MEET THE AUTHORS

J. W. Dolphin, M.E.I.C., Head, department of civil engineering, Royal Military College of Canada, Kingston, Ont. *(Demonstrations of Plastic Behaviour of Steel Frames).*

Prof. Dolphin graduated from the University of British Columbia in 1937 with a B.A.Sc. degree in civil engineering.

Until the beginning of World War II he was employed by the Hydrographic Service. During the war, he served the R.C.A.F. as a works officer and later as navigator. He returned to Canada in 1946 and was appointed lecturer at the University of Manitoba. Upon obtaining a M.Sc. degree from the University of Minnesota in 1948, he was named assistant professor of civil engineering at the University of Manitoba. In 1952 he joined the staff of the Royal Military College in his present position.

Robert F. Legget, M.E.I.C., Director, Division of Building Research, National Research Council of Canada, Ottawa. *(The Cost of Housing).*

Born in Liverpool, England, Mr. Legget graduated from the University of Liverpool in 1925 and received the degree of master of engineering from the same institution in 1927.

On his arrival in Canada in 1929, he joined the Power Corporation of Canada. He was engaged in heavy construction engineering until 1936, when he entered the educational field. After remaining on the staff of Queen's University for two years, he transferred his services to the University of Toronto, where he was successively assistant professor, then associate professor and consultant on soil and foundation problems. In 1947 he was appointed by the National Research Council to head the new Division of Building Research, of which he has been the director ever since.

Mr. Legget is an Honorary Fellow of the Royal Architectural Institute of Canada and of the Ontario Association of Architects; he is also a Fellow of the Royal Society of Canada and of the Geological Society of America, and has served the Toronto and Ottawa branches of the Engineering Institute as chairman.

F. L. Lawton, M.E.I.C., Chief Engineer, power department, Aluminum Laboratories, Montreal. *(Underground Hydro-Electric Power Stations).*

Mr. Lawton graduated from the University of Toronto in 1923 with a B.A.Sc. degree in electrical engineering. In the course of his career, he was associated, during the first eighteen years, with the Canadian Westinghouse Company Limited at Hamilton, following which he joined the General Electric Company at Schenectady, N.Y., on a test course. In 1925 he joined the Quebec Development Company, resigning in 1927 to accept a position with the Duke Price Company Limited as assistant to the superintendent of operations. In 1937 he was appointed chief engineer of Saguenay Power Company Limited, successor to the Duke Price Company.

He joined the Aluminum Company of Canada Limited as assistant chief engineer in 1941, and was named to his present post with Aluminum Laboratories in 1948.

Mr. Lawton is a past chairman of the Saguenay and Montreal branches of the Engineering Institute, a Fellow and past vice-president of the American Institute of Electrical Engineers, and past president of the Canadian Electrical Association.

It's FORANO for GEARS of every type

The production of long-wearing, high quality gears is a specialty of Forano. Evidence of this is the fact that Forano was the *first in Canada* to install the Sykes method of continuous tooth herringbone gear generation and the *first* to adopt the electronic control gear flame-hardening process.

Today, Forano has one of the most modern, completely equipped gear shops in Canada with a full range of cutters and hobs for 14½ and 20 degrees. Forano also has a reputation for "on-time" delivery. We would be pleased to quote on your next gear requirement, without obligation.

Underground Hydro Electric Power Stations

F. L. Lawton, M.E.I.C. *Chief Engineer,*

Power Department, Aluminum Laboratories Limited

Read at the 72nd Annual General and Professional Meeting of the Engineering Institute of Canada, Quebec City, May 1958

THE paper deals with underground power plants, mostly hydro-electric, a notable development since World War II. Numerous underground hydro-electric power developments had been successfully completed and placed in service prior to World War II but most of these were located in Europe, although three early examples were located in the U.S.A. Since the war, the number of underground power plants has increased very materially. All of these have been built for economic reasons. The underground power plant has become a classic type, with a substantial influence on conventional power developments.

It is the purpose of this paper to explain why the underground hydro-electric power plant is being so widely adopted today, all over the world.

The historical development of underground hydro-electric power plants is briefly reviewed; reference is made to thermal and nuclear types of underground power stations. After dealing with the extent of present application, the reasons for this type of hydro-electric development and the economics thereof are reviewed. The impact of modern excavation methods is discussed.

In order that necessary background can be provided, the paper deals briefly with the typical elements of underground power plants. The significance of the geological formation is then considered. Attention is devoted to some special design considerations, following which operating experience is discussed.

The paper closes with a brief review of certain outstanding underground hydro-electric plants.

Historical Development

As far as known, the first development of waterpower underground was effected at Le Locle in Switzerland over a century ago, where a mill was established in a cavern on an underground stream.

About 1889 what may have been the world's first underground hydro-electric power development was installed in one of the mines of the Comstock Lode at Virginia City, Nevada. This plant comprised six 40-in. impulse waterwheels operating under a vertical head of 1680 ft., each wheel being directly connected to an electrical generator, the output of which was supplied to the mill a short distance away. The underground development received water which had been previously utilized to drive a Pelton wheel on the surface under a head of 460 ft. The discharge from this unit was conveyed through a pipe installed in the Chollar shaft to the underground station at the level of the Sutro tunnel. Some 400 h.p. was developed by this plant which rendered reliable and economic service for some two years before being supplemented by a somewhat similar plant. This latter consisted of a 36 in. diameter impulse wheel operating under a head of 2100 ft., of which 460 ft. was obtained from the pipeline of the surface plant previously noted and the remaining 1640 ft. from the drop through the Chollar shaft to the Sutro tunnel level. The impulse turbine was directly connected to an electrical generator, the output of which was supplied to the mill. (1) (2)

The Snoqualmie Falls Power Co. completed its Snoqualmie Falls development in the State of Washington, U.S.A., in 1899. This plant appears to have been the first truly underground hydro-electric power plant, designed as such. The intake is constructed about 300 ft. upstream from the brink of the 270 ft. high falls. After passing through a trash rack the power water is conveyed by two 7.5 ft. diameter penstocks to four generating units housed in a cavern 200 ft. long, 40 ft. wide and 30 ft. high, excavated in hard basalt with no regular cleavage. Water discharged from the Doble 2500 h.p. turbines, each consisting of six tangential jet wheels, with two nozzles per wheel, is returned to the river at the foot of the falls through a short 12 ft. wide by 24 ft. high tailrace tunnel. The output of the four 1500 kw., 3-phase, 300 r.p.m. 1000-volt, rotary-armature generators, excited by separate waterwheel-driven exciters, is conveyed to step-up transformers near the head of the vertical shaft. Here the 1000-volt generator output was originally stepped up to 29,000 volts for transmission some 31 miles to Seattle and 45 miles to Tacoma. Incidentally, this transmission was over stranded aluminum conductors.(3) The Snoqualmie Falls development, in its essentials, is very similar to many of the underground power developments which have since been constructed in Sweden.

The next underground plant appears to have been a small one (700 kw. in two units) at Fairfax Falls in Vermont, completed about 1904, destroyed by collapse in 1927.(13) This was followed by a plant at Breckbergmuehle in Germany, completed in 1907. This was a small power plant, with one pressure shaft supplying six Francis turbines at ratings from 930 to 1300 h.p., operating under a static head of 203 to 215 ft., with the discharge channel being an unlined grade tunnel 3600 ft. in length.

In 1910 the Mockfjard underground hydro-electric plant was placed in service in Sweden. This plant contained four horizontal Francis turbines, with a total capacity of 12,000 kw. under a static head of 79 ft., in a powerhouse cavern having a length of 105 ft., width of 31 ft. and height of 36 ft. It was soon followed by the notable Porjus development on the Lule River in Sweden, above the Arctic Circle, constructed during the years 1910-1914. Here two 538 square feet pressure conduits, one 1710 ft. and the other 2200 ft. in length, supply an open forebay from which vertical pressure shafts, or penstocks, convey the water to eight Francis turbines with a total capacity somewhat in excess of 100,000 h.p., under a static head of 184 ft. The discharge from the turbines is returned to the Lule River through two grade tunnels, each with a cross-sectional area of 540 sq. ft. and a length of 4270 ft. This development, in a granite formation, has been trouble-free throughout its existence.

The Pacific Gas and Electric Co. placed its Spaulding No. 1 underground hydro-electric plant in service in 1917, with one vertical Francis turbine operating under a static head of 197 ft. This plant has an output of 6400 kw. in a powerhouse cavern measuring 85 ft. in length by 30 ft. in width and 60 ft. in height.[13]

The nearest Canadian approach to the present-day underground power plants are the Toronto and Rankine developments at Niagara Falls. In the latter, the turbines are located in a wheel pit 171 ft. below the generator floor, with the discharge from the wheels flowing through a tailrace tunnel 2164 ft. in length. While the turbines themselves are underground, the generators are above ground.

Extent of Present Underground Power Developments

Today almost 300 underground hydro-electric power plants are in service or under construction, with an installed capacity of about 31,000,000 kw. Many more are planned, with an installed capacity of approximately 30,000,000 kw.

Underground hydro-electric plants have been widely built in Norway, Sweden, Switzerland, France, Italy and Yugoslavia. They have been constructed in at least 29 countries and this number will shortly be materially increased.

There are 60 underground hydro-electric power schemes in service in Italy,[20] with eight under construction. By 1960 the total underground capacity is expected to be 4,500,000 kw. or some 30 per cent of the total capacity for the country. Italy leads the world in number of underground plants despite very poor geological formations embracing badly faulted and jointed sedimentary and metamorphic rocks, with heavy percolation of water.

Sweden is probably second in number of underground power plants, with 26 in service having a total capacity of 2,700,000 kw. or about 50 percent of the total for the country. Another 18 plants are under construction, which will add about 2,000,000 kw. capacity.[16] By contrast with Italy, geological formations are generally good to excellent, although far from universally so.

Norway, as of 1956, had 26 underground hydro-electric plants in service, with a total capacity of 1,381,000 kw. Twelve more were under construction. Full capacity of the 38 stations will total 2,370,000 kw.

Where the underground hydro-electric plant matches geological and economic requirements, neither geography nor climate affect their use. Such plants have been built in the far north, well above the Arctic Circle, examples being the Porjus and Harspranget developments in Sweden and the Niva development in Russia. They have been built in the hotter climates such as Algeria, Brazil, Peru and El Salvador. Underground power developments of great interest have been built under far from excellent geological conditions in Brazil, Peru and Australia.

Neither head nor flow nor size limit development of water-power resources by means of underground power plants. Heads range from a low of about 36 ft. to an existing high of 3500 ft. at Tyin (Norway) and a planned high of 4822 ft. at Froges (France). The design flow ranges from as low as 15 c.f.s. at Foce Ponale in Italy to a maximum of 14,200 c.f.s. at Harspranget in Sweden.

Underground hydro-electric power plants have been built in all types of geological formation, this comprising igneous, metamorphic and sedimentary rocks. Many underground plants, as in Sweden, are built in sound, hard rocks such as granite, requiring practically no support. Some, like Sulak, are in badly fissured and even somewhat distintegrated rocks which require substantial and nearly continuous roof support.

Underground power plants now in service operate as run-of-river, storage, base-load and peak-load developments. The Palue in Switzerland and the Coghinas development in Sardinia are pumped-storage plants.

Until the Kemano hydro-electric development was placed in service in 1954, Canada did not have any underground power developments. Since then the Bersimis I plant has been placed in operation and the Chute-des-Passes plant is under construction. These plants lead the world, pertinent features being shown by Table I. [7] [8] [11] [14] [18]

Reasons For Underground Developments

In order to develop design philosophy covering the underground hydro-electric plant, it will be helpful to recall considerations which enter into the engineering, design and construction of a waterpower development.

A sound solution entails utilization of the head of a falls, rapids or stretch of river in the optimum manner, so that the lowest possible annual costs are secured. Economic studies involve interest on the necessary investment, depreciation, taxes if affected by the scheme of development, cost of operation and superintendence, and maintenance costs.

In working out of the best solution for the dam whereby the potential head in the stretch of river to be developed is concentrated and pondage created, preliminary surveys and studies are made covering cost of construction of the dam and related structures — that is, head race, power-house and tailrace, for various alternatives.

The best alternative is chosen by comparison of annual costs for all parts of the development, this varying with the actual selection of the dam site. Many factors enter into this, such as topography, underlying geological structure, unwatering procedure, etc Consideration has to be given to the value of the head created, and the storage made available, by the proposed dam; the cost of lands flooded; of coffer dams and diversion of the river during construction; of log flumes and fishways (if necessary); of the powerhouse proper; of the mechanical and electrical equipment; of the power connections to step-up transformers and the switchgear; and of all related elements.

When site conditions are such a

Table I—Comparative Data for Canadian Underground Hydro-Electric Power Plants

rockfill dam is the most feasible and economical type, the best overall solution is frequently that in which rock removed from the other elements of the power development, such as the powerhouse chamber, is used for the construction of the dam.

A definite consideration in comparing development by means of a normal surface type power plant as contrasted with an underground plant is the fact that the costs of maintaining tunnels for the headrace and the tailrace, whether these latter are of the pressure or grade type, are generally lower than the corresponding elements of surface developments where concrete and steel are largely utilized. This general comment applied also to depreciation charges, as sound rock has a much longer life than the best concrete.

In this connection, recent Swedish practice in charges for renewals and maintenance, on the basis of money at 4% interest, is as shown in Table II. The difference applicable to conventional and underground power plants will be readily recognized.

The reasons favouring underground power developments on rivers with a moderate gradient, as in Sweden, may be materially different from those applying to high-head developments in mountainous areas.

Dealing with the low-head type or so-called "head" development, as utilized in Sweden, it should be noted that the marked post-war progress in methods has made it economically feasible to concentrate the head on a reach of river with moderate gradient. Some idea of this progress is shown by Fig. 1, showing Swedish tunnelling costs.

Rivers with moderate gradients do not ordinarily permit the construction of high dams. The river banks may not be very high and may adjoin valuable farmland and built-up areas which cannot be inundated on a large scale. Such conditions lead to the concentration of the portion of the head which can be economically developed by means of river-bed clearances, tunnels and canals.

While intake works may often form a component part of the dam, it is frequently more economical to lead the water from an intake so sited as to permit using a lesser total length of waterway between the intake and the point of return of the water to the river, thus reducing the cost of the water passages and, where the pressure conduit can be shortened, improving turbine regulation. Pressure conduits in the form of steel penstocks are ordinarily employed except for very low heads. If the underlying geological structure is sound and the surface is sufficiently high, the generating units can be placed in a chamber excavated underground, with the tailrace built either partially or wholly as a tunnel in rock. Such a solution leads to the shortest possible penstocks, placed vertically, in many cases. Where the underlying geological formation involves poor rock, it will be desirable to locate surface penstocks on a slope and place the power station proper at a greater distance from the intake, so that it will be a surface station with no discharge tunnel.

If site conditions provide a sound rock formation, the normal surface-type station would either necessitate

Table II—Charges to Renewals Fund and Maintenance Costs

	Annual Charges, as Percent of Investment Cost		
	Renewals Fund	*Maintenance*	*Total*

Turbines, Generators, etc	1.78	2.0	3.8

placing the turbines in deep shafts, as in the underground station with the generators at the surface, or entail construction of the station with sloping penstocks and a tailrace canal. Such a solution, with deep turbine pits and long driving shafts, is ordinarily not as economical as an underground station in rock. It is also less advantageous from the point of view of operation. Long penstocks make the problem of turbine regulation more difficult and frequently involve the use of relief valves, in addition to the added cost for the longer sloping penstocks. The additional cost of such penstocks is usually considerably greater than the saving resulting from the absence of the discharge tunnel or a shorter tunnel. The costs associated with the power plant proper must also be taken into comparison but it will be found that these are frequently no greater when the plant is located in an underground chamber excavated in rock than on the surface as the cost of removing the rock from the chamber is partially compensated for by the diminished cost of walls and roof. However, due allowance must be made for the cost of access facilities and surge chamber if these are necessitated by a long tailrace tunnel.

With high-head or so-called "tail" developments, the technical arguments in favour of a solution embracing an underground power station vary. These arguments comprise, among others:—

1. In certain cases there is no feasible site for the ordinary arrangement with surge tanks and steeply-inclined penstock or penstocks, or there may be no suitable site for location of the powerhouse in a narrow valley subject to rockslides or avalanches.

2. An underground power station can be most economically constructed when the site geological structure provides sound rock. Modern tunnelling technique may make such a solution quite as economic as a surface-type powerhouse, depending on site topographical and geological features.

3. It is possible under severe climatic conditions to continue work on an underground development throughout the year.

4. Steel-lined penstocks emplaced in massive rock, as associated with underground power stations, are much safer than ordinary penstocks located on surface and may be more economical in very rugged country. They are not vulnerable to damage by rockslides or avalanches.

5. It is frequently possible with an underground powerhouse to secure improved regulation, of the hydraulic system, or even avoid an expensive surge tank.

6. In some cases an unlined tailrace tunnel may be much cheaper than a pressure tunnel and penstock system, especially if the latter has to be provided with a steel lining.

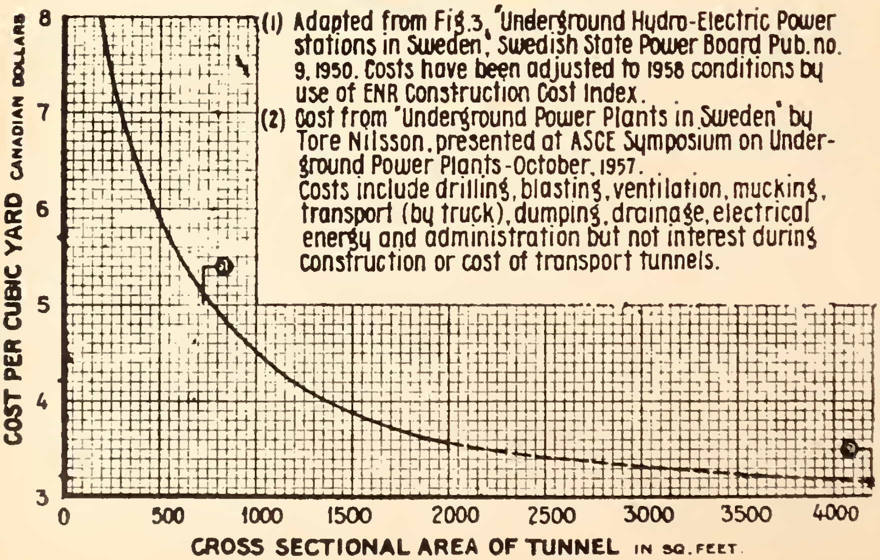
7. Location of the penstocks and power plant underground avoids the marring of scenic features.

Perhaps the major disadvantage of the power underground station is the necessity for protection of the generators against damage by water discharged from ruptured penstock connections. However, this is not a serious consideration as it is necessary to take suitable precautions in any high-head plant.

The construction of an access road or tunnel may be rather expensive, being largely governed by the topography; it may be necessary to resort to access by way of vertical shafts.

Despite the impression frequently held, even on the part of well-informed hydro-electric engineers, that an underground hydro-electric plant is so built because of its superior security in the event of aerial attack, the real reason is economic. Virtually all of the approximately 31,000,000 kw. installed capacity in underground hydro-electric power developments, which capacity is rapidly increasing, has been developed purely on economic and technical grounds. Even in Sweden, militarily exposed, underground power stations are so designed and built because they are the most economic solution, with the added advantage of greater wartime safety.

Fig. 1 Swedish Tunnelling Cost.



Typical Elements of Underground Hydro-Electric Power Schemes

Underground hydro-electric plants comprise all the elements found in the ordinary types of developments with powerhouses on the surface. These elements are:—

1. *Storage and diversion facilities*. In the case of lowhead developments, the head may be concentrated by the dam or dams forming the diversion and storage facilities.

2. *Intake works*. In low-head developments, these are frequently but not necessarily combined with the main dam constituting the diversion and storage works, and ordinarily the concentration of head in the reach of river developed. In high-head developments, the intake works are normally separate from the main dam. Intake works ordinarily consist of trash racks and control gates, together with operating facilities.

