, Sixth Atomic Energy in Industry Conference.

Preprints of Congress papers at fifty cents each may be ordered from the order form to be included in the Advance Program for the Congress which will be distributed in January.

Those interested should request copies of this program from the secretary of the society to which they belong or from the Secretary of Engineers' Joint Council, 29 West 29 Street, New York 1, New York.

American Power Conference

The twentieth anniversary meeting of the American Power Conference will be held March 26-28, 1958, at the Hotel Sherman in Chicago.

The conference is sponsored annually by the Illinois Institute of Technology in co-operation with 14 colleges and universities and nine technical societies. Inquiries should be addressed to: R. A. Budenholzer, Esq., Conference director, Mechanical Engineering Department, Illinois Institute of Technology, 3300 Federal St., Chicago 16.

British Electrical Conference

The 1958 British Electrical Conference will be held at Brussels, May 16-17, under the patronage of the Belgian Commissariat-General, 1958 Universal and International Exhibition, Brussels.

For further information contact: The Organizing Secretary, 1958 British Electrical Conference, 36 Kingsway, London, WC2, England.

I.I.W. to Meet in Vienna

The annual assembly of the International Institute of Welding will be held from June 29 to July 6, 1958 in Vienna, Austria.

After the annual assembly participants will have the opportunity to choose one of the tours to a number of leading industrial establishments in Austria. Guests will be shown scenic parts of the country and acquainted with culturally important places.

A detailed program of the congress may be obtained from: W. R. Stickney, Executive Secretary, Canadian Council of the International Institute of Welding, 7 Pleasant Boulevard, Toronto, Ont.

For those who may wish to holiday in Austria after the congress the Austrian Organizing Committee is willing to undertake arrangements. Application for such arrangements must be made before January 31, to: Oesterreichisches Organizationkomitee, IIW/IIS Jahresversammlung 1958, c/o Schweisstechnische Zentralanstalt, Wien XVIII, Schumanngasse 31, Austria.

Tool Engineers Annual Meeting, Tool Show

The American Society of Tool Engineers will hold an annual meeting and tool show, May 1-8, 1958, at the Philadelphia Convention Centre, Philadelphia, Pa. For further information write: 10700 Puritan, Detroit 38, Mich.

Instrument Society Symposium

The Tenth annual symposium of the New Jersey section of the Instrument Society of America will be held April 1, 1958, at the Essex House, Newark. Control systems engineering is the subject to be covered at the conclave. Further information may be had on writing: Norman Dayton, Esq., Registration chairman, c/o Norman Brager Company, 1060 Broad Street, Newark, New Jersey.

Steel Founders' Society Annual Meeting

The fifty-sixth annual meeting of the Steel Founders' Society of America, will be held at the Drake Hotel, Chicago, Ill., on March 17 and 18, 1958. Enquiries should be directed to: George K. Dreher, market development director, Steel Founders' Society of America, 606 Terminal Tower, Cleveland 13, Ohio.

Chemical Institute Meet

A joint conference of the American Institute of Chemical Engineers and Chemical Engineering subject division, C.I.C., Montreal, Que., will be held from April 20-23, 1958. For further information write: The Chemical Institute of Canada, 18 Rideau Street, Ottawa 2, Ontario.

Plastics Society Conferences

The Sixteenth Annual S.P.I. Canadian Section Conference will be held at the Royal Connaught Hotel, at Hamilton, Ont., on March 6 and 7, 1958, by the Society of the Plastics Industry Canada, Incorporated. For further information contact: the Canadian office at 77 York Street, Toronto, Ont.

The Fifteenth Annual Pacific Coast Section Conference of The Society of the Plastics Industry, Inc., will be held March 26, 27, 28, at El Mirador Hotel, Palm Springs, California. For further information contact: The Society of the Plastics Industry, Inc., 250 Park Avenue, New York 17, N.Y., U.S.A.

Muskeg Research Conference

A Muskeg Research Conference will be held in Ottawa, Tuesday, 11 March 1958. This conference is the fourth such annual meeting and is sponsored by the Associate Committee on Soil and Snow Mechanics of the National Research Council of Canada.

Anyone interested in attending this conference should write to I. C. MacFarlane, Division of Building Research, National Research Council, Ottawa 2, Ontario.

Convention on Radio Aids to Aeronautical and Marine Navigation

27 and 28 March, 1958

This Convention will be held in the Institution of Electrical Engineers building, Savoy Place, London W.C.2.

Members of E.I.C. are invited to attend the sessions. Will any who plan to be present please inform the General Secretary, Engineering Institute of Canada.

BOOK REVIEW

REGIME BEHAVIOUR OF CANALS AND RIVERS

This book deals with the hydraulics of rivers and canals with mobile boundaries, that is, those flowing in alluvial soil deposits. A vast amount of civil engineering construction work is associated with such streams. To be adequate the engineering on such projects must assess with a reasonable degree of accuracy the immediate and long term effects of the construction on the equilibrium flow conditions, (stream regime), and also the fluctuation in conditions which are to be expected within the normal regime conditions.

A review of current engineering literature will convince one that substantial damage is continually occurring to engineering works due to inadequate analysis of the conditions governing the flow of rivers having mobile boundaries. More difficult of assessment is the economic waste resulting from the "factor of ignorance" which of necessity has been applied to such works due to lack of understanding of the natural laws involved.

The author is professor of civil engineering at the University of Alberta and assumed his present position after some twenty years experience in irrigation and river work in Pakistan and Hindustan. It has been the experience over the past seventy years with the behaviour of irrigation canals and rivers in these areas which has made possible the systematization of this specific branch of hydraulics, and its extension from the field of canal design to rivers with mobile boundaries.

At the present time little is taught on this subject at the universities and the material presented in the standard texts and handbooks has been largely along purely qualitative lines. The major contribution of this book is that after a review of the qualitative approach it proceeds to methods of quantitative analysis which are not currently appreciated by the practising engineer or the young student of hydraulics. Information is presented permitting a rational analysis to be made of such specific problems as depth of scour for bridge piers, control works for rivers, effects of damming on the overall river equilibrium and stable canal cross-sections, to mention but a few such practical problems. The book also includes an interesting chapter on the application and design of river models.

Advanced training in the field of hydraulics is not assumed of the reader. The book is written for those with an average civil engineering background, and the vocabulary peculiar to the subject is carefully defined. It will be of interest to the young engineer who wishes to broaden his background in the general field of hydraulics, as well as to the practising engineer, who from his experience is aware of the importance or problems of river hydraulics in civil engineering construction. (T. Blench. Toronto, Butterworth, 1957. 138p., $6.00.)

Dean R. M. Hardy, M.E.I.C.

Members may borrow the books mentioned in these Notes on application to the librarian. Two books may be borrowed for two weeks.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

AIR CONDITIONING — REFRIGERATING DATA BOOK, DESIGN VOLUME

In this volume are found the fundamental engineering facts on which the companion volume to this, Applications, is based. It has been largely revised, and includes an expanded index.

Topics covered include: Theory, heat transfer fundamentals, fluid flow, compression refrigeration, etc.; Physical data on refrigerants, brines, piping, moisture, lubrication and thermal insulation; Application design, load and air conditioning calculations, air distribution, etc.; Basic equipment, compressors, condensers and evaporators; Auxiliaries, fans, cooling towers, household refrigerators, etc.; Operation. Also included are various tables, codes and standards, abbreviations and symbols, definitions, a list of refrigeration associations, and a classified buyers guide.

This is the last of the series of the two-volume Data Book which has been published since 1932. In future the Society will publish 4 volumes, Refrigeration Applications; Air Conditioning Applications; Refrigeration and Air Conditioning Equipment; Refrigeration and Air Conditioning Tables and Fundamentals. The first three will appear in three consecutive years, and the fourth will be published every five or ten years. (New York, American Society of Refrigerating Engineers, 1957. Irreg. paging, $10.50.)

• LIBRARY NOTES

APPLICATIONS DE LA THEORIE DU FLUAGE

Translated from the Russian by P. Mrozowicz, a consulting engineer and professor of civil engineering at the Ecole Nationale des Ponts et Chaussees, this volume is the first to attempt to take the creep of materials into account in calculating their resistance.

The book is concerned with various questions of plasticity, and with the development of theoretical methods of construction calculations, especially in concrete and reinforced concrete, which will take into account the creep of materials. The material in the book is the result of experiments conducted at the Institute of Mathematics and Mechanics of the Academy of Sciences of the Armenian S.S.R.

The first two chapters consider the theory of creep based on the general law of the relation between stress and deformation, and present equations for solving two of the problems connected with this. The second and third parts of the book are concerned with concrete and reinforced concrete construction, and the applications of the general equations.

The treatment is mathematical, but, as M. L'Hermite says in his preface to the book, it is a valuable piece of research, and will be of interest to many engineers. It is unfortunate that the results of Russian research cannot be made available in this way more often. (N. Kh. Aroutiounian. Paris, Eyrolles, 1957. 319p., fr. 4765.)

BIEGE—UND TORSIONSVERFORMUNGEN DÜNNWANDIGER STÄBE MIT OFFENEM PROFIL

Translated from the Russian edition published in 1952, this treatment of the subject of bending and torsion performance of thin, open structural shapes will be of interest to those concerned with design where the stresses of thin members must be taken into consideration.

The theories and results given in the first two chapters are applied in the third which consists of worked examples. (J. I. Jagn. Leipzig, Teubner, 1957. 79p., DM 7.20.)

CAHIERS DE SYNTHESE ORGANIQUE

In this series, the authors' intention is to create a new type of organic chemistry textbook for chemists working in laboratories and research departments in the field of organic synthesis. The reactions and methods of organic chemistry are arranged in a different manner to that usually found, and reactions which are similar in their principles, mechanism, or results are grouped together.

The series will be completed in ten or twelve volumes, and is divided into four sections: the growth, breakdown, and transposition of compounds, and their cyclization.

In each chapter, the different reactions are developed according to their importance, but even minor ones are not

neglected if they are of interest. The principal reactions are given with a brief critical examination of the conditions of the experiment, secondary reactions, and fields of application. Many examples and references are included. (Jean Mathieu and Andre Allais. Paris, Masson, 1957. 3 vols., fr. 4200, 4400 and 4400.)

EPICS OF INVENTION

The nine great men whose biographies appear in this book have, through their inventions, caused great changes in the world.

The first in time, although not necessarily in importance was Richard Trevithick, the probable actual inventor of the steam locomotive, so often associated with Stephenson. The other inventors and inventions included are Humphrey Davy and the miner's safety lamp; William Henry Perkins and aniline dyes; Friese-Greene and motion pictures and John Baird and television. Four men whose name is known to everyone also find their place in this book: Ford, Marconi, Watson-Watt and Whittle.

The lives of the inventors are presented against the background of their own time, and the book will appeal to the general reader. It would be an excellent gift to the student interested in science and engineering, or to a school or public library. (John Rowland. London, Werner Laurie, 1957. 206p., 12/6.)

EXPLANATORY HANDBOOK ON THE B.S. CODE OF PRACTICE FOR REINFORCED CONCRETE, NO. 114, 1957

This new edition of the Handbook is in the same form as previous editions, and is based on the revised B.S. Code of Practice which is included in its entirety. The Code is indicated by black lines in the left-hand margin. Each clause is followed by the authors' explanations and comments. The Code now makes provision for the design of structures by the load-factor method, as well as by the elastic theory. Tables and figures prepared by the authors are separately numbered. (W. L. Scott, W. H. Glanville, F. G. Thomas. London, Concrete Publications, 1957. 154p., $3.00.)

FBI REGISTER OF BRITISH MANUFACTURERS

In the latest edition of this useful trade directory, the products and services of over 7,500 members of the F.B.I. are listed under more than 5,400 headings. F.B.I. in this instance stands for Federation of British Industries, and not the Federal Bureau of Investigation!

In addition to this classified buyers guide are included: glossaries of product terms in French, German and Spanish; and alphabetical lists of addresses of companies; trade associations; brands and trade names; and trade marks. (F.B.I. London, Iliffe, 1957. 1137p., 42/-.)

*FASTENERS HANDBOOK

For each fastener included in this complete handbook there is a picture or diagram and a paragraph or so on each of the following: description, features, uses, the standard material used in making the fastener and the standard sizes into which it is made. Anything unusual about the fastener or its use is given under "Remarks", and finally the name of the manufacturer is given. Types of fasteners include: rivets; inserts; screws; bolts and studs; nuts; washers; pins; nails; retaining rings; metal stitching; quick release fasteners; masonry anchoring devices; and hose clamps. An alphabetical list of the manufacturers with addresses is included at the end of the book. (Julius Soled. New York, Reinhold, 1957. 430p., $12.50.)

HANDBOOK OF ALUMINUM

This is a reference book on aluminum and its alloys, their production and the principal industrial processes for working and finishing them. The following topics are covered: properties of aluminum and its alloys; aluminum wrought products; castings; heat treatment of aluminum alloys; joining and finishing; general workshop practice. The tables give the composition, properties, etc. of various Alcan alloys, products, etc. (Montreal, Aluminum Co. of Canada, 1957. 266p., $3.00.)

*HANDBOOK OF LAYOUT AND DIMENSIONING FOR PRODUCTION

A practical guide to layout, detail design, and production dimensioning practices in the metalworking industries. Each step in product development from technical sketch to final drawing is illustrated and detailed in terms of the procedures, principles and theory involved. (H. H. Katz. Toronto, Brett-Macmillan, 1957. 479p., $15.00.)

*HANDBOOK OF NOISE CONTROL

Forty chapters with accompanying lists of references, provide comprehensive coverage of the nature of noise, its measurement, and techniques of its control in buildings, industry, transportation, and the community. Prepared by forty-six experts, the handbook treats vibration isolation, damping, and measurement; acoustical filters and mufflers; special types of noise such as that in bearings, gears, fans, water systems, and electric motors; and physiological, psychological, and legal aspects of noise. Examples from existing installations illustrate the application of methods for solving problems of noise control. (Ed. by C. M. Harris. Toronto, McGraw-Hill, 1957. Various pagings, $19.80.)

METHODS FOR EMISSION SPECTROCHEMICAL ANALYSIS, 1957

This compilation contains all the spectrochemical practices and methods published by the ASTM, as well as excerpts from other ASTM methods or practices which are of direct interest to people making use of emission spectrochemistry.

The book is divided into four sections: general practices, nomenclature, spectrochemical analysis of metals, and spectrochemical analysis of nonmetals. It contains about 80 suggested practices and methods altogether. (American Society for Testing Materials, Committee E-2. Philadelphia, ASTM, 1957. 490p., $7.00.)

PRINCIPES DE SYNTHESE ORGANIQUE; INTRODUCTION AU MECANISME DES REACTIONS

An introductory volume to the Cahiers de Synthese Organique noted above, this book considers the modern theories of organic chemistry, and presents a theoretical analysis of the mechanics of reactions. The four parts of the book cover electronic factors, the mechanics of reactions, steric factors, and steric aspects of reactions. (Jean Mathieu and André Allais. Paris, Masson, 1958. 598p., fr. 8500.)

PRESSURE MEASUREMENT IN VACUUM SYSTEMS

Several books have been written on vacuum technology in general, but this is the first to be devoted exclusively to the measurement of pressure. The choice of a suitable pressure gauge in vacuum systems and correct interpretation of its reading are important because neither a bad design nor an incorrect interpretation is obvious at once.

The first five of the six chapters in the book are concerned with the different methods of pressure measurement in use, and the last chapter discusses gauge calibration. Topics covered include mechanical manometers, thermal conductivity gauges, ionization gauges, the Knudsen radiometer gauge and surface reaction techniques. (J. H. Leck. London, Chapman and Hall for the Institute of Physics, 1957. 144p., 30/-.)

PROCEEDINGS OF THE THIRD INTERNATIONAL CONFERENCE OF MANUFACTURERS

The three topics considered at this third conference held in New York in December 1956 were nuclear energy; automation; and modern management, the internal organization of companies.

The three basic conference papers were all printed in full, as are the addresses given at the conference luncheons and banquet and the opening and closing plenary sessions. It was unfortunately not possible to include the proceedings of the working parties in which more than 200 delegates participated.

In his paper on Nuclear Energy, John Jay Hopkins the Chairman and President of General Dynamics Corp. considered the world's energy requirements, and how they can be met by atomic energy, the effect of atomic energy on industry, and some of the problems connected with its development. He presented a summary of international atomic energy developments, and included a brief, non-technical description of the fundamentals of nuclear energy.

Malcolm P. Ferguson the President of Bendix Aviation Corp. concentrated on the economic aspects of automation, discussing what was meant by it, the factors determining its growth and adoption, and its effect on labour and business.

The final paper by Milton C. Lightner, the President of the Singer Manufacturing Co. considered the management of business, the need for systematic organization, its principles, and their practice. (New York, National Association of Manufacturers, 1957. 278p., $7.50.)

QANTUM MECHANICS, 2ND ED.

In this second edition of a book first published in 1954 the approach and scope of the first edition have not been changed, but two new topics have been included. One of these is partial wave analysis in scattering theory, an important subject in atomic, nuclear and high-energy physics. The second is the Dirac equation. Other minor changes and corrections have been made.

Other subjects covered include: wave-mechanical concepts; energy eigenfunctions, matrix mechanics; systems of many particles; time independent perturbation theory; collision processes; an introduction to group-theoretical ideas; the relativistic theory of the electron.

Problems are included with each chapter, and there is a bibliography. The author is a member of the Atomic Energy Research Establishment at Harwell. (F. Mandl. Toronto, Butterworth, 1957. 267p., $7.00.)

REFERENCES ON FATIGUE, 1956

This list of references to articles published in 1956 dealing with fatigue of structures and materials is the seventh to be issued by the American Society for Testing Materials. Earlier lists cover the period 1950-55. A brief abstract is given for each article, and the material is mimeographed and arranged so that it can be cut and filed on cards if desired. (Philadelphia, ASTM, 1957. 68p., $3.00. s.t.p. no. 9-H.)

REPAIRING HI-FI SYSTEMS

Written both for technicians and for the many owners of hi-fi systems who, from choice or necessity, do their own repairs, this book covers all phases of servicing. It discusses the location of faults in, and servicing of, amplifiers, preamplifiers, tuners and tape recorders, as well as their installation. (David Fidelman. New York, Rider, Toronto, Pointon, 1957. 203p., $3.90.)

SPACE RESEARCH AND EXPLORATION

Published some months before the arrival of Sputnik, this collection of twelve articles for the layman provides a concise introduction to the theories and problems of space exploration. The authors are all prominent in Great Britain in this field,

• LIBRARY NOTES

and have combined to present a survey of the whole subject from the construction of rockets and the research already done on the upper atmosphere to the launching of satellites and the possibility of travel to the nearer planets.

The problems actually facing research workers, and the way in which they might be overcome are discussed under the following headings: Rockets and rocket propellants; Exploration of the upper atmosphere; Cosmic radiation and space-flight; meteor hazards; Manned satellite stations; Interplanetary orbits; Difficulties of space navigation; Medical and biological problems; Conditions on the moon and nearer planets.

The main text can easily be understood by a reader with no scientific training, but accuracy has not been sacrificed. Where it appeared that a mathematical treatment would be useful, it has been included in the appendix. (Ed. by D. R. Bates. London, Eyre and Spottiswoode, 1957. 224p., 25/-.)

SPANNBETONBAU, TEIL 2

This second volume on prestressed concrete structures contains many detailed tables, diagrams and photographs, as well as a 223 item bibliography covering the years 1896 to 1956.

The first part of the book deals with construction: the method of construction of prestressed concrete supporting works; formwork for bridges, high buildings and underground works; reinforcements; prestressing cables. The second and third parts deal with the use of prestressed concrete in bridges and high buildings. The last section describes the various jacks used for prestressing, mixing concrete, etc.

The first volume covered the principles of prestressed concrete, the materials used, and design calculations. Together, the two volumes form a valuable treatise on the subject of prestressed concrete construction. (Wolfgang Herberg. Leipzig, Teubner, 1957. 407p., DM 26.)

STRENGTH OF MATERIALS

In this undergraduate textbook, particular attention has been paid to the order in which the material is presented, and the topics are developed to the point where further elaboration is unnecessary from an engineering point of view, or where further development would require the use of mathematics beyond the scope of an undergraduate.

Throughout, the emphasis is on material which forms the basis of all types of structural analysis and design, with examples drawn from the civil, aeronautical and mechanical engineering fields. The scope of the book is in some respects different to that which might be expected: for example, the principles of statistics have been reviewed early, and extended to cover two-dimensional force fields; energy has also been included. Emphasis has been placed on the direct use of curves, and the solution of problems by the use of tabular computation forms.

Some subjects usually found only in advanced courses are treated here in a simple way. These include methods of predicting inelastic behaviour under combined stresses, and the buckling loads for inelastic eccentric columns, and a method of design for repeated loading under stresses of variable amplitude.

The author has drawn on his many years of experience in the industrial and teaching fields in the compilation of this book which is a valuable addition to the literature on the subject. (F. R. Shanley. Toronto, McGraw-Hill, 1957. 783p., $8.93.)

THE SUPPLY AND DEMAND OF ENGINEERS, 1950-1960

This report issued by Deutsch and Shea analyzes the present situation regarding the supply and shortage of engineers, and forecasts future trends.

It shows that in the last seven years over 46,000 engineers a year have been needed in the United States, and less than 34,000 have graduated from university. The demand will increase in the next few years, and it is unlikely that the shortage will be met until 1960 or even later.

Much of the material is presented in tabular form, and for the years 1950-1957 the information given includes: the supply of engineers; additions to the profession; number of engineering graduates; supply and demand of engineers by field.

The report points out that the demand for engineers depends on the amount spent by industry and government on research and development, etc. The forecast demand per year is over 46,000, but the estimated number of graduates falls short of this. The number of college graduates is expected to increase in the 1960's, but the proportionate number of graduates will increase only if every effort is made to make the profession attractive to students.

Although this report applies to the United States, conditions in Canada are much the same, and presumably will continue to be. This Deutsch and Shea report and their earlier one, The Profile of the Engineer, are very interesting analyses of the profession. (Deutsch and Shea. New York, Industrial Relations News, 1957. 56p., $3.00.)

TECHNICAL DRAWING
PART 2 APPLIED GEOMETRY
PART 3 ENGINEERING PRACTICE

The first part of this text contained a basic introduction to the subject of technical drawing intended for students in technical schools.

● LIBRARY NOTES

Part 2 deals with the geometric constructions which the student needs to know: rectangles, triangles, polygons, circles, parabola, loci, spirals, etc. The second section of the book deals with the principles of projection.

In Part 3 the constructions and geometry covered in the first two parts are applied to the preparation of engineering drawings. No practical engineering knowledge is required, and the examples given are limited to the common fastenings and simpler engineering parts.

Some knowledge of elementary engineering technology is desirable in using these books, and if the student actually handles the components he is drawing, it is much better. (W. Abbott. London, Blackie, 1957. 2 vols., 7/6 each.)

TECHNICAL REPORT WRITING

Intended for both undergraduates and practicing engineers, this book covers the fundamentals of technical report writing, emphasizing method, and concentrating on the actual writing of the report. The author has tried to apply the principles of engineering design with which his readers are familiar, to the writing of industrial reports. He treats the subject under four headings: Analysis, the purpose of the report, its role and its audience; Investigation, gathering and evaluating material; Design, determining content, form, and illustrative material; Application, determining the point of view, writing the report, checking and modifying it, and preparing the final copy.

As the author points out in his introduction, effective writing is not easy, but it can be made easier by a liberal expenditure of time and effort. Mr. Souther's book should be a great help in showing how both may be put to the best advantage. (J. W. Souther. New York, Wiley, 1957. 70p., $2.95.)

TRACER APPLICATIONS FOR THE STUDY OF ORGANIC REACTIONS

Written primarily for organic chemists, who are interested in the organic reaction rather than the use of the isotope, this book is essentially a review of existing literature. The author tries to provide a comprehensive survey of tracer applications in organic chemistry, and a general idea of the principles of isotopic tracer use. He also includes background information on the reaction mechanisms so that the advantages and disadvantages of the method can be judged.

The topics covered include: isotopic exchange reactions; proton transfer in nonaromatic substances; free radical processes; carbonium ion processes; polymerization reactions, etc. The bibliographies contain a list of text books on the properties, uses and analysis of isotopes; a list of review articles on the application of isotopes; the papers on the subject which appeared from 1952 to 1955. (J. G. Burr. New York, Interscience, 1957. 291p., $7.50.)

YEAR BOOK OF THE HEATING AND VENTILATING INDUSTRY, 1957

The five technical articles at the beginning of this yearbook deal with the following topics: a long term analysis of fuel consumption; nomograms for finding the heat conductance of closed air spaces; technical education for the heating and ventilating industry; a review of the industry in 1956-7; differences of design in British and continental heating and hot-water service installations.

There is a useful index to the material on heating and ventilating published in 1956 in some 70 British periodicals. There is also a list of relevant British standards.

The trade directory includes a classified buyers' guide, a list of trade name and manufacturers addresses. There is a list of trade and technical associations, and of the members of the Association of Heating, Ventilating and Domestic Engineering Employers who collaborated in the compilation of this volume. (London, Technitrade Journals, 1957. 426p., 12/-.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Atomic Energy

Nuclear energy in Britain. Reference division, Central Office of Information, London.

Building Materials

How to design pole-type buildings by D. Patterson. Chicago, American Wood Preservers Institute, 1957, $1.50.

Products of stainless steel for architects and builders. N.Y., American Iron and Steel Inst., 1957.

Canada. Mines and Mining

Facts and figures about Canadian oil. Imperial Oil Ltd., 1957.

Metal and industrial mineral mines in Canada. (Canada, Dept. of Mines and Technical Surveys List 2-1) Ottawa, 1957, 25 cents.

Education

A bulletin on the supply and demand situation in regard to university graduates. Canada. Unemployment Insurance Commission, 1957.

EUSEC engineering education and training. N.Y., E.C.P.D., 1957. $5.00.

Electrical Engineering

Electrical Research Association; Technical reports; F/T190—A further simple method for the calculation of cyclic rating factors and emergency loading for cables laid direct or in ducts by H. Goldenburg. F/T192 — The calculation of external thermal resistance and cyclic rating factors for groups of cables laid direct in the ground or in ducts by H. Goldenberg. L/T348 — Debye losses due to electrons trapped at vacancies by J. A. Sussmann. ST73 — Surge voltage distribution in transformer windings due to current chopping by E. L. White. S/T79 — The surge electric strength of oil impregnated paper wrappings by G. W. Bowdler. S/T80 —Developments in E.R.A. impulse testing technique, by J. L. Miller and E. M. Dembinski. V/T130 — Electronic voltage stabilizers for laboratories computers and control systems by J. Miedzinski and S. J. Zgorski. V/T131 — A network analyser test problem by P. G. Kendall. Z/T114 — An experimental investigation of tooth-ripple flux pulsations in smooth laminated pole-shoes by J. Greig and K. C. Mukherji.

Engineering Abstracts

Bibliography of engineering abstracting services. N.Y., Special Libraries Assoc., 1955, $1.50.

Engineers

Survey of attitudes of scientists and engineers in government and industry. Washington, G.P.O., 1957, 50 cents.

International Geophysical Year

Bibliography for the International Geophysical Year. National Science Foundation, 1957, 20 cents.

The Canadian program for the International Geophysical Year, May 1957. Ottawa. National Research Council, 1957.

Lubrication — Steam Turbines

Symposium on steam turbine oils. (ASTM Special Technical Publication No. 211.)

Metals and Alloys — Cleaning

1957 supplement to the metal cleaning bibliographical abstracts, by J. C. Harris. (ASTM Special Technical publication no. 90-D.) $2.00

Soil Mechanics

The mechanism of flow slides in cohesive soils. G. G. Meyerof. (NRC Technical memorandum no. 50.)

The Nicolet slide. J. E. Hurtubise and P. A. Rochette. (NRC Technical memorandum no. 48.)

Permafrost; a digest of current information. (NRC Technical memorandum no. 49.)

Proceedings of the 3rd muskeg research conference, February 20 and 21, 1957. (NRC Technical memorandum no. 47.)

Strength of Materials

Corrosion fatigue cracking resulting from wetting of heated metal surfaces with special reference to steam power plant. Manchester, National Boiler General Insurance Co. Ltd., 1957.

The non-destructive testing of engineering materials. Middlesex, A. E. Cawkell, 1957.

Viscosity

ASTM viscosity tables for kinematic viscosity conversions and viscosity index calculations. (ASTM stp. no. 43-B) Philadelphia, 1957.

Appointments and Transfers

Shawinigan Chemicals — Appointment of R. J. Southwell, president of Canadian Resins and Chemicals Limited, as a vice-president of Carbide Chemicals Company and also of Bakelite Company is announced. Both companies are divisions of Union Carbide Canada, Ltd.

Mersey Paper Company—The retirement of B. J. Waters as president of Mersey Paper Company Limited has been announced, effective July 1st; he will be succeeded by J. H. M. Jones, now vice-president and general manager, who will continue as general manager of Mersey. R. L. Seaborne, M.E.I.C., a vice-president and the woodlands manager of the company, will retire on July 1st also. J. A. Parker, secretary-treasurer, becomes in addition a vice-president.

The Canadiana Company Limited — The Grolier Society of Canada Limited has announced the appointment of the executives of The Canadiana Company Limited, distributors of the new *Encyclopedia Canadiana*, and a division of the Grolier Society: K. L. Brown, vice-president in charge of sales, and continuing as executive editor and art director of the publication; J. A. McBride, vice-president and manager; G. A. Dobbin, sales manager, in charge of recruiting of sales staff and supervision of sales programs across the country.

H. C. Pitcher

Shell Oil — R. C. Wiens has been appointed co-ordinator of management development and training, Shell Oil Company of Canada, Limited, and will make his headquarters in the company's head office in Toronto.

M. W. Kellogg — The appointment has been announced of H. C. Pitcher as construction manager, the M. W. Kellogg, Company, New York, in charge of all Canadian and South American construction for The M. W. Kellogg subsidiaries — The Canadian Kellogg Company, Ltd., Toronto, and Kellogg Pan-American Corporation, New York; he will also be in charge of the construction activities of M. W. Kellogg's fabricated products division.

Canadian Resins and Chemicals — G. M. Hale has been appointed to the newly-created position of vice-president and general manager of Canadian Resins and Chemicals Limited.

Power Corporation Designers & Consultants — The appointment of J. W. Rook as president of Power Corporation Designers & Consultants Limited, Montreal, has been announced; D. D. Dick, M.E.I.C, has been made vice-president and general manager.

Pacific Petroleums — Announced recently was the appointment of C. R. Hetherington as managing director of Pacific Petroleums Ltd., Calgary.

Westcoast Transmission Company — D. P. McDonald has been named managing director of Westcoast Transmission Company Limited, Calgary.

MacMillan & Bloedel — Election of J. V. Clyne, former Judge of the Supreme Court of B.C., to chairmanship of the board of directors of MacMillan & Bloedel Limited, Vancouver, has been announced.

R. C. Wiens

Leland Electric—B. V. Elliot, Q.C., has been elected to the board of directors of Leland Electric Canada Limited.

Ontario Hydro — The following appointments have been announced by The Hydro-Electric Power Commission of Ontario: O. S. Russell, director of the organization services division; W. H. Edwards, manager of the Commission's west central region, with headquarters in Hamilton; F. O. Price, director of frequency standardization.

B.C. Engineering Co. — Announced recently were the following appointments to B.C. Engineering Co. Ltd., the design and engineering firm for B.C. Electric: W. G. Huber, special assistant to the president, T. Ingledow; H. W. Smith, general manager; R. M. Bibbs, assistant general manager; H. W. Peck, executive assistant to Mr. Ingledow; C. H. Maartman, JR.E.I.C., design superintendent of Hydro-electric projects; H. M. Ellis, chief of technical research; R. C. Hausch and F. J. Spook, staff engineers.

Collins Radio Company — J. P. Giacoletto has been appointed general manager of Collins Radio Company of Canada Ltd.

• BRIEFS

Trans-Canada Pipe Lines — C. C. Whitaker, formerly construction supervisor for Trans-Canada Pipe Lines Limited, has been appointed superintendent of operations for the company, and will make his headquarters in Toronto.

Robertshaw-Fulton — The following appointments have been announced by Robertshaw-Fulton Controls (Canada) Limited: F. H. Barker, general sales manager; G. H. Warren, plant manager; P. S. Barkhouse, field service manager.

J. A. Wilson Lighting & Display — The appointment has been announced of V. Labbe to the position of eastern district manager of J. A. Wilson Lighting & Display Limited; Mr. Labbe will be located in Montreal.

Pitney-Bowes of Canada, Ltd. — R. Vanier has been made manager of the Quebec City district office of Pitney-Bowes of Canada, Ltd.

F. S. B. Heward & Co. — B. J. Roffey has joined the staff of F. S. B. Heward & Co. Limited, Montreal; Mr. Roffey will represent Dewrance & Company Limited, London, England, the British principals of F. S. B. Heward & Co.

Barber-Greene — The following two field sales appointments have been announced by Barber-Greene Canada Ltd.; W. H. Worden, field engineer, with headquarters in Calgary; F. G. LeDez, JR.E.I.C., field engineer, with headquarters in Don Mills, Ontario.

B. F. Goodrich — H. S. Alderson has been made manager of B. F. Goodrich Koroseal pipe sales.

Inco Appointments — R. D. Parker, vice-president in charge of Canadian operations of The International Nickel Company of Canada, Limited, will move his headquarters from Copper Cliff, Ontario, to the company's offices in Toronto early in the year. The following Inco appointments have been announced: R. H. Waddington, assistant vice-president of the company and general manager of the parent company, Ontario division; J. C. Parlee, assistant vice-president and general manager of the Manitoba division; R. A. Cabell and P. Queneau, assistant vice-presidents of The International Nickel Company of Canada, Limited, and also vice-presidents of The International Nickel Company, Inc., the United States subsidiary of the company. F. Benard, assistant to the vice-president, will assume the additional position of assistant general manager of Ontario division; A. Godfrey and G. A. Harcourt, assistants

SERCOMBE
DOMINION

to the vice-president, will assume the additional positions of assistants to the general manager of Ontario Division. Promotions announced are as follows: T. M. Gaetz, manager of mines; R. A. Saddington, manager of reduction plants; J. A. Pigott, superintendent of mines; C. H. Stewart, assistant to the manager of mines; H. W. Peterson, assistant superintendent of mines.

W. S. Atkins & Associates—G. G. Hatch has been appointed president of W. S. Atkins & Associates Limited, a firm of consulting engineers having offices in Toronto and Montreal; he was recently plant superintendent of the Quebec Iron and Titanium Corporation, Sorel, Que.

Neptune Meters—It was recently announced that W. O. Randall has been appointed vice-president and general manager of Neptune Meters Limited and Neptune Patterns Limited.

Goodyear Appointments—The following appointments have been announced by The Goodyear Tire & Rubber Company of Canada, Ltd.: D. S. Hewitt, acting manager, Central Ontario division, with headquarters in Toronto; W. M. Ecclestone, assistant manager, Central Ontario division.

Practor & Redfern — E. M. Proctor, M.E.I.C., senior partner of Proctor & Redfern, consulting engineers, Toronto, has announced that R. G. Tredgett has become a full partner in the firm.

News of Business and Industry

Refinery Development—Canadian Oil Companies Ltd. announce an $8,000,000 expansion of the company's Sarnia refinery. Built in 1952 to refine 20,000 barrels of crude oil per day, the refinery has already expanded its daily capacity to 30,000 barrels. In order to meet the indicated rise in consumption of petroleum products, a building program to further increase the capacity of the company's refinery to 50,000 barrels per day will be undertaken. The first step will be the erection of a 20,000-barrel per day crude distillation unit, scheduled for completion early in 1959 at a cost of $4,000,000. The remainder of the expansion program is expected to be completed by 1961.

Mold for Large Tire—United Tire Sales have announced the purchase and arrival of a Lodi of California T-98 mold for earthmover and construction tire recapping. This is the first mold of its kind in Ontario and will take over 3 weeks to install at United Tire Sales' newly expanded 45,000 square feet recapping and retreading plant at 33 Tippett Road in Toronto. Imported from California, the huge mold weighs over 68,000 pounds, and is designed to recap tires of all sizes from 44 ins. up to and including the 98-in. diameter tires—regardless of cross sections or rim diameter. The mold is, in effect, flexible—and intended to accommodate today's sizes as well as any new sizes or shapes that may come into use in the future.

Incorporation of Firm—J. Edgar Dion, M.E.I.C., has announced the incorporation of his present firm. Effective December 1st, 1957, the company name is now J. Edgar Dion & Company Ltd.; address, 4643 Sherbrooke Street West, Montreal 6.

Alkon Distributors—The Alkon Products Corporation, 200 Central Avenue, Hawthorne, New Jersey, manufacturers of precision pneumatic and hydraulic equipment has appointed J. B. Morrison Machine Co. Ltd., Toronto, and L. S. Tarshis and Sons Co. Ltd., Montreal, as Alkon stocking distributors in their provinces.

Dominion Bridge Subsidiaries—Dominion Bridge Company, Limited has recently announced that the operations of two of its wholly owned subsidiary companies, Riverside Iron and Engineering Works Limited, Calgary, Alberta, and Sault Structural Steel Company, Sault Ste. Marie, Ontario, will henceforth be carried out under the Dominion Bridge Company name. In both cases, the principal reason for the change is stated to be the widening scope of activities of the subsidiaries concerned.

Canadian Oil Companies, Limited announce that the executive offices and the offices of the Southern Ontario division are now located at Canadian Oil Building, 188 University Avenue, Toronto 1; the telephone number will be EMpire 2-2844.

● BRIEFS

New Office Location — Z. Przygoda, M.E.I.C., consulting engineer, has announced the new location of his office at 7 Sultan Street, Toronto. Services include structural, industrial and town planning engineering.

Plant Expansion—Liquid Carbonic Canadian Corporation Limited and its associated company, Imperial Oxygen Limited, both of which companies have recently been acquired by General Dynamics Corporation, announce plans for a $1,000,000 plant at Weston, Ontario, for a daily capacity of 17 tons of liquid oxygen, nitrogen and argon, a new depot in Windsor, Ontario, at an investment of $110,000, and a new depot in Montreal, at a cost of $60,000.

Exclusive Franchise—Pye Canada Limited has completed negotiations with Utility Tower Manufacturing and Fabricating Company of Oklahoma, Okla. As a result of the negotiations, Pye Canada Limited has the exclusive franchise throughout the Dominion for the products and services of this American company.

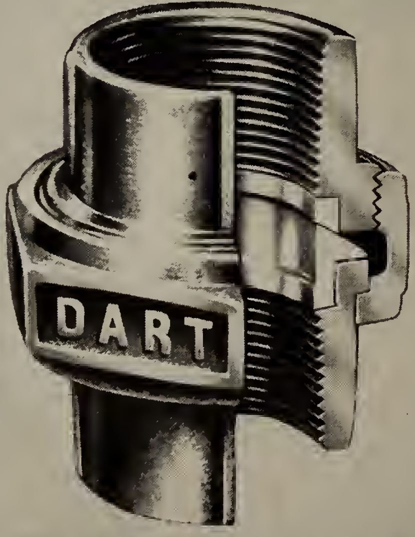
Air Conditioning System Contract—Carrier Engineering Limited has announced the award to the company of a contract with Imperial Life for the installation of an air conditioning system for the 21-storey Imperial Life Tower Building and the 9-storey head office building located on Victoria Street in Toronto.

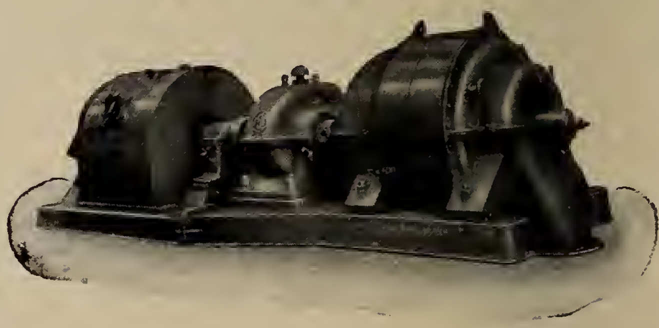
Copper Price Change—In view of the Canadian-U.S. dollar exchange rate, International Nickel has adjusted its price for Canadian domestic copper deliveries to 25.875 Canadian cents per pound delivered Toronto. This price corresponds to the published 27 cents U.S. price for primary copper.

C.I.L. Expansion—The latest unit in a three-year expansion program at the Cornwall works of Canadian Industries Limited and its associated company, Cornwall Chemicals Limited, has been completed and is now in commercial production. The new unit, a plant producing carbon tetrachloride, is an addition to the facilities of Cornwall Chemicals Ltd. The unit uses the only process of its kind in Canada and is the second carbon tetrachloride plant in the country.

The plant is a three-storey building of structural steel with sandwich-type asbestos corrugated board siding and fibre glass insulation. An overhead sprinkler system throughout the operating areas and additional equipment comprise the fire protection system. An elaborate ventilating system is capable of completely changing the air in the entire building in five minutes. Because of the nature of the chemicals used, reaction vessels are made up of several types of metal such as nickel, Inconel and stainless steel. Much of the equipment is glass lined and Pyrex glass piping is used extensively.

Federal Public Works Contracts—Public Works Minister Howard Green has announced that contracts involving expenditures totalling $5,228,449.00 were awarded by the Federal Department of Public Works during the month of September, 1957. The amount for new works in building construction and harbours and rivers engineering is $2,737,173.45; for the repair and maintenance of existing structures $586,157.15; for dredging $73,304.40; and for construction of Trans-Canada Highway and other roads in National Parks, $1,831,814.00. Contracts involving expenditures totalling $4,951,036.26 were awarded by the Federal Department of Public Works during the month of October, 1957. The amount for new works in building construction and harbours and rivers engineering is $1,837,281.26; for the repair and maintenance of existing structures $699,095.00; for dredging $2,165,760.-





00; and for construction of Trans-Canada Highway and other roads in National Parks $248,900.00. During the month of November, 1957, contracts involving expenditures totalling $1,664,124.00 were awarded by the Federal Department of Public Works. The amount for new works in building construction and harbours and rivers engineering is $1,477,799.00; and for the repair and maintenance of existing structures $186,325.00.

New Equipment and Developments

A New Construction Material — Rosco "V-V Protected" roofing, siding and insulated panels are exclusive products of Rosco Metal & Roofing Products Ltd. They are produced under an agreement with Heaman Paint Co., Ltd. the manufacturers of Vinsynite in Canada. The new line of Rosco "V-V Protected" corrugated sheets and fabricated panels is available in a variety of colours in highly durable factory coated vinyl plastic finishes manufactured entirely from Canadian materials. This multiple protection is welded to the base metal through the use of Vinsynite.

Vinsynite provides an unequalled base for additional top coats that are selected for long term weathering. The complete system adds many years to the life of the formed metal sheet.

Chain Saws — Two new chain saws have been introduced by McCulloch Company of Canada, Toronto. Said to be 20 per cent more powerful than previous models, the two new saws also feature improved cooling, longer life and easier maintenance. The McCulloch Super 44 produces 6.5 horsepower and weighs only 19 pounds. Its gear-driven companion, the McCulloch Super 55, produces 6.5 horsepower and weighs just 22 pounds.

New Impulse Monitor — A new impulse monitor which automatically provides for shutting down an electric salt bath heat treating furnace in the event of control instrument or relay failure has recently been introduced by Canadian General Electric Company Limited. Not subject to the shortcomings of conventional safety controls using thermocouples or other heat-measuring devices, the impulse monitor responds to the duration of the energy input feeding the furnace. The monitor is set manually. Timing devices offer two ranges, either from 0 to 240 minutes, or from ½ to 30 hours. Should the power input to the furnace continue longer than the time selected, the monitor first endeavours to shut off the power. Failing in this because of fused contact tips or similar trouble, it then signals an alarm over telephone lines, lights, bells or other protective devices. Separate contacts provide for whatever external alarm system is desired.

Incandescent Lighting — The new Inca-Light line of incandescent lighting by J. A. Wilson Lighting and Display Limited offers a modern concept for both commercial and residential applications. Available in four shapes and three sizes, the Inca-Light glassware is moulded from high-efficiency, single layer glass. A completely new glass collar design provides a five inch wide standard reinforced opening for all shapes and sizes. Both the close-up holder and the 6 in. or 18 in. pendant hangers are finished in chrome or brass. The 'Lev-R-Lok' holder is self-locking and assures absolute safety in glass retention.

There is a simple order form on page 163 of this issue.

MEET THE AUTHORS

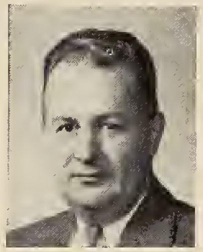
S. D. Lash, M.E.I.C. Head, Civil Engineering Department, Queen's University, Kingston, Ont. *(Planning of Recent New Towns in Canada.)* Dr. Lash is an honours graduate, University of London, and Ph.D., University of Birmingham. He came to Canada in 1929 and worked for engineering firms in Montreal and Vancouver before becoming an instructor at the University of B.C. In 1938 he joined the National Research Council, where he was later acting secretary of the National Building Code project. Dr. Lash joined the staff of Queen's University in 1941. In 1942 he was awarded the Gzowski Medal of the E.I.C.

O. W. Titus, M.E.I.C. President, Canada Wire and Cable Co. Limited, Toronto. *(St. Lawrence Estuary Submarine Power Transmission System.)* Graduated from University of Toronto (B.A.Sc., Elec.) and became a demonstrator there in 1919. After considerable experience in the electrical industry, becoming chief engineer of Canada Wire and Cable, he was appointed vice-president and director of the English Electric Company of Canada in January 1948. In May of that year, Mr. Titus became general manager of Canada Wire and Cable, a director in 1954, and president in 1957. He is president and a director of Telecables & Wires Limited. Mr. Titus is also a prominent member of many technical associations, institutes, and committees, member of Senate, University of Toronto, and member of council, Toronto Board of Trade. He is the author of several papers.

R. Patterson. Technical Manager, Small Arms Division, Canadian Arsenals Limited. *(The F.N. Rifle.)* Mr. Patterson has been associated with the small-arms field since joining the John Inglis Company (Ordnance Division) in 1938, where he took part in the study of British production methods in preparation for the manufacture of Bren guns in Canada, and was engaged on their early production. During the war years he was engineering and inspection manager in Canada, working on many Government contracts. In 1946 Mr. Patterson transferred to Canadian Arsenals Limited in his present capacity.

W. Goldstern. Director, Steam Storage Co. Ltd., Leeds, England, and Toronto. *(Important Applications of Heat Storage in Industry.)* Mr. Goldstern graduated from the Technical University, Munich, in 1928 (mechanical engineering). For some years he worked with Dr. J. Ruths, inventor of the steam accumulator, and became a consultant in 1940, specializing in fuel economy and heat storage. Mr. Goldstern founded his present company in 1948, in Leeds, and established the Toronto branch in 1957, in co-operation with Dominion Bridge Company Limited. He has published a book on steam storage; heat charts of V.D.I. (German Engineers Association); and three series of fuel saving charts. He has also patented an external charging device.

M. A. Scheil



G. E. Fratcher

Four co-authors, Messrs. M. A. Scheil, G. E. Fratcher, S. L. Henry, and E. H. Uecker (all of the A. O. Smith Corporation, Milwaukee, Wis.) contributed to the papers *Brittle Fracture in Steel as Related to Flash-Welded Line Pipe* and *Low-Temperature Burst Tests of Flash-Welded Line Pipe,* which are parts II and III of a series. Part I (*Manufacture and Metallurgy of Flash-Welded Line Pipe)* was published in the February 1958 issue of the *Journal*, together with biographical sketches of the authors.

Planning of Recent New Towns in Canada

S. D. Lash, M.E.I.C.
Head, Department of Civil Engineering, Queen's University, Kingston, Ontario

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June, 1957

Many new towns have been started in Canada during recent years. This paper is concerned primarily with new industrial towns in rural or undeveloped areas. The organization and planning of such towns has been based partly on previous Canadian experience with company towns and partly on British experience in building garden cities and "New Towns".

The plans of some of these towns are discussed firstly in terms of general structure and then in connection with the arrangement of streets. The planning of town centres is briefly considered. Some consideration is given to general problems of site engineering. The paper concludes with recommendations for the establishment and planning of future new towns.

One of the consequences of the rapid development of Canada since the war has been the construction of a considerable number of new towns located for the most part in previously undeveloped areas. The planning of some of these towns is the subject of the present paper. No attempt has been made to provide a complete record of what has been done. The author has tried to discuss the principles involved in building new towns and to illustrate these principles by examples taken from recent Canadian experience.

The Company Town and the Garden City

From the early nineteenth century industrial development in North America has often taken place in areas remote from existing towns. This has resulted in towns planned and built by industry so as to provide housing for their workers. Such towns are commonly referred to as "company towns" or more generally as "single enterprise communities".[1]

The degree of control exercised in the town by the company has varied considerably. In its most complete form the company owns all the land including the roads and may therefore limit public access to the town: it owns the houses and may require workers to buy at company stores. There is no democratic local government. Although such "closed company towns" are not unknown in Canada, they are few in number and relatively unimportant. More common is the company town to which the public has free right of access and in which private stores are permitted. A substantial proportion of the houses are company owned, but private building is also permitted. There may be an elected municipal council though the relations between the council and the company are often rather delicate. Some times the company town is deliberately planned as a "model community".

Company towns are essentially the product of a private enterprise system. Until recently, government has had little to say about the planning and development of company towns though it has sometimes faciliated their establishment by making land available at low cost. Such towns, by reason of careful planning combined with some attempts at town design, are frequently quite attractive especially in comparison with unplanned communities. In the United States, company towns have acquired a bad reputation. At the best they are considered unduly restrictive of human liberties and at the worst they are regarded as a tool for the control and exploitation of labour.

On the whole, experience in Canada with company towns has been good. Nevertheless they are seldom popular. The workers prefer a freer environment; the industrialist dislikes the diversion of capital and effort required to build a town and recognizes that being a landlord makes for poor labour relations; governments regard such towns with suspicion as being at least temporarily beyond the pale of ordinary municipal government. A further difficulty in Canada is that company towns associated with primary industry such as mining may have a very short life before they finish up as "ghosts".

Possibly the first example of government planning of a new industrial town occurred at Kapuskasing. This resulted from an agreement in 1921 between the Government of Ontario and the Spruce Falls Company in which it was stated that "the Government is desirous of creating a town and having same planned and developed on model lines." The planning and laying out of the townsite and all other work connected therewith was done entirely by various officials of the Ontario Government.[2]

Within recent years Ontario and Alberta have taken definite steps to discourage the establishment of any more company towns particularly on crown land. One official has said "The Province (of Ontario) has indicated that they do not like company towns and they're going to do everything they can to stop the development of company towns".[3] The Mining Act as amended in 1954 provides that the surface rights of mining claims may be reserved by the government through Order-in-Council for the purpose of developing townsites. The New Towns Act of Alberta[4] provides that the Lieutenant Governor in Council upon the recommendation of the Provincial Planning Advisory Board may "declare such a town is governed by a Board of Administrators created by the Lieutenant Governor in Council" who are required to submit "comprehensive proposals for the planning and orderly development of the new town".

In Manitoba the Lieutenant Governor in Council has power to incorporate as a "local government district" communities in unorganized territories adjacent to a place where mining or other industrial operations are being carried on.[5]

In Quebec "No holder of a mining license can develop a mining town, or even a semblance of a few buildings as a mining town without the control of the Government. The Minister of Mines in co-operation with that of Municipal Affairs decides what is to be done".[6, 7]

In British Columbia, although a number of successful company towns have been built in the past, the present policy is to incorporate new communities as municipalities at a very early stage in their development.

It seems clear that nobody really loves the company town and it is not surprising therefore that encouragement is being given to other ways of building towns in primitive areas. The "New Town" is the most promising of these ways.

The "New Town" is essentially a development of the "Garden City" idea proposed by Ebenezer Howard in England in 1898 and first put into practice at Letchworth Garden City in 1904. A "Garden City" is defined as follows:

"A Garden City is a Town designed for healthy living and industry; of a size that makes possible a full measure of social life but not larger; surrounded by a rural belt; the whole of the land being in public ownership or held in trust for the community."[8]

A number of garden cities were built in England and elsewhere and these served not only to demonstrate the essential soundness of Howard's ideas but also to test out new concepts of physical planning. These concepts included "use and density zoning, a form of ward or neighbourhood planning, employment of an agricultural green-belt to control urban size."[9]

The financial difficulties inherent in building garden cities with limited capital resources, showed that Howard's ideas could only be put into practice on any substantial scale with government support. The British "New Towns Act" passed in 1946 made the building of new towns an important activity of the government of the country. At the end of 1956, construction of 15 new towns with a total ultimate population of 685,000 was under way and 321,000 people were already living in these towns. The success of this large scale experiment both from a social and a financial standpoint appears to be assured.

In Canadian new towns we can recognize these two major influences—the company town and the garden city. Administratively, the new town is the alternative to the company town and it comes into being when "the existing system of local government cannot cope with the problems brought on by a very rapid rate of growth".[10] As a result of the experience gained in building garden cities it is now possible to plan detached industrial communities on virgin sites so that the inhabitants may enjoy a full social life amidst pleasant and healthy surroundings.

Table I lists the principal new towns started in Canada since 1945*.

Many Canadian new towns are being built in primitive areas a long way from the big metropolitan cities and are the direct consequence of mining or industrial activity. Kitimat (British Columbia) and Elliot Lake (Ontario) are examples of this kind. Others, such as Aklavik, Frobisher Bay, and Great Whale River are primarily attempts to deal with some of the problems created by the im-

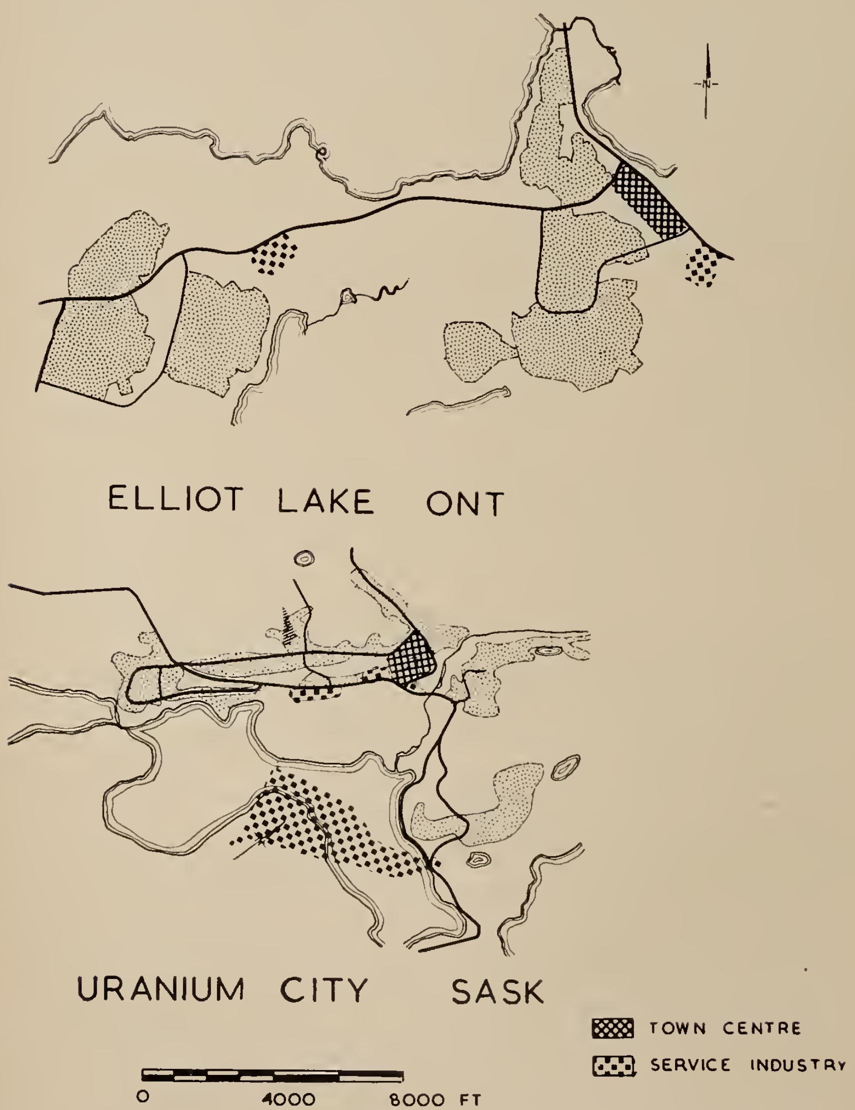

Fig. 1 (top). Elliot Lake, Ontario. Fig. 2. Uranium City, Sask. (General plans.)

*For a more complete list, reference may be made to "Single-Enterprise Communities in Canada", Institute of Local Government, Queen's University, Kingston, published by Central Mortgage and Housing Corporation, Ottawa.

pact of current events on native peoples. Some, for example, Devon (Alberta) and Ajax (Ontario) are primarily satellite towns. Finally, there are large carefully planned real estate developments located within metropolitan areas. An outstanding example is Don Mills (Toronto). It can also be argued that some of the larger military establishments, such as Gagetown (New Brunswick), are in fact "new towns". However a military camp presents many planning problems quite different from those of ordinary towns. This study is confined to new towns having an industrial base and located in primitive or rural areas.

The Beginning

A new town comes into existence as a result of a decision to build a new town. It does not just happen. The decision may be made by an industrial company which needs housing, by a real estate company which hopes to make a profit or by a government whose primary concern is to stimulate seemly development.

It has already been stated that there are serious objections to single, private, ownership of town sites and consequently there is much to be said for government sponsorship. In this way professional planning of the town can be ensured and adequate financing of the town in its early stages can be arranged. Experience has shown that the large initial capital expenditure required for new towns is the greatest single obstacle to their establishment. Roads and utility services have to be paid for before there is a tax revenue to pay for them. In Great Britain, government advances to 14 new town corporations for capital expenditures amounted to £140 million by 31 March 1956.

The New Towns Act of Alberta provides that the government may grant or loan up to $1,000,000 to aid in establishing a new town. In Ontario, the provincial government made the sum of $600,000 available for the establishment of the new town of Manitouwadge. A willingness on the part of governments to make capital advances is an essential feature of an effective new town policy. So far Ontario and Alberta are the only provinces who have established this as a definite policy. A town which is sufficiently capitalized in this way can,

(*a*) make adequate engineering studies as to the general location of

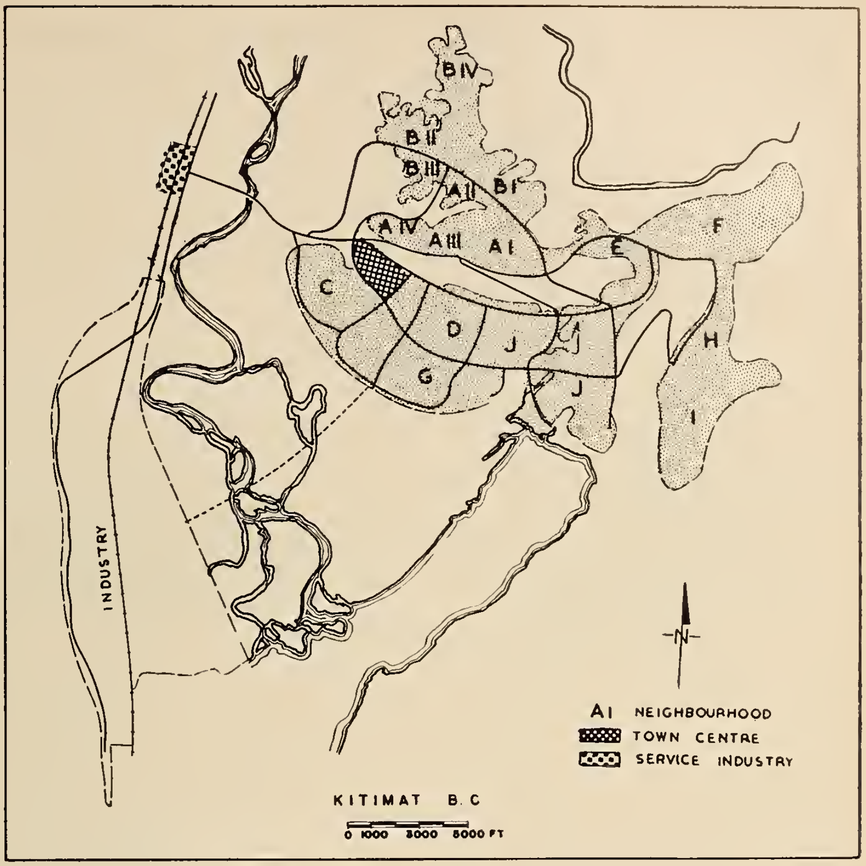

Fig. 3. Kitimat, B.C. — general plan.

Table I.—Principal New Towns in Canada 1945-57

Province	*Town*	*Major Industry or basis of town*	*Authority responsible for initial development*
Newfoundland	Gander	Airport	Government of Canada
Quebec	Chapais	Mining	Opemiska Copper Mines Provincial Government
	Chibougamau	Mining	Provincial Government
	Murdochville	Mining	Gaspe Copper Mines
	Schefferville	Mining	Iron Ore Co. of Canada

	Great Whale River	Regional centre	Government of Canada

the town and of its principal utility services,

(b) build utilities such as sewers, sewage treatment plants in advance of need thus avoiding for example the wasteful practice of installing septic tanks only to find them unsatisfactory after a few years,

(c) build satisfactory paved roads as required or in advance of need thus avoiding the extensive use of gravel roads which are often quite

known that the population of a mining camp has different characteristics from that of an older town. It differs particularly in age and sex distribution and in cultural values. These considerations as they affect Elliot Lake have been discussed recently by Hall[11] and Phillips.[12]

Hall points out that initially the population is distressingly mobile, employers reporting labour turnovers of from 15 to 50 per cent per month.

or eighty prisoners were shipped by bus each week from Blind River to Sault Ste. Marie, a distance of 85 miles, for trial because the local jail could not hold them.

If the industry becomes established on a permanent basis, a more conventional population structure may be expected to emerge at Elliot Lake. Only when this happens will the town begin to take shape and develop a coherent social structure.

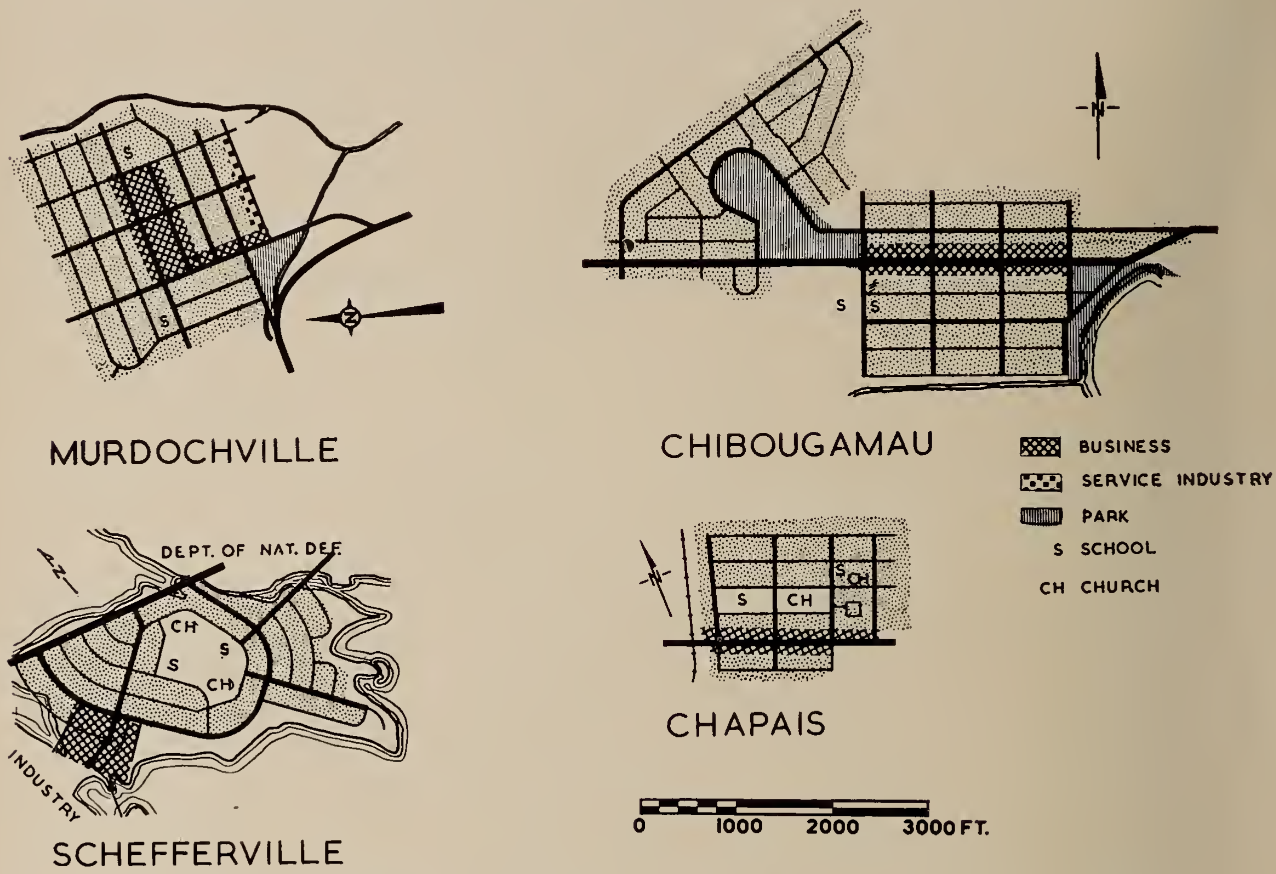

Fig. 4. New towns in Quebec; (a) Murdochville. (b) Chibougamau, (c) Schefferville, (d) Chapais.

unsuitable as urban streets.

In general, advances to establish new towns are in the form of capital loans. These may be repaid by the sale of lots or they may be gradually recovered from tax revenue including taxes on industry.

Economic and Social Base

The new towns we are discussing have mostly come into existence as a result of industrial development much of which is in the form of primary industry. Past experience in Canada suggests that such industry may not provide a sufficiently stable basis for a permanent modern town. In most places secondary industries are unlikely. It seems inevitable therefore that some Canadian new towns must have the characteristics of mining camps rather than towns. It is well

Employment is almost exclusively male and so far there is a lack of suitable housing for married men. It is probable that mill workers will be mostly French-speaking Canadians whereas mine workers are most commonly recent immigrants, many from Italy. There are no old people and relatively few children.

A group of this kind does not appear to provide a sound basis for the establishment of a new town and it creates acute problems for the neighbouring town of Blind River. A "well planned" modern town seldom provides for the "disreputable activities which are typical of recreation and leisure in a modern community" and as a consequence a peripheral town becomes a sort of "moral garbage heap for the planned community". Thus, in 1956 seventy

A further problem in any new development is that of providing temporary housing accommodation for construction workers and others. This must be done in such a way as not to prejudice the development of a more permanent community.

Location

There is often a considerable freedom of choice of site for a new town in a primitive area. Whilst it must be reasonably close to the industry providing employment it need not be on top of it and if the industry is of a noxious or hazardous character may have to be separated from it.

Taylor[13] has described in some detail the considerations affecting the location of Elliot Lake. Briefly these were as follows:

(a) Geology—location of ore zones

of proven ore potential, depth and physical characteristics of the soil overlaying the bedrock, areas of unstable physical form.

(b) Topography — delineation of areas of low to moderate slope and uncomplicated surface form.

(c) Water Resources—definition of drainage basins, stream flow and water quality.

(d) Transportation — highway location, possibility of port development on Lake Huron.

(e) Power distribution.

(f) Land ownership patterns.

(g) Distribution and extent of employment sources.

The preceding studies covered a wide area and led to the conclusion that the area immediately south of Elliot Lake was the best townsite available. Further detailed studies were then made of this area to confirm the information collected previously and to provide the basic information needed to plan the new town. In all preliminary studies of town sites airphoto interpretation has proved to be a most valuable tool. It may be mentioned for example that the preliminary plan of Uranium City is based almost entirely upon studies of this kind.

Although there is infinite space for towns, good town sites are often hard to find especially in the Laurentian shield. The prevalence of lakes, muskeg, and rock, and the relative absence of sand and gravel deposits make it difficult to locate town sites of sufficient size. In some instances the town sites are unduly confined and expansion will be difficult (See for example, Schefferville, Quebec, Fig. 3). In others, towns tend to be fragmented into a number of separate parts. This is shown by the plans of Kitimat, Elliot Lake and Uranium City (Fig. 1 and 2).

These "sub-towns" create difficult problems for the planner more particularly in terms of their social structure. The two parts of Elliot Lake appear to be approximately equal in size and rank and they are two miles apart. Although "twin cities" are not uncommon this is possibly the first occasion when a town has been deliberately planned that way. At Kitimat one suspects that the upper classes will live on the higher ground and the lower orders down below. This of course tends to be the natural order of things, as can well be seen in Montreal, Vancouver, and Banff but the sociologists are not in agreement as to whether such a situation should be deliberately established in a new town.

Size and Structure

According to the definition of a garden city quoted previously, such a town is of limited size and surrounded by a rural belt. The idea that a town should need any provision for a rural belt is at first glance fantastic for a town located in any undeveloped part of Canada, but in point of fact it is only in this way that undesirable fringe development can be prevented. The typical Canadian town in new and old areas alike is partially surrounded by shacks. These can be kept at a distance, though not necessarily prevented by a rural or green belt of sufficient width.

In the case of the Ontario new towns the municipal boundaries are twelve miles square and the policy has been adopted of building one town to serve mines scattered over a

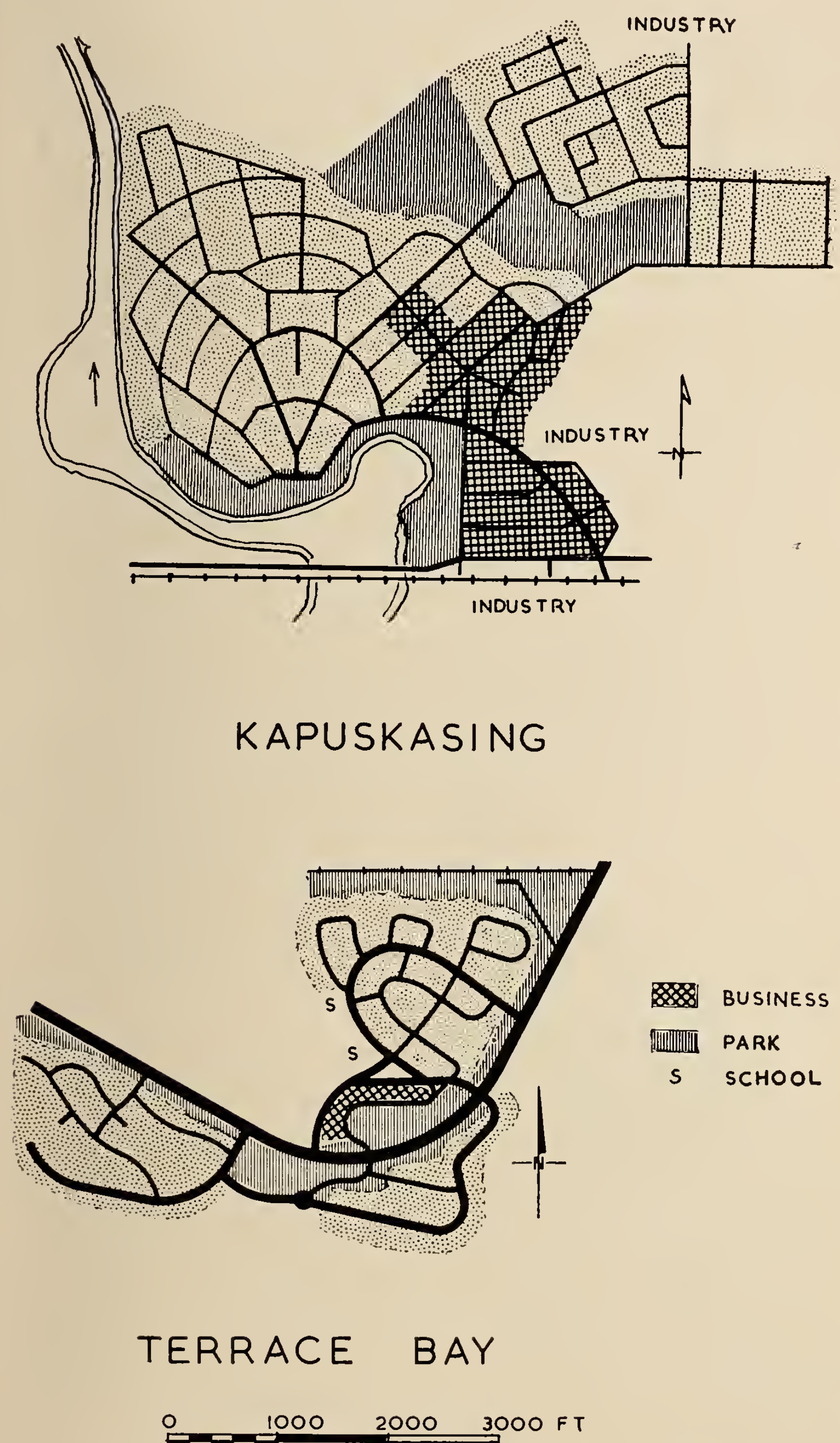

Fig. 5. New towns in Ontario: (a) Kapuskasing, (b) Terrace Bay.

considerable area. In the Pembina area of Alberta several small new towns (Cynthia, Lodgepole, Hinton, and Drayton Valley) are being built within an area about 20 miles square. The decision as to the size of a new town and the overall settlement pattern should be based upon adequate regional studies. Regional planning, in this sense, is in its infancy not only in Canada but throughout the world. It would appear to be further advanced in Alberta and British Columbia than in most other places.

There has been much discussion about the value of the "neighbourhood" as a town planning concept. Much of this discussion arises from a lack of a generally accepted definition. For some, a neighbourhood is essentially a residential area tributary to an elementary school; for others, it is a more or less self-contained small town which in turn is part of a larger town.

The latter concept has influenced the design of new towns in England. These are planned to have neighbourhoods with a population of from 5,000 to 10,000, each neighbourhood having schools, churches, shops, parks, community buildings and so forth. It is intended that the neighbourhood include both rich and poor who would regard themselves as members of the neighbourhood community. A typical neighbourhood would have several schools. The American concept was based essentially upon a single school and community centre and has therefore tended to be smaller, though the neighbourhoods planned by Stein at Radburn, N.J., were intended to have populations from 7,500-10,000. Langlois[14] has suggested that the neighbourhood in a new town having a severe climate should be limited to about 1,000 persons thus reducing the walking distance to school and to local shops. Schools would be planned for not more than 100 pupils and would have an intimate quality lacking in most larger schools.

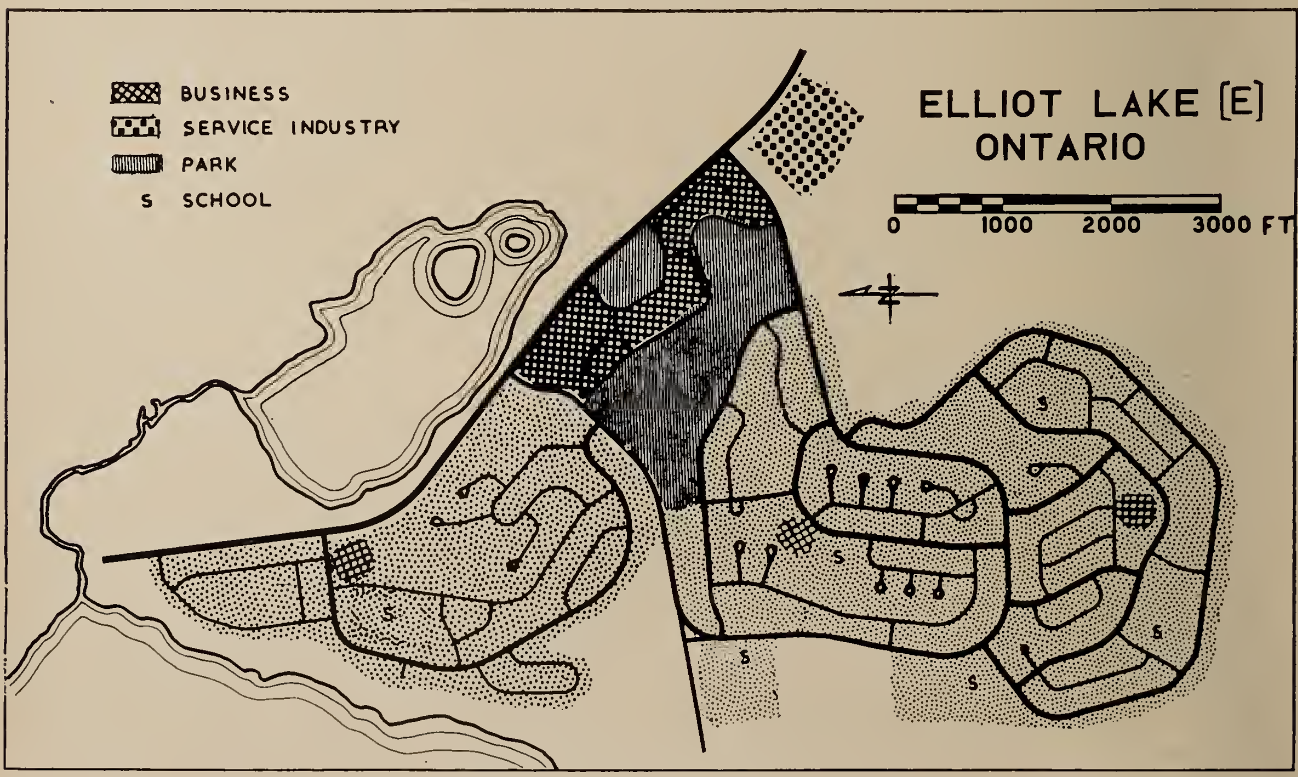
The neighbourhood concept has recently been re-examined by Rasmussen.[15] He concludes "that the idea of the metropolis divided up into small, self-containing units, within which people of all classes live a harmonious and full communal life, is a lovely dream. It can only be a reality for children". Considering the needs of children he says "well arranged towns are much less suitable for children than a small, old-fashioned provincial town with its odd mixtures of workshops, small industries, private gardens, shopping street . . . and a hundred other places that all appeal to a small person's imagination and interprise". He concludes that "the metropolis should be a richly differentiated pattern of small and large units woven into each other, clearly articulated and as rich and complex as life itself". The Canadian new town that approaches this concept most closely is Kitimat. Here there will be twelve neighbourhoods ranging in population from 1200 to 6000, each having one or more schools plus neighbourhood shopping and social centre. At Elliot Lake seven neighbourhoods with populations of the order of 3,000-4,000 have been planned.

In the more restricted sense most new towns reflect some attempt at neighbourhood planning. Commonly this takes the form of a school situated near the centre of a neighbourhood and a street pattern such that children do not have to cross major traffic arteries on their way to school. There has been no attempt except at Kitimat to carry this idea through to the extent of providing a separate system of paths.

One important practical advantage of the neighbourhood unit is that it leads to a proper programme of construction. One or more units can be built as the need arises and an efficient and compact town exists at all times.

In an interesting book Egli[16] has discussed the relationship between climate and the form of towns. He suggests that the kind of town appropriate for a temperate climate is not well suited to a sub-arctic one and implies that with the settlement of sub-arctic areas a distinctive kind of town may emerge. Egli goes on to say "No new town structures con-

Fig. 6. Elliot Lake, Ontario — street plan.



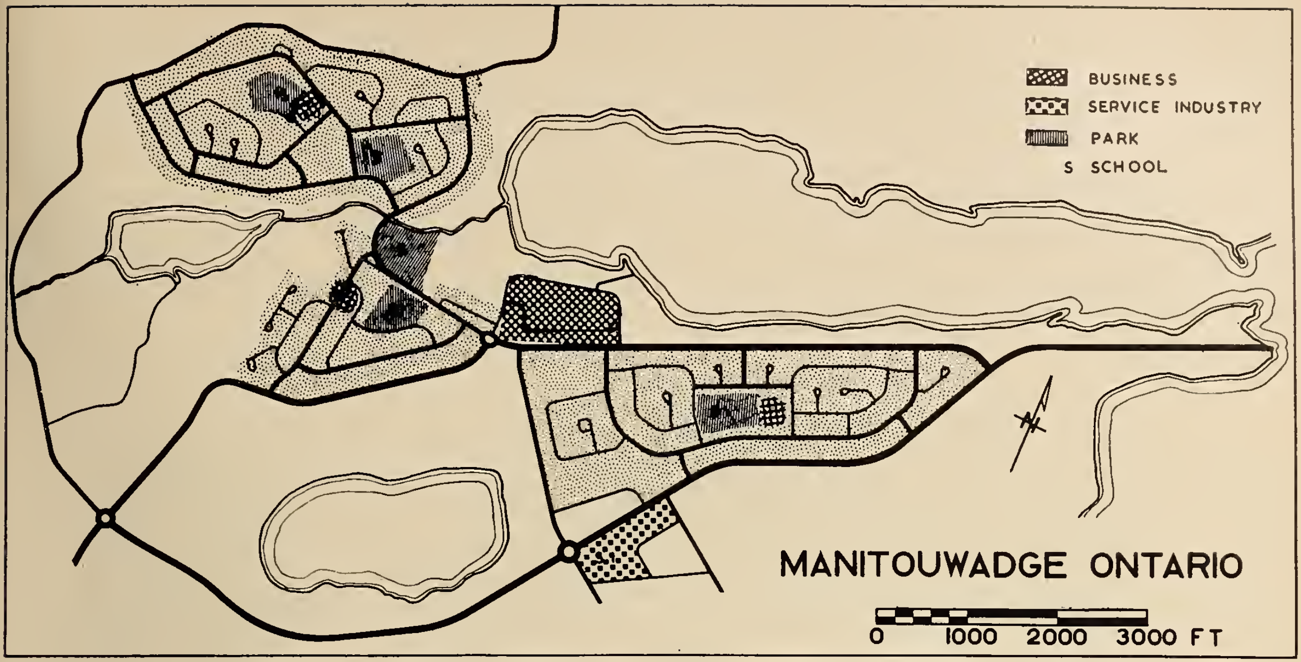


Fig. 7. Manitouwadge, Ontario — street plan.

ceived and developed from their immediate surroundings have as yet been found at all either in the arctic or the sub-arctic zone. This is a great climatic zone that has hardly a sign of authentic creativeness to show, at least in town planning."

An examination of the plans of Canadian new towns supports this view. They all appear to follow the urban patterns developed in more temperate climates. Such differences as do occur, as for example between the plans of Kitimat and Elliot Lake, reflect the preferences of their designers rather than the climatic differences between the coastal region of northern British Columbia and northern Ontario. This lack of sensitivity to environment may be partly a result of inexperience in planning and building new towns and partly a sign of the tendencies to conformity and mass consumption characteristics of our age. The northern town has yet to find its soul.

Street Plans

The street plans of Canadian new towns are of various types (Figs. 3-9). The oldest sort of plan—the grid—still has its adherents, especially in Quebec (see plans of Chapais and Murdochville, Fig. 4); the formal radial plan may be seen at Kapuskasing; the "can of worms" plan at Terrace, and the "superblock" at Kitimat. No simple name has yet been devised for the kind of plans used for the Ontario and Alberta new towns but these resemble the plans of the English Garden Cities and New Towns.

A good street plan has the following characteristics:

(1) It provides an adequate system of major roads so that travel by automobile from one part of the town to another is rapid and safe.

(2) It provides attractive residential streets in which traffic is kept to a minimum.

(3) Adequate space is provided in the central business district both for traffic and for parking.

(4) The plan is such that utility services can be installed economically.

(5) The lots created by the street plan, both residential and commercial are suitable for their proposed uses.

(6) The whole plan has a sense of unity and design appropriate to the site—this means that it has individuality and character.

(7) The plan recognizes the importance of land uses other than houses and shops.

(8) Maintenance including snow removal is economical.

The grid plan fails to meet almost all of the above criteria. The numerous street intersections make it dangerous; residential streets are monotonous and often used by other than local traffic; there is congestion and lack of parking space at the centre; an excessive amount of land is often devoted to streets; the plan may not fit the contours, resulting in excessive development costs; the plan lacks character. The only advantages are those resulting from simplicity—lower planning and drafting cost, less surveying, greater simplicity of municipal records including assessments. On balance, the advantages are far outweighed by the disadvantages and it seems unfortunate that this obsolete kind of planning is being used in some Canadian new towns. One may surmise that this results from entrusting the planning of such towns to those who lack expert knowledge in this field.

The "can of worms" type of planning—seen in many upper class suburbs and some new towns, is the reaction against the sterility of grid planning. It is essentially romantic and frequently rather impractical. It seems fairly safe to regard it as a fashion that has now passed, for it seems poorly adapted to the facts of life in the Canadian bush.

Formal planning of the Versailles-Kapuskasing kind is also out of fashion and ill adapted to rugged terrain. Nevertheless there may be new town sites perhaps in Quebec or the Prairie Provinces where new classical forms can be evolved. As one writer has said, "Every noble city has been a crystallization of the contentment, pride, and order of the community."[17]

The "garden city" kind of planning is much more difficult to evaluate. As the plan is based on a detailed study of the site and the estimated needs of a new community it must be judged on its own terms. This makes generalizations impossible or at least unwise. Certain aspects of modern planning are however evident simply from looking at street plans. Firstly there are three kinds of streets in towns of any size—minor residential streets, collector streets and major thoroughfares. The latter commonly form boundaries of neighbourhoods and are often divided highways. The streets are likely to vary in width both of right-of-way and paving. The minor residential streets are most commonly loops, though cul-de-sacs are also used. Experience with cul-de-sacs at Kitimat has shown that these are less suitable than loops where snow plowing is necessary. In fact it may be said that any street plan involving sharp curves is likely to involve additional trouble and expense in regions of substantial snowfall.

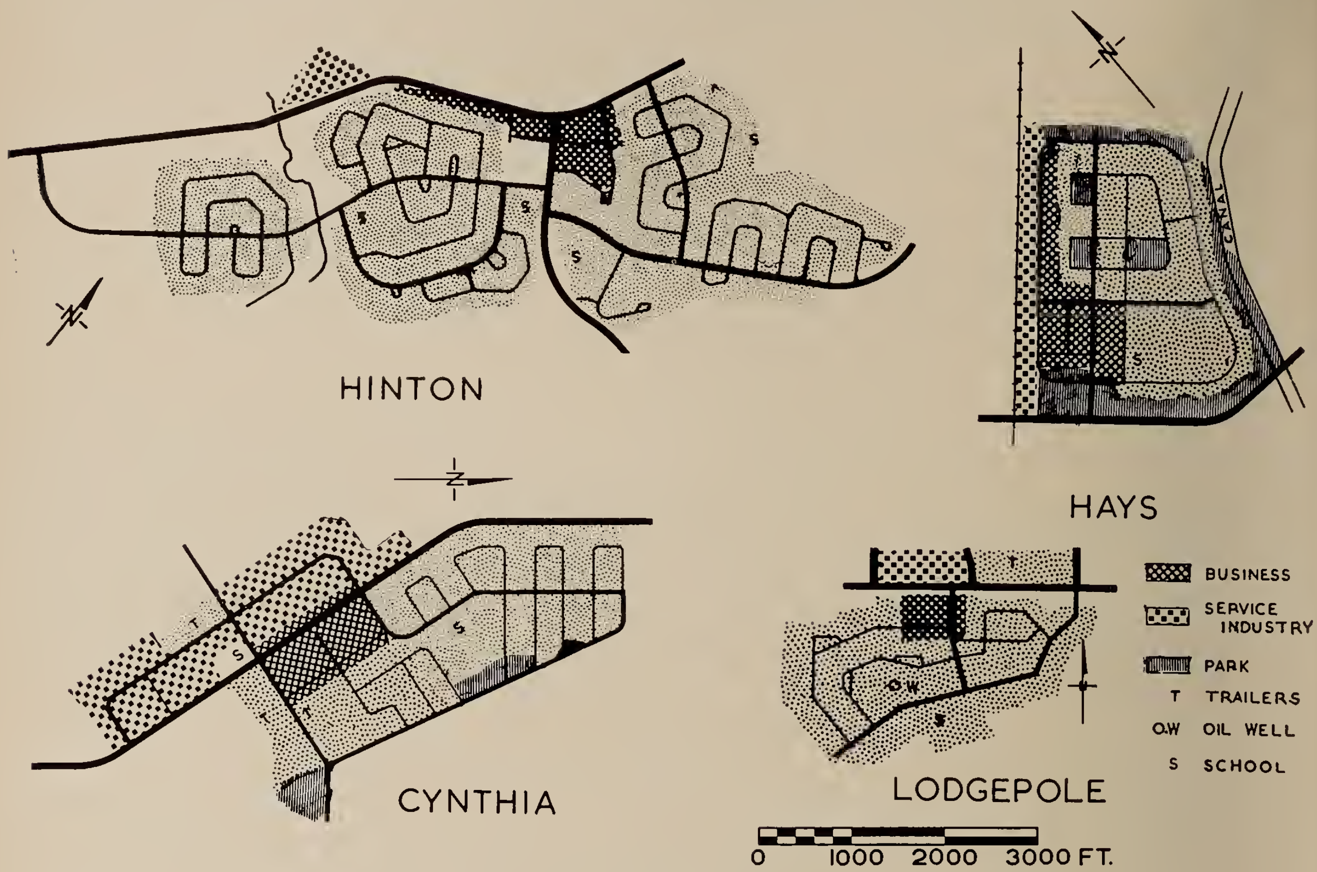

Fig. 8. New towns in Alberta: (a) Hinton, (b) Hays, (c) Cynthia, (d) Lodgepole.

Central Areas

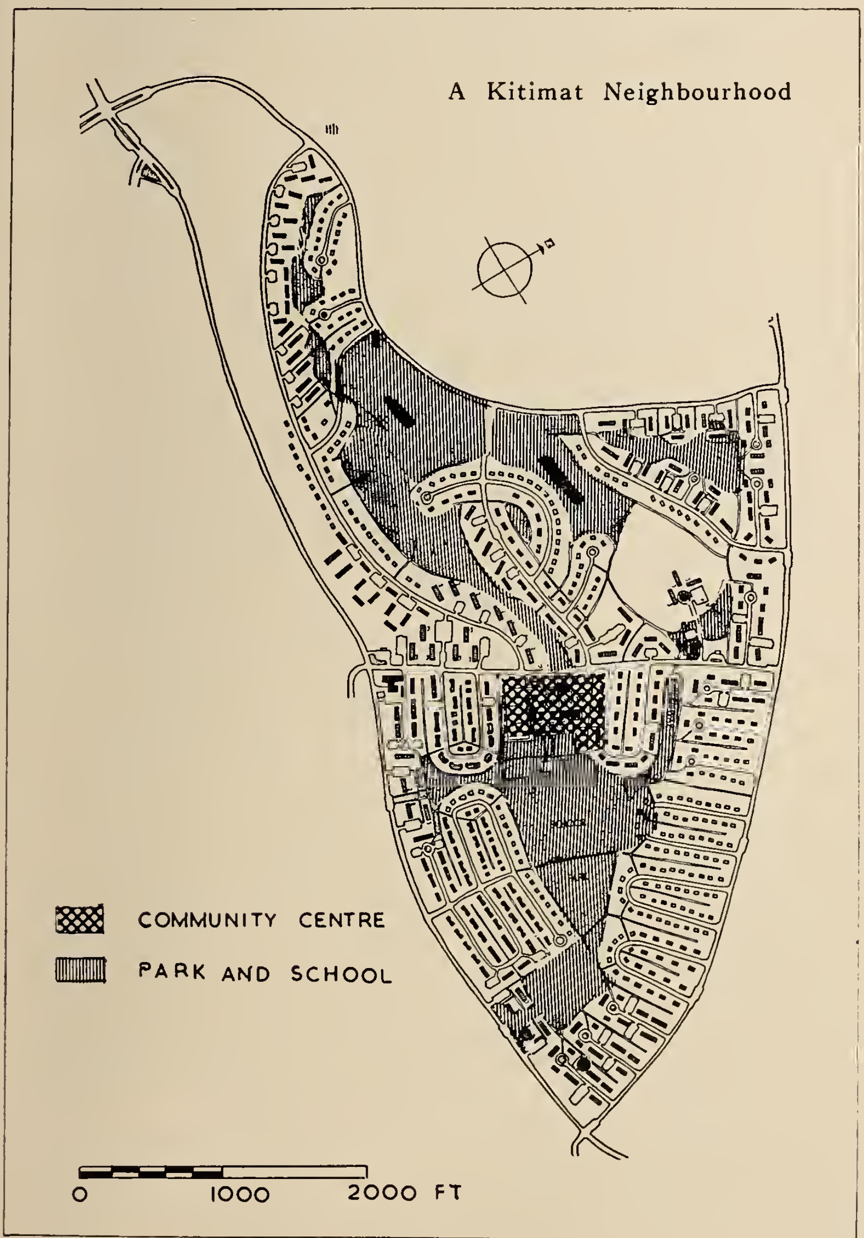
The central area of any town provides the greatest challenge to the town planner. In very small towns the central area is little more than a shopping centre, whereas in larger towns, restaurants, theatres, churches, offices, and government buildings are all important elements of the central area. In Canadian new towns we can see examples of various kinds of central areas. In its simplest and most traditional form the central area consists of "Main Street" as for example at Chibougamau. There is little to be said in its favour. "Main Street" suffers from congestion, lack of parking facilities, lack of protection from wind and sun and a lack of sites for buildings, other than stores. It frequently lacks beginning and end. Much better is the small shopping centre, such as that at Lodgepole (Fig. 10). The traffic on the main road is relatively unimpeded, off-street parking is provided and there is space for people to walk around. As in the traditional English village, a church will be built in proximity to the market place. In the new town of Hinton we can see a somewhat more elaborate centre (Fig. 11). This includes sites for a community recreation centre, a hotel, public buildings and for some high density residential developments. In addition the separate school and the high school are located in close proximity to the centre.

The city centre at Kitimat provides for a hotel, two movie theatres, a library, an auditorium, municipal buildings, office buildings, stores, and parking for 2500 cars. The latter create a very difficult planning problem. The central area is by tradition animated and even congested, with impressive buildings often of considerable height. The modern town centre is in danger of becoming a dreary waste of asphalt paving or parked cars punctuated with low buildings resembling stables. In Canadian towns such as Kitimat and Manitouwadge an attempt is being made to alleviate this situation by landscaping. At Manitouwadge for example "Landscaping was made an integral part of the scheme. To screen the area from the noise and fumes of motors, the parking areas were designed to be surrounded with boulevards of grass, trees, and shrubs. The pedestrian ways were provided with planting areas so that the pedestrian might be afforded shade and protection from the winter winds. The whole landscaping scheme was arranged so that it would be in full harmony with the architectural shapes of the buildings."[18] This appears to be making the best of a bad situation but the problem still awaits solution. Careful planning of a relatively large town centre is evident at Elliott Lake (Fig. 12).

One problem that arises in a new town is deciding when to construct the central business district. In British new towns the tendency has been to delay this construction until there is a sufficient population to justify substantial buildings. In some Canadian new towns the opposite policy has been followed. Business lots have been sold by auction at an early stage in the history of the town for relatively small amounts and inferior buildings have been erected thereon. This happened at Chibougamau. In 1950, the government sold 48 lots by auction for an average price of $2,000 each. By 1955 many of these lots were occupied by second-rate commercial buildings which will have to be demolished later.

This problem was considered in the planning of Kapuskasing in 1921 when it was decided to establish initially a secondary business area where cheap and temporary buildings could be erected and to develop the main business area later. It has not worked out as planned. The secondary area has remained the main shopping centre and what was intended to be the town centre has developed as a residential district. Two observations may be made. Firstly, the supremacy of the central business district should be established as soon as possible; secondly, the land, if publicly owned, should not be sold, if at all, until its true value has been established. It could of course be leased for short periods thus enabling careful control of its use to be made. In this connection a recent study of the economics of the development of Hemel Hempstead town centre may be of interest.[19] (Hemel Hempstead is one of the English new towns.) Land which, including development costs, was worth about £38,000 an acre is now worth from £79,000 to £160,000 and values are expected to rise to a maximum of £250,000 an acre. Many will agree with Professor Robson that "Property and land values which have been created by public expenditure and the efforts of public authorities should not be handed over to private persons or profit-making companies."[20]

Fig. 9. Kitimat, B.C. — neighbourhood plan.



Service Industry

There are many commercial uses that cannot properly be located either in the town centre or within neighbourhoods. These include lumber yards, used car lots, automobile repair shops, warehouses of various kinds, and so forth. In addition there are small industries which may or may not be good neighbours in a residential district. The term "service industry" is commonly used to include both kinds of use. It is desirable to give more thought to the proper location of these commercial and industrial uses than is commonly done. Certainly the practice of permitting a ribbon of these unsightly uses on the main approaches to a town is as deplorable as it is common in Canadian towns. There are signs that this problem has been tackled in some new towns. At Kitimat for example an area for service industry has been reserved well away from other uses but readily accessible to the town centre and the principal lines of communication. Similar areas are indicated on the plans of Elliot Lake and Manitouwadge.

Residential Areas

Most Canadian new towns are based on the assumption that people prefer single-family dwellings, and residential areas are designed accordingly. There can be little doubt that the assumption is correct but one cannot help wondering whether circumstances may not dictate a greater use of multiple-family dwellings including row houses. These factors include: *(a)* the high costs of site development, *(b)* high building costs, *(c)* severe climatic conditions. In this connection it is significant that the plans for neighbourhood A at Kitimat (Fig. 9) provided for only 238 single family houses out of a total of 1,412 dwelling units; 308 families were to be housed in twin houses, 618 in group or row houses and 248 in apartment houses. These figures represented a decision as to what should be built in order to provide accommodation in an efficient manner. The actual development of this neighbourhood has been carried out largely by private builders. Out of a total of 1217 dwelling units 513 (41%) are single family houses, 298 (23%) are twin houses, 147 (12%) are row houses and 259 (25%) are apartment houses. These changes have resulted in a lower overall density in spite of smaller lots for single-family houses. It may be maintained that these figures are the result of a free choice, but actually this is not so for a free choice seldom exists and those coming to the town have to take what is available. Perhaps all we can say is that architects and large scale developers recognize the advantage of multiple dwellings whereas most individuals do not. There are however regional differences and it may be noted that, in Quebec new towns, multiple dwellings are very common.

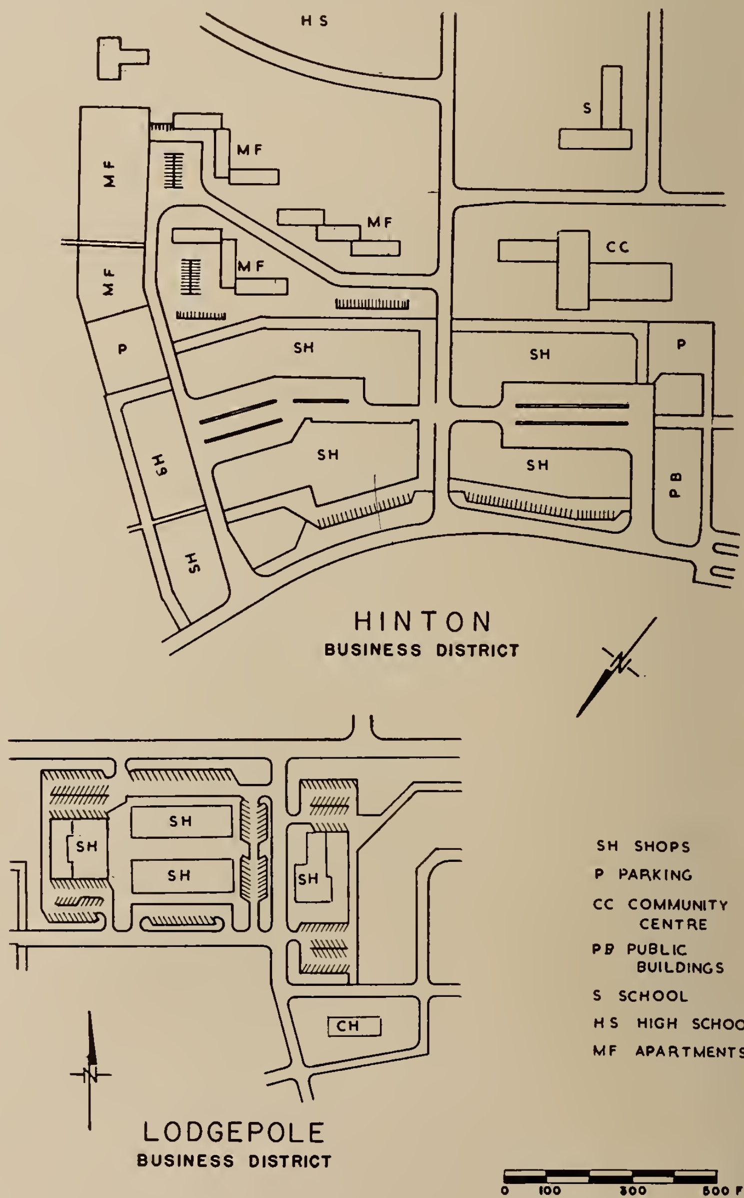
In general, high density housing is located close to the central area, as for example at Hinton (Fig. 10), and this seems a proper arrangement. Outside the central area single-family housing is most common and in most Canadian new towns this means lots approximately 50 ft. x 100 ft. or a little larger. The difficulty is to plan an attractive town composed for the most part of such minimum sized lots. The deadly foe is monotony and this cannot be avoided simply by insisting on a variety of house types. The new towns offer ample opportunity for experiment in this important aspect of civic design. Among the devices that are being used in an attempt to improve the appearance of residential areas, the following may be observed: the use of curved streets to shorten monotonous vistas, varied lines of set back to produce more interesting house groupings, the careful siting of open spaces, schools, and churches. It is doubtful if these measures will be sufficient by themselves to produce attractive residential districts. A greater willingness to experiment with different patterns of residential development is needed. One fact is evident—modern planning of residential areas greatly reduces the number of dangerous intersections. In Manitouwadge and Elliot Lake for example there are virtually no X intersections except for one or two crossings of major roads where traffic circles or other traffic control devices can be used.

It is generally considered that some public open space should be preserved in residential districts, and Central Mortgage and Housing Corporation have stated that properties may be down-graded for appraisal purposes if assurance of adequate open space is lacking.[21] This necessary open space may be provided in the form of internal parks as in a "superblock", e.g. at Kitimat (Fig. 9), or in a more conventional manner with considerable road frontage as at Chibougamau. Neither system is entirely satisfactory and further study of the purposes for which public open space is required and the way in which it is used appear needed.

Site Engineering

It is usual in new towns to construct water supply systems and sanitary sewers, and to grade and gravel the streets before any building takes place. The completeness of these services naturally varies with the size of the town and other factors. The cost of these works may be borne by the town if incorporated, by industry, or by advances from the government. If borne by the town part or all of the cost may be charged back against the lots in the same way as local improvements. Such charges may become more than the lot owner can be reasonably expected to carry. One basic difficulty in a new town is that everything is new and must be paid for at the same time. This problem is common to all new residential areas but is particularly acute in a new town. Practical difficulties have arisen in some new towns in the installation of services. Langlois[14] referring to Chibougamau describes the town as a failure and

Fig. 10 (bottom). Lodgepole — business district. Fig. 11. Hinton — business district.



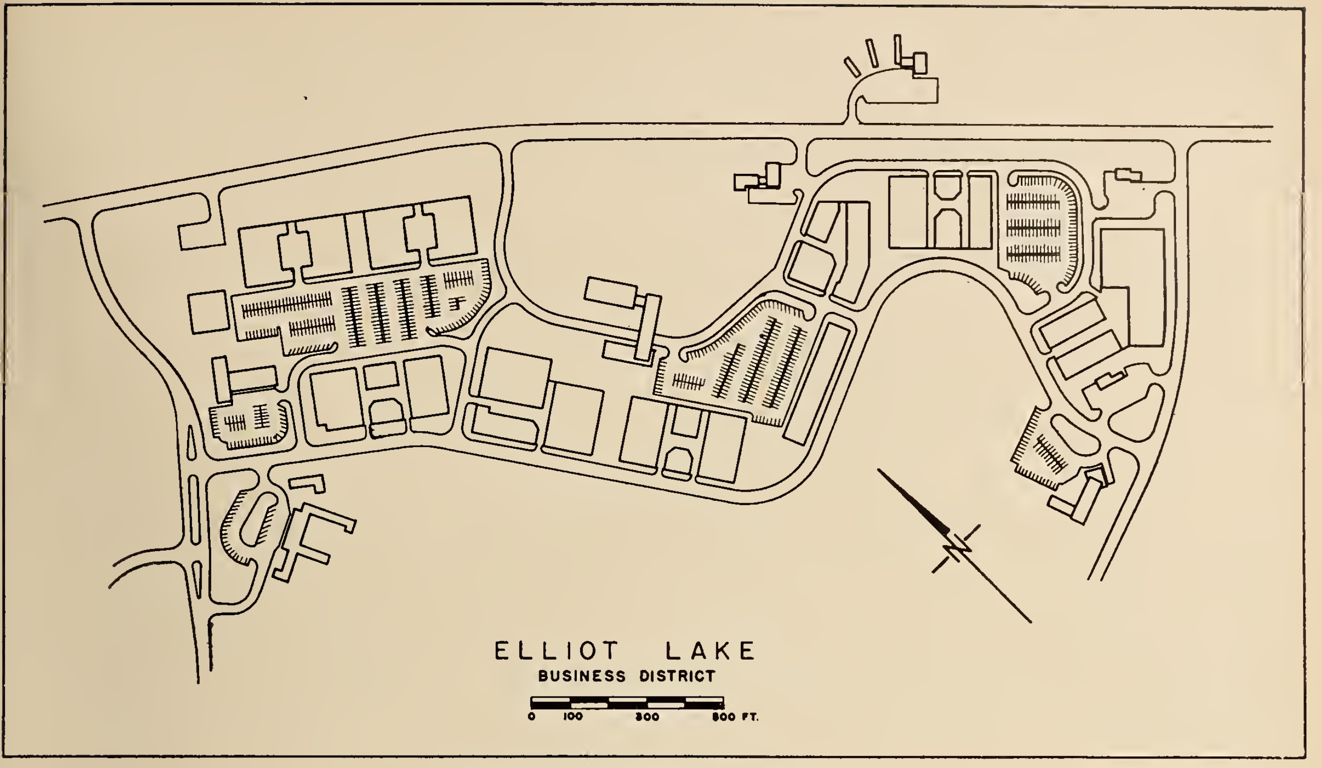


Fig. 12. Elliot Lake — business district.

gives as one reason the errors made by the Provincial government in constructing water mains. In towns having carefully planned road systems it appears to be common to pave the major roads at an early stage in the history of the town. Minor roads are normally paved, if at all, following the construction of the houses. In most parts of Canada it would seem desirable to construct hard surfaced roads as soon as may be practicable rather than to expect the residents to contend with the dust, mud, and pot holes common to unpaved roads.

Sidewalks, except on major thoroughfares, are a luxury and with good planning may not be needed. Few have been built so far.

The most common arrangement for electricity and telephone service is the joint use of poles located at the rear of the lots. In this connection it may be observed that lanes are commonly provided in Alberta but are not popular elsewhere. Underground wiring is being installed in the central areas of some of the larger towns. Off-street parking facilities are common in business districts and are usually paid for by the town as a whole though in some instances part of the cost is charged against business.

Conclusions

It is too early to attempt any evaluation of Canadian new towns and it would be presumptuous to do so in the present brief study. It would seem to be important however that a continuous appraisal be made. Every new town is to some extent an experiment and much can be learned from careful observation of such experiments. In the meantime it seems to the author that the following conclusions may be useful as a basis of discussion.

(1) Governments should accept a general responsibility for the planning of new towns and for the control of development in accordance with general plans.

(2) Governments should be prepared to advance money to finance the construction of new towns.

(3) The location of new towns should be based on adequate regional studies.

(4) Town sites should always be sufficiently large to permit a green belt of substantial width. In the absence of an effective system of regional planning it may be necessary for town sites to be of the order of twenty miles square or more.

(5) The planning of new towns should be done by town planners of high professional standing. In this connection it is desirable that some use be made of consultants.

(6) New towns should be built to good municipal standards. Water supply and sewage disposal systems, storm water drainage systems, hard surfaced roads, sidewalks where needed, street lighting should be constructed if possible in advance of houses.

(7) New towns should be planned and developed as a series of neighbourhoods having populations ranging from 1000 or less up to about 5000.

(8) A start should be made on the central business district early in the history of the town.

(9) It will usually be desirable to encourage some multi-family dwelling units and these should be located close to the central area.

(10) Adequate provision should be made for service industry, the less attractive commercial uses and noxious industry.

Acknowledgments

This paper could not have been written without the willing co-operation of those who are actively concerned with the planning and development of new towns in Canada. In particular, the author wishes to record his appreciation of the advice and assistance received from Mr. D. F. Taylor, Chief Planner, Department of Planning and Development, Province of Ontario, Mr. H. N. Lash, Director of the Long Range Planning Division, City of Toronto Planning Board, formerly Director of Town and Rural Planning, Province

St. Lawrence Estuary Submarine Power Transmission System

O. W. Titus, M.E.I.C.
President, Canada Wire and Cable Company Limited

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June, 1957

THIS PAPER describes in broad lines one of the phases in the placing into the service of the people and the economy of the Province of Quebec, the water power resources of the north shore of the Lower St. Lawrence.

The Problem

To bring into focus the basic economic and social aspects, it is appropriate to recapitulate the population versus power resources in the areas affected by this cable project. On the North Shore of the St. Lawrence consider the area draining into the St. Lawrence and lying between the Saguenay River and the Province of Newfoundland. On the South Shore consider that part of Quebec from East of Rivière du Loup through to and including the Gaspé Peninsula. These two areas lie opposite one another, both in many respects the oldest parts of Canada from the white man's viewpoint, and both now entering a turning point in their respective developments.

The North Shore is startlingly rich in power resources but of very meagre agricultural potential, the South Shore very limited in power resources but with very considerable agricultural potential, some moderate sized cities, large towns, and a general population development organized and capable of ready expansion, well served by water, road, and rail transportation, and with large potential in mineral resources. (One large copper mine, that of Gaspé Copper Mines Ltd., already is in large scale production since the installation of the cable. It supports a modern and expanding town in the heart of the Gaspé.)

The one element lacking to let the South Shore achieve its potential was an adequate supply of cheap electrical power.

The North Shore on the other hand is not naturally hospitable to human habitation. Its economic development would appear to trend toward large individual units located on account of some natural resource such as mining or availability of large blocks of cheap power close to deep water transportation. Its development entails the movement of peoples to those sites. The South Shore's future growth one expects should be less individually spectacular. It envisages the enlargement of the potential of present peoples and communities in a more kindly and amenable environment.

In summary, the statistics were approximately as shown in Tables I and II.

The paper describes the economic considerations and the installation of a submarine cable system to link the South Shore of the St. Lawrence estuary to the large hydro-electric power resources of the North Shore via the Manicouagan Peninsula.

The "unshackling" of the South Shore by the provision to it of ample electrical power was the problem. It was attacked with vision, vigour, and courage by the Quebec Hydro-Electric Commission.

Studies were made comparing the estimated long range costs of power for the South Shore area based on:—

(1) Initial installation approximately 75,000 h.p.

(2) Locally developed — Hydro-electric power, 15,000 h.p.; thermal sources, (a) diesel, 6,000 h.p., (b) steam, private industrial plants only.

Studies also were made to compare the economics and operational problems of transmitting from the North Shore via overhead lines via North Shore to vicinity of Quebec City, overhead span across river and overhead along South Shore to vicinity of Rimouski.

These estimates gave overall costs approximately as follows.

Overhead	$7,000,000
Submarine	$6,000,000
Switching and substation	$ 500,000

Consultants of international reputations were employed to advise on the electrical and mechanical problems and feasibilities of such a cable installation and the details of the various elements. It was agreed that the project was feasible.

Accordingly it was decided to proceed with the installation because of:

(1) The economics.

(2) The greatly increased economies as loads increased in the future.

(3) The experience gained which would be of inestimable value in future decisions.

(4) The greatly simplified problems of system stability and voltage control with the relatively short transmission distance to the load centre of 40 miles as against approximately 450 miles via Quebec City and overhead.

(5) The greatly reduced mileage of overhead exposed to icing in a district subject on occasion to extraordinarily bad icing conditions (the overhead part of the South Shore was seriously interrupted for three weeks during the winter of 1955-56 from this cause).

(6) Ease of adding additional circuit or circuits with experience gained in initial installations.

(7) The adaptability of such a cable system to high voltage direct current purposes if that becomes an

accepted and economic method of transmitting large blocks of power.

A reconnaissance of possible crossing sites indicated that the most feasible and economical would be from the Manicouagan Peninsula (between the mouths of Manicouagan and Outarde Rivers, west of Baie Comeau, to Les Boules on the South Shore, approximately 35 miles east of Rimouski).

The choice fell here because:—

(1) It was close to immediately available power (5 miles from the Outarde power plant) and, on the South Shore, Les Boules was well situated as a load centre for the area to be served.

(2) The river bottom conditions were favourable, no submerged ridges, valleys or obstructions.

(3) The small bay at Les Boules offered the minimum risks from rock outcroppings, large boulders, and similar hazards. Also it was possible to bring a cable scow quite close to shore.

(4) The North Shore beach, being an alluvial deposit offered no hazards from rock ridges or boulders. Also it was possible at low spring tides to trench in the cables for 5,000 feet out from high water mark. The distance from high water mark to high water mark was 31½ miles (nautical) and from terminal structure to terminal structure, 32 miles (nautical).

The maximum depth was 1,200 feet at about 2½ miles off shore at each end.

Table I.—General Statistics

	*South Shore	**North Shore
(1) Area (square miles)	15,000	50,000
(2) Population (1951)	248,400	42,700
(3) Water power potential (h.p.)	25,000	6,000,000
(4) Water power developed (1951) (h.p.)	15,000	130,000
(5) Estimated average capital cost per horsepower of undeveloped power (1951) (dollars)	350	175

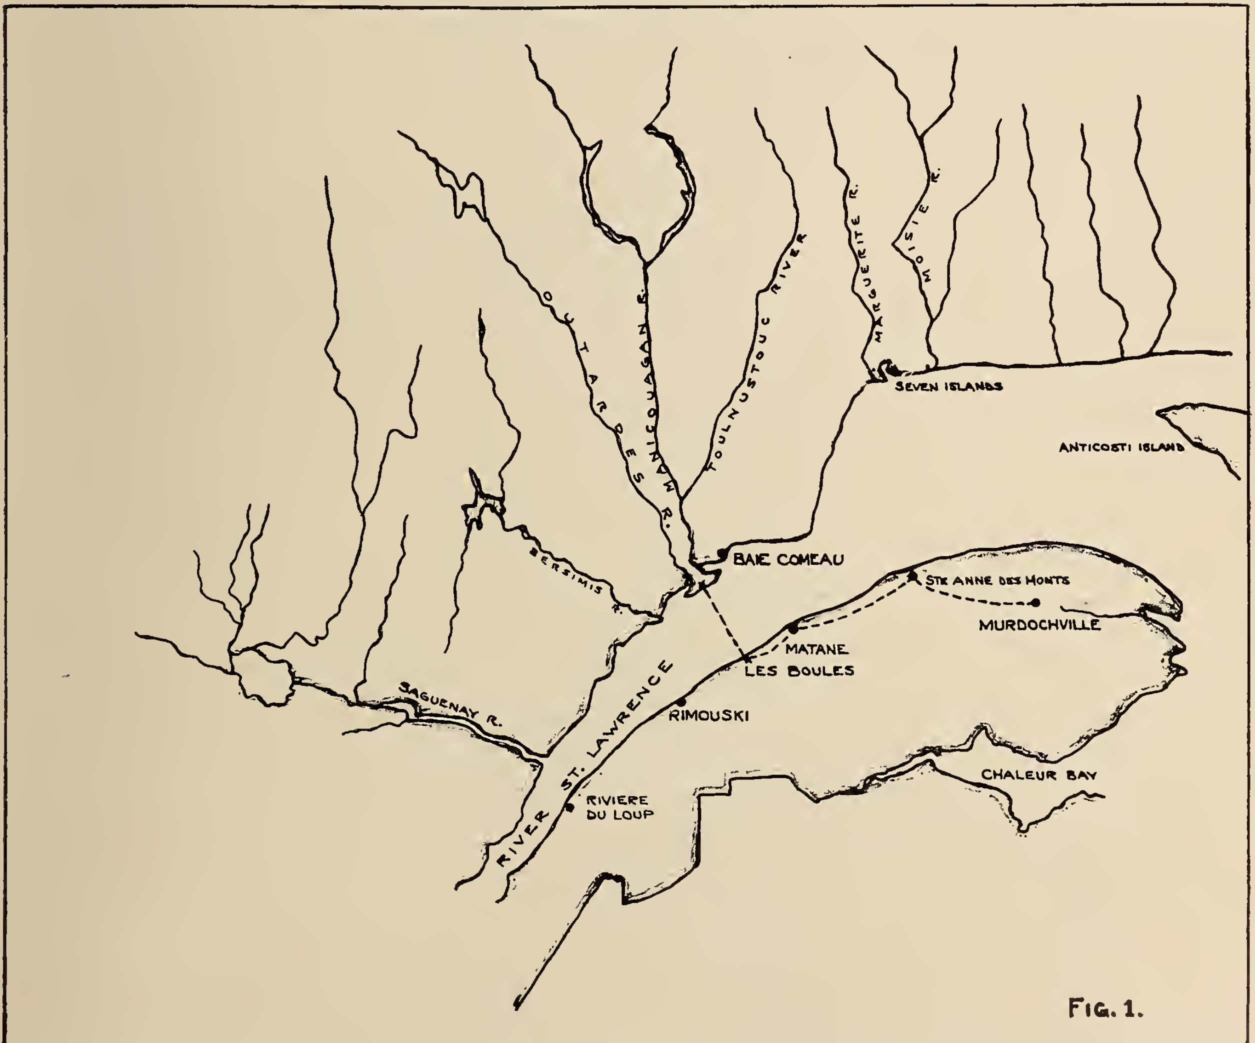
Table II.—Estimated Power Demands of South Shore in Horsepower

	1951	1956	1961	1966
Normal, industrial and commercial	19,000	20,000	25,000	30,000
Domestic	6,000	7,000	10,000	14,000
Major industrial and mining	0	10,000	12,000	18,000
	25,000	37,000	47,000	62,000

*South Shore—Province of Quebec, from east of Rivière du Loup to extremity of Gaspé Peninsula.

**North Shore—Watershed flowing into St. Lawrence eastward from Saguenay River to eastern boundary of Quebec.

Fig. 1. Sketch map of the St. Lawrence estuary area.



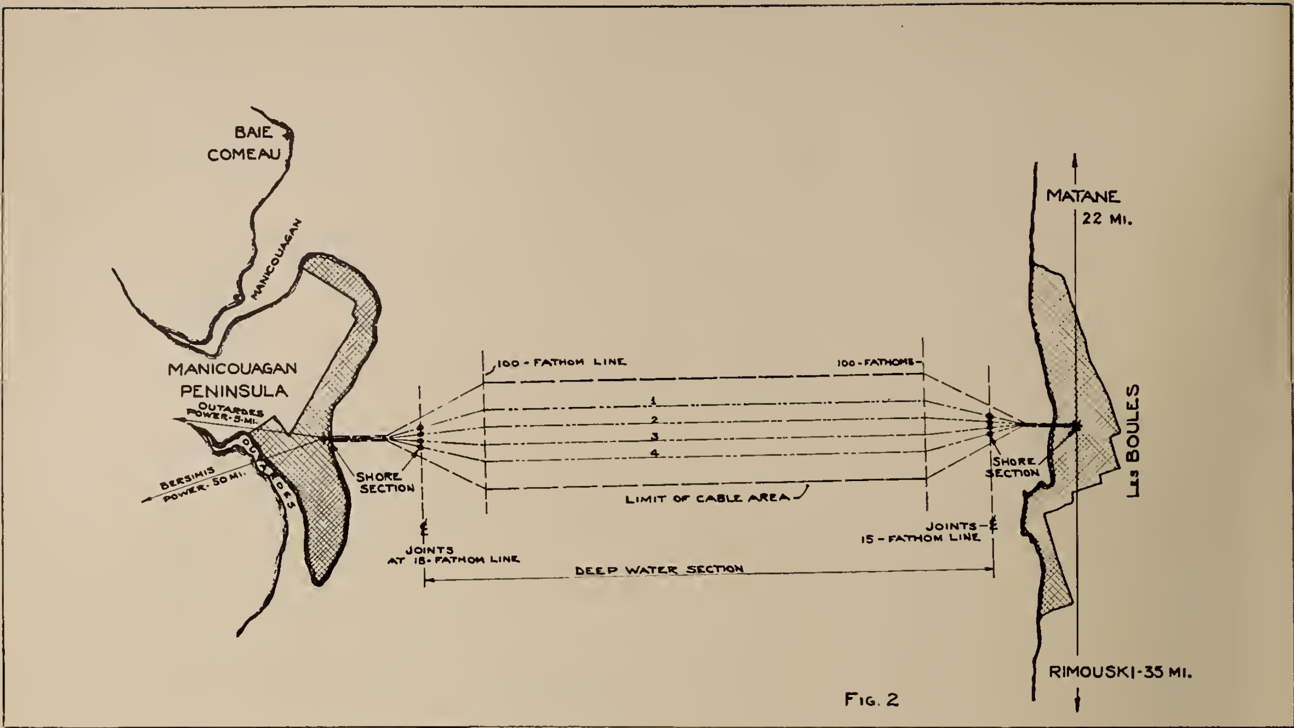


Fig. 2. Map of the site investigated and the cable routes chosen.

The senior captain of the consultants on the laying of the cables viewed the site, and the consultants considered the site suitable.

The site closely investigated and the cable routes chosen are shown in Fig. 2.

Cable Design

The voltage chosen was 69 kv., grounded neutral.

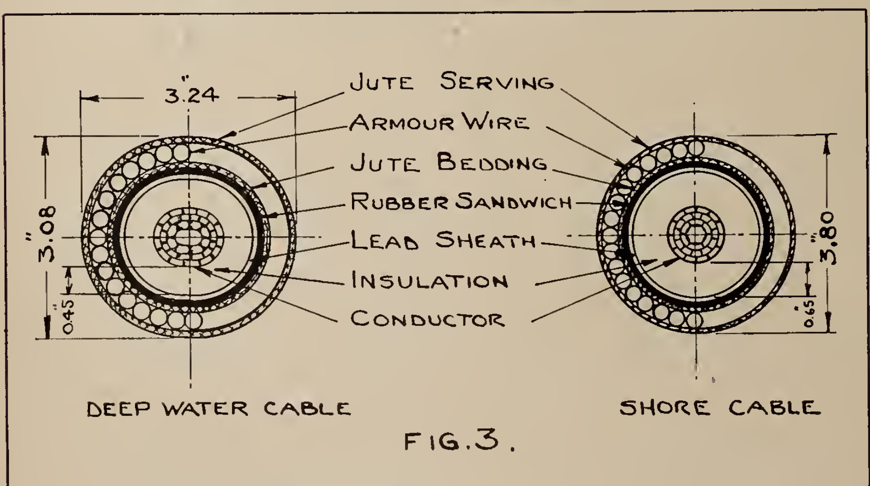
In the design of the cable it was obvious that advantage should be taken of the high external pressures inherent throughout most of the cable route. Insulation thickness was adopted for deepwater section appropriate to a minimum external pressure of 50 p.s.i. (that about 2½ miles off shore) and was chosen as 0.450 inch. An oval cross section was chosen in order to reduce a risk of fatigue due to load cycles working the lead sheathing.

Rather than introduce three cable types, the shore section cables (from about 2½ miles off shore to the terminal structures) were based on "on shore" conditions of ambient temperature, thermal dissipation and absence of external pressure—i.e. a conventional "solid" type 69 kv. directly buried in the earth.

The two types of cable adopted were in detail as in Table III. and are illustrated by Fig. 3.

Aluminum alloy of a type highly resistant to salt water attack was chosen for the armouring rather than steel wire, due to its better electrical and non-magnetic characteristics and its much lesser weight.

Fig. 3. Illustration of the types of cable adopted.



The electrical and magnetic properties of the armour wire are of importance since these are single conductor cables on an alternating current circuit, and induced sheath currents are permitted to flow, the sheaths and armour of each cable being bonded together at approximately three-mile intervals and the sheaths and armour of all cables being bonded together and grounded at each end of the crossing.

The manufacturing problem was one of producing the deepwater cable in four lengths each approximately 150,000 ft. long, and the shore sections in six lengths averaging 15,000 ft. each, and in a position from which they could be loaded into a cable ship.

It was decided that the cable up to and including lead sheathing should be manufactured in the longest lengths reasonably practical from the viewpoints of: (a) handling, and (b) testing at service frequency (i.e. 60 cycles), then shipping to a site on the lower St. Lawrence for splicing together, applying of protective coverings and armour, and coiling down adjacent to a cable ship berth.

The site chosen for the armouring plant was the wharf at Rimouski. A suitable building was erected; a large armouring machine and a wire drawing machine for drawing the aluminum alloy armour wire were installed. External to this building a temporary steel structure was erected, 70 ft. in height and 500 ft. long, with an enclosed gallery on the top into which the cable was fed by haulage gear from the main armouring machine capstan, and along the gallery to the appropriate coiling bay.

This arrangement is illustrated by Fig. 4 (taken when preparing for loading the cable ship).

This method of producing long lengths of submarine cables depended on design of a suitable splice.

Such a splice required to be: (a) of outside dimensions close to that of the lead sheathed cable itself; (b) of mechanical strength close to that of the conductor; (c) of electrical strength close to that of the factory applied insulation; and (d) of flexibility close to that of the cable.

Such a splice was designed and utilized in the cable. This development itself is of outstanding importance. It permits the choice of any type of extra-high voltage cable insulation for use in extra long length submarine power cables. It also permits the cable proper to be subjected, prior to splicing, to all the usual service frequency and over-voltage tests normally demanded by standard specifications.

Fig. 4. Withdrawing deep-water cable from coil No. 1. End of armouring plant in background. Fig. 5 (below) Splices between shore ends and deepwater sections of cable.

Subsequent tests on joints subjected to the numerous bends during flaking down, loading in the cable ship, laying in deep water, lifting back into the cable ship and unloading on to the wharf (a total of at least fifteen to twenty flexures, some under heavy torsional stresses) showed large factors of dielectric strength and practicability of the design.

The splices between the shore ends and the deepwater sections were of a different design as it was not considered necessary that they should be flexible. These splices were made on a barge after picking up the buoyed ends of the previously laid sections. These splices are illustrated by Fig. 5. After completion the splice normally was lowered by slings from the side of the barge as the barge was traversed laterally, although the illustration is an instance of the joint being paid over the end of the barge.

As protection against ice, the shore ends were trenched in to a depth of two feet, out to a depth of six feet, below low water mark.

Additionally on the south shore end when the cables lay over a region of medium sized boulders and reef rock, it was protected until a depth of six feet below low water was reached by coverings of dry concrete in bags.

Also on the north shore where the cable leaves the water, it climbs a clay bluff subject to erosion by wave action. Here the erosion is arrested and the cable protected by a system of stone loaded timber cribbing.

The remainder of the cable on shore was trenched in and buried in the conventional "buried solid" method.

The terminals were of conventional 69 kv. design, were oil-filled, and require no comment.

The principal difficulties encountered in installation were due to several factors.

(1) The tidal currents being variable in direction and force, resulted in serious looping of the first shore length cable which had to be spliced and relocated. Also in one other instance one phase overlaid another and required re-laying.

(2) Heavy weather delaying operations. In one case the side effects of hurricane Carol built up so quickly that the tug and barge became unmanageable as the last 200 feet of a shore length was being laid, resulting in that length fouling other buoy anchor lines and injuring that part of the cable, necessitating an additional joint.

(3) A tendency of the North Shore bottom to scour due to tidal currents caused a cable end mushroom anchor not to hold, resulting in a kink in the cable.

(4) Fog delayed the cable laying operations.

(5) The power content in the induced voltages between the armour and sheath due to the charging currents in single conductor cables of this voltage in a distance of over thirty miles was sufficient to burn a hole in the lead sheath, resulting, after moisture access, in a phase to ground failure. This was overcome by bonding together the sheath and armour every three miles. This reduced the power content at any one point from about 15 kw. to about 28 watts, a value too low to injure the sheath.

(6) Unusually heavy storms in the area twice resulted in the temporary plant on the Rimouski wharf being damaged by heavy seas coming over the wharf and smashing part of the building as well as sinking a dredge in the loading area. Fortunately, neither seriously delayed operations, although inconvenient and expensive.

Final repairs were effected in 1955 and the cable placed in successful operation on November 13th, 1955.

The timing of the project was approximately as follows:—

Table III.—Types of Cable Adopted

	Deepwater Section Oval	*Shore Section Round*
Conductor		
Area (C.M.)	500,000	1,000,000
Stranding (Compack)		
long diam.	0.826 in.	1.060 in.
short diam.	0.666 in.	
Insulation thickness	0.450 in.	0.650 in.
Lead thickness	0.105 in.	0.115 in.
Protective covering over lead	Bitumized rubber sandwich	
Armour	Aluminum alloy 29/0.296 in.	
Protective jute over armour	2 jute servings	
Overall diameter	3.24 in. x 3.080 in.	3.80 in.
Weight/ft.	10 lb.	15 lb.
Total installed length	595,000 ft.	136,000 ft.
" " weight	5,950,000 lb.	2,040,000 lb.

May 1951 — first discussions and studies

Nov. 1951 — tenders received.

Dec. 1951 — letter of intent issued by Quebec Hydro-Electric Commission.

Jan. 1952 — Manufacture of first experimental lengths started at Leaside.

Jun. 1952 — Prime contracts awarded to Canada Wire and Cable Company Limited.

Dec. 12, 1952 — Manufacture of first production length started at Leaside.

Apr. 28, 1953 — Armouring and splicing started at Rimouski.

Jul. 17, 1954 — Cable ship *Monarch* arrived Rimouski.

Aug. 7, 1954 — Laying of deepwater sections completed.

Aug. 20, 1954 — Laying of shore sections completed.

Oct. 3, 1954 — Kedging anchor area splicing completed.

Oct. 9, 1954 — Open circuit discovered.

Oct. 28, 1954 to Dec. 3, 1954; July 15, 1955 to Nov. 13, 1955: Repairs employing cable ship *Lord Kelvin.*

Nov. 13, 1955 — System placed in operation.

Acknowledgments

In charge of the project were D. M Farnham, for Hydro-Quebec, and H. D Short, for Canada Wire and Cable Company Limited who were also prime contractors for cable and accessories and for installation. Consultants were G. B Shanklin, the General Electric Company; Dr. P. A. Bricout; and The Telegraph Construction and Maintenance Co. Ltd.

Contributed by the ASME Petroleum Division for presentation at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June, 1957

A GAS PIPELINE in operation is in essence a pressure vessel when one considers that within a hundred miles of line (between compressor stations) there are over 13,000 pieces of 40-ft. length pipe involving over 31,000 tons of steel for a 30-in. diam. line. It is therefore interesting to consider the literature on pressure vessels with this in mind.

An excellent article was prepared by Prof. L. J. McGeady[1] of Lafayette College for the Pressure Vessel Research Committee covering the effects of temperature on pressure-vessel steels in the range from +32° to —50°F, with particular emphasis on transition-temperature behavior. This article contains a bibliography of important literature references.

The data of MacKenzie[2] from McGeady's article is plotted in Fig. 1 to show the range in transition temperature obtained from 68 heats of semi-killed and rimming steel rolled to different plate thickness. MacKenzie's data covered plates 0.4 to 1.5 in. thick. In Fig. 1 we have added the results from the Armour Research Foundation (ARF)[3] report to the American Gas Association (AGA) on transverse and longitudinal 2/3 standard size Charpy vee-notch-impact tests taken from 198 heats of API Grade X52 steel expanded line pipe produced by six pipe manufacturers in sizes 20 to 34 in. diam. and from 0.281 to 0.375 in. wall thickness. ARF used 10 ft.-lb. as the transition temperature and obtained a spread of —30° to +74°F with a mean of +34.9°F for transverse specimens from 198 different heats of steel. The longitudinal specimens from 53 heats of steel had a spread in transition temperature of —50° to +45°F with a mean of —4.5°F. It is observed that the extension of the plotted line for average transition temperature at 10 ft.-lb. obtained from MacKenzie's data runs through the point for the mean transition temperature for X52 grade steels of 0.281 to 0.375 in.

Fig. 1 shows that an increase in rolled-plate thickness from 0.3 to 1.5 in. results in an increase of the Charpy vee-notch transition temperatures of 5.5°F per 0.1 in. increase in plate thickness. This figure shows agreement with Vanderbeck's data[4] on rolled plate of ½ to 1½ in. thickness reported as an increase in transition temperature of about 20° to 40°F per ½ in. increase in thickness in several varieties of steels.

ARF in its report to AGA comments as follows: "Under most service conditions overstressing causes steel to yield in a perfectly normal manner. If the stress continues to increase, the steel eventually fails by separation along active slip planes after a large amount of shear deformation has been introduced. Because of the large amount of deformation preceding fracture the energy absorbed is high. Under other conditions, overstressing the same piece of steel results in sudden fracture of the piece by cleavage, with little or no shear deformation preceding failure. The energy absorbed is much lower. The conditions favouring cleavage failure are known in a general way. Low temperatures, high concentrations of triaxial stress, and rapid application of stress (shock loading) all tend to increase the probability of cleavage failure of a given specimen of steel. If a group of different specimens of nearly identical strength properties is investigated, the ease with which cleavage failure can be induced generally will vary from specimen to specimen. This variability has been found in many investigations to be related in a complicated way to chemical composition and microstructure. It is also known that differences in the manufacturing process can influence the variability[5].

No discussion on brittle fracture of steel would be complete without reference to the work at the U.S. Naval Research Laboratory by W. S. Pellini, P. P. Puzak, and others.

Mr. Pellini presents a convincing story and has the only explanation which, at this time, can be used to fit together the tests which have been made to determine the tendency toward brittle behavior of ferritic steel. His viewpoint has considerable support and until a better one is found or until facts can be presented to

---

This is Part II of three papers dealing with flash-welded line pipe. It discusses the concepts of brittle fracture for 0.20%-0.30% carbon medium manganese steel. Part I, published in The Engineering Journal, *Jan. 1958, pp. 60-71, described the manufacture of flash welded line pipe, the research facilities required, and metallurgical properties. Part III follows this paper* *on page 64 of this issue.*

prove him wrong, his thinking will influence design for a large percentage of fabricated structures over ½ in. in thickness of ferritic materials.

We will examine some of the concepts that Pellini has presented and see how they fit large-diameter line pipe for low-temperature services.

General Considerations of Brittle Fracture

(1) Brittle fracture of structures operating at 0°F and higher is a serious problem at this time only in thicknesses of ¾ in. or more. In tests made on 68 heats of steel the British have shown that at 0.4-in. thickness the 10-ft.-lb. transition is —24° to +45°F. For thinner sections of hot-rolled steel the transition from ductile to brittle behavior is increasingly lowered. ARF reports —50° to +45°F with a mean of —4.5°F for 0.281 to 0.375 in. expanded line pipe.

(2) Pellini and his group are not advocating a demand for notch ductility unless service failures demand it or unless the operating risk is so great that no possibility of failure can be tolerated. Critical locations in atomic-energy plants and certain military applications are an example of the latter. It is recognized that specification of notch ductility in carbon steel is expensive and would cripple our steelmaking capacity* greatly if used indiscriminately[6].

Ductile failure in structures is no problem for it seldom occurs. If it does occur it is due to poor engineering design or overloads. Brittle fracture, since it occurs at stresses below design stress, is dangerous and, if economical methods can be found which will avoid it, most assuredly those methods will find wide acceptance.

The best known and most used test method of determining brittle behavior is the Charpy vee-notch-impact test. The actual energy absorbed is a variable for comparing different steel types. The type of fracture is the criterion. For example, a malleable iron with 8 or 10 ft.-lb. energy in the standard Charpy vee-notch test may break in shear at this energy level. On the other hand, a heat-treated alloy steel may be considered unsatisfactory at its 35 to 45-ft.-lb. temperature in the same test if the fracture is by cleavage.

The concept of ductility transition and fracture transition was described by the Lehigh group in 1948. The stress necessary to propagate brittle fracture, about 5000 psi, in mild steel was separately arrived at by Robertson in England and Feely of the Esso Research and Engineering Company in the U.S.A. The Naval Research Laboratory's contribution has been a formulation of these various studies and correlation of the Charpy vee with all the other fracture-test specimens.

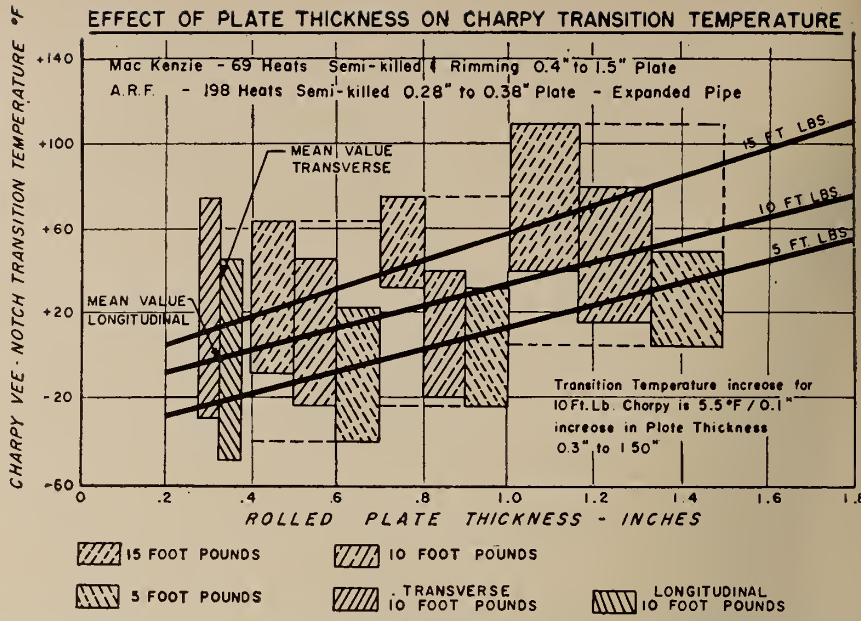

Fig. 1. Relation of Charpy transition temperature with plate thickness of mild steel and semi-killed steel.

Definition of Terms Used to Describe Transition Temperature

The nil ductility transition (NDT) is that temperature below which minute plastic deformation cannot be developed in the presence of a sharp crack defect. Under even nominal elastic loads in the presence of a sharp crack, brittle fractures can initiate at or below the NDT temperature. Fracture transition is defined as follows: FTE (fracture transition for elastic loading) is that temperature below which fracture may propagate easily through elastic-load regions (virgin material) but above which propagation is possible only through cold-worked (deformed) material; e.g., below FTE, fracture will not initiate under nominal elastic loads but will require the forcing (plastic deformation) to get it started. However, once started below the FTE temperature, propagation is possible even though the remainder of the structure is under nominal elastic loads. Above the FTE temperature forcing is again required to initiate brittle fracture but propagation is confined solely to plastically deformed regions. FTP (fracture transition for plastic loading) is defined as that temperature above which only shear tearing is possible irrespective of conditions of loading.

The Robertson and Feely tests do not indicate that 5000 psi is necessary to initiate brittle fracture in the presence of a sharp crack, but instead, that nominally elastic loads as low as 5000 psi are sufficient to maintain fracture propagation at temperatures below the FTE, which is equivalent to Robertson's crack-arrest temperature (CAT) and the Feely Esso brittle temperature (EBT).

Metallurgical Concepts

(1) The "brittle-fracture" concept explained by Pellini applies only to ferritic steel. For example, copper, aluminum, and austentic steel do not fail in cleavage.

(2) The ductility and fracture transition may be related to the Charpy vee-notch performance. The actual foot-pound energy measured in the Charpy test is meaningless except for one specific composition and heat-treatment. The shape of the transition curve must be established.

(3) Brittle fracture has no directionality sense. The energy absorbed in the Charpy vee-notch test will vary according to specimen orientation with respect to rolling direction, but the shape and transition features of the curve will not show directionality effects.

(4) There is no difference, in so far as transition temperature is concerned, between cast and wrought alloys if composition is the same and a crack exists. If no crack exists the

---

*15 million tons/year is the capacity of USA for killed steel.

ductility transition of the wrought plate may be lower than the cast plate because fewer material (metallurgical) cracks exist in the wrought material.

(5) Transition temperature is structure sensitive and it is believed that the thinner material is more resistant to brittle fracture because of the greater working which it receives. It is Pellini's opinion that the nickel steels are useful in low-temperature work mainly because of their extremely fine grain size. Research[7] indicates that smaller ASTM grain size lowers the transition temperature. Doubling the number of ferrite grains (corresponding to an increase of one grain-size number on the ASTM scale) by heat-treatment causes approximately 25°F decrease in Charpy vee-notch transition temperature.

(6) Phosphorus and carbon raise the ductility transition temperature. Silicon raises it when greater than about 2 per cent. Manganese acts to lower the ductility transition.

(7) Generally, welds have a lower ductility transition than comparable plate stock.

(8) Cleavage strength is not sensitive to temperature. Shear strength is sensitive to temperature, rising rapidly as the temperature of ferritic steel is lowered. One can force cleavage failure by lowering the temperature or introducing a stress concentration or both. Lowering the temperature acts to cause a cleavage fracture by increasing the shear strength above the cleavage strength with the result that failure is by cleavage. A crack acts to cause brittle behavior because a small area under high stress is surrounded by a large area under relatively low stress. This acts to discourage slip or shear, thereby raising the shear strength. The point is made that the maximum stress at a sharp crack position under uniaxial loading is three times the nominal uniaxial yield stress. Thus it is inferred that the maximum effective stress concentration factor is 3.*

Table I—Average of Armour Research Foundation Tests

Charpy Transition Temperature, deg. F. Based on 10 ft.-lb., 2/3 standard Charpy vee-notch bar		Fracture Transition Temperature, deg. F. Based on 50% shear fracture on Charpy specimen	
Longitudinal deg. F.	Transverse, deg. F.	Longitudinal, deg. F.	Transverse, deg. F.
−2	+32	+50	+58

(9) The NRL uses the explosion-crack starter test to determine the fracture-transition temperature. The drop-weight test[8] also establishes the NDT temperature. For one given steel, the NDT temperature found by either the explosion-bulge test or the drop-weight test is essentially equal. Since the speed of the two tests differs greatly but the same NDT temperature is established in both tests, it is concluded that in the presence of the cleavage cracks developed in the crack-starter weld, the rate of application of load has no significant effect on the NDT temperature. In both the drop-weight and explosion-crack-starter tests, the same hard-facing weld deposit is used to initiate the sharp crack which develops at the moment the surface fibers of the test specimens reach incipient yield-stress conditions.

Mechanical and Design Concepts

The design concept offered by Pellini and the Naval Research Laboratory group is a method of design to guard against brittle fracture. It is a consideration in only certain specific cases, as for instance when:

(a) The operating risk is so great that no possibility of failure can be tolerated.

(b) Thickness is over ½ or ¾ in.

(c) Material is ferritic steel or iron.

(d) Temperature of service is below 180°F (depending on the material).

(e) Sharp notches must be present.

Figure 2 shows the nil-ductility range for a number of steels and iron. There are four possibilities which a designer should consider before using the values in Fig. 2.

(a) If the consequences of a brittle failure are not important obviously it is not necessary to use it as a design criterion.

(b) Below the nil-ductility-temperature range in the presence of a sharp notch or crack a brittle fracture can initiate and propagate at a nominal stress of 5000 psi.†

(c) From the nil-ductility range to a temperature of approximately 40 or 50 deg. F above this range a sharp crack cannot initiate brittle fracture under nominal elastic loads, but if forced (plastic deformation) it can propagate.

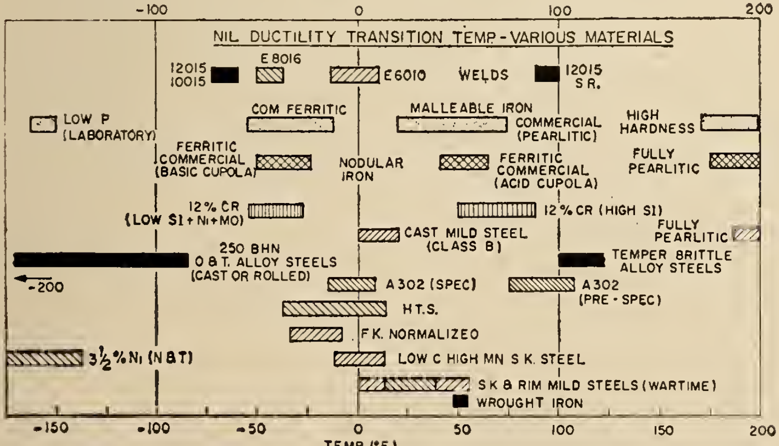
(d) At 100 deg. F above the nil-ductility transition, fracture is entirely shear.

Discussion of Pellini's Concepts

Of interest to pipeline engineers should be statement (3) of Metallurgical Concepts. We took 53 heats of expanded X52 grades steel line pipe and compared the Charpy transition temperature for longitudinal and transverse direction to rolling. An average of the ARF tests revealed the results in Table I.

The maximum energy in foot-lb. for longitudinal direction was 44 ft.-lb. as compared to 25ft.-lb. for the transverse direction. Better agreement in the transition temperature for longitudinal and transverse direction is obtained by the criterion of 50 per cent shear on the fracture surface of the Charpy bars. Fracture transition temperature (50 per cent cleavage) is very insensitive to specimen type or geometry, wheras ductility or energy transition temperatures are quite sensitive to these variables. The average

Fig. 2. Nil ductility range for steels and irons (from Pellini).



---

*From the work of Orowan, Felbeck, and others at Massachusetts Innstitute of Technology, Cambridge, Mass.

†From Robertson and also Esso Group.

values indicated in Table I should be compared with mean transition temperatures of minus 4.5°F (longitudinal) and +34.9°F (transverse); the former from 53 heats, the latter from 198 heats.

information can be translated into formulas and tables of value to the designer.

Pellini[8] and Puzak have developed a test at NRL, now widely used for guidance by the Bureau of Ships, called the drop-weight test. The test operates on the principle that a steel which is unable to develop a small amount of deformation below a certain temperature (NDT—nil ductility transition temperature) in the presence of a sharp crack, is potentially capable of experiencing catastrophic failure in service below that subject temperature.

Table II—Charpy Tests of AWS E7010 Weld Metal *

Temperature of test	75°F	0°F	−50°F	−75°F	−100°F
Vee notch	40.0	23.5	12.0	15.6	4.2
	42.1	25.6	17.9	13.5	12.9
	42.2	30.2	15.2	16.7	14.1
Keyhole notch	21.9	19.0	17.9	17.2	15.4
	20.7	19.4	21.3	3.0	16.5
	22.5	20.3	16.1	18.2	19.2
Ratio keyhole/vee	0.52	0.74	1.23	0.84	1.63

* Electrode developed especially for pipeline welding

Concept 4 poses an interesting problem for the chief inspector on pipelines for the field girth seam and longitudinal seams of arc-welded pipe. Barkow and Strong [8, 9, 10] have reported good articles on the control and inspection of line-pipe welding.