3. *Penstocks*. In low-head plants the penstocks may be relatively short, sloping or vertical, penstocks excavated in the rock, and lined or not as dictated by rock conditions. In high-head developments, the pressure conduit may be a combination of a pressure tunnel of considerable length and a sloping or vertical penstock emplaced in the rock. In such cases, a surge chamber excavated in the rock is ordinarily necessary at the junction between the downstream end of the pressure tunnel and the penstock, in order to provide acceptable pressure conditions in the penstock under fluctuating loads and limit pressure rises on rejection of load.

4. *Powerhouse*. In the case of underground power plants, the chamber

housing the generating units is excavated in the rock. Provision may be made for housing the step-up transformers adjacent to the generators in part of the same chamber or in a separate chamber. In some cases the step-up transformers are placed on the surface but there is an increasing tendency to place these underground also.

Control valves in the branches of the penstock serving individual waterwheels may be located in the powerhouse chamber or, as is frequently the case in high-head developments, in a separate chamber with its own drainage connection to the tailrace tunnel.

5. *Tailrace tunnel.* The discharge from the waterwheels may be handled through a pressure or a grade tunnel. In either case, a tailrace surge chamber adjacent to the powerhouse may be required, in order to secure stable hydraulic operation.

Fig. 2 shows the essential elements of the four basic concepts for development of underground hydro-electric power plants. A and B involve a penstock without a pressure supply tunnel and may be described as "head" developments. C and D, which are most nearly typical of high-head power plants, involve in addition a pressure supply tunnel. These may be termed "tail" developments. All underground hydro-electric power developments are essentially variants of the above four schemes.

Finally, underground power developments include means for discharging flood and surplus water by means of spillways or high-pressure outlets. As these are not peculiar to underground power plants, no further reference need be made to them.

Fig. 2. Elements in Basic Development Concepts — Underground Hydro-Electric Schemes.

Economics of Underground Power Plants

Every hydro-electric project is, in effect, "tailor-made"; it differs from all others. There is no general rule which can be utilized to determine whether a particular site is more amenable to economic development as a surface development or as an underground plant. Various alternative possibilities must be carefully evaluated in order that the most economic solution can be ascertained.

Some considerations affecting the relative cost of surface as compared with underground plants are as follows:—

1. In low to moderate-head plants, an underground development may permit a more effective concentration of head and thus the utilization of larger generating units with lower specific costs.

2. In valleys deeply filled with glacio-fluvial deposits, an underground development frequently enables utilization of lower-cost foundations for the heavy generating units.

3. Where a power plant must be sited in a narrow valley with steep walls having talus deposits encumbering the lower slopes, a lower-cost emplacement for the powerhouse can frequently be found underground.

4. Rock from underground excavations often can be used for construction of the diversion and storage dam, at a material saving in cost as compared with opening up a quarry for the provision of rockfill.

5. Although the excavation of the powerhouse proper may be relatively expensive these costs are offset by savings in the cost of walls and roof due to the use of rock as a construction element.

6. Year-round construction possible with underground developments permits securing lower costs.

7. The underground power plant frequently permits the usage of a surge shaft or chamber excavated in the rock mass as contrasted with the expensive steel tank necessary with the conventional plant.

8. The underground power plant, with penstocks emplaced in a rock mass of reasonable homogeneity, free from faults or serious fractures, may permit securing very substantial savings in steel due to the use of the rock as a part of the load-bearing structure. Frequently a shorter penstock can be used. Offsetting this are the additional costs due to longer access, cable and tailrace tunnels.

9. The underground power plant, being emplaced in a rock mass, possesses greater freedom than a conventional one from damage in an area subject to frequent and heavy earthquake shocks, such as Japan.

10. The underground power plant may eliminate the need for otherwise obligatory property purchases. The underground plant minimizes surface rights necessary.

Additional factors resulting in savings in construction costs with underground plants arise from the tremendous improvement in drill steel and drilling equipment which has taken place during the postwar period, particularly in the better quality tungsten-carbide-tipped steel. A greater appreciation of the effective use of explosives has resulted in much less damage to the rock left in place in an underground plant for use as a structural element. With better utilization of explosives, much less scaling has been necessary and hence a lower volume of concrete to replace rock which would otherwise have been utilized. Another element is that it is now possible to carry out blasting in such a way as to secure smoother residual surfaces and thus lower hydraulic losses, a matter of considerable importance in supply and tailrace tunnels.

Improvements in construction techniques used for driving vertical shafts have led to substantial economies. Nowadays a hole of suitable size is drilled, a wire threaded through to the bottom, in the underground working, and a platform attached. From this a small raise is excavated to the top, after which the opening is slashed down to final size.

Long-hole diamond drilling has been used to remove the bulk of the rock in a powerhouse chamber, following excavation and concreting of the roof arch, as at Kemano. (11)

A more comprehensive knowledge of rock mechanics and recognition of the possibilities of remedial grouting in powerhouse chambers, penstocks, surge chambers and tunnels have resulted in appreciable savings in underground power plants.

Another postwar development, adopted from mining practice, has been the usage of rock bolting for supports in large underground excavations, such as tunnels, powerhouse chambers, etc. The use of this technique, to which reference is made in more detail later, has enabled constructing underground power developments in relatively poor rock formations, badly fissured, at a reasonable cost.

However, as pointed out in another section, economic underground excavation is dependent on a correct interpretation of limited advance geological information. Thus higher allowances for contingencies should be made in estimating the cost of underground elements, although in reality these may not be incurred.

In a recent paper T. Nilsson, Civil Engineering Director, Swedish State Power Board, compared a group of conventional power plants placed in service after 1950 or under construction in 1956 with a corresponding group of underground plants. With costs on a common (1956) basis, the weighted average cost per kw. for the surface plants was 1020 Swedish crowns (a range of 640 to 1390) as compared with 720 (a range of 560 to 1140) for the underground stations. Mr. Nilsson carefully emphasized these figures do not constitute evidence underground plants are cheaper than conventional plants but nevertheless the comparison is quite striking.[16]

Table III shows the specific volume per kw. of capacity for the same groups of Swedish power plants. The striking decrease in concrete requirements is indicative of some of the potential cost savings with the underground plant.

As in any hydro-electric power project, a very careful evaluation of the various alternative solutions is necessary if the full economies inherent in an underground design are to be realized. An excellent illustration of this is the Haas power development of the Pacific Gas and Electric Co.[19]

There seems to be little doubt that the cost of excavation and the extent and nature of necessary grouting are the two most significant factors contributing to the cost of underground hydro-electric power plants.

Bergman has shown how the cost of underground excavation has declined due to improved drilling equipment by comparison with the increase in cost of reinforced concrete placed in such excavations, in Table A applicable to underground chambers in rock in Sweden.[9]

Total volume in cu. m.	*Cost of Excavation, in Sw. Cr. per cu. m.* 1946-49	1950-51	*Cost of reinforced concrete in Sw. Cr. per cu. m.* 1946-49	1950-51

20,000	40	33	58	66
40,000	34	28	51	59

TABLE A

T. Nilsson late in 1957 discussed the 500,000 kw. Stornorrfors underground plant in Sweden. It embodies a 2.5 mi. unlined tailrace tunnel carrying 28,000 c.f.s. The tunnel is 53 ft. wide and 87 ft. high, the cross-sectional area about 4200 sq. ft. Driven through good rock, the tailrace tunnel is being taken out in a 1730 sq. ft. top heading and two benches. The labour requirements are 0.56 man-hours per cu. yd. for the top heading, 0.25 for the benches and 0.37 average. Explosives needed are 1.33 lbs. per cu. yd. for the top heading, 0.97 for the benches and 1.08 average. Labour is essentially on a piece-work basis and the average wage is 7.50 Sw. crowns (Can. $1.43)* per hour.[16]

Actual costs together with estimated costs (for incomplete work) show that the total cost for excavation in the top heading is 21 Sw. crowns (Can. $4.00) per cu. yd., in the benches 13.5 (Can. $2.57) and the average 16.5 (Can. $3.14). Such costs are indicative of the low costs which have been obtained in Sweden in the postwar years. They are attributable only in part to good rock, mostly to effective construction procedures, equipment and labour.[16]

*At Can. $0.19 per Swedish crown.

**Including draft tubes, but excluding penstocks.

Geological Aspects

The cost of tunnelling and removal of rock constitutes a particularly significant factor in an underground hydro-electric power development. The cost of pressure tunnels, of penstocks, of the powerhouse chamber and access shafts or tunnels, and of tailrace tunnels is influenced to a very substantial degree by the proper engineering application of advanced methods of analysis of linings, of roof arches and roof supports, and consequently on an effective determination of rock pressures and stresses. This can be most important in the case of high-head developments where the rock itself may be utilized to resist hydraulic pressures in pressure tunnels and penstocks, thus minimizing the cost of lining, normally steel in penstocks embedded in a rock mass but in some cases reinforced and prestressed concrete.[10, 17]

The proper interpretation of the geological features surrounding a power development has always been important but it is much more so with underground projects, due to the judgment which the engineer must bring to bear on the orientation of underground structures, the type and amount of support involved, the type and amount of overbreak likely to be encountered in underground excavations, the possibility and magnitude of water influxes into workings, and difficulties with some rock formations giving rise to rock bursts, "heavy" ground or "slaking" surfaces.

Geological investigations must be carried out in such a manner as to make available to the design engineers and the construction organization full information on the geological structure and the physical properties of the rocks involved in the scheme. The information should be sufficient to determine the probable stresses on exposed rock faces and on any lining in pressure tunnels, penstocks, surge chambers or grade tunnels, as well as the economic cross-section of tunnels suited to the particular rock formation, optimum driving procedures, the best methods of taking care of infiltration of water and thicknesses of linings. It is well to bear in mind that underground power plants are built, not of concrete or steel, for the greater part, but of rock in place, a building material about which not too much is known as yet.

In this connection theoretical considerations have led to marked advances in the design of the various elements of underground power developments. However, experimental methods permitting determination of the deformation of the rock structure under loading so that the elastic properties of the rock, the time lag of plastic deformation and any lack of symmetry can be fully ascertained and properly applied in the design, are invaluable. Nevertheless, it must always be remembered that rock in situ is neither homogeneous nor isotropic. Its properties vary from point to point in what appears to be a uniform formation.

The engineer concerned with planning and design for an underground power scheme must be able, on the strength of advice from the geologist, to appraise the probable behaviour of the formation in which a tunnel or powerhouse chamber excavation is located. Will the formation arch favourably? For example, if the strike of the formation is parallel to the axis of the excavation a weak arch may be anticipated as contrasted with a stronger one when the strike is at right angles to the axis. Proper interpretation of the geological facts will enable a correct assessment of the magnitude and type of outbreak and thus an appraisal of, for instance, rugosity in unlined pressure tunnels.

The significance of a thorough understanding of the site geological features can be appreciated from a discussion of their relationship to the design considerations associated with the pressure conduits or penstocks in an underground power scheme. While the design of surface penstocks is founded on a rather definite basis, design of pressure conduits or penstocks emplaced in a rock mass is much less tangible. The major problem is: What is the distribution of load between the steel liner and its surrounding rock envelope? Design is influenced by many variables introduced by the natural site conditions and the construction techniques utilized. Some of these are jointing, stratification, attitude and residual stresses of the rock formation; variations in strength and modulus of elasticity of the rock; shrinkage and imperfection of concrete in the backfill between liner and rock envelope; and variations in properties of the steel liner, even though furnished to standard specifications. Experience has demonstrated that, with a penstock emplaced in a rock mass, the rock acquires a permanent set under initial loading, with a tendency to modification of the contact between the liner and the concrete backfill under normal service conditions.[14]

A thorough understanding of the rock mechanics of the geological formation involved in a given development is important. Lack of much fundamental knowledge of the elements is one of the reasons why the design of embedded penstocks or pressure conduits is more of an art than a science at present. This is most applicable to rock mechanics, in which connection Lord Kelvin's famous observation —

> "When you can measure what you are speaking about and express it in numbers, you know something about it; but when you cannot measure it, when you cannot express it in numbers, your knowledge is of a meagre and unsatisfactory kind; it may be the beginning of knowledge but you have scarcely, in your thoughts, advanced to the stage of science whatever the matter may be"—

is particularly appropriate.

The significance of adequate knowledge of the properties of rock will be apparent from a brief consideration of the interaction between the steel liner and the surrounding sheath of concrete backfill and rock in an embedded penstock. Assuming the liner is in intimate contact with the concrete sheath around it, the interaction is about as follows:—

1. The internal pressure in the penstock will cause the steel liner to increase slightly in diameter, under the hoop stress set up, and tend to shorten longitudinally; being restrained, longitudinal and transverse stresses will be set up in the girth welds, at joints.

2. Expansion of the steel liner will transfer some load to the concrete sheath, thence to the rock; at the same time hoop stresses will develop in the concrete sheath. If these hoop stresses exceed the low tensile strength of the unreinforced concrete sheath it will develop minute cracks.

3. That part of the internal hydrostatic pressure load transferred to the rock immediately adjacent to the sheath will cause it to plasticly deform to some unknown degree. This will continue until "packing" under load has taken up the fissure and void spaces which exist naturally or arise from shaft-driving operations and are not completely filled with grout. Some minute cracking of the rock can be anticipated in the vicinity of the penstock since the tensile strength of rock is moderately low, compared with its compressive strength.

4. When the steel liner, surrounding grouted concrete backfill and rock sheath reach equilibrium under normal operating and maximum surge pressures, the stress in the steel should not exceed a "safe" value under the worst conditions of operation and corrosion foreseeable.

5. When the penstock is drained for maintenance work, the steel liner, if

it has not been stressed previously beyond the elastic limit and undergone sufficient permanent deformation, will decrease in diameter more than the surrounding grouted concrete backfill and rock sheath which has previously incurred a permanent plastic (packing) deformation plus some elastic deformation. Obviously the smooth external periphery of the liner will tend to separate, to some extent, from the surrounding sheath. Such a separation gap, through the fissures and hairline cracks in the grouted concrete backfill and rock sheath, will fill with ground water under such pressure heads as exist in the formation through which the penstock runs.

6. Provided such external pressure heads are insufficient to cause inward buckling, refilling of the conduit and its return to service result in the steel liner and surrounding sheath resuming its loaded state as before.

The proportion of load from the internal hydrostatic pressure transmitted by the steel liner to the rock can be calculated if the moduli of elasticity of the steel and of the rock are known, the elastic deformation of the liner in the radial direction being equated to the radial deformation of the rock. The principal difficulty with this procedure is lack of knowledge as to the real value of the modulus of elasticity of the rock formation traversed by the penstock. The important consideration is that stresses in the liner, under any service condition whatsoever, remain below the yield point of the steel.

During the last decade, rock bolting has come to the fore as an economic means of providing support in excavations for underground hydroelectric power developments, eliminating to a substantial extent use of the more expensive steel sets.

Rock bolting consists of drilling a hole into the formation involved, inserting a wedge and split-end bolt of suitable length and diameter, and tapping it with a hammer to wedge the split end of the bolt tightly into place. A steel plate-washer is placed over the free end of the bolt and a nut is screwed on and seated against the plate washer. Tightening of the nut with an impact wrench results in high friction being developed between the spread end of the bolt and the rock. Depending on circumstances, a steel channel or other member may serve as a washer for two or more rock bolts.

Other forms of rock bolts have been used. For instance, at the Pacific Gas and Electric Co.'s Haas underground plant, the Perfo method of the Sika

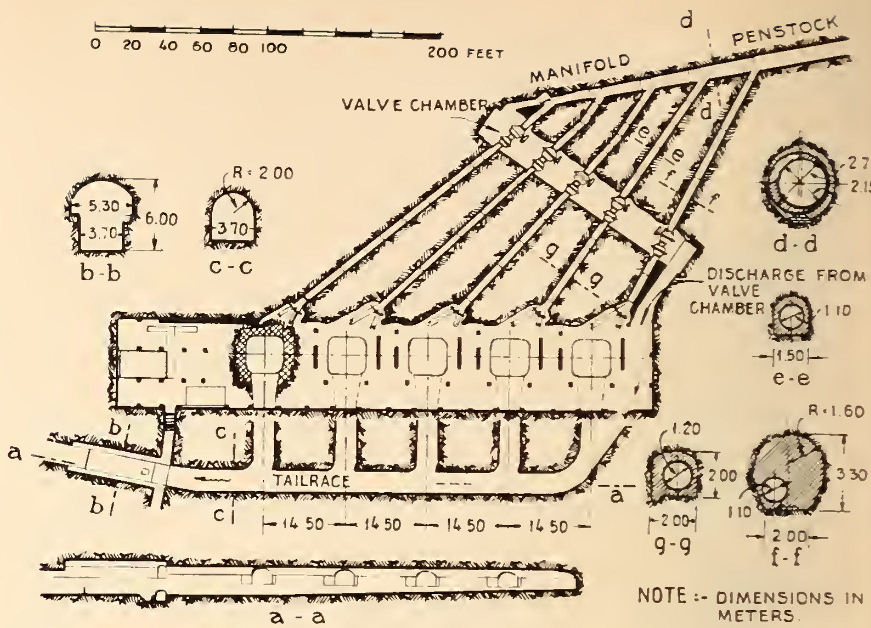

Fig. 3. General Plan of Innertkirchen Underground Power Plant.

Chemical Corporation was used. This involves two half-round perforated tubes of sheet metal the full length of the hole which are filled with a stiff sand cement grout and then wired together. This is inserted in the hole and the reinforcing bar serving as the rock anchor is driven in by an air hammer. The volume of grout is such that a small amount is extruded as the rod is driven to the end of the hole.[19]

At Stornorrfors, in Sweden, a procedure for rock bolting, known as the SN method, is claimed to develop greater stress and be more reliable than the conventional technique. The method involves inserting the bolts into the holes and then forcing in grout, beginning from the bottom, under air pressure.

Rock bolting is generally effective in slabby or blocky rock and in such rocks as shales, slates, some sandstones and coal. They are not very effective in soft shales, soft sandstones and similar formations.

Rock bolting, properly used, can be very economic but there is a clear necessity to apply it only under the direction of an engineer. Psychologically, what appears to be a thoroughly-rock-bolted formation may convey a strong sense of security to underground workers; contractors' representatives are inclined to look favourably on such a practice, as eliminating otherwise necessary scaling, especially when the owner is paying for the application of the rock bolts. However, indiscriminate use does not necessarily secure expected results, in the form of the safety anticipated.

A moot question relates to the effective life of rock bolts where installed in the presence of a corrosive water content in the rock formation. In Norway, cement-grouted stainless-steel bolts have been used, in some cases. In Canada, aluminum-alloy bolts have been used, in one instance.

Lang has observed that "The view . . . rock bolts only 'pin' or 'nail' blocks or slabs of rock which are loose to the sounder rock behind them is erroneous". It is true they have been used for this purpose for a long time but such usage without a thorough knowledge of the controlling factors can be dangerous. Properly speaking, rock bolting means the planned use of rock bolts to convert a jointed rock into a structural entity of adequate competence for the part played by it in an underground structure.[15]

Lang has noted "Another concept in regard to the behaviour of rock bolts, is that they create a principal compressive stress normal to the free surface of an excavation where, without them, there would be only one principal stress parallel to the surface. This is borne out by their very effective use to stabilize "popping" rock. This implies that, either at or immediately behind the free surface, the bolts form a diaphragm of material somewhat less in thickness than the length of the rock bolt, which can be used as a structural member whose properties can be ascertained and whose behaviour can be assessed and designed for. It is obvious that, if rock bolts are to be designed to carry out the tasks enunciated above, then it is necessary to know their behaviour in relation to both intact and jointed rock. This requires not only knowledge of the behaviour of rock bolts but also the behaviour of jointed rock, either with or without rock bolts".[15]

Design Considerations

It will be apparent, from the discussion of the geological aspects associated with an underground hydroelectric power plant, that design considerations can only be finalized when the working area has been reached, either by a shaft or tunnel intended for permanent use or for exploration only, although normally it will be utilized as part of the permanent facilities. Inspection of the geological formation may well indicate, for instance, the desirability of changing the orientation of the powerhouse longitudinal axis, in order to secure a stronger roof or minimize wall support.