The Charpy transition temperature for AWS E7010 electrodes developed especially for pipe-line welding used on girth seams of 30-in. x 0.375-in.-wall line pipe X52 grade steel gave the vee-notch and keyhole energy values in Table II; e.g. 5/32 in. diameter for the stringer or root bead and hot pass, and 3/16 in. diam. for the filler layers. Welding technique was standard linepipe welding procedure, interpass temperature 190°F maximum. Charpy tests, 2/3 standard size 0.263 in. x 0.394 in.

The ratio of area below the notch keyhole/vee=0.625. (Table II)

Concept 5 is certainly of interest to mechanical engineers as it is true that while a great deal of study has been devoted to cleavage failure of steel, it is unfortunately true that little of this

Table III presents data reported by NRL* of more recent investigations of casualty material from a number of sources.

From a consideration of the mechanical and design concepts listed previously, four possibilities are presented to the pipeline design engineer to avoid possible brittle fracture in service.

It is obvious that the design engineer cannot limit line-pipe stresses to 5000 psi, so according to Pellini, brittle fracture will initiate and propagate from a sharp notch below the NDT transition (approximately 10 ft.-lb. Charpy vee notch for rimming and semi-killed steels).

Mr. Pellini states that a crack cannot initiate brittle fracture if the service temperature is about 50 deg. F above NDT but if forced will propagate. Epstein[11] states that generally the 15 ft.-lb. vee-notch Charpy transition temperature occurs at about 35 deg. F higher temperature than the 15-ft.-lb. keyhole Charpy transition temperature. This is the basis for the somewhat widely accepted Charpy keyhole value of 15 ft.-lb. Similarly, Charpy vee-notch value of about 5 ft.-lb. to 10 ft.-lb. correspond to about 15 ft.-lb. keyhole value[12].

Of most importance, we believe, is our generalization for semi-killed steel: that to obtain 100 per cent shear fracture, the service temperature must be at least 100 deg. F over the toughness temperature required to prevent nonductile crack propagation.

From a study of many temperature-transition-Charpy vee-notch curves, there is a definite correlation in the 100 per cent shear-fracture transition temperature and the so-called upper plateau of the impact transition curve. The upper plateau of the impact transition curve correlates in temperature to Pellini's value of NDT plus 100 deg. F for shear.

In the ARF report on expanded X52-grade steel line pipe, adding 100 deg. F to the mean value of +34.9 for Charpy transition temperature would give a temperature which always produced 100 per cent shear fracture and was on the upper plateau of the impact-transition curve. There is no doubt then that if the pipeline engineer desires to have a ductile shear-type failure in present-day expanded X52 grade steel line pipe this

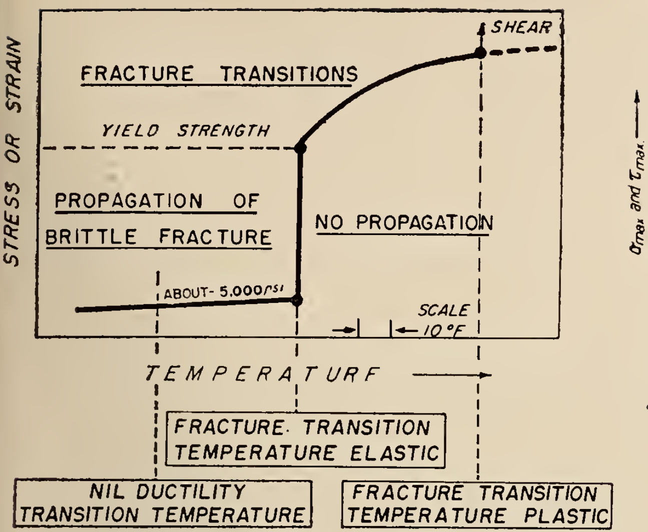

Fig. 3. Summary of metallurgical concepts for brittle fracture in steel (from Pellini).

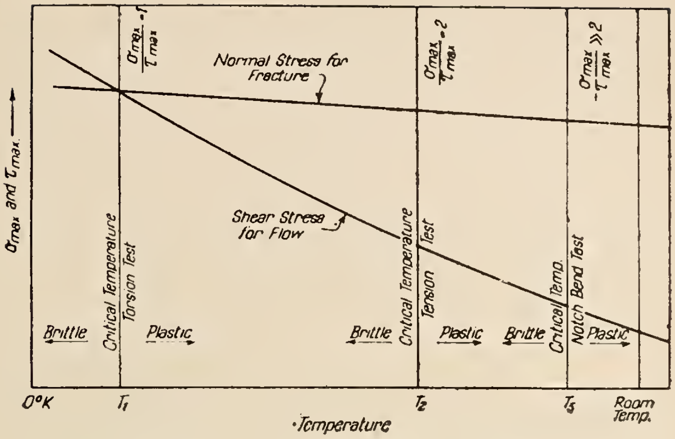

Temperature dependence of critical flow stress and critical fracture stress. The brittle temperature in several tests. The brittle temperature comes where: $\frac{\text{shear stress for flow}}{\text{normal stress for fracture}} = \frac{\tau \text{ max. in test}}{\sigma \text{ max. in test}}$

Fig. 4. Effect of temperature on fracture of steel in tension, torsion, and notch bending (from "Strength of Metals under Combined Stresses", by Dr. M. Gensamer).

can be obtained only with the steel heated to 140 to 180°F.

Summary

To summarize, the metallurgical concepts presently held for brittle fracture in steel can be graphically presented in Fig. 3 showing a typical curve for a mild steel with the stress and temperature necessary to propagate a fracture.

The point of the fracture transition shifts up or down in temperature depending on deoxidation treatment, steelmaking practice and on rolled plate thickness.

The curve is obtained as follows: A plate 6 in. wide is gripped in a testing machine under a series of temperature and stresses. A small sharp crack is forced to initiate at one side of the plate. At any temperature below the fracture transition the crack will proceed across the plate with no measurable deformation at a stress of about 5000 psi. Above the fracture transition temperature the crack will not propagate until the load is over the yield strength of the steel. This type of curve was developed by Robertson in England and by the Esso Standard Oil Development[13] group in the U.S.A.

The nil-ductility transition temperature shown is obtained from either Charpy tests, drop-weight test or explosion-bulge test.

Prof. Maxwell Gensamer, Columbia University has prepared an excellent treatise for engineers in his series of educational lectures entitled "Strength of Metals Under Combined Stresses."*

*Copyright 1941, American Society for Metals, Cleveland, Ohio.

As an illustration of the effect of temperature in making a metal become brittle in tension, compression and torsion, Fig 4 shows schematically how the relative temperature dependence of resistance to flow and to fracture predicts such behavior. Whether or not the metal will be brittle or ductile depends on whether it first reaches the maximum normal stress required for fracture or the maximum shear stress required for flow. For example, at a sufficiently high temperature, the maximum shear stress required for flow is so low that under almost any condition of loading it will be reached before the maximum normal stress reaches its critical value, so in almost any test a metal will be ductile at high temperatures.

As temperature is lowered, the shear stress required for flow increases, while the normal stress for fracture changes very little, so that as the temperature is lowered the danger of brittle failure becomes greater.

Of the three tests shown in Fig 4, the notch-bend test provides the greatest ratio of maximum normal to maximum shear stress, and it is generally the case that as the temperature is lowered metals become brittle in the notch-bend test before they lose their ductility in tension or twisting. The danger of brittle behavior is expected to be greater in tension than in twisting, and it is true that at low temperatures metals may be brittle in tension but retain their ductility in torsion.

There is no mystery in obtaining 100 per cent shear-type fracture in a steel structure with the knowledge we now have of the transition temperature on steel. If the pipeline engineer wants to operate steel at 0°F and desires to have a notch-ductile steel at that temperature which will always fail in shear, he is going to have to pay the price for specially alloyed, heat-treated steel with a Charpy transition temperature of at least —100°F and a value of something between 20 to 25 ft.-lb. Charpy vee-notch energy depending on whether the steel is hot-rolled or heat-treated.

WITH THE THOUGHT expressed by company engineers that burst tests of X52 steel at subzero temperatures would contribute to the knowledge of the performance under low-temperature conditions, line-pipe tests down to —50°F were conducted. The results were compared with more than 2000 burst tests at atmospheric temperatures of all sizes and grades that had been manufactured by the company since 1927.

In order better to compare the performance of pipe under hydrostatic burst conditions at —50°F with pipe at a temperature where 100 per cent ductile shear fracture was assured from transition-temperature data a single test was performed at +180°F.

Test Procedure

The following procedure was used in cooling the test pipe to the desired temperature. After the entire system was filled with brine the brine tank of 750 gal. capacity was cooled by the addition of dry ice, and the cold brine was circulated by means of a pump through two accumulator pipes connected in series having a total capacity of 120 gal. and then to the test pipe which had a capacity of approximately 550 gal. and back to the brine cooling tank. A schematic diagram is shown in Fig. 1. After the test pipe had attained the uniform desired temperature, as determined by thermocouples cemented to its outside diameter, circulation of the cold brine was stopped. The burst test was accomplished at the desired temperature by pumping brine at atmospheric temperature from the measuring column (water column) with the high-pressure pump into the closed system. This forced only refrigerated brine from the accumulator pipe into the test pipe. Approximately 6 hr. were required to cool the test pipe uniformly to minus 50°F.

This is Part III of three papers dealing with flash-welded line pipe. It discusses several burst tests conducted down to —50°F. and compares them with similar data for ambient temperature. Ductility developed in burst tests at the different temperatures was comparable. Part I of the series The Engineering Journal, *Jan. 1958, p. 60) dealt with manufacture of flash-welded line pipe, research, and metallurgy. Part II is on p.59, this issue.*

The calcium-chloride brine was made up to a specific gravity of 1.260 at plus 60° F which resulted in a freezing point of approximately minus 60°F. Flake $CaCl_2$ amounting to 5.1 lb. per gal. of water was used to arrive at the desired specific gravity and the solution was inhibited with 20 lb. of sodium dichromate per 1000 gal. of solution.

The temperature rise of the test pipe during a burst test which was of approximately 30 min. duration was determined as 5°F per hr. after circulation of the refrigerated brine was stopped. This low rate was attained because of the frost insulation and the confinement of the pipe in the test pit.

The burst test at plus 180°F was accomplished by using the foregoing system with water. The water was heated in the mixing tank by direct admission of steam and the resulting hot water was circulated through the accumulator pipes and the test pipe.

Chemistry

Chemical analyses taken from each pipe are given in Table I. The carbon equivalent, C+Mn/4 ranged from 0.495 to 0.585 and had no apparent effect on the performance of the individual pipe in the burst tests or the notch bar tests. Little, if any, effect can be noted of the carbon equivalent on the other mechanical properties.

Transverse Charpy vee-notch tests were made on each of the pipes tested in this program. The results of these conducted over a range of temperatures from minus 100° to +212°F are presented as Table II and are plotted as transition curves in Fig 2. It will be noted that the transition temperature is consistent between 32° and 60°F.

The results of strip tensile tests, both longitudinal and transverse are presented in Table III. The results of these tests meet the requirements of X52 pipe.

The results of the burst tests are presented in Table III and the water-column curves of the burst tests are attached as Figs. 3 and through 9.

Discussion of Results

Test A-1

Test A-1 was made on a 15-ft. length of X52 line pipe 26 in. diam. by 0.500 in. wall thickness with welded-on flat heads. The pipe was removed from storage at the Milwaukee Works and the flat heads were obtained from stock. The pipe was cooled to minus 3°F and the burst test was completed with a final temperature of 0°F. In the preliminary discussions of pipelines to be located in the colder regions of Canada it was estimated that the majority of the line could be at a temperature 0°F. The yield strength of the pipe was obtained from the pressure at a volumetric set of 0.2 per cent as measured by the water column and the ultimate strength was calculated from the burst pressure. The Barlow formula was used in calculating these values. The yield and ultimate strength thus determined compared favorably with the transverse-strip tensile tests. The circumferential stretch as measured after burst was an average of 3.91 in. In a survey of 1200 burst tests made at normal atmospheric temperatures the average stretch in ¼ to ½-in. wall pipe was 2⅝ in. after burst.

C.	0.92	0.04	0.05	0.09	0.01	0.01	0.28	0.01	Nil	Nil

The length of burst was approximately 6 ft. with origin of fracture ¾ in. from the longitudinal weld seam. The pattern of fracture is as shown in Fig. 10. The fracture surface was cleavage in nature with chevrons pointing to the origin. The ductility, fracture pattern, and fracture surface were comparable to those exhibited by the many burst tests made at atmospheric temperatures (60° to 100° F).

Test A-2

Test A-2 was made on the other half of pipe A, again with flat heads. The pipe was cooled to minus 50°F and the burst test was completed with a final temperature of minus 48°F. A comparable yield strength to test A-1 was reached. However, the girth weld of the heavy flat head fractured before the ultimate strength of the pipe steel was realized. The bending stress at the root of the integral chill design due to stretching of the pipe caused premature failure through the girth weld. Fig. 11 is a view of this test. An average circumferential stretch of 0.63 in. was measured after the head was torn off. Eighteen inches were removed from the failed end of this pipe and semi-elliptical ASTM A212 Grade B heads were welded on and the pipe was retested as test A-2-1.

Test A-2-1

Test A-2-1, a retest of test A-2 was conducted with the pipe cooled to minus 49°F with a final temperature of minus 46°F at burst. The yield strength as measured by water column at 0.2 per cent volumetric set was increased approximately 6000 psi by the cold expansion of the previous test. The ultimate bursting stress as calculated was approximately 2000 psi higher than test A-1 on the other half of this pipe. An additional average 3 in. of circumferential stretch was produced in this test which again is normal ductility for similar pipe tested at atmospheric temperature. The additional cold expansion of the previous test has not impaired the ductility of this pipe as measured by the low-temperature burst test. The failure started ½ in. from the longitudinal seam near one end of the pipe and crossed this weld several times before encircling the pipe 5 ft. from the end and progressing into the head as shown in Fig. 12. The fracture surface was cleavage in nature with chevron markings.

Test C-1

Test C-1 was made on a 15-ft. length of X52 line pipe 30 in. diam x 0.344-in. wall received from customer storage in the Southern Illinois area. Semi-elliptical heads were welded to this pipe and the pipe was cooled to minus 52°F (in preliminary discussion of pipelines to be located in the colder regions of Canada, it was estimated that approximately 10 per cent of a line could be at temperatures estimated at —50°F for approximately 6 months of the year) with a final temperature at conclusion of the test of minus 48°F. The pipe exhibited a high yield strength as measured by the water column at 0.2 per cent volumetric set. Even though the calculated burst strength was 97,000 psi, the pipe stretched circumferentially an average of 4.82 in. which is greater than average stretch experienced during normal burst testing at atmospheric temperature. In over 2000 burst tests surveyed the maximum stretch ever measured was 6 in. on a burst pipe at normal atmospheric temperature. Fracture originated ½ in. from the longitudinal weld seam as shown in Fig. 13. The fracture surface was of a cleavage nature with chevron markings.

Test C-1-2

Test C-1-2 was made on a 19-ft. length of the same pipe as tested in C-1. A circumferential weld was made using field welding procedures* staggering the longitudinal weld seams approximately 18 in. Radiographs revealed some evidence of lack of pene-

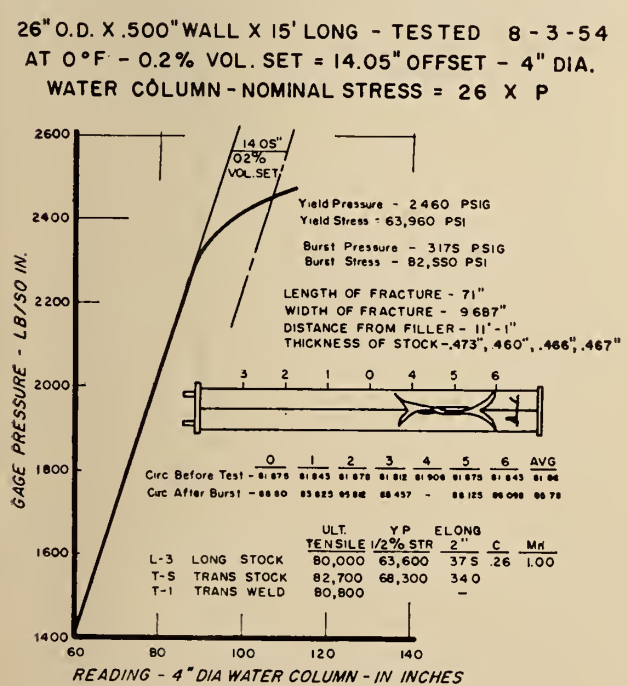
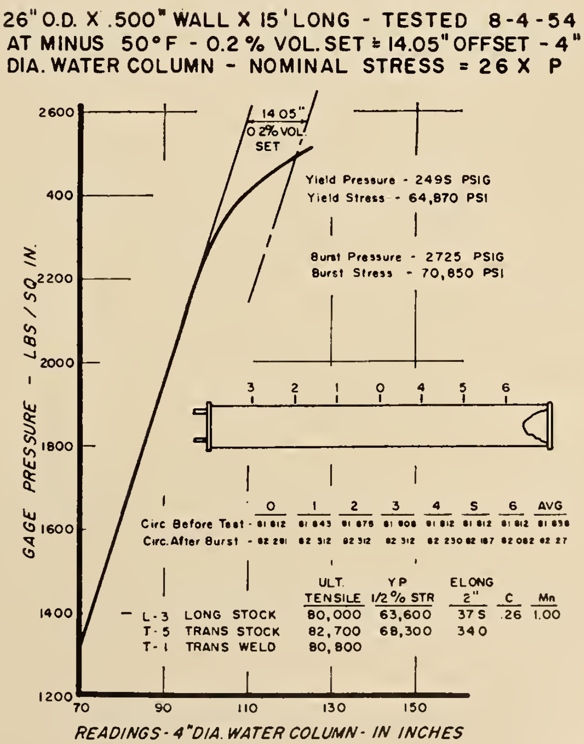
tration which was judged acceptable by Standard API 1104. Semi-elliptical heads were welded to this pipe. The pipe was cooled to minus 49°F and at completion of test the temperature was minus 46°F. Fracture started in the longitudinal seam 4 in. from field girth seam and ran into one head and, in the other direction, the fracture proceeded through the field girth seam and then encircled the pipe as shown in Fig. 14. The yield strength was equal to that determined in test C-1. The ultimate bursting strength was lower than that of the other end of this pipe (test C-1) but was 18 per cent greater than the minimum ultimate strength specified (72,000 psi). A circumferential stretch of 1.1 in. was recorded on both sides of the girth seam and ⅞ in. on the field weld. The fracture surface was of the cleavage type with chevron markings.

Test E-1

Test E-1 was made on a 15-ft. length of X52 line pipe 30 in. diam. x 0.500 in. wall with welded-on semi-elliptical heads. This pipe was shipped from customer storage in Southern Texas. The pipe was cooled to minus 50°F and a semi-elliptical tup weighing 750 lb. was dropped from

Fig. 3. Water-column curve of burst test on pipe A-1.
Fig. 4 (right). Water-column curve of burst test on pipe A-2.





a height of 13 ft.-4 in. to impart 10,000 ft-lb. energy to the pipe which was at a pressure simulating the working pressure. A saddle made from a cutout from a 30-in. x 0.344-in. wall pipe was placed at the point of impact to prevent gouging of the test pipe. The drop of the tup was made over the longitudinal weld seam of the test pipe. Extra-heavy pipe nipples with high-pressure valves were provided at both inlet and outlet of the test pipe so that working pressure could be maintained. The drop of the tup severely gouged the saddle with no apparent damage to the test pipe. Both extra-heavy nipples broke from the heads as a result of the impact with subsequent escape of the cold brine.

After the piping system was repaired the pipe was cooled to minus 50°F and a burst test was made. The temperature was minus 47°F at completion of the test. The yield strength as determined by the water column at 0.2 per cent volumetric set was several thousand psi higher than determined from transverse strip tensile tests which could be due to expansion caused by surge of pressure during the drop test. Even though the pipe was subjected to a severe shock at sub-zero temperature, the burst strength was 6 per cent above the minimum ultimate strength specified (72,000 psi). Fig. 15 is a view of this pipe. Fracture started in the longitudinal weld seam and progressed along the seam through the head until a section of the pipe was blown out. Fracture surface was cleavage with chevron markings throughout including the ¾-in-thick ASTM A212 killed-steel heads.

Test F-1

Test F-1 was made on a 15-ft length of X52 line pipe 30 in. diam. x 0.375 in. wall with welded-on semi-elliptical heads. It was desired to produce a shear-type fracture and a test temperature of plus 180°F was selected. The water in the tank was heated and circulated through the pipe until a temperature of plus 182°F was reached. At this point the burst test was started and final temperature at the completion of the test was plus 179°F. The pipe exhibited calculated yield and ultimate burst strengths nearly equal to those determined from transverse strip tensile tests. The circumferential stretch after burst averaged 3.0 in. Fracture started 4 in. from the longitudinal weld seam and is shown in Fig. 16. The fracture was characteristic of a 45-deg. shear type without chevrons.

Summary

It was determined that the data secured from burst tests of X52 grade line pipe at subzero temperatures was within the normal range of tests conducted at atmospheric temperatures. The pipe exhibited the same ductility when burst tested at subzero temperatures as at normal atmospheric temperatures. The fracture appearance after burst testing at subzero temperatures was cleavage with chevron markings the same as when tested at atmospheric temperatures. The carbon equivalent had no apparent effect on the performance of the individual pipe in the burst tests or the notch-bar tests. It is difficult to correlate the performance of the pipe with the Charpy vee-notch specimens of the material based on some arbitrary value of energy between the upper and lower plateaus of the energy-temperature transition curve, as measured by the Charpy vee-notch bar. It is significant that whether the pipe is to be in service at +40°F where there is the longest service record or at 0°F, the steel is on the lower plateau of the energy-temperature transition curve. To obtain shear-type fracture in the burst test the results of a single test at plus 180°F would indicate that the pipe should be at a temperature which is well up on the upper plateau of the energy-temperature transition curve. The average circumferential stretch of the pipe burst at plus 180°F was no greater than that obtained in atmospheric or subzero temperature tests. Shear-type fractures in semi-killed steels have not been obtained to date on line-pipe burst tests at atmospheric tempera-

tures. The field girth seam showed ductility as measured by the stretch during burst testing at minus 50°F. No attempt was made to place artificial notches in the pipe tested; however, in some of the pipe tested there were defects up to 12½ per cent of the wall thickness such as chain marks, score marks, and gouges due to handling which did not affect the test results. None of the pipe burst at 0° or —50°F had any tendency to shatter.

Based on the foregoing test results of flash-welded line pipe, together with several —50°F burst tests of special silicon-aluminum killed low-carbon steel and low alloy-high tensile proprietary steels*,† all submerged arc welded, we conclude the following:

Regardless of the Charpy transition temperature of the parent metal, of great differences between the longitudinal and transverse transition temperature (variation of +10° to +60°F at 10 ft-lb. for 2/3 standard Charpy vee-notch tests), the performance of all pipe tested was comparable and equivalent to burst tests made at normal atmospheric temperatures. All burst fractures were of the cleavage type with chevron markings, and no shattering occurred.

Ductility of the steel at —50°F is shown by the elongation or stretch of the circumference of the pipe tested. This amounted to more than 2.6 in. for the 20 in. x 0.375 in.‡ special killed steels, and over 2.6 in. for 26 in. x 0.500 in. and 30 in. x 0.344 in. flash-welded X52 grade steel line pipe. All pipe tested at —50°F developed in excess of the minimum mechanical properties of yield and tensile strength required for X52 expanded line pipe.

These facts give support to our

engineering judgment on the use of special low-temperature steels for low temperature service conditions. We believe that it is more economical to use commercial semi-killed steel of Grade X52 but to exercise greater care in the field operations of welding and trenching pipe than it is to procure, if possible, a steel which would insure more notch toughness as insurance against the bad defect in the field that can cause a blowout burst. This amounts to increased supervision and inspection prior to covering the pipe to prevent sharp, crack-like defects.

Fig. 15. Burst tested pipe E-1.

Fig. 16. Burst tested pipe F-1.

It has been stated in the many reports of the Ship Structure Committee that to replace all the steel necessary for the large shipbuilding program of World War II with hot-topped killed steel, with a lower transition temperature, would have been impossible because of the lack of facilities in the steel mills to make this quantity of killed steel properly.

The user of line pipe for low-temperature service should consider carefully the standards of inspection he is maintaining in the field to lay pipe —if these are not adequate from the concept of the metallurgical hazard due to the notch effect he would do his company great good by improving these standards accordingly.

Acknowledgments

In the preparation of the foregoing series of papers under the general subject of "The Metallurgy and Cold-Temperature Testing of Flash-Welded X52 Pipe," the authors wish to acknowledge the co-operation received from Mr. H. F. Detrick, vice-president in charge of petroleum products and for permission from the officials of the A. O. Smith Corporation to publish these papers. They also are indebted to many others who did much useful work in making this series of papers possible. We wish to especially thank the following: R. A. Huseby, metallurgical engineer, Research and and Development Division; H. Ebling, metallurgical engineer, Research and Development Division; W. Hoppe, mechanical engineer, Tubular Products Division; E. J. Limpel, director of Electrical Research, Research and Development Division; J. J. Chyle, director of Welding Research, Research and Development Division.

The F.N. Rifle

R. Patterson,

Technical Manager, Small Arms Division, Canadian Arsenals Limited.

The F.N. rifle was adopted by several nations as standard for service use, and its manufacture has been undertaken by various countries, including Canada. A major operation was the conversion from Belgian standards and drawings to Canadian practice. The paper indicates the complexity of the work involved. Similar problems might be found in the adaptation of other equipment from European standards.

FABRIQUE NATIONALE d'Armes de Guerre, Société Anonyme, is a private company, located at Herstal-lez-Liège, Belgium, which has specialized for many years in precision engineering products such as small arms, ammunition, A.A. guns, motorcycles, military vehicles, and so on, and has a long experience in dealing with government contracts of all kinds.

The Company was founded in 1889, by a group of Liége gunsmiths, to manufacture the Mauser 89 Rifle for the Belgian Army. Later on, this activity was extended to cover hunting and sporting weapons, and an agreement was entered into with the American inventor, J. M. Browning, for the manufacture of weapons of his design. It was thus that the first automatic pistol in the world came to be manufactured in the Fabrique Nationale (F.N.) factories at Herstal. This was followed by many other weapons of F.N. and Browning design, which were put on the market.

Modern warfare has brought about many changes in military tactics, necessitating the design and development of equipment, weapons and strategic stores to meet the altered role. With this thought in mind and with their wide experience Fabrique Nationale developed and produced a new light automatic rifle which became known as the F.N. (Fig. 1.)

At about this time allied nations, realizing that to unify forces most effectively ammunition and weapons should be made common, formed an International Small Arms Ammunition Committee and in 1953 officially announced the adoption of a standard 7.62mm. (.30 calibre) small arms round.

This decision initiated comparative firing trials of various rifles presented by several nations for test. In this demonstration, the F.N. rifle was conspicuous in design, performance and target accuracy. The collaborating countries were so impressed with the possibilities of the prototype weapon that production rifles were obtained for more rugged troop and engineering trials and extensive programmes were undertaken to prove thousands of the rifles under the adverse conditions encountered in the snow and sub-zero temperatures of the Arctic, the heat and humidity of the tropics and the sands of the deserts.

The results of these trials were favourable and several countries were quick to accept the F.N. type rifle for national service use. By international agreement and as a result of the field trials in extreme climates and the different tactical doctrines of the countries involved, the basic weapon only was adopted by collaborating countries, with each country being permitted to adopt "national preference items" which best suited its particular purpose and desirable military characteristics as long as interchangeability of parts was not affected. This "national preference" policy can best be described by saying that, though parts must be interchangeable individually or as assemblies, the portion which "fits air" can be designed to meet the service needs of the individual country.

This basic F.N. rifle is an air-cooled, gas-operated, magazine-fed, self-loading weapon having an adjustable gas regulator to ensure smoothness of operation without excessive recoil. (Fig. 1.)

The breech block is mechanically locked before firing and is not unlocked until the bullet has left the barrel. Since the breech block is in the forward or closed position when the trigger is pressed, there is no disturbance of the shooter's aim by a heavy mass moving forward.

After firing, the mechanism extracts the spent case from the chamber, ejects the case laterally to the right and slightly forward of the shooter, then feeds a new round from the magazine into the chamber, recocking the hammer in the process thus leaving the rifle in readiness for firing again.

When the magazine is empty, the recoiling parts are held in the rear position by a holding-open device, indicating to the shooter the need to reload or replace the magazine, and providing maximum convenience for the purpose, since it requires only the release of the holding-open catch after reloading to have the rifle once again in readiness for immediate firing.

To serve international interests a "rifle steering committee" was set up. This committee, made up of service, design and production representatives of the countries involved, meets regularly and is chaired by Canada, since Canada was selected as the "design authority". As the "design authority" Canada was made responsible for engineering investigation and compiling a set of "inch standard

drawings" suitable for mass production of the rifle by modern North American manufacturing methods, then finally, on behalf of the Rifle Steering Committee, striking out a master set of basic rifle component and assembly drawings to control interchangeability and standardization of design. The Directorate of Armament Development, Department of National Defence (Army) Canada, assigned the programme of conversion to Canadian Arsenals Limited for fulfilment at their Small Arms Division, in Long Branch, near Toronto.

It was decided that since weapon design was being standardized it was an opportune time to combine a unified drawing standard. Accordingly, the design authority specified the Canadian Standard CSA-B78.1-1954 along with the British Standard BS 308-1953 as a supporting step toward the development of an International and Unified ABC (America, Britain, Canada) Drawing Standard. The result is that the "inch standard" drawings referred to remove the problems resulting from the use of different drawing practices with varying methods of projection, terminology, tolerances, geometrical expressions, machining, and roughness symbols.

Fig. 2 shows examples of symbols of basic tolerances, and Fig. 3 symbols of surface finishes, used on Fabrique Nationale drawings. Figs. 4, 6, and 8 compare F.N. and "inch standard" drawings for three parts of the rifle. The F.N. and CAL version have been redrawn, for better reproduction, but follow the originals closely. Figs. 5 and 7 are photographs of various components.

As Canadian Arsenals up to this time was accustomed to working with both British and American designs expressed in the earlier conventional methods, the new system now undertaken required a programme of study and education.

Due to the urgency and time limit set for the completion of this work, it was necessary to streamline the preparatory approach to acquaint the drawing office staff with the new drawing system. Accordingly, senior engineers undertook the primary study of the B78.1-1954 mechanical engineering drawing standards book and compiled from this a simplified manual as a local design practice. Where the formal book gave examples of methods of presenting features together with approved alternatives the engineers selected one presentation only for each expression and showed this in the local manual. Information, pertinent only to work on hand, was entered for use.

The rifle was then classified into four major sections, namely: barrel assembly, body assembly, action parts, and butt assembly, and a senior designer was assigned to each section with a group of the draughting staff under his jurisdiction for guidance and completion of the required drawings in accordance with the manual issued. The official standards book was retained by the senior as a reference. With this breakdown the concept of the new practice was readily acquired and the work progressed with reasonable speed to produce the full set of basic drawings.

In accordance with the manufacturing agreement. Fabrique Nationale supplied their complement of drawings with engineering notes. As the Belgian data and method of drawing practice differs widely from the conventions commonly used on this continent, the first step was detailed perusal to ensure a true interpretation of all information. A translation of the French inscriptions and engineering notes on each drawing was made and attached to the respective original F. N. print. Examples of the Belgian practice and of final conversion to inch measurements are shown in Figs. 4, 6, and 8.

It was essential also to make a comprehensive simile in English text of all the F.N. general specifications, instruction sheets, tables, charts, and symbols explaining the principles and application to the drawings on hand. Examples of some of the symbols employed and their significant values are shown in Figures 2 and 3.

The first drafting board action was to make pictorial transpositions from the first angle projection method used on the Belgian prints to third angle projection on tracing material but without any ascribed dimensions. From these transposed tracings two sepia or brownline prints were taken. On one, the metric dimensions were added after being converted to have unilateral tolerances including the calculated values implied by the symbols and supplementary directions prevalent on the original F.N. print. Some refinements of presentation were made, such as sectional views, etc., as needed for clarification.

The second sepia print known as the "inch replica" was in turn brought in line carrying the same corresponding dimensions but converted from the metric system to inch measurements, to conform to North American standards and thus simplify tooling, gauging, and so on. This then was a direct reading drawing illustrating the requirements of a finished component part, fully dimensioned for size and tolerance without resorting to by-notes and indirect tool allowance calculations. (Figs. 4, 6, and 8.)

At this stage a "tool room" model rifle was made up by Canadian Arsenals to prove dimensions and functioning of an equipment manufactured to the converted drawings.

Fig. 2. Examples of symbols of basic tolerances to be accorded to the profile of a tool (Fabrique Nationale drawings). The tolerance expressed by the symbol which is adjacent to the dimension on the drawing is to be calculated from a table of formulae.

The "inch replica", now representing the true proportions of the F.N. design, was turned over for study from a process and tooling aspect to determine the nearest suitable inch sizes for North American procurement and practice. Holes were considered for preferred inch diameters in keeping with suppliers' catalogues of drills, reamers, and other tools. Pins, rods, etc., were compared to the regular sizes common to the general mill run of bar stock selections. A close observation was made of datum surfaces with a thought to substantial bearing locations when making machine cuts and gauging. During this survey, the "inch replica" drawing was marked to show the recommended choice against each respective detail. In the case of screws and threads the Unified Thread Standard was applied throughout. Included also during this phase of the work was a complete review of the material specifications to tie in with North American supply

Fig. 5. Above, from top: body, block breech, and carrier of the F.N. rifle, illustrate typical parts on which machining operations are carried out.

and where possible improve machinability or the strength of the component. Typical examples of substitute or material changes follow.

The 1% chromium type steel assigned by F.N. for the barrel was replaced by a 5% nickel steel, the purpose being to utilize the experience developed over the years in deep hole drilling, reaming, and broach rifling techniques which were well-proven during the manufacture and service of the Bren gun barrel using this identical material. A nickel-chrome-molybdenum steel was recommended for several components displacing the plain carbon type steel previously used. On these particular applications the Ni-Cr-Mo steel is heat treated to a hardness of 245 to 300 D.P.N. prior to machining and in this condition has a yield strength factor higher than plain carbon steel but the machinability ratings are comparable. Because of the increased physical characteristics there is less tendency for wear and pick-up on slide friction surfaces and it is unnecessary to harden these wear points locally thus avoiding warpage and subsequent straightening. The presence of alloying elements also tends to increase the corrosion and erosion resistance of the surfaces exposed to the effects of the gases generated.

For some groups of components it was deemed beneficial to up-grade or substitute direct-hardening materials for case-hardening class steels and vice versa, according to the nature of the stresses involved. Economy also had a direct influence in these evaluations.

Early collapse of springs functioning in close proximity to the hot gases operating the weapon was apparent. A series of tests on four types of spring wire was conducted to compare the deflection under load at temperatures varying from 200 F. to 1000 F., in increments of 100 F. Specimen springs made of plain carbon, chrome-vanadium, and two classes of stainless steel wire were used. The test results, plotted in graph form, showed the comparative merits of each example. Heat resisting stainless steel (also specified as steel, wire corrosion resistant) proved most satisfactory and capable of rendering long service in the elevated temperature conditions.

Sand and mud, which inevitably enter the mechanism of a rifle in operational use, have always presented

a challenge to weapon designers and manufacturers. The advancement in hard chrome-plating technique offers some relief to this problem as, in recent years specialists in the electroplating field have developed processes adequate for plating the full length of the bore and chamber of rifle barrels with a reliable degree of accuracy control to maintain the desired precision of size and contour.

Barrels treated by this method give improved performance as the plated chamber surface resists indentation of

(*Continued on page 85*)

Important Applications of Heat Storage in Industry

W. Goldstern,

Steam Storage Company Limited, Leeds, England, and Toronto, Ont.

HEAT STORAGE AS A basic principle has been known and applied by engineers for many centuries. Steam storage was first introduced as a practical solution by Professor Rateau for the use of exhaust steam in low-pressure turbines, mainly in collieries and steelworks. Dr. Ruths developed the high-pressure accumulator for balancing the boiler load and opened-up the great field of steam-using industries, such as paper mills and surgar refineries, but at the same time restricted its economic value by greatly overrating the size of plant required. During the last few years, various improvements have been made both in respect of technical design and economical application.

In an article "Some Important Applications of Heat Storage in Industry" (*Fuel Economy Review*, 1954*), the author illustrated five typical heat storage installations which embody these principles of reduced cost and improved performance. The examples ("cases") used were: (1) steam storage for peak demand; (2) balancing boiler load; (3) boiler-accumulator; (4) hot-water storage; (5) storage of exhaust steam. The present article also appeared in *Fuel Economy Review*, 1957 (published by the Federation of British Industries).

IN A PREVIOUS article,* heat storage was explained by five typical applications. In various other industries heat accumulators have been installed for similar purposes, and in fact many new applications are found every year. The basic principle that steam and heat can be stored is still not sufficiently appreciated and it is hoped that the following five further examples may help to show the great possibilities.

Case 6: Indirect Balance of H.P. Peaks

The Problem

It is obvious that a steam accumulator between boiler and low-pressure (L.P.) consumers can balance load fluctuations, as the steam discharged from the accumulator can be automatically adjusted to the demand. It is not so well-known, that a similar effect can be obtained by indirect balance, if the fluctuations are on the high pressure (H.P.) side.

To illustrate the difference, Fig. 1 shows a typical arrangement of an accumulator in a steam plant including H.P. and L.P. consumers. Inserted are "steam charts" characterising the steady H.P. and the fluctuating L.P. demand. Without an accumulator these would add up to an irregular boiler load indicated by the dotted line. The effect of the accumulator is to turn the L.P. demand into a constant load, resulting in a total boiler load which is maintained at a steady level.

In the same simple way, Fig. 2 shows the indirect balance. Here, the peaks are caused by the H.P. consumers, and added to the steady L.P. demand would cause considerable changes in boiler output. The balance is effected in this case by a surplus regulator controlling the charging of the accumulator in such a way that the total load remains constant. When more steam is required for the H.P. consumers, less is passed to the accumulator; and vice versa, when there is a reduced H.P. demand, an increased proportion of the steam generated is passed into the accumulator. This varying rate of steam flow into the accumulator is turned into a constant flow of steam from the accumulator to the L.P. consumers, thereby obtaining a perfect indirect balance and a steady total boiler load.

Load conditions in steelworks

These are particularly suitable for the application of indirect balance, as steam hammers and presses require a relatively high steam pressure for efficient working. At the same time, their steam demand is one of the most erratic experienced in any industry. They may be standing for long periods, start operation practically without any notice, require full steam rate for a relatively short period, and then stop equally suddenly.

The steam demand graph reproduced in Fig. 3 is based on extensive tests and is characteristic for steelworks having a number of hammers as well as a large press, shown in Fig. 4. The individual steam

---

*Reprints of the first article are available on application to Steam Storage Co., Ltd., 199 Bay Street, Toronto, Ont.

requirements are shown in Table I as metered during these tests:

Accumulator effect

It is not difficult to realize the difficulties created by a steam load of this character. During periods of low demand, the fire in the two boilers used at this plant had to be damped down to a fraction of their steaming capacity. Before the press started a light signal was given to the boiler fireman who increased the firing rate; but due to unavoidable delays, this caused serious steam loss through the safety valve. During press operation the boiler pressure dropped continuously, as the demand exceeded the boiler capacity. Frequently the pressure fell below the lowest pressure at which the press could work (about 120 p.s.i.), causing interruption of work and periods of waiting until the boiler pressure was recovered.

The installation of an accumulator, shown in Fig 5, which works on the principle explained under "the problem", has resulted in a balanced boiler load. During periods when the press is standing, the boiler firing can be maintained and all steam not actually required is charged into the accumulator. When press operation starts, the boilers can be quickly brought up to full steaming rate and easily supply all the steam required by the press, whilst all the steam for the hammers is supplied by the accumulator. In this way, as stated in a letter received from the clients, the accumulator "irons-out peaks most satisfactorily and allows steady firing to take place on the boilers throughout the day". It has been proved that the saving in extra labour costs alone, previously caused by waiting time (when boiler pressure was low) has paid for the accumulator during the first three years, and in addition there is a 5 per cent increase in production.

Table 1. Individual Steam Requirements

No.	*Type*	*Size*	*Pressure p.s.i.*	*Steam Demand lb./hr.*
1	Steam press	3,000 ton	160	5,500–18,000
1	Cogging hammer	15 cwt.	80	800– 1,200
1	Steam hammer	15 cwt.	80	1,500– 2,500
1	Steam hammer	50 cwt.	80	3,000– 5,000

Case 7: Supply of Dry Saturated Steam

Ideal steam

Perfectly dry saturated steam can well be called ideal, because it cannot exist in practical operation, except immediately after steam is formed over an evaporative surface. In its further flow through boiler or steam plant it is bound either to lose some of its heat content by cooling, thereby forming wet steam, or if further heated to become superheated steam.

There is no doubt that wetness is a disadvantage, and great efforts are made to ensure correct trapping which can drain the condensate formed. But superheat too can be a disadvantage under certain conditions or cause difficulties above a certain temperature.

The fact that steam discharged from an accumulator is produced direct by re-evaporation means that at the point it leaves the accumulator the steam is practically dry saturated steam.

Accumulator as de-superheater

Steam accumulators are therefore often used to transform superheated steam into saturated. This requires, of course, that all the steam is charged into and discharged from the accumulator by the so-called "series arrangement" shown in Fig. 6. The steam charged into the accumulator may have any degree of superheat; condensation is assured by correct design of the charging equipment. (It is possible to install the accumulator in the so-called "parallel arrangement" shown in Fig. 7, whereby a proportion of the steam will by-pass the accumulator, and the temperature in the L.P. main will vary correspondingly.)

It is important to note that considerable additional steam savings may result from the de-superheating

Fig. 1. Direct balance of L.P. peaks.

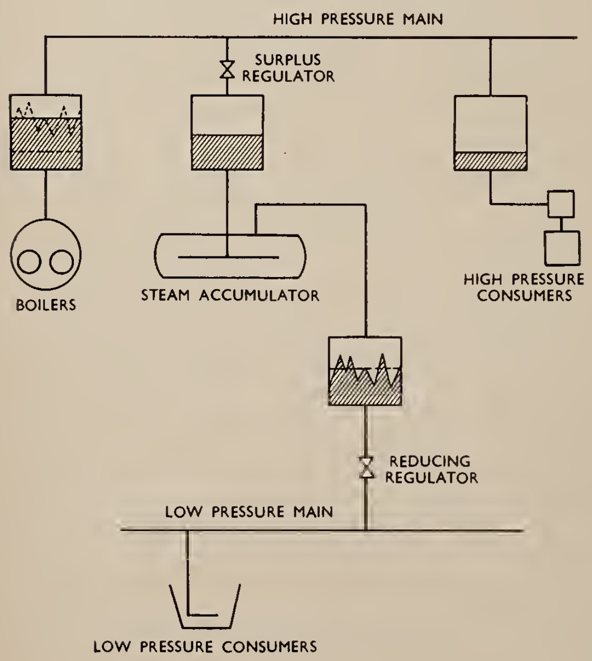

Fig. 2. Indirect balance of H.P. peaks.

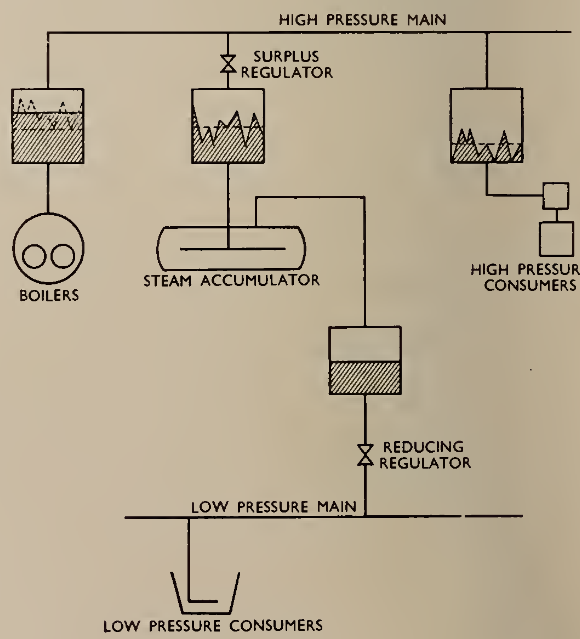

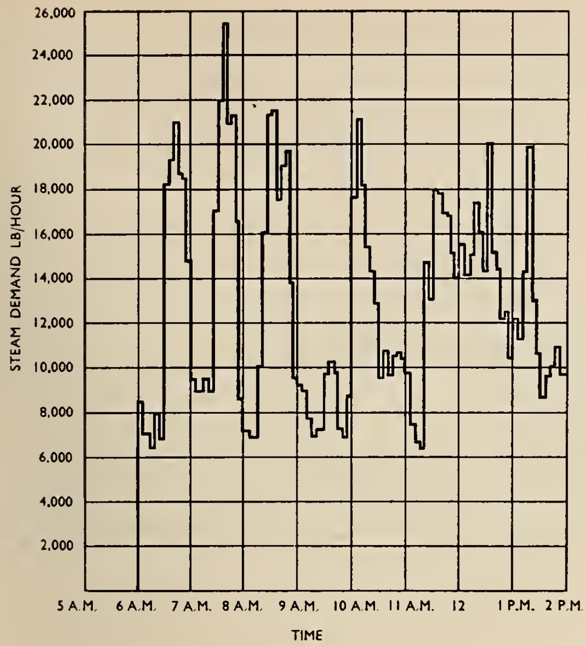

Fig. 3. Steam demand of a steel-works.

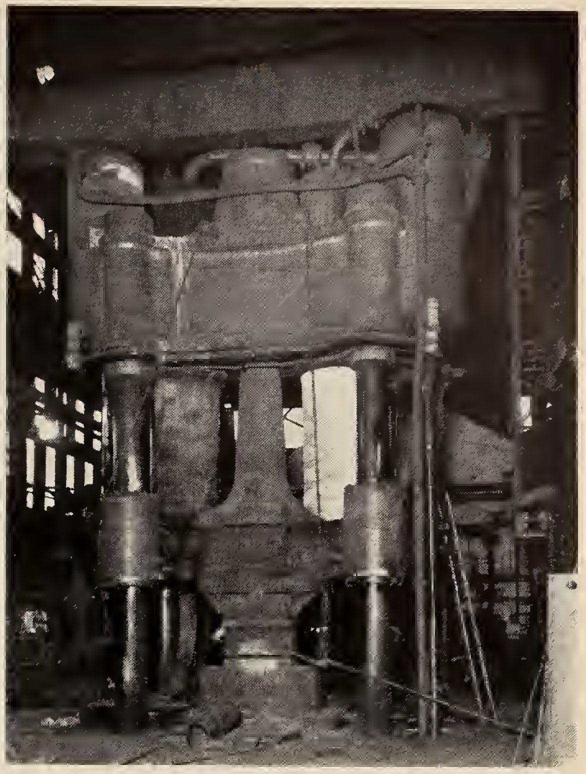

Fig. 4. Steam press in a steel-works.

effect of an accumulator. More steam can actually be discharged from the accumulator than has been charged into it. This gain, which of course is due to the lower heat content (in B.t.u. per lb. of saturated steam), can be very important. For instance, with boiler steam of 160 p.s.i. and 600° F., the theoretical quantity of steam supplied from the accumulator at an average pressure of 50 p.s.i. will be 12 per cent higher than the quantity used for charging. (In practice, however, this may be somewhat less, due to the heat lost by radiation.)

Eliminating wet steam

Wet steam may be due to various circumstances, but basically it can only be caused either by cooling losses, for instance in the pipe system, or by carry-over from the boilers. The first mentioned type can be overcome by providing steam traps; the second, however, is more difficult to cure. It depends on various factors of boiler operation, such as height of water level in the boiler, steam pressure, chemical nature of water (mainly characterized by the total dissolved solids), boiler design and the rate of evaporation. It is easy to realise that the greatest danger of carry-over exists during the period of peak demand, especially if the boiler water level has been brought up to its highest point in anticipation of such a peak, and near the time when the boiler is due for cleaning.

The amount of water carried over by steam is generally underrated, but it has a marked effect on the production side. A steam accumulator, which again must be arranged in series, can eliminate the steam wetness completely. For instance, steam of 10 per cent wetness or more may be charged into the accumulator, but the discharged steam is practically saturated, and after the reducing valve will have a slight degree of superheat.

A steam accumulator installation in a large chemical works has proved this effect; the liquid content of the vats previously increased considerably during the heating-up period. All the steam is now discharged from the accumulator and the liquid content can be maintained at a minimum. A layout of the accumulator is shown in Fig. 8, and a photograph in Fig. 9. Boiler efficiency increased from 72 to 76 per cent immediately after the accumulator was put into operation.

Case 8: Heat Storage in Boilers or Accumulators?

Storage in boilers

Before trying to decide which is the better solution of the problem—to store heat in a boiler plant which is intended for steam generation, or in an accumulator specifically provided for this purpose—it is essential to know exactly what heat storage is. Obviously, it cannot be obtained from any plant or machinery, unless more heat can be drawn from it than is produced (for instance, by combustion) at any given moment.

For a boiler to be of any use as an accumulator, one of two methods (or both) must be possible:

(*a*) a considerable pressure drop, or

(*b*) some drop in water level.

Under normal conditions this is quite impracticable, especially where pressure and/or water level are automatically controlled. In any case, it creates serious difficulties if the boiler pressure is allowed to fluctuate widely. Such conditions may lead to excessive temperatures in the economizer and undue strain on boiler tubes. Economic boilers are quite unsuitable for such working conditions (due to high gas temperatures at the back of the boiler) and steady load conditions are usually specified by the makers.

Heat accumulators, on the other hand, are designed and operated to allow the maximum change of temperature and pressure, thereby reaching the best storage effect for a given volume. As there is no combustion taking place in an accumulator, there are no high temperatures, and with no feedwater intake there are no chemical problems of corrosion or scale.

In short, no boiler plant can maintain its highest efficiency and best working conditions, and at the same time give the same heat storage effect as a separate heat accumulator. This is especially true of the more modern types where the water content is reduced to obtain greater flexibility and quicker response to changes in firing. A typical example of water tube boiler plant fitted with a steam accumulator will illustrate this point.

Water tube boilers and back-pressure engines

The plant shown schematically in Fig. 10 includes water tube boilers, working at a pressure of 300 p.s.i. and having a total output of 92,000 lb./hr. Steam is used for power generation in back-pressure engines of a total output of 1,500 kw. The back-pressure steam is used for various processes at 30 p.s.i. In view of the long distances, the L.P. steam is taken back to the boilers, and passing through superheaters obtains a temperature of 450°F.

The heat storage effect of water tube boilers is, of course, negligible, because as explained above, neither the water content (or level), nor the pressure, can be allowed to drop.

The accumulator, of 9 feet diameter x 40 feet length, works in parallel to the back-pressure engines, but its maximum pressure is limited at 150 p.s.i. In view of the discharge pressure of 30 p.s.i., it has been found that it is more economical to design the accumulator for 150 p.s.i. than 300 p.s.i., whereby the length could be reduced to 27 feet. The saving in the area of steel plates (and insulation) is more than offset by the extra thickness of the plates due to the higher pressure.

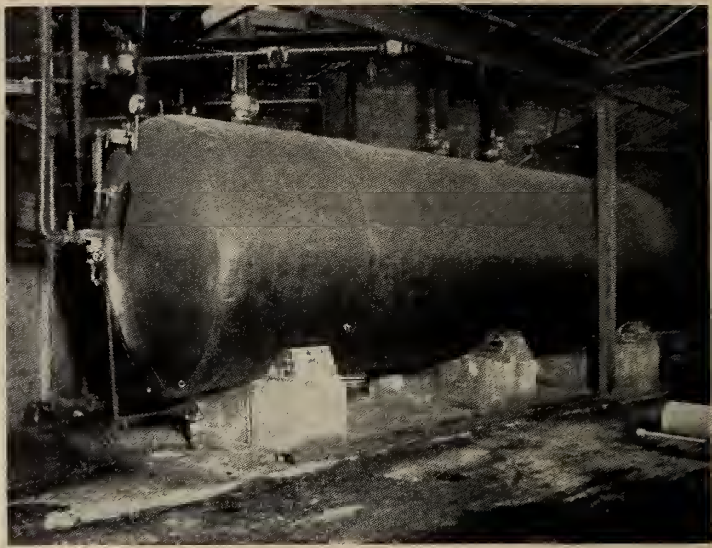

Fig. 5. The installation of this steam accumulator resulted in a balanced boiler load.

Steam requirements in breweries

The processes requiring steam in a brewery are mainly for: copper boiling; hot liquor tanks; pasteurizing; bottle washing; sterilizing. (For further interesting details see an article by S. R. Broadbent and M. V. Murray in the *Journal of The Institute of Fuel*, August 1955, page 383.) Some of these consumers are operated throughout the day at a fairly constant rate. Where the coppers are directly heated by coal or oil, conditions may not cause any special difficulties, even where water tube boilers are in operation.

There are serious peak-load problems, however, in breweries where the coppers are indirectly heated by steam coils. The coppers are usually filled with liquid of approximately 140° to 150°F. Steam is used to bring the liquids to the boiling point and then to evaporate a certain proportion; usually 10 to 15 per cent of the copper content within a period of 1½ to 2 hours. Each copper is boiled generally once per day, and as this demand is additional to all other consumers, creates a peak load as illustrated in Fig. 11. In this brewery there are a number of small coppers working to a definite plan and the demand has been calculated accordingly. In many breweries larger units are used and sometimes only one copper is boiled per day, creating a very serious peak problem for the boiler house. In many cases the period of evaporation has to be extended in an effort to reduce the peak demand (in lb./hr.), and this is, no doubt, connected with additional heat losses and operational difficulties. The best solution for the boiler house and

Fig. 6. Series arrangement of a steam accumulator.

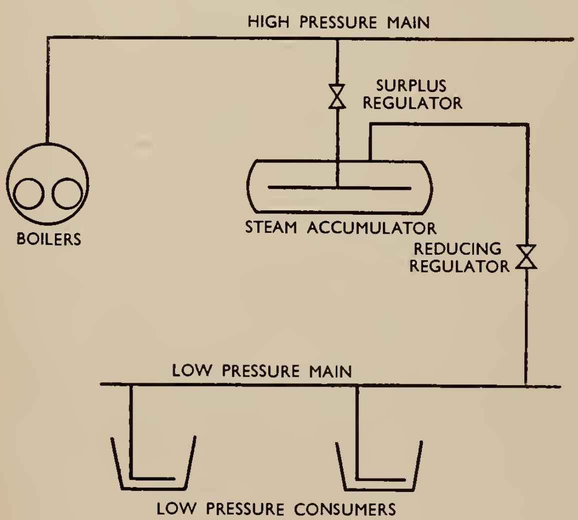

Fig. 7. Parallel arrangement of a steam accumulator.

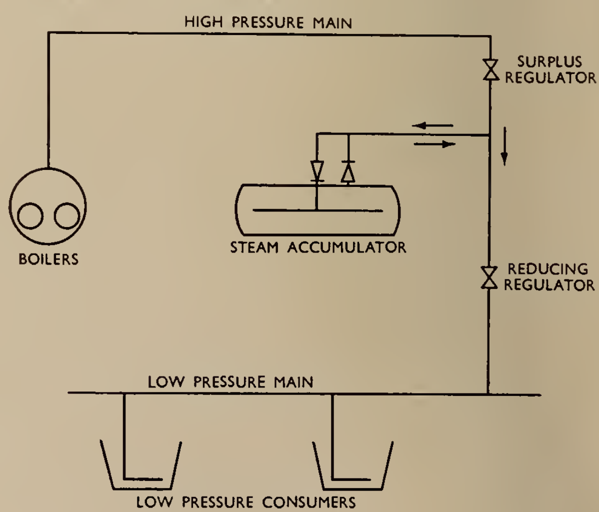

pressure power generation, in the case of the brewery described, was found to be the installation of a steam accumulator.

Case 9: Automatic Hot-Water Storage

The purpose of automatic control

It may be necessary to start with a short explanation of what is *not* automatic hot-water storage, because there are so many failuures caused by overlooking the following facts. A tank full of hot water is not yet a hot-water accumulator. Very often such a tank is even automatically prevented from having any heat storage effect at all: there is a level switch or ball tap which keeps the tank permanently full of water. In addition, the water temperature is automatically maintained at the full values of, say, 180°F. The heat content therefore will remain constant at its full value, and the storage effect is practically nil. As soon as any peak demand for hot water occurs, it is immediately passed on to the boilers, which therefore work under most favourable conditions.

In the case of a real hot-water accumulator the automatic control is used to balance the boiler load. Steam supply is kept independent from hot-water peak demand. When consumers, for instance vats in laundries, dyeworks or leather factories, are started, the hot water is supplied from the accumulator, which is gradually emptied during the peak period. No extra steam is required from the boilers, which are thereby protected from peak-load difficulties. Steam is charged to the accumulator through a surplus valve, which opens only when the boiler pressure is high so that the accumulator is re-filled with hot water during periods of reduced hot-water demand.

Hot-water accumulator in a laundry

An example of such an accumulator, shown in Fig. 12, is interesting in respect of the power and heat balance obtained. The Lancashire boiler supplied steam at 120 p.s.i. to an 80 h.p. vertical back-pressure engine; the L.P. steam was used directly for various consumers working at 10 p.s.i. and in a heat exchanger for the generation of hot water required for various washing machines. Their demand during peak periods greatly exceeded the quantities of water which could be heated-up to the temperature required, as the amount of L.P. steam obtained from the engine was strictly limited. The effect was, of course, that the pressure could not be maintained at the full 10 p.s.i., but dropped every day to 5. p.s.i. and less.

A scheme was put forward for an automatic hot-water accumulator including a sectional cast iron tank of 14 feet x 10 feet x 8 feet deep, holding 6,000 gallons of hot-water. The automatic control consists of a surplus regulator with over-riding L.P. control; this means boiler steam can by-pass the back-pressure engine only under one (or both) of the following conditions:

(*a*) when the boiler pressure exceeds the normal 120 p.s.i.

(*b*) when the low-pressure drops below the minimum 9 p.s.i.

Under normal working conditions this valve is shut, and all the steam for process consumers comes from the exhaust of the engine at a practically steady rate. All the L.P. steam which at any moment is not required for steam consumers flows through a second surplus regulator to a heat exchanger. As this steam heats-up the water in the heat exchanger, a thermostat opens the cold water supply and maintains the flow at a predetermined rate which charges the water into the accumulator at high level.

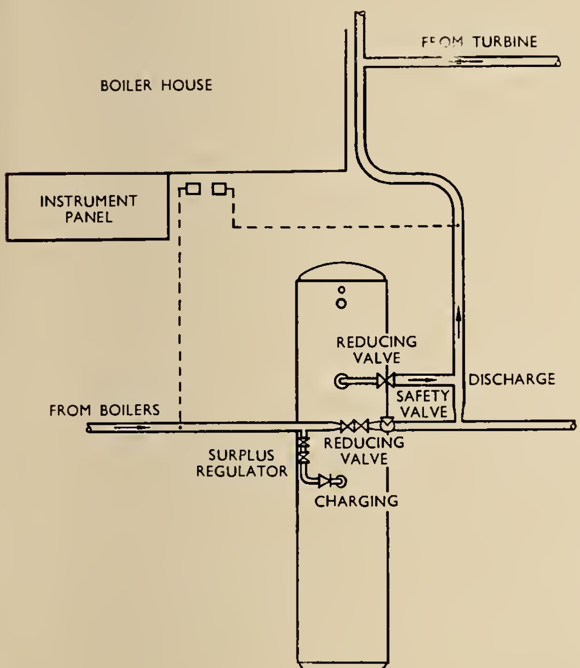

Fig. 8. General lay-out of a steam accumulator.

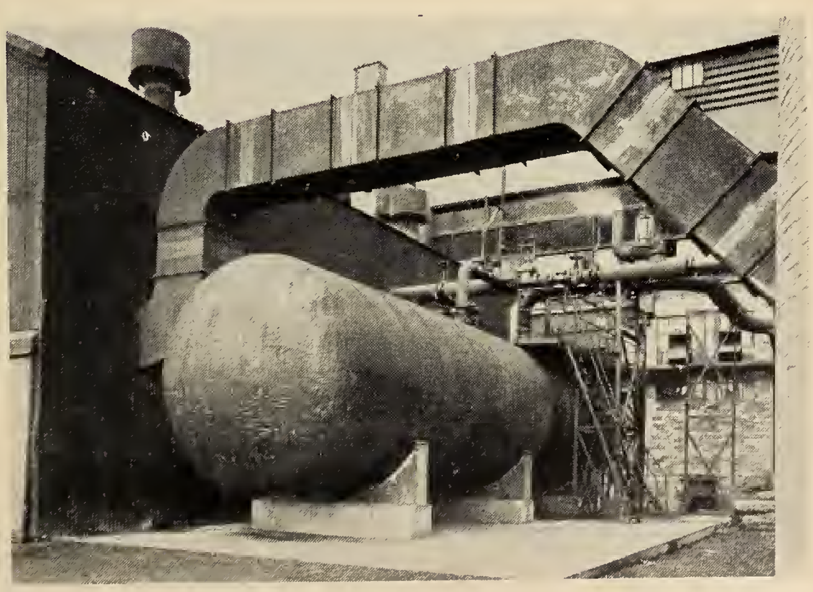

Fig. 9. A steam accumulator in a large chemical works.

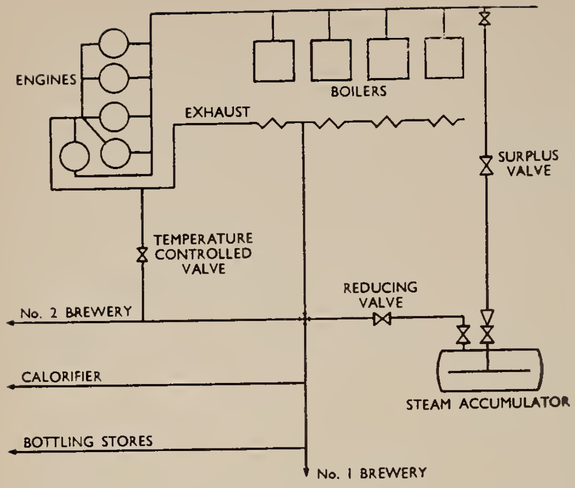

Fig. 10. A steam accumulator installation in a brewery.

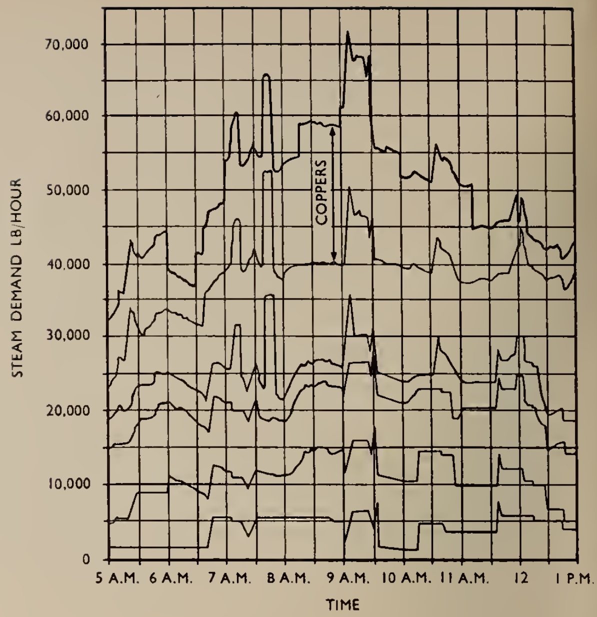

Fig. 11. Load chart of a brewery, illustrating peak load.

The accumulator is full of hot-water in the morning, and when the peak-demand starts (which exceeds the inflow of hot-water) the accumulator discharges. The results have proved the great value of the scheme: production has been increased by over 10 per cent, and at the same time coal consumption reduced by over 15 per cent.

Case 10: Electro-Heat-Storage

Peaks in power supply

Whatever the case for turning electricity into heat or steam (and no doubt it has great advantages in cleanliness, availability and automatic working, especially for the small boilers), there is a case for storing the electrically produced steam or hot-water. The main reason is, first of all, the well-known peak-load problem at the power station. Methods of overcoming this problem at the generating end, in thermal power stations, are extremely difficult and costly to accomplish, because the steam is used in the turbines at extremely high (and still increasing) pressures. Electricity itself cannot be stored, except (in chemical form) in batteries not applicable for industrial power conditions. But it has been proved that wherever electricity is used for generating heat or steam, thermal storage becomes an interesting solution on a sound economic basis. This basis is provided by the usual tariffs, which include a considerable standing charge and/or a considerable reduction in the unit rate for electricity used during the off-peak periods.

There are therefore two main applications possible:

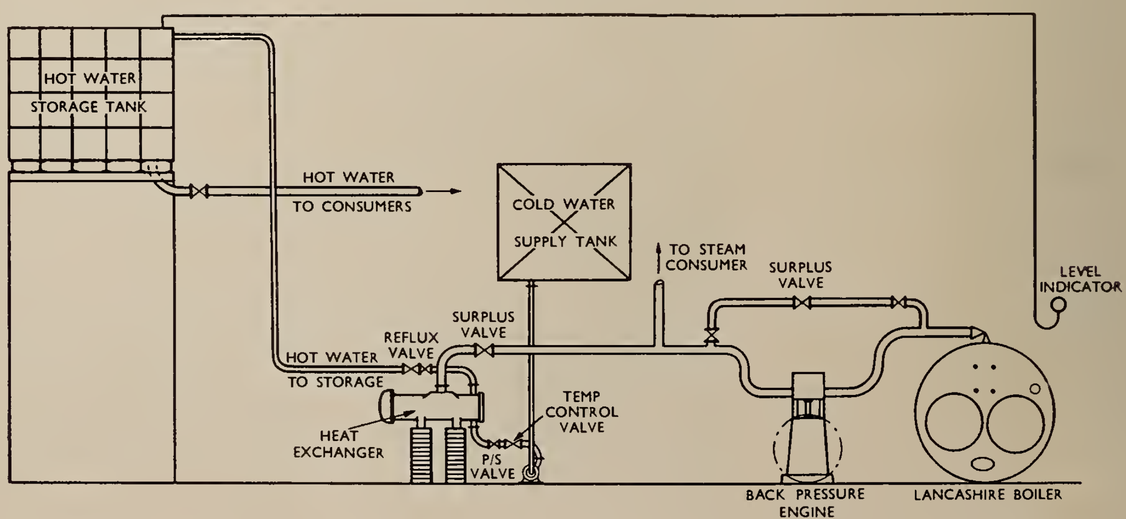
(*a*) to use accumulators which will supply steam or hot-water for peak requirements, thereby reducing the standing charge to the rate of the average kva. demand (which may be as low as 50 per cent of the peak kva. figure), or

(*b*) to charge accumulators during the night at the off-peak cheap rate and to discharge again during peak periods.

Accumulator for off-peak charging

A very interesting plant, shown in Figs. 13 and 14, includes an electrode boiler of 300 kw., working at a maximum pressure of 150 p.s.i., and an

Fig. 12. Hot water accumulator in a laundry.



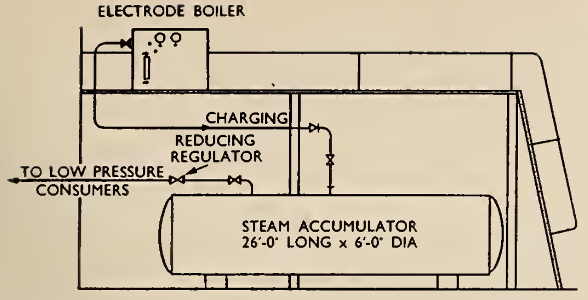


Fig. 13. An electrode boiler with accumulator for off-peak charging.

accumulator, which, discharging at 15 p.s.i., has a storage capacity of 4,500 lb. steam.

Steam is generated during the night and stored in the accumulator at a rising pressure in both boiler and accumulator. Electricity is automatically switched off during the peak periods (normally 8 a.m. to 12 noon and again 4 to 6 p.m.), when all the steam required for a large canteen and other processes is discharged from the accumulator.

The whole plant works completely automatically and has proved its operational and economic value. It constitutes a perfect illustration for smoke-free steam supply.

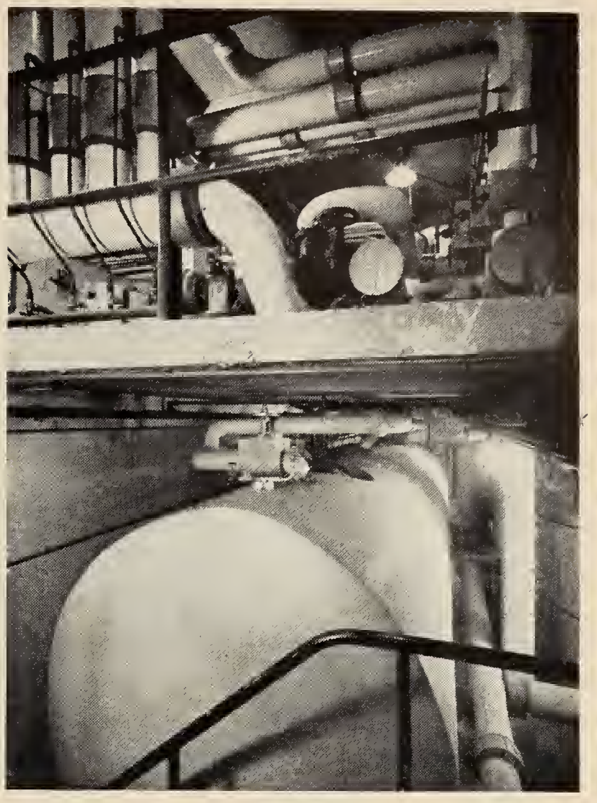

Fig. 14. A steam accumulator charged from a 300 kw. electrode boiler at off-peak periods.

The F.N. Rifle

(Continued from page 78)

the trapped sand, which under pressure of the exploded charge becomes embedded in the softer material of the cartridge case and is carried clear with extraction and ejection action. Also, under normal firing conditions, the life of the barrel when plated is increased approximately 100 per cent. As a result plated barrels have been adopted.

As the study and drawings neared completion, a small number of prototype weapons, to the new standards, were made by Canadian Arsenals Ltd., and were subjected to endurance, engineering and user trials by the Canadian Army to substantiate the design, not only of the basic weapon but of the Canadian National Preference items. These rifles were also demonstrated in U.K. and U.S.A. and the results of all trials were excellent.

Suggestions from other participating countries were introduced into the "basic design" drawings where unanimous requirement existed and when the full set of basic drawings was completed, the Armament Research and Development Establishment, in Britain, undertook a complete dimensional analysis of these drawings as a cross check.

Though it is to be expected that changes will be made in the basic drawings as the use of the rifle becomes more extensive, the final stage was reached when the basic design drawings were officially certified by the rifle steering committee for manufacture and the Small Arms Division of Canadian Arsenals went into production.

Future Annual Meetings

ABSTRACTS

BASED ON CURRENT LITERATURE AND EVENTS

LITERATURE ON STANDARDS ACTIVITY IN EUROPE

"Modular Coordination in Building," a report on modular measure published by the European Productivity Agency (EPA) of the Organization for European Economic Cooperation (OEEC), is a compilation of national reports prepared by the eleven Western European countries participating in EPA project No. 174 on modular coordination. As the culmination of phase I of that project, the report summarizes the various national concepts of modular design, the current manufacturing practices in the rapidly changing building industry, and the assembly processes or methods used for building construction.

Intended as the basis for the adoption of a common module, the studies from which the report has been prepared are comparable with the 1938-45 investigation in the U.S.A. leading to the adoption of the American Standard four-inch module approved by the American Standards Association. Some recognition is given in the report to the United States experience and to the American Standards on modular measure. It is, however, a new treatment of the subject primarily reflecting the European concepts of modular design and component sizing which do not always agree with the United States approach.

The module proposed by the report for European use is one decimeter for the metric countries and four inches for the foot-inch countries. The four-inch module fortunately would coincide with the American Standard and the one decimeter module would be very nearly the same size (3.94 inches).

Adoption of a common module by the Western European countries could stimulate building construction in that area and would provide further evidence that there is European industrial integration. Since it could also affect the dimensioning of every building material product, the module selection has significance to American industry as well. Of the $245 million export of building products in 1956, nearly one quarter went to Western Europe.

The modular standardization program in the U.S.A. has, since 1938, been centred in ASA Project A62 for which the selectional committee is the standards developing group. Preliminary information to Sectional Committee A62 regarding the EPA activity and the current report have resulted in considerable interest among the American manufacturers of building materials and supplies. The ASA project is jointly sponsored by the American Institute of Architects, the Producers' Council, the National Association of Home Builders, and the Associated General Contractors of America. Under their leadership two basic American Standards on modular measure and two on specific products, clay and concrete masonry units and clay flue linings, have been developed by the sectional committee. Extensive additional work is near completion on many other building materials and products.

In view of this United States experience, the EPA group has been anxious from the inception of this project to have American cooperation in the study. While only a limited contribution was made to the present report, arrangements now are being completed for direct American participation in the remainder of the project which will be known as phase II. Cooperative participation will be effected through a contract between the EPS and the American Standards Association and will include the preparation of a report on actual United States experience with modular construction. This phase of the project will consist of national reports of this type which will then be compiled in a second international report.

A copy of the current report may be obtained from the OEEC/EPA Washington Mission, Suite 1223, 1346 Connecticut Avenue, N.W., Washington, D.C., cost $1.50.

GERMAN RESEARCH AND INDUSTRIAL NOTES

The special program of the German Research Council *(Deutsche Forschungsgemeinschaft)* is discussed in the September 1957 issue of *Hochschul-Dienst*. The Council is the central research organization in the German Federal Republic; it furthers the collaboration of scientists, advises public authorities on scientific matters, and provides financial assistance for specific research projects. The *Notgemeinschaft* (Emergency Association for German Scientific Research), founded in 1920, was dissolved in 1945. The present Council was established by various groups in 1949 to support basic research, applied research being left to individual interested parties to finance. The German Federal Government and Parliament then granted DM 5 million in 1952, to be devoted to research in which Germany had to catch up with other countries. Grants were increased in following years and are now DM 15 million a year.

Among the first fields covered by a special project program were virus research, microbiology, nuclear physics, and aviation research. Later, shipbuilding research, finishing techniques, technical thermodynamics, and research into macro-molecular substances were added. Institutions with large electronic computers were established to accelerate calculations and solve many problems. The liberal arts were included in the second year of the program.

Existing programs have been extended to include such fields as radiology, cell research, botanic photobiology, genetics and behaviour research, analytical chemistry and photo-chemistry, acoustics, solid substances and metallurgical physics, and radio astronomy. German participation in the International Geophysical Year was supported. Further projects included gearing and propulsion, construction engineering, water economics, land cultivation, and agricultural and forestry problems, among many others.

Radiation Hazards — W. Theimer, in *Deutsche Korrespondenz* (14 Jan. 1958) discusses the danger of radioactive fallout of strontium 90 (Sr 90), considered one of the most dangerous elements, which can produce cancer of the bone and other serious diseases. Absorption is a long process via the soil to plant and animal foods, but it is cumulative. Some scientists estimate that fallout from nuclear tests already carried out will cause dangerous concentrations after about fifteen years. Further tests will increase the danger.

Professor E. H. Graul, of the Institute of Radiation Biology, Marburg University, has recently surveyed all the factors involved. Children are particularly susceptible, having a higher absorption potential than adults, and growth of bones may be affected in addition to the other effects. Studies in America, Britain, and India have not given a unified picture, but the present standard for maximum permissible concentration (MPC) is one-thousandth of a microcurie of Sr 90 per gram of body calcium. In 1955 the concentration of Sr 90 in the human body was only one ten-thousandth of the MPC, but by 1970 the continuing fallout will raise this by a factor of ten. If no further major nuclear tests are made in the interval, equilibrium will then be reached between intake and radioactive decay. Sr 90 has a half-life of 28 years.

According to Prof. Graul, contamination by Sr 90 in Western Germany is only two-thirds of the world average. However, concentration in the age group 0 to 4 reaches ten times that in the group 40 to 50, and although the *average* contamination will have reached only one-thousandth of the MPC, even in ten years, owing to statistical distribution some people will have absorbed ten times that concentration. This is still only one per cent of MPC, but many experts believe that the MPC has been fixed at too high a level and should be reduced to a tenth of its present value, so that average people will carry one per cent of the real MPC, while the statistically most unfortunate will have accumulated as much as 20 per cent of MPC in their bones.

This would still be far below the critical limit, but would ominously reduce the margin of safety for further nuclear weapon tests. As for children, Prof. Graul feels that their MPC should be assessed at one-third to one-tenth of that for adults, and it is likely that certain of the children who will be 10 to 15 about 1970 may have a concentration of Sr 90 of the order of the critical limit.

PREFABRICATION FOR £1,000,000 TEXTILE MILL IN NIGERIA

An interior view of a £1,000,000 textile mill opened in November 1957 at Kaduna, Northern Nigeria. The plant will have a capacity of about 12 million yards a year of cloth from locally-grown cotton. The factory covers an area of 140,000 sq. ft. and the superstructure is a steel-framed multi-span sawtooth roof, supplied by Taylor Woodrow (Building Exports) Ltd., who market for the Arcon group of prefabricated building manufacturers. It is 650 ft. long and 225 ft. wide, and is one of the largest prefabricated buildings to be shipped from one country to another. Components, including over 330 tons of steelwork, 170 tons of glass and glazing bars, and 75 tons of aluminum, were manufactured, assembled, and shipped within eight weeks of receipt of the order. From Lagos, components made a rail and road journey of 560 miles to the site, where excavation of 53,000 cu. yd. of soil was necessary. The mill is clad in concrete blocks, some 90,000 of which were made on site. A total of 1400 tons of cement were used, and 4000 tons of stone from a local quarry were crushed on site. David Whitehead and Sons Ltd., managing agents for the mill, installed steam and textile machinery, including 14,000 spindles and 300 automatic looms. The air-conditioned mill will employ about 700, on three shifts, at full production.

RECENT LOANS MADE BY THE WORLD BANK

Among many loans made by the International Bank for Reconstruction and Development (known as the World Bank), five widely diversified countries have been assisted in recent months—India, the Philippines, the Belgian Congo, Pakistan, and Mexico.

India — The privately-owned Tata Iron and Steel Company Limited, the largest in India, received $32,500,000 towards completion of an expansion program aimed at doubling the company's steel ingot producing capacity to two million tons a year (1.1 million in 1950); finished and semi-finished steel output will be raised to 1.5 million tons. Main installations to be completed are a battery of coke ovens, an ore crushing and sintering plant, a blast furnace, increased converter and open hearth capacity, a blooming mill, continuous sheet-bar and billet mill, and a structural mill. All major works, under supervision of Henry J. Kaiser Co. engineers, are expected to be completed by June 1958, the remainder within two years thereafter. This is part of a program to bring domestic steel production abreast of demand by March 1961. Another large contribution will come from the privately-owned Indian Iron and Steel Company, also with World Bank support.

The Philippines — The first loan to the Philippines, equivalent to $21 million, will assist the National Power Corporation to build the Binga hydro-electric project in the island of Luzon. There will be a dam and reservoir on the Agno River in northern Luzon, an underground powerhouse with an installed capacity of 100,000 kw., and transmission lines to Manila, about 120 miles to the south, and to various provincial areas. Work has begun and is expected to be completed in 1960. Of a potential of at least 600,000 kw. in Luzon, only about one-sixth has been exploited. Binga is the second of six projects planned to exploit the potential of the Agno and Toboy Rivers.

Belgian Congo — A loan equivalent to $40 million was made towards road construction and improvement, forming part of the ten-year plan for the development of the Belgian Congo. The project involves the construction of 750 miles of new highways, the improvement of 560 miles of existing roads, and preparation for mechanized maintenance of a further 2060 miles. Improved road transport is urgently needed to encourage the change from subsistence agriculture to cash-crop cultivation, to open up tracts of unused land, and to allow for further growth of industrial employment. The Congo has become the world's largest supplier of cobalt and industrial diamonds, a major exporter of copper and other minerals, and an important source of vegetable oils and other agricultural commodities.

Pakistan — The Pakistan Industrial Credit and Investment Corporation, formed by Pakistani, British, American, and Japanese investors, has received $4.2 million to assist in the expansion or modernization of small and medium sized industries and to help create new ones. Esgo T. Kuiper, of the Netherlands, who organized and was first managing director of the Indonesian Industrial Bank, is general manager of the Corporation.

Mexico — The privately-owned Mexican Light and Power Company (Mexlight) has received the equivalent of $11 million for the expansion of the Company's electric power system. Transmission and distribution systems are being extended, and generating capacity expanded by some 95,000 kw., or about one-fifth. The 12,000 sq. mile area served by Mexlight is the chief governmental, industrial, and commercial centre of Mexico. Expansion now being undertaken includes the addition of an 82,400 kw. unit to the 66,000 kw. Lecheria thermal plant, modification of two generating units in the Nonoalco thermal plant to increase capacity by 12,500 kw., and extension of transmission and distribution networks. Completion of work at Lecheria is scheduled for April 1958.

ENGINEERING NEWS FROM THE U.S.S.R.

Soviet News Bulletin, 17, 22, and 29 Jan. 1958; *UNESCO Features*, Oct. 1957

Inter-Planetary Flight — A recent article by Y. Khlebtsevitch discusses the idea of sending a manned expedition to the moon. To make a round trip, returning to earth a manned unit weighing 10 tons would require an eight-stage rocket weighing initially nearly 4,000,000 tons, according to the rocket-flight equation developed by the Russian scientist K. Tsiolkovsky. Apart from the unknown factors engineering problems are insuperable. The only solution seen at present is the use of intermediate stations in outer space.

Discussing the proposal of Dr. Wernher von Braun (designer of the rocket that recently launched the first successful United States earth satellite) to build a 260-foot dia. circular satellite (Flying Isle), that would revolve round the earth at an altitude of 1075 miles, the author states that the project has many weak points. About a thousand 6400-ton rockets would be needed to convey the satellite parts to their orbit before assembly, after which a further 1500 similar rockets would take men and equipment for assembling the space ship that would proceed to the moon. The expenditure of fuel alone would be several dozen million tons. The alternative use of nuclear fuels is not foreseen as practicable before the end of the century. The Russian approach is to concentrate on one-way trips to the moon (or Mars) with much smaller unmanned rockets containing recording instruments including television cameras.

Another Viewpoint

Another point of view was expressed by Prof. G. Chebotarev, of the Soviet Academy of Sciences, in an interview reported by *UNESCO Features*, October 1957. This proposes a trip from earth to moon and back by a rocket which would not use fuel for most of the time, but would be motivated by gravitational forces. A three-stage 16.8-ton rocket would follow an elliptical course reaching a point 18,000 miles beyond the moon. The speed to escape from the earth's gravitational pull would be about eight miles a second. The influence of the sun's attraction was calculated to be negligible.

Solar Energy

Solar Electric Station — Small solar-heat units have been in use for some time in the southern districts of the U.S.S.R. Prof. V. Khashchinsky describes the first experimental industrial helio-electric station, being built in the Ararat valley, near Yerevan, the capital of Armenia. Average annual sunshine is 2600 hours — about seven hours a day. The site is circular, over half a mile in diameter, with a projected 130-foot tower in the centre, equipped with a large revolving boiler. Surrounding the tower will be 23 concentric railway lines, on which 23 trains will carry 1293 large reflecting mirrors. These mirrors will automatically follow the sun and the boiler will rotate to present its radiation-absorbing "screen" continually to the reflected rays. A model is already undergoing tests.

The planned electrical capacity from the steam generated in the boiler is 1200 kw., and power will be supplied to neighbouring communities and to irrigation pumps. When there is no sunshine, the existing electrical supply will be brought in to serve the consumers. Underground heat accumulators will also store solar-heated water at about 80°C. Research into the direct conversion of solar energy into electric energy includes a thermo-electric generator designed in the Institute of Energetics of the U.S.S.R. This uses bi-metallic elements for the conversion, but photo-elements and semi-conductors are also being investigated.

Welding

High-Frequency Welding — A high-frequency current generator has been developed to supply welding equipment with which pipe up to about 2.4 in. diameter can be welded continuously from sheet metal at a speed of 325 feet a minute.

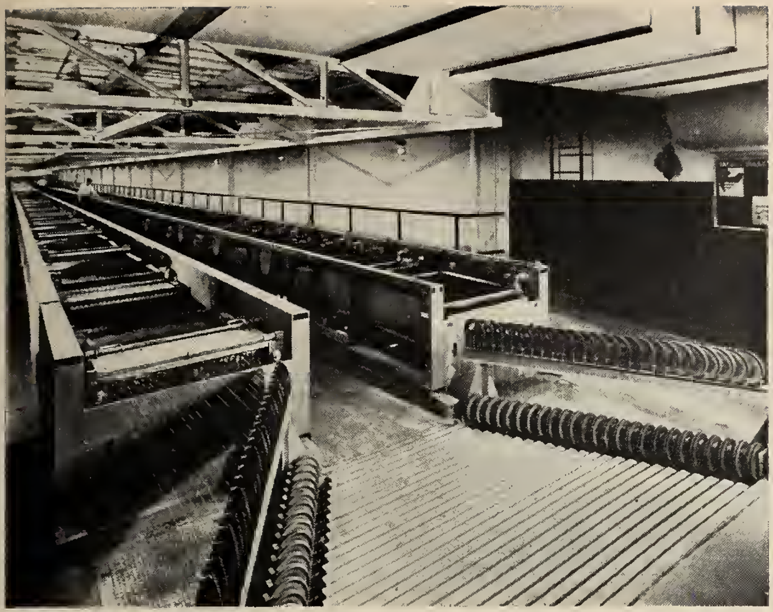

Fig. 1. One of the two 600-ft. long units for heavy copper-plating of wire. The 25 channels of wire are cleaned and partly plated in the tanks at left and then travel back the length of the building for completion of coating.

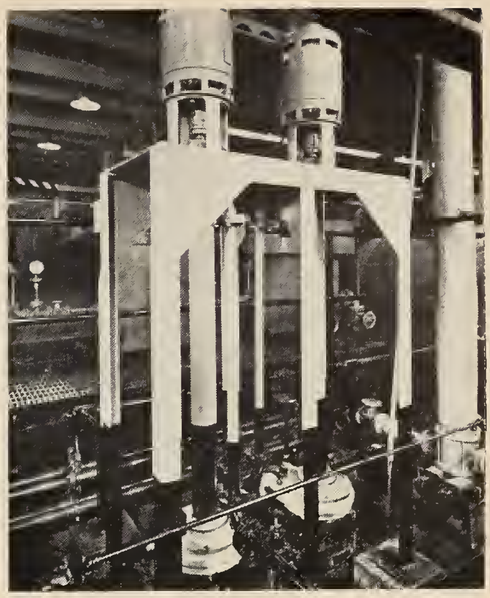

Fig. 2. Heavy duty vertical sump pumps handle the corrosive electrolytes. These are mounted above the storage tanks, others are submerged.

CAST STAINLESS PUMPS FOR CORROSIVE ELECTROLYTES

Alloy Casting Institute, Mineola, N.Y.

Continuous heavy copper plating of steel wire, at the Point Breeze Works of the Western Electric Company, Baltimore, Md., has posed serious problems of handling extremely corrosive electrolytes, which have been partly solved by the extensive use of cast stainless steel pumps.

Housed in a special building, the 600-foot long tanks for producing telephone drop wire are shown in Fig. 1. One electrolyte solution of copper fluoborate contains about five ounces per gallon of fluoboric acid and 20 ounces of copper, has a pH of less than 1, and is used in the temperature range 120° to 135°F. Other corrosive solutions are involved in the process, and extensive use is made of corrosion-resistant materials in tanks, mixing devices, piping, and so on. To handle the solutions, Western Electric standardized on heavy-duty vertical sump pumps (Fig. 2) supplied by the Aurora Pump Division of the New York Air Brake Company, Aurora, Ill.

All metallic pump components below the base plate are of cast stainless alloy, except for studs and nuts, which are made of a corresponding grade of wrought stainless steel. Most of the parts such as the impeller and its housing are statically cast; but the supporting and discharge pipes are centrifugally cast. The cast stainless alloys chosen for all parts in contact with the solution were (Alloy Casting Institute designations): type CN-7M, which contains about 29% nickel, 20% chromium, 2% molybdenum, 3% copper, with 0.07% max. carbon; type CF-8M alloy, which has about 20% chromium, 11% nickel, 2.5% molybdenum, with 0.08% max. carbon. To avoid intergranular corrosion the castings are given a solution heat treatment — heating to between 1950° and 2100°F., followed by water quenching.

To make the completed conductor, the wire receives 32 separate treatments in nine different chemical solutions, six of which require the use of cast stainless pumps. An alkali cleaner removes oil and other impurities; a sulphuric acid pickle removes scale, rust, and other mechanical particles and imparts a slight etch. Both of these use the stainless sump pumps. A thin flash of copper is deposited from copper cyanide solutions, which do not require special pumps, and the wire then enters the production plating section, in which there are 58 plating cells alternating with 57 copper contact rolls to prevent overheating of the wire and to ensure close control of the copper deposit. Four out of six CN-7M alloy pumps continuously circulate the copper fluoborate solution from storage tanks to plating cells. Pumps are submerged in the storage tanks, and each delivers 800 g.p.m. at 60 ft. head. Four of six type CF-8M alloy pumps circulate the solution during continuous filtering and intermittent solution handling. These pumps are mounted outside the storage tanks (as in Fig. 2) and deliver 50 g.p.m. at 125 ft. head.

The wire is finished by passing through a hydrofluosilicic acid bath to remove oxide formed during an intermediate annealing treatment, followed by lead plating from lead fluosilicate (both solutions requiring CN-7M pumps), and a final brass coating from a cyanide solution, which does not need special pumps.

THERMONUCLEAR RESEARCH IN SWEDEN

The Swedish — International Press Bureau, 29 Jan. 1958

For two years at Upsala University Professors Per Ohlin and Kai Siegbahn have experimented with thermonuclear reactions, in close collaboration with the ASEA company and with the Swedish State Power Board. Apparatus similar to the British Zeta (see "International News, p. 90), but smaller, has been built. A much bigger unit, due to be completed this spring, will be able to store considerably more energy than Zeta, but will have a smaller discharge tube. It is expected that results, in terms of length of fusion (i.e., thousandths of a second) will be comparable with British work.

INTERNATIONAL NEWS

Fusion and Fission in the United Kingdom

THE OUTSTANDING ADVANCE in recent times in the field of nuclear energy was announced to the public on 24 January 1958. Compared with some of the ensuing effusions in the press, the official announcement by the United Kingdom Atomic Energy Authority was modestly phrased.

"Research at Harwell [the UKAEA research centre in Berkshire] with the latest apparatus has led British scientists to the conclusion that control of thermonuclear reactions for electricity generation may well be a possibility for the future, though its practical application is still a long way off. . .

"Results obtained with the Harwell apparatus Zeta suggest that 'thermonuclear neutrons' have been obtained, but further experiments will be necessary before this can be proved conclusively. Temperatures reached in this apparatus have been as high as five million degrees Centigrade, higher than the measured surface temperatures of any star."

The announcement continues with further details of the apparatus and the results obtained. (See also ref. [5])

Zeta

The apparatus known as Zeta was designed and built by the U.K. Atomic Energy Authority with the collaboration of the Metropolitan-Vickers Electrical Company, Limited. A discharge chamber consists of a ring-shaped tube or torus of one metre bore and three metres mean diameter, containing deuterium gas at low pressure. (Deuterium, known as "heavy hydrogen", is an isotope with twice the atomic weight of "ordinary" hydrogen.) The tube is encircled over part of its length by the iron core of a large pulse transformer. A current pulse is passed into the primary winding of the transformer from a bank of capacitors capable of storing 500,000 joules of energy. The pulse induces a large unidirectional pulse of current in the gas; peak currents up to 200,000 amp. have been passed through the ionized gas for periods up to 5 milliseconds. (Longer times, perhaps several seconds, will be required for useful power output; these times, with higher temperatures, are foreseen to be eventually possible.)

The pulse, or discharge, heats the gas and also produces a strong magnetic field which causes the particles to be pulled to the centre of the tube and away from the walls, also raising the temperature further. The effect is known as a pinched toroidal gas discharge. In early experiments it was found that the discharge was unstable and tended to "wriggle", eventually coming in contact with the walls of the tube, causing serious heat losses and vaporizing the walls. An additional magnetic field helps to prevent the wriggling.

The operation of Zeta is illustrated on page 91.

Zeta was started up on 12 August, 1957, and nuclear reactions were produced on 30 August. Neutrons produced during the experiments were observed and, although their source was not claimed to be definitely established, there were good reasons to think that they came from thermonuclear reactions such as the fusion of two deuterium atoms to produce helium, neutrons, and energy.

(This fusion of light atoms — at very high temperatures to produce nuclear velocities sufficient to overcome the Coulomb barrier, or repulsive force of the particles' like electric fields — is the reaction which produces the high thermal energy of the sun and similar stars.)

There is not space here to discuss details of the work and the results obtained, but various papers on the subject have been published. [1,2,3]

Control desk of the thermonuclear apparatus Zeta (Zero Energy Thermonuclear Assembly). Oscillographic measurements are being made on the gas discharge.

Sceptre III

Work on thermonuclear research was first started by independent groups, one at the Clarendon Laboratory, Oxford, which moved in 1951 to Harwell; the other, under Sir George Thomson, at Imperial College, University of London, transferred in 1951 to Associated Electrical Industries (A.E.I.) research laboratory at Aldermaston, some 20 miles from Harwell. The two groups have collaborated closely, and following the satisfactory results obtained at Harwell a similar discharge was produced and high temperatures reached in the A.E.I. apparatus, called Sceptre III.

Sceptre III is smaller than Zeta, with an aluminum toroidal tube of 12-inch tube-diameter and 45-inch mean torus diameter, threaded with an iron core weighing four tons. Energies up to 40,000 joules have been discharged into the apparatus (cf. 200,000 joules in Zeta); currents up to 200,000 amp. have been generated and temperatures of nearly four million deg. C. have been measured.

Research in thermonuclear physics

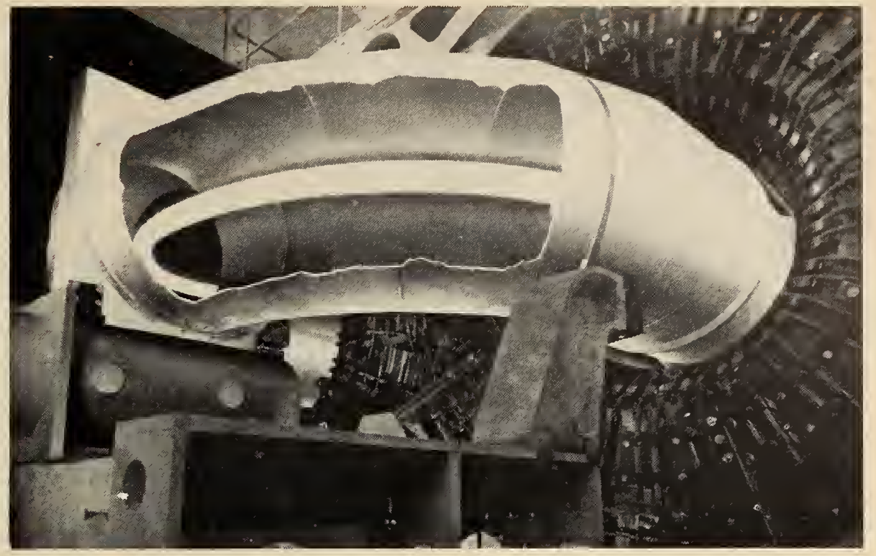
is also pursued in the United States, the U.S.S.R.[4], France, Germany, and Sweden. (A note on Swedish work is on page 89 of this issue.)

Personalities

Head of the General Physics Division, and Chief Physicist, Atomic Energy Research Establishment, Harwell, is D. W. Fry; leading the group responsible for Zeta is Dr. P. C. Thonemann, an Australian, who worked on the early stages of the program, at the Clarendon Laboratory, Oxford. Other senior members of the group are: R. Carruthers, concerned with design and prototype experiments; R. S. Pease, leader of the Zeta team; J. T. D. Mitchell, assistant chief engineer at Harwell; and Dr. W. B. Thompson, honours graduate of the University of British Columbia.

Sir George Thomson, who started experimental work on controlled thermonuclear reactions at Imperial College in 1947, and who continues to advise the group at the A.E.I. Research Laboratory, was awarded the Nobel Prize for Physics in 1937 and is a Royal Medallist of the Royal Society, among many other distinctions in the field. Dr. T. E. Allibone is director of the Laboratory, and senior members of the Aldermaston group are D. R. Chick and Dr. A. A. Ware.

Full collaboration in the field of thermonuclear research was established with the United States Atomic Energy Commission in October 1956.



A cut-away view of the Zeta torus, showing the transformer on the right. The white strip in the centre of the torus indicates the pinched gas discharge.

NUCLEAR POWER PROJECTS

Contracts for the world's first three nuclear power stations designed exclusively for power generation were announced in London on 13 December 1957. Negotiations for a fourth have been started. Net output of the three stations will be nearly 900 megawatts.

The largest will be built in the south of Scotland by the General Electric Company — Simon Carves group, with installed capacity up to 360 Mw. and guaranteed output of 320 Mw. Coal saving will be at least a million tons a year, and expected use before shut-down is at least 20 years. The station will cost about £35-million plus £2-million for initial research; cost of electricity delivered (in 1961) will be 0.7 pence per unit.

The second and third units will be at Bradwell, Essex (Nuclear Power Plant Company), and at Berkeley, Glos. (A.E.I.—John Thompson group), with respective net outputs of 300 Mw. and 274 Mw.

In addition, the Central Electricity Authority is negotiating with the English Electric, Babcock and Wilcox, and the Taylor Woodrow group for a fourth station in Somerset, in the west of England. The stations will be improved versions of the gas-cooled graphite-moderated type used at Calder Hall.

Capital investment for the four stations will be more than £150-million. Cost of the first three new stations will not be less than two and a half to three times that of conventional stations, but it is hoped that the cost of further units will be progressively reduced until nuclear power will become competitive with or even cheaper than that produced from coal and oil.

New Nuclear Power Group

A further British group was formed in December 1957 to tender for design and supply of nuclear power stations in the U.K. and abroad. The companies involved are: Richardson's Westgarth and Co. Ltd., suppliers of generating plant; International Combustion (Holdings) Ltd., steam generating equipment, including reactor, heat exchangers, and pressure vessels; and Crompton Parkinson Ltd., switchgear, transformers, cables, and motors The group will operate through a joint company — Atomic Constructions Ltd. — with authorized capital of £1-million.

OTHER NUCLEAR DEVELOPMENTS

Recent developments in Britain include expansion of the Radio-chemical Centre, at Amersham, Bucks., where radio-isotopes are processed and some 18,000 consignments a year are distributed in Britain and fifty different countries; a new research establishment (reactor design and development) at Winfrith Heath; and the Rutherford High-energy Laboratory, at Harwell.

A £1-million contract for the latter, to be directed by Dr. T. G. Pickavance, has been awarded by the National Institute for Research in Nuclear Science for buildings that will house the Institute's new large accelerator (proton synchrotron). The magnet of the synchroton will be in a concrete building with a roof 4 ft. 6 in. thick plus a covering of 10 ft. of earth and provision for a further 10 ft. of earth if necessary. The main shielding wall will be 28 ft. of concrete, with movable blocks up to a height of 12 feet. The magnet yoke will consist of 340 steel blocks, each weighing 20 tons, and will cost over £1,250,000.

Expenditure on Nuclear Energy

Gross expenditure on atomic energy authorized by Parliament, for five years to 31 March 1958, totalled about £340-million, excluding sums not disclosed for security reasons, and expenditures on their own account by industry and universities.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

Nuclear Power Plant Division for A.E.C.L.

As announced February 1, 1958, by the Hon. Gordon S. Churchill, Atomic Energy of Canada Limited will set up a Nuclear Power Plant Division which will be responsible for directing and co-ordinating the Nuclear Power Demonstration (NPD) project and the development program for a 200,000 kilowatt nuclear power plant. The division will be located in Toronto. The Hydro Electric Power Commission of Ontario will provide the office accommodation.

The H.E.P.C. of Ontario has also agreed to make available the services of H. A. Smith, Hydro's assistant general manager (engineering), as manager of the new division. Mr. Smith has been on loan to A.E.C.L. for the past four years, during which time he was in charge of the Nuclear Power Branch at Chalk River. This branch prepared the outline specifications for the NPD reactor and also carried out the preliminary design study for the nuclear power plant.

John S. Foster has been appointed deputy manager of the new division. Mr. Foster's services were loaned to A.E.C.L. by the Montreal Engineering Company Limited early in 1954. He was associated with Mr. Smith in the work of the Nuclear Power Branch in 1954 and 1955. During the past two years Mr. Foster has been on loan to the Canadian General Electric Company in connection with the detailed design of the NPD reactor.

Several utilities in addition to the H.E.P.C. of Ontario and several manufacturers have already indicated a desire to provide staff to the new division. A.E.C.L. would welcome enquiries from the other utilities and from all the manufacturers which are now engaged in the program or which may have an interest in the program.

The development program for the 200,000-kilowatt nuclear power station will require a period of from 3½ to 4 years for its execution. The object of the program will be to demonstrate the engineering feasibility of the design concepts and to prepare a cost estimate for a station of this design. The major part of the development work will be undertaken by Canadian manufacturers. That part of the program requiring the use of reactor facilities—reactor core design and the design and development of fuel elements—will be carried out at Chalk River. The NRX reactor proved to be a unique tool in this type of applied research and development. The NRU reactor which came into operation on November 3, 1957, will make available even better facilities for research and test.

Design of the NPD reactor and the conceptual design for the nuclear power plant are based on technology which Canada has pioneered with the NRX reactor—that is the use of natural uranium as a fuel and heavy water as a moderator. This technology offers excellent promise of producing power at a cost which will be acceptable in some parts of Canada. In the early years of power reactor development, Canada was alone in applying this particular technology. It is significant that a number of other countries are now showing considerable interest in the natural uranium-heavy-water system. It is said to be well adapted to European requirements.

The successful development of a nuclear power station using natural uranium as a fuel will help to provide a larger, more diversified market for natural uranium produced in Canada.

Sturgeon Lake Power Plant

Canadian Utilities, Limited, Edmonton, started full production at the $1 million generating plant at Sturgeon Lake, a gas turbine powered unit.

The full load test, January 21st. was made under the supervision of engineers of Brown Boveri Canada, Ltd. The test established a new engineering record in that this was the first time this particular type and size of gas turbine generator has ever produced 10,000 k.w., it is reported.

Regular production was to be interrupted February 1st for a routine three-day inspection of bearings and other critical factors.

The new plant will serve the entire Canadian Utilities, Limited, Grande Prairie area and the Slave Lake group of communities. In addition, power will be supplied to the Northland Utilities, Limited system in the High Prairie area. The inter-company exchange will be made through an interconnection located between the Sturgeon plant and Joussard. A total 395 miles of C.U.L. transmission line, in the north-west, will be served from the Sturgeon plant.

The Grande Prairie diesel powered generating plant with a capacity of 6,000 k.w. will serve as a stand-by unit for emergencies, following completion of the February inspection at Sturgeon.

Located 12 miles from Valleyview the new plant has the first gas turbine to burn flare gas direct from an oilfield and particularly in the generation of electricity. Construction was commenced in September, 1956.

St. Lawrence Seaway and Power Project

With first half of January comparatively mild, weather was generally favourable for work on the seaway. With dredging and some excavation closed down for winter, overall employment had fallen to around 9,000 or about 43 per cent of the peak employment last fall.

Progress By Ontario Hydro

Employment for the month averaged 3,100. Work, exclusive of equipment and machinery installation on Canadian half of the international power-house, had reached some 83 per cent of completion, while placing of concrete was 90 per cent completed and was continuing, with 895,000 yards poured to month end.

All the trash racks were in place on the intake structure and the majority of the intake gates were delivered. Drum gates were being installed on the ice sluice. The intake gantry was in operation and the power-house gantry was operating on part load. Two turbines were installed. Assembly of the first four generators was under way, with one stator aligned and levelled, and two more stators nearly completed. Assembly of two rotors was 90 per cent complete.

All dikes on the Canadian side were completed. Excavation at Iroquois Point was 66 per cent finished, with only dredging to complete. Channel improvement at Chimney Island had been 70 per cent completed. At Galops Island there was some work left on dredging, and on cofferdam removal on the first stage. At Point-three-Points, with 75 per cent of channel improvement completed, work was being continued, while near Morrisburg and at Cardinal channel improvement had reached 10 and 25 per cent respectively. Dredging at all these points was adequate for 14-foot navigation.

Clearing of bushland and trees on the Canadian side was 80 per cent completed, and demolition of houses was proceeding. A start will be made in April on the removal of the first four cells of the downstream power-house cofferdam. Drilling of the earth cofferdam upstream was under way in preparation for its removal in the spring by blasting. Town services at both Ingleside and Long Sault had been turned over to the respective municipalities. The Morrisburg pumping station was put on line. Churches had been opened for use or were nearing completion, while public school construction was progressing.

Progress by NYSPA

Employment during January averaged 1,950 persons. 1.9 million yards of concrete had been placed on all structures and 49.4 million yards of excavation or 94 per cent had been moved. On the American half of the international power-house, work exclusive of equipment installation was 82 per cent completed. Ninety per cent of the concrete had been placed, with placing continuing on a five day schedule. The ice-sluice drum gates were being installed and work of installing the trash racks had commenced. None of the intake gates had been delivered.

Three turbines had been installed at month-end, with a fourth being assembled on the erection bay. Two generators were being assembled. The 300-ton gantry crane was in operation. Installation of electrical equipment had reached about 20 per cent of completion. The switchyard was 40 per cent completed, with structural steel being erected and transformers being installed.

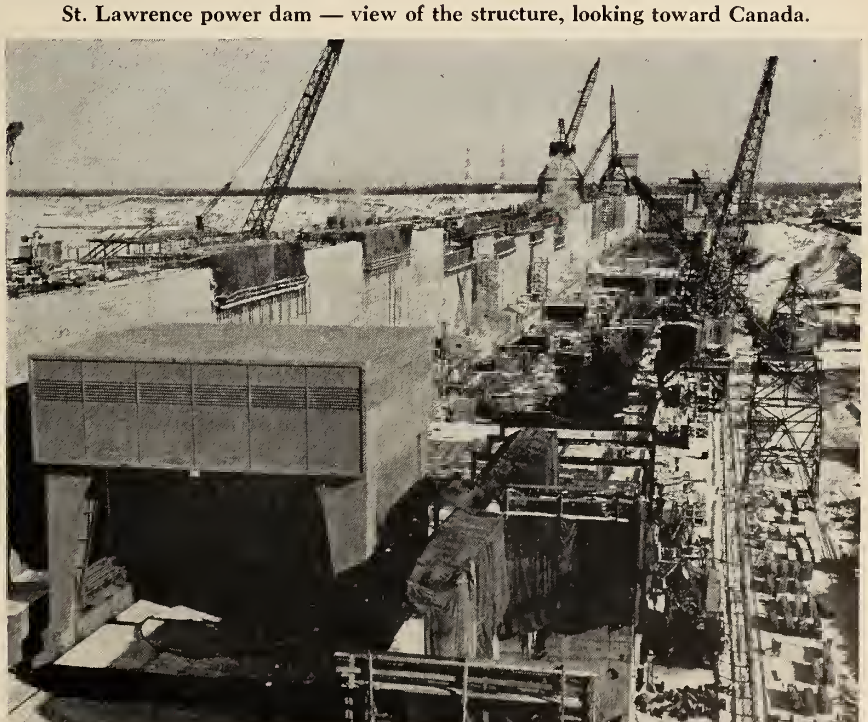
Four cells of the downstream cofferdam will be removed, starting in April, in preparation for passing water through the plant to test the first units to go 'on line' after the pond is raised. Drilling of the upstream earth cofferdam, preparatory to blasting it in July, is already under way.

On the Long Sault dam, with work 90 per cent done, second stage cofferdams were being removed. Placing of concrete was continuing intermittently from the power-house mixing plant on north bulkhead blocks. In March, placing of concrete will be resumed on the rollaways in stage I from pontoons on the downstream side. Diversion of the flow through the stage II tunnels will be commenced after the ice goes out of the river.

Elsewhere, the Massena intake was completed, as was the Iroquois dam with exception of removal of the last piece of cofferdam. Operation of the dam was commenced in mid December by Ontario Hydro.

Dikes on the American side were completed except for two gaps left for railway spurs. Dredging for channel improvement at Chimney Island was completed, as also was the dry excavation of the channel at Sparrowhawk-Toussaint, though dredging at the latter was continued on the rim dike throughout January. Channel excavation with exception of cofferdam removal was also completed at Point-Three-Points, Leishman's Point and Ogden Island. At all of the places the channels were adequate for 14-foot navigation. January was marked by completion of reservoir clearing, several months ahead of schedule.

St. Lawrence power dam — view of the structure, looking toward Canada.



Progress by SLSDC

With concrete excavation and dredging closed down for winter, employment was sharply reduced to some 400 persons. At the Eisenhower lock there remained some 200,000 cubic yards of earth to remove at the downstream approach, while excavation of road approaches and completion of the highway underpass paving was deferred until spring. With gate installation completed, work on installing machinery and electrical controls was proceeding.

At Grass River lock 700,000 cubic yards still remained to remove from a 'plug' to make 27-foot navigation possible. A third of this material must be removed before July to permit 14-foot navigation. Lock gates were installed and installation of electrical controls was under way. On the mainland section of the Long Sault canal, now 97 per cent finished, only some 200,000 cubic yards remained to be cleaned out of the bottom.

On the Cornwall Island channel, some dredging remains to be done for 14-foot navigation on the American side next spring, but excavation at Raquette Point was completed. On the Canadian side work was continuing on schedule during the winter months. There was only one point on Cornwall Island to be removed to permit 14 ft. navigation.

On the new high level highway bridge at Cornwall, new rings of steel sheet piling had been driven around the pier base to permit additional grouting. This work, interrupted by winter weather, will be resumed in the spring after the ice goes out. Except for this grouting, piers and approach trestles were completed. The old bridge was still in operation but ferry docks were being built at each shore. A ferry had been delivered and was being assembled. A contract had been awarded for the superstructure steel, but delivery had not commenced.

Progress by SLSA

Locks: On the St. Lambert lock excavation was continued during January with some 125,000 yards removed. Placing of concrete had been suspended in December with some 4,000 cubic yards left to complete with ready-mix. At lower end the stiffleg derrick had been set up and stoplogs were being placed. Installation of taintor gate valves had been started. Gate installation had not been started. With the trunk sewer completed along the south shore, regulating gates were being installed at the north end. The cofferdam in the excavation was practically completed on the upstream approach; while water had been let in at the lower end of the lock.

At the Cote Ste. Catherine lock, while no concrete was being placed this winter excepting small amounts of ready-mix, excavation of rock was being continued, with 1½ million yards removed to date. Bedded parts were being installed for the sector gates and the lower installation of mitre gates and electrical equipment was proceeding.

At upper Beauharnois lock, excavation was continuing and some 22,000 yards of rock removed in January brought total to date to over a million yards. Placing of concrete had been stopped at year-end. Excavation was proceeding in the canal upstream. On the lower Beauharnois lock, with placing of concrete closed down, excavation was proceeding. One derrick had been erected and the upstream stoplogs had been installed, but no gate erection had been started.

Bridges: At Victoria bridge, erection was proceeding on the vertical lift span, building it around the tracks which were temporarily supported on falsework. On the Jacques Cartier bridge, all bailey bridges, falsework and erection trestles had been removed and jacking up of the superstructure was continuing on schedule. On the south end of the Mercier bridge, erection of the structural steel deck spans was proceeding at three places, with four spans completed in places. On the C.P.R.-N.Y.C. rail bridge at Caughnawaga, with both north and south approach spans erected, work was proceeding on the lift spans, with the portions which lift installed on one track and proceeding on the other.

Other Seaway News

Welland Enlargement

A new Welland canal, costing some $75 to $100 million, will be needed within 10 years if the seaway is to carry its full potential and pay for itself in 50 years. Toll plans will assume Canada will build this duplicate canal soon enough to allow full development of traffic. In all Canada-U.S. negotiations Canada has been given credit for the $132 million spent on the Welland up to 1932. But the existing Welland locks will impose the limit on through traffic after the seaway is opened in 1959. Seaway authorities are counting now on a traffic build-up to 65 to 70 million tons by 1970. Prospects of this large expenditure in the near future is one of the major reasons against keeping the canal free of tolls. Canada will want to keep the reconstructed Welland on the same self-liquidating basis as the rest of the seaway. The greater volume of traffic will also make possible, it is believed, a rate of tolls close to the level the Seaway's advocates in the U.S. assumed in 1953.

Dominion Marine Association

At the annual convention in January the D.M.A. proposed that an experimental toll collection system be established for the seaway, but that no actual tolls be collected for three to five years.

Admiral Lyndon Spencer, president of the U.S. Lake Carriers Association, felt personally there should be no tolls. "Let's pay it off in taxes and be done with it", he said. But his association would not oppose tolls, he added. He did not see what could be accomplished by setting up a tolls system without actually collecting tolls.

D.M.A. officials also consider it of vital importance that facilities built on Canadian territory should remain under Canadian control, whatever the policy of the U.S. government. A joint toll agreement such as appears possible under provisions of the Seaway Authority Act was viewed with alarm. Any agreement at Authority level could have the same effect as a treaty commiting Canadian territory to control by a foreign body. Imposition of a single tolls system over which Canadian government would lack complete sovereignty, must be avoided, D.M.A. warned.

SLSA President Charles Gavsie, stated on January 28, that "it is fully expected that 27-foot channels being dredged under contracts awarded by the Authority will have been completed by the opening of navigation in 1959 to a stage that Seaway shipping will be accommodated safely". This was in answer to the opinion expressed by DMA President, Captain R. B. Angus earlier that there were doubts as to the completion of the seaway for the Spring of 1959 because of dredging having fallen behind schedule.

Such work as will remain to be done during the 1959 season of navigation would not unduly restrict or be hazardous to shipping, said Mr. Gavsie. Expectations were that at the opening of navigation in 1959, the channel will be fully completed from Montreal harbour through the Laprairie Basin, Lake St. Louis, Beauharnois canal and Lake St. Francis.

The SLSA portion of the south Cornwall channel will be dredged to full depth for a minimum of 400 feet prior to the opening of navigation in 1959. The channel approaches above and below the Iroquois lock will be fully completed. The improvement of the Thousand Islands section by removal of scattered shoals will be completed to a minimum width of 400 feet. The deepening of the Welland chip canal will be completed.

The turning basin at the entrance to Montreal harbour will not be completed during 1958. This may necessitate the turning of large vessels further downstream, within the harbour.

Mr. Gavsie also referred to a statement made by Captain J. S. Walton. Commodore of Colonial Steamships Ltd. fleet, that the currents in the approaches to Iroquois lock would make unsafe the handling of large Great Lakes vessels when the 27-foot navigation is opened.

An inspection was made on January 29 of the Ontario Hydro hydraulic models at Islington, by two groups of Great Lakes steamship operating personnel with particular reference to the Seaway Authority's Iroquois lock. Among the officers present were Captain Scott Misener, President of Colonial Steamships, and Capt. Bruce Angus, President of the Dominion Marine Association.

All present were satisfied that conditions that will exist in the downstream approach will be excellent and present no difficulties to navigation. A cross-current at the upstream approach will render navigation a little tricky, but consensus of opinion was that when the masters of vessels become familiar with conditions there will be no obstacle to safe navigation.

U.S. Railways Behind Free Port

A group of midwest and western U.S. railroads are reported considering using Chicago as a mammoth terminus for future seaway traffic. They would incorporate a steamship company and use Mortier Bay on the south coast of Newfoundland as an eastern terminus, trans-shipment and processing point for inbound and outbound goods.

Mortier Bay is an undeveloped, almost fog-free port. A free port there would involve investment of hundreds of millions.

Deas Island Tunnel

The four-lane, 2,100-foot tunnel under the Fraser River at Deas Island, B.C., will connect Vancouver via Lulu Island with a new highway to the U.S. Border. It is scheduled for completion next year.

Total length of the crossing including approaches will be 8,000 feet.

Concrete sections are built in drydock, floated into position, sunk in a prepared trench and then joined. Since these pictures were taken, one of the elements has been floated into position and sunk.

The sections are 344 feet long, 78 feet wide and 24 feet high, each containing two tubes with 24-foot roadways. Roadways are separated by concrete bulkhead, and a duct at the outside of each roadway is provided for ventilation, wiring and drainage.

When completed, the tunnel will be capable of handling 7,000 cars an hour. It will contain 100,000 yards of concrete, 12,000 tons of steel, and will require 2.5 million cubic yards of excavation and backfill, plus 200,000 yards of riverbank protection. Total cost is expected to be $16.6 million.

It is one of six major crossings being undertaken by the B.C. Toll Highways and Bridge Authority. It was designed by, and is being built under supervision of the joint venture of Foundation of Canada Engineering Corp. Ltd., and Christiani & Neilsen of Canada Ltd.

Canadian Pipeline Projects

The natural gas industry of Canada can look back on 1957 as a year of solid accomplishment. Eight months production at 206 billion cubic feet was up some 22 per cent over the 169.2 billion feet for the previous year.

All main pipeline projects scheduled for completion in 1957 were laid, tested and filled. Several cities and many smaller communities were already using natural gas for the first time. Some 2,000 miles of main gas lines, 2,300 miles of laterals and distribution mains had been laid during the year.

Yet natural gas, after nine years as a political football, was still a resource without adequate assured markets, whose owners do not know when or if they will be permitted to serve markets currently open to them. The result; — increasing economic pressure on all members of the industry from the $150 million of non-revenue producing capital so far tied up in gas lands and capped wells.

The consensus of opinion among producers is that regardless of what happens before the next election, there is not the slightest chance of the Federal Government reversing its policy on export immediately. They look for a long, tough, and possibly unrewarding fight.

Canada's bargaining position in respect to oil exports is also weakened by the persistent refusal to commit ourselves officially to a policy of liberal gas export. This is a challenge to the Alberta government as well as to Federal authorities. Alberta has not stated how much gas it is prepared to declare surplus beyond quantities now committed. If such a statement were made it would demonstrate Ottawa had no reason to suspend action about a matter on which operators and the local conservation authority are in complete accord.

Westcoast Transmission

Westcoast Transmission attained a throughput volume of 300 MM c.f.d. average by the middle of January in its mainline from Taylor to Huntingdon, B.C., according to the annual report for 1957, released January 8. "In the short period between the official opening on October 8th and year end, deliveries were being built up to Inland, to B.C. Electric and to Pacific Northwest Pipeline Corp."

Trans Canada Pipelines

Trans Canada Pipelines early in January announced awards for contracts on the 486 miles of 30-inch pipeline to be built this year from Kapuskasing to Maple, Ontario, near Toronto.

Spread 9: 83 miles from Potter to main highway southwest of Kirkland Lake; — to Majestic Contractors Ltd. This spread is entirely in the clay belt, with glacial till and boulders.

Spread 10: 57 miles from Kirkland Lake to Rib Lake; to Dutton Williams Brothers Ltd. Starting in the clay-belt this spread merges into granite rock terrain in the southerly half.

Spread 11: 47 miles from Rib Lake to near Tilden Lake; to Canadian Bechtel Ltd. The spread is almost all in granite rock.

Spread 12: 62 miles Tilden Lake to South River, passing through North Bay; to Morrison Shivers Ltd. The spread has some granite at the north end, but merges into sandy clay and sand to the south.

Spread 13: 63 miles from South River to Bracebridge; to Price Poole Ltd. Starting in sandy clay, the spread runs into granite at the south.

Spread 14: 92 miles Bracebridge to Maple: to Oklahoma Constructors Ltd. Traversing the rest of the granite rock as far south as Orillia the spread merges into sandy pine country to Barrie then through cultivated farmland to Maple.

Start of pipelaying is planned for about May 1st. Major water crossings to be let separately are over the Kapuskasing, Groundhog, Mattagami, Wattabeag and Muskoka rivers, and Gull Lake.

Delivery of natural gas to the Lakehead cities of Fort William and Port Arthur was officially commenced at the end of January.

Inland Natural Gas

Almost 90 per cent of the homes in the B.C. interior connected for natural gas are using the fuel for heating. Sales of gas-fired heating equipment in the 27 communities served by Inland Gas were estimated by appliance dealers at 4,000 units in the last quarter of 1957.

Winnipeg and Central Gas

Plans for reorganization of the Company were announced in mid-January. Many problems are facing it and it may be necessary to change the Company's name. Blame for the Company's position was placed on representations during 1957 by other gas utility interests to some of the municipalities in the Greater Winnipeg area. The publicity accompanying these representations plus a deterioration in national security markets had so far made it impossible to arrange a long term financial program. If terms of reorganization are implemented, prominent interests in the utility field will participate in the company's new financing.

Northern Ontario Gas Sales

The first major contract for sale of natural gas to industry in Northern Ontario was completed in January. A contract was signed between Twin City Gas Co. and Abitibi Power and Paper Co. for delivery of 20.8 billion cubic feet of gas over a 10 year period at a cost of $7.7 million. This represents a major portion of Abitibi's fuel needs for its three mills at Port Arthur and Fort William. Another important gas sales contract has been made with Canada Malting Co. at Port Arthur. Further east, Northern Ontario Natural Gas Co. and affiliated companies with an extensive franchise area in north-western Ontario is negotiating large sales contracts with four other pulp and paper companies. Work on distribution systems in Kenora, Dryden and Fort William and Port Arthur is on schedule. Twin City has installed 41 miles of an eventual 300 miles of distribution lines.

Consumers Gas Company

An aggressive sales campaign throughout the greater Toronto area, second largest residential market in Canada, has brought about connection of natural gas to some 75 per cent of all single family houses built last year in the greater metropolitan area, while almost two thirds of them have water-heating service also installed. Virtually every major builder of small and medium priced houses in the area has either swung over to gas service or plans to do so at an early date.

Lakeland Natural Gas

Lakeland has completed the first stage of construction of its gas distribution facilities costing $2 million in Port Hope, Cobourg, Trenton, Belleville, Napanee, Gananoque, Prescott and Cornwall. Delivery of gas will commence early in February in all eight communities.

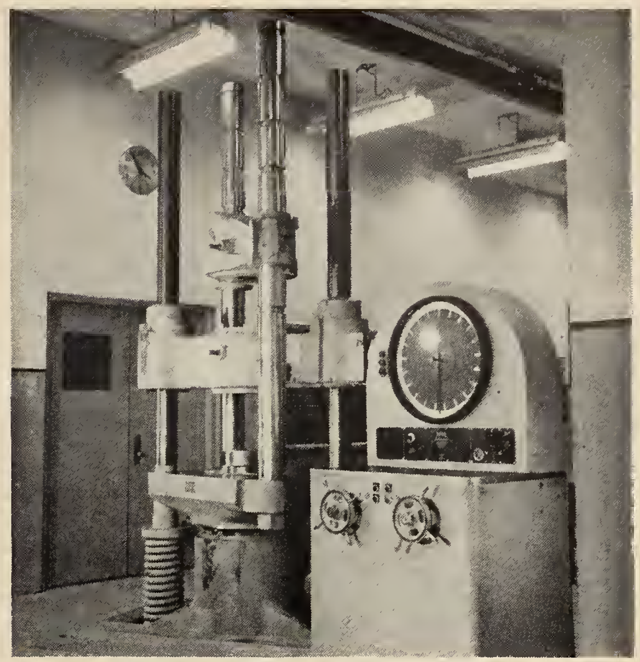
Quebec Natural Gas

A new rate structure is being prepared by company officials for submission to the Quebec Electricity Board. New rates will not come into effect until after the entire city has been converted from manufactured to natural gas about the end of May 1958.

Alberta and Southern Gas

Alberta and Southern Gas Co. Ltd. has more than enough natural gas under contract or option with Alberta producers to supply the 450 million c.f.d. specified in its application to the Alberta Conservation Board. Contracts are signed with a dozen leading producers in addition to those previously announced with Shell and producers in the Pembina field. New contracts cover supplies from the Dick Lake, Pine Coulee, Holmglen Rimbey, Minnehik, Cattle River and other areas. They cover deliveries adding up to some 175 million c.f.d.

Low speed wind tunnel at U.B.C.



Baldwin-Southwark testing machine.

The Faculty of Applied Science of the University of British Columbia

The University of British Columbia has undertaken "The Plan for 1965", a development program which would correct physical deficiencies and provide for another, greater and permanent influx of students now developing.

The university, with a student body which at the end of World War II more than doubled in one year to a figure of 6,600, now comprises ten faculties and five schools, as compared to its three faculties of 1944.

The development program will affect the university as a whole, providing urgently needed buildings and services, and it will benefit the faculty of applied science in the form of an engineering building at an estimated cost of $2 million.

In the meanwhile, as Dean H. C. Gunning of the faculty of applied science reports, only one small engineering building has been added in recent years—for physical metallurgy.

About $15,000 of capital has been spent on modernizing and improving the accommodation in various departments, particularly in chemical engineering and electrical. The special need was improved laboratory facilities and increased space and equipment in shops to handle the increased amount of research work at the undergraduate and graduate levels.

To meet the needs of a greatly enlarged enrolment, there are preliminary plans for building construction for the faculty as follows — subject to readjustments as time passes and enrolment estimates are adjusted.

The first phase — 1958-1959 — would provide 80,000 square feet of space chiefly for chemical, mechanical, electrical and metallurgical departments.

The second phase — 1960-1961 — would provide 92,000 square feet. This is for the same departments, but it also includes extra space for the first two (common) years of engineering and extra office and research space for civil engineering.

The third phase — 1962-1963 — would give 47,700 square feet. This is additional space for mechanical, civil, electrical, mining and metallurgy.

These plans should meet the needs of the faculty until about 1965, Dean Gunning reports. The program envisages the eventual abandonment of about 50,000 square feet of temporary buildings that are at present occupied by all the departments except civil engineering.

New equipment

The major items of new equipment obtained recently are:

I. 400,000-lb. Baldwin - Southwark testing machine for the civil engineering department;

II. 60-k.v. X-ray fluorescent analysis equipment, by Philips, jointly for the departments of metallurgy and geology;

III. Low speed wind tunnel, in the department of mechanical engineering.

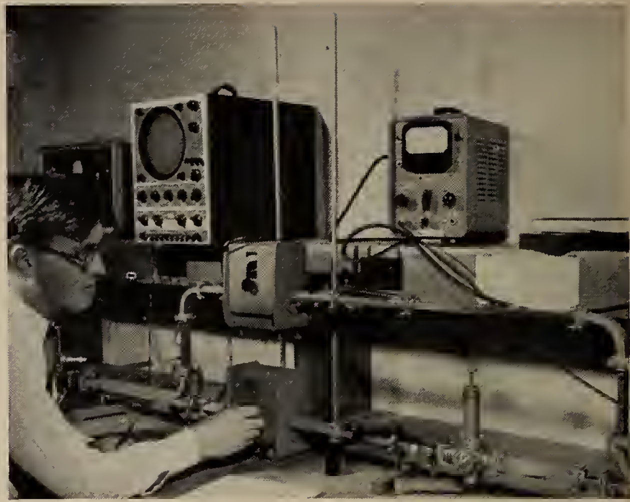
This wind tunnel, designed by Dr. G. V. Parkinson of the department, was first put into operation in July, 1957, and is still being subjected to a program of calibration prior to its general use in student laboratory work and faculty and graduate research programs.

It is of the horizontal, closed-circuit type, with enclosed test section. Through a modified Ward-Leonard drive system, a motor-generator set

The *Journal* Reports Growth in Engineering Faculties in Canada

Third article of a series.

Electronics research — gaseous discharges.



Microwave research — multi-mode cavity filter.

supplies up to 15 horsepower to a d-c motor driving a commercial axial-flow fan. This fan provides airspeeds up to 100 m.p.h. through the test section, which is 3 ft. by 2¼ ft. in cross-section, and 8-2/3 ft. in length. A nozzle upstream of the test section accelerates the air flow to the required velocity, and improves the flow uniformity. The use of a settling section 6¾ ft. by 6½ ft. in cross-section, and 5-2/3 ft. long, containing up to three fine mesh wire screens, upstream of the nozzle, also improves the flow uniformity, and reduces the turbulence level. The settling section is also used as an auxiliary test section for testing large models at low speeds.

The tunnel airspeed can be set accurately to any value up to the maximum by adjustment of generator and motor field rheostats on the control panel, the airspeed being inferred from the reading on a micromanometer connected across piezometer rings upstream and downstream of the nozzle.

The tunnel will be used as a laboratory tool in aerodynamics and fluid mechanics instruction, and as a research tool by faculty and graduate students.

Calibration results to date indicate that the air flow is satisfactorily uniform, and that the tunnel can be run successfully by one person for many types of test. Some useful data have already been obtained on building roof patterns and pressure distributions from model tests in the settling section, and studies of aerodynamically excited vibrations will soon be started in the test section.

Construction of the tunnel has been made possible by National Research Council grants.

Equipment additions in the mechanical engineering department over the past few years have also included: two new lathes; a hair-pin heat exchanger from Brown Fintube (Canada) Ltd.; several items of instrumentation and electronic strain gauge equipment obtained mainly from funds supplied by N.R.C. grants in aid of research.

A workshop acquired in chemical engineering by rearrangement of space will facilitate the modernization and extension of laboratory teaching equipment.

Courses and Curricula

The department of electrical engineering during the past year has continued to improve its facilities both for undergraduate and post-graduate instruction. The undergraduate program has been re-examined and two general options introduced. One is a course of studies along traditional lines with the usual emphasis on technology. Both power and electronics are covered. The second is a course in which greater emphasis is placed on the mathematical and physical bases of electrical engineering, and attention is directed toward the information and energy processing aspects of electrical engineering.

In March 1957 the university installed an Alwac III E digital computer as an aid to scientific research on the campus. The project is being financed by local industry, the Defence Research Board and the National Research Council. The department of electrical engineering has accepted the responsibility for the technical supervision of the computing facility as well as provision of courses of instruction on both digital and analogue computing devices.

The research facilities in the department have been extended particularly in the fields of micro-wave research, analogue computation and control systems. Current research projects include ferrite micro-wave devices, multi-mode filters, general purpose analogue computer, variable torque induction motors, speech compression, studies in gaseous discharges, delta modulation, medical electronics, electronic isograph and klystron amplifier design techniques.

The curriculum in mechanical engineering has recently been revised with the emphasis being placed on the theory and scientific basis for engineering decisions rather than on past practice. The elementary metallurgy course has been shifted from the fourth year to the third to allow an option in design and metallurgy for students who wish more training in physical metallurgy to better fit them for today's difficult problems of material selection and design.

A course in industrial engineering has been introduced which is taken by all mechanical engineers. This course requires considerable outside reading, and is expected to help in improving the ability of the students to express themselves well in speech and in writing. To this end also, a course in English was introduced into the third year a couple of years ago.

In the session 1958-1959 it is intended to begin accepting in the department of chemical engineering post-graduate students working for the degree of Ph.D.

Civil engineering is considering consolidation of some of its courses on soil mechanics, foundations and earth pressures. It is also giving serious consideration to optional courses for juniors and seniors. Metallurgy has provided a number of options, in physics, chemistry, and mechanical for its upper year students and has attracted and will attract a large number of students from the other engineering departments by providing suitable optional courses in metallurgy. The first year course in physics has been broadened to include more modern physics, and this necessitates some adjustments in engineering courses in statics, dynamics and strength of materials. The course in geological engineering is being adjusted to include more training in basic photogrammetry and in soil mechanics.

All departments are placing greater emphasis on research at the undergraduate and graduate level, and several of them are making use of the new digital computer.

The emphasis on the humanities continues to expand by the inclusion in the curriculum of more class or seminar work in English, human relations, and basic economics. Voluntary work in these areas is encouraged.

Kelowna Floating Bridge

To the middle of January work on the Kelowna Floating Bridge, being constructed for the B.C. Toll Highways and Bridges Authority was approximately two-thirds complete and at the present rate of progress the bridge will be in operation on or before the scheduled completion date at the end of August.

Construction of the concrete pontoons and the lift span piers has been completed without any serious difficulties arising. The contractor's graving docks, concreting facilities and cell forms, as described in a previous article (*Engineering Journal* April 1957) were very well planned and were mainly responsible for the excellent progress achieved.

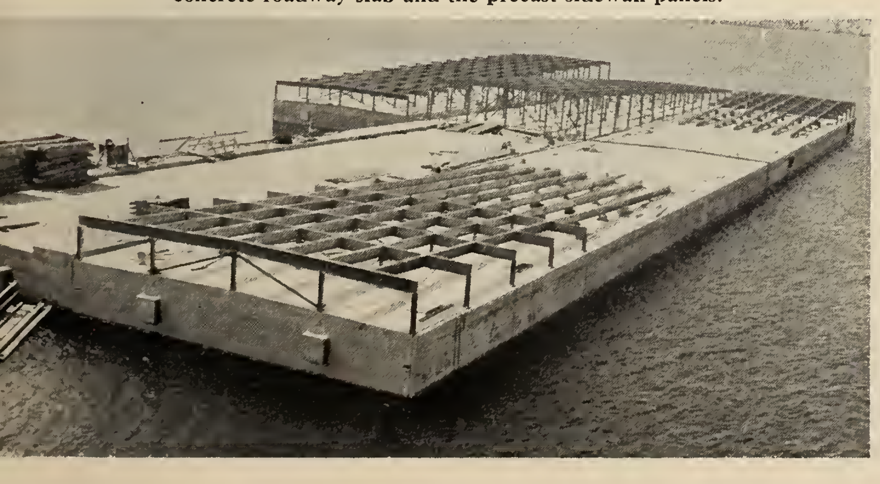
The contractor is now placing the concrete anchors which will hold the pontoons in position. The first pair of these anchors placed did not reach a sufficient embedment and it was necessary to redesign the jetting system. One of these anchors projected only two feet above the bottom and its embedment was later increased by backfilling with pit run gravel. The other anchor was raised, the bottom excavated and the anchor then placed in the excavation which was also backfilled with pit run gravel.

The original jetting system consisted of 21—1 in. diameter and 1½ in. diameter jets cast into the concrete anchors and a pump supplying about 1,200 U.S. g.p.m. The new system attached to the face of the anchor walls has 16—2½-in. jets and three pumps with approximately three times the original capacity. The majority of the anchors placed with this new jetting system have reached the required embedment and those few that do project slightly above the bottom will be covered with pit run gravel.

The final phase of this work, connecting the pontoons to the anchor cables, will be underway shortly and should be completed in March.

The Dominion Bridge Company started erection of the steel trusses early in January. By the end of May they intend to complete the erection of three approach spans, two lift span towers and the lift span.

Structural steel in place on the superstructure pontoons ready for the lightweight concrete roadway slab and the precast sidewall panels.



What Goes On

Bell Telephone

The complete microwave network from Sydney, N.S., to Victoria, B.C., will be operational in 1958.

The network carried telephone and television west in 1957, and linked Quebec and Saint John, N.B., in February 1958, adding the Maritime network. Links between Montreal-North Bay-Sudbury-Sault Ste. Marie were being developed in 1957 — as well as a chain between Montreal and New York. Nipigon, in Ontario, Goose Bay, in Labrador, Seven Islands, Quebec, and other northern centres have or will have new or better communication by means of links with the Trans-Canada Telephone System.

Niagara Falls Power

Hydro Electric Power Commission of Ontario reported at year end that work at Niagara Falls was going ahead rapidly on the installation of four additional units at the Sir Adam Beck-Niagara Generating Station No. 2. By the end of the year two of these generators were in operation, while the other two will come into service by the summer of 1958. These, together with the 12-unit-phase completed in 1955 and the associated pumping-generating station will bring the total capacity of this plant up to 1,370,000 kilowatts.

Hydro started work in August, 1953, on the pumping-generating project and a 750-acre reservoir with a capacity of 650,000,000 cubic feet. By the end of 1957, the first three of six units were in operation. A particularly interesting feature of this unique undertaking is the reversible type of turbine-generator which was designed for this station. During low power demand periods, the units, operating as pumps, lift water from the power canal into the reservoir. Then, at peak demand periods, by the simple moving of a switch, they operate in reverse to act as generators. In this process, the water is discharged back into the canal, permitting fuller use of all generating units in the Sir Adam Beck-Niagara generating stations.

At Niagara Falls also, the far-reaching Remedial Works Program, carried out by Ontario Hydro and the Corps of Engineers, United States Army, was officially completed in September.

AND TRANSFERS

IAESTE Annual Conference

The Engineering Institute participated in the annual conference of IAESTE which took place in Madrid, Spain, in January, with the Spanish IAESTE committee acting as hosts. This non-political, non-profit association of 22 nations (The International Association for the Exchange of Students for Technical Experience) is the agency which has for 10 years been placing undergraduate engineering students in positions abroad during the vacation prior to their final year. These students then return to their own countries to complete their courses.

Professor J. Pazo, of Spain, was elected as conference chairman. Canadian delegate to the Madrid conference was E. C. Luke, assistant general secretary of the E.I.C., who is secretary of the Canadian national committee of IAESTE. Administration of the exchange is provided for Canada through E.I.C. Headquarters.

Mr. Luke's report of the proceedings told of discussion of points of exchange administration, of treatment of applications for admission of Greece and Tunisia, and of the decision that the next conference will be held in Istanbul, Turkey in January, 1959, and the following one in 1960, in Yugoslavia.

A forecast of the new year's operations disclosed that exchanges can be anticipated at about 5,300 in 1958, showing a slight downward trend which is thought not to be a serious development. A slight increase in national subscriptions was called for in view of higher administrative travel costs. A recommendation was adopted that an IAESTE publicity leaflet be prepared in English, for distribution by all interested countries. Translations were to be considered later.

James Newby, of Great Britain, relinquishing his post on the IAESTE advisory committee, was tendered an enthusiastic vote of thanks for his excellent work and long association with the exchange plan, actually dating back to its beginning.

Observations reported by Mr. Luke to the Canadian committee and E.I.C. Council commented on the dignity and friendly atmosphere of the conference. The European nations attach great importance to the IAESTE plan, whereby nearly 35,000 students have now been exchanged. The opinion is evident that of all the international movements started after the war, IAESTE has grown and prospered probably more than any other, and is therefore a considerable influence for mutual understanding and peace.

IAESTE Conference, Madrid: Delegates at the first plenary session, January 13, by countries, right to left: Canada, India, Sweden, Spain, Denmark, Italy, France, Netherlands — (remainder not identifiable).

The Eastern Field Secretary

John A. McLaren is the new eastern field secretary of the Engineering Institute, with offices in Toronto, having succeeded Colonel L. F. Grant, who retired at the end of 1957.

Mr. McLaren was born in the Ottawa Valley at Cobden, Ontario. He attended Brown's School in Toronto and Beamsville High School, and the University of Toronto from which he received the degree of B.A.Sc. in chemical engineering in 1931.

John A. McLaren, M.E.I.C.

He commenced his career as assistant engineer in the Division of Sanitary Engineering of the Ontario Department of Health, and was for two years in the research and control laboratory of the Brewing Corporation of Canada. In 1936 he went to Wm. R. Warner to set up a control laboratory, later becoming assistant superintendent, and finally plant superintendent for that company. During the war years, 1940 to 1945, he was with Defence Industries Limited, first at Nobel where he was a supervisor during the start up of the cordite manufacturing operation and later superintendent of the T.N.T. plant. Then, at the Villeray fuse filling plant, as superintendent of quality control, he was in charge of the technical and inspection staff.

Since the war, Mr. McLaren has been engaged in management, being connected with Lyman's Limited and Lyman Agencies as general operations manager; organizing and managing Georgian Bay Airways Limited; acting as secretary-manager of the Sudbury and District Chamber of Commerce during 1949 and 1950; leaving that position to organize Leland Sales (Eastern) Limited, in Toronto, and later acting as technical and financial consultant to the firm.

He became a Member of the Engineering Institute of Canada in 1950, and has been a Fellow of the Chemical Institute of Canada since 1943.

Mr. McLaren and his staff are actively concerned with assisting branches and student sections of the Institute in Eastern Canada. Mr. McLaren's particular attention will be paid to assisting the branches and sections in obtaining speakers, organizing Professional Development Courses. For those members who reside too far from the nearest branch to take part in branch activity, he will attempt to provide personal contact with the Institute, so that each member may continue to enjoy the services which the Institute offers to its members.

Correspondence

"Daylight through the Mountain"

Dear Dr. Wright,

Mr. W. A. Deacon, literary editor of the Globe and Mail, Toronto, has recently assigned to me the pleasant task of reviewing the new book by the Walkers, "Daylight Through the Mountain". I have read and reviewed it with much interest and profit, and am of the opinion that it is a quite valuable addition to Canadian Letters.

May I also express my gratitude as an engineer to the Engineering Institute for the support given to Canadian arts in the publication of such material.

W. F. SUTHERLAND, P.Eng.
Toronto, November, 1957.

THIRTY-FIVE YEARS AGO

Comment on the Journal of March, 1923

The March 1923 issue of *The Engineering Journal* indicates some of the great trends that have developed in engineering over the past three to four decades. Two of the four papers published in the issue emphasize how Canadian developments in the past ten years have changed our thinking and re-directed it into different channels.

The first of these papers deals with railway electrification. In the 'twenties' Canada, conscious of the rising prices for coal and of the vast potential of the nation's water power, was watching electrification of railway lines in the United States and noting the implication it had for Canada's many rail lines. Little did we suspect that in the 'fifties' with great oil discoveries, Canadian railroads and even railroads in the United States would be almost completely dieselized.

The second paper, pointing to the lack of coal deposits in Central Canada and the abundance of low grade ores of Northern Ontario, advocated the conversion of these ores electrically. Today, with vast resources of rich ore available from Ungava and Northern Ontario, with shortages of electric power facing Ontario and Nova Scotia and with new processes such as oxygen furnaces, being developed, there appears much less incentive to add to the 12 per cent of ingot capacity where low grade ores are now converted electrically, nor for that matter to the 80 odd steel furnaces now electrically operated either, except along the lower St. Lawrence river.

The section devoted to Branch News also contained abstracts of papers presented at branch meetings which, when read thirty-five years later, further emphasize new trends in engineering practice. A paper presented to the Hamilton Branch drew attention to the use of rolled rail steel for reinforcing. Today it is almost universally accepted for this purpose. The Saint John Branch heard an address pointing to highway engineering as an 'important engineering project'. Today's expenditure for Canadian highways of some $800 or 900 millions annually would have surprised the listeners.

At the Toronto Branch, Canadian radial lines were discussed. Today the electrified radial lines have all but disappeared, their place being taken by gas or diesel driven bus and coach lines, and the automobile. The Peterborough Branch heard a paper on 'the chemistry of the insulating varnishes'. But advances in the art of insulation for electrical apparatus have brought about tremendous changes and improvement.

Other papers presented,—to the Saint John Branch on land surveying; to the Calgary Branch on "The Aeroplane"; to the Toronto Branch on meteorology, could not visualize the far reaching changes that have been developed since 1923; air surveys, 'Shoran', Canada's huge aircraft industry and worldwide airlines; and the remarkable accuracy of weather forecasting today.

Reading the *Journals* of thirty-five years ago draws one's attention to an improvement in the presentation of papers and addresses. This is the current custom of briefly summarizing the contents of each paper in a 'box' at the beginning of the article.

The Association in 1923

Membership of Associations of Professional Engineers in Canada was recorded as follows: Alberta 321; British Columbia 603; Manitoba 306; Ontario 479; Quebec 905; New Brunswick 176 and Nova Scotia 240 a total of 3,030. Of the total exclusive of Quebec which gave no breakdown, some 60 per cent of the six other associations reporting recorded 60 per cent of the membership were civil engineers. *H.G.C.*

Did You Know That . . .

Close to 20,000 copies of this issue of the *Journal* have been printed and distributed. It costs about twelve thousand dollars to print one issue of the *Journal*.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council held at Calgary, Alberta, on January 25, 1958.

Members: R. G. Billinghurst, Windsor; E. J. Bobyn, Quebec; J. W. Bradstock, Toronto; D. C. Brazier, Toronto; F. A. De Marco, Windsor; I. J. Dickinson, Rossland; J. S. Ellis, Kingston; P. G. Goldsbro, Trail; K. Holbek, Oakville; W. J. Horton, Baie Comeau; W. R. Keating, Baie Comeau; Z. P. Kekes, Montreal; T. M. Lees, Corner Brook; F. Machin, Montreal; J. Manuel, Montreal; F. R. Mottershead, London, Ont. G. E. Plant, Vancouver; G. W. Scott, Baie Comeau; D. L. Servage, Windsor; J. H. Seymour, Toronto; P. H. F. Shanks, Montreal; D. L. Spanjer, Montreal; A. R. White, Peterborough; C. B. Woodley, Lakeside.

Juniors: A. A. Allart, Port Credit; D. Atkinson, Toronto; K. J. Barkley, Halifax; D. D. Craig, Montreal; J. O. Down, Danville; J. F. Macleod, Calgary; T. A. Qureshi, Toronto; J. N. Raftis, Sudbury; T. J. Stephen, Saint John, N.B.; P. G. Wilson, London, Ont.; V. S. Zachovay, Montreal.

Junior to Member: A. F. Barnard, Hamilton; E. E. Bredin, Sarnia; R. E. Chamberlain, Montreal; D. A. Foster, Moncton; A. P. Kilroy, Montreal; P. H. Langlais, Quebec; R. A. F. Latham, Toronto; R. W. McMeekin, London, Ont.; J. Sylvester, Montreal; C. R. Thompson, New York.

Affil. to Member: D. F. Rhodes, Sarnia.

Affiliate: J. A. Forsyth, Vancouver.

STUDENTS ADMITTED:

Queen's University: W. A. Anderson, T. R. Beamish, R. G. Beckman, J. F. Boadway, S. Bosnick, L. F. Buttner, T. E. Callaghan, D. A. Dunsire, P. G. Falkner, R. A. Fuller, C. A. Giovanella, S. W. Guzik, H. R. Hanson, W. H. D. Harris, A. T. Hawkins, R. H. Healey, D. L. Heins, T. A. Hickey, R. D. S. Holmes, J. H. Hutt, R. G. Johnson, D. J. G. Lamarre, R. J. Mackinnon, R. E. MacLaren.
H. R. B. McIntyre, B. D. McLaughlan, R. F. Mikitish, J. T. Milton, W. P. Nolting, H. C. Organ, R. W. Penty, A. J. Pouti, R. M. Pow, E. J. Richards, R. F. Robertson, G. M. Royer, G. A. Schultz, E. F. Schutt, D. D. Smith, D. A. Sutherland, J. M. Van den Berg, M. P. Varcoe, L. B. Webster, J. D. Wilford, S. C. Wilson, W. J. Wilson, O. Zawalsky.

University of Toronto: H. K. Anderson, D. F. Barr, G. N. G. Birch, S. M. Blumenfeld, D. E. Cass, D. L. Comish, S. Fedchak, Z. W. Fedun, P. C. Grace, G. W. Haight, P. B. Long, R. S. Lougheed, J. S. Preece, E. B. Smythe, J. A. Tattle, S. L. Webster.

Memorial University of Newfoundland: E. W. Bown, S. G. Dyke, G. A. Hill, R. L. Janes, G. W. Moores, E. G. Paul, G. R. Peters, C. L. Powell, G. H. Simms, A. Strauss, H. F. Young.

University of Alberta: R. S. Daniels, R. E. Listander, J. W. Twach, A. Willumsen.

Royal Military College: R. Dube, J. W. Y. Lemieux, T. A. London, R. C. Salmon.

Acadia University: R. C. Demmings, J. E. Hutchinson, A. L. McEachern, J. D. Winter.

Univ. of Western Ontario: G. S. P. Castle, T. B. Collings, S. R. Hunt, D. R. Thomson.

Sir George Williams College: H. C. Deys, R. T. Ratony, P. C. Sakany.

Laval University: Y. R. Bourassa, C. E. G. Lafrance.

McGill University: B. F. Rumsey.

Univ. of Saskatchewan: I. H. Brockman.

Graduates: J. M. Campbell, B.A.Sc., (Civil) 1957 Toronto; N. M. Laughlen, B.A.Sc. (Elec.) 1957 Toronto.

Applications through Associations

By virtue of the co-operative agreements with the Associations of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Member: E. W. Abercrombie; **Junior to Member:** R. D. Grantham, R. Pilkington, E. Sherwood; **Student to Junior:** A. G. Swanson.

SASKATCHEWAN

Member: R. M. Bailey; **Junior:** G. B. Babej.

NOVA SCOTIA

Junior to Member: B. W. Allen, L. S. Prikler.

NEW BRUNSWICK

Junior to Member: B. W. Cosman.

French Government Scholarships For Canadian Engineers and Technicians

Several thousand foreign students are working in French institutions, universities and laboratories in many fields of knowledge. The number of engineering and technical students, in particular, has greatly increased since the war on account of the importance of techniques which have been discovered or perfected in France. These students have arranged to take formal courses or to do practical work in industry, often combining both. It has become necessary to organize and co-ordinate these professional "stages". The French Government has created a service to this end (Service de Coopération Technique) and has endowed a great many scholarships, a number of which have been reserved for Canadian engineers or technical men of similar standing. Most "stages" last from November to May.

Value of Grants

a) Payment of 75,000 francs a month for the standard period of six months. (This period can be lengthened or shortened if necessary and possible.) This is worth more in purchasing value than $200 a month in Canada;

b) Free return trip from France to Canada by boat in cabin class or by plane in tourist class;

c) Free transportation in France for authorized trips related to the purpose of the scholarship;

d) Privileges normally reserved to university students, to the extent available (lodging and restaurant facilities, community activities, libraries, lectures, etc.). Many Canadian students in Paris live at "Canadian House" in the "Cité Universitaire"

e) An allowance of 20,000 francs for the purchase of technical books and of 3,000 francs for the cost of typing a final report on the "stage";

f) "Social Security" benefits covering a large part of expenditures in case of illness.

Qualifications of Candidates

a) The candidate must hold, or expect to receive next Spring, an engineering degree from a university or institution of high standing, or he must have an equivalent training;

b) He must have had some field experience in his specialty for *at least* one year, obtained after graduation or through employment during summer vacations;

c) He must possess a sufficient knowledge of French. Arrangements can be made to improve his fluency during the earlier part of his stay in France;

d) He must have good references regarding his academic and professional ability, his general standing and his health;

e) He must propose a precise program for his "stage" in France and be able to carry it out profitably;

f) If he is already working, he must obtain a written leave of absence from his employer. He can continue to receive a salary from the latter, but must devote his time and energy to his "stage" program.

Selection of Candidates

The selection is made by the Commercial Counsellors of the French Embassy, assisted by a panel of French engineers and scientists residing in Canada and called the "Comité France-Technique". A candidate who has been chosen in Canada has a very good chance of being accepted by the Service de Coopération Technique in France, provided it proves feasible to make the material arrangements for carrying out the proposed program.

Prompt Action Suggested

Before filing a formal application, which must be made on an official form and accompanied by several detailed documents, a simplified procedure is suggested, namely, that you *write immediately a letter covering as briefly as possible the following points:*

(1) Name, address and telephone number. (2) Date and place of birth. (3) Academic training or equivalent (specify degree and specialty. (4) Practical experience. (5) References (give name and telephone number of two persons). (6) Knowledge of French. (7) Program and duration of proposed "stage" in France. *This letter should be addressed in triplicate to:*

Mr. Raymond Treuil, Chairman of the Comité France-Technique, c/o French Embassy, 464 Wilbrod Street, Ottawa, Ontario.

Annual General and Professional Meeting of the Engineering Institute of Canada

Quebec City, Quebec

Chateau Frontenac

May 21, 22, 23 1958

EVERY MEMBER is invited, and expected.

THE TECHNICAL PROGRAM is in an advanced stage of preparation, with a varied list of subjects to be treated by the engineers who have been directing the projects that have commanded attention lately.

Some of the subjects are: the Deas Island tunnel; highway research and construction; controls for underground excavations; processing of Ilmenite ores; control system of the CF-105 aircraft; vertical take-off aircraft; the International Geophysical Year; earth satellites and rockets; the Baie Comeau plant of Canadian British Aluminum Company; use of electronic computers; thermal power generation; underground power stations; the Quebec-Labrador radio system.

Developments in Quebec will receive special attention, with nine papers devoted to engineering achievements in the province. Some of these will be presented in the French language.

THE GREAT CHARM and historical interest of Quebec City are already famous. This is the opportunity to make a long intended trip to Quebec, or a return visit. The Quebec hosts are always ready with a gracious welcome. Monsieur Bonhomme, the living spirit of the Quebec Carnival, will put in an appearance, even though the carnival will have been finished.

THE LADIES are welcome, as always, and will be provided with an interesting program of their own.

MORE COMPLETE INFORMATION will be published in the April issue. Advance notices and registration forms will be mailed to members during March. Meanwhile, members who will be travelling great distances are urged to make train and plane reservations early.

The Engineering Institute of Canada and The Provincial Associations of Professional Engineers

Editor's Note

This reprint tells the story of the development of registration in Canada from 1896 up to 1943 and of the Institute's responsibility for it, as well as the continuing efforts of the Institute to keep the associations and itself close together in their expanding activities.

This is a documented and authenticated history. It is not coloured in any way by prejudices, misinformation, or misunderstanding. You will see as you read that the statements are documented by references to reports and documents appearing in *The Engineering Journal*, or to reports which are on file in the library.

In these days when much thought is being given to Confederation, perusal of this document should be helpful. A person will be better able to reach a decision on the present situation if he has a knowledge of this background.

This report was first published in *The Engineering Journal* in October 1943.

Foreword

During the past ten years notable progress has been made in clarifying the position and functions of the various provincial associations of professional engineers, in relation to each other and to The Engineering Institute of Canada—the body to which the associations owe their inception and much of their development.

All members of the engineering profession in Canada are naturally concerned with the inter-relation of the activities of our various professional and technical organizations. The present situation is sufficiently complicated. Among distinctively technical societies we have, to begin with, The Engineering Institute of Canada, a Dominion-wide Canadian organization, which includes engineers of all branches of the profession. Another Dominion-wide organization, the Canadian Institute of Mining and Metallurgy, ably represents the mining industry as well as the professional mining engineer. Further, there are in Canada a number of active branches or sections of American engineering societies which deal with specific subdivisions of engineering work. Their members naturally look to the United States rather than to Canadian sources for technical guidance.

With aims distinct from those of the voluntary bodies just named, eight provincial associations of professional engineers have been created to deal with questions regarding the licensing of engineers and the protection of the public against incompetent practitioners. Membership in them, in most cases, is compulsory, their activities are regulated by provincial enactments, and they now exist in all the provinces of the Dominion except Prince Edward Island.

The difficulties arising from this complex structure have, for many years, received consideration from the Council of The Engineering Institute, and there has developed a general desire for progress towards an ideal condition in which the activities and requirements of all these bodies will be mutually co-ordinated. Many have expressed the hope that eventually engineers will not be faced with the necessity of belonging (and contributing) to a multiplicity of entirely independent organizations.

The recent conclusion of agreements between the Institute and four of the Associations, providing for joint membership and a considerable measure of co-operation, gives a fitting opportunity to present the following record of the events which have led up to this desirable achievement, and the activities of the Institute regarding them.

In its present form the account is due to the kindness of S. G. Porter, who was president of the Institute in 1931 and vice-president of the Association of Professional Engineers of Alberta, in 1923. Much of it is based on material which has already appeared in *The Engineering Journal*.

Professional Organization Begins in Canada

The first movement towards the formation of an engineering society in Canada appears to have been set on foot before Confederation by Sandford Fleming, who, with other prominent engineers, endeavoured to interest members of the profession in the advantages of such an association. The regulation of professional activities, as well as the dissemination of professional knowledge, was desired by the men who sponsored these early efforts. It was not until considerable engineering development had taken place in the west, that conditions enabled a society to be organized with success.

An early attempt at the legal regulation of civil engineers in Ontario was made in February 1881, when "an act respecting civil engineers" was introduced in the Legislative

Assembly of that province. However, the bill did not commend itself to the Legislature, or, indeed, to all of the engineers named in it, and it never became law.

Formation and Growth of the Canadian Society of Civil Engineers

About this time, the authorities of Toronto and McGill Universities realized the importance of having educational facilities for training engineers, and the advantages of having an association with which to cooperate, if such could be formed. Further, Montreal, Toronto and Ottawa were the cities most frequented by the profession, and conditions suitable for the formation of a society were gradually developing at these places.

During this period the idea of a Canadian engineering society was in the minds of many members of the profession, and the scheme was thoroughly canvassed both in Ontario and Quebec. Among the men who were active in this matter, and who later became officers or prominent members of the society they were proposing to form, may be mentioned Alan MacDougall, C. E. W. Dodwell, T. C. Keefer, Sir Sandford Fleming, J. L. P. O'Hanly, S. Keefer, Frank Shanly and Kivas Tully. As a result, meetings took place in Toronto, Ottawa and Montreal. Perhaps the most important of these was that held in Montreal on the fourth of March, 1886, of which the manuscript minutes have been preserved. Alan MacDougall was in the chair, and P. W. St. George acted as secretary. On the motion of H. D. Lumsden, seconded by P. A. Peterson, it was resolved that

> "A Society of engineers in Canada be formed, comprising *all branches of engineers*, and that a committee be appointed to meet the other committees of engineers from other cities and then to arrange and form a preliminary constitution, which . . . shall be sent around to those gentlemen who send in their names as being willing to form such a Society . . ."

A similar local committee had been acting in Toronto and also appointed delegates to confer with those from Ottawa and Montreal.

Discussions continued until a provisional committee was chosen. At its meeting on December 9th, 1886, it was decided to call the proposed society the Canadian Society of Civil Engineers, and to send out a circular regarding membership, together with a copy of the constitution proposed for the new body. Applications for membership were numerous, the Society was formed, and a charter of incorporation was applied for in due course. That charter received Royal sanction on June 23, 1887.

The objects of the Society, as set forth in its Act of Incorporation were "to facilitate the acquirement and interchange of professional knowledge among its members, and more particularly to promote the acquisition of that species of knowledge which has special reference to the profession of civil engineering . . ." The Society was also given power to make regulations and by-laws "including all rules that may be deemed necessary for the maintenance of the honour and dignity of the profession." These aims, as defined and expanded in the by-laws, have remained unchanged to the present day.

The by-laws of the Society made it clear that the term 'civil' engineering, used in the Act, had reference to all types of engineering activity other than military.

It should be remembered that in 1887 mechanical, chemical, mining, electrical and other specialized branches of engineering as we now know them, were only in process of development in Canada. It was, therefore, natural that most of the early members of the new organization should be men engaged in railway surveys or construction, in contracting for public works, or in municipal or governmental service. The founders of the new body could not possibly foresee the extent of future development of all branches of engineering work in Canada, but they saw the trend and, accordingly it was provided that its membership should include every branch of the profession.

In drawing up these by-laws it was realized that the membership of such a Dominion-wide body would necessarily be scattered geographically, so that a decentralized type of organization was adopted. For this purpose the formation of local branches was authorized; later, geographical districts and provincial zones were provided for. The first branch was formed in Toronto in 1890; the second in Cape Breton in 1905. By 1912 branches had been formed in Quebec, Winnipeg, Ottawa, Vancouver, Kingston, and Victoria, and others followed as opportunity occurred, until to-day there are twenty-five, located in the principal cities of the Dominion from Sydney, Cape Breton, to Victoria, Vancouver Island. These branch organizations perform an indispensable function, giving the Institute, as it now exists, a local habitation in every important centre, and stimulating there an appreciation of the engineer and his work, both in a personal and a professional sense.

Growth in numbers was accompanied by a corresponding increase in the diversity of the branches of engineering followed by the members. This soon resulted in the formation of four sections, general, electrical, mechanical and mining. After about ten years of the Society's existence it was felt that the term 'civil' engineering had come to be generally used in a much more restricted sense than that in which it had been employed at the time of the Society's foundation; this feeling was later to be one of the motives leading to a change in the Society's name and the extension of its activities.

Among the members there were always many who felt that in addition to promoting the dissemination of professional knowledge, the new body should take steps to enable the public to distinguish between qualified and unqualified engineers. At the Annual Meeting of 1896 a committee was appointed to consider the question of professional status. In consultation with provincial subcommittees a draft act of provincial incorporation of the Society was prepared, which, with some modifications, became law in Manitoba in 1896, and in Quebec in 1898, limiting the practice of 'civil' engineering to the members. These enactments, however, did not prove satisfactory in operation, and further legislation was not attempted at that time. But it was then realized that provincial (not federal) legislation had to be secured, the protection of the public, as provided in the British North America Act, being essentially a provincial, not a federal responsibility.

First Canadian engineering society was formed in 1887 and formation of local branches was authorized.

The Can. Soc. C. E. Becomes The Engineering Institute of Canada

During nearly thirty years of healthy growth of the Society, Canada's industrial development and the accompanying tendency towards greater specialization in the profession made it evident that some changes in organization were desirable to increase and extend the Society's usefulness.

Accordingly, a Committee on Society Affairs was formed; its report, presented to the Council in October, 1917, proposed a revision of the by-laws and recommended that the name of the Society be changed to "The Engineering Institute of Canada" as being more expressive of the functions which the organization was performing. This revision was approved, and by Dominion Act of April 15, 1918, the Canadian Society of Civil Engineers became "The Engineering Institute of Canada."

Under its new and comprehensive charter, the national organization of the profession was further developed. A permanent secretariat was provided and, in 1918, the *Journal* of the Institute was established.

The First Professional Meeting of the Institute was held in Toronto on March 26-28, 1918. Mr. H. H. Vaughan, in his presidential message, pointed out that "The change in name implies the attempt to unite all engineers in Canada, to whatever branch of the profession they may belong, into one society."

The Institute Approves a 'Model Act'

At the Second General Professional Meeting of the Institute, which was held in Saskatoon, on August 10, 1918, a paper was read by Mr. F. H. Peters, which drew attention to the benefits to be derived by the profession through legal enactments regulating professional practice, discussion of this matter having been introduced by a resolution passed by the Calgary Branch during the summer of 1917. It will be recalled that at this time there was in force in the province of Quebec an act respecting the practice of engineering passed in 1898, and revised in 1900, and in the Province of Manitoba an act passed in the year 1896, incorporating the Canadian Society of Civil Engineers in that province.

The sentiment throughout the profession that the engineer would benefit by the legal establishment of his professional rights found further expression at the Institute's Annual Meeting in Ottawa, on February 12, 1919, in the formation of a committee for the purpose of drawing up a Model Act* for submission to the various provincial legislatures. Prompt action followed, and this act served as a basis for legislation which was obtained shortly thereafter, establishing associations of professional engineers in nearly all of the provinces of the Dominion. It is to be noted that no provision was made in the Act to relate these new legal organizations to the Institute in any way.

At its meeting of September 23, 1919, Council approved the proposed legislation, encouraged the Branches and Provincial Divisions to co-operate in the promotion of provincial enactments, and gave Council's moral support to this movement. On the ballot which approved the Model Act, seventy per cent of the votes cast by Institute members were in the affirmative.

The Model Act defined the "practice of a Professional Engineer" and described the powers and duties of a provincial association of professional engineers. It covered the admission of candidates to the study and practice of the profession as members of such an association, regulate their government and discipline, and provided that only registered members or licensees of the association could use the title "professional engineer". Suitable provision was made for administration by a president and council, penalties were prescribed for unauthorized practice, and methods of registration and examination were indicated.

The functions of a provincial association under such an act would therefore be to regulate admission to the profession and to administer the provincial law regarding its practice.

In March 1920, Council appointed a committee to report on the question of the remuneration of engineers, a matter very much to the fore in the profession at that time. In fact, reactions in this regard were largely responsible for the great activity in the promotion of provincial enactments which was then manifest.

Associations Established By Provincial Legislation

During 1920 provincial acts based on the Model Act were obtained in British Columbia, Quebec, Manitoba, Alberta, New Brunswick and Nova Scotia. The Ontario Act followed on June 5, 1922.

Thus, by 1923, similar legislation had been obtained in all the provinces except Prince Edward Island and Saskatchewan. An act was obtained in the latter province in 1930.

It should be noted that, in British Columbia, the passing of the act was largely due to the activities of a body formed for that specific purpose, and called the British Columbia Technical Association.

Experience with these enactments soon raised a question as to the definition of the term "professional engineer."**

Further, the acts, though they were all based on the Model Act, were not alike in all their provisions. Thus the legal powers of the various associations differed in degree, and from time to time amendments to several of the acts, tending to emphasize this lack of uniformity, have caused difficulties. On the whole, however, the main lines of the Model Act have proved to have been correctly drawn.

In some cases a tendency developed for the new provincial organizations to function in a manner contrary to the idea which prompted their formation, and certain representations having been received from the west, the Council of the Institute at its meeting in February 1923, unanimously adopted the following resolution:—

"Whereas it is the opinion of the Council of The Engineering Institute of Canada that all technical matters in connection with engi-

Model Act approved 1919 by E.I.C. Council, defining "practice of a Professional Engineer" and describing role of provincial association, led to legislation in seven provinces by 1923.

---

*See The Engineering Journal, May, 1919, p. 411.

**See a comprehensive discussion by Mr. A. D. Flinn, of the American Engineering Council in The Engineering Journal 1929, p. 387.

neering should be the function of The Engineering Institute of Canada, and that the various Corporations and Associations of Professional Engineers in the different provinces are, or should be, designed solely for the purpose of administering the provincial laws in connection with legislation;

Be it resolved:—That the Council of The Engineering Institute of Canada go on record as approving the above principle and that all possible steps be taken towards the adoption of this principle;

Be it further resolved:—That the Secretary be instructed to write the various provincial bodies calling their attention to this resolution and asking their co-operation to that end;

Also be it resolved:—That the Council of The Engineering Institute of Canada suggest to each of the various provincial bodies that they send one or more representatives to a meeting for the purpose of discussing the relations of those bodies to The Engineering Institute of Canada, to the end that finally an Act may be enacted similar in principle to the Roddick Medical Bill*.

It is unfortunate that the relations of the Institute (a voluntary body) with the new associations (provincially constituted bodies having compulsory membership), could not be clearly defined from the outset, for it soon became evident that such questions as the duplication of fees and the diversity of standards for admission as between the associations and the Institute, and also between the associations themselves, would have to receive consideration.

The Institute Calls Conference of Association Delegates

On the invitation of the Council of the Institute in December, 1925, a conference of delegates of the provincial professional associations was held at the Institute Headquarters in Montreal in February, 1926, in order to consider this situation and other matters affecting the common interests of the associations. The principal item on the agenda of this meeting was co-operation with The Engineering Institute of Canada. The seven associations then existing were represented and the discussions lasted for three days, the resulting recommendations being submitted in due course to the councils of the several professional associations. Although defraying the expenses of the delegates, the Institute was not represented officially at this conference.

After appointing a corresponding secretary, the delegates left with a resolution recording the sense of close association developed by the conference and their appreciation of the courtesy extended to them by the Institute.

Activities of The Institute Council

At its meeting of January 18, 1927, Council was advised that, in accordance with its instructions, the secretary of the Institute had written to the secretary of the Corporation of Professional Engineers of the Province of Quebec, requesting him to communicate with the governing bodies of the various provincial associations of professional engineers, with a view to discussions as to the best method to be adopted to bring about substantial uniformity in the requirements for admission by examination to the several provincial associations and to the Institute.

In the same year the Institute's Board of Examiners, on instructions from Council, exchanged views with the Boards of Examiners of a number of the professional associations to see what could be done towards obtaining uniformity in examination requirements. No definite progress in this respect seemed possible at that time without meetings for discussion, but in 1928 a revised examination syllabus of the Institute was prepared and communicated to the associations, as a possible basis for further action.

In October, 1927, the First Plenary Meeting of the Council of The Engineering Institute of Canada took place. The afternoon session of October 11th was devoted to a consideration of the policy to be pursued as regards the Institute's relations with the various provincial associations. The necessity of developing uniform admission examination requirements was stressed and it was resolved "that a standing committee representative of all the interested provinces of the Dominion of Canada be appointed by the Council of The Engineering Institute to study the problems involved in co-ordinating the activities of The Engineering Institute of Canada and the several associations of professional engineers." This committee was called the Committee on Relations of the Institute with the Professional Associations, and its personnel was named at the Council meeting of November 25, 1927.** It consisted of Institute members from all the provinces.

Work of The Institute's Committee on Relations

The Committee was unable to commence work for some time and made no report at the annual meeting of February 1928. In June of that year Mr. George McLeod, the chairman, was compelled to resign through pressure of other work and Mr. S. G. Porter was appointed chairman.

The Second Plenary Meeting of Council was held in Montreal on October 15, 16 and 17, 1928. At this meeting the chairman of the Committee on Relations was able to present an interim report which stated that this committee was studying the following questions:—

> "1. Considering the welfare of the profession in its broadest sense, what relationship should exist between The Engineering Institute of Canada and the various provincial associations?
>
> 2. What obstacles are there in the way of attaining the desired end?
>
> 3. What procedure do you suggest for overcoming them?"

While the Committee was not yet in a position to make a definite recommendation, it appeared that many of its members believed that the ultimate integration of all the provincial professional organizations was attainable, but the Committee had not been able to define the action which in its opinion The Engineering Institute should take in this movement.

The Committee was continued under the chairmanship of Mr. Porter to report at the next plenary meeting of Council; discussion brought out the suggestion that the provincial associations might possibly function as provincial divisions of the Institute.

At the meeting of Council on January 22, 1929, upon the request of the chairman of the Committee on Relations, the secretary was directed to communicate with the council of each of the provincial associations suggesting the appointment of provincial committees to co-operate with the committee of the Engineering In-

**See The Engineering Journal, November 1927, page 497.

stitute. In its report for the year 1928, Council indicated "that some progress had been made towards the establishment of a more uniform standard of requirements for admission to these bodies (professional associations) and to the Institute, whether by examination or otherwise."

The Committee on Relations made a report to the annual meeting in February, 1929, indicating that this Committee was in active correspondence with members of the provincial associations and stating—"it is felt that events are tending towards the amalgamation of the various provincial associations into some kind of Dominion-wide organization, and that the time is now opportune for the Engineering Institute to offer the benefit of its organization and the machinery to bring all these organizations together . . . The sentiment for consolidation with the Engineering Institute is favourable among a large body of members of the provincial associations."

In March, 1929, Council appointed a Committee on Policy, under the chairmanship of Dr. O. O. Lefebvre, to investigate and make recommendations as to such changes as seemed desirable in respect of the present classes of membership in the Institute, its organization, publications, and general policy.

At its meeting of September 10, 1929, on the suggestion of Mr. Porter, Council decided to invite a representative from each provincial association, who was also a member of the Institute's Committee on Relations, to take part in a meeting of that Committee to be held at Headquarters on October 5, 1929, just previous to the coming plenary meeting of Council.

The Third Plenary Meeting of Council was held in Montreal on October 7, 8 and 9, 1929. To this meeting Mr. S. G. Porter presented the report of the Committee on Relations, which was unanimously adopted by the Council. On the motion of Dr. Lefebvre it was unanimously resolved:

> "That the secretary renew the invitation sent to each of the provincial associations in February 1929, requesting them to co-operate with The Engineering Institute of Canada, and sending them a copy of the report of Mr. Porter's committee, with the statement that the Council of the Institute had adopted the recommendations contained therein."

This report of the Committee on Relations was presented at the Annual Meeting of February 12, 1930, and after considerable discussion was adopted, one member dissenting. It dealt with uniformity of requirements for admission; reciprocal registration arrangements; advantages of a national organization to represent the whole profession, especially in connection with legislation and public welfare; and the increased ability to promote the educational function of the profession. Its recommendations were as follows:

1. That this Committee or a similar one be continued.
2. That at least one member of Council in each province be added to the Committee to act during his term of office in all cases where Council is not already represented.
3. That this committee be authorized to appoint a small sub-committee whose duty it shall be to approach the provincial associations and in conjunction with them devise a detailed proposal to bring about a co-ordination of the interests and activities of the various provincial associations and The Engineering Institute of Canada; and further, it is recommended that a sum of $1,800 be appropriated towards a fund to provide for the expense of this work.
4. That The Engineering Institute of Canada, through the *Journal* and otherwise, continue to encourage and support the activities of the provincial associations, and contribute in every reasonable way to their success.
5. That immediate steps be taken to arrive at an agreement among the professional associations, and the Institute, for the adoption of standard uniform requirements for admission to membership, and that these requirements be rigidly adhered to.
6. That upon the acceptance of such standard requirements, the Institute should adopt the policy of accepting membership in a professional association as sufficient evidence of qualifications for admission to The Engineering Institute of Canada.
7. That steps be taken to secure the necessary amendments to the by-laws so that membership or registration in a professional association be one of the requirements for admission to corporate membership in The Engineering Institute of Canada for all applicants residing in a province where an engineering profession act is in effect.

The Committee on Relations was accordingly continued, and at the meeting of Council held on April 11, 1930, Past-President H. H. Vaughan was appointed chairman in succession to Mr. Porter, and a sub-committee was appointed in accordance with recommendation No. 3 to approach the provincial associations.

At this meeting the Council was informed that the Professional Association of New Brunswick had appointed a committee to consider the question of closer co-operation between the various provincial associations and the Institute.

At this point it is of interest to note that the recommendations of the 1930 report of the Committee on Relations — particularly items 5 and 6— contained provisions which were very similar to those of the agreements now in force or pending between some of the professional associations and the Institute.

A National Committee Proposed by Institute

At the Fourth Plenary Meeting of Council, held in September, 1930. Mr. Vaughan presented a further report from the Committee on Relations, which recommended that a study of the possibilities in the matter should be made by a national committee nominated by all of the provincial associations and the Engineering Institute. This national committee would be asked to make an analysis and comparison of the various provincial acts and requirements for admission, which it was hoped would lead to the working out of a draft set of by-laws and requirements for membership that could apply to all the provincial associations and to The Engineering Institute of Canada. This work of analysis and drafting was to be done by a sub-committee of three (afterwards changed to four) members of the National Committee, representing the Maritime Provinces, Quebec and Ontario, the Prairie Provinces, and British Columbia respectively. It was thought that when such a draft had been prepared and had been criticized by all members of the National Committee it might then be submitted to the councils of the associations and of The Engineering Institute of Canada for their consideration. This proposal was at once approved by the Institute's Council.

At the Institute's Annual Meeting

in February, 1931, the Committee on Relations reported* that the proposals for a National Committee were under consideration by the governing bodies of the professional associations, and that some of these had already approved of the suggestion and had appointed their members on that committee. Ultimately members of the National Committee were appointed by the councils of seven of the eight professional associations, who thus concurred with the course proposed.

Uniformity was sought by E.I.C. and Associations. Report of the Associations' Committee of Four, 1931, gave rise in 1933 to the present Dominion Council of Professional Engineers, E.I.C. offering co-operation.

At this point, however, the council of one of the provincial associations maintained that co-ordination of all activities of engineering associations throughout Canada might be obtained more readily by developing a plan which would at first apply only to the provincial associations. Definite objection was made to any plan which would at once include The Engineering Institute of Canada. Further, the council in question was unable to approve of the proposed Committee of Four unless its members were accredited by the associations alone, the Institute taking no further active part for the time being.

After due consideration, the president of the Institute and the chairman of its Committee on Relations felt it necessary to allow this objection, and consequently the matter rested at this stage, awaiting further action by the associations. Meanwhile the Council of the Institute again further expressed its desire to co-operate with the associations in furthering the best interests of the profession throughout Canada.

Associations Alone Establish Committee of Four

The Committee of Four—all representatives of the provincial associations—was convened in Montreal, August 24, 1931. The members of this committee were:

J. M. Robertson, M.E.I.C., representing Ontario and Quebec.

C. C. Kirby, M.E.I.C., representing New Brunswick and Nova Scotia.

R. S. L. Wilson, M.E.I.C., representing Manitoba, Saskatchewan and Alberta.

A. S. Gentles, M.E.I.C., representing British Columbia.

Their report, which was made to the councils of the professional associations, was dated September 4, 1931, and contained recommendations which ultimately gave rise to the present Dominion Council of Professional Engineers.

The opinion of this committee was that "a Dominion-wide body representing the entire engineering profession and embracing all of its activities is a practical ultimate possibility . . ."

The objective of such a body would be "the co-ordination of all activities permissible under the provisions of the British North America Act."

Thus, in 1931, the professional associations and the Engineering Institute were agreed on the fundamentals of such co-ordination, but it has taken a further ten years to work out details of any practical working agreement.

The Fifth Plenary Meeting of Council was held in Montreal on September 21, 22 and 23, 1931. At this meeting the report of the Committee on Relations was received which outlined the formation and policy of the Committee of Four of the provincial associations, and stated that to meet the views of the British Columbia Association the Institute had officially withdrawn from deliberations on co-ordination for the time being. The Institute, however, was ready to co-operate in every possible way to promote the work of the Committee of Four.

The Committee of Four reported on September 4 to the professional associations and recommended the formation of a larger body, the "Dominion Council of the Engineering Profession" composed entirely of representatives of the professional associations.

At the Annual Meeting of February 1932, the Institute approved the action of the plenary meeting with reference to the activities of the Committee of Four of the professional associations.

There was little activity in professional engineering legislation in 1932, except that the Ontario Association endeavoured to get an amendment to their act so as to prevent the practice of professional engineering by unregistered persons. Their original act merely prevented the unauthorized use of the title "Professional Engineer". The act in British Columbia had been amended along these lines in 1930.

Dominion Council Formed by Associations

The provincial professional associations, having appointed representatives to a "Dominion Council of the Engineering Profession" as recommended by the Committee of Four, this Council, beginning as a "Committee of Eight," met in Montreal on February 1, 1933, and issued a report under date of February 4, in which it stated, "We believe that there is every reason to expect that the ultimate outcome of such studies will be the complete co-ordination of all activities of the engineering profession in Canada." A proposed constitution for the Dominion Council was drawn up and included in the report. The Committee of Eight held no further meetings, its work having been continued by the Dominion Council.

Institute Shows Continued Interest

The Maritime Professional Meeting of the Institute which was held at White Point Beach, Nova Scotia, in July 1933 was noteworthy as being the first professional meeting of the Institute to be held with the active co-operation and support of one of the provincial associations of professional engineers. It was in fact a joint undertaking. Some of the sessions were those of a Maritime General Professional Meeting of the Institute; a portion of the time was devoted to a General Meeting of the Association of Professional Engineers of Nova Scotia. The great majority of engineers attending were members of both organizations, so that this arrangement presented no difficulty. It gave an effective demonstration of the way in which the educative and technical work of the Institute could be carried on in conjunction with the official duties of a professional association.

Representatives of all the four Maritime Branches of the Institute

*See The Engineering Journal, February 1931, p. 102.

were present, as well as members of the Association of Professional Engineers of New Brunswick. The onerous work of preparation for the meeting was actually performed by a joint committee composed of members of the Halifax Branch of the Institute and members of the Association of Professional Engineers of Nova Scotia.

The Sixth Plenary Meeting of Council was held in Montreal on October 30, 31 and November 1, 1933. It considered in detail the proposals of a Committee on Development which had been appointed in November 1931 to review the constitution and aims of the Institute. After discussion, the proposals were approved for submission at the annual meeting and subsequent ballot by the membership. The Council placed on record its desire to co-operate in every way with the provincial associations of professional engineers and it was resolved that the Institute should take every opportunity to collaborate with the provincial associations, particularly in endeavouring to secure a generally acceptable uniform scheme of registration of engineers in all parts of the Dominion.

At the Annual Meeting of the Institute held in Montreal on February 8, 1934, the final report of the Committee on Development, as expressed in a proposed revision of the by-laws of the Institute, was received and caused considerable discussion. It was pointed out that the wording of some of these by-laws would be affected by the policy to be followed regarding closer relationships with the provincial associations, and the suggestion was put forward that it might be wise to forego sending these by-laws out to a ballot of the general membership until further efforts had been made toward closer co-operation between the Institute and the professional associations, which might modify to a considerable extent some of the by-laws proposed. It was found, however, that the regulations of the Institute would not permit this delay. When the ballot was taken, the proposed amendments failed to carry.

At the meeting of Council of June 5, 1934, a proposal was presented for renewed action by the Institute, looking toward the co-ordination of the profession in Canada, but consideration of this matter was postponed until the fall. This Council meeting decided that the subject for the Past-Presidents' Prize for the year 1934-35 should be, "The Co-ordination of the Activities of the Various Engineering Organizations in Canada."

Institute Branches Request Further Action

During 1934 Council received a number of communications making suggestions regarding co-operation with the associations. In October, the Halifax Branch forwarded a resolution to Council favouring the consolidation of the profession in each province and throughout the Dominion.

At its meeting of November 16, Council received a communication from the Vancouver Branch dealing with the future policy and lines of development of the Institute. At this meeting the Council approved certain amendments to the Winnipeg Branch by-laws, which were calculated to facilitate the co-operation of that branch with the Association of Professional Engineers of Manitoba. This meeting of Council also discussed a suggestion from the president of the Association of Professional Engineers of Alberta, that the Institute might act as a clearing house in communications between the associations of professional engineers and the Department of Immigration with regard to applications for admission of foreign engineers to Canada. The suggestion was approved, provided the consent of all professional associations to the arrangement could be secured.

The Montreal Branch, at its Annual Meeting of January 10, 1935, discussed the question of consolidation, and at a further meeting of January 30, forwarded to the Council for presentation at the annual meeting, a resolution similar to that of the Halifax Branch.

Consolidation was chief business of annual meetings of 1935 and 1936. Committee on Consolidation was formed to establish closer relations with eight provincial associations.

Work of The Institute Committee on Consolidation

At the Annual General Meeting of the Institute held in Toronto on February 7, 1935, the above resolutions, together with resolutions from the Ottawa Branch, the executive committee of the Quebec Branch, the executive committee of the Border Cities Branch, the Lethbridge Branch and the Association of Professional Engineers of the Province of New Brunswick, were presented, and thus the question of consolidation became the chief business of the meeting. As a result, a Committee on Consolidation was formed, under the chairmanship of Gordon MacL. Pitts, "to develop the possibilities of consolidation of the engineering profession in Canada." This committee was instructed to report its findings through Council to a general meeting of the Institute.

Thus the Committee on Consolidation had necessarily as its principal object the establishment of closer relations with the eight provincial associations of professional engineers, as a first step towards the organization of the engineering profession in Canada on a truly national basis.

It was obvious that the diversity of the interests concerned made the problem difficult of solution. While there are a large number of Canadian engineers who actively support the registration movement by belonging to the associations, there are many who do not do so. Some of the corporate members of the Institute are not registered. As regards non-members of the Institute, some belong to no organization at all, some belong to a professional association, and others have joined non-Canadian engineering bodies.

There seemed to be at least two main schools of thought on this question. On the one hand there was the view that everyone should be registered who is engaged in any kind of engineering work requiring professional training as distinguished from the work of a foreman or skilled craftsman. On the other hand some believed that legal registration as a professional engineer should be required only of those whose work makes them personally responsible for the protection of the public. A totally different doctrine was held by those few who did not believe in registration, and were of the opinion that legal authorization to practice is unnecessary for any engineer, either in his own interest or that of the public.

Any scheme for the better organization of the profession which can commend itself to all, or even a majority, of the holders of these divergent opinions must evidently contain features on which some compromise has been made. In fact, both the engineers whose main interest lies with the legal work of the associations, and those who attach more importance to the technical and educational work of the Institute, would have to give some effective recognition to their opponents' views before any workable plan could be evolved.

In regard to this matter, the attitude of the Council of the Institute has been consistent ever since 1919, when it gave approval to the proposed provincial legislation based on the Model Act prepared by an Institute committee. It is true that at that time no attempt was made to relate the new legal organizations to the Institute, and, in the light of later events this was perhaps unfortunate. It would seem that if the legal and other difficulties involved in forming such a relation had been faced at that time, more rapid progress would have been possible.

The Institute Council, however, has constantly endeavoured to promote closer relations with the provincial associations and thus bring about a measure of unity in the profession in Canada. The history of these efforts was summarized in the report* of the Committee on Consolidation which its chairman presented at the Annual Meeting of 1936.

In this report, prepared after a year of strenuous work, the committee put forward a series of proposals for the amendment of the Institute by-laws, defining the lines along which, in the committee's opinion, the Institute could best co-operate with the associations.

The principal features of the proposals were, the recognition by the Institute of membership in the associations as a qualification for membership, the establishment of a standing committee to be known as the Committee on Association Affairs, representation of the associations on the Institute Council, the abandonment of the grade of Associate Member in the Institute; associations which co-operated with the Institute would be known as Component Associations. In a province where a Component Association existed, membership in that association would in future be essential for admission to the Institute.

After preliminary discussion at the annual general meeting of 1936, these proposals, and in fact the whole relations of the Institute with the professional associations, were the main subjects of debate at the Seventh Plenary Meeting of Council held in Montreal October 1936.

At that meeting the proposals of the committee underwent some modifications before being approved by Council for submission to the next annual meeting and, if then accepted, for ballot of the membership as required by the by-laws.

During the discussion, Mr. C. C. Kirby, president of the Dominion Council of Professional Engineers, said that he believed the desires of the majority of engineers in Canada were: —

(a) Closer co-operation between the provincial associations;
(b) Some form of alliance with a national body organized so as to avoid the present duplication of fees; and
(c) The national body to be representative of the whole engineering profession.

The idea of creating a new body to implement (a) and (c) was acceptable in some provinces, but unacceptable in others, because the Institute with its history of service to the profession was available. The provinces themselves were not unanimous on the registration movement, and some engineers now members of the Institute were not required by the nature of their employment to become registered. The idea that the associations should also maintain permanently their own Dominion Council had proved unacceptable to some associations. He believed that the proposals of the Committee on Consolidation appeared a practical compromise between all these views.

Mr. Kirby presented a suggestion from British Columbia that all associations should have representation on the Council of the Institute in proportion to the number of their members, provision also being made for accredited substitutes with proxy rights.

Mr. Kirby did not think that such a proposal had ever been made in connection with the Dominion Council, and said that under the committee's proposals every member of an association would be represented on the Institute Council by his own association's appointee.

There was no intention or possibility of transferring any powers legally belonging to the associations to the Institute or its standing committee.

The proposals of the Committee on Consolidation were duly discussed at the Annual General Meeting in January, 1937, and the proposed revisions to the by-laws were sent forward to ballot by the membership. A difference of opinion between Council and the Committee on Consolidation led to the submission of an alternative proposal by Council in respect to one section of the proposed amendments.

The proposals submitted to the membership were intended to be a compromise to safeguard the interests of all members of the Institute. It was also hoped that the proposals would enable the professional associations to unite in co-operating with the Institute. Such co-operation would make it possible ultimately to build up a Dominion-wide organization which would represent the profession as a whole.

In this connection it must be remembered that apart from the Institute and the professional associations, there exist in Canada a number of important technical societies, some of which are branches of non-Canadian organizations, whose ultimate co-operation would be essential for the full development of the organization movement. As yet it had not been feasible to consult officially with these bodies, since it was first necessary to find a solution for the problem of co-operation with and between the professional associations.

When the ballot was taken in April 1937, however, there was a substantial majority against the amendments which embodied the proposals of the Committee on Consolidation. It seemed evident, however, from the many discussions which had taken place, that most Institute members, while objecting to certain details of this particular scheme, were, nevertheless, sincere supporters of the principle of co-operation between the Institute and the associations.

Discussions with some Associations Begin

Following the announcement of the results of this ballot, the subject of the Institute's relations with the associations came up at practically every Council meeting during the year. It soon appeared that in certain provinces, particularly Nova Scotia, New Brunswick, Manitoba,

*See The Engineering Journal, January 1936, pp. 35-39.

Saskatchewan and Alberta, the problem of co-operation might be regarded as comparatively simple. In these instances the number of members involved is not large, and it was felt that working arrangements could be established with some of these bodies if the Council were authorized to enter into agreements with the associations concerned. But as regards the three other associations, the situation seemed different. Their membership is larger and contains a greater proportion of association members who are not in the Institute. There are also a considerable number of members of the Institute who do not belong to those associations. For these and other reasons, the desirable objects, such as common membership, or uniform standards of admission as between the associations themselves and with the Institute, are more difficult of attainment in these cases.

In fact, at its meeting in May 1937, Council was informed that a local committee in Nova Scotia was studying the possibilities of co-operation there between the Institute and the Professional Association. Discussions along similar lines were taking place in Saskatchewan and Manitoba. The president reported in regard to a visit to Winnipeg, which he had made at the request of Council to meet the members of the Winnipeg Branch and the members of the Manitoba Professional Association. He outlined the proposals for co-operation between the Institute and the Association in Winnipeg which had been under consideration there. It was reported that the Council of the Association of Professional Engineers of New Brunswick was also considering the matter. In compliance with a suggestion from Halifax, Professor H. W. McKiel and Mr. C. A. Fowler were appointed to represent the Institute Council in the Nova Scotia discussions.

The Council Forms Committee on Professional Interests

The Eighth Plenary Meeting of Council was held in June, 1937. At this meeting, Council discussed the relations of the Institute with the professional associations in Nova Scotia, New Brunswick, Manitoba and Saskatchewan, and a resolution was unanimously passed expressing Council's desire to co-operate with all the associations. After discussion, it was decided to appoint a Committee on Professional Interests under the chairmanship of Past-President F. A. Gaby, with Past-President O. O. Lefebvre and Councillor F. Newell as members. Its duty would be to deal *inter alia* with matters involving negotiations with the professional associations, without prejudice, however, to the negotiations in Nova Scotia, and working with the aid of provincial sub-committees.

In October 1937 a number of proposals for the amendment of the Institute by-laws were received from thirty-one corporate members for submission to Council. These were based on some of the important provisions submitted by the Committee of Consolidation in 1936. They proposed the retention of the class of Associate Member; the automatic admission of corporate members of the professional associations, subject to classification by Council; the establishment of Component Associations, and of a Committee on Association Affairs; the payment by a Component Association annually to the Institute of a fee of 50 cents for each member of a Component Association licensed to practise; the payment by a Component Association whose corporate members are admitted as members of the Institute of a *per capita* annual fee to be determined by the Council, which would include the *per capita* fee of 50 cents referred to, and an annual subscription to the *Journal;* the recognition of a new class of non-corporate membership to be called "Provincial Associates" which would comprise those members of an association who do not become members of the Institute; the compulsory investigation by Council of the conduct of any member who might be expelled from a Component Association; the fixing of the entrance fee of the Institute for all corporate members at $15.00.

At the October meeting of Council, Messrs. McKiel and Fowler attended and presented their report on the situation in Nova Scotia, outlining a scheme for co-operation which had been endorsed by the Council of the Association and by the Institute branches in Nova Scotia. They recommended that Council express its willingness to enter into an agreement with the Association whereby the Institute would accept all members of the Association as corporate members of the Institute, while the Association would collect a single fee from all of its members, covering the annual fee to the Institute, a sum for the operation of the Institute branches in Nova Scotia, and the annual fee to the Association. This arrangement would be conditional on all members of the Association joining the Institute.

After discussion, the scheme was approved in principle, and it was directed that a letter ballot of Council should be taken as to Council's willingness to enter into such an agreement. It was noted that as the proposal would involve a change in the schedule of fees for Nova Scotia members, it would be necessary to obtain an amendment to the by-laws empowering Council to enter into an agreement of this kind.

At the same Council meeting, the proposals of the thirty-one corporate members for the amendment of the Institute by-laws, which had been sent in on October 1st, were submitted for Council's consideration in accordance with Section 75 of the by-laws.

Council was of the opinion that in view of the report just received from Nova Scotia and the activities of the Committee on Professional Interests, it would be desirable to suggest to the representatives of the thirty-one proposers either the withdrawal of their proposals and the substitution of an amendment legalizing Council's action regarding the Nova Scotia agreement, or some modification of their proposals which would bring them more in line with Council's views as developed during the year. With this in mind a committee consisting of the president, Past-President Shearwood, and the presidential nominee, J. B. Challies, was appointed to confer with representatives of the proposers.

In Council's view, the length and apparent complexity of the proposals of the thirty-one members, as well as the retention of many points of similarity with the consolidation proposals which had been so recently rejected on ballot, would make it very difficult to secure their acceptance by vote of the general membership, whereas a briefer and broader proposal would have a much better chance of obtaining the necessary majority. Further, these proposals might tend to confuse the promising negotiations presently in hand with several of the associations.

After discussion, the representatives of the thirty-one proposers felt that, without consulting their principals, they could not undertake to withdraw the proposals. Such consultation would take place as quickly as possible.

At the Council meeting held in November, it was reported that on letter ballot a majority of councillors thought that Council should express willingness to enter into an agreement with the Nova Scotia Association. No negative votes were cast.

A similar request having been received from New Brunswick it was decided to take similar action in that case and to notify our representatives in both provinces of Council's favourable decision in both cases.

In regard to by-law amendment, the president submitted three sections drafted as a compromise and reported that they had not been acceptable to the representatives of the thirty-one proposers. On the other hand, after a full discussion, Council felt unable to accept the new sections put forward by the thirty-one proposers.

New By-Law Enables Council to Negotiate Agreements

The members of Council present then agreed on the draft of a new by-law merely enabling Council to co-operate with any of the professional associations and enter into agreements with them in furtherance of the mutual interests of the members of the Institute and of the associations, and in particular respecting the admission of their members to the Institute and the amount and method of collection of fees. It was directed that this draft should be submitted to all members of Council for approval by letter ballot before being put forward as a definite proposal of Council.

It was the opinion of Council that the situation arising from the rejection of the proposals of the Committee on Consolidation would be met most effectively by this simple by-law, giving Council the power to enter into agreements with the associations. When this was explained to the representatives of the thirty-one corporate members, they accepted the suggested by-law in lieu of their proposals, an action which was appreciated, since it opened the way for immediate action on co-operative agreements with several of the associations.

Accordingly, the proposed new by-law (now Section 78) was presented by Council, and discussed at the Annual Meeting of 1938; it was then accepted for ballot. When voted upon in March, the membership approved it by an overwhelming majority.

Meeting of Dominion Council in Montreal

An event of interest to the Institute as well as to all association members was a meeting of the Dominion Council of Professional Engineers, held in Montreal in April 1938, and attended by representatives of seven of the provincial associations.

The principal business before the meeting was consideration of the differences between the various provincial associations of professional engineers in respect to charters, by-laws and methods of procedure, with special reference to those features governing interprovincial practice.

The Engineering Institute and several associations of Professional Engineers formulated and adopted individual co-operative agreements. The first one was signed in 1938 by the E.I.C. and the Saskatchewan Association.

Discussions With Nova Scotia

In 1938 the first draft* of a proposed agreement between the Institute and the Association of Professional Engineers of Nova Scotia had already been under discussion for some time by accredited representatives of both bodies. After publication in the *Journal* it had been approved almost unanimously by letter ballot of the Institute Council, and by vote of corporate members of the Institute resident in Nova Scotia. Definite action on the part of the Nova Scotia Association did not follow immediately, however, some doubt having arisen as to the Association's legislative authority to complete the agreement in the precise form which had then been negotiated.

Agreement with Saskatchewan Association

During the winter of 1937-38 a committee of the Saskatchewan Branch of the Institute had been studying the possibility of co-operation in that province, and had prepared a draft agreement. The relations of that Branch with the Association of Professional Engineers of Saskatchewan have always been cordial; in fact, it had been the regular practice to hold joint meetings and functions. The executive committees of the Branch and of the Association jointly considered the draft and approved it with minor amendments on April 22, 1938. It was published in the *Journal* in August.** In September it was approved by ballots of the Institute Council, of the Institute's corporate members resident in Saskatchewan, and of the members of the Association. Thus it was possible to arrange for the formal signing in Regina on October 29, 1938, of the first co-operative agreement between The Engineering Institute of Canada and one of the provincial associations of professional engineers.

The president of the Institute, the general secretary and the chairman of the Institute's Committee on Professional Interests journeyed to Regina for this important ceremony. Addresses marking the occasion were delivered by the president of the Institute, Dr. J. B. Challies, and by the president of the Association, Mr. J. W. D. Farrell; the proceedings were broadcast from coast to coast.

The main purposes of this agreement for the co-operation of the two bodies may be stated as:

(a) Common membership in the province of the Institute and the Association,
(b) Simplification of arrangements for the collection of fees,
(c) Reduction in total fees payable by those who are members of both bodies,
(d) Management by a common executive.

Under the Saskatchewan agreement all registered professional engineers in the province, not already members of the Institute, became corporate members without entrance fee. The Association's "Engineers-in-Training" became Juniors of the Institute.

Thus the Saskatchewan Branch of the Institute now consists of all members of the Institute resident in Saskatchewan and all members of the Association.

The Association collects one joint annual subscription from each of its members, from which an agreed sum is paid to the Institute in lieu of its ordinary membership fee.

The officers and council of the Association become the officers and executive committee of the Saskatche-

*Published in The Engineering Journal, March, 1938, p. 247.
**See The Engineering Journal, August 1938, p. 396.

wan Branch and are responsible for its financing and management.

All meetings are announced as meetings of The Engineering Institute of Canada and the Association of Professional Engineers of Saskatchewan.

The tangible results of this agreement, which has now been in operation for five years, are the best evidence of the benefits accruing to the engineering profession in a province by the consummation of such an agreement. During the first year forty-eight members of the Saskatchewan Association, who were not previously members of the Institute. joined the latter body, and thirty-three members of the Institute became members of the Professional Association. In addition fifty-four members of the Association automatically became members of the Institute with the signing of the agreements in 1938.

Agreement with Nova Scotia Association

As regards Nova Scotia, discussions on the draft agreement prepared in 1937-38 continued for some time, while efforts were made to remove or avoid certain technical difficulties. It was not until 1939 that a revised proposal* was ready for submission to ballot. The qualified voters, both of the Association and the Institute, approved it, and it was formally signed in Halifax on January 25, 1940. The Institute was represented at the ceremony by President H. W. McKiel and the general secretary. The president—S. W. Gray—and the registrar signed on behalf of the Association. Thus the seal was set on the result of discussions which had commenced as early as 1934.

The Nova Scotia Agreement, while not identical with the Saskatchewan document, contains many similar provisions. It places the management of the joint affairs of both bodies in the hands of a Joint Finance Committee. A single fee is paid by members to the treasurer of the Association, from which the necessary payments to the Institute and its Nova Scotia branches are made.

Agreement with Alberta Association

By January 1940 the discussions regarding co-operation between the Institute and the Association of Professional Engineers of Alberta had enabled the joint committee—which represented both bodies—to draw up a draft agreement. This draft received the general approval of the Association at its Annual Meeting in March, after similar approval had been given by the Institute Council.

After discussion with the officers of both bodies, and following a conference with two headquarters representatives of the Institute's Committee on Professional Interests who went to Calgary for the purpose, the joint committee completed a final version of the agreement, which, after being accepted by the Council of the Association, was ready in August for formal approval by both bodies. This approval involved the publication of the agreement** and its submission by ballot to the members of the Association and to the members of the Institute.

These ballots were overwhelmingly in favour of the agreement, which was accordingly signed in Calgary on December 14, 1940, by President T. H. Hogg and the general secretary for the Institute, and by President H. J. McLean and the registrar for the Association.

This agreement is generally similar to that with the Saskatchewan Association. As in the case of Nova Scotia, the Alberta Agreement states that to promote close co-operation beween the two bodies, the objects are:

(a) A common membership in the province of the Institute and the Association.

(b) A simplification of the existing arrangements for the collection of fees.

Agreement with New Brunswick Association

In New Brunswick, conferences on co-operation between the Institute and the Professional Association began in 1937, and discussions continued for some time.

As a result a draft agreement was prepared during 1941 following the general lines of those already in force, but with some modifications to meet local conditions.† It was then duly approved by the Institute Council, by the two Institute Branches in New Brunswick, and by an almost unanimous ballot of the members of the Association.

The ceremony of its signature took place in Saint John on the evening of January 12, 1942, at the time of the Annual Meeting of the Association. The signing officers were Vice-President K. M. Cameron and the general secretary of the Institute, together with the president of the Association, G. L. Dickson, and its secretary.

Thus there are now four provinces in which the provincial body and the Institute have come to a working arrangement whereby the benefits of each become available to the other.

Manitoba

Discussions initiated in 1934 have also been proceeding with the Association of Professional Engineers of Manitoba. After some unavoidable delay, a draft‡ was arrived at in 1942 and is now (September 1943) being voted upon by the Association membership and by the Institute membership in Manitoba, having been approved by the Institute Council at its February meeting.

Present Situation

The foregoing review of the various events which have led to the results already achieved, gives some idea of the difficulties which have had to be surmounted in each case by the give-and-take of the representatives of the contracting parties. The situation is complicated, not because of unwillingness or animosity, but largely because of the diversity in the character of the professional engineer's work in the different provinces, the preponderance of one or more branches of engineering in a province, or the association's general policy as determined by industrial or economic conditions in the province concerned.

The cordial relations existing between the Engineering Institute and the Dominion Council brighten the prospect for an eventual solution of the engineering registration problem in Canada. In the Dominion Council the profession has an influential body which can do much to secure the necessary uniformity in the professional requirements and legal regulations obtaining in our different provinces.

In The Engineering Institute of Canada there is available a Dominion-wide organization of recognized standing admitting members of all branches of the profession, and promoting united action as regards technical matters, professional information, and the general welfare of its members.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

New Group Life Insurance Plan

For several years, the Corporation has had a life insurance program for the benefit of its members, thus offering them an opportunity to buy insurance coverage at advantageous rates.

The experience of the group has been most satisfactory. On the other hand, it was felt that some of the features of the original plan could stand improvement. As a result, an investigation was undertaken which culminated in a new plan being adopted by Council at its January meeting. One of the major features of the plan consists of allowing those who might have to leave the Province to retaining their group insurance privileges provided they become and remain members of another provincial Association of Professional Engineers. It will therefore be possible for those people to become legally entitled to practise engineering in the province they go to, and at the same time retain their privileges in the Corporation insurance group without having to remain in the Corporation. It is felt that this feature is in keeping with our common objective to facilitate membership transfers from one association to the other. Otherwise, the new plan is essentially the same as that sponsored by some other provincial Associations.

Montreal Consultant Wins Court Case

A Montreal consulting engineer has recently been awarded damages by the Superior Court in a case which adds to the jurisprudence affecting the work of consultants.

This consultant, retained by a municipality in the Montreal area for the design and supervision of a given project had had his plans finalized and specifications accepted by the municipality, when the latter decided to sever its connection with the consulting engineer, although supervision of the project, for which the consultant was responsible, was to be terminated only several months later.

The municipality paid the fees for services rendered before dismissal, but refused to pay the supervision fees. It claimed that: a) the engineer was to render professional services for a period of indefinite duration; b) the case was not one in which damages were involved; c) the engineer had not experienced any damages; d) the engineer had neglected to offer his services for the supervision.

The Court ruled however, that to all intents and purposes, this case was identical to a case involving an architect and his client, in which the Supreme Court decided that article 1691 of the Civil Code was applicable, and that if "the owner may cancel the contract . . . although the work have been begun . . .", he must indemnify the other party to the contract . . . "for all his actual expenses and labor, and pay damages according to the circumstances of the case."

The engineer testified that in order to carry out his contract with the municipality, he had assigned a two-man team to the job, comprising an engineer and his assistant. The team worked on a part-time basis, and in the meanwhile, carried out other assignments. After the contract was rescinded, it was not possible for the consulting engineer to secure work that would have filled the gap in the activities of the two-man team. The Court therefore felt that the cancellation of the contract has resulted in a loss of fees for the consulting engineer, although his overhead expenses were in no way reduced. In the light of this, the Court ruled that the consulting engineer was entitled to his full fee for the unjustified cancellation of his contract with the municipality.

More Specialization?

by George W. Joly, P.Eng., assistant dean, engineering, McGill University

In its last issue, the *Journal* presented in graphical form, an analysis of the replies to a questionnaire on Professional Training which the Corporation of Professional Engineers of Quebec sent its members in 1956. At that time, members were invited to submit more detailed answers to any questions on which they held strong opinions, and to present other questions which they may have felt should have been raised in the questionnaire. The viewpoints presented by members might be grouped under these headings: a) fundamental science; b) specialized engineering; c) business administration; d) professional attitude; e) humanities.

The replies, none of which touched on all five of these topics, in every case called upon the engineering schools to place more emphasis on these matters in the undergraduate curriculum. What the reaction of an engineering school to this request might be is what is worthwhile examining here.

To demand that more of the fundamentals of science be presented and that more attention be given to specialized engineering practices is to raise the question of what an engineering school does to those men who submit themselves to its discipline. Basically the school imposes a method of thinking on the minds of its students, not a body of facts but primarily a manner of viewing facts. Except if he be the occasional brilliant student, a man who graduates without some habitual way of looking at the data of engineering is not, and will not become an engineer. Now, the student under the influence of the curriculum may adopt a characteristic point of view towards engineering ranging from the purely theoretical to the purely practical. At one end of this spectrum, for there are an infinite number of intermediate positions, a graduate would not be surprised at the strangeness of the engineering problems of 1978 if suddenly he faced them today, but he would not know how to tackle the practical solution even of the problems of 1958. At the other end, a graduate would be shocked at the problems he must face in 1958 although he might be able easily to solve those of 1938.

The creative engineer—which is supposedly the kind every engineer secretly imagines himself to be—if he is to fulfill himself, must be more concerned with today's and tomorrow's theories than with yesterday's practice. The graduates of yesterday will solve yesterday's problems without any help from today's graduates.

It would seem then, if it is creative engineers that are needed for the economy, that any increased emphasis should be placed on fundamental science rather than on specialized training.

Le Chapître de Québec Choisit Les Membres de Son Comité Exécutif

Les membres du premier chapître officiel de la Corporation, fondé à Québec le 6 décembre dernier, ont élu le même jour les membres du comité exécutif du nouveau chapitre. Ce sont les ingénieurs: Roger Desjardins, président, Jacques Roy, vice-président, Lionel Boulet, Marc Cimon, Jean B. Delage, Jean-P. Gourdeau, Jean-Marc Lagacé et Francois L'Anglais, directeurs. La Corporation compte deux autres chapitres, fondés de façon non-officielle il y a quelques années: ceux de Sorel et du Saguenay.

Le président, Monsieur Desjardins,

gradué de Polytechnique en 1939, a été au Service de l'Electrification Rurale de 1939 à 1945; depuis cette date il est ingénieur en charge des Services d'Acqueducs et d'Egoûts à la Régie des Services Publics, Monsieur Desjardins est également chargé de la surveillance du laboratoire thermo-dynamique à la Faculté des Sciences de l'Université Laval.

En plus d'être président du chapitre de la Corporation, Monsieur Desjardins vient d'être élu président de la branche de Québec de l'E.I.C. pour l'année 1958. Le nouveau président du chapitre québecois est capitaine d'Etat Major du 8ième groupe de milice et fait partie d'un comité du Carnaval de Québec, d'un comité de la Fédération des Oeuvres de même que de l'Institut des Services Unis.

ONTARIO

Annual Meeting

The Royal York Hotel, Toronto, was the centre of activity for the Association of Professional Engineers of Ontario on Saturday, February 1, 1958 when members and guests of the 16,000 strong member organization met for the annual meeting and luncheon. Delegates of engineering organizations from other parts of Canada as well as the United States attended the one-day meeting, presenting a review of 1957 and a forecast of the engineering situation during 1958. Official delegates from the provincial areas in attendance were G. S. Halter, Fort William, representing the Lakehead; Harry Sproule, Chatham, representing Kent County; F. Bainbridge, Chalk River; W. S. Taylor, Niagara Falls, representing the Niagara area; and Yorke H. Williamson, Pamour, representing the professional engineers in the Porcupine area.

Elections of the Council of the Association, reported in the February issue of the *Journal*, resulted in the naming of C. T. Carson, vice-president and manager of production for Hiram Walker and Sons Ltd., Walkerville, Ont., as 1958 president of the organization. Mr Carson took over his duties during the meeting from predecessor John H. Fox, 1957 head of the organization.

In his forecast for 1958 the president-elect predicted that the engineering profession in Canada was on the threshold of a new era in which professional recognition and status would be universally achieved. "This year will see a continuation of the great work being carried out by this Association, and there must be no let-up in the program of bringing about an awareness of professional status in the individual engineer and with it realization of the values of professional integrity and responsibility," he said. He felt such a program was bound to bring with it professional recognition on the part of the employer and the general public.

"Realization on the part of the employers of the potential that exists in the young engineer is of the utmost importance. Encouragement of these young men and women by providing an atmosphere that will foster professional growth and the knowledge that they will receive a corresponding monetary return will produce surprising results," Mr. Carson pointed out. There was also an urgent need, he said, for a reappraisal of our teaching methods in high schools to ensure that the engineering subjects, mathematics, chemistry and physics, do not fall by the wayside. Mr. Carson said that there was a danger of this happening and called for an awareness of the present situation on the part of the educational authorities. He urged that special merit be accorded teachers of mathematics and physics who distinguish themselves in carrying out their duties.

In reviewing 1957, Mr. Carson referred to the establishment of a certification program for engineering technicians and technologists as the year's significant achievement.

Luncheon guest speaker Dr. Conrad A. Posz, of Michigan State University in an address entitled, "Why Do We Behave Like People," gave voice to his special skills in the subject of communication in relation to the conveying of thoughts from one human being to another.

Medal Awarded Dr. T. H. Hogg

One of the highlights of the day was the presentation of the highest award of the Association, the coveted Professional Engineers Medal to the late Dr. Thomas H. Hogg of Toronto. Dr. Hogg died three weeks later, on February 24, 1958. Former chairman of the Ontario Hydro-Electric Commission and pioneer of one of the foremost authorities on hydraulic engineering in Canada, he has frequently served in a consulting capacity. The government of Canada, the Province of Ontario, the Province of Manitoba all called upon him. He was, for thirteen years chief hydraulics engineer with the Hydro-Electric Power Commission of Ontario. In 1937 he was named chairman and chief engineer of the organization and held this post until his retirement in 1947. He was president of the E.I.C. in 1940.

Awarded only five times previously the medal is presented for distinguished service and outstanding contribution to the engineering profession. The five previous recipients of the medal are C. D. Howe, former Minister of Trade and Commerce; Dr. C. R. Young, former dean of engineering, University of Toronto; General A. G. L. McNaughton; the late Dr. J. F. Tyrrell, veteran geologist and explorer; and Dr. R. L. Hearn, former chairman of the Ontario Hydro-Electric Commission.

Student Awards

The Gold Medal of the Association was presented to the two engineering students who graduated with the highest standing in 1957 from the University of Toronto and Queen's University. They are John A. Norton of Toronto, and Peter W. McBurney, of Ottawa.

The awards, presented annually by the Association also include a $50.00 cheque to be used by the winners in the purchase of text books. The Association also provides a $500.00 university entrance scholarship awarded alternately at the University of Toronto and at Queen's to the student with the highest academic standing upon entering the faculty of applied science. In addition the A.P.O.E. grants six annual scholarships of $250.00 each, at these universities in first, second and third years.

At morning and afternoon sessions of the meeting reports were heard from the chairmen of some twenty active committees.

BRITISH COLUMBIA

(Taken from an editorial written by George C. Lipsey, president of the Association of Professional Engineers of British Columbia and published in the "B.C. Professional Engineers," January 1958)

Year of Consolidation

After several years of unprecedented peacetime economy in Canada, British Columbia and the rest of North America, signs are appearing which show a distinct levelling off in the economy. It is to be hoped that it is a levelling-off period and that no severe recession will develop. It must be remembered that what goes up must also come down. The cost of carrying on a business enterprise has been increasing more rapidly than the earnings of the enterprise.

This will be a year of retrenchment and consolidation rather than one of continued expansion at an increasing rate, as has been the case for several years. There will be a general shaking down in the industrial life of B.C., and there will be several casualties. This trend will adversely affect the members of the Association of Professional Engineers of British Columbia, but at the same time will challenge the ingenuity and abilities of the engineer. The cost of goods and services will have to be reduced in order that we can compete in world markets. The engineer will be called on during the coming year to get more done for less money and effort, the complete reverse of the challenge of the last several years to complete a job as quickly as possible, regardless of cost. In this period the engineer who can change his methods of thinking and who can draw on past experience will be the most wanted man in industry.

In the period ahead one group of engineers will remain employed but will have to work harder than ever before. Another group will find that there is little demand for their services. The first group can help the second group by remembering the "Golden Rule" and using as many of group two as possible even if the opportunities provided to

(Continued on page 118)

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

William J. Dick, M.E.I.C., prominent in the coal mining industry, first as a mining executive and later as a consultant, a member of the Alberta Power Commission and a director of Inland Cement Company Limited, died on July 3, 1957, at Edmonton.

Born at Nanaimo, B.C., on March 25, 1883, Mr. Dick attended McGill University and was in 1908 awarded a B.Sc. degree in mining engineering. He received a master of science in mining engineering in 1911.

From 1908 to 1910 he worked as a consulting mining engineer for a mining company in Brazil. In 1911 he served as a member of the former Conservation Commission of Canada until 1918. Later at Winnipeg and Calgary he worked as general manager of North American Colleries.

In 1922 Mr. Dick became president and general manager of Cadomin Coal Company of Edmonton, a post which he held until he retired in 1939.

In 1940 he was appointed Western Canada's representative for Allied War Supplies Corporation. Mr. Dick was appointed part-time member of the Workman's Compensation Board in 1941. He became regional oil controller for Alberta in 1942. He also served on the technical personnel board throughout the war. In 1943 Mr. Dick investigated emergency coal production and relative problems in Nova Scotia at the request of the Province of Nova Scotia.

On several occasions in recent years Mr. Dick served on provincial government commissions. Chairman of the Alberta Co-Terminus Boundaries Commission he also headed the Royal Commission on Bow River flood conditions. In 1948 Mr. Dick was president of the Alberta and North Western Chamber of Mines and Resources. At one time he was permanent secretary of the Interprovincial Oil and Gas Board. Mr. Dick had also served as a director of Ducks Unlimited of Canada.

Mr. Dick became an Associate Member of the Institute in 1911. He transferred to Member in 1918, attained Life membership in 1947.

John Goodall Dickenson, M.E.I.C., Toronto mining consultant and former manager and vice-president of the O'Brien Gold Mine Company died at Toronto on January 8, 1958.

Born at Tor Bay, Guysborough County, N.S., on March 17, 1883, Mr. Dickenson had his early schooling with the Nova Scotia Public Schools and at Loyola College, Montreal. He graduated from McGill University, with B.A. and B.Sc. degrees in mining in 1904 and 1907. He held various positions on railway surveys and was employed as a miner in coal and metal mines in Pennsylvania, New York, Idaho, B.C., and Eastern Canada. In 1907, after a period as surveying instructor for McGill University he became a foreman on subway construction with the New York and New Jersey Telephones. Promoted to division commercial engineer with headquarters at Albany, N.Y., in 1909, he remained in this work until 1916. At that time, accepted for the post of manager of the O'Brien Mining Company, he moved to Cobalt, Ont. He was called to head office, Ottawa, as general manager of mines in 1932. Subsequently he became vice-president and general manager of mines. Mr. Dickenson retained this post until his retirement in 1940.

Later he opened an office in Toronto, became interested in the Red Lake district of Ontario, and was instrumental in the development of the New Dickenson mine of that area. In 1948 ill-health forced his resignation.

While at Cobalt Mr. Dickenson directed the development of the first gold mine in the province of Quebec, the O'Brien gold mine at Cadillac.

He joined the Institute as a Student member in 1905, became an Associate member in 1912, and transferred to Member in 1919. He achieved Life membership in the Institute in 1947.

L. H. Laffoley, M.E.I.C., engineer of hotels for the Canadian Pacific Railway, Montreal, died in that city on February 1, 1958.

Laurence Herbert Laffoley was born on March 14, 1894, at Montreal. First associated with the C.P.R. as a draughtsman as early as 1912, he later attended McGill University, graduating with a B.Sc. degree in civil engineering in 1916. He served the Canadian Engineers and the Royal Flying Corps overseas from 1916 to 1918, for part of the time as instructor in military engineering. At war's end returning to Canada he worked as a demonstrator in mechanical draughting at McGill University. The following year he again entered the service of the Canadian Pacific Railway as a draughtsman. Promoted to assistant engineer in 1923 he assumed office as assistant engineer of buildings in 1937. Nine years later he became engineer of buildings.

In 1956 Mr. Laffoley was named to the post of engineer of hotels, retaining the appointment until the time of his death.

Noted for his part in the construction of a great many buildings across Canada, a few of these are, the Royal York Hotel, Toronto, the recent extension to the building, the St. Antoine Street extension to Windsor Station, Montreal, Banff Springs Hotel, Banff, Alta., and the Chateau Frontenac, Quebec, Que., as well as many other large projects associated with the construction and railroad industries.

Mr. Laffoley joined the Institute as a Student member in 1914, transferred to Associate membership in 1921. He became a Member in 1940.

George W. Rayner, M.E.I.C., co-founder and president of the Rayner Construction Company, Toronto, died at Toronto on January 1, 1958.

Born in Suffolk, England, George William Rayner came to Canada at a very early age. He graduated from the University of Toronto in 1905, then followed post-graduate studies in mining. His early work included two years with the Cataract Power Company and the Kaministigua Power Company, in Ontario. He gained experience in prospecting in Northern Ontario, Quebec, and the Queen Charlotte Islands, B.C.

During the nineteen twenties he founded the Rayner Construction Company with A. W. Robertson, was managing director of the Ontario Amcsite Limited, and was associated with the

W. J. Dick, M.E.I.C.

L. H. Laffoley, M.E.I.C.

Fuller Gravel Limited, all at Toronto. Mr. Rayner headed Rayner Atlas Limited, which company was concerned with the hydraulic tunnel under Niagara Falls and with the Iroquois Constructors Limited. The latter was concerned with carrying out power and seaway assignments on the St. Lawrence Seaway.

On completion of the construction of a hydro tunnel on the Mississagi river near Thessalon, Ont., he was in 1951 honoured when the Ontario Hydro-Electric Commission gave the power plant his name.

Mr. Rayner joined the Institute as a Member in 1920. He attained Life membership in the organization in 1954.

A. V. Gale, M.E.I.C., retired vice-president and general manager of the Hull Electric Company, and manager of the Hull division of the Gatineau Power Company, Hull, Que., died on November 1957, at Hull.

Alfred Valiant Gale was born at Quebec City on September 7, 1884. He attended the Quebec High School and Poughkepsie Business College.

Beginning his engineering career as an assistant in the lighting department of the Hull Electric Company in 1907 he rose to the post of superintendent of lighting and distribution for the company in 1912.

His first work in the field of engineering was with the Canadian Rubber Company at Montreal. For many years he was employed as an engineering officer for the Hull Electric Company.

Mr. Gale joined the Institute as an Associate Member in 1916, transferred to Member in 1940 and attained Life Membership in 1952.

R. K. Robertson, M.E.I.C., vice-president of the Laprairie Brick and Tile Company for more than 32 years and vice-president and general manager of the Clay products division of the Dominion Tar and Chemical Company, died at Montreal on December 26, 1957.

Randal Killaly Robertson was born at Dickenson's Landing, Ontario on July 16, 1892. He graduated from the Royal Military College, Kingston, in 1912. Two years later he graduated from McGill University with a B.Sc. degree. His first professional work was with the Toronto firm of Chapman and Power of Toronto, in London where he was engaged in work on sewer construction. From 1915 to 1918 he served with the Canadian Army infantry. He was transferred to the Engineers corps in 1918 in France. On his discharge the following year he held the rank of captain. In 1919 he took charge of the engineering department of the Cooksville Company of Canada Limited and in 1921 he was appointed works manager. In 1924 he joined the Canadian Marconi Company at Montreal. With the expansion of the Cooksville Company into the Quebec area in 1927 he rejoined the firm. In 1933 the company became known as the La Prairie Brick and Tile Company.

Mr. Robertson joined the Institute as an Associate member in 1923, transferred to Member in 1940.

George E. Robertson, father of Mr. R. K. Robertson was one of the chartered members of the E.I.C.

Roland Charles Duquette, M.E.I.C., overhead distribution engineer with the Quebec Hydro-Electric Commission, at Montreal, died in that city on June 20, 1957.

Born at Montreal on January 18, 1915, Mr. Duquette had his early schooling at the Academie St. Paul and Strathcona University. He entered McGill University in 1936 and was graduated with a B.Eng. degree in 1940. While a student he gained experience with the Empire Food Corporation and the Montreal Light, Heat and Power Consolidated. Immediately on graduation he accepted a position as an assistant electrical engineer with the distribution division of the Gatineau Power Company, at Hull, Que. In 1945 he joined the Quebec Hydro-Electric Commission, at Montreal as an electrical engineer. After a number of years' work in this capacity he was in 1954 promoted to overhead distribution engineer for the organization.

Mr. Duquette joined the Engineering Institute as a Student Member in 1940, transferred to Junior member in 1943. He became a Member in 1945.

News of the Associations and Corporation

(Continued from page 116)

BRITISH COLUMBIA (Cont'd)

them are of a non-technical nature. The second group can use the period of slack employment to prepare themselves for the future and make themselves more valuable to future employers. A few suggested studies are accounting and business management courses, labour relations, public speaking, and taking any kind of a job available, for there is something new to learn in every kind of endeavour.

This year is the Centennial year of the Province and from present indications it looks like a year of retrenchment and consolidation, rather than a year of exploration and development as it was a century ago.

ALBERTA

(Taken from a report by H. L. Roblin, committee chairman, published in "The Alberta Professional Engineer," January 1958)

Membership, Enforcement Committee Report

Mr. Roblin states that the two-fold responsibilities of the Committee in that province are to protect the public by making effective the provisions of Section 45 of "The Engineering Profession Act, 1955" and of making the privilege of membership available to all those who are qualified to practice engineering.

In carrying out enforcement duties the committee must deal with all infractions coming to its attention. Thirty cases now being dealt with may be classified as follows:

1. Those people who through ignorance of the provisions of "The Engineering Profession Act" imply wrongly that they can or do practice.
2. Those who seek prestige or advertising gain by describing themselves as professional engineers.
3. Companies using the words "engineer" or "engineering", thereby implying that they are qualified to practice.

The committee has found that many cases can be satisfactorily dealt with through friendly persuasion by either a committee member or the executive-secretary. Corrective action has been taken in about 50 per cent of the cases that have come before the committee in the past year. Most of the remainder are still under review. Where it is not possible to get corrective action in this way, the cases are referred to Council to be sent to the Courts. This course has been adopted in several instances.

One of the major problems facing the committee is that of listings in the telephone directories. This has been discussed with the advertising departments of the telephone companies with a view to improving the situation.

Because of the heavy load of enforcement problems that committee has had little time to give to its membership function. Through the efforts of the executive-secretary and his staff, about two hundred engineers qualified for membership were contacted throughout the province, but there is still a great deal of membership work to be done. In view of the amount of work involved —and for other reasons—it often appears that the subjects of membership and enforcement should be administered by separate committees.

The success of the Membership and Enforcement Committee is in a large measure dependent on the co-operation of the members of the Association.

1958 ANNUAL MEETING
Quebec, Chateau Frontenac,
May 21, 22, 23
(see announcement on page 103 of this issue)

Personals

News of the Personal Activities of Members of the Institute

Dean R. M. Hardy, M.E.I.C., (B.Sc., civil, Manitoba, 1929; M.Sc., McGill, 1930; Hon. D.Sc., Manitoba, 1957), of the faculty of engineering at the University of Alberta, has been named to the six-member Royal Commission on Energy. Canada's oil, natural gas and pipelines industry will be the subject of the Commission's early hearings to be carried on in Western Canada. Formation of a natural gas policy is planned.

D. M. Stephens, M.E.I.C., (B.Sc. civil, Manitoba, 1931), 1954 president of the Engineering Institute, chairman of the Manitoba Hydro-Electric Board, Winnipeg, has been named a member of the Canadian section of the International Joint Commission. A former deputy minister of resources for Manitoba, Mr. Stephens has been chairman of the hydro-electric board since 1951.

Dr. Lyle G. Trorey, M.B.E., M.E.I.C., (B.Sc., London, 1927; Ph.D., London, 1944), consulting engineer of Vancouver has recently been elected a Fellow of the American Association for the Advancement of Science. Dr. Trorey is well-known outside Canada for original scientific and engineering work in a number of fields.

Ian F. McRae, M.E.I.C., of the Canadian General Electric Company Limited, has been elected chairman of the board of directors of the company. He will retain the responsibility of general manager of the civilian atomic power department at Toronto, along with his new duties. Elected a company director earlier this year, Mr. McRae has a long-standing interest in industrial organization work and is currently serving as first vice-president of the Canadian Manufacturers Association.

G. N. Martin, M.E.I.C.

G. H. Midgley, M.E.I.C.

George H. Midgley, M.E.I.C., (B.Sc., mech., Nova Scotia Technical College, 1924), general sales manager of the Dominion Bridge Company, Limited, and formerly also sales manager of the Eastern Division will now devote his entire time to the general sales policies of the Company. Mr. Midgley joined Dominion Bridge Company in 1936, gained the post of general sales manager in 1956.

P. G. A. Brault, M.E.I.C.

J. P. Borbey, M.E.I.C.

John P. Borbey, M.E.I.C., (B.A. Sc., civil, Toronto, 1934), assistant sales manager of the Eastern division of the Dominion Bridge Company Limited has been appointed sales manager of this division. He joined Dominion Bridge in 1936, since then he has held various positions in the engineering and sales departments, until his appointment in 1955 as assistant sales manager of the Eastern division.

Gerald N. Martin, M.E.I.C., (B.Sc., civil, Ecole Polytechnique, 1934), formerly combustion sales engineer with the Dominion Bridge Company Limited has been appointed assistant sales manager with the organization. He has held the position of combustion sales engineer at Dominion Bridge since 1944.

P. G. A. Brault, M.E.I.C., (B.Sc., civil, McGill, 1921), has been appointed assistant chief engineer of the engineering department of the Eastern Division of the Dominion Bridge Company Limited. He formerly held the title of design engineer, Eastern division. Employed with the firm since the early days of his career, his appointment as design engineer dates to 1951.

Dr. G. Vibert Douglas, M.E.I.C., retired professor of geology at Dalhousie University, who recently opened a practice in Toronto as consulting geologist has announced a new address: 40 Sherbourne Street N., Toronto 5, Ont. (See 'Personals', November 1957.)

E. C. Hay, M.E.I.C., (B.A.Sc., elec., U.B.C., 1930), was recently appointed manager of the Vancouver plant, industrial control division of Canadian Westinghouse Company Limited. He formerly served the organization as an application engineer at Vancouver.

Harry M. White, M.E.I.C., (B.Sc., mech., Toronto, 1910), retired from the staff of the Dominion Bridge Company Limited as chief engineer, Western division, in October 1957, after forty-seven years of continuous service with the company. He was retained in a consulting capacity until the end of March, 1958. Mr. White started his duties with the company at Lachine, Que., head office, and then transferred first to the Winnipeg Branch of the firm as designing engineer, then engineer. He became chief engineer of the western division (Manitoba, Saskatchewan and Alberta), in 1930. During World War II he was placed in charge of shell production for the firm.

H. M. White, M.E.I.C.

J. C. Trueman, M.E.I.C.

D. C. Beam, M.E.I.C.

J. C. Trueman, M.E.I.C., (B.Sc., civil, Manitoba, 1923; M.Sc., McGill, 1924), has been appointed chief engineer of the Western division of Dominion Bridge Company Limited. Mr. Trueman joined the company in 1927 as a design engineer and three years later was appointed design engineer, Western division.

M. J. Lupton, M.E.I.C., (B.Sc., mech., Manitoba, 1924; M.Sc., McGill, 1936), has been appointed structural engineer in charge of structural design with the Winnipeg Branch of Dominion Bridge Company Limited. His association with the firm dates to 1936 when he joined the structural design department at head office, Lachine, Que.

Donald C. Beam, M.E.I.C., (B.A.Sc., civil, Toronto, 1928), chief engineer of the Canadian Institute of Steel Construction, Inc., has been appointed general manager of the organization. He joined the Canadian Institute of Steel Construction as chief engineer in charge of its technical program in 1949.

M. J. Lupton, M.E.I.C.

D. L. Tarlton, M.E.I.C.

Derek L. Tarlton, M.E.I.C., (B.A.Sc., civil, Toronto, 1952), has been appointed development engineer with the Canadian Institute of Steel Construction, Inc. Experienced in structural design, in industry and with a firm of consulting engineers, he joined the Institute at the beginning of 1956 as district engineer for Ontario.

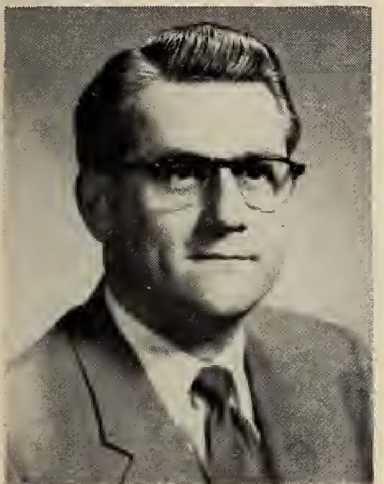
W. L. Todd, M.E.I.C., (B.Eng., mech., McGill, 1941), and **G. J. Monarque**, M.E.I.C., (B.Eng., chem., McGill, 1946), have been named among the officers and senior executive of a newly formed company to be known as Stadler Hurter International Ltd. A private company with offices in Montreal, New York, and Mexico City it will take over all work formerly undertaken outside the Province of Quebec by Stadler, Hurter and Company. The firm will continue to practice in the province as in the past.

B. Hardcastle, M.E.I.C., (B.Sc., civil, Edinburgh, 1945), secretary of the Joint Area Committee of the Toronto Branch of the Engineering Institute, has been named chairman, 1958, of the technical committee of the Petroleum Association of Ontario.

W. C. Wilkinson, M.E.I.C., (B.Sc., elec., New Brunswick, 1937), has left Australia and has accepted an appointment with the Canadian National Telegraphs, radio group, at Toronto. Mr. Wilkinson was formerly with Amalgamated Television Services Party Ltd., at Sydney, Australia as a senior television engineer. Earlier in his career he devoted ten years to the communications field in Canada.

W. G. Huber, M.E.I.C., (B.Sc., civil, Wisconsin, 1920), has resigned his position following three years in which he served as general manager of the B.C. Engineering Company limited, at Vancouver. During the five-year period preceding this appointment which dated to 1954, he held a similar post for B.C. International Engineering Company Limited, principally on the Alcan B.C. Power Development. Mr. Huber will practise in Vancouver as a consultant on heavy civil engineering for the B.C. Engineering Company and other clients.

J. A. D'Angelo, M.E.I.C., whose recent appointment as comptroller of the



J. A. D'Angelo, M.E.I.C.

Joseph Campan engine plant of the Chrysler Corporation, Detroit, was announced in the January issue of the *Journal*, page 104.

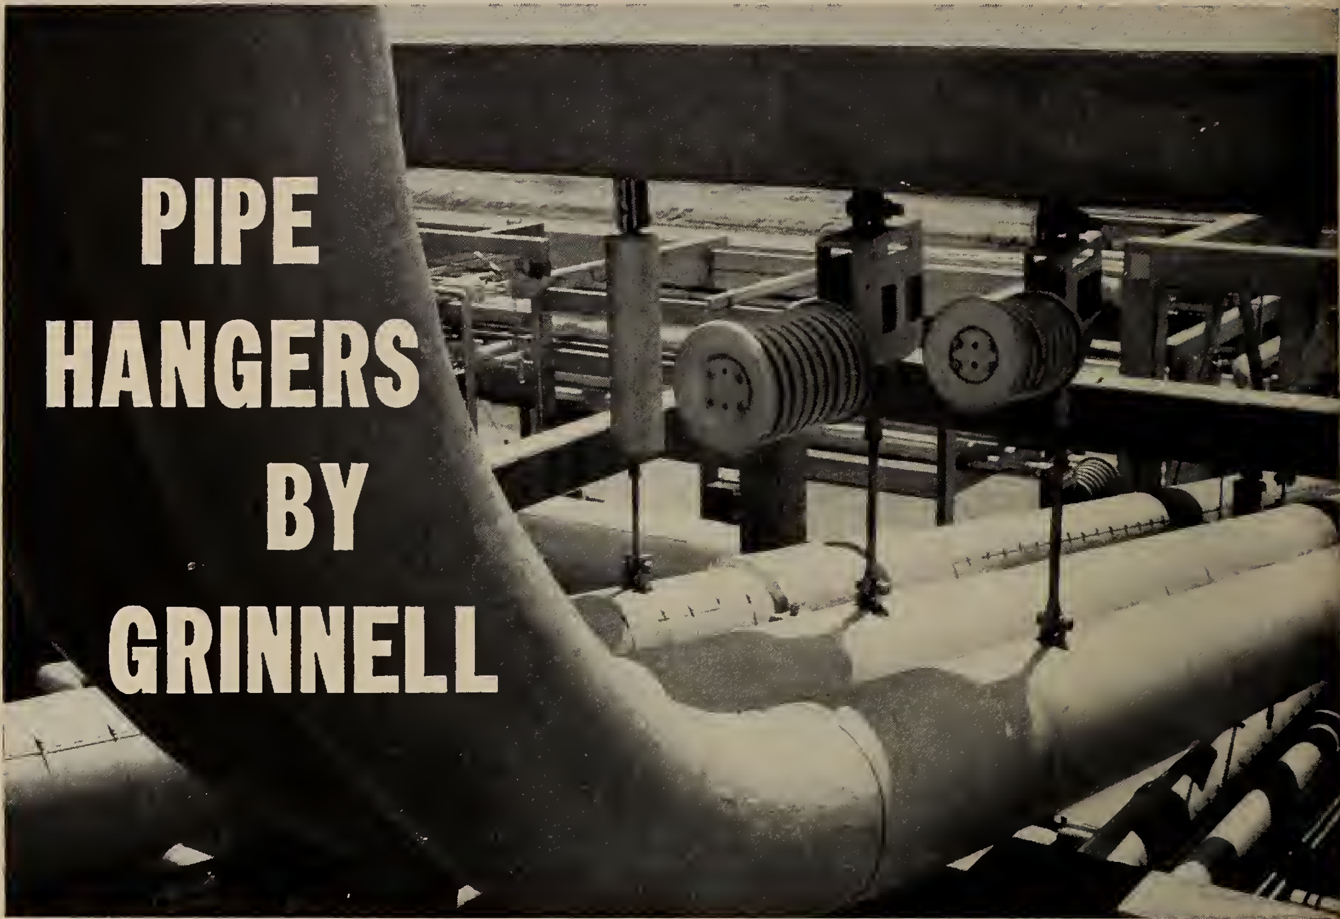
M. L. Laquerre, M.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1942), for the past twelve years a member of the firm of Delisle and Laquerre of Chicoutimi, has organized a consulting engineering firm at Jonquiere, Que., with **L. Lemieux**, JR.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1955). Mr. Lemieux has been associated with the firm of William Gravel, consulting engineer, Chicoutimi, since graduation.

In his career, to date, Mr. Laquerre has been especially active in building design and construction, sewerage and water supply.

Arthur W. Norman, M.E.I.C., (B.Eng., mech., Nova Scotia Technical College, 1946), has been named assistant to the manager, Wm. Stairs, Son and Morrow,

A. W. Norman, M.E.I.C.

At Tidewater's new Delaware Refinery...



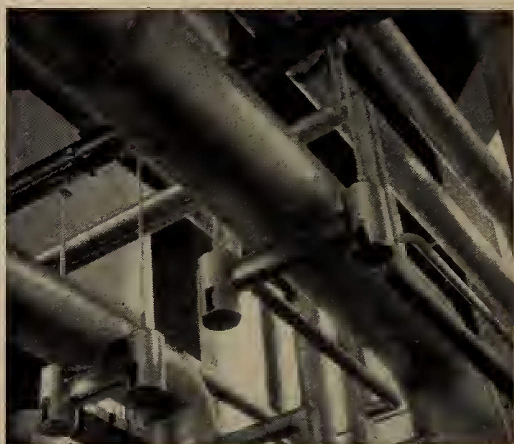
Tidewater Oil Company's new ultramodern $200-million, 5000-acre refinery, south of Wilmington, is the largest ever constructed at one time. Capable of processing 130,000 barrels of crude oil daily, the Delaware Refinery boasts eleven major processing units, including six of world-record size.

Pipe suspension problems, too, were bigger and more challenging at this record-breaking refinery. That's why Tidewater turned to Grinnell for pipe hangers and supports.

A volume producer of pipe hangers, Grinnell backs up its high capacity and diversification with an efficient coast-to-coast network of warehouses and jobbers. Even complex hanger requirements very often can be met with hanger assemblies right off the shelf. This not only saves you time, but it can save you money, by cutting down on the number of special items which must be manufactured.

If you have a pipe suspension problem, you are invited to write: Grinnell Company of Canada, Ltd., Edmonton, Montreal, Toronto, Vancouver.

GRINNELL CONSTANT-SUPPORT HANGERS are engineered to maintain full safety factor. Constancy of support is mathematically perfect for all positions of travel. Note low headroom requirement. Load ranges from 30 lbs. to 32,260 lbs., with travels up to 12 inches.



GRINNELL VARIABLE SPRING HANGERS have pre-compression feature which assures operation of spring within its proper working range. Maximum variation in supporting force per ½" of deflection is 10½% of rated capacity — in all sizes. Available in 21 sizes for loads ranging from 50 lbs. to 28,200 lbs.

Limited, construction machinery division at Halifax, N.S. Since his graduation Mr. Norman has held posts with the Construction Equipment Company, Limited, and with the Atlantic Tug and Equipment Company, Inc.

CORRECTION: In the Personals Section of the *Journal*, January issue, it was wrongly stated that R. Walker, M.E.I.C., of the Associated Engineering Services Ltd., Edmonton, had been appointed chief electrical engineer with the firm. Actually the appointment is that of chief industrial engineer. The Journal regrets the error.

A. Gordon Macdonald, JR.E.I.C., (B.Eng., elec., McGill, 1953), has left the firm of Burns and Company, where he was employed at head office, engineering department, Calgary, Alta., and has accepted employment in the Calgary office of Brown and Root Limited, engineers and constructors.

Gordon Gracie, JR.E.I.C., (B.A.Sc., civil, Toronto, 1952), has accepted the appointment of instructor in civil engineering with the University of Illinois, Urbana, Ill. Mr. Gracie who intends to carry on further studies in structural engineering has recently obtained a degree in photogrammetric engineering from the International Training Centre for Aerial Survey at Delft, Holland.

Phil. H. Walker, JR.E.I.C., (B.Sc., civil, Alberta, 1956), formerly employed by K. C. Stanley and Associates, architects and engineers, of Edmonton, as an assistant structural design engineer has joined the City of Edmonton engineering staff. Associated with the waterworks department his appointment is that of chief engineer.

Donald K. Turner, JR.E.I.C., (B.A.Sc., civil, Toronto, 1954), has been appointed regional engineer for Ontario with the Canadian Institute of Steel Construction,

D. K. Turner, JR.E.I.C.

• PERSONALS

Inc. He was previously employed by the City of Toronto building department as plan examiner. In his present position he will service needs of designers and users of structural steel in his region.

Flight Lieutenant Kenneth E. Rideout, JR.E.I.C., (B.S., civil, New Brunswick, 1950), has been promoted to the rank of squadron leader. He is stationed at Randolph Air Force Base, San Antonio, Texas, on a two-year exchange posting with the United States Air Force.

F. H. Sutcliffe, JR.E.I.C., (B.Eng., civil, McGill, 1953), structural engineer, with the Foundation of Canada Engineering Corporation, bridge department, Montreal, is among those engineers who have quite recently benefitted from an Athlone Fellowship. Enrolled at the Imperial College of Science and Technology, London, he studied concrete technology and gained the Diploma of the Imperial College, (D.I.C.). During his second year in Great Britain Mr. Sutcliffe worked with the firm of Stressed Concrete Design Limited, a subsidiary of E. J. Cook and Company, (Engineers) Limited, specializing in prestressed concrete design and construction.

G. B. Weld, JR.E.I.C., (B.Eng., mech., N.S.T.C., 1955), returned to Canada three months ago, following twenty months engineering experience in Great Britain under the provisions of an Athlone Fellowship. Mr. Weld spent six months at Loughborough, England, at the Brush Factory, on the design and manufacture of steam turbines. For an additional thirteen months he was engaged in research on the running-in of lubricated gear mechanisms. He was awarded a master of engineering degree.

Now associated with the National Research Council Mr. Weld is with the Atlantic Regional Laboratory, Halifax, N.S.

H. M. Tomlinson, JR.E.I.C., (B.Eng., civil, N.S.T.C., 1954), has left the staff of the Shawinigan Engineering Company, Shawinigan Falls, Que., and is now resident in Newfoundland. Mr. Tomlinson is employed with the Department of Transport, Government of Canada, at St. John's.

Bjorn Pedersen, JR.E.I.C., (B.Sc., elec., Manitoba, 1956), is engaged in the work of junior research offices, with National Research Council, radio and electrical engineering division, at Ottawa.

Barry J. Ferries, JR.E.I.C., (B.Sc., mech., Manitoba, 1955), has severed his connections with the Amalgamated Electric Corporation Limited, Winnipeg, and has accepted the appointment of chief engineer with the Inter-City Gas Company Limited at Portage La Prairie, Man.

J. W. Marshall, JR.E.I.C., (B.A.Sc., mech., Toronto, 1953, holds the post of lecturer in management, and engineering, at the Ryerson Institute of Technology, Toronto.

T. E. Flinn, M.E.I.C., *Branch News Editor*

CONTRIBUTIONS TO PUBLIC HEALTH have not been overlooked by the engineer, according to Dr. Milton G. Townsend, medical director, Northern Electric Company Limited, Montreal. Dr. Townsend addressed the Belleville Branch at a meeting held January 13, 1958. Engineers, he explained, had contributed to the good health of mankind in the development of processes for the mass production of drugs, and in the design and construction of such public works as sewage disposal and filtration plants, so vital to public health. He also credited the engineer with the sense of responsibility which called on him to determine health hazards in the processes of his design and to find suitable solution for the problem.

Absenteeism, occupational diseases, and the new hazard of radioactivity were discussed. The study of attendance records was mentioned as the best method of studying the health of employees in industry. In certain plants it had been found that 5 per cent of the employees were responsible for 50 per cent of time lost due to illness. A great deal of absenteeism in industry invites question from the medical point of view. This appears to be closely associated with employee attitude to the job. The supervisor rather than the company physician is in the best position to help such employees.

Effects of noise on human behaviour was a part of the discussion.

Shown here are some of the newly elected officers of the Halifax Branch. Left to right are: B. E. Langley, Bridgewater; W. J. Phillips, vice-chairman; J. D. Kline, chairman; J. G. Bell, executive, Halifax; K. R. Mitchell, Halifax.

Taken at a meeting of the Eastern Township Branch on the occasion of a talk given by R. L. Beck, of the Canadian General Electric Company, Limited, on January 10, 1958. Left to right are G. P. Cote, C. D. Borror, C.I.M.M., Branch chairman; R. D. Mawhood, Branch chairman, E.I.C.; R. L. Beck; A. C. Stevens; Jean Bourassa; Eric Webster; J. M. Fletcher, C.I.M.M. Branch secretary-treasurer; and G. M. Dick, vice-president, E.I.C.

W. E. Morden, M.E.I.C.,
Branch News Editor

PROBLEMS AND RESPONSIBILITIES of management were up for discussion on January 23, 1958 when the Brockville Branch and the Professional Development Group gathered to hear a talk by L. Cunningham, personnel director and secretary of the United Steel Corporation Limited. He divided the responsibilities of management into three groups: shareholders, employees, and to the public or consumer.

Mr. Cunningham stressed the importance of acquainting the employee with the many fringe benefits that are provided. He felt that the monetary value of such things as a pension plan, insurance and paid holidays should be evaluated as a part of the income. He went on to discuss what he considered to be the correct way to pay for a job, the problem of obtaining sufficiently skilled artisans, union negotiation and other problems.

Forty-five members and guests attended the meeting chaired by Eric Ward.

EASTERN TOWNSHIPS

Jean Bourassa, JR.E.I.C., *Secretary*

PROGRESS IN ATOMIC ENERGY was reviewed for the Eastern Townships Branch, E.I.C., and the Sherbrooke Branch of the Canadian Institute of Mining and Metallurgy at a meeting, January 10, 1958. R. L. Beck, application engineer, Canadian General Electric Company, civilian department of atomic energy, presented the address.

Introducing his talk with an explanation of the basic principles of nuclear fission, Mr. Beck followed this with a review of the various installations of atomic reactors. He recalled the early experiments on atomic energy during the war, and the tremendous efforts which contributed to the production of atomic bombs. The early peaceful application of atomic energy was made possible by the developments in radioactive isotopes in agriculture, cobalt bombs in the treatment for cancer and atomic reactors for power generation. The basic elements of a reactor were outlined and the operation explained.

Various reactor installations in the United Kingdom, the United States and Canada were reviewed as well as main features of important installations.

Mr. Beck pointed out the important achievements performed by the Canadian group at Chalk River, Ont. In spite of recent discoveries of oil and natural gas in the Western provinces, Canada remains significant in the import of energy. When nuclear power takes its place among fuels less expensive than conventional fuel plants, Canada, he felt, may enjoy an improved trade balance.

Finally Mr. Beck discussed the economic factors related to the production of nuclear power: capital expenditure, operating costs, and fuel costs. E.I.C. branch chairman R. D. Mawhood extended a welcome to the large turn-out of C.I.M.M. members.

HALIFAX

J. E. Reardon, M.E.I.C., *Sec.-Treas.*

G. H. Dunphy, M.E.I.C., *Branch News Reporter*

The 1957 annual meeting of the Halifax Branch took place in the Nova Scotia Hotel on December 17.

A one minute silence for deceased members preceded approval of the annual minutes.

A highlight of the meeting was the discussion regarding students activities and guidance. Professor M. L. Baker and assistant professor V. E. Vaughan presented reports on these subjects. Professor Baker stressed the fact the E.I.C., through its Nova Scotia membership are giving advice and guidance to matriculation students in our high schools regarding the choice of engineering as a profession. Professor Baker expressed the hope that these activities would increase. He commented on the E.I.C. publication, "Engineering Careers in Canada", which has been distributed to freshmen and final year engineers, and in limited number to high schools. Enthusiastic discussion ensued. It was generally felt that the utmost should be done to assist in this program.

F. C. Bennett outlined the activities at the annual meeting of the E.I.C., and provided a brief summary of Council activities.

In his report on confederation, H. W. L. Doane, vice-president of the Institute, gave some encouragement that progress was being made in this direction.

Chairman J. D. Kline reviewed the activities of the Branch during 1957. Twelve meetings, including two field trips took place.

The following were elected to office: chairman, J. D. Kline; vice-chairman, W. J. Phillips; executive for Halifax area, J. G. Bell, G. McD. Haliburton, K. R. Mitchell; executive for area outside Halifax, J. R. Cameron of Milford, and B. E. Langley of Bridgewater.

HAMILTON

W. A. H. Filer, JR.E.I.C., *Sec.-Treas.*

J. R. Currie, M.E.I.C., *Branch News Editor*

The annual meeting of the Hamilton Branch was held January 16, 1958 at the Hamilton Golf and Country Club at Ancaster, Ont. The evening speaker, A. P. Craig, vice-president, Trans-Canada Pipeline delivered a talk entitled, "Up-

To-Date with Trans-Canada Pipeline". Many comparisons illustrating the impact of the Trans-Canada Pipeline on the Canadian economy were given. The talk was accompanied by color film of pipeline laying operations and general operating aspects.

One interesting sidelight of the pipeline will be the production of sulphur as a by-product in the processing of the raw gas. This sulphur production will amount to 1,000 tons per day, more than replacing the amount of sulphur now being imported from the United States. When in full operation Trans-Canada Pipeline expcets to provide about 30,000 permanent jobs in the operation and maintenance of the pipeline. Mr. Craig mentioned the impact on the economy through the establishment of supplier plants such as Page Hersey Tubes Limited. Reporting briefly the stages through which the project moved during the financing arrangements, he noted that firm commitments covering gas deliveries for twenty years were required of the major utilities in Eastern Canada covering upwards of two billion dollars in total sales before senior financing could be arranged. Since signing of the original contract, the utilities have revised their requirements drastically upward, with the result that Trans-Canada Pipeline expect to reach maximum through-put in about 1962.

With reference to the construction progress, Mr. Craig stated that the pipeline was 60 per cent completed by the end of 1957 and his company expects to have the pipeline fully completed by the end of this year. Natural gas already serves communities as far east as the lakehead.

Following Mr. Craig's address, the election of officers of the Branch took place, with R. C. Mitchell elected chairman, H. E. Seely, vice-chairman, and W. A. H. Filer, sec.-treas.

HURONIA

L. Morgante, JR.E.I.C., *Sec.-Treas.*

B. C. Lamble, M.E.I.C., *Branch News Editor*

GEOLOGY IN LABRADOR was the subject of discussion at the monthly meeting of the Huronia Branch, at Orillia, Ont., on January 16, 1958, when Dr. George Vilbert Douglas gave a talk. One of the most distinguished geologists in the country, Dr. Douglas has travelled the world as a representative of government and scientific bodies. His address was entitled, "The Geology of the Labrador Coast."

The geological survey in Labrador, profusely illustrated by lantern slides, was conducted for the former Government of Newfoundland, primarily to locate mineral deposits. Dr. Douglas went into great detail to explain the rock formations and deposits encountered during the trip and gave many interesting accounts of his geological studies. He spoke highly of his staff of 12 men, all of them outstanding geologists and engineers.

The audience numbering 30 included two representatives from Toronto. They were J. H. McLaren, Eastern field secretary of the Institute, and T. Keefer, travelling secretary of the Professional Engineers of Ontario.

Shown together at a meeting of the Huronia Branch, held January 16, 1958 are, left to right: F. Alport, Dr. G. Vibert Douglas, and H. C. Bates, Branch chairman. Dr. Douglas a noted geologist, addressed the meeting on "The Geology of the Labrador Coast".

KINGSTON

D. I. Ourom, JR.E.I.C., *Sec.-Treas.*

A PANEL DISCUSSION on engineering education was arranged for February 6, 1958 for all those interested in discussing the topic of education. Moderated by L. F. Grant, retired field secretary of the Institute, teacher and alderman, panel members were Prof. D. M. Jemmett, electrical engineering, Queen's; V. S. Ready, principal, K.C.V.I.; D. L. Rigsby, general superintendent of engineering and services, Aluminum Company of Canada Limited; and R. W. T. Birchard, assistant engineer, Canadian Industries Limited.

During the past few years increasing public interest has been directed to the modern educational system recently prominent in the news. Therefore it was decided that an open discussion should be held for all those members and friends who might care to show an interest or express an opinion.

LAKEHEAD

C. M. Cotton, JR.E.I.C., *Sec.-Treas.*

George A. Walker, JR.E.I.C., *Publicity Chairman*

PERHAPS THE MOST OUTSTANDING meeting of the current year was held at the Fort William Armouries in January when a team of three engineer members of the Branch from Canadian Car Company Limited took over. The evening was spent in observation of the development work of the company's new air suspension system on the busses. One of the company busses especially adjusted for demonstration purposes was used. The under-chassis lights were turned on the suspension units and it was possible to see the new system in action. The members were impressed by the quietness and smoothness of the ride, an outstanding feature of this particular suspension system.

Automotive project engineer, N. Kuster, provided introductory remarks, while J. Rymes dealt with the suspension layout covering the unique problems encountered during the design and the solutions now available. It was illustrated that the application of patented air suspension system could be made in fields of transportation other than the bus industry.

Interesting comments on the new air suspension system offered by the automobile manufacturers were passed on. More than 50 members turned out.

LONDON

G. W. Chorley, M.E.I.C., *Sec.-Treas.*

AN ADDRESS ENTITLED "CANADA", was read by V. B. King, of King Trucks Limited, London, Ont., before the London Branch on January 21, 1958.

Mr. King urged that Canadians bring to light the problems of the nation, to face and overcome them by realistic measures. In this way he felt Canada would gain its real place in the sun.

Mr. King began his talk by remarking that a great deal is said about the progress and future of this country. It has been popular to call it an unknown country, to extoll its greatness, and to raise new horizons. It had become desirable to promote a feeling of strong national pride, perhaps to counteract the constant unfluence of the United States, and the feelings derived from our recent colonial status he suggested. As regards the former issue as a factor in our behavior, Mr. King felt that while our material standard of living is almost as high as in the United States the differential still attracts many of our best young people who emigrate to the U.S. So long as Canadians are complacent about the fact that this country is not sufficiently attractive to keep Canadians at home to take part in the development of the country, Mr. King warned, they will be attracted to the United States.

Canada has also proved complacent on the educational system. "If we cannot find ways and means of developing this, our best natural resource, we do not deserve better than mediocrity in the field of science," he said.

Turning his thoughts to legislation Mr. King stated that security and welfare have been demanded by and given to Canadians in numerous ways. However, he pointed out, increased service through pressure on the government for benefits, boosts the tax-rate and in the process the incentive for individuals and corporations to work and strive diminishes. High taxation inhibits corporations from expanding, thus limiting the employment potential of industry. This may discourage industry. This and other factors may actually bring about the flight of industry from a community or even from the country. Mr. King cited an instance of a company who had concluded that economic and other conditions here were not conducive to the continuation of business, and closed down. He suggested that no attempt was made on the part of any government to approach the company to discuss its difficulties or to try to determine if anything might be done to induce it to continue its operations here.

That the climate for industry and manufacturing in this country is excellent, Mr. King believed was a popular fallacy. He suggested that this applied especially with respect to secondary manufacturing, firstly from the question of taxation where difficulties in connection with the corporation tax, sales tax, and succession duties in the case of private ownership exist. Mr. King felt that manufacturing should receive benefits comparable to the mining industry and agriculture which are granted a tax-exemption for a tune-up period, and for three years thereafter. The tariff protection or umbrella under which secondary industry operates is uncertain, he went on, stating that although he would not advocate that tariffs be raised, "the trick," he said, "is to obtain 'Made in Canada' status." Until this is accomplished a company must operate with little or no tariff protection, and an unfavourable exchange rate. He also urged a policy of "buy Canadian" as important to the welfare of this country. While manufacturing had not kept pace with the boom Canada had been experiencing, the main benefit of the big Canadian boom since 1953, he said, had gone to U.S. manufacturers of both capital and consumer goods.

Mr. King appealed to Canadians to become better acquainted with the Canadian Arctic and sub-Arctic through organized group trips. "If Canadians do not study and know our Arctic and sub-Arctic and prepare for feasible and economic developments," he said, "do we deserve to hold this vast territory?"

He also mentioned Canada's growing part in the organization known as UPADI.

In closing Mr. King remarked that the purpose of his talk had not been to be critical or pessimistic. All of these situations mentioned could and must in time be corrected.

NIPISSING AND UPPER OTTAWA

R. A. Booy, JR.E.I.C., *Sec.-Treas.*

J. W. Millar, M.E.I.C., *Branch News Editor*

A social evening devoted to mixed curling was an event of December 10, at Temiskaming, Que. Bad weather failed to impede either attendance or enjoyment.

Aerial Photography

Aerial photography invoked sufficient interest among Branch members to draw a large attendance to hear Lt. Col. J. A. Warburton deliver an address on the "Interpretation and Utilization of Aerial Photographs for Engineering Purposes." The occasion was the regular monthly meeting at the King Edward Hotel at Sturgeon Falls, Ont., January 15, 1958.

Mr. Warburton who displayed a collection of aerial photographs and maps made from aerial photographs, showed a film which portrayed a plane taking off with crew and photographic equipment, the taking of photographs from the air, development of the film, study of the prints, and later the actual tracing of maps from the aerial photographs by the use of special viewing machines.

Aerial photography was actually started in the mid-nineteenth century when photographs were taken from captive balloons. Wide use of aerial photography was made in World War I for locating enemy trenches and gun emplacements. Before the Armistice was signed, the full significance of aerial photography was realized, and a civilian committee was set up to study aerial surveys for civilian use.

Photogrammetic surveys are useful in making forest inventory, and it is possible to determine size of limit, type of wood, and estimate height of trees. It is valuable in preliminary locations of highways and railways as it saves arduous ground surveys, and can be used to gauge flood waters and estimate the size of culverts. It can be used for estimating the contents of stock piles of coal or wood or the size of gravel pits. In all these instances it is necessary to have two or more actual points of reference determined by actual ground survey. The nature of the ground under clear water can be studied from aerial photographs, and aerial surveys were extensively used in preliminary work on the Dew Line and the Trans-Canada microwave system.

In studying aerial photographs or making maps from them, it is necessary to have pairs of photographs, each photograph in the pair overlapping the other by about 60 per cent. Then these pairs of photographs are studied in stereoscopic machines which bring out the subject in three dimensions. In mapping, the lines of contours can be followed rapidly and duplicated on a map by special machines.

ST. MAURICE VALLEY

J. O. Hachey, JR.E.I.C., *Secretary*

E. A. Love, JR.E.I.C.,

Publicity Committee

DR. JACQUES BELAND, of the Department of Mines and Resources of the Province of Quebec, on November 4, 1957, gave an interesting talk on the geology of the St. Maurice Valley. He discussed the formation found in the valley, the reasons for them, as well as the geology of the eastern part of the country. Coloured slides were used to illustrate the talk which was followed by a lively question and answer period.

President's Visit

President Anson, Dr. L. A. Wright, and G. M. Dick, regional vice-president of the Institute, Mrs. Dick and Mrs. Anson visited the Branch on November 26, 1957. A luncheon was held at Laurentide Inn, Grand'Mere, with the executive and their wives acting as hosts for the occasion. This was followed by an executive meeting in the afternoon.

Mrs. Anson and Mrs. Dick were entertained by Mrs. W. Seline and Mrs. E. A. Love. A tour of the Grand-Mere Knitting Mills, followed by a dinner.

In the evening a Branch dinner was held at the Laurentide Inn, Grand'Mere after which President Anson delivered a timely address to those assembled. He was introduced by E. A. Love and thanked by E. T. Buchanan.

SAULT STE. MARIE

R. L. Wimperis, JR.E.I.C., *Sec.-Treas.*

THE ANNUAL BRANCH MEETING was held January 10, 1958. Reports were heard from the papers, membership and entertainment committees in review of activities during 1957. The financial statement was read and auditors appointed.

R. H. Tooley, newly elected Branch chairman expressed his optimism for 1958 as a successful year for the branch.

W. D. Adams, Life Member

W. D. Adams, for thirty-five years a member of the E.I.C., attained Life Membership effective January 1, 1958. Mr. Adams graduated from the Royal Military College in 1908. Overseas in World War I with the 14 Battalion he was mentioned in dispatches, received the Military Cross. He has been associated in his engineering career with the Toronto Transportation Commission, the firm of Walter J. Francis, Toronto, and the Algoma Steel Corporation. He joined the latter in 1939, retired in 1957.

SUDBURY

W. J. Ripley, JR.E.I.C., *Sec.-Treas.*

M. D. Head, M.E.I.C., *Publicity Committee*

THE JANUARY DINNER MEETING of the Sudbury Branch, was held at the Granite Club, January 16 with 28 members and guests attending. First speaker of the evening Father Y. Ferland, dean of the faculty of arts of the University of Sudbury, chose to acquaint members with the new university's aims and plans for a faculty of engineering, which is to be opened next fall. He pointed out that the district normally provides about 50 new engineering students each year. There were indications that this number would increase appreciably with the provision of the new university's facilities. Initially only first and second year courses will be offered, and Toronto and other universities will accept Sudbury students for their third and fourth years. In due course Sudbury will offer facilities for studies in at least one branch of engineering through all four years. Tuition fees will probably be about $350 per year. Entrance qualifications will be the same as those of the University of Toronto. Three floors of the Empire Building are to be rented until a building is erected on the new campus in Neelon-Garson township. Financing of the new undertaking would be provided by students' fees plus contributions from the Federal, Provincial and municipal governments, and industrial organizations. Staff will be recruited from among suitably qualified professors from other Jesuit universities, and it is hoped to obtain lay teachers from University of Toronto staff. Father Ferland also invited local engineers to deliver part time courses of two or three lectures per week. In the faculty of engineering all instruction will be given in English. The faculty of arts will organise separate French and English speaking colleges.

The thanks of the meeting were expressed by Lennox Lane.

Dr. B. M. Wilson of Sudbury, second speaker, discussed civil defence co-ordination in terms of the ABC of total war, atomic, bacteriological and chemical. Civil defence planning apparently places most emphasis on combatting the effects of atomic warfare. The general effects of nuclear explosions and the damage caused by heat, blast, immediate radiation and delayed radiation or "fallout", and in precautions for mitigation of harmful effects were indicated. Finally Dr. Wilson described in outline the Civil Defence Organization that has been set up to meet the emergencies of a modern war.

TORONTO

D. S. Moyer, M.E.I.C., *Sec.-Treas.*

A. C. Davidson, M.E.I.C.,

Branch News Reporter

THE ANNUAL MEETING held January 17 and attended by 100 persons, provided an occasion for the Toronto Branch to recognize the work carried out by Col. L. F. Grant, retiring field secretary. Binoculars and a wind gauge, both for use on his "racing" yacht were presented by retiring Branch chairman E. R. Davis. Colonel Grant remarked with usual gentle good humour that the binoculars would be a most welcome gift in that in a race he would now be able to make out the stern of the nearest competitor.

After the business of the meeting was dealt with a scrutineers' report was read by Dunc Whitson. New officers elected were: chairman, Harvey Self; vice-chairman, A. C. Davidson; senior members of the executive: Dean R. R. McLaughin, faculty of applied science and engineering; I. S. Patterson, and Russel Rule. Junior members of the executive elected were: S. Gauley and Morgan Price. Members of the executive whose term is not yet finished, continue for another year.

Following the business meeting, Profesor M. W. Hewer of the department of mining engineering at the University of Toronto gave an illustrated lecture on "Life in Pakistan". These were impressions gathered while Professor Hewer was on leave of absence to supervise work sponsored by Canada under the Colombo plan. The commentary was good, as were the slides. The entire evening was enjoyed. In the words of General Secretary, Dr. L. Austin Wright, it was wonderful to be with a group who budgetted for a deficit and made their budget.

Professional Development

Professional development program director W. W. Walker and his committee who invited fourth year engineering students, University of Toronto, to meet with approximately 30 members of the P.D. course got together on January 27, 1958. Arranged in order to provide an opportunity of discussing informally with them the experience of recent graduates in engineering, especial attention was given to counselling them in the matter of choosing positions and companies in the engineering field.

Professor Davidson, the Institute liaison member with the student body, acted as chairman. Mr. Walker addressed the students on the aims of Professional Development and gave sound advice to young engineers about to graduate.

J. A. McLaren, Eastern Field Secretary of the Institute outlined the aims of the Institute, its part in sponsoring P.D. courses, and the efforts made on the part of Colonel L. F. Grant, retired

Building, modernizing or moving a plant?
PROVINCIAL OFFERS YOU A COMPLETE PACKAGE DEAL
There's much to be gained by having one well-equipped prime contractor like Provincial Engineering, instead of loading your staff with the job of co-ordinating many trades.
Provincial's Construction Division normally employs 2500 men on piping supply and installation, complete electrical installation, millwrighting and rigging, sheet metal work, welding of all types, and structural steel erection.
Everything needed is done to provide you with a ready-to-run plant . . . machine moving, foundations, and installation, bins, hoppers, duct work, wiring and instrumentation, etc.
Many industries, such as manufacturing and processing, paper-making, mining, chemical, cement, have found this Provincial service invaluable.
When your project is in the planning stage feel free to call upon Provincial Engineering for their assistance or advice without obligation. When your plans are completed be sure to get a Provincial proposal on your construction jobs.
PROVINCIAL ENGINEERING LTD.
Construction Division
NIAGARA FALLS, ONTARIO
Montreal Chicoutimi Toronto
Other Divisions: Crane and Hoist — Manufacturers of Hoisting Equipment from ¼ ton hoists to 500 ton cranes.
Transmission Tower — Transmission Tower design, detail, fabrication and erection.
MC2
PROVINCIAL

eastern field secretary, in organizing courses throughout numerous branches of the Institute.

For discussion purposes the group of 60 students and 30 graduates were distributed at 5 tables. A graduate engineer initiated the discussion of employment and employees and responded to undergraduate queries.

Student representative Norman Seagram, thanked Mr. Walker and members for their efforts on behalf of the students.

Joint Meeting E.I.C.-I.C.E.-A.S.C.E.

The Joint Toronto Area Committee on February 6, 1958 heard G. R. Stunden, director and supervising engineer, Atlas Construction Company, in an address on Earth Moving and Earth Moving Equipment, as applied to the St. Lawrence Seaway project. Mr. Stunden summarized the excavation phases of the various contracts involved in the project and the types of equipment and number of units.

Students' Night

The Toronto Branch played host to seven teams of students from the faculty of applied science and engineering, University of Toronto on February 7, 1958. The contest was closed for a quiz offering substantial cash prizes and called the "$64.00 Question". Winners were the Electrical Club and the Engineering Business Club, tied, followed by the Mining and Metallurgical Club who took second place. Each team member drew a prize and the evening was enjoyed by contestants and audience alike.

Arrangements were under the direction of C. MacInnis, assisted by Norm Seagram. Professor L. E. Jones, A. Toye, and Harry Tryhorn acted as moderator and judges. Coffee and doughnuts were served in the Great Hall.

Joint E.I.C.-I.E.F. Meeting

The problem of transformer noise was discussed by A. T. Edwards, research engineer with the Hydro-Electric Power Commission of Ontario at a joint meeting of the Toronto Branches of the E.I.C. and the I.E.E., on February 11, 1958. Mr. Edwards has had considerable experience on vibration and acoustic problems. In addition to the purely technical aspects of the subject he discussed "Neighborhood Reaction," in such places where transformers are located close to residential areas.

VANCOUVER

A. D. Cronk, JR.E.I.C., *Secretary*

J. J. Kaller, M.E.I.C., *Publicity Branch*

ENGINEERING ETHICS was the subject of a panel discussion, moderated by Dr. H. C. Gunning at a joint meeting of the Vancouver Branch, E.I.C., and the Association of Professional Engineers. Panel members were: D. F. Kidd, consulting

• BRANCH NEWS

mining geologist, V. M. W. Gsyther, consulting engineer and G. M. Ellis, chief engineer, Pacific division, Commonwealth Construction. Each member of the panel made a short statement on engineering ethics relating particularly to their respective fields of engineering activity. An exceptionally large number of questions and problems were submitted for comment. Great numbers of these remained unanswered at the end of the evening. The interest in the topic manifested itself in a resolution that the undiscussed problems receive comment in the B.C. Professional Engineer, preferably as a new and permanent feature of that publication.

1958 Professional Development Course

The importance of such a course and the caliber of speakers engaged has influenced the Vancouver Branch executive in making the 1958 Professional Development course available to the general public. The subject of economics, with special reference to B.C. and its natural resources is being discussed during February and March. It was thought to be of great value to those interested in the economy of the province of British Columbia.

Eight Wednesday evening lectures arranged under the direction of Dr. A. D. Scott of the department of economics of the University of British Columbia, feature addresses by prominent business men, outstanding in their respective fields and representative of the primary industries of B.C.

Top-flight economists and engineers have much in common in that their work revolves around "logical thinking" and the application of a few basic laws. With a little insight into the fundamentals of economics, the engineer can learn to add a new dimension to his thinking.

VANCOUVER ISLAND

J. A. Cowlin, JR.E.I.C., *Sec.-Treas.*

THE FIRST MEETING of the year, held January 22, 1958, successfully commenced the 1958 session.

Philip J. Croft, stations engineer for the B.C. Power Commission offered an illustrated talk on "Field Problems with Power Cables." Croft is well-known across Canada in the power field as a result of the number of years spent with Canada Wire and Cable Company as chief engineer. His presentation of some of the power cable problems was so developed as to be of considerable interest to all engineers, regardless of specialty.

Joint meetings with the Association of Professional Engineers have been discontinued in Victoria, and accordingly, the Institute and the Association sponsor alternate meetings. January's meeting was the first such affair and was held at a new location. An attendance of 40 caused disappointment, however, it is expected that as the new arrangements are better known attendance will improve.

News of Other Societies

C.C.A. Annual Meeting at Quebec

The 40th annual meeting of the Canadian Construction Association was held at the Chateau Frontenac, Quebec City, January 26-29, 1958. Some 1,000 delegates and their wives were welcomed to the city by His Worship Mayor Wilfrid Hamel. H. J. Ball, president of Ball Brothers Ltd., Kitchener, Ont., was elected President of the Association for 1958.

Following registration and meetings of the Management and Resolutions Committees on January 26, the Monday morning session was devoted to presentation of reports from the committees.

Reports of Committees

Chairman H. C. Nicholls of the Apprenticeship Committee reported apprentice registrations at 8,224, up by more than 7 per cent over the 1956 figure for the eight provinces having agreements with the Federal Government. He recommended more activity and encouragement by local committees, careful selection of candidates and a greater interest on the part of employers.

Business and Contractor Relations Committee Chairman, R. F. Legget, told the meeting the most difficult question his committee faced had been the use of bid depositories in connection with tenders for major federal public works. Formal approach to government authorities, he said, must wait until existing bid depositories have worked out a satisfactory system of co-operation to assure that no firm could possibly be excluded from submitting a bid. Following his committee's review of the 'Code of Good Practice' he called for a resolution endorsing the code in its new form. His report included a synopsis of the recently conducted C.C.A. bid depository survey.

Chairman Robert Hewitt of the Construction Equipment Committee reported that major projects during 1957 had been revision of the C.C.A. rental guide, and completion of a brief to the Minister of National Revenue regarding "Capital Cost Allowance Rates on Contractors Movable Equipment". The committee was hopeful that the rate for the 'average' capital cost allowance would be increased and/or recognition given to conditions that seriously reduce the effective life of equipment.

The Supreme Court of Canada, he said, had expressed its desire to re-hear evidence on the appeal from Tariff Board and Exchequer Court rulings regarding power shovels. There was an abnormal surplus of used equipment on the Canadian market due to conclusion of several large projects. There was also a trend to equipping larger projects with new machines and selling them off at the end of a job.

V. L. Leigh, Chairman of the Housing Committee, told the meeting completions in 1957 had risen to around 118,000 compared to a predicted total of 100,000 and the large number of 'starts' in the second half of the year together with a predicted decrease in competing demands for investment funds gave promise of an increasing housing program in 1958.

He expressed belief that the C.C.A. Housing Conference last November would be remembered as an important milestone in the history of the house building section of the industry. His committee is looking forward to a follow-up conference next spring.

Labour Relations Committee Chairman J. J. Pigott, recommended steps that must be taken by all member companies of the C.C.A. throughout Canada if the labour problems of contractors were to be met. Just as the building trade unions have co-ordinated their planning, policies and operations to their advantage across the nation it is essential that employers develop a similar program of co-ordinated effort, in his opinion.

His committee proposed that an experienced labour-relations man be added to the C.C.A. staff.

Reviewing highlights of C.C.A labour relations activities during the past year, Mr. Pigott reported that Messrs. Allan C. Ross and Raymond Brunet continued to represent the C.C.A. on the Canada Labour Relations Board and the National Employment Advisory Committee respectively. Messrs F. W. Purdy and Don Chutter had been the Association's delegates to the 1957 International Labour Conference at Geneva.

Income and Sales Tax

Legislation Committee Chairman, J. Hastie Holden, told delegates the main subject occupying the attention of his committee last year had been the Income Tax Act as it related to reporting of profits on lump-sum projects. Recommendations in the C.C.A. Brief to National Revenue in July 1956 had not been accepted and in January 1957 a decision had been handed down that 'no change in departmental procedure should be made at the present time'. A new brief had been submitted last December.

There had been an increase in overall C.C.A. efforts to obtain legislative changes during the year. The practice of presenting a detailed submission by a C.C.A. delegation to the federal cabinet was extended to include five provincial cabinets. Amendments to the National Housing Act were enacted in accordance with C.C.A. representations.

W. A. Marshall, chairman of the Sales Tax Committee, told the meeting his committee had continued to advocate a general exemption from federal sales tax to all construction materials and equipment. While most, though not all house building materials are exempt from sales tax, a 75 per cent exemption has been given to trailers used as homes.

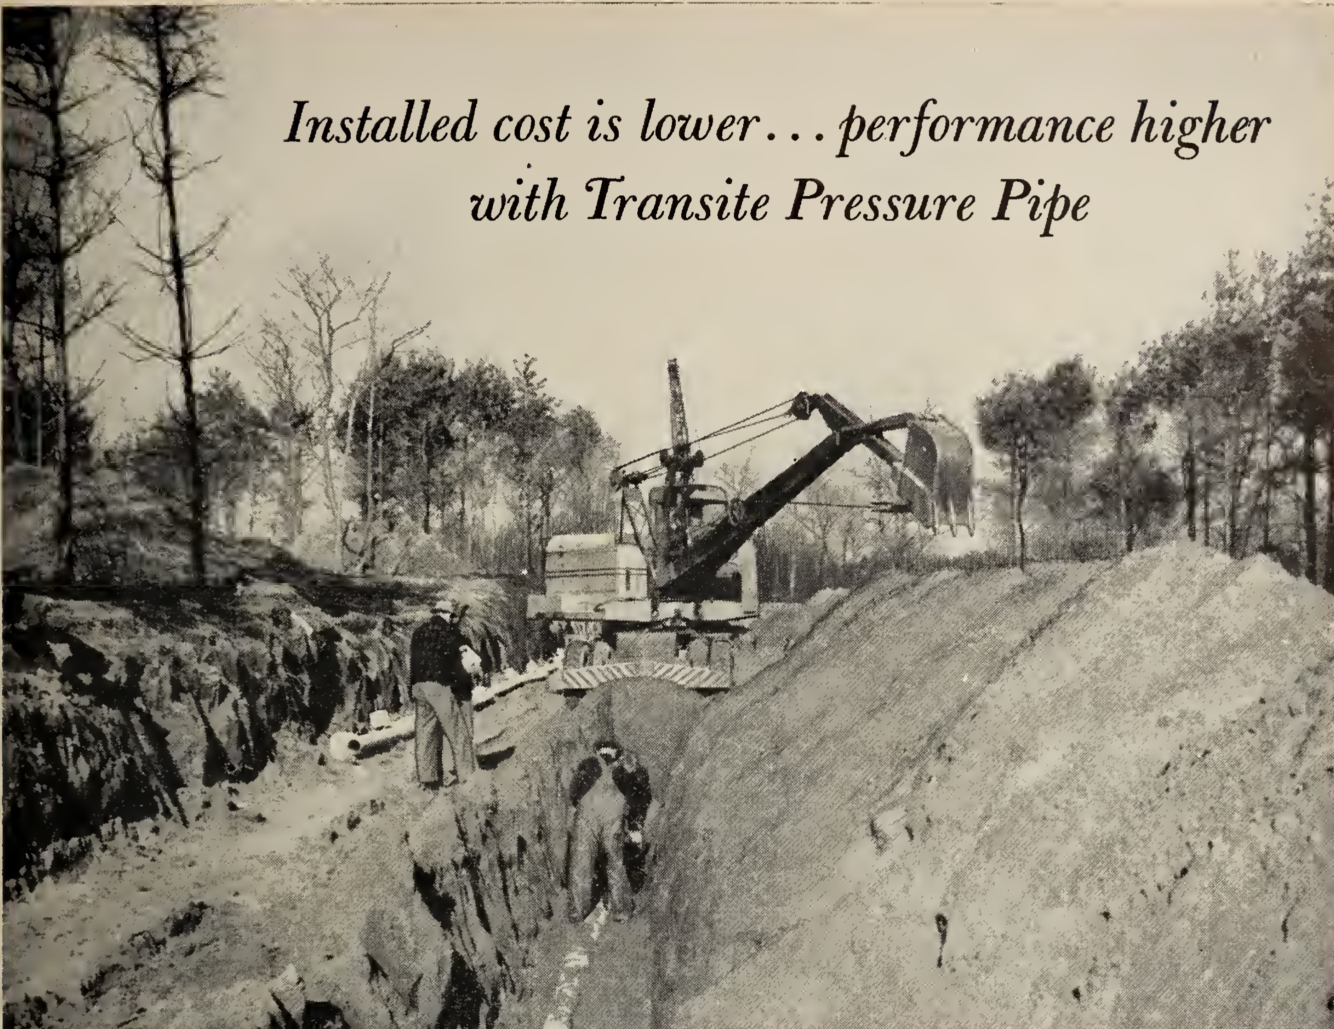
Taxes had been repealed on structural steel and precast concrete shapes for bridges on public highway systems, chimney caps, circulating pumps for heating of buildings, doors and window screens, and septic tanks. A brief in October had called for expansion of present exemptions for lumber, plumbing, heating and cooling systems, soil and sewer pipe, hardware, bridge materials.

Chairman, J. D. Allan, of the Research and Education Committee, following announcements of awards in the C.C.A. construction thesis competition to R. W. Cockfield, a 1957 graduate of Queen's, and of six prizes to other students, commented that not a single actual application had been made last year for the post graduate fellowship.

The past year had seen actual commencement of the post-graduate course in highway engineering at the University of Alberta. The University of Toronto Extension Department had offered their fifth year course in construction management in the fall of 1957, with enrolment limited to 60. The University of Manitoba and the Winnipeg Builders Exchange had successfully conducted their second series of lectures on work measurement, financing, and managing large projects.

Standard Practices Committee Chairman, A. Burke Doran, pointed out that the many resolutions on tendering practices at C.C.A. conventions, though a healthy sign, showed much remained to be done to bring about satisfactory standard practices. Public tender openings were now universal procedure for federal projects opened in Ottawa with exception of a few 'secret' defence jobs and F.D.C. projects. F.D.C. practice will be reviewed, the prime minister's office had assured. C.M.H.C. did not yet conduct public tender openings but did agree lists of bids would be sent directly after tenders were opened.

Installed cost is lower... performance higher with Transite Pressure Pipe

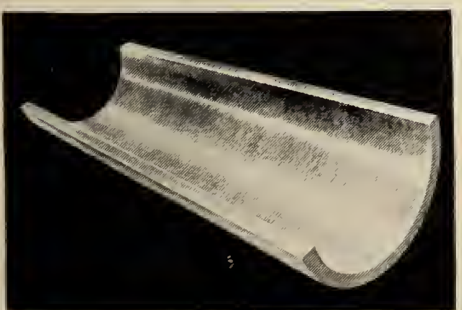


This Transite Pipe is being laid as fast as the trench is opened.

JOHNS-MANVILLE
JM
PRODUCTS

Transite® Pressure Pipe cuts installation costs because it is lighter and more easily handled than conventional pipe. Quicker unloading and handling, and bigger truckloads, cut a healthy slice from the price of installation. And the economy story doesn't end there!

Transite has high corrosion resistance inside and out. Replacements are fewer, flow is faster, pumping is cheaper. Because it's made with asbestos and cement, Transite actually grows stronger with age.



Transite's exceptionally smooth interior surface is immune to clogging corrosion, gives and keeps high rate of flow.

The easy to assemble Ring-Tite® coupling is an added advantage as the rings, which cannot blow out, help to relieve line stresses. For more information, write for Booklet TR160A, to Dept. IA, Canadian Johns-Manville, Port Credit, Ontario.

● OTHER SOCIETIES

It had been gratifying, he said, to note the increasing number of provincial departments and municipal governments conducting openings with bidders present. He appealed to all members to be vigilant for undesirable tendering requirements.

Chairman Raymond Brunet of the National Joint Wintertime Construction Committee told members the percentage of seasonally unemployed workers in the industry had been steadily decreasing, but in mid-winter it was still upwards of 25 per cent of the peak number employed in September.

Today, he pointed out, the number of seasonally unemployed in the industry was at its greatest in many years, yet employment was also at record levels for the time of the year. But the present problem would be much worse without the wintertime construction campaign. The main credit should properly go to the federal Department of Labour for its national publicity program.

A statement by the architectural and engineering professions had been issued with approval of the committee, pointing out the advantages of winter construction, he reported.

President's Address

C.C.A. President, Tullis N. Carter, in his presidential address, told delegates the various forecasts for construction volume predicted a level roughly the same as the record program of some $6.9 billion carried out in 1957. For the first time in some fifteen years, however, volume would be moving sideways rather than upwards. In some sections it would be a matter of expansion, in others one of consolidation, and in still others one of contraction.

Easing of the tightness of money gave promise of larger municipal and housing programs. Recent reduction in N.H.A. financing requirements and a record immigration program would increase demand for housing; more mortgage funds and serviced land would be needed, however. The federal minister of public works had expressed the hope that 140,000 units would be started in 1958.

Defence construction would fall off, without a change in present plans, but the total volume of federal public works projects might increase. Road construction would also increase, said Mr. Carter. Capital expansion for industry and commerce appeared to be dropping, with a marked decrease in large scale engineering projects.

Companies active in export markets and business in general were taking a critical look at the price of new projects, and construction costs must be kept at levels that will continue to attract investors Mr. Carter warned. Pricing of equipment and some materials was also causing concern. It was not entirely coincidental that the high wage areas were among those with a reduction of business or that the president of the A.F.L.-C.I.O. building trades department should advocate a year's stability in wage rates for construction and related industries in the U.S.A.

Capacity had surpassed the demand for construction services. This, he pointed out, would possibly mean the industry would see increased efficiency. It would also mean even keener competition, if that were possible. Owner resistance to higher costs would place a greater strain on committees negotiating with labour unions. If current trends continue, there would likely be less profits and more failures.

Federal taxation statistics for 1955 recently published, had shown 27 per cent of incorporated construction companies operated at a loss. This high percentage of loss was not a healthy sign. Those operating in the building contract field should be especially careful of their bidding in 1958.

"Bid as low as your skill, experience and ingenuity will permit, by all means, but then add an allowance for a profit in keeping with the contribution of your skill, experience and ingenuity," the president advised. These remarks applied equally to road builders. It was a fact that the percentage of loss companies among road and bridge contractors was above the industry's average, he added.

Immigration Needed for Development

With seasonal unemployment and layoffs there was naturally a clamour for public works and curtailment of immigration. The speaker said he has no quarrel with expanded public works programs, provided they were not uneconomical 'make-work' projects but were investments in Canada's future.

But as to suggestions that immigration be cut off virtually to a standstill, he expressed concern about the effect that such policies, designed to meet short-term problems, would have on long term policies designed to expand our economy and improve our living standards. If a country rich in resources wishes to grow, immigration should continue at a high level. The prospects of many of those now unemployed, indeed, might well depend on job opportunities provided by the larger market of a larger population. A levelling off period, coupled with great potential development, was the time to keep immigrants coming in reasonable numbers.

Government Policy on Public Works

The Hon. Howard Green, federal minister of public works, guest speaker at the annual banquet, gave members and delegates a look at the government's intentions respecting public works. There would be greatly expanded dredging taking place. Every year his department spent $175-$200 million on buildings, and it hoped to be building a postal terminal in Quebec at an early date.

Besides a joint-venture bridge at Campbellton to be undertaken soon, investigations were proceeding regarding a causeway to Prince Edward Island. There would be harbour developments at Lakehead, Sault Ste. Marie, Windsor, Toronto, Hamilton and St. John's.

The Federal Government, he said, would be continuing as a partner in highway building. It was interested in developing roads into Northern Canada. Help could and should be given in supplying power to those provinces where such help was needed: thermal plants and power lines in the Maritimes; dams on the Saskatchewan and development of the Columbia; before long there would be tremendous developments on the Yukon river, exclusively within Dominion jurisdiction.

Following government adoption of the Agency Loan Plan almost $200 million had been loaned for small homes and modestly priced apartments. This was a field in which the government was particularly interested, he stated. Great re-development programs would be under way before long.

Defence Construction for 1958

R. G. Johnson, president and general manager, Defence Construction (1951) Ltd. after giving an outline of work accomplished by D.C.L. since its inception seven years ago valued at some $1.2 billion, told the meeting what was planned ahead for 1958 and beyond. New defence work was likely to be awarded close to a value of $100 million compared with awards last year amounting to $58 million. Defence works would be put in place having a value of $65 million, compared with some $100 million in 1957. In addition he estimated an expenditure of a further $58 million on the Northern Ontario Crown Pipeline and some $12-14 million on other non-defence programs such as the Colombo Plan.

Value of work under existing contracts together with projects still to be awarded during the 1957-58. fiscal year totalled nearly $35 million, he stated.

Of this over $24 million represented work already under way. Major projects planned for the near future included the R.C.A.F. station at Summerside, P.E.I., where work would start before summer on hangars and other facilities valued at $8 million. A similar program was planned at Greenwood, N.S.

Cost Price Inflation

Ralph C. Pybus, President, Canadian Chamber of Commerce, and a C.C.A. member from British Columbia, made a stirring appeal for control of the alarming cost price inflation squeeze — before we lose our hard won markets, add to our unemployment, and see the value of our life insurance and pension funds shrink — before it kills the will to save and invest.

The desire for a higher standard of

living was common to us all, he said, but wage rates increasing faster than national productivity unhappily added to cost and to price, with much of the real wage gain lost. From September 1949 to September 1947 the average weekly wage rate had risen 59 per cent, productivity had risen only 43 per cent, while consumer prices had gone up 23 per cent, showing a loss in the value of our dollar. Comparing reports for nine months of 1957 against the same period of 1956 was even more alarming.

"Could we sustain our present living standard", he asked. He was sure we could if some level heads prevailed. He challenged management and business leadership, and union leaders and government leaders too, to face up to this serious problem of cost price inflation. Efficient productivity, he warned, was the key to our continuing prosperity. Labour and management were partners in progress and prosperity, and must share responsibilities as they share the benefits. They must find a way to work together to restrain excessive wage demands and excessive prices.

Canada—U.S. Chemical Engineering Conference

The executive committee of the Canada-U.S. Chemical Engineering Conference has extended an invitation to members of the Engineering Institute to attend the conference to be held at the Sheraton Mount Royal Hotel, Montreal, April 20-23, 1958. Sponsoring societies are the American Institute of Chemical Engineers and the Chemical Institute of Canada, chemical engineering division.

Pre-registration forms and additional information may be obtained from the secretary of the executive committee: Frank Rogers, c/o Shawinigan Chemicals Ltd., P.O. Box 6072, Montreal, Que.

The technical program contains a number of matters of great interest.

Symposia: Chemical Engineering Education in the U.S. and Canada; Statistics in Chemical Engineering; Chemical Engineering Problems in Heavy Water Reactors; Chemical Engineering in Mineral Processing; High Temperature Materials for Jets and Rockets; Fluid Mechanics; Noise in the Chemical Industry; Future Sources of Energy; Chemical Engineering in the Pulp and Paper Industry.

Technical Sessions: The Chemical Industry in Europe Today — three sessions reviewing the situation in the United Kingdom, France, West Germany, and Italy; Modern Engineering Construction Techniques; ten technical papers on other important separate subjects.

Panel Discussions: Relationship Between Investors and Chemical Industry Management; Career Opportunities in Chemical Engineering.

The program also includes a number of plant visits, luncheons with such well known speakers as The Hon. J. Paul Beaulieu, Quebec's Minister of Industry and Commerce, The Hon. Lester B. Pearson, and W. M. V. Ash, president of Shell Oil Company of Canada Ltd. There will be a real French Canadian "Habitant" dinner dance on April 22.

C. A. Peachey, on Engineering Education

The part played by professional engineers in the development of the province of Quebec is an ever-increasing one, C. A. Peachey, president of the Corporation of Professional Engineers of Quebec stated in January.

Mr. Peachey reviewed the situation existing since the appearance of Sputnik, and examined the view that the nation's security is in jeopardy and that a "crash" program is needed to produce more engineers. He said, "We should not hastily assume that Russia is ahead of the western world in basic research. They have demonstrated a very high quality of advanced technology, but there is little evidence that they, any more than the western world, are building up a backlog of basic knowledge on which future developments will depend. It is probably fair to assume that the incentives which they offer to students at the high school level to study science and mathematics, as compared with the Canadian system, will lead to a higher percentage of those who are particularly gifted following such a career."

The president of the Corporation said it might be prudent to assume that unless our system is altered somewhat, Russia may eventually take the lead in basic research; in his opinion emphasis should be placed on science and mathematics in our high schools, with guidance of competent, adequately paid science and mathematics teachers.

"At the top of the scale", said Mr. Peachey, "we have students graduating in engineering, science and mathematics, and immediately moving into industry, because of high starting salaries". He went on to express the opinion that the real shortage in Canada as in the United States, lies "more in men trained to higher than a bachelor's degree, and in men who wish to make a career of moving forward the boundaries of science."

"Since we cannot live forever from our present pool of fundamental scientific knowledge", Mr. Peachey concluded, "we should make it worth while for more gifted students to study towards a higher degree."

Calendar

Chemical Engineering

The next annual meeting of the Chemical Institute of Canada (18 Rideau Street, Ottawa 2, Ont.) is scheduled for Toronto, May 26, 27, 28, 1958.

Welding Conferences

The American Welding Society (33 West 39 St., New York 18, N.Y.) will present a welding conference and show in St. Louis during the week of April 14 to 18. The annual meeting of the Society is part of the program, as well as the Adams Lecture, and 63 technical papers.

The Canadian Council of the International Institute of Welding (7 Pleasant Blvd., Toronto, Ont.) offers information on the annual assembly of the I.I.W., to be held in Vienna, Austria, June 29 to July 6, 1958.

Interested people are invited to obtain as soon as possible enrolment forms and the provisional official program from the national committee concerned.

Fifteen technical commissions will hold meetings on the following subjects: Gas Welding and Allied Processes; Arc Welding; Documentation; Hygiene and Safety; Residual Stresses and Stress Relieving; Pressure Vessels, Boilers and Pipelines; Welding Instruction; Resistance Welding; Testing, Measurement and Control of Welds; Terminology; Standardization; Behaviour of Metals Subjected to Welding; Special Arc Welding Processes; Fatigue Testing; Fundamentals of Design and Fabrication for Welding.

Chemical Engineering

For the twelfth chemical engineering exhibition and congress, scheduled for May 31 to June 8, 1958, at Frankfurt, Germany, a technical program of 232 papers has been arranged under the auspices of societies representing 18 different countries.

Information can be obtained from DECHEMA, Postfach, Frankfurt am Main 7, Germany; or from the American Chemical Society, Chicago Section, 86 East Randolph St., Chicago 1, Ill.

Automatic Control

The University of Michigan, College of Engineering, has announced a summer Intensive Course in Automatic Control, June 16 to 25, 1958.

April 15 is the closing date for registration. Further information may be obtained by writing to Prof. L. L. Rauch, Room 1525 B, East Engineering Building, University of Michigan, Ann Arbor, Mich.

Photogrammetry

The University of Alberta, Department of Extension, is arranging a course in Photogrammetry to take place in Edmonton from April 8 to 12. Registration is limited, and the tuition fee is $40.00. Enquiries should be addressed to the director of the Department of Extension.

Rosco Wall Panels Speed Construction of Davie Shipbuilding Plant

Architects:
Wood, Blanchford and Ship, Montreal

General Contractor:
Foundation Company of Canada Ltd.

In choosing Rosco Wall Panels, Davie Shipbuilding quickly by-passed many construction problems. The large wall area was erected quickly and easily with no wet materials and with a minimum of scaffolding.

The owners selected Rosco Type 3 aluminum panels with 1½" of fibre insulation sandwiched between .036 and .032 Kingstrong Aluminum.

These panels gave insulating values of 12" masonry walls yet reduced the dead load weight by 95%. Galvanized steel strips were added to the back panel sheet for welded construction.

All joints were caulked for weatherproofing. Panels can be removed for alterations at any time.

No other wall construction can give you such permanent protection and, at the same time save man-hours and money on construction costs. See exactly how Rosco Wall Panels can help you! Write ROSCO, 840 Dupont St., Toronto.

BOOK REVIEW

ELECTRICAL ENGINEER'S NOTEBOOK

Frank P. Vaughan, Life Member E.I.C. from St. John, New Brunswick, recently presented his engineer's notebook to the Institute Library.

The notebook contains drawings of electrical apparatus and notes on methods of calculations, accumulated during a long and active career as an electrical engineer. The earliest entry, showing "Station Connections for Two Arc Dynamos", is dated September 18th, 1890.

Sections of the notebook are devoted to "Railway Apparatus" and to "Light and Power Apparatus". These are illustrated by drawings on linen of some of the equipment in use before the turn of the century. The section on light and power contains drawings of series street-light installations, two-phase and three-phase transformer connections, and other equipment. There are interesting notes on pole line construction, including a table showing the number of men required to set poles of different lengths and whether pike poles or derricks were needed.

Another section of the book is devoted to radio circuitry. Mr. Vaughan was one of the pioneers of radiotelephone communication. One of the notes mentions that he talked with Partridge Island by Radio Telephone from his residence in St. John in 1906. In 1912, he obtained one of the first ten radio experimental licences granted in Canada. Another note records that "the first broadcasting station in New Brunswick, designed and built by Frank P. Vaughan, went on the air in June, 1922." There are circuit diagrams of transmitter and receiver components.

Mr. Vaughan is an amateur artist of considerable talent, as shown by his paintings of birds which adorn the walls at headquarters. His notebook indicates his proficiency as a penman, including many pages done in flowing script with shaded pen-strokes.

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*ACI MANUAL OF CONCRETE INSPECTION 4TH ED.

Describes methods of inspecting concrete construction generally accepted as good practice. This manual supplements the specifications of a job and provides guidance in areas not covered by specifications. Areas included are the inspector, proportioning of mixes, inspection and testing of materials, inspection before, during, and after concreting, testing of concrete, and records and reports. Special features are a list of standard specifications and test methods, and a checklist of inspection. It is intended to be useful not only to inspectors but to engineers and contractors as well. (Detroit, American Concrete Institute, 1957. 240p., $3.50.)

*ATOMIC POWER, AN APPRAISAL

The contents of this volume are based on an informal panel discussion held by the International Bank for Reconstruction and Development. The participants, all leading world figures in atomic energy development, present a picture of the present and future potentialities of nuclear power in economic terms and its probable impact upon individuals and nations. To provide an introductory framework, the volume begins with a series of chapters devoted to the atom, atomic energy, radioisotopes, and related subjects.

Those taking part in the discussion included Sir John Cockcroft and Sir Eugene Plowden from the United Kingdom A.E.A., the Hon. Lewis L. Strauss and W. Kenneth Davis of the United States A.E.C., Francis Perrin of the French National Atomic Energy Commission, and the Hon. Antonio Carrillo Flores and Eugene R. Black of the World Bank. This is the first of a series of monographs on the economic aspects of nuclear energy. (Ed. by Corbin Allardice. New York, Pergamon, 1957. 151p., $3.50.)