A basic precept applicable to underground power projects is that the design of the scheme should be made in principle only, prior to effecting entrance to the working area.

There are no fundamental differences between the intake works for the classical type of power project and the underground type, so there is no need to comment on design aspects for this element.

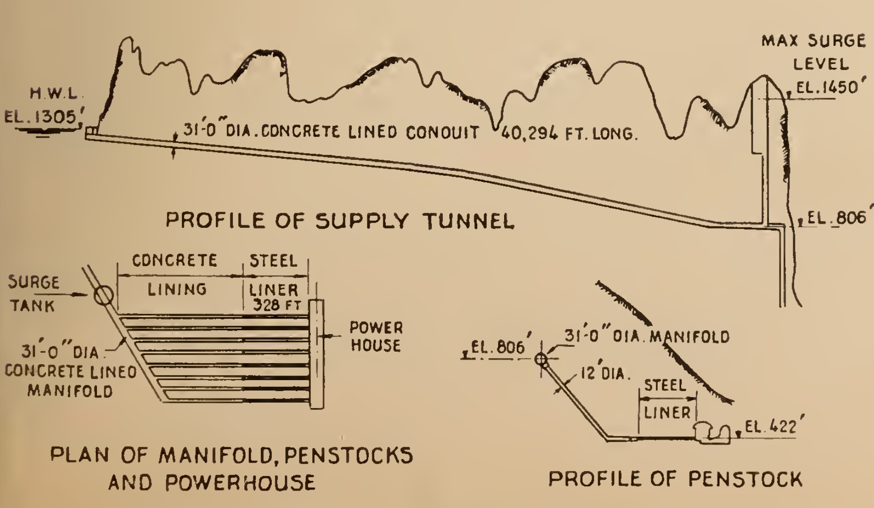
In the case of pressure tunnels, the decision as to whether these should be lined or unlined is purely a matter of economics. The higher coefficient of friction with an unlined tunnel may dictate a substantial increase in effective diameter, which must be weighed against the cost of lining a smaller tunnel.

Surge chambers in the pressure conduit are not ordinarily required with low to medium-head underground developments. Thus, so-called "head" developments do not involve surge chambers on the pressure conduits. The long pressure tunnels and penstocks associated with high-head or so-called "tail" underground power plants normally involve surge chambers on the pressure line. These may consist of either a vertical or an inclined shaft, with one or more chambers of various sections. The entire structure is excavated in the rock and may be unlined or concrete lined. In some plants, surge chambers with restricted orifices are used. Care must be given to the provision for spilling any water ejected from the surge chamber during load rejection.

In the case of low-to-medium-head or "head" developments, separate penstocks are ordinarily used for each turbine. On the other hand, the high-head or "tail" developments normally have one or more penstocks from the surge chamber to the powerhouse, these penstocks branching off to the individual turbines just upstream from the powerhouse chamber.

Embedded penstocks are designed to take full hydrostatic head. In all cases they are concrete lined and frequently a steel lining is added, the steel lining increasing in thickness from the top to the bottom of the pressure shaft. At Krangede, for instance, the upper part of the pressure shaft is lined with 25/64 in. steel, increasing to 1-1/32 in. steel in the lower part. The upper part was not grouted and the space between the concrete and steel linings is used for drainage; the lower part of the shaft was pressure grouted. At Hjalta, with a static head of 285 ft., the pressure shaft was lined only with concrete, 8 in. thick at the top and 12 at the bottom. By proper attention to design, taking full advantage of the strength of surrounding rock, selection of optimum grouting pressures and of the economic form of lining, the overall cost can be minimized.

Fig. 4. Bersimis 1.



The design of underground penstocks has been discussed in connection with the geological aspects. The design considerations relative to internal pressures are well recognized. However, treatment to withstand external pressures, when the penstock is drained, is on a less satisfactory basis. Some designers provide an external drainage system consisting of drainage pipes running parallel to the penstock and tapping the rock envelope. However, these are liable to become clogged during grouting operations or later. Other designs rely on bonding the liner to the concrete envelope through various forms of spines and brackets. Still others provide an inspection gallery adjacent to the penstock, as at Gerlos in Austria. Main reliance, however, is placed on effective grouting.

An important consideration in the design of an underground hydroelectric power plant is securing such a layout of the pressure tunnel, penstock manifold and penstocks that hydraulic losses at deflections and branches are minimized. Note Figs. 3-6, inclusive, showing the arrangements at Innertkirchen, Bersimis I, Chute-des-Passes and Kemano, respectively.

Particular attention must be paid to water tightness of the lower part of the penstock in order to minimize the entrance of ground water into the chamber constituting the power plant proper. In many cases, provision is made for the elimination of such ground water by ducts connecting with the tailrace. Well-planned grout curtains are most commonly used. At Sudagai, in Japan, a grout curtain is combined with an inner curtain of upward-drilled drainage boreholes emptying to a drainage tunnel around the plant.[21]

In the case of low-to-medium head developments, control of water passing through the pressure conduits is ordinarily provided by various types of intake gates, but several forms of valves are sometimes utilized. In the case of high-head developments, a valve is ordinarily located at the upstream end of the penstock. Such valves are frequently butterfly valves, as at Kemano and Haas.[14, 19] Control is ordinarily provided such that these valves close automatically on the occurrence of excessive velocities associated with a ruptured conduit, valve, turbine scroll, etc. However, in some cases, as at Fionnay, these valves are eliminated and reliance is placed on automatic closing devices at the tunnel intake. Ample provision for automatic air inlet must be made just downstream from such valves or closing devices to avoid collapsing of the penstock liners due to vacuum. Unit valves are ordinarily installed on the branch connections to the individual turbines. These may be single or duplicate valves, as used at Innertkirchen. Various types of valves are used, such as cone, butterfly, spherical or cylindrical, depending usually on the head involved. These valves may be operated by hydraulic or electric control mechanisms. They are sometimes automatically controlled by the turbine governor. Current practice is to utilize the double-seal type so that a single valve meets all requirements for maintenance.

The valves may be located in a separate chamber as at Innertkirchen and Kemano; in a passage between the penstock tunnel and the powerhouse; or in the powerhouse proper, as at Brommat and elsewhere. Actual location is governed to a substantial extent by the nature of the rock formation. Placement of the valves in a separate chamber reduces the necessary width of the chamber required for the generating units but does necessitate a separate crane and access passage. The overall volume of excavation is somewhat greater. In the case of high-head developments, where serious consideration must be given to the possibility of a ruptured pressure line, the valve chamber is ordinarily provided with its own discharge tunnel connecting with the tailrace. See Figs. 3, 7 and 8.

As to the powerhouse proper, it is obvious that size, construction and cost are influenced to a marked extent by the choice and arrangement of turbines, generators and auxiliaries. Large, high-specific-speed units contribute to a substantial saving in installation and maintenance costs, in common with experience with the classical type of power development.

Horizontal and vertical generating units have been widely used, with the vertical units preferred for low-to-medium heads. For high-head developments, horizontal impulse waterwheels are normally used in Europe although at Innertkirchen twin-nozzle vertical impulse units were selected. At Kemano four-nozzle, vertical impulse units were installed. Horizontal reaction turbines operating at 164 ft. head were selected for the Guayabo underground plant on the Lempa River in El Salvador. See Fig. 9.

Although many changes in the type and arrangement of the major equipment in underground power plants have been worked out since the early plants were built, present practice, aside from the Guayabo and Ambuklao developments, definitely involves vertical units. Most of the later schemes have been this type—for instance, Krangede with its six 54,000 h.p. units, Innertkirchen with its five 66,000 h.p. units, Hjalta with its three 73,600 h.p. units, Hojum with four 78,500 h.p. units, Soverzene with its four 90,000 h.p. units, Harspranget with its four 130,000 h.p. units,

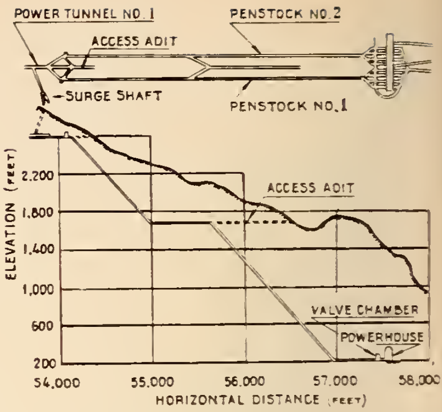


Fig. 6. Kemano Penstocks Nos. 1 and 2.

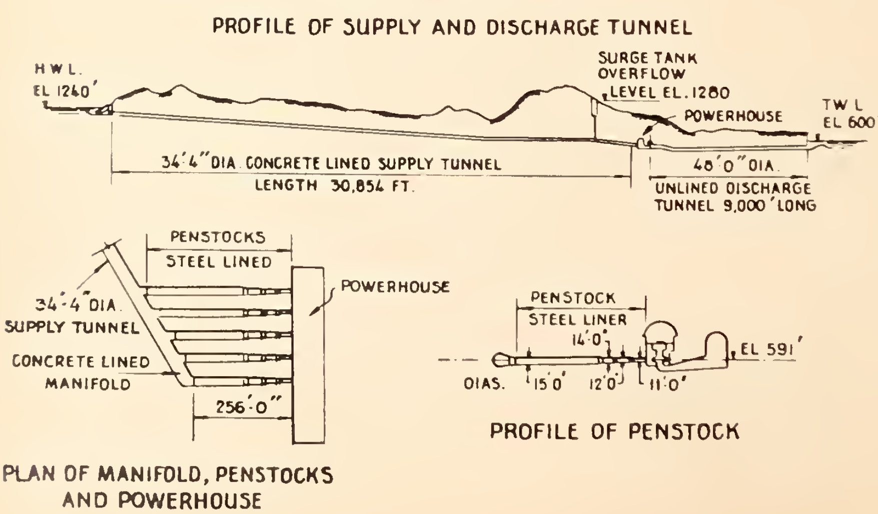
Kemano, with its ultimate sixteen 150,000 h.p. units, Bersimis 1 with its eight 175,000 h.p. units and Chute-des-Passes with its five 200,000 h.p. units. A governing consideration in the selection of vertical generating units is minimum excavation and minimum width. See Figs. 10 and 11.

Advantages claimed for the horizontal reaction turbine setting, as used at Guayabo and Ambuklao, are lower excavation volume, better hydraulic efficiency due to elimination of one penstock bend and the elbow draft tube bend, and separate erection and dismantling of turbine and generator. Disadvantages are the special handling facilities for the turbines, slow unwatering, and special handling and working conditions associated with the turbine erection.

Some of the significant data for the Kemano, Bersimis 1 and Chute-des-Passes underground developments, as shown by Table 1, indicate the marked progress which has been made in this direction.

An underground power development will entail less excavation for the chamber housing the generating units if requirements for headroom are kept to a minimum. This was accomplished at Krangede and at Innertkirchen by the development of a structural steel support interposed between the generator and waterwheel casing, whereby the generator dead load and the hydraulic thrust is transferred through the steel supporting structure to the waterwheel casing, without intervening concrete piers. Another means of minimizing head-room requirements is the selection of umbrella-type generators, with combined guide and thrust bearing below the rotor. Still another method is the use of station cranes specially designed to minimize head-room requirements. Finally, considerable thought is being

Fig. 5. Chute-des-Passes.



given to the elimination of high-capacity station cranes, used during erection and very seldom thereafter, by the provision of built-in jacking facilities whereby the generator stator can be lifted to permit access to and removal of the rotor.

Considerable economy in the cost of the chamber housing the generator units can be affected by giving proper attention to the structural features, taking full account of the strength of the rock. The powerhouse chamber usually has a semi-circular or elliptical roof and vertical walls. In the case of relatively weak rock structures, the roof arch is used to carry the full load. In sound rock, the arch is designed for only a part, in some cases as low as 25%, of the estimated rock load. The roof arch is abutted into recesses in the rock walls, thus transferring the load into the walls, reducing the stresses in the free vertical faces of the rock and stabilizing the walls.

At Krangede, reinforced inverted T-beams were used in the roof arch, so that an interspace between the rock and the ceiling resulted, which picks up any infiltration of ground water. Normally, the roof arch is monolithic concrete, placed against the rock and grouted. In such cases, a suspended second arch is frequently provided, ordinarily quite thin, with a waterproof membrane on top. Such a solution was adopted at Brommat and at Innertkirchen. At Brommat, gutters collect the infiltration of ground-water which accumulates on the second arch. Roof arches have been built of hollow concrete blocks, pumice blocks and brick. One form of roof-arch construction employed in some Swedish plants is illustrated by Fig. 12.

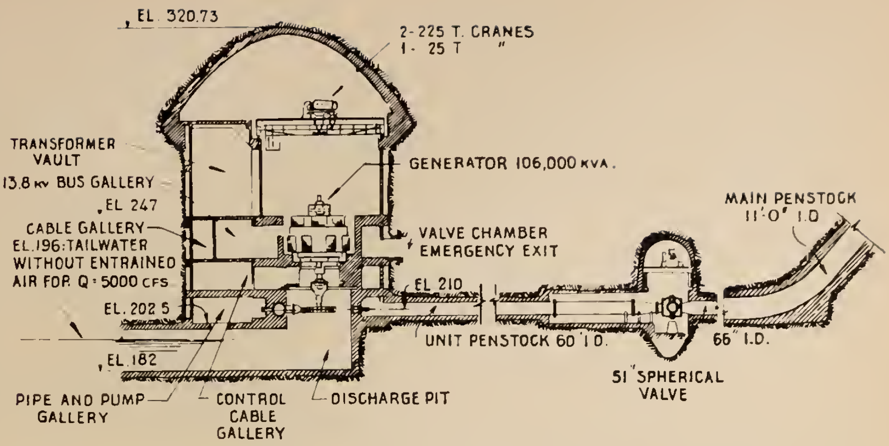


Fig. 7. Cross-Section Through Kemano Valve and Power Chambers.

Ordinarily, in good rock formations, the rock walls need no support. An exception was Soverzene where a weak zone was supported by a reinforced concrete wall. Sometimes vertical arches are used for the support of horizontal loads. While the rock walls are sometimes gunited and frequently concreted, in many cases it is possible to leave the walls as excavated. Properly sealed and cleaned, such bare rock walls constitute a very attractive feature of many underground plants.

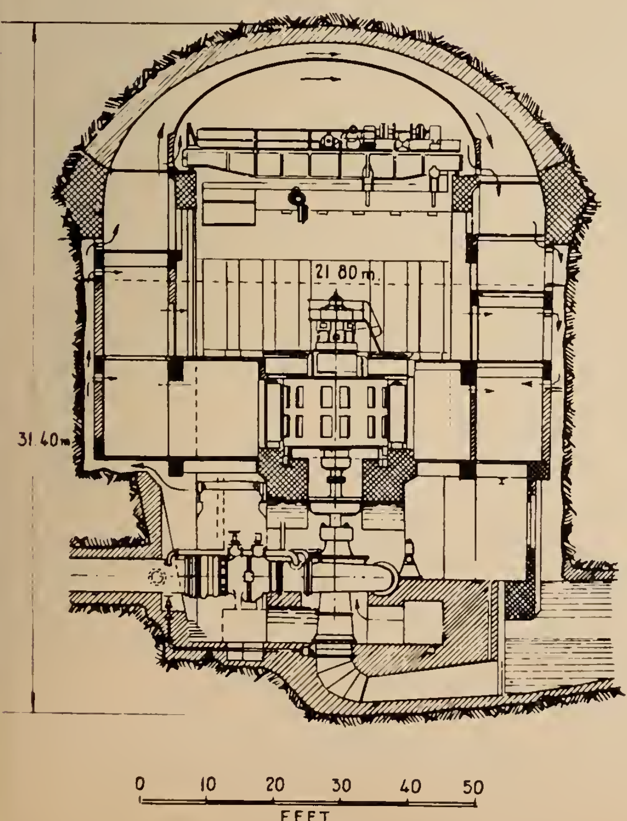

Fig. 8. Cross-Section through the Brommat Underground power plant utilizing the waters of the Truyere and Bromme Rivers, France, and constructed from 1928 to 1933.

Although the walls of underground power-plants are normally vertical, with a semi-circular or elliptical roof, high rock pressures in a bad geological formation may necessitate another form of cross section. For instance, at Santa Giustina, in Italy, an elliptical cross-section is used with the generator floor heavily reinforced to resist a high horizontal component of the rock pressure from swelling of the marls in which the plant is emplaced. A parabolic shape was used at Peccia and Cavergno for a similar reason.

In many underground hydro-electric power plants, the designer has provided a second wall with an interspace between the rock and the wall through which air is circulated, thus removing accumulations of moisture accruing from groundwater penetrating to the rock surface. Such a solution was adopted at Brommat and at Krangede. Note Figs. 8 and 10.

Ordinarily the powerhouse cranes in underground stations are carried on beams supported on free-standing columns, independent of the rock walls. Such a solution has been widely adopted, an instance being the Lavey development in Switzerland as in Fig. 13. At the Forsmo and other developments, the crane bridge extends downstream over the draft-tube stop logs, so these can be operated by the crane. In some plants special galleries with monorails and other lifting devices are provided for the operation of draft-tube stoplogs or gates, as shown by Fig. 14. At Krangede these are operated from the vent shaft while at Soverzene they are handled from the transformer gallery. A special consideration in the design of the powerhouse chamber is that of proper provision for handling a break in the penstock, valve, casing, etc., whereby a substantial volume of water could be released. In Sweden, the practice is to reinforce the concrete floor to take full water pressure. In many Italian plants, turbine floors are designed only for the pressure from surges in the tailrace tunnel. At Innertkirchen and Kemano, the valve chamber is drained to the tailrace tunnel by a separate tunnel.

Underground powerhouses are particularly adaptable to a pleasing architectural treatment, if proper consideration is given to this at an early stage. The arched roof can be quite attractive. It is possible to work out very economical and pleasing indirect lighting. This is particularly evident to anyone familiar with the classic types of power plants who visits underground schemes and examines them critically. Decorative murals or frequently clean bare rock walls constitute attractive features in some plants.

Fire protection is no more difficult with an underground power development than with the surface type but more consideration has to be given to removal of fumes resulting from a fire. Suitable close-sealing fire doors are desirable where transformers are installed immediately adjacent to the generating units, as at Kemano. Either CO_2 or water-spray fire protection can be utilized, depending upon the requirements of the protected apparatus.

An important problem in underground hydro-electric plants is that of adequate ventilation. Fresh air is normally taken from the surface and circulated by fans through an access shaft or tunnel into the powerhouse or through a separate ventilation shaft or tunnel, which in some Swedish and other plants serves as a cableway for outgoing power cables. In some cases the air is filtered or dehumidified. In other instances the air is cooled in heat exchangers using water pumped from the tailrace or with the heat exchangers inserted in the tailrace. In some plants the incoming air is conditioned by drawing it in over the water in the tailrace. The incoming cooled air is circulated initially through the generators, either in a closed or open circuit, through the powerhouse interior and through the interspace between the rock walls of the chamber and the inner shell of the powerhouse. This is the case at Brommat. In lower-head developments warm air from the powerhouse proper passes to the intake works in order to provide temperature conditions conducive to prevention of ice formation on the trash racks, etc.