*CONTROL VALVES

The author furnishes descriptions of the variety of automatic control valves and actuators available for use by the instrument engineer or plant operator. Considerable emphasis is placed upon the actuator since, in addition to its use with the control valve body, it has wide application for positioning other pieces of equipment. Aspects of control valves included are capacity, flow characteristics and mechanical features, and selection. Actuators discussed are the pneumatic, solenoid and motor, and combination types. The articles were first published serially in Instruments and Automation. (C. S. Beard. Pittsburgh, Instruments Publishing Co., 1957. 222p., $2.00.)

CREEP AND RECOVERY

The fourteen papers in this volume were presented at a seminar held at

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m. — 5 p.m.; Saturday, 9 a.m. — 12 noon.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

• LIBRARY NOTES

Cleveland during the thirty-eighth National Metal Congress in 1956. The first group of papers is concerned with various aspects of recovery, thermodynamics, defects, and the recovery of various physical and mechanical properties including polygonization and the mechanism of annealing in neutron irradiated metals.

The second group deals with the interaction of dislocations and vacancies and grain boundary behaviour in creep of crystalline metals. The last paper discusses the creep of crystalline non-metals. The value of the book is increased by the detailed subject index and the bibliographies included with each paper giving a total of 570 references. (Cleveland, American Society for Metals, 1957. 372p., $7.50.)

DISLOCATIONS AND MECHANICAL PROPERTIES OF CRYSTALS

This report of an international conference held at Lake Placid in 1956 presents a comprehensive, up-to-date account of the subject by fifty-four of the world's authorities, and includes the papers presented at the conference and the discussions they provoked, both oral and written.

The papers are divided into eight sections: direct observations of dislocations; deformation of pure single crystals; work hardening and recovery; alloy crystals, impurities and yield point phenomena; dislocation damping and fatigue; theory of dislocations; whiskers and thin crystals; radiation damage.

The conference was sponsored by the U.S. Air Force Office of Scientific Research, Air Research and Development Command, and the General Electric Research Laboratory. (Ed. by J. C. Fisher and others. New York, Wiley, 1957. 634p., $15.00.)

*EDUCATION FOR PLANNING: CITY, STATE AND REGIONAL

With rapid urbanization, the spread of industry, and pressures on water, land, and energy resources in various parts of the country there has come about an increased need for formal planning activities. The question of what constitutes an appropriate basis for the education of city and regional planners is raised in this book and an attempt is made at some tentative answers. The three essays included deal with these topics and in addition review University of Chicago experiments in these areas. (H. S. Perloff. Baltimore, Johns Hopkins Press, 1957. 189p., $3.50.)

*ELECTRONIC DESIGNERS' HANDBOOK

Design data and fundamental information on electronics are presented in this handbook with somewhat more than usual attention to theoretical explanations, which are supplemented by design examples. Areas covered include vacuum tube fundamentals, computer and servomechanism techniques, and waveform and network analysis. In addition attention is given to such rapidly developing fields as transistor fundamentals and circuit design, design of stabilized d-c amplifiers, and advanced regulated power supply design. There is an unusually thorough section devoted to receivers. (R. W. Landee, D. C. Davis and A. P. Albrecht. Toronto, McGraw-Hill, 1957. Various paging, $16.50.)

*ELEMENTARE SCHALENSTATIK, 2ND ED.

An introductory treatise on the statics of shells. Originally published as a textbook, the new edition has been enlarged and revised so as to be useful to the practicing engineer as well. After a brief explanation of the shell concept, the author discusses in detail the membrane theory of rotation shells, the bending theory of rotation shells, and, specifically, the membrane theory of cylindrical shells. There are also notes on the states of stress and a tabular summary of membrane theory solutions for shells of various forms. (A. Pfluger. Berlin, Springer Verlag, 1957. 112p., DM 19.50.)

ELEMENTS OF CLASSICAL THERMODYNAMICS

Intended primarily for advanced students of physics, this short account of the fundamental ideas of classical thermodynamics will also be of interest to research workers in chemistry and engineering. It develops the subject from the postulated laws of thermodynamics to conclusions which can be reached without using advanced mathematics.

The first and second laws of thermodynamics are discussed in the first five chapters, and succeeding chapters show how they can be applied to correlating the properties of simple systems, especially fluids and magnetic substances. The law of increase of entropy is analyzed, and applied to problems of phase equilibrium and higher order transitions.

Problems, illustrative examples and bibliographic footnotes are included, but details of experimental methods have been excluded. (A. B. Pippard. Cambridge, University Press, Toronto, Macmillan, 1957. 165p., $4.25.)

*FLUGLEHRE

Originally intended for pilot training, this introductory text on the theory and design of airplanes covers the following topics: general data on air forces and air resistance; wing structures; motorless flight; the propeller; the power plant; airplane performance; controls and stability; take-off and landing; helicopters; navigation and transportation. (R. von Hises. Sixth edition revised by Kurt Hohenemser. Berlin, Springer Verlag, 1957. 402p., DM 25.50.)

FLUID MECHANICS FOR ENGINEERS

An undergraduate textbook which emphasises the fundamentals of fluid mechanics, this book includes many worked examples to illustrate the theories presented, and will be equally useful to students in Mechanical and Civil Engineering.

The first part deals with fluid statics, perfect and viscous fluids in motion, flow in closed conduits and open channels, fluid metering, dimensional analysis of fluid flow phenomena, boundary layer theory and the elements of wing theory. Part two is concerned with the fundamentals of the flow of compressible fluids, whilst part three covers centrifugal pumps and fans, axial flow pumps and fans and hydraulic turbines. (P. S. Barna. Toronto, Butterworth, 1957. 377p., $11.50.)

GEOLOGY AND ECONOMIC MINERALS OF CANADA, 4TH ED.

Since the third edition of this book was published in 1947 Canada's mineral production has more than trebled. The major changes have come from oil and gas production, but there have also been spectacular developments of uranium deposits, and developments in base metals, iron ore, lithium and asbestos. Advances in air transportation have made possible increased geological exploration and mineral discovery in remote areas.

The various chapters are written by members of the Geological Survey of Canada who are experts in their special fields, and the material is arranged according to geological province: Canadian Shield; Appalachian region; St. Lawrence and Hudson Bay Lowlands, and Palaeozoic outliers; the Interior Plains; and the Cordilleran region. There is a useful new chapter on the geology of the Arctic Archipelago, and a final chapter on Pleistocene geology and surficial deposits.

The book is illustrated by many photographs, tables and line drawings, and recent geological maps and charts are included in an inside cover pocket. There are also lists of references for further reading. (Ed. by C. H. Stockwell. Ottawa, Queen's Printer, 1957. 517p., $2.00. Geological Survey of Canada, Economic Research Series No. 1.)

HANDBOOK OF CHEMISTRY AND PHYSICS

This latest edition of a well-known, standard handbook contains material on all branches of chemistry and physics and closely related sciences which are likely to be used frequently. The material is largely in tabular form, and is divided into five sections: mathematical tables; properties and physical constants; general chemical tables and tables of specific gravity and properties of matter; heat, hygrometry, sound, electricity and magnetism, and light; quantities and units.

New tables in this edition include those for nuclear spin and moments; relative sensitivities; superconductivity of some metals, alloys and compounds; energy, mass and velocity relations for the electron; magnetic properties of certain transformer steels and high perme-

ability materials. The table of isotopes has been extended and revised, and the transuranium elements through element 101 added. New tables have also been added containing the dielectric constants and dipole moments of substances in the gaseous state.

The volume is clearly printed on india paper, and remains a convenient size in spite of its large number of pages. (Ed. by C. D. Hodgman. Cleveland, Chemical Rubber Pub. Co., Toronto, Ambassador, 1957. 3213p., $12.50.)

HEAT

One of the Basic Science Series issued by Rider, this volume by the Chairman of the Physics Department of a New York High School takes a new approach to the subject by including the coverage of modern heat engines and the thermodynamics needed to understand their operation.

The first chapter explains the difference between heat and temperature, and also covers thermometry and the expansion and contraction of solids, liquids and gases. The second and third chapters deal with heat measurement and transfer. The final two chapters cover the change of state and heat engines, including steam turbines, gas and diesel engines, turboprops, ramjets, rockets and reciprocating steam engines. (Alexander Efron. New York, Rider, Toronto, Pointon, 1957. 105p., $1.50.)

*HEAT TRANSFER, VOLUME II

A direct continuation of volume one, this volume consists of three sections: heat radiation in spaces of simple configuration, selected fields of application, and supplements to volume one. The largest portion of the book consists of specific applications such as heat transfer in thermometry, recuperators, regenerators, cooling towers, cooling of surfaces exposed to hot gases, heat transfer through laminar boundary layer at high fluid velocity, and heat transfer in liquid metals. The concluding section brings the material in volume one up to date. (M. Jakob. New York, Wiley, 1957. 652p., $15.00.)

HIGH-TALENT MANPOWER FOR SCIENCE AND INDUSTRY

That the development of high-talent manpower for science and industry is of critical importance is today widely recognized.

In the two essays of which this volume is composed, the authors emphasize that it is the men of high-talent, the "seed-corn" human resources as they call them, who are the initiators of change and progress in both the industrialized and underdeveloped countries, and that this talent cannot be mass-produced but must be carefully developed.

The first essay discusses the United States and the role which should be played by corporations, universities and the government in developing the creative scientist, the research engineer and the outstanding administrator.

The second essay examines the needs of the less developed countries for the high-talent manpower which will transform an agrarian to an industrial society, and concludes that the creation of this manpower must take precedence over an attempt to provide general education for the masses.

This is a most timely and thought-provoking book. (J. D. Brown and Frederick Harbison. Princeton, University Industrial Relations Section, 1957. 97p., $3.00.)

*A HISTORY OF TECHNOLOGY, V. 3—FROM THE RENAISSANCE TO THE INDUSTRIAL REVOLUTION

This is the third of a five-volume history which will cover the subject from the Old Stone Age to the later nineteenth century. The present volume gives due attention to the pendulum clock, inquiries into the properties of metals, and to improvements in scientific instruments — developments of significance for future centuries — as well as to the great wooden ships, huge machines for raising water, and massive stone buildings that were the culmination of long technological traditions. Like others in the series the volume is superbly printed and illustrated. (Ed. by Charles Singer and others. Toronto, Oxford University Press, 1957. 766p., $25.50.)

HOW TO READ SCHEMATIC DIAGRAMS

Intended for students, technicians and those who have no prior knowledge of electricity or electronics, this book explains the basic theory of the subject, symbolism, technical notations and the organization of schematics in pictorial form.

The various chapters cover electrical and electronic symbols and diagrams used for direct-current circuits; alternating-current circuits; electronic equipment power supply circuits; audio amplifier circuits. The final chapter discusses the reading and interpretation of complex and complete schematic diagrams, using radio and television circuits as examples. (David Mark. New York, Rider, Toronto, Pointon, 1957. 147p., $3.50.)

INDETERMINATE STRUCTURAL ANALYSIS

A knowledge of determinate structural analysis is expected of the reader of this introductory volume written for both the student and practicing structural engineer or architect.

The first chapter contains a brief history of the development of structural theory, while the next three chapters discuss the theories on which the book is based, the stability and determinateness of structures, various basic concepts, and the methods for computing deflections.

In chapters five to thirteen there are detailed discussions of the methods used in the analysis of indeterminate structures, together with examples of their use. These include Maxwell's method as modified by Mohr and Müller-Breslau, the method of least work, the column analogy, moment distribution, the slope-deflection method, influence lines and elastic arches.

The final chapter on model analysis of structures is based on the author's experience in developing the structural model laboratories at Rensselaer Polytechnic Institute, and includes the basic principles and methods of direct and indirect structural model analysis.

Many problems and references for further reading are included throughout.

An abridged edition of this work has also been published, and is intended for use as a textbook for a one-semester course. It includes chapters 1-7 of the complete edition, and the greater part of chapters 8, 11 and 12. (J. S. Kinney. Reading, Addison-Wesley, 1957. 655p., $9.50. Abridged ed. 352p., $7.50.)

MECHANICAL VIBRATIONS

Based on courses given at New York University, and the author's earlier Elementary Mechanical Vibrations, this book presents the basic principles of vibration analysis through the application of which many of the vibration problems arising in design can be dealt with or avoided. The author does not cover the more complicated problems, but the principles he gives can be used as a foundation for further study of such topics as self-excited vibrations, non-linear systems, damping in systems with more than one degree of freedom, etc.

In this edition greater emphasis has been placed on vector methods and the use of complex numbers. The chapters cover undamped and damped free vibrations and forced vibrations with a single degree of freedom; two degrees of freedom; multimass and equivalent torsional systems; multimass transverse systems; balancing; electrical analogies. Individual topics covered include forced vibrations of multimass systems; harmonic analysis; torsional critical speeds; coupling action; the balancing of angle or vee engines. (A. H. Church. New York, Wiley, 1957. 275 p., $6.75.)

METAL STATISTICS, 1947-1956

The statistical tables on aluminum, lead, copper, zinc, tin, cadmium, magnesium, nickel, mercury and silver in this forty-fourth annual edition cover for the most part the years 1947-1956.

The larger part of the book is devoted to a survey, by country, of each metal, giving detailed statistics on production, exports, imports, manufacture, etc. Other tables show world production, mine and smelter production, and consumption of the metals, and the metals recovered from scrap. (Frankfurt, Metallgesellschaft, 1957. 234p.)

*NUCLEAR CHEMICAL ENGINEERING

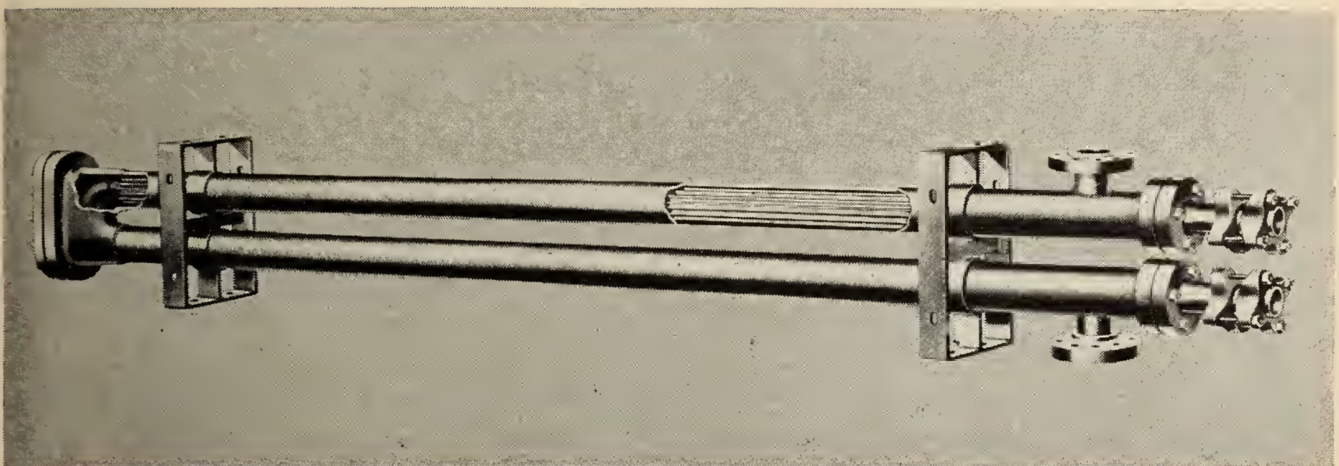
This volume describes the materials of importance in nuclear reactors and the processes which have been developed to concentrate, purify, and separate

KEY TO YOUR BEST OPPORTUNITIES IN METALS...

NORANDA COPPER AND BRASS LIMITED

COPPER ALLOY BULLETIN

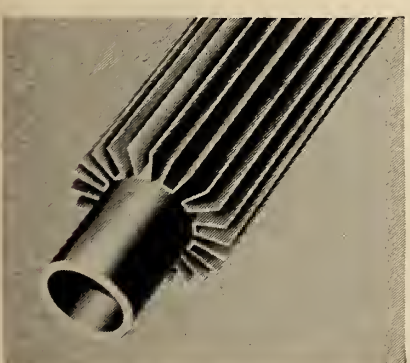
MILLS AT MONTREAL EAST—OFFICES IN MONTREAL, TORONTO, EDMONTON, VANCOUVER
Export Department, P. O. Box 1238 Place D'Armes, Montreal, P. Q., Canada



Cutaway view of a Brown Fintube Sectional Hairpin Heat Exchanger, especially designed for high-pressure operations.

Unique Heat Exchanger Uses Noranda Brass For Longer Life And Added Efficiency ....

Brown Fintubes, manufactured by Brown Fintube (Canada) Limited, St. Thomas, Ont., feature a design which provides unusual economy and efficiency in chemical and refinery heat exchanger operations. Fins are first soldered to a tube to form the completed Fintube. The Fintubes are then assembled into sheets to form sectional exchangers which can be arranged in series, parallel, or series-parallel construction. The advantages claimed for this arrangement are flexibility, freedom from obsolescence, reduced fouling and easy cleaning.



View of the Fintube showing the Admiralty Brass Tube and the Yellow Brass Strip channels which are welded to the tube.

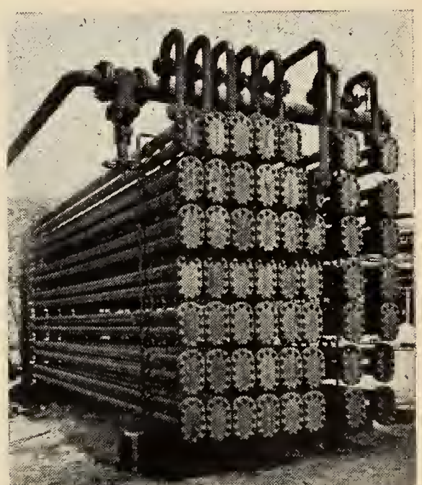
Where applications for Brown Fintubes demand maximum corrosion-resistance and heat transfer efficiency, Noranda brass strip, tube and rod are used throughout.

In the case shown, 1.9000″ OD Noranda Admiralty Brass Tube is used for the basic tube construction. The tube is supplied in wall thicknesses of .109″ and .145″. Excellent heat conductivity, freedom from defects and straightness are all important conditions which Noranda readily meets.

Fins are made of Noranda Yellow Brass Strip. Easy workability is a prime requisite since the strip is formed into channels on a Yoder Machine prior to soldering to the tube.

To form the fittings, Brown uses Noranda Naval Brass Rod because of the high strength and corrosion-resistance this alloy offers.

Thus in three different forms—tube, rod and strip—Brown Fintube (Canada) Limited fills exacting needs for exacting applications. And by making use of the many unique properties inherent in brass and copper alloys, Brown Fintube is able to solve many different application problems which would be more difficult and expensive using other materials.



Typical bank heat exchanger installation in operation at a large oil company.

It will pay you to investigate how Noranda copper and brass can improve your products or simplify your production. Our Technical Service Department is always ready to assist you on any problem you may have. Call your nearest Noranda Sales Office and let

THE MAN FROM NORANDA SHOW YOU THE KEY TO NEW OPPORTUNITIES IN METALS.

these materials. After two introductory chapters the following topics are considered: fuel cycles in thermal nuclear reactors; production of uranium feed materials; solvent extraction of metals; properties of irradiated fuels; separation of reactor products; principles and methods of isotope separation for both light and heavy elements. References for further reading, and problems are given at the end of each chapter. (M. Benedict and T. H. Pigford. Toronto, McGraw-Hill, 1957. 594p., $10.95.)

*NUCLEAR POWER REACTORS

Selected and arranged information from the papers at the Geneva Conference. After a discussion of the present outlook for heavy power production from nuclear sources the book covers basic facts on reactor design and construction and a comparison of various types as power producers. An extensive chapter is devoted to economic considerations, and detailed studies are presented of the different types of reactors. (Ed. by J. K. Pickard. Toronto, Van Nostrand, 1957. 388p., $9.25.)

ON THE OLD LINES

Sub-titled "Locomotives round the world", this is the author's personal record of the trains he has seen in thirty-seven countries, and it is written for all those who are fascinated by locomotives, and by steam engines in particular. To the author, the diesel "just isn't an engine any more."

According to Mr. Allen, this is just a picture book with lengthy captions, which often are a full page, a look through his photograph album, for he has personally taken all the many photographs in the book.

Continental Europe, the Near East, North and South America, Australasia and the East, all are represented in this fascinating book. Narrow-gauge, wide-gauge, coal burning, wood-burning, the Canadian Rockies, the Australian plains, freight and passenger, the old and new, Mr. Allen is interested in them all, and his reader cannot fail but be interested too in this type of locomotive which seems doomed to eventual extinction. (P.C. Allen. London, Cleaver-Hume, 1957. 185p., 25/-.)

PHYSICO-CHEMICAL EFFECTS OF PRESSURE

This survey of the effects of high pressure in the field of physical chemistry will be of interest to both physicists and chemists and to chemical engineers wanting to exploit these effects. Most of the book is concerned with changes brought about by pressures over a hundred atmospheres, but some data on lower pressure is included where the experimental pressure range was restricted or where the effects were unusually large.

Topics covered include: technique of high pressure experiments; volumetric effects of pressure; changes of phase under pressure; transport properties and the velocity of sound; dielectric and optical effects; electrolytic conduction; equilibria in and the kinetics of chemical reactions under pressure; and miscellaneous effects of pressure. (S. D. Hamann, Toronto, Butterworth, 1957. 246p., $8.50.)

*PRINCIPLES OF THE PROPERTIES OF MATERIALS

A study of the properties of materials which utilizes a new approach by emphasizing principles and properties rather than treating materials separately. The properties dealt with in separate chapters are conductivity, heating, diffusivity, electrochemistry, elasticity, plasticity, fracture, viscosity, and general considerations of crystallinity. An introductory section on physico-chemical foundations deals with atoms, equilibrium, structure, cohesion, and the electron theory of metals. (J. P. Frankel. Toronto, McGraw-Hill, 1957. 228p., $6.90.)

*PROCESS INSTRUMENTS AND CONTROLS HANDBOOK

A thorough and systematic treatment of the operating and design fundamentals of measurement and automatic control systems used in the process fields. Although specifically slanted toward the process industries, the fundamental techniques described are applicable to non-process fields such as medical, military and aircraft instrumentation. Among areas covered are measurement standards, primary elements, measurement systems, indicators and recorders, automatic controllers, electric and pneumatic telemetering, fundamental principles of process control, and mathematical techniques for solving automatic control problems. (Ed. by D. M. Considine. Toronto, McGraw-Hill, 1957. Various paging, $22.45.)

*RAFT FOUNDATIONS: THE SOIL-LINE METHOD OF DESIGN

This volume is planned to give engineers a method of raft design that takes into account variations in soil pressure. Recent advances have provided more information concerning means of arriving at the value of the modulus of elasticity of the soil, which in turn has given more precision to the use of this method. Present methods of raft design are discussed and followed by a detailed analysis of the soil line method. The conclusion then deals with examples of the applications of this method and with determination of the coefficient of subgrade reaction. (A. L. L. Baker. London, Concrete Publications, 1957. 148p., $2.80.)

*REFRIGERATION, AIR CONDITIONING, AND COLD STORAGE

A comprehensive text for engineers, technicians, and students, presenting in clear language with numerous illustrations the principles of refrigeration and allied subjects. Beginning with the required physics, the book takes up in order refrigerants, the mechanical refrigeration cycle, equipment, controls, and the application, operation, and maintenance of the refrigeration system. Brines, cold storage, lubrication, and air conditioning are treated in separate chapters. (R. C. Gunther. Philadelphia, Chilton, Montreal, Wallace, 1957. 1232p., $17.50.)

*SAFETY ASPECTS OF NUCLEAR REACTORS

Composed of key papers from the Geneva Conference on the Peaceful Uses of Atomic Energy, the material has been carefully selected, edited, and grouped under the following headings: normal reactor and chemical plant operations; development of radiation safety criteria; reactor accidents and their consequences; super-critical reactor experience. Since little has been available on the subject, this is a useful contribution in an area that will assume more importance as the power reactor program is developed. (Ed. by C. R. McCullough. Toronto, Van Nostrand, 1957. 237p., $8.50.)

SOUND

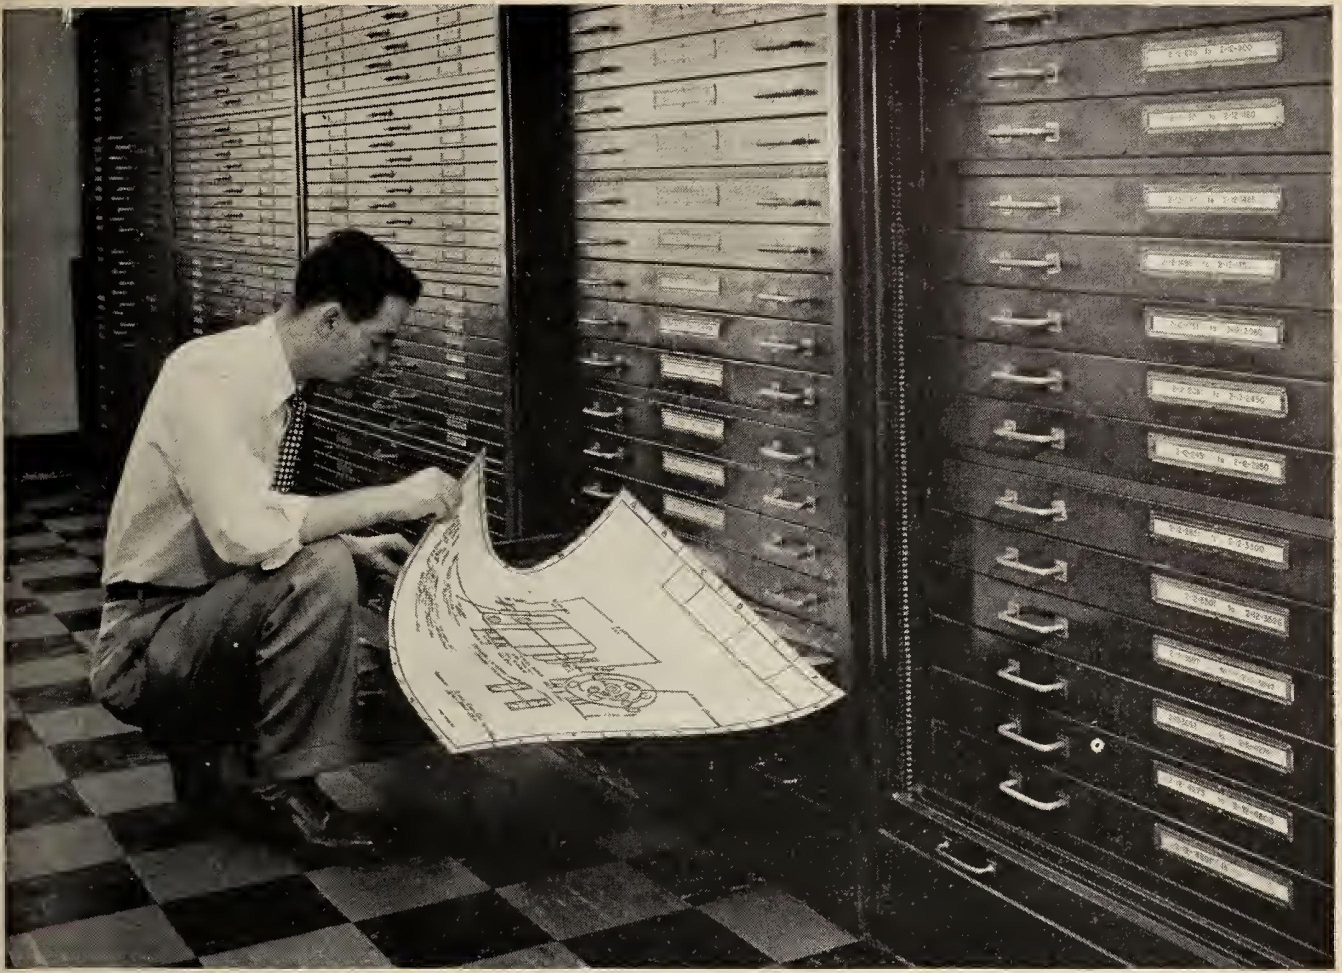
Another in the series of the Basic Science Books being published by Rider, this volume contains an introductory outline of the subject. The first chapter considers the physical aspects of sound, its mode of production and propagation, the nature of the vibratory process, and the properties of audible vibrations. The second chapter deals with hearing, speech and music, and the last chapter considers sound waves in detail. (Alexander Efron. New York, Rider, Toronto, Pointon, 1957. 72p., $1.25.)

STATICALLY-INDETERMINATE STRUCTURES, 3RD ED.

The first edition of this work was published in 1944, the main change in this edition being the inclusion of a chapter on the "plastic hinge" method of designing reinforced concrete frames. Additions have been made to the chapter on curved beams, and the section on distribution methods (Hardy-Cross) revised and enlarged. The chapter on elasticity equations with only one unknown in each equation has been omitted, as the plastic method simplifies the calculation of the simultaneous equations by giving the designer an opportunity of choosing a range of values. (R. Gartner. London, Concrete Publications, 1958. 126p., $4.00.)

SURVEY OF MINES 1958

In 1957 Canada's mining industry was in a consolidating position as the general demand for minerals decreased, but continued industrialization throughout the world is expected to lead to an ever increasing demand for essential materials. Increasing quantities of uranium are being produced, as are other atomic energy age minerals such as lithium,



columbium, molybdenum and beryllium, and industrial minerals like sulphur and feldspar.

This survey gives detailed information on all Canadian mining companies including production, earnings, dividends, ore reserves, directors and significant mining property development. There are 26 pages of maps showing the producing companies and developers, and the tables included cover statistics of mineral production, dividends paid by mining companies, and price ranges of stocks from 1950 to 1957. (Toronto, Financial Post, 1957. 388p., $3.00.)

UNDERGROUND SYSTEMS REFERENCE BOOK

The first revision of a work originally published in 1931, this volume is a comprehensive and practical study of the best practices in the design, construction, operation, and maintenance, of power cable systems. Its fifteen chapters prepared by a staff of 134 engineers cover thoroughly cable and cable insulation; bulk power systems; underground radial and loop systems; street lighting systems; cable joints and terminations; testing and fault location; corrosion; safety; and related subjects. A detailed subject index is included. (Transmission and Distribution Committee of the Edison Electric Institute. New York, Edison Electric Institute, 1957. Various paging, $13.50.)

VISCOUS FLOW THEORY, VOLUME II: TURBULENT FLOW

This second part of a two volume work on viscous flow deals with the fluid dynamics of turbulence. Two different approaches to the study of turbulent flow are used: the semi-empirical or phenomenological theory of both incompressible and compressible fluids, and the statistical theory. Such topics as probability distribution, random walk, correlation tensor, spectrum, and their relations to turbulence are discussed. Also covered are turbulent diffusion, locally isotropic and non-isotropic turbulence, and turbulence in a compressible fluid flow and in magnetohydrodynamics. (Shih-I Pai. Toronto, Van Nostrand, 1957. 277p., $7.25.)

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Ludlow Valve Company — D. D. Ackerman has been elected president and a director of the Ludlow Valve Manufacturing Company Inc., Troy, N.Y., and its Canadian subsidiary Canadian Ludlow Valve Manufacturing Co., Ltd.

International Nickel — It has been announced that L. H. Cooper of London, England, vice-president of The International Nickel Company of Canada, Limited, has been elected a director of the company; Mr. Cooper is chairman of Inco's United Kingdom affiliate, The Mond Nickel Company, Limited. Also announced is the appointment of S. H. Ward to the staff of the Canadian development and research division of The International Nickel Company of Canada, Limited.

Dominion Engineering — J. Jeffrey has been appointed vice-president, administration, of Dominion Engineering Works Limited.

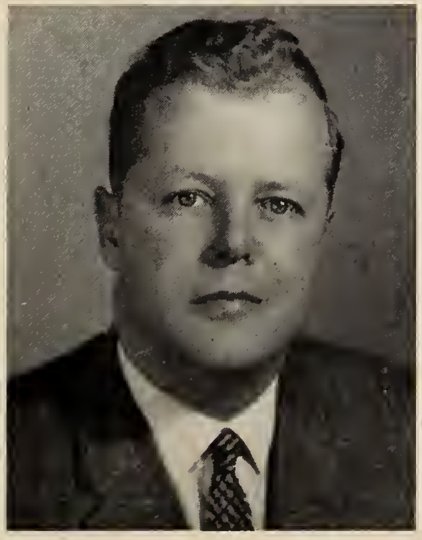
J. Jeffrey

Shell Oil Company — The appointment of D. B. Vale as executive vice-president of Shell Oil Company of Canada, Limited has been announced.

Atlas Copco — Announced recently was the appointment of J. A. Perham as resident director in the United States of Atlas Copco Eastern and Atlas Copco Pacific.

Rolls-Royce of Canada — The appointment of A. J. Geraghty as United Kingdom liaison engineer of Rolls-Royce of Canada Limited, Montreal, has been announced. Mr. Geraghty, recently retired from the Royal Canadian Navy, Air Branch, will remain at the Montreal plant until the spring; he will then be transferred to Rolls-Royce Limited, Derby, England, to replace W. Skelding as Canadian liaison engineer; Mr. Skelding will subsequently return to Rolls-Royce of Canada Limited for company duties in North America.

A. J. Geraghty



J. A. Perham

Canada Wire and Cable — The appointment has been announced of N. R. Spencer as western regional engineer of Canada Wire and Cable Company, Limited. Mr. Spencer will be located at the Vancouver sales office of the company at 1494 Powell Street, Vancouver.

B. F. Goodrich — The following appointments have been announced by B. G. Goodrich: K. Zettel, Toronto district manager, industrial products division; J. Warrell, general supervisor, industrial products division, Toronto district; L. Ratz, supervisor, moulded and extruded sales, industrial products division; R. Schnarr, manager, industrial products development and construction. G. L. Callfas, of Kitchener, has been appointed sales representative for the international B. F. Goodrich company industrial products division at Venezuela, South America.

General Motors Diesel — J. Depuydt has been made district service manager for the Maritimes, eastern Quebec and Newfoundland, for General Motors Diesel Limited, London, Ontario.

• BRIEFS

Canadian General Electric—The following appointments in the company's wholesale department were announced recently by Canadian General Electric Company Limited: A. M. Hurley, manager of the newly formed Alberta district, with headquarters at Calgary; B. W. Donaldson, manager, mid-west district, with headquarters at Winnipeg.

Bakelite Company — J. F. Goudey has joined the marketing and development group staff of Bakelite Company, division of Union Carbide Canada Limited, Belleville, Ontario.

American-Standard Products — Recent appointments announced by American-Standard Products (Canada) Ltd. are as follows: R. Cheshire, resident salesman of plumbing products in southwestern Ontario; I. McKellar, sales representative of wet heat products in eastern and northern Ontario and warm air products in northern Ontario only; P. Rogers, sales representative, specializing in plumbing products in northern and eastern Ontario.

New Equipment

Centrifugal Fans — A new series of all-purpose centrifugal fans with airfoil blading has been announced by the B. F. Sturtevant Co. of Canada Limited. Since 1950, the airfoil construction has been applied by Sturtevant to its larger, heavy-duty type of fans for power generation and vehicular tunnel applications. After a record of superior performance had been established in these applications, Sturtevant decided to supersede its present line of flat-bladed fans with the new airfoil construction.

The complete line (series 8000) will therefore bring airfoil centrifugal fans in an effective range of applications including building ventilation, general air supply and exhaust, conventional and high-pressure air conditioning, industrial processing, tunnel and combustion air supply.

Speed Deviation Recorder — A speed deviation recorder with an accuracy to one-tenth of one per cent has been announced by Canadian General Electric Company Limited. The Type HE speed deviation round chart recorder is designed for use in processes where it is necessary to maintain constant speed. An example is in the manufacture of nylon or other man-made fibers, with similar applications in the steel, rubber, paper and chemical industries.

The instrument indicates and records per cent deviation from a predetermined but adjustable speed. Input signal is received from a precision d-c tachometer generator and compared with a stable adjustable d-c reference.

News of Business and Industry

After the proper "set speed" is determined, the speed deviation recorder will indicate and record — in per cent — any deviation from the set speed and show the deviation in a highly expanded chart and scale. Deviations as slight as .01 per cent can easily be read.

Crawler Equipment — A new series of crawler equipment for shaft and tunnel excavation consisting of an overhead shovel loader, a bulldozer and a utility tractor has been announced by the Joy Manufacturing Company (Canada) Limited. Called the JSL-7 Shovel Loader, JMD-7 Mining Dozer and JMT-7 Mining Tractor, the machines come with either air or electric drive. With separate motors and independent track control for each track, one track can run forward and the other reverse to permit gradual or pivot turns or complete reversals within the machine radius. Joy says the equipment can be tailored for virtually any head room or loading height requirements.

Joy claims that the shovel loader can load two to four tons per minute. The loader can muck in round or rectangular shafts and takes over loading in the tunnel when the shaft reaches bottom. Buckets ranging in size from 5 to 11½ cubic feet are available.

In tunnel construction, the JMD-7 dozer cleans up invert sections before concrete is placed. It is used for cleaning out old, silt-laden water and sewage tunnels.

The tractor serves not only as a base for the shovel loader and dozer, but for various other attachments as well. These make it a full-face drill jumbo, roof bolter, front end loader, back-hoe, scaler or fork lift; it can do general drawbar work. Drawbar pull is 12,080 pounds.

Differential Pressure Transmitter — Bothersome purge and seal problems have been eliminated with the announcement of the new Taylor volumetric differential pressure transmitter. This instrument has been found to be ideal for many difficult flow and liquid level applications, such as measurement of slurries, colloidal suspensions, fluids that jell when not in motion and many corrosive liquids. Corrosion-resistant diaphragms of stainless steel or nickel prevent process material from reaching the instrument, and thus the need for purges is eliminated. Two mountings are available for applications involving corrosive liquids or slurries. For corrosive liquids, if the diaphragm need not be flush mounted, a wafer-type sensing element is available. This element, mounted in a standard three inch ASA flange is particularly useful for liquid level measurement.

Rayonier Expansion — Rayonier Incorporated have announced that the chemical cellulose producers' major expansion and modernization program of its Port Alice, British Columbia mill is nearing completion, and that the company's new mill at Jesup, Georgia will be in commercial production by mid-November of this year.

Change of Address — Grant Bros. Sales Ltd. of Toronto, Canada, Canadian sales representatives for Cummins Power Tools, recently moved from 334 Lauder Avenue to 18 Hook Avenue, Toronto, Ontario.

Canadian Comstock Company Limited, engineering construction, Toronto, announced recently that Canadian Comstock had acquired a partnership interest in Consolidated International Electric Co. Inc., New York and Toronto. Consolidated International Electric is similarly an engineering construction firm operating throughout the world in areas outside Canada and the United States.

Canadian Westinghouse — The Canadian Westinghouse Company, Ltd., will step up its capital spending in the next two years to the rate of $5,000,000 annually, according to a report by George L. Wilcox, president of the company. Purpose of the increased capital investment will be to improve the company's earning power and productivity, and to enable it to keep up with the growth of its business and the progress of the electrical manufacturing industry in Canada. The company's capital expenditures in 1957 will total about $3,500,000, and in 1956 were about $1,200,000.

New Diesel Organization — The board of directors of the Propane Credit Corporation Ltd., Edmonton, have announced that they have acquired control of Western Diesel Energy Ltd., as a wholly owned subsidiary. Western Diesel Energy Ltd. will be the retail outlet for Deutz Diesel engines and equipment, and Propane Credit Corporation Ltd. has acquired the sole distributorship for Deutz Diesel in Alberta, Saskatchewan, Yukon and the North West Territories. A new building has been erected for the use of Western Diesel Energy Ltd. and Propane Credit Corporation Ltd., and is located at 9765-63rd Avenue, Edmonton.

Exploration Service — A completely integrated exploration service has been announced by Geophysical Prospecting Company Limited, London, and Canadian Aero Service Limited, Ottawa. The two companies have joined their technical skills and capabilities for air and ground surveys outside Canada, for the oil and mining industries and for governments interested in developing their natural resources. Their headquarters are located at 20 Albert Embankment, London, S.E.11. Geoprosco and Canadian Aero will perform airborne geophysical surveys by magnetometer, scintillation counter, and electromagnetic detector, as well as magnetic, electric, gravimetric and seismic surveys.

Price of Commercial Explosives — A reduction in the price of commercial explosives shipped in fibre boxes has been announced by Du Pont of Canada. The reduction, 25 cents per 100 pounds from regular prices, is effective on all shipments in fibre containers. The company said that fibre shipping boxes produced at Nipissing Works, its explosives plant near North Bay, Ont., afforded economies in manufacture and in line with its policy these economies were being reflected in its price structure. Prices on explosives packed in wooden boxes remain the same.

Polystyrene Foam — Dow Chemical of Canada, Limited, has announced the construction of a plant in Sarnia for the production of an entirely new product for the Canadian market. A polystyrene foam plant is now in the early construction stages and is expected to come on stream in the spring of 1958. The new product will be processed from polystyrene, expanded to produce a sparkling white non-interconnecting cellular structure. Product qualities include light weight, low thermal conductivity, inherent water resistance and high compressive strength. The new polystyrene foam plant brings to a total of fourteen the number of plants operated by Dow in the Chemical Valley.

New Office Location — Foundation of Canada Engineering Corporation Limited has announced a change of location of its Toronto office to 8 Spadina Road, Toronto 4, Ontario, telephone WA. 4-3737.

C.N.R. Contract — Canadian National Railways recently awarded a contract to Bridge & Tank Company of Canada Limited of Hamilton, Ont., for the manufacture and erection of the steel superstructure for the Victoria Bridge Railway diversion at Montreal. Victoria Bridge is one of the spans linking Montreal Island with the mainland. The contract is said to be one of the largest fabricated steel contracts to be awarded in Canada in recent years. The 13,000 tons of steel required in the Victoria Bridge construction will result in the maintenance of substantial employment in the Hamilton Bridge division of Bridge & Tank for the next three years and will benefit Canadian steel mills at this time of decreasing steel production. Work is expected to begin on the project early in the spring. The take-off point for the alternate structure on the upstream side will be two-thirds of the way across the bridge from the Montreal side. The project is in co-ordination with the St.

● BRIEFS

Lawrence Seaway Authority lock at St. Lambert and is necessary to provide for the passage of trains with a minimum of interruption. Operation of the nearly mile-long diversion route is expected to be under way prior to the opening of seasonal navigation in the spring of 1961. Total costs of the work in connection with the structure, including the contract now being awarded, is estimated at $17 million.

Federal Public Works Contracts — Public Works Minister Howard Green has announced that contracts involving expenditures totalling $562,267.54 were awarded by the Federal Department of Public Works during the month of December, 1957. The amount for new works in building construction is $542,597.00 and for the repair and maintenance of existing structures is $6,250.00. The amount for the repair and maintenance of existing structures in harbours and rivers is $13,420.54.

Contracts involving expenditures totalling $3,314,060.43 were awarded by the Federal Department of Public Works during the month of January, 1958. The amount for new works in building construction and harbours and rivers engineering is $2,676,890.16; for the repair and maintenance of existing structures $137,170.27; and for the extension of the Mackenzie Highway $500,000.00.

Cellulose Sponge Manufacture Discontinued — Plans to discontinue manufacture of cellulose sponge, produced at its Shawinigan Falls, Que., plant were announced recently by Du Pont of Canada. The company said the Canadian-made product could not compete with the increasing flow of imports entering this country. The company instead will supply the Canadian market through the resale of sponge imported from the United States.

Winter Unemployment — The efforts of one company to relieve winter unemployment problems were described recently to the Electric Club of Ottawa. J. S. Keenan, vice president and general manager of Canadian General Electric Company's industrial products department, said his department was scheduling its capital expenditures so that much of the work involved could be done during the winter months. Other projects, such as renovation of buildings and relocation of equipment, were also being pushed forward during the winter. Mr. Keenan said his department is manufacturing special export orders this winter which were taken some months ago on a no-profit basis. These export orders have reduced the layoffs caused by the temporarily smaller home market for some electrical products. He indicated his department was pursuing a vigorous 'Buy Made in Canada' program in the purchase of machinery and materials to help Canadian suppliers of these items provide more jobs in their factories.

Union Carbide's New Division — Union Carbide Canada Limited has taken over the assets and undertakings of Visking Limited, Lindsay, Ontario. Visking's business will now be carried on under the name Visking Company, division of Union Carbide Canada Limited, and will join the other five divisions of Union Carbide Canada Limited which are Bakelite Company, Carbide Chemicals Company, Electro Metallurgical Company, Linde Air Products Company and National Carbon Company. Mr. L. A. Hanson, formerly vice-president of Visking Limited, becomes president of Visking Company, division of Union Carbide Canada Limited. Visking makes a wide variety of food casings used by packers for processed meat and sausage products, as well as polyethylene film and tubing. The main plant and offices are in Lindsay, Ontario and a second plant is being built and is nearing completion in Winnipeg.

Price Change of Domestic Nickel — To compensate for recent changes in foreign exchange rates, and to keep the domestic price of nickel in accord with the basic export price, The International Nickel Company of Canada, Limited recently announced a change of 2½ cents per pound in its price of electrolytically refined nickel, for consumption in Canada, increasing the price from 69 cents

(Canadian currency) to 71½ cents per pound from its Port Colborne, Ontario, refinery. The price change does not alter the company's price of nickel for the United States or any other markets.

Vidamp Distributors — The appointment of distributors to handle the sale of Vidamp machine mountings has been announced by the manufacturer, textile division, of Dominion Rubber Company Limited. Vidamp will be generally available through branches of The Canadian Fairbanks-Morse Company Limited and Rudel Machinery Company Limited, while sales to the textile industry will be handled by W. J. Westaway Company Limited. These appointments have been made to provide industry with more rapid service and assistance in the use of Vidamp, a Canadian made felt product especially designed as an anti-vibration mounting for machinery of all types. Vidamp is said to have found wide use in machine shops, textile mills and printing plants, where it also allows the installation of machinery without lag bolts or braces, and provides more satisfactory working conditions for employees.

Publications

A new quarterly customer publication "Atlas Copco Compressed Air Comments" has been announced by Atlas Copco Canada Ltd., the Canadian affiliate of the world-wide Atlas Copco Group, manufacturers of compressed air equipment. The two-colour publication will carry news and information about the various applications of compressed air in industry.

The first issue carries two special stories — "The Use of Compressed Air for Winter Ice Removal" and "Growth in World Markets for Tungsten Carbide Drill Steels."

Maintenance of Air Tools—A 28-page booklet, "Working on Air", released recently, is a humorous guide to the maintenance of air tools, using cartoon technique by the Canadian artist, "Ricky". Atlas Copco Canada Ltd.

Radiographic Materials — Kodak industrial radiographic materials are illustrated and described in a new Kodak pamphlet, "Materials and Accessories for Industrial Radiography", which contains a guide chart for selection of Kodak film for various material thicknesses.

Lumber Packaging and Loading—A new "Handbook of Instructions for Packaging and Loading Lumber for Shipment in Box Cars" (AD 243 1-58) is a 28-page manual containing over 50 illustrations and diagrams. Acme Steel Company.

Architectural Aluminum — Three new brochures describe finishes, care during construction, and care in service for Alcan architectural aluminum. Appendix of proprietary products available also. Aluminum Company of Canada, Limited.

● BRIEFS

Ductile Iron — An illustrated 8-page booklet has been published describing a new cast material combining the founding characteristics of cast iron with toughness and strength levels usually associated with carbon steel. The booklet contains 24 case records. The International Nickel Company of Canada, Limited.

Photogrammetry — Canadian Aero Service Limited have available a new brochure which reports on the application of aerial surveys to engineering problems.

"Timing" Belt Drive — Catalogue TB-58 recently announced by Morse Chain Company is said to mark the first time information on all five basic "Timing" Belt pitches has been available in a single catalogue, and is available on request to the company.

Insulation — Brochure R.A.I.C. File No. 37-C has been designed basically as a reference book for the architect and the engineer when including J-M Spintex insulation in specifications for mineral wool home insulation. Canadian Johns-Manville.

Ancient Use of Nickel — Early history of nickel has been rolled back some 4,000 years as the result of research findings presented in a paper published in the October 1957 issue (Vol 61, No. 4) of the *American Journal of Archaeology*. The International Nickel Company of Canada, Limited.

Pipe Laying — Canada Iron Foundries, Limited have made available a booklet describing the Tyton Joint, a new, tight joint for cast iron pipe.

Utility Sets — A new 28-page illustrated 2-colour catalogue describing the new line of HS Utility sets is now available from American-Standard Products (Canada) Limited—Canadian Sirocco Products (Bulletin 8414).

Machine Control — Recently made available by the electronics division of Canadian Westinghouse Company—a 12-page booklet on the Westinghouse "Nultrax" electronic machine tool control unit; there is a section on application to machine tools, precision instruments, and assembly operations.

Drop Forged Turnbuckles — This 4-page brochure gives details of Stelco drop forged turnbuckles and hot galvanised turnbuckle assemblies. The Steel Company of Canada, Limited.

Models in Plant Design — Published recently by The M. W. Kellogg Company, "Models: New Route to Better Plant Design" discusses scale models as a tool to communicate engineering concepts and to improve methods of designing process plants (Kelloggram, 1957 series, issue No. 5.).

United Kingdom Trade — A booklet describing their services has been made available by Transatlantic Engineering, a firm of British consultants. The booklet may be of assistance to any Canadian firms interested in dealing with the United Kingdom.

"The Testing World" — Soiltest Incorporated would be glad to send regularly a copy of their publication "The Testing World" to anyone interested in receiving it.

Notes from Britain

New Boilers For Oil Refinery — Two new package boiler units each weighing 36 tons were supplied recently by Mitchell Engineering Ltd., Bedford Square, London, W.C.1, England, to the Shell Petroleum Company, Ltd., oil refinery at Lutong in North Borneo. The boilers, which are of the water tube type, can generate 33,100 pounds (15,013.9 kilograms) of steam per hour and are fired by oil or gas.

Dust Collection—A new range of dust control equipment for industry is being introduced by Dallow Lambert and Company, Ltd., of Thurmaston, Leicestershire, England. The firm claims that it is particularly suitable for engineering works where there is machining, grinding and polishing of metals, for foundries and for coal and coke handling plants. Dust collected by the equipment is drawn into a main collecting chamber where it is mixed with water to form a sludge. The advantages offered by the equipment are said to be a high collection efficiency and absence of fire risk, less space and no secondary disposal problems when dust is removed.

Glass Fabric Strengthens Bitumen — A new fabric named "Tygascrim" is now in production by Fothergill and Harvey, Ltd., of Manchester, England. Although light in weight—only 2.2 ozs. (57 grams) per square yard (0.84 square metre)—this fabric has considerable tensile and bursting strengths. The coating ensures compatability with most compounds used in water-proofing. The fabric will withstand temperatures up to 1,000 degrees Fahrenheit, and prevents compounds to which it is applied drying out by conduction of vaporisable oils to the surface, a process which the glass filaments of the fabric inhibit. It is stated that "Tygascrim" is suitable for all roofing and water-proofing applications, and that it can be successfully used for the spiral wrapping of underground pipes and the lining of interiors of oil storage tanks.

Plastic Bonded To Steel — What is claimed to be one of the most remarkable materials ever produced by the steel industry, "Stelvetite", is now being made by John Summers and Sons Ltd., Shotton, Chester, England, in co-operation with BX Plastics Ltd., of London. It consists of a sheet of steel permanently covered on one side with a sheet of specially formulated Velbex P.V.C. (polyvinylchloride) made by BX Plastics Ltd. The plastic is a thick coating, not a film, available in a very wide variety of finishes and colours. Described by the manufacturers as the "steel with the built in finish" it is claimed that it will revolutionize many industries.

Electronic Milk Testing—A portable device which is simple to operate has been developed by an English firm for use in the examination of milk by farmers. An electronic device, it has been designed to aid farmers to detect the occurrence of mastitis infection in milk during the early stages of the disease. The testing of milk takes only a few seconds to perform and the Mastitis Meter, as it is called, gives a direct reading showing the condition of the milk on a dial. The device registers the electrical conductivity of the milk. The conductivity measurement changes when mastitis infection occurs due to the presence of increased quantities of chloride in the milk. The development is important as it may enable farmers to spot the onset of mastitis infection in a herd at a very early stage and thereby enable the sick animal or animals to be isolated and treated before the disease can spread. Firm: W. G. Pye, Ltd., Granta Works, Newmarket Road, Cambridge, England.

OFFICE OF THE PRIME MINISTER · CABINET DU PREMIER MINISTRE · CANADA

Ottawa,
April 4, 1958.

Mr. C.M. Anson, M.E.I.C.,
President,
The Engineering Institute of Canada,
Montreal 2, Que.

Dear Mr. Anson:

To the Engineering Institute of Canada I extend my heartiest congratulations on the completion, this month, of forty years of continuous production of THE ENGINEERING JOURNAL.

The Institute had completed thirty years of service to Canada and the profession of engineering when, in 1918, it commenced publication of its Journal "to facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public". Ever since its inception this outstanding all-Canadian technical publication has fulfilled its purpose.

Today Canada is experiencing one of the greatest periods of industrial expansion known to mankind. It is my earnest hope that THE ENGINEERING JOURNAL may continue to be of increasing service to Canada, through her engineers who are playing such leading parts in so many aspects of our beloved country's development.

Yours sincerely,

John Diefenbaker

CANADA IN 1957

THE CANADIAN economy slowed down in 1957 from its upward surge of the past few years. A softening in world commodity markets affected most of the agricultural, forest, and mineral products important in Canada's export trade. Industrial production slid gently downward throughout the year from its February peaks. The gross national product at some $31 billion exceeded the 1956 volume of $29.55 billion by about 4 per cent, but after taking price increases into account, total production of goods and services showed little change from 1956 and on a *per capita* basis were somewhat lower.

The rate of capital expansion for the past few years, though maintained, was at a slower rate, and volume of new work coming forward declined. Though activity in the principal service lines continued to expand, mining and manufacturing output had declined since early in the year. Whereas demand for forest products had weakened, increased output was seen in chemicals, electrical and industrial machinery, primary iron and steel, and railway transportation items. Sales of autos and trucks were somewhat below 1956. Fewer housing completions softened the market for appliances.

Total employment increased about 2½ per cent. Total labour income, though levelling off in the 4th quarter, had risen by 9 per cent in the first three quarters. Personal incomes, in aggregate, continued upward. Real purchasing power rose by about 3 per cent. Consumer credit showed little further increase.

World trade did not expand as rapidly in 1957 as in the two preceding years. Canadian merchandise exports changed very little from 1956. Base metals and lumber were in much easier supply, though exports of uranium increased threefold. Oil exports increased about 40 per cent but demand fell off considerably in the last two quarters. The upward trend in iron ore shipments had flattened out. Though imports remained steady for the first three quarters they declined in the fourth quarter.

Bank executives point out that levelling out of Canada's boom has its advantages; continuation of the 1956 rate of expansion would have subjected the economy to severe stresses and strains. A slackening was desirable so it might consolidate its recent gains and resume its advance from a more solid foundation.

Trade Minister Gordon Churchill, in a year-end message, described the present economic situation as a "pause in expansion". Though there was little likelihood of significant strengthening in world commodity markets, there was strong underlying supports for the economy, he pointed out. Consumer demand would be an important sustaining influence.

Employment Drop Sharpest in Resources Industries

At year-end, unemployment was becoming serious. Industries which had been showing the greatest drop in employment were forestry—down more than a third from 1956; agriculture—down less than 3 per cent; and construction and transportation —each down about 1 per cent. Utilities and service industries remained buoyant, continuing the pronounced trend of recent years. The current slackness was thus most pronounced in resource and export industries, especially forest products and minerals, whose pick-up must depend on events in the United States and overseas.

But output per man was increasing. Since October, employment had been falling more rapidly than production. It was catching up with the decline in production which had started almost a year before. Falling employment thus represented, in part, a shakeout which had to come.

Employment Covered in Review

Employment at some 2,230,000 in the mining, petroleum, transportation, construction and heavy manufacturing industries that are covered in the following review, represents the production effort of some 43/45 per cent of Canada's civilian non-farm labour force, which averaged 4,608,000 for the year, or the effort of some 48 per cent of all paid workers. The remaining proportion are employed in such industries as clothing, textiles, food, beverage, retail trade, printing and publishing, tobacco, rubber and leather footwear, and all service industries.

In the pages that follow, the coverage for each industry is confined to records of production supplied by the Dominion Bureau of Statistics, from financial reports and press statements, and from Government information releases. In addition, comments and forecasts of industry leaders are quoted. In view of the uncertainty in predicting future trends, no general forecasts are made about the outlook for 1958.

40 YEARS OF PUBLICATION 1918 - 1958

This issue of *The Engineering Journal* marks the completion of forty years of uninterrupted publication — a period that includes two world wars and the depression years of the thirties. The progress of the *Journal* is reviewed on pages 135 and 232.

Symbolizing the work of the miners who play such a large part in the development of Canada's mineral resources, the picture at right shows cars removing rock and gravel from the second 2 1/2-mile tunnel under Mission Mountain, B.C. Many hardrock miners are engaged in the work, although the primary purpose is the development of the Bridge River for hydro-electric power. In addition to mineral ores, oil and gas are major natural resources; the lower picture shows a typical oil-drilling rig in south-western Manitoba.

METALLIC ORES

NON - METALLICS

PETROLEUM

NATURAL GAS

MINERAL RESOURCES

CANADA's MINERAL production set another all-time record for value in 1957, in spite of lower prices and lessening demand combining to shrink markets and cut production of many minerals, thus reducing earnings of many companies to well below 1956, the nation's mining industry on the whole enjoyed another big and profitable year. With inclusion of petroleum and natural gas, both of which showed moderate increases, total production value of $2,085 million in 1956 was topped by 2.5 per cent, at $2,134 million.

The year 1958 will be a difficult one in some respects, with further reductions expected in many items unless the overall business picture improves materially. Yet the promised threefold expansion next year in uranium output could turn the tide and result in another all-time record for the industry as a whole for 1958.

Base Metals, Gold, and Coal Output Off

Many minerals in 1957 showed a smaller volume of output and many had their production curtailed by reduced prices. Outstanding in this category were copper, lead, and zinc, usually the industry's star performers. Worldwide expansion of production of these metals had raised their production to high levels, while demand from the consuming industries, as well as government demands for stockpiling, had fallen off. Today with more supplies available than demands can absorb, production cutbacks are widespread.

Metals declined in value to $1,136 million from $1,146 million in 1956. Prices of copper, lead and zinc fell. Gold production for 1957 was about the same as 1956, but its value was reduced by about $2 million due to the premium on Canada's dollar cutting the price.

Other metals show a combined reduction of production amounting to some $5 million, while non-metallics production value showed a gain of some $7 million.

The value of coal production suffered another $5 million drop, due to the further inroads of competition from other fuels and to the lessening demands from industry generally. Fuels other than coal showed a gain of $42 million, and structural materials gained $15 million.

Uranium, Asbestos, and Nickel Better

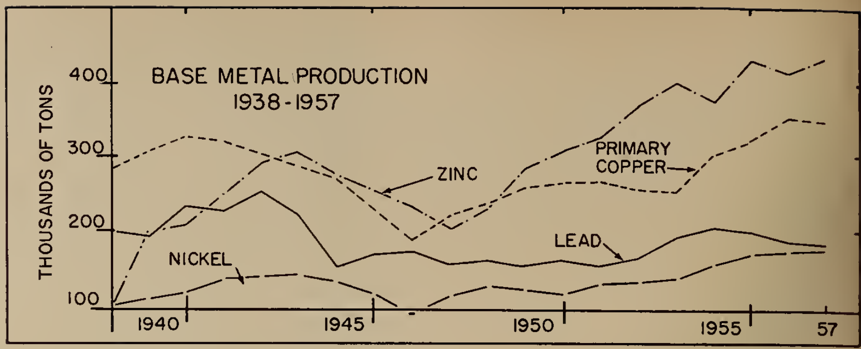
Canada is established as one of the world's top uranium producers and has the advantage of fixed-price sales contracts with the government. Since few of the contract mines are yet in full production, Canadian output will increase sharply during the next two years. Output has jumped to some 12.9 million pounds, worth $131 million in 1957 from $46 million the previous year, and by mid-1958 will be established at a rate exceeding $300 million yearly.

Iron ore continued to grow in importance and 1957 output was close to 1956 tonnage despite slackening steel activity in the United States where most of it is marketed. Prices were up 5 to 6 per cent. Production in 1957 will reach a total of slightly in excess of 22 million tons with a value of $156 million. A few years ahead it will exceed 40 million tons annually valued at about $400 million.

The outlook for nickel is also encouraging. In spite of abatement of U.S. stockpile requirements, unlimited supplies will now be available for civilian industry for the first time since 1939. Nickel producers will be now able to make unrestricated sales efforts and increased usages and sales can be expected.

Industry Affairs

A delegation of Canadian Cabinet ministers conferred in Washington last fall with their counterparts in the American Administration on trade relations, and voiced the alarm and



dismay felt by the mining industry at the prospect of increased U.S. import duties on lead, zinc, and copper. The industry will have an opportunity of voicing its views to the U.S. Tariff Commission when that body reviews the lead and zinc situation.

The Diefenbaker government announced its intention to revise the Industrial Relations and Dispute Investigations Act (Federal Labour Code), a matter of great importance to the mining industry. All uranium producers with one exception now operate under the code.

During the month-long tour across Canada last September the sixth Commonwealth Mining and Metallurgical Congress visited all the important Canadian mining camps and metallurgical centres from Kitimat and Trail in the west through Edmonton, Beaverlodge, Steep Rock, Blind River, Sudbury, Timmins and Noranda to Schefferville in Ungava and Sydney, Nova Scotia. They also toured the St. Lawrence Seaway. The party included some 350 visitors from 36 countries. The tour was sponsored by the Canadian Institute of Mining and Metallurgy.

METALLICS

Iron Ore

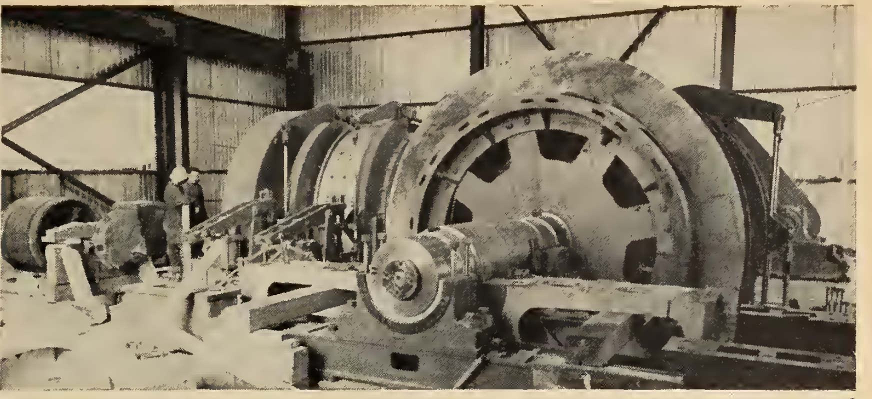
Steel producers who have been worried over an ore famine since World War II now find there is a plentiful supply, yet both prices and consumption are holding close to peak levels. Canada has climbed to fourth place behind the U.S., Russia, and France; ahead of Sweden, the U.K., and West Germany. Final figures for 1957 showed its 10 producers had turned out 22 million long tons worth $156 million, with 1958 production pointing definitely higher.

As a result of the new trend to beneficiation and increased use of high-grade pellets of 64% iron as an ideal blast-furnace feed, most big U.S. ore consumers are looking to Canada for lean Canadian ores that can give a richer pellet than U.S. taconites and jaspers.

The bulk of Canada's iron ore is exported: 13.7 million tons of the nation's 1956 production total (22.3 million tons) went across the border, 2.5 million tons went to Britain, while shipments to West Germany, the Netherlands, and Japan followed in that order. Canada imported 4.52 million tons in 1956, most of it going to Hamilton steel mills. In 1957 essentially the same export import pattern was followed, but with a quickening interest by West German and other European nations for high grade concentrates.

More than half Canada's production comes from the Ungava Knob Lake fields. Marketing some 12.6 million tons in 1957, Iron Ore Co. of Canada should expand output to 20 million tons in the next few years. Two new producers are assured for 1958: Hilton Mines in the Ottawa Valley is readying a $16 million concentration plant, while Lowphos Ore Ltd. will ship concentrates from its plant near Capreol, Ont. Caland Ore Co. is continuing its huge dredging operation but will not be in production before 1959.

Canadian Charlson, near Steep Rock, plans a concentration plant for a 250,000-ton production in 1959. Leading the search for low grade deposits that can be agglomerated and which promise tomorrow's big developments is U.S. Steel's Quebec Cartier Mining Co., 300 miles north of Shelter Bay on the St. Lawrence. With expenditures already reaching $10 million, it could go as high as $300 million by time production starts in 1961. It may turn out to be a 10-million ton yearly operation. Other big interests in the exploration stage include Canadian Javelin, Quebec Cobalt, and Albanel Minerals.



Hoist room floor at Steep Rock development. Two 132-in. skip hoists on parallel mounts, right, and 100-in. cage hoist, at left rear.

Uranium

Canada continues to rank third in uranium production after the United States and South Africa, though it will probably assume leadership during late 1958 or early 1959. In 1957 Canada produced 12.9 million pounds of uranium oxide, valued at $131 million, almost a threefold increase over 1956. Canadian reserves are estimated at 225 million tons, containing some 237,000 tons of uranium oxide, compared with some 175,000 tons of oxide in the U.S., and 370,000 tons of oxide in South Africa.

There was little incentive for prospecting for new deposits during 1957. Deadlines for qualification for premium price contracts are passed and, with no promise of five-year amortization, only exceptionally rich further deposits could be mined economically at present. Premium price contracts have been designed to repay capital within a five-year period, which made it easier to raise the huge sums of money needed.

The need for cheap energy has forced Europe and to a lesser extent America to make use of oil, gas, and coal as primary fuels for producing electrical energy. Britain with less plentiful supplies has taken the lead in developing uranium-burning power plants. With demand increasing it is natural to consider possible successors to uranium but, so far, none exist.

Canadian contracts for uranium awarded to companies now producing or with plants under construction total over $1.5 billion. These contracts expire in 1963. Prices average around $10 per pound of contained uranium oxide. Eldorado has options on further production at prices equivalent to the U.S. price of $8 per pound until 1966. The standard price in Canada for other than contracts calling for premium prices remains unchanged at $6.00. Eventual maximum rate of output from companies now in production alone is estimated at close to $400 million annually.

Producers

In the Beaverlodge camp, Eldorado Mines' new plant commenced production in 1957 at 500 tons daily, to be raised to 750 tons in 1958. It takes ore from Cinch Lake, National Explorations, and Cayzor Athabaska Mines. Eldorado moved treatment rate at its Uranium City plant up to 2000 tons daily and handles 150 tons daily from Rix Athabaska on a three year contract. Rayrock started a 150-ton mill at Marian River in June. The Eldorado Plant at Port Radium continued at normal production of 200 tons a day.

In the Bancroft area of Ontario, Bicroft smoothed out operations at its 1000-ton plant, while Faraday started its new plant up in April. This mill also handles shipments from Greyhawk. Canadian Dyno continued construction and will produce 1000 tons daily early in 1958.

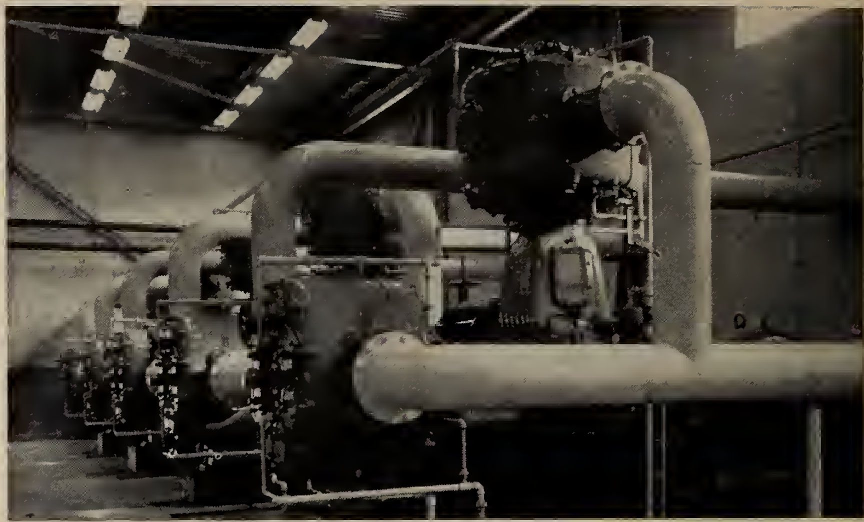
At its Blind River plant in Western Ontario, Pronto Uranium stepped up tonnage to 1500 tons daily and is proceeding with deeper development.

Milliken Lake Uranium Mines property in early winter. In foreground: mine dry and office building, grinding and crushing bay, service and production headframes. Enclosed concentrator in the background.

Algom brought its first 3000-ton mill into operation in 1956 at Quirke and the second one of the same size at Nordic was operating at capacity early in 1957.

Precipitate shipments from Consolidated Denison started in June 1957 and the mill is gradually being brought up to 4000 tons daily with a target of 6000 tons daily early this year. Northspan's Nordic Lake Mill of 4000-ton capacity started production at 2000 tons in September. Its Panel Lake Mill will open late in 1958 and its 2000-ton operation at Spanish is close to production.

Can-Met Explorations' 3000-ton mill will be operating below capacity until underground work is opened up further. Stanleigh started feeding its 3000-ton mill late in 1957, while Stanrock expects to have its 3300-ton mill ready for production in February 1958. Milliken Lake Uranium will commence production at its 3000-ton mill in the spring.



Dry vacuum systems using piston type pumps in the Algoma Blind River mining area. Design factor is 1 c.f.m. piston displacement per sq. ft. filter surface.

Nickel

With a slowdown in the industrial boom, slackening in defence orders, and large scale diversions of U.S. stockpile quotas, the grey market for premium priced nickel is tapering off and producers face a struggle to regain markets lost to substitutes. Diversion of stockpile quotas, however, merely means producers may attempt to dispose of nickel contracted for by the U.S. Government to private industry. If unable to get the price they would receive from the Government the producers can require the Government to buy it at the contract price.

Canada, world's largest producer of nickel, produced close to 376 million pounds, worth $261.2 million in 1957, compared with 357 million pounds the previous year. This is 75.3 per cent of estimated 1957 world production of some 490 million pounds. Anticipated world production is estimated at 650 million pounds by 1961. Availability of this greatly increased supply may create serious marketing problems for producers, especially if defence consumption should be further curtailed, requiring a 75 per cent increase in peacetime industrial uses of nickel by 1960.

Open pit and smelter of Hudson Bay Mining and Smelting Co. Limited, Flin Flon, Man.

International Nickel, world's largest producer, sees the most promising field for expansion in stainless steel, turbines, machine tools, corrosion resistant uses, and for chemical plants, electronics, nuclear power, missiles, and space ships, as well as in the hundreds of conventional peacetime uses. A vast increase in Inco's production will come from the new properties in Manitoba, now under development. These are being readied for production by 1960.

Arcadia Nickel will commence production early in 1958. Another possible addition is the Gordon Lake division of Eastern Mining and Smelting near Kenora. E.M. & S. is also planning another smelter and refinery at Chicoutimi, Quebec. This smelter will treat ores from Nickel Rim, Gordon Lake, Arcadia, North Rankin, and Canalask, as well as ores from custom smelting from other parts of the world. During the year 1957 North Rankin Nickel mines brought its 250-ton per day mill into operation.

Copper

Overproduction and sharply reduced prices spread gloom over the copper mining industry throughout 1957. The all-time highs in tonnage production and value in 1956 of 353,293 tons valued at $293 million were cut sharply. Production of new primary copper in 1957 averaged some 28,000 tons monthly, off some 1,700 tons from the pace set in 1956. Production for 1957 was valued at $199.5 million, a drop of almost one-third.

What this means to Canadian copper mines is shown in Canada's export trade figures. Annually we export some 70 per cent of our output. In the first 8 months of 1957 we exported 37,500 tons more than in the previous year, yet we received $4.9 million less for it.

World production has not only caught up with demand, but has passed it by a substantial margin. Fabricators took only slightly less than the previous year's tonnage, but weakness in prices (down to 25¾ cents in October from the all-time high of 46 cents in July '56) was the severest on record. To remedy the situation, producers must develop increased consumption or cut back production, neither of which is easy.

Some New Mines - - Some Failures

While the search for new mines slowed down during 1957, Maritimes Mining opened an 1800 ton mill in Newfoundland in September, while Buchans Mining Co. continued shaft-deepening operations. Heath Steele Mines began tune-up of their 1500 ton concentrator in New Brunswick. Merrill Island will start up its 650-ton plant in January; Copper Rand, Bouzan, Quebec Chibougamau, and Bateman Bay are in various stages of exploration and development. Chibougamau-Jaculet has suspended operations due to lack of ore. Beattie-Duquesne, Lyndhurst, and Duvan have suspended operations.

The five month strike at Gaspé Copper Mines held off a large slice of production. Geco Mines and Wilroy Mines commenced production in Ontario. Coldstream was treating 600 tons daily. Hudson Bay Mining profits were down for 1957 though Sherritt Gordon has done better. In B.C., Woodgreen copper is in bankruptcy, Midwest and Granby have ceased work, and Britannia is considering closing down.

Two of the Rio Tinto group operations are Northspan Panel Uranium Mines, top, and Northspan Spanish American, at Quirke Lake, Ontario. The Panel mine has the two mine shafts on islands in the lake; No. 1 shaft is reached by a causeway.

Lead

The available supply of lead has been running in excess of consumption. Decreased industrial activity, levelling off of U.S. stock-piling and barter programs and intended British stockpile sales, have upset the delicate pattern of supply and demand. Canadian production for 1957, valued at $52.4 million, was 10% below the same period of 1956. Refined output has been running close to 1956 figures when total output was 147,865 tons. Canadian exports have shown some increases over the previous year.

During 1957, due to softer markets and suspension of U.S. barter deals, four price-cuts reduced the price from 16¼ cents in May to 12¾ cents in October. The U.S. Tarriff Commission may raise the lead import duty by 2.55 cents per pound from the current 1.0625 cents. Lead imports were slashed considerably in 1957 following the opening late in 1956 of the Ethyl Corporation of Canada plant at Sarnia. Lead consumption in Canada should show an uptrend for the full year 1957 due to the opening of this plant.

Principal source of lead and zinc in Canada is the Sullivan Mine of Consolidated Smelters at Kimberley, B.C. The Company operates the only lead refinery in Canada and treats domestic and foreign ores and concentrates. It also operates the H. B. and the Bluebell producing mines.

Production at Tulsequah and the open-pit mine at Sullivan, Jardun mines at 'the Soo', and the Mayo mine in the Yukon, all suspended operations during the year. Consolidated Sudbury Basin Mines has deferred plans to open. Heath Steele Mines in New Brunswick is producing lead from its 1500 ton mill.

Zinc

The year 1957 was discouraging for most zinc producers and the immediate outlook for the future is cloudy. Output in 1957 was valued at $99.7 million, 20 per cent below that of the previous year. Price declines due to oversupply forced production curtailment or suspension. The U.S. stockpile of zinc is bulging and is unlikely to be added to. The U.S. barter system initiated in 1956 to trade farm surpluses for foreign metal supplies has met with disfavour. Slab zinc consumption is down for 1957 in the U.S., world's largest consumer.

Zinc producers in the U.S. are urging tariff increases. Hearings were scheduled for year end, with strong probability for a hike in duties. This would be a severe blow to all zinc-producing countries. Four drops in prices between May and August totalling 3½ cents brought Canadian price for prime western zinc to 10 cents.

In spite of all these ills, it was

predicted early last year that world production would create a new record. Today the estimate seems optimistic. Many U.S. and Canadian mines have shut down or curtailed production during 1957. For the first three quarters of 1957 U.S. zinc output was running 3½% over the previous year, though Canadian output for the same period was some 2% lower than in 1956.

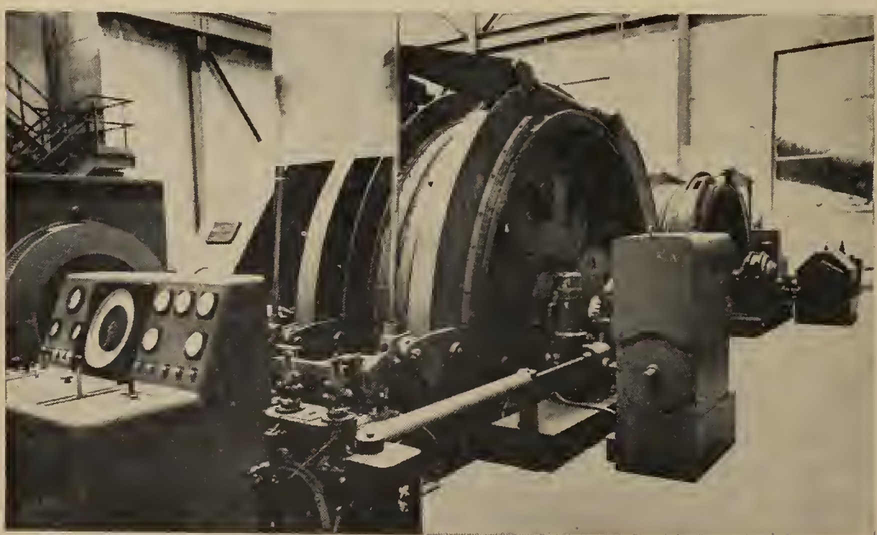
Besides the Consolidated Smelters' Kimberley Mine in B.C., where zinc is refined, Hudson Bay Mining and Smelting at Flin Flon produces and refines slab zinc. In 1957 the Company began shaft sinking at a new property at Snow Lake, Manitoba with an indicated deposit of nearly four million tons. Elsewhere, Heath Steele mines in New Brunswick commenced production in 1957 while Buchans in Newfoundland continued production and Brunswick Mining will soon be in production. Barvue and New Calumet mines in Quebec curtailed their production. Geco and Wilroy, in Manitoba, began production in 1957 with capacities of 3300 and 1000 tons daily, respectively. Surveys were under way for a rail route to the south shore of Great Slave Lake in the N.W.T. where large deposits are located.

Gold

Gold mines of the world have been passing through another difficult year. Free world production will again show a small increase of some $10/20 million: this will reflect merely the remarkable expansion in output from South Africa. Canada, in second position, will produce about 60,000 ounces less than in 1956, for a decrease of some $2.0 million in value.

From the mine standpoint there were few developments of importance during the past year. One new gold mine had made its appearance: French Mines, in B.C., with a 30/50-ton milling plant having started production. Howe Sound, in Manitoba, is on a salvage basis. Some old-established producers have raised their capacity slightly. Only one prospect, Taurcanis in the N.W.T., was doing underground development.

The 220-ft. concrete headframe at Geco Mines Limited, Manitouwadge, Ont., above. The friction type mine hoist, below, was designed and built in Canada.



Cobalt

Cobalt is passing through a transition period from the stimulus of government stockpiling to the growing pains of a civilian market. Canadian production will be close to the 1956 total of 1,843 tons, though domestic consumption will be sharply lower than the previous year's 218 tons, or nearer 63 tons. Exports are expected to total as much as 1,250 tons. Relatively little cobalt is imported into Canada. Price for cobalt in concentrate form, now pegged at $2.00, is only about half the rate of a year ago.

Canadian nickel producers are the principal sources of cobalt. Some 35% to 40% of all production is in the alloy field for high temperature alloys, jet engines, and atomic equipment, and offers best chances for the future. The permanent magnet industry uses 30% of all production, but is threatened by new materials.

Platinum

Reversing the position in 1956, when demand for platinum greatly exceeded the supply, the platinum metals are now in oversupply. Falling prices have cut values to $84/87 an ounce. The oil industry, largest consumer, has cut back its buying. Its use was a catalyst for making high-octane gasoline.

The United States is the main consumer of platinoids, last year at 975,000 oz.; Canada exported 287,544 oz. to the U.S. in 1956. A new use for platinum has recently appeared in the U.S.—an automatic electrical system using platinum disc anodes has been developed to protect ships' hulls and propellers against corrosion.

Canada's production for 1957 is not likely to be in short supply. Most of it comes from nickel producers. International Nickel's Manitoba development, and Eastern Mining and Smelting Co., at Kenora, are the largest untapped sources of the metal. Canada's domestic consumption in 1956 was valued at some $6 million and by 1958 it will rise with the increase in oil production. Canada's exports were down about $7 million below 1956 for the first seven months of 1957.

Silver

Canadian silver production in 1957 was at a rate only slightly higher than that of 1956, at about 30,100 ounces. Exports of silver in all forms based on production for the first three quarters had fallen about 10% below that of 1956. The market has been stable and indications are that it will continue so.

The three North American countries, Mexico, United States, and Canada, in that order, account for over half the world's production. Silver coinage takes much of the metal; Canada has been using greater amounts for coinage the past few years. The U.S. Treasury, Mexico, Saudi Arabia, West Germany, and Canada are largest users for this purpose. Most of it comes from producers of zinc, lead and copper.

Diamond drilling at the International Nickel Co. of Canada Ltd. site at Moak Lake.

Titanium

Titanium, the 'wonder-metal', has failed to live up to the publicity lavished upon it. Now the United States has indicated defence requirements for the metal will be substantially cut back. If it is to maintain its steady record of growth new markets must be developed for commercial use, and price reductions must be achieved in mill products. Today only half of the U.S. capacity production of 31,500 tons is in operation.

Ninety per cent of the titanium produced has been for jet aircraft and missile components, where its high strength-to-weight ratio and resistance to corrosion and fatigue gave it advantages. But the metal is meeting sharp competition from nickel alloys which, though heavier, can withstand more heat.

Potential civilian markets are in civilian aircraft, automobiles, anodizing and plating, papermill and chemical process equipment, and marine fittings, while 95% of world output of titanium-bearing minerals is used in the titanium pigment industry, a market of first importance to Canada, which is the world's leading producer of titanium slag and has the largest known deposits of ilmenite. World production of ilmenite and rutile concentrates doubled in five years to 1,789,400 tons in 1956.

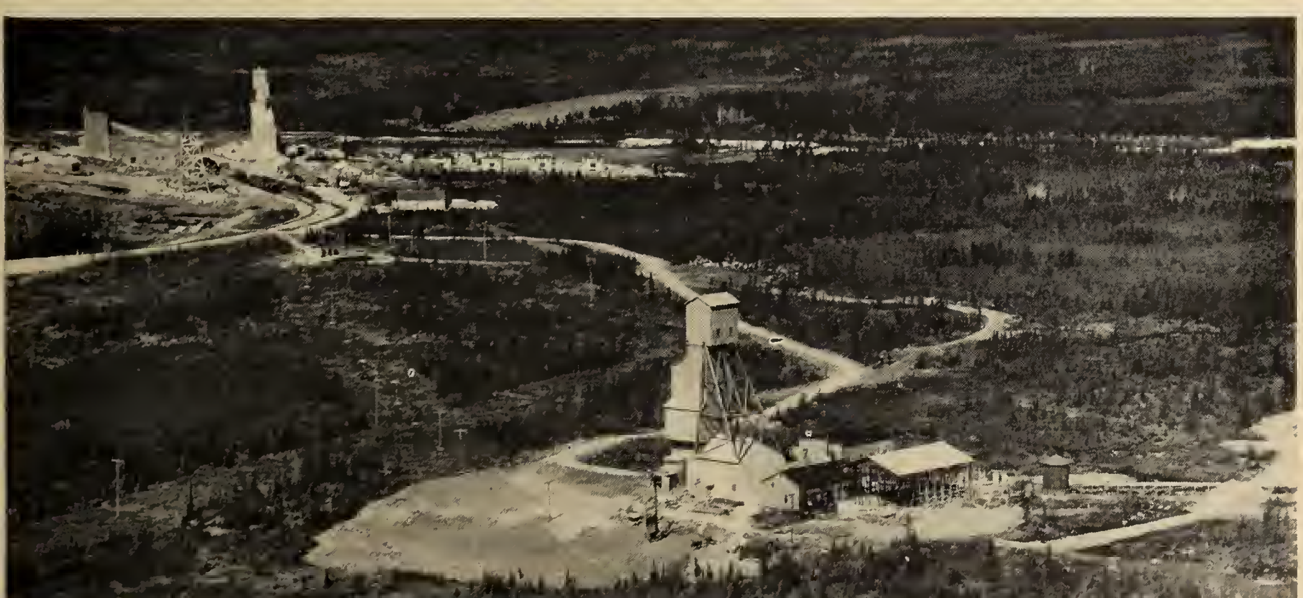
Price of titanium sponge has been cut from $5 per pound to $2.25 since 1951 and will go lower. Titanium mill products at $10/12 per pound must compete with stainless steel at about $1.00. Recent technological developments suggest its price will fall still further.

Canadian Titanium Pigments, Ltd. opened Canada's first pigment plant at Varennes, Que., late in 1957. Slag will be fed to it from Quebec Iron and Titanium's five electric furnaces at Sorel, where three more furnaces were lately added to boost capacity to 375,000 tons yearly by 1959. Baie St. Paul Titanic Iron Ore Co. produces ilmenite, and Continental Iron & Titanium Mining plans a 500-ton plant there. Several other companies have prospect in Quebec. Some 10,500 tons were produced in Canada in 1957 compared with 2300 tons last year.

Manganese

Canada is not a producer of manganese ore, but relies entirely on im-

One of the projects in the developing Chibougamau area of Quebec is the Opemiska copper mine, now expanding mill capacity.



ports from India, South Africa and Morocco. Strategic Manganese Corp. is planning an electric smelter at Woodstock, N.B. for processing low-grade manganese iron ore from its Woodstock property. Capacity will be 5,000 tons daily with annual production of 70,000 tons of 7.6% ferro manganese and 74,000 tons of ingot iron. Manganese ore imports in 1956 totalled 208,000 tons. Ferromanganese exports totalled 59,445 tons valued at over $10 million.

Magnesium

Canada ranks third after the United States and Russia in production with 19,000 tons output in 1956. As opposed to the general trend of non-ferrous metal production, output of primary magnesium in the U.S. continued at capacity during the first half of 1957, though July showed the first substantial decline. Figures for Canadian production, exports and imports of magnesium metal are not published but annual capacity amounts to some 8,000 tons, 60% from Dominion Magnesium and 40% from Magnesium Co. of Canada, an Alcan subsidiary.

Lithium

Lithium is a newcomer to Canadian mining. Some 5.4 million pounds of lithia were produced in 1957, vs. 4.8 million in 1956. To date there is only one producing company, Quebec Lithium, which with other partners has discovered the largest and richest deposits in the world. With a 1,500-ton per day mill capacity, it has a 5-year contract with Lithium Corp. of America to supply 165 tons daily of concentrates. The Company will proceed in 1958 with construction of its own lithium refinery and chemical facilities to process its lithia concentrates produced at Val d'Or, Quebec, at a cost of some $3 million. A 450-acre area has been bought at Rouses Point, in New York State just south of the Quebec/New York border, where work will be started next April.

Molybdenum

World production of molybdenum reached a new high in 1955 at an estimated 33,600 short tons of ores and concentrates of which the U.S. produced 31,000 tons. U.S. production in 1957 indicates it will compare favourably with 1956.

All Canadian production comes from Molybdenite Corporation of Canada, at Val d'Or, which in 1956 produced 707 tons of molybdenite and 117,044 pounds of bismuth metal. In 1957 the Company produced 874,600 pounds. The Company expects to mine 188,000 tons and mill 168,000 tons during the full year of 1957.

NON-METALLICS

Asbestos

Canadian asbestos production was maintained during 1957 at close to all-time record levels. Shipments totalled about 1,061,400, worth $106.4 million, up 3% over 1956. Increase in capacity in 1958 should boost shipments over the 1,064,000-ton record attained in 1955. Looking ahead, it is estimated domestic production will increase by close to 30% by 1960. Currently production and demand are about balanced, with small oversupply in a few particular grades.

Only a minor amount is consumed domestically. In 1956, 92½% or 963,921 tons of raw asbestos were exported, while manufactured asbestos articles exported were valued at $3.75 million. The United States remains by far the largest export market for raw asbestos while the United Kingdom is the second largest. West Germany, Japan, and France, in that order, come next. Top customers for manufactured asbestos articles are United States, Colombia, Mexico, Cuba, South Africa, Venezuela, Lebanon, and Syria.

Five major Quebec producers are carrying out expansion or modernization programs which will add several thousand tons of production daily next year. Potential new producers have appeared: Advocate Mines in Newfoundland is developing a 1,600 sq. mile deposit of chrysolite and is seeking financing. Cassiar Asbestos in B.C. has optioned three properties in Northern B.C. and the Yukon from Conwest Exploration.

Barite

Canada takes third place in world production of barite with the U.S. leading at 1 million tons annually and West Germany, with 400,000 ton output, only slightly ahead of Canada's 321,000 tons in 1956. For 1957, production in Canada fell to 216,000 tons. Canadian consumption is small, most of it is used in oil well drilling muds, and showed a drop in 1957 with the reduction in well drilling.

Magnet Cove Barium Corp. in Nova Scotia produces 90% of Canada's output, and owns one of the largest deposits in the world. So far it has been an open-pit production but a shaft is nearing completion.

Fluorspar

World production and consumption of fluorspar eased considerably during 1957 and the outlook is uncertain. Canadian production at 68,463 tons in 1956 was sharply down to less than a half of the record 140,000 tons mined in 1956. Almost half Canada's production is exported to the United States. Exports last year were down sharply due to suspension of operations by St. Lawrence Corp. of Newfoundland. Much of its output had been shipped in prior years to the parent Company's processing mill in Delaware.

Largest domestic consumer is the aluminum industry, with the steel trade second, which in 1955 (latest year reported) took 68,600 and 18,600 tons respectively of Canada's 88,000-ton consumption. Last fall it was announced Ottawa would hold an investigation into the tariff structure on fluorspar, but no date is set for the hearings.

Potash

Potash is used as a fertilizer. World production in 1957 was estimated at 8.2 million tons of K_2O equivalent to a mine production of 35/40 million tons. The U.S. is the largest producer and consumer. Ninety per cent of production is in New Mexico. A year ago Canada imported 90,000 pounds.

Saskatchewan's potash potential is estimated at 30 billion tons. Estimate for ore grading higher than 25% K_2O at depths less than 4,000 feet and of minable thickness is 5 billion tons. Exploration is in the hands of American companies. Potash Co. of America has a 2,000-ft. shaft on its property east of Saskatoon. Shaft sinking is slow and very expensive. For example, a 650,000-ton/year potash mine will require 3½ years to put it into production at a cost of close to $30 million. Yet Saskatchewan potash reserves are the richest known in the world and there is no doubt a great industry will develop there. To date no production has been started.

Sulphur

Threatened world shortages of sulphur of a few years ago have now been averted, mainly due to the rapid development of production in Canada. Canada's sulphur production for 1956 from all sources totalled 763,736 tons valued at $7.44 million. By end of 1960 some million tons of sulphur yearly will be available as a by-product from natural gas in Western Canada.

Production of pyrite from Canadian copper, nickel, and lead smelters has been expanding, much of it being used for the rapidly expanding uranium production in Canada. The pulp and paper industry is by far the largest consumer, with fertilizer plants a close second.

The United States is still the largest producer, turning out more than half of the free world's requirements and amounting to 7-9 million long tons in 1956. Currently, new plants in Western Canada are adding 2,100 tons daily to the 130-ton per day output a year ago from sour gas.

Other Minerals

Production of other minerals and fuels in 1957 included: gypsum 4.5 million tons, 8% lower than in 1956; salt, 1.76 million tons, up 10% over 1956; lime, 1.38 million tons, 22 per cent higher than in 1956; sand and gravel, 145 million tons, down 2½% from 1956; and coal, 13.2 million tons, down 11½ per cent below the previous year.

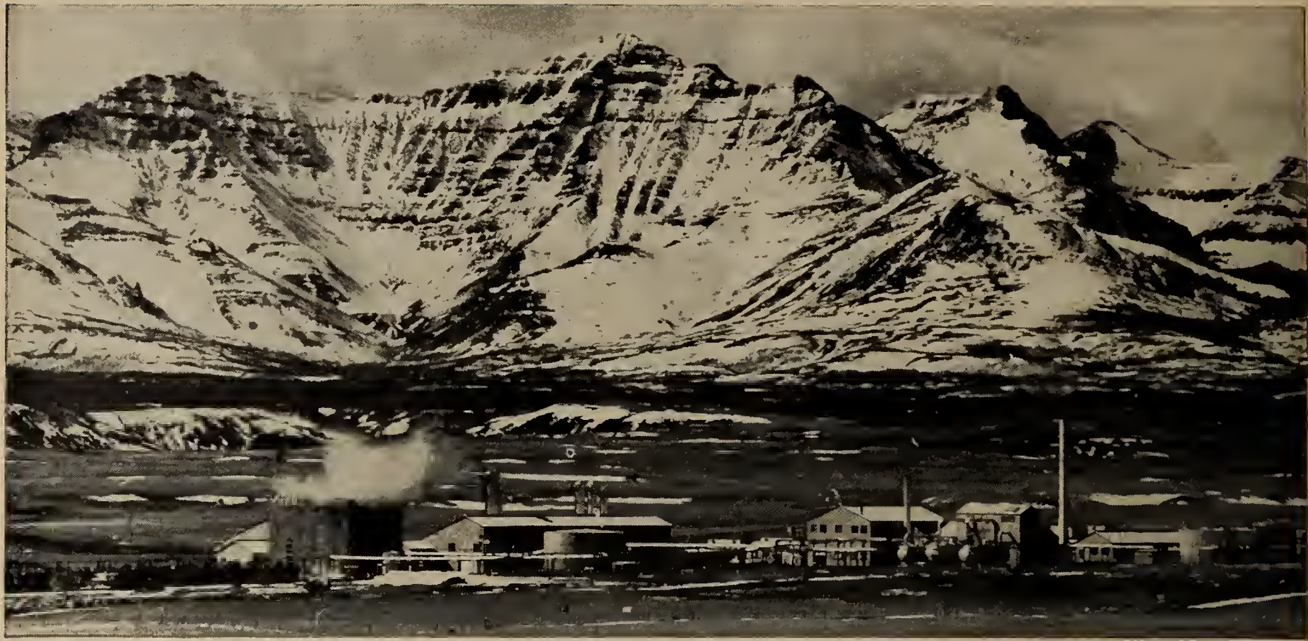
PETROLEUM

CANADIAN PRODUCTION of crude oil in 1957 failed to record a gain similar to the 32 per cent growth recorded for each of the past two years. First hints of a flattening out of the 10 year continuous upward trend began to appear in the second quarter. By the fourth quarter output fell behind the same period of 1956 by some 2½ million barrels. Final production figures for the full year, however, are expected to show another new record at about 183 million barrels, 7% over the 171 million barrels produced in 1956. Estimated gross value of production at $444 million compares with $406.5 million in 1956.

In spite of the claims by marketing experts that the bottom had been reached in the current market slump for Alberta crude, the slower marketing pace was noticeably affecting development drilling. Producibility was at least two to three years ahead of indicated market growth and continuing to increase at the rate of some 100 new oil wells per month. The possibility that 1958 may show a further decline was raising the question at year-end of the need for proration of development drilling.

Yet nowhere was the slowdown looked upon as more than an awkward 'breathing spell'. Though development wells drilled during the year were down about 10 per cent, a record number of wildcats drilled totalled 12% more than in 1956, the success ratio holding close to the one-in-four ratio of the previous year. Footage of holes declined to about 15% below 1956, yet geophysical activity continued at a consistent pace. Only 180 drilling rigs were active at year-end, compared with 240 at the end of 1956. Total wells drilled since the Leduc discovery in 1947 numbered some 20,000 including dry wells. Though no new oil pools were discovered in 1957 comparable to the finds in Pembina or Sturgeon Lake, important discoveries were made in the Innisfail area, the Virginia Hills, Swan Hills and Edith Lake areas and in the Kaybob-Iosegun area southeast of Sturgeon Lake, all in Alberta.



The first British American Oil plant at Pincher Creek, Alberta. A second stage plant is being built. Pincher Creek will be the largest single supplier of natural gas to the Trans-Canada Pipe Line when the expansion has been completed.

Saskatchewan and B.C. Up—Manitoba Steady

Repeating the spectacular 66 per cent gain in production experienced in Saskatchewan in 1956, producers in that province recorded another 68 per cent gain in output over the previous year. Much of this gain was at the expense of Alberta producers. With her many light gravity fields in the southeast corner of the province some 800 miles nearer Ontario and mid-U.S. markets, Saskatchewan producers have captured an increasing proportion of these markets. Output for 1957 will approach 36½ million barrels.

British Columbia production for the first year exceeded 300,000 barrels, double its previous all-time total output. On the other hand Manitoba, with production of some 6 million barrels, failed to duplicate the 37% gain in output recorded there in 1956. Only a moderate gain of some 6% has been shown for 1957.

New Pattern Set on Export

The export market for Canadian crude which accounted in 1956 for a third of production, was bettered during the past year. The healthy increase in export volume of some 21% over 1956 was encouraging, but was marked by a substantial decrease in exports to the Pacific Coast and a sharp increase in exports to the northern states. The collapse during the second half of the year in the export demand for westbound oil was due to softening of tanker rates, a long refinery strike at Vancouver, and a general U.S. opposition to imports.

A realistic appraisal of all the divergent factors makes a forecast of exports for 1958 extremely hazardous. The down-trend in tanker rates, the extent to which natural gas may replace oil for heating, the possible imposition of fairly rigid import quotas across the border, and new supplies to the California market from New Mexico starting in January, cannot be intelligently weighted. But the general feeling appears to be that a levelling-off or moderate uptrend in exports of Canadian crude is to be expected during the coming year.

Temporary Cut-back

Canada's oil exports to the United States will be cut 15%, it was announced at year end. The effective cut-back will amount to only some 5%, however, and is only temporary. Back of it is a strong powerful lobby of smaller U.S. companies who feel they are being squeezed out by large oil imports.

Independents Seek Montreal Market

Many of the independent companies think Alberta producers should set their sights on the Quebec market area now served with foreign crude from the big 250,000/300,000 b/d Montreal refineries. Here is concentrated about a third of Canada's refinery capacity. Most of the major integrated companies are strongly opposing the move.

Though capture of the Montreal market for western oil would raise western Canada's output by around 25% there would have to be a cut in current wellhead prices all across Canada. Besides this, a second west-east oil pipeline could be financed only if and when the half dozen big Montreal refining companies sign long term throughput agreements to buy western oil exclusively.

The independents argue pipeline charges could be re-adjusted upwards for intermediate delivery points such as Toronto and Sarnia to permit a 10c lower rate to Montreal. They also advocate a 10c customs tariff on foreign oil at Montreal. These adjustments, plus a 10% cut in wellhead prices would make western oil competitive with Mid-East oil in the Montreal market. But integrated companies foresee an assurance of price cuts by the present suppliers of ocean-borne crude. They also look for a bigger potential market in the United States within five to seven years. They believe it better for western producers to wait for this certain market rather than to cut wellhead prices and gain the Montreal market.

Oil Pipe Mileage Substantial

Although the mileage of crude oil pipelines laid during the year was small compared with gas pipelines, more than 800 miles were laid, including 156 miles of new 20-inch line for Interprovincial Pipeline Co. in Ontario from Sarnia to Port Credit outside of Toronto. The balance was entirely looping programs designed to provide in advance for expected increases in throughput for strategic regions. Trans-Mountain's main pipeline was looped for 100 miles with 30-inch, Westspur laid a 75-mile 16-inch loop in Saskatchewan, the Pembina Pipeline main was looped for 36 miles and Interprovincial looped 33 miles with 24-inch in Saskatchewan.

Westcoast Transmission is considering the building of a 650-mile 'big-inch' crude pipeline from Peace River fields to Vancouver, paralleling the company's natural gas pipeline, though the project may be two years away due to the softness in the current market for crude on the Pacific Coast. Pacific Petroleums is also interested, due to its development in the Boundary Creek, Fort St. John, and Buick Creek fields which the line would tap. A similar line is planned to Bella-Coola by Act Oils Ltd., which is owned by Canada Southern Petroleums and others.

Developments Down-North

A 250-mile crude oil pipeline will be built by Bituminous Oil Pipeline Co. Ltd., a company recently formed to transport oil from the oil sands area in north eastern Alberta to Edmonton. The Company is jointly owned by Royalite Oil and Can-America Oil Sands Development Ltd., partners in the $50 million project announced last year. The Coulson process using centrifugal force to bring commercial production will be used. Size of the pipe is not yet determined.

British interest in the oil sands is reaching the stage of definite planning. A committee has been set up in the U. K. to make a long term study. Largely undisclosed U.K. interests are expected to announce development plans in a few months. The British government, interested mainly from the point of view of world strategy, looks to development of a major energy source should it lose the big Mid-East oil fields.

The oil refining and distribution project for the Northern B.C.-Yukon-Alaska area is moving closer to reality with financing of Alaska-Yukon Pipelines Ltd. Properties and facilities at Haines and Whitehorse of Alaska Yukon Refiners & Distributors, now used for marketing in the Yukon for trucking of products from tidewater at Haines, will be acquired by the pipeline company.

This Shell Oil Company of Canada alkylation plant at Montreal East, Que., will produce alkylate for gasoline and heavier types for detergent manufacture.

Refinery Capacity Up Moderately

Canadian refinery capacity moved up to 724,550 b/d in 1957, an increase of some 67,000 b/d over capacity at the end of 1956. Cracking capacity at some 336,000 b/d was reduced by 6,600 b/d during the same period. Present crude refining capacity in b/d is divided as follows: Maritime provinces, 45,000; Quebec, 260,800; Ontario, 207,500; Prairie provinces, 192,000; British Columbia, 68,000; and N.W.T. 1,300.

Cities Service Oil Co. and Shell are each adding 20,000 b/d capacity at Bronte near Toronto over the next two years. The shifting over of a now-operating Sarnia refinery to western crude will boost further the west's share of the Canadian market. Construction will begin this spring on rebuilding and expansion of Imperial's Calgary refinery for completion in 1959, adding 6,700 b/d to capacity. Shell's Shellburn refinery at Vancouver will expand for production of a wide variety of solvents, while North Star Oil has just completed arrangements for addition of catalytic reforming at St. Boniface, Manitoba.

Refined Products

With a modest increase in refinery capacity during the year 1957 of some 67,000 barrels per day, total runs to stills of some 206.5 million barrels of all refinery products during the first 10 months of 1957 was 5 per cent higher than for the same period in 1956.

During the full year 1956, Canadian refineries received 234.3 million barrels of crude oil and natural gas liquids, 65% of it from Canadian sources and 35% in imports. Total runs to stills amounted to 234.3 million barrels. Refineries in various areas received raw materials in millions of barrels as follows: B.C. 21.9; Alberta and N.W.T., 27.9; Saskatchewan, 18.2; Manitoba, 9.9; Ontario, 58.4; Maritimes and Quebec, 96.2.

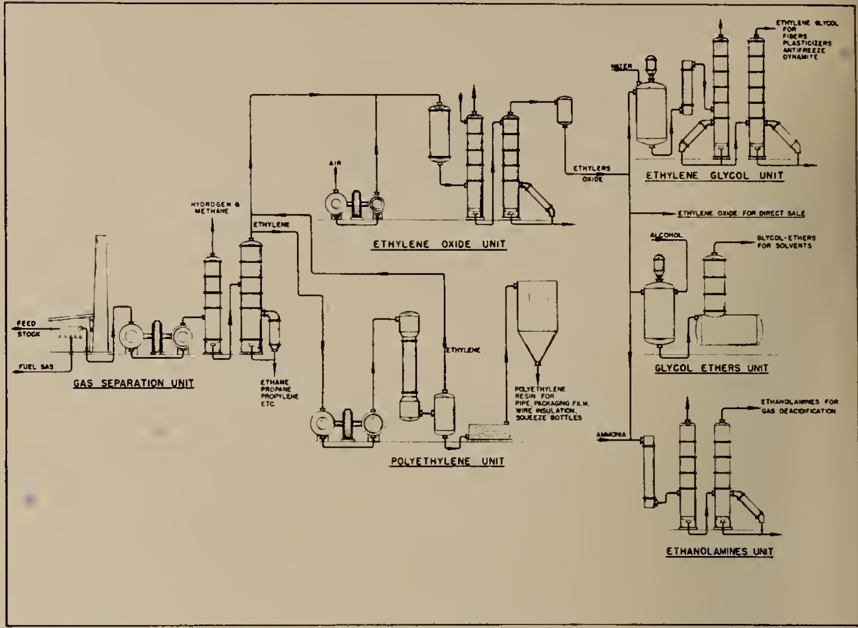
For the year 1956, net sales of finished petroleum products in Canada from all Canadian refineries, in millions of barrels of 35 Imperial gallon capacity, were as follows: liquefied petroleum gas, 3.7; feed stocks, 2.1; naphtha specialties, 1.3; aviation gasoline, 3.9; motor gasoline, 83.0; tractor fuel, 0.12; aviation turbo-fuel, 3.16; kerosene and stove oil, 16.0; diesel fuel oil, 18.9; light fuel oil, 46.5; heavy fuel oil, 50.5; asphalt, 8.05; coke, 2.7; lubricating oils and greases, 3.0; wax and candles, 0.28; still gas, 0.1; other products, 0.66. Total all products, 244.1; unfinished products, 0.04.

Petrochemical Industry's Growth

Petrochemicals continued to expand in 1957 at a rate unparalleled in recent years by any other industry. By 1957 Canada had 24 plants, involving a capital outlay of more than $300 million. Further plants now being planned represent a further investment of close to $100 million. Thus they have been mainly based on crude oil hydrocarbons. But the current development of natural gas will bring about a great expansion in petrochemical manufacture.

In 1957 only two percent of crude oil and natural gas production in North America was going into Petrochemicals. That year, nearly 20 separate projects for production of primary raw materials were under way or announced for early construction in Canada.

Since the discovery 11 years ago of large reserves of oil and gas in Western Canada, growth of petrochemicals and their derivatives has been greater relative to local population there than it has in eastern Canada. But availability of raw materials in eastern provinces from crude oil at low cost, in spite of the long haul distances involved, suggest that petrochemical industries will flourish and grow faster in Ontario and Quebec than in the prairie provinces.



A simplified flow program of the processes and products in a petrochemical plant.

NATURAL GAS

In sharp contrast to the oil industry's failure to set the usual new production record in 1957, the natural gas industry looks back on 1957 as a year of spectacular accomplishments. Eight months production at 206.2 billion cubic feet was 22% over the 169.2 billion cu. ft. produced in 1956.

With completion of the Westcoast Transmissions system in October, Peace River gas deliveries commenced to customers through the completed distribution systems in mainland British Columbia communities served by Inland Natural Gas Co. Canadian gas replaced imported gas in the Vancouver area and reversed the northward flow by feeding Canadian gas into the Pacific Northwest Pipeline

Station No. 1 on the Westcoast Transmission Company's line at Fort St. John, B.C.

south of the International Boundary.

To the east, Trans Canada completed its 34-inch western leg as far as Winnipeg by the early September, and gas deliveries to Regina, Brandon, Portage la Prairie, and Winnipeg commenced by the end of the same month. The pipeline was completed to the Ontario border by late in October. The long open fall weather permitted the Northern Ontario Crown Corporation finally to reach Fort William-Port Arthur with its 310-mile 30-inch pipeline by the first week in December. By year end Alberta gas was available through 910 miles of line from Alberta gas fields to Lakehead cities.

Still further east, Trans Canada's 20-inch diameter section between Toronto and Montreal was completed to the Island of Montreal, as well as branches to serve Lindsay and the Ottawa-Hull area, awaiting a temporary supply of borrowed gas from the Dawn Township Storage fields of Union Gas Co.

In Southwestern Ontario, Union Gas was close to completion of its 142-mile main pipeline from Dawn Township to Hamilton and to connect up with the Toronto-Montreal leg of the Trans Canada Pipeline.

Second Pipeline by 1962?

Thus with natural gas available to most of the important centres across Canada, with exception of those between Lakehead and Toronto, and distribution systems in various stages of completion, a serious re-appraisal of Canada's export position is called for. The indicated rapid market build-up in Eastern Canada and on the West coast has even exceeded earlier expectations. A maximum throughput rate, including export, of some 650 million cubic feet daily within four or five years is considered not only possible but practically certain.

This means both Westcoast and Trans Canada must have vast looping programs under way by that time to provide added capacity for the next round of expansion. This in turn calls for more development of gas fields, the proving up of further gas reserves, and federal and provincial approval for the movement of further gas to these markets.

Several of the large gas distributing companies have forecast that within a year they will be in the market for 1963 contract volume increases ranging from 40 per cent upward. Besides this are the potential fuel and raw material needs for large industrial, metallurgical and petrochemical application. Top iron-ore and

steel firms have their eyes on direct ore - to - sheet - steel operations for Northern Ontario based on a new process recently discovered by a Canadian metallurgist.

Export Permits Granted and Sought

Trans Canada has an export permit from the Alberta government for 4.35 trillion cubic feet, subject to a daily limitation of 650 million cubic feet. It now appears these peak requirements will be met as early as 1961-62. Westcoast Transmission, with government approval for a throughput of 660 million c.f.d., 83% of which is exported, applied early in 1957 for permits to increase its exports by 170 million feet daily from Savanna Creek field in Southwestern Alberta. Alberta and Southern Gas. Co. seeks permission to export 450 million c.f.d. to the California market through a 1,300-mile pipeline via the Crow's Nest Pass costing $330 million. Competition among Westcoast and Canada

Southern is stiffening wellhead prices and forcing Trans Canada back into the gas buying role in Alberta.

Toronto, Vancouver Set the Pace

The best measure of the popular appeal and rapid acceptance of natural gas as a Canadian fuel is evidenced by the experience of Consumers' Gas of Toronto and of British Columbia Electric, the first two utilities to distribute gas from the new pipelines. Consumers' Gas Co. showed a net profit of $1.18 a share for fiscal year ending Sept. 30, 1957, a 46% improvement over the previous year despite major rate reductions. In the 1956-57 heating season, 30,000 houses were heated with natural gas compared with 4,000 the previous winter, while almost 15 billion cubic feet had been sold in the full fiscal year, up 63% over the previous year. Some 300 miles of distribution lines were laid in 1957.

British Columbia Electric reports that sales of gas appliances have vastly exceeded the sale of electrical appliances since natural gas was first delivered late in 1956. Furthermore, president A. E. Grauer announced at the time Canadian natural gas reached Vancouver that his company would purchase Peace River gas for a giant new thermal power plant. The contract will call for 144 million c.f.d. and the gas will replace much of the heavy electric demand in the lower mainland area of B. C. These are reasons why West Coast's president, Frank McMahon, speaks confidently of a second parallel pipeline from the Peace River area.

The Borden Commission

Appointment of the Royal Commission (The Borden Commission) by Prime Minister Diefenbaker in October '57 to study the whole Canadian energy picture was considered long overdue. It will make recommendations on gas export policy and the need for government controls to safeguard public interests. It may delay approval of Trans Canada's standing gas-export contract with Mid-Western Gas Transmission, promised by the former Liberal government.

The Prime Minister's first declaration of November 1st on gas export policy, that no action would be taken on applications for export permits until the Borden Commission had made its report, was a shock to pipeline and gas producers and gas company officials. U. S. Utility and pipeline officials and Canadian natural gas producers were deeply disappointed at the implied long deferment of any further export business.

Indignation of the whole Canadian natural gas industry found expression in November in three addresses by leading oil and pipeline company executive officers. They demanded that the Commission should get on with investigation of the gas phase of its study right away, and bring in an early interim recommendation on export.

Reserves and their Allocations

Western Canada's gas reserves are placed today at anywhere from 25 to 28 trillion cubic feet, of which 18.3 trillion are in Alberta. Alberta's 30-year requirements are estimated at 7½ trillion feet, and approved exports to other provinces and to the U. S. are 5.75 trillion feet, leaving a present surplus of 5 trillion feet. It is estimated that reserves are increasing at the rate of two to three trillion feet yearly, most of it incidental to the search for oil. Recent major discoveries in Alberta's southwestern foothills and at East Calgary and Crossfield have added tremendously to reserves. The big Pembina oilfield will also be a large gas producer once facilities are completed to make use of flare gas. Some gas authorities claim reserves will grow at a rate of 12-15 per cent yearly, which would mean reserves of 60 million cubic feet by 1967.

The search for natural gas to supply the various pipeline systems, completed and proposed, has spread to most of the areas tributary to them within the provinces of British Columbia and Alberta. Almost every active company has had a part, large or small, in the exploration and development. Pacific Petroleums has played the major role in the Peace River and Fort St. John fields that supply West coast transmission. Prominent among the groups that will supply Trans Canada stand Canadian Delhi, British American Oil, Shell Oil, and Provo Gas.

Active in the exploration and development of gas fields for supplying the second westcoast project from Savanna Creek were Phillips Petroleum and Canadian Husky. Gas fields tributary to the proposed Canada Southern project include reserves of Canadian Western Natural Gas Co.; a 500-mile gathering line is envisaged from the Fort St. John area through Pembina and Sundre, with possibly the south half of British American's Pincher Creek field. The East Calgary field, discovered by Jefferson Lake Sulphur Co. and Merrill Petroleums, would also be tied in, as well as the recent Texaco foothill discovery at Castle River and the Shell Waterton find north west of Pincher Creek field.

Gordon Report Discusses Energy

As the year 1957 drew to a close, attention of the entire Canadian petroleum industry was being focussed on the report of the Gordon Commission on 'Canada's Economic Prospects'. Prepared for the Commission by Dr. John Davis and released in December, it provided a new perspective on the advantages and limitations of energy export. 'Countries or provinces that put energy to work effectively, rather than those that produce the most energy, are the ones that win the most of the rewards. From this it follows', states the report, 'that Canada will benefit from development of its energy sources, but it will benefit more if a growing proportion of that energy can be put to work at home'. This, of course, did not mean refusing to export energy we cannot use in Canada now or in the future.

According to the report, by 1980 Canada will be using three times as much energy as in 1955. We will use three times as much oil, eighteen times as much gas, four times as much water power, and twice as much coal. Atomic power will furnish about two per cent of our total energy.

Davis, making this report for Gordon, has assumed the wellhead price for gas will double in the next 25 years. He draws the conclusion that export of gas is not very beneficial, that perhaps it would be better to hold gas in the ground until more of it can be used in Canada.

Editorially, *Oil in Canada* points out that "the basic fallacy in this reasoning is the assumption that there is any advantage in holding on to an expendible commodity in the hopes of an ultimate price rise. This was done very effectively by John MacFarland with wheat in the early 'thirties'—so effectively that Canada has not yet recovered some of the lost markets".

"Energy demand cannot be stored up. It has to be satisfied from some source . . . Few companies in the petroleum industry can afford to hold producible hydrocarbons for ten to twenty years for a possible but not guaranteed price rise if an immediate market is offered at a lower return . . . a great deal of independent study is called for."

The New Brunswick Electric Power Commission's 102,000-kw. hydro-electric development on the St. John River, under construction for three years.

POWER
PRODUCTION AND DISTRIBUTION

CONSTRUCTION of hydro-electric plants in Canada continued to accelerate during 1957 as a result of increasing power demands. The 1,501,560 h.p. of new capacity added during the year represents the second highest annual increase to date. Other installations currently under construction are expected to add about 2,200,000 h.p. of new capacity during 1958 and more than 4,300,000 h.p. in the succeeding few years.

There are also several sites with large potential capacities, which are currently under investigation and on which it is probable that development will be undertaken within a few years' time. The total installed capacity of water-power plants in Canada is now listed at 19,871,000 h.p. which, however, represents less than 28% of total resources.

In addition to hydro-electric developments, the building of new thermal-electric plants and extensions was increasing in some areas of the country; construction of main transmission lines, distribution lines and substation capacity also proceeded vigorously during the year.

If installed thermal capacity of some 3 million h.p. is added, the grand total is more than 23 million h.p. A review of the year's activities both by utilities and by industrial establishments for each province is shown in Table 1. (Page 66)

BRITISH COLUMBIA

In British Columbia a total of 607,500 h.p. of new capacity was installed during the year, the highest among the provinces. An additional 192,000 h.p. is under construction for 1958 operation and more is in the planning or early development stages.

The B.C. Power Commission completed installation at Ladore Falls of the second of two units, each consisting of a 35,000 h.p. turbine. The Commission is also proceeding with its Upper Campbell Lake development, where the initial installation of 42,000 h.p. will be in service by May 1958. Here, a huge earth-fill dam will store water in both Upper Campbell and Buttle Lakes for use in all three Campbell River plants. The Quinsam diversion has been completed, while two more diversions are under way.

Additional construction on Vancouver Island included the commencement of a development on the Ash River near Port Alberni. The water will be conducted five miles from Elsie Lake to the powerhouse on the north shore of Great Central Lake. Here a 35,000 h.p. turbine will be installed for service by March 1959. Development on the mainland included a third unit at the Whatshan development, comprising a 16,500 h.p. reaction-type turbine completed in January 1957.

In addition, three developments are in active prospect: two in the Alberni area of Vancouver Island, with potentials of 35,000 h.p. and 17,000 h.p. respectively, and the third on the Kokish River in upper Vancouver Island, with a potential of 51,500 h.p. Four additional possible developments are under active study and investigation by the Commission: one on Vancouver Island with a potential of 81,500 h.p. on the Nimpkish River, the remaining three on the mainland. These are: a development of up to 1,900,000 h.p. by diverting water from the Chilko to the Homathko Rivers, a second development on the Murtle River, tributary to the Clearwater, with a potential of 140,000 h.p. and the third, also in the Clearwater system, with a potential of 120,000 h.p.

In the thermal-electric field, the Commission completed installation at its Georgia gas turbine plant at Chemainus, of the first two simple cycle 26,500 h.p. gas turbine units.

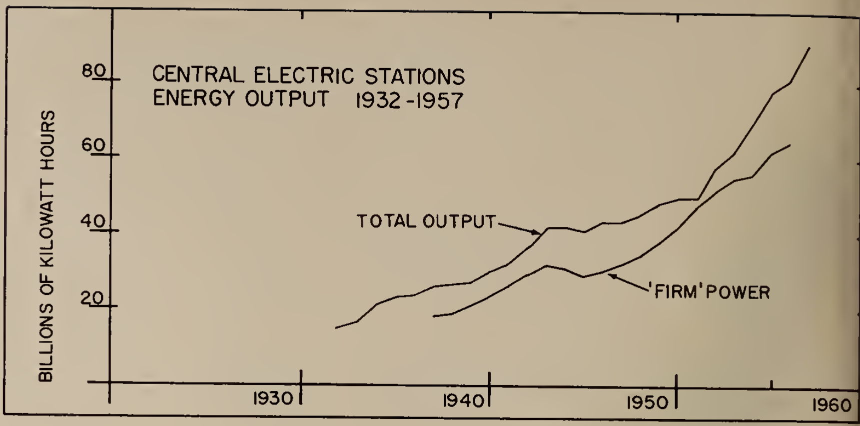

Table I—Power Installation for 1957, 1958, 1959 and Planned for Future Years

	Installed 1957 Hydro h.p.	Installed 1957 Thermal kw.	Scheduled for 1958 Hydro h.p.	Scheduled for 1958 Thermal kw.	Scheduled for 1959 Hydro h.p.	Scheduled for 1959 Thermal kw.	Planned for Future Hydro h.p.	Planned for Future Thermal kw.	Notes

(1) Excluding Mica Dam and diversion of Columbia.
(2) Excluding Lachine development.
(3) Excluding 4 million h.p. at Grand Falls.
(4) Excluding 4 million h.p. in Yukon.

Currently being added to this plant are two regenerative cycle 24,000 h.p. gas turbine units, for operation by July 1958.

Current additions to tri-fuel internal combustion engine and diesel plants at Dawson Creek, Prince George, Tofino, Quesnel, Terrace, and Fort St. James will bring total capacity of these plants to 11,000 kw., 12,000 kw., 4,200 kw., and 1,250 kw., respectively.

The British Columbia Electric Company started operation of its Cheakamus development in October when the first of two 95,000 h.p. units was brought into service. The development at Clowhom Falls on Sechelt Peninsula was rebuilt and the 4,000 h.p. two-unit installation replaced by a single unit consisting of a 40,000 h.p. turbine. The concrete gravity dam was raised to a maximum height of 71 feet. The plant was to go into operation in December 1957.

On the Company's Bridge River system, the power plant at the La Joie dam commenced operation in November when a 30,000 h.p. turbine and 24,500 kva. generator were placed in service. Work was continued on the final phase of the Bridge River development involving a large storage dam, a second tunnel through Mission Mountain and a new powerhouse on Seton Lake. The storage dam will provide an additional 750,000 acre-feet of storage, and is expected to increase the total capacity from 248,000 h.p. to 276,000 h.p.

At the Bridge River No. 2 development, four 82,000 h.p. units are expected to be installed during the latter half of 1959, which will provide a total installed capacity of 328,000 h.p.

In addition to its hydro-electric installations, the British Columbia Electric Company started construction of a 122,000 kw. gas turbine plant at Port Mann. The four units will be capable of operating on either oil or natural gas fuel and are scheduled for operation late in 1958. At Ioco, on Burrard Inlet, land acquisition negotiations for government permits were initiated for a large steam plant of six units, each rated at 210,000 h.p. The first unit will go into operation in January 1961.

The Aluminum Company of Canada Limited installed the fifth and sixth units, each of 150,000 h.p. in its Kemano plant, bringing the total capacity to 900,000 h.p. A seventh unit, also of 150,000 h.p. may be installed early in 1958. Alaska Pine and Cellulose Limited installed a 7,500 kw. double extraction condensing steam turbine, at its mill at Port Alice, British Columbia.

Consolidated Mining and Smelting (Cominco) started field investigation at the second power site on the Pend d'Oreille River six miles upstream from its Waneta plant.

The City of Nelson completed several additions to its substations. East Kootenay Power constructed two miles of 66 kv. transmission line and 21 miles of rural lines, while the Wenner-Gren Foundation commenced preliminary investigations of the water power potential in the Rocky Mountain Trench area of the Peace River, and will continue this work in 1958.

Kilowatts or Fish from the Fraser?

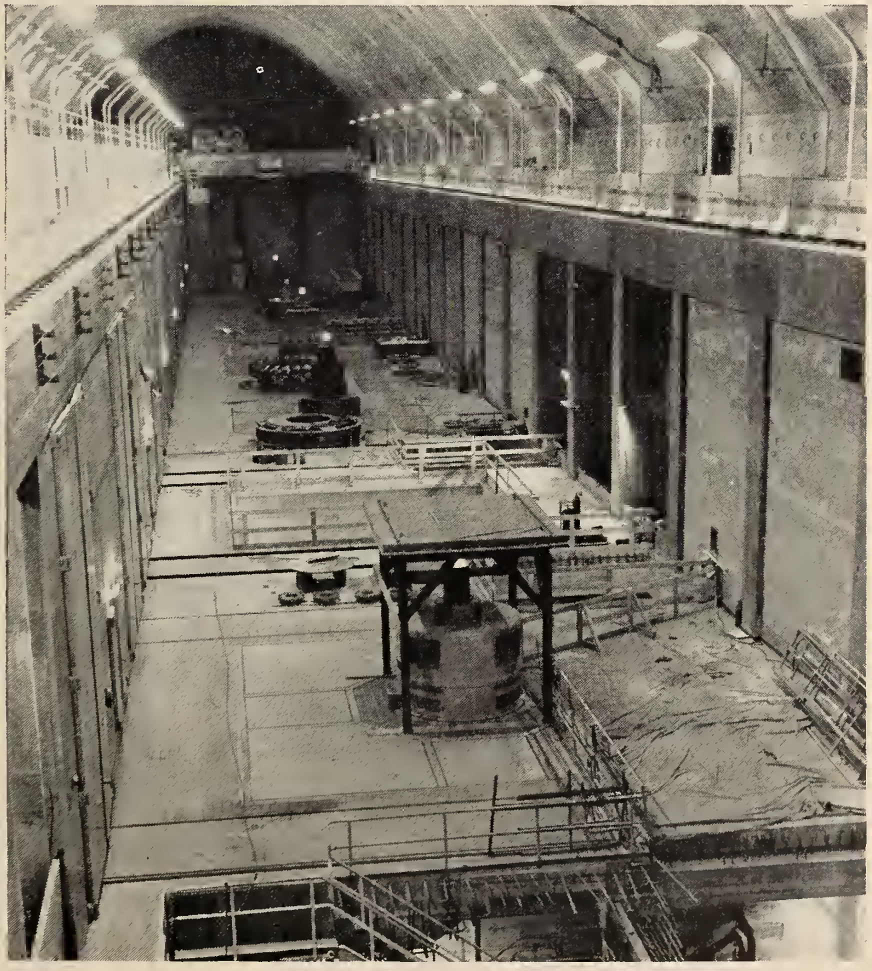
General A. G. L. MacNaughton, chairman of the Canadian Section of the International Joint Commission, told the Canadian Parliament in December that harnessing of the Fraser

River (feasible only by increasing low flow) was the only way to provide cheap power for British Columbia; that each day's delay in a decision increases the chances that B.C. power resources may come under control of the United States.

Tremendous pressure was building up in the U.S., he said, to permit the U.S. financed dams on the upper Columbia river to provide water for lower Columbia power plants. This was indicative of the widening breach between the two countries over the ultimate development of the Columbia. "Fish must take a back seat," he warned.

Fishing interests claim dams on the Fraser would wreck the $45 million yearly salmon fishing industry. Officials of the provincial government are known to prefer development of the Columbia with the United States before the Fraser is dammed.

Power developments in British Columbia include the new Cheakamus hydro-electric station, above. A sixth generator operated in 1957 at Kemano, and a seventh was built.



ALBERTA

Calgary Power Limited placed in service in October a second 23,000 h.p. unit at its Cascades plant, which operates under a head of 320 feet. The Company has begun construction of extensions to its two plants in the Spray Lakes development, to double capacity. Both are scheduled for completion in October 1959. In thermal power development, the Company is adding to its Wabamun plant a second 66,000 kw. unit for operation in October 1958. Thermal installations in Alberta during the year also included a 1,250 kw. gas unit by Northland Utilities at Jasper, a 3,000 kw. gas turbine unit for operation early in 1958. City of Lethbridge was installing a new 7,500 kw. gas turbine generating unit in its steam plant for operation early in 1958.

SASKATCHEWAN

The Hudson Bay Mining and Smelting Company plans to add a 19,000 h.p. stand-by unit to the Churchill River Power Company plant at Island Falls. Construction of the unit will be started in 1958 with a view to operation early in 1959.

The Saskatchewan Power Corporation at present depends exclusively on thermal units for power. During the year it added a 30,000 kw. unit to its Estevan plant, an 8,000 kw. unit to its Kindersley plant, and a 3,000 kw. unit to its plant at Swift Current.

MANITOBA

The Manitoba Hydro-Electric Board was proceeding with its development on the Nelson River at Grand Rapid, 400 miles north of Winnipeg, for the International Nickel Development at Moak, Mystery, and Thompson Lakes. The initial installation will comprise four 42,000 h.p. propeller-type turbines under normal head of 50 feet. Two units are scheduled for operation by July 1960, and the remaining two by January 1961. Additional features include the excavation of a channel to divert the entire flow of the Nelson River around Grand Rapid, and of a permanent dam which will provide a mean head of 55 feet. Other work includes a cantilever bridge across the river at Grand Rapid, and 14 miles of railway track between the site and the C.N.R. line at Mile 256.

At the Board's steam-electric plant at Brandon, the first two 33,000 kw. generator units were to start operation in December 1957 and the remaining two in the autumn of 1958. At the Selkirk thermal station two 66,000 kw. generator units are scheduled for initial operation late in 1959. The Board's program of present and proposed generation and transmission is designed to handle expected power demands up to and including the winter of 1961-62.

Sherritt-Gordon Mines had completed its Laurie River No. 2 development consisting of one 7,000 h.p. Francis turbine under a head of 55 feet. This plant is connected to the downstream No. 1 plant by 5 miles of 69 kv. transmission line and is to be automatically controlled from that plant.

The City of Winnipeg is continuing with the renovation of its Pointe du Bois hydro station and made repairs to the spillway and sluice gates at the Slave Falls station, both on the Winnipeg River. The Department of National Defence at Churchill maintains a 2,100 kw. diesel. Construction is under way for a 1,136 kw. addition.

The B.C. Power Commission's 100,000-h.p. Georgia generating station, above, is the world's largest gas turbine installation. Another of the Commission's projects is the Upper Campbell earthfill dam, 1700 feet long and 175 feet high, which will turn the Upper Campbell and Buttle Lakes into a 30-mile stretch of water. The first 42,000-h.p. generating unit will go into service during 1958.

ONTARIO

Demands for power in past years have resulted in an intensive program by The Hydro-Electric Power Commission of Ontario, and growth in power requirements has been met. Major work during 1957 included developments at the St. Lawrence Power Project, at Sir Adam Beck-Niagara Generating Station No. 2, and at six projects in northwestern Ontario. The Commission also completed a canal and control works for the diversion of water from Lake St. Joseph in the Albany River drainage to lac Seul in the English River drainage via the Root River.

Seaway Power

The St. Lawrence power project, a joint development of the International Rapids Section, was begun in August 1954. The main features include two adjoining powerhouses which form an integral part of a gravity-type dam structure, a dam at Long Sault to control the level of the headpond, a dam at Iroquois Point to regulate flow from Lake Ontario, and some 14 miles of dyke. Other work included a heavy program of channel improvement and excavation, the relocation of highways, railways, transmission facilities, and the design and construction of new townsites. (See 'Construction'.)

At Niagara Falls

At the Sir Adam Beck-Niagara Generating Station No. 2, at Niagara, the Commission amended its program in 1953 to provide for an associated pumping-generating station and four additional units at the main station. By the end of 1957 work on both these projects was well advanced, and two of the additional units were placed in service in December. The final two will be placed in service in May and July of 1958 respectively.

Each unit has a rated capacity of

105,000 h.p. At the pumping-generating station three units of the six were placed in service late in 1957. During periods of low demand the units will pump water diverted from the main power canal into a reservoir having a capacity of some 16,000 acre-feet. In periods of high demand they will operate in reverse as turbines, each unit having a capacity of 47,000 h.p. Flow from the reservoir in turn will augment the flow in the power canal and thus increase the output of the units in the main generating station. Installation and assembly of the generators for the three remaining units progressed favourably. They will be in service in the spring of 1958.

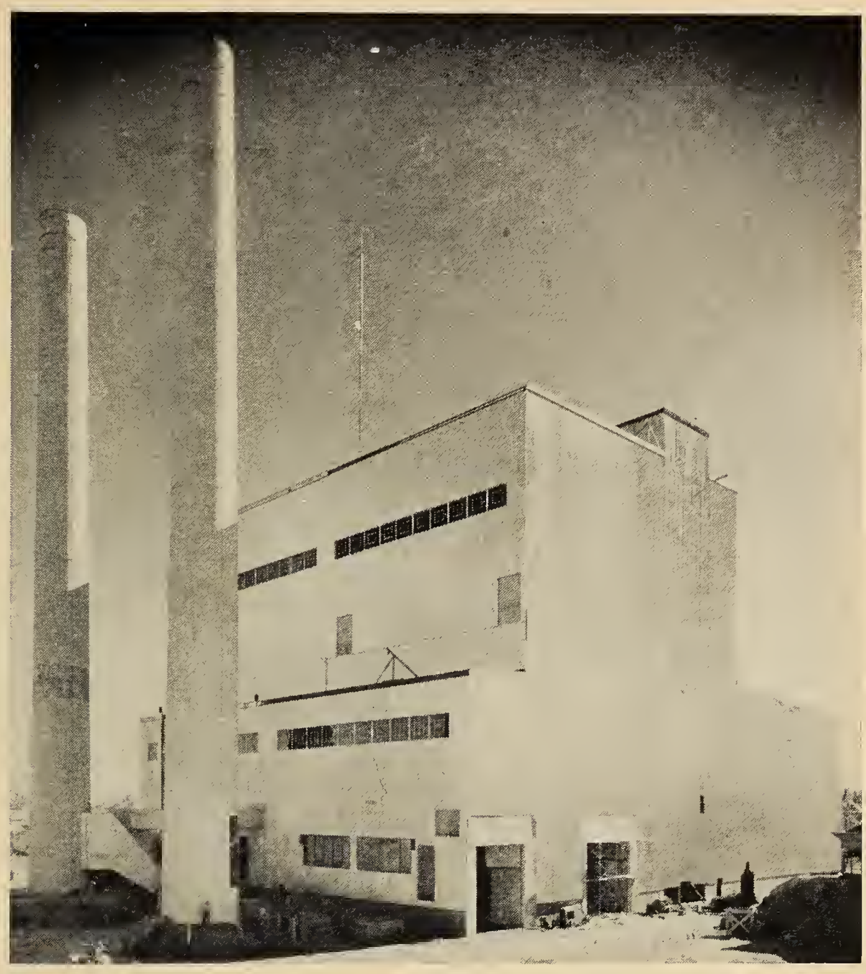
A control dam in the Niagara River about a mile upstream from the falls was completed last year and the last four gates were placed in operation. Other portions of the remedial works program involved the excavation of certain areas of the river-bed and the placing of fill on the United States side of the river, which was carried out by United States Army Engineers in 1954, and similar work on the Canadian side carried out by the Commission in 1955.

Developments in Northwestern Ontario

The development of Whitedog Falls on the Winnipeg River was started in 1955 and considerable preparatory work was carried out in 1956. Total turbine capacity will be 81,000 h.p. and initial service is scheduled for February 1958. By the end of the year the dam, the south bulkhead, gate sluices, log-chute head-block, and a compacted earth-fill wing dam had been completed. Mechanical equipment for sluice-gates was installed. Concrete placing in the powerhouse structure was completed and work crews had begun erection of turbines and generators.

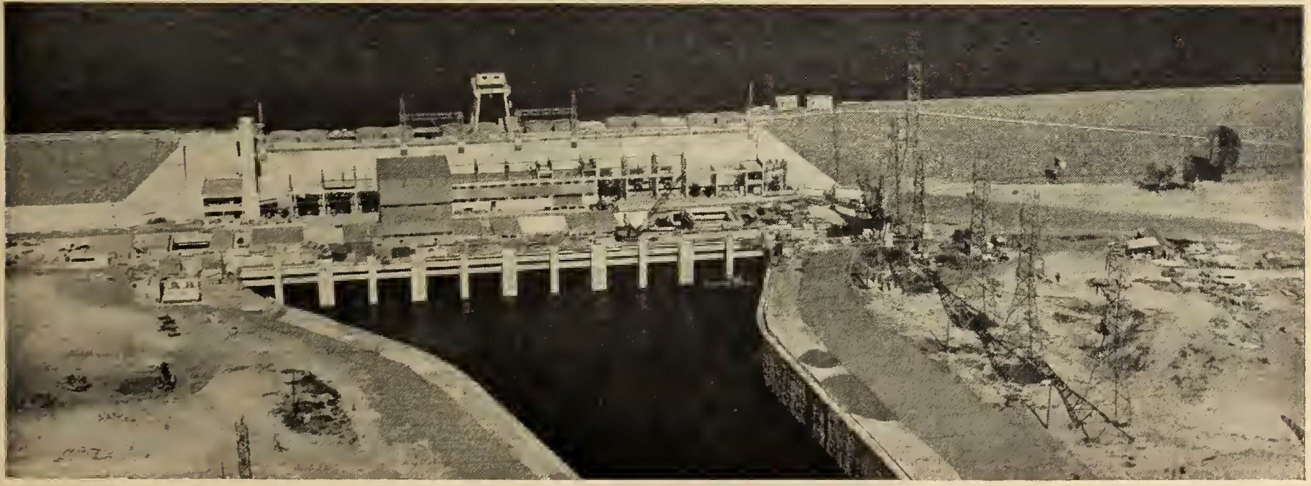
The Caribou Falls generating station was begun in 1956. Located on the English River 17 miles northeast from Whitedog Falls, its three units, which will total 102,000 h.p., are scheduled for service by October 1958. In addition to this work, four auxiliary block dams were built to assist in containing the headpond.

At the Manitou Falls generating station, provision for a fifth unit was made in the headworks in the event of increases in loads in the northwestern section of the province. In the spring of 1957 the Commission began work on an additional 18,500 h.p. unit, and such excellent progress



The Wabamun power plant of the Calgary Power Limited, showing the new stack and extension to the plant which will house a second 66,000-kw. generating unit.

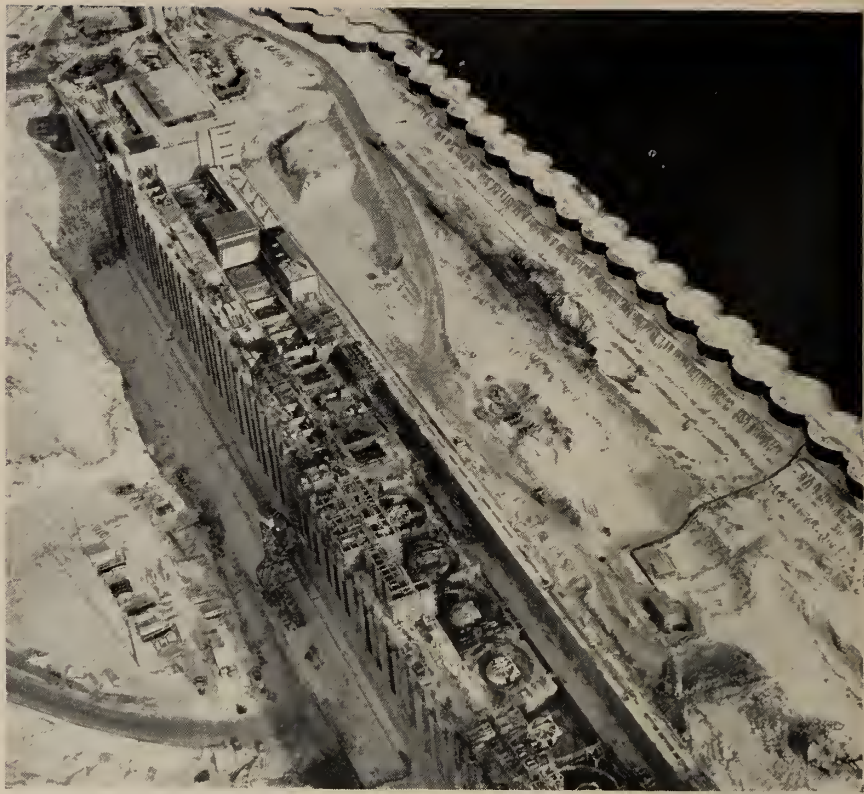
Ontario Hydro's 170,000-kw. pumping-generating station at Queenston. Three generating units are already operating.



was made that the in-service date was advanced to March 1958.

In its Cameron Falls and Alexander generating stations on the Nipigon River the Commission began installation units of 25,000 h.p. and 19,000 h.p. respectively in 1956. At the Cameron Falls station the unit will be housed in a separate structure. By the year end the work at Cameron Falls was near completion and the turbine for the unit was partially assembled. At the Alexander Falls station the turbine was installed and the generator partially assembled. Both additional units will be in service by mid-1958.

A single-unit station at Silver Falls on the Kaministikwia River is scheduled for service in September 1959. A 14 ft. lined tunnel will convey water some 9,000 feet to a powerhouse housing a 60,000 h.p. unit. Preparatory work began early in the year. By December about 1,500 feet of tunnel had been driven.



The Canadian/United States powerhouses of the St. Lawrence Power project will have a combined capacity of 1,640,000 kw., each country providing half the output. Initial service is scheduled for July 1958, and the project is to be complete in 1960.

Thermal Installations

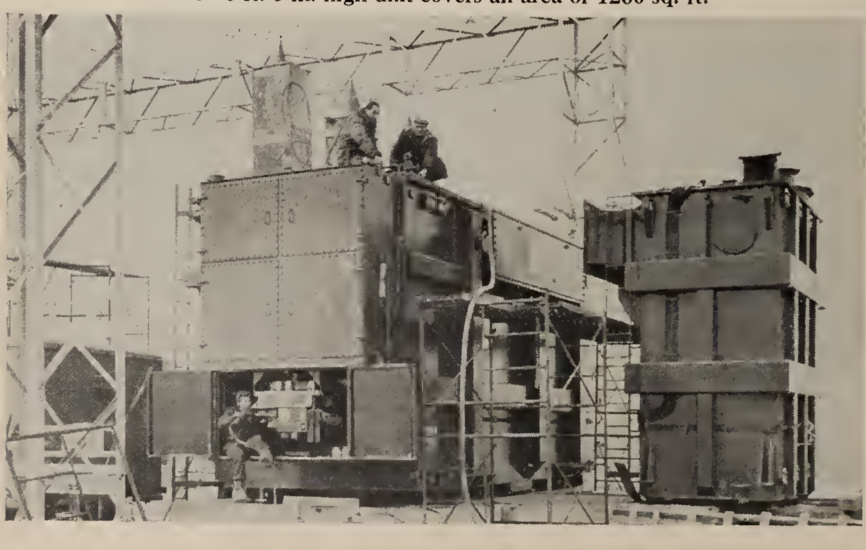
The St. Lawrence power project is the last major hydro development within economic distance of large Ontario load centres. Even in northwestern Ontario distinct advantages are to be derived from thermal-electric resources. In the fall of 1957 the Commission undertook to build three new thermal-electric stations, one at Fort William and two in the Toronto-Hamilton area.

Meanwhile work was well under way for the enlargement of the present Richard L. Hearn Station in Toronto to 1,200,000 kw., or three times its present size. Studies are being continued in conjunction with Atomic Energy of Canada Limited and other interested agencies with regard to the development of a large-scale reactor.

Apart from the activities of the Commission, the Great Lakes Power Company placed in operation in April a 30,000 h.p. unit at its Upper Falls plant on the Montreal River. Total plant capacity is now 55,300 h.p. The dam had been raised previously to a height of 86 feet, providing an average operating head of 232 feet.

The Company also is proceeding with two other hydro-electric developments; one on the Montreal River at Centre Falls where one unit of 30,300 h.p. will come into operation in April 1958, and the other on the Michipicoten River at Cat Falls having a similar turbine but with an average operating head of 100 feet, scheduled for operation in May 1959.

A 200,000-kva. transformer at Hydro-Quebec's Beauharnois power development. The 20 ft. 9 in. high unit covers an area of 1260 sq. ft.



QUEBEC

The Province of Quebec continued its extensive hydro power activities with a net capacity increase during 1957 of 473,900 h.p. after allowing for the dismantling of 10,100 h.p. of capacity. In addition, new capacity currently under construction will add about 900,000 h.p. during 1958 and more than 2,700,000 h.p. in later years.

The Quebec Hydro-Electric Commission completed the installation of the fourth and fifth units in its Bersimis I plant, some 300 miles northeast of Montreal, raising the installed capacity of the plant to 750,000 h.p. Each unit is rated at 150,000 h.p. and operates under a head of 875 feet; power is delivered to the new Bout-de-l'Ile substation on the Island of Montreal. The ultimate capacity of the underground powerhouse will be 1,200,000 h.p. in eight units.

At Bersimis II, 23 miles downstream, good progress was achieved in the preliminary stages of construction. The project involves an intake tunnel 4,000 feet long and a diversion tunnel 1,100 feet in length, the erection of two dams—one of concrete and the other of rock fill—and the construction of 60 miles of road. The powerhouse will have a total installation of 855,000 h.p. in five units, each turbine being rated at 171,000 h.p. under a head of 375 feet.

At the Beauharnois development on the St. Lawrence 30 miles from Montreal, the Commission proceeded with the third and final section of the powerhouse which will contain 11 units each of 73,700 h.p. under a head of 80 feet. Dredging operations were continued for enlargement of the intake canal. Initial operation of this section is expected late in 1958 and the completion of the entire plant, with a total installed capacity of 2,235,000 h.p., in 1960.

Among other Commission activities a storage dam on the Toulnoustouc River, a tributary of the Manicouagan, is nearing completion. This dam will allow a higher firm output from the plant of the Manicouagan Power Company, which is installing additional capacity to meet the initial power requirements of Canadian British Aluminum Company plant near Baie Comeau.

Studies and surveys are being carried out for developments in the Lachine Rapids section of the St. Lawrence River, and in the Manicouagan region on the north shore. In the field of transmission, progress was made on the construction of three additional 300 kv. lines—Labrieville to Quebec City, Labrieville to Hauterive (near Baie Comeau) and a tie line between the plants Bersimis I and Bersimis II.

The New Brunswick Electric Power Commission's hydro-electric station at Beechwood.

Price Brothers Company placed in service in September its new Murdock-Willson development at the mouth of the Shipshaw River. The plant contains one 92,000 h.p. turbine under a head of 265 feet, and is remotely controlled from the substation in the Kanogami Paper Mill three miles away. The Company's existing 10,100 h.p. Murdock plant will be abandoned.

The Manicouagan Power Company was 'on schedule' with its McCormick Dam Project No. 2, an extension of the Company's Manicouagan River plant at First Falls near Baie Comeau. The first of three additional 60,000 h.p. units, was placed in operation in December. Units Nos. 4 and 5 will be installed early in 1958. The Company's 161 kv. transmission line from the McCormick Dam to the Canadian British Aluminum smelter was placed in service in November.

Eastern Smelting and Refining Company completed and placed in operation in May its 42,000 h.p. hydro-electric plant on the Chicoutimi River. Power is supplied to the Company's nearby smelter by a one-mile 161 kv. line.

A section of the penstock and powerhouse under construction for Bowater Power Company at Corner Brook, Newfoundland. The two-million dollar project is nearly complete.

The Aluminum Company of Canada proceeded with its development on the Peribonka at Chutes des Passes, which will contain five units at 200,000 h.p. each under a head of 625 feet. The first unit will start service in the autumn of 1959. Two transmission line circuits will tie the station with the Company's present network at Isle Maligne. Work is expected to be essentially completed in 1958 on a project to divert water from Manouan Lake into the Bonard River which empties into the Peribonka.

The Shawinigan Water and Power Company made good progress on its 330,000 h.p. development on the St. Maurice River at Rapide Beaumont. The plant will comprise six 55,000 h.p. turbines under a head of 125 feet, initial operation being scheduled for November 1958, and completion of the six units in 1959.

The James Maclaren Company, which is affiliated with the Maclaren-Quebec Power Company, is building for completion in 1959, a hydro-electric station of 50,000 h.p. on the Lievre River at Dufferin Falls in Buckingham.

The Quebec Department of Hydraulic Resources, through its storage reservoirs, successfully maintained regulation of flow for power production and flood control on a number of important rivers. Extensive repairs to the Gouin Dam on the upper St. Maurice River, to Mercier Dam on the Gatineau River and to the Allard Dam on the St. Francois River at the outlet of Lake St. Francois, will be completed in the near future.

NEW BRUNSWICK

The New Brunswick Electric Power Commission placed on test, in November, the first 45,000 h.p. unit of its Beechwood development on the Saint John River, with the second unit scheduled for completion by January 1958. Provision is made for a third similar unit. Currently under construction at Saint John is a new 50,000 kw. steam plant, to be completed in July 1959.

During the year, the Commission extended its transmission and rural distribution facilities by 279 miles of line of various capacities.

NOVA SCOTIA

The Nova Scotia Power Commission completed in August its Bear River plant, in Annapolis County, with one 5,300 h.p. turbine. A 25,000 h.p. development on the Sissiboo River, in Digby County, is in active prospect and investigations are proceeding with respect to the Commission's proposed Wreck Cove development on Cape Breton Island. Under construction for completion in July 1959 is a 20,000 kw. addition to the Trenton steam plant.

The Nova Scotia Light and Power Company, at its Hemlock Falls plant on the Avon River at Windsor Forks, is installing a 5,000 h.p. unit which, late in 1958, will replace the existing two units of 1,150 h.p. each. Last February the Company dismantled its 360 h.p. plant at Chester. In active prospect is a 6,500 h.p. development on the Mictaux River at Alpena. In the thermal-electric field, the Company completed in October the addition of a 45,000 kw. unit to its Water Street plant in Halifax and is currently adding another similar unit for operation in August 1959.

The Seaboard Power Corporation is currently constructing for operation in September 1959, an additional 16,000 kw. unit to its steam plant in Sydney.

Hamilton River Falls, Labrador, where British Newfoundland Corporation Ltd. has rights to develop 4,000,000 h.p. at a single site.

NEWFOUNDLAND

Maritime Mining Corporation completed in February, on Venams Brook at Green Bay, a 460 h.p. unit operating under a head of 229 feet. In August a 760 h.p. unit, under a head of 241 feet, was installed on Snooks Arm at Green Bay.

The Bowater Power Company is continuing its hydro-electric development on the Corner Brook River where two 6,000 h.p. turbines under a head of 526 feet will start operation early in 1958. In the Grand Lake Watershed two developments are in active prospect; one of 50,000 h.p. on Hinds Brook, the other with a 14,000 h.p. unit on Little Grand Lake.

The Newfoundland Light and Power Company is constructing, for operation late in 1958, a new hydroelectric plant at Rattling Brook near Norris Arm with 17,000 h.p. in two units under a head of 307 feet. Also under construction for late 1958 operation is an additional 20,000 kw. unit at the St. John's steam plant.

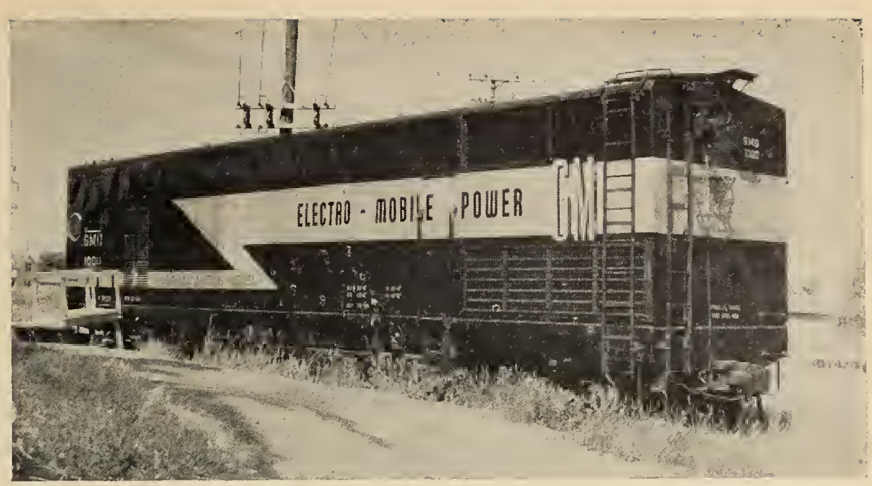
The Union Electric Light and Power Company is expanding its Trinity River Hydro-electric plant near Trinity by the addition of one 2,000 h.p. unit, under a head of 260 feet. Completion is expected in 1958.

The United Towns Electric Company Limited is adding a third unit of 3,600 h.p. capacity to its hydro-

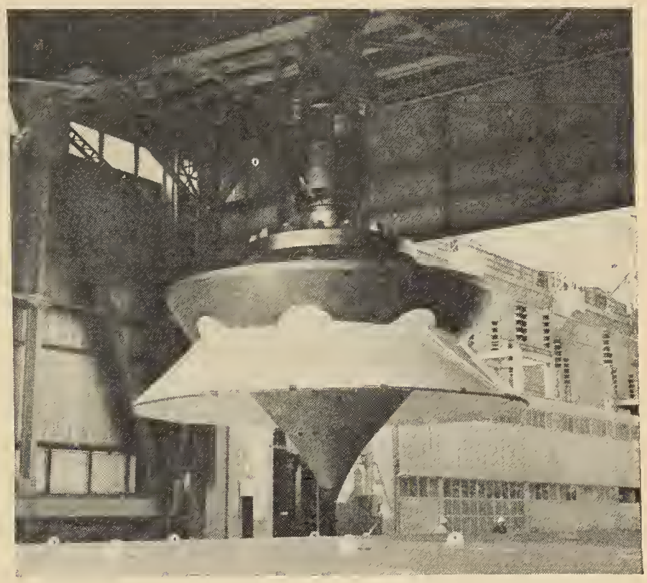
A foot-bridge over the Hamilton River and a 25-ton cable-way, under construction at the left, provide access to the 4-million h.p. Hamilton Falls project.

electric plant at Lookout Brook. The unit, when completed in 1958, will increase total installed capacity of the plant to 7,300 h.p.

The British Newfoundland Corporation is actively considering a hydro-electric development at Bay d'Espoir, where 350,000 h.p. may be developed under a head of about 530 feet. In connection with its proposed Hamilton River site in Labrador, the Corporation completed the all-weather access road from Mile 286 on the Quebec-North Shore and Labrador Railway, to the Hamilton River. The Division of Northern Labrador Affairs reports installation of three 17.5 kw. generators at Nain for public buildings serving the largely Indian and Eskimo population.



A 1000-kw. mobile Diesel-electric unit for emergency use by power utilities.



Variable - pitch blade impeller runner for the Niagara pumping - generating plant of Ontario Hydro. The six impellers will be the largest of the type built.

YUKON AND N.W. TERRITORIES

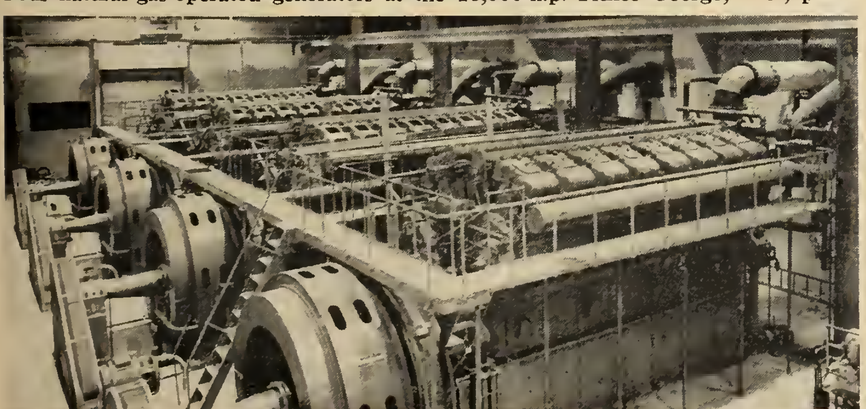
To encourage the development of resources in Northern Canada, the Federal Government established in 1948 the Northern Canada Power Commission, an agency for the construction and management of electric power utilities. Activities of the Commission during 1957 were confined to the Yukon Territory. These included the installation of a second 3,000 h.p. unit at its Mayo River hydro-electric plant, placed in operation in December; also steady progress was made on development of the Whitehorse Rapids project on the Yukon River, where the initial installation is scheduled for completion late in 1958 and will consist of two 7,500 h.p. Kaplan units under a head of 63 feet.

OUTPUT OF ENERGY

The annual D.B.S. Report on Electric Power Statistics for 1956, the latest year for which a full report has been published, shows 859 firms reporting, of which 610 were utilities and 249 were industrial establishments. The former sell most of their production while the latter generate energy for their own plants.

Of the 87.9 billion kilowatt hours generated in 1956, 68.6 billion kwh. or 78.1 per cent was generated by utilities, while 19.3 billion kwh. or 21.9 per cent was generated by industrial establishments. Of total Canadian output 92.6 per cent was provided from water power and 7.4 per cent from thermal stations.

Four natural-gas-operated generators at the 16,000-h.p. Prince George, B.C., plant.



Total ultimate customers equalled 4.43 million, of which 3.83 million were domestic and farm, 0.49 million commercial, and 0.096 million were power customers. About half a million farms in Canada were served with electricity. Average domestic and farm consumption rose 6.9 per cent from 3,500 kwh. in 1955 to 3,740 in 1956. The average annual consumption varied widely however, from a low of 1,348 kwh. in P.E.I. to a high of 5,636 in Manitoba.

Utilities only employed 36,600 persons excluding construction workers in 1956. They showed operating revenue of $789 million, expenses of $489 million, and operating income of $300 million. Net after income tax and deductions was $103 million.

Delegates to the Canadian Electrical Association meeting in June 1957 were told that firm energy requirements had stood at 82.7 billion kilowatt hours for 1956, 11.7 per cent over the previous year. The total was expected to climb to 114.4 billion by 1960, an increase in the four years of 37.6 per cent over 1956. Preliminary reports on total net generation during 1957 indicate that production, though increasing substantially in the first 9 months, had fallen sharply during the last quarter below the same period in 1957 and for the full year had reached a total of 90.25 billion kwh., up 9% over 1956.

SUPPLY AND DEMAND BY REGIONS

British Columbia, spurred by its current industrial expansion, led all provinces in power installed during 1957, with as much again under construction for completion in 1958 or 1959. The province has ample hydro resources for years to come.

Alberta is barely keeping pace with demands, which double every five years. Saskatchewan depends on thermal power and foresees half its power from nuclear sources in another 20 years. Manitoba now relies on thermal power for industrial growth in the southern areas, while developing its northern waterpowers for mining and metallurgical projects.

Ontario will have developed all its economic hydro resources by 1970. This outlook led to decision two years ago to triple the size of the H.E.P.C. thermal station at Toronto, and enlargement is now under way. Three more thermal electric stations are planned. Quebec will meet all its power needs for the next 20 years without the necessity of developing thermal power stations.

Newfoundland, with large but remote water power resources, must look to large extractive industries to develop them. Though Nova Scotia's future needs must be met with thermal plants, New Brunswick is well endowed with hydro resources. The Atlantic Provinces Economic Council has marshalled public support for its effort in awakening realization of what capital and electric power could do in expanding the Maritime economy. Adequate power for normal needs, the Council finds, are at present available. At year end Federal assistance for financing Maritime power developments was an active issue in the House of Commons.

ATOMIC ENERGY

Scientists from all over the world flocked to Chalk River in 1957 to hear what Canada was doing with nuclear energy. They learned about a new type of uranium oxide fuel assembly that had been developed for use in a power reactor. A new design for the active core of a reactor had been evolved, replacing the large pressurized vessels used in U.S. and British nuclear power plants. This design is applicable for use in stations of several hundred thousand kilowatt capacity. The N.P.D. reactor, to be built by Ontario Hydro and A.E.C.L. at Des Joachims, will be changed to this design, and construction may proceed early in 1958.

The modified design also incorporates "on-power" fuelling which has very attractive operating advantages. This change in approach has introduced some delay in the completion date, and inasmuch as NPD-2 will be more representative of the large power reactors required by utilities in future, the benefits justify the change.

Fuelling costs for some nuclear power reactors are already lower than fossil fuel costs for conventional thermo-plants. Achievement of competitive nuclear power requires substantial reduction in the present high capital costs of nuclear plants. With this in view, development work is being done which is directed towards major reductions in capital costs. For instance, the use of an organic material rather than heavy water as a reactor coolant promises great savings through lower pressures and higher temperatures, without attendant corrosion problems. Such development work may well hasten the advent of competitive nuclear power in ratings of 100,000 kilowatts and below, as well as in higher ratings.

Certainly Canada's undesirable position as the largest net importer of fossil fuel in the world would be greatly improved by the reduction of her considerable coal imports from the U.S. and the substitution of her own natural uranium fuel for electric power production. Achievement of competitive nuclear power using natural uranium will also help ensure the continued prosperity of Canada's huge uranium mining developments. The first nuclear power plants built were not expected to produce competitive power; they were built primarily to provide information and 'know-how'. These plants have performed well to date and their subsequent operation will undoubtedly provide much of the data which will allow design engineers to achieve reliability and safety at greatly reduced cost.

Operation of the N.R.U. reactor was started in November. Following preliminary tests, its power output will be raised to 200 million watts. This complicated device, which took six years to build, started operation exactly on schedule. It will provide a wide variety of new information and produce valuable radio-isotopes and plutonium. See *The Engineering Journal*, 1957, August.)

Several A.E.C.L. and Shawinigan Engineering Co. engineers are in Bombay supervising construction of the research reactor which Canada is giving to India under the Colombo Plan.

During the year the group of Canadian Utility engineers who have been at Chalk River completed a study of a full-scale uranium heavy-water nuclear power plant, based on a new conceptual design of using pressurized tubing. Once development costs on one or two large stations have been paid for, subsequent plants should be competitive with coal-fired ones such as the R. L. Hearn Station at Toronto. The recently installed pool test reactor and the beta-ray spectrometer will both enable A.E.C.L. scientists to contribute to the more efficient use of nuclear energy. The 200,000 curies of radio-isotopes shipped last year will be found useful to research, refineries, hospitals, and manufacturers.

Dam and power plant at Whitehorse, N.W.T.

Combining rail and road transport facilities is the 'piggyback' service provided by Canadian railroads. Below is the tallest of the Trans-Canada Telephone System's microwave towers (350 feet) which, at the end of 1957, linked Quebec City and the foothills of the Rockies.

PIPELINES

COMMUNICATION AND TRANSPORT

RECORDS SET in 1956 by The Bell Telephone Company, Canada's largest telephone system were again topped in 1957, in capital expenditures and in local and long distance calls. Telephones installed at 190,000 were down considerably below the 288,000 added in the previous year. A total of 2,960,000 telephones were in service at the end of the year. The list of waiting customers was reduced by 8,000 and stood at 20,000 at year-end. This was indicated in year end reports of the Bell Telephone Co. of Canada, which owns some two-thirds of all telephones in operation, and accounts for 66 per cent of the employment and 70 per cent of the gross revenue received by Canada's fifteen largest telephone systems.

Industry Pattern

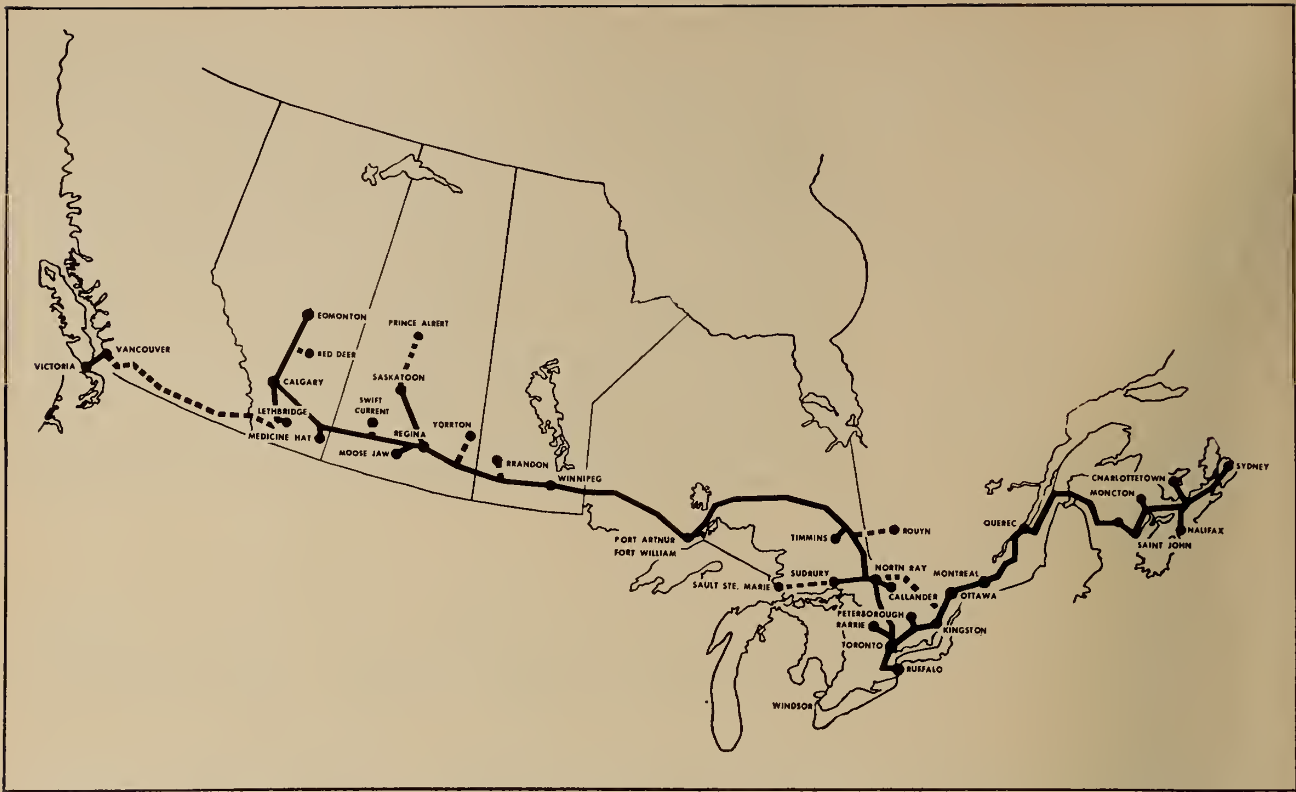
In 1956, the latest year for which full statistics of the industry are available these fifteen largest telephone systems earned 96 per cent of the telephone revenue and operated 92 per cent of the telephones in Canada. These systems operated 4,182,488 telephones, 9 per cent more than in the previous year. Cost of property and equipment at $1,609,138,000 was up 14 per cent and revenues at $397.4 million were up 12 per cent. Net income $53.5 million exceeded that earned in the previous year by 16 per cent. Employees at 58,022 increased 8 per cent and salaries and wages at $188.4 million were up 12 per cent from 1955.

Conversations, estimates of which were only available from 12 systems, increased over 1955 by nearly 13 per cent, numbering 7.44 billion or an average of 1,816 per telephone. Included in this estimate were 163,852,000 completed long distance calls, 7 per cent above the 1955 count.

Bell Telephone Progress in 1957

The use of the telephone for both local and long-distance calling in 1957 again increased substantially. Long distance calls handled showed an increase of almost 8 per cent over 1956. Introduced at Windsor for the first time in 1956, direct dialling by customers of their own long distance calls was extended to Amherstburg and in May 1958 will be introduced in Toronto. Several weeks later it will go into effect in Guelph. Within a few years this service will be steadily widened across the continent.

Acting as agent for the Trans



The telephone and television microwave network of the Trans-Canada Telephone System, including the link between Quebec City and St. John, N.B. opened in February 1958. The dotted routes indicate proposed subsequent extensions to the system.

Canada Telephone System, the Company last year completed construction of the Mid-Canada Early Warning Line. The Trans Canada system is now responsible for maintaining the larger part of the line. Together with other members of the Trans Canada telephone system, Bell is also building a 4,000 mile microwave radio relay network from Sydney to Victoria. The network is now in operation from Quebec City to Calgary, Edmonton, and Lethbridge, while the full network from coast to coast will come into service during the coming summer.

Telephone channels were added to the Toronto-Buffalo microwave link last year, while a new chain is being built between Montreal and New York. A link for T.V. and telephone was built from North Bay to Sudbury. A new dial exchange is being built at Goose Bay. In co-operation with Quebec Telephone a radio-link chain is under construction from Goose Bay to Quebec City via Knob Lake and Sept Iles. Industrial activity in the northern areas of Ontario and Quebec continues to expand, calling for extension of services.

Following approval and Royal Assent last year for permission to increase the Company's capitalization from $500 million to $1 billion, Bell applied to the Board of Transport Commissioners for permission to increase its rates, and its case was being heard at the end of the year.

Telegraph and Cable Systems

Earnings of Canadian telegraph and cable companies continued to advance in 1956, the latest full year for which records are available. A new record was established for that year at $6,784,395 — 9.7 per cent above the previous year. Operating revenues at $40.7 million were 3.6% higher than in 1955. Included in the 1956 totals, however, were results of Canadian operations of the Eastern Telephone and Telegraph Co. for the first time. Comparable figures for the remaining companies showed a 1.4% decline in net operating revenue and an increase in net earnings of only 5%.

Investment in property and equipment by eleven companies at $150 million was 20.6 per cent above that reported by 10 companies the previous year. C.N.T. and C.P.T. showed gains of $6.9 and $4.6 million respectively. Canadian Overseas Telecommunication Corp. almost doubled its investment of the previous year, with an expenditure of $13.5 million partly towards Canada's share of the new transatlantic telephone cable.

Telegrams transmitted during 1956 totalled 20,381,641; a 3.4% increase over those sent in 1955. Cablegrams transmitted at 2,429,893 were 8.6% higher than for 1955. Total pole mileage at 48,067 miles showed little change, though wire mileage at 442,891 was increased by 1%. Employment at 10,833 was decreased slightly but salaries and wages showed an increase of 3.7%.

During 1957, Canadian National Telegraphs established 47,000 miles of carrier telephone and 110,000 miles of carrier telegraph channels to meet the continuing heavy demand for private wire and other related services. Extensive facilities were provided also for government use in defence purposes. C.N.T. also placed in operation tape relay message centres at Moncton, Winnipeg and Vancouver and work was proceeding on a similar installation at Montreal for completion in 1958. These relay centres speed the service and save money in message relay handling.

'Telex' service, inaugurated jointly with Canadian Pacific Telegraphs in 1956 between Canada and overseas countries, was expanded in 1957 to provide service between many larger cities in Canada. Telex provides direct dialing and instantaneous two-way communication by teleprinter, and is receiving excellent response from business organizations.

Overseas Telecommunications

Canadian Overseas Telecommunication Corporation was established in 1950 by the Federal Department of Transport, to maintain and operate in Canada and elsewhere external communication service for the public, by cable, radio telegraph, radio telephone and other means between Canada and any other country, and between Newfoundland and other parts of Canada.

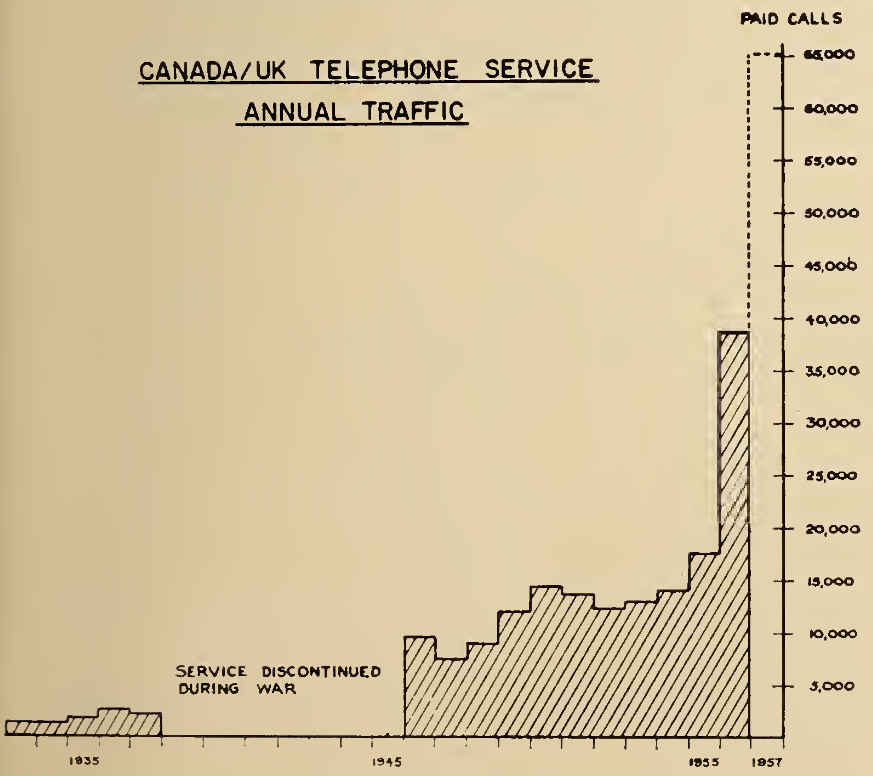
It makes use of all developments in cable and radio transmission and reception for external telecommunication service. Its objectives are improvement of service generally and the co-ordination of Canada's external services with the services of other parts of the Commonwealth. The most important project was Canada's participation in the transatlantic telephone cable, completed in August 1956, at a cost of some $40 million, of which the Corporation's share was some $4 million.

Montreal overseas Telex switchboard.

In December 1956, International Telex was brought into service. It connects teletype service through the Corporation's International Telex switchboard at Montreal, with all parts of Canada via Bell Telephone and Canadian Pacific and Canadian National Telegraphs.

At present, six cable and up to four radio channels are available for transatlantic telephone service, and have been more or less fully taken up since being placed in service in September 1956. Thirty-eight thousand paid calls were made in 1956.

The six Canadian circuits of the transatlantic telephone cable accommodate eleven FM voice frequency telegraph channels plus one pilot. Two teleprinter circuits can be provided on each. It is predicted ultimately four teleprinter circuits can be carried on each channel. International Telex service has increased by leaps and bounds. Commencing with 2 million chargeable minutes in 1947 it had risen to over 72 million chargeable minutes in 1955, and while records of growth since that time are not available there is no doubt rate of expansion has increased greatly.



Engineers predict the future holds little prospect for provision of many new high-frequency international radio circuits, but that a large number of transatlantic coaxial cables with submerged repeaters will take their place. In the telegraph communications field they believe telex will continue to grow and the public telegraph services may cease to operate as a separate system.

Canadian Broadcasting Corporation

The annual report of the C.B.C. for 1956/57, published in July last year, showed capital assets (exclusive of international facilities), less accumulated depreciation, amounting to $21.2 million. Gross income for the fiscal year 1956/57 at $49.3 million was $10.3 million higher than the previous year. Expense at $48.9 million exceeded that of the previous year by some $10 million. Excess of expense over income for the year was $1.56 million vs. $1.36 million in 1955/56. Radio services showed a profit of $202,300, while T.V. services recorded a deficit of $1.76 million.

The reports showed C.B.C. transmission facilities as follows: radio broadcast stations, 22; F.M. stations, 5; shortwave — national service frequencies, 11; low power relay sta-

Transmitting antenna used in tests over the 130 miles between Hamilton and Kinmount, Ont., in a project to develop a new communications system.

tions, 54; television stations, 8. International service was carried on eighteen frequencies with power of 50,000 watts. In addition there were a further 128 private radio stations or 'affiliates' across the nation which carry varying amounts of C.B.C. network service under various arrangements. At the end of the 1956/57 fiscal year the C.B.C. employed 5,939 persons, an increase of 917 over the previous year, mainly due to expansion and development of T.V. service.

National radio service is available to some 97 per cent of the population from all C.B.C. networks, which uses 120 of Canada's 191 radio stations plus 54 low power repeater stations as outlets. The national T.V. service at mid-1958 came within reach of some 86 per cent of Canadians through the T.V. networks, which consisted of 40 stations. Of the four million households in Canada at that time, some 2,490,000 or 62 per cent were equipped with T.V. sets, an increase of 310,000 over the previous year and almost double the number in March 1955. A further 960,000 homes without T.V. sets were within good coverage range. With completion in 1958 of the Cross Canada microwave network a considerable increase in T.V. ownership is expected in the maritime and western provinces.

CIVIL AVIATION

The spectacular 880 per cent growth in Canada's commercial air transport over a ten year period to the end of 1956 was continued throughout most of 1957. Passenger and freight traffic for the first half of the year showed increases over the same period for 1956 of 20 per cent each. During the second half, however, there was evidence of weakening demand on scheduled airlines, giving some cause for concern towards year-end.

Trans Canada Airlines

In spite of this, the full year will show increases of 16 per cent for passenger travel and 10 per cent for air freight on Trans Canada airlines, Canada's "chosen instrument". T.C.A. carries some 80 per cent of the nation's domestic air travel and 25 per cent of its air freight. Air express showed a slight gain while mail traffic continued its impressive growth.

During the year T.C.A. provided the greatest capacity in its history, 19 per cent above that of the previous year. Its fleet at year-end included 32 Viscounts and 18 other turbo-props, 11 Super Constellations, 21 DC-3's, with 13 Viscounts, 20 Vanguards, and several DC-8's on order. The T.C.A. staff numbered 9,800.

Features of the year included inauguration of non-stop transcontinental and transocean flights; new through transcontinental flights via Windsor, raising its tourist-class capacity to 30 per cent of total service offered, and approval of revisions to the Company's fare structure reducing tourist fares to 30 per cent lower than first class fares, effective on January 1, 1958.

Canadian Pacific Airlines

C.P.A., whose domestic air service in Canada is limited to routes of lower traffic density, sought authority in 1956 from the Air Transport Board to operate a competitive domestic transcontinental air service on a new main-line route pattern linking nine Canadian cities between Montreal and Vancouver.

C.P.A. service operates from Vancouver to Mexico and South America, to the South Pacific, to Japan, and via the North Pole to Amsterdam. It serves Mexico City from Montreal and Toronto. A new service to Lisbon and Madrid ex Toronto was inaugurated in May 1957, while in September the South American service was extended to Santiago, Chile.

The C.P.A. fleet at year-end included eight DC6B 'Empress' airliners, with six Bristol 'Britannia' long range turboprops scheduled for delivery in 1958. Placing of a $20 million order for six more 100-passenger Bristol 'Britannias' with a further five under option, highlighted the company's expansion programme last year. With delivery of six 'Britannias' early in 1958, C.P.A. will be the first major airline to operate this world's fastest and largest commercial airliner.

Canadian Airline Operations for 1956

In 1956, the latest year for which complete statistics are available, Canada's six scheduled airlines owned 216 aircraft of various types and leased 17 aircraft. They employed 10,980 persons, carried 2,196,000 passengers, and operated 982.7 million passenger miles and 10.87 freight ton miles. Load factor was 69.2.

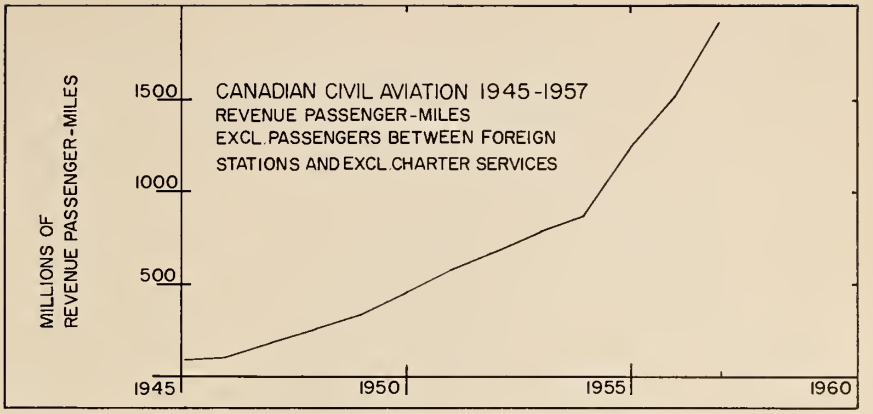
Canadian non-scheduled airlines owned 524 aircraft and leased 45. They employed 2,024 persons. Passengers carried totalled 437,750. Together they operated 4.87 million passenger miles and 237,000 million freight ton miles.

Trans-border services carried 556,600 passengers, operated 192 million passenger miles and 1.59 million freight ton miles. Atlantic and Pacific services carried 126,360 passengers and operated 359 million passenger miles and 6.59 million freight ton miles. Foreign services carried 545,000 passengers and operated 69 million passenger miles and 927 milion freight ton miles.

All the above services together owned 753 aircraft and rented 62. They employed 15,785 persons, carried 3,860,928 passengers, with a load factor of 65.1; operated 1.61 billion passenger miles and 20.2 million freight ton miles. Operating revenue at $180.5 million was 18.2% higher than in the previous year. Revenue for scheduled airlines totalled $145.4 million; revenue for 'non-scheds' totalled $35.1 million. These services transported 3,316,815 revenue passengers — 22% more than in 1955 — and flew 97.9 million miles.

For the six scheduled airlines, number of aircraft owned, millions of miles flown and operating revenue in millions of dollars respectively were as follows: Trans Canada, 66, 29.6, $91.3; Canadian Pacific Airlines, 32, 9.3, $28; Pacific Western Airlines, 53, 7.2, $10.2; Maritime Central Airlines, 25, 5.6, $10.04; Transair, 30, 2.4, $3.11; and Quebecair, 10, 1.66, $2.69.

Total operating revenue for the six scheduled airlines was $145.39 million; total operating expense was $139.73 million; net revenue $5.66 million. Operating revenue for Class B 'non-sched' carriers in domestic services was $32.74 million and expenses $29.65 million, net $2.49 million. Operating revenue for Class C 'non-sched' carriers was $2.4 million, and expenses $2.14 million, leaving net of $89,000.



Ground Facilities and Services

Airport development continued active throughout 1957. A contract for completion of the new terminal building at Dorval costing $8.5 million was awarded in December for completion in September 1959, with steel framework already completed. A $10-million airport expansion project was started at Winnipeg in June, with a building to cost $5 million. A modern terminal building was opened in May at Stephenville. Contracts were awarded in July for an international airport at Edmonton 10 miles south of the city, for completion in 1960. A 10-year $25-million expansion for Malton airport is planned.

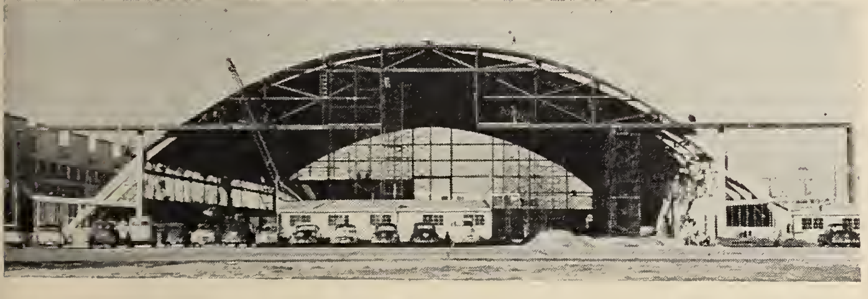
Tenders were called in December for the new Halifax International Terminal at Kelly Lake 20 miles north of the city, for completion in 1959. Tenders will be asked early in 1958 for one of the world's largest, most modern overhaul and maintenance bases at Dorval Airport. This is Trans Canada's new DC8 Jet and Vanguard turboprop headquarters, to cost $20 million. Completion is planned for late 1959. Early in 1958 the Dept. of Transport will take over from the R.C.A.F. the Tofino and Abbotsford Airports for commercial traffic, the latter becoming Vancouver's official alternate.

Medium-range radar installed last April at Dorval permits a continuous flow of aircraft and avoids stacking. Similar units followed for Toronto, Winnipeg, and Vancouver. Ultimately there will be long-range radar at all airports across Canada, with maximum range of 75 miles and up to 15,000 ft. altitude.

But, just as highway construction continues to fall behind the flood of motor vehicle production, airport authorities are being sorely taxed to keep pace with the airlines' efforts to fill the demand for better service with bigger and faster aircraft.

Trans Canada has been authorized by A.T.B. to delete Goose Bay as a point served by Class A scheduled service. The Company has applied for authority to abandon scheduled service to Kapuskasing, Ontario. Pan-American has resumed service between Gander and Shannon. Pre-inspection of U.S. Customs was commenced at Dorval in September. Last year, combined 'family' and 'fly-now-pay-later' plans were producing an astonishing volume of business for C.P.A.'s polar route to Amsterdam.

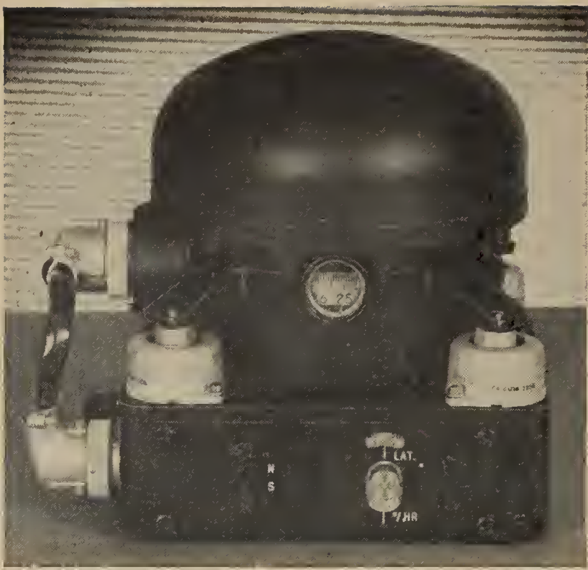
In August Nordair Ltd., successor to Mont Laurier Aviation Ltd. and Boreal Airways, inaugurated a new service from Roberval, Quebec, to Frobisher Bay in the Arctic.



The largest civil aviation hangar in Canada, shown above during construction, was recently completed at Vancouver International Airport. The unobstructed floor space will accommodate two Bristol Britannias. Another development at this airport is the first flight simulator of its kind built in Canada, to train Super DC-6B pilots. A second electronic flight trainer, for the Britannia, will be installed in 1958.

Special Flying Services

Northern operations include aerial surveys, spraying of forests for budworm control, exploration and geo-



A non-floated pattern low-drift gyro produces a random drift of less than ± 1° per hour, allowing precise navigation in polar regions where magnetic references are impossible.

logical air surveying for mineral and petroleum resources, special freight airlifts for construction and mining equipment, transport of uranium concentrates from Port Radium, rescue and mercy flights, and various charter services such as the servicing of radar personnel in the northern radar warning lines. With completion the DEW radar line early last year northern flying operations were curtailed during the winter season 1957/58, but further airlifts for missile detection equipment are expected.

RAILWAY TRANSPORT

Decreasing freight tonnage, lower carloadings, falling gross revenue, rising costs of labour and materials, disappointing net earnings in spite of some rate relief, and gains only in passenger revenue; this in brief describes what the year 1957 brought for the large majority of Canadian railroads.

Although a carryover from the previous year's heavy investment in new machinery and non-residential construction helped to maintain the economy's strength, there was a marked fall-off in residential construction. This, coupled with inventory adjustments in many industries, brought lower car-loadings for a wide range of commodity groups. Grain traffic was sharply lower, revenue freight tonnage for the first months fell some 10 per cent below the same period of 1956 and probably showed a further drop for the full year.

During the year, however, there were many indications of real progress in all phases of railroad activities. Freight and passenger services were improved, several new rail lines were brought into operation to bring rich natural resources to markets, and communications and operating techniques were modernized. Programmes for replacement of steam locomotives with diesel equipment were maintained and many 'Dayliners' placed in service. Several unprofitable passenger services were eliminated and additions made to freight-yard facilities.

Carloadings dipped 8.3 per cent to 4,037,381 from 4,402,831 in 1956 and 4,064,909 in 1955. Receipts from foreign connections were 7% below 1956; grain loadings were down 20%; grain products down 10%; coal down 10%; N. F. ores and concentrates down 9%; cement down 20%; gravel sand and stone down 15%; and L.C.L. down 9%.

Railway Statistics for 1955

In 1955, the most recent year for which statistics are published in full to date for the Canadian National and Canadian Pacific systems (which between them handle 90 per cent of the nation's rail traffic), the following figures were shown. Between them these two systems employed 207,636 persons; salaries and wages paid totalled $753.1 million; mileage of single track totalled 41,417 miles; freight traffic amounted to 72.37 billion ton miles and passenger traffic to 1.81 billion passenger miles; operating revenue amounted to $1,322.4 million. Expenses came to $1,172.9 million, leaving $149.49 million net revenue.

Equipment in Service, 1956

At the end of 1956, all Canada's railroads had 191,974 freight cars, 6,220 cars in passenger service, 90 self-propelled passenger train cars, 19,389 work cars—a total of 217,583 for all cars in service. Cars leased from other roads totalled 3,554. There were 1895 diesel-electric locomotives in service on lines in Canada, and 2849 steam locomotives.

Track mileage operated totalled 59,830 miles. First main track route mileage stood at 43,652 miles, and second track route mileage 2,476 miles. During 1956, 477,184 tons of rail costing $10.3 million were laid; 5,587,297 tons of bituminous coal, 213.4 million gallons of diesel oil, 231.2 million gallons of fuel oil, and 98,724 gallons of gasoline were consumed.

Canadian Pacific Railway

Revenues during the first 10 months of 1957 for the Canadian Pacific declined by some $13.8 million despite some traffic rate relief, freight revenues were down 11.4 million, and revenues other than from freight and passenger service were lower by $3.2 million; rail passenger receipts improved by $800,000 over 1956.

Equipment and Track

During the year, new equipment acquired included 154 diesel units, bringing to 822 the number in service. A further 122 units are on order for delivery in 1958. During the year 232 discarded steam locomotives were scrapped. Also placed in service during the year were 4825 new freight cars of all types. Twelve R.C.D. 'Dayliners' were acquired, bringing the Canadian Pacific fleet to 43 units, which have realized operating economies on low-density runs formerly served by steam trains.

During 1957, 400 miles of new rail and 250 miles of relay rail were laid on main tracks, 1.8 million ties were installed and 525 miles of track reballasted. Installation of centralized traffic control (CTC) system signalling proceeded on the Montreal-Toronto line, with control being located in Toronto. Automatic block signals were installed on the last 26 miles of the Toronto-Sudbury line and on 55 miles between Calgary and Edmonton.

"Piggyback" Started

Inauguration of common-carrier 'Piggyback' service between Montreal and Toronto took place in October, providing for the carriage of highway semi-trailers on specially equipped railway flat cars. This will result in more efficient service to users of transportation, and a considerable expansion of piggyback operation is expected.

Canadian Pacific transport continued to operate a co-ordinated rail-highway service in Western Canada, meeting with increasing success. A new head office and truck terminal were completed in 1957 in Winnipeg, and expansion of the service is continuing.

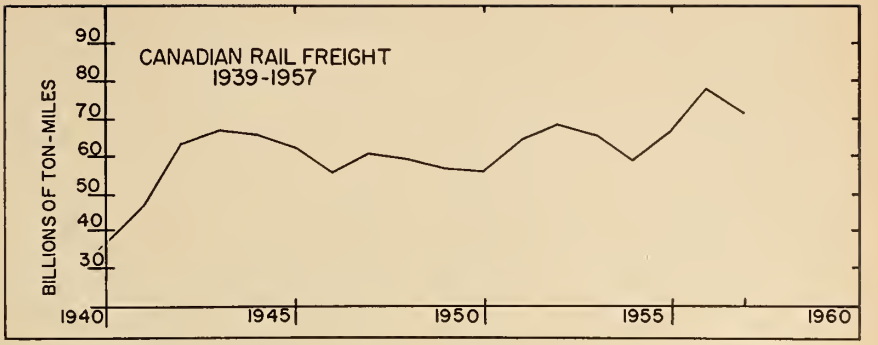
Expansion During 1957

Building projects during 1957 included modernization of passenger station facilities at Calgary, a start on a communications building at Winnipeg and enlargement of diesel servicing shops at Calgary and Montreal. Progress on the 17-storey 400-room extension to the Royal York Hotel at Toronto continued on schedule.

The outstanding development in communications services was the introduction, jointly with Canadian National, of "Telex". This new service enables subscribers to 'dial' others for direct teletype communication. Through it subscribers can communicate with 30,000 subscribers throughout the world.

Electronic Computer

Completion of the essential links in the largest system of advanced integrated data processing in Canada was achieved, with installation of the high-speed electronic computer early in the year. Under this new system information for operating, transportation, traffic, statistical, and accounting purposes is recorded on punched cards or tape at source. Information is transmitted over the company's network for processing on the high-speed electronic computer in Montreal, thence transmitted in processed form to points of use. Source recording is now in operation at 30 points with advanced equipment, and at 34 others using temporary equipment.



Canadian Pacific Steamships

The new 25,500 ton C.P.S. *Empress of England* arrived at Montreal on her maiden voyage in April. Plans were announced for construction of a third and larger White Empress. Yet un-named, this 27,500 ton vessel costing $23 million, will enter the trans-atlantic service in the spring of 1961, and will be the largest vessel of the C.P.S. fleet. It will be air-conditioned and will carry 200 first-class and 875 tourist passengers; it will be built by Vickers Armstrong Ltd. A modernization program for the *Empress of France* planned for the winter 1957-58 will provide C.P.S. with three vessels for weekly service between Britain and Canada.

Inauguration of a steamship cargo service in 1957 between Europe and Great Lakes ports reflects the Company's interest in potentialities of seaway traffic. Two small freighters made five round trips each during the 1957 season between European and Great Lakes ports.

A new diesel maintenance shop at Cote de Liesse, Montreal, for Canadian National Railways, is due to be in operation during 1958.

Canadian National Railways

Revenue freight tonnage on Canadian National Railways during the year showed a decline of 11 million tons or 11 per cent from the record tonnage of 1956. Because most of the drop occurred in low-rated commodities, and because of freight rate increases, freight revenue showed a drop of only some four per cent. If contract demands of non-operating unions costing some $77 million now pending were extended to other employees the total annual wage bill would be increased by about $100 million.

The major decreases were recorded in movement of grain, coal, ores and concentrates, some forest products, and petroleum, while main offsetting increases occurred in fuel oil, other mine products, and manufactured iron and steel articles.

Passenger revenues rose for the third consecutive year, last year by 3½ per cent, due largely to a record movement of immigrants, and to increases in fares last September of 10% for first class and 5% for coach class. In its elimination program of passenger services which resulted in large deficits, the Company discontinued train runs representing an annual saving of 290,000 train miles.

Rate increases continued to lag behind increased costs. An interim general increase of 11% in lieu of the interim 7% increase granted in 1956 was allowed in January by the Board of Transport Commissioners. A further 10% general increase was applied for in the fall. Certain competitive rates were extended to meet increasing highway competition. The Maritime Freight Rate subsidy was upped last spring from 20% to 30%. In October

'Piggyback' rates between Montreal and Toronto were put into effect.

Operations Now 70 Per Cent Diesel

New rolling stock acquired during 1957 included 6,524 freight cars, 100 passenger train units, and 152 units of work equipment. By mid-1958 all train operation on the Atlantic region, in British Columbia and on lines south of the St. Lawrence River will be dieselized. Locomotive deliveries of 144 diesel units in 1958 will make possible dieselization of the Quebec and Alberta districts.

By last September, 70 per cent of all freight traffic on the system was in diesel operation, as was 72 per cent of yard operation, and some 44 per cent of passenger train-miles. Complete dieselization of the Chicago division of Grand Trunk-Western and of the Central Vermont Railway, as well as through passenger service between Montreal and Sarnia, was accomplished during the year. Five each of new dinette and cafeteria car models were put in service on Maritime runs. New R.C.D. 'Dayliners' were placed in service on seven routes from Nova Scotia to Saskatchewan.

Buildings, Yards and Communications

New diesel maintenance shops at Montreal and Edmonton were underway and will be opened for service in 1958. Conversion of motive power shops from steam to diesel-electric repairs was commenced at Moncton, Montreal, and Battle Creek, Mich., and a similar conversion at Winnipeg is planned.

New yard facilities at Battle Creek, Flint, Pontiac, Joffre, and Sarnia will be operation in 1958. Studies on development of major classification yards were centred in Moncton, Montreal, and Winnipeg. At Montreal, grading of the site was commenced for the new hump yard, largest of its kind on the continent, a $3-million order was placed for signalling equipment. The six-year track-improvement program on the Western Region moved ahead on schedule, with widening and ballasting completed on some 300 miles. Opening of the Queen Elizabeth Hotel adjoining the C.N.R. Central Station at Montreal, scheduled for mid-April, 1958, will make Montreal one of the world's largest convention cities.

Other improvements in operating procedures included partial completion of a through teletype service for handling train manifests, car tracing teletype services, and progressive installation of C.T.C. type signalling on the transcontinental line. An advanced IBM type 650 electronic computer was installed at Montreal for computing and production of pay cheques for the entire system and for speed and efficiency of accounting and clerical operations and statistics.

New Railway Construction

The 161-mile westerly arm of the C.N.R. Chibougamau line from Beattyville to Chibougamau was officially opened in November. Grading of the first 66 miles of the easterly arm north-west from St. Felicien was nearly completed and contracts were awarded for the remainder of this arm. A second official opening marked completion by the C.N.R. of a 22-mile branch line from Bartibog to Heath Steele in New Brunswick. Both these branches will transport valuable mineral ores. A 30-mile branch from Sipiwesk on the Hudson Bay line to serve the Moak-Mystery Lake nickel project in northern Manitoba was also opened during the year.

Another $50-million 190-mile railway project will be started early in the summer of 1958 by the Cartier Railway Co., a subsidiary of Quebec Cartier Mining Co., which will open up a new iron ore area. The line, which will run from Shelter Bay on the Gulf of St. Lawrence to the Mt. Reed-Mt. Wright area of northern Quebec, will be ready for shipment of concentrates some time in 1961.

HIGHWAY FREIGHT

Unlike the railroads, which are well established and regulated by the Federal Board of Transport Commissioners, the motor trucking industry comes under jurisdiction of the various provinces. There are ten different sets of motor carrier laws and regulations, one in each province, each with major differences in policy and administration. The principal regulatory items relate to control of entry, rates, licence fees, and permissible gross weights. There is poor enforcement of regulations, even in provinces where control of entry exists. Some planning and co-ordination on a national scale is essential. One brief provincial conference on the subject since delegation of federal powers in 1954, has been held, but it proved abortive.

Since little capital is needed to enter the trucking business, many marginal operators are entering and leaving the industry each year. The large turnover makes the collection of complete and reliable statistics extremely difficult. In co-operation with provincial authorities and trucking associations, the Dominion Bureau of Statistics is steadily improving the records, though much still remains to be done.

In 1955, the latest year for which a full report has been issued, there were 912 larger carriers in the 'over $20,000 revenue' group, which together earn more than 94 per cent of the industry's total revenue, though they comprise only about a third of the firms reporting. These 912 carriers reporting operated 6,572 trucks, 7,047 road tractors, 9,330 semi-trailers, 627 full trailers and 56 buses; a total of 24,423 vehicles. An average of 22,338 employees earned $76.5 million in wages. These carriers handled 24 million tons of freight and 414,000 passengers. Total revenue amounted to $202,266,000, expenses to $192,718,000, and net to $13,548,000.

By comparison, *all* freight carriers, including those earning less than $20,000, totalled 2,681. They operated a total of 26,571 vehicles. They employed 23,518 persons. Total revenue amounted to $220,260,000, total expenses were $203,489,000, and net operating revenue was $16,536,000.

Freight carried by the smaller group, by regions or provinces, in millions of tons, was as follows: Atlantic provinces 0.27; Quebec 3.5; Ontario 9.9; Manitoba 0.6; Saskatchewan 3.2; Alberta 2.9; and B.C. 3.6. Operating revenue for the entire group of 2,681 operators in 1955 was 22 per cent higher than for 1954 and 18 per cent higher than in 1953.

Gordon Commission Report

In November 1956 the Royal Commission on Canada's Economic prospects (the Gordon Commission) issued a report on "Transportation in Canada". Thirty years ago, according to the report, freight traffic in Canada totalling 85.8 billion ton-miles was all handled by rail, water or highway. Railways carried 83.8%, another 16.1% moved by water, while only 0.1% was handled by truck. By 1945, the respective shares of these three carrier systems was 74.1%, 21.4%, and 4%. Less than 0.5% moved by air while 0.5% was handled by pipelines.

By 1953, with total traffic 25% higher at 108.7 billion ton miles, the percentage handled by railways had fallen to 60.5%, while the percentage moving by water fell to 20.1%. Motor trucks however had increased their share to 13.1% while the pipelines took 6.3%. The percentage moving by air showed little change.

The report indicated that railroads had lost considerable ground during the preceding 25 years compared with air, water, and highway transportation. Air and water carriers were the most heavily subsidized transportation agencies at some 22% each. Highway transportation received the smallest government assistance, at some 3 per cent.

Pipelines Gain, Water, Rail, and Truck Traffic Lose

By 1956, according to more recent DBS records, the total freight traffic had increased by a further 22 per cent, to some 133 billion ton miles. Of the total of some 90 billion ton miles carried by rail and truck only, motor carriers handled some 13 per cent. Of the 133 billion ton miles including water, air and pipeline transportation, however, the proportions hauled by railways and trucks had dropped; the share of water haul was slightly higher, while the proportion carried by pipeline had almost doubled.

Sample Surveys

Over the past three years the Dominion Bureau of Statistics, with co-operation of provincial authorities, has undertaken sample surveys on highway transport with a view to obtaining more complete and accurate data. To date, results of these surveys have been published for Ontario and the four western provinces, including volumes of freight carried on both highways and streets. Sample surveys in other provinces are under way. When compared with the tonnage carried in Ontario and Western provinces as shown in the full report of the industry for 1955, these sample surveys showed a greatly increased number of vehicles as well as a much larger tonnage of goods carried.

Advantages of Motor Transport

The rapid development of light industries is one of the main reasons for the growth of motor carrier operations, according to the Gordon Commission Report. Trucks are ideally suited to the movement of shipments over short and medium distances on fast, regular and flexible schedules. This type of transport can provide door to door delivery, can be more economical through lower terminal costs as well as through less rigid requirements for packing and crating.

Another basic reason for its growth is the continuous improvement in Canada's standard of living. Large increases in consumption of fresh fruits and vegetables, meat and milk products require quick delivery from farm to market to reduce spoilage. Local distribution within a 30 mile radius has represented the principal use of privately owned trucks. Companies whose operations are in different localities, each plant performing a specialized operation in manufacture of the end product can readily adjust their production and delivery requirements.

Canada's Railways Try 'Piggyback'

Most of the inter-city motor truck activity is concentrated on routes of between 20 and 600 miles. A large volume of traffic also moves on routes up to 1,500 miles in length, but beyond that point the practicability is doubtful. Development of the "piggyback" hauling of truck trailers on flatcars between Montreal and Toronto by both C.N.R. and C.P.R. systems over the past few years, has met with success, with railways hauling their own trucks.

An extension of "piggy-back" with joint use of it by railways and for-hire motor carriers, as used in the United States on a large scale, gives promise of national advantage if competitive differences of opinion could be reconciled. But there is divided opinion as to the advantages to the railways — one being that the railways earn revenue they would not otherwise obtain, the other being that any short term advantage would over the longer term be outweighed by the loss of competitive traffic.

Haulage Costs on Foods Increasing

According to a study by the Agricultural Marketing Service, U.S. Dept. of Agriculture, a year ago, the transportation bill on retail food had increased nearly fourfold since before World War II. In 1956, eight cents out of every food dollar was paid for transportation. For some commodities the hauls are growing longer as fruits and vegetables come 'in season' in various areas. The number of carlots of fruits and vegetables shipped by truck from Florida increased fourfold between 1946 and 1954. Truck rates tend to go up whenever rail rate increases are allowed. For much of transportation the rail rates are a ceiling below which trucklines want to stay. Sometimes speed is so important that truck service is used even at higher rates than those for rail movement. Similar trends are occurring in Canada.

Current Developments

- In September 1957, the Smith Transport Co. and the Canadian Pacific Railway announced jointly that the latter had an option to purchase majority stock of Smithson's Holdings Ltd., the holding company for Smith Transport and affiliated companies. The Canadian Transport Association will oppose the move. Smith Transport operates 2,000 pieces of equipment over 5,000 miles of roads. Its purchase would put the C.P.R. into operation on 8,000 miles of highway routes.

- The Department of Transport announced last June that it had authorized use of two-way radios on 'for-hire' trucks. This will substantially increase the efficiency of trucking operations.

- At the annual meeting of the Canadian Manufacturers' Association last June, President J. J. Harold of the Quebec Transportation Board pointed out highway transport had been expanding at enormous speed over the past decade. Though expansion brings many problems, he warned, the answer to these problems did not lay in trying to 'drive the trucks off the road'; as industry needed the service.

- Kingsway Transport, Ltd., a subsidiary of Canada Steamship Lines, recently opened a new transport terminal on 25 acres adjoining the Dorval airport near Montreal. It has a capacity for housing 48 trucks at a time. Buildings include a garage, warehouse, head office, and driver's headquarters. Kingsway operates a fleet of 1,150 units, owns 16 terminals along the route between Quebec City and Detroit, Mich. It also operates into New York City.

- For truck drivers, a $250 electronic device is on the market which automatically prints the date, time, mileage and gas level every time the ignition is turned on or off. It also records every time the vehicle exceeds a preset speed. And because of a shortage of trained drivers, a number of trucking companies are training their own men. A course for training the trainers, first of its kind in Canada, is planned by the Ontario Safety League.

"Fishy-Back" Trucking a Possibility

The possibility of a new combination transport service is looming, somewhat similar to the 'piggy-back' highway-rail service now in operation between Toronto and Montreal over the C.P.R. and C.N.R.: It is the 'fishy-back' service proposed by a large highway transport company, whose highway trailers would be loaded on to decks of vessels plying the seaway route.

A recent announcement stated that Kingsway Transports, Ltd., had purchased the medium-size Gossett and Sons Transport Ltd. of Calgary. Kingsway is a wholly owned subsidiary of Canada Steamship Lines Ltd., a Great Lakes and St. Lawrence shipping firm. Gossett Transport owns routes extending from Toronto to Alberta, including the Lakehead.

During the navigation season Kingsway, which operates between Quebec City, New York City and Detroit, would load on to C.S.L. vessels at Quebec, Montreal or other seaway ports for water carriage to Lakehead, while Gossett Transport would pick the trailers up at Lakehead for transport by road across the prairie provinces. The merger and expansion appears to be the nucleus of a huge transport network, with the possibility of a tie-in through B.C. via Canadian Pacific's western trucking operations which it is seeking to expand.

WATER TRANSPORT

For the year 1956, last year for which full statistics are published, Canadian water transportation companies reported a total of 2219 vessels in operation, including 1,728 owner-operated and 491 chartered. An additional 99 Canadian-owned vessels were not in operation. Of the 2,219 vessels in service, 1,043 were in the Pacific division, 692 in the Atlantic division, and 484 in the Inland division which includes the Great Lakes. Whereas 90 per cent of the vessels in the Pacific division are classed as tugs, barges and scows, only about 50 per cent in the Inland and 15 per cent in the Atlantic divisions fall into this category.

Net value of property after depreciation increased in 1956 to $157.9 million, 21% higher than in 1955. Net value rose 24% in the Atlantic division and rose 46% in the Pacific division but declined 2% in the inland division.

During the year vessels of Canadian registry carried a total of 29.3 million short tons or 32.6% of the 89.9 million tons of cargo loaded and unloaded at Canadian ports in international trade. In coastal trade, Canadian vessels carried 34.6 million tons or 89% of the total 39.1 million tons unloaded. Canadian vessels presumably handled in addition, all freight traffic on inland lakes and rivers. Total operating revenue exceeded the previous year by 23.3%, rising to $324.6 million.

A total of 21,261 employees earned wages and salaries amounting to $66.15 million. The number compared with 21,408 employees in 1955. The average wage for vessel crews rose 16.8% to $3,162, while dock and warehouse employees earned an average of $2,596 as against $2,285 the previous year.

For the first nine months of 1957, seaborne cargo both loaded and unloaded was slightly higher than for the same period of 1956, while coastwise cargo unloaded was about 8% lower. Though navigation remained open well into December the trend of loadings and unloadings continued downward for the rest of the year.

Ocean Rates Sharply Lower

Two years ago a very cold winter in the 'low countries' of Europe caused an acute shortage of coal, creating a heavy demand. Long term contracts were filled at high freight rates. Foreign trade generally was brisk. By January 1957 the rate for carrying a ton of coal from America to Europe had skyrocketed to $14.00 and, since coal is the yardstick for other dry cargoes, rates generally followed suit.

With Europe overstocked during the mild 1956/57 winter and production easing slightly, the coal rate began to soften, followed of course by rates for other commodities. The year 1957 saw cut-backs in shipments of iron ore, bauxite, titanium slag, grain, lumber and other commodities. On top of all this, there was an 8 cent per bushel higher price at Pacific ports than for the same grade of wheat at Atlantic ports. Result: no market for Canada's wheat stored at Atlantic ports; wheat cargoes hard to obtain at Vancouver. Total visible Canadian stocks of wheat of all grades stood at 369 million bushels at year's end compared with 352 million at the end of 1956.

A sharp tobogganing of dry cargo rates was inevitable. Shipbuilding had accelerated the previous fall and winter, with yards booked to capacity till 1958/59 for larger, faster vessels. The United States had been releasing 146 Liberty vessels from its mothball fleets. Even the charter hire market for vessels began to be affected, and tramp business fell considerably. By the end of 1957 the coal rate had dropped to less than $4.00 a ton and had not yet reached a levelling off point. Other rates were similarly affected. The outlook for 1958 was discouraging, and many shipowners were tying up tonnage. The Canadian National Steamships' West Indies fleet was lying, strikebound, in Halifax harbour.

More Ports but Worse Ice

New harbours are being opened up on the lower St. Lawrence. At Baie Comeau, Canadian British Aluminium Co. will unload alumina, coke, cryolite, and fluorspar, and load metal, pulp and paper. The Spar Mica Corporation has a new harbour installation at Baie Johann Beetz. Pneumatic unloaders are going in at Baie Comeau and Sept Iles, and a large grain elevator for Baie Comeau is being considered to permit a quicker turn-around for ocean tramps, and to save the 270 mile run to Montreal. Eastern sugar refiners have installed bulk discharging equipment.

Last spring the St. Lawrence and Saguenay rivers were open and remained open, while the Gulf of St. Lawrence was plugged with ice. Many vessels were caught in the ice fields and suffered great damage. Relief for this situation is claimed to be possible through building underwater dams at certain strategic points to direct the currents, but the expense would be very high.

Lake Shipping Shows Drop

In contrast to trends over the past few years, bulk cargo tonnages on the Great Lakes were lower for 1957 at most ports. During the year, 9,147 vessels passed through the Welland Canal, compared with 9,360 for 1956. Tonnage fell to 21,800,000 tons from the 1956 total of 22,200,000 tons. Iron ore shipments on the lakes were shut down in late September. Tonnage through the Cornwall Canal system was down 9% for the year. Loadings at Windsor to end of September were 12% below same period of 1956. Grain handled at Goderich was only 70% of the 1956 tonnage. Tonnage handled at Toronto was 10% lower than 1956.

Several American cities also reported lower tonnages. Cleveland predicted a 30% drop in tonnage handled below the previous year, while the New York State canal system which carries mostly bulk products was running a million tons behind. Chicago however reported higher totals with increases for ore, coal and grain.

Importers and exporters in the Great Lakes areas have been very active on studies of what effect the larger vessels coming into the lakes will mean to their business and how they can prepare for the opening of deep-draught navigation. Though no announcement had yet been made by Canada on possible legislative changes for coastal shipping, a joint decision by Canada and United States governments on the question of Seaway tolls was expected in the spring of 1958.

Maiden voyages into Montreal were made during the year by Cunard's 22,000-ton *Sylvania*, by Canadian Pacific Steamships' *Empress of England*. Other vessels appearing on the St. Lawrence run for the first time in 1956 included Saguenay Shipping's *Sunvictor*, *Roland*, *Sunpalermo*, *Sunny Girl*, and *Suminger*.

Among numerous vessels under construction were included Saguenay Shippings' *Sunhenderson* launched at Hamburg in May; N. M. Patterson & Sons Ltd. flagship *Senator of Canada*, completed in October, the 50,000-t. Imperial Oil tanker, *Imperial Quebec*, launched in August for lake and coastwise traffic, and a new dry bulk cargo carrier of about 16,000 d.w. tonnage and speed of 15 knots, now building at Quebec.

Accepted by Canadian Pacific Steamships in March 1957, the 25,500-ton *Empress of England* saw service during the year. Completely air-conditioned, the ship can carry over 1000 passengers. Double reduction geared turbines provide 30,000 s.h.p.

Shipowners' Association Asks Help

Canadian Shipowners want assistance from the Canadian government to put them on competitive terms with other countries. A Canadian merchant fleet owned and operated by Canadians, should be part of any national development policy.

In a memorandum submitted at year-end to Transport Minister George Hees, they listed the following changes as necessary to remove restrictions and tax regulations that put them at a disadvantage.

(1) An investment allowance allowing full depreciation and 40% of income tax free.

(2) Better depreciation allowance on straight line method instead of diminishing balances.

(3) Capital assistance in modernizing the Canadian fleet.

(4) Subsidy of $5 million to keep Canadian ships registered here, and Canadian-manned.

URBAN TRANSIT

Urban transit statistics for the first 11 months of 1957 indicate that, while the downtrend in passengers carried over the past 12 years was continued during the year, sharpest drops were confined to Atlantic provinces and Manitoba, other provinces showing a loss of less than three per cent compared with 1956.

For Canada as a whole, electric trams carried 11% fewer passengers, trolley buses carried 9% fewer passengers, while buses carried 4% more. Buses now carry almost 54% of the total traffic and the trend towards gas or diesel buses is growing year by year.

Gross revenue for the year showed only a moderate gain of 3% over the previous year, in which the gain over 1955 had almost reached 10%. Only two fare increases, for London and Winnipeg, were recorded.

Three years ago, at the end of 1954, 21 transit properties in Canada owned 2,128 electric trams, 1,144 trolley buses, and 2,348 buses. Today total vehicles operated include 1,447 electric cars, 1,173 trolley coaches, 4,198 buses, and for interurban and sight-seeing operations 3,504 buses.

Outstanding conversion from electric tram to bus operation was the City of Montreal's modernization program, costing $10 million in 1957. With 939 trams, 82 trolley coaches, and 522 buses in 1951, the city now operates 327 trams, 1,469 buses and 82 trolley coaches. During 1958 withdrawal of a further 185 trams and purchase of a further 345 buses is planned.

At the annual convention of the Canadian Transit Association at Winnipeg in June, W. E. P. Duncan was elected president for the year 1957/58. Predicting a 250% increase in urban population and number of automobiles by 1980, he urged a study of possible improvements in transit. President Paul Dittmar of the A.T.A., guest speaker, told members transit had either not yet learned how to merchandise the ride or transit cannot be merchandised. Transit's main efforts, he said, should be public relations, upgrading of services, and mobilization of passengers into political voting forces, for a three-legged program of social acceptance, faster service, and political support.

Transit consultant Wilbur S. Smith urged transit men to work towards a co-ordinated urban transportation system. Traffic-transit integration was one of the greatest needs for a modern city. "Some automobile transportation and some transit transportation are both needed," he pointed out. "Put the two together in the proper proportions for each city. The objective is transportation — not transit alone and not traffic alone."

Interurban and Rural Bus Lines

According to a D.B.S. report issued in September, 183 Canadian intercity carriers had reported for the first 10 months of 1957 a total of 49.6 million passengers carried, down 1.8% from the same period the previous year. Vehicle miles operated were 4% lower than for ten months in 1956. Gross revenue for the ten months at $36.2 million was up 4.8% over the revenue for the first ten months of 1956.

A new type of service appeared last year north of Edmonton, where Canadian Coachways commenced operation with the express-bus — a combination of bus and truck for northern transportation service, to take care of a sharply increased volume of express on a one-way haul. The service will be extended in 1958 as far as Fort St. John and Taylor, B.C.

PIPELINE TRANSPORT

SPECTACULAR OIL development in Western Canada over the past decade, and the success in marketing natural gas over the past two years, have resulted in a record burst of activity in building pipelines. Continuing the record set in 1956 when 776 miles of oil pipelines, 2200 miles of gas mains, and 2,970 miles of distribution lines were built, 1957 construction repeated that of the previous year in expenditure, with some 800 miles of main pipelines for oil, 2,000 main pipelines for natural gas, and 2,300 miles of laterals and distribution lines, laid during the year. The mileages laid on the various systems is shown on the accompanying Table I.

Construction methods have been streamlined in many respects with new types of equipment, especially on pipe welding where the greatest technical advances are taking place each season; unfamiliar types of terrain have taught some contractors new respect for Canadian granite and muskeg. The ability of the domestic manufacturing industry to supply pipe for Canadian projects has been vastly increased by the start-up of a number of large pipe mills. Though 1958 mileage of new main pipeline will not reach the total laid in 1957, the coming year will show great activity in building distribution systems and installing services.

Pipeline Operation

Though statistics regarding the movement of natural gas through Canadian pipelines are not yet recorded on a national basis, preparations are underway to do so by the Dominion Bureau of Statistics. Commencement of deliveries of natural gas, however, by Trans-Canada Pipelines as far as Lakehead, and the opening of Westcoast Transmission's pipeline from the Peace River to serve British Columbia communities, with export of large volumes to Pacific Coast States, no doubt increased total throughput sharply in 1957 over the previous year.

Despite the failure of the oil industry to show the usual sharp gain in annual production in 1957, net deliveries of oil by pipeline for the full year 1957 will show about an eight per cent increase over the previous year. This compares with an increase in net deliveries in 1956 over 1955 of 22.6% and an increase in net income of 51% over 1955.

Total deliveries of oil, including duplication between companies, for the first 10 months of 1957 amounted to slightly over 246 million barrels, 9.6 per cent more than for the same period in 1956. Traffic during the 10 months was divided between pipeline systems as follows, in millions of barrels: Imperial Pipeline Co., 38.7; Interprovincial, 85.2; Montreal Pipeline, 68.6; Trans Mountain, 50.9; Pembina Pipeline, 32.8; and other pipelines (including products and natural gasoline), 407.5.

Operations are being improved constantly with the use of automatic equipment on an accelerated scale, particularly in the realm of automatic custody transfer. Constant experimentation is being applied in the form of finished control mechanisms. The ultimate objective is to eliminate all purely routine manual jobs in order to upgrade every pipeline employee to a position that involves not only higher pay but more job satisfaction and more usefulness to the operating company.

CONSTRUCTION

Bridge at Nine Mile Canyon on Trans Canada Highway in B.C.

THE CONSTRUCTION industry leads all other Canadian industries in the number of persons it employs and in value of production. It has recorded a new high in physical volume of work done for every year since the end of World War II, and today its potential is double that of a decade ago. Some 600,000 full time construction workers receive each year about $2¼ billion in cheques or pay envelopes, or over a third of the value of work done. They install or use new materials and equipment annually worth more than $3¼ billion. The construction program today represents 21½ per cent of the nation's gross national product, compared with 16½ per cent in 1948.

Despite the reported down-trend at year-end in rail traffic, ocean freight, and in production of petroleum, base metals, steel, lumber, motor vehicles, and several other industries, there was little recession talk at the Canadian Construction Association's Annual Meeting in January 1958. The industry may not hope for a new record volume in 1958, but they expect to do as much work as they did in 1957.

But competition has been getting keener, and industry leaders were voicing concern about unrealistic bidding, with too many failures as a result, as well as difficulties for those trying to compete. Bids, they emphasize, should not be so low as to exclude the legitimate profit needed for survival.

1957 Record to be Repeated

In a year-end forecast, C.C.A. president T. N. Carter predicted that construction volume in 1958 would be within a small percentage either way of the record 1957 level of $6.9 billion. Although there would likely be considerable swings in the various sectors of the industry, by and large the outlook for 1958 was favourable. This was due, he said, to the continued general strength of business and the sizeable carry-over of construction work from 1957. But construction figures for 1958 would be somewhat inflated by higher wage rates that in many cases had already been negotiated in long-term wage agreements. Increases in the prices of equipment and some materials were also causing concern.

Though housing completions had fallen off by some 12 per cent last year from the record number built in 1956, the program was on a large scale and the average size of units had increased. There had been an increase in the volume of 'home im-

provement loans and of repairs to existing houses. 'On schedule' progress was made on the Seaway and on other large projects in the news, such as the Westcoast and Trans Canada gas pipelines and several hydro, mining, and petrochemical contracts.

Looking ahead to 1958, Mr. Carter foresaw an increase in highway construction, and a promise of larger municipal and housing construction programs.

Capital expansion for industry and commerce appeared to be dropping somewhat, and there had been a marked decrease in the number of large-scale engineering projects in the $100-million and over class. Companies active in the export market and businesses in general were taking a critical look at the price of new projects, and costs, he warned, must be kept at levels that would continue to attract investors.

How Construction Statistics are Reported

Collection and publication of an annual report relating to the construction industry by the Dominion Bureau of Statistics, due to its size, presents many problems. At or shortly after the end of each year (e.g. 1957) a full preliminary report is published recording work done the previous year (e.g. 1956), or one year late. At the same time an estimate is given of intended construction for the following year (i.e. 1957). This estimate is based mainly on data collected at the same time and from the same sources as that used in 'Private Investments in Canada, Outlook 1957', issued earlier in the year.

The outlook for each coming year in the construction industry, as construction men well know, is a matter of widespread interest to banks, investment houses, to contractors, and to manufacturers and suppliers of steel, lumber, cement, and other building products, as well as of machinery and equipment. The forecast of intended construction, published early each year by the Department of Trade and Commerce, is eagerly awaited. The construction industry is Canada's biggest buyer.

Another barometer carefully watched is the Hugh C. MacLean *Building Report of Contract Awards,* issued monthly. This report gives

Centre Consolidated School under construction at Lunenburg, N.S.

Alberta Government Telephone Bldg., Calgary.

total dollar values of awards in each province, with cumulative 'to date' figures each month compared with awards for the same period the previous year. Because some three-quarters of all construction is carried out by contract, the balance being done with day labour by utilities, manufacturers, mining and logging firms, governments and home owner-builders, this coverage is never complete.

Actually the reported contract awards usually cover somewhat less than half the construction actually carried out, for there is always a 'carry-over' of uncompleted contracts each year. Nevertheless, these monthly reports are useful in indicating the trend.

Reported 'contract awards' in 1957, for example, at $2.89 billion were 15½ per cent lower than awards during the previous year.

Industry Statistics for 1955, 1956, 1957

Values of construction actually performed in 1956, and of intended construction in 1957 are shown in the following tables. Table I shows the value by principal types of construction with percentages of total for each; Table II gives value by industry or sector; Table III gives value by provinces.

In total, construction in 1957 was not expected to be greatly increased over 1956, largely due to an anticipated decline of some $275 million in residential construction. Other categories, however, forecast substantial increases. Largest was expected to occur in electric power construction, with an expected rise of $166 million. Intentions for all other engineering categories showed increases for 1957 except dams and irrigation work.

Contractors continue to account for a greater proportion of construction work each year. In 1953 and 1954 they handled 72 per cent of all work. In 1955 and 1956 they handled 73 and 76 per cent respectively. This trend was apparent in both new and repair construction. Of the 605,772 workers employed in the industry in 1956, contractors employed 409,287; utilities employed 86,266; governments employed 59,590; while others employed 50,579. The trend was expected to continue in 1957.

Table I—Value of Construction Work Performed, by Principal Types of Construction, 1955-1957.

	ACTUAL 1955		ACTUAL 1956		INTENTIONS 1957	
	Value $ million	Per cent of total %	Value $ million	Per cent of total %	Value $ million	Per cent of total %

Gas turbine thermal-electric generating plant under construction at Port Mann, B.C.

Trend to Wintertime Construction

Up to the early 'fifties' annual reports of the industry used to record the total number of workers employed by months. A comparison of the peak monthly employment in the summer with the lowest monthly employment in February or March measured the seasonal swings in employment. In pre-war years winter employment customarily fell to less than half the summer peaks, but with increased volume of construction during war years the seasonal fluctuations became smaller.

Today, with emphasis increasing by industry leaders and the Federal Department of Labour on wintertime construction, the seasonal fluctuation has dropped considerably. During 1950, last year for which monthly employment totals are available, winter employment was 69 per cent of that in the summer peak, and no doubt the trend to smaller fluctuations is continuing.

Shortage of Apprentices

The continuous rise in construction volume in the post-war years has brought about a labour shortage in many of the skilled trades, notably mechanics, plumbers, plasterers, bricklayers and painters. This has posed a problem for the industry and an earnest effort is being made to cure it. But over the past few years only about half the required apprentices were recruited yearly, and the majority were articled in the province of Quebec which has led all other provinces in the establishment of training centres.

Other industries are today overtaking construction in the drive for apprentices. Total registrations in the industry only amounted to 8,224 last year. This total was up 7 per cent over 1956 but still far below requirements. There was a definite increase in the mechanical and electrical trades but registrations in bricklaying, plastering and painting trades were almost nil.

Bell River bridge on the C.N.R. Chibougamau line, Quebec.

Highlights of the 1957 Program

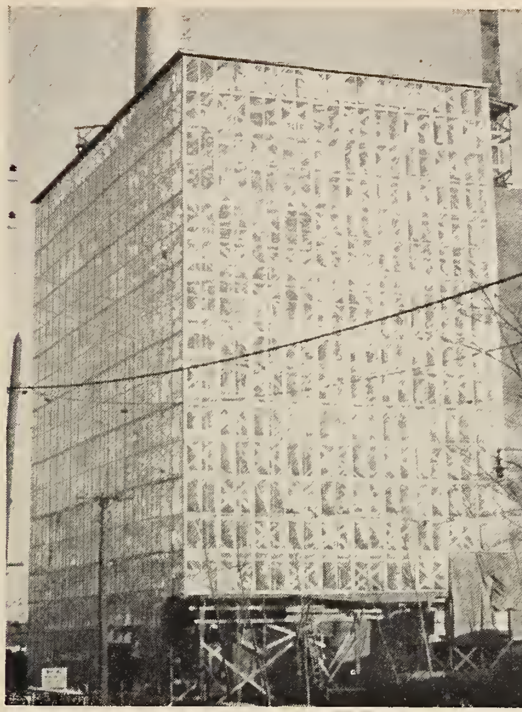
Among the many buildings and other projects which, added together, made up the $7 billion dollars worth of construction accomplished in 1956, there were many worthy of mention, but some of the highlights only can be recorded. Among them were the 650 mile natural gas pipeline from Peace River to Vancouver and Pacific States, and the Trans Canada gas pipeline from Alberta as far as Fort William, with their gathering and distribution lines; extension of the interprovincial crude oil pipeline from Sarnia to Clarkson; the DEW and Mid-Canada radar warning lines; completion of some 90 per cent of the channels and structures for the St. Lawrence Seaway and Power Project; three Canadian National branch railway lines in Quebec, New Brunswick and northern Manitoba totalling 359 miles; two of the reversed flow pumping units at Ontario Hydro's Sir Adam Beck-Niagara station No. 2, and Canadian British Aluminium's $132 million development at Baie Comeau.

Among other completions should be mentioned the Stratford Shakespeare Theatre; the reactor at McMaster University; three new furnaces for the steel industry; replacement of the seaway channel span on the Jacques Cartier Bridge; and many major highway bridges across Canada particularly in British Columbia and New Brunswick (included in expenditure of some $800 million on Canadian highways); over 100 new motels, hospitals costing a total of $136 million, as well as near-completion of the C.N.R. hotel, the "Queen Elizabeth", in Montreal, and of the 'Skyway' high level bridge at Burlington, near Hamilton, Ont.

Seaway Power

The year 1957 was the year of maximum employment on the St. Lawrence Seaway and Power Project, with the labour force on both power and navigation features peaking at some 21,000 persons in the late summer. The good progress for the year was due to good weather, a long open fall, little time lost through

Above. 60,000-kw steam power plant at Wabamun, Alberta, for Calgary Power Limited.



Builder of this Howard Smith Paper Mills Ltd. recovery furnace building at Cornwall, used method of wrapping a specially built falsework in polyethylene film as an aid to winter construction.

strikes, and an easier supply of both materials and labour in the latter half of the year.

On both the American and Canadian halves of the International Powerhouse placing of concrete had reached 95 per cent of completion, with setting of the turbine equipment well advanced and installation of generators progressing. Dikes on both sides of the river were completed. Moving of houses to new locations outside the flooded area, building of new dwellings, shopping centres, and services for them, were substantially completed.

On the American side, both the Long Sault and Iroquois dams were complete excepting for closing of sluices and cleaning up. Clearing of the park areas on both sides of the river was completed and demolition of houses will continue throughout the winter. Improvement of channels upstream from the powerhouse, a joint Canadian and American effort, though not all completed, will not retard the raising of water in the headpond next July.

Navigation Channels and Locks

At year's end S.L.S.A. president, Charles Gavsie, announced that "work on the Canadian navigation channels, locks and bridges was three quarters completed, with work progressing satisfactorily. A total of 125 contracts worth $235 million had been awarded and 29 of them were finished".

Dredging on the Canadian channels was 56 per cent completed; dry excavation was 78 per cent done, while the Iroquois lock was tested and opened for navigation in November. All concrete had been placed for the Côte St. Catherine and St. Lambert locks, while at the Upper and Lower Beauharnois locks concrete placing would be completed early in 1958. Installation of gates and machinery was under way at the Côte St. Catherine and St. Lambert locks.

Erection of lift spans over the Seaway channel was proceeding at the Victoria rail and highway bridge and erection of one temporary span over the channel on the C.P.R. rail bridge at Lachine made possible an early start on diversion of rail traffic while the new main line twin lift spans were erected over the channel. Steel erection on new highway bridge piers at the south end of Mercier bridge was started, while jacking up of the superstructure over the south half of Jacques Cartier bridge continued, following insertion of the new through-span over the Seaway channel early in October.

On the American side, with the Long Sault canal completed and all concrete placed on the Eisenhower and Grasse River locks, gate and machinery installation was under way. Dredging of three sections of the South Cornwall Channel was nearly half completed, with two further sections not started.

Little Slackening Seen for 1958

Looking ahead to 1958 and beyond, besides the substantial carryovers on seaway, highways, pipelines, micro-wave lines, gas distribution lines, steel mills, and many hydroelectric and thermo-electric power stations, there will be two nuclear reactors to build; national defence projects costing some $1½ billion plus a carryover of $54 million; hotel extensions and modernizations costing some $40 million; school construction valued at some $180 million; hospital construction costing $150 million; and motels, several millions; as well as the C.N.R. 'Place Ville Marie' development in Montreal costing $40 million.

There are several large airport projects to be awarded to accommodate scheduled air lines, and for four large jet-tanker airports in the far north, as well as another iron-ore railway in Ungava. Some sixty shopping centres are proposed for completion over the next three years costing $60 million each year. In 1958 alone it is estimated some $150 million will be spent on heating and air conditioning. Close to $900 million will be the annual outlay on highways in the future. Canada's universities are embarking on a 10-year $150/$200 million boom due to the expected 100 per cent increase in enrolments. New awards for Defence Construction will add another $100 million.

There is little likelihood of any cutback in Federal public works during 1958. Beside completions already noted, public works already awarded and under way include buildings valued at a total of some $65 million and wharves valued at $8 million.

Roads and Bridges

In the year 1957 an all time record was again established for expenditure on Canadian highways. The total outlay by ten provinces, by municipalities and by the Federal government will amount to some $861 million by the end of the fiscal year, March 31st, 1958. This is 20 per cent higher than the $722 million budgeted for fiscal year 1956. Due to higher prices, however, the increase in the physical volume of work done will be nearer to 15 per cent over 1956. The total value in 1957 represented a four-fold increase in highway expenditure over that of the first postwar year of 1946, eleven years ago.

A breakdown at various government levels reveals that provincial budgets had called for 1957 expenditures totalling $604 million—70% of the total and 24% higher than in 1956; federal budget at $71 million was 14% above 1956, while municipal budgets at $167 million were up 9% above 1956.

Per capita expenditures for highways in the various provinces during the year 1956 had shown Alberta and British Columbia leading with $51 and $50 respectively; Nova Scotia spent $47 per capita; Ontario $45; New Brunswick $43; Prince Edward Island $40; Saskatchewan $38; Manitoba $28; Newfoundland $27; and Quebec $26.

Roads Roundup

Each year at the Canadian Good Roads Association Convention a 'Roads Roundup' is held, at which provinces report their highway construction during the current year. These reports were published on page 1895 of the December 1957 issue of

The Engineering Journal. Unfortunately the method of reporting by provinces varies widely and a summary of progress on miles of grading, paving, and on structures for the whole of Canada is not possible.

The Trans Canada highway at year-end was completed west of the province of Quebec except for gaps of 100 miles in B.C., some 50 miles in Manitoba, and 160 miles in Northwestern Ontario. Of the 4,470 miles of T.C.H., 1,709 had been paved at year-end and 2,435 had been graded. Only 200 miles of the total presented any driving problems. British Columbia reported heavy rock work; Alberta, Nova Scotia, and New Brunswick recorded completion of one and three major bridges respectively, while some 90 major bridge projects were under construction across the nation, most of them in Alberta, New Brunswick, and Nova Scotia.

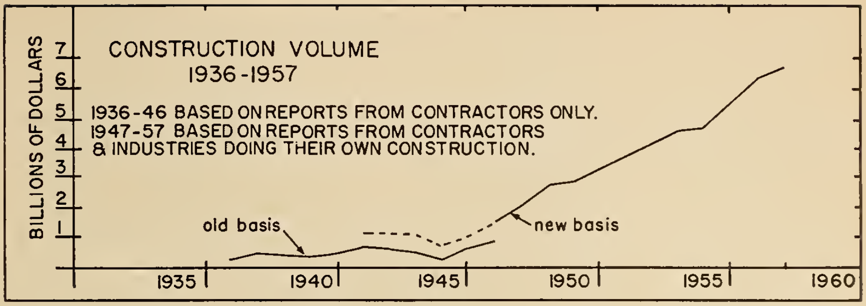
Every year since the end of World War II, while paved road mileage has been increasing steadily, the number of automobiles and trucks has been increasing even more rapidly. According to the C.G.R.A., motor vehicles travelled 38.8 billion vehicle miles in 1956, compared with 34.9 billion vehicle miles in the previous year. Ontario vehicles travelled 14.8 billion miles, Quebec vehicles did 9 billion miles of travel, while B.C. vehicles travelled 3.8 billion miles.

Thus a substantial backlog of roads still exists. However, with the reduced number of automobiles sold during 1957 and the possibility of still lower sales in 1958, as well as the likelihood of more expenditure on highways, the ratio of vehicles per mile may be in for a temporary levelling-off or down-turn.

According to the Gordon Commission Report, however, any lightening in the pressure of road traffic seems a forlorn hope. C.G.R.A.'s managing director, C. W. Gilchrist, foresees that, with the prospect of annual sales of over a million vehicles by 1975, traffic is expected to double and there is little prospect of any reversal of the steady upward trend in highway rebuilding and modernization.

Materials Outlook

Structural steel supply will be easier in 1958. Production of heavy structurals and plate increased about 20 per cent last year, while demand has levelled off. Fabricators will be able to take care of all orders with normal deliveries if large orders are placed 2 to 3 months ahead.



Though domestic lumber consumption was down last year, steady progress in both production and technology was seen in 1957 for the laminated timber construction industry. Total dollar volume was more than 53% greater than in 1956. Greatest increase was in the field of industrial building, in which laminated construction was more than three times that of 1956.

The precast concrete industry may exceed its 1957 production, valued at some $25 million, during the coming year by 25 per cent. While curtain wall panels, channel roof slabs, and bridge beams make up the 'bread-and-butter' orders for the industry, other uses are growing. Cement capacity will be adequate for demand. In the clay products industry, brick and tile manufacturers are in the midst of an expansion program for new plants and modernization of older plants, which will increase capacity.

Capital Investment Forecast, 1958/59

A forecast of capital investment for 1958-59, recently released by the Department of Trade and Commerce, predicts an expenditure of $8.5 billion, just short of the record of $8.7 billion set for 1957. Key feature of the forecast is an expected resurgence in construction activity, led by heavier outlays for housing, universities and hospitals, plus increased expenditures at all government levels. Total outlays for construction are expected to reach $5.99 billion, compared with the $5.92 billion forecast for last year. While the overall volume of capital spending may be slightly below last year, the anticipated decline will be wholly in machinery purchases, about 50 per cent of which are normally imported.

Trends

The engineer, the architect, and the constructor must all be alert to new trends in methods and materials. On 'engineering' projects, for example, drilling of rock by the jet-piercing method, erection of high concrete structures by the Swedish slip-form method, and a swing toward the use of open-air generators in hydro power construction even in cold climates, have gained popularity over the last year or two. More and more materials are being handled mechanically as labour rates continue to advance.

But it is in building construction that most of the changes appear, as twentieth century architecture replaces the last century's massive 'sculptural' appearance by the "new look" of geometric simplicity. Today's window-walled 'glass houses' are attaining wide acceptance and popularity.

Adjoining Canadian and American powerhouses on the St. Lawrence River, will have a combined capacity of 1.64 million kilowatts.

the precast concrete field is the hollow floor slab for use as raceways for the installation of services. It makes for fluid floor-planning of offices, and its fire resistant qualities more than meet the most exacting demands of fire-rating boards.

The lift slab method of building construction was patented in the U.S. and over a million dollars was spent in developing it. Sets of hydraulically operated jacks mounted on the columns and synchronized manually or automatically, maintain the level of the slab to within ½ inch. It is not a new design but a new method. The whole idea was unique only in that floors and roofs are poured on the ground and then lifted in place. Formwork and shores are eliminated as well as plastered or hung ceilings. There is great economy in working on the ground.

Heating and air-conditioning systems are being inter-related more closely than ever before. Radiant heating is popular for schools and institutions. Aluminum and glass panels, electrically-heated, are gaining in popularity. Radiant cooling is still something for the future though some pilot installations have been made in city skyscrapers.

Forced hot-water installations are still the choice for most commercial and office buildings. Industrial buildings on the other hand, favor low pressure steam heating. For either steam or hot water few new products are in greater current demand than the packaged unit boiler.

A newer and more startling innovation in the heating and air conditioning field is the 'air-door'.

Floodlighting of buildings is increasing in popularity. One immediate reason has been the recent development of higher-output fluorescent lamps which operate at 13 watts per foot, giving one-third more light and using the rapid-start rather than the instant-start principle. Reflector type incandescent lamps are also coming into greater use. Outstanding examples have been the $154,000 contract for floodlighting Niagara Falls, and the floodlighting of the Parliament Buildings at Ottawa.

Table III—Values of Construction, 1955-56-57, by Provinces (in thousands of dollars).

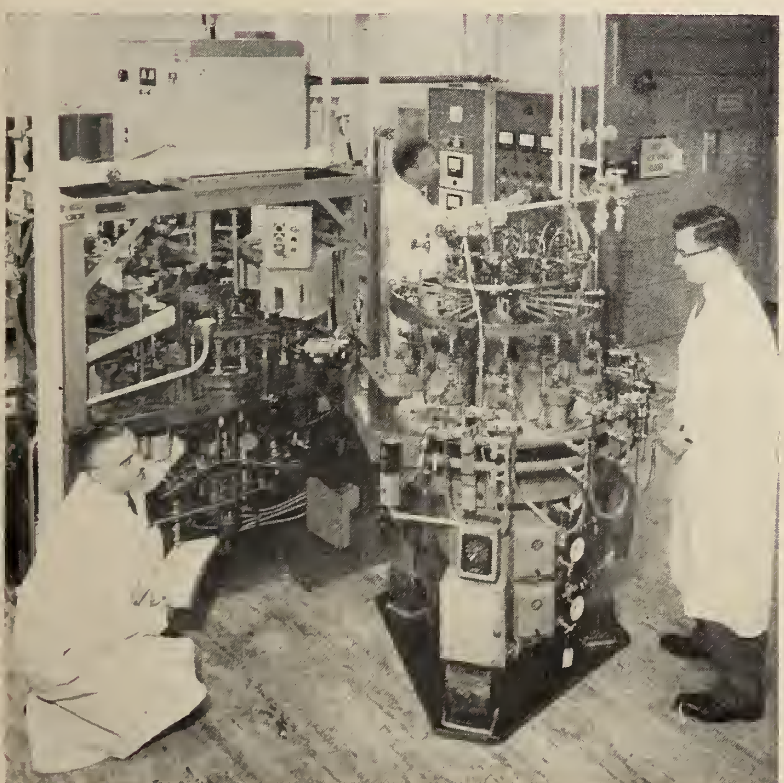
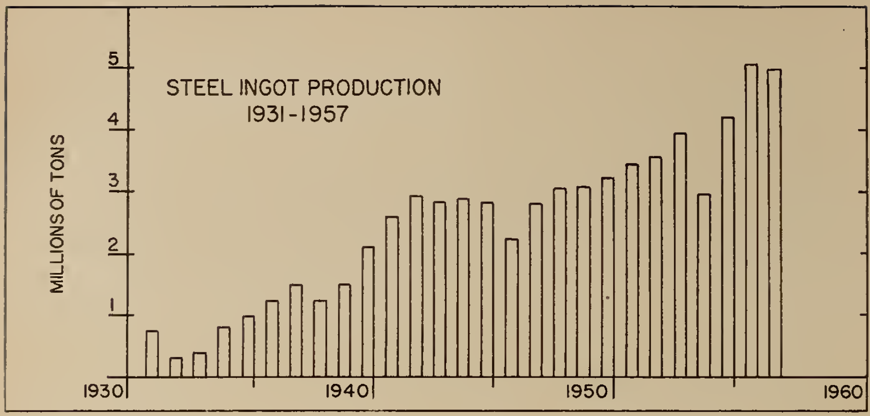
Piers for the substructure of the new high-level bridge across the St. Lawrence between Cornwall Island and Rooseveltown, N.Y.

A contrast in industrial products is afforded by the illustrations on this page of a hydro-electric hub casting, and the sealing and exhausting of electronic tubes in a controlled atmosphere.

INDUSTRIAL PRODUCTION





IRON AND STEEL

Canada's primary steel production for the full year of 1957, at some 4.92 million tons of ingots showed a decrease of 5 per cent compared with the record level of 5.18 million tons established in 1956. Production for the year averaged 89.5% of capacity. Production of pig iron at 3.72 million tons, however, recorded a gain of 4% over the previous year. The decline in ingot output was first noticeable in the second quarter, but became more pronounced during the last quarter of 1957. At year end, however, the production rate was lower than for any year since 1954, with operation at 80% of capacity.

The Steel Company of Canada is the leading producer in the industry, with some 40% of total ingot capacity. Algoma is in second place with about 19.3% of capacity, followed by Dominion Iron and Steel, The Dominion Foundries and Steel group, and Atlas Steels, in that order.

Although Canadian ingot capacity has expanded rapidly over the past four years, little further capacity was added during 1957. However, Algoma continued with the installation of oxygen steel-making equipment similar to that of Dofasco, where continuing success of its process is of wide interest to steel-makers. Dosco added a 250-ton tilting open-hearth furnace. Dominion Foundries and Steel added two new blast furnaces. Stelco added a new blooming mill, while Atlas Steels continued on its $12 million expansion plan with an expenditure of some $4 million on buildings.

In recent years Canada's primary iron and steel industry has expanded more rapidly than that of any other major nation. Sixteen blast furnaces at the end of 1956 had a combined rated annual capacity of 4.22 million tons of pig iron. Steel furnace capacity was rated at 5.81 million tons, five per cent over the capacity at the end of the previous year. Of the 124 furnaces, 82 were electric furnaces whose combined capacity was 16½% of the total. Ingot capacity of 5.47 million tons was 88% from basic open hearth furnaces (including oxygen vessels) while the remaining 12% was from electric furnaces. Capacity for steel castings was 343,150 tons.

The Industry in 1956

In 1956, the last year for which full statistics are available, 48 firms were included in the industry and reports came from 63 plants or departments including 5 blast furnace departments, 4 ferro-alloy plants, 38 steel furnace divisions, and 16 rolling or drawing mills. The industry employed a total of 36,043 persons, divided as follows: 25,654 in Ontario; 4,366 in Nova Scotia; 4,273 in Quebec; and 1,750 in Manitoba, Alberta, and British Columbia. Total salaries and wages amounted to $162.9 million. Materials used in processes cost $301.3 million.

Factory sales of pig iron, ferroalloys, ingots and castings at $680.9 million were 29.4% higher than 1955. Eighteen plants in Ontario accounted for 78.1% of the total, fifteen plants in Quebec accounted for 10.6%, three plants in Nova Scotia accounted for 7.5%, while the remaining 3.8% was accounted for by 14 plants in Manitoba, Alberta and B.C.

Pig Iron

Output of 3,568,200 net tons of pig iron in 1956 was 11% higher than in the previous year. Production of basic iron amounted to 2.99 million tons or 83.8% of the total, while foundry iron amounted to 150,354 tons and malleable iron to 427,627 tons. Producers sales of pig iron totalled 649,213 tons. Charges to iron blast furnaces included 4.67 million tons of crude iron ore, 1.85 million tons of beneficiated iron ore, 3.05 million tons of coke, and 1.09 million tons of limestone. Imports of pig iron totalled 12,637 tons and exports totalled 257,627 tons. Apparent consumption in Canada amounted to 3.35 million tons.

Ferro-Alloys

Ferro-alloys were produced by 10 establishments, 5 of which recovered ferrosilicon as a by-product. Output for the year at 240,480 tons was 26.7% higher than in 1955. Altogether ferrosilicon was made in nine plants, ferrochrome cilicon in two, ferromanganese in one, silicomanganese in one, speigeleisen in two, and ferrophosphorus in one.

Steel Ingots and Castings

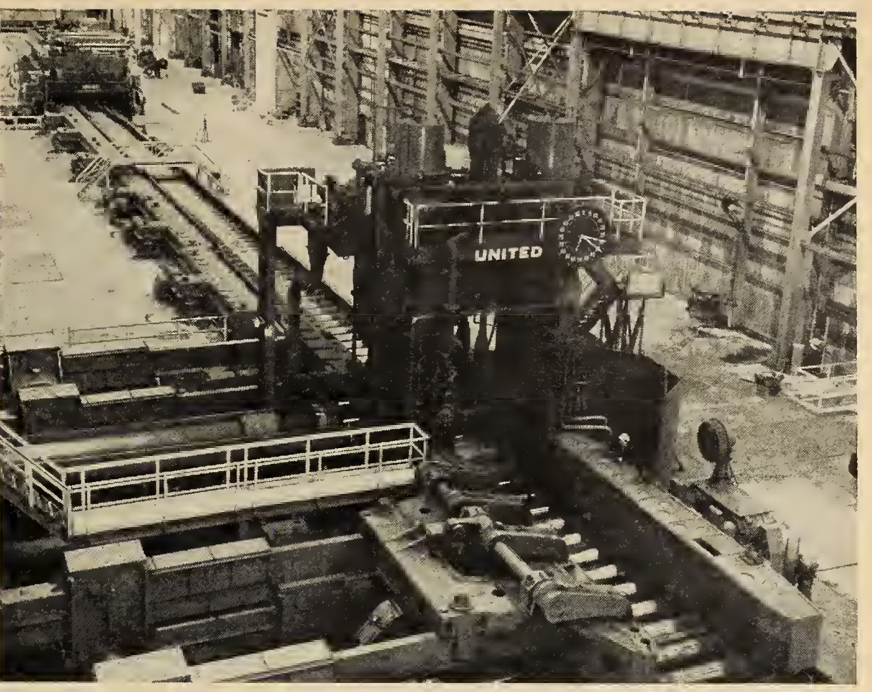
Steel production in 1956 at 5.3 million tons was 169% higher than in 1955. Of the total, steel ingots amounted to 5.18 million tons and castings to 120,781 tons worth $55.33 million. The thirty-eight steel plants in operation used 2.9 million net tons

This ore bridge has a capacity of 17 tons and can unload ore and coal boats at a rate of 1200 tons an hour.

of pig iron, 2.86 million tons of scrap iron or steel, 472,476 tons of iron ore, 232,065 tons of limestone, 202,352 tons of dolomite, 147,911 tons of lime, 138,763 tons of silica sand, 10,784 tons of magnesite, and 67,123 tons of ferro alloys.

Rolled or Drawn Steel

There were 13 mills occupied chiefly in hot-rolling of steel products and 3 mills making only cold-drawn or cold-rolled shapes. Nine mills were in Ontario, two in Nova Scotia, two in Quebec and one each in Manitoba, Alberta, and B.C. Rolling mill sales at $545.5 million were 30% higher than in 1955. Values of main items sold during the year were: hot-rolled bars, $112.3 million; plates, $36.9 million; rails and fastenings, $45.6 million; blooms, billets, etc., $20.6 million; structural shapes, $36.4 million; wire rods, $42.6 million; cold-rolled strip, $14 million; skelp, $35.3 million; and other rolled products, $177.9 million.



The new bloom mill at the Steel Company of Canada plant in Hamilton was nearing completion at the end of 1957. During the year, ore dock facilities were extended, a new pumphouse, continuous pickle line, and roll shop were completed, and other major works were in progress.

Mostly Domestic Market—Exports Small

Canada's steel production is geared almost wholly to the domestic market. Export of primary steel or steel products comprise a small proportion of total output. Most manufacturing industries and many of the primary and service industries are buyers of steel.

Large tonnages of steel are used in production of consumer durables — stoves, refrigerators, automobiles, and the like. An extensive variety and quantity of steel goes into capital goods — buildings, bridges, housing, factory buildings. When these industries are busy the steel industry is also busy. Any important reduction in the operations of these consumers is immediately reflected in steel output.

Consumption of Carbon and Alloy Steel

End disposal during 1956 of carbon and alloy steel products to various destinations and industries, in thousands of net tons and in order of importance, was as follows: building construction, 680; pipes and tubes, 464; railway operation, 404; merchant trade, 382; wholesalers and warehouses, 363; containers, 298; machinery and tools, 229; exports, 212; automotive industry, 199; railway rolling stock, 187; pressing, forming and stamping, 164; mining and lumbering, 92; agricultural, 78; public works and utilities, 40; shipbuilding, 34; miscellaneous, 7; and national defence, 5.

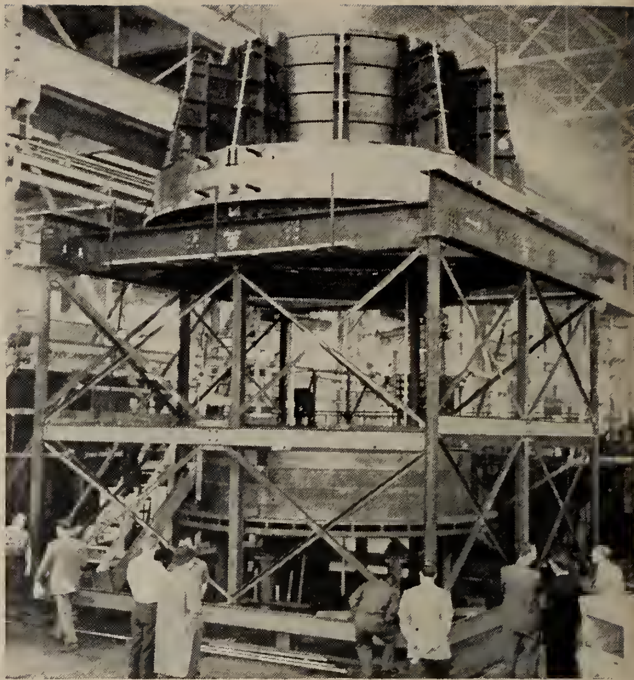
Preparing to complete a pour of 200,000 pounds of steel for a large casting.

The Threat of Foreign Competition

World steel capacity has been growing steadily since World War II. Damaged plants in Europe, the U.K., and Japan have been replaced with the most modern equipment. Low wage rates enable steel producers outside America to manufacture products at costs well below Canada's. The advantage that Canada once had in terms of up-to-date plants has largely disappeared. Nor have governments seen fit to bring up to date the provisions of Canadian customs tariffs, designed half a century ago at a time when steel capacity was less than 15 per cent of the present level.

Today the Canadian steel industry is equipped to produce most of Canada's steel needs. Heavy structural beams and other steel products, now imported, could be made in Canada if adequate and equitable tariff protection were provided. The Canadian market is customarily invaded by British and European producers at times when their own markets are soft. When shortages develop in their home markets or when higher prices are available elsewhere, the competition vanishes, leaving Canadian mills to cope with increased demand.

World oversupply of steel products today makes Canada most vulnerable to active and low-priced competition from overseas, that cannot be met if we are to maintain our standard of living and a high degree of employment.



The steel fabricating industry has a new customer in the nuclear power field. Here are pile core components of the Canada-India reactor.

Steel's Future As Seen by Ontario Research Foundation

The most striking development in the past three years was not in the field of iron and steel production, according to Director P. E. Cavanagh of the Ontario Research Foundation. It came in the field of discovery, promotion and development of iron ore deposits. The use of new exploration techniques, combined with the proof that low grade deposits can be worked to produce a profitable marketable product, more attractive as blast furnace feed than average direct-shipping American ore, has had a great impact on Canada's future as an iron-ore producing nation.

Much research and development now going on will develop processes suitable for partially processing ore into metallic melting stock before it is exported. The availabilty of reasonably priced natural gas in Northern Ontario and British Columbia can radically change the economics of iron mining and processing. Work is proceeding rapidly on special processes to take advantage of the combination of natural gas and concentrated iron ore for turning an uneconomic deposit into a profitable operation.

Production of steel melting stock from rich concentrates and natural gas is one of the most interesting possibilities. It offers the chances of operating on a small but profitable scale (marketing a $60 product in place of a $15 product) and it eliminates the need of very high concentrates for sale on the open market to blast furnace operators, when slightly lower grades might be smelted profitably at the mine into melting stock, he observed.

Under Canadian conditions and for certain types of steel products the installation of the oxygen process is more profitable than installation of the standard open hearth for making steel. Commercial use of continuous casting and a hot planetary rolling mill to make specialty steels at Atlas is demonstrating the profitable fields for the combined application of these methods for the first time.

A 123½-ft. process tower for the chemical industry—a large platework product.

Trends in Investment and in Consumption

In most postwar years, the rate of growth of investment in steel has far outstripped the rate of investment in total manufacturing facilities. The Canadian primary iron and steel industry in the ten years 1948-1957 spent some $411 million on new plant and equipment. Of equal significance was the contrast in percentage of profits retained for expansion —41% for steel, 31% for all corporations, as against the percentage paid out for dividends, 16% for steel, 24% for all corporations.

Compared with the 'thirties' Canada made a greater advance than any other important country in *per capita* steel consumption by the early 'fifties', and ranked second to United States among all nations in the world. But by 1955 our *per capita* consumption had fallen off a little, while it was increasing in nearly every other country. The U.K., West Germany, Sweden and Australia had all moved ahead of Canada.

Is Steel Industry Too Cautious in Expanding?

A study of the future for the steel industry of Canada, prepared for the Gordon Commission on Canada's Economic Prospects, estimates that by 1980 Canada's annual steel consumption will be between 14 and 16 million tons, a 300% increase over the present rate. Production will be between 12 and 14 million tons, against a little over three million in the early 'fifties'—a 200% increase.

The cost of additional facilities needed might reach $2 billion with present processes, but new processes, such as oxygen sponge iron and continuous castings may well cut this cost per ton of capacity quite sharply —perhaps 50% in some cases. Growth of this sort is needed if Canada is to maintain the expansion and prosperity achieved in the past decade, for steel remains the foundation of an industrial economy.

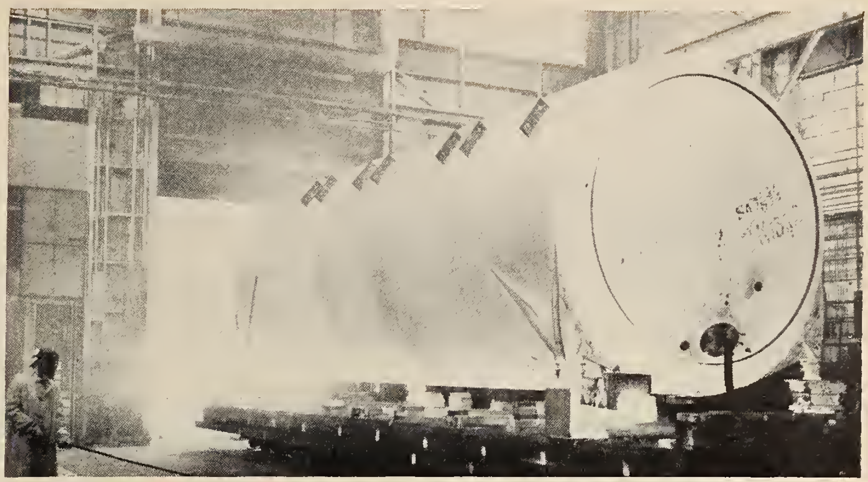
IRON CASTINGS

Production of iron castings, pipes and fittings in 1957 at 743,716 tons was 17% lower than production for the previous year. Shipments at 583,420 tons were 10½% lower than in the previous year. The biggest decrease occurred in cast iron water pipe and fittings, which showed a drop of some 29%. This drop was due to curtailment of municipal expansion plans because of tight credit. Pig iron used at 298,173 tons and scrap at some 600,000 tons were both some 16½% lower than in the previous year.

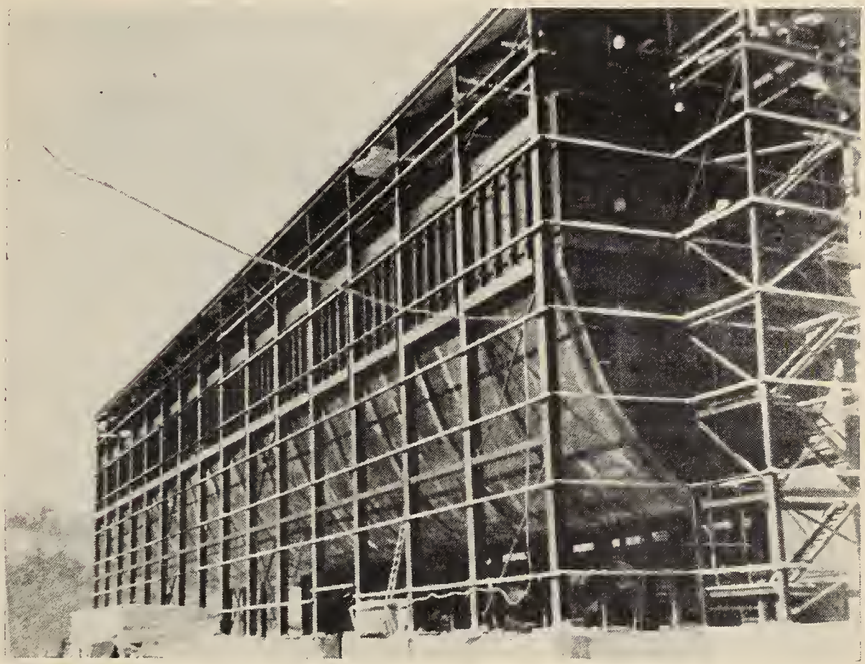
The industry covers operations of iron and steel works which were chiefly occupied in making commercial iron castings or iron and steel pipe and tubing. Some machinery boilers, engines, stoves and furnaces, etc., were made as secondary or minor products. Some iron foundries have not been included in the Iron Castings Industry, but are classified to other special groups such as manufacturers of agricultural implements, stoves, etc.

The year 1957 was marked by a continued rise in production and shipments of alloyed irons. Production of ductile iron rose 61% and production of 'Ni-hard' increased 38% in the first half of the year. For cast iron pipe a new type of slip-on joint was introduced, using a rubber sealing ring instead of bolts and glands, permitting faster assembly while preserving the water tightness.

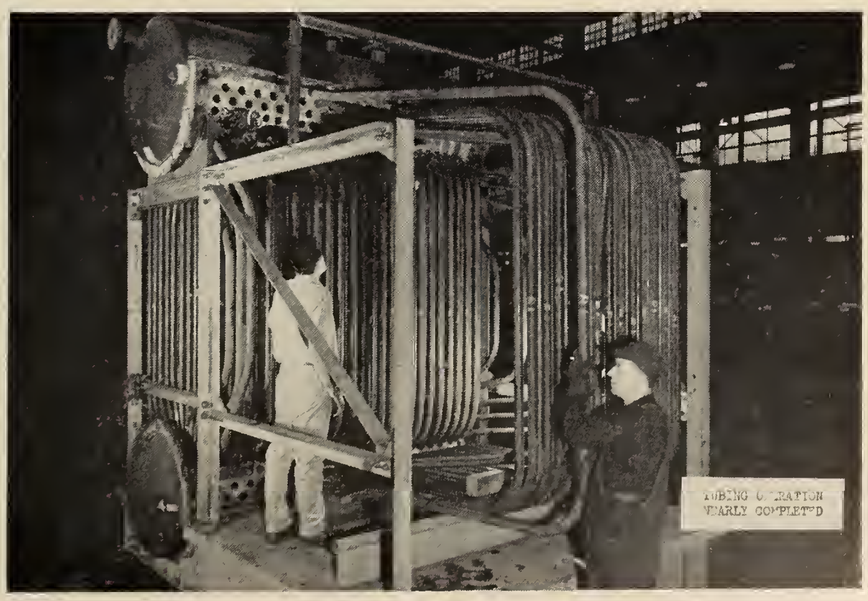
During the year Canada's first water-cooled hot-blast cupola was



A 40-ft. long glass-lined steel storage tank leaving the firing furnace.



Above: 1000 tons of steel were used to make this 15,000-ton capacity ore bin. Below, assembling tubes for a 9,000-lb/hr. package water tube boiler unit.



installed at Toronto, among the early few of such installations on the continent. The first fully automatic crane-type charging unit in Canada was put into operation in Quebec City, while a new modern cast iron water pipe plant was completed in Calgary.

The Industry in 1955

Last full report of the iron castings industry published was for the year 1955, when 201 establishments employed 15,266 persons, who earned $55.27 million (9,831 of these workers were employed in Ontario and 3,664 in Quebec). Cost of materials was $84.45 million, and gross selling value of products totalled $182.9 million.

A special study of all reports in 1955 showed some 400 operating foundries in Canada, which used 345,000 net tons of pig iron, 627,000 tons of scrap iron and 136,000 tons of cupola coke. Production of iron castings totalled 849,000 tons.

BOILERS AND PLATE WORK

Judging from preliminary reports for the first nine months of 1957, value of shipments in 1957 by the boiler and plate-work industry at some $145 million was up about 16 per cent over the value of some $124.6 million shown for the previous year.

The boiler and plate-work industry covers the operations of establishments that make as their chief products such articles as heating and power boilers, heating radiators, tanks and miscellaneous products from steel plate such as bins, hoppers, smoke-stacks, etc.

In 1955, latest year for which a complete report is available, there were 101 establishments in this industry employing 8,378 persons. Ontario employment by 51 plants totalled 5,473; 21 plants in Quebec and Nova Scotia employed 2,093; British Columbia's 15 plants employed 436; while the three prairie provinces' 14 plants employed 376 between them. Total salaries and wages amounted to $31.2 million, materials cost $41.39 million, value added by manufacture was $51.8 million, and gross selling value of products was $93.48 million.

Value of production in 1955 by categories was made up roughly as follows; heating boilers, $5 million; power boilers and parts, $9.5 million; radiators, $3.4 million; fabricated plate and structural shapes $14 million; miscellaneous plate work, $4 million; tanks, $16 million; and all other production $41 million.

STRUCTURAL STEEL

Based on preliminary reports during the first three quarters of 1957, shipments from the bridge building and structural steel industry were valued at some $152 million, compared with a value of $199.5 million in 1956, a drop of some 24 per cent. Shipments were only about 2 per cent below the total for 1955.

This industry includes all firms occupied chiefly in fabricating and erecting steel for bridges, buildings, etc. During 1955, the most recent year for which complete statistics are available, it covered the operations of 49 plants of which 25 were in Ontario, 13 in Quebec, 4 in British Columbia, 4 in Alberta, 2 in Manitoba, and 1 in Nova Scotia. Employment of 11,863 persons was divided as follows: Ontario, 4,711; Quebec, 3,964; B.C., 1,342; Nova Scotia and Manitoba, 1,156; and Alberta, 690. Salaries and wages totalled $46.6 million, cost of materials totalled $79.7 million, value added by manufacture was $76.4 million and gross selling value of products amounted to $157.7 million.

Tonnages of steel delivered during 1955 were as follows; for buildings, 285,600; bridges, 31,276; transmission towers, 14,693; other structural work, 29,174 — a total of 360,741 tons valued at $110 million. Other production valued at $89.3 million included plate and tank work, cranes, trolleys, boilers, machinery, unfabricated channels, etc., custom work and repairs, barges, reinforcing steel and castings.

A 46-ton 92-ft. long atmospheric column for a new petroleum refinery.

SHEET METAL PRODUCTS

Based on preliminary reports for the first three quarters of 1957, value of shipments in that year from the sheet metal products industry at some $285 million was about 2% higher than the value of shipments in 1956 of $278.6 million.

The industry chiefly manufactures articles from steel sheets, tinplate or galvanized plate. Main products are tin cans, galvanized sheets, metal bottle caps, sheet metal building materials, enamelled kitchen ware, culverts, galvanized ware, steel barrels and drums, eavestrough, stove pipe, etc. Many sheet metal shops doing contract and repair work, but not making a regular line of goods for sale, are not included.

During 1955, most recent year for which a full report was published, there were 360 establishments employing 19,080 persons, whose earnings totalled $66.6 million. Ontario plants numbering 189 accounted for 11,300 workers, while Quebec's 88 plants employed 5,013 workers. Thirty-one plants in British Columbia and the Yukon employed 967 persons; Alberta with 13 plants employed 474; Saskatchewan employed 256; New Brunswick 99; and Nova Scotia 67.

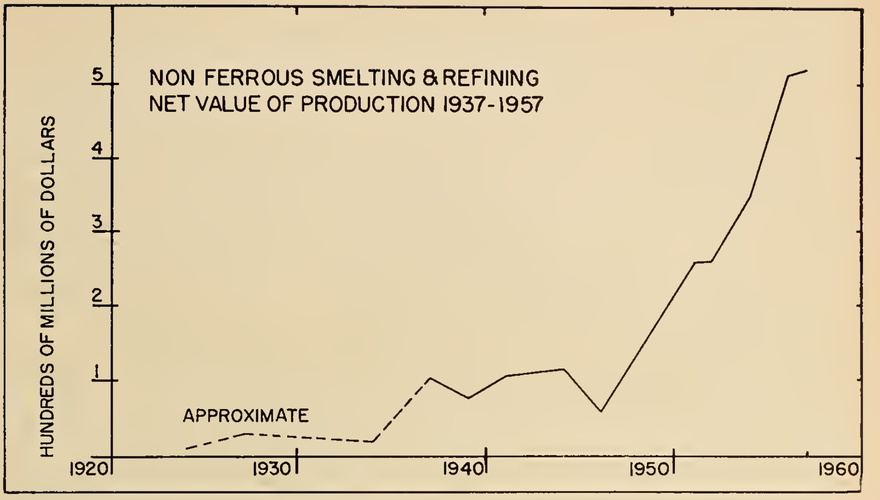
Cost of materials at all plants totalled $138.2 million. Value added by manufacture amounted to $121 million, while gross selling value of products was $260.2 million. Values of production by categories was made up roughly as follows: cans $88.5 million; bottle caps and seals $11.5 million; kitchen ware, $6.7 million; windows and screens $23.5 million; metal building material products $36.7 million; culvert pipe, $14 million; motor vehicle bodies $5.4 million; barrels and drums, $4 million; other products $70 million.

MISCELLANEOUS PRODUCTS

Based on preliminary reports, production by the miscellaneous iron and steel industry reached a value of some $160 million in 1957, which would be 40 per cent higher than shipments recorded in 1955 of $114.26 million. This industry includes the establishments not classified to any of the special groups into which the iron and steel industry is divided for statistical purposes. Products made include ornamental and architectural iron-work, steel forgings, safes, vaults, railway track equipment, mining machinery, steel wool, fireplace furnishings, horseshoes, chains, sanitary ware, etc.

Of the 347 firms reporting in 1955, last complete report available, 177 were in Ontario; 109 in Quebec; 33 in British Columbia; 13 in Alberta; 11 in Manitoba; 3 in Nova Scotia; and 1 in New Brunswick. These firms employed 11,207 persons of whom 9,340 were in Ontario and Quebec. Earnings totalled $39.8 million; materials used cost $46.6 million; value added by manufacture was $65.35 million; selling value of products totalled $114.26 million.

Products made were valued as follows: steel forgings, $17.2 million; architectural work, $16.8 million; sanitary ware, $16.4 million; structural shapes, fabricated, $3.5 million; safes, railway frogs, machinery, repair and custom work some $2 million each; and other products, $51.3 million.



SMELTING AND REFINING

Though the net value added by smelting and refining of non-ferrous ores or concentrates in 1957 has not been reported, a comparison of the total value of production in 1957 and 1956 for the principal non-ferrous metals indicates that there was little change in 1957 from the net value added by smelting and refining in 1956. Values of production were lower in 1957 for copper and zinc by some 33% and 20% respectively. On the other hand the production value of uranium was up almost three-fold, while value of nickel production was up 5½%.

The smelting and refining industry includes only those firms engaged primarily in smelting of non-ferrous ores or concentrates and in the refining of metals recovered therefrom. The smelting of imported ores is included, but secondary smelters, which treat scrap metals only, are not. The list of metals covered includes copper, nickel, lead, zinc, aluminum, magnesium, titanium, molybdenum, tungsten, cobalt, antimony, bismuth, cadmium, selenium, tellurium, and precious metals. Refining of crude oil is not included.

In 1956, the last complete year reported in full, 23 establishments had total employment of 30,788 persons, earning $130.14 million, and cost of ores and raw materials was $745.9 million. Cost of process supplies and containers was $74.68 million, gross value of products shipped including containers was $1,396.6 million and net value of production was $511 million.

Capacities of Canada's copper smelting and refining works in 1956 were as follows: Falconbridge nickel mines, 700,000 tons yearly of ores and concentrates from three blast furnaces; Hudson Bay Mining and Smelting Co., 575,000 tons of reverberatory capacity; Noranda Mines, 1,300,000 tons capacity from six blast furnaces and 3,500,000 tons reverberatory capacity from nine reverberators.

Capacities of electrolytic zinc plants include one of 200,000 tons annually at Consolidated Mining and Smelting Co., Trail, B.C., and one of 73,000 tons annually at Hudson Bay Mining Co. plant, Flin Flon, Manitoba. Consolidated Smelters, at Trail, B.C., also has five furnaces for lead smelting with annual capacity of 711,000 tons.

Fertilizer plant and concentrator at Kimberley, B.C., the site of the only lead refinery in Canada.

A second pneumatic alumina unloader was installed on the dock at Kitimat in 1957.

Canadian production of aluminum ingots in 1957 at some 534,800 tons was down 13% from the 614,721 tons produced in 1956, though imports of bauxite ore were some 9½% higher than in 1956. The decrease in ingot production was due in part to a drop in world consumption and a cut-back to 90% of capacity in the latter part of the year. It was also due to the prolonged four months labour strike at Aluminum Company of Canada's Arvida works. For the full year, dollar volume of sales was down only about 10%, reflecting price increases in the U.S. where a third of sales are made. Employment in the primary aluminum industry by the Aluminum Company of Canada, Limited, the only Canadian producer in 1957, averaged some 12,300 workers for the year.

In all world markets aluminum became freely available in 1957, replacing a supply shortage which, despite vigorous expansion efforts, had prevailed for nearly ten years. This return to easier supply may be regarded as a more normal state of affairs for the industry with supply and demand more nearly in balance.

Last October, Aluminium Limited indefinitely deferred completion of another 80,000 tons of capacity at Kitimat, which was to have raised total capacity of all its plants to 850,000 tons. Other phases of the expansion program, which had a target of close to a million tons yearly by the end of 1959, are also being held back.

Early in January 1958 the Company further curtailed ingot production by another 60,000 tons of annual capacity, to a point 20%, or more than 150,000 tons, below full rated capacity. Its principal operating subsidiary, Aluminum Company of Canada (Alcan), cut back operations at the Arvida and Shawinigan plants, by closing down 60,000 tons of smelter capacity. This resulted in layoffs of some 500 of the 9,000 employees of Alcan in Quebec. Construction of new hydro-electric facilities of a million horsepower on the Peribonka river is being continued, however, with first power to be available in 1959.

During the year, Canadian British Aluminum Ltd. completed the first stage of its four-stage 180,000-ton capacity smelter at Baie Comeau, Quebec. The smelter represents an investment of $77 million in the first two stages of 45,000-ton capacity each, with decisions on the third and fourth stages to be taken in 1959 or later. Manicouagan Power Co., in which Canadian British Aluminum holds 40 per cent interest, has expanded output from 100,000 h.p. to 250,000 h.p. to supply the smelter from its power site 11 miles away. At year-end production started with pouring of the first ingot.

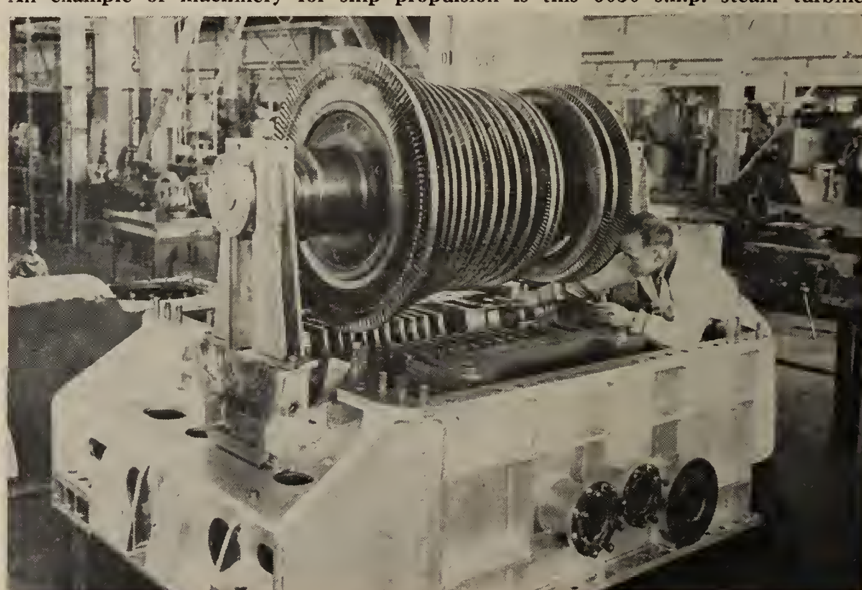
Reflecting the new availability of metal, Alcan has stepped up sales and research activities to develop expanded markets. Promising results are reported being achieved in the fields of transportation equipment for railroad and water transportation, in containers and packaging, electrical equipment, and in architectural uses.

The Aluminum Products Industry

This industry comprises the operations of factories chiefly occupied in the fabrication, casting or rolling of aluminum to make bars, sheets, wire, cable, foil, and cooking utensils. It does not include primary aluminum smelting or castings, cable, utensils, and the like, made as secondary or minor products in brass or iron foundries.

In 1955, last year for which a full report is available, there were 93 factories, 22 of them in Quebec, 59 in Ontario, and 12 in western provinces. There were 6,832 employees in factories, two-thirds of them in Ontario, who received wages of $24 million; cost of materials purchased amounted to $45,961,000; value added by production was $31,733,600; and gross selling value amounted to $79,839,600. Imports amounted to a value of $19.97 million, divided as follows: plates and strips $2.94 million; kitchenware $2.04 million; other manufactures $11.2 million. Exports were valued at $212.7 million, of which $197.6 million was in primary form.

An example of machinery for ship propulsion is this 6050 s.h.p. steam turbine.



MACHINES AND EQUIPMENT

Based on preliminary reports, for the first nine months of 1957, the value of shipments by the industrial machinery industry at some $372.5 million showed an increase of about two per cent over the value of shipments in 1956 of $366 million.

This industry covers operations of iron and steel works occupied chiefly in making industrial, household, office, and business machinery, and machine tools. Farm and electrical machinery and supplies are covered elsewhere. Some concerns in other industrial groups make machinery as secondary or minor products, so production figures quoted do not represent total Canadian output.

In 1955, the latest year for which a full report has been published, there were 408 establishments which together employed 33,308 workers. Salaries and wages totalled $119.2 million; materials cost $153 million; value added by manufacture was $210.6 million; and gross selling value of products totalled $368.4 million. Of the 33,308 employees 92% were employed in Ontario and Quebec.

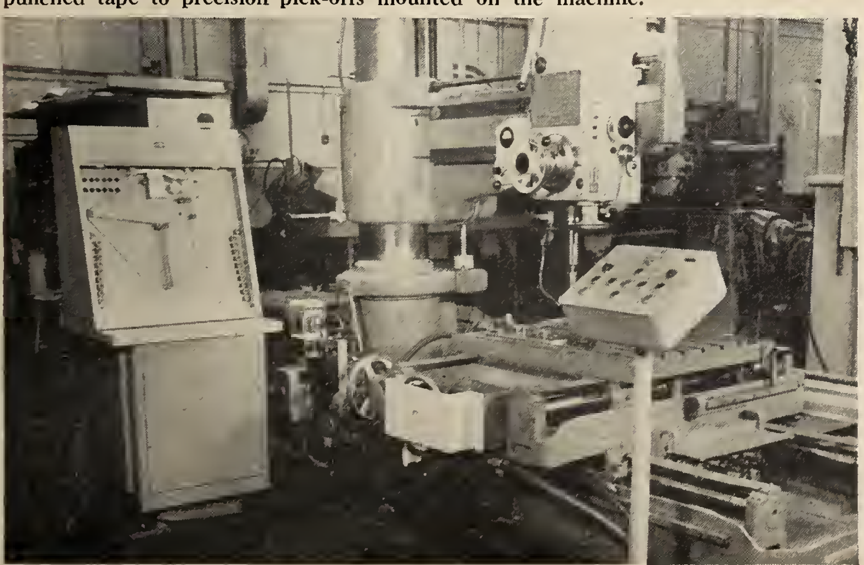
Values of production for some of the larger categories included: power shovels, glass blowing and rolling mill machinery, $38.5 million; household machinery and parts, $39.2 million; office business and store machinery and parts, $37.6 million; ventilating and dust collecting machinery, $18.0 million; pumps and parts, $18.5 million; mining and metallurgical equipment, $18 million; steam diesel and gas engines, $17 million; pulp and paper mill machinery, $15.3 million; conveying and elevating machinery, $13 million; elevators, $12.5 million; refrigerating machinery, $7.9 million; road making, ship, service station, metal working, hoisting turbine, woodworking, and air compressor machinery, about $6 million each.

MACHINE SHOPS INDUSTRY

The machine shops industry includes all independent machine shops occupied chiefly or solely in custom machining or repair work and which have gross yearly incomes exceeding $5,000 each. Smaller shops with less than $5,000 worth of business are not included, nor are shops operating in connection with factories, mines, paper mills, etc. Shops which make a regular line of products for sale are classed as manufacturing plants and are included in the appropriate industries. The industry has shown a steady growth since 1941 excepting for decreases in 1945 and 1946, and value of production has increased almost fourfold since 1941, while employment more than doubled.

In 1955, most recent year a full report was issued, a total of 674 shops —more than half of them in the two central provinces — employed 6,814 persons who earned $21.4 million. Cost of materials used was $15.83 million; value added by manufacture amounted to $31.72 million; and gross value of work done totalled $48.9 million. Nearly three quarters of the value of work done was by incorporated companies or co-operatives, the balance by shops under individual ownership or partnership.

A machine tool control, here used in conjunction with a spacer table, which is a device for positioning a table, carriage or tool part to ±0.00025 inch to one, two or three axes. Dimensional information is fed from a decimal keyboard or punched tape to precision pick-offs mounted on the machine.



AGRICULTURAL IMPLEMENTS

This industry covers only firms which produce agricultural implements as their main product. However, some firms classified in other groups produce implements as a minor part of their production. The latter are excluded from statistics on employment and value of shipments. Preliminary reports of shipments during 1957 indicated a total value of some $112 million for that year.

In 1955, most recent year for which a full report is available, there were 77 factories in Canada employing 11,753 workers. Of these, 29 plants in Ontario accounted for 93% of the total employment. Earnings totalled $41.9 million; cost of materials used totalled $59.3 million; value added by manufacture was $54.46 million; and gross selling value of products amounted to $113,923,000. This compared with the peak year of 1952 when 18,000 workers produced implements valued at $205.8 million.

In 1955 the agricultural implement industry produced implements valued at $109.7 million. Implements valued at $178.2 million were imported, while implements valued at $76 million were exported. Sales in various regions were divided as follows: Atlantic provinces, $6.8 million; Quebec, $21.7 million; Ontario, $43.8 million; Prairie Provinces, $77.6 million; British Columbia, $5.2 million. Values of imports of some of the major types of implements were as follows, in round figures: tractors, $115 million; harvesters, $15 million; pruning hooks and shears, $10 million; hay presses and parts, $7.8 million; dairy machinery, $5 million. Reaper threshers were the principal item exported.

Values of principal types of farm implements produced in 1955 from *all* Canadian industries in millions of dollars was; plows, $4.6; mowers, $5.0; harrows, $3.1; grain binders, $0.06 (down from $2.3 million in 1947); threshers, $36.4; seed drills, $0.8; cream separators, $0.2; discs, harrow plows and tiller combines, $1.7; cultivators, $2.8; weeders and cornplanters, $0.2; hayloaders, $2.2; manure spreaders, $1.7.

Sales of farm implements and equipment in 1956 to Canadian customers, including imports, but excluding export sales, amounted to

$170.77 million, an increase of 11% over the previous year. This value is at wholesale prices. Information supplied by manufacturers and importer-distributors indicates an average mark-up of 23.7% would produce a reasonably accurate estimate of expenditures by Canadian farmers on new implements and equipment in 1956. On this basis retail sales were estimated at $211.2 million. Sales in the prairie provinces accounted for about 70% of the total. Sales of repair parts at $31.8 million were up from the previous year.

HARDWARE TOOLS CUTLERY

From preliminary reports covering the first nine months of 1957, production of hardware, tools, and cutlery at some $153 million was 19% lower than the production valued at $191 million in 1956.

The most recent complete report of the hardware tools and cutlery industry was for the year 1955, when 370 establishments employed a total of 13,115 persons who earned $44.58 million. Of these, 2,731 worked in 272 Ontario plants, while 76 plants in Quebec employed 2,779 persons. British Columbia employed 506 persons; Nova Scotia and New Brunswick employed 38; Manitoba 33; and Alberta 28. Cost at plant of materials used was $49.2 million, value added by manufacture totalled $83.5 million, and gross selling value amounted to $133.57 million.

Products in various categories made by the industry in 1955 were valued roughly as follows; razors and blades, scissors and knives, $5.3 million; hardware, $26.2 million; hand and small tools, $20.8 million; hand implements, $4.1 million; tungsten carbide products, $6.6 million; bolts, nuts, rivets, washers, screws and allied products, $24.4 million; casters, dies and saws, $23.5 million; other products $22.4 million.

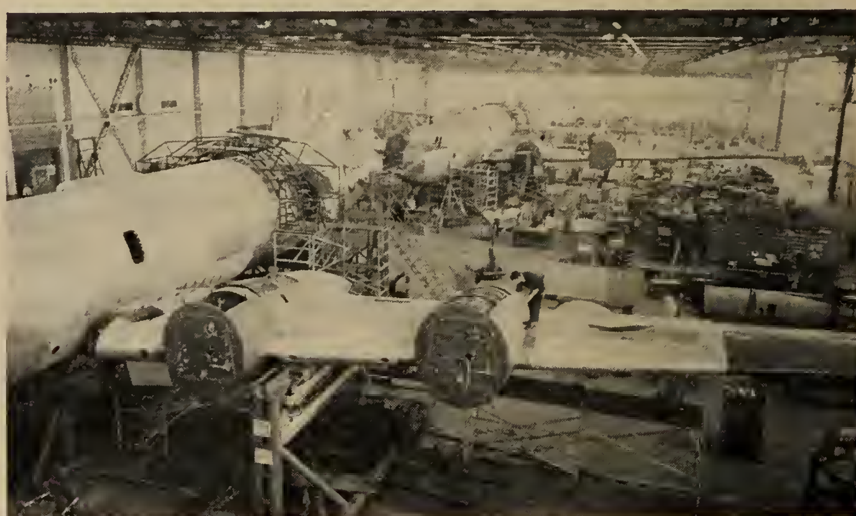
Imports during 1955 of various items of hardware, tools and cutlery added up to a value of more than $45 million, while exports amounted to a value of $269,000.

HEATING AND COOKING APPARATUS

This industry is a division of the iron and steel group and includes only factories making stoves, furnaces, oilburners, etc., as their chief products. Production includes as minor some iron castings, machinery and other items, which do not normally belong with the industry. Some heating equipment was made as secondary products of concerns classified with other industries.

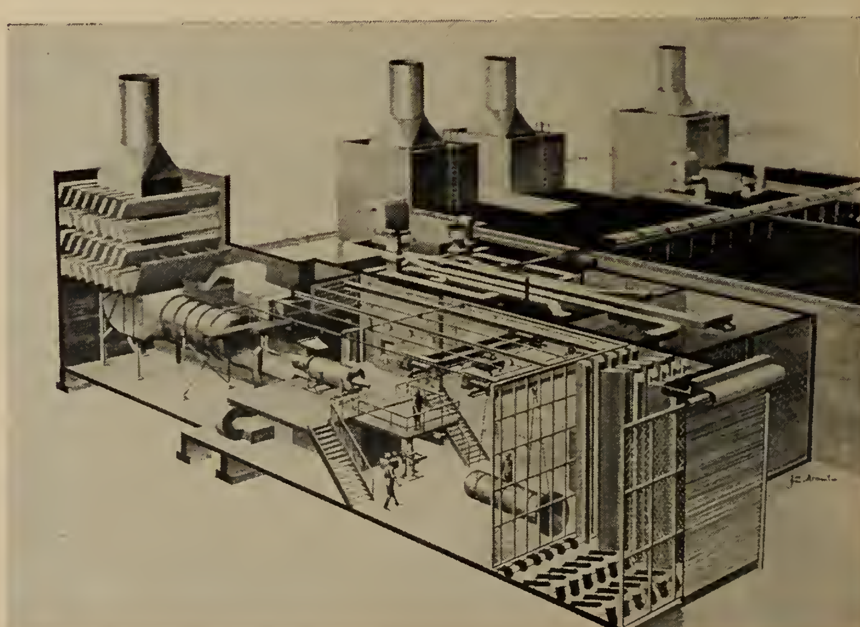
In 1955, latest year for which a full report has been published, 123 factories employed 9,148 workers, 5,980 of whom were in Ontario and 1,825 in Quebec. Total earnings were $29.8 million; materials used cost $56.76 million; value added by manufacture was $55.4 million and value of factory shipments totalled $113 million. No reports on production during 1956 and 1957 are available.

Factory shipments from all industries in 1955 by categories were valued as follows:—electric stoves, $40 million; other stoves $9.6 million; domestic watertank heaters, $6.6 million; oilburners, $11.3 million; furnace blowers, $1.76 million; mechanical stokers, $916,000, unit heaters, $4.43 million; air registers and grills, $1.84 million; heating radiators, $10.3 million; warm air furnaces, $24.1 million; and heating and power boilers, $18.08 million.



AIRCRAFT MANUFACTURE

Above is part of the assembly line of the CL-28 'Argus' anti-submarine aircraft. Below is a view of the aero-engine test cells of Orendâ Engines Limited, showing splitter vane intake-air silencers, right, test bed and working platform, centre, and exhaust silencing system at left.



TRANSPORT EQUIPMENT

AIRCRAFT

The year 1957 was one of outstanding achievement for the Canadian aircraft industry. Highlights included R.C.A.F. acceptance of the 'Argus' CP-107 submarine hunter, maritime reconnaissance version of the Britannia, largest aircraft ever produced in Canada; the unveiling of the 'Iroquois' by Orenda Engines Ltd., world's most powerful jet engine; and acceptance of Avro's CF-105 'Arrow', Canada's first supersonic fighter.

Industry Pattern

In 1955, latest year for which a complete report was published, 52 establishments employed 33,036 persons, who earned $130.3 million. Twenty-three Ontario plants employed 19,036 of the total, Quebec's 24 plants employed 11,066, while Nova Scotia, Manitoba, Alberta, and British Columbia between them employed 2,934. Cost of materials used was $140.8 million, value added by manufacture totalled $208.8 million, and gross selling value amounted to $354.3 million. The year 1944 established an all-time peak, when 45 plants employing 79,572 persons produced aircraft and parts valued at almost $426 million.

The industry is made up of primary assembly plants and establishments occupied solely or chiefly in making parts. In the four assembly plants which constitute the core of the industry there were 19,343 workers in 1955. Output for complete aircraft totalled $108.4 million while the remainder of the output at $245.9 was for parts.

During the same year 470 complete aircraft, not including engines, valued at $51.42 million and aircraft parts valued at $86.67 million were imported. Aircraft engines totalling 1,236 valued at $15.3 million and engine parts valued at $18.1 million were also imported. Exports and re-exports of aircraft and parts totalled $19.9 million for exports and $2.12 million for re-exports.

Canada's aircraft industry, ranking third in employment and ninth in volume of sales, in 1956 had 38 establishments employing some 35,000 persons and showed production valued at $360 million. Preliminary figures for the first three quarters of 1957 indicate employment rose about 10 per cent over the previous year, while sales somewhat exceeded the value reached in 1956. This prediction is based on a 16 per cent higher traffic for air carriers, on Canadian defence expenditures about equal to those of 1956, plus outstanding success in the export field.

Aircraft Production and Exports

Other projects for defence under way during the year included the CL-44 military transport for the R.C.A.F., with first delivery scheduled for late 1959.

In June, Belgium placed an order for 54 Avro CF-100 Mk. V's for NATO. Canadair Ltd. announced in November its decision to proceed with production of two prototypes of its ab-initio jet basic trainer, the CL-41, while CAE Ltd. of Montreal delivered the first of twelve CF-100 flight simulators to the R.C.A.F.

Placing in production of the CF-105 Avro 'Arrow' interceptor in November, however, with an initial order for 40 valued at some $300 million, replacing the CF-100's, assured the 650 firms holding subcontracts of continuing employment for some 15,000 workers. Yet for the industry the project is a big gamble. Much was spent on tooling-up and cancellation would be a serious blow.

Outstanding events during the year relating to export included commencement of work by Canadair Ltd. on an order from the West German Republic for 225 Sabre VI's, an order representing a value of $80 million including 400 Orenda-14 turbojet engines and parts; licensing agreements with Bristol Aircraft Ltd. for production and sale of Canadair-modified commercial versions of the 'Britannia' to be powered by Bristol Orion propeller engines; and permission from the American Defence Department to place an evaluation order to de Havilland Aircraft of Canada for five 'Caribous'.

Another event of importance was Canadair's decision to build passenger and cargo versions of the CL-44 for intercontintental routes. Powered by four Bristol 'Orion' engines they will have a range of 5,000 miles, with capacity of 150 passengers or 35 tons of cargo, and will be the second largest civil turboprops in the world.

As the year ended, the Air Industries and Transport Association began preparing for talks with the government, with a view to making a concerted effort to eliminate the 15 per cent tariff now imposed by United States on aircraft imported from Canada. No similar Canadian barrier against aircraft imports into Canada is in force.

Missile Production

Events in the final quarter of 1957 focussed attention on the production of guided missiles in Canada—a matter long subject to vacillation and indecision. Requirements for all three services have been long under study. So far Canada's missile potential is concentrated on the air-to-air variety. The costly all-Canadian 'Velvet Glove' programme has been succeeded by a licensing arrangement for production of a suitable American missile.

Late in the year Canadair Ltd. and Canadian Westinghouse, respectively responsible for airframe and guidance systems, were at last able to begin tooling up for 'Sparrow' production. Much of the program will be sub-contracted.

The Royal Canadian Navy is known to be interested in both an air-to-air and air-to-ship system. Army interest is in ground-to-ground and ground-to-air missiles. What steps will be taken to meet these requirements will depend on the final outcome of discussions which took place between

Working on a mock-up of Canadair's new side-by-side jet-powered basic trainer.

Canada's top defence officials and NATO representatives at the NATO meeting last December. Meantime a number of Canadian firms, such as de Havilland, have been building up trained staffs for missile research.

Other aircraft industry production during the year, for defence, though not classified as aircraft production, included a tracked vehicle developed by Canadair for the army for use in the Arctic. One of these vehicles, capable of carrying personnel or cargo weighing half a ton and of towing another half ton, after rigorous trials was taken to Antarctica by a U.S. government expedition.

Canadair's nuclear division also completed two major installations for Atomic Energy of Canada Ltd. at Chalk River, namely, a pool test reactor and a spectrometer, both for use with other atomic reactors.

MOTOR VEHICLES

The canadian automotive output in 1957 fell more than 13 per cent below that of the previous year. This resulted from a ten-month slump in commercial vehicle construction and monthly outputs lower than the previous year for passenger vehicles during the last three quarters. The nation's assembly plants shipped 409,821 vehicles in the 12 months, compared with 470,674 in 1956. Passenger car production at 340,014 units was 9 per cent under the previous year, while commercial vehicle output at 71,478 units was 29 per cent lower than in 1956.

Employment in the industry averaged 39,000 persons for the year, down 3 per cent from the 1956 average of 40,253 persons. Payrolls for 1957 were close to the $170 million paid out in 1956, the largest in the history of the industry. The year was relatively free from strikes.

The only auto manufacturer to score a gain over 1956 was General Motors of Canada, whose passenger car total surpassed the previous year by 3½ per cent. Ford Motor Co. output declined eight per cent; Chrysler Corporation output fell 25 per cent; Studebaker and American Motors dropped 37 and 68 per cent, respectively, below the previous year. Percentage declines suffered by Canadian truck manufacturers were: General Motors 30; Ford 17; Chrysler 42; International Harvester 68.

This made General Motors the leading producer for the year with 153,417 passenger cars; followed by Ford and Chrysler in that order with 109,889 and 69,418 passenger cars respectively, giving GM 45.1%, Ford 32.3%, and Chrysler 20.4% of the total.

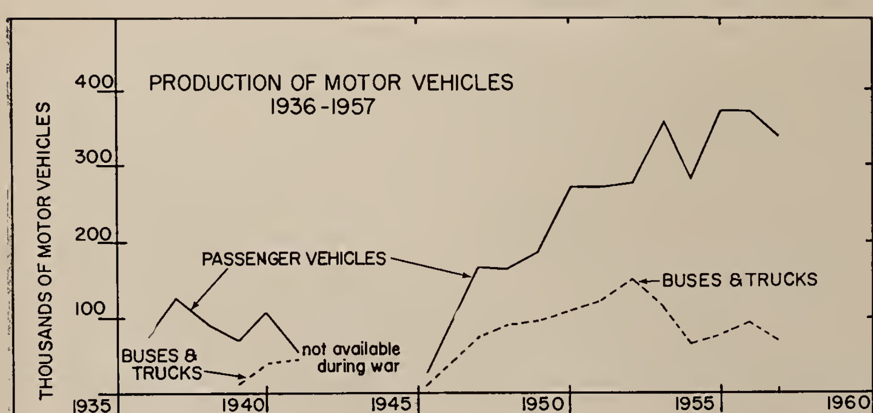
Factory shipments of made-in-Canada vehicles for 1957 will total some 409,821 vehicles, 13 per cent below the previous year. Sales of cars and trucks during the first four months were the greatest in the industry's history but did not hold at this level during the later months. The sharp decline was due to a tightening supply of credit and to the lack of ready cash in the hands of the industry. Lack of industry funds hit the truck market particularly, forcing reappraisal and postponement of truck purchases by many business men.

Despite such problems, passenger car sales during the year 1958, according to industry observers, should reach some 380,000 units, close to the 1955 level and only 7 per cent below the 1956 record of 408,000 units. The estimated number of vehicles of all types withdrawn from service has ranged from 160,000 to 202,000 over the past four years, 75 to 85 per cent of which were passenger vehicles.

Truck sales at 78,000 were 15 per cent under 1956 and about equal to 1955 sales. Truck exports at 7,500 units, were at a six-year low. The decline in exports was mainly due to the Suez crisis and in some measure to the scarcity of Canadian dollars abroad.

Imports of European vehicles took a larger slice of the Canadian passenger car market, accounting for nearly 12 per cent of total sales during the first three quarters of the year. This represented a 61 per cent increase over the same period of 1956, and showed increasing percentages of 9, 12½, 13½ and 17½ per cent for the first, second, third, and fourth quarters respectively.

With an expected easing in credit and money supply during the coming year, together with the reduction last year on the excise tax on automobiles from 10 per cent to 7½ per cent, auto manufacturers are looking ahead to a higher volume of purchasing power and better sales in 1958 than in the year just passed. The year 1958, however, started badly, with a 55,000-man-day lay off in January by Ford and Chrysler following the 17% cuts in December.