The tailrace tunnel is one of the most important elements of an underground power scheme in its bearing on the overall economy. This is particularly true in the case of low-to-medium-head plants where the investment in the tailrace tunnel may represent a substantial part of the overall investment. Tailrace tunnels, with a gradient of 0.01 to 0.025, are usually constructed as unlined grade tunnels designed for a velocity of six to eight f.p.s. The usual cross-section is either horseshoe-shaped or egg-shaped, but

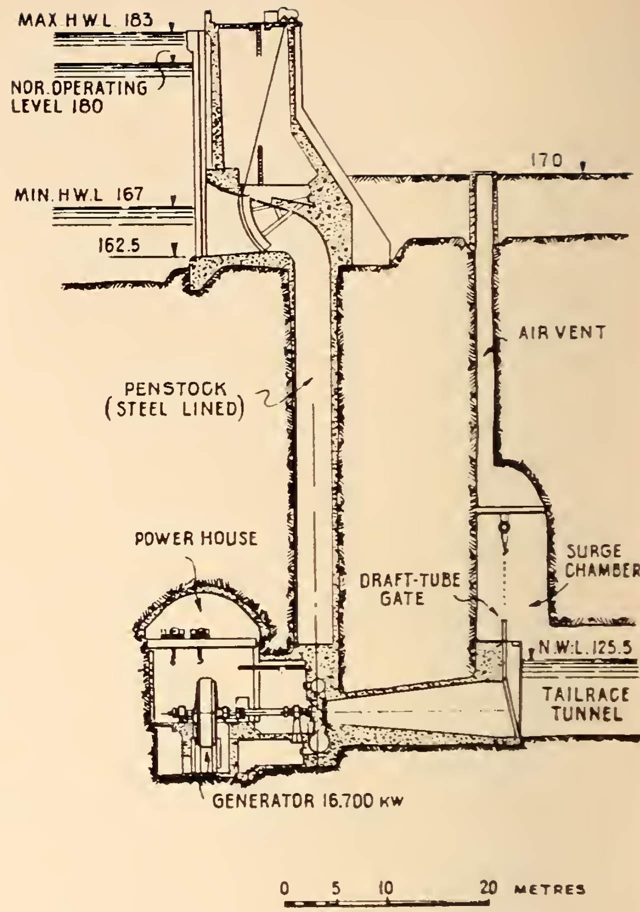

Fig. 9. Cross-Section through the 75,000 KW. ultimate capacity, 188.6 ft. gross head Guayabo Hydro-electric plant on the Lempa River, El Salvador.

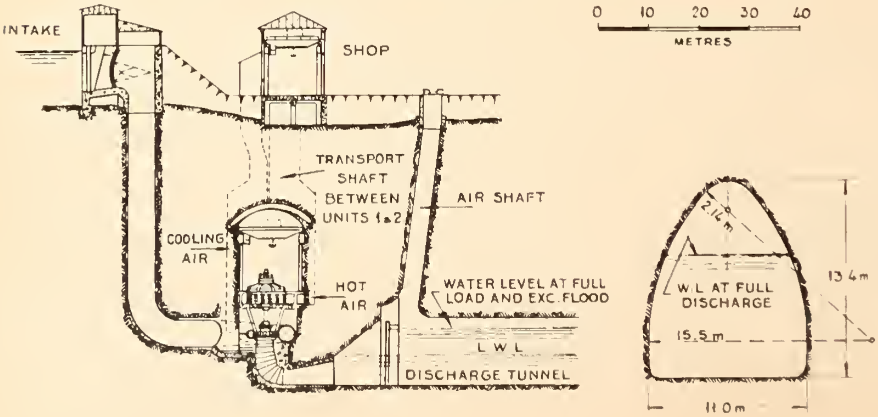

Fig. 10. Krangede Underground Power Plant showing, a) cross-section of Power Plant and b) cross-section of Tailrace Tunnel.

a triangular cross-section was employed in the Niva development. This Russian power plant utilizes a head of 243 ft. between its intake on the Niva River and Kandalaksha Bay. The inverts of the draft tubes and of the tailrace tunnel fixed the flow line in the tunnel at a slightly higher level than that of the tide, permitting full utilization of the available head. The lined 7,215 ft. long grade tailrace tunnel has essentially a triangular cross-section 27 ft. wide by 35 ft. high. It discharges to a lined, open-cut tailrace canal just under 2400 ft. long.

The tailrace tunnel handles a fluctuating flow, depending on load variations. Consequently, it is feasible to design the tunnel in three different ways hydraulically. In the first, the tailrace tunnel is designed to act as a free-surface grade tunnel at all times, not only when carrying steady full-load flow, but also the maximum surge flow or wave arising from rapid fluctuations in load. Under such circumstances, the cross-section is large but it is not necessary to provide a surge chamber or shaft adjacent to the power plant proper.

The second method is to design the tunnel as a free-surface (grade) tunnel at steady flows but filled by the surge wave resulting from fluctuations in flow, at which times the tunnel acts as a pressure tunnel. This entails an enlargement in the form of a surge chamber at the head of the tunnel adjacent to the power plant.

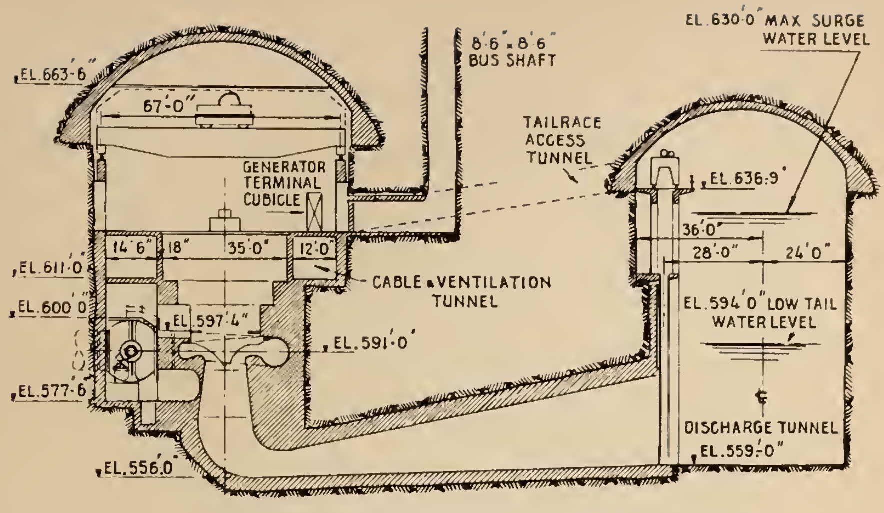

Fig. 11. Cross-Section through Chute-des-Passes Power Plant.

The third method treats the tailrace tunnel as a pressure tunnel during steady and unsteady flows, requiring a surge shaft or chamber and a vent shaft.

For tailrace tunnels up to 1500 or 2000 ft. in length, the economical choice appears to be the first type. As the length increases, a horizontal surge chamber in the form of an enlargement reduces the average size of the tunnel cross-section and is advisable for tunnel lengths of 7000 to 9000 ft. For the longer tunnels, surge shafts appear to be more economical. The economic solution for the proper accommodation of unsteady flow or surges in tailrace tunnels can best be ascertained from model tests.

Control rooms for underground hydro-electric power plants occasion no more difficulty than with the conventional type of power plant. Occasionally, as at Krangede and Bersimis I, the control room is placed at the surface.

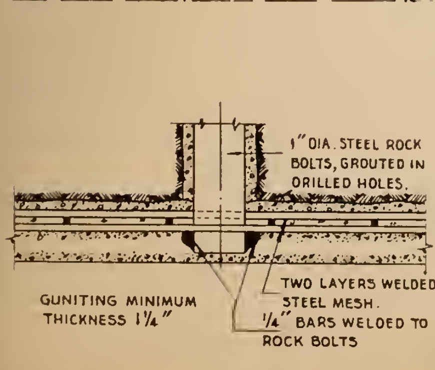
Step-up power transformers associated with underground power schemes have been placed both underground, in cuts and on the surface, but there is an increasing tendency to place this equipment underground. Switchyards are almost invariably placed on the surface. Where transformers are installed underground, they may be placed at the same level and opposite to the generators, in an extension of the generator room, or in a separate chamber adjacent to the power chamber. The highest voltage so far employed for transformers placed underground is 400 kv., used at the Harspranget plant in Sweden. See Figs. 15 and 16.

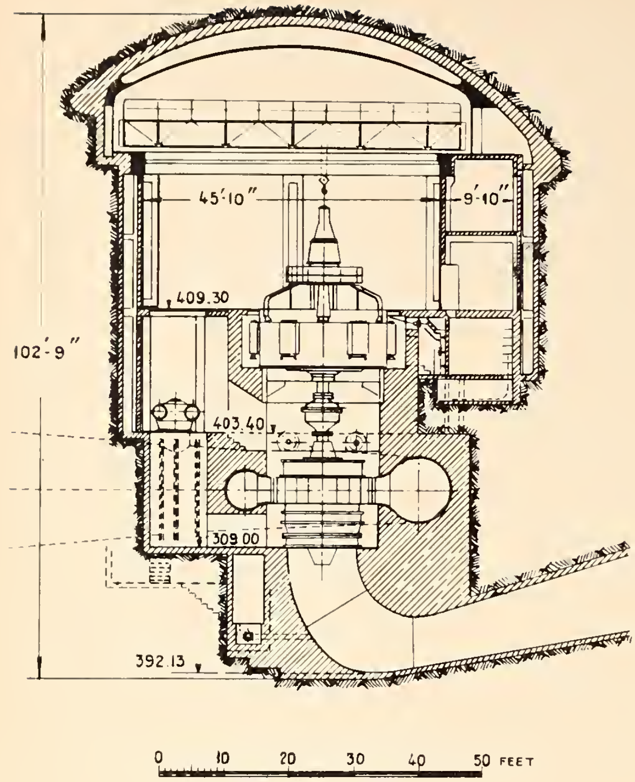
Connections between the generators and their transformers can be either bus or cable, depending on the economic solution in the particular case. Where the duct, tunnel or shaft carrying the high-tension leads from underground transformers to the surface is long, high-voltage cables to the switchyard are ordinarily used, as at Kemano.

An important element associated with underground power developments is means of access and exit. The nature of communications depends largely on the relationship of the power chamber to the surface, as this fixes whether a vertical shaft or a horizontal or an inclined tunnel is the most economical solution. Duplicate means of ingress and exit are desirable, from the psychological viewpoint, but are not always provided as cable ducts and other features can be used for emergency exits. Low-to-medium-head developments ordinarily utilize vertical access shafts while high-head developments normally have horizontal access tunnels. Brommat is an instance of an underground development with an inclined shaft. Haas, the first modern underground power plant in the U.S.A., provides emergency access and exit through the upper section of the tailrace tunnel. [19] See Figs. 10, 15 and 16.

The dimensions of shafts or tunnels providing access to an underground power plant from the surface are governed by the largest pieces to be moved into the plant. Vertical shafts are ordinarily smaller in cross-section than sloping or horizontal tunnels. However, the excavation of shafts is more expensive than that of tunnels and freight elevators are necessary,

Fig. 12. One method of treating the roof of Swedish underground generator chambers.





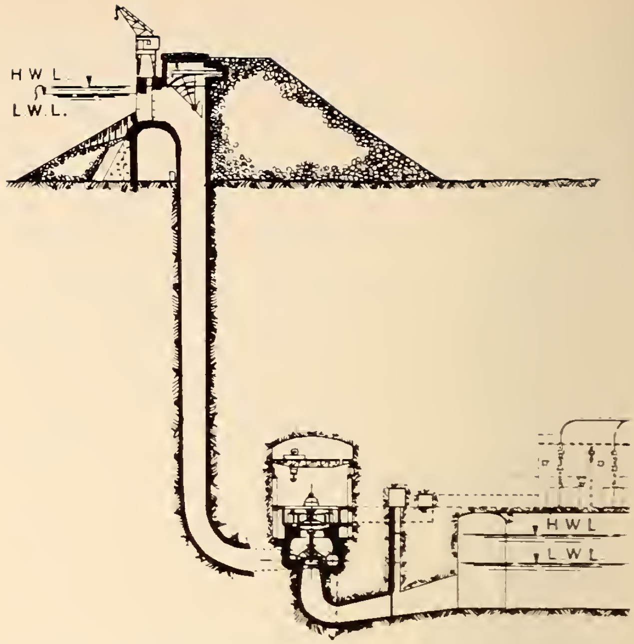


Fig. 13. Left: Cross-section of the low-head Lavey underground power plant in Switzerland.

Fig. 14. Above: A Typical Swedish underground power plant emplaced at a substantial distance below the surface.

whereas horizontal or sloping tunnels can be provided for rail transport, as at Innertkirchen, or truck transport as at Kemano and Chute-des Passes.

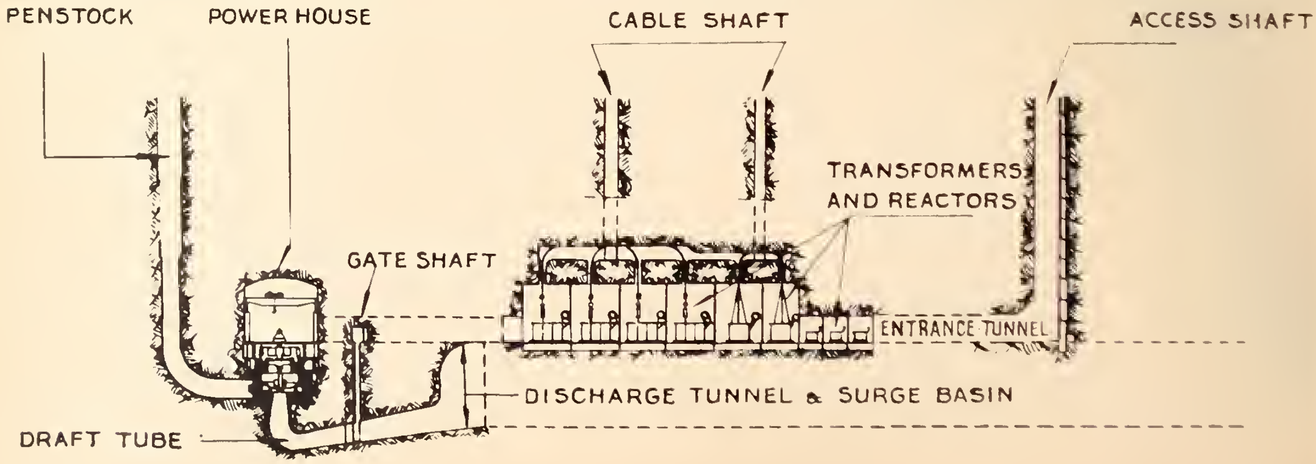
Careful consideration has to be given to moisture in underground power plants. Mention has been made of this as being provided through the use of interwall spaces, properly designed grout curtains, ventilating means and other features. It is of particular significance in connection with corrosion, particularly where rock bolting is relied on for the stability of walls and arches.

Operating Experience

Operating personnel in an underground power plant is about the same as that required for a conventional station. No direct disadvantage in the operation or maintenance of underground stations can be observed by comparison with surface stations.

Experience with underground power plants has shown that personnel find working conditions quite acceptable. It is true that an operator in an underground station does not have an opportunity of seeing the sun during his period on shift, but aside from this there is no difference between conditions in the two types of stations. With the underground plants, working conditions are more equable. Psychological factors may have some bearing but no difficulties have been experienced on this account because the power-station employee works in a dry, well-heated, well-ventilated and well-illuminated working area barely distinguishable from the normal station. In extensive power systems with both types of stations, there has been no noticeable tendency among the staff to apply for a discharge or trans-

Fig. 15. Vertical section through Harspranget underground power station, Sweden. At full development four Francis turbines will generate 96,000 KW each under a net head of 346 ft. using 15,120 C.F.S.



fer to a surface station, indicating apparently no discomfort is associated with working in an underground plant.

The author's own observations indicate that underground power plants are just as attractive as conventional plants from the point of view of comfort. There is usually less noise and vibration. Well-designed underground power plants with good lighting and even atmospheric conditions produce absolutely no impression or feeling of claustrophobia.

In an underground hydro-electric power station where full consideration is given to proper ventilation and associated air conditioning with control of humidity, good lighting and an attractive colour scheme, working conditions are fully acceptable. This was demonstrated by experience with underground factories in Germany, Japan, Italy, Czechoslovakia and Sweden during the war.

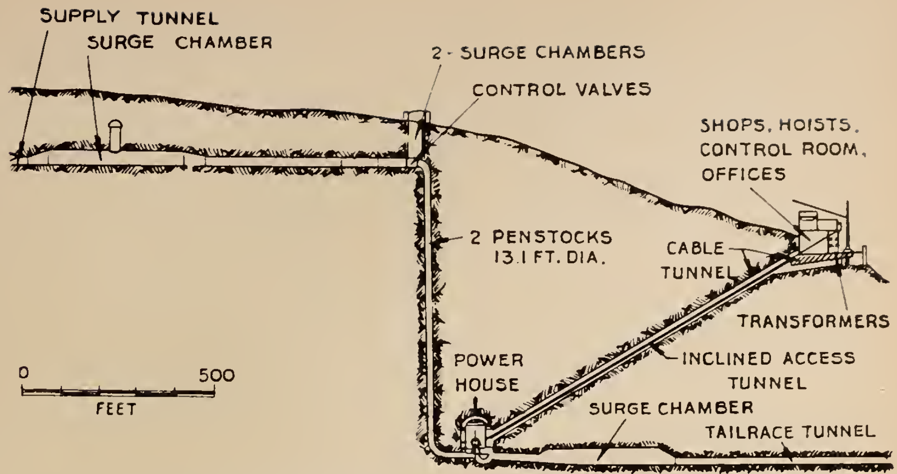


Fig. 16. General arrangement of Brommat underground power plant.

With a very few exceptions, underground factories in Germany, Japan and Italy were hurriedly located in existing caves, mines, quarries or tunnels, these being enlarged or altered as necessary to fit them for the new service, and without advance planning. Due to shortage of manpower, materials and equipment, desirable and necessary features, such as air conditioning, were often omitted. Many German and Japanese plants were subject to excessive dampness which caused rapid corrosion and deterioration of equipment, as well as discomfort and illness. The Japanese underground factories, in particular, have been reported as notoriously lacking in features conducive to worker efficiency, comfort and health.

On the other hand, underground factories in Sweden proved to be satisfactory, very largely due to the fact that proper consideration was given to ventilation and air conditioning, lighting and heating. Swedish workers are reported as liking the clean warm atmosphere of the underground factories, particularly during the long, dark winters. No special measures, such as sun-lamp treatments or special rest periods, were found necessary to maintain morale. Productivity proved to be as high as, if not higher than, that in surface plants. Employee turn-over was no greater than in ordinary factories, less than one per cent being reported as leaving due to location of the factory underground. Swedish industrialists were apparently pleasantly surprised to find how acceptable the underground factory conditions proved to their workers, as well as being economical.

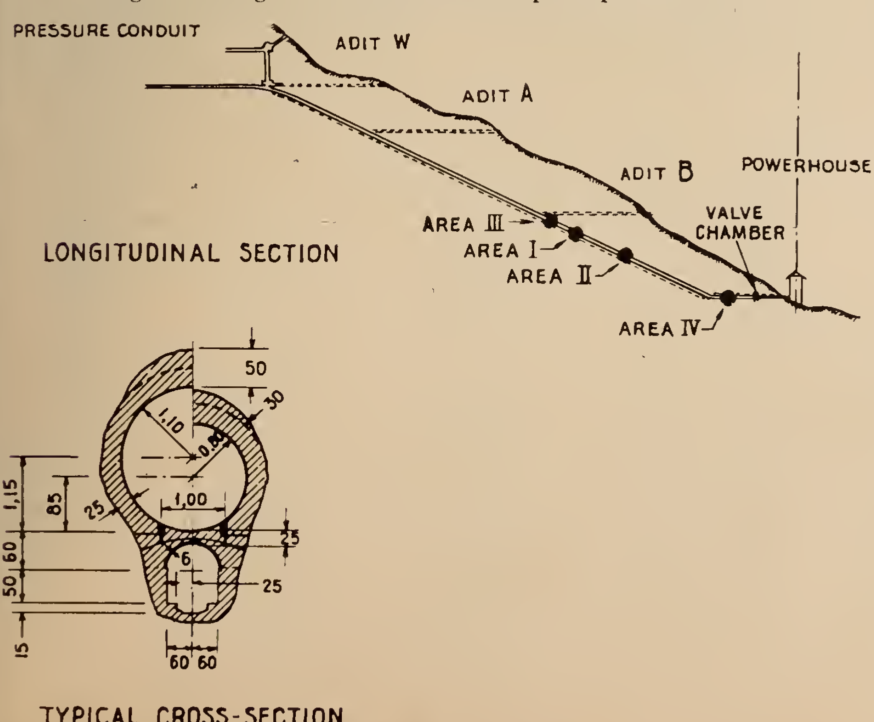
Failures

Pressure tunnels and conduits have been ruptured due to water hammer. It is less commonly known that several steel-lined pressure tunnels have been ruptured due to the inability of the surrounding rock to withstand the internal pressure.[10, 17]

Cases are known where ruptures have occured along fissures in the rock occasioning local concentrations of pressure and high resultant bending stresses in the liner.[10, 17]

The most notable failures were those at Gerlos, Austria, in 1945 and 1948. The steel-lined underground penstock serving the conventional Gerlos power plant was placed in service in August, 1945. On October 30th that year two failures along the penstock caused extensive damage. After repairing the damage and a single refilling, another similar accident of lesser severity occured. The plant was returned to service in March, 1948, but a fourth similar failure took place in September, 1948. Repairs were effected and the plant was back in operation December 22nd, 1948, since when it is understood to have operated without trouble arising from the penstock.[4, 5] Note Fig. 17.