The Industry in 1956

A measure of magnitude of the Canadian Motor Vehicles Industry is seen in the 1956 report compiled by D.B.S., the latest year for which full statistics are available. In that year factory shipments valued at $988.1 million showed an increase in value of 8.9 per cent over the previous year. Value of finished vehicles amounted to $836.7 million, while parts and miscellaneous products accounted for $151.4 million.

All vehicles shipped from factories during the year totalled 467,864 or 3.1 percent more than in 1955. Passenger cars produced totalled 374,312, of which 24,500 were made for export; trucks produced totalled 93,157, of which 8,410 were made for export; buses numbered 395, of which 48 were made for export. Actual export of all vehicles totalled 19,034 valued at $22.5 million. Imports amounted to 89,232 units worth 171.4 million.

The industry in 1956 included 16 establishments, nine of which were located in Ontario and seven in other provinces. Employment at 35,100 (97 per cent of which was in Ontario) was 1,700 higher than in the previous year. Wages and salaries at $149,948,000 showed a 10 per cent increase. Expenditures for fuel and electricity totalled $5.98 million; cost of material at works was $697.3 million; and value added by manufacture amounted to $298.2 million.

Growth in Registrations, Revenues, and Gasoline Consumption

The 1956 registration year brought a 7 per cent increase in the number of motor vehicles licensed in Canada to 4,230,647. Passenger car registrations were up 8.6 per cent at 3.187,099, while commercial vehicle registrations were up 3.2 per cent at 1,007,968. Motorcycles and motorized bicycles fell slightly to 35,580. Increases by provinces in order of magnitude were: Newfoundland 15%; Quebec 11%; British Columbia 10%; Manitoba 7%; Alberta 6.8%; Yukon & N.W.T. 6.6%; Saskatchewan 5.9%; Ontario 5.7%; and New Brunswick 4%.

At the end of 1956 there were ten motor vehicles registered for every 38 Canadians. Alberta's ratio was the highest with ten for every 29 persons, while Ontario led in passenger cars at ten per 39 persons. All regions showed increases over the previous year in vehicles *per capita* except Nova Scotia. During the 12-year period 1945 to 1956 there was an increase of 186% in all motor vehicles registered, 175% in passenger cars, and 212% in commercial vehicles.

During 1956 Provincial and Territorial governments collected $422.5 million in revenues from gasoline taxes and the licensing of vehicles, drivers and dealers, 11.8 per cent more than in the previous year. Consumption of taxable gasoline for automotive purposes at 2,457 million gallons was 10.3 per cent higher than in 1955. Increases in tax per gallon included Prince Edward Island from 13 to 16 cents; Ontario from 11 to 13 cents; and Saskatchewan from 11c to 12c.

A general view of assembly-line operations at Canadian Car's Fort William bus plant.

Motor Vehicles Parts Industry

This industry includes only factories which made parts and accessories as their chief products. Parts such as tires, batteries, brake linings, etc., made in other industries are not included, nor are lacquers and upholstering, etc. Among products made are included engines, bodies, differentials, transmissions, radiators, spark plugs, starters, axles, piston rings, wheels, glass, trailers, springs, bumpers, steering gears, hubs, lubricating systems, etc.

No statistics for the industry are available for 1956 and 1957. For 1955, however, a complete report showed 180 establishments, 108 of which were in Ontario, 23 in Quebec, 18 in British Columbia, 17 in Alberta, 14 in Manitoba, 5 in Saskatchewan, 2 in New Brunswick, and 1 in Nova Scotia. The industry employed 20,000 people, who earned $74.6 million. Total production of specified parts and accessories from all industries including tires, batteries, radios, etc. amounted to $523.1 million compared with $406.3 million in 1954. Imports of parts during 1955 totalled to a value of some $278 million, while exports were valued at $24.7 million.

New 2400-h.p. diesel-electric locomotive in test service on Canadian railroads is designed for special heavy-duty freight and high speed passenger service.

RAILWAY EQUIPMENT

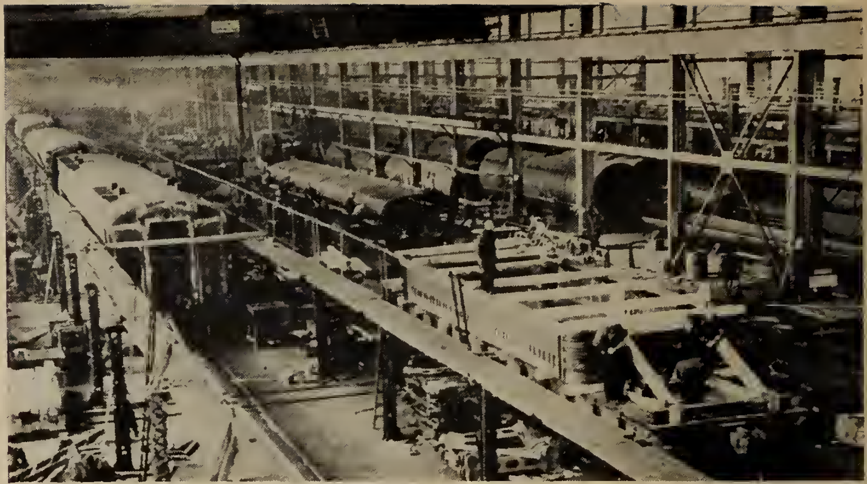
Canada's 29 establishments which furnish railroad equipment to Canada's railroads enjoyed an excellent year in 1957. Some 11,350 freight cars of all types were delivered to the two principal railway systems alone, compared with 9,214 for the entire railroad industry the previous year. Diesel locomotive production continued at about the same rate as during the previous year when 446 units were produced. One hundred passenger units and 152 units of work equipment were delivered to Canadian National. The preliminary reports indicate shipments in 1957 reached a value of some $380 million or 10 per cent higher than the peak of $345.5 million reached in 1956.

The annual review of the industry covering the year 1956, recently off the press, showed a reversal in 1956 of the downtrend in output obtaining since the year 1953, when gross value of production reached an all time peak of some $338 million. Gross value of production for 1955 at $245.7 million was the lowest since the late 'forties'.

For 1956, twenty-nine establishments, 12 of them in Ontario, employed 28,118 persons, purchased materials valued at $207 million, added $134 million by manufacture, and produced goods with gross selling value of $345.5 million. Comparable figures for the previous year were 32 establishments, 25,400 employees, material purchases $1,395 million and gross selling value of $245.5 million.

This industry includes all establishments chiefly occupied in making railway cars and locomotives, and component parts such as wheels, brakes, tires, bolsters, springs, etc. The principal repair shops of the C.N.R. and C.P.R. are included. These are located in the province of Quebec, which accounts for nearly half the employment in the industry.

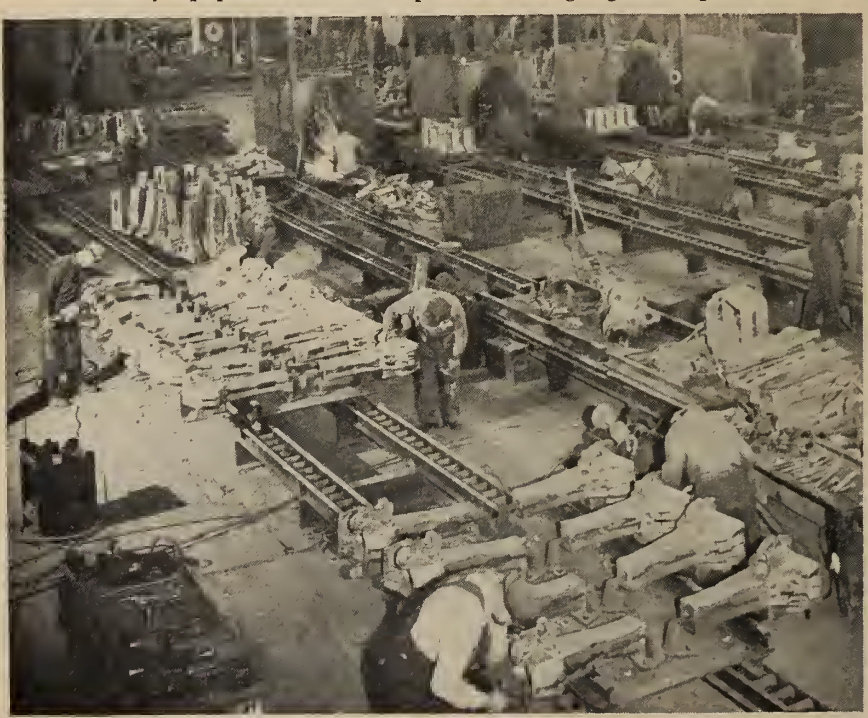
There were 29 establishments in 1956 with 28,118 employees whose total earnings were $100.73 million. Numbers employed by provinces were as follows: Quebec 12,596; Ontario, 6,268; Manitoba, 4,956; Nova Scotia and New Brunswick, 2,246; Alberta and B.C., 2,052. Output of materials included new railway cars valued at $71 million, new locomotives valued at $78.2 million, and other lines, such as wheels, parts for railway cars and locomotives, repair work, etc. Rail fastenings were valued at $12.6 million, while car wheels were valued at $6.5 million, and spikes at $2.2 million.



Railway coaches and tank cars under construction.

Looking ahead to the future, equipment manufacturers already had firm orders at year end from the two main railway systems for cars and locomotives totalling over $100 million in value for 1958 delivery. Completion of the C.N.R. and C.P.R. dieselization programs by 1961 calls for some 1,500/1,700 more diesel units or an average of 400 units yearly, though orders placed by year end totalled only some 266 units.

Railway equipment includes couplers and draught gear components.



Also at year end railway car builders held orders for some 4,000 freight cars of various types for 1958 delivery. This compares with an average of some 8,100 freight cars annually over the years 1955/56, and 1957. In the latest request from Canadian National, however, boxcar orders were conspicuously missing. In addition, car makers have orders from a number of the nation's smaller railroads, as well as from some industrial concerns.

SHIPBUILDING

CANADIAN SHIPYARDS enjoyed a reasonably active year in 1957, with most of the yards busy. Besides a very active naval programme, orders for a diversified range of commercial vessels for Canadian coastal trade helped to maintain monthly average of employment at around 14,900 workers on shipbuilding and repairs during the first three quarters. During the last quarter, however, with the current naval program drawing to a close, employment fell by some 1,500 as workers were dropped from the payrolls. Further layoffs were pending during the next few months as the remaining seven destroyer escorts neared completion.

Sixteen naval vessels were added to Canada's navy during the year: these included four destroyer escorts, five minesweepers, two ocean tugs, four crane lighters, and an ammunition lighter. Vessels for other departments of government included the R.C.M.P. patrol vessel, *Victoria,* the icebreaker *Montcalm,* the lighthouse tender *Montmorency* and the auto passenger ferry *Lord Selkirk.*

Specialized types of vessels built

for domestic commercial owners to serve differing modes of water transportation included a "canaller", an oil tanker, a bulk freighter, a "coaster", four dredges, a drill boat, a river ferry, a tug, and twenty barges. No ships were built for export. The commercial ship-repairing business showed an improvement on the St. Lawrence and on both coasts, but this trend was reversed later in the year due to the sharp drop in ocean freight rates, which caused owners to tie up many vessels.

Tenders were called early in 1958 for a stepped-up government shipbuilding programme to provide winter work. It will include six new vessels at a cost of $10-million and conversion of two wartime tank landing craft for carrying cargo to DEW line sites in the Arctic. Tenders will be called in February for a small ferry to operate between Pelee Island and the Ontario shore of Lake Erie.

Shipyard employment, while slightly better than that obtaining during 1956, was considerably lower than in 1954, last year for which complete statistics are available. During that year 76 shipyard establishments had more than 19,000 persons on their payrolls. Employment in the past year was only about one-fifth of the number employed in shipyards during 1943, the most active year in the industry's history.

What the longer-term future holds for Canadian shipbuilding, as far as domestic commercial shipping is concerned, depends on the report of the Royal Commission on Coastal Trade appointed in 1955, and the Government's decision regarding its recommendations. At present, ships built and registered in the Commonwealth have equal rights with Canadian ships within Canadian waters. If after completion of the Seaway this is not changed, consequences will be disastrous for Canadian shipyards. Many Canadian coastal operators are delaying construction pending results.

A shipbuilding and ship repairing industry in Canada with adequate and continuing production is an indispensable need, if the Royal Canadian Navy is to be supplied with the latest and best ships, ready to serve as an effective deterrent force. In a troubled world Canada cannot afford to allow her shipyards to close down.

PULP AND PAPER: Two of the industry's latest mills. Columbia Cellulose, top; North Western Pulp and Power Limited, Hinton, below. **(See review on pp.119-122.)**

BOAT BUILDING

THE BOAT BUILDING industry comprises firms making small vessels and pleasure craft such as row boats, canoes, sailboats, motor boats, etc. The 204 plants reporting for 1955, last year for which a full report is available, were distributed as follows: Ontario, 61; British Columbia, 58; Nova Scotia, 36; Quebec, 36; Manitoba, 7; New Brunswick, 3; Alberta, 2; and Saskatchewan, 1. Employees numbering 1,666 earned $4.18 million, materials used cost $4.4 million, value added by manufacture totalled $5.54 million, and gross selling value amounted to $10.27 million. Ontario's production from 61 plants at $4.8 million accounted for nearly half of the total.

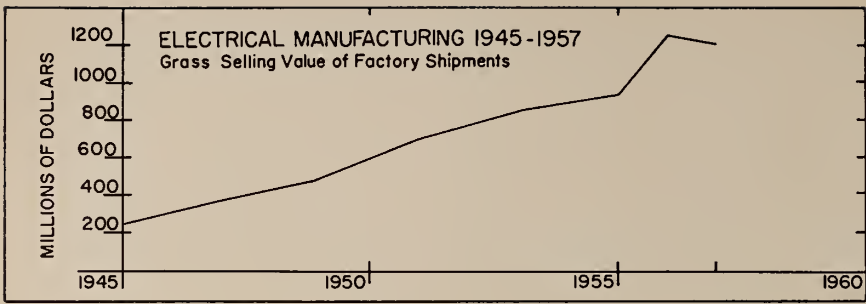
Production by categories (and values) included: 12,166 outboard boats ($3.2 million); 474 motor boats ($2.2 million); 11,049 other boats ($1.7 million); 3,689 canoes ($272,-500); rowboats, skiffs, dories, etc. ($331,800); 154 sailboats ($92,000); and other products valued at some $2.5 million.

MISCELLANEOUS EQUIPMENT

To round out production of transportion equipment, records of the miscellaneous transportation equipment and of the bicycle industry should be included. The former produces carriages, sleighs, bodies and boxes for vehicles, wheels, wheelbarrows, and baby buggies. The latter produces, bicycles, tricycles and bicycle parts, ice skates, children's wagons, strollers.

In 1956 the miscellaneous transportion equipment industry included 27 firms employing 886 persons who earned $2.47 million, cost of materials totalled $5 million, value added by manufacture amounted to $5.04 million and gross selling value of products totalled $10.1 million.

The bicycle industry in the same year included five establishments employing 627 persons who earned $2.19 million. Two plants were in Quebec and three in Ontario. Materials used cost $2.06 million. Factory shipments amounted to 100,884 bicycles valued at $3.11 million at factory prices; gross selling value totalled $6.42 million.



ELECTRICAL EQUIPMENT

Preliminary Estimates indicate the 1957 output of manufactured goods by the Canadian electrical manufacturing industry will reach a value of some $1,200 million, a decline of two per cent from 1956's figure of $1,226 million.

Pattern of the Industry

In 1955, most recent year for which full statistics are published, employment in the industry totalled 76,244 persons. Factory shipments at $962.6 million showed an increase of 11.4% over 1954. Output of electrical apparatus in other industries including electrical accessories for automobile and household use but excluding office and industrial machinery amounted to $131.5 million. Shipments of subgroups were valued in millions of dollars as follows: batteries $40.6; heavy electrical equipment $198.4; radios and parts $263.4; refrigerators and appliances $135.67; miscellaneous wires and cables $155.96; other miscellaneous electrical products $169.1.

Principal imports during the year, in millions of dollars, included: electrical apparatus n.o.p. and parts $24; radios and wireless apparatus $61; refrigerators $17.8; refrigerator parts $16.1; electric motors $12.8; radio tubes $12.8; telephone apparatus $12.2; generators and parts $10.2; switches and switchboards $11.4; heating and cooking apparatus $11.3; generators and parts $10.2; farm freezers $9.6; radio receiving sets $8.9; rheostats $8. Principal exports included: radio and wireless apparatus $4.8; electrical apparatus n.o.p. $4.22; spark plugs $2.1; telephones and apparatus $2.07.

Levelling of Expansion Programs

The year 1957 was one of challenge for electrical manufacturing as the various divisions of the industry adjusted to meet the changing needs of the Canadian economy. The year saw a levelling-off in industrial expansion programs as well as a decline in demand for consumer goods, largely caused by the sharp reduction in housing starts and a tight money supply. Working off a backlog of orders, heavy apparatus manufacture continued at a high level in 1957, but demand for consumer durables and the associated industrial products declined faster than had been expected.

Appliance Market Weaker

The Federal monetary policy followed during the past year, and its results, were largely responsible for a sharp decline in sales of major appliances. Refrigerator sales were down 15%, range sales were down 14%, and wringer-washer sales were down 9% from 1956. However, automatic laundry equipment continued to show a growth trend with sales increasing by 11% over 1956.

Present indications are that for 1958 major appliance sales generally will at least equal the 1957 volume. Low saturation levels should continue to provide growth potential for automatic laundry equipment. Based on the assumption that recent monetary policies will be continued, particularly for residential construction, range sales should reach the 1956 sales level, with built-in ranges reflecting the greatest sales growth rate in this segment.

Yet Canadian appliance manufacturers are becoming increasingly concerned at the extent to which American-built appliances are invading the domestic market, with a resultant drop in production and dislocation of employment in Canadian appliance plants. The products most effected are refrigerators, laundry equipment, and, to a lesser degree, ranges. Despite this invasion of the Canadian market, however, domestic appliance manufacturers are not asking for increases in tariff protection.

Apparatus Market was Strong

During 1957, the heavy capital goods segment of the industry produced a record volume of apparatus of utilities and industries. This equipment is basic to the capital expansion programs which have been such dominant features of the economy for the past several years.

For power production, deliveries of waterwheel generators, power transformers and circuit breakers were at peak levels. In 1958, the industry expects a new high in production of waterwheel generators, though a somewhat lower volume of production of transformers and circuit breakers is seen for the coming year. The mining industry, too, placed a heavy volume of orders on apparatus manufacturers in 1957, as did expansion programs at Canadian steel mills.

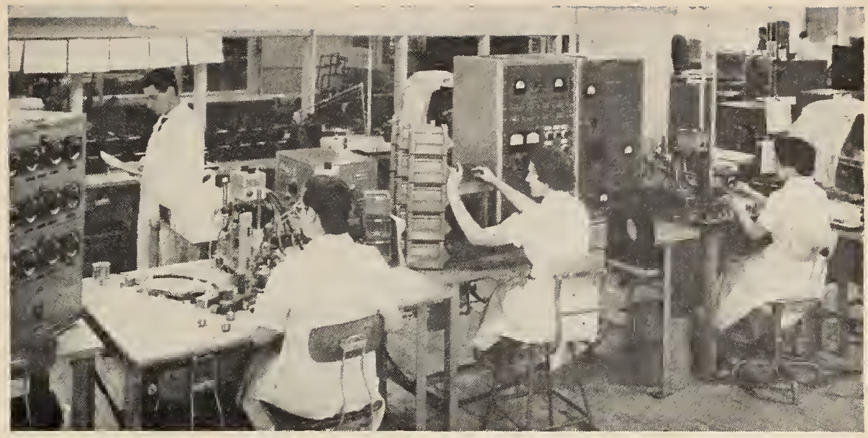
Looking ahead, the apparatus segment foresaw some softening in orders from Canadian utilities. Industrial business is expected to level off to a somewhat greater degree as industries digest recent expansion programs. The rapidly expanding petrochemical industry, however, will create a source of new apparatus business while a moderate continuing demand for equipment is expected to support the modernization and expansion plans of the steel industry.

It is becoming increasing evident that Europe will be the world's first large market for economic nuclear power. It was reassuring to note the enthusiasm of Euratom's "Three Wise Men" concerning the Canadian power reactor design and development program. Canadian design is based on fuelling with natural rather than with enriched uranium which, in the Free World, is largely controlled from the U.S. Natural uranium, on the other hand, has many important sources throughout the world and supply will be comparatively free.

Big Market in Thermal Power Equipment

Over 3½ million h.p., or 16 per cent of Canada's generating capacity is now thermal. There will be growing trend toward thermal generation of power as full development of the few remaining hydro sites within economical transmission distances of population centres is completed. Seaway power, for example, represents the last major source of hydro-electric power in Southern Ontario.

Because of this expanding market for thermal power equipment, Canada's electrical manufacturers are actively studying the possible manufacture of turbo-generator units and other equipment for use in thermal plants. At present all such equipment in Canada is of foreign manufacture. But here Canadian electrical manufacturers face a double handicap. They would compete with manufacturers in low-wage-level countries overseas and, to start with at least, would have no tariff protection from certain overseas producers. Yet in the years to come Canadian electrical manufacturers may become world leaders in thermal generating equipment, as they are now in the hydro-electric field.



Dry reed switches for electron tubes being made in an air-conditioned area.

TV Market Down, Radio and Players Up

Television receiver sales declined by some 27% during 1957, but now appear to have reached a level which will be maintained over the next year. The industry expects that TV set sales in 1958 will be in the order of 470,000 sets. The 'second-set' market is becoming an increasingly important factor, however, as is the replacement market for older receivers.

Radio sales were up some 6% last year, and continue at a high level with well over 700,000 units sold in 1957. Introduction of low-cost portable and clock radios, plus the utilization of transistors in place of vacuum tubes, has aided in sparking consumer demand. Sales of record players exceeded those of 1956 by some 34%.

Wiring and Lighting Market Promising

The majority of Canadian homes do not have adequate electrical wiring systems to support even a small portion of the household electrical appliances presently available. Besides older homes, many recently completed homes have wiring that does not allow the owner the full advantages of electrical living.

More than 150,000,000 light bulbs were used for electrical lighting in Canada in 1957. Office, store, and factory lighting all advanced during the year. Even casual observation of new buildings indicated the attention being given to better lighting. Offices with 100 foot-candles of general illumination are not uncommon.

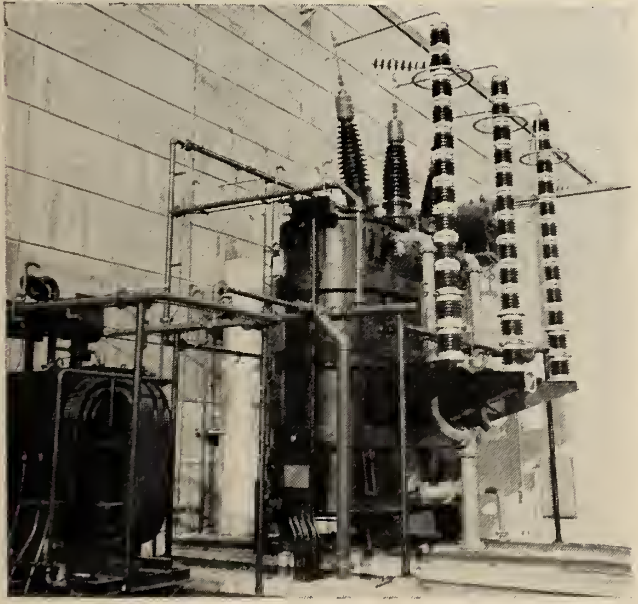
There was noticed during the past year an improvement in outdoor lighting and, in general, in floodlighting, street lighting, and electric signs. Sodium and mercury discharge lamps are now being used in floodlighting. Both fluorescent lamps of higher light output, and mercury lamps of various sizes and types, are more generally used in street lighting. Fluorescent lamps which can be flashed have contributed to new designs and greater attraction in electric signs.

In the home, there is a trend back to the use of more lighting fixtures and built-in lighting. Fluorescent lamps are coming into greater use in the home. Line fluorescent lamps provide a very satisfactory lighting effect for valances used in almost every room in the house.

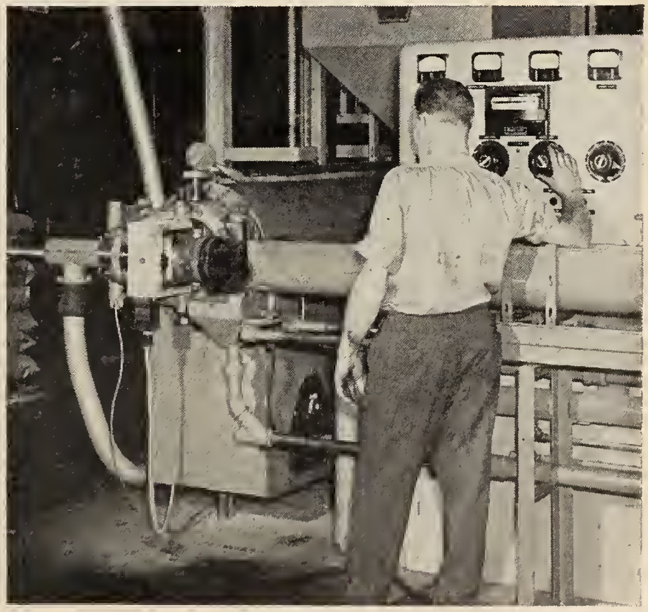
Production in Electronics

Developments in the field of electronics—and their application in communications, defence, and industry—are, and will continue to be, much in the public eye. Increasing applications for electronic equipment are constantly being found in defence work for radar; in aircraft and guided missiles; in the field of nuclear energy; in industry, for the greater use of automation and remote control; for communications, pipeline transporta-

A 400,000 kva. generator unit transformer at a hydro plant.



Extruder applying polyethylene coat over electric cable.



tion, railway signalling, and a host of other uses.

There is an evident trend toward diversification on the part of many electronics manufacturers. This is a result of over-capacity to produce within the industry. In the early 'fifties', the industry built up capacity beyond a level supportable by the nation's industrial and commercial economy. Defence requirements dropped from some $120 million in 1955/56 to about $80 million in 1957/58 and may drop even lower in 1958/59. The resulting competition means unsoundly depressed prices. Expanding commercial and industrial demand and an upturn in defence are needed to support present capacity.

The industry foresees less emphasis in the future on large quantities of individual defence equipments, and more on integrated and complicated systems combining early detection, plotting, communications, and automatic fire control. In commercial and industrial fields a more orderly expansion is expected based on automation, remote control, and electronic business devices.

Danger from Free Trade with U.K.

Leaders of the electrical manufacturing industry draw attention to suggestions advanced in recent months which, if implemented, could only weaken Canada's manufacturing base and thus result in long-term damage to the nation's economy. One such suggestion concerned the possibility of free trade with the United Kingdom. If this were implemented, they point out, it could only result in further access to our market for goods from a country with much lower wage rates than our own, without any attendant reciprocal advantages to this country.

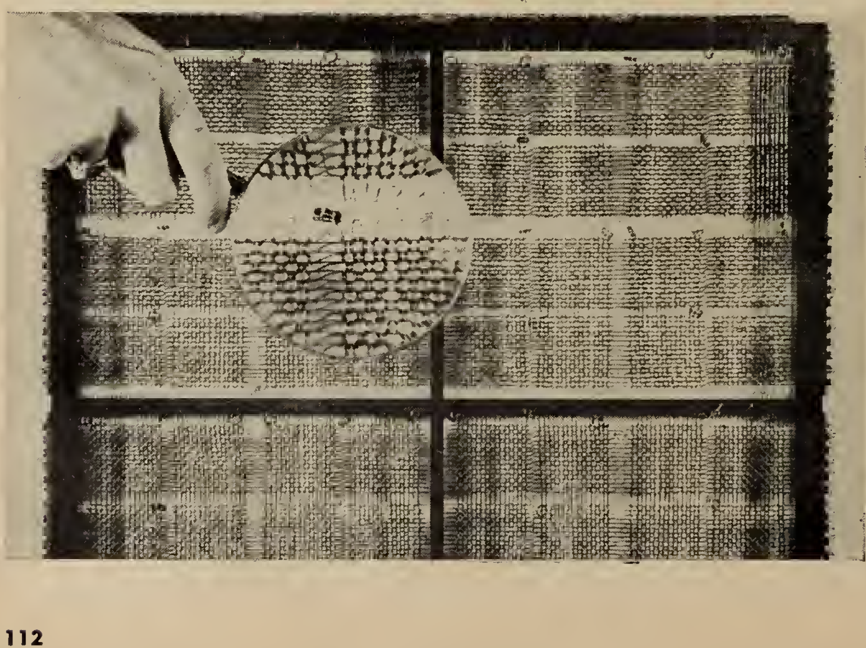
Despite the growth of secondary manufacturing since the war years, manufacturing's share of the Gross National Product in recent years has been a declining percentage. This is a reflection of the difficulties facing Canadian manufacturers in operating in a small market economy which offers relatively easy access to foreign producers. In this respect, there is current public emphasis on diverting Canadian purchases from the United States to the United Kingdom.

Public acceptance of this principle and desire to support it is already beginning to take effect. There is a danger here, it is emphasized, that Canadian purchases of domestically produced goods may also be affected, and that, in the enthusiasm for this program, orders for goods which should logically be placed in Canada would also be diverted to the U.K. Over the long-term, such an approach could only serve to weaken the country's manufacturing base and provide reduced job opportunities in the manufacturing industries which currently employ over 25 per cent of the labour force.

Industry Events in 1957

Production during the past year included many 60/100-thousand kva. generators and transformers for Canadian utilities; steel mill drive apparatus for Algoma Steel Corporation; power transformers for Brazil; ignition rectifier equipment for India; world's largest installation of magnetic amplifier control for Dofasco, Hamilton; and new combination plate and blooming mill for Algoma equipped with programmed digital automatic control. Outstanding developments included testing of new scatter-wave propagation for long-range multi-channel communication; new type pneumatic hoist airbrakes for mine-hoist equipment; the 'Litegard' photoelectric safety device to stop equipment if any object obstructs a guarding light beam. Other examples of new developments were the 'snow-white' area for filtering dust from the air supply to dwellings or factory rooms; development of polyethylene insulated (PIC) cables; and Canada's first oil-filled pipe cable system (piped power) at Edmonton.

Part of a core array, believed to be the largest single unit made, containing 16,384 magnetic cores. It is used for information storage in computing equipment.



An electro-mechanical computer for the nuclear energy field. The device uses data from nuclear reactor power to give information about the concentration of certain isotopes in the fuel rods.

Industry's Future Bright

Electrical manufacturers face 1958 with inventories in better balance than a year ago. Recent changes in interest rates, indications of general easing of credit, and increased federal action on housing have introduced a note of optimism that 1958 levels will be somewhat higher than those prevailing in the latter half of 1957. The effect of an expected significant increase in housing starts will be felt in the consumer durable market in the latter half of the year, and should be reflected in a lift in the overall economy.

Despite the 1957 decline in the

electrical manufacturing industry, a glance at past industry performance indicates that the long-term trend is up. Value of output in 1957 was well over double what it was a decade ago. Looking ahead, the industry expects to produce over twice as much equipment over the next decade as it has since its inception 65 years ago.

Our Electrical Future

The electrical manufacturing industry, looking ahead another twenty years, sees living standards 50 per cent higher than today. Well over 100 different appliances will be available. Heat-pumps will be in general use, and may consume more power than the entire country could supply in 1957. Dusting the house will be done with an electrostatic cleaning wand; bedrooms will be provided with laundro-closets to clean clothing quickly; dirt being removed by ultrasonic energy. Kitchen refrigeration will cool by current passed through the junction of two dissimilar metals.

Automation will combine food storage and cooking machines, allowing complete pre-selection of meals; 'rayescent' lighting panels no thicker than a pane of glass will be used electrically as a decoration. Transistors will bring widespread changes in the application of direct current in almost every field. Silicon diodes can already be built in package units to obtain large blocks of DC power.

A pre-designed alloy called 'Nivco', five times stronger than chrome steel, will improve the operation and efficiency of electrical apparatus to an extent never yet realized. Solventless silicone resins will revolutionize insulation for motor and generator coils.

An element known as 'Cypak', a control circuit with no moving parts or contacts, will perform basic functions of logical deduction, and send, receive, compare, collate, store, rearrange, and issue information needed to make a machine perform a predetermined series of operations automatically, with greater reliability and at no increase in cost. Many clerical offices in accounting, purchasing, production and order service departments will consist of a bank of computing machines operated by only a few skilled mechanics.

But new emphasis must first be placed on research and development. Young engineers must be kept interested in this field. The electrical industry must continue to adventure, promote and sell the idea of living better—electrically.

INDUSTRIAL MATERIALS

THE INDUSTRIAL materials considered here are used in the construction and other industries. They include asbestos, cement and concrete, clay and its products, and lumber.

ASBESTOS

CANADIAN PRODUCERS of asbestos shipped 1,061,419 tons in 1957 valued at $106.4 million, compared with 1,014,249 tons in 1956 valued at $99.86 million. These figures exclude the value of containers. The quantity increased 6.2% and value increased 6.5% over that of the previous year.

The largest producing area continued to be in the Eastern Townships of Quebec around Thetford Mines, Black Lake, East Broughton, and Danville. Ontario's production came from Munro Township. In Northern British Columbia the Cassiar Asbestos Corporation milled asbestos ore. Development work was done by Eastern Asbestos Co. Ltd. at Notre Dame de Sallette. Some discoveries were made in Newfoundland.

The Industry in 1956

In 1956, most recent year for which a full report is available, 23 establishments employed 7,065 persons whose earnings totalled $5.54 million. Cost of process supplies and containers at works was $12.33 million, gross selling value of products totalled $103.3 million, while net value of production amounted to $85.43 million. For the year 21.9 million tons of rock were mined and 13.74 million tons were milled. Values for shipments of various grades were as follows: crude No. 1 and No. 2, and other, $692,677; milled group 3 (spinning), $14.07 million; group 4 (shingle), $42.12 million; group 5 (paper), $13.2 million; group 6 (stucco), $12.68 million; group 7 (refuse), $16.67 million; group 8, $407,859. Exports for the year were valued at $163.64 million, while imports were valued at $5.38 million.

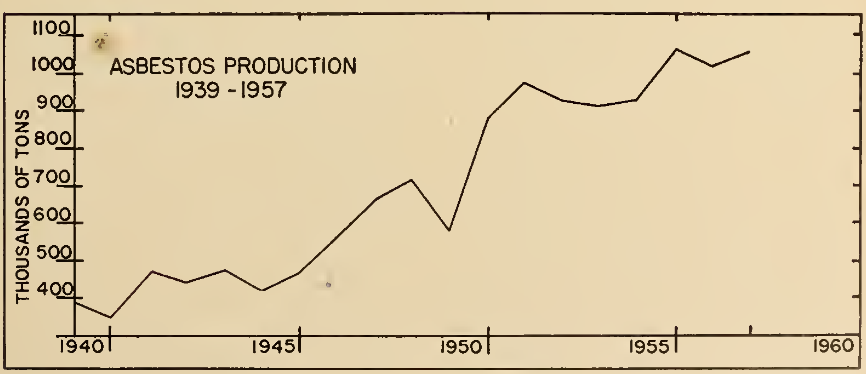
Asbestos has a variety of industrial uses. The longer-fibred spinning material is formed into textiles, packing and certain insulating and heat resisting friction materials. Other fibres are used in the asbestos cement industry for the production of pipe, shingle, tile, millboard, siding, roofing, etc., and for production of asbestos paper. The short-fibred material is used in protective coatings, plastics, lubricating greases and a number of specialized applications as an industrial filler. Canada produces some 62% of the world's supply, with Russia holding second place at 13½%.

CEMENT AND CONCRETE

PRODUCTION OF Portland cement in Canada during 1957 amounted to 6,056,038 tons valued at $93.76 million. Volume exceeded that of the previous year by 12%, while value exceeded that of 1956 by 12½%.

Cement production during the year, by provinces, in tons was as follows: British Columbia, 443,389; Alberta, 559,500; Saskatchewan 148,750; Manitoba, 424,000; Ontario, 2,182,200; Quebec, 2,079,524; New Brunswick, 161,000; and Newfoundland, 57,675.

During 1957, concrete products shipped (with comparative numbers shipped in 1956 for each item following in brackets) were as follows: concrete brick, 94.1 million (102.6 million); gravel concrete blocks, 78.6 million (84 million); cinder concrete blocks, 9.75 million (11.16 million); concrete blocks made from haydite, slag, etc., 17 million (12.1 million); concrete chimney blocks, 834,669 (862,193); cement drainpipe, sewers and water pipe and culvert tile, 453,226 (553,692); and ready mix



concrete, 4.966 cubic yards (4.987 cubic yards). These figures of production by principal manufacturers account for 85% of total Canadian output.

Industry Pattern

In 1955, latest year for which a full report has been published, the cement industry consisted of 12 plants with combined employment of 2,800 persons. Supplies and containers cost $11.5 million, while value of production at works amounted to $144.3 million. There were 29 kilns in all, with total capacity of 70,000 barrels per 24 hours. Apparent consumption (shipments plus imports, less exports) amounted to 27.16 million barrels.

For the same year, the concrete products industry included 592 establishments employing 9,780 persons; 4,457 of whom worked in Ontario; 3,051 in Quebec, 895 in Alberta; 743 in B.C.; 265 in Manitoba; 157 in Saskatchewan; and less than 70 each in the four Atlantic provinces. Wages and salaries totalled $30.7 million, materials used cost $63.3 million, and gross selling value of products totalled $133.83 million. During the year $15 million capital and repair expenditures were made.

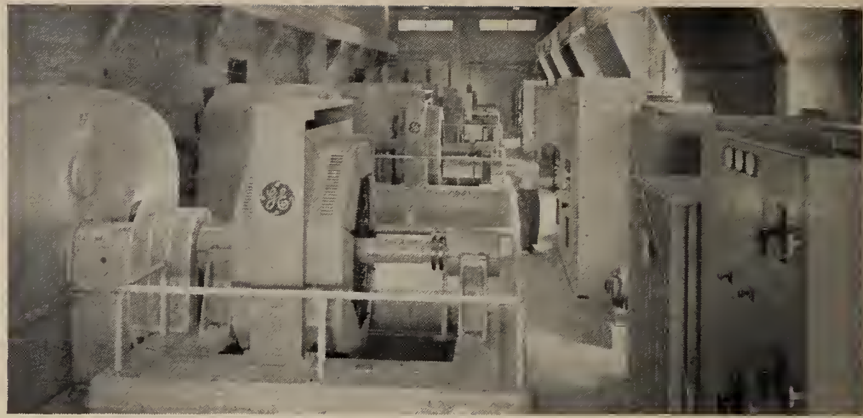
CLAY AND PRODUCTS

Clay products made from Canadian clays during 1957, valued at $34.7 million were 8.2% lower than the value of production for the previous year of building brick, sewer pipe and structural tile. Output of pottery and other clay products was higher than in 1956.

The industrial clays of Canada may be classed as common clays, stoneclays, fireclays, and china clays. Common clays are produced in all provinces. Stoneware clays are found in Saskatchewan, Manitoba and Nova Scotia. Fireclays are found in Saskatchewan and British Columbia, and to a lesser extent in Nova Scotia. China clay is not produced in Canada, but ball clay is produced in Saskatchewan. Bentonite is found in Manitoba and Alberta. Large quantities of fireclay and china clay are imported.

Production in 1956

The clay products industry is divided into two sections for statistical purposes: production from domestic clays, including building brick, structural drain, and roofing tile, stoneware, sewer pipe, pottery, and refractories came from 119 plants, in 1956, which employed 4,418 persons earning $14.8 million. Process supplies cost $1.12 million, gross selling value totalled $37.8 million and net value of production $30.45 million. Employment by provinces was: Ontario 2,203; Quebec, 796; Alberta, 471; British Columbia, 345; Nova Scotia, 227, Manitoba, 160; Saskatchewan, 125; New Brunswick, 103; and Newfoundland 8.



Motor room at the Canada Cement company's new Woodstock plant. The large synchronous motors power the raw and clinker mills. Annual production is 3,250,000 barrels.

Production from imported clays includes electrical porcelains, sanitary ware, sewer pipe, tableware, artware, floor and wall tile and fireclay blocks and shapes. Production in 1956 came from 37 establishments which employed 2,131 persons earning $7.5 million. Process supplies cost $6.22 million, gross selling value was $20.95 million and net value of production was $14.2 million. Employment by provinces was: Ontario, 1,200; Quebec, 744; Alberta and British Columbia, 162.

Four plants operated in the sand-lime brick industry in 1956—three in Ontario and one in Quebec. Employment totalled 135 persons earning $473,000, materials cost $366,258, while gross selling value totalled $1.3 million.

LUMBER

Production of lumber in Canada during 1957 at some 6.76 billion board feet showed a drop of 11½% from the previous year. This estimate was based on reports of production for the first nine months of the year. Production in the three prairie provinces showed a drop of 17%, British Columbia production was down 11.6%, while production in Ontario, Quebec, and Atlantic provinces was down 10.1%.

Canadian lumbermen are well aware that when export markets weaken, production immediately follows the same pattern. Ten years ago our export percentages were: United Kingdom, 41%; United States, 39%; other commonwealth countries, 12%; and other countries, 8%. Two years ago, in 1956, about one board foot out of every two produced was exported. That year 78% of our exports went to the United States, 12% went to the United Kingdom, 7% to other commonwealth countries, and 3% to all other countries.

But, during the past two years Canada's export markets have dropped by close to a billion board feet. Last year Canada lost between 17% and 23% of spruce and pine exports to the U.S., the U.K., and commonwealth countries. Exports of spruce and pine softwood species gained by some 50% to 65%. Hardwood exports decreased by about 17%.

Industry Statistics

In 1956, latest year for which full data on production were published, sawn lumber totalled 7.92 billion board feet, exceeding the 7 billion mark for the third year in succession and up 3.4% over the previous peak of 7.3 billion for 1953. Value of production at $541.56 million was up 6.7% over 1955. The industry includes production of shingles, box shooks, staves and headings, other sawn products and barking of pulpwood in plants other than pulpmills, woods operations are not included.

Of the 7,333 active sawmills reporting in 1955, there were 1,875 in British Columbia, 1,875 in Quebec, 1,039 in Ontario, 761 in Alberta, 643 in Nova Scotia, 549 in Newfoundland, 385 in New Brunswick, 303 in Saskatchewan, 121 in Manitoba, 69 in P.E.I., and 13 in Yukon and N.W.T. For the year 1,010 small mills were excluded as well as a few hundred small plants in other groups.

Employment totalled 58,586, 2.8% above the previous year. Salaries and wages paid amounted to $152.5 million. Cost of materials and supplies was $338.9 million. Production value at $644.5 million was up 12.6% compared with the previous year.

Production of softwoods at 7.546 billion feet was divided by species as follows: spruce 32%; Douglas Fir 31.2%; hemlock 13.2%; cedar 6.9%; white pine, 5.5%; jackpine 3.3%; balsam 3%; remaining 4% included tamarack, lodgepole pine, red pine, ponderosa and yellow cypress, in that order.

Production of hardwoods at 373,522 board feet was divided by species as follows: yellow birch, 36.8%; maple 25.6%; poplar 11.7%; basswood 6%; elm 5%; aspen 4.2%. Remaining 5½% was beech, oak, ash, alder, and cherry, in that order.

Principal sawn products for the year were as follows:

	billion feet	Value ($ million)
Lumber	6.92	541.56
Shingles	2.90	29.80
Ties	4.49	8.96
Box shooks	0.36	3.09
Laths	0.15	6.61
Hardwood sq.	0.01	1.15
Pickets, staves, headings	0.001	1.57

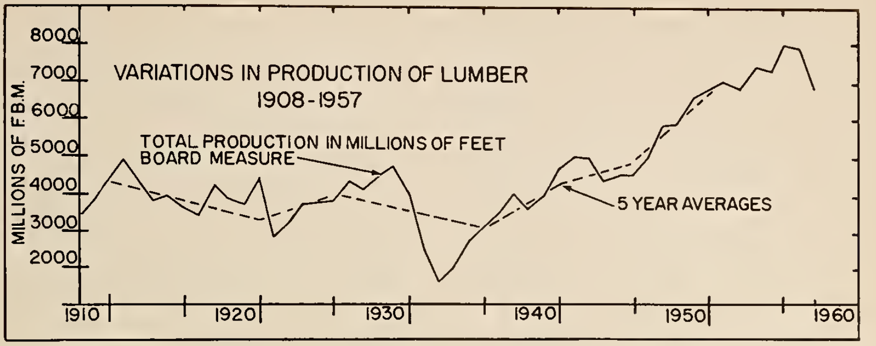
The mills range in size from the giant mills on the Pacific Coast, cutting up to half a million board feet per shift, to the small mills which only turn out a carload of lumber in ten days. The larger mills are concentrated around Vancouver, New Westminster, and the lower mainland of British Columbia as well as on Vancouver Island, along the Ottawa valley, Georgian Bay, Rainy River, and the Coast of New Brunswick.

C.L.A. Convention Hears Industry Problems

At the annual meeting of the Canadian Lumbermen's Association early in 1958, newly appointed secretary-manager, G. E. Bell, outlined some of the industry's major problems. Compared with Federal revenues of $200 million from agriculture, over half of which was spent on industry research, of the corresponding federal revenues from forest industries of $200 million only some $10 million were used for forestry research.

He called for a study of the problem of equalization of freight rates and for development of specialized freight cars for handling lumber. The latter, he said, promised savings of up to $40,000 yearly for larger lumber firms.

Pointing out that the United States had replaced Britain as Canada's main lumber export market, he urged greater attention be given to markets in other parts of the world, by meeting all trade delegations and maintaining close contact with Canadian trade officials.



Yet, he reminded delegates, domestic lumber sales amounting to half our total production, must not be taken for granted. The C.L.A. must act as a united body in promoting the use of lumber to combat the inroads made by substitutes. There was a tremendous potential in the home-improvement market for the lumber industry, he pointed out, variously estimated at between 500 and 650 millions annually. Of Canada's four-million dwelling units valued at some $25 billion, more than two and a half million were more than 22 years old and in need of repairs or alterations.

But the industry's trade journals, while not overlooking any of the above problems, have been emphasizing other almost equally urgent. Among them are:

(1) Properly designed mills and equipment, with better techniques and processes.

(2) Earlier replacement of equipment.

(3) Accuracy in production.

(4) Lumber to be sawn and graded for end use.

(5) A development program to find new and useful products.

(6) Better utilization of sawmill wastes by making slabs and edgings into chips.

(7) Assurance of fullest use before granting forest licenses.

Leaders Voice a Warning

Years of prosperity have blinded Canadian lumbermen to a realization of what is happening. Superimposed on obsolescence and demands for the repair of war destruction came the postwar era of industrial expansion and population growth. The world consumed lumber as fast as it could be produced.

But, in the belief that a change is coming, industry leaders are strongly warning the Canadian lumber trade to get ready for the competitive era ahead. Russia is a big potential competitor for lumber markets. It is not lack of Russian ability to compete that is protecting Canada's lumber export markets at the moment, but Russia's home needs for lumber to meet her vast building program and to service her rapid industrial expansion.

New Research Laboratory

One of the finest forestry laboratories of its kind in the world was formally opened at Petawawa, Ontario, on September 25 last year. It is the Forestry Experimental Station. This laboratory will provide facilities for scientific research carried out by the Forestry Branch, Department of Northern Affairs and Natural Resources. Furnished with the most modern equipment, its activities will include forest fire research, a tree breeding program and fundamental research.

B.C. Taxes on Timber Too High

In his report to the British Columbia government last year, Chief Justice Sloan found that the level of direct charges for government timber plus taxes assessed against loggers, owners and industry were dangerously high and directly opposed to the public interest.

At the Canadian Tax Foundation Conference, last September, at University of British Columbia, Ian Mahood, forest operation manager, McMillan and Bloedel Ltd., pointed out that Mr. Sloan's report had emphasized the high and discriminatory taxes that bleed off capital invested in private silviculture. Canadian capital created and saved from developing our resources was moving southward to start afresh in American forestry growth, he said. Unless we were prepared to get down to serious silviculture with our own choice species on land close to mills, we would face a declining forest economy and end up with high wood costs and no customers. The problem was the same across Canada.

THE CHEMICAL INDUSTRY

Canadian output of chemicals and allied products in 1957 was about five per cent above the value of production in the previous year, largely due to an increase in volume. Sales are estimated to have a value of some $1,200 million, but profits did not increase in proportion to the general rise because of higher labour and capital costs.

Capital expansion in 1957 was at a high rate, and preliminary estimates put the investment figure at about $135 million, or rather more than in 1956, from which several intended projects were carried over into the following year.

About 26 major chemical plants were completed in 1957, with a further thirty-odd under construction in addition to various expansion projects.

Only five outlets account for about 70 per cent of the demand for chemical products, of which some 27 per cent go to consumer industries, 15 percent to construction, and 6 per cent to agriculture. The increase in volume produced in 1957 was partly due to greater purchases by the construction industries and partly to the indigenous manufacture of materials that were previously imported.

Among the latter, a notable example is tetra-ethyl lead, of which about 90 per cent of imports were replaced by domestic production in the first half of 1957. Other chemicals made in Canada for the commercial market for the first time in 1957 included titanium dioxide, xanthates, synthetic silica-alumina cracking catalysts, and hydrogen fluoride.

Increases were noted in the production of sulphur from natural gas, ammonia, bulk oxygen (for metallurgical operations), sodium chlorate, caustic soda, and chlorine. The output of explosives and paints also showed an increase.

Organic Chemicals

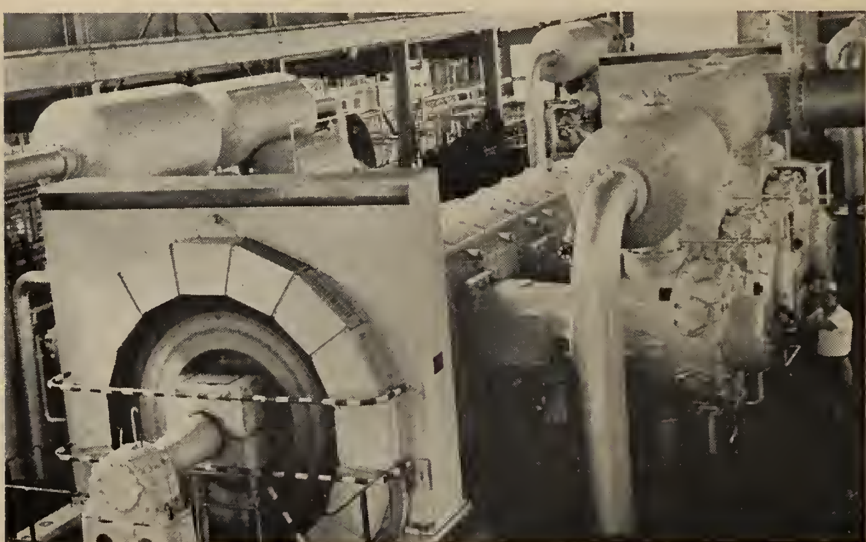
Several organic chemicals were among products for which production capacity was added during the year, notably: ethylene and other olefines, butadiene and benzene; coal tar chemicals; phenol and acetone; ethanolamines; nylon intermediates; polyester, polyvinyl chloride, nylon, and other resins, their fibres and derivatives; and synthetic rubbers.

Whereas expansion in 1956 was largely for the industrial inorganic chemicals, current developments are aimed more at increasing organic petrochemical capacity.

Imports and Exports

Imports of chemical and allied products in 1956 amounted to some $200 million, compared with exports at $228 million. Imports in 1957 are estimated to be of the order of $295 million, but exports may have been somewhat less than the 1956 figure, thus showing a larger adverse import/export balance. Nearly 87 per cent of chemical imports into Canada come from the United States, which take about half Canada's exports in this field.

Largest in Canada, this compressor at the Millhaven, Ont., ammonia plant of Canadian Industries Limited weighs 250 tons and has a 6000-h.p. motor. There are two such multi-stage compressors in the plant.



In 1954 the total value of chemical and allied products manufactured in the world was about $50,000 million, of which Canada, ranking ninth in the list of producers, accounted only for about two per cent.

Among the fields in which Canadian exports increased in 1957 compared with 1956 were fertilizers and synthetic resins.

Expansion Across Canada

Major expansions in the chemical industry, completed or under way in 1957, were mainly in British Columbia, Ontario, and Quebec. Some of the developments that took place are indicated in the following list.

British Columbia — Major expansion of facilities for producing sodium chlorate, chlorine, and caustic soda, which will reduce the need to import these materials from the United States. Petrochemicals and sulphur capacity also increased.

Alberta — An addition was made to capacity for caustic soda, polyethylene, and resins.

Saskatchewan — Sulphuric acid production was increased to keep pace with the demands of expanding uranium processing.

Ontario — Industrial chemical expansion included chlorine, carbon tetrachloride, caustic soda, soda ash, sulphuric acid, sulphates, phosphoric acid and phosphates, hydrogen peroxide, oxygen, actylene, argon, ammonia, and water-treatment chemicals. In the organic chemical field facilities were developed for: epoxy and phenolic resins; ethylene glycol, ethanolamines, polystyrene foam; Orlon and nylon intermediates; cellulose; various plastics; detergents. Other fields included: fertilizers; pesticides; adhesives and asphaltic coatings; paint and varnish; explosives; various petrochemicals; and pharmaceuticals.

Quebec — Expansion was largely in the fields of industrial and organic chemicals. Among the former were: anhydrous hydrogen fluoride; acetylene and oxygen; caustic soda and chlorine; nitric acid; sulphuric acid and explosives. In the organic chemical field were: phthalic anhydride; polyethylene resins; epoxy resins; vinyl-coated fabrics; detergent alkylates; synthetic fluid cracking catalyst; rubber chemicals; and pharmaceuticals.

Pattern of the Industry

The accompanying table shows how

A general view of the Shawinigan East chlorine—caustic soda plant of Shawinigan Chemicals Limited. It is expected that production will start early in 1958.

Manufacturing Statistics 1956—Chemicals and Allied Products Group

	Establishments No.	*Selling value of factory shipments* $
Acids, alkalies and salts	48	193,541,164
Miscellaneous chemical products	259	226,427,832
Fertilizers	45	83,399,218
Medicinal and Pharmaceutical preparations	212	122,592,220
Paints, varnishes and lacquers	126	126,312,114
Soaps, washing compounds and cleaning preparations	142	109,384,798
Toilet preparations	91	41,324,564
Vegetable oils	12	42,239,497
Primary plastics	25	82,738,552
Inks	33	15,902,813
Polishes and dressings	45	20,847,347
Coal tar distillations	11	13,221,192
Gases, compressed	53	20,972,581
Adhesives	29	12,329,512
Totals	1,131	1,111,233,404

the chemical and allied products industry is broken down for statistical purposes, and gives the number of establishments and selling value of factory shipments for the year 1956, the last period for which complete figures are available.

The 'miscellaneous chemical products' category includes such items as explosives, hardwood distillation, insecticides, matches, dry colours, and so on.

Tariffs

Among the difficulties facing the Canadian chemical industry, with its high rate of capital investment and relatively high labour costs, is the intensively competitive market in which it has to compete with, in particular, the United States and with Germany and Japan. In some fields these problems are aggravated by existing unfavourable tariff regulations.

In general, tariff rates on most chemicals are considered to be reasonably satisfactory, but there are notable exceptions, such as the synthetic resins. Tariff rates on synthetic resins imported into Canada range from zero to 7½ per cent, whereas corresponding tariffs on products going into the United States vary between 35 per cent and 40 per cent. Furthermore, the U.S. enjoys the advantage of lower production costs, related to a much larger home market.

At the request of the Minister of Finance, the Tariff Board is to start hearings on a review of tariff schedules for items in the chemical field, and revisions have recently been made to include synthetic resins and ethylene glycol.

Members of the industry are preparing recommendations for the consideration of the Board.

It is anticipated that, although there may be no drastic change in policy on tariffs in, say, the next five years, nevertheless the Government attitude towards this question may well be revised.

Future Expansion

The progress of the chemical industry is largely linked with the development of the major Canadian natural resource industries, such as agriculture, mining and metal refining, lumber, pulp and paper, and petroleum and natural gas — all of which are large markets for chemical products.

The expansion of these industries, which is a long-term probability, the development of the country by such projects as the St. Lawrence Seaway, and the anticipated increase in population are all factors which have to be taken into account in predicting the future progress of the chemical industry. New applications will probably be found for existing materials, and an enlarged domestic market may find applications for new products in the chemical field.

The Gordon Commission, in its findings, considered that chemicals would represent some 10 per cent of the gross national product by 1980, as compared with 5.1 per cent in 1955 and only 2.4 per cent in 1928. In terms of overall growth, this would mean that the chemical volume in 1980 would be about five times that in 1955.

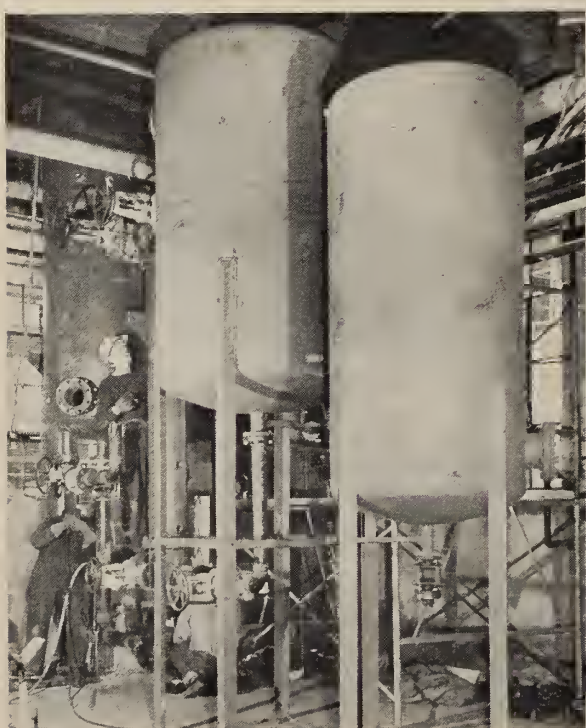
For the immediate future it is expected that some parts of the industry will be operating below full capacity, for example, the chlorine and alkali industry, which will feel the effect of the general slow-down by its industrial consumers. On the other hand, the sulphuric acid industry was due to expand by some 70 per cent over the three-year period 1956 to 1958, largely stimulated by the increase in uranium ore leaching.

Despite this possibility of a period of over-capacity, it seems likely that the factors of increased population, advances in technology, and development of natural resources will lead to the slack being taken up in the chemical industry in the next two or three years.

Research

The amount spent by Canadian chemical companies on research is only about a fifth, on a *per capita* basis, of that spent in the United States, where about 3 to 3½ per cent of sales dollars go to research and development. In 1955, the fourteen major U.S. companies spent some $200 million in this direction, whereas Canadian expenditure was $8 million.

Although purely Canadian research is relatively small, there were important additions to chemical research facilities during 1957, and it is estimated that the industry accounts for almost one quarter of investment in such assets by Canadian manufacturers.



Partial view of new equipment being installed for the production of rubber chemicals at the Ville LaSalle plant of Monsanto Canada Limited.

Rubber

Canada's Supply of synthetic rubber is entirely produced at Sarnia, Ontario, by Polymer Corporation of Canada, Ltd., while the nation's supply of natural rubber is all imported. Polymer Corporation, with employment of about 1,600 persons, produced some 132,100 long tons of synthetic rubber in 1957, an increase of 10% over the previous year. Production of reclaimed rubber at 5,025 long tons was up 6½% over 1956. Synthetic production is more than 80% in the form of Buna-S, followed by butyl, neoprene, Buna-N, and other types in that order.

Total consumption of rubber in 1956, by types, in millions of pounds, was: natural, 96.4; synthetic, 108.4; and reclaimed, 37.3. Canadian industry used more synthetic than natural rubber in 1956 for the first time since the end of World War II. Consumption of synthetic rose to a record of nearly 46% of all rubber used.

The Rubber Products Industry

In 1956, factory shipments by the rubber products industry were valued at $355.6 million, or 10% higher than the previous year. Employment stood at 21,913 persons. Materials used in manufacture cost $160.7 million, 17% higher than in 1955. Production was practically confined to Ontario and Quebec, with 82% and 18% of factory shipments respectively.

Tires and tubes accounted for 52% of the value of shipments. Tires numbered 8.6 million valued at $175.6 million. Footwear ranked second in importance and 16.5 million pairs were shipped, valued at $37.9 million. The balance of the output consisted of rubber heels and soles, belting and hose, medical and druggists supplies, mechanical rubber goods, etc., valued at $133 million. Composition by main types was: for tires and tubes, 41% natural, 44% synthetic and 14½% reclaimed; for footwear 40% natural, 46% synthetic and 14½% reclaimed; and for wire and cable, 88% synthetic and 12% natural.

Pulpwood at a mill in Corner Brook, Newfoundland

PULP AND PAPER

The total value of pulp and paper produced in 1957 was slightly lower than the record valued at $1.4 billion established in 1956. Yet tonnage of wood pulp produced at 10,176,700 tons was the second highest in history, slightly below 1956 but well above 1955. Newsprint production at 6,396,000 tons was less than one per cent under the 6,469,000 tons produced the previous year. Pulp exports at 2,232,200 tons were some 7% below exports in 1956, while exports of newsprint at 5,901,500 tons fell about 1% below 1956. Paperboard production declined about 4% while wrapping paper production fell by the same percentage, though export of wrapping paper rose sharply. Output of fine papers was up about 2 per cent.

Measure of the Industry

Though a complete government report of the industry for the past year is not yet published, the full up-to-date statistics are maintained by the Canadian Pulp and Paper Association. Its Research Institute is recognized as one of the chief centres of world knowledge on wood, pulp and paper.

Including 95,000 woods workers cutting wood for sales to mills, close to 270,000 seasonal workers cut and move the pulpwood harvest. The 75,000 pulp and paper people permanently employed in the mills, woods, and services are amongst the highest paid workers in industry.

In all, pulp and paper creates employment for some 335,000 workers. Woods employment runs counter to the normal seasonal pattern, providing work in late autumn and winter when work elsewhere is at low-ebb, thus helping to stabilize overall employment. Of the industry's annual wage bill of some $460 million, about 60% goes to the mill workers and the remainder to woods workers.

There are 80 pulp and paper companies operating 130 mills in eight provinces. Their output is one quarter greater than that of all the Scandinavian countries combined. Canada has 26 companies making newsprint. They operate 146 newsprint machines in 42 mills with a combined capacity exceeding six million tons yearly.

Next to the newsprint mills, the paperboard plants are the largest paper producers in the industry. They turn out 900,000 tons per year and give permanent employment to some 5,000 Canadians. Value of their output amounts to $125 million annually. Some paperboard is made of wood pulp and some, wholly or partly, from straw or repulped paper. The wrapping-paper industry with 13 mills creates some $55 million of new wealth yearly and including seasonal workers employs 16,000 persons.

The fine paper industry consists of 15 mills operated by 9 companies which produce annually more than 250,000 tons of fine papers having a value of some $80 million. These mills provide employment for about 28,000 persons, 8,000 of whom work in the mills.

The Canadian industry has an annual output of some 10½ to 11 million tons including 2½ million tons for sale; 6½ million tons of newsprint and 1.8 million tons of other papers, paperboard, building papers and board.

More than four fifths of the total output moves abroad. Some 92% of newsprint and 90% of the pulp produced for sale goes to foreign markets. Almost a third of the U.S. wood fibre requirements comes from Canada. Of the total, 45% comes from Quebec; 26% from Ontario; 13% from British Columbia; and 16% from the other five producing provinces. Pulp and paper accounts for about 5% of Canada's gross national product.

In newsprint Canada has a production four times that of any other country and provides more than half of the world's supply. Every hour, night and day, Canada's newsprint mills produce the equivalent of a

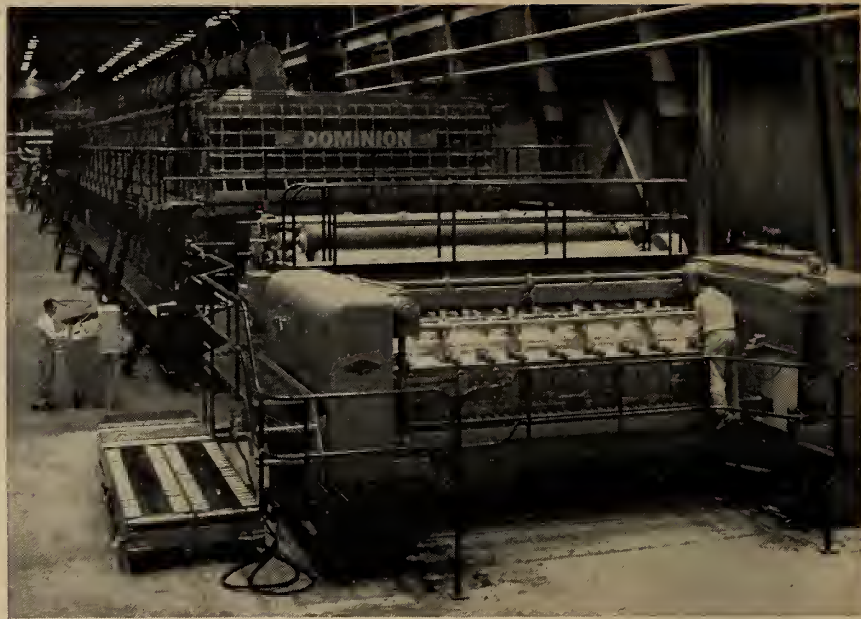
6,000-mile five-foot ribbon of paper, enough to stretch from Toronto to Baghdad. With exports of $708 million newsprint is Canada's largest item in Canada's export trade, accounting for 15% of all exports.

Based on the replacement value of the mills, the industry represents an investment of $45,000 for each mill employee.

CPPA President Reviews Industry Affairs

Addressing the Canadian Pulp and Paper Association convention at Montreal in January 1958, Association president, R. M. Fowler, told delegates that the industry was facing problems it had not faced for more than 15 years. Demand had fallen below available supply; mills were operating at the close of the year on a five-day week or even less; woods operations were 25 per cent below a year ago; competition within the industry and from other world producers was increasing. The long record of industrial peace had been shattered by a long and costly strike in the British Columbia mills.

Canadian newsprint mills produced the same total number of tons in 1957 as in 1956, he pointed out. But the fixed number of tons was nearly 104% of rated capacity in 1956, only 95% of capacity in 1957, and might be about 85% of 1958 capacity. The immediate future looked bleak, with the prospect of more curtailments, more difficult marketing problems, and more industrial unrest to come.



Pulp drier at the North Western Pulp and Power mill, Hinton, Alta., starts with a slush pulp of about 99/1 water/fibre and reduces it to 95%–100% fibre. The totally-enclosed machine has 66 driers, reportedly the largest number in one unit. The dry end is equipped with automatic baling and weighing machinery.

"For a decade we have seen—and indeed enjoyed—the greatest boom in history. A full belly maketh the heart glad. But a full belly requires time for digestion", he declared. "Some day North America must pause to digest the immense capital investment expansion that still continues even after eleven years of unprecedented industrial growth."

Even if normal growth had occurred in total world demand last year, we would still have had too rapid an expansion of productive capacity. This, he observed, was the classic dilemma of a capitalistic society: the sum total of individual decisions to expand capacity exceeded the normal growth of demand, and produced over-capacity. But we must rely on the forces of the free market to produce their own corrections, and on the same individual power and right of decision to solve the problems they have created.

Principal Statistics for the Pulp and Paper Industry*

	Production 1957	Production 1956	Exports 1957	Exports 1956
Gross value of output	$1.4 billion	$1.4 billion	$1 billion	$1,045 million
	tons	tons	tons	tons
Total wood pulp	10,176,707	10,542,300	2,232,185	2,388,484
Dissolving & Spec. chem.	341,411	411,194	291,523	344,551
Bleached sulphite paper grades	583,300	674,765	384,736	443,530
Unbleached sulphite	1,754,162	1,834,146	297,036	379,893
Bleached sulphate	882,970	812,534	716,353	670,281
Unbleached sulphate	775,391	801,285	256,020	225,385
Other chemical	244,823	234,022	41,311	45,628
Groundwood	5,516,713	5,679,983	237,697	268,491
Newsprint	6,396,114	6,468,815	5,901,527	5,971,692
Containerboard	455,495	474,071	57,402	56,555
Boxboard	390,063	412,348	22,262	25,274
Total paperboard	846,008	886,419	79,664	81,829
Fine paper	252,086	248,005	16,270	16.733
Coated paper	29,450	29,167	1,202	1,006
Other printing paper	80,925	92,620	54,590	61,764
Special papers	124,800	122,171	5,218	6,437
Wrapping paper	269,177	280,591	18,836	14,309
Bldg. papers and boards	272,000	281,000	20,000	22,500

There are some slight duplications in the foregoing figures. Some paper board and wrapping paper is used by the mills for packaging. Coated paper covers a tonnage that undergoes a further processing after it leaves the paper machine and thus is also included under other grades. Total wood pulp production includes screenings, but excludes defibrated and exploded pulp. In addition to wood pulp, the industry uses annually in the manufacture of paper some 470,000 tons of stock including waste paper, straw, rags, cotton linters, flax, jute, rope, and other fibres.

* Preliminary 1957 figures provided by the Canadian Pulp and Paper Association.

A Return to Normality

Questioning that the present situation should be described as a temporary recession, Mr. Fowler expressed belief that in reality it was a return to normality, in an economy of abundance, after nineteen years of abnormality caused by war and its aftermath. Specifically the newsprint industry had created an excess of capacity to look after sudden surges of demand, as it ought to be able to do. Believing the future of newsprint demand was a bright one he expressed doubt that most of his listeners would live to see a return, except for brief intervals, to the full capacity operations we had enjoyed for the last decade. One could regard excess capacity as a man regards an ulcer and learn to live with it. Or one could look at this new situation as a challenge and rise to meet it, and have excitement doing so.

Four Prescriptions Proposed

On the assumption we would choose the latter, more imaginative course, there were four specific things that should be done. Most of them were in our own hands, he said. First, we should look to our productive efficiency. We must learn to produce our pulp and paper products as efficiently as and more economically than, any other producers in the world. We must be in the forefront of technological progress.

Secondly, we had a job to do in co-operation with our labour leaders. More had to be done to bring the industry's economic facts to their attention, and to try to enlist their skills and influence in the strengthening of the competitive position of the industry in world markets. This was a partnership, in which the partners had the same objectives; the creation of the maximum number of jobs.

Thirdly, there was a role for government to play in collaboration with the industry, he suggested. In a country as dependent as Canada is on export trade, national commercial policies could profoundly influence the success or failure of Canadian competition in world markets. Here, again, there was no conflict of interests. If the industry makes a dollar the federal government gets 47 cents, and provinces and municipalities also gain.

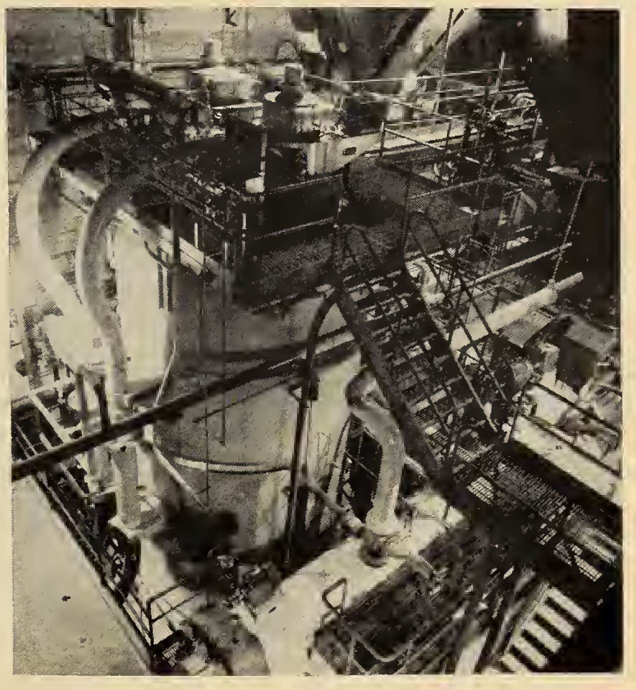
1957 a Year of Permanent Change

Fourthly and finally, each inindividual company must look to its merchandizing. Merchandizing skills had had little practice over the past fifteen or twenty years and our weapons had grown a little rusty. The merchandizing decisions of even the smallest company could strengthen or weaken the fabric of the whole industry.

Concluding, the speaker declared he refused to believe today's economic situation was one of distress or anything even remotely resembling calamity. The long term economic demand for pulp and paper was high and would undoubtedly increase greatly. But, looking back, we would see that 1957 was a year of great and permanent change in the conditions of our enterprise.

We had been rudely shown something we had refused to believe before: that the western world is in a race for intellectual leadership when we had not even realized there was a race. In the complacency of what we thought was an assured technicological lead, we had confused high living standards with intellectual stature.

The new bleached sulphate pulp mill of B.C. Forest Products Limited at Crofton, B.C., started test runs in 1957 and was to come into full production early in 1958.



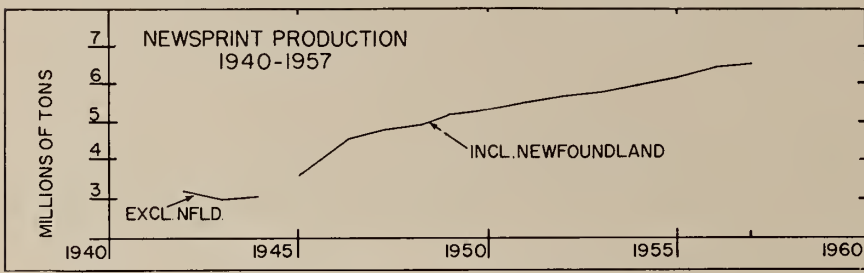
Top of continuous digester, showing chip feeders and high pressure inlets, at North Western Pulp and Power mill, Hinton, Alberta.

Woodfibre plant of Alaska Pine & Cellulose Limited, B.C.

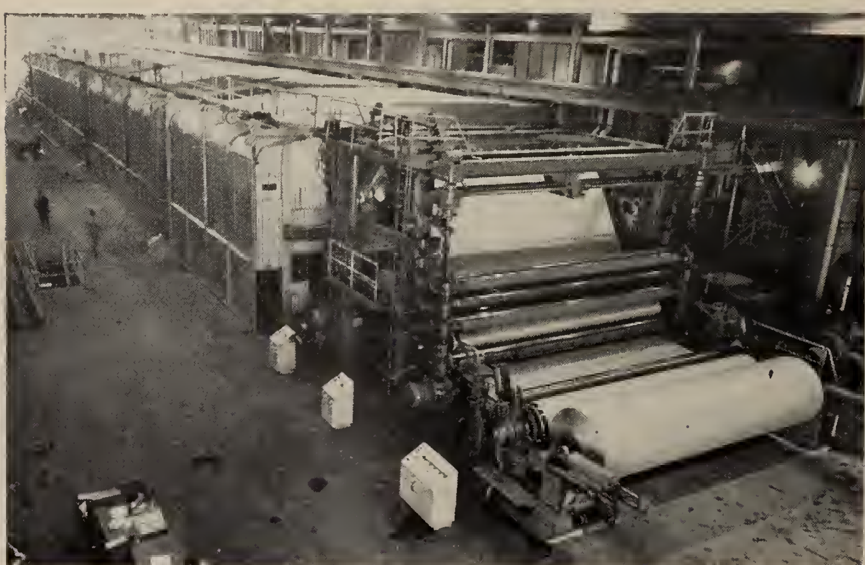
This could be an extravagant and dangerous mistake.

New Peaks in 1980

By contrast, a survey for the Gordon Economic Commission, recently released, predicts Canada's forest industries will reach new peaks by 1980. Production of all forestry products would reach a value of $4 billion by that time, an increase of 120 per cent. An average annual outlay of between $300 million and $400 million would be required. Employment in forestry industries might rise by a third to 370,000 workers, though this would represent a drop from 5.3% to about 3.8% of the total Canadian labour forces of 9,637,000 in 1980. Canada's pulp and paper production might more than double, to reach a total of 21.9 million tons annually by 1980. Most of the tonnage increase would be due to a big jump in newsprint demand to 12.5 million tons a year from the 6 million tons produced in 1954. The demand from overseas markets for newsprint would far exceed the rise in U.S. requirements.



Paper plant of the Canada Paper Company, at Windsor Mills, Que., where expansion was under way during 1957. Below is the new board and paper machine in the La Tuque mill of Canadian International Paper Company, part of a $20,000,000 expansion. Machine covers raise automatically opposite any paper break.



Additions to Capacity in 1957-58

The end of 1957 saw an approach to the close of an unprecedented era of expansion in the Canadian pulp and paper industry. Many major projects had come to fruition and were either in operation or nearing completion during 1958. In Canada the ten-year period 1946-1956 witnessed some 1.6 million tons of added capacity, four-fifths of it by improvements to existing equipment. The year 1956 saw a further 513,000 tons of capacity added, while during the year 1957 another 394,000 tons of capacity were added to the total — 36 per cent addition in twelve years. Of the capacity added during 1956 and 1957 new plants and new machines, costing in all more than half a billion dollars, have added two thirds of the total and improvements have added the other third. A further ten or more projects have been abandoned or deferred.

In the past year the North Western mill at Hinton, Alberta, reached completion, as well as expansion programs at Elk Falls and Alberni in British Columbia. The current year will see completion of Alaska Pine, Great Lakes, and Abitibi programs, and startup of the Crofton mill in British Columbia and of the Thurso mill in Quebec. The Powell River modernization and the McMillan-Bloedel expansion in British Columbia are well on the way to completion, while three Consolidated Paper expansion programs, two in Quebec and one in Ontario, costing some $27 million, are in progress. Renewals and expansion for B.C. Forest Products at Crofton will soon reach production stage.

This era of expansion is now ending, and the pulp and paper industry has entered a period of cautious adjustment, with emphasis on cost production, modernization, improvement and speedup, growth of converting operations, and increased regard for a higher degree of utilization and materials research.

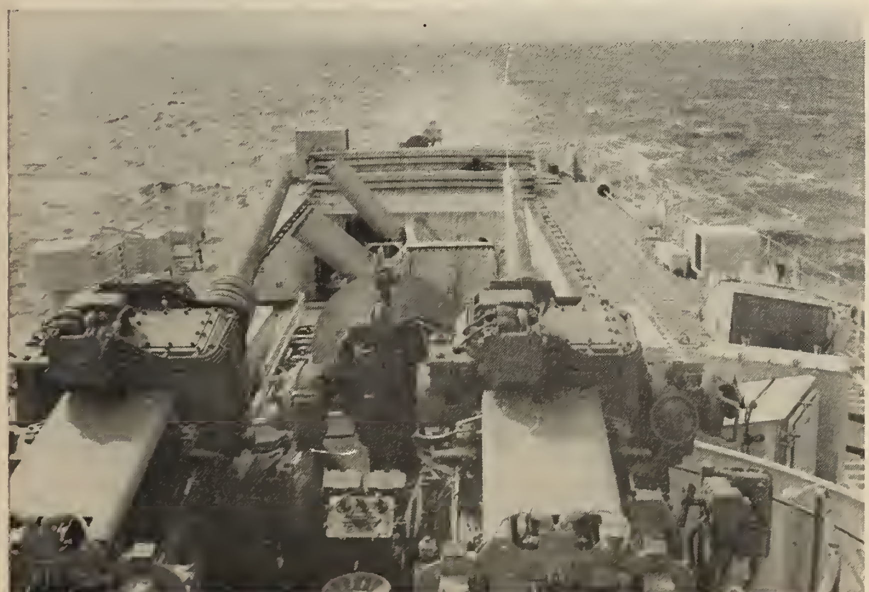
NATIONAL DEFENCE AND DEFENCE CONSTRUCTION

THE 1957-58 DEFENCE Budget for the fiscal year ending March 31/1958 called for an expenditure of $1,789,964,000, a reduction of some $52.16 million from the appropriation for the previous year. It also included $63.8 million from special accounts. In addition, $3.3 million incurred for aircrew training, to be recovered, were deducted from the gross estimate. The estimates included proposed expenditures, by services, in millions of dollars, as follows: Navy, $309; Army, $478.8; Air, $844.76; Defence Research Board, $64.8; mutual aid, $21.56; and other, $70.96.

Strength of the Forces

At 31 December, 1956, the strength of Canada's Regular Forces stood at 117,177 officers and other ranks, including officer cadets and apprentices. Of this total 19,005 were enlisted in the Navy, 47,632 in the Army, and 50,540 in the Air Force. Total strength of the Reserve Forces was 53,551, of whom 5,739 were on the Navy active list; 42,212 were in the Militia; and 1,958 were in the R.C.A.F. Auxiliary. Officer candidates in training at the same date totalled 6,774; of which 1,053 were in training for Navy, 3,330 for Army, and 2,391 for R.C.A.F. The civilian strength listed some 53,000 personnel of whom 4,745 were non-continuing or casual employees.

Above is an 'Argus' (CL-28) submarine hunter designed and built in Canada for the R.C.A.F. The Navy's role in anti-submarine warfare is exemplified by the view, below, of the quarterdeck of the new destroyer escort HMCS *Fraser*.



Defence Estimates for 1957-58

Each service prepares its estimates, gets them approved by Parliament and does much of its own engineering and design. Purchase of supplies and equipment are made through the Department of Defence Production, while contracts for construction and for engineering supervision thereof are awarded by Defence Construction (1951) Ltd., a crown company.

The value of all Canadian production of equipment for the services, as well as the value of construction of airfields, barracks and other facilities are covered elsewhere in this Review under the reports of the various Canadian industries and under construction statistics, as well as the labour forces involved. To avoid duplication they need not be recorded hereunder, except for the purpose of showing the values of the end products going to the various services.

Division of Appropriations by Categories and by Services

National Defence appropriations for the fiscal year 1957/58 were divided by major categories as follows: military personnel costs, $516.8 million; operations and maintenance, $605.7 million; procurement of equipment, $497.9 million; construction, $132 million; contributions to Infrastructure and NATO Budgets, $18.3 million; and Mid-Canada Line, $19.2 million; a total of $1,790 million.

After deductions for charges to special accounts, of $67.1 million, resulting total of budgetary amounted to $1,722.8 million.

Personnel Costs

A breakdown of military personnel costs of $516.8 million noted above showed: pay and allowances, $422.7 million; travelling and removal, $45.9 million; medical and dental services, $5.09 million; medical and dental supplies, $2.14 million; laundry and dry cleaning, $1.9 million.

Operations and Maintenance Costs

A breakdown of the $605.7 million noted above for operations and maintenance was: Navy, $95.9 million; Army, $133 million; Air Force, $282.9 million; Defence Research, $24.3 million; and other, $69.5 million. About a third of the total provided for repair and upkeep of equipment, and of buildings and works, rental of buildings, and utility services. Pension funds accounted for a little more than a further third. The remainder included $40.5 million for gasoline, fuel oil and lubricants, $18.8 million for fuels for heating and cooking, and lesser amounts for barracks and hospital stores, freight, postage, and so forth.

Equipment Costs

A breakdown of the $497.9 million noted above for major equipment procurement was divided among the services as follows: Navy, $116.5 million; Army, $63.8 million; Air Force, $275.8 million; D.R.B., $38 million and other, $3.8 million. The total excludes initial equipment costs in connection with the mid-Canada Radar Line which is dealt with elsewhere. Army equipment purchases were mostly financed from special account funds.

Construction

The construction program for 1957/58 amounting to $128.6 million was divided by services, as follows: Navy, $10.35 million; Army, $68.05 million; Air, $50.25 million. Provision for barracks, mess halls, hangars, depots, etc. was $84.9 million; married quarters and schools, $26.1 million; airdrome development, $4.78 million; minor projects, $8.3 million; purchase of property, $4.55 million. Expenditures directly related to the building of the mid-Canada line, including installation of equipment amounted to some $47 million in 1955/56 and $124 million in 1956/57. Expenditure to complete it in 1957/58 was estimated at $19.2 million, with an additional $18.2 million to be provided for the first year's operation and maintenance by contract.

D.R.B. and Mutual Aid

Added to the above were appropriations for the Defence Research Board of $24.2 million for research and $40.6 million for development. Provision of $130 million for mutual aid included NATO aircrew training, $28.6 million; transfers of equipment from service stocks and from direct production, $83.1 million; and Infrastructure and NATO budgets, $18.3 million.

Steam for aircraft catapults is stored in accumulators below the flight deck of the carrier HMCS *Bonaventure*.

The 20,000-ton aircraft carrier, HMCS *Bonaventure*, showing angled flight deck.

The Navy in 1957

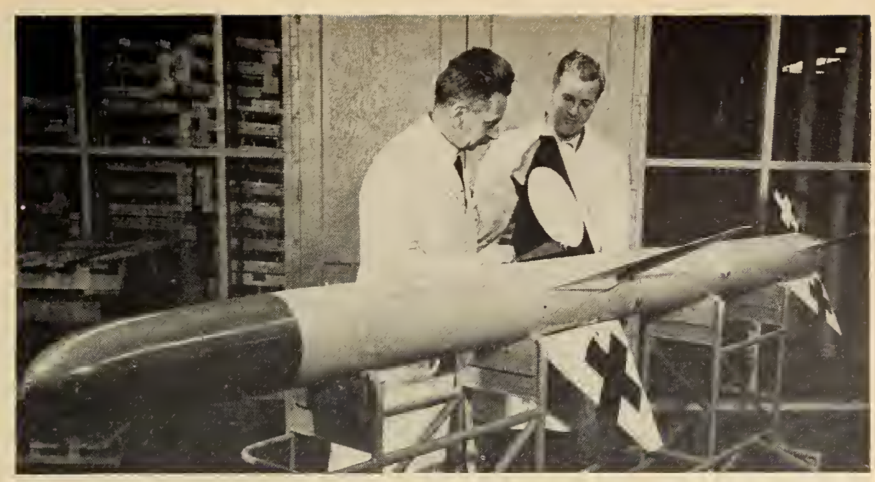
During 1957 the Royal Canadian Navy concentrated its main efforts on creation of a fleet capable of meeting the threat of missile-armed submarines. Major additions to the fleet were the new aircraft carrier, H.M.C.S. *Bonaventure*, a modern mobile base for anti-submarine aircraft; three new destroyer escorts, the *Skeena*, *Fraser*, and *Margaree*, and four frigates returned to service after modernization and addition of new weapons.

In the air, one naval air squadron was re-armed with anti-sub Trackers, with a second on the way to being equipped with this new and powerful aircraft. Two fighter squadrons were re-armed with all-weather 'Banshee' jets, and Tracker and Banshee squadrons were embarked on the *Bonaventure* in September. Training and experiments were continued in the use of helicopters for anti-sub warfare. Coastal defences were strengthened with five *Bay* class minesweepers equipped with latest sweeping equipment.

At year-end the Navy's combat ships in commission numbered 45, excluding five vessels undergoing refit and three R.N. submarines under R.N. operational control. To man the ships and aircraft and provide shore support the R.C.N. had a regular force at year-end of 19,558 officers, men and Wrens.

During the year, under Mutual Aid, five *Bangor* class coastal escorts were transferred to Turkey. The aircraft carrier *Magnificent* was returned to the Royal Navy, while the Arctic patrol ship *Labrador*, after co-òperating with U.S. Coast Guard vessels in establishing an escape route for deep draught ships through the Arctic was paid off for refit before transfer to the Dept. of Transport.

Climax to the year's seagoing activities came in September with the NATO fall exercises, in which eight Canadian destroyers took part, operating with naval units of five other NATO nations in the North Atlantic, Bay of Biscay, and Baltic approaches. Later six of them visited Germany and five Scandinavian countries.



The Sparrow II air-to-air guided missile is being developed for the R.C.A.F.

R.C.A.F. Accomplishments in 1957

The year 1957 saw the Royal Canadian Air Force add materially to its operational effectiveness. During the year the Mid Canada early warning line was placed on an operational footing. Built and operated by Canada, it stretches some 2,500 miles westward from the Labrador coast—a valuable addition to the American Air Defence System.

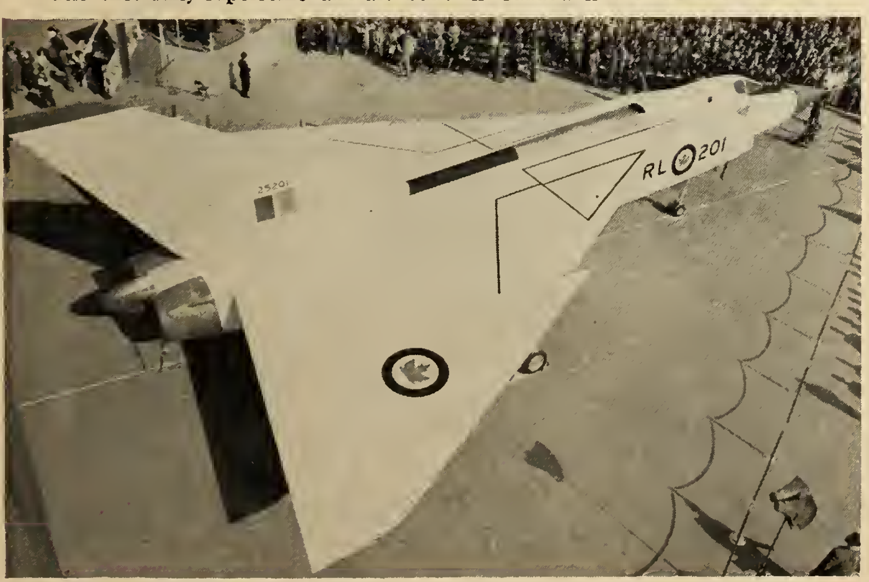
In September the R.C.A.F. took delivery of the first of its big 'Argus' sub-killer aircraft from Canadair of Montreal. Destined for operational service with Maritime Air Command, the Argus is the largest aircraft ever built in Canada and the most potent aircraft of its type yet produced. Early in October the supersonic all-weather 'Arrow' jet interceptor, designed and built by Avro Aircraft of Malton was unveiled. The big interceptor, crammed with the latest in electronic equipment, and designed to carry guided air-to-air missiles, is the first supersonic aircraft made in Canada.

Canadian-developed navigational devices, the R-Theta computer and the positioning and homing indicator, continued in production, as well as work on a number of projects for safety equipment, improved parachutes and other aids to safer flying.

In Europe, 1957 saw completion of the transfer of four CF-100 all-weather interceptor squadrons to Canada's Air Division in Europe. Together with the Division's eight F-86 Sabre day-fighter squadrons they are providing our air Division's combat forces with an around-the-clock combat capability.

Announcement was made of joint Canadian-U.S. mutual aid contribution of 53 Canadian-built CF-100 interceptors to Belgium. The first 14 were ferried across the Atlantic in December. A small group of Belgian ground technicians were given training by R.C.A.F.'s Air Division Overseas to facilitate servicing these craft.

The first fully-supersonic aircraft built in Canada is the CF-105 Arrow.



In addition 10 pilots and observers from the Belgian Air Force were given CF-100 flight training at Cold Lake, Alberta. During the year the first of 360 West German aircrew trainees also arrived in Canada for pilot training.

During the year R.C.A.F.'s Air Transport Command carried more than 50,000 passengers and airlifted more than 14 million pounds of cargo from Indo China, the Middle East, Europe and throughout Canada. A.T.C. squadrons continued to provide air transport in support of the United Nations' Emergency Force in the Middle East, as well as carrying out several trips to Saigon on behalf of the Canadian Indo-China Truce Commission.

The year also saw the completion of No. 408 Squadron's nine-year-old Shoran aerial survey program in Northern Canada. A rise in R.C.A.F. search and rescue operations activity occurred, with a total of 8,200 aircraft hours flown on air searches and rescue missions; 25% above the previous year. Nos. 404 and 405 Squadrons, Maritime Air Command, based at Greenwood, N.S., operated their Lockheed 'Neptune' aircraft from both sides of the Atlantic during such training schemes as 'Sea Spray' 'Sea Watch' and 'Fend-Off'.

Last summer Air Marshal Slemon was named Deputy Commander-in-Chief of the North American Air Defence Command (NORAD) with headquarters at Colorado Springs. NORAD will provide integrated planning and operational wartime control of the aerial defences of North America and will contribute to a more effective air defence system for the whole continent. Air Defence Command's nine squadrons, whose re-equipping with Mark V CF-100's was completed in

1957, participated during the year with the U.S.A.F., in a series of cross-border training exercises.

Army Adjust to New Conditions of Warfare

A comparison of army equipment of today with that in use towards the end of World War II shows clearly the substantial improvements that have been made in virtually every arm of the service. 'Centurion' tanks have replaced 'Shermans'. A complete new range of combat vehicles has been produced, and new field, medium and anti-aircraft artillery.

The 'Heller' anti-tank weapon and the 'Iroquois' flame thrower, a new sub-machine gun, mine detector, and counter-mortar radar detection equipment, as well as improved communications equipment, are now in service. Production of the new FN-C1 rifle began to come into service in 1957. The Army has designed a lightweight tracked vehicle capable of operating in deep loose snow, in water and over rough timbered terrain. It was built by Canadair, Ltd.

In addition to the 'Flying Truck' project, developments to enhance the mobility of land forces has included work on traction devices, over-snow tractors and navigational aids. The tracked carrier project continues, aimed at developing a multi-purpose tracked chassis for armour, artillery, infantry and other uses.

Many changes were seen in 1957 concerned with the adjustments to new conditions of warfare expected under the influence of nuclear weapons and rocket propulsion. Soldiers have been concerned with the new era of tactics and strategy for some years, but last year the army practised the new tactics with simulated nuclear devices at Camp Gagetown; more than 100,000 regular army troops fought a mock nuclear war, and thousands of rounds of live ammunition were fired during the exercises without incident.

Canadian-built Sabre VI fighters for the West German Air Force.

In Germany, the 2nd Canadian Infantry Brigade Group completed two years of intensive training as part of the NATO ground forces. On this side of the Atlantic for the first time a tactical formation of several hundred Canadian troops took part in exercises in the presence of an actual nuclear weapon in Nevada, while R.C.A. gunners trained with the U.S. army at Fort Bliss, Texas and with the British Army in the U.K. to keep abreast of latest developments in the guided missile field.

As a result of this training and experimentation, reorganization has been taking place. A third armoured regiment was raised in January and two battalions of the Regiment of Canadian Infantry Division were disbanded. At year end the Headquarters of the 1st Canadian Infantry Division at Petawawa were disbanded. The army will henceforth be organized into four balanced brigade groups, three in Canada and one in Germany.

During their first year in Egypt, Canadian troops scored an impressive record with UNEF. Responsible for second-line transport for the entire force, Canada's No. 56 Transport Company, RCASC, logged almost 2 million miles, most of it over sandy desert roads. An RCAMC hospital in Egypt treated or cared for thousands of sick or injured soldiers. No. 56 Signal Squadron R.C.S. strung 500 miles of telephone cable, and handled 18,000 messages monthly. At year end No. 56 Canadian Reconnaissance Squadron R.C.A.C. was patrolling the Israeli-Eygptian border in 'Ferret' scout cars from the Gaza Strip to Gulf of Aqaba, while the 1st Middle East Detachment, R.C.E., removed or blew up an uncounted number of mines in sand-covered minefields.

Three 'RAT' articulated tracked vehicles under development for the Army.

Defence Research Board

In addition to its support of and co-operation with the armed services, D.R.B. carries out work in several less directly related fields. The Board's co-operation with Universities of Toronto, McGill, and Laval on radar, aerophysics, and medical research has been notably productive. D.R.B. conducts considerable personnel research. Medical, psychological, and environmental problems are increasing in scope and complexity, demanding more and more effort in these fields.

The Board is also concerned with geophysical and Arctic research, particularly as these apply to winter warfare. Its aim is to provide the forces with information on oceanography, the atmosphere, climatology, magnetism, meteorology, hydrology, and navigation. The emphasis remains on the arctic aspects of these sciences.

Emphasis on the Board's studies on civil defence is on problems arising from the threat of attack with thermonuclear weapons. Investigations include development of techniques for predicting the probability of fall-out and for verifying the extent. A number of questions relating to evacuation of cities have been studied.

DEFENCE CONSTRUCTION

Defence Construction (1951) Ltd. was established in November 1950 for the purpose of administering the National Defence construction program. In addition, DCL has been administering the Capital Assistance Program, Colombo Plan Projects, some of the defence projects financed by the U.S. government, and most recently the construction of the Natural Gas Pipe Line (Northern Ontario Section).

The dollar volume of all defence and non-defence projects administered by DCL in the past seven years amounted to about $1.2 billion dollars. Value of defence construction work put in place during this period was equivalent to 50% of all Federal expenditures on new construction projects, excluding housing and capital works projects financed by government-owned enterprises like the Film Board, T.C.A., etc. At year-end DCL had under its administration over 900 contracts with a value of $460 million. These contracts cover work in Canada, France, India, Pakistan, and Ceylon and will cost over $90 million to complete—$69 million in Canada and $21 million overseas. In the fiscal year 1958/9 expenditures on current and new projects for which DCL is responsible will amount to $135 million.

Translated into physical terms this defence construction program means thousands of buildings and structures, either erected or still under construction in some 300 locations spreading from Halifax to Vancouver and from Whitehorse and Frobisher Bay to the U.S. border. The program includes roads, bridges, railways, runways, dams, wharfs, radar stations, laboratories, warehouses, barrack blocks, housing units and many other buildings and structures.

Supervision

To supervise a construction programs of this volume requires a unique supervisory force, which now includes 92 fully qualified engineers and a large number of technicians. Its operations are controlled through six Branch Offices located in Halifax, Montreal, Toronto, Winnipeg, Edmonton and Vancouver, and over 80 'on site' field offices which are being set up and closed down with the start and completion of work. R.C.A.F. projects in Europe are handled by DCL office in Paris.

Most supervision is done by DCL personnel, but policy on supervision calls for substantial aid from the professions. When there is reason to believe that a project having special engineering requirements can best be supervised by a consultant, either the designer or an engineer who specializes in this type of work, then a consultant is retained.

At year-end DCL had under administration nearly 400 contracts for architectural and engineering services for defence projects. Of the work represented by these contracts some $2.6 million remain to be expended. Of this amount over $400,000 is for supervision by engineers.

A typical main station of the Mid-Canada Line during construction.

The Year 1957 in Review

1957 was another busy year for DCL. Expenditures on defence contracts alone amounted to $108 million, compared with $98 million in 1954, $105 million in 1955, and the record high $160 million in 1956. However, new contract awards at $58 million were considerably less than in previous years, and consequently DCL entered the year 1958 with a carry-over of work more modest than in previous years. It is expected that in 1958 the situation will be reversed: expenditures on defence projects will go down but a considerable volume of new contract awards will greatly increase the carry-over for 1959.

Major projects under way last year included completion of the Mid-Canada Line, secondly the work on the Northern Ontario Section of the Natural Gas Pipe Line, and thirdly the further progress on Colombo Plan projects.

The Mid-Canada Line, now completed, was the challenge of the north to contractors and transportation men. For two years this was DCL's major project, differing in problems which it created from anything undertaken before. Only those who took part in this project know of the tremendous effort which was necessary to bring men and materials on to the construction sites, and the amount of planning it took to have them there at the right time. Canadians had never before participated on such a wide scale in a combined operation of air-lift and tractor train transportation of such magnitudes. Including electronic equipment and transportation, the project involved over $200 million.

Under an agreement with the Northern Ontario Pipe Line Crown Corporation, DCL is providing engineering liaison for the Northern Ontario Section of the Line, calling tenders, recommending contract awards, and providing general field supervision of construction work.

The Northern Ontario Section eastward from the Manitoba-Ontario border was divided into two portions.

The first portion, 311 miles long from the Border to Lakehead, was subdivided into four spreads, and four contracting firms were working simultaneously one on each spread. They met their target of bringing pipe to the Lakehead at the beginning of this year. At present work is proceeding on the second portion, 365 miles between the Lakehead and Kapuskasing. It is divided into 5 spreads and the five contractors are working on clearing the right-of-way.

Contracts for construction work and supply of materials for the Crown project amount to about $100 million. The work involves placing of about 215,000 tons of 30-in. diameter steel line pipe. The quantity of dynamite used in making right-of-way and ditch in the first section only, 311 miles from the Border to Lakehead, is estimated at 4,500,000 lb.

Progress on Colombo Plan Projects

Since 1953 DCL has assisted the International Technical Co-operation Division of the Department of Trade and Commerce by assuming the responsibility of the negotiating and administration of engineering and construction contracts connected with the Canadian Colombo Plan Construction Program. The total value of the eleven projects located in Pakistan, India and Ceylon reached the $186 million mark in 1957, of which $78 million represents Canadian participation.

During the past year, three of the eleven projects were completed and handed over to the recipient countries. These include the 350 metric ton per day cement plant at Daud Khel, Pakistan, the 10,000 h.p. hydro-electric plant at Mayurakshi, in India, and the fish refrigeration plant at Colombo, Ceylon, capable of processing 300 tons of fish per week. During the coming year, a 10,000 kw. steam plant will be completed in East Pakistan and the balance of a 52 mile transmission line in Ceylon is expected to be completed.

In west Pakistan good progress was made on the 160,000 kw. hydro-electric power and irrigation project at Warsak. A colony of nearly 300 Canadians have been established at the site of the work in the tribal area of the North West Frontier, not far from the Khyber Pass. Here, there was a labour force of 7,557 (138 Canadians, 19 Europeans, and 7,400 Pakistanis).

Also in West Pakistan a substantial start had been made at Shadiwal, where 12,000 kw. are being developed to operate tube wells to reclaim water-logged land and simultaneously use the pumped out water for irrigation in other areas. The Dacca Chittagong transmission line and the Goalpara steam power plant, both in East Pakistan, and the Kundah hydro-electric power project in India were well under way.

All of these projects have been designed and equipment and material specified by Canadian engineering companies and construction firms.

In so far as possible, material and equipment of Canadian manufacture is specified and supplied to these projects, with the result that in some instances 90% of the equipment and services is of Canadian origin.

The search and rescue homing device 'SARAH' has a beacon effective up to 75 miles and voice unit for close range.

Forecast for 1958

In 1958 DCL will probably award new defence work close to a value of $100 million, compared with awards in 1957 amounting to $58 million. It is expected that defence works put in place in 1958 will have a value of $65 million, compared with some $100 million placed in 1957. In addition there will be an expenditure of some $58 million on the pipeline and some $12-14 million on the other non-defence program—the Colombo Plan. This would involve administering a total defence and non-defence expenditure of $135 million in 1958, if estimating proves reasonably accurate

On the major projects planned for the near future should be mentioned the RCAF Station at Summerside, P.E.I. where it is expected work will be started before summer on the construction of hangars and on facilities estimated to cost $8 million. A similar program is planned for Greenwood, N.S. at an estimated cost of $7 million.

Canada's Defence Policy

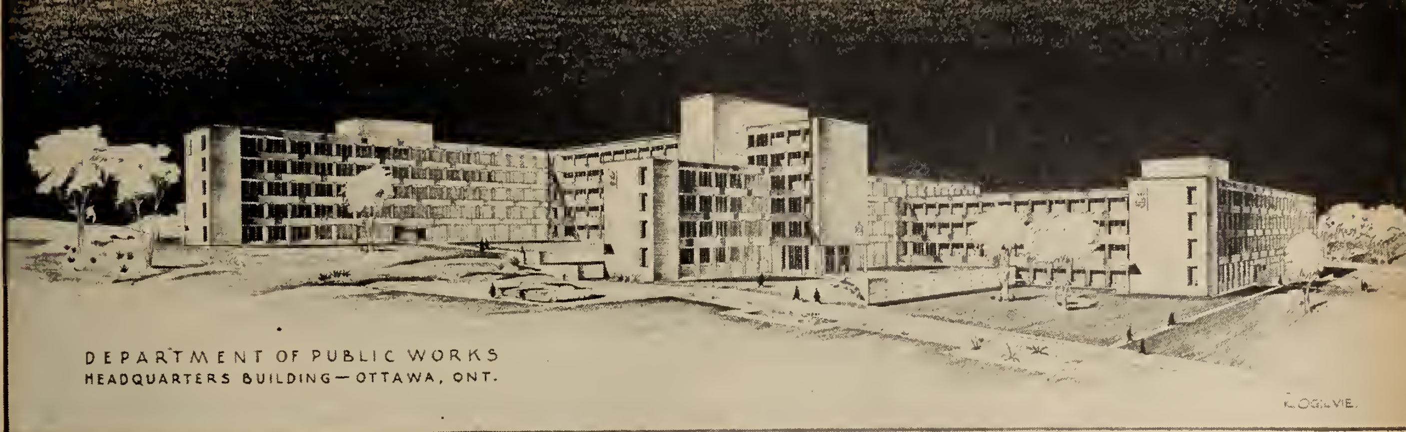
Addressing the House of Commons on December 5, 1957, the Hon G. R. Pearkes, V.C., Minister of National Defence, explained Canada's defence policy and commitments. It was 'to provide for the security of Canada, and the Government believed the best way to achieve that aim was through membership in NATO . . . The best way to prevent war is to make it clear to a potential enemy that war would be so disastrous it must not be contemplated.' Summing up Canada's contributions of 12 squadrons of interceptor aircraft, forty naval fighting ships, and a Canadian infantry brigade of 5,000 men, he explained to the members that if we were drawn into a major conflict, the situation would be quite different from those of 1914 and 1939.

One of the first and vital battles, he warned, might well be for survival within our own boundaries.

Knowledge that the U.S.S.R. have many long-range submarines capable of launching missiles far from our shores at targets well inland emphasized the importance of the anti-sub role of our navy. Because the initiative will always rest with the enemy the navy must be operationally ready before any war begins.

The officer appointed as Commander-in-Chief, North American Air Defence, was made responsible to both governments for air defence of North America, and to report directly to the U.S. joint chiefs of staff and the Canadian chiefs of staff committee. All plans must be approved by both and, when necessary, by both governments.

'Our military advisers believed a third world war would commence with a sudden ferocious thermonuclear attack from several directions' stated Mr. Pearkes. This initial period, when the fight for survival was paramount, would be likely to decide the eventual outcome. It was important that the forces required be trained, equipped and in position, he warned. There would be no time for mobilization. That was why we must continue to give top priority to our regular forces. Only if we survive that initial stage would it be possible to raise and train additional forces.



A contract has been awarded for the construction of a headquarters building in Ottawa for the Department of Public Works.

GOVERNMENT WORKS

FEDERAL • PROVINCIAL • MUNICIPAL

THE ANNUAL survey of proposed capital investment in construction for 1957, made by the Department of Trade and Commerce in the fall of 1956, disclosed intentions for 1957 adding up to a value of some $2½ billion by all three levels of government. Expenditures at Federal level were estimated as follows: by government-owned enterprises, $302.8 million; housing, $35.5 million; government departments, $322.5 million; a total of $660.8 million.

Expenditures at Provincial level had been forecast as follows: by government enterprises, $474.0 million; by institutions, $55.6 million; and by government departments, $541 million; a total of $1,070.6 million. Expenditures at municipal level had been forecast as follows; by government enterprises, $162.4 million; by institutions, $198.5 million; and by government departments $404.7 million; a total of $765.6 million.

Intentions in 1957

In the annual report of the Construction Industry 1956-1957, intentions for 1957 had been recorded for total construction in each province, for both public and private account. Though not shown separately in these tabulations, expenditures by provinces or regions for highways, bridges and fences, and for schools, hospitals, other institutions and waterworks and sewage systems at all government levels which are mainly built with public funds, can be found. (Table 1.)

Table 1 Intentions by Regions for Certain Types of Public Construction in 1957

Millions of Dollars

Type	Maritimes	Quebec	Ontario	Prairies	B.C.	Canada
Schools..........	$11.8	$50.9	$96.0	$55.8	$34.0	$248.5
Hospitals........	10.8	37.4	53.6	35.1	27.0	163.9
Other Institutions	15.1	18.0	24.2	12.2	3.1	72.6
Sub-Total........	37.7	106.3	173.8	103'1	64.1	485.0
Water and Sewers	7.1	64.5	110.0	54.1	21.2	256.9
Roads, Bridges...	67.9	162.7	340.2	182.2	99.4	852.4
Total...........	112.7	333.5	624.0	339.4	184.7	1,594.3

Per capita expenditures on these categories of public construction are above the national average for British Columbia, the prairie provinces and Ontario, in that order, but below the national average in Quebec and the maritime provinces.

Federal Department of Public Works

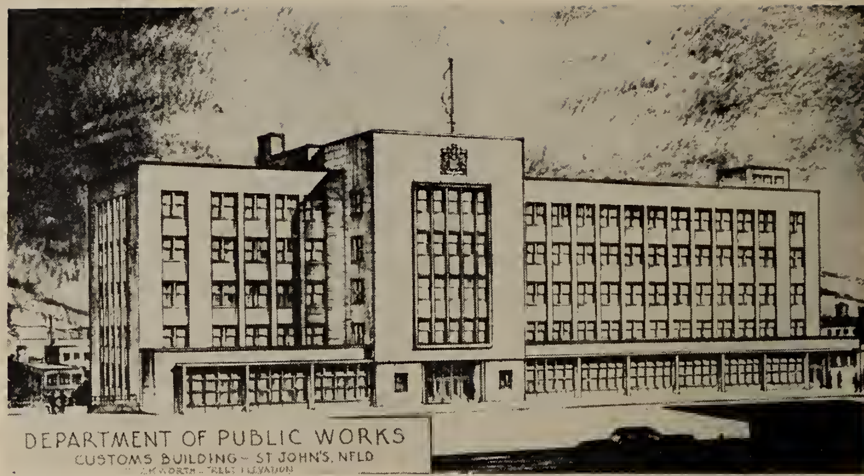
During the fiscal years 1956/57 construction and repairs were made to 302 wharves, breakwaters and other harbour facilities, of which 232 were completed. In addition, 1339 smaller projects were undertaken. Work was under way for National Defence at Dartmouth and Esquimalt. Dredging was carried out in 304 locations involving removal of some 7½ million yards of material.

Contracts for construction, alterations and improvements were awarded during the year. The extensive program of building in Ottawa was continued. An expanded program of fairly large building was also in progress across Canada.

Total expenditure during the fiscal year 1956/57 totalled $189.7 million, divided as follows: public buildings, $88.3 million; Trans Canada Highway $36.1 million; harbour and river works, $27.5 million; dredging $6.7 million; engineering and building for other departments, $26.3 million; other outlays, $4.8 million.

Construction intentions by the Federal Department of Public Works for fiscal year 1957/58 totalled some $322.5 millions, of which $196.6 million was for building and $125.5 million was for engineering construction. A statement released at the end of 1957 announced a total of 1426 different types of projects would cost some $100 million to complete. The Department had also undertaken 48 building projects for other federal departments on which there remained $14 million to be spent.

Under way at year end were: harbours and rivers, 861 projects on which $16.2 million was still to be spent, development engineering projects on roads and structures in Parks and N.W.T., including Trans Canada Highway totalled 19, on which $6.7 million remained to be spent. Building numbering 87 in various parts of Canada would cost some $75 million to complete.



Proposed building for the Customs and Excise Divisions, Department of National Revenue, in St. John's, Newfoundland, for which a contract has been awarded.

Provincial and Municipal Construction in 1957/58

Work accomplished in the fiscal year 1957/58 by various provinces is noted elsewhere in this issue for provincial roads and bridges under the section dealing with construction. In Table I are given trade and commerce forecasts of 1957 expenditures on roads and streets and on waterworks and sewerage projects by regions, performed by all three levels of government.

Though no information is available from various cities or municipalities, and while Provincial Public Works Departments generally have failed to supply detailed reports, work on public buildings by the Department of Public Works of Ontario is probably typical. Ontario accounts for more than a third of all the public building construction done at provincial level in Canada.

Ontario Public Works 1957/58

For the fiscal year 1956/57 expenditures on public works by Ontario on capital account totalled some $30 million. During the year 1957/58 it has exceeded $40 million; while for 1958/59 the Department estimates there will be more work done than in the year 1957/58.

During the year just ended several administrative units were provided for the Ontario Provincial Police. A building on Fleet Street in Toronto was renovated for a Headquarters and a crime detection laboratory. New district headquarters were built at Port Arthur, Barrie, Niagara Falls and Timmins. Detachment buildings were completed or under way at 13 stations across the province. Registry offices were built at North Bay and Port Arthur and houses for personnel at 16 other points. Many garages were also built.

For the Highways Department, garages and other buildings were completed at seven points. Divisional garages were completed at Huntsville, Kenora, Ottawa, and others started at Kingston, Bancroft, and McFarlane Lake. Garages of various sizes were under construction at eight places and additions were under way at Downsview. Other work was progressing at Hearst, Marathon, and Ear Falls.

For Ontario medical hospitals much work was carried out to provide bed accommodation, with other ancillary factors. The 1200 bed hospital at North Bay was opened last October. Hospital buildings are well advanced for the 500 bed hospital at Kingston. Two new continued treatment pavilions were nearing completion at Brockville, one for male and one for female patients. Additions to the Chest Diseases Division at Woodstock are well advanced, while buildings for a pasteurization plant, a central power plant and a trades building were under way. An extension to the Criminally Insane Building at the

One of the bridges built by the Ministry of Public Works, Quebec, crosses the St. Francois River between Grantham West and Wendover, Drummond County.

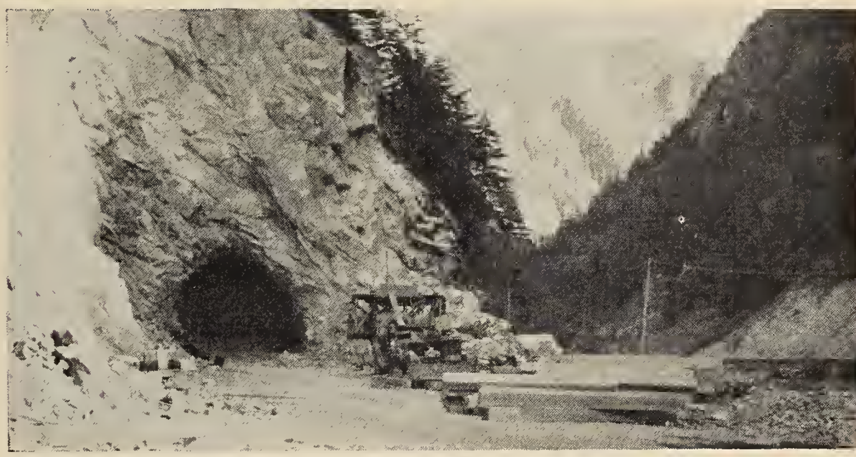
Ontario Hospital, Penetanguishene, was opened in November. New additions were under way at Whitby, and for Ontario hospitals at six other cities. Buildings were extended and renovated at Sarnia, Toronto and Hamilton. A complete new hospital unit for retarded children is planned in the Chatham district.

Regional buildings for the Public Works Department were added to at London, Port Arthur, Mimico, Orillia, and Sault Ste. Marie. For the Department of Lands and Forests new buildings and renovations were under way at Maple, Pembroke, Plevna, Uxbridge, Forest, and Fort Frances, as well as for a new Mining Recorder's office at Kirkland Lake. Six cottages were under construction at Elliott Lake for mine inspectors.

For reform institutions, a training school for incorrigible boys was completed at Guelph, as well as a similar centre for incorrigible girls at Galt. The new reformatory at Millbrook was opened last June. Work on a new training centre for reformable women at Brampton had re-commenced.

In the field of education, work was completed for the new Lakehead college of Arts, Science and Technology, while the old State Street School at Ottawa was renovated to accommodate the Eastern Ontario School of Technology. The teachers College at Hamilton was opened and work was under way for another at London. Three Toronto buildings were being renovated for the Institute of Trades. At the Ontario Agricultural College in Guelph an extensive program of work was under way. Other building renovation and construction was completed or partly completed at Ridgetown, and Vineland.

Major renovations to services and property at the Legislative and Departmental Buildings at Toronto is constant, with much work required each year to maintain, alter, and improve existing buildings.



Pembina (Man.) overpass, and tunnel in the Fraser Canyon, Trans Canada Highway.

Deerhome mental hospital at Red Deer, Alberta.

P.F.R.A.

The Prairie Farm Rehabilitation Administration, or P.F.R.A. as it is generally referred to, was set up under the Prairie Farm Rehabilitation Act of 1935 during the severe drought and depression of the thirties. The Act was amended in 1937 to increase its scope and authority. Administered through the Federal Dept. of Agriculture, its head office is in Regina, with regional offices in Kamloops and Winnipeg, and 18 district offices in the four western provinces.

Its two primary functions are water development, and land utilization within the 105 million acre area under its supervision. The grand total of Federal outlays to a year ago amounted to some $122 million. This financial assistance was divided to provinces as follows; Manitoba $9.38 million; Saskatchewan, $54.8 million; Alberta $54.5 million; and British Columbia, $3.37 million.

Water Development

Under the water development program 43,600 dugouts, 6,718 stockwatering dams, and 53,500 individual irrigation projects were built up to March 31, 1957, at a cost of $34.7 million. Eleven major irrigation and acres, were also built jointly with the provinces concerned at a cost to the Federal Treasury of $63.3 million.

There are some 2.7 million acres of reclamation projects at present serving 930,000 acres, which can ultimately be extended to serve 2,703,000 acres within the so-called 'drought area' of western Canada, for which there are water supplies available in the rivers, and so situated that they can be economically irrigated. Today Alberta has some 783,000 acres under irrigation, while in Saskatchewan there are about 200,000 'under the ditch'.

In British Columbia, in addition to several small projects built prior to 1935, some 3,900 acres have been brought under irrigation by P.F.R.A., with further projects now under study to serve some 48,000 acres. The recently completed Lilloet project has resulted in protection of land under cultivation and in the reclamation of an additional 14,000 acres. In all, some 30,000 acres of high class land were salvaged. Several major large irrigation projects are built and under operation in Alberta and Saskatchewan. These are in addition to the larger projects built prior to 1935 and operated as Districts by the water users, such as the two projects drawing water for 250,000 acres from the Bow River at Calgary and at Bassano (originally built by Canadian Pacific Railway), and the Lethbridge Northern Irrigation District of 75,000 acres.

Among the P.F.R.A. projects is the St. Mary project for watering 510,000 acres in the Lethbridge Medicine Hat areas, now partly completed jointly with the Alberta government. A second is the Bow River Project taken over by P.F.R.A. from a private company in 1951, which now waters some 60,000 acres out of a potential total of 240,000. In Saskatchewan there are some ten P.F.R.A. projects in operation now serving 142,000 acres with water, whose ultimate irrigable potention is some 530,000 acres. Besides these, the huge south Saskatchewan project, which may be undertaken in 1958, would bring water to another 470,000 acres.

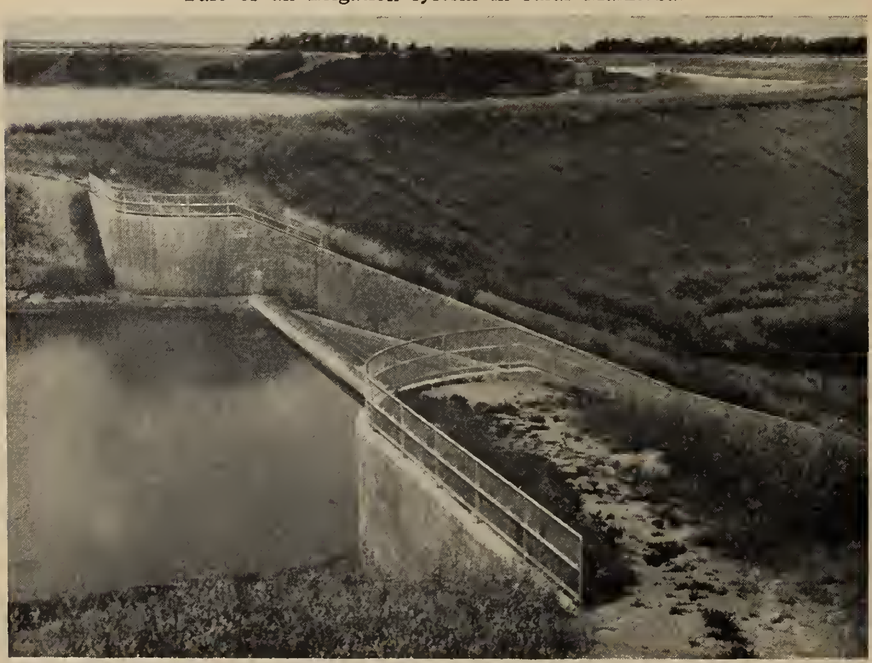
Though no large irrigation projects are built or proposed for Manitoba, at the Pas (northern Manitoba) the Saskatchewan River Reclamation project is under way for reclaiming a million acres from annual flooding in the delta of the river. Canada's share of 35,000 acres in Manitoba is now completed.

Land Utilization

Expenditure to the same date on the Land Utilization Program, which involves 61 separate "community pastures", has totalled $13.5 million. On cultural work and on soil drifting control, expenditures were $4.97 million including administration and equipment at $1.64 million and $4.07 million, respectively.

The land utilization policy is based on a complete soil survey of the prairie provinces covering an area of 50 million acres. It provides a means of taking sub-marginal land out of cultivation and regrassing these areas for grazing purposes as 'community pastures'. Some 1,750,000 acres so far have been taken out of cultivation, and 200,000 acres have been regrassed. Sixty-one operating units at present graze 110,000 cattle yearly. Measures are also provided for control and prevention of soil drifting and erosion, for encouraging improved tillage and cropping practices, and for tree-planting.

Part of an irrigation system in rural Manitoba.



The Department of Trade and Commerce 'Survey of Capital Investment Intentions' for 1957 disclosed proposed expenditures by the Federal government for dams, reservoirs, and irrigation and reclamation projects during 1957 at some $10.3 million, while total proposals in these categories by Federal and Provincial governments added up to some $42 million in the four western provinces. These expenditures may be equalled or exceeded during 1958.

MARITIME MARSHLANDS REHABILITATION

Under the Maritime Marshlands Rehabilitation Act of 1948, Canada participates with the provinces of Nova Scotia, New Brunswick and Prince Edward Island in construction and reconstruction of protective works to prevent tidal flooding. The provinces negotiate agreements with groups of marshland owners, build and maintain fresh water drainage ditches and promote effective land-use programs. Headquarters of the Administration was established at Amherst, N.S., and the Director is responsible to the Federal Department of Agriculture.

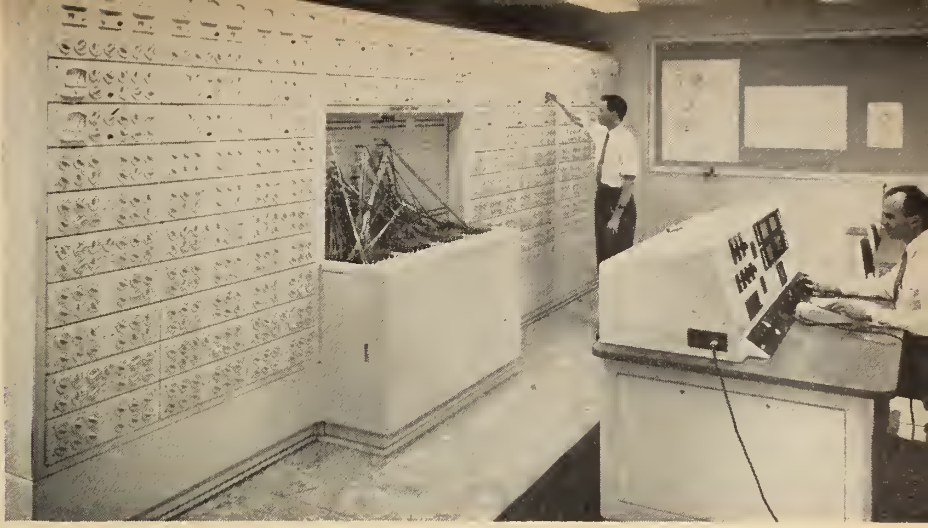
The Marshland areas are mainly adjacent to rivers flowing down into the Bay of Fundy, comprising some 100,000 acres. Up to the end of fiscal year 1956/57 active and non-active projects approved or being considered for active projects included 73,388 protected acres and 13,502 unprotected (salt marsh) acres. Total acreages in projects, by provinces, were, Nova Scotia 44,471; New Brunswick, 39,174; and P.E.I., 275. Non-active projects included 2,217 acres in Nova Scotia and 1,887 acres in New Brunswick.

Federal expenditure to end of fiscal year 1956/57 totalled $11.93 million, of which $4.28 million was spent in Nova Scotia; $3.72 in New Brunswick; and some $20,000 in Prince Edward Island. Federal administration, engineering, workshops, and supervision totalled $3.36 million.

Special Projects

Studies have been made as to the feasibility of building a dam across the Annapolis River. Such a structure, with adequate fresh water discharge facilities would protect some 4,300 acres of marshland. A similar project has been studied for a dam across the Tantramar River to protect 18,000 acres of marshland. It is expected these two projects will be undertaken at an early date.

An electric network analyzer, right, recently installed in the University of Alberta, for which $100,000 was provided by Calgary Power Limited — an example of collaboration between university and industry. Below is a Miller high-speed photographic recorder, the first of its kind in Canada, used by Orenda Engines Limited in conjunction with their aero-engine test cells. Sixteen different recordings can be made simultaneously.



RESEARCH AND DEVELOPMENT

PURE AND APPLIED research programs are under way in many centres in Canada, and it is not possible, here, to deal with the many phases of work in detail.

In general, research and development programs are carried out by government, universities, independent research organizations, and industry. The National Research Council, established in 1916 by the Government of Canada under its full title of the Honorary Advisory Council for Scientific and Industrial Research, is the largest centre for research in the country. The Ontario Research Foundation serves many industrial fields, and the Pulp and Paper Research Institute serves the pulp and paper industry.

Research in engineering subjects at Canadian universities is now developing more rapidly than hitherto, and it is hoped to give some further details of this work in a later issue of *The Engineering Journal.*

Apart from the resource industries of Canada, such as agriculture, mining, and pulp and paper, indigenous industrial research has been rather limited in comparison with the United Kingdom, the United States, and the U.S.S.R. This has partly been due to the existence of many large industrial organizations which rely on parent companies in other countries, notably in Britain and the U.S.A., for their basic research and development work. It is not possible to compile accurate figures for research expenditures by Canadian industry.

Figures for government expenditure in 1957 on research in Canada are not yet available, but in the fiscal year 1956/57 this amounted to some $105 million plus about $30 million on defence development contracts.

National Research Council

The National Research Council (N.R.C.) in 1956/57 had an operating budget of about $20 million, of which $3.5 million was devoted to scholarships and assisted research grants to universities, and so on. Of some 540 research scientists, about 170 were engineers.

The N.R.C. has five laboratory divisions, three engineering divisions (Building Research, Mechanical Engineering, and Radio and Electrical Engineering), two regional laboratories (Halifax and Saskatoon), and a Division of Medical Research.

In 1957 a separate Northern Section was formed to continue northern research work, and the station at Norman Wells, N.W.T., which has a completely-equipped soil mechanics laboratory, is the base for permafrost studies and work on northern building problems. Another important new development which neared completion

Above: new metallurgical and chemical laboratories of the Steel Company of Canada. Centre: library of the Division of Building Research, N.R.C. Bottom: a sub-critical nuclear reactor being checked before delivery to the University of Toronto. Research in atomic energy is developing rapidly in Canada.

during 1957 is the Fire Laboratory, being built near the Building Research Centre, in Ottawa. (In 1955 a total of 76,000 fires in Canada resulted in a property loss of $103 million and the far more serious loss of 569 lives.)

Aeronautical Engineering

Research and development in aeronautical engineering is carried out by the major aircraft and other industries, and at N.R.C.

Civil Engineering

The Division of Building Research, N.R.C., is very active in work on construction problems. Among the university programs is work being done on the plastic theory of structural design.

Chemical Engineering

Research in pure and applied chemistry and in chemical engineering is fairly active in Canada. During 1957 several industrial laboratories were completed or under construction to serve such fields as plastics, coated fabrics, and explosives.

Electrical Engineering

In addition to the work of the Radio and Electrical Engineering Division, N.R.C., several industrial research laboratories were active in 1957. Development work has resulted in new scatter communication equipment for extended telephone and television circuits. The new Fetherstonhaugh high voltage laboratory at the University of Manitoba will ultimately provide complete high-voltage testing facilities.

Mechanical Engineering

Work on many aspects of mechanical engineering and metallurgy continued in 1957, notably at N.R.C. Research on metal cutting was pursued at the university level for eventual industrial application.

Mining Engineering

Towards the development of Canada's mineral resources, the Government authorized, in 1957, the expenditure of over $6 million to map about 500,000 square miles of Arctic Canada. Many other development programs were under way, and some are mentioned in this issue under Mineral Resources. The Consolidated Mining and Smelting Company opened a new $250,000 research wing during the year at its centre at Trail, British Columbia.

40 YEARS OF PUBLICATION

THIS ISSUE completes forty years of uninterrupted publication of *The Engineering Journal*, which was started during the first World War and survived the depression years of the 'thirties and a second World War.

During these forty years, "the *Journal*," as it has familiarly become known to its readers, has maintained a consistently high editorial standard and has provided a unique record of the impressive development of Canada through the great engineering and other works that have helped to make the country what it is today.

The First Issue

The aims of the *Journal* were well expressed in the May 1918 issue by the words of Fraser S. Keith, then secretary and first editor and manager of the new publication for which he was largely responsible.

> Your faith that some day an intercommunicating medium would be provided, devoted to the welfare of the Institute and its members, assumes realization in the appearance of this, the first issue of the Journal of the Engineering Institute of Canada.
>
> It is yours.
>
> With you rests the decision as to its future . . .
>
> Just how human it may become will be determined by the amount of active co-operative interest you take in it. Here, all that pertains to the doings of the Institute, will receive full and free discussion. In it, our activities and our expectations may find expression.

The timing of the first issue was particularly appropriate. In April 1918 the Bill to secure adoption of the name The Engineering Institute of Canada was passed by the Senate and received the approval of the Governor General in Council. From its founding in 1887, what now became the Institute had been known as the Canadian Society of Civil Engineers (in distinction to the military engineering field). Furthermore, the *Journal* was able to record the first general professional meeting, held in March 1918, in Toronto.

Following a foreword by H. H. Vaughan, the first president of the Institute under its new title, the *Journal* records the discussion at the meeting of the existing fuel and power situation in Canada, which 'marked a new era in the affairs of the Engineers in Canada, by meeting to discuss a question of general public interest'.

Since that time the 'Engineers in Canada' have contributed greatly to many questions of public interest, and the *Journal* has faithfully recorded their work.

Function of the Journal

Among the features to be published in each issue of the *Journal* were: minutes of Council meetings; reports from branches; applications for admission and transfer; papers to be published in *Transactions* and to be presented at general professional meetings; branch papers of merit; discussion of papers; correspondence; letters from members serving in the armed forces; 'personals'; an engineering index or review of current engineering literature; and an employment bureau. Many of these sections are familiar today.

Physical Growth

The editorial content of the first issues of the *Journal* was not small by existing standards, averaging over 50 pages per issue in 1918, including the Engineering Index. However, the membership in that year was just over 3,200.

In recent years the *Journal* has contained over 100 pages of editorial material per issue, and nearly 20,000 copies of the publication for April 1958 will be printed.

Major Features

Throughout its history the *Journal* has presented information of interest and assistance to the members of the engineering profession and has followed the progress of industry and other developments in Canada.

Some of the major fields dealt with are: the development of aviation in Canada, mentioned as early as 1919; the development of the St. Lawrence as a traffic route, including the Welland Canal works; the progress of power; the construction of large bridges, buildings, transport and communication facilities of vital interest to the nation's growth; the development of the country's natural resources; and, not least, the development of the profession through engineering education.

Notable Issues

Some notable issues of the *Journal* have been devoted to subjects of particular importance, and a few are mentioned here.

In 1924 the first World Power Conference was held in London, England, and the July issue contained 228 pages of editorial material, mostly devoted to the Canadian contribution to the Conference. The authors of papers included such well-known names as J. B. Challies, B. P. Haanel, H. G. Acres, Julian C. Smith, F. A. Gaby, L. E. Westman, and Lawrence J. Burpee.

In 1925 Fraser S. Keith retired as secretary and editor, and was succeeded by R. J. Durley. An important symposium on engineering education was recorded this year.

A prominent paper published in April 1929 was 'The St. Lawrence Problem', by Lesslie R. Thomson. This is still a masterly review of transport, power, and economics of the waterway; it occupies 116 pages of the issue.

The Canadian contribution to the second World Power Conference, held in Berlin, is recorded in the *Journal* for July 1930.

The following year, an interesting editorial comment on a review made by United States engineering societies on the conditions of employment of professional and technical men in Russia, noting that 'it has been found necessary to enlist the aid of a large number of technically trained men from capitalist countries to plan and operate projects in the U.S.S.R.' At that time the Russians were implementing great plans for the country's industrial development.

During the depression years of the 'thirties, there are many mentions of the work of the Institute in promoting relief measures, such as the National Committee on Construction Recovery, on which several members served.

In 1935 and 1936 major subjects discussed included water resources and soil conservation in the prairie provinces; and the development of civil aviation, stressing the future importance of Canada as a link in the world's airways.

Semi-Centennial of the Institute

The Coronation of King George VI was marked in 1937, which was also the semi-centennial year of the Institute. The special June issue of the *Journal*, in 230 editorial pages, recorded fifty years of Canadian achievement in engineering and industry. The following month over 80 pages of papers dealt with Canadian coals, and a later issue noted the new North Atlantic air service between London and Montreal.

In 1938 R. J. Durley retired as general secretary and editor, and was succeeded by L. Austin Wright. Already this year, the world situation was reflected in an editorial 'War and the Engineer'.

War and Post-War Years

During the war years the *Journal* continued its service and helped in the contribution made by Canadian engineers to the war effort. The wartime paper shortage affected the *Journal*, which had adopted an improved style and introduced wider coverage of subjects, and several economies were introduced, including dropping certain departments.

After the war, the emphasis was on rehabilitation and post-war recovery, and hitherto restricted subjects such as radar and atomic energy were discussed.

In the last ten years, the development of Canada has been at a greatly accelerated rate. The same rapid development can also be seen in the *Journal*.

The amount of editorial material, the fields covered, and the circulation have all increased, and the style of the presentation has been improved to make reading easier for the busy engineer.

The *Journal* has not stood still during its forty years of life, and its aim is always to serve the engineering profession in Canada by the best possible means.

THE ADVERTISERS

Many engineering and industrial organizations have made their contributions to the pages of *The Engineering Journal* during the past forty years. These contributions have been factual and informative, and their 'editorial' value to the reader must not be overlooked. A review of the part played by these organizations since 1918 appears on page 232.

CONTRIBUTORS TO THIS ISSUE

This review of engineering and industrial progress in Canada during 1957 has been made possible by the co-operation of many government departments, industrial organizations, and individual contributors. Though they cannot all be named here, **The Engineering Journal** wishes to express sincere appreciation for their assistance.

Particular thanks are due to Mr. H. G. Cochrane (Life Member, E.I.C.) who undertook extensive statistical research and prepared most of the reviews published here.

The assistance of those who supplied illustrations of many recent developments in Canada is also appreciated, and the names of these contributors to the various sections of the review are listed below.

Mineral Resources
British Columbia Electric Company; Government of Manitoba; Steep Rock Iron Mines Limited; The Rio Tinto Mining Company of Canada Limited; Canadian Ingersoll-Rand Company Limited; Canadian General Electric Company Limited; Canadian National Railways; British American Oil Company Limited; Shell Oil Company of Canada Limited; Carbide Chemicals Company, Division of Union Carbide Canada Limited.

Power
New Brunswick Electric Power Commission; British Columbia Electric Company; The Aluminum Company of Canada; The British Columbia Power Commission; Calgary Power Limited; The Hydro-Electric Power Commission of Ontario; Canadian General Electric Company Limited; Pemberton, Freeman, Bennett and Milne Limited (for Bowater Power Company and British Newfoundland Corporation); General Motors Diesel Limited; English Electric Company of Canada Limited; Poole Construction Co. Limited.

Communication and Transport
Canadian Pacific Railway Company; The Bell Telephone Company of Canada; Canadian Overseas Telecommunication Corporation; Canadian Westinghouse Limited (Photo: Tom Bochsler Jr.); Canadian Pacific Airlines; Sperry Gyroscope Company of Canada Limited; Canadian National Railways; Canadian Pacific Steamships.

Construction
Foundation Company of Canada Limited; British Columbia Government; Greenspoon, Freedlander & Dunne, Architects; Department of Public Works, Ottawa; Acadia Construction; British American Oil Co. Limited; Alberta Government; British Columbia Electric Company; Canadian National Railways; Poole Construction Co. Limited; Byers Construction Co. Limited; Manitoba Government; **Globe and Mail**; Ontario Hydro; McNamara Construction Co. Limited.

Industrial Production

SEVENTY SECOND

ANNUAL GENERAL AND PROFESSIONAL MEETING

OF

THE ENGINEERING INSTITUTE OF CANADA

MAY 21, 22, 23, 1958

CHATEAU FRONTENAC, QUEBEC, QUE.

ANNUAL MEETING NOTES

REGISTRATION

Members of the Institute have received in the mail the Preliminary Program giving detailed and complete information about the annual meeting. The program of this meeting will be centred in and around the Chateau Frontenac.

It is a distinct advantage to members and to the Headquarters staff, if members register in advance. The Preliminary Program contains information about the procedure of advance registration through Headquarters. This arrangement will be in effect until Saturday, May 3; thereafter reservations must be made by direct communication with the Quebec hotels. Registration at Quebec opens on Tuesday, May 20 at 3.00 p.m., and continues each morning at 9.00 a.m.

ACCOMMODATION

The Chateau Frontenac has reserved accommodations for 700 people. Accommodations will also be available at alternate hotels and motels in the Quebec area.

CONFERENCES

Three conferences will start on Tuesday, May 20 — the Students' Conference, at 9.00 a.m., and the Branch Officers' Conference and the Engineering Deans' Conference at 9.30 a.m. Delegates to these conferences will attend a joint luncheon on May 20.

ANNUAL MEETINGS

The Annual Meeting of Council is scheduled for 10.00 a.m. on May 20, and the Annual General Meeting of the Institute at 10.00 a.m. on May 21.

TECHNICAL PROGRAM

The technical program is listed on the next two pages. Thirty-two papers are to be presented, which can be classified under the fields of civil engineering, mechanical and thermal power, electrical, chemical, metallurgical, aeronautical, and mining engineering, and general, including science and physics. The subjects represent many of the important concerns of engineers—from highway design to aircraft systems, electronic computing, power plants, and the International Geophysical Year. There will be two speakers from England.

The technical program will start on Wednesday, May 21, at 2.00 p.m., and will be concluded late on Friday afternoon.

For more information, please read the following three pages.

TECHNICAL PROGRAM

Subject to change

WEDNESDAY, MAY 21

2:00 p.m.

Economic Study of Pump Storage Application

Dr. Charles Jaeger, Consulting Engineer to English Electric Co., England.

The Deas Island Tunnel

Per Hall, M.E.I.C., Executive Vice-President, Foundation of Canada Engineering Corp. Ltd., Montreal.

Partial and Complete Sewage Treatment

Jacques Benoit, M.E.I.C., Consulting Engineer, Montreal.

Non-Destructive Testing of Materials and Parts

W. E. Havercroft, Radiographer, Physical Metallurgy Division, Dept. of Mines and Technical Surveys, Ottawa.

3:00 p.m.

Variable Pitch Mixed Flow Propeller Pump Turbines

J. G. Warnock, Head, Hydraulic Department, English Electric Company Limited, Toronto, Ont.

The Deas Island Tunnel (Continued)

E.I.C. ANNUAL MEETING, 1958

Quebec-Labrador Tropospheric Scatter Radio System

D. J. McDonald, Area Radio Engineer, The Bell Telephone Company of Canada, Montreal; and C. E. Frost, M.E.I.C., Construction Contract Engineer, Bell Telephone Company of Canada, Montreal.

Correction of Non Linearities Using Varistors

Lieut.-Col. G. W. Holbrook, M.E.I.C., Head, Department of Electrical Engineering; Royal Military College, Kingston, Ont.

4:00 p.m.

Combatting Ice and Snow Conditions

J. E. Cousineau, M.E.I.C., Surveys Engineer, Power Development Division, Hydro-Quebec, Montreal.

Quebec-Labrador Tropospheric Scatter Radio System (Continued)

New Concept of Engineering in Semiconductor Device Development

J. A. Watters, M.E.I.C., Superintendent of Engineering Methods, Northern Electric Company Limited, Montreal.

THURSDAY, MAY 22nd

9:00 a.m.

Baie Comeau Plant, Canadian British Aluminium Co. Ltd.

V. M. Wallingford, M.E.I.C., Resident Engineer, Canadian British Aluminium Co. Ltd., Baie Comeau, Quebec.

Cavitation Damage of Metals

W. C. Leith, M.E.I.C., Mechanical Research Engineer, Dominion Engineering Works Limited, Montreal.

Electronic Computing in Engineering

B. J. Kaganov, Assistant Chief Engineer for Research and Development, Canadair Limited, Montreal.

10:00 a.m.

Baie Comeau Plant, Canadian British Aluminium Co. Ltd. (Continued)

Thermal Power Generation

Basil Wood, Head of Research & Development Department, Merz and McLellan, Consulting Engineers, London, England.

Civil and Structural Engineering Aspects of Electronic Computer Applications

A. M. Lount, M.E.I.C., A. M. Lount and Associates, Consulting Engineers, Toronto.

11:00 a.m.

Baie Comeau Plant, Canadian British Aluminium Co. Ltd. (Continued)

The Georgia Generating Station, Vancouver Island

J. P. Sinclair, Project Engineer, British Columbia Power Commission, Victoria, B.C.

TECHNICAL PROGRAM

Subject to change

Photogrammetry and Its Application to Engineering

T. J. Blachut, National Research Council, Ottawa, Ont.

FRIDAY, MAY 23rd

9:00 a.m.

The International Geophysical Year

Dr. D. C. Rose, M.E.I.C., Principal Research Officer, National Research Council, Ottawa. Chairman of the Canadian National Committee, for the International Geophysical Year.

Engineering Features of the Beechwood Development

J. A. Thomas, M.E.I.C., Chief Engineer, Civil Division, Shawinigan Engineering Co. Ltd., Montreal; R. E. Grout, M.E.I.C., Chief Engineer, Elect. Division, Shawinigan Engineering Co. Ltd., Montreal.

Aluminum in Railway Rolling Stock

R. A. Campbell, Manager, Development Division, Railway-Marine, Aluminum Company of Canada, Montreal.

The Preparation of Ilmenite Ore for Smelting

George E. Wagner, Operations Superintendent, Quebec Iron & Titanium Corporation, Sorel, Quebec.

10:00 a.m.

The C.A.R.D.E. IGY Upper Air Research Program

R. F. Chinnick, Superintendent, Electronics Wing, C.A.R.D.E., Quebec.

Design Features of the Beechwood Kaplan Turbines

L. M. Boyd, M.E.I.C., Chief Engineer, Hydraulic Division, Dominion Engineering Works, Limited, Montreal; W. S. McIlquham, M.E.I.C., Hydraulic Engineer, Hydraulic Division, Dominion Engineering Works, Limited, Montreal.

Design and Development of Control System CF-105 Aircraft.

Colin Marshall, Chief of Systems Engineering, Avro Aircraft Limited, Toronto.

Varennes Operation, English Reduction Company

R. M. O. Maunsell, Vice-President, Research & Development, Electric Reduction Company of Canada, Ltd., Toronto.

11:00 a.m.

Modification of the Jacques Cartier Bridge

Ross Chamberlain, M.E.I.C, Engineer, Structural Design Department, Dominion Bridge Co. Ltd., Montreal.

Vertical Take-Off Aircraft and Their Power Plants

P. J. Pocock, Low Speed Aerodynamics Laboratory, National Research Council, Ottawa; and Dr. E. P. Cockshutt, Engine Laboratory, National Research Council, Ottawa.

2:30 p.m.

Underground Hydro-Electric Power Stations

F. L. Lawton, M.E.I.C., Chief Engineer, Power Department, Aluminum Company of Canada, Ltd., Montreal.

Highway Research Activities in Canada

Dr. Gordon Campbell, JR.E.I.C., Director of Technical Services, Canadian Good Roads Association, Ottawa.

3:30 p.m.

Management Panel

Particulars to be announced.

Design of a Functional Structure In or On Rock

A. V. Corlett, M.E.I.C., Head, Dept. of Mining Engineering, Queen's University, Kingston, Ont.; and C. L. Emery, M.E.I.C., Professor, Engineering Department, Waterloo College, Waterloo, Ont.

QUEBEC CITY, MAY 21, 22, 23.

Lower St. Lawrence North Shore Highway Development

Arthur Branchaud, Assistant Chief Engineer, Department of Roads, Quebec.

4:30 p.m.

Management Panel (Continued)

Nelson River Bridge at the Kelsey Generating Station

J. R. Rettie, M.E.I.C., Manager, Surveys and Construction Division, The Manitoba Hydro-Electric Board, Winnipeg, Man.; and P. A. Benn, M.E.I.C., Executive Vice-President, Pre-Compressed Concrete Engineering Co. Ltd., Montreal.

Fundamentals of Transportation Engineering

S. M. Breuning, M.E.I.C., Assistant Professor of Civil Engineering, University of Alberta, Edmonton, Alta.

E.I.C. ANNUAL MEETING

MEETING NOTES (continued)

SOCIAL EVENTS

The President's Dinner for past and present Institute officers and special guests will be at 7.00 on Tuesday evening, May 20.

The Wednesday Dinner, 7.00 p.m., will be presided over by Roger Desjardins, Quebec Branch chairman, with C. M. Anson, retiring president of the Institute, addressing the assembly. There will be dancing from 10.00 p.m.

Thursday's program includes, at 7.30 p.m., the annual dinner of the Association of Consulting Engineers of Canada. There is a tentative arrangement for a buffet supper for E.I.C. members at the same time Thursday evening. The decision about this depends on the response indicated in advance registration. There will be dancing again on Thursday evening.

ANNUAL BANQUET AND DANCE

The annual banquet and dance will be on Friday, May 23. C. M. Anson, retiring president will preside. During dinner he will introduce the new president, K. F. Tupper, and the new members of Council. The speaker will be R. G. Gustavson, president and executive director of Resources for the Future Inc., Washington, D.C.

All places for the annual banquet will be reserved. Members who wish to be seated with friends or in special parties must provide this information with advance registration. Places will be allocated in the order in which they are received.

LUNCHEONS

Luncheons on Wednesday and Thursday are informal with members making arrangements independently. Friday's luncheon, at 12.30, will be the occasion of the presentation of the Institute honours and awards. Chairman will be Vice-President Albert Deschamps.

BOAT TRIP AND FIELD TRIPS

On Thursday at 2.00 p.m. there will be a scenic boat trip on the St. Lawrence River, with music and refreshments by courtesy of the Quebec Branch. Special field trips may be organized for Saturday, the 24th. The committee will arrange them as required.

PHOTOGRAPHIC EXHIBITION

The Photographic Exhibition will again be a feature. Canadian firms and individual members will be exhibiting photographs of Canadian engineering achievements of 1957. Please see page 254 for details.

ANNIVERSARY OF QUEBEC

Many historic and entertaining attractions are to be found in Quebec. This year, Quebec will celebrate its 350th anniversary, and honour is being paid to the great Samuel de Champlain, who erected the first settlement in 1608.

LADIES' PROGRAM

The ladies can be assured of a gracious welcome. There will be a Ladies' Program prepared by the ladies' committee, headed by Madame Roger Desjardins and Mrs. Ben O. Baker.

TRANSPORTATION

The Preliminary Program contains information about railway, air, and road travel. The usual reduced convention train fares will be available under the conditions listed there. Air lines normally grant reduced fares to parties of ten persons or more.

QUEBEC COMMITTEE

Chairman: Ben O. Baker

Treasurer, Pierre Duchastel

Publicity, Louis Joncas, Jacques Roy

Reception and Transportation, Jean B. Delage

Vice-Chairman, Roger Desjardins

Meeting arrangements, L. P. Bonneau

Entertainment, Paul Begin

Secretary, Marc Bergeron

Ladies' Committee, Mme Roger Desjardins, Mrs. Ben O. Baker

Month to Month

News of the Institute and the Profession

COMMENT
CORRESPONDENCE
ELECTIONS
AND TRANSFERS

E.I.C. and Saskatchewan Association

The first of all the associations to sign the co-operative agreement with The Engineering Institute of Canada was Saskatchewan. This was done in 1938.

Conditions have changed materially in Saskatchewan as they have in other provinces and today there are many people practising there under the Professional Engineer's Act who are not, strictly speaking, engineers. This refers to such persons as geologists, geophysicists, etc.

One of the features of the Saskatchewan agreement is that a member joining the Association automatically becomes a member of the Institute. With the new types of professional workers coming into the province, it was only natural that some of them would prefer to belong to a specialized society catering particularly to their specialty rather than to The Engineering Institute. They have suggested to the Association that the agreement be altered, so that membership in the Institute would be optional.

The matter was discussed very widely at the annual meeting of the Association and the outcome was that it was agreed that a referendum be circulated in which the whole matter would be gone into in considerable detail. The referendum proposed these alternatives:

1) That the agreement be left as it is.
2) That E.I.C. membership be made optional.
3) That the agreement be cancelled.
4) If the ballot showed a majority in favour of cancelling the agreement, would the members (a) retain their E.I.C. membership (b) drop their E.I.C. memship in favour of some other organization.

At the recent annual meeting of the Association, the results of the referendum were reported. The ballot is quite clear and gives encouraging support to the maintenance of the present relationships between the Association and the Institute. Here are the results:

Question 1 would suggest that the agreement be left as it is. 76.4 per cent voted in favour of this. That membership in the E.I.C. be made optional was supported by 23 per cent, whereas the inquiry as to cancelling the agreement entirely was supported by only .6 per cent.

In answer to what action would be taken by the members if the agreement were cancelled, the replies were far from complete. 31.4 per cent of the persons voting recorded no opinion on this question, which seemed to suggest they were not interested in it and therefore were not keen on dropping out of the Institute. Only 13.1 per cent suggested that they would drop their membership if it were made optional.

Although there was no question to cover it, it was interesting to note that three members said that if the agreement were cancelled, they would retain their E.I.C. membership but would drop their Association membership.

All in all, these results are very comforting to the people who are responsible for the operation of both these organizations. It indicates that the oldest agreement of all, has in a general way, met the needs and the wishes of the membership.

"The Fathers of Confederation", taken at the meeting of the two committees at Toronto, January 18, 1958. Left to right: H. T. Libby, Vancouver, T. Foulkes, Ottawa, I. R. Tait, chairman, E.I.C. committee, Montreal, L. J. Hammerschmid, secretary, E.I.C. committee, Montreal, John Fox, chairman, Canadian Council committee, Toronto, W. S. Wilson, Toronto, J. G. Dale, Edmonton, Henri Gaudefroy, Montreal, James McMillan, Calgary, J. H. Smith, Toronto, G. Piette, Quebec, W. O. Richmond, Vancouver, D. O. Turnbull, Saint John, H. W. L. Doane, Halifax.

In Honour of a Great Engineer

C. M. Anson, left, with Mrs. C. S. McGaffin, daughter of the late Henry J. Cambie, Dr. L. Austin Wright, of the E.I.C., Harry B. Cambie, son of the famous engineer being honoured on this occasion, and Mrs. N. F. Townsend, another daughter.

The Institute's memorial tablet to H. J. Cambie, M.E.I.C., was unveiled by the president of the Institute, C. M. Anson, on Monday February 10th, in the Canadian Pacific Railway station at Vancouver, B.C.

This tablet was first put on view at the annual meeting of the Institute in Banff in June, 1957. Since then it has gone to Vancouver and has been placed in its permanent position on the wall of the Vancouver depot. It seems appropriate that that should be the site of the memorial in view of the fact that it was Mr. Cambie himself who was responsible for Vancouver being selected as the terminal for the great Canadian Pacific Railway system.

The audience attending the ceremony was made up of about 200 Vancouver citizens and included a great many people in engineering and other circles who had known Mr. Cambie and his family.

The three most important members of the audience were Mr. Cambie's own children. His two daughters Mrs. N. F. Townsend, Mrs. C. S. McGaffin and his son Harry B. Cambie. All three of them are shown in the accompanying photograph.

The president sketched out for the audience some of the many and important accomplishments of Mr. Cambie's career. He made reference also to the fact that Mr. Cambie had achieved a great place for himself in other circles as well as engineering. The president's address follows this short item.

Others who participated in the service were T. E. Price, M.E.I.C., who spoke on behalf of the family. Mr. Price knew Mr. Cambie and his family intimately and throughout their joint services to the C.P.R. they had many things in common.

Accepting the tablet on behalf of the Canadian Pacific Railway Company was J. N. Fraine who also had been a close associate of Mr. Cambie. The memorial itself consists of a large shield made of stainless steel. Probably this is the first time that stainless steel has been used for this purpose and the results have been very gratifying.

In one corner is the crest of The Engineering Institute of Canada and in the other an excellent etching of Mr. Cambie. The inscription reads thus:

"In recognition of the outstanding engineering achievements of Henry John Cambie, M.E.I.C., 1836-1928, whose surveys and explorations determined the location of the Canadian Pacific Railway through British Columbia and who supervised its construction through the Fraser River Canyons, 1880-1884. Erected and dedicated by The Engineering Institute of Canada, June 1957."

This concludes another event in the Institute's program of commemorating

This large group attended the ceremony in Vancouver honouring the achievements of the late Henry J. Cambie, C.P.R. engineer.

the memory of the early and great Canadian engineers. First there was the fountain erected in Ottawa in memory of Colonel By; then the book "Daylight through the Mountain" in honour of the Shanly Brothers; and now this latest tribute to the distinguished gentleman who did so much to solve the almost impossible problems of the railroads in British Columbia. The Institute has other projects in mind to honour other worthy engineers, details of which will be made available later.

Dedication by C. M. Anson

We are gathered together this afternoon to honour a great Canadian engineer, one of the stalwart men who laid the foundations, and laid them well, upon which Canada has grown to nationhood. Henry John Cambie, member of The Engineering Institute of Canada, was one of that elite coterie of men who in the early stages of our country's development had the courage and vision to do things which even today with our modern facilities are looked upon as almost impossible tasks.

In recent years we have seen and have regarded with wonder, such projects as Shipshaw in Quebec, the St. Lawrence Seaway, the wonders of Alberta oil, and the Kitimat project, but with our modern means of transportation, our tools which make work easy, such projects pale almost to insignificance beside the project of nearly one hundred years ago of building a railway from Winnipeg through to the foothills of Alberta and thence over what to most people must have seemed an insurmountable barrier, the Rockies, and into Vancouver. Thank God for such men as Henry John Cambie.

Born in Ireland, at 16 he came to Canada with his parents and shortly thereafter embarked on his life's work, entering the employ of the Toronto and Guelph Railway. Later he worked for engineering contractors building the Grand Trunk Railway. In 1861 he qualified as a land surveyor and in that profession conducted surveys and explorations for several of the early railway systems in Maritime and Central Canada.

Eighty-seven years ago British Columbia entered Confederation and one of the stipulations of that agreement was that a transcontinental railway would be built. Some years of the usual procrastination attendant on such matters followed. Many personalities entered the picture, played their part and faded away. Finally Henry Cambie was placed in charge of surveys and explorations in British Columbia. From 1876 to 1878 the different passes over the Cascade Mountains were surveyed and the route from Burrard Inlet via the Fraser and Thompson Rivers was selected by Cambie as the most favourable. While his recommendation was not accepted immediately and indeed was the subject of violent opposition for some considerable time, the thoroughness with which his surveys had been carried out and the logical conclusions which Cambie had reached, finally prevailed. The route through the Fraser River Canyons was adopted.

Henry Cambie's work was just starting. He was engineer in charge of construction for that part of the work running from Emory's Bar to Boston Bar territory which included the most difficult 29 miles through the canyons. This work was completed in 1884 and Cambie who up to that time had been in the employ of the Federal Government, joined the staff of the Canadian Pacific Railway as engineer in charge of construction from Savond eastward to Shuswap Lake. In 1885 he had the supreme satisfaction of seeing the railway that he had envisaged, over a route which he had selected, finally completed by the symbolic driving of the last spike. He was present at that ceremony as representative of the railway engineers. For 35 years after that memorable date Henry Cambie continued in full active service. Upon his retirement in 1920 the C.P.R. still retained him as consultant.

Many of you here today must also recall Cambie's activity in community, church and professional affairs. His signature appears among those who applied for the charter of the City of Vancouver. Christ Church acknowledges his worth as a Christian by a memorial window. Vancouver has perpetuated his memory by naming a street after him, and the C.P.R. has a station called Cambie.

The members of his profession, the engineers of Canada through their national body, The Engineering Institute of Canada, an Institute of which he was proud to be a member and to which he rendered active service as member of Council, also desire to give tribute. To that end and so that future generations of Canadians shall not forget or overlook the magnificient contributions made by those whose vision and courage made our Canada possible, I have the honour and privilege of unveiling this plaque.

The Engineering Institute of Canada, on behalf of the engineers of Canada, present this plaque to the Canadian Pacific Railway and to the people of Canada to honour Henry John Cambie and to recognize his outstanding engineering achievements from 1836 to 1928. On behalf of the Institute I hereby dedicate this plaque to the memory of a great engineer, an outstanding Canadian.

May his works be an inspiration to the engineers of future generations. May his courage and vision be with us always.

"S.E.I.C."

A study of the membership figures of the Institute indicates that there has been a substantial increase in the number of students joining the organization. Although the enrolment is not yet complete for the college year the figures for new applications from September to March are in excess of 1,500.

This increase, added to the numbers within the Institute previously, now brings the total to over 4,000 S.E.I.C's.

While it is possible to be pleased with these figures it must be admitted there is still room for improvement. It is hoped that the acceleration which is now under way will continue throughout the years so that eventually the numbers will be even more impressive. The significant thing is that these figures are the highest ever achieved by the Institute.

This increase in applications follows several developments, not least of which is the Student Conference held every year at the time of the annual meeting. The creation of faculty advisors last year also has been helpful, and acknowledgement must be made of the wonderful support given at most universities by one or more members of the faculty who have passed on to the students some of their enthusiasm for the Institute.

Did You Know That...

The Engineering Institute holds a Student Conference every year as a feature of the annual meeting. The E.I.C. Education Conference also forms part of the annual meeting, when Council directs.

Toronto and Points West in the President's Tour

Saskatoon—the Branch dinner dance. Left to right: L. Austin Wright, Mrs. I. M. Fraser, President C. M. Anson, Mrs. W. G. McKay, H. McI. Weir, Mrs. Anson, Dean I. M. Fraser, Mrs. Weir. and W. G. McKay.

Mr. Anson presented student prize to Robert G. McIntosh, at the University of Saskatchewan.

Chairman of the Toronto Branch E. R. Davis (standing), introduced the president.

Edmonton. The executive met with the president. Left to right: H. Hole, H. L. Roblin, R. H. Nicolson, J. Langworth, S. J. Hampton, S. R. Sinclair, T. H. Newton, R. N. McManus, R. Hardy, R. H. Gardener, G. Hodge, A. Peterson. C. M. Anson is in the foreground.

Regina. Left to right: E. J. Durnin, J. C. Traynor, C. M. Anson.

In Toronto, Mr. Anson was interviewed by Percy Saltzman on the Tabloid T.V. program.

Fetherstonhaugh High Voltage Laboratory

The *Journal* Reports Growth in Engineering Faculties in Canada

Fourth article of a series

The University of Manitoba

Degree courses offered at the University of Manitoba are those of civil, electrical, mechanical and geological engineering, and engineering physics. The fiftieth anniversary of formal engineering instruction at this university was celebrated in March 1957.

A. E. Macdonald, M.E.I.C., dean of engineering and architecture, has advised that the undergraduate curriculum is in a quite stable form, with no extensive changes at present contemplated. Curricula are under constant review however, and subjects are revised, added, or dropped, as found to be advisable or feasible.

There is a slight trend, Dean Macdonald reports, toward an increase in fundamental mathematics and science subjects at the expense of the "practical" subjects. There already is a core of humanistic-social subjects.

The university has observed a mounting demand for graduate courses and expects to satisfy this demand as it increases further by means of additional courses.

Physical expansion in the engineering faculties has been accomplished by the addition of the Fetherstonhaugh high voltage laboratory, formally opened on March 22, 1957, and will be further affected by new extensions to existing mechanical, civil and electrical laboratories.

High Voltage Laboratory

The Fetherstonhaugh high voltage testing laboratory has a frontage of approximately 60 feet and a depth of approximately 64 feet. It provides a high voltage testing area as well as accommodation for a sub-laboratory for the Canadian Standards Association. The former occupies a clear open space some 37 feet by 60 feet by 38 feet high, with a large roll-up entrance door providing an opening some 22 feet high by 16 feet wide for accommodating large test equipment. The sub-laboratory occupies, on two floors under a total roof height of approximately 25 feet, most of the remaining space. At the second floor level there is an observation mezzanine overlooking the high voltage area. It is intended that this high voltage laboratory will serve both industrial needs as well as educational purposes. Equipment plans are as follows:

Power Frequency High Voltage

A supply voltage variable up to 2300 volts at 60 cycles will be available from a 230-kva. alternator driven by a d-c motor. Installation of this apparatus is now nearing completion. Three transformers rated at 55-kv. are available, and industry is expected to donate another of approximately 200 to 300-kv. rating.

It is expected that a Schering bridge will be built during the summer of 1958. A Hartmann and Braun 250-kv. compressed gas capacitator has been obtained for the "standard" in this bridge circuit. Facilities for measurement of ratio and phase angle of potential transformers will also be included. It is intended that measurements of radio interference from high voltage apparatus will also be possible.

High Voltage Direct Current

Cascade rectifier equipment capable of an output of 440-kv. total, 220-kv to ground, is available, but requires suitable primary control and metering equipment. This is expected to be of very considerable value in insulation research.

Impulse Testing

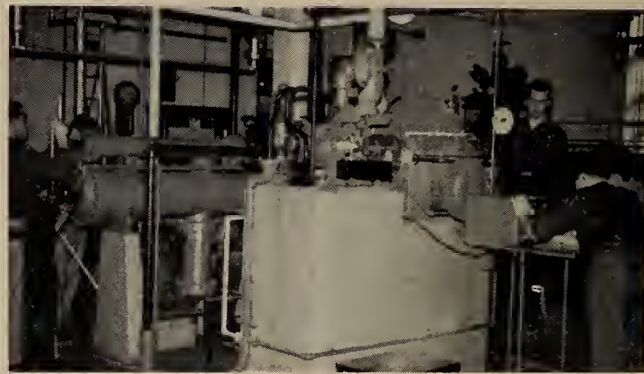
The building design will permit an installation of the order of 2,000-kv. rating. No equipment is as yet available, but it is expected that many of the components required for the construction of a generator will be donated by manufacturers. The same applies to the necessary high voltage high speed oscillograph.

To sum up, the development of the high voltage laboratory into a well equipped operating unit is expected to extend over a period of several years, and considerable aid from industry in the provision of apparatus and components is anticipated. A course in high voltage technology, at the graduate level, should be available for the 1958-59 session.

Extensions to Laboratories

Mechanical, civil, and electrical laboratories are to be expanded. Sketch plans are presently under way for a 70-foot by 107-foot one-storey extension to the end of the existing mechanical engineering laboratory. Sketch plans are also under way for a 70-foot by 107-foot second and third storey extension to the existing one-storey civil engineering materials testing laboratory. It is hoped that these additional floor areas will be available for occupancy by the open-

Group in electrical laboratory, Manitoba.



Steam turbine test in mechanical laboratory.

ing of the fall term in 1958. Temporarily, it is planned to use much of the new space for classrooms.

Equipment which has been added recently in civil engineering includes: a Baldwin 30,000-pound universal testing machine; Baldwin portable dial strain indicator using a large clock dial for easy group visibility; two Baldwin SR-4 strain gauge type load application cells; a Wilde geodetic transit reading directly to 1.0 second; and a miniature compaction apparatus for the soils laboratory.

Equipment added during 1957 in mechanical engineering consists of: a two-stroke, 75-hp. General Motors diesel engine; four-stroke, 225-hp. Caterpillar diesel engine; a Heenan & Froude dynamometer to absorb the latter hp.; and, with equipment donated by Honeywell Control, a set-up for carrying on experiments in automatic control.

Recent equipment additions to the electrical laboratory are an educational amplidyne set; a motor-generator set; a precision Kelvin-Wheatsone bridge; and various measurement standards. A very fine donation of carrier and high frequency communication equipment was received from industry in 1957.

Electronic Computer

The University of Manitoba received a donation of $32,000 in January from the Pioneer Electric Company of Winnipeg, which will provide an electronic computer.

The computer, to be purchased from the Bendix Corporation, will be used to solve involved calculations by the mathematics, physics and engineering faculties. It will be installed by April, probably in the engineering building, to be ready for use by the fall term.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admission Committee, the following elections and transfers were effected at a meeting of Council on March 1, 1958.

Members: R. M. Allemang, Peterborough; M. K. Baillargeon, Cardinal; G. K. Barkovits, Montreal; H. F. Bartram, Montreal; L. M. Bell, Morrisburg; R. A. Campbell, Montreal; H. Chochlewicz, Toronto; G. K. Cranna, Welland; M. A. Dau, Montreal; J. Davis, Vancouver; A. J. Dewdney, Preston; R. E. Evans, Montreal; A. E. H. Fair, Boston; H. H. Fickel, Victoria; A. Foster, Brockville; G. J. Gelencser, Montreal; G. Goodwin, Ottawa; R. B. Hamel, Montreal; A. S. Hayes, Montreal; A. Hedefine, New York; J. G. Hodges, Sudbury; J. W. Hodgins, Hamilton; D. T. MacLachlan, Montreal; R. N. McLellan, Vancouver; J. Paszkiewicz, Montreal; T. B. Peart, Calgary; R. L. Raikes, Toronto; J. M. Richardson, Peterborough; R. C. Sadler, Toronto; D. Silverman, Granby; D. M. Sloan, Montreal; W. Strok, Vernon; I. T. Szametz, Kitimat; R. M. Trim, London, England; H. J. Vale, Montreal; J. F. White, Montreal.

Juniors: C. Y. Chang, Toronto; D. R. Coates, Montreal; J. E. Dowell, Sept Iles; T. R. Fredriksen, London; W. G. Geddes, Montreal; D. W. Parks, Toronto; A. Shewchenko, Montreal; K. G. Tamberg, Toronto.

Junior to Member: J. S. R. Beck, Hamilton; R. E. Burridge, Fredericton; R. K. Coates, Banff; R. P. Crawford, Copper Cliff; E. W. Hutchinson, Point Ann; B. C. Kaulback, Montreal; N. W. Kuster, Fort William; J. S. Kyle, Peterborough; P. E. Poisson, Montreal; G. C. Willeumier, Vancouver.

STUDENTS ADMITTED:

Ecole Polytechnique: A. Adjouri, A. Aimaro, Y. Ainsley, Y. V. Arsenault, P. A. Aubuchon, G. Auger, L. Beauchemin, M. G. Beaudoin, P. Beaudry, J. M. G. Beausejour, U. Bechard, J. M. Beland, B. Belanger, J. Belanger, M. Beliveau, J. Bellemare, P. Bellemare, C. Bellier, G. Bergevin, C. Berthiaume, N. Berthiaume, P. Berthiaume, C. Bertrand, R. Bissonnette, C. Blanchard, J. T. J. Blouin, C. Baj, G. Bodis, J. L. R. Bouchard, R. P. Bouchard, M. Boucher, R. Boucher, M. Boulet, A. Bourdeau, P. Bourbeau, J. C. Brisebois, R. Brosseau, P. Brunel, T. Buithieu, D. Buron, M. Buteau, B. Cardolle, J. E. Carriere, M. Chamberland, A. Charest, J. J. Charest, C. Charron, J. Chartrand, R. Choquette, J. Clermont, B. Cliche, A. Cloutier, J. A. P. R. Cloutier, R. Cloutier, J. P. Corbeil, J. Cormier, C. Cossette, L. Dang Tran, A. DeLormier, D. Demers, J. Desrochers, J. Dionne, R. Dionne, J. P. Drapeau, V. Dubois, G. R. Dubreuil, F. Dubuc, P. Ducharme, R. Dufresne, M. Dupuis, J. Dussault, C. Fagnan, G. Fontaine, P. Fontaine, C. Forti, J. R. Fournelle, A. Fournier, G. Fournier, J. A. Fournier, F. Furstner.

J. G. Gagne, C. M. Gagnon, C. Y. Gagnon, R. Gagnon, S. Galarneau, A. J. Galipeau, A. Gatien, A. J. Gauthier, M. Gelinas, P. Gelinas, G. Genereux, J. Gerin, G. Germain, A. C. Gervais, G. Girard, A. Gonneville, T. Gonzalez, R. Goyer, G. Grou, J. Guay, D. Guimond, L. E. A. H. Habets, R. Harbec, J. M. G. Henault, J. C. Huot, R. A. J. Huot, J. Janson, A. K. Keilani, C. Laberge, G. Laberge, J. A. H. Laberge, R. J. Laberge, G. A. Lafontaine, G. Lafontaine, J. P. Lalande, J. D. P. Lalonde, R. Lamarche, A. Lamarre, G. Lambert, J. G. Lampron, Y. Lanctot, P. Landry, D. Y. Laplante, G. Lapointe, D. Laporte, J. G. Laurin, P. E. Lavergne, G. Lavigne, J. A. R. Lavoie, R. Leblanc, G. Lebrun, S. Leclaire, J. Lefebvre, P. Lefrancois, J. W. J. G. Legare, M. Leger, C. Lemieux, J. Lenghan, Y. Letourneau, K. Le-tuong, H. Levesque, C. M. Luneau, J. P. Madore, M. Malinowski, P. Malo, C. Marchessault, D. Marcil, F. Martin, G. Martin, R. Martineau, E. Masse, J. B. Massicotte, G. Mercier, D. Metaxas, R. E. Miller, Y. Morin, F. E. Morissette, J. R. G. Nadeau, P. Nantel, H. Nguyen-Kim, V. D. Nguyen, M. Paquin, L. Paquin, C. Paradis, G. Paradis, R. Parisien, P. Peloquin, J. G. Pepin, V. Perluzzi, H. Pham-Chuong, H. Pham Quy, B. Pham-Viet, J. Poisson, G. Poulin, L. Poulin, R. Pronovost, J. Prophete.

Lariviere, J. M. L'Ecuyer, D. Lefrancois, M. Levesque, L. D. Massicotte, P. A. Plourde, G. G. Poulin, F. Roger, C. Roy, G. Tanguay, J. H. B. Tremblay, J. F. Voisine.

Royal Military College: P. Alexander, R. F. Bertrand, C. W. W. Darling, D. Dicicher, B. Dion, I. B. Engh, R. Mongeau, R. W. R. Neville, J. P. Reilly, J. L. Smith, W. A. Stenton, A. J. Tattersall, J. A. Torck, G. K. Welch, G. G. Whatman.

(Continued on page 147)

THIRTY-FIVE YEARS AGO

Comment on the Journal of April, 1923

The April 1923 issue of *The Engineering Journal* introduced the incoming president for the year, Walter J. Francis. In partnership with Frederick B. Brown, C.E., in 1910, he formed the consulting firm of Walter J. Francis and Co., and after reporting on many power developments and on municipal undertakings in various Canadian cities, in 1922 he became consulting engineer to the Royal Commission respecting the activities of the Hydro Electric Commission of Ontario. He played a prominent role in Institute affairs, and was instrumental in establishing the Montreal Branch, of which he was the first chairman.

Five papers were published in this issue, of which the subjects were: Design and Economics of City Refuse Destructors; The Fuel Situation in Canada; Electrons, Atoms and the Ether; The Cost of Industrial Power; and Electricity for Heating Buildings. In the last, a summary of conclusions by the author, G. Gordon Gale, vice-president and manager, Hull Electric Co., were given as follows: "The direct use of hydro electricity for heating is not desirable to the individual because the cost is too high. It is not possible to supply the community because there is not enough to supply everyone, nor is it in the interest of the country because electric power has another and more useful sphere."

Under Branch News, the Border Cities Branch recorded an address by D. A. Molitor, M.E.I.C., in which he described studies of the location for the Panama Canal, its construction and commercial advantages. The Hamilton Branch reported on a debate on the railway situation in that city, in which many prominent members took part. E. G. Cameron, M.E.I.C., chief engineer, Saint John Dry Dock and Shipbuilding Co., addressed the Saint John Branch regarding the construction of the Courtenay Bay breakwater and the 1150-ft. long drydock at Saint John. The London Branch heard H. B. R. Craig, M.E.I.C., in an address on harbour engineering. At Halifax, the Branch reported addresses by F. W. W. Doane, city engineer, on problems of the municipal engineer, and by W. B. MacKay on Recent Developments in Ventilation.

The Ottawa Branch recorded three papers, one on "Mining in Ontario," by John McLeish, director of the Mine Branch, who told the meeting that during the past five years northern Ontario had contributed over 95 per cent of the metal mineral production of Canada. J. D. Craig, M.E.I.C., Commander of the Canadian Arctic Expedition of 1922, predicted the Arctic archipeligo, might become a prized territory if the resources were developed. A third speaker was Major E. O. Wheeler, M.C., R.E., a member of the famous expedition which had reached an altitude of over 27,000 feet in an attempt to scale Mount Everest.

The Winnipeg Branch heard a paper on Three-Wire Distribution as Applied to Electric Traction, by W. Nelson Smith, M.E.I.C., while James Stewart of the late grain board addressed a second meeting on The Marketing of Grain. The Calgary Branch heard a talk on Coal Formations in Alberta by Lt. Col. F. M. Steele, D.S.O., M.E.I.C. The Edmonton Branch heard a paper on Alberta Highways by H. G. Dinsdale, M.E.I.C., and an address by Dr. Wyatt of the University of Alberta on the soil survey of the province.

The Montreal Branch had set up a committee to investigate the local coal situation. Lectures were given on the construction of dams by Major J. A. Brace, M.E.I.C., with particular reference to the Gouin Dam; and by J. L. Busfield, M.E.I.C., on water power resources of Manitoba, with illustrations of the Great Falls development on the Winnipeg river. An address was given at the Institute headquarters by H. J. Vennes of the Northern Electric Company, with another by Professor A. S. Eve at his home on Mountain Street. Both addresses were heard at both places through loud speakers. This experiment to show how a human voice could be taken apart, sent in waves to another place; then reassembled and distributed in all its original characteristics was a unique event.

At its Branch meeting, the Toronto Branch reported a membership of 650. Subjects of papers given included Methods of Purifying Water Supplies, by R. L. Dobbin, M.E.I.C; Electrification of Railways, by A. L. M. Mudge, M.E.I.C., and Valuation of Railways, by Arthur Crumpton, M.E.I.C. The Kingston Branch heard papers on Plant Used in Concrete Road Construction, by Professor L. Malcolm, M.E.I.C., of Queen's, and a paper by Norman Gibson, M.E.I.C., hydraulic engineer of Niagara Falls, N.Y., on the application of his new method of measurement of water flow in penstocks.

COMMITTEES

Admissions
Roger Brais, chairman; W. H. Gauvin, D. H. Hobbs, J. H. R. Dansereau, R. J. Harvey.

Board of Examiners
J. L. deStein, chairman; John M. Cape, J. Hurtubise.

Canadian Standards Association (Technical Council)
P. L. Pratley—Institute Representative.

Finance
A. Deschamps, chairman; R. L. Dunsmore, R. A. Emerson, R. G. Ferrabee, J. M. Breen, O. M. Solandt, R. L. Weldon.

Canadian Chamber of Commerce
F. G. Rutley—Institute representative on National Board of Directors.

Legislation
C. G. Kingsmill, chairman; D. C. MacCallum, J. B. Stirling.

Library and House
C. E. Frost chairman; L. A. Duchastel, W. D. Kirk, E. D. Gray-Donald, W. C. M. Luscombe.

Membership
R. H. Self, chairman.

Publication
H. A. Mullins, chairman; J. A. Audet, William Bruce, W. H. Gauvin, B. D. McDermott, D. W. R. McKinley.

Papers
J. H. Budden, chairman; D. H. Hobbs, H. L. Johnston, M. McMurray, W. B. Pennock, E. R. Smallhorn, H. S. Van Patter, L. P. Bonneau, R. Boucher.

Prairie Water Problems
G. A. Gaherty, chairman; P. M. Sauder, vice-chairman; T. D. Stanley, secretary; C. S. Clendening, D. W. Hays, B. Russell, T. H. Hogg, G. L. MacKenzie, J. H. McLean, J. M. Wardle.

Policy
R. L. Dunsmore, chairman; B. G. Ballard, A. Deschamps, I. P. Macnab, D. M. Stephens, R. L. Hearn, R. E. Heartz, J. B. Stirling, W. G. Swan, I. R. Tait.

Professional Interests
E. B. Jubien, chairman; G. A. Gaherty, vice-chairman; W. E. Brown, G. J. Currie, W. G. Swan, H. L. Branchaud, E. K. Phillips, I. R. Tait.

Property
F. G. Rutley, chairman; A. Deschamps, V. B. King, C. N. Murray, R. C. Pybus.

Student Policy
C. G. Southmayd, chairman; R. E. Jamieson, J. Dubuc, E. J. Muszinski, J. F. Riel, A. Pakalnins.

Technical Operations
F. L. Lawton, chairman; B. G. Ballard, W. H. Paterson, C. E. Frost, D. L. Rigsby, R. M. Hardy, S. Sillitoe, A. R. Harrington, E. R. Smallhorn.

OFFICERS OF THE BRANCHES

AMHERST
Chairman, J. W. Wilson; *Vice-Chair.,* D. J. Rockwell; *Executive,* F. C. Wightman, L. E. Burrill, R. G. Baxter.
Sec.-Treas., G. R. Pond, 7 Victoria Street West, Amherst, N.S.

BAIE COMEAU
Chairman, V. M. Wallingford; *Executive,* Peter Suttie, G. Scott, J. M. Pope; *Treasurer,* T. G. Rust.
Secretary, Norman Lapierre, P.O. Box 1073, Baie Comeau, Que.

BELLEVILLE
Chairman, J. A. Grant; *Vice-Chair.,* A. E. Argue; *Executive,* T. E. Flinn, B. D. Pullen, H. T. Floyd, W. C. Benger, T. J. McQuaid, W. L. Canniff.
Sec.-Treas., F. E. Moore, 71 Golfdale Blvd., Belleville, Ont.

BORDER CITIES
Chairman, C. Maurice Armstrong; *Vice-Chair.,* J. E. Dykeman; *Executive,* R. H. Darke F. P. Mascarin, A. W. Malmberg; *Treasurer,* E. R. Carpenter.
Secretary, J. M. Reid, 1511 York Street, Windsor, Ont.

BROCKVILLE
Chairman, W. N. Simmons; *Vice-chair.,* D. C. Turner; *Executive,* R. B. McRuer, W. E. Morden, F. E. Trewartha, K. R. Bullock, J. F. Preston.
Sec.-Treas., G. R. Bowes, 152 King Street East, Brockville, Ont.

CALGARY
Chairman, A. W. Howard; *Executive,* K. L. Broe, W. J. McGill, R. S. White, J. L. Mitchell; *Treasurer,* R. G. Price.
Secretary, O. O. Junker, c/o Cumming, Galbraith Limited, 1510a - 1st St., S.W., Calgary, Alta.

CAPE BRETON
Chairman, J. V. Palmer; *Vice-Chair.,* W. L. Dodson; *Executive,* G. Ross, J. R. Wallace, H. Maitland, R. Bradley, P. Terry, J. Stevens; *Treasurer,* C. A. Campbell.
Secretary, H. M. Aspinall, P.O. Box 485, Sydney, N.S.

CENTRAL BRITISH COLUMBIA
Chairman, E. R. Gayfer; *Vice-Chair.,* P. Tassie; *Executive,* R. G. Harris, D. G. Hepburn, D. Wales.
Sec.-Treas., W. J. M. Owen, 634 Eckhardt Avenue West, Penticton, B.C.

CORNER BROOK
Chairman, Milton G. Green; *Vice-Chair.,* E. J. Leja; *Treasurer,* W. S. Read.
Secretary, Eric R. Skanes, c/o Bowater's Engineering Dept., Corner Brook, Nfld.

CORNWALL
Chairman, W. Rothwell; *Executive,* L. H. Snelgrove, J. Moriarity, J. Pescod, M. Broadbent, M. S. Thompson, F. J. Willis.
Sec.-Treas., D. W. C. McEwan, c/o Courtaulds (Canada) Ltd., Cornwall, Ont.

EASTERN TOWNSHIPS
Hon. Chair., A. C. Crepeau; *Chairman,* R. D. Mawhood; *Vice-Chair.,* G. P. Cote; *Executive,* J. P. Champagne, J. E. Freeman, C. D. McKinney, E. T. Harbert, M. Lafreniere, G. B. Moffat; *Treas.,* A. S. Mitchell.
Secretary, Jean Bourassa, 450 Belvedere St., S., Sherbrooke, Que.

EDMONTON
Chairman, S. J. Hampton; *Vice-Chair.,* T. H. Newton; *Executive,* R. H. Cronkhite, D. H. Sands, G. Ross, S. R. Sinclair, H. Hole, R. H. Gardener, R. H. Nicolson, J. Longworth.
Sec.-Treas., G. Hodge, 10615-146th St., Edmonton, Alta.

FREDERICTON
Chairman, R. P. Lynch; *Vice-Chair.,* O. I. Logue; *Executive,* J. J. Gorman, W. L. Barrett, L. W. Smith, F. J. Abbass, R. S. Shephard, L. W. Bailey; *Treasurer,* R. D. Neal.
Secretary, A. M. Stevens, Box 62, Marysville, N.B.

HALIFAX
Chairman, J. D. Kline; *Vice-Chair.,* W. J. Phillips; *Executive,* J. G. Belliveau, G. M. Haliburton, A. H. MacKinnon, K. R. Mitchell, M. C. Sutherland-Brown, J. R. Cameron, L. D. Hopkins, B. E. Langley, R. B. Killam, M. A. Marshall.
Sec.-Treas., J. E. Reardon, Public Service Commission, Halifax, N.S.

HAMILTON
Chairman, R. C. Mitchell; *Vice-chair.,* H. E. Seely; *Executive,* P. J. McNally, T. O. Watts, J. A. Michell, A. F. Barnard.
Sec.-Treas., W. A. H. Filer, 2 Maple Ave., Hamilton, Ont.

HURONIA
Chairman, H. C. Bates; *Vice-Chair.,* S. R. Walkinshaw; *Executive,* D. M. Harris, C. G. Campbell, J. L. Armstrong, J. E. Sears, J. W. Davies, R. G. Freeman.
Sec.-Treas., L. Morgante, 36 Borland Street West, Orillia, Ont.

KINGSTON
Chairman, J. W. Dolphin; *Vice-Chair.,* R. B. Wotherspoon; *Exec.,* W. M. Campbell, D. C. MacPherson, W. B. Rice.
Secretary, D. I. Ourom, 991 Princess St., Kingston.

KITCHENER
Chairman, C. A. Leicht; *Vice-chair.,* W. J. Horner; *Executive,* R. Dahmer, W. Bobbie, G. Tidswell, H. Walters.
Sec.-Treas., A. H. Austin, Armco Drainage & Metal Products of Canada Ltd., Box 300, Guelph, Ont.

KOOTENAY
Chairman, J. T. Higgins; *Vice-chair.,* D. J. Turland; *Executive,* R. F. Bailey, L. S. Piper, G. C. Rogers, E. Rohatynski, W. V. Nicholon, R. J. Portman; *Treasurer,* J. I. McClelland.
Secretary, P. L. J. Limbert, 649 Forrest Drive, Trail, B.C.

LAKEHEAD
Chairman, V. B. Cook; *Vice-Chair.,* W. D. MacKinnon; *Exec.,* W. H. Bulger, P. W. Pinn, J. W. Lukey, J. E. Rymes, G. S. C. Smith, G. A. Walker, J. H. Hargrave, A. T. Sherrett; *Sec.-Treas.,* C. M. Cotton, 320 North Syndicate Ave., Suite 2, Fort William, Ont.

LETHBRIDGE
Chairman, J. R. Milne; *Vice-Chair.,* W. B. Thomson; *Executive,* G. B. Davies, R. L. Francis, J. A. Wilihan.
Sec.-Treas., R. D. Hall, 421-26th Street South, Lethbridge, Alta.

LONDON
Chairman, R. W. McMeekin; *Vice-chair.,* C. H. Osborne; *Executive,* G. W. Chorley, H. E. Martin, L. S. Lauchland, G. O. Hayman, G. E. Wilson.
Sec.-Treas., W. C. Sinkins, London Steel Construction Co. Ltd., P.O. Box 69, 48 Burslem Street, London, Ont.

LOWER ST. LAWRENCE
Chairman, Jean R. Menard; Vice-Chair., M. Lanouette; *Executive,* T. Bernier, R. Joncas, A. Leroux, G. Santerre.
Sec.-Treas., Claude St. Hilaire, 10 Rue St. Jean, Rimouski, Que.

MONCTON
Chairman, G. E. Franklin; *Vice-Chair.,* C. L. Trenholm; *Executive,* H. S. McCleave, L. McIsaac, G. A. Peck, C. E. Spear, W. M. Steeves.
Sec.-Treas., V. C. Blackett, 97 MacBeath Avenue, Moncton, N.B.

MONTREAL
Chairman, P. W. Gooch; *Vice-chair.,* R. A. Phillips; *Executive,* R. J. Harvey, R. J. Kane, L. L'Allier, H. Audet, C. A. Colpitts, J. O. McCutcheon.
Sec.-Treas., G. M. Boissonneault, Shawinigan Water and Power Co., P.O. Box 6072, Room 809, Montreal, Que.

NEWFOUNDLAND
Chairman, G. E. Knight; *Vice-Chair.,* C. W. Henry; *Executive,* R. P. Hunt, A. H. McKinnon, D. S. Templeton, G. N. Cater, R. W. Myers, R. F. Martin.
Sec.-Treas., R. L. Smyth, c/o Imperial Oil Limited, Centre Building, St. John's, Nfld.

OFFICERS OF THE BRANCHES

NIAGARA PENINSULA

Chairman, E. C. Little; *Vice-Chair.,* D. A. Barnum; *Executive,* H. J. Saaltink, G. N. Cotton, H. C. L. Joe, D. O. Ramsdale, W. D. Tanner, G. E. Griffiths, C. A. MacDonald.
Sec.-Treas., Malcolm Stevenson, Box 196, Fonthill, Ont.

NIPISSING AND UPPER OTTAWA

Chairman, J. F. Chantler; *Vice-Chair.,* J. S. Cooper; *Executive,* E. A. Watson, R. S. MacLennan, J. Crothers, J. Warburton, P. Rebin, H. Staniforth.
Sec.-Treas., R. A. Booy, Box 1, Temiskaming, Que.

NORTH EASTERN ONTARIO

Chairman, A. A. Kidd; *Vice-Chair.,* J. S. Whyte; *Executive,* C. McIntyre, J. Blakeman, J. N. Greggain, J. Shipman, M. McLean, W. Swann, G. Flett.
Sec.-Treas., J. S. Busby, c/o C.N.R., Cochrane, Ont.

NORTHERN NEW BRUNSWICK

Chairman, L. L. Marshall; *Vice-Chair.,* D. C. MacCallum; *Executive,* Stewart Henry, A. R. Bonnell, J. A. Mesereau, C. K. Steeves, Martin Cyr, R. A. Cameron.
Sec.-Treas., G. P. Milton, 272 Millhaven St., Bathurst, N.B.

NORTH NOVA SCOTIA

Chairman, D. J. MacNeil; *Vice-Chair.,* W. I. Fisher; *Exec.,* C. McGibbon, M. Wolfe, Rev. W. Fogerty, J. K. Godfrey.
Sec.-Treas., D. G. Dunbar, Pictou County Power Board, New Glasgow, N.S.

NORTH SHORE LOWER ST. LAWRENCE

Chairman, B. M. Monaghan; *Executive,* R. W. Kenway, M. Michaud, M. Storrier.
Sec.-Treas., L. E. Fisher, Iron Ore Company of Canada, Dock Terminal, Sept-Iles, Que.

OTTAWA

Chairman, Hector Chaput; *Vice-Chair.,* John S. Watt; *Executive,* A. H. Graves, T. M. Patterson, R. C. Silver, H. A. MacKenzie; *Treasurer,* Hugh C. Brown.
Secretary, W. V. Morris, 2078 Knightsbridge Road, Ottawa, Ont.

PETERBOROUGH

Chairman, I. N. MacKay; *Executive,* J. L. Olsen, V. Aare, R. A. Blount, W. H. Powell, J. G. Hooper, C. W. Holman, D. J. Kawaja, P. Tuck, G. W. McPhee, E. R. Shirley.
Sec.-Treas., G. M. Locke, 1269A Clonsilla Ave., Peterborough, Ont.

PORT HOPE

Chairman, T. F. Kennedy; *Vice-chair.,* J. A. Pollock; *Executive,* J. L. Sulvester, D. A. Runciman, T. S. Bradfield.
Sec.-Treas., R. Waterfall, 81 Hope Street North, Port Hope, Ont.

PRINCE EDWARD ISLAND

Chairman, C. W. Currie; *Vice-chair.,* A. Coles; *Executive,* J. D. M. MacDonald, L. E. Slaght, A. D. Cameron.
Sec.-Treas., R. D. Donnelly, P.O. Box 184, Charlottetown, P.E.I.

QUEBEC

Life Honorary Chairman, A. R. Decary; *Chairman,* Roger Desjardins; *Vice-chair.,* P. A. Duchastel; *Executive,* Lionel Boulet, J. B. Delage, Hugh Kane, P. E. Begin, L. Joncas, Jacques Roy.
Sec.-Treas., Marc Bergeron, Concrete Repairs and Waterproofing Co., 128 Blvd. Ste. Anne, Quebec, Que.

SAGUENAY

Chairman, J. Roch Boisvert; *Vice-Chair.,* F. A. Brown; *Executive,* L. Tessier, G. C. Gauthier, E. Paine, J. J. Falardeau, R. Bodie, P. R. Thomas.
Sec.-Treas., D. L. Aker, c/o Aluminum Company of Canada Limited, Arvida, Que.

SAINT JOHN

Chairman, H. W. M. Townshend; *Vice-chair.,* J. W. G. Scott; *Executive,* G. C. Robinson, P. W. Hastings, K. V. Cox, G. C. Mouland; *Sec-Treas.,* D. I. Higgins, 30 Elizabeth Court, Saint John, N.B.

ST. MAURICE VALLEY

Chairman, D. M. McKim; *Vice-Chair.,* J. B. Edwards; *Executive,* G. Boucher, J. W. Gathercole, P. Hansen, D. C. Kinley, E. A. Love, C. H. Neil, B. Pangborn, J. H. A. Pearson; *Treasurer,* T. J. Goddard.
Secretary, J. O. Hachey, 53 Spruce St., Apt. 13, Shawinigan Falls, Que.

SARNIA

Chairman, J. H. Douglas; *Executive,* M. Waghorne, J. Miller, A. W. Wirth, C. M. Stewart, M. Brown.
Secretary, R. F. Routledge, c/o Imperial Oil Limited, Sarnia Refinery, Sarnia, Ont.

SASKATCHEWAN

Chairman, W. G. McKay; *Vice-Chair.,* J. C. Traynor; *Executive,* K. W. Allcock, M. B. Pierce, B. B. Torchinsky, J. B. Mantle, W. F. Hayes, K. R. Pattison, J. A. Wedgwood.
Sec.-Treas., R. Bing-Wo, 2043 Cameron St., Regina, Sask.

SAULT STE. MARIE

Chairman, R. H. Tooley; *Vice-Chair.,* L. F. Mason-Tulby; *Executive,* K. I. Fletcher, K. E. Kansikas, W. M. Hogg, W. B. Sproule.
Sec.-Treas., R. L. Wimperis, c/o General Delivery, Sault Ste. Marie, Ont.

SUDBURY

Chairman, J. W. Smith; *Vice-Chair.,* W. B. Ibbotson; *Executive,* F. J. DeStefano, H. Stavang, E. A. Fletcher, J. F. McCallum.
Sec-Treas., W. J. Ripley, 14 Miller Crescent, Lockerby, Ont.

TORONTO

Chairman, R. Harvey Self; *Vice-chair.,* A. C. Davidson; *Executive,* L. F. Bresolin, A. M. Toye, G. F. R. Norton, R. R. McLaughlin, I. S. Patterson, R. A. Rule, B. L. Farrand, Cameron MacInnis, I. S. Gauley, M. H. Pryce.
Sec.-Treas., D. S. Moyer, c/o Canadian Radio Manufacturing Corp., 11-19 Brentcliffe Road, Leaside, Ont.

VANCOUVER

Chairman, P. N. Bland; *Vice-Chair.,* W. G. Heslop; *Executive,* C. H. White, J. F. Muir, W. J. Johnson, J. H. Swerdfeger, J. J. Kaller, E. S. Hare; *Treasurer,* R. H. Carswell,
Secretary, A. D. Cronk, 658 West 13th Ave., Vancouver, B.C.

VANCOUVER ISLAND

Chairman, G. Griffiths; *Vice-Chair.,* H. Graham; *Executive,* H. T. Miard, L. C. Johnson, W. G. McIntosh, A. F. Paget.
Sec.-Treas., J. A. Cowlin, 3340 Richmond Rd., Victoria, B.C.

Sec.-Treas., C. S. Landon, Room 418—265 Portage Ave., Winnipeg 2, Man.

YUKON

Chairman, Capt. S. Thomson; *Executive,* C. E. White; *Treasurer,* J. D. Scott.
Secretary, Capt. E. I. Crouse, H.Q., NWHME, Camp Takhini, Whitehorse, Y.T.

ONTARIO DIVISION

Chairman, G. R. Henderson; *Vice-Chair.,* M. A. Montgomery; *Board of Management,* P. E. Buss, H. G. Conn, H. R. Sills; *Treasurer,* G. R. Turner.
Secretary, G. H. Rogers, c/o Engineering Institute of Canada, 160 Eglinton Ave. E., Toronto.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Brigadier General Sir Alexander Gibb, Hon. M.E.I.C., noted engineer and former adviser to the Canadian government on seaport development died at Hartley Wintney, England on January 21, 1958.

Born at Broughty Ferry, Scotland, on February 12, 1872, Alexander Gibb represented the fifth generation in direct succession, of civil engineers. He was educated at Rugby School, England, and at University College, London, before going on to engineering studies as an articled pupil with the office of Sir John Wolfe Barry and H. M. Brunel.

In 1900 Gibb left Wolfe Barry to assist his father, a member of the firm of Easton Gibb and Company. During the next sixteen years one of his greatest contracts was the naval dockyard at Rosyth, of which it was publicly announced at the Institution of Civil Engineers that "it was due to the sagacity, fortitude, and enthusiasm of Sir Alexander Gibb that the works had been completed in time to be of immense use to the Fleet during the vital periods of the war."

In 1916 he was appointed chief engineer, ports construction, to the British armies in France. Later he became civil engineer in chief, Admiralty, concerned with measures to counter the U-boat menace. Gibb was granted a C.B. for his services to the armies in France and a K.B.E. on appointment to the Admiralty. His work there was recognized by advancement to G.B.E.

In 1919 Sir Eric Geddes, an old associate, then minister of transport, appointed Sir Alexander Gibb director-general of civil engineering, with the responsibility of creating a new department in a new ministry while dealing with a variety of problems connected with communications in the British Isles.

In 1921, opening a consulting engineering practice in London he set up the two-room office in Victoria Street, later to grow into the firm of Sir Alexander Gibb and Partners, Queen Anne's Lodge, Westminster, which historic eighteenth century building is its headquarters today. Branch offices are located in Britain and overseas, as well as an associate, Sir Alexander Gibb and Partner (Africa) at Nairobi.

Later, during World War II, poor health forced him into semi-retirement. A son, Michael Gibb has become a partner in the firm.

Sir Alexander Gibb was an associate member and member of the Institution of Civil Engineers for more than sixty years and president of the organization in 1936-7.

He joined the Institute in 1932 as a Member. He was named to Honorary membership in 1937.

Dr. T. H. Hogg, M.E.I.C., noted consulting engineer and former chairman of the Hydro-Electric Commission of Ontario, died at Toronto, on February 24, 1958.

Thomas H. Hogg was born at Chippawa, Ontario on April 20, 1884. He received his education at the Niagara Falls Collegiate Institute and the University of Toronto. He graduated from the latter institution in 1907 with the degree B.A.Sc. in civil engineering. He was employed with the Ontario Power Company, Niagara Falls, in various capacities, from his undergraduate days of 1902 until 1911. After his graduation his field of work broadened to include developments in New York State. A brief interlude of editorial work created contacts for him with engineers in many fields at a time noted for rapid material progress throughout Canada.

Dr. T. H. Hogg, M.E.I.C

In 1913 Dr. Hogg joined the staff of the Hydro-Electric Power Commission of Ontario as an assistant hydraulic engineer, and in succeeding years filled the position of chief hydraulic engineer, chief engineer and finally, chairman and chief engineer of the Commission in 1927. He retired in 1947 and became engaged in the work of consultant to the Federal government on hydraulic matters and western water problems.

Dr. Hogg served as a member of the Senate of the University of Toronto, representing graduates in applied science and engineering for twenty-five years.

He was awarded the honorary degree of D. Eng. from that university in 1927.

He was in 1948 named winner of the Sir John Kennedy Medal of the Engineering Institute. The citation which accompanied the award read "Thomas Henry Hogg was born close to the site where he was to build for himself a record as a great engineer and a great citizen. Chippawa and the Niagara Falls area were the locale for many important events of his life from his birth to his greatest engineering achievement."

Dr. Hogg held directorships in a number of organizations including the Chartered Trust Company and the Brazilian Traction, Light and Power Company Limited.

Dr. Hogg joined the Institute as a Student in 1904, transferred to Associate member in 1912, and to Member in 1922. He attained Life membership in 1948.

George Edward Cole, M.E.I.C., former director of the Manitoba Mines Branch and past-president of the Canadian Institute of Mining and Metallurgy, died at Winnipeg on December 11, 1957.

Born at Alymer, Que., on December 2, 1879, Mr. Cole was a graduate of McGill University. He received a B.A. degree in 1902, and qualified for the degree, B.Sc. in mining, at that university, four years later.

A period of mining engineering with numerous concerns marked his early professional experience.

Enlisting in the 159th Overseas Battalion, Canadian Expeditionary Force in 1915, he later transferred to the Canadian Engineers, serving in France and Belgium. In 1919, returned to Canada, he was employed as a mining instructor at the Haileybury School of Mines, Haileybury, Ont., by the Department of Soldiers' Civil Re-establishment, in training returned soldiers in mining, milling and prospecting work. Continuing his army affiliations in peacetime he commanded the Algonquin Rifles at Winnipeg, retiring with the rank of lieutenant-colonel in 1932.

Mr. Cole was in 1921 appointed to the department of mines, Province of Ontario, in the capacity of inspector of mines. He accepted office with the Province of Manitoba as chief inspector of mines in 1928. The appointment came at a time when preparations were underway for the control of natural resources, previously a Dominion government concern, to be assumed by that province. As a result of this move, Mr. Cole was named chief inspector of the department of mines and resources. Promoted to director of the mines branch in 1930, he continued this work until his retirement in 1945.

In 1941-42 he was loaned to the Federal government to serve with the Wartime Bureau of Technical Personnel, Ottawa.

He became a member of the Canadian Institute of Mining and Metallurgy in 1914, was elected vice-president for 1933-34, and president for 1936-37. He became a life member in 1945. Elected president of the Association of Professional Engineers of Manitoba in 1941, he was again asked to serve that body in 1944. He was active as a Freemason.

Mr. Cole joined the Engineering Institute as a Student member in 1905. He transferred to Associate membership in 1912, and to member in 1940. He attained life membership in the organization in 1946.

W. G. Milne, M.E.I.C., retired managing director of the N. Slater Company Limited, Hamilton, Ont., died in that city on November 27, 1957.

Winford Gladstone Milne was born on June 16, 1877, at Scarborough, Ontario, and studied engineering at the School of Practical Science of the University of Toronto, from 1898 to 1902. Before graduating he gained experience with the Lindsay Light and Power Company and the W. H. Johnston Electric Company. He entered the service of the Hamilton Bridge Works drafting department in 1909, and the following year became plant engineer, which post he held for eleven years.

Joining the N. Slater Company in 1920, Mr. Milne's first responsibility was that of works superintendent and later chief engineer and managing director. Mr. Milne held patents to many electrical and mechanical items.

Retiring two years ago, he was a director of the firm until his death.

Mr. Milne joined the Institute as an Associate member in 1919; and transferred to member in 1935. He became a life member in 1949.

W. G. Milne, M.E.I.C.

C. P. Haltalin, M.E.I.C., manager of the operating division of the Winnipeg Electric Company, Winnipeg, Man., died in that city on February 7, 1958.

Born at Winnipeg, Man., on December 28, 1906, Clifford Paul Haltalin was educated at the Daniel McIntyre Collegiate and at the University of Manitoba. He was awarded a B.Sc. degree in electrical engineering in 1929. Shortly after graduation he joined the Winnipeg Electric Company and advanced as junior engineer, assistant electrical engineer, supervisory engineer, and chief electrical engineer. In 1953 he was appointed manager of the operating division.

Mr. Haltalin was chairman of the Winnipeg Branch of the Institute in 1945 and represented the Winnipeg Branch of the Institute as Councillor in 1954.

He joined the Institute as a Student member in 1927; transferred to Associate member in 1934 and to Member in 1940.

A. M. Reid, M.E.I.C., district engineer with the Department of Public Works, Province of Alberta, died at Edmonton on January 28, 1958.

Alexander MacLaren Reid was born at Glasserton, Whithorn, Wigtownshire, Scotland, on December 21, 1895. He was educated at Whithorn High Grade School, and then served with the British Army and the King's Own Scottish Borderers during World War I. He later returned to Glasgow and underwent private tuition and technical evening classes in order to study engineering.

His first post outside the armed forces was an assistant to the county surveyors at Stranraer, Scotland. Leaving Great Britain in 1921, he accepted employment with the Anglo-Persian Oil Company to assist in a road-building project in Persia. He remained in the service of this organization for a period of six and a half years. The next phase of his professional career brought him to Canada where he joined the firm of E.G.M. Cape and Company, engineers and contractors, Montreal. The following year he first became associated with the Department of Public Works, Province of Alberta, Edmonton, as an instrumentman.

Named resident engineer on the survey and construction of the main highways in 1930, he was a few years later associated with the Alberta Relief Commission, in the administration of relief and relief work in the Alberta drouth areas during the depression years. Later he was appointed resident engineer on the main highway branch at Edmonton, and district engineer at St. Paul, Alta.

F. C. Kresz, M.E.I.C.

Mr. Reid joined the Institute as an Associate Member in 1939, transferred to Member in 1940.

Francis Charles Kresz, M.E.I.C., consulting engineer, associated with the firm of R. P. Allsop and Associates Ltd., Toronto, a prominent member of the Hungarian community of Toronto and founder of the Canadian Hungarian Professional Engineers' Society died at Toronto on June 16, 1957.

Mr. Kresz was born at Budapest, Hungary on July 11, 1883. He attended the Royal Technical University at Budapest and graduated in mechanical and electrical engineering in 1905. Thereupon he joined the Belgian branch of the world-wide Koerting Company. In 1909 he was called to the Austrian office of the firm at Vienna which move was followed a short time later by his appointment as export manager for the Balkans. Before the first World War, the troublesome years of the two Balkan Wars, he worked in this area, with headquarters at Sofia. Also in that period of his career he was recalled to Vienna and given the new assignment of re-organizing the Hungarian branch of the Koerting Company, developing the company into the foremost of its kind in Hungary. He became its president in 1935. After the break-up of the Hungarian-Austrian empire, Mr. Kresz gradually acquired ownership of the Hungarian Koerting Company. In 1948, due to Communist influence he was forced to abandon his claim to the company in which he had taken so large a part. Arriving in Canada later that year, he worked with the firm of A. Brittain and Associates Limited.

The Canadian Hungarian Professional Engineers' Society, of which he was the founder, today boasts a membership of 150 persons.

Mr. Kresz joined the Institute as a member in 1952.

Alfred Joseph Altrogge, M.E.I.C., district engineer with the Department of Highways, at Saskatoon, Sask., died suddenly on January 20, 1958.

Mr. Altrogge was born at St. Benedict, Sask., on September 26, 1926. He attended St. Peter's College, Muenster, Sask., in 1943 and 1944. He enrolled at the University of Saskatchewan as an engineering student in 1945. Gaining experience during vacation time, he worked with the Department of Mines and Resources, Ottawa, as a surveyor on the Alaska Highway; with the Hudson Bay Mining and Smelting Company at Flin Flon, Man., and with the Department of Highways at Regina. Mr. Altrogge graduated with a B.Sc. degree in civil engineering in 1949. Since 1950 he had been employed with the Province of Saskatchewan in the capacity he served at the time of his death.

Mr. Altrogge joined the Engineering Institute as a Member in 1952.

The B.C. Electric Strike

(From "News of the Engineering Profession", published by The Association of Professional Engineers of B.C.)

Criticism which has been expressed in certain quarters concerning the efforts of professional engineers of the B.C. Electric staff to maintain essential electrical services to the public is unfounded and unfair, according to J. A. Merchant, P.Eng, registrar of the Association of Professional Engineers of B.C.

All professional engineers subscribe to a strict code of ethics, which specifies that their prime responsibility is to the public, and secondly their employer. This principle of professional responsibility precludes strike action as a means of enforcing group demands. It is the reason that, in common with other learned professions, they are specifically exempted from the provisions of the Labour Relations Act. Their sole ethical consideration must be fulfillment of the public trust imposed upon them by the nature of their duties.

Public confidence in the engineering profession is based upon the knowledge that so long as an engineer occupies a position of responsibility, all the obligations of that position will be faithfully carried out without regard to any other consideration whatsoever.

His only relief from that responsibility would be to resign his position. In the case of a public utility, when interruption of electrical services would mean not only inconvenience but actual hardship and danger to the public, he would not be justified in abandoning his post even by resignation.

The responsibility of the professional engineers employed by a public utility is to provide essential electrical services to the public, with or without the assistance of other personnel. It is hoped that the public will appreciate that the position of professional engineers in the present wage controversy is based upon a deeply rooted ethical principle which is primarily designed to insure that whatever a professional engineer undertakes to do he must faithfully perform.

NOVA SCOTIA

Annual elections held

L. D. Wickshire, of Liverpool, N.S., engineer of the Mersey Paper Company Limited, has been elected president of the Association of Professional Engineers of Nova Scotia. J. D. Kline, of Halifax, newly appointed general manager of the Public Service Commission, was elected vice-president of the Association.

The following members have been elected councillors for 1958-59: G. D. Mader, G. H. Dunphy, O. N. Mann, and J. B. Ternan, all of Halifax; B. N. Cain, Wolfville; J. R. Cameron, Milford; A. B. Rossetti, Sydney, and C. S. Williams, Antigonish.

Mr. Wickwire is a graduate of Colchester County Academy, Dalhousie University and the Nova Scotia Technical College. He served overseas with the R.C.A.F. and was commanding officer of the Air Force depot at Gander, Nfld., following service as chief engineer at the Scoudouc, N.B. base. He has served the Association in numerous capacities including those of councillor and vice-president.

L. D. Wickwire, P.ENG.

Mr. Kline is a graduate of St. Mary's High School, St. Mary's University and the Nova Scotia Technical College. He was appointed manager of the Public Service Commission following appointments as designer engineer, chief engineer and assistant manager. He served the Association for a period of ten years as secretary-treasurer, followed by a period as councillor.

ONTARIO

Canadian industry has been guilty of misemployment of its professional engineering manpower, and this has been the major reason for the so-called shortage of engineers, T. M. Medland, executive director of the Association of Professional Engineers of Ontario declares in his annual report.

"There has never been a crippling shortage of professional engineers in this country, but we have been guilty of misemployment of the engineering brains that have been available," he said.

"The major need at the moment is for industry to provide an atmosphere in which our engineers may grow professionally—to provide them with technicians and clerical assistance that will enable the engineer to have time to think and to create," Col. Medland points out.

"I suggest that our national life is being threatened—not by sputniks or I.C.B.M.s (intercontinental ballistics missiles) but by the fate of our export trade.

"The answer to this is increased productivity and new, purely-Canadian products. More research is required and more time for professional engineers to think and to create."

Earlier in his report, Col. Medland noted that of the 1,731 persons admitted to the profession in Ontario last year, 46% received their education outside of Canada. He also pointed out that of 563 applications for registration dealt with by the Executive Council on Jan. 31, 35.1% were of Canadian origin and training; 39.9% of Commonwealth origin and training; 2.9% United States, and 22.1% European.

Engineers in the News

Walter G. Pengelley, P.ENG., who since 1951 has been assistant sales manager at Toronto for Canadian Westinghouse Co. Ltd., has been appointed Ontario district manager. Mr. Pengelley graduated in electrical engineering from McGill University and joined Westinghouse in 1911. Engaged in apparatus sales for most of his career he was manager of the company's apparatus division in Toronto for a number of years.

F. A. Pankhurst, P.ENG., of Canada Wire & Cable Co. Ltd., Toronto has relinquished his duties as general works manager of the Leaside plant to take the post of executive representative reporting directly to the president and vice-president. Mr. Pankhurst, who is a graduate of Faraday House, London, Eng., has been with the Canada Wire & Cable Company since 1934.

W. J. McNicol, P.ENG., of the Canadian Westinghouse Co. Ltd., Hamilton, Ont., has been appointed assistant Ontario district manager. A graduate of the University of British Columbia, he joined the Company in 1950 and in 1953 was appointed manager, sales department, turbine division. Two years later he became sales manager for the power products division. Prior to his most recent appointment Mr. McNicol was sales manager for the company's motor generation division at Hamilton.

Gordon E. Marshall, P.ENG., is sales supervisor with Canadian Chromalox Co. Ltd., Toronto. In this capacity he will supervise the company's industrial sales and advertising programs.

Mr. Marshall obtained his degree in electrical engineering in 1951 at the University of Toronto and was formerly with Canadian General Electric Co. Ltd. engineering and manufacturing department of the electrical heating devices division.

D. J. Dudley, P.ENG., who was formerly radio performance and standards engineer with the Canadian National Telegraphs in Toronto, is now employed as a field engineer with the Telechrome Manufacturing Corp., Amityville, Long Island, N.Y.

F. C. Boyd, P.ENG., of the Canadian General Electric Co. Ltd., has recently been appointed systems appraisal engineer in the Civilian Atomic Power Department of the company. In this post he will be responsible for general appraisal of the nuclear systems, evaluation of reactor hazards and preparation of applications for licenses from the Atomic Energy Control Board.

David L. Featherstone, P.ENG., of Dunnville, Ont., has been elected warden of the County of Haldimand, on whose County Council he has served as Dunnville's representative since 1951.

His entry into Town Council of Dunnville was in 1949 and in 1951 he was elected deputy reeve, serving in that capacity until the end of 1954. In 1955 he became reeve, continuing in office during 1956 and 1957. This year he was again elected reeve but under the newly inaugurated two-year term.

While on Council Mr. Featherstone has served continuously as chairman of the public works committee of Dunnville, except for 1953. He has also been on the Haldemand country roads committee and last year was its chairman.

Wesley G. Nilson, P.ENG., has concluded his current assignment at the Atomic Energy of Canada Ltd., Chalk River, Ont., and has returned to the research laboratory of the International Nickel Co. Inc., at Bayonne, N.J.

Peter M. Sandham, P.ENG., of the Royal Canadian Air Force has been promoted to the rank of Squadron Leader. He is a graduate of the University of Toronto and first joined the R.C.A.F. in 1943. Sqdn. Ldr. Sandham is presently construction engineering officer at the R.C.A.F. Station, Cold Lake, Alta.

D. H. Craighead, P.ENG., is principal of the Hamilton Institute of Technology, Hamilton Institute of Technology, Hamilton., Ont., succeeding **C. C. Ashcroft**, P.ENG., who has retired. Prior to assuming the principalship in Hamilton Mr. Craighead was director of studies at the Ryerson Institute of Technology in Toronto.

W. A. Hutchinson, P.ENG., formerly managing director of Preston East Dome Mines, is now general manager of Phelps Dodge Corporation of Canada Ltd., 55 Yonge St., Toronto.

James Ball, P.ENG., **K. N. Craig**, P.ENG., and **K. W. Short**, P.ENG., have announced the formation of the consulting firm of Ball, Craig, Short & Co. Ltd., with offices at 5385 Yonge Street, Toronto. The principals of this firm were formerly chief electrical, mechanical and structural engineers, respectively, with R. M. Way & Co. Ltd., Toronto.

C. T. Carson, P.ENG., president of the Association of Professional Engineers of Ontario.

H. F. Hurlbut, P.ENG., has joined Shea's Winnipeg Brewery Ltd., 137 Colony St., Winnipeg, Man., in the capacity of assistant brewmaster. His previous employment was with the Kiewel Brewing Company in St. Boniface, Man.

C. M. Jackson, P.ENG., who was a staff member of the faculty of electronics technology of the Ryerson Institute of Technology, Toronto, has been transferred to the Hamilton Institute of Technology where he is directing the course in electrical and electronics technology.

T. H. Dobbin, P.ENG., who has been engineer-in-charge of the design and special projects branch in the department of planning and works of the City of Ottawa, has been given the position of deputy director of planning and works of the Corporation.

Mr. Dobbin is a graduate in civil engineering of the University of New Brunswick and prior to going to Ottawa was Commissioner of Works, Sarnia, Ont.

D. L. George Turvey, P.ENG., of Armco Drainage & Metal Products of Canada Ltd., has been assigned the management of sales activities for his firm in the Ottawa and St. Lawrence Valley area. In this connection the company has recently opened a sales branch office in Ottawa and Mr. Turvey has moved from Guelph to Ottawa.

Stanley J. Bullis, P.ENG., has been appointed to the inspection staff of the Ontario Fuel Board for Ottawa. His duties will include the registration of installation contractors and dealers of oil and gas-fired appliances in the area, as well as other enforcement of the Board's legislation.

Theodore Golob, P.ENG., has accepted the position of design engineer and head of the engineering design office of Canadian Trailmobile Ltd., 807 Pharmacy Ave., Scarboro, Ont. His previous employment was with Eastern Steel Products, Preston, Ont.

Bryan J. McKenna, P.ENG., is now living in Montreal and is employed by Dr. P. L. Pratley, P.Eng., consulting engineer, 1117 St. Catherine Street West, Montreal.

J. Owen Dibbs, P.ENG., has left Toronto for Australia, where he has accepted a position as manager of the marketing division of W. D. Scott & Co. Pty. Ltd., management and industrial engineering consultants, 37 Mount St., North Sydney, Australia.

James H. Graham, P.ENG., is now residing in Thetford Mines, Que., where he is assistant to the chief mechanical engineer of the Asbestos Corporation Ltd. He was formerly with the Canadian Locomotive Co. Ltd., in Kingston, Ont.

A. T. Sloane, P.ENG., who formerly was project superintendent with The Gas Machinery Co. (Canada) Ltd., Hamilton, has accepted the position of maintenance superintendent with the North Star Oil Refinery at St. Boniface, Man.

G. Donald McPherson, P.ENG., has recently been appointed to the staff of the Associate Faculties of Waterloo College, Waterloo, Ont., as lecturer.

Mr. McPherson is a '55 graduate of the University of Toronto in engineering physics and in 1957 obtained his Master's degree from Ottawa University, being one of the first graduating class of that university's course in nuclear engineering.

Col. D. F. MacRae, P.ENG., director of industrial research services of the Ontario Research Foundation, Toronto, has gone to Europe for three months as a special industrial consultant to European productivity agencies.

Personals

News of the Personal Activities of Members of the Institute

Dr. R. L. Hearn, M.E.I.C., (B.A.Sc., Toronto, 1913), has been named a director of the British Newfoundland Corporation Ltd. Dr. Hearn was chairman of the Hydro-Electric Commission of Ontario until his resignation in 1957.

Air Vice-Marshall Alan Ferrier, M.E.I.C., (B.Sc., civil, McGill, 1920), retired from the post of assistant secretary general for air navigation with the International Civil Aviation Organization on January 1, 1958. Air Vice-Marshall Ferrier spent eight years with the organization.

Dr. Ira P. Macnab, Hon. M.E.I.C., (B.Sc., mech., N.S.T.C., 1913), president of the Institute in 1951, has retired from the appointment of general manager of the Public Service Commission of Halifax which he has held since 1947.

His professional career began with the Nova Scotia Light and Power Company. Within the next few years he worked with the Riverside Iron Works, Calgary, and the Royal Securities Corporation on the inspection of properties in South America. In 1925 he was named general manager of the Venezuela Power Company. Later he was transferred to the Monterey Railway, Light and Power Company. He returned to Halifax in 1931 to join the Nova Scotia Board of Commissioners of Public Utilities.

Dr. Macnab took part in establishing the Halifax Branch of the Institute.

Dr. I. P. Macnab, M.E.I.C.

J. D. Kline, M.E.I.C.

J. D. Kline, M.E.I.C., (B.Sc., St. Mary's College, 1938; B. Eng., civil, N.S.T.C., 1940), newly elected chairman of the Halifax Branch has been appointed general manager of the Public Service Commission of Halifax, N.S., following the retirement of I. P. Macnab.

After the organization of the Public Service Commission in 1944 Mr. Kline was appointed design engineer. Two years later he became chief engineer and in January 1955 was appointed assistant manager, still retaining his duties as chief engineer.

He is vice-president of the Association of Professional Engineers of Nova Scotia.

H. F. Beique, M.E.I.C.

A. R. Harrington, M.E.I.C.

Henri F. Beique, M.E.I.C., (B.Sc., Sorbonne, 1930; B.A.Sc., elec., 1936), has been appointed vice-president and general manager of the Quebec Power Company and has been elected to the board of directors of the organization. In 1954 he was named assistant general manager. Mr. Beique was first associated with the company in 1937 after a transfer from the Shawinigan Water and Power Company. He also became assistant general manager of the Quebec Railway, Light and Power Company in 1954.

A. R. Harrington, M.E.I.C., (B.Eng. elec., Nova Scotia Technical College, 1936), has been appointed manager of the Nova Scotia Light and Power Company, Limited, and its subsidiaries. Mr. Harrington has held the position of assistant manager since 1951 and has been employed by Nova Scotia Light and Power Company Limited since 1936.

James T. Cawley, M.E.I.C., (B.A.Sc., mining, Toronto, 1943), deputy minister of mineral resources, Province of Saskatchewan, has been named petroleum adviser on the United Nations technical assistance mission to Pakistan. The appointment followed a request for his

of sales engineer in the Toronto district sales office. Mr. Warren joined his present company in 1956 following a number of years employment in the field of industrial sales.

H. G. E. Rhodes, M.E.I.C., (B.Sc., elec., Manitoba, 1933), of the George A. Fuller Company, has been transferred from New York to the Pittsburgh branch of the organization.

Before moving to the United States in 1956, Mr. Rhodes had been associated with the firm of Morrison, Hershfield, Millman and Huggins, Toronto; in private consulting work; and with the City of Regina, Sask., engineering department.

E. O. Butts, M.E.I.C., (dipl., civil, Loughborough, Eng., 1949), has established a consulting civil engineering practice specializing in site investigation and soil mechanics in Ottawa. The firm operates in association with the Topo Aerial Surveys Company Limited. Mr. Butts was earlier located at Port Hope, Ont., as town engineer, later moved to Ottawa.

H. J. Gordon, M.E.I.C., (B. Eng., civil, McGill, 1933), has been appointed division engineer at Medicine Hat, Alta., for the Canadian Pacific Railway. He held the post of special engineer at Calgary during the past two years, where he was assigned to changes made to the station. He was assistant engineer of track, 1952-1956, at Montreal.

Mr. Gordon has devoted his entire professional career to the Canadian Pacific Railway.

R. K. Hesse, M.E.I.C., (diploma, mech., Dresden, 1932), previously mechanical engineer for North American Cyanamid Limited, Niagara Falls, Ont., is now associated with Provincial Engineering Limited, as production control supervisor. Prior to these appointments Mr. Hesse worked for Slack Bros., in Waterloo, Que.

Harry I. Hamilton, M.E.I.C., (B.Sc., mech., Queen's 1941), has accepted a position with the Aluminum Company of Canada at Arvida, Que. Mr. Hamilton was previously superintendent of the shops department of the Sao Paulo Light and Power Company Limited, at Sao Paulo, Brazil. He was responsible for the administration and supervision of the general shops, from 1953 to 1957. Mr. Hamilton spent a number of years in South America.

Norwood Bartlett, M.E.I.C., (B.Sc., mech., Univ. of Melbourne, 1940), has accepted the post of project engineer for Dominion Wabana Ore Division, in Newfoundland. He was formerly construction engineer with the Foundation Company of Canada Limited at Montreal.

Maurice H. Nelson, M.E.I.C., (B.A.Sc., civil, Toronto, 1950), has left his work at Saskatoon, Sask., as field engineer with the International Water Supply Ltd., and has taken the position of executive vice-president of the firm of Layne Pacific Inc., at Seattle, Wash.

M. D. H. Dickson, M.E.I.C., (B.A., mech., Cambridge, 1946), has relinquished his post with Defence Construction (1951) Ltd., at Suffield Experimental Station, Ralston, Alberta. He is at present associated with T. H. Newton Engineering Ltd., general construction supervision at Toronto.

H. Fealdman, M.E.I.C., (B.A., Cambridge, 1947; M.A., mech. services, Cambridge, 1951), who has for some time been associated with Sprostons (Jamaica) Limited, Kingston, Jamaica, has joined Cadillac Contracting and Development, Ltd., Toronto.

D. H. Evers, M.E.I.C., (B.Eng., civil, McGill, 1949), of the Dominion Bridge Company Limited, has been appointed Alberta sales manager for the firm. He

has been given charge of sales for Dominion Bridge, Calgary, and for Standard Iron and Engineering Works Limited, Edmonton. He was formerly contract sales engineer for the latter firm at Calgary.

D. A. Ferguson, M.E.I.C., (B.Sc., civil, Alberta, 1945), has been named chairman of the board of Underwood, McLellan and Associates, Ltd., at Saskatoon, Sask. He became associated with the firm immediately after his graduation.

Rene A. LeBlanc, M.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1946), has been appointed city manager of Dorval, Que., for a four-year term. Prior to this appointment Mr. LeBlanc served as city engineer from mid-1955 to September 1957, and as acting city manager from September to December 1957. Prior to this development in his professional career he was associated with the firm of Wallace and Tiernan, Montreal.

A. F. Bauer, M.E.I.C., (dipl., mech., Tech. Hochschule, Vienna, 1948), has left his post with Canadian Bechtel Corporation, Vancouver, and is now associated with the firm of Goliad Ltd., Calgary, Alta., in the capacity of project engineer. He is working on the gas conservation program with the oil and gas company in the Pembina Field, Alta.

J. T. Dokken, M.E.I.C., (B. Sc., civil, Saskatchewan, 1948), of the Inland Cement Company Limited has been transferred from Saskatoon, Sask., to head office at Edmonton. He joined the firm as a district sales engineer for the province of Saskatchewan in 1957.

G. Koster, M.E.I.C., (civil, Delft, 1947), formerly of the Department of Public Works, Victoria, B.C., has left Vancouver Island and has accepted a position with the Superior Concrete Products Ltd., at Burnaby, B.C.

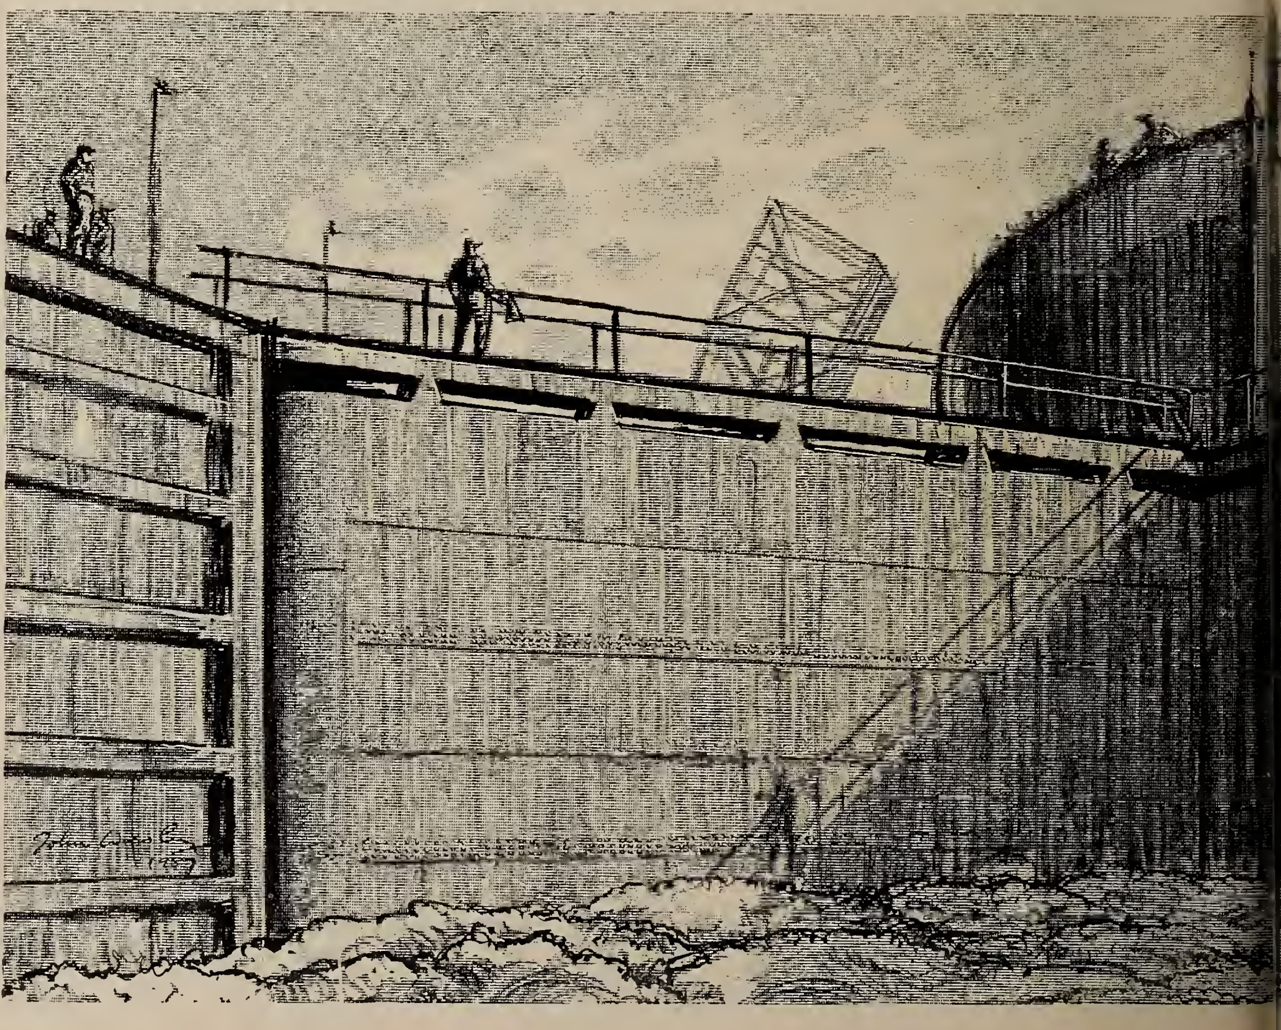
T. H. Dobbin, M.E.I.C., (B.Sc., civil, Univ. of N.B., 1949), of the City of Ottawa, engineering department, has been promoted from engineer in charge of design and special projects branch, department of planning and works, to deputy director, planning and works. He has been devoted to the municipal engineering field since 1950.

A. M. Butt, M.E.I.C., (B. Eng., civil, N.S.T.C., 1946), has assumed responsibility as operations manager of the St. John's, Nfld., plant of Imperial Oil Limited. Previously resident at Halifax, his duties with the company were those of operations analyst, and division engineer, with the St. John's office of the company.

Sean Martyn, M.E.I.C., (B.Eng., civil, University College, Galway, 1947), who was employed with Fraser-Brace Engineering Company Limited in 1956 at Val D'Or, Que., has moved to Newfoundland where he is employed with F. A. Tucker, (Canada) Limited. His work is that of project engineer on the construction of a hydro-electric plant at Nomis Arm, Nfld., for the Newfoundland Light and Power.

E. R. Carpenter, M.E.I.C., B.Sc., mech., Univ. of Sask., 1946), has resigned from his position as building superintendent of Ford Motor Company of Canada in Windsor, Ont., to become director of maintenance for the Winnipeg School District No. 1 in Winnipeg, Man.

Kenneth M. Mote, M.E.I.C., (Higher Nat. Dipl., mech. and production, Central Technical College, 1949), has relinquished the position of plant engineer with the firm of Borg-Wamer Ltd., Letchworth, Herts, England, and has accepted the appointment of chief engi-



• PERSONALS

neer with Aplin and Berrett Ltd., at Yeovil, Somerset, England. In 1952 and 1953 Mr. Mote was in Canada with T.C.F. of Canada Ltd., Cornwall, Ont., as a project engineer.

F. L. Mason, M.E.I.C., (B.Eng., civil, Nova Scotia Technical College, 1950) has left the Department of Highways, Halifax, N.S., and has joined the Eastern Woodworkers Limited, at New Glasgow, N.S. His former post entailed the duties of resident engineer.

P. Langeman, JR.E.I.C.

A. B. Barnes, M.E.I.C., (Higher Nat'l. Cert., elec., Birmingham, 1950), has returned to Canada, to rejoin the De Havilland Aircraft of Canada, Limited, guided missiles division, Toronto, in the capacity of development engineer following a sojourn in the United States. Mr. Barnes was associated with the Boeing Airplane Company of Seattle, as a design engineer for a short time.

Donald B. Dorey, M.E.I.C., (B.Eng., civil, N.S.T.C., 1952), has joined the firm of Leslie R. Fairn and Associates, architects, of Wolfville and Halifax, N.S. Mr. Dorey was employed as a research officer with the division of building research of the National Research Council for five years. During this time he was for three years associated with the building design section, Ottawa. For two years he was officer in charge of the Atlantic regional station at Halifax.

Edward Puchalski, M.E.I.C., (Higher National Cert., mech., S.W. Essex Tech. Coll., 1952), of Calgary is associated with the firm of Angus Butler and Associates Ltd., consulting engineers, in that city. His work involves the design of heating, ventilating and plumbing systems of offices, churches and schools.

Nashmul Huq, M.E.I.C., (dipl, Faraday House, England, 1952), formerly an electrical engineer with the Canadian Pacific Railway Company at Montreal has transferred his services to the Manitoba Power Commission, Brandon, Man., maintenance department.

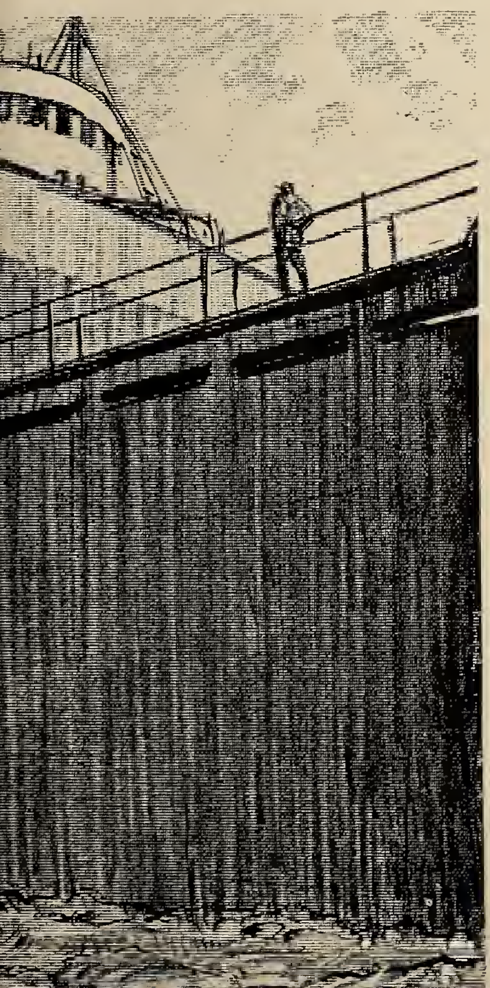
P. Langeman, JR.E.I.C., (B.Sc., civil, Sask., 1955), in Great Britain recently on an Athlone Fellowship, has returned to Canada and is with the Dominion Bridge Company Limited, western division, as a structural designer. Presently he serves as site engineer at Estevan, Sask., on erection of a power station.

Under the fellowship scheme, Mr. Langeman spent one year in London at the Imperial College of Science and Technology doing post graduate work in advanced structures and structural analysis. For the latter work he studied under Dr. A. J. Pippard and Dr. Z. S. Makowski.

During his second year in Britain, he was associated with the Dorman Long Steel organization.

He was awarded the degree D.I.C.

Graham P. Kemp, JR.E.I.C., (B.A.Sc., mech., Univ. of Toronto, 1949), has re-



cently joined the sales engineering staff of the Toronto office of Worthington Canada (1955) Ltd. Mr. Kemp brings to Worthington Canada Ltd. several years experience in design and application of pumping machinery having been previously associated with Dilworth Ewbank, consulting engineers of Toronto, Wm. Kennedy and Sons of Owen Sound and the Smart Turner Company of Hamilton.

M. Nadeau, JR.E.I.C., (B. Eng., civil, McGill, 1949), who was for some time with the Warnock Hersey Company Ltd., in Ville La Salle, has now formed his own company of consulting engineers, M. Nadeau and Associates, in Montreal.

H. N. Halton, JR.E.I.C., (B.A.Sc., mech., U.B.C., 1951; M.Sc., engineering production, Birmingham, 1957), an Athlone Fellowship winner of 1955 has returned to Canada and has accepted a position with the Aluminum Company of Canada as a staff engineer. Mr. Halton took a master's degree in engineering production at the University of Birmingham in 1956. Later he followed a special training course at Vauxhall Motors Limited, at Luton, England.

Mr. Halton, who thoroughly enjoyed his time in England, highly recommends the Athlone Fellowship scheme for engineers.

Lieutenant Commander J. Douglas, R.C.N., JR.E.I.C., (B.A.Sc., elec., U.B.C., 1952), has been transferred from Hamilton, where he was resident naval overseer, to naval headquarters in Ottawa to assume the post of destroyer escort project officer, new construction ships, on the staff of the chief of naval technical services.

F. Cameron Brown, JR.E.I.C., (B.Sc., civil, Queen's, 1950), has recently been appointed development road engineer for the Ontario Department of Highways in Toronto. Prior to this appointment Mr. Brown was assistant municipal engineer, Kingston district.

Ian J. Billington, JR.E.I.C., (B.A.Sc., eng. physics, U.B.C., M.A.Sc., eng. physics, 1951, Ph.D., Univ. of Toronto, 1955), is employed as aerodynamicist for Dilworth Ewbank, consulting engineers. He was formerly associated with the Canadian Westinghouse Company Limited.

A. V. Delcloo, JR.E.I.C., (B.Sc., mech., Univ. of Man., 1950), associated with Dominion Rubber Company Limited since graduation, and formerly assistant sales manager for Montreal, holds the post of sales manager for tires in the Maritime division of the company.

Alan P. Sentance, JR.E.I.C., (B.Sc., Univ. of Toronto, 1948), is employed by Avro Aircraft Limited, in Malton, as senior structures engineer, in the preliminary design office.

C. H. Maartman, JR.E.I.C., (B.A.Sc., civil, Univ. of B.A., 1950). Until recently principal design engineer for the British Columbia Engineering Company Limited, Mr. Maartman has now been named design superintendent of hydro-electric projects.

Keith E. Hunt, JR.E.I.C., (B.Sc., elec., Queen's, 1951), has accepted the position of assistant general superintendent, Grand Trunk Western Railway, C.N.R. at Battle Creek, Michigan.

Mr. Hunt has been with the Canadian National Railways since graduation. In 1956 he was named assistant superintendent of motive power for the company at Montreal and for a time was temporarily on loan to the economics branch of the railroads research and development department for cost control and budget studies.

John K. Cavers, JR.E.I.C., (B.Sc., mech., U.B.C., 1951), district sales manager of Pioneer Electric Limited, in charge of sales of all pioneer products in British

THE CASTING VOTE

CSF Sales Engineers can help your plant benefit from steel castings.

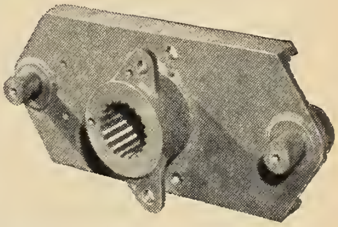
The blue-print stage is a very good time to get a "casting vote" — from your CSF Sales Engineer. He's a first-rate castings specialist, with cost-cutting facts at his fingertips.

Time and again, new products, new components are being made better and more economically by using STEEL CASTINGS. They're the big thing today. Existing designs are frequently improved by using CASTINGS to replace other methods.

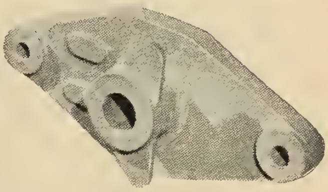
By calling in the CSF Sales Engineer at the start, you'll make the best use of steel castings — and of the design-to-finished-product service that Canada's largest and most modern steel foundries offer you. Profit from his "casting vote" — this service is without cost to you.

HOW CASTINGS CUT YOUR COSTS
An actual case →

BEFORE . . .



AND AFTER . . .



This brake spider for power shovels was originally produced as a weldment. By redesigning it to a steel casting, **cost was reduced 34%, weight 20%.**

Other advantages of castings include: greater strength, better weight distribution, improved appearance.

CSF

CANADIAN STEEL FOUNDRIES (1956) LIMITED

5227 NOTRE DAME ST. E., MONTREAL 4, QUE.

Member: A. V. Roe Canada Limited and The Hawker Siddeley Group

• PERSONALS

Columbia, Mr. Cavers was previously associated with Douglas Power Equipment Limited.

John D. Carmichael, JR.E.I.C., (B.A.Sc., U.B.C., 1951), has been appointed assistant production manager of Frank W. Horner Limited, pharmaceuticals, Montreal. Formerly he was associated with Canadian Safety Fuse Co. Ltd., in Brownsburg, Que., and before that with Canadian Industries Limited as engineering assistant.

W. H. R. Gibney, JR.E.I.C., (B.A.Sc., mining, British Columbia, 1950), has been appointed section engineer at the Sullivan Mine of the Consolidated Mining and Smelting Company at Kimberley, B.C. Mr. Gibney has been associated with Consolidated since graduation.

Barclay G. Jones, JR.E.I.C., (B.Sc., mech., Saskatchewan, 1954), of Canadair Limited, has been working in the reactor feasibility group, Montreal, nuclear division at Montreal, since his return to Canada from an Athlone Fellowship awarded him in 1954. Mr. Jones has been professionally associated, under the Fellowship, with the English Electric Company Limited, at Rugby, England, in general mechanical engineering of power plant equipment. The second year of the Fellowship consisted of experience with the Atomic Energy Research Establishment, at Harwell, England. On completion of the Fellowship a further seven months employment was arranged with the reactor division at Harwell. The first four months took the form of reactor-start-up and operation followed by three months on reactor feasibility study.

Adelbert J. Comeau, JR.E.I.C., (B.Eng., elec., N.S.T.C., 1956), has terminated his employment with the Avro Aircraft Limited, Malton, Ont., and has taken a position with the Garrett Manufacturing Company of Canada, Rexdale, Ont., as assistant to the electronics engineer.

R. (Bob) Gauthier, JR.E.I.C., (B.A.Sc., mining, Laval, 1957) who following graduation joined the Aluminum Company of Canada Limited as development engineer, chemical section, at their Wakefield works, was some months ago transferred to the Company's Arvida plant and appointed maintenance engineer, chemical section.

H. E. T. North, JR.E.I.C., (B.Sc., mech., Queen's, 1955), awarded an Athlone Fellowship in 1955, studied aeronautical sciences at the College of Aeronautics, Cranfield, Bed., Eng. On completing the general course, he specialised in economics and production of aircraft and aircraft propulsion.

Returning to Canada, Mr. North spent six weeks with the RCN (R) flying Bell and Sikorsky helicopters before joining the Canadian Pratt and Whitney Aircraft Co. Ltd., Longueuil, Que., as a junior engineer in November 1957.

David M. Robertson, JR.E.I.C., (B.Eng., civil, N.S.T.C., 1956), has returned from Geneva, Switzerland, where he attended Le Centre d'Etudes Industrielles' to join the staff of the industrial engineering department of the Aluminum Company of Canada Limited in Kitimat, B.C.

B. R. Titcomb, JR.E.I.C., (B.Eng., mech., McGill, 1956), who has been in Europe since last summer with the intention of working there for several years, is presently employed as constructor for the Schweizerische Lokomotiv-und Maschinenfabrik in Winterthur, Switzerland.

James Wright, S.E.I.C., (B.Sc., mech., Univ. of Manitoba, 1957), has been appointed silicones sales representative in the Central Ontario district. His previous engineering experience was with the Imperial Oil Company Ltd.

Allan G. Davenport, S.E.I.C., (M.A., Cambridge, M.A.Sc., Univ. of Toronto, 1957), has joined the building structures section of the division of building research at National Research Council, having previously been on the staff of the department of civil engineering at the University of Toronto and also engaged there in graduate research.

B. H. Hamilton, S.E.I.C., (B. Eng., mech., Sask., 1957), is plant engineer, grade I, with the Saskatchewan Power Corporation.

Darrell Allen, S.E.I.C., (B.A.Sc., civil, Univ. of Toronto, 1957), joined H. G. Acres and Company Limited on his graduation as a civil engineer in the hydraulic department of their head office in Niagara Falls.

G. R. Fanjoy, S.E.I.C., (B.Sc., elec., Queen's 1957), has left the Royal Canadian Horse Artillery and has joined the Canadian General Electric Company Limited at its Peterborough works as an electrical engineer.

Harold O. Lacy, S.E.I.C., (B.A.Sc., agri. British Columbia, 1957), formerly of Vancouver, has moved to Ottawa, where he is employed at Central Experimental Farm.

Jean Landriault, S.E.I.C., (B.Eng., mech., McGill, 1955), is employed with Davie Shipbuilding Limited, as a design engineer at Lauzon, Que.

NEWS OF THE BRANCHES

Activities of the Forty-Nine Branches of the Institute and abstracts of the papers presented at their meetings

BORDER CITIES

A. W. MALMBERG, JR.E.I.C.,
Branch News Editor

A JOINT MEETING of the Border Cities Branch E.I.C., and the Association of Professional Engineers was held on March 27. A reception and dinner were also enjoyed.

Guest speaker C. T. Carson, president of the A.P.E.O., is the first Windsor resident to be elected president of the Association since J. Clarke Keith held office in 1935. During the intervening years membership in the Association has grown from 1150 to its present force of 16,700.

J. A. McLaren, Eastern region field secretary of the Institute attended the meeting.

BROCKVILLE

W. E. MORDEN, M.E.I.C.,
Branch News Editor

A JOINT DINNER MEETING with the Chemical Institute of Canada on February 28 welcomed J. N. Pryce, president of the Montreal-Ottawa chapter of the Society of Fire Protection Engineers. A member of the Dominion Board of Insurance Underwriters, Mr. Pryce is concerned with the co-ordination of fire protection engineering activities across Canada, and the idea of establishing uniform practices. The scope of operations includes the development and publication of numerous fire protection standards for distribution in Canada as sponsored by the Board fire insurance companies.

Study of the causes of large city fires revealed that the actual extent of damage caused, coincided with predictions outlined in reports prepared by field engineers, with a surprising accuracy. Consequently, surveys were carried out to include all large cities and towns. It is now a well-defined engineering method in which nothing remains to guess work, but is reduced to unquestionable mathematical accuracy.

The survey of a city, a tremendous job, may involve a corps of engineers for several years, as indicated by the fact that two years were required to survey the City of Ottawa. There is also a system of deficiencies, or variance from recognized good standards.

All communities are rated from first class down to tenth class, and basic rates are set accordingly. These are determined by the regional insurance companies and those who contribute to the surveys are known as Board companies.

A highlight of the Border Cities branch activities was the tour of the Canadian Rock Salt Company mine at Ojibway, Ont. More than one hundred branch members and guests saw modern mechanized salt mining operations. A piece of crystalline rock salt was given to each visitor as a souvenir. A delicious lunch was served to all visitors by the Canadian Rock Salt Company in a modern employee lounge after the tour.

CALGARY

FRED L. PERRY, M.E.I.C., *Publicity*

THE SIXTH ANNUAL SLIDE RULE SOIREE of the Calgary Branch was held on February 14 in the main ballroom of the Palliser Hotel. Three hundred and twenty-one members and wives, a sell-out crowd, enjoyed cocktails before dinner, followed by a full evening of dancing and the traditional branch talent show.

This year's production took the form of a "Showboat Revue," written and directed by Jessie Neil and featuring Stan Rokosh as master of ceremonies. In large measure, the success of the show was due to the musical arrangements composed by Roy Price which provided the background music for Joan Smith's spotlight rendition of "The Man I Love." In all, forty-seven members and wives participated as singers, dancers, skit boys and stage hands.

For the most part, the same people who staged the "Pipeline Revue" in 1957, which was repeated at the E.I.C. annual meeting at Banff were stars of the show again this year. In particular, Joan Smith was the same feature singer who stopped the show as "Maime", the girl who very nearly "prevented the pipeline from getting to the east on time."

(for Calgary Branch photo see p. 174)

CORNER BROOK

ERIC R. SKANES, JR.E.I.C.,
Branch News Reporter

AIR SYSTEMS APPLICATION to industry were generally outlined under two main headings, by Ralph Willis, assistant general manager of Ross Engineering of Canada at a meeting of the Corner Brook Branch, February 25, 1958.

Introduced by W. Spurrell, New Brunswick representative for Ross Engineering, Mr. Willis discussed the use of air for human comfort, and for process in plants, factories, etc. Heating, ventilating and cooling were described in relation to human comfort, while drying, baking and dust control were factors for consideration in the use of air for process in plants and factories. Mr. Willis spoke at length on the subject of dust control, dealing with the different methods of separation, and where applicable, dust collection and conveyance. The talk was thoroughly enjoyed by the group and an active discussion period followed. A vote

of thanks was extended by Henry Carter. Adjournment was moved by H. Clarke and seconded by G. P. Hobbs. Twenty-six persons attended the meeting.

EASTERN TOWNSHIPS

JEAN BOURASSA, JR.E.I.C., *Secretary*

A JOINT MEETING of the Eastern Townships Branch and the Corporation of Professional Engineers of Quebec, held at Sherbrooke, Que., on February 7, drew an attendance of more than 90 persons to hear C. A. Peachey, president of the Corporation and general manager of the communications equipment division of the Northern Electric Company Limited, discuss the subject of confederation. Mr. Peachey was introduced by Gaston Masse, meeting chairman, and regional representative of the C.P.E.Q. In his talk, entitled "Plan for Unity", Mr. Peachey reviewed the progress made by the Canadian professional engineering organizations toward confederation. He outlined the history of the Engineering Institute of Canada, the provincial associations, and the formation of the Dominion Council of professional engineers associations. Mr. Peachey also gave an account of the achievement of the various committees at work on the issue and expressed confidence that important results would soon be realized. George M. Dick, Institute vice-president for Quebec thanked Mr. Peachey for his talk.

Compliments were extended by Pierre Bournival, general secretary of the Corporation, to the E.I.C., for its co-operation with the provincial organization.

A buffet supper was served at the meeting, courtesy Codere Ltd., of Sherbrooke.

FREDERICTON

JOE WHITELEY, S.E.I.C., *Branch News Editor*

MUNICIPAL ENGINEERING, an outline of its applicability to the City of Fredericton was discussed by City engineer W. L. Barrett, of Fredericton at a branch meeting on February 13. Mr. Barrett explained the way in which the chain of command extends from the city council meetings to the city engineer's department and others. He went into the various responsibilities and duties of the department with respect to roads, streets, water and sewerage systems, public parks, sanitation, and associated works.

HAMILTON

J. R. CURRIE, M.E.I.C., *Branch News Editor*

A PLANT TOUR of the new Parkdale works of the Steel Company of Canada Limited was held by the Hamilton Branch on February 17, 1958. Approximately 70 engineers were welcomed by Parkdale works officials in the plant cafeteria. After refreshments were served a description of the basic planning and engineering aspects of the new mill was given by F. I. Morrissey, plant engineer.

Parkdale works is the newest and most modern of the four wire mills in Canada. The new annealing furnace installation is as large as any in North America. The nail mill division is the second largest nail mill in the country with an output of from 30,000 to 35,000 kegs per month. The plant is located at the eastern end of Hamilton harbour and is well serviced by ship, train, and truck. A description of the general operating features of the new mill was outlined by G. H. Layt, plant superintendent.

A tour of the plant including the electrical power distribution facilities and the boiler room followed. The mill buildings are dominated by the rod storage shed which at the present time also houses the patenting furnace. After this heat treating operation, wire coils are transferred to the pickle house to remove scale in preparation of the wire drawing operations.

The wire drawing machines are perhaps the core of the mill and are of the latest type, utilizing variable speed electric drives and tungsten carbide dies. The continuous galvanizing line occupies almost the entire east side of the new mill.

The feature of the nail mill was the manufacture of the spiral ardox nail, which is a development of the Steel Co. of Canada Ltd. Several large mills in the United States are now licensed to manufacture this special type of nail. Automation is the keynote in the production operations, with the number of actual production workers required at a very low figure.

Shown together during the Sixth Annual Slide Rule Soiree of the Calgary Branch, held at the Palliser Hotel, February 14, are l. to r.: Mrs. Smith, and W. A. Smith, branch counsellor, Mrs. Howard and A. W. Howard, Branch chairman.

MONCTON

V. C. BLACKETT, M.E.I.C., *Sec.-Treas.*

PROBLEMS OF OUTER SPACE were discussed in an address, by an outstanding scientist and astronomer, Father Burke-Gaffney, dean of the science faculty and professor of applied mathematics, Saint Mary's University, Halifax, N.S., at a joint dinner meeting of the Amherst and Moncton Branches, held at Moncton, on February 17. Sixty-five persons attended.

The speaker was introduced by G. E. Franklin, Moncton Branch chairman.

If satellites have issued in a new age, said Fr. Burke-Gaffney, it is a new age in transport. The new age is an age of Airless transport. In air transport, the aero engine is dependent on the air around it for the combustion of its fuel.

There are, already, two types of vehicles for airless transport,—the rocket and the satellite. The rocket differs from the jet aircraft in that it does not rely on the air around it for the combustion of its fuel, it carries its own oxygen with it, hence it can operate where there is no air. The satellite has no fuel. It has to be launched by a rocket,—thereafter it relys on its own inertial energy (due to the initial impulse given to it combined with the downward force of the attraction of the earth.)

The launching of the satellites was not begun to further the progress of transport, but as a project in pure science. Research satellites are an extension of the rocket research program.

Rocket research was organized during the International Geophysical Year in order to study the upper atmosphere, in particular the ionosphere. The chief centre of rocket research in North America is in Churchill, Man. Preliminary results from rocket research indicate that, after great activity on the sun, the lower layer of our ionosphere sometimes falls as low as 34 miles, that northern

lights and southern lights occur simultaneously, that the density of the atmosphere at a height of 140 miles is greater than was anticipated, and that the extent of our atmosphere (considered as particles which rotate in unison with the earth) is greater than we thought.

Incidentally, practical results may result from the findings of pure science. Our new knowledge of the ionosphere, may lead to long range radar, long range TV, long range weather forecasts. A knowledge of the properties of the upper atmosphere is essential if we are to design space-ships to pass through it.

Missiles and research rockets are very different projects. It is sufficient for the research rocket, or satellite-launching satellite to reach a certain height. A missile must be able to re-enter the earth's atmosphere without melting from the heat due to friction with atoms or molecules. The United States Army seemed to have solved the problem of re-entry for their missiles. It is only a question of adaption to solve it for satellites. For missiles there is the added problem of guidance. A rocket with liquid fuel is not easily guided, and solid fuels are not as efficient as liquid fuels. For the present, liquid fuels are being used for the first stage, and solid fuels for the later stages.

Failures in rocket launchings are inevitable, as they cannot be tested but by trial and error. The Germans had failures in their first V-2 launchings. The Russians probably did not proceed to success without preliminary failures. The first Vanguard failure was due to plumbing rather than science. The second, to one of the hazards of ergonomics (the human factor). The U. S. Army success, and the nature of its satellite, suggest that it was the Russian Army also, which was responsible for the sputniks.

Most anxious to get to the moon are astronomers desirous of being able to photograph sun, planets and stars without the interference of an atmosphere.

Fr. Burke-Gaffney was very critical of those who advocate a super-scientific educational program. Illustrating his point by referring to German technical supremacy at the opening of the Second World War, he stated that in any country a thorough general educational system could always cope with aggression on the part of a technically advanced society.

A lengthy question and answer period followed the address.

The thanks of the gathering was extended Fr. Burke-Gaffney by J. W. Wilson, chairman of the Amherst Branch.

NEWFOUNDLAND

R. P. HUNT, JR.E.I.C.,
Branch News Editor

NEWSPRINT MARKET CONDITIONS AND the operations of Bowater's Newfoundland were outlined by mill manager, George Hobbs of Bowater's paper mill, Corner Brook, Nfld., at a February 10 meeting. Members of the Association of Professional Engineers were invited to hear the talk. Mr. Hobbs gave a general outline of the production of paper at Bowater's mill, Corner Brook, from the woods operations through various precesses to the shipping of paper. Causes of the present conditions in the newsprint market, which have caused Bowater's to reduce their labour force was also discussed.

Bowater's operations in various parts of the world were illustrated by means of a short film.

After a lively question and answer period a vote of thanks was extended by Roy Myers.

Dinner meetings are a new enterprise for the Newfoundland Br. this year. Previously only annual meetings took this form. The large turnout of members at the dinner meetings this year indicated the popularity of this form of meeting.

Annual Meeting
1958

Quebec, Chateau Frontenac
May 21, 22, 23

NIAGARA PENINSULA

B. H. CHICK, JR.E.I.C.,
Branch News Editor

ROCKETS AND ALLIED FEATURES were the subject of a talk delivered at a meeting on January 30, 1958, to the Niagara Peninsula Branch of the Institute and the Niagara Group of Professional Engineers, who had been invited to attend. D. A. Bornum introduced guest speaker W. H. Smith, manager of the rocket division of the Bell Aircraft Corporation, Buffalo, N.Y., who discussed the development, operation and fuels used for various types of rockets. Mr. Smith also discussed some of the work being done at the Bell Aircraft Corporation. A film showing the testing of an experimental aircraft was also presented. A question and answer period followed.

SASKATOON

ROGER B. DUPUIS, M.E.I.C.,
Branch News Editor

THE DOUGLAS FIR PLYWOOD, its properties and uses was discussed before the Saskatoon Branch at a meeting held March 5, by A. W. Weston, Vancouver, and R. L. Robinson, Winnipeg, both members of the Plywood Manufacturer's Association of B.C.

The talk, which revealed interesting possibilities for the use of plywood in the structural field, offered instruction on the processes in manufacture of plywoods and the properties of the finished product. Another part of the discussion

● BRANCH NEWS

involved the uses of the product in fabrication of load supporting members.

Election of Officers

Elected for the 1958-59 term of offices were: chairman, J. B. Mantle; program committee, R. C. Strayer, chairman, P. Riemer, F. Catteral, N. E. Greenway, N. Peters; secretary-treasurer, R. E. Ludwig; publicity, R. B. Dupuis.

SAULT STE. MARIE

B. L. WIMPERIS, JR.E.I.C., *Sec.-Treas.*

THE REGULAR MONTHLY MEETING was held on February 14, 1958, and drew an attendance of twenty-eight members and guests.

After the business of the meeting, R. H. Tooley, Branch chairman introduced J. N. McLaren, Eastern field secretary, who addressed the group in order that members might be more familiar with the general aims involved in the work of the field secretary.

The Wellington Street underpass, Sault Ste. Marie, was the subject of a talk given by J. MacKenzie, City engineer of that locality. With traffic on the increase, he pointed out, the Western part of Sault Ste. Marie and outlying districts are accessible by only one major artery. To further complicate this matter the street is blocked off for considerable periods by switching from an adjacent railroad yard. A former road through a major steel plant has also been removed due to expansion of the plant, cutting off the area to a greater extent.

As a result an almost impossible traffic situation has resulted. The problem has been known for several years but little action has been taken until recently. This is mainly due to the fact that a breakdown for financing the project, between the railroad, the City and the department of highways, could not be decided.

Due to local interest in the underpass and publicity accorded it over the past few years Mr. MacKenzie's talk on financing and engineering details for the project, proved very interesting.

SUDBURY

M. D. HEAD, M.E.I.C., *Publicity*

THIRTY MEMBERS and guests attended a dinner meeting at the Granite Club on February 13.

J. F. McCallum introduced his colleague, D. W. Gray, assistant woods manager and logging engineer of the K.V.P. Company, Espanola, who delivered a very interesting talk on the company's woods operations. Mr. Gray described, in some detail, the extent of the company's "limits", or "concession", which covers more than five thousand square miles, and includes the watersheds of the Spanish and Vermilion rivers, and an adjacent area north of the height of land draining into Hudson's Bay. The company is cutting approximately 130,000 cords annually, and purchases a further 85,000 cords, including chips and sawmill waste. Jackpine forms the bulk of the pulpwood crop, but substantial amounts of spruce and poplar are also harvested. Mr. Gray stressed the fact that the forests are not a wasting asset. He summarised the company's policy as "The growing and harvesting at economical cost of the preatest amount of wood fibre per year, in perpetuity". The annual wood cut is actually considerably less than the annual growth and is spread over the whole of the presently accessible area.

In recent years, mechanisation of logging methods and improvement of handling and transportation facilities have greatly increased productivity. The bulk of the labour force can be fully employed from about May 1st to the following March, whereas at one time the season extended only from September to March. The once typical output of one cord per man day has been increased by more than one hundred and fifty percent. Further mechanical improvements currently being developed include facilities for handling full tree lengths without cutting, and integrated slashers and debarkers on the site.

After showing a number of slides, Mr. Gray faced an extended question period which demonstrated the meeting's keen interest in forest engineering.

Students' Night at the University of Toronto was reported in the March Journal. Here, a few of the student participants wait for turn at the quiz prize money.

TORONTO

GORDON F. R. NORTON, JR.E.I.C.,
Branch News Editor

FROM ICARUS TO EARTH SATELLITES was the subject of a paper delivered by Professor B. Etkin, professor of aeronautical engineering and research associate of the Institute of Aerophysics, University of Toronto, at a meeting on March 1, 1958.

The lecture covered the scientific story of flight, beginning with the first visions of human flight, and tracing the application of scientific discoveries to the solution of the problems of flight. It covered the work of the early experiments, carried out before the time of the Wright brothers, and the subsequent

QUALITY...

SHAWINIGAN STAINLESS STEEL

Why does industry demand 'Shawinigan' Stainless Steel when it wants castings of the highest quality?

Because experience has convinced our customers that Shawinigan's *full laboratory control* of every processing stage produces the finest corrosion and heat resisting castings in Canada.

Every casting produced by Shawinigan is closely checked and inspected at every stage of the process. X-ray tests, Gamma radiography, fluoroscopic examination of non-magnetic materials and magnaflux inspection of ferritic and martensitic type stainless steel . . . these are only some of the checks employed by Shawinigan.

Discover how you can be sure of top quality and save money by using 'Shawinigan' Stainless Steel corrosion and heat resisting castings.

developments up to the time of supersonic flight. Jet propulsion, the sound barrier, and supersonic flight were touched upon, as well as problems confronted at the present time in relation to the heat barrier in flight at extreme altitudes and speeds. Professor Etkin concluded his talk with a discussion of earth satellites and astronautics,

The occasion was a joint meeting with the Royal Canadian Institute, at which Gordon G. Cosens, meeting chairman and president of the R.C.I., introduced Dr. Etkin.

R. N. Self, chairman of the Toronto Branch extended a vote of thanks to Dr. Etkin for his talk. Later the E.I.C. members were guests of the R.C.I. in the mechanical building.

VANCOUVER

J. J. KALLER, M.E.I.C., *Publicity*

PRESIDENT C. M. ANSON arrived in Vancouver for a two-day visit to the Vancouver Branch on February 9. He was accompanied by Dr. L. A. Wright, general secretary of the Institute.

After a brief tour of points of interest around the city, the Branch executive entertained Mr. Anson at a cocktail party at the home of Commodore A. C. M. Davy.

Following the tradition that each president visits the University of British Columbia engineering department, Mr. Anson addressed the engineering student body.

Following the tradition of each president visiting the University of British Columbia engineering department, Mr. Anson addressed the engineering students.

The Cambie Memorial

Old and young alike paid tribute to the man responsible for the planning of the entire course of the Canadian Pacific Railway through British Columbia, as the President on February 10, unveiled a plaque in honour of Henry J. Cambie, explorer, surveyor and engineer. The Cambie Street station, one of the main thoroughfares of the city, and previously named for the great man, was scene of the ceremony.

Unveiling the plaque, President Anson said, "Future generations of Canadians shall never forget the magnificent contributions of a great engineer and outstanding Canadian." The plaque was accepted on behalf of the C.P.R. by W. G. Dyer of Winnipeg, regional C.P.R. engineer.

The late Mr. Cambie was identified with the Toronto and Guelph Railway; conducted surveys for the Intercolonial Railway in Quebec, Nova Scotia and New Brunswick from 1865 to 1866, and supervised construction of the Windsor and Annapolis Railway in Nova Scotia in 1868.

A son and two daughters of the honoured man were present for the unveiling.

Professional Development Course—1958

The professional development course has again proved to be a great success. Prominent business men, outstanding in their respective fields of activity generously offered time in order to assist in broadening the knowledge of the participants of the course in the field of economics related to primary industries of British Columbia. The course was arranged for the Vancouver Branch under the able direction of Cliff H. White, chairman of the committee for professional development and Dr. A. D. Scott, of the department of economics of the University of British Columbia. The idea of economic appraisal of the natural resources of British Columbia has proven its value by the fact that enrollment for the course included men from professions other than engineering.

U.B.C. Student Section

BLAKE TWEDDLE, S.E.I.C.,
Student Representative

THE 1958 STUDENTS' NIGHT held February 4, 1958, in the lounge at Brock Hall, U.B.C., featured three student speakers selected by the members of the Student Branch "Toastmasters' Club". The students were the guests of the downtown members. Approximately one hundred members and students attended. After dinner Professor Heslop turned the meet-

ing over to student chairman Ship Saimoto who outlined student activities to date. Mr. Saimoto introduced John Duerksen, student vice-chairman, and chairman of the Toastmaster's club who introduced the speakers. First speaker to take the stand was Gero von Dehn whose subject was satellites. Construction, methods of launching, tracking and recovering satellites was discussed. Phil Hahn, second speaker, dealt with "The History of Aluminum" and supplemented his talk by remarking on his experience while an employee with the Aluminum Company of Canada Limited at Kitimat, B.C. Stan Toole, winding up the talks, gave a description of the Avro Arrow.

Named in order of merit as speakers, judges awarded first place to Stan Toole; second and third to Gero von Dehn and Phil Hahn.

President's Visit

President Anson, accompanied by Dr. L. A. Wright, general secretary of the Institute visited the University on February 10. Addressing engineering students Mr. Anson spoke of the part the Institute may play in an engineer's career.

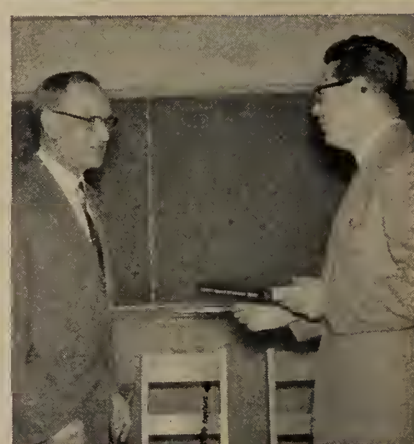
Dr. Wright outlined the services provided by the E.I.C.

Mr. Anson presented the E.I.C. prize to Keith Minielly in recognition of his outstanding contributions to student activities and also for his outstanding scholastic record.

A copy of "Daylight Through the Mountain" was presented to Murray Roblin on behalf of the E.I.C. and Engineering Undergraduate Society by the president. The book will be placed in the library of the engineering building.

The meeting was followed by luncheon at the faculty club, attended by the executive of the student branch and the E.U.S., Dean Gunning, Professor Heslop, Professor de Jong, Professor Richmond, Mr. Anson and Dr. Wright.

Featured at Students' Night at U.B.C., held February 4, 1958, were talks by three student speakers. In top photo with student executive are, l. to r.: Gero von Dehn, Ship Saimoto, student chairman, Phil Hahn, Stan Toole, and John Duerkson, student vice-president and chairman of the Toastmasters' Club. Below, Mr. Anson presents the E.I.C. prize to Keith Minielly, and a copy of "Daylight Through the Mountain," to Murray Roblin on behalf of the E.I.C. and the Engineering Undergraduate Society.



News of Other Societies

Canada-U.S. Chemical Engineering Conference

The Canadian-U.S. Chemical Engineering Conference, sponsored jointly by the American Institute of Chemical Engineers and the Chemical Institute of Canada, Chemical Engineering Division, is expected to be one of the outstanding conventions in North America this year.

The conference will be at the Mount Royal Hotel, Montreal, April 20-23, 1958. The conference secretary is F. K. Rogers, Shawinigan Chemicals Limited, Montreal.

There will be seven European participants in a review of the chemical industry on that continent. They are Dr. Paul Ferraro, Belgium; Dr. R. Holroyd, London; J. J. Desportes, Paris; Dr. Karl Winnacker, Frankfurt, West Germany; Prof. Giulio Natta, Milan, Italy; and two members of the Soviet Academy of Sciences, Moscow.

Scheduled for Sunday, April 20, is a symposium on "Chemical Engineering Education in the U.S. and Canada". Three Canadian and three American university representatives will discuss the subject.

Three technical sessions on April 21 are to be chaired by Dr. H. H. Lank, of DuPont of Canada (1956) Ltd., Montreal, Dr. R. S. Jane, of Shawinigan Chemicals Ltd., Montreal and Dr. J. H. Shipley, chairman of the C.I.C. Montreal section. They will consist of the discussions of "The Chemical Industry in Europe Today" presented by the European speakers mentioned above.

A technical session on "Statistics in Chemical Engineering", April 21, will have speakers representing the U.S. chemical industry and one from Princeton University. Also on April 21, there will be a symposium on "Chemical Engineering Problems in Heavy Water Reactors" with chairman and speakers drawn from the Canadian and American specialists in nuclear reactor research and design. "Chemical Engineering in Mineral Processing", and "High Temperature Materials for Jets and Rockets" are the topics of technical sessions on April 22, with the Canadian and American industries represented. There will be two sessions on "Fluid Mechanics" on April 22, with speakers representing nine universities.

A panel discussion on "Relationships between Investors and Chemical Industry Management" is on the program of April 22; "Noise in the Chemical Industry" will be treated in a symposium. There are Canadian and Americans participating in both sessions.

The sessions of April 23 start with a symposium on "Future Sources of Energy" with five speakers and, simultaneously, a symposium on "Chemical Engineering in the Pulp and Paper Industry". There will be two sessions the same day for General Technical Papers in which a variety of important papers will be presented.

"Modern Engineering Construction Techniques" will be discussed in a symposium by four American speakers; and "Career Opportunities in Chemical Engineering" in Canada and in the United States will be discussed in a afternoon session.

In addition, the program includes a number of plant visits, luncheons with well known speakers, and a French Canadian "Habitant" dinner and square dance.

Canadian Institute of Timber Construction Convention

The fifth annual convention of the Canadian Institute of Timber Construction was held in Ottawa, February 24-28. Participating in a one-day session known as "open day" were architects, engineers, and government officials in a program designed to review advances made by the wood products industry.

Many active committees reported progress. The design manual committee reported that the C.I.T.C. design manual will in 1958 appear for the first time in one volume.

The standards committee finalized work on the qualification code being established to ensure uniformly high standards of quality in wood products plants.

The service records committee reported progress in the collection of service records of pressure-treated timber construction jobs across Canada.

Members of C.I.T.C. and industry staff members have been active in the development of C.S.A. standards. New specifications on engineering design in timber are approaching completion.

Incoming president D. E. Ness, president of timber structures division of Foldaway Furniture Ltd., Peterborough, Ont., pointed out that during the previous year, work calculated to create an entirely new basis for engineered timber construction had been completed and would appear in printed form in 1958.

Luncheon speaker on "open day" was Professor Carson F. Morrison, head of the department of civil engineering, University of Toronto. In a statistical breakdown of the type of work being conducted by engineers, Professor Morrison remarked that only 15 per cent of Canada's engineers were actively engaged in research.

A highlight of the convention was an outstanding group of exhibits from many countries which told the story of the industry.

Chemical Institute Appointment

T. H. Glynn Michael was recently appointed general manager and secretary of The Chemical Institute of Canada. Mr. Michael was formerly director of research, Howards & Sons (Canada) Limited, Cornwall, Ont.

As general manager, Mr. Michael will serve as executive officer of the Institute, under the direction of the board of directors. He will be responsible for the administration of the numerous services provided by the head office of the Institute in Ottawa. Mr. Michael will also serve as managing editor of the C.I.C. publications *Chemistry in Canada* and *The Journal of Chemical Engineering.*

Calendar

F.I.S.I.T.A. Congress at Paris

The Federation Internationale des Societes d'Ingenieurs et Techniciens de l'Automobile will hold its Seventh International Technical Congress from May 19 to 28. The event will include visits to principal factories of the French automobile industry.

About twenty technical papers prepared by eminent writers on subjects of their choice will be presented and discussed. These will represent a most valuable contribution on the part of the eight European societies belonging to the Federation. Also, in granting their co-operation, several world famous lecturers will render the 7th F.I.S.I.T.A. Congress all the more successful. Member societies affiliated with F.I.S.I.T.A. will be represented at the congress from Germany, Great Britain, Austria, Belgium, Spain, France, Italy, Poland, and Switzerland.

For information on the congress and registration forms write: the Secretariat General, F.I.S.I.T.A., 5, Avenue de Friedland, Paris 8.

Fifth World Petroleum Congress, Inc.

The first international oil congress ever to be held in the United States, will open on May 31, 1959. The event is expected to attract some five thousand scientists and technologists from more than thirty-five countries. The congress is being widely supported by the petroleum industry in the United States.

Chairman of the national committee for Canada is C. E. Carson, 111 St. Clair Avenue West, Toronto.

Mechanical Handling Exhibition

The Mechanical Handling Exhibition, first organized in 1948 to impress upon the world of production the importance of materials handling as a vital means of reducing manufacturing costs and increasing output, will be held in London, England, from 7-17 May, 1958. With upwards of half-a-million square feet of floor space, it will be the largest exhibition of its kind anywhere in the world. For the first time in its history, the 1958 exhibition will be international and will be open to leading manufacturers throughout the world.

For further information please contact: Derek Page, press officer, Associated Iliffe Press, Dorset House, Stamford Street, London S.E.1.

Operations Research Society of America

The thirteenth national and sixth annual meeting of the Operations Research Society of America will be held at Boston, Mass., on May 15, 16 at the Sheraton-Plaza Hotel.

Inquiries should be addressed to: Dr. Herbert P. Galliher, Operations Research Project, Room 6-218, Massachusetts Institute of Technology, Cambridge 39, Mass.

The American Society of Mechanical Engineers

The Society will sponsor or co-sponsor twenty-four major events dealing with numerous technical subjects at locations throughout the country during 1958. These meetings are open to interested persons, members or non-members. During May and June four meetings will take place. These are the Oil and Gas Power Conference and Exhibit at Philadelphia, May 11-15; the Materials Handling Conference, at Cleveland, June 9-12; participation in the 3rd U.S. Congress of Theoretical and Applied Mechanics, Providence, R.I., June 11-14; and a semi-annual meeting in Detroit, June 15-19.

The information was released from: L. S. Dennegar, director of public relations, The American Society of Mechanical Engineers, 29 West 39th Street, New York 18, New York.

American Institute of Chemical Engineers

The American Institute of Chemical Engineers will celebrate its fiftieth anniversary with a Golden Jubilee Celebration from June 22-27 at its birthplace of Philadelphia. It will include an interesting technical program, summarizing the accomplishments of chemical engineering in all fields of unit operations and allied areas over the past half-century. Deficiencies in the present state of knowledge will be spotlighted and possible methods to close these gaps will be forecasted.

For further information write: Joseph I. Sacova, Socony Mobil Oil Company, Inc., Paulsboro, New Jersey.

Experimental Stress Analysis Meeting

The Society for Experimental Stress Analysis 1958 Spring Meeting will be held on May 14, 15, and 16, 1958, at the Hotel Manger, Cleveland, Ohio. Further information regarding this event may be obtained by writing: Dr. W. M. Murray, secretary-treasurer, Society for Experimental Stress Analysis, P.O. Box 168, Cambridge 39, Mass.

American Society of Tool Engineers

The American Society of Tool Engineers will hold its 26th Annual Convention and Tool Show in the Philadelphia Convention Center, May 1 to 8. Nearly 500 exhibitors will participate in the show which has as its theme "Tooling on Competition".

For further information contact: Richard Gebers, public relations manager, American Society of Tool Engineers, 10700 Puritan Avenue, Detroit 38, Mich.

Cost Reduction Conference

Sponsoring the Cost Reduction Conference is the Illinois Institute of Technology, Chicago, Illinois, at a meeting to be held May 8 and 9, 1958, in the Metallurgical and Chemical Engineering Building, at 10 W. 33rd Street.

Inquiries concerning the conference should be made to LeRoy A. Wickstrom, Illinois Institute of Technology, Chicago 16, Ill.

French Public Works Congress

The International Exhibition of Public Works and Building Equipment will be held near Paris from May 14-24, 1958. Theme of the congress will be adaptation of equipment plants to present day technique. For information write: Syndicat M.T.P.S., 10, Ave. Hoche, Paris VIIIe.

LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*ADVANCED DYNAMICS

Covers the dynamics of beams, rectilinear motion, angular motion, plane motion, and motion in three dimensions. Concepts used include D'Alembert's principle, Lagrange's equation of motion, the free-body diagram, and the ellipsoid of inertia. Numerous problems are worked out in detail to illustrate the application of principles and methods, and where possible alternate methods of solution are presented. (J. E. Younger. New York, Ronald Press, 1958. 265p., $8.50.)

*ANALYSIS OF MULTISTORY FRAMES

Translated from the fifth German edition by C. J. Hyman, this text emphasizes frames with linearly displaceable joints. An iteration procedure is used that consists of a repetition of the same operation, thereby reducing the probability of a computational error. Aspects discussed include analysis of structures with nontranslatory joints, story frames with joints movable horizontally, separate verification of end movements, influence lines, and structures with bars of variable cross section. (Gaspar Kani. London, Crosby Lockwood, 1957. 113pp., £2.)

*AUTOMATION AND MANAGEMENT

Three major aspects of automation are studied extensively in this report. The first section provides a background on the nature of production line mechanization and the growth of automacity in manufacturing, while the second describes the automation programs of thirteen plants with respect to conception, design procurement, installation, and debugging experiences. The final section discusses the impact of automation on maintenance, the skill requirements of the work force, and management. (J. R. Bright. Boston, Harvard Business School, 1958. 270p., $10.00).

*BASIC ELECTRICAL ENGINEERING

Both alternating and direct current circuits are presented. Basic network considerations are developed and a treatment of node-voltage and mesh-current methods is given. The material on magnetism and magnetic circuits includes the concepts of domain theory, and a final chapter explains the theory and operation of modern electrical instruments and meters. The rationalized MKS system of units is used. (R. H. Nau. New York, Ronald, 1958. 437p., $7.00.)

*LE CALCUL DES TUYAUTERIES A HAUTE TEMPERATURE

The growing use of extensive piping systems in increasing complexity and under conditions of high pressures and temperatures necessitates design methods to establish the most economic lengths and pipe thicknesses for various installations. This work provides first a theoretical treatment of the problem, and following this a section on practical application. Arranged for solution by an electronic computer, the book gives symbolic representations for 40 different combinations of joints, anchorages, and constraints, and one fully worked out design problem. (A. Gage. Paris, Dunod, 1957. 166p., 2,900 fr.)

*DICTIONAIRE FRANCAIS-ANGLAIS DES TERMES RELATIFS A L'ELECTROTECHNIQUE, L'ELECTRONIQUE, ET AUX APPLICATIONS CONNEXES

This new compilation covers all aspects of electrical engineering with particular attention to both theoretical and practical electronics: radio, television, radar, hyperfrequencies (microwave region), photoelectricity, etc. Many words and terms are included from related fields, such as acoustics, optics, plastic materials, machinery, and nuclear physics. The English terms conform to the recommendations of the American Standards Association and the British Standards Institution. (H. Piraux. Paris, Editions Eyrolles, 1956. 168p., 960 fr.)

*DIRECTORY OF GEOLOGICAL MATERIAL IN NORTH AMERICA, 2ND ED.

Although primarily of interest to the petroleum geologist the information contained is broad enough to be of value to other geologists as well. It is divided into two parts, a general section listing sources in the U.S., Canada, Mexico and the West Indies, and a local section indicating sources restricted to states and provinces. Sources for a variety of information are given such as for maps, air photographs, guide books, drillers and electric logs, scouting and drilling information, well cuttings, well elevations, publications, etc. (J. V. Howell and A. I. Levorsen. Washington, American Geological Institute, 1957. 208p., $3.00.)

*ENGINEERED WORK MEASUREMENT

A unified text that encompasses the essential principles, data, and techniques of methods-time measurement, modern time and motion study, and related applications engineering data with a view to developing labor standards and better manufacturing methods. The major portion of the book is devoted to the fundamentals of methods-time measurement. Terms are defined and illustrated, and special mathematics, standards, applications, and the development of training courses are covered in detail. (D. W. Karger and F. H. Bayha. New York, Industrial Press, 1957. 635p., $12.00.)

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m. — 5 p.m.; Saturday, 9 a.m. — 12 noon.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

● LIBRARY NOTES

*HIGHWAY RESEARCH BOARD PROCEEDINGS, 36TH ANNUAL MEETING

A collection of papers, presented at the 1957 meeting, covering virtually every phase of research activities in the field of highway administration and technology. The contents are grouped as follows: economics, finance and administration, including cost studies made in several geographic areas; design, with particular reference to airport pavement; materials and construction; maintenance; traffic and operations, including an extended study of the California Freeway capacity, and soils. (Washington, U.S. National Research Council, 1957. 834p.)

*HISTORY OF HYDRAULICS

The authors have chosen as their historical theme the formulation of the underlying principles of fluid motion. Considerable attention is given to the men who bore the brunt of the development and to their related interests and accomplishments. In general the subject of hydraulics is not treated as an isolated phenomenon but is placed within its proper historical perspective beginning with antiquity and progressing to the twentieth century. (Hunter Rouse and Simon Ince. Iowa City, Iowa Institute of Hydraulic Research, 1957. 269p., $5.00.)

*KEMPE'S ENGINEER'S YEARBOOK

A new edition of a handbook covering virtually all fields of engineering. Although all sections have been rewritten to some extent, the following areas have been extensively revised: welding and cutting; water engineering; corrosion and protective coatings; blasting processes and new abrasive material; aerodynamics and aircraft propulsion; electronic engineering; atomic power; heating; ventilating, and air conditioning. (London, Morgan, 1958. 2 vols., 82/6.)

*MANUFACTURING MANAGEMENT, REV. ED.

In the revised edition of this comprehensive test increased emphasis has been placed on capital expenditures, cost control, operations research, and linear programming. Also included is a realistic appraisal of the advantages and disadvantages of computers. Case studies have been incorporated into the text rather than at the end of the book as in the previous edition. (F. G. Moore. Homewood, Ill., Irwin, 1958. 843p., $8.35.)

*MECHANICAL ENGINEERING LABORATORY PRACTICE

This textbook covering the general field of mechanical engineering is divided into three parts. Part 1, principles of mechanical engineering, deals with laboratory philosophy, techniques of laboratory procedure and the writing of the engineering report. Part 2 is devoted to the discussion of laboratory instruments while part 3 includes laboratory exercises. The appendix contains useful tables giving conversion factors, properties of common substances, properties of steam, etc. (E. E. Ambrosius and R. D. Fellows. New York, Ronald, 1957. 539p., $7.00.)

*MOTION AND TIME STUDY, 4TH ED.

In addition to the basic material contained in previous editions of this work five new chapters have been added dealing with motion study, mechanization, and automation; mechanized time study and electronic data processing; systems of motion-time data; work sampling; evaluating and controlling factors other than labor. New material is included on developments in the industrial use of pulse rate as an index of physical activity, and all known systems of motion data are outlined and described. (R. M. Barnes. New York, Wiley, 1958. 665p., $9.25.)

*PAPERS ON SOILS

Papers dealing with testing and research projects on soils. Topics investigated include: soil explorations for site selection and engineering design; theory of soil resistance; evaluating friction and cohesion of soils; microseismics; vibration techniques used in soil compaction; field tests of piles in sand; properties of soil cement mixtures. (Philadelphia, A.S.T.-M., 1957. 178p., $4.50. s.t.p. 206.)

*QUEUES, INVENTORIES AND MAINTENANCE

The first of three projected volumes, this volume is an introductory monograph to the subject of queuing problems and discusses the effect of change of arrival and service distributions on queuing results. Queuing problems are dealt with from the standpoint of the Kolmogorov equations relating the probabilities, and specific applications such as those relating to repair and maintenance of machinery are analyzed and

solved. The book is No. 1 in the series.

• LIBRARY NOTES

Operations Research Society of America, Publications in Operations Research. (P. M. Morse. New York, Wiley, 1958. 202p., $6.50.)

*SYMPOSIUM ON THERMAL CONDUCTIVITY MEASUREMENTS AND APPLICATIONS OF THERMAL INSULATIONS

Six papers dealing with the development of specifications and methods of test for thermal insulating materials. Aspects included are analyses and experimental procedures by which criteria may be developed, improvements and modifications of the apparatus within the scope of the test method, the effect of moisture on thermal insulation, and the use of thermal insulation for underground piping. (Philadelphia, A.S.T.M., 1957. 86p., $2.75. s.t.p. 217.)

*SYMPOSIUM ON VANE SHEAR TESTING OF SOILS

Papers dealing with a comparatively recent development in the testing of soils. An introductory paper on the apparatus and method of vane shear testing is followed by three specific applications: deep vane tests in the Gulf of Mexico; a vane in-place soil shear measuring device developed and applied in Oregon; the use of a field vane apparatus in sensitive clay. (Philadelphia, A.S.T.M. 70p., $2.50. s.t.p. 193.)

*TECHNIQUES OF MAGNETIC RECORDING

After an historical introduction to the development of magnetic recording, information is provided on technical aspects such as recording media, drive mechanisms, erasing, recording procedures, and spurious printing. Considerable attention is given to the techniques employed in its use, particularly in relation to radio, motion-picture and television, medicine, and education. (J. Tail. Toronto, Brett-Macmillan, 1958. 472p., $7.95.)

*THERMODYNAMICS OF HEAT POWER

Although descriptive material has been included, major emphasis is on the development and application of theory, particularly as applied to steady flow systems. Topics included are ideal gases; compressors; turbines; internal combustion engines; liquids and vapours; heat exchangers; nozzles and fluid flow; reciprocating steam engines; mixtures; fuels and combustion; pumps and fans. The book is a revised edition of the author's "Theory and Practice of Heat Engines". (V. M. Faires. Toronto, Brett-Macmillan, 1958. 432p., $8.00.)

*TRAITE DE MECANIQUE DES SOLS

A comprehensive treatment of soil mechanics, beginning with a general section on the physical properties of soils, especially permeability. The second section deals with specific mechanical properties of soils: stresses and deformations; settlement; vibration phenomena; equilibrium; and shearing action in both cohesive and cohesionless soils. The third section covers engineering applications: methods for improving soil properties; pressures on retaining walls; pressure distribution under foundations and bearing capacities; and special topics such as piling, tunnels, roadway loading, and earth slopes. (A. Caquot and J. Kerisel. Paris, Gauthier-Villars, 1956. 558p., $11.15.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Aeronautical Engineering

Dual-operation powerplants for vertical take-off transport aircraft; a preliminary analysis of several gas-turbine cycles, by E. P. Cockshutt. Ottawa, National Aeronautical Establishment, 1957. (Laboratory report LR-201)

VTOL transport aircraft; a brief discussion of Canadian requirements and project study results for tilting-wing configurations with two propellers and four propellers, by P. J. Pocock and A. J. Bowker. Ottawa, National Aeronautical Establishment, 1957. (Laboratory report LR-204).

Business Forecasting

The business forecast for 1958. Prudential Insurance Company of America.

Canadian economic forecast for 1958. Prudential Insurance Company of America, Canadian Head Office.

Concrete

Loss in prestress of post-tensioned members due to creep and shrinkage of concrete. S. Ban and others. (Technical reports of the Engineering Research Institute, Kyoto University. v. 7, n. 5, Report no. 39)

Safe loads and properties for square tied columns to CP. 114 (1957) part one, by A. d'O. Smith. Richmond, Surrey, 1957.

Electrical Engineering

The attenuation characteristics of the coaxial laminated cable, by S. Hayashi and K. U-O. (Technical reports of the Engineering Research Institute Kyoto University, v. 7, no. 6, report no. 40)

Co-operative electrical research, being the journal of the British Electrical & Allied Industries Research Assn. No. 4, Jan. 1958.

Electrical Research Association; technical reports: C/T116—The testing of wind-driven generators operating in parallel with a network, by D. E. Villers. D/T102—Synthetic resin cements for glass-to-metal seals for use in flameproof enclosures, by H. F. Church. G/T306—The variables that arise in contactor testing, by H. W. Baxter and Z. Cetnarowicz. G/XT160—A simple and inexpensive emission regulator for ionization gauges, by M. P. Reece. L/T341—Reverse driving of short arcs, by A. E. Robson. N/T74—Some magnetic properties of dilute anisotropic ferromagnetic alloys, by W. Sucksmith.

Rules governing the short-circuit testing of air-blast circuit-breakers for alternating current systems. (Assoc. of Short-Circuit Testing Authorities.)

Engineering Education

The case for increasing student aid. Toronto, Industrial Foundation on Education, 1958.

Industrial Management

16 questions about the selection and training of managers, by L. Urwick. Lond., 1958.

Techniques and procedures in labor arbitration: selected references. Industrial Relations Section, Princeton University, No. 79, Jan. 1958.

Metals and Alloys

Nickel in ancient bronzes, by C. F. Cheng and C. M. Schwitter. (reprint from American Journal of Archaeology, v. 61, n. 4, Oct. 1957.)

Quick determination of creep limit, by T. Nishihara and others. (Technical reports of the Engineering Research Institute, Kyoto University, v. 7, n. 4, Report no. 38)

Natural Gas

Facts about natural gas in Alberta. Calgary, Canadian Western Natural Gas Co. Ltd., 1957.

STANDARDS RECEIVED

ASTM standards. American Society for Testing Materials, 1916 Race St., Philadelphia 3, Pa.

ASTM standards on petroleum products and lubricants.

ASTM standards on refractory materials, manual.

1957 supplement to book of ASTM standards including tentatives. Part 1, Ferrous metals; Part 2, Non-ferrous metals; Part 3, Cement, concrete, ceramics, thermal insulation. road materials, waterproofing, soils; Part 4, Paint, naval stores, wood, cellulose, wax polishes, sandwich and building construction, fire tests; Part 5, Fuels, petroleum, aromatic hydrocarbons, engine antifreezes; Part 6, Rubber, plastics, electrical insulation; Part 7, Textiles, soap water, paper adhesives, shipping containers.

Canadian Standards. Canadian Standards Association, 235 Montreal Rd., Ottawa 2, Ont.

CSA C22.1-1958: Canadian electrical code, part 1, essential requirements and minimum standards governing electrical installations for buildings, structures and premises.

CSA testing laboratories list of approved oil-burning equipment, 4th ed.

CORRECTION

In the February issue Specification W55.2-1957: Specification for resistance welding practice was incorrectly listed as an ASTM Standard.

It is, of course, issued by the Canadian Standards Association.

1918

Each issue of *The Engineering Journal* has been of value and interest to its readers because of the high quality of its technical content and the "news" it has contained.

The word "news" is intended to include the advertising pages. During forty years of continuous publication these pages have presented a concise and accurate description of the products and services required by engineers in the furtherance of their work.

When the *Journal* was founded in May 1918, World War I was in its final stages. During that war Canada started to emerge from the chrysalis stage in power development, manufacturing and general industrial expansion.

First Professional Periodical

Before the founding of *The Engineering Journal* there was no Canadian periodical directed primarily at our professional engineers. As a result they read foreign periodicals. The introduction of the Journal changed all this. At last, here was an all-Canadian publication designed, edited, and produced for, and by, Canadian engineers. Progressive organizations with goods and services to offer Canada's engineers were quick to realize the important market they could reach through *The Engineering Journal* and from number one of volume one each issue has carried informative advertising.

It is interesting to note that a number of the companies which advertised in the first volume are still represented on the advertising pages of the *Journal*. It is also encouraging to note that these firms, like the Institute, have shown steady progress and that their names, products, and services are now "household words" among Canada's engineers.

The advertisements in the first issues, as today, were accurate and concise in their messages and generous in their offers of service to the engineer in his work.

Varied Products

The products offered were varied and the advertising content of the first few issues can be used as a good indication of what, in 1918, the engineer required or bought.

The Pratt & Whitney Co. of Canada Limited offered small tools with emphasis on adjustable blade reamers.

Here is a description of some of the advertisements which appeared in the 1918 issues of the *Journal*. They represent a good cross-section of Canadian industry and what engineers required and bought forty years ago.

It is of interest to note that many of the firms represented in volume one are still regular *Journal* advertisers. These early technical advertisements, as today, constituted a rich source of valuable information for the buyer of engineering services and equipment.

The John Bertram & Sons Co. Ltd. complimented the Institute on the inception of the *Journal* which "increased Institute activities and broadened scope". The advertisement continued by reminding the readers that "for sixty years the Bertram organization has been supplying in Canada machine tools built for safety and service".

Canadian General Electric Co. Ltd. offered electric furnaces, arc welders, motors, generators, transformers, switchboards and "general supplies". The copy, in many ways, is a masterpiece of concise statement. For example: "Among the advantages of electric heat are greater thermal efficiency, since electricity is changed into heat without loss." The copy concludes with the statement "Any problem involving the use of power can be simplified by the application of electricity. The Canadian General Electric Company is well equipped to lend valuable assistance in working out such problems and is glad to cooperate with manufacturers, engineers and contractors in every possible way". Under the company name is a listing of thirteen C.G.E. offices, centred in what are, today, among the hubs of our industrial developments. Then, as now, the letters "C.G.E." stood for quality and service in electrical work — small wonder that through the years this organization has played a leading part in the progress of Canada.

A Long Connection

Dominion Bridge Company Limited featured a large coal handling conveyor in their first advertisements. Even as far back as May 1918 this fine Canadian Company had four principal "works" and seven sales offices. The range of products and services offered included "railway and highway bridges, buildings, turn-

. . . a 40-year-old partnership in progress

The first Jenkins Valves advertisement in The Engineering Journal appeared in October, 1918. During the intervening 40 years, the pages of the Journal have reflected the rapid expansion of Canada as one of the world's leading industrial nations. This industrial progress has been paralleled by the continued growth of Jenkins Bros. Limited and its service to increasing numbers of clients across Canada — many of whom are professional engineers.

ON THE OCCASION OF ITS 40TH "BIRTHDAY", we of Jenkins Bros. Limited salute The Engineering Journal for its major contribution to the engineering profession. Its pages have played a part in making the "Diamond" trade mark a familiar symbol of quality and efficiency in valves.

tables, electric and hand-power travelling cranes, coal and ore handling machinery; lift locks and hydraulic regulating gates; transmission poles, towers — forgings, gear cutting and general machine work."

The Canadian engineer knows and respects "Dominion Bridge" for its "know-how" and co-operative service. How many contacts between engineer-customers and this fine engineering organization have been brought about — and strengthened — by the advertising in *The Engineering Journal?* Evidently the Company has good reason to think that the answer is "plenty" because this publication heads the list of the technical periodicals in which "D.B." advertising is placed.

A British organization **Electro-Metals Limited** offered Electric Steel furnaces, and on the facing page of issue number one is the advertisement of another organization which is still using the *Journal* on a regular basis — **Neptune Meter Company** — Neptune sales and service have kept apace with the development of Canada. For example, the community in which the writer of this article resides was a village of under 1,000 people in 1918; in 1945 it was under 5,000 and today it is a "city" of over 15,000 and *every home* is equipped with a Neptune water meter. The city engineer and his consultants are members of the Institute. No doubt, the continuous advertising of this company in *The Engineering Journal* assisted them in their decision to recommend and buy "Neptune".

Unbroken Record

On the page facing the listing of editorial content **Canadian Ingersoll-Rand Company** greets the first issue of The Journal and congratulates the Institute on its expansion. The "ad" continues "Members! When you hear the name Canadian Ingersoll-Rand Company you *immediately* think of compressed air machinery — compressors, drill hoists, 'Little David' riveters, and grinders. Why? — because 'quality' has always been our watchword; you may be sure it always will be". Again, Canada-wide branches are listed, all in what are today, as then, strategic and logical distribution centres.

A special word must be written here about Canadian Ingersoll-Rand and *The Engineering Journal.* This all-Canadian Company has advertised in *every issue.* The early advertisements occupied the page facing "Contents", but ever since cover spaces have been sold "C.I.R." has been on the outside back cover. None will dispute the important part "Ingersoll-Rand" has played in providing equipment and employment for countless thousands of Canadians. The Company has grown, and is growing, with Canada. A few years ago the sales development manager of the Company said: "It has always been our policy to use the periodicals of professional associations as keystones in our advertising programs" — the *Journal* is proud of this long association and the confidence this advertiser has in its "effectiveness".

A Fine Letter

In the first issue The Canadian Fairbanks Morse Company Limited, then, as now, with headquarters on St. Antoine Street, Montreal, has a full page advertisement facing the "first page of editorial matter". The advertisement is in the form of the reproduction of a congratulatory letter which so concisely explains the function of the *Journal* that it is quoted below:

> "The Institute is to be congratulated upon the growth which has made the *Journal* possible and the actual development of the publication.
>
> The quality of the whole fabric of closely interwoven interests which it serves will be improved by the *Journal.* It is an organ needed by both the Dominion and the Institute. It will bind the branches together and facilitate the gain and interchange of professional knowledge.
>
> The development of Canada's vast material resources, from the conception to consumption—the production, transportation and marketing must be brought about by engineers in all fields. A medium which stimulates their work aids in the increase of Canadian production.
>
> As merchants of the tools for this material development we fully appreciate the importance to the *Journal's* mission and we wish it all success".