Fig. 17. Underground Penstock for Gerlos power plant in Austria.



The penstock, inclined at an angle of about 27° to the horizontal, is some 4170 ft. long. It operates under a maximum head of 2035 ft. The internal diameter decreases from 7.22 ft. at the upper end to 5.25 ft. at the lower. Thickness of the liner varies from 0.472 in. to 1.20 in. Tensile strength of the steel is about 58,300 to 68,300 p.s.i. The penstock was designed to withstand full hydrostatic pressure without reaching the yield point of the steel. Shop and field joints were electrically welded and X-rayed. [4]

The penstock is emplaced in quartz phyllite and shale rocks, showing frequent transitions from compact to badly fractured schistose or argillaceous zones. The light to dark grey phyllite is intercalated with thin bands of limestone and dolomite. Some soft plastic zones were filled with fine greasy material. [4]

The four penstock failures involved extensive ruptures along lines parallel to the inspection and drainage gallery of 2.65 ft. width located under the penstock from which it was separated by a rather thin concrete masonry member. The failures were accompanied by erosion of substantial volumes of rock and flooding of the generating units. [4, 5]

All factors pertaining to the failures were closely investigated.[5] The evidence points to failure of the concrete sheath surrounding the liner with a strong presumption that failure occurred initially in the concrete masonry between the penstock and the inspection and drainage gallery. However, there is a very substantial volume of evidence linking brittle fracture of the steel with the failures.

Other Underground Power Plants

A 4375 h.p. underground diesel power plant was constructed in Hawaii during World War II. No particular difficulties were encountered with this station, from an operating point of view, although a diesel generating plant is inherently noisier than a hydro-electric power plant.

A 32,000 kw., 1482 p.s.i., 932° F. steam-turbine power plant was installed underground in Mannheim, Germany, and operated from July, 1941, to June, 1945, quite successfully. The Berne Electricity Co. built a 9,400 kw. underground steam-power plant at Engehalde near Berne. Although this is a standby plant, it has operated quite successfully. The French have built an underground steam power plant at Brest-Portzic with a capacity of 40,000 kw. in two units, since the war.

More recently the Stenungsund steam power station has been under construction in Sweden. Provision is made for two 140,000 kw. units to be completed in 1959 and 1960 respectively, with a third 200,000 kw. unit ready by 1961. The excavation provides for a fourth unit and provision is made for an additional two units. Though the first two units will burn oil only, the third will use either oil or coal, provision being made for transition to the latter. Steam temperature is 1000° F. and pressure 1050 p.s.i. for the first two units. Each boiler with its associated turbogenerator and transformer is placed in a separate chamber, the dimensions of which, for the first two units, are 410 ft. long, 80 ft. wide and 100 ft. high, excavated underground. Cooling water is carried through supply and discharge tunnels. Oil storage will be in unlined chambers underground.

Sweden is constructing a 75,000 kw. thermal capacity heavy-water-moderated nuclear reactor underground, near Vasteras. This plant will supply 250° F. hot water for heating dwellings and industries in the city. The reactor room, with dimensions of about 200 by 50 by 90 ft., the control room and the transformer room will be excavated from the rock underground, with the office facilities and storage rooms being located on the surface.

Typical Underground Power Schemes

With almost 300 underground hydro-electric power plants in service or under construction, it is difficult to select the most notable examples, given the wide range of location, geological settings, head, discharge, capacity and number of units involved, as well as date of construction. Table IV is a comparative tabulation of the head, number of units, installed capacity, type of waterwheel and setting (horizontal or vertical) for 18 of the world's leading underground plants. It will be noted the heads range from 244 ft. for Stornorrfors in Sweden to 2600 ft. for Kemano in Canada. The number of units runs from two, in several plants, to an ultimate 16 in Kemano. The minimum capacity is 61,600 h.p. in Japan's first plant, Sudagai, and the maximum the 2,400,000 h.p. for the complete Kemano scheme. With one exception the generating units are vertical, whether Francis or impulse types of turbines are used.

Table V furnishes a comparison of

Table V—General Features of some Underground Hydro-Electric Power Plants

the geological settings, step-up transformer and unit valve locations for the same plants as Table IV. The wide variety of geological conditions is noteworthy.

Table VI is a comparison, for most of the plants included in Tables IV and V, of the volume of excavation in the powerhouse chamber per kilowatt of installed capacity. It will be noted only 25 percent of the plants compared run over 0.35 cu.yd./kw. Somewhat over a third involve less than 0.25 cu.yd./kw.

A most important element in underground hydro-electric power schemes is the penstock or penstocks, because these facilities ordinarily represent a substantial percentage of the total construction cost, particularly in high-head plants. Table VII indicates the pertinent features for many of the world's notable underground plants.

Table VIII indicates the type of steel, with its ultimate strength and yield point, used in a number of the outstanding underground power plant penstocks.

By way of contrast and as an indication of possible savings in steel necessary for the lining of underground penstocks, attention is drawn in Table IX to three penstocks designed by Marinoni. These are characterized by linings of corrugated steel plates less than 1/10 in. thick over ordinary concrete sheaths. The steel lining acts only as a watertight membrane, the hydrostatic load due to the water in the penstock being transmitted to the surrounding rock. During thirty years of service there have been various incidents involving failure of the steel linings, particularly at Mese, due to collapse arising from the external pressure. These have been quickly repaired. The Mese liner has also been ruptured due to internal pressure.[10, 17]

The TI power station of the Snowy Mountains scheme in Australia is notable as the first major underground plant in which rock bolts have been used, in a planned manner, to form a diaphragm of material somewhat less in thickness than the length of the rock bolt, at or immediately behind the free surfaces of the power chamber excavation, which diaphragm is utilised as a structural member of ascertainable properties and behaviour.[15] Fig. 18 shows the general layout of the T1 plant while Fig. 19 illustrates a cross-section through power plant itself.

Table VI—Excavation Volumes for Underground Hydro-Electric Power Plants

Plant	Country	Year of Initial Service	Total Capacity in kw.	Powerhouse Excavation cu.yd.	Excavation for Transformer and/or Valve Chambers cu.yd.	Powerhouse Excavation cu.yd./kw.

Table VII—Pertinent Features of Embedded Steel-Lined Penstocks for Underground Power Plants

The plant was emplaced in a formation of granitic gneiss and granite, described by Lang[15] in the following terms:—

"The granite occurs in sheets 100 to 300 ft. thick intrusive into the gneiss. These sheets strike nearly east-west and dip towards the south at 40° to 50°. Their contacts with the gneiss show embankments, tongues and veins of granite in the gneiss. Several nearly vertical dykes of dolerite and basalt occur intrusive into both granite and gneiss, and vary in width from a few inches up to 40 ft. With the exception of one very thin basalt dyke which passes across the north eastern corner of the machine hall, none of the dykes intersect the Power Station."

The formation was found to be extensively jointed, with three principal directions of jointing, in a not very regular pattern, described by Lang[15] as follows (see Fig. 20).

"(a) Joints striking N 40° to 60° E, nearly parallel to the long axis of the machine hall, and dipping 25° to 35° upstream. A zone of joints in this direction persisted over the full length of the machine hall roof, varying from one to several major joints in width ½ to 1 in. of crushed rock and a little clay in the granite, to a zone 5 to 10 ft. wide of close jointing (2 to 6 in. spacing) in the granitic gneiss.

"(b) Joints striking N 30° E making an angle of about 30° to the long axis of the machine hall, with dips varying from 65° W to 80° E. In one localized zone these joints in both the granitic gneiss and granite were closely spaced, clay coated and persistent.

"(c) Joints striking N 130° E, nearly at right angles to the machine hall, with an almost vertical dip. Certain joints in this direction spaced 40 to 80 feet apart were very persistent, open up to ¼ in. and limonite stained. All the main water inflows occurred along these joints.

"The two rock types exhibited characteristic differences in the general spacing of the joints and the nature of the joint surfaces.

"The joint spacing in granitic gneiss was usually between 6 in. and 2 ft. The joint surfaces were usually smooth and slickensided and dark green in colour due to thin coatings of chlorite. Clay coatings were not common and most joints were tightly closed. Because of the nature of the joint surfaces it was common in the excavations for the granitic gneiss to break to the natural joint planes rather than break across the rock resulting in angular surfaces and local small overbreak in many places. The joint spacing in granite was variable but was generally in the range of 1 to 5 ft. The more closely jointed zones occurred irregularly.

"Slickensided joints were not so common as in the gneiss. The joints were

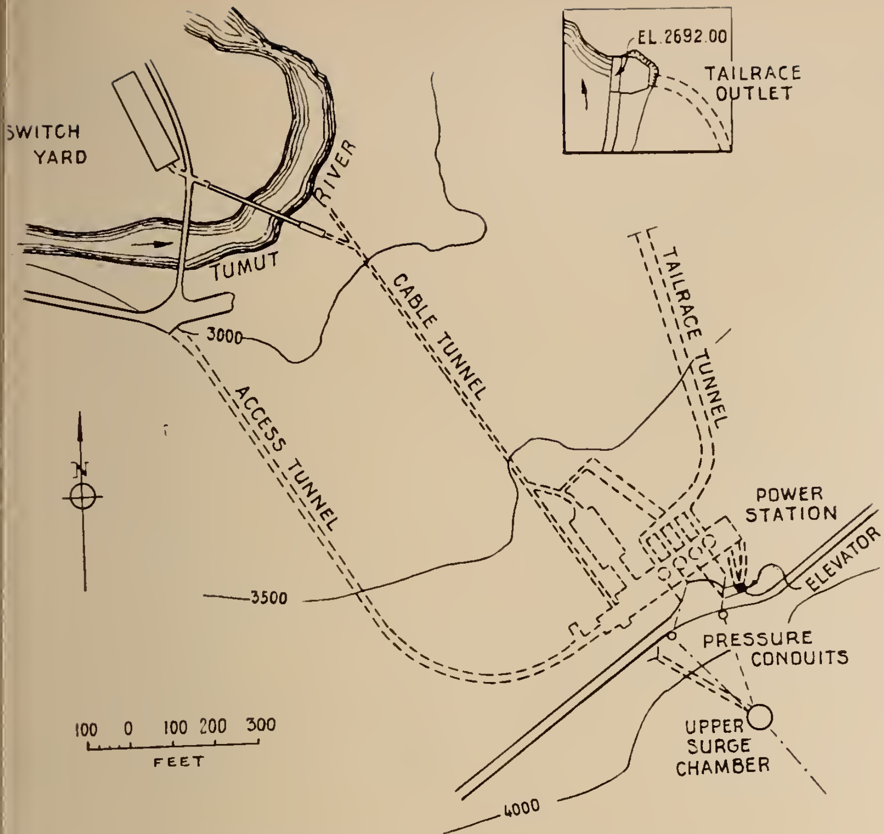

Fig. 18. General layout of the Snowy Mountains, T1 Power station.

mostly tightly closed with the exception of certain joints with strike N 130° E already mentioned which were open, limonite stained, and water bearing. Because of the generally tight nature of the joints in the granite, it was found that breakage of the rock often occurred along new fracture surfaces rather than along natural joints.

"Another geological structure of importance was a nearly horizontal persistent zone of close fracturing, a few inches wide with heavy limonite staining along the fractures which occurred throughout the machine hall and transformer hall area [(d) Fig. 20]. It was located a short distance above the portals of the penstock tunnels on the upstream wall, and above the tailrace tunnels on the downstream wall."

CONCLUSIONS

The following significant factors relative to the design, construction, operation and maintenance of underground power plants have been developed in the paper:—

1. Some 300 hydro-electric plants are in service or under construction, with an installed capacity of about 31,000,000 kw.
2. About the same capacity is in the planning stage.
3. No limitations due to climate, location, head, flow or capacity exist, in development in underground plants.
4. Major steam and atomic power plants have been, or are being, built

PLASTIC BEHAVIOUR OF STEEL FRAMES

Experimental Verification of Theory

J. W. Dolphin, *Professor and Head of Department of Civil Engineering, Royal Military College, Kingston.*

Although three structures designed using the Plastic Theory are in use in Canada today, little evidence is available illustrating the behaviour of members and structures loaded to collapse. A series of tests were made on beams and frames of standard rolled sections and the results which include the verification of basic principles are presented.

As part of a short course dealing with the use of the Plastic Theory in structural design, several tests were made on full sized beams and frames in order to show the relationship between the theory and the behaviour of full sized members. The tests were arranged to show:

(a) The moment-curvature relationship.
(b) The fundamental concept of moment redistribution.
(c) The correspondence between predicted and experimental loads and collapsed forms.
(d) The effects of shear and instability.

Moment Curvature Relationship

The basic concepts of the Plastic Theory have been presented elsewhere.[1, 2] The moment curvature relationship developed in that theory is shown in Figure 1. Also plotted in this figure is a curve of the experimental values found during the test of a 10 WF 25, eleven feet long, loaded at the third points in pure bending.

Residual stresses in the beam caused local yielding and resulted in a divergence from the theoretical curve. Full plastic moment was realized however and the flat top characteristic of the M-ϕ curve was obtained. Since the Plastic Theory is based, among other things, on the assumption that a material will satisfy the theoretical M-ϕ relationship, this demonstration is graphic proof that structural shapes may be used in Plastic Design.

Redistribution of Bending Moment

The redistribution of bending moment in a continuous structure with portions within the plastic range is one of the most important basic concepts of the plastic theory. Once yielding occurs in one portion of a statically indeterminate structure, additional loads result in other points accepting a greater share of the moment. This continues until a sufficient number of points within the structure have yielded (developed "plastic hinges") so that the structure becomes a mechanism and can no longer support additional load.

An 8 B 13 beam, span 12 feet, was rigidly fixed at one end and simply supported at the other. It was loaded to collapse to show the redistribution of moments, the loading arrangement being as shown in Figure 2. The curves of this figure show:

(a) The typical load deflection curve.
(b) That the moment at *A* did not reach full plastic moment because of the high shear at the point. This was partially offset by strain hardening at *A* caused by the large rotation at this point.
(c) Even though some rotation of the beam axis at *A* did occur, the moment at *B* reached full plastic moment and failure of the structure occurred at a value only slightly higher than the predicted 29,300 lb.

From this test it can be seen that the moment was eventually distributed as predicted and that the Plastic Theory can be applied to indeterminate structures.

Simple Frames

In order to prove the application of the plastic theory to frames, six small frames and two large portal frames were tested to collapse. The small frames were fabricated at 4 B 13 sections to the dimensions shown in Figure 3. Two frames each were tested as follows:

(a) single vertical load, midspan on the beam
(b) single horizontal load, at the top of the column
(c) vertical and horizontal loads combined

Figure 3 shows the results of the tests on one of the frames tested with horizontal and vertical loads. The formation of plastic hinges in the frame as the loading increased is clearly shown by the change in slope of the curves. The failure of the frame at a value only slightly higher than the predicted collapse load shows again that the plastic theory can be applied to frames.

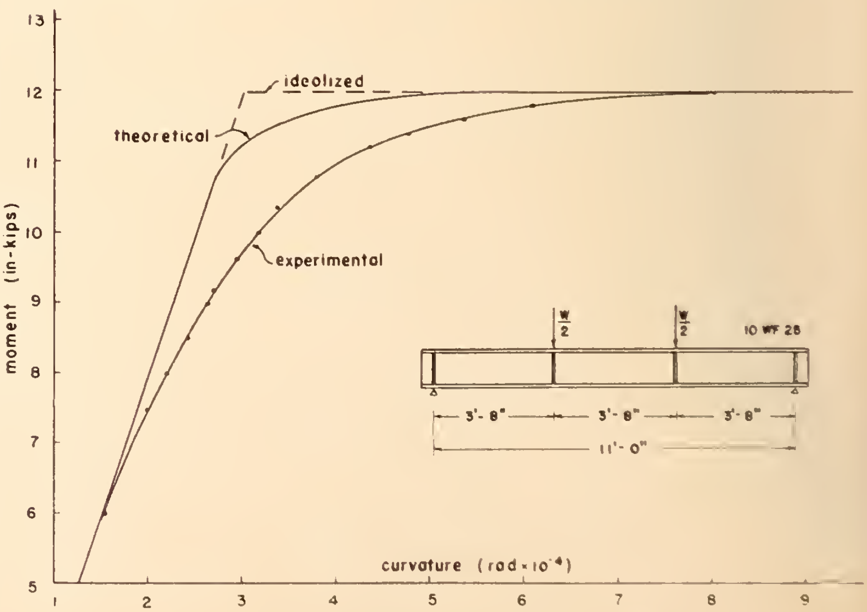

FIG. 1 MOMENT - CURVATURE RELATION

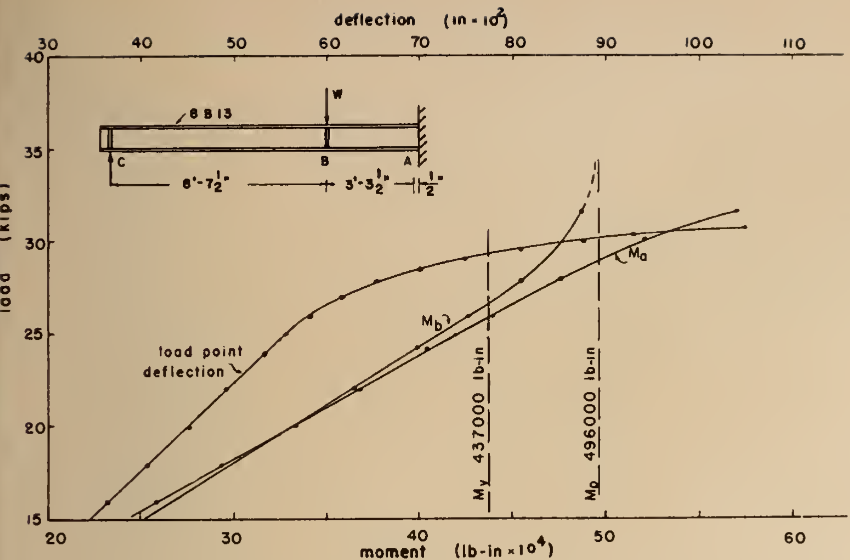

FIG · 2

The results of the other tests on the small frames showed almost identical results. It is interesting to note here that 20,000 p.s.i. at the most stressed point would have resulted in *W* being restricted to approximately 5*K* whereas the factor of safety usually used in Plastic Design of 1.88 would have given a working load of 9.2*k*. This value is still below the load at which yield first occurred anywhere in the frame and permits an additional 84 per cent load to be carried without distortion or fear of collapse.

The large portal frame which was tested is shown in Figure 4 and the loading arrangement in Figure 5. The result of the test of one frame is plotted and again shows the same applicability of the Plastic Design method. The first deviation from elastic conditions appeared at 23 kips when the curve of the vertical deflection at the ridge ceased to be linear. Maximum permissible design load (governed by 26,600 p.s.i. at *E*) occurred at a value of *W* of approximately 6 kips which indicates a factor of safety of over 1.9. The factor of safety of 1.41 intended by the Plastic Theory when wind forces are present was slightly exceeded leaving a safe margin before first yield in the structure.

The theory of failure of the small frames and of portal frames is discussed in other publications.[1, 2]

Shear, Instability and Connections

The effect of shear on plastic behaviour is complex but is essentially a reduction in plastic bending capacity due to yielding of the web under combined stresses. This phenomenon is discussed and formulae derived in references 2 and 3 but it should be noted that the formulae do not allow for strain hardening which accompanies yielding of this type. Tests on a 10 WF 25 beam of 8 foot span loaded equally at points 21 inches from the reactions showed less reduction in flexural strength than was predicted. The tests did serve to show however, that formulae designed to predict failure when shear is present are satisfactory.

Lateral instability of a 10 WF 21 loaded equally at points 28 inches from the ends of a 10 foot span and unsupported laterally, failed when the load was only 65 percent of the estimated plastic collapse load. It was definitely shown that if large rotations are to be permitted to occur, lateral movement must be prevented. In practice, points of possible hinge formation are braced laterally as in conventional lateral design.

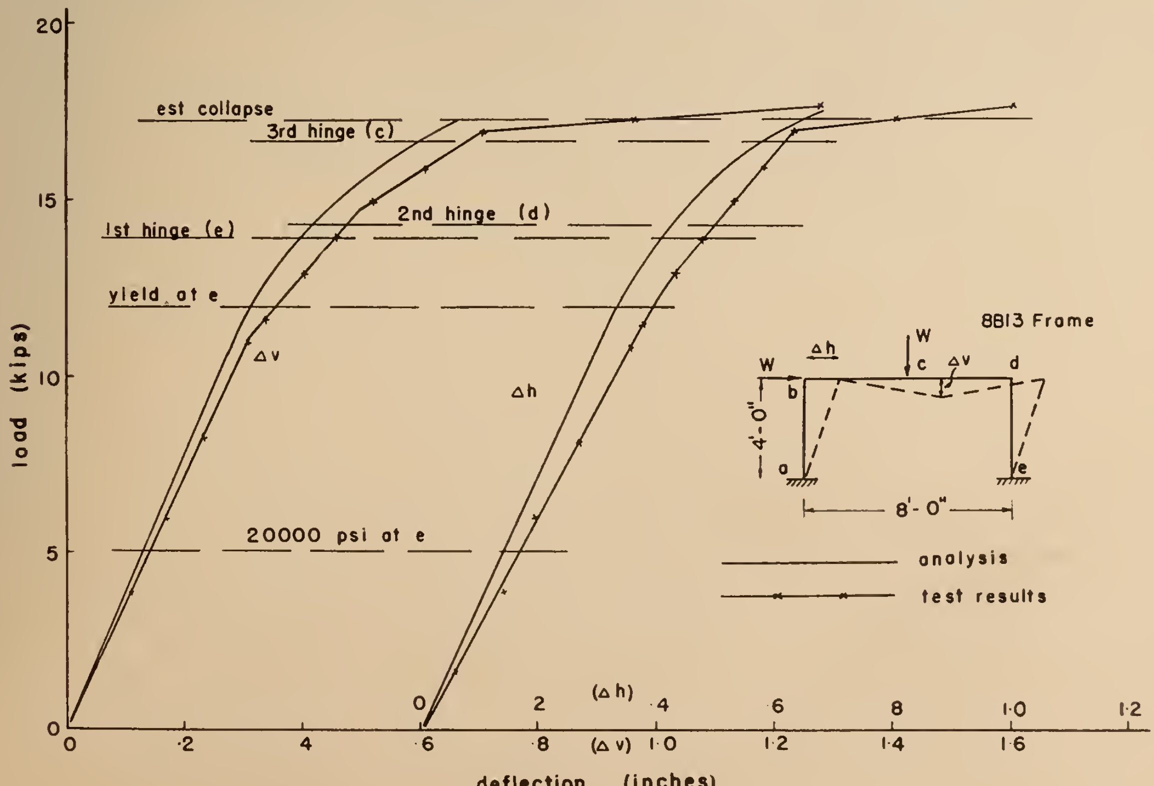

FIG · 3

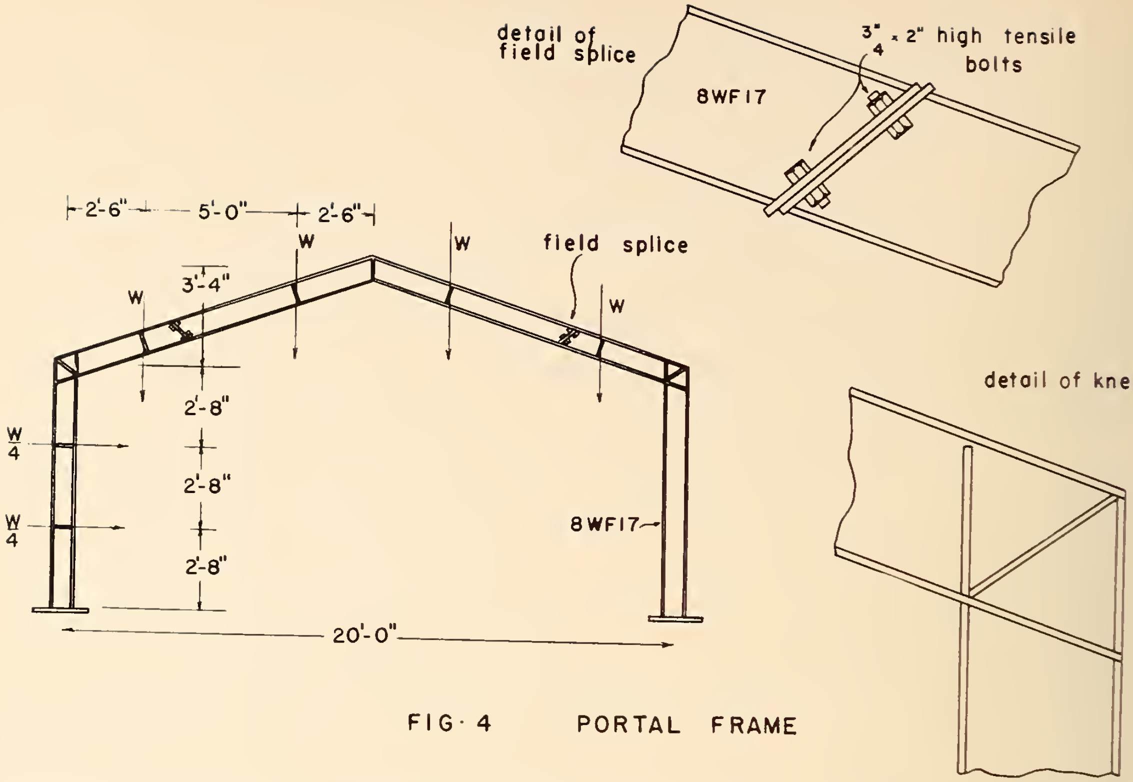
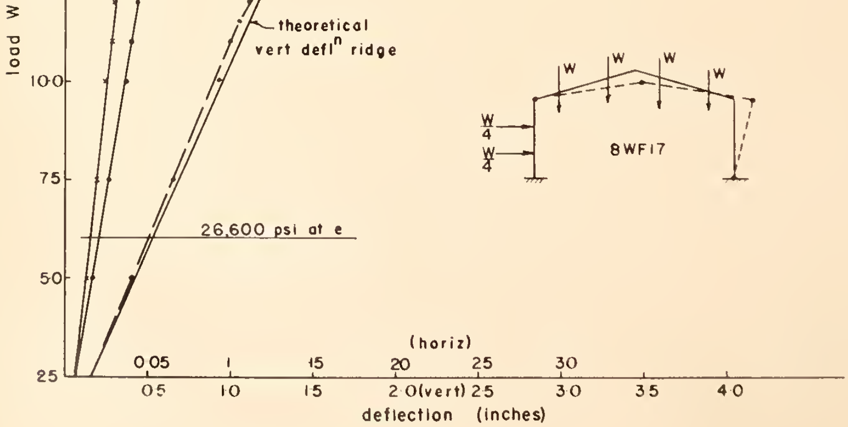


FIG· 4 PORTAL FRAME

Local deformations sometimes occur in WF and I sections when large strains occur. For full plastic development of a hinge resulting in proper moment redistribution, large strains are required. To test this condition a 6 WF 15.5 beam of 10 foot span was loaded at its third points and full plastic resistance attained without flange buckling. The ratio of flange breadth to flange thickness for this beam is over 22 while the recommended[4] maximum ratio is 17. In certain other tests, particularly in the portal frame test, flange buckling did occur, but not until after the hinge had been formed so that no reduction in capacity occurred.

Structures designed to take advantage of moment redistribution must be continuous. Frequently a knee joint is required. The combination of bending and shear at this joint usually requires that the web be reinforced and simple rules have now been formulated for these joints.[5, 6]



FIG· 5

Tests were made on two knee joints using 6 B 12 sections. One knee was unreinforced, the other was reinforced in the web. Without web reinforcement the joint carried only 79 percent of the theoretical capacity while the reinforced joint carried 99 per cent.

Conclusion

These tests demonstrated beyond doubt that the Plastic Theory can be applied to large size frames built up of rolled structural shapes and that the use of higher working loads will, in most cases, result in more efficient use of the material with a consequent saving in cost while not causing permanent distortions.

Further details of these tests and photographs of deformed members may be seen in another paper on this subject.[7]

The Cost Of Housing

Robert F. Legget, M.E.I.C.

Director, Division of Building Research
National Research Council, Ottawa.

Paper presented to the Toronto Branch of the Engineering Institute of Canada, 10th April 1958

THE COST OF HOUSING is an important public question in Canada today. It is the subject of many discussions, both public and private. The man in the street is vitally concerned with housing, if only because of the difficulty that so many people have in finding the sort of homes they need. All too many citizens are continually concerned with the problem of financing the shelter they use. Almost all Canadians indulge in dreams, at some time or other, if not of castles in the air at least of a modern house unencumbered by mortgage.

Not only is housing a matter of concern to the man in the street, but it now occupies a dominant position in the national economy. The value of housing built in Canada each year is approximately equivalent to the total cost of all major heavy engineering construction. When thought is given to the many miles of roads, air fields, and the great dams and power plants that are under construction in Canada today, this one fact illustrates vividly the national importance of housing. This importance has been made clear in the recent report of the Royal Commission on Canada's Economic Prospects (the Gordon Commission) which estimates that between 1956 and 1980 Canada will spend on housing forty-three billion, seven-hundred million dollars, based on the 1955 value of the dollar.

It is not inappropriate, therefore, for the Division of Building Research of the National Research Council to regard research into the technical aspects of housing as one of its greatest responsibilities. All of its studies in this field are carried out in close association with Central Mortgage and Housing Corporation which it serves as a research wing on all aspects of technical research. Both the Corporation and the Division have the pleasure of co-operating with the National House Builders Association, through its Research Committee. In all questions affecting the use of wood in house construction, the Division correspondingly works closely with the Forest Products Laboratories of Canada.

In the many discussions on housing in which members of the Division of Building Research staff take part, often in association with members of the staffs of the other organizations mentioned, the cost of housing is paramount. Over the years it has become clear that there are many misconceptions in the public mind about this vital aspect of housing. It is not going too far to say that the Division knows of no technical question on which there is so much uninformed thinking in Canada today as the cost of housing. Correspondingly there are few things that are criticized more, in connection with housing, than the high costs that have to be met in the provision of shelter in Canada in 1958. There is, accordingly, a desperate and widespread search for some solution to the problem of "low cost housing". The Division also encounters remarkable misconceptions regarding the relative position of the cost of renting shelter and of purchasing it. There are probably more misconceptions about rentals than about the cost of new housing.

Comparisons are repeatedly made, in discussion between the cost of new housing and of rentals today, and the corresponding costs in 1939. The Division hears all too much in the way of uninformed criticism about the effect of standards and codes upon the progress of housing, and even upon its cost. Statements are made, often by amateur "experts", about the fact that European countries can produce low-cost housing, and suggest that Canada should be able to do the same. Scandinavia is usually mentioned prominently in such discussions. Some speakers will even point to the United States, again in contrast with Canada, as a country in which low-cost housing is being achieved. There is a claim that if codes would permit the use of prefabrication (on the assumption that they impede this progress), in some mysterious way low-cost housing would immediately be available to Everyman. And in extreme cases speakers will wax eloquent about the wonderful possibilities which "plastics" present as the final answer to the great low-cost housing problem.

This paper is an attempt to cut through the fog of popular misconception on this problem and to make available in convenient form some of the facts of the situation upon which discussion must be based, if it is to be effective. It is, in fact, a simple application of what is sometimes called "engineering economics" to a subject with which engineers, most unfortunately, all too often have too little to do. In order to make the presentation as straightforward as possible, figures will be used for illustrative purposes only, discussion being confined rather to matters of principle. The objective will be to discover what is really meant by the cost of housing and, if this can readily be stated, to see in which directions reductions in current costs are possible.

The Cost Of New Houses

Confining discussion initially to the construction of individual single-family houses, which today make up the great majority of residences for Canadians and which represented 69% of all new home construction in 1957, what is really meant by the cost of such new housing? Many people think only of the cost of the structure itself or the amount that has to be paid to the builder. This, however, is only part of the cost. Table I shows a breakdown of the items which, together, must be considered in all proper considerations of the actual first cost, or capital cost, of a new house in Canada today. One small item which is persistently neglected is the interest upon capital which must be paid during the construction of a house until such time as the house is actually occupied.

Real Or Annual Cost

Perhaps the most difficult aspect of the entire question of housing costs is to gain general appreciation for the fact that the real cost of housing is not the first or capital cost, but is the annual cost. To engineers and others concerned with the economics of building, this is so obvious that it is almost a truism. Unfortunately, however, this appreciation of the importance of annual cost is restricted to a very narrow circle. It is only by proper consideration of annual costs that any true comparison of real housing costs can be made. Table II lists the items that must be considered in an assessment of the real or annual cost of a house in Canada today.

Some comment is required on the following items shown in Table II:

(*a*) This must be the interest, at the current interest rate for real estate loans, upon the *total* capital outlay for the house, i.e. upon the total of all the items in Table I, irrespective of what "down payment" has been paid in connection with a first mortgage.

(*b*) Payments for the anticipated *amortization* of the property must be included in realistic calculations of housing costs, if only because such payments must be made when houses are purchased under the National Housing Act. Further than this, however, it is only sound economics to allow for such payments. They represent the liquidating of the mortgage within a specified number of years from the time the house is completed, a period of up to thirty years under existing N.H.A. regulations. This means that, at the end of the mortgage period, a house will be free of debt and yet, if maintenance has been carried out effectively, the house will have a certain market value. This value represents what can best be expressed as "enforced savings".

It is easy to overlook the fact that exactly the same savings could have been achieved if the house owner had, for example, rented accommodation throughout the period of the mortgage and invested soundly exactly the same regular capital amounts as he has paid on his mortgage. What has tended to obscure this aspect of house purchase has been the steady devaluation of the dollar during recent years, the sale value of a house therefore increasing in the course of time instead of decreasing, as it does in real value. And since human nature is what it is, the enforced saving which the purchase of a house usually involves is, for most citizens, one of the few really effective ways of saving regularly.

(*c*) *Maintenance* costs for a house are all too often forgotten, especially in cost calculations made very shortly after a house has been occupied when everything is ship-shape and nothing obviously in need of repair. But over the effective life of a house, even when designed and built to the highest standards, maintenance costs must be incurred to cover the repair of ordinary wear and tear, the replacement of breakage, the repainting of painted surfaces, the maintenance of mechanical and electrical equipment in good order etc. Some of these individual items can be appreciable but long experience has shown that if total maintenance costs are averaged over the useful life of a house, an annual average cost can be obtained that may conveniently be expressed as a percentage of the total first cost of the house. For modern well-built Canadian houses, an average annual sum of 1¼% is the minimum that can be safely allowed.

As with all averages, there can be substantial deviations from the figure suggested. For example, maintenance of the ordinary Canadian house involves painting at least a part of the

exterior of the structure. If this costs, say, $60 per year ($180 every three years), it can readily be seen that, with an interest rate of 6%, this annual payment is the equivalent of $1,000 added to the capital cost of the house. If a satisfactory exterior finish which does not require any painting can be obtained for less than $1,000, then there exists economic justification for changing the design to include this finish, although there may sometimes be aesthetic or other personal objections to such a course. Correspondingly, taxes may be higher if the exterior finish of a house is improved.

(*d*) Little need be said about *taxes,* as a component part of the real cost of housing, since they are generally so recognized. It is sometimes necessary, however, to point out that it is this item which must include the financial allowances for new schools, new hospitals, new fire and police services and the many other necessary civic provisions for new housing areas.

(*e*) Costs of *operation* of a house are well recognized household expenses; that they must be considered in determining the true cost of housing will be evident when it is recalled that rents may or may not include the four items listed (heating, light, power, and water) so that all must be included in any comparisons that are to be valid. Further, the cost of house heating is directly related to the expenditure upon insulation. There are available helpful papers which enable the economic thickness of insulation to be determined for any locality in Canada, with varying prices of insulation and fuel, there being for any combination of these prices and a fixed heating load a thickness of insulation beyond which it does not "pay" to go in increased capital expenditure.

(*f*) The cost of *insurance* upon a house, for possible loss due to fire and damage due to "Acts of God", is not only an essential annual charge against a house when so required in connection with the issue of a mortgage, but is also a more than desirable expenditure even without this imperative.

(*g*) The inclusion of the cost of *transportation* as a part of the real or annual cost of housing may at first sight be surprising. It is certainly a hidden cost, or is perhaps more accurately described as the element of housing cost usually neglected, if indeed it is even recognized. The essential character of this item, if housing costs are to be realistically assessed and equitably compared, is shown as soon as it is remembered that in practically all Canadian cities new housing developments are located on the outer fringes of the existing built-up areas, thus being removed by steadily increasing distances from existing industrial and commercial office areas.

There are, of course, new industries also being built on the peripheries of cities but in general the steadily increasing distances to be travelled by new householders, as the scramble for relatively low cost building lots continues, cannot be denied. Public transportation may be used, in which case the cost is clear cut and easily recognized, but even when private automobiles are used, the cost is still there, even though it may not be so generally recognized or acknowledged. To all this should really be added the value of this time wasted in travelling, beyond a certain minimum that will always be necessary.

An Example Of Annual Housing Costs

Against the background provided by these explanatory notes, it may be useful to illustrate the discussion with a typical numerical example. This is shown in Table III, a computation based on existing rates and interest charges, applied to a capital investment of $20,000. This sum may be broken down into $15,000 as the cost of the structure, and $5,000 for the land, services and all other capital items shown in Table I.

Table III

Example of Annual Housing Costs

	Annual Amount	Percentage of Total
Interest on capital at 6%	$ 1200	50
Amortization charges, based on 25 years, compounded semi-annually	335	14
Maintenance at 1¼%	250	10
Taxes (at least . . .)	300	13
Insurance	35	1
Operation — heating and water	180	8
— light and power	100	4
Total excluding transportation	$ 2400	100

Some of the figures suggested might be criticized as being too low; they cannot be regarded as unreasonable. Accordingly, it is significant that the total annual payment is the equivalent of $200 per month. This is one per cent of the total invested capital. Older readers will perhaps remember, from the days when renting accommodation was not as uncommon in Canada as it is today, that a generally accepted rough and ready rule for calculated rentals was precisely the figure arrived at (with no preconceived ideas) in the above calculation—one per cent of the total capital cost per month. It is the annual cost shown in the Table that should be compared with annual rental charges. And it is rather more than surprising to find how many Canadian citizens have no idea at all of the rental they would have to pay to obtain accommodation equivalent to the houses in which they live.