This firm, too, has grown with Canada and it is interesting to note that even forty years ago two factories (one in Toronto and one in Sherbrooke) and twelve branches, from Saint John, N.B. to Victoria, B.C. were in operation.

The **"Barrett" Company Limited,** with six branches, offered samples of "All made in Canada" building materials. The Company's range has expanded but the trade names shown in the advertisement are as well, or better, known today than they were forty years ago.

Oil and Power

Imperial Oil Limited ran its first advertisement in the December 1918 issue. The copy theme is most interesting because it is based on postwar activities. Emphasis is on road building and the advertisement states:

"Imperial Oil is ready to meet every call. Our facilities for production were never better. Our big, modern refinery at Montreal East, which we have recently enlarged, is engaged in refining all kinds of Imperial asphalts in huge quantities". Reference is made to "our own fleet of tankers".

Imperial Oil has grown with Canada. Always a progressive organization, we wonder if, even in their most elaborate plans for the future, they visualized what terrific expansion Canada would experience during the middle of this century and the important part Imperial would play in these developments.

The Shawinigan Water & Power Company—Quebec's "free enterprise" power developing and distributing organization — commenced its long association with the *Journal* in the October 1918 issue. The advertisement features the area served by the company and the copy reads: "Manufacturers find their power costs much reduced when Shawinigan Power supplants steam power".

A remarkable story could be told about the work the Shawinigan group has accomplished in the development of industry in Quebec. This group of companies can be regarded as an outstanding example of what can be done under the guidance of good engineer-management. The Shawinigan organization and The Engineering Institute of Canada have always worked closely together. Currently every member of Shawinigan's professional engineering staff is a member of the Institute. From the ranks of Shawinigan have come E.I.C. officers for many years. These men know the field served by the *Journal* and have always insisted that advertising be placed in it to keep the name "Shawinigan", its products and services, before potential customers.

Elevators, Tanks and Castings

The Turnbull Elevator Manufacturing Co. commenced advertising in the December 1918 issue of the *Journal*. The first advertisement mentions passenger and freight elevators.

Another elevator advertiser was the **A.B. See Electric Elevator Company of Canada Limited** with offices in Montreal and Toronto.

In the same issue **The Toronto Iron Works Limited** have a half page advertisement which shows a huge metal tank being drawn on a sleigh by a team of horses. The copy features tanks, penstocks, bins and hoppers, blast furnaces, stand-pipes, stacks, and water towers.

This Company, too, has had long and continuing association with the members of the Institute through the advertising pages of the *Journal*. Today, as forty years ago, Toronto Iron Works Limited will be found in the advertising sections of selected issues.

Canadian Steel Foundries is another consistent advertiser to Canada's professional engineers in the December 1918 *Journal*. The advertisement offers "Acid and basic open hearth steel castings—ferro-alloy steel castings — manganese-steel trackwork". Here is another example of a Canadian company which will go down in history as one of the major contributors to the engineering work required to build a great nation.

Maritime Firms

In the October and November issues **Union Foundry and Machine Works Limited** of Saint John, New Brunswick offer their services in connection with "Mill, marine and pulp machinery of every description, iron and brass castings, ship work of all kinds". **Engineers and Contractors Limited** of the same city describe, in part, a job they recently completed — the Moncton bridge foundations at the Petitcodiac River. The copy reads in part "Tide 30 feet. Current 10 miles per hour. Pneumatic caissons sunk to rock 50 feet below low water, through silt, quick sand, boulders and clay. Complete information on this work in the Engineering Institute of Canada, *Proceedings* Feb. 22, 1917."

• **Advertisers 1918**

The president of the company was E. R. Reid, and E. M. Archibald the chief engineer.

The Maritime Bridge Company Limited of New Glasgow, Nova Scotia, advertised throughout the last months of 1918 to bring their products and services to the attention of E.I.C. members.

They offered "steel railway and highway bridges, buildings, girders, trusses, towers, turntables, tanks, smoke stacks, riveted pipe, and structural steel and plate work of all descriptions". It is of special interest to note that they claimed "the only complete stock of steel shapes, plates and bars in the Maritime Provinces."

Bedford Construction Company Limited, with offices in Halifax and East Saint John, N.B., emphasized their services as railroad contractors and listed as work on hand construction of dry dock and shipyards at Halifax, N.S., and of dry dock and shipyards and a breakwater at Courtney Bay, East Saint John.

Grant & Horne, of Saint John, N.B., engineers, contractors, and shipbuilders, used the last two issues of the 1918 volume to advertise the fact that they had constructed two buildings, one in 1916 and one in 1918 for T. McAvity and Sons Limited and an Imperial Munition Board ship the *War Fundy* in 1918.

It is interesting to note that in all these early advertisements the abbreviation "St." is used when mentioning Saint John, New Brunswick.

Restoration of Halifax

The Nova Scotia Construction Company, of Halifax, N.S., advertisement is headed "Hydrostone" and the copy ties in with the restoration of Halifax after the explosion. The copy reads, in part, "The Halifax Relief Commission have adopted this stone for the re-building of the restricted residential portion of devastated Halifax, making it a fire-proof district.

"This stone was adopted by the Commission on the advice of the architect after an extensive study of new town sites in the United States".

William Stairs, Son & Morrow Limited, established in 1810, and still very much to the fore as suppliers of tools, materials, paints, "hardware", etc.: advertised in the October issue. Their copy, too, makes reference to the reconstruction of Halifax, following the explosion. An extract from the advertisement is an indication of what was going on in the Nova Scotia capital at that time. "Halifax in the grip of reconstruction is a powerful magnet drawing to its doors Canada's Master Builders. It may be your turn next to come to Halifax. If it is, we stand ready to render you a service unsurpassed in Eastern Canada so far as supplying the prime and basic requisites for construction and reconstruction."

The Nova Scotia Government was, in 1918 as today, "advertising-minded" and in issues throughout the first volume they advertise the water and other natural resources of the province and the maritime transportation facilities adjacent to areas suitable for industrial development. **T. McAvity & Sons Ltd.** of Saint John, N. B. offer fire hydrants, gate valves, "World" brass valves "tested for STEAM working pressures to 250 lbs." It is of interest to note that this highly respected Eastern Canadian company as far back as 1918 had a

coast-to-coast organization and offices in London, England, and Durban, South Africa. Many Canadian plants and mills, buildings, mines, vessels, homes, are today equipped with "T. McAvity" products. This company's long contribution to the development of Canada as a whole and to the welfare of the citizens of Saint John in particular must be in the nature of a record. This firm is still advertising, regularly, in the *Journal.*

Many of us are inclined to regard "reinforced concrete pipe" as something comparatively new. Yet, it is advertised, on page eighty of issue number one, by **Canada Lock Joint Pipe Limited** of Winnipeg, Manitoba. The advertisement describes a "66 in. pressure pipe for greater Winnipeg Water District with heads 45 ft. to 90 ft."

In current issues of the *Journal* "Renold Chains" are advertised by **Renold Chains (Canada) Limited.** In the May 1918 issue these products and "Morse" chains are offered by Jones & Glassco (Inc.), the predecessors of the present advertiser. The advertisement features "space-saving", "efficiency", "chain drives from ¼ h.p. to 5,000 h.p. in successful operation".

Construction and E.I.C.

The construction side of engineering is featured in the advertisements of **E. G. M. Cape & Co. Ltd.** who, in 1918 and until very recently, had head offices in the New Birks Building, Montreal. They now have their own building on Western Avenue, Montreal. In the May 1918 issue they feature the Ross Memorial Wing of The Royal Victoria Hospital, Montreal. The copy states: "The above building was erected by us. Other contracts recently completed include: The Lewis Building, Montreal; factory building for Northern Electric Co.; shipbuilding plant and launchways for Canadian Vickers; Liverpool and London and Globe Insurance Co.'s new building; Atlantic Sugar Refinery, Saint John, N.B.; reinforced concrete pattern store for J. Bertram & Sons Ltd., Dundas, Ont."

E. G. M. Cape & Company has enjoyed a long and successful career, and their personnel have remained very close to the Institute. Today, the founder of the Company, Colonel E. G. M. Cape, M.E.I.C., is chairman of the board, his son, Lt.-Col. John Cape, M.E.I.C., is vice-president, and Col. John Bertram Stirling, M.E.I.C., is president—and a very active past-president of the Institute. The words "Cape" and "construction" in Canada are synonymous and at regular intervals the advertising sections of the *Journal* are used to re-emphasize this fact.

Fine Papers

An all-Canadian paper manufacturing company used the 1918 issues to promote the sale of fine papers. The firm, **The Rolland Paper Co. Ltd.,** of Montreal. This old-established organization pioneered in the making of fine paper in Canada and in 1918, as today, discriminating paper users, looked for "The R Shield Watermark".

On the inside back cover of issue number one **Dominion Copper Products Company Limited,** with works at Lachine, Que., offered "seamless tubes, sheets and strips in all commercial sizes".

The "Dominion" Group

All the outside back covers in 1918 carried the advertising of **Dominion Iron and Steel Company Limited** of Sydney, N.S., and Montreal. The direct successors and affiliates of this Company are still advertising, regularly, in the *Journal* under the name of the **Dominion Steel and Coal Corporation Limited.**

Also in the 1918 issues are full-page advertisements of the **Nova Scotia Steel & Coal Company Limited** which offered products comparable with those of the Dominion Iron and Steel Company. In 1938 the Nova Scotia Steel and Coal Limited became a subsidiary of the Dominion Steel and Coal Corporation Limited.

Where would Canadian industry and transportation be today if these Maritime organizations had not produced and supplied iron, steel, coal, rails, plates, bars, wire, and the countless allied basic and manufactured products necessary for their completion and maintenance? There has always been a strong link between the maritime "Dominion" group and the Institute. The engineers of the companies in the organization have been active participants in E.I.C. affairs, one of the outstanding of these being our present president, C. M. Anson, M.E.I.C.

The Cook Construction Company Limited & Wheaton Brothers builders of the Halifax Ocean Terminals Railway advertised, in the October, November and December issues. This terminal work and the illustration showed the Tower Road bridge, Halifax, which has a 144 foot span over a cut 65 feet deep.

Cement Distribution

Canada Cement Company Limited commenced advertising in the *Journal* in the fall of 1918 and has been regularly represented in the advertising sections in all subsequent volumes. The 1918 advertisements state "Canada Cement can now be secured from over 2,000 dealers in nearly every city, town and village in Canada". The copy theme of the advertisement is concrete for highways with emphasis on the necessity for building roads capable of handling heavy, high-speed, commercial trucks.

Another current and consistent advertiser, whose *Journal* advertising commenced in the October 1918 issue, is **Jenkins Brothers Limited.** The advertisements featured "Valves, packings and mechanical rubber goods".

• Advertisers 1918

Through forty years this outstanding Canadian organization has been using space, on a regular basis, in the *Journal.* The Company has always had a reputation for quality service and there are very few mechanical engineering jobs, particularly where valves are concerned, when the name "Jenkins" does not occur to the consultant, the designer or the purchaser.

Western Advertisement

From the middle West came the advertising, during the middle months of the year, of the **Manitoba Bridge & Iron Works Limited** who offered structural steel, gray iron castings, plate work, bolts, rivets, and forgings. They referred to their reinforcing hydraulic upsetting and galvanizing plants. **McGreggor and McIntyre Limited** of Toronto advertised as structural steel and bridge builders and in addition to bridge work referred to roof trusses, tanks, hoppers, stair-work, fire escapes, and so on.

Wettlauffer Brothers Limited, of Spadina Avenue, Toronto, advertised in four mid-year issues offering contractors building machinery. There are two illustrations in the advertisements, one of a concrete mixer "of our famous heart-shape design" and the other of hoists "mounted with steam, gas or electric power".

First Printer

The printer of the *Journal* in 1918 was the **Modern Printing Company** of Dowd Street, Montreal. They were regular users of advertising space in the 1918 issue.

Water Cooling

From the United States came the advertising of **Spray Engineering Company** of whom the Canadian representatives were the "Rudel-Belnap Machinery Company Limited" of Montreal and Toronto. The advertisement claims "the Spraco System for cooling condensing water costs much less to install and operate than cooling towers". The copy then briefly describes the method of operation and refers to important users.

Wood Pipe

The Canadian Pipe Company Limited of Vancouver offers wire wound wood pipe "one inch to twenty-four inch" and continuous stave pipe "any size". Manufacture was in what was claimed as "the best equipped factory of its kind in Canada". Many of our developments owe much to the use of "woodpipe", and these pipe manufacturing industries have since taken advantage of improved production methods, new "glues" and other commodities. The story of the use of wood in engineering pre-dates history; it is still unsurpassed for many purposes, and Canada is still pioneering in its use.

Another firm offering wood stave pipe ("Michigan" Brand) was **T. A. Morrison and Company** of St. James Street, Montreal. Lumber, "by rail in carload lots from Nova Scotia and New Brunswick" was offered by **Dunfield and Company Limited** of Halifax and Saint John, N.B.

National Iron Corporation Limited with premises in Toronto, Port Arthur and Montreal offered cast ironpipe "every size for water, gas, culvert, or sewer".

In 1918, as in 1958, consultants and advisors offered their services to their fellow engineers by means of "professional cards" in the *Journal.*

• Advertisers 1918

The "Cards" in the 1918 issues are worthy of very special mention, not only because of the variety of service offered but because the illustrious Canadian engineers whose names are mentioned are truly among the most important of the builders of Canada.

Professional Cards

J. M. Robertson, offers services in the mechanical and electrical field. **Arthur Surveyer & Co.** (Arthur Surveyer and R. DeL. French) offers services in the civil field; **DeGaspe Beaubien** in the hydro-electric field; **Chipman & Power,** civil; **Dominion Engineering and Inspection Co.** list testing and inspection services covering a wide field and **Ewing, Lovelace & Tremblay** present themselves as civil engineers and land surveyors and offer reports, plans, estimates, etc. for industrial and municipal undertakings. **Walter J. Francis & Co.** were consultants for civil and mechanical projects and **R.S. & W.S. Lea** were in the water supply and drainage and sewage treatment field. **John S. Metcalf & Co.** advertise as designing and constructing engineers with emphasis on grain elevators, wharves and power plants. **Rudolph Hering,** of Broadway, New York—a member of the Institute—offered his services with respect to water supply, sewage and refuse disposal; **James, Loudon and Hertzberg Limited** of Toronto Street, Toronto, also advertised specialization in those lines as well as "incinerators, pavements, bridges and structural work including reinforced concrete and architectural engineering".

Featherstonhaugh & Co., patent attorneys, had professional cards in six issues of volume 1. Their addresses, in 1918, were Royal Bank Building, Toronto, and 5 Elgin Street, Ottawa. Their advertisements state: "The old established firm. Patents and Trade Marks everywhere".

Another firm which has made extensive use of the *Journal* throughout the years is **Milton Hersey & Co. Ltd.,** now located at 128 Elmslie Street, Montreal, and operating under the name The Warnock Hersey Co. Ltd. This organization has grown with Canada and now, as in 1918, is operating one of the best testing laboratories in the country. In their first advertisements they state: "The largest and best equipped commercial laboratories in Canada". "Established 27 years".

Marion & Marion used the first issues to advertise the fact that they could secure "patents promptly in all countries". Their address was 364 University Street, Montreal. This fine organization is still operating under the name **Marion, Marion, Robic & Bastien** and their principal address is 1512 Drummond Street, Montreal. Their advertising has appeared in the *Journal* almost without interruption since their first advertisement was published in the December 1918 issue.

It is gratifying to learn through these advertisements that forty years ago, as today, Canada's leading engineering consultants were members of the Institute, and supporters and readers of its publication. Many of these early advertisers are still actively practising their profession and playing an unsurpassed part in the development of a great nation. Long may they be spared—long will they be respected and remembered!

DESIGNERS • FABRICATORS • ERECTORS

* **Advertisers 1918**

pages of the *Journal* from 1918 to 1958 has failed to disclose a single advertisement which is not highly informative and in the best of taste. This scrutiny also showed that "advertised goods sell", because it is evident that the most successful firms in Canada are those which, year after year, have advertised through the media most directly connected with their sales prospects. To reach Canada's engineers, the best medium was and still is, obviously, *The Engineering Journal.* Apart from the benefits derived by the readers through informative advertisements there is another feature which cannot be overlooked—the revenue derived by the Institute through the sale of advertising space, which makes publication possible.

Production Costs

The cost of producing the *Journal* is greater than the revenue derived from a combination of membership fees and *Journal* subscription. However, like all other reputable professional "news-technical" periodicals, advertising is not accepted solely as a means of raising money, but rather to obtain the funds necessary to produce a Journal of the finest quality.

Production costs are comparable with those of any other "quality" periodical produced in Canada but in *The Engineering Journal* the percentage of non-revenue producing pages is much higher than the average. The advertising revenue enables us to produce a better publication—in the sense that we present two types of informative messages, advertising and editorial, both of which are important educational forces.

Low Rates

The advertisers are given good value for their money because even with today's high printing and paper costs the basic advertising rate—per page per thousand of circulation—is not much higher than it was twenty years ago. The maintenance of a high volume of advertising means that The Institute can continue to produce a publication of ever-increasing value and interest to the readers.

Every advertisement is carefully prepared and produced to give the maximum amount of information in the fewest possible words. Take advantage of this service and read the advertisements as they are intended to be read—as a source of authentic information.

Reader Service Cards

A few years ago the Institute decided to publish in each issue of the *Journal* "Reader Service Cards". They are in this issue. Make regular use of them and see what a wealth of information they will bring to you. The processing of these cards is one way in which the Institute can demonstrate the effectiveness and show its appreciation of the advertising in the *Journal* —the more they are used the greater the *Journal* will become!

Photographic Exhibition

1958 Annual Meeting

The collection of photographs shown at the 1957 Annual Meeting of the Engineering Institute was subsequently exhibited, from coast to coast. In addition to the showings at Canadian universities, the photographs were shown at Eaton's Montreal store in October. Despite the competition for the attention of the public, the exhibitions across Canada were very successful and another exhibition is planned for this year's Annual Meeting at Quebec, May 21, 22, 23.

Already, Journal advertisers have been invited, by letter, to participate. However, there are quite a few individual members of the Institute who are camera enthusiasts and they too may enter their photographs depicting engineering achievements of 1957.

***The rules are simple.* Each exhibitor may enter one or two photographs of engineering interest, preferably recording work done in 1957. The prints should be 8" x 10" or larger and mounted on standard 16" x 20" mounts. Larger mounts cannot be considered as they will not fit the travelling cases.**

Each photograph should have the following information suitably printed on the face of the mount; the title of the picture and the name of the member submitting it. Additional information and photographic data may be shown on the back.

***Awards of merit,* suitable for framing will be presented to the exhibitors of the five best photographs. The exhibition committee reserves the right to withhold from exhibition any photographs not considered suitable. All photographs submitted become the property of the Engineering Institute to be exhibited and published subsequently at the discretion of the Institute.**

***The closing date* for receiving photographs from individual members has been set at May 10th. Please mail photographs to:**

Business and Industrial Briefs

A DIGEST OF INFORMATION RECEIVED BY THE EDITOR

Appointments and Transfers

Gresham Transformers — Announced recently were the following three appointments to Gresham Transformers (Canada) Ltd., the Canadian subsidiary of Gresham Transformers Limited, England: C. C. Kent, president; H. R. Smith, vice-president; and N. E. Hale, director. Mr. Hale will also be retained as technical consultant.

Canadian Westinghouse — The Hon. Leon Methot has been elected to the board of directors of the Canadian Westinghouse Company Limited.

Marine Industries Limited — Recently announced was the appointment of A. Simard as vice-president of Marine Industries Limited. Mr. Simard joined Marine Industries in 1940 and was named director of personnel in 1942, which position he maintained until his appointment as vice-president.

United Steel Corporation — H. LeBel, formerly chief engineer, has been appointed assistant manager of the Canadian Mead-Morrison division of the United Steel Corporation Limited, following the retirement of R. T. Northcote, plant manager.

A. Simard

Bird-Archer Appointments — The Bird-Archer Company Limited, water treatment engineers, recently announced the following new executive appointments: H. C. Harragin, president since 1943, becomes chairman; E. L. Ruggles, M.E.I.C. vice-president and general manager since 1951, has been made president; J. E. Koyl, manager of railway and general chemical divisions since 1951, becomes vice-president.

Catalytic Construction Appointments — R. G. Peers and J. R. Nicholson have been named directors of Catalytic Construction of Canada Ltd.

Cominco — Recent appointments by The Consolidated Mining and Smelting Company of Canada Limited at Trail, B.C., are T. T. Dobie, JR.E.I.C., maintenance superintendent, phosphate plant, chemicals and fertilizers division, and C. H. Albright, materials handling engineer, yards and services, engineering division.

Canadian Aero Service Limited — Dr. Ta Liang has joined the consultants' staff of Canadian Aero Service Limited, Ottawa, and will direct the company's photo interpreters in their work for engineers and governments, and for the oil, mining and forest industries.

C-I-L Appointment — Canadian Industries Limited announce the appointment of H. G. Campbell to sales manager of their chemicals division; he succeeds G. D. Pratt who will serve as a sales consultant for the division. Also announced is the appointment of A. K. Cameron as manager, "Fabrikoid" division plant at New Toronto, Ont., succeeding W. H. Shaw who has been named special assistant to the division's general manager, D. S. Kirkbride, M.E.I.C.

Monsanto — J. H. Langstaff has been appointed product sales manager for general chemicals, and J. K. McCabe a technical sales representative for the plastics and resins sales department, Monsanto Canada Limited.

H. Lebel

C.G.E. Appointment—R. W. McDonnell has been appointed manager—advertising and sales promotion in Canadian General Electric Company's lamp department, Toronto.

Ex-Cell-O of Canada — James Harvie has been appointed to the new post of general sales manager of Ex-Cell-O Corporation's industrial sales organization in Canada, and will guide the sales operations of the industrial products of both Ex-Cell-O of Canada in London, Ont. and Colonial Tool Company, an Ex-Cell-O subsidiary in Windsor, Ont.; his headquarters will be in Toronto.

Shell Oil Company — A. R. Michell has been named manager, central division, purchasing-stores of the Shell Oil Company of Canada Limited, Toronto; he replaces N. V. Swail, who has been appointed Hamilton plant superintendent.

Sun Oil Company — The following appointments have been announced by Sun Oil Company Limited: K. F. Heddon, district manager, London, Ont.; C. B. Pitt, manager, wholesale and fuel oil departments, H. S. Ostrander, manager, industrial products department, G. R. Burns, technical representative, industrial products department, all of home office, Toronto; W. H. Sanson, manager, industrial products, wholesale and fuel oil departments, Toronto district office.

Business News

Power Transformers Order — The Aluminum Company of Canada has ordered sixteen big 55,000 kilovolt-ampere power transformers from the Canadian Westinghouse Company, Hamilton, for its Chute des Passes power generating development on the Peribonka River some 350 miles north of Quebec City. The transformers will step up the generator voltage of 13,800 volts to a high voltage of 380,000 volts for long-haul transmission to Alcan smelters at Isle Maligne, P.Q. The transformers are said to be the most powerful yet built in Canada to use aluminum windings in place of conventional copper. They will stand over 24 feet high and will each weigh more than 110 tons.

Change of Location — Foundation of Canada Engineering Corporation Limited recently announced movement of its head office in Toronto from the Manufacturer's Life Building to establish single occupancy at 8 Spadina Road. Fenco also maintains offices in Montreal and Vancouver.

Shawinigan Subsidiary — St. Maurice Chemicals Limited is to become wholly-owned by Shawinigan Chemicals Limited under a plan announced recently. At present the St. Maurice company is owned jointly by Shawinigan Chemicals, itself a wholly-owned subsidiary of The Shawinigan Water and Power Company, and by Heyden Newport Chemical Corporation, of New York. To carry out the purchase, The Shawinigan Water and Power Company, subject to approval of the Provincial Electricity Board, proposes to issue 75,000 additional common shares to exchange for Heyden Newport's 50 per cent interest in St. Maurice Chemicals. Shawinigan Water and Power then plans to transfer this interest to Shawinigan Chemicals in exchange for additional Chemicals common stock.

Federal Public Works Contracts — According to a statement authorized by Works Minister Green contracts involving expenditures totalling $7,253,452.56 were awarded by the Federal Department of Public Works during the month of February, 1958. The amount for new works in building construction and harbours and rivers engineering is $6,753,397.56; for the repair and maintenance of existing structures $25,055.00; and for the extension of the Mackenzie Highway $475,000.00.

MEET THE AUTHORS

R. David, M.E.I.C., District Engineer, Canadian Institute of Steel Construction, Inc., Montreal. *(Composite Construction of Bridges Using Steel and Concrete.)* Mr. David graduated from Paris University in 1912, (B.Sc.). He served in the French Armed Forces, 1914-1918, and graduated from the French Govt. Engineering School, Ecole Centrale Paris, in 1921. After 26 years of French government public works service overseas he came to Canada in 1947: he has held his present position since 1953.

G. G. Meyerhof, M.E.I.C., Head, Department of Civil Engineering, Nova Scotia Technical College, Halifax, N.S. *(Composite Construction of Bridges Using Steel and Concrete.)* An honours graduate in civil engineering from London University, (later a Ph.D.) Dr. Meyerhof worked for several years with consulting structural engineers in England. In 1948 he joined the staff of the British Government Building Research Station, and for his research on soil mechanics and foundation problems was awarded the degree of Doctor of Science in 1954 (U. of London). On coming to Canada Dr. Meyerhof joined the Foundation of Canada Engineering Corporation; he is the author of several papers.

P. K. Peterson, Chief Equipment Engineer, Orenda Engines Limited, Toronto. *(The Altitude Test Facility at Orenda Engines Limited.)* Mr. Peterson served as an engineer officer in the R.A.F. during World War II, after which he joined the Bristol Aeroplane Company on research and development of performance and mechanical aspects of early propeller-jet and turbo-jet engines. In 1951 he joined the gas turbine division of A. V. Roe Canada which later became Orenda Engines Limited. For three years he has been responsible for design of a wide variety of test rigs, test facilities, and instrumentation.

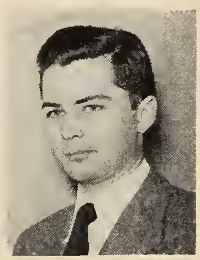
Three co-authors (l. to r. below), C. B. Cowan, W. S. Peterson, and G. L. Osberg, contributed to the paper *Spouting of Large Particles.*

C. B. Cowan, Imperial Chemical Industries Ltd. A graduate of the University of St. Andrews (B.Sc., Hons. chemistry, 1948; Ph.D., 1952, Dr. Cowan spent the period September 1955 to September 1956 on leave of absence from I.C.I. at the Division of Applied Chemistry, National Research Council, Ottawa, Ont., on a postdoctoral fellowship.

W. S. Peterson, Division of Applied Chemistry, National Research Council, Ottawa, Ont. Mr. Peterson graduated from the University of Alberta, B.Sc., chemical engineering, 1942, and M.Sc., 1944; he joined the chemical engineering section of N.R.C. in 1944.

G. L. Osberg, Division of Applied Chemistry, N.R.C., Ottawa, Ont. Dr. Osberg graduated from the University of Alberta in 1939 (B.Sc., chemical engineering) and obtained a Ph.D. in physical chemistry at the University of Toronto in 1949. He has held his present position since 1949.

R. R. Keith, M.E.I.C., P.Eng. Assistant General Manager in Charge of Operations, Saskatchewan Power Corporation, Regina, Sask. *(Saskatchewan River Generating Station of Saskatchewan Power Corporation.)* Attended University of Saskatchewan (B.Sc., mechanical engineering, 1937). Mr. Keith has been continuously associated with the Saskatchewan Power Commission and the Saskatchewan Power Corporation since 1937. He has held positions at Saskatoon Generating Station, North Battleford, and Prince Albert; he became Power Production Superintendent in 1952, and has held his present position since 1956.



G. D. Campbell, JR.E.I.C., Director of Technical Services, Canadian Good Roads Association, Ottawa, Ont. *(The AASHO Road Test).* Dr. Campbell graduated from the University of Manitoba in 1951, and in 1952 received an M.S.C.E. degree from Purdue University. After two years with the Trans-Canada Highway Division, Department of Public Works, he did post-graduate work at Purdue University (Ph. D., highway planning and economics, 1956). In June 1956 Dr. Campbell became Engineer-Observer for the Canadian Good Roads Association at the AASHO Road Test in Ottawa, Illinois, and recently returned to CGRA headquarters in Ottawa, Ontario, to assume his present position.

H. L. Johnston, M.E.I.C., Chief Engineer, Du Pont Company of Canada (1956) Limited, Montreal. *(Evaluating Performance in an Engineering Department.)* Mr. Johnston served with the Canadian Engineers and Imperial Artillery from 1915 to 1919; he was mentioned in Dispatches and awarded the the Military Cross. He attended the University of British Columbia and McGill University and graduated from the latter in 1927 (B.Sc., civil engineering). After early experience on railway construction and land surveying he was commissioned B.C.L.S. 1924. Mr. Johnston joined Bremner Norris in 1927; from 1928 to 1936 he was plant engineer with Canada Paper Company and became a project engineer with Canadian Industries Limited, Montreal. From 1936 to 1953 he held many senior positions with C-I-L and was appointed to his present position on the separation of C-I-L and Du Pont in 1953.

COVER PICTURE

On April 5th, 1958, two-and-a-half million pounds of explosive were used to demolish the top of Ripple Rock. The cover picture was taken several seconds after the detonation of the explosive in the successful attempt to remove this hazard to navigation. Further information on Page 96.

• This Hoffman Kiln is constructed entirely of refractory concrete. Tunnel is 164 feet long and 8 feet wide. Average thickness of arch is 8 inches. Seven bags of Ciment Fondu per cubic yard were used. Aggregate old firebrick, 30% alumina graded 0.6 in. to dust. Immersion vibrators were used. All vertical forms were removed three hours after placing. The arch forms were removed between 12 and 24 hours after placing. A recent visit revealed that after working one year, the kiln is as new.

Here's Why Ciment Fondu makes Industry's Quickest, Most Economical Castable Refractory!

THERE IS A PLACE FOR CIMENT FONDU REFRACTORY CONCRETE IN EVERY INDUSTRY

—Order a few bags of Ciment Fondu TODAY!

Write for your copy of booklet "Refractory Concrete"

CIMENT FONDU
Regd Trade Mark
ALUMINOUS CEMENT

Ciment Fondu is the registered trade-mark of Lafarge Aluminous Cement Co., Ltd.

Castable Refractory Concrete made with CIMENT FONDU has these advantages:

- **Flexibility of Design**
- **Low Installation Costs**
- **Low Cost of Materials**
- **Avoidance of Delay**

IN ADDITION:

CIMENT FONDU Refractory Concrete eliminates brick by brick construction—permits quick pouring of monolithic walls, roofs, hearths, any shape, size or form.

CIMENT FONDU Refractory Concrete gives you high strength, before, during and after firing—service temperature up to 2500°F.

CIMENT FONDU Refractory Concrete is cast in one piece—permits faster construction, smoother surfaces, and stronger suspended roofs.

CIMENT FONDU easily produces refractory concretes of varying refractoriness and thermal conductivity.

Composite Construction of Bridges Using Steel and Concrete

R. David, M.E.I.C., *District Engineer, Canadian Institute of Steel Construction, Inc., Montreal*

G. G. Meyerhof, M.E.I.C., *Head, Dept. of Civil Engineering, Nova Scotia Technical College*

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June 1957.

Revised paper received 19 August 1957

The paper briefly summarizes the history of composite construction and presents the main design aspects and construction procedures, with special reference to bridges. Methods of analysis are outlined to compute dead and live load stresses, failure loads and to determine the effects of shrinkage, creep and temperature. It is shown that the difference between the thermal expansion co-efficients of concrete and steel may be an important factor, especially in continuous structures exposed to the elements. The merits of various shear connectors are briefly discussed and the methods of prestressing composite structures are indicated.

COMPOSITE construction consisting of structural steel members working in conjunction with the surrounding concrete seems to have been used before ordinary reinforced concrete. The Melan system, which consisted of steel beams encased in concrete, was used extensively both in Europe and in the United States during the last decades of the nineteenth century. In France, rigid lattice frameworks, to which the form-work was fixed before concreting, have been used since 1890.

In Canada, tests on "steel beam and slab construction" were made at McGill University in 1923[1].

This early work, together with other research in Europe, led to an interesting development. The sponsoring steel fabricator developed a comprehensive system of composite construction, known as the Kane System of Composite Construction[2]. In building construction this took the form chiefly of latticed beams and columns surrounded by concrete, but it applied equally as well to solid beams and columns in buildings and bridges. Several large buildings and some bridges have been built of such construction in and around Montreal between 1934 and the beginning of World War II.

In 1937 a series of tests on concrete slabs on steel beams were conducted at the University of Toronto[3] under the auspices of the Canadian Institute of Steel Construction. These tests gave an indication of the combined strength of concrete slabs bearing on top of steel beams with and without shear connectors as well as with partial encasement of the steel beams. They also proved the efficiency of shear connectors as a means of increasing the bond between steel and concrete.

As a result of this work design methods were established in Canada for concrete slab and steel beam construction and governing clauses were incorporated in the National Building Code of Canada (1941). Such construction has been used to some extent in buildings, but it is only since World War II that its use has been extended to bridges other than those built earlier in Montreal. The general use of composite construction in bridges on this continent has been made practical by some interesting research at various universities in the United States on the subject of shear connectors[4].

General Design Considerations

The original tests made in Canada together with tests made recently in the United States and Europe[5] have shown that whenever a heavy concrete slab rests on a steel member, to which it is not purposely anchored, it reacts as a composite member to stresses induced by superimposed loads. Bond and frictional stresses within working limits are such that any strain of the steel girders is identical to that of the concrete along the contact surface of the two materials. Thus any calculated stresses which entirely ignore composite action do not correspond to the actual stresses.

For this reason, when a concrete slab and a supporting steel member are being considered, a design utilizing composite action is the logical solution. It is also much more economical. The design procedures for dead and live load stresses are well known and do not differ appreciably from reinforced concrete computation. An example is given in the Appendix. Design criteria may be different for bridges than it is for buildings. It is the purpose of this paper to present some of the important factors in composite bridge design and construction.

Factors Influencing the Design of Composite Bridges

Specifications— As no Canadian specification relating to composite bridge design has as yet been formulated, engineers in Canada are generally following the A.A.S.H.O. Specification (1953) though only a short paragraph in it refers to composite construction.

The designer will find it useful to study the new German tentative bridge design specification DIN 1078 (1955) (English translation)[6], which follows an extensive study of composite construction in a number of universities. Considerable information may also be found in many papers published by the University of Illinois.

Factor of Safety and Ultimate Load

As calculated according to the A.A.S.H.O. Specifications, composite bridges have a factor of safety (ultimate load in terms of live load) varying from 5 to 6 or even higher if diaphragms are riveted or bolted with high-strength bolts or welded to the stringers so as to form a rigid grid system, which is mainly responsible for the exceptional toughness of such a structure. The exact computation of the stresses involved in a composite structure with rigid diaphragms is almost impossible except by electronic computers, but it has been shown by tests[7] on bridges with spans from 100 to 200 feet that observed stresses vary from 35 to 60 per cent of calculated stresses. Similarly, for short spans (40 to 100 feet) deflections vary from 20 to 30 per cent of calculated deflections, and for longer spans (200 to 300 feet) about 50 per cent of the calculated deflections are generally recorded.

On the other hand, studies based on complete plastification of the section and tests up to failure using proper shear connectors indicate that failure loads can be predicted accurately and that the neutral axis shifts toward the plane of separation of the two materials during the process of plastification[8].

Calculation of Dead and Live Load Stresses

The magnitude of the dead and live load stresses at any section of a composite member will depend not only on the relative stiffnesses of the steel and the concrete components but also whether the steel beam is shored during the construction of the slab. For this reason it is the responsibility of the designer to decide whether or not shoring is to be used during erection. If shoring is used, both dead and live load stresses are computed on the basis of the composite section. Without shoring, the dead load stresses are calculated on the basis of being carried by the steel beam only and to these are added the stresses due to loads imposed after the concrete has set and which are calculated on the basis of composite action.

Residual and Incidental Stresses

The determination of residual stressess due to shrinkage and creep in the concrete and those due to possible difference of slab and beam temperatures are problems of some difficulty (see Fig. 1) and, as a rule, have been evaded or at least have had superficial examination. When shoring is used to support a steel member, the effect of plastic flow or creep due to a continuous compressive stress on the concrete due to dead load may be a factor worthy of consideration.

The effects due to the difference between the thermal expansion of steel and various kinds of concrete are important, but have been almost entirely overlooked on the assumption that the relative expansions of steel and concrete are about the same.

Concrete growth due to chemical or physical modifications has also to be considered since its possibility presents a serious problem whenever such concrete is used for a structure.

Stresses Due to Shrinkage, Creep and Relative Temperature Differences

Concrete shrinkage strain is taken as equal to 1×10^{-4}, and this value can be considered as a maximum if the slab is divided transversely into a certain number of sections which are allowed to set separately.

When shoring is used to support the steel member the effect of plastic flow or creep due to a continuous compressive stress in the concrete upon removal of the shoring should also be considered. This creep amounts to an equivalent contractual strain of about 2×10^{-4}.

Careful consideration of the stresses involved may suggest that shoring is unnecessary and uneconomical since the failure load with shoring is almost the same as that developed when no shoring is used. This is due to redistribution of stresses in the steel beam, which has little effect on the final plastic moment capacity of the beam.

Shoring will, however, be of interest when the composite section is prestressed by erection means, as described later; in which case the higher permanent compression in the concrete may create strains due to creep of relative importance in the order of 2×10^{-4}.

During a sudden rise in temperature, a steel beam may be warmer than the connected concrete slab due to a quicker temperature stabilization of the steel. This kind of temperature differential will create an additional strain of 1×10^{-4} which should be considered in stress computations.

Some authorities advocate compensating for stresses due to temperature differential by using different values for the modular ratio n. For example, they use $n = 10$ for live load calculations and $n = 20$ to 30 for dead load calculations in order to compensate for the effect of possible difference in slab and beam temperatures of $\pm$ 30°F. with $n = 30$, the estimated stresses are relatively lower in the concrete slab and higher in the bottom flange of the steel beam.

On the contrary, experimental studies and true analysis of these effects show that relatively high stresses are found along the plane of contact between the two materials where stresses are developed to compensate for potential strains since none can take place at that plane.

The net combined effect of shrinkage, creep, and temperature differential between cold concrete and warmer steel, involves potential tensile stresses in the concrete, an increase in the compressive stresses in the top flange of the beam and a slight increase in the tensile stress in the bottom flange of the beam.[9]

An example given in the appendix shows that their effect on the final distribution of stresses is of relative importance.

Stresses Due to Difference Between The Thermal Expansion of Concrete and Steel (Fig. 1)

(Hereafter the word expansion will be used in a general sense and then might be positive or negative.)

Since concrete is closely associated with steel structures, as well as composite structures, and forms the bulk of reinforced concrete and prestressed concrete structures, it is of importance to be aware of some physical or chemical changes which affect the linear dimensions of concrete and increase stresses to such an extent that failure may occur.

The effect of the difference between the thermal expansion of concrete and steel has not been given the attention by designers that it warrants. As gravel concrete aggregates were generally used at the beginning of reinforced concrete construction and these had practically the same coefficient of thermal expansion as steel (6.5×10^{-6} per °F.), it led to the general belief that concrete has the same thermal

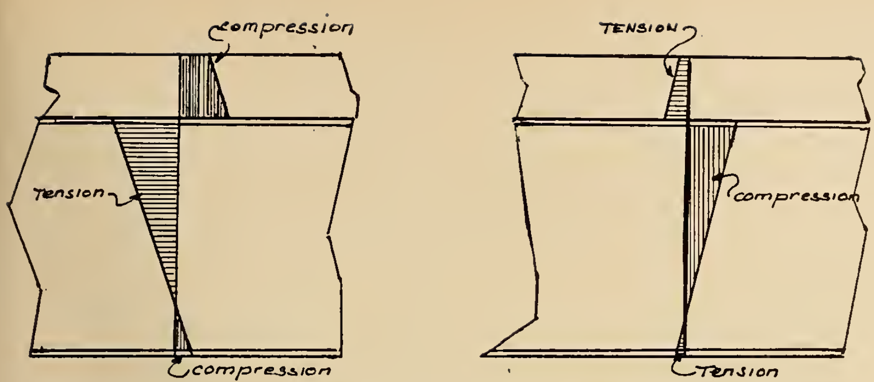

Fig. 1. Left: diagram of stresses due to thermal expansion difference between concrete and steel (between 70°F. and −40°F.).

Right: diagram of stresses due to concrete shrinkage or creep.

expansion regardless of the choice of aggregates and of cement. Thermal expansion of concrete above 32°F. has been thoroughly studied in England at the Building Research Station[10]. The coefficient of thermal expansion has a tendency to diminish under freezing conditions.[11]

Table I. Coefficient of Thermal Expansion of Concretes with Different Aggregates above 32°F.

	Coefficient per °F. $\times 10^{-6}$	
Aggregates	Air Storage	Wet Storage
Gravel	7.3	6.8
Granite	5.3	4.8
Quartzite	7.1	6.8
Dolerite	5.3	4.7
Sandstone	6.5	5.6
Limestone	4.1	3.4
Portland Stone	4.1	3.4
Blast Furnace	5.9	5.1
Foamed Slag	6.7	5.1

University of McGill tests[12] on thermal expansion of concrete at low temperatures have shown that Montreal limestone concrete has a thermal expansion which varies from 3.5 to 2.32 x 10^{-6} when temperature varies from 70° to -30°F.

As extreme climatic conditions exist in most sections of Canada, the possible effects of differences of thermal expansion of the concrete and steel may become critical, hence they have been studied in an example of a composite beam given in the Appendix. This study shows that a thermal expansion difference at low temperatures produces compression in the concrete, tension in the top flange of the steel beam, and compression in the bottom flange. The resulting negative bending moment may be as large as the total positive moment at this section due to the dead and live loads. Thus, in the case of simple beams, a difference of thermal expansion between concrete and steel, at low temperature, diminishes the maximum steel stresses while it increases the concrete stresses. It is important to note however that in the case of continuous steel beams with continuous concrete slabs the high tensile stresses developed in the top flange have to be added to the tensile stresses due to the negative bending moment in sections above the intermediate supports. Apart from large flange stresses, the stresses in the web may also become critical at these supports where bending and large shearing stresses combine. For these reasons it is considered that a gap of 2 to 3 inches should be provided between the concrete slabs resting on two consecutive spans and that shear connectors are unnecessary where negative moments occur. In the latter case these moments are resisted only by the steel beam. A continuous slab should be used only if the steel and the concrete have approximately the same coefficient of expansion.

Stresses Due to Possible Concrete Growth

Extensive field and laboratory work have investigated causes of concrete growth. Recently the Canadian National Research Council has made a very important contribution on this subject which is a valuable source of information.[13]

Concrete growth may be due to physical causes such as freezing-thawing, wetting-drying, heating-cooling, etc. Chemical causes are specially due to the fact that alkalies released during hydration of high-alkali Portland cements react with certain rocks and minerals of aggregate with consequent expansion and ultimate deterioration of the concrete. Tests on mortar bars containing high- or low-alkali cement and many different samples of common rocks and minerals crushed to form the aggregate showed that after twelve months storage at 100°F. linear expansion ranged from nil to more than 3 per cent. The studies showed that all silicate and silica minerals react with alkalies in Portland cement, but fortunately, the greater number react only to an insignificant extent. Expansion at any given age tends to increase with alkali content of the cement, temperature during aging, moisture availability, cement content of the concrete or mortar and amount, size and radioactivity of the aggregate.

Concrete growth will cause stresses in composite bridges similar to that produced by differences in thermal expansion coefficients of steel and concrete at low temperatures.

The growth is generally a very slow process, the amount of which is unpredictable in most cases, but with certain cement-aggregate combinations it can be very serious.

Thus it is extremely advisable to circumvent any long-term adverse effects by choosing a concrete mix that is composed of low-alkali cement and chemically inert aggregate, on which freezing-thawing and wetting-drying cycles have very little effect.

Shear Connectors (Fig. 2)

Although it has been demonstrated by tests[14] that there is considerable bond strength between the unpainted surface of the top flange of the beam and the concrete slab, which is capable of transmitting horizontal shear causes by static loads, further research[15] has indicated that severe impact loading may destroy this bond and thus composite action would cease. For this reason in bridges, the beam and the slab are interconnected by means of shear connectors which are designed to transmit the full horizontal shear as well as prevent both vertical and horizontal movement of the slab relative to the beam.

Shear connectors may be either rigid, semi-rigid or bond type. All have recently been the subject of numerous tests at various universities all over the world.

Rigid connectors are relatively inflexible and remain so at ultimate load capacity. Semi-rigid connectors are somewhat more flexible and will generally yield before crushing of the concrete occurs. Bond connectors, as the name implies, depend entirely on bond stresses to develop anchorage.[16] Numerous forms have been devised, including spirals.

Among semi-rigid connectors are to be found both the channel type and the steel stud. University of Illinois tests[17] have proved that when either type is properly designed and used, the ultimate bending capacity of the composite section is reached before shear failure occurs.

Permissible compressive stresses and bond stresses will depend on concrete strength. It is important to have proper spacing between consecutive shear connectors so as to develop the pressure on the largest possible section of the concrete and also avoid any shearing plane in the concrete both longitudinally and tangentially to the shear connectors.

The amount of longitudinal shear which must be taken into account will include that produced by the dead loads (if shoring is used), live loads, shrinkage, creep, temperature difference, and any difference between the thermal coefficients of expansion of the slab and the beam.

From numerous tests it has been shown that if shear connectors are properly designed, composite beam failure is due only to ultimate compressive stress in the concrete slab or full plasticity in the steel beam, or both combined.

It is the responsibility of the designer to state which type of shear connector is to be used. However, there are many variations of each main type. In the interest of economy it is advisable to allow some latitude in this respect so that the fabricator might suggest the shear connector best suited to his facilities.

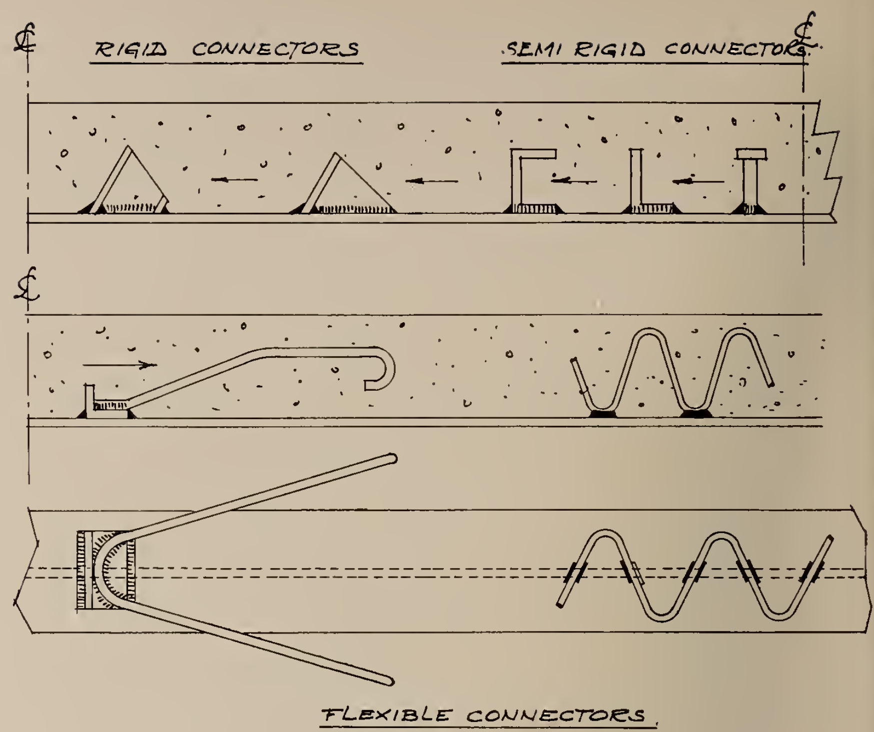

Fig. 2. Shear connectors.

Prestressing

The Reasons for Prestressing — Prestressing of the steel beam is sometimes done in order to produce stresses of opposite sense to those that are anticipated during the application of dead and live loads. Therefore the net bending moment at any section is usually less under design load conditions than would be the case where no prestress was applied. Hence design based on allowable unit stresses generally results in the utilization of a smaller section where prestressing can be employed and therefore some economy may be gained if the cost of prestressing is less than the cost of the material saved.[18]

The computed deflection of composite bridge girders is usually in the order of L/1200 to L/1400 and observed deflections are often in the order of 50 per cent of these values. Since the limiting deflection in bridge specifications is generally about L/800 there appears to be a saving in weight of steel of 15 per cent to 30 per cent if the composite section is chosen on the basis of the limiting deflection. However, in order that allowable unit stresses are not exceeded in such a section, prestressing may be necessary.

Prestressing the Structural Steel During Erection

In simple span construction prestressing may be accomplished by shoring approximately the middle third of the steel beam to some elevation higher than the elevation of the end bearings and then forcing both ends of the beam back onto the bearings, in effect compressing the bottom flange and tensioning the top flange. The concrete slab is then poured and allowed to cure before the shoring is removed. The composite section then has a "built-in" prestress of opposite sign to stresses caused by dead and live loads.

Erection prestressing procedures for continuous spans depend on the number of spans that are continuous, but usually involve producing temporary differences of level on the different piers. In general, mid-span moments will increase while moments over supports will decrease. However, since support moments are usually carried by the steel only, some economy of steel is therefore realized (Fig. 3).

Prestressing the Concrete Slab

Lateral prestressing of concrete slabs of composite bridges has been done in this country. It reduces the weight of the slab when the stringers are widely spaced. Concrete slabs of continuous composite construction bridges have also been prestressed longtitudinally over the supports to ensure that the concrete does not come under tension and thus lose its effectiveness in the composite section.

Although prestressing of the slab can result in some economy of material, the extra work involved always offsets this to some degree.

Maintenance Aspects

For composite bridges to withstand the extreme climatic conditions in Canada, it is considered desirable to apply bituminous wearing surface so as to avoid bad effects due to freezing and thawing. Steel stringers should be painted and not encased in concrete since this increases the weight, and the overall economy is correspondingly diminished. Concrete never protects perfectly against corrosion since cracks appear after a few years and it is practically impossible to prevent corrosion once air and moisture have this means of access. Trucks can readily be equipped with paint guns, power-driven rotary steel brushes, nylon nets to permit easy inspection of the road surface and the expansion joints. Maintenance costs can be reduced to a minimum if periodic inspection is undertaken at reasonable intervals.

Economic Considerations

The matter of economy is of paramount interest to a designer and owner in the consideration of the use of composite construction for bridges. Since the cost of shear connectors, together with the extra welding involved, is not negligible, composite construction is generally more economical for medium spans (above 40 ft.) and long spans. Many comparative designs have proved its economy in such bridges, especially in connection with expressway overpasses and elevated highways. However, composite design is often chosen for the additional advantages of unusual flexibility, rapidity of construction and the lack of shoring which permits the free movement of traffic during construction. All of these again contribute to the overall economy of the project.

Generally, a steel beam with a cover plate over two-thirds of its length and welded to the bottom flange constitutes the most economical composite beam. Built-up sections and Canadian sections can be used effectively. When shoring is used its advantage is somewhat offset by the additional stresses due to creep, which need not be considered for unshored beams.

If calculated elastically and shored, a composite steel beam will be 15 to 25 per cent lighter than a steel beam with no composite action. A composite steel beam with a built-up bottom flange may be as much as 30 to 40 per cent lighter.

When shoring is not used, the economy in the beam design may be less. It depends on the ratio of live load to dead load and may be anywhere between 8 to 35 per cent. However, shoring costs are eliminated.

If a plastic analysis is made, there is practically no difference at failure load between identical shored and unshored composite beam. The only difference is the deflection under working load which is slightly larger with unshored beams. This is usually of little consequence since deflections of composite beams are small. It seems likely that when all aspects are considered, unshored composite construction will generally be more economical, unless the shoring is to be also used as a means of prestressing.

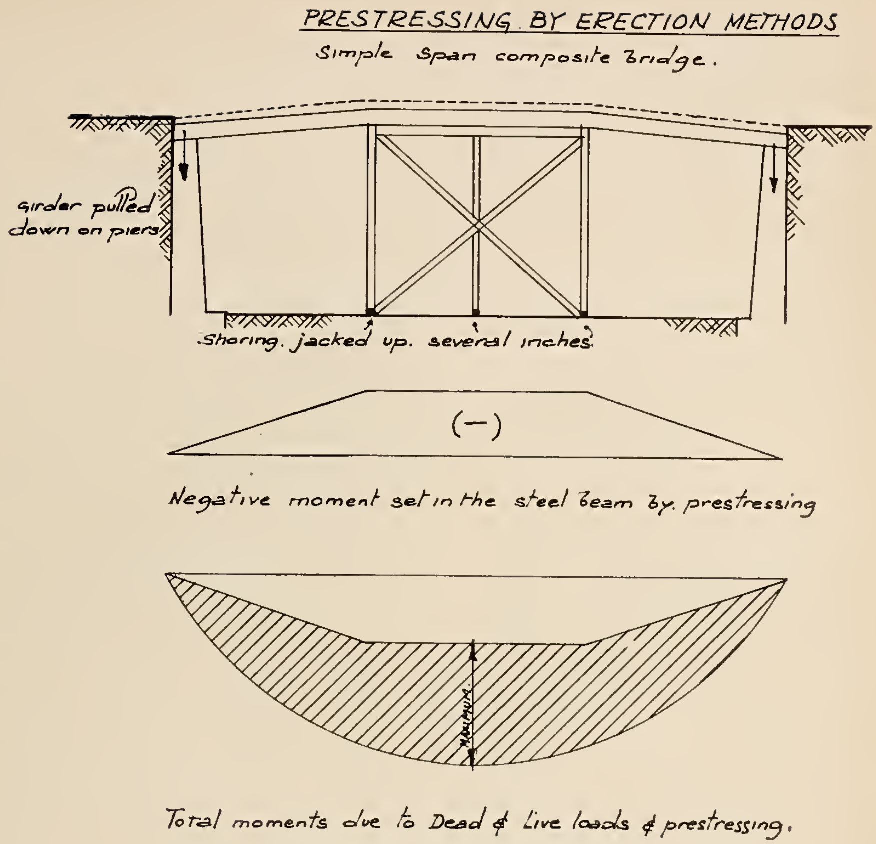

Fig. 3. Erection prestressing.

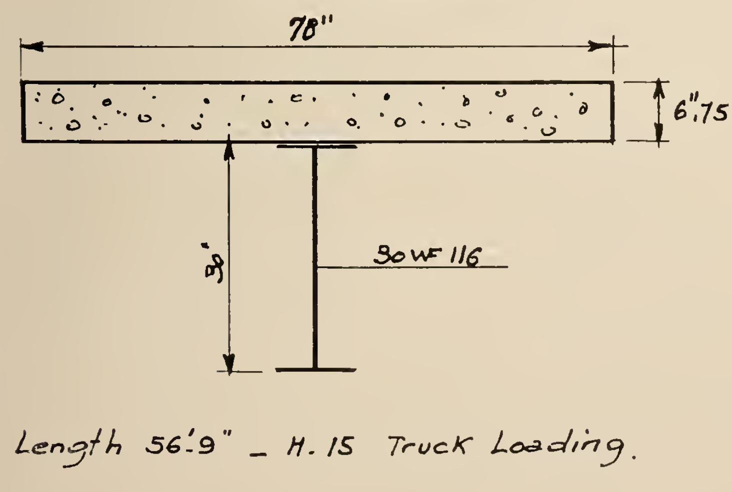
Conclusion

The use of composite action between structural steel beams and concrete slab bridge decks, provides a rapid and economical means of construction.

Fig. 4. Composite beam.



Structural design is generally less complicated than similar designs using reinforced concrete and involves only slightly different calculations than those used in ordinary steel design. The "extra" factors such as creep, shrinkage and differential thermal contraction stresses that are indicated in this paper, as well as possible concrete growth, are not unique in composite construction but exist in varying degrees in all bridges where steel and concrete are combined in some manner. The lack of recognition accorded these factors in the past has at times resulted in disastrous consequences.

Construction procedures are no different than are common to ordinary "beam and slab" construction.

The last ten years have seen an ever-growing number of bridges and elevated expressways utilizing composite action in order to achieve simplicity, harmony and economy.

Economy has been gained not only in savings in materials combined with simple erection techniques, but also due to simplified traffic handling made possible by the absence of shoring.

Composite construction is worthy of consideration for any bridge project and, with intelligent design, will prove itself effective and economical.

APPENDIX

Example of Analysis of Simply-supported Composite Beam

1. Properties of Section (Fig. 4)

(based on paper by N. M. Newmark and C. P. Siess in *Public Roads*, 1943, vol. 23, p. 157).

Concrete slab:
area $A_c = 527$ in.^{2},
moment of inertia $I_c = 1980$ in.^{4}

Steel beam:
area $A_s = 34.1$ in.^{2},
moment of inertia $I_s = 4920$ in.^{4}
section modulus $S = 328$ in.^{3}.

Composite section:
overall depth $D = 36.75$ in.,
thickness of slab $t = 6.75$ in.,
depth of neutral axis $d = 10.6$ in.,
moment of inertia (eff. steel)
$I = 12120$ in.^{4}

Modular ratio $n = 10$.

2. Dead and Live Load Stresses at Mid-Span (Fig. 5)

Dead load moment (60 ft. span)
$M_d = 3215$ kip.-in.

Live load moment (AASHO H15 load)
$M_l = 3470$ kip.-in.

Dead load stresses:
Concrete stresses $f = 0$
Steel stresses (beam only)
$f = M_d/S = \pm 9800$ p.s.i.

Live load stresses:
concrete stress top of slab
$f_1 = M_l d/nI = -304$ p.s.i.
Concrete stress bottom of slab
$f_2 = M_l(d - t)/nI = -111$ p.s.i.
Steel stress top flange:
$f_3 = nf_2 = -1110$ p.s.i.
Steel stress bottom flange
$f_4 = M_l(D - d)/I = +7480$ p.s.i.

Sum of dead live load stresses:
$f_1 = -304$ p.s.i., $f_2 = -111$ p.s.i.,
$f_3 = -10910$ p.s.i., and
$f_4 = +17280$ p.s.i.

3. Computation of Stresses Due to Shrinkage, Creep, Temperature Difference Between Slab and Girder, Thermal Expansion, Difference of Thermal Expansion at Low Temperatures and Concrete Growth (Fig. 6).

Their effects on composite structures are identical though producing either tension or compression.

Let ϵ be the difference of elongation produced by any of the above mentioned causes, between slab and girder if both materials were free to expand. Since this is not the case, two identical forces N_s and N_c ($N_s = N_c = N$) must be applied at the centres of gravity so that the corresponding strains ϵ_s and ϵ_c are such that

(1) $\epsilon_s + \epsilon_c = \epsilon$

Since no strain can occur in the plane of separation concrete-girder, ϵ_s and ϵ_c have to be substituted by corresponding stresses.

$$\epsilon_s = \frac{1}{E_s}\left[\frac{N}{A_s} + \frac{M_s \cdot C}{I_s}\right]$$

$$\epsilon_c = \frac{1}{E_c}\left[\frac{N}{A_c} + \frac{M_c \times t/2}{I_c}\right]$$

$M_s = M_c = N \times$ d (no external moment)

$$\frac{M_s}{E_s I_s} = \frac{M_c}{E_c I_c}$$

(composite action = identical slope for strains)

Substituting and solving for N

$$N = \frac{\epsilon}{\left(\frac{1}{A_s E_s} + \frac{1}{A_c E_c} + \frac{d^2}{E_s I_s + E_c I_c}\right)}$$

$$M_s = E_s I_s \cdot \frac{Nd}{E_s I_s + E_c I_c}$$

$$M_c = E_c I_c \cdot \frac{Nd}{E_s I_s + E_c I_c}$$

$$f_c = \frac{N}{A_c} \pm \frac{M_c \cdot t/2}{I_c}$$

$$f_s = \frac{N}{A_s} \pm \frac{M_s \cdot C}{I_s}$$

Positive signs in f_c and f_s correspond to concrete and steel stresses in the plane of separation of materials.

Example

Considering the same slab and girder of the former example and assuming that $\epsilon = 1 \times 10^{-4}$ inch per inch, we find in the concrete slab: stress on the top fibre, 17.6 p.s.i.; lower fibre, 81 p.s.i. (both of the same sign). In the steel girder: on the top flange, 2170 p.s.i.; and lower flanges, 655 p.s.i. (both of opposite sign).

4. Effect of thermal expansion difference at low temperatures and concrete growth

In these cases, the stresses as indicated above are reversed and hence decrease existing stresses in sections subjected to positive moments. Thus their effects have to be considered only in the case of continuous bridges in sections above the piers where negative moments are taken by steel girders only.

Assuming that concrete has set at 70°F. and that temperature drops to −40°F. and that its thermal expansion is 3.5×10^{-6} per °F. against 6.5×10^{-6} for steel, $\epsilon = (6.5 - 3.5) \times 10^{-6} \times 110 = 3.3 \times 10^{-4}$ assuming that in the negative moment section the total stresses in the extreme girder fibres reach 20,000 p.s.i., as authorized by specifications.

For a limestone concrete the figure 3.5×10^{-6} is rather conservative since lower figures have been reported. If any possibility of concrete growth exists then buckling of the web may occur due to combination of longitudinal high stresses and

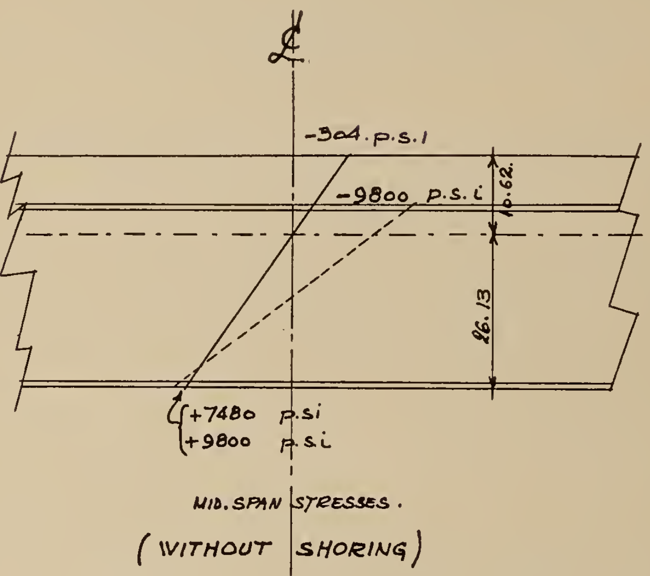


Fig. 5. Dead and live load stresses (span 56 ft. 9 in.; M.15 truck loading).

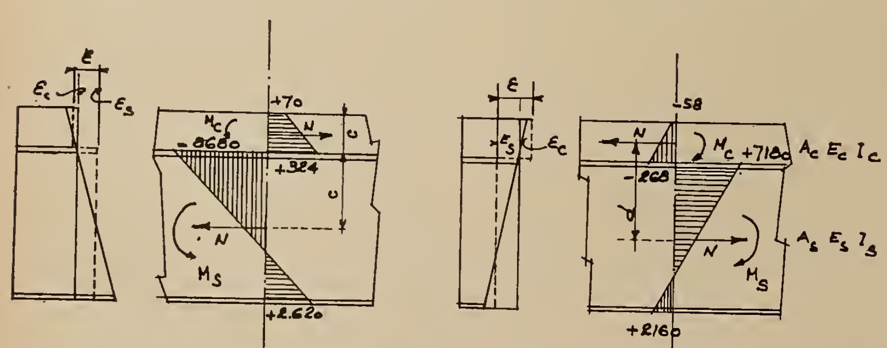

Fig. 6. Shrinkage and thermal stresses. Right: strains and stresses due to shrinkage creep and temperature difference; $\epsilon = 4 \times 10^{-4}$. Right: Strains and stresses due to thermal expansion between concrete (3.5×10^{-6}) and steel (6.5×10^{-6}) between 70°F. and −40°F.

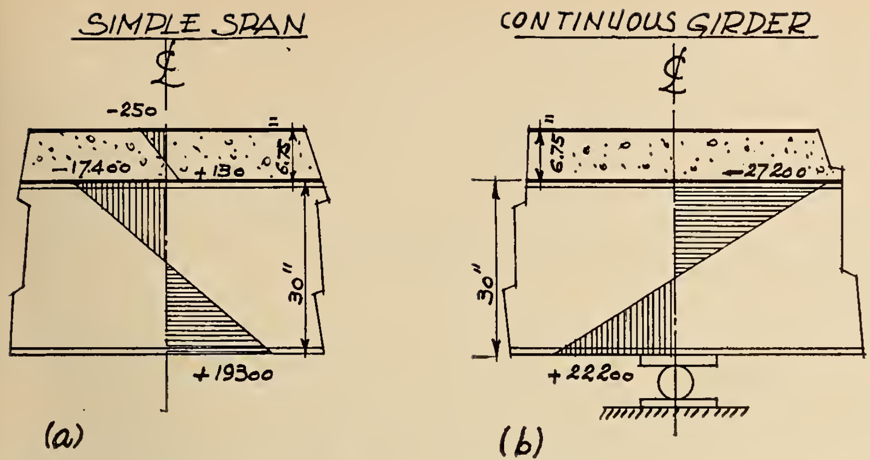

Fig. 7. Total stresses. (a) Stresses due to shrinkage, temperature difference, dead and live load (table). (b) Stresses in section above piers due to thermal expansion difference at —40°F. and dead and live loads (table).

Table II. (Fig. 7a)

Type of Stress	Concrete Slab Top f_1(p.s.i.)	Concrete Slab Bottom f_2(p.s.i.)	Steel Beam Top f_3(p.s.i.)	Steel Beam Bottom f_4(p.s.i.)
Shrinkage (1×10^{-4})	+17.6	+81	−2170	+655
Creep (2×10^{-4})	+35.2	+162	−4340	+1310
Temperature difference (1×10^{-4})	+17.6	+81	−2170	+655
Total	+70.4	+324	−8680	+2620

Without shoring, creep is not considered, thus the total stresses are[3]

Shrinkage and temperature	+ 53	+243	−6510	+ 1965
Live and dead load	−304	−111	−10910	+17280
Total	−251	+132	−17420	+19245

Continuous Steel Girder (Fig.7b)

Type of Stress	Section above Piers: Concrete Slab Top f_1(p.s.i.)	Concrete Slab Bottom f_2(p.s.i.)	Steel beam Top f_3(p.s.i.)	Steel beam Bottom f_4(p.s.i.)
Live and dead load stresses	0	0	+20000	20000
Expansion stresses (3.3×10^{-4})	0	0	+7200	2200
Total	0	0	+27200	22200

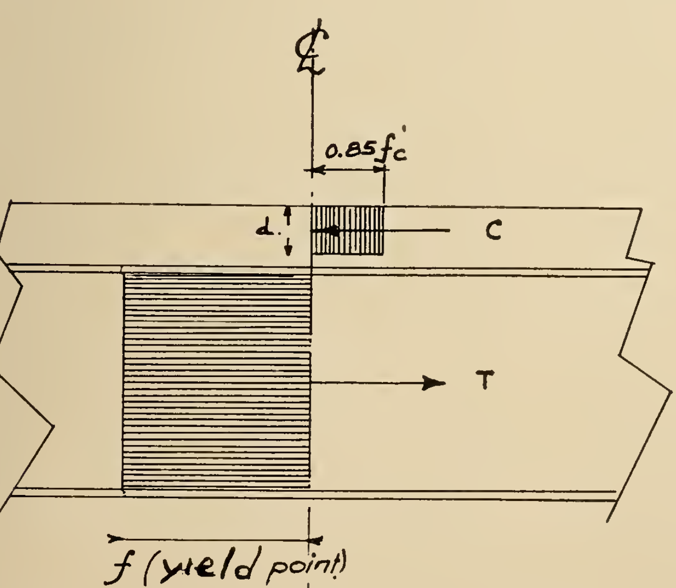

Fig. 8. Ultimate stresses. Distribution of stresses at failure.

shear stresses which are maximum in these sections. No anchorage and discontinuity of the slab above the piers is the best solution to suppress expansion stresses where negative moment exists.

5. Load Factor of Safety (Fig. 8)

Concrete cylinder strength

$f_c = 3000$ p.s.i.

and steel yield point

$f_y = 33000$ p.s.i.

Depth of neutral axis

$d = tA_sf_y/0.85A_cf_c = 5.65$ in.

Plastic moment of resistance

$M_p = A_sf_y(t + c - d/2)$

$= 21300$ kip. in.

Hence total load factor

$= M_y/(M_d + M_l) = 3.2$, and

live load factor $= (M_p - M_d)M_l = 5.2$.

The Altitude Test Facility at Orenda Engines Limited

P. K. Peterson

Chief Equipment Engineer, Orenda Engines Limited

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., May 1957.

Paper received 5 April 1957

THE REQUIREMENTS of modern interceptor aircraft dictate the continual expansion of the flight envelope of altitude and forward speed that must be met by both the engine and aircraft designer. Greater altitude and forward speed coupled with the constant demand for reduction of specific weight and frontal area require that design engineers must be prepared to introduce, into almost every new engine project, features and principles that are unique and reach to the extreme limit of current research and theory.

Provided the basic design is sound, and the more irrevocable steps that introduce new materials and principles justify the judgement of the designers, it is usual for a period of from three to four years to elapse between the time that the original design leaves the drawing boards and the first production version is built. During this time prototype engines and component parts are subjected to extensive bench testing to reveal weaknesses in the mechanical or performance design and, through constant modification and further testing, the engine is developed to the point that it becomes a marketable product.

The success and prosperity of a company engaged in this highly competitive business depend to a large extent upon the speed with which it can convert the raw design into a mechanically proven unit that meets the performance specifications. The ability of the development organization to carry out this task depends, in turn, upon having the correct tools for the job and, in this case, the 'tools' are the right type, quality and quantity of testing facilities and these must be available at the right time.

The advance of current engines into the rapidly widening range of altitude and forward speed has extended the problems of mechanical design, fuel control, combustion stability, ignition and general performance beyond the limits of acceptable assurance of satisfactory behaviour that have, in the past, been obtained solely from static test beds and flight test aircraft. The need has arisen for a test facility in which an engine, physically static on the ground, may be operated over the wide range of conditions that will be met during service in a modern interceptor aircraft. To meet this challenge several 'engine altitude test facilities' have been designed and are now in service, mainly in the United States.

This paper describes the altitude test facility designed by Orenda Engines Limited for the development of the 'Iroquois' engine. The purpose of such a test facility is to operate an engine, which is physically static on the ground, over the wide range of conditions that will be met during service in a modern interceptor aircraft. The facility provides the correct environmental conditions of pressure and temperature to which the engine would be subjected in flight for all combinations of forward speed and altitude, within a test chamber that contains the engine.

The subject of this paper is the particular engine altitude facility that has been designed by Orenda Engines Limited, for the development of the 'Iroquois' engine.

The subject of this paper involves a very specialized field of engineering. but the paper has been written to provide a general understanding for those to whom the field is strange rather than presenting a complete technical description that would suit specialists. The Orenda facility is designed to test the 'Iroquois' engine. As the size and performance of this engine are classified, all reference to the facility size has been avoided and, where flight envelopes have been shown, it is emphasized that these are typical rather than specific.

BASIC PRINCIPLES AND ARRANGEMENT OF A STANDARD ALTITUDE TEST FACILITY

The essential requirement for testing engines at simulated altitudes whilst they are physically static on the ground is the provision of the correct environmental conditions of pressure and temperature to which the engine would be subjected in flight. The basic function of the facility is therefore to provide these conditions, for any possible combination of forward speed and altitude, within a test chamber that contains the engine. Further, the temperatures and pressures must be held constant throughout any engine transient, e.g. acceleration or deceleration of r.p.m. at a fixed flight condition. The capacity of the facility in terms of the quantity of air is mainly a function of the size of engine to be tested and has no general significance. The capacity in terms of the range of environmental pressures and temperatures is dependent upon the flight operating range and the principles involved in establishing this range should be understood.

Capacity

Figures 1 and 2 show the variation of atmospheric pressure and temperature with altitude. When an engine is moved forward through a static atmosphere, air is compressed in the intake duct and is received by the engine at a pressure and temperature that exceed the ambient conditions of Fig. 1 and 2. The degree of compression is a function of the forward speed and is expressed as the 'ram pressure ratio', this being the ratio of total pressure at the compressor intake to the ambient static pressure. Figure 3 shows the graphical relationship of both ram pressure and ram temperature ratio with forward speed. Forward speed is expressed in the common dimensionless form of Mach No. which is the ratio of the actual forward speed of the engine to sonic velocity in the environment in which it is moving.

To obtain the correct environment for simulating a particular flight condition it is therefore necessary that the following pressures and temperatures in the test chambers be matched with flight conditions:—

(*a*) Engine intake total pressure (P_1)

(*b*) Engine intake total temperature (T_1)

(c) Ambient static pressure (p_1).

(*d*) Ram pressure ratio (P_1/p_1).

Although it is essential that the correct ram pressure ratio be established whilst the gases are discharged from the engine final nozzle at subsonic velocity, some alleviation of the problem occurs once the final nozzle is 'choked' (sonic velocity is achieved) as the engine is then no longer responsive to ram ratio and only to the intake total pressure and temperature. Intake total pressure and temperature (P_1 and T_1) may be derived quite simply from Fig. 1, 2 and 3 for any given flight condition. Figure 4 shows a typical interceptor aircraft flight envelope and Fig. 5 indicates the range

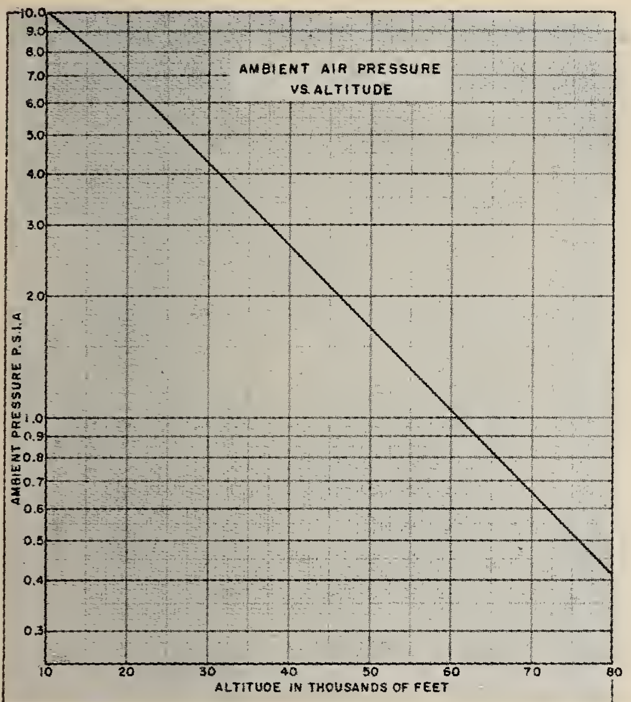

Fig. 1. (left)

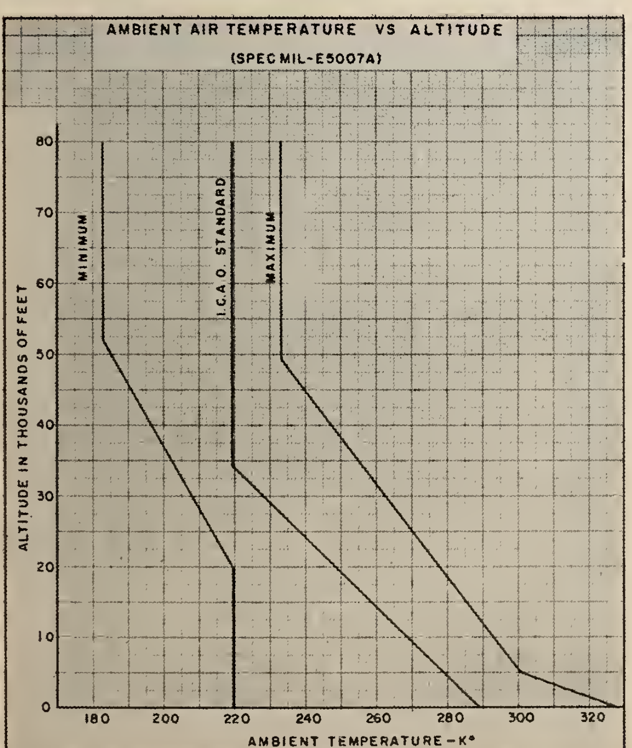

Fig. 2. (Below, l.)

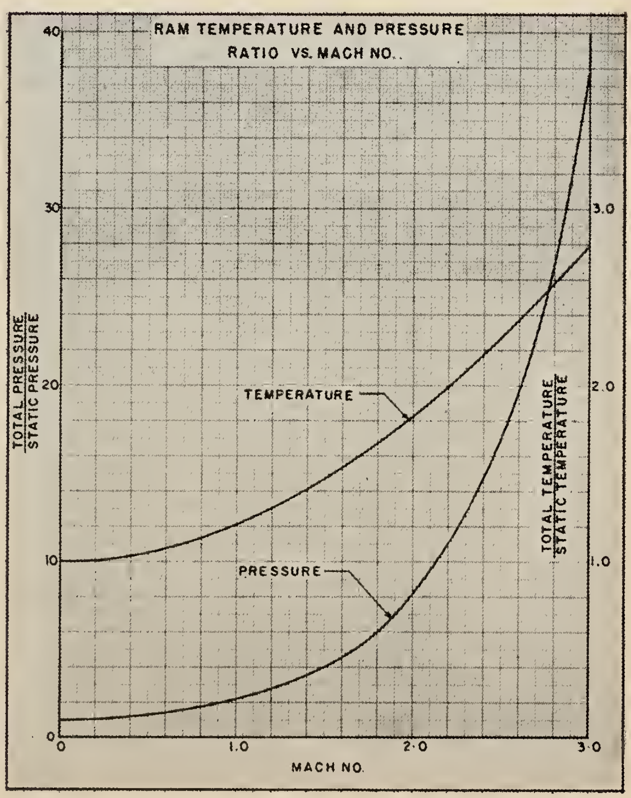

Fig. 3. (below, r.)

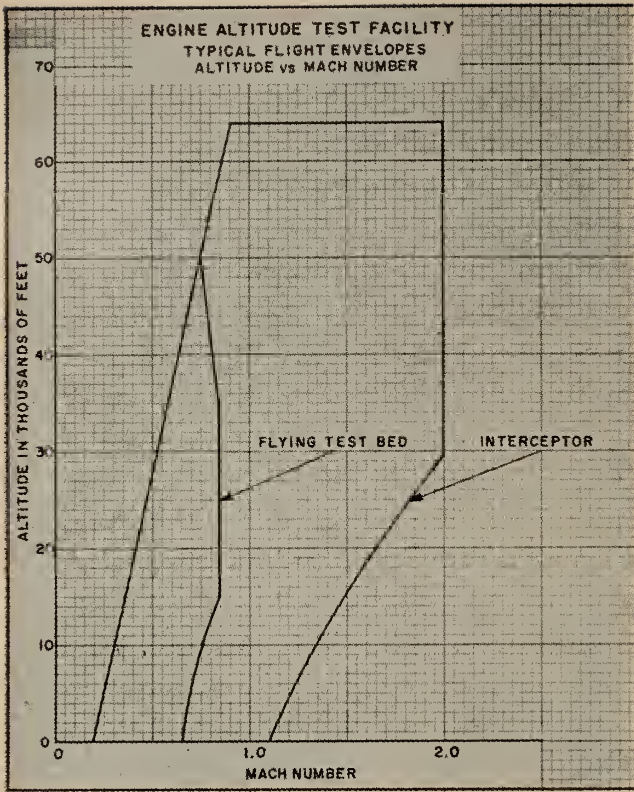

Fig. 4.

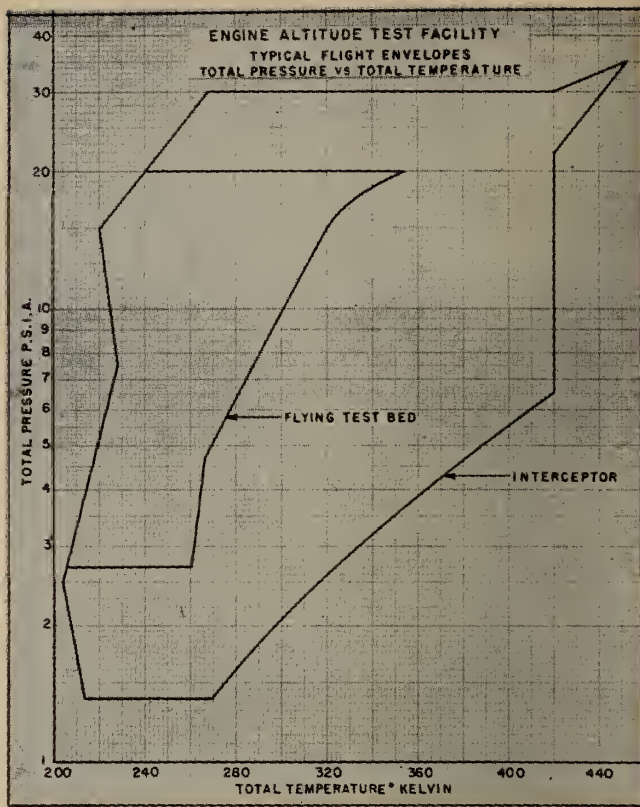

Fig. 5.

of P_1 and T_1 that would be required from a facility designed to meet this envelope. It will be noted that pressures from approximately 1.4 to 35 p.s.i.a. and temperatures from -60 deg. C. to 150 deg. C. are required.

Arrangement of Equipment

It has been stated that the basic function of the facility is the provision and control of the correct environment in the test chamber. This function is performed by various pieces of equipment and plant, operating either independently or jointly, both to condition the air delivered to the engine and create the environment into which the engine discharges. The general arrangement of the equipment may be most clearly understood by reference to the simplified flow diagram of Fig. 6. Air entering the facility may be passed directly to the test chamber to obtain the closest comparison with static test bed operation, or pre-conditioned for both temperature and pressure to simulate the requirements of flight operation. Sub-atmospheric pressures are provided by valve 'A', and pressures above atmospheric by the 'compressor set'. The air may be cooled, within the sub-atmospheric pressure range, by expansion turbines preceded by air drying equipment.

When it is required that the environmental pressure into which the engine discharges be less than 14.7 p.s.i.a., the environment is drawn down to the required pressure level by means of an 'exhauster set'. Some form of gas pre-cooler is essential from consideration of the mechanical aspects of the exhauster pumps and the volume capacity that would otherwise be involved. Any one of the five air intake routes shown on Fig. 6 may be used with the exhauster set, but routes 1 or 4 provide no temperature control and ambient or compressor delivery conditions must be accepted. Controlled pressures and temperatures, either above or below ambient, are available by selection of routes 2, 3 or 5.

The test chamber may be discharged directly to atmosphere for simulating flight at sea-level or when the engine operation is such that the final nozzle is choked and the ram pressure ratio no longer influences performance. With direct atmospheric discharge all but route 3 of the five air intake routes may be usefully selected. Route 3 would not be realistic as the inlet pressure drop, inevitable with the usual methods of cooling directly induced air, would result in a ram pressure ratio of less than unity without the exhauster set in operation.

Although Fig. 6 is entirely diagrammatic it may be employed quite usefully for visualizing the facility as two independent groups of equipment, the first concerned with conditioning the air delivered to the engine, the second with conditioning the environmental pressure into which the exhaust gases are discharged. The two groups of equipment are separated by the test chamber enclosing the engine and some form of diaphragm has to be installed to separate the two environments, intake total and ambient static, to which the engine is subjected. In this way the diaphragm also forms the physical division between the two groups of equipment and is subjected to the full ram pressure ratio applied to the engine.

It is essential that any desired pressure, within the capacity of the facility, be produced exactly, and that the set pressure be held within close limits during any transient condition of the engine or during fluctuations originating in the facility equipment. Engine environmental pressures are established by valve 'A' controlling intake total pressure and valve 'B' controlling the static pressure downstream of the test chamber diaphragm. Valve 'C' controls the inlet pressure to the exhausters and set conditions throughout are closely maintained by the addition of automatic controllers to each of these valves. With direct atmospheric discharge, it is desirable to maintain the pressure at the test chamber outlet as close to 14.7 p.s.i.a. as possible and valve 'C' is not required. The environment pressure downstream of the diaphragm is greater than atmospheric to the extent of the duct losses and these are generally of an acceptably small order.

THE ORENDA FACILITY

The preceding text has dealt solely with general principles and features. Further description must inevitably refer to the variations that are dependent upon such factors as the air pumping capacity, the equipment available, financial limitations, and the designers' or operators' preferences. The remainder of this paper is devoted to a description of the facility at Orenda Engines Limited.

Although designed for testing one of the larger of the current aircraft engines, the Orenda facility is relatively modest in scope and general size, in comparison with some of the eight similar installations known to the writer. Economic necessity has demanded many short cuts and compromises but, throughout the entire design, great care has been taken to provide for extension of the range and increase of the capacity in the future.

Comparing the simplified flow diagram of the Orenda facility (Fig. 7) with the basic flow diagram of Fig. 6, it will be noted that there are two major points of difference. Primarily, the Orenda facility does not have separate plant for pressure and suction air, and it is therefore impossible to pressurize the engine intake and simultaneously evacuate the exhaust. The single installation of motor drive units, gearboxes, and foundations for driven machinery will restrict operation to either intake pressurization or exhaust evacuation at any one time and it will be necessary to interchange compressor with exhauster units as the programme demands. The loss of flight operating range as a result of this limitation and the inconvenience of interchanging the air pumping machinery is not too severe a penalty, however, since this relatively austere arrangement provided the only way the project could be realized without prohibitive costs.

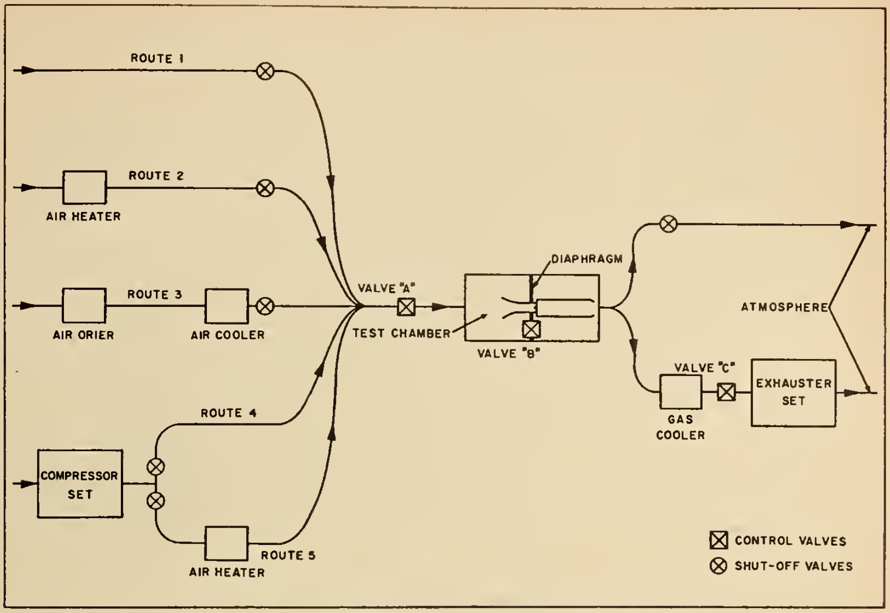

Fig. 6. Simplified flow diagram of basic circuit.

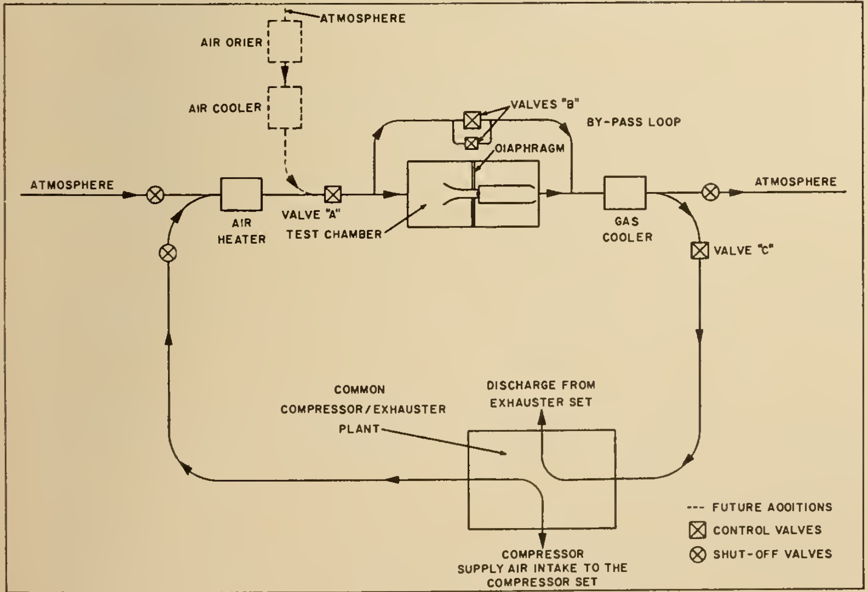
The second major difference is the introduction of a by-pass loop around the test chamber. The loop is essential for a facility that is designed to operate at constant mass flow irrespective of a changing engine demand due to variation of engine rotational speed. A constant mass flow facility was chosen because of the economy of constant speed electric motors and the way in which such a system lends itself to close control of the important parameters that affect engine performance.

When the test chamber is evacuated, air that is surplus to the requirement of the engine is spilled through the by-pass duct to re-enter the system downstream of the test chamber. Valve 'B' transferred from the test chamber diaphragm to the by-pass duct, is changed from a single small valve to two valves of different sizes, placed in parallel, to obtain fine control of the downstream static pressure within the wide range of flows involved. When air is supplied to the engine under pressure, valve 'A' is opened fully and valve 'B' then performs the alternative duty of automatically maintaining the engine intake total pressure constant by acting as a blow-off or spill-control valve.

Fig. 7. Simplified flow diagram of Orenda circuit.



General Arrangement

Figure 8 contains views of the building showing the location of equipment internally and externally. The single-story building occupies an area of approximately 40,000 square feet and is divided into the following six general areas of activity: Compressor room; plant maintenance and boiler room area; office and domestic area; storage and work area; control room; and test cell.

Two major equipment units, the 'air heater' and 'gas cooler', together with sections of the process air ducting are outside the building. The air drying and refrigeration equipment, which are scheduled for later addition to the facility, are not shown but may be located externally if the building is not extended.

Air enters the test chamber either directly from intake No. 1 or indirectly through the compressor set from the dual intakes Nos. 2A and 2B. Exhaust silencer No. 1, in conjunction with intake No. 1, is used for all operations with exhausters and silencer No. 2 is used for all other operations. The air heater, which is located in the common section of ducting leading to the test chamber, is available for heating the air whether it be supplied by the compressors or induced by the exhauster set. The 'compressor room' contains foundations and bed-rails for two strings of compressors or exhausters. Each string, which may consist of a maximum of five units arranged mechanically in series, is driven by a 10,000 h.p. synchronous motor. The two strings, which are entirely independent of one another both mechanically and aerodynamically, draw from, or supply air to, common suction or pressure manifolds connected with the test chamber. The division of the power plant into two independent groups of machinery provides the means of economically testing, within the capacity of a single string, smaller engines in the main test chamber or other test rigs that may be located in adjoining buildings in the future. In addition, the arrangement will permit continued operation at 50 per cent output during a period of maintenance or repair to one of the strings, whenever such operation is feasible.

The test chamber delivers high-temperature gases from the engine into the gas cooler, which is immediately downstream. The gases are cooled to a temperature that is acceptable to the exhauster units by the exchange of heat to circulated water and the cooled gases are then delivered to a large manifold from which separate ducts connect with the two strings of exhauster units in the compressor room. The maximum thermal capacity of the gas cooler corresponds to the maximum heat load under exhauster operation but a greater heat load occurs when air is supplied to the test chamber by the compressor set and the exhaust gases are discharged directly to atmosphere through silencer No. 2. The size and cost of this silencer would be excessive if it were required to handle the volume and temperature of gases in the uncooled state. The gas cooler is therefore used as a pre-cooler and the balance of the heat load is dissipated by direct water injection as damage would otherwise be sustained. Water injection could not be tolerated during operation with the exhauster units because of the increase of volume flow.

For better perception of the general area and features described above, Fig. 9 shows a perspective view of the region of the facility bounded by the ducting leading to the test chamber and the manifold and exhaust silencer downstream of the gas cooler.

Design features of interest are described in more detail in the following section.

Major Features of Interest — Building, Equipment and Services

The single-story building encloses a total volume of 844,300 cubic feet and a floor area of 38,570 square feet. For all structures other than the test cell, which is reinforced concrete throughout, reinforced concrete foundation walls support a steel frame superstructure which carries a 1.5 inch inner sheet and 0.250 inch outer sheet of insulated asbestos siding and pre-cast concrete roof slabs. The compressor room contains a large open pit 7 feet deep, 77 feet long and 63 feet wide that provides headroom for the intercoolers and the runs of ducting connecting the compressor or exhauster machinery and the various manifold ducts drawing from or delivering to the test chamber. Details of this pit are shown on Fig. 8. Permanent internal partition walls are of concrete block and a 120,000 cu. ft./-min. capacity ventilation system, consisting of nine extractor units driven by a total of 38 h.p., is located on the roof of the building to remove the great heat load released by equipment and ducting in the compressor room and test cell. The facility is close to domestic dwellings and offices, and much attention has been given to noise suppression. The walls and roof enclosing the test cell have been designed to provide suitable attenuation and all doors or other openings from noisy areas are suitably treated to prevent the transmission of high noise levels either outside or inside the building. The walls of the compressor room are designed for the later addition of a sound suppression medium should it be found necessary.

Air Heater

The air is heated by direct firing with propane gas as the degree of contamination of the engine air by combustion products is of an acceptably small order.

The heater is a cylindrical vessel approximately 10 ft. dia. by 15 ft. long and weighs approximately 45 tons. Propane gas is injected through burners mounted in the end cover and air enters the main shell radially through a scroll type manifold and passes into the combustion region through holes in an internal liner. Both the body of the vessel and the liner are fabricated from carbon steel. The air outlet temperature is controlled by the rate of gas injection and temperatures are automatically held to within ± 0.5 per cent of any set value by an actuator on the control valve and a control loop which senses air temperature at a point close to the engine intake.

The unit is designed for an air mass flow range of from 20 to 450 lb/sec. A maximum air outlet temperature of 330 deg. C. has been set to meet future applications of the unit.

Test Chamber

The test chamber is formed from three cylindrical sections and one conical section: the latter connects with the inlet ducting from the air heater. Each of the cylindrical sections is 20 ft. long and the screen and conical section are 2 and 15 ft. long, respectively, giving a total length of 77 ft. for the entire vessel. The internal diameter is 12 ft. and the conical section reduces to five ft. six in. to match the diameter of the inlet ducting. The cylindrical walls are one and a half inches thick in the engine section, one inch thick in the remaining two 20-ft. sections and 15/16 in. thick in the conical section. Flanges are 3-in. thick throughout.

When air refrigeration equipment is installed in the future, the chamber will be subjected to temperatures as low as -60 deg. C. and special consideration has therefore been given to the material from which it is constructed. A low (approximately 2.5%) nickel alloy steel (A.S.T.M. Spec. A.203 Grade B) has been selected to give resistance against embrittlement at these temperatures.

The engine is carried by a steel

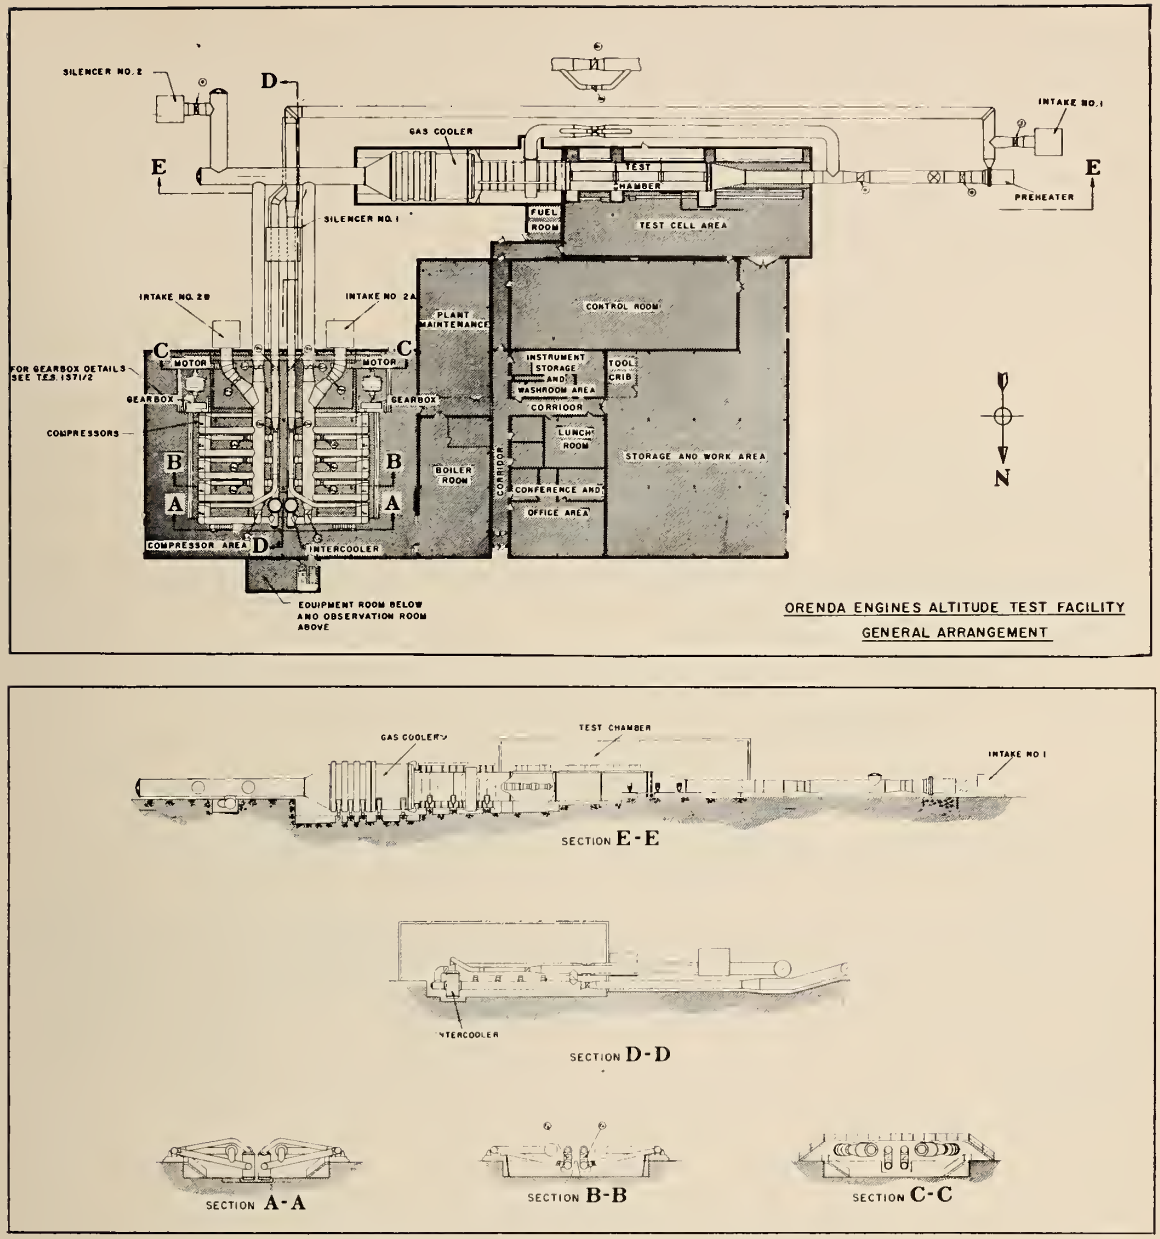


Fig. 8. General arrangement of Orenda Engines altitude test facility

framework attached to the top of the engine section of the chamber through flexible members. These members ensure that there is no restraint in the axial direction other than through the thrust measuring gear that is fitted between the supporting framework and the thrust support anchor. To provide access for installation or removal of the engine, a flange connection may be broken and the entire forward portion of the chamber rolled away from the engine section by means of a power-operated pinion driving a rack attached to the chamber. The displaced portion of the test chamber occupies a space of the test cell that is made available by the prior removal of a suitable length of small diameter upstream ducting. Manholes in the wall of the vessel allow simple adjustments or engine inspection during a test programme, and observation windows are provided for a constant watch of the engine while tests are in progress.

The engine mass flow is measured by instruments placed in a long duct that has a bell mouth opening and is attached to the engine intake. To ensure that the mass flow measurements are accurate and the engine performance is not affected by 'rig' factors, the velocity of the air passing down the test chamber must be uniformly distributed. Two heavy wire mesh screens are fitted across the diameter of the chamber between the conical and cylindrical sections and ahead of the measuring duct, to smooth out any maldistribution of the velocity.

The test chamber diaphragm is of a dished-head form and surrounds the air measurement duct attached to the engine. It is supported at the flange connection, which is split for engine access, and together with the measuring duct remains with the portion of the vessel that is removed. The chamber is supported by twenty cantilevered brackets, each carrying a roller assembly. The rollers are in contact with machined guide rails attached to structural steel beams set in foundation walls raised two feet above floor level. Between the foundation walls a trench, 13 ft. wide and sloping from a depth of 2½ ft. at one end to 6½ ft. at the other, provides clearance for the vessel and suitable drainage. When the test chamber is opened for access to the engine a false floor is introduced to span this trench and facilitate work in the area.

Gas Cooling System

The size of the gas cooler depends on two factors, the maximum heat load to be dissipated without direct water injection and the maximum gas pressure loss that can be tolerated, can be tolerated as the gases are discharged directly to atmosphere through silencer No. 2.

The cooler is divided into the inlet, furnace, cooler and outlet sections, of which the inlet and cooler sections are double-skinned to provide water jackets. The inlet section, which is of the same diameter (12 ft.) as the test chamber to which it is attached, includes an annular manifold through which the by-pass air of the dynamic head (that would otherwise be energy lost in the engine jet stream) and possibly increase the simulated altitude by 15,000 feet at low forward speeds, or increase forward speed from Mach 1.5 to Mach 1.8 at high altitudes.

The furnace and cooler sections are approximately 20 ft. in diameter and reduce, through the conically formed outlet section, to the 90-in. diameter of the downstream manifold.

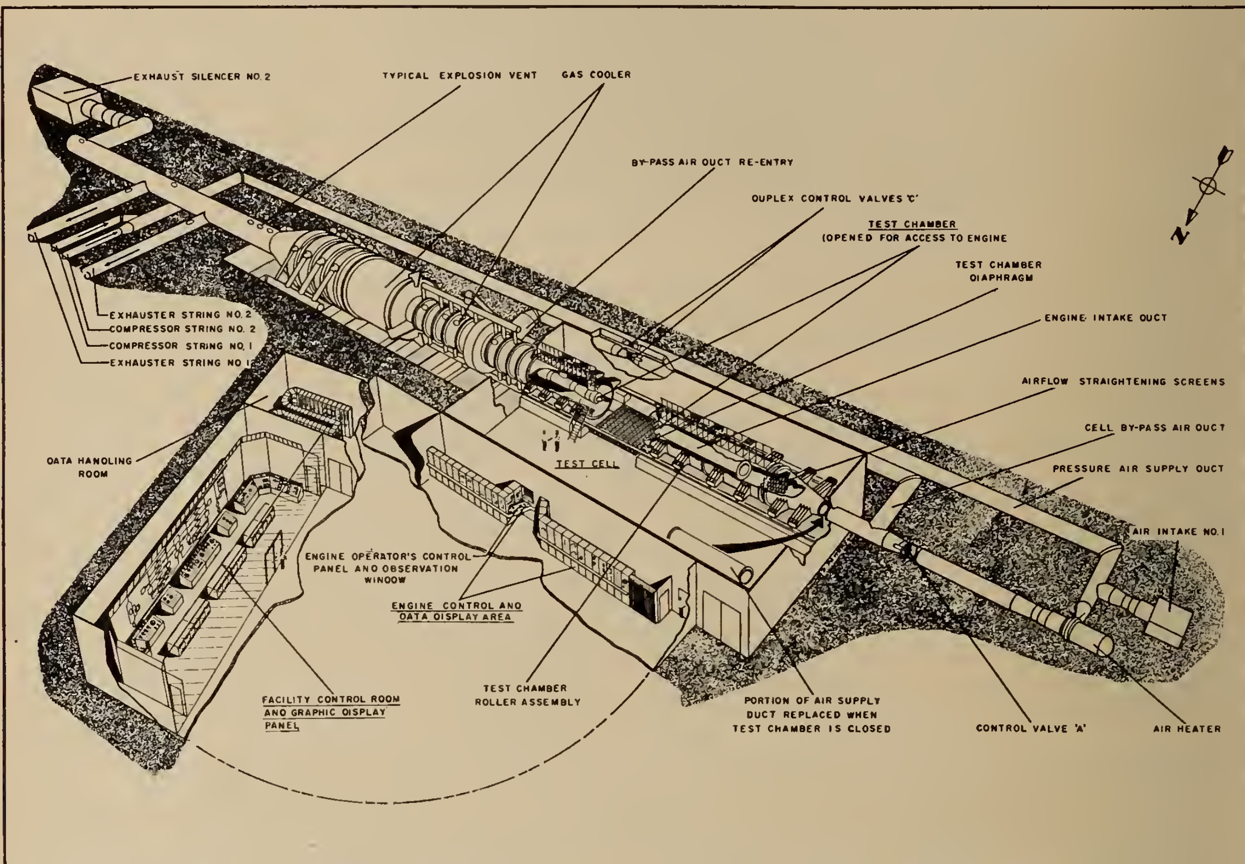

Fig. 9. General arrangement of the Orenda altitude facility, test cell, gas cooler, and control room.

also without water injection. The maximum heat load occurs under conditions of single-stage exhausting and 450 x 10^6 B.t.u./hr. results from cooling 150 lb/sec. of gas from 1770 deg. C. to 65 deg. C. The critical pressure drop occurs during two-stage exhausting and must not exceed 0.12 p.s.i. with a gas throughput of 41 lb/sec. at an inlet pressure of one p.s.i.a., the temperature drop being, as before, from 1770 deg. C. to 65 deg. C. During operations with air blown at the engine by the compressors, the mass flow may reach 450 lb/sec. and the heat load will therefore be tripled. This additional heat load is absorbed by the direct injection of water into the cooler, for in this case the increased pressure drop and gas volume re-enters the circuit. This section of the cooler performs three other important functions. Firstly, as part of the gas cooler design, it provides space for divergence of the engine exhaust jet before it strikes the first row of transverse cooling tubes. Secondly, by virtue of a short conically-formed diaphragm attachment on the test chamber and a flat plate diaphragm attachment on the main body of the gas cooler, it acts as the link in a mechanically flexible coupling unit to absorb possible axial misalignments between these two major units during operation. Thirdly, it provides space for the early inclusion of a conical diffuser at engine outlet. It has been shown by model test that such a diffuser may recover a portion

Two rows of tubes in tangential contact are placed parallel with the cooler axis around the inside wall of the furnace section to remove heat by direct radiation, and four banks of transverse tubing placed across the cooler section downstream of the furnace section remove the remaining heat by convection. Plain steel tubing is used throughout the furnace section, and a mixture of plain and finned steel tubing is used in the first rows in the cooler section. The last bank of tubes in the cooler section is a mixture of copper and copper-aluminum finned tubes.

The total water circulation rate is 11,500 Imp. gal/min. and, with a maximum inlet temperature of 85 deg. F., the water is returned to the reservoir at a maximum temperature of 150 deg. F. When direct water injection is required the consumption is expected to be 1600 Imp. gal/min.

The overall length of the gas cooler is approximately 83 ft. and the weight, under operating conditions, approximately 220 tons.

Reservoir, Cooling Towers and Water Treatment System

Heat is transferred to water circulated through the gas cooler and exhauster intercoolers and from the water to atmosphere in the cooling towers situated above the reservoir. The reservoir is totally enclosed and has a capacity of 660,000 Imp. gallons. The circulated water is treated to prevent deterioration of the heat exchangers and cooling towers and to stop the collection of slime and bacterial growth in the reservoir.

Figure 11 is a schematic diagram showing the entire circulated water system. It will be seen that the make-up water required to replace evaporative losses in the cooling towers is taken from the city water supply and is chemically treated before delivery to the reservoir. Water is drawn from the reservoir and driven through the system by two vertical turbine pumps, each driven by a 450 h.p. squirrel cage motor and delivering approximately 7000 Imp. gal. at a total dynamic head of 170 ft. Operation at extreme conditions for an appreciable period may result in the general level of temperature in the reservoir becoming too high. Rapid cooling of the reservoir water is possible with a by-pass line that circulates directly through the cooler with the facility shut-down.

The cooling towers are formed from three double sections with an induced-draught fan for each of the six single sections so that cooling air entering at the bottom flows in a direction counter to the water entering at the top. California redwood is used in the construction of the towers which have base dimensions of 90 ft. by 60 ft. and are 40 ft. high.

The water treatment system carries out the following basic functions.

(*a*) Provides a slight acidity for protection of the cooling towers.

(*b*) Reduces the calcium and magnesium content to control the deposit of scale on piping and equipment.

(*c*) Deposits a micro-film protective coating on the walls of all metal passages to counteract the corrosive effects resulting from the slight acidity introduced for protection of the cooling towers.

(*d*) Controls the formation of slime and algae in the reservoir.

The acidity is controlled to a pH value of 6.8 (acidic) to 7.0 (neutral) by the introduction of sulphuric acid through the hydrogen cycle cation exchanger. Calcium and magnesium are reduced from 97 and 30 to 0.8 and 0.2 p.p.m. respectively in the duplex unit sodium cycle ion exchanger. The hydrogen and sodium cycles operate on a split stream basis and are designed so that the correct acidity and hardness are achieved when the streams are blended at outlet.

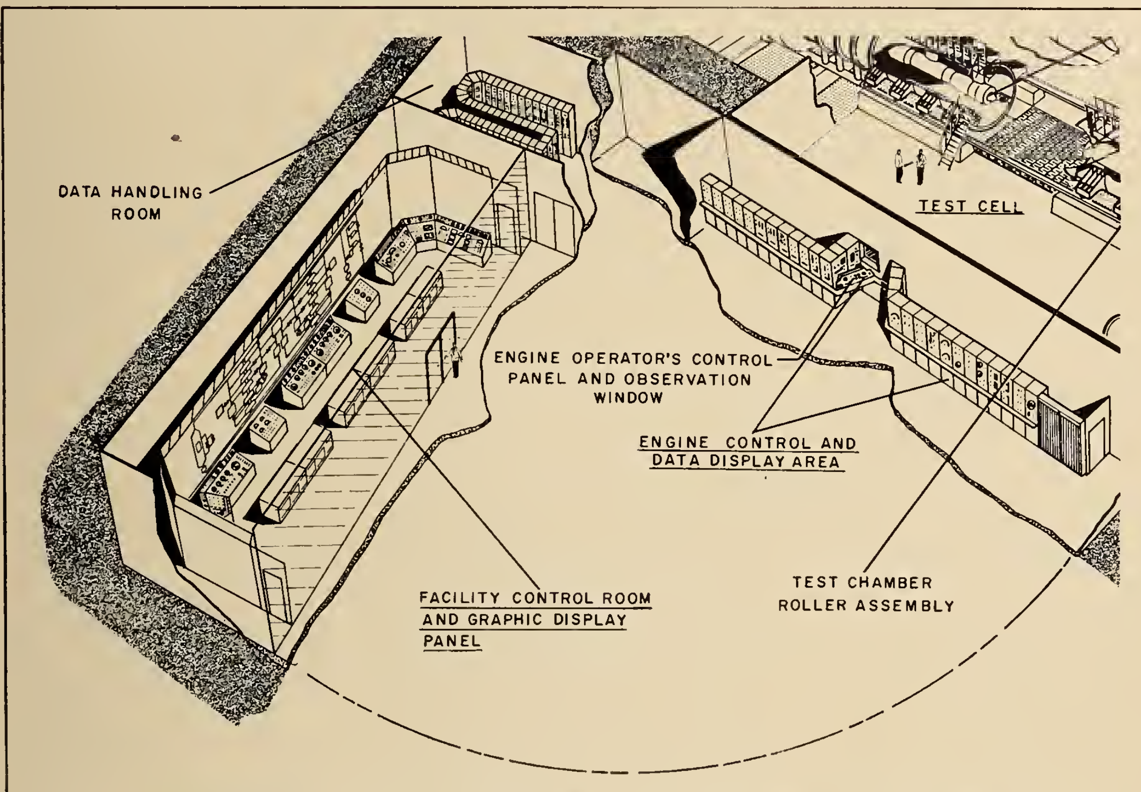

Fig. 10. General arrangement of the Orenda altitude facility control room.

Microfilm corrosion protection for the piping is provided by dosage control of polyphosphate additives introduced into the make-up water line downstream of the hydrogen and sodium cycles.

Slime and algae in the reservoir are prevented by shock treatment injection of metered quantities of chlorine in the make-up water at predetermined intervals.

Compressor/Exhauster Plant

General Description—The axial type compressors that are standard in the Orenda engine were chosen as the basic unit for both the compressors and the exhausters. These units were readily available and it was found that an inexcessive number could quite adequately cover the required range of pressure ratio and mass flow by suitably grouping them in three different configurations, each configuration covering a portion of the total operating range. Further, the compressor and exhauster units are mechanically interchangeable and differ only in the internal blading arrangement. Whereas the blading of the exhausters is identical with that of the engine from which the units are taken, the compressors contain only the first four of the ten rotor and stator blades rows to give a greater mass flow at a sacrifice of pressure ratio.

The range of flight operation is covered by two different arrangements of the exhauster units and one arrangement of the compressor units. For extreme altitudes where minimum exhaust environment pressures are required, two stage exhausting is employed to give a total pressure ratio of approximately 18:1 across the set. In this arrangement ten exhauster units are suitably ducted so that the first four in each string are aerodynamically in parallel and the fifth is in series with an intercooler between the series stages to reduce the temperature and volume of the gases. For medium altitudes, the last two units of each string are mechanically disconnected to give the larger mass flows that are required by the engine and may be derived from a single stage of three units per string with a pressure ratio of approximately 4.5:1. Thirdly, the low altitude portion of the flight envelope is obtained by replacing the exhauster units with two, aerodynamically parallel, compressor type units in each string to provide still greater quantities of air ducted to the engine intake at pressures above atmospheric.

Electric Motor Drives

The ideal form of drive would supply variable torque at any speed from zero to 7200 r.p.m. and any selected speed would have to be regulated within ± 0.5 per cent. This would probably require induction motors and a variable frequency supply would have to be obtained from alternators driven by variable regulated speed direct current motors. D.C. supply would in turn demand motor-generator sets. The constant mass flow system obviates the need for such an expensive arrangement and a constant speed drive with synchronous motors has been chosen as the most simple and economical. The supply frequency is maintained within ± 0.25 per cent so that no speed regulation is necessary. The two 10,000 h.p. motors are supplied from a common 4160 volt bus which is fed by two 10,000 kva. outdoor transformers which step-down the supply voltage from 27.6 kv. to 4160 volts. Disconnect switches enable either of the transformers to be used separately to supply part load to both drives, or to supply either drive at full load. Provision has been made for forced air cooling of the transformers and this would increase their rating to 13,333 kva. The load break switch shown on Fig. 12 will normally be open so that the 550 volt supply to the facility will be affected as little as possible by load variations on the 4160 volt bus.

Each motor must be started separately and at reduced voltage to meet the Ontario H.E.P.C. requirement that the voltage drop at the 4160 volt bus shall not exceed five per cent. Control and protection of the motors is provided by Magneblast circuit breakers with an interrupting rating of 250 Mva. The starting sequence is automatic. On pushing the 'start' button of, say, motor 'A', No. 1 start breaker closes connecting the motor through current limiting reactors. After six seconds, No. 2 start breaker closes and No. 1 opens, so that the motor then is connected through part of the reactors. After a further five seconds the 'run' breaker closes and No. 2 opens, connecting the motor at full voltage. The periods are selected to allow sufficient time for the H.E.P.C. tap changing mechanism at the distribution centre to increase the supply voltage. When the motor has reached approximately 97 per cent full speed, the d.c. excitation is applied automatically. Two separate 60 volt d.c. motor-generator sets provide excitation of the rotors and overvoltage can be supplied for a period of one minute. If motor 'A' is running under load when motor 'B' is starting, the field of 'A' can be forced to counteract the tendency to pull out of synchronism as a result of the drop in supply voltage.

The two 10,000 h.p. motors rotate at synchronous speeds of 1200 r.p.m., have a power factor of 1.0, and are supplied with 3-phase 60-cycle current at 4160 volts. The locked rotor torque is approximately 50 per cent and the pull-out torque is 150 per cent with normal line reactance. Control circuits include protection against overcurrent, undervoltage, automatic reclosure of breakers, circulating currents, overheating, and incomplete starting sequence.

Gearboxes

A single-ratio speed-increasing gear unit is used in each string of compressor/exhauster units to step-up the synchronous speed of the 10,000 h.p. electric motors from 1200 r.p.m. to 7223 r.p.m., the design point speed of the driven machinery.

Double helical involute form spur gear teeth are used and the pinion is cut from a solid high-grade steel forging that is integral with the shaft. The low speed gear is fabricated from a carbon steel rim shrunk on a carbon steel hub and the teeth are cut with full face contact.

The casing is split at the centreline of the gears, and supports steel-backed, babbit-filled, horizontally-split sleeve bearings that may be removed without disturbing the gears. The force-feed lubrication system is self-contained within the gear unit and the oil is cooled by water in an external tubular type heat exchanger.

Intercoolers

The function of the intercooler is to reduce the temperature and volume of the air, that has been compressed in the first stage exhausters, to conditions that are acceptable to the second stage. An identical unit is installed in each of the two independent strings of machinery located in the compressor room.

The main shell of each unit is a cylinder 5.5 ft. in diameter and 8 ft. long mounted with the axis of the cylinder vertical. Double-pass banks of finned tubing are supported from the top of the shell and sealed at the bottom with a floating diaphragm. Dished heads are used to close each end of the vessel, and the upper head is divided to serve as a combined inlet and outlet manifold for the water circulated through the double-pass banks of tubes.

Air flows across the tube coils, at right angles to the cooler axis, between inlet and outlet headers attached to the walls of the vessel. The first six rows of finned tubing are copper and the remaining fourteen are aluminum with copper lining.

Each cooler is designed to dissipate 12.7×10^6 B.t.u./hr. using approximately 400 Imp. gal/min. of treated water entering at 85 deg. F. The maximum airflow capacity will be 41 lb/sec. at 7.8 p.s.i.a. and the air will be cooled from 265 deg. C. to 65 deg. C. The air pressure drop is a maxi-

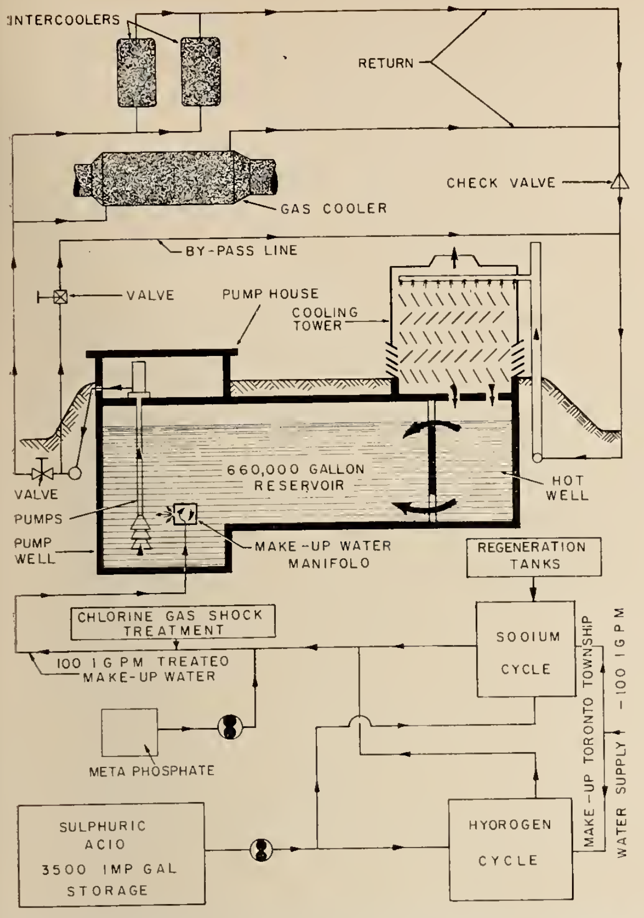

Fig. 11. Schematic of the circulation through water cooling and water treatment system in the Orenda altitude facility.

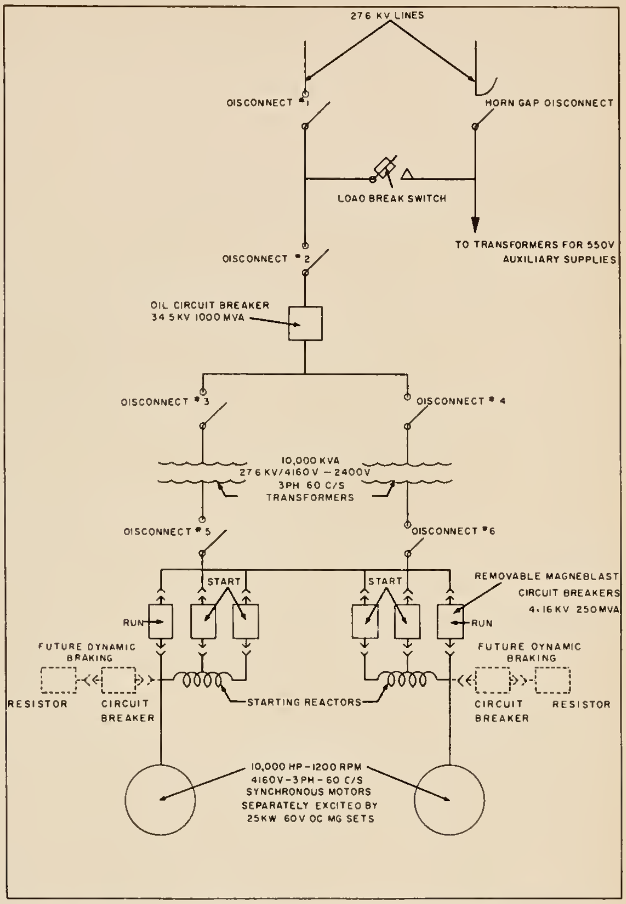

Fig. 12. One line diagram of electric power supplies to 10,000 h.p. motors in Orenda altitude test facility.

mum of 0.18 p.s.i. at 21 lb/sec. throughput and 3.7 p.s.i.a. inlet pressure.

Mechanical Installation of the Compressor/Exhauster Units

To protect the compressor or exhauster set from a two-phase to ground short of the driving motors, a shear coupling between each motor and gearbox is designed to fail at a torque that will be 50 per cent greater than that which will result from the emergency use of aerodynamic braking. Aerodynamic braking can be applied by the rapid operation of control valves to increase the air load, and a reduction from 7000 to 1000 r.p.m. in three seconds is possible.

The driven units of each string are mounted from two pairs of 45-ft. long structural steel bedrails, machined on the top surface to carry support plates, and set in a continuous, reinforced concrete foundation. Two pairs of support legs are mounted on the bedrails for each unit and carry, through trunnions, two heavy cast rings within which the unit is is supported by means of six tangenial links at the fore and aft planes. Two axial links on the forward ring take the small axial thrust. All links are adjustable and provide for the maintenance of concentric alignment of the units within the rings, as set up under assembly shop conditions, irrespective of thermal expansions during operation. Axial and transverse forces resulting from air pressure and ducting loads are transferred through trunnion brackets on the support rings to the support legs and foundation rails.

The driving torque is transmitted from the gearbox to the first unit, and between each of two succeeding units of the string, through a short shaft with a toothed coupling at each end to provide the required flexibility at each connection.

A perspective view of the mounting arrangement described above is shown on Fig. 13.

Control System

The control system is required to carry out the following functions:

(*a*) Control of inlet pressure and temperature to the test chamber.

(*b*) Control of static pressure at outlet from the test chamber.

(*c*) Maintenance of constant mass flow for any given simulated flight setting of the facility.

(*d*) Prevention of 'surge' either of the compressors or exhauster units.

(*e*) Programme control for starting and shutting-down the compressor/exhauster plant.

(*f*) Aerodynamic braking of the compressor/exhauster plant.

Items (*a*) and (*b*) concern the engine environment and (*c*), (*d*) and (*e*) are directly associated with control of the compressor/exhauster plant. These two systems are described separately below.

Engine Environment Control System—Three valves are used to control the engine environment. The function of valves 'A' and 'B' (Fig. 7) have been described previously but to recapitulate briefly, valve 'A' governs the total pressure delivered to the test chamber and valve 'B', located in the by-pass duct, controls the static pressure into which the engine discharges. When air is supplied to the engine at pressures greater than atmospheric, valve 'A' is fully opened and valve 'B' then governs the inlet pressure by controlling the amount of air spilled through the by-pass. Inlet temperature to the test chamber is controlled by the third valve which governs the rate of injection of propane gas into the air heater.

Better appreciation of the pressure control system may be gained by considering the action of the two valves during an engine acceleration from half to full speed at any given simulated flight condition of altitude and forward speed. The period involved may be two to three seconds, and the environmental conditions at the engine intake and exhaust will have been established at the start of the acceleration. It is the function of the control system to maintain these conditions as closely as possible as the engine accelerates. The engine air consumption increases as the fuel control throttle is opened, but with a constant facility mass flow system the total flow through valve 'A' will remain approximately constant whilst the proportion of the total flow that is by-passed through valve 'B' will decrease progressively. Small changes of the engine upstream total pressure due to the transient operation will be sensed and compensated by rapid automatic action of valve 'A'. As a result of the reduction of by-pass airflow and the maintenance of a constant upstream total pressure, the static pressure downstream of valve 'B' will increase if the valve position remains unchanged. Valve 'B' responds to the downstream static pressure and restoration of the preset value of this pressure and, in consequence, the ram pressure ratio across the engine, is accomplished by progressive closing of the valve.

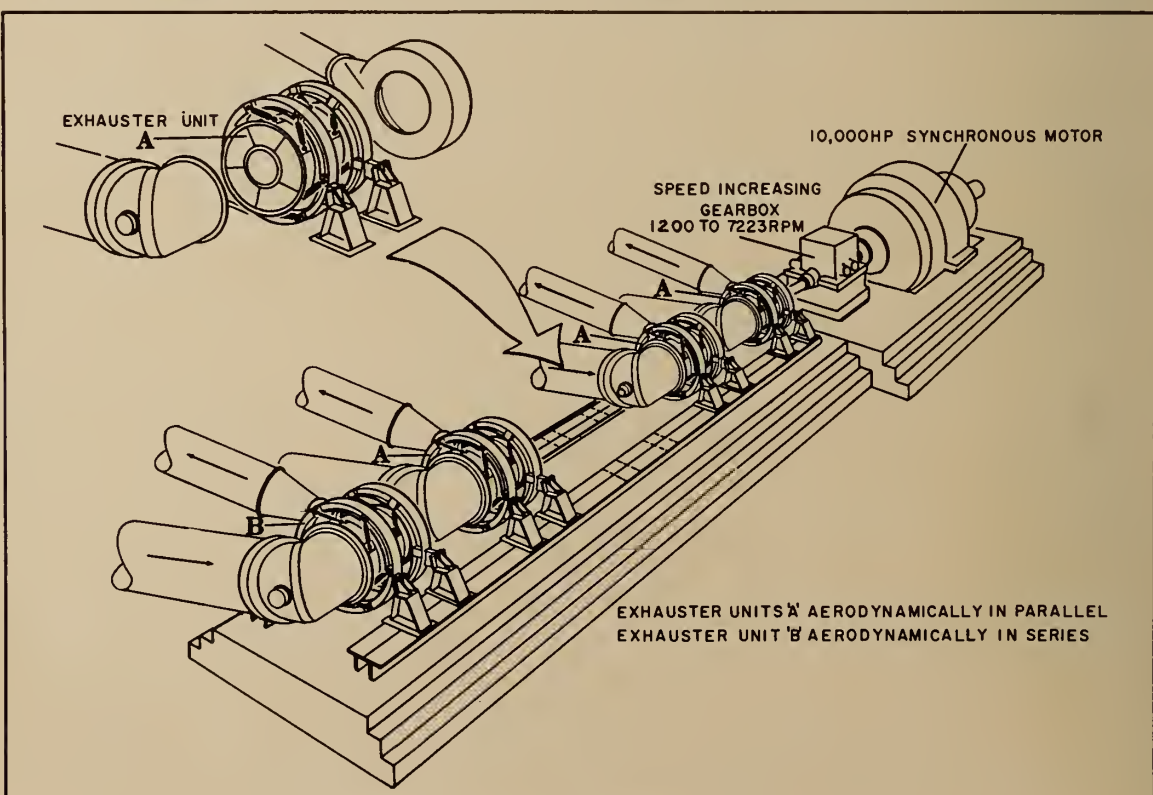
The initial installation will permit the study of performance during engine transient conditions but not during flight-transients (trajectories) of forward speed and altitude. The design does, however, provide for this extension of scope in the future.

Compressor/Exhauster Set Control System—Figure 14 is a schematic diagram of the compressor/exhauster plant showing the location of control and configuration valves in the ductwork connecting the units.

The air mass flow induced by the exhausters, when operating at a fixed rotational speed and discharging to atmosphere, is dependent upon the temperature and pressure of the air at intake. The inlet temperature is held constant by the gas cooler and small variations have little effect. The inlet pressure is controlled automatically to a preset value by valves 'C', and this control therefore holds the air mass flow constant for the selected operating condition.

The Ontario H.E.P.C. requirements for voltage regulation make it necessary that the two 10,000 h.p. motors be started at reduced voltage, and the incoming current limiting reactors are cut out in two steps. To prevent burning out the starting windings it is essential that the motors reach synchronous speed as rapidly as possible. To resolve these two conflicting demands, the aerodynamic load imposed by the exhausters during the start-up phase is kept as low as possible. To obtain minimum start-up loads the pressure ratio of both the first and second stages of exhausters is controlled according to a preset programme in terms of rotational speed. The characteristics of the exhauster units are such that minimum load is achieved with maximum pressure ratio and it is therefore desirable to hold the operation as close to the surge line as possible. Maximum pressure ratio is achieved with minimum inlet pressure and during start-up with either single-stage or two-stage exhausters valves 'C' are kept closed. During single-stage exhausting (three units in parallel) valves 'M' are programmed to open just sufficiently to keep the units out of surge as they accelerate. With two-stage exhausting, valves 'L' and 'F' are programmed to allow a controlled proportion of the flow

Fig. 13. Arrangement of one string of exhausters and driving equipment in the Orenda altitude facility.



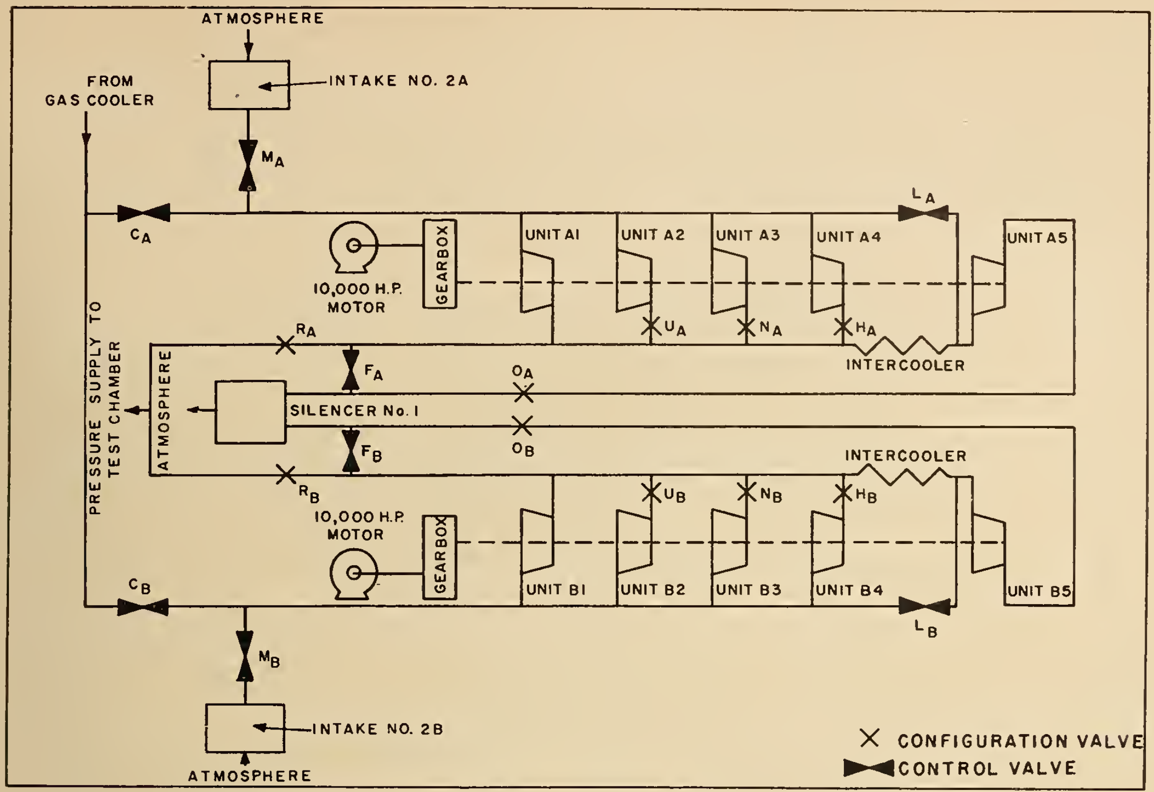


Fig. 14. Compressor/exhauster set control system, schematic diagram.

to be recirculated through the first and second stages respectively and maintain, as before, operation close to surge.

Throughout the start-up phase the programme control cannot take effect until the volume upstream of the compressors has been drawn down to the correct pressure level by the exhauster units. The duct lengths have been kept to the minimum to enable the volume to be evacuated as rapidly as possible. The programmed control used during this start-up procedure is applied when the motors are shut-off to maintain similar operation, in relation to the surge line, during the run-down.

During steady running, it is possible that, for some reason such as mishandling of the facility, the compressor or exhauster units may go into surge and create a condition that could cause considerable damage to the units and associated equipment. The first stage of exhausters is protected by the automatic opening of valves 'M' to increase mass flow and bring the operating point away from surge when a pre-set limiting pressure ratio is reached. Valves 'C' are locked open to counteract the automatic tendency to close and re-establish the lower intake pressure. The second stage exhausters are protected by valves 'F' which open automatically to recirculate when a limiting pressure ratio is reached.

Rapid deceleration of the set is possible by increasing the aerodynamic loading either by increasing the inlet density or increasing the pressure ratio across the set. During exhauster operation, the load is increased by programmed opening of valves 'M' to increase the inlet density. The compressors draw from atmosphere and as the inlet density cannot be increased in this case, the load can only be increased by outlet throttling through valve 'A'. The tendency to surge during the rapid deceleration is counteracted by valves 'L' that are operated on a programmed basis to recirculate controlled quantities of air through the compressors and intercoolers. Any one of four different rates of deceleration may be selected for emergency use either with compressors or exhausters installed.

Butterfly valves are used throughout the entire control system including valves 'A' and 'B' in the test chamber area. All valves other than the two valves 'B' are tight shut-off and neoprene seats are used wherever temperatures are less than 100 deg. C.; for greater temperatures piston ring seals are used. The valves are operated by hydraulic actuators through electro-hydraulic servo-valves integral with the main valve and supplied with hydraulic oil at 3000 p.s.i. through a check valve and accumulator. One 30 h.p. (15 g.p.m.) hydraulic pumping unit serves each exhauster string and valves 'A' and 'B' are served by 10 and 20 h.p. units respectively.

Control Room

The control room is shown in perspective view in Fig. 9 and 10. From this room, which is virtually the nerve centre of the entire facility, signals are transmitted and received to govern and report the state both of the process air system and the test engine as follows.

1. (*a*) Control of the process air system and equipment.
   (*b*) Monitoring of signals received from the process air system and equipment.
2. (*a*) Control of the test engine.
   (*b*) Monitoring signals from the test engine.
3. Handling and recording of data originating at the test engine.

It is essential that there be close co-operation between the groups of operators responsible for the three

Spouting of Large Particles

C. B. Cowan, W. S. Peterson, and G. L. Osberg

Division of Applied Chemistry, National Research Council

Read at the 71st Annual General and Professional Meeting of the Engineering Institute of Canada, Banff, Alta., June 1957.

Revised paper received 7 October 1957

The recently discovered method of gas-solid contact called "spouting" are reviewed and compared with firmly established operations such as fluidized and moving packed beds. Experimental data obtained from the drying of wood chips are used to illustrate one of its potential applications to large particle sizes.

THE SPOUTING bed method of contacting gas and granular solids has recently been described by Mathur and Gishler.[4] This is a new development which has potential application to the drying or chemical treatment of large particles which normally fluidize poorly, if at all. This paper will review the properties of a spouted bed, compare them with similar properties of the closely related fluidized bed. The results of experiments with the spouting of cellulose acetate and wood chips will then be presented.

Fluidized and Spouted Beds

The fluidized bed is a gas-solid method of contacting which is very extensively used in chemical reactors employed in the petroleum refining, chemical processing, and metallurgical industry. It is obtained by passing a fluid up through a bed of powder at a velocity which suspends part of the bed on the fluid stream. Turbulent mixing of the powder and fluid will then occur. Diagram A in Figure 1 illustrates diagrammatically a fluidized bed. Here a bed of fine powder is depicted as undergoing a motion within a vessel as a result of gas flowing up through its porous bottom. Such a bed provides excellent gas-solid contact, and hence is efficient for chemical reactions involving such heterogeneous systems. Its pseudo-fluid behaviour makes the addition and withdrawal of powder from the vessel quite easy. Particle sizes used in fluidization are usually in the range 60 to 325 Tyler mesh, though particle sizes up to ¼ inch have been reported.

Larger particle sizes than ⅛ inch, however, exhibit poor fluidizing behavior. Such coarse particles tend to slug, a condition caused by the formation of excessively large bubbles within the bed. This slugging results in poor mixing within the bed and less uniformity in the properties of the bed.

It was the "slugging" behaviour which Mathur and Gishler [4,5] encountered when trying to fluidize wheat in a 6-inch diameter column, and which they avoided by modifying the air inlet so as to produce a well-defined air lift core up the centre of the bed. The particles carried up the core appeared at the top as a fountain, then fell back on to the bed, moving down the annulus as a loosely packed bed. The bed particles thus go up the spout and down the annulus, migrating as they descend back into the spout. Particle motion within the annulus is streamline and without lateral mixing; in this respect it is unlike the fluidized bed, where more random motion of the bed particles leads to lateral as well as longitudinal mixing. Diagram B, in Figure 1, illustrates a spouted bed. Diagram C illustrates a conventional moving packed bed[9] which is similar in many respects to the annulus section of the spouted bed. In all cases addition and continuous withdrawal of bed particles can be arranged.

Pressure Drop-Flow Relationship

The pressure drop versus flow relationship is illustrated in Figure 2. Curve A is a generalized plot for a fluidized bed, and curve B for a spouted bed. The initial section 1-2 of curve A is typical for a packed bed and can be predicted from a modified Carman-Kozeny equation for fixed beds. At 2 the pressure drop across the bed deviates from linearity and corresponds to the beginning of expansion of the bed. At 3 fluidization begins, and at 4 the whole bed is fully fluidized. As the flow is increased motion becomes more violent, but pressure drop remains constant and is equal to the weight of the suspended bed.

In curve B, the section 1-2 corresponds to a flow through a packed bed. At 2 there is sharp expansion in the bed as an internal spout forms at the inlet. The internal spout increases in size, and at 3 breaks through the top of the bed. This point is defined as incipient spouting. Further increases in flow cause a slight drop in pressure to 4. The pressure drop for a spouted bed is lower than it would be for a fluidized bed of the same height simply because part of the air flow by-passes through a large hole in the bed. With wheat, for example, about 60 per cent of air flow is through the annulus, and 40 per cent through the core. On reducing the air flow the pressure relationship follows 3′-1. At 3′ the spout has collapsed

Section 1′-2′ is the relationship for a loosely packed bed. The difference in Δp vs. G relationship between fluidized and spouted bed is due to the formation of the spout and, as the bed height reaches the maximum spoutable height, the two curves become much alike.

Minimum Spouting Velocity

The conditions of inlet air diameter, air flow rate, bed depth, and particle size necessary for spouting are critical. For a particular particle size and column diameter, there is a maximum inlet air size beyond which spouting does not occur. The maximum bed depth to which a certain material can be made to spout is also limited and depends on the column diameter and inlet air size.

The minimum amount of air required to cause spouting has been determined under a variety of conditions by Mathur and Gishler and by Thorley et al.[4 8] Particle sizes ranging from 0.025 to 0.25 inch have been spouted in 6, 12, and 24 inch diameter columns. Materials such as wheat, rice, gravel, peas, etc. have been spouted in air and water. They have proposed the following correlation:

$$V_s = \left(\frac{d_p}{d_c}\right)\left(\frac{d_i}{d_c}\right)^n \left(\frac{2gL(\rho_s - \rho_f)}{\rho_f}\right)^{1/2} \quad (1)$$

where n = 0.23 for a 45° cone
= 0.13 for a 85° cone
V_s = min. flow required for spouting
d_p = diameter of particle
d_c = diameter of column
d_i = diameter of inlet orifice
L = depth of bed
ρ_s = absolute density of solid
ρ_f = density of fluid

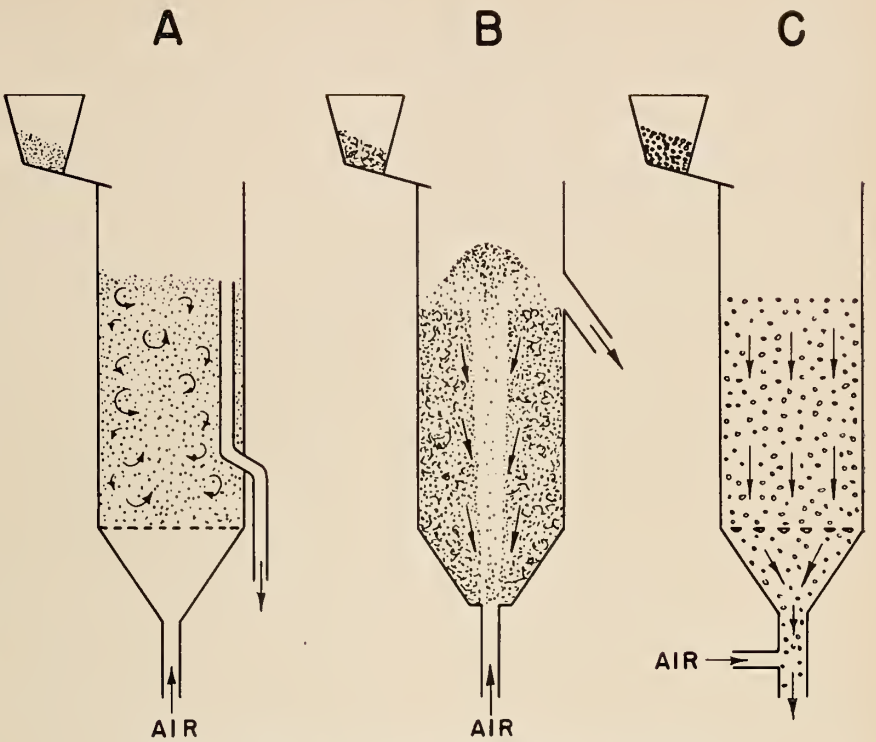

Fig. 1. Diagrammatic fluidized, spouting, and moving beds.

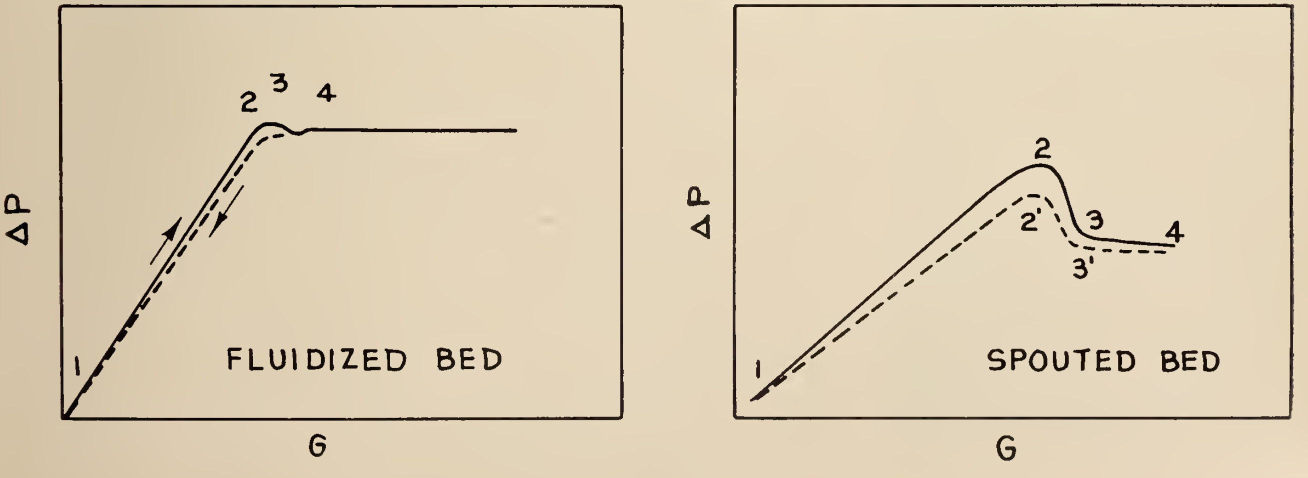
From this formula an estimate of the minimum gas velocity required for spouting can be made for materials whose properties are within the range of the variables on which the correlation is based. In practice, a gas velocity about 10 per cent larger than calculated should yield satisfactory spouting.

Heat and Mass Transfer

In the particle size range 40 mesh to ⅛ inch, a bed of powder can be fluidized or spouted although, as noted earlier, fluidization will be poor. Nevertheless, a useful comparison of such properties as heat transfer and mass transfer can be made between the two modes of bed agitation.

In the case of heat transfer between a bed and a heated wall, the heat transfer coefficients are substantially higher for a fluidized bed than for a spouted bed. In Figure 3, some comparative data by Klassen and Gishler[2] are given. For a fluidized bed of Ottawa sand (20-30 mesh), the maximum value was about 40 Btu/hr/sq. ft./°F. as compared with a maximum of about 10 Btu/hr/sq. ft./°F. for a spouted bed of the same sand. Similar data are given for wheat

Fig 2. Pressure drop (ΔP) *v.* mass flow (G) relationship for fluidized and spouted bed.



and rice. The higher heat transfer values for fluidized beds are probably due to the higher particle velocities and greater particle mixing at the wall.