It may be objected that the total annual cost shown in Table III includes the "enforced saving" in the amortization item, an objection that is well taken. But this sum is only $335 per year ($28 per month), so that if it is completely deducted (a questionable procedure) the over-all picture is still not substantially changed, the annual cost of the $20,000 property still exceeding $2,000 without including any transportation costs.

Another objection to such figures as those just presented is that many Canadians build their own homes, at least in part, again an objection often well founded. But the labour of the owner has some value, if only as the equivalent of the labour saved in the house-building operation. This will be little more than "common labour" in most cases, skilled tradesmen having usually to be employed for all specialist work. As an extreme case (and anyone who has participated in house building while performing his regular daily job will be the first to admit that it is an extreme case) consider the work of a man who spends 20 hours every week at his house-building "hobby" for 50 weeks of the year, long enough to include the usual duration of the construction of one house. This would be a total of 1,000 hours which would be worth, at $1.50 an hour, a total of $1500 or just 10 per cent of the total cost of such a typical house as used for an example in Table III. The corresponding reduction in annual cost would be a maximum of $115 (or 4.8%) but only if the amortization item is neglected. Admittedly these figures make no allowance for the personal satisfaction that self-building gives but even this reaction should not be allowed to obscure the basic economics of the cost of housing.

The percentages included in Table III are worthy of note. Approximately two-thirds of the total annual cost of housing is in the first two items, an amount arrived at by combining the total capital cost with a given interest rate. The remaining third is made up of items that do not depend directly upon the current interest rate for money and items which, if determined as has been suggested, are almost fixed amounts, capable of little change. Any appreciable saving in the real cost of housing must, therefore, come from a reduction in capital cost or in interest rate, or from an increase in the amortization period. Of these three components, the third is almost negligible as compared to the other two; there is also little probability of any substantial increase in amortization periods for Canadian houses in the immediate future. In considering possibilities for reducing the cost of housing, attention must therefore be concentrated upon interest rates as well as capital costs.

A Note On Transportation Costs And Housing

It is only with the development of post-war "urban sprawl" and the concurrent increase in the ownership and use of private automobiles, that the cost of transportation has loomed so large in the housing picture. Transit authorities are all too well aware of the changing pattern of the urban transportation picture, possibly the most serious aspect of which is that as the areas to be served by urban transportation facilities have increased, so also has the use of private automobiles. In consequence, while passenger volume has often dropped, route mileage has had to be increased. So serious is this that some Canadian municipalities are facing the prospect of subsidizing their local transportation systems. When this has to be done, transportation costs will be partially reflected in municipal taxes in addition to the direct costs involved which are obvious, even if usually neglected, in discussions of housing costs.

Assume that in order to obtain a building lot at "reasonable" cost, a prospective householder has to buy land ten miles away from his place of work and that he works the usual five-day week. Table IV shows the transportation costs involved, using various means of transport and minimum mileage rates. It will be seen that, even with the minimum figures used, at least $10 per month must be included in any estimate of housing cost (and corresponding figures for other housing proposals), if realistic comparisons are to be made between various alternatives. It may usefully be noted that since the cost of the house structure will be approximately the same within any one municipal area, the extra cost of transportation can properly be equated against the decrease in the cost of land and services with increasing distance from the civic centre (a decrease to which there is, of course, a limit).

$125 per year represents, at 6% interest, a capital amount of over $2,000 which therefore represents the absolute minimum difference in the cost of a building lot to justify the selection of a location ten miles from place of work instead of a location adjacent to it, if available, such that no transportation cost would be involved.

A Further Look At Capital Costs

If reference be made again to Table I it will be noted that the only cost over which a prospective householder has any control is the cost of the structure. The cost of land will be determined by land-market conditions for the area in which he wishes to build, a matter to be referred to again later. The cost to him of the necessary services will be determined by the actual installation costs, either by municipal authority or the land developing agency. Land survey costs are based on fixed professional charges. Legal and realtor's fees are based on the cost of the property at percentages fixed for every locality. Interest during construction will depend on the duration of the construction period and current interest rates.

What of the cost of the house itself? For a typical Canadian house of today, the total cost can be broken down, roughly, into:

Materials	45%
Labour	45%
Overhead and Profit	10%
Total	100%

Some readers will remember the old saying that "one third of the cost of a house goes to the local lumber yard", a rough and ready guide that agrees with the suggested breakdown of costs.

For the conventional type of modern house, containing what the "average Canadian" today demands, there can be little saving in the cost of materials, if purchased through the usual sales channels. Any appreciable savings can, therefore, only come from a more efficient use of labour such as by the use of prefabrication. Canadian house building practice, however, is not unduly inefficient; on the contrary, the operation of most well established builders is reasonably efficient; it has to be, to avoid the inevitable consequence of competition. Big savings in labour costs, for conventional construction, are not therefore to be expected. Even if a saving of 10% could be effected, this would mean only a saving of 4.5% on the total cost of the structure, and certainly not more than 3% on the total capital expenditure.

Do Standards Affect Costs?

When those who are concerned about the cost of housing first encounter figures such as those just cited, an almost immediate reaction is that they do not tell the true story "since building codes (or standards) interfere with any *real* reduction in costs." What are the facts?

On the technical side, most of the housing built in Canada since the war has been under the aegis of Central Mortgage and Housing Corporation, and therefore subject to the C.M.H.C. Building Standards*. The

Table IV

Typical Transportation Costs

Two trips per day of 10 miles each: 5 days per week: 50 weeks per year	ANNUAL COST
(a) If public transportation is used, at 25c per trip	$125
(b) If private car is used with single passenger at 10c per mile	$500
(c) If private car is used, shared by 4 passengers at 10c per mile	$125

* Published by the National Research Council, Division of Building Research, as "Housing Standards" since Jan 1st 1958.

Corporation permits the statement to be made that few, if any, of the houses built under the NHA have been constructed down to the minimum requirements of their "Building Standards".

There are other standards, however, in the housing field, those purely personal preferences which arise from social pressures. Lest it be thought that this is a facetious reference, Table V is included to show how these "social standards" (and certain other factors) do affect the cost of housing. The figures represent national averages for single family houses constructed under the National Housing Act for the years noted.

(*i*) It was not "Standards" or "Codes" that caused the increase here noted but mainly the desire of the average purchaser to get a larger home than the minimum required under CMHC requirements.

(*ii*) Although the increase in the size of the average home is surprising, some increase in the cost per square foot for house building is to be expected in view of the decrease in the value of money between 1947 and 1957. When it is recalled that during the period under review the actual value of the building dollar has decreased by about 43%, it will be seen that Canadian builders, on the average, have been doing a good job and that they are not to be blamed for the state of housing costs in this country today.

(*iii*) This increase is typical of the figures commonly used in current popular discussions of housing costs. It will illustrate the misleading character of cost comparisons on a total cost basis (a matter to be dealt with in the next section). Its true character can only be realized when it is recalled that it includes for a much larger average size of house as well as the over-all increase due to the change in the value of money in these last ten years.

(*iv*) Finally, if there are any doubts about the serious effect that land costs have had upon housing costs, this over-all national average of an increase in the cost of land for single family dwellings of 336% should serve to remove all such indecision. When it is remembered that in many smaller localities, the cost of building lots has not changed appreciably, the full significance of this figure will become apparent. It must be pointed out that a part of the increase shown must almost certainly be accounted for by the fact that it is more common today than in 1947 to include in the cost of land for housing the cost of the necessary services. Making every possible allowance for this, however, and for the change in the value of the dollar since 1947, the fact remains that increases in the cost of Canadian building lots in the last decade cannot be rationalized in any way at all; the increase constitutes one of the major unsolved problems in the high cost of housing in Canada today.

How Should Capital Costs Be Compared?

The third column in Table V shows clearly how misleading a comparison of unqualified capital costs for housing can be. It is therefore essential, in any reasonable discussion of housing costs, to specify capital costs with reference to (*a*) the year of building and (*b*) the size of house involved.

All citizens are well aware that the value of the dollar has changed appreciably during recent years. A convenient way of measuring the change, with reference to housing costs, is by means of a "construction index", a figure compounded from a number of individual unit costs which, together, give a good general index for true building costs in any one year. Typical constructions cost indices are:

1929	–	100
1940	–	93
1955	–	235

These figures show that building costs in 1955 (and so today) are at least two and one half times what they were in 1940, due only to the change in the value of money. It is therefore essential that when capital house costs are mentioned, the year of construction be given too, so that due allowance can be made for the change in the value of money.

It is not without interest to note that, in view of this, and making allowance for the change in the standards of house equipment (such as the modern heating systems and tiled bathrooms, demanded today) it can easily be shown that the true value of house structures as built in Canada today is at least as good as, if not a good deal better than, the value of houses built before the war.

Total costs of houses must also be defined in relation to the size of the house in question, as can be seen from Table V. A common way of doing this is to divide the total cost of a house by the finished floor area, thus getting a cost per square foot of floor, as used in the table. This is a useful "unit cost", much more meaningful than any total cost can ever be. At the same time, even this unit cost can be somewhat misleading. Its use is based on the assumption that the ceiling heights are the same for all the houses, the costs of which are to be compared. This may be true if all the houses under review have been built under C.M.H.C. regulations. But if older houses, or some houses of advanced architectural design, are to be included in any comparison, then square foot costs may not be accurate since the volumes of enclosed space represented by one square foot of floor area will not be the same. Further than this, the calculation of the "finished floor area" of a house (especially if stairways are involved) is not a straightforward matter and, to some extent, is dependent upon individual judgment.

An alternative suggestion has been advanced of measuring the total area of finished floors, walls and ceilings, i.e. the total finished area within the house, and then dividing the total cost by this figure to give a unit cost per square foot of finished surface.

Table V

Estimated Costs of Single-Family Dwellings Financed Under the National Housing Acts

* Estimated by loan applicants.
** Land cost data reflect the prices paid for lots. These prices vary with changing proportions of fully serviced, partially serviced, and unserviced lots. In the case of serviced lots, prices also vary with changes in the method of financing as between municipal financing, where part of the cost is covered by local improvement charges, and full financing by builders or developers.
*** 1957 figure includes the cost of oil burners; 1947 figure does not.

Theoretically desirable though such a unit cost might be shown to be, it is very cumbersome and time-consuming to use in practice. There is, fortunately, another type of unit cost that is very much easier to use, that is clear cut in application, and that can conveniently be applied to any type of building. This is to determine the cost per cubic foot of usable space within the outer shell of a house. The total volume is easily calculated, and even though slight errors (or differences) might be made in the over-all dimensions selected for the volume calculation for any particular building, the error thus produced in the final total volume will usually be so small as to be negligible. It is therefore recommended that, in all comparisons of house costs, the *year of building* be always mentioned and that *costs per cubic foot* should always be used as the basis of comparison.

Some Examples Of Cubic-Foot Costs

Costs per cubic foot have been used as indices of building costs by architects and engineers for a long time. There is, therefore, much relevant and useful information available from which the limiting values for "cube-costs" as they are sometimes called can be determined. Based on 1958 prices, the following ranges of cubic foot building costs will be found to be applicable in Canada:

Extreme Limits	50c to $3.00
Limits for Normal Buildings	60c to $2.00
Limits for Residential Buildings	75c to $1.50

These limits will be surprising to some readers, especially when it is realized that the range of unit costs for residential buildings is only in the ratio of 1:2. Since this includes domestic accommodation from the simplest type of shelter to the most completely equipped and beautifully finished house, it will be seen that the possibilities for major savings in the cost of the structure of houses of a given size is strictly limited.

Table VI is presented to illustrate the utility of the cost per cubic foot as a basis for comparison of house costs. The figures quoted show clearly the slight variation there is, for the unit cost of buildings in Toronto in 1955, despite differences in type, in floor area, and in total cost. Table VII illustrates the application of the same unit-cost procedure to large blocks of flats and apartments, showing clearly that typical unit costs of this type of housing today have a spread in cost only of between $1.05 and $1.43 per cubic foot.

Table VI

Typical House Costs For Toronto 1955

New York (1957)	Brick and Reinforced Concrete	2,025	21,556,064	1.12

How Can Reductions In Cost Be Achieved?

Behind all the foregoing analysis of housing costs is the continuing question which is of such concern in Canada today — how can reductions in house costs be achieved, with special reference to the needs of those citizens whose incomes are lower than the national average. If it has done nothing else, this analysis will have shown that there is no easy answer to this question.

It will now be clear that there is no single factor which can be blamed for the "high cost of housing" since many factors combine to make the cost of residential accommodation what it is today. Let it be said once again that the cost of a house structure itself is not, as is so commonly supposed, the only item of importance in such considerations.

It has been shown that from the long-term point of view the only sound basis upon which housing costs can properly be judged is by considering the real or annual cost. Sound though this point of view most certainly is, it is admittedly difficult to get the "man in the street" to appreciate this essential aspect of housing costs when he is faced with the problem of finding the down payment and arranging for the necessary monthly payments of the house he wants to buy.

Even though a reduction in first or capital cost is what the average citizen would like to see in connection with the housing that he needs, reference to Table III will show clearly that quite the most important factor in the cost of housing in Canada today is the cost of money, as represented by the interest and the necessary capital investment and in the calculation of the necessary amortization payments. It can be stated without qualification that an appreciable reduction in the interest rate upon money would do more to reduce the cost of housing in Canada than any technological improvements in house structures that can be foreseen at present. This does not imply that no technical improvements are to be expected, the statement rather placing emphasis where it should be placed in any over-all assessment of housing costs today.

When Table II is considered in relation to Table IV it will be appreciated that the most serious increases of cost have occurred in connection with the land necessary for house construction in urban areas. What can be done to control or reduce present land costs is a matter beyond the province of this paper. It must be stressed, however, that much of the basis for the complaints made today against the "high cost of housing" is to be charged against the high cost of developed land and not to the cost of house structures themselves.

Turning next to the cost of house structures, but remembering that this item is only one of many in the whole picture of housing costs, it has been shown that part of the recent increases in the average cost of housing in Canada is attributable to the steady increase in the size of the average Canadian single family homes built in recent years. One most effective way of reducing housing costs is, therefore, by reducing the size of houses built for sale, at least down to the minimum level required by current housing regulations. Such a move would have to be made, however, in the face of public demands for changes in exactly the opposite direction. Only when houses are being built to approximately the minimum sizes called for under current regulations can complaint properly be made that codes or standards are standing in the way of further reductions in cost.

It may be objected that all the costs cited for house structures relate to what can best be called conventional construction as practiced in Canada today. This is true, but a detailed analysis of the costs of the various components of houses — such as the foundation, the walls, the floors, the roofs, and the necessary equipment — shows quite clearly that even the use of some radical new material for one or more of these components, if it were to be generally accepted by Canadian householders, would have a relatively small effect on the total capital outlay for a new house and correspondingly upon the real or annual cost of such accommodation.

Small though such cost reductions may be, they will contribute their small quota to the over-all and desirable reduction in housing costs. Search for such technical improvements is the continuing responsibility of the Division of Building Research of the National Research Council which works, in this field, closely with Central Mortgage and Housing Corporation and with such bodies as the Forest Products Laboratories of Canada. Theoretical analysis and laboratory studies are in progress, and have been so for some time, into possible improvements not only in house structures (for which purpose a full-scale house was tested almost to destruction) but also in relation to the main components of housing structures. A recent publication put out jointly by DBR, CMHC and FPL, which presents a series of designs for wooden roof trusses, is but one indication of the advances that are being made, steadily if slowly, in this direction.

Many Canadians point to experiences in other countries in low cost housing developments and ask why the same results cannot be achieved in this country. In their continuing search for improvements in housing, the writer and his colleagues in the Division of Building Research, N.R.C., have now visited more than a dozen other countries in order to study local house building methods and housing practice. Nothing has yet been seen which would suggest that Canadian house builders are neglecting any technical advances which would contribute appreciably to the reduction in the costs of single family dwellings. When low cost housing is achieved in other countries, and this applies particularly to Scandinavia, it is found in every case to be due to a combination of the use of multiple dwelling apartment blocks, with living areas much smaller than are used in Canada today, and low interest rates ranging down even to 1¾%, associated with amortization periods up to 75 years.

Conclusion

It is not the province of this paper to comment upon the possibilities which any of the foreign practices present for the Canadian scene since so many sociological factors and matters of public policy are involved. The conclusion is inescapable, however, that, looking only at the Canadian scene and without reference to the experience of other countries, one development to be expected may well be a change in the trend of Canadian housing towards the redevelopment of central urban areas rather than a continuation of the building of single family dwellings on the steadily expanding peripheries of Canadian cities. In this way land costs can be controlled, land can be put to more efficient use than at present, unnecessary transportation costs can be avoided, and some progress made towards actual reduction of the cost of housing structures themselves by competent design and construction which utilizes the facilities of large construction equipment rather than the efforts of the builder of single homes.

Attention is directed again to Table III since it points so clearly to other conclusions, notably the importance of the "cost of money" in any consideration of the true cost of housing. For example, if it were possible to borrow money in Canada today for first mortgages on houses at an interest rate of 5%, the change from 6% to 5% in the Table would mean an annual saving of more than $240, or more than 10%, a saving that can not be achieved at present to the same extent in any other way, without reducing appreciably the size of the house.

It is well accepted practice in Canada to regard approximately one quarter of a family's income as the maximum amount which should be spent on the provision of shelter. Applying this to Table III (and using 24% for convenience) it can be seen that a house costing, with land, $20,000 corresponds to an annual income of

$$\frac{2400}{24} \times 100 = \$10,000$$

This suggests as a guide to thinking in Canada today about house costs (i.e. at 6% interest), that the *total* capital cost of a single family house should not exceed twice the annual family income. For those with annual incomes of $5,000, the "$10,000 house" is therefore the maximum that should be considered. This is the real challenge of low-cost housing.

The main conclusion to be drawn from this study of housing costs in Canada today is that there are no miracles to be expected in the direction of sudden and appreciable reductions in the cost of housing of any type. So many factors are involved and they are so closely interwoven that cost reductions, when they can be achieved, will only come gradually and cannot possibly be of any considerable magnitude without rather drastic changes to the social and economic setting in which housing in Canada today must be viewed. It may be objected that nobody bothers to think about the over-all economics of housing in Canada today, as outlined in this paper. To this there is only one reply which can be made — they should.

INSTRUMENTATION IN INDUSTRY

INTRODUCTION

to a series of articles
to be published in

THE ENGINEERING JOURNAL

Systems engineering is not a new discovery. It is a common engineering approach, with a new and important meaning because of the greater complexity and scope of problems to be solved. While it can be extremely complex it may be simply defined as "logical engineering within physical, economic and technical limits", bridging the gap between fundamental laws and a practical operating system.

Instrument and control engineering is simply one aspect of systems engineering. It is vitally important and highly publicized, because ability to create automatic controls within overall systems has made possible the reaching of objectives never before attainable. Though automatic controls are vital to systems that are to be controlled, *every* aspect of a system is essential.

Control engineers have been leaders in building up a systems approach in the various technologies. Some of them have gradually become specialists in measurement and control, and this has created the nucleus of a new emphasis on systems engineering.

Systems engineering calls for highly trained technical personnel. Its direction must be closely tied to top management and must be recognized as more than merely a mechanical job, since it involves both technical training and administration. With the current shortages of university graduates, engineers now employed in industry should be given every opportunity to become trained through practical experience in this field.

Extending as it does over all types of industries and technologies, instrumentation is rapidly approaching the status of an independent profession. If this recognition can be achieved it will benefit everyone connected with this relatively new branch of engineering.

Purpose of the Articles

In this issue *The Engineering Journal* publishes the first in a series of articles relating to instrumentation in Canadian industry. This series has been designed and is being undertaken by the Engineering Institute of Canada as a service to Canada's fast growing and widely diversified manufacturing and processing industries. Through it, it is hoped, companies within each group covered will benefit from the information reported by other organizations in the same group. But the long-range purpose of the series is the exchange of 'knowhow' about instrumentation between one group and another, to show how any industry may adapt methods used elsewhere to its own advantage.

The articles covering various industrial groups and the monthly issues in which they will appear are scheduled for 1959 as follows:

- January: Chemical Manufacturing
- February: Pulp and Paper
- March: Food Industry
- April: Metal Fabrication
- May: Power—Development and Distribution
- June: Waterworks
- July: Steel Making & Foundries
- August: Oil and Gas Industries
- September: Chemical Processing
- October: Modern Boiler Rooms
- November: Textile Industry
- December: Business and Institutional Buildings.

In general, the object of the series is to determine to what extent the application of instrumentation and control lead to more uniform production; how costs per unit can be reduced; how installation of instruments has already cut down operating costs; how it has reduced spoilage and led to greater uniformity in the end-products, and speeded up production.

Other information to be brought out will deal with: initial cost of instruments, the cost of maintaining and repairing them, and the resulting over-all savings; how long it takes to recover the original investment; who is responsible in the plant for maintenance and repair, and what these items cost annually; who specifies the types of instruments; who buys them; who installs and services them; and what are the various instrument applications.

Firms representative of each industry grouping are being approached for specific information. They are being invited to indicate the source of information, but the companies' names will not be published. Manufacturers or suppliers of instruments are not being asked to supply data required for this series.

INSTRUMENTATION IN INDUSTRY

Part One of a Series

CHEMICAL MANUFACTURING

IN 1957, THE LATEST year for which full statistics are available, there were 1,140 plants in Canada with some 54,600 employees in the entire chemical and allied products group, of whose products the selling value amounted to $1,201.6 million. Materials used that year in manufacturing processes cost $561.9 million, and fuel and electricity cost 42 million. Salaries and wages amounted to $218 million.

Imports were valued at $293.8 million, and exports at $195.3 million. Only fertilizers, toilet preparations, and miscellaneous groups showed declines from the previous year. Greatest gains were shown for vegetable oils, 42.7%; heavy chemicals, 17%; compressed gases, 15%; medicinals and pharmaceuticals, 12.2%; primary plastics, 12.2%; adhesives, 10.6%; soaps, polishes, and dressings, each 9.1%; paints, 5.5%. Profits, however, did not increase in proportion, due to higher labour and capital costs.

In 1958, sales of all chemical products during the first nine months showed an increase of some 7.3 per cent over the same period of 1957.

Though statistics do not record a breakdown as between chemical manufacturing and chemical processing, due to considerable overlapping and to the fact that many firms both produce and process chemicals, manufacturing probably accounts for about 40 per cent of the total selling value.

Fivefold Increase Foreseen by 1980

For the immediate future it is anticipated some sectors of the industry, for example those producing chlorine and alkalies, will be operating below full capacity due to the current slowdown in consuming industries. In contrast, however, the production of sulphuric acid has risen sharply and will continue to do so in 1959, due to greater production of sulphur as a by-product from natural gas, and to a sharp rise in consumption for leaching uranium ores.

Despite the possibility of a period of overcapacity during the next year or so, the longer term prospects for the industry are full of promise. The Gordon Commission predicted the volume of chemicals produced in Canada would represent some 10 per cent of the GNP by 1980 as compared with 5½ per cent in 1928, or about five times the volume produced in 1955. This would amount to a selling value of more than $5 million in constant dollars.

What Producers Say About Instrumentation

As might be expected in a country where almost every manufacturing area enjoys an abundant supply of dependable and cheap electrical energy, nearly all chemical industries buy their power from central electric stations. A few, however, have standby equipment and alternative fuel supplies available to maintain heating, process steam, light, feed-water and compressed air supplies in the event of a temporary shut-down.

Generally, input and output of power is not checked by the manufacturer, who relies entirely on the metering recorded by the utility from whom he purchases electrical power.

• The information contained in this article is based on replies to a questionnaire sent to chemical companies with manufacturing centres located across Canada.

• As expected, the replies to specific questions have shown a wide diversity in the extent and use of instrumentation. Therefore this article, in common with succeeding items in the series INSTRUMENTATION IN INDUSTRY, has been written to present a cross-section of the extent of utilization and the cost of instrumentation within a specific field.

• Those who replied to the questionnaire from which this article was compiled are producers of heavy or industrial chemicals, acids, alkalies, ammonia, primaries for plastics, organic chemicals, and compressed gases; and allied organizations that use chemical engineering principles.

Steam Power Plant Instruments

Instruments most commonly used in the steam boiler plants are those for boiler control and for metering steam-flow; for recording and controlling air-flow, steam pressure, temperature, boiler output, and feedwater. A list of such instruments would normally include flow-meters; oil pressure gauges; draught gauges; level controls; temperature and steam pressure controllers and gauges; control valves; and thermometers. The capital cost for the entire group of these devices is normally estimated at between $5,000 and $10,000, depending on the size of the plant.

In most cases separate plants are not used for steam heating and processing, the one steam boiler plant being used for both purposes. Most of the replies received indicated that the instruments in these boiler plants were installed at the time the plant was originally built, with only minor changes and additions made as requirements demanded. Provision has been made for the installation of further instruments whenever the investment is justified for costing or for proper control of the operation. Steam is rarely used for power generation, but almost entirely for heating buildings and for processing the chemicals produced.

Who Specifies the Instruments?

Instrumentation installations in the original plant are usually designed and specified by consultants in conjunction with the company's engineering department. Any additional instruments found to be necessary during operation are generally designed and specified by the manufacturer's own staff.

Some companies have had instruments supplied with their boiler plant, but in other cases these have been installed during the construction period. Frequently an instrument engineer is maintained by the company, who recommends, and designs or specifies, additional instrumentation when the need arises.

Instrumentation in Manufacturing Plants

It is in the manufacturing plant that the application of automatic instrumentation differs between one type of product and another, and between various companies producing the same or similar end-products. This is mainly due to differences in the chemical processes used.

Most chemical manufacturing uses continuous processes, controlled by automatic instrumentation. This is largely pneumatic, though in some cases electronic devices are used; for example, for pH analyzers, chemical composition, oxygen analysis, and so on. Controllers, indicators, and recorders are installed for controlling measuring, and recording process steam, fluid flow, pressures, and temperatures. The trend appears to be towards broader use of spectroscopic instruments for in-line analytical work.

In this field, as in the case of boiler plants, initial instrumentation arrangements have been designed, specified, and installed under the direction of the consultants, though in the case of some smaller manufacturers this is done by the company's own engineering department. It appears to be the general practice to purchase all instruments outright. Though in most cases specifications are drawn up by the company engineering staffs, advice is sought from consultants for the more important and expensive pieces of equipment. Instruments are generally bought through the company's own central purchasing department, on the recommendation of the engineering department.

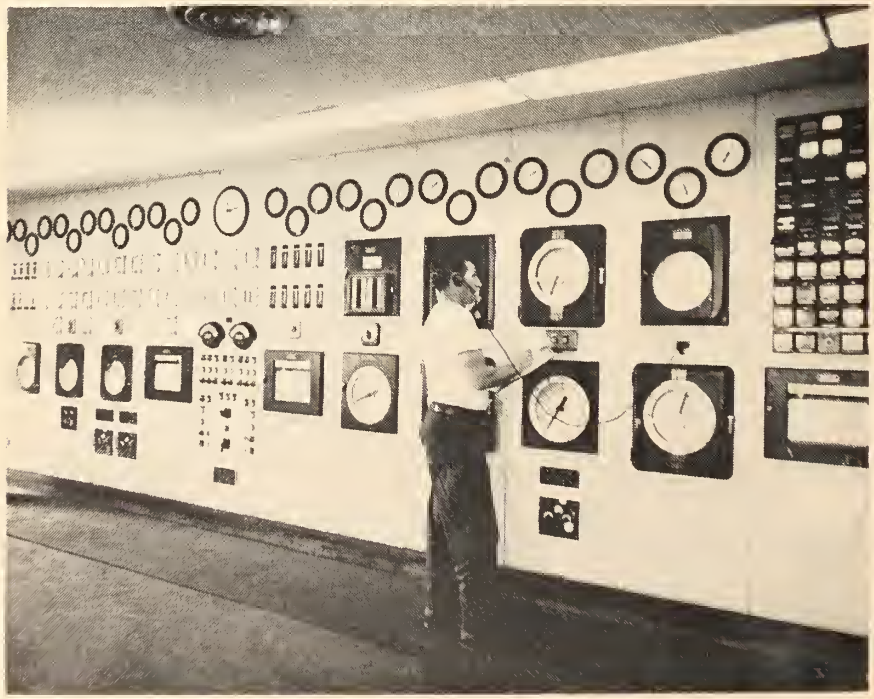
Replacements and Repairs

Though some of the smaller producing companies carry a complete line of replacements, the trend is for the larger industries to carry inventories of only the most essential parts for replacement and repair, as indicated by experience.

The practice followed depends on the importance of the instrument involved and on the availability of parts from the supplier. Occasionally subassemblies are carried in stock for quick interchange, and in special cases a few complete spare instruments are kept on hand to avoid delays in shipment, clearing of customs, etc.

Most of the larger chemical producers do their own servicing and repair work. Often it is found that in smaller plants this can be accomplished with one first class mechanic, skilled in the use of very fine and up-to-date tools. Larger establishments may require several top-notch mechanics working full time. Reliance on instrument manufacturers for repairs and upkeep is usually limited to the most complicated work, such as a complete thermal system or temperature instruments.

Brain centre of the ammonia plant of Canadian Industries Ltd. at Millhaven, Ontario, is the control panel where almost every facet of production process is indicated. Many of these can be controlled by the board man. Operator wears phones to keep in touch with other operators in the plant through an intercommunication system.



Costs and Maintenance of Instruments

Capital cost of instruments including cost of installation varies widely between large and small producers. A large company with several plants and diverse products may have an investment for instrumentation running as high as $1 million, and the average for smaller companies appears to be in the vicinity of $25,000 or even less.

Annual maintenance reported varies accordingly, with figures of between $25,000 and $30,000 yearly for a large comapny, and some $4,000 yearly for the smaller producer. Annual cost of servicing and repairs only, exclusive of replacement parts, would approach $15,000/20,000 yearly, in the case of the larger company, wheras for the smaller plant it might be as low as $1,000.

One large producer of heavy chemicals which does its own replacing, servicing, repairing, recalibration, etc., estimates that it uses one man per each $3-million worth of plant investment. Its annual cost for building, test equipment, and repair equipment amounts to about $6,000 for each of its own instrument maintenance employees.

Savings Through Instrumentation

A most important aspect of the information sought was "How much time and money is saved by the use of instrumentation in various departments, namely, . . . in fuel consumption, regularity in pressures, evenness of flow, quality of product, saving in man-power, etc." Answers here varied widely depending on size of plant, number of different departments or products, number of shifts operating per day, and length of time the company had been in operation.

The reply from one of the major

producers of heavy chemicals emphasizes the difficulty in answering, and points up the resulting reluctance on the part of some producers to give a definite answer. In this instance, the producer's comment was: "The degree of automation is set by the complexity of the process and the close tolerance of product specifications. It is doubtful that operation without instruments would be feasible or safe. Minimum man-power for safe operation, and for requirements should emergencies arise, limit further economic use of instruments."

The reply to the same question from another producer read: "This plant would not be operable without automatic control. Some 150 control loops give continuous surveillance to the process. Without them, perhaps 50 or 75 people could do this same job with perhaps the same quality of product." (The reply noted that the alternative use of manual control is of academic significance only.)

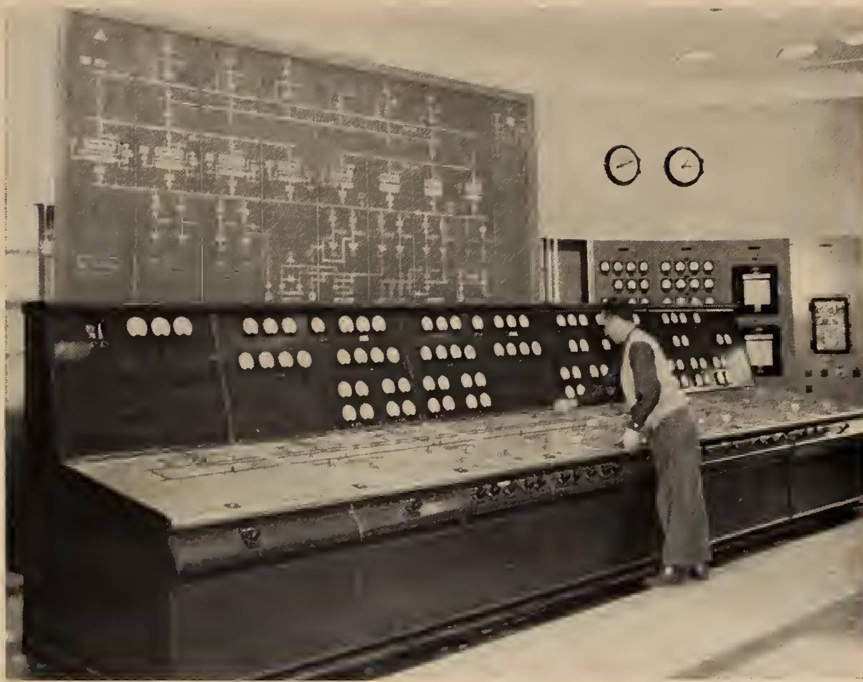
Larger chemical producers found even more difficulty in giving specific answers. This has been particularly true of the larger plants which have had complete instrumentation systems from the start of operation, as is generally the case. Such plants would, of course, not be able to function today without automatic control.

Smaller plants, with only limited use of instruments, generally had less difficulty in assessing the savings in such terms 'one man per shift'. In these cases an annual wage saving of some $4,500/14,000 per year could be visualized, depending on the number of shifts operated. This, however, is of little informative value unless related to the average volume of output of product.

Instrumentation Here to Stay

Many of the important chemical producers in Canada have been established more recently than their American or European counterparts, and were able to prepare for production after the general introduction of automation. All replies indicated a growing tendency towards extensive instrumentation, and in cases where extreme accuracy is essential the general opinion was "The plant could not operate without it."

In other cases, where controls and instruments are not immediately essential, they are being added piecemeal to existing plants, and more are being incorporated in designs for new plants than would have been the case even a few years ago. It is known that this greater application of instrumentation will result in higher efficiencies, more constant or improved quality of product, and greater ease of operation.



Section of control room at Shawinigan Water and Power Company's Trois-Rivières Terminal station. The alarm and light diagram is in the background. At far right on the wall is the automatic synchronizer and under the clock is metering for capacitors. On the benchboard are switchgear controls and meters for main transformers.

Trend to More Instrumentation

The important point brought out by this initial study is the conclusion that future trends in chemical production are toward the increasing use of instrumentation, as new instruments are brought on the market and whenever such installations can be justified economically. There is a strong tendency to the use of process steam analyzers and sequence controls, as well as to greater use of electronic instruments, and this trend is expected to continue.

Canadian producers are fortunate in having access to information about new developments in instrumentation in Canada and other countries. Canadian instrument engineers are ever alert in watching for improved processes and the introduction of new and better instruments. Many Canadian chemical producers are associated with foreign companies and can benefit from the latter's research and experience.

There is little doubt that the returns from the other eleven industries listed in the "Foreword" will disclose important information about their basic experience with instrumentation and the savings effected thereby. Perhaps some of this experience can be adapted by the chemical industry to its advantage.

EDITOR'S NOTE

It is appreciated that the vast scope of the field to be covered by this series of articles will make it impossible to go into detail with respect to the varied applications of instruments.

Therefore, it is planned to write the articles so that they will be of interest to engineers engaged in all phases of the profession and industry.

Readers' comments and suggestions on this, and other, portions of THE ENGINEERING JOURNAL will be gratefully received.

INTERNATIONAL NEWS

MAIN ACHIEVEMENT OF ELECTRONICS IN JAPAN

REMARKABLE PROGRESS in electronic techniques has recently been made throughout the world and Japan has also been studying them in various fields with excellent achievement, some examples of which will be introduced here.

Super-multiplication of Micro Waves and TV Relay Device

The multiplication communication by micro wave has been studied since 1948 using disc seal tubes or magnetron tubes, and in 1951 a 23 channel device of PPM-AM system at 4,000 m c/s was completed into practical use. This device was installed between Tokyo and Yokohama by Japan Telegram and Telephone Corporation and between Aomori and Hakodate by Japan Railway Corporation.

Researches on the super-multiplication device have been conducted for the public communicational use by means of a disc seal tube and a travelling-wave tube. However, from a manufacturing point of view, the travelling-wave tube was deemed to be more prospective, and FS-B1 apparatus of 480 tone channels was developed. This apparatus was applied to the construction of the super-multiplication telephone lines and TV relay lines between Tokyo and Osaka in March 1954. This is an FM modulation system at frequency range of 3,700-4,200 M c/s, by means of path length antenna and 2-stage travelling-wave-tube amplifier (transmitting output of 1W). After that, FS-B2 apparatus, an improved system, was applied to the construction of the telephone and TV lines between Tokyo, Sendai and Saporo in September 1956. The micro-circuit-lines have been set at almost all the main cities in Japan. The whole relayed distance of these public communications at 4,000 M c/s band attains 10,338 route Km (1 route has a capacity of 480 telephone tone channels or 1 TV line) and the expansion plan is being successfully carried out. The principal characteristics of FS-B2 system are: the frequency range of 3,700-4,200 M c/s, FM modulation system, 11 feet parabola antenna, 1 stage travelling-tube amplification (transmitting output of 1 W), no-break-alternative power supply system and no-man-station system.

Additionally, the 120 telephone tone channels or the TV relay apparatus at 2,000 M c/s band by a disc seal tube is put into practical use for the local lines. The micro wave ST link apparatus which combines the TV broadcast stations and the TV relay line terminal stations is used at 6,000 M c/s band. Besides, Japan National Railway Corporation and other electrical power companies established their own specific telephone lines.

Electron Microscope

The research on the electron microscope began in May 1939 when the Electron Microscope Subcommittee of Japan Society for the Promotion of Science was established. At that time the study was mainly proceeded in Germany where the invention was made, and was still in its early stage. Nevertheless, many specialists both in scientific circles and industrial fields, participating in the committee, cooperated with each other and pushed forward vigorous research activities. As a result, an electron microscope of highest ability in the world was developed, and this achievement was highly evaluated at the International Electron Microscope Society held in Tokyo in October 1956. Japan has already exported the electron microscopes to many countries such as U.S.A., France, U.S.S.R. and others.

Some examples of the electron microscopes manufactured in Japan are as follows: Hitachi Manufacturing Co. have developed the research on the block lenses made by an ultra-precision finish, using them at the high excitation of magnetic fields. A great achievement was reached in eliminating aberration and an HU-10 type electron microscope of high efficiency with dissolving power limit of 10 AU (angstrom unit) was manufactured. Further, a middle size microscope of HS-6 type (dissolving power 25 AU) and a popular table model of HM-5 type (dissolving power of 80 AU), are being produced. Those two types, utilizing a permanent magnet, can be maintained and adjusted easily.

The Japan Electron Optics Laboratory Co. carried on trial work which has led to the manufacture of the universal JEM 5 type electron microscope. As for its major characteristics, it is noted that its dissolving power attains 10 AU, and a diffraction pattern as well as a transmitting image can be observed in the same region, thus a new application field has been developed in obtaining a reflective image (at any angle of reflection within 30° by deflecting continuously the incident electron beam). In addition, a minor test piece heating furnace enabling the observation of configurations up to 1000°C and a cooling apparatus at low temperature of 180°C below zero are attached to the electron microscope so as to make it possible to observe the configurations of metals at high temperature and the conditions of water, mercury and fibre when cooled.

The strong requirements of scientists especially in the medical field and the effort made by scholars and private companies for the competition of manufacturing microscopes have brought the development of the microscope in Japan. The number of the microscopes in Japan now amounts to more than 400, being next to that of USA and nearly equal to that of USSR, and has made a great contribution to scientific and technical researches.

Parametron

Successful development has been achieved in Japan in the research for the application of electronic techniques as artificial brains to electronic computers, telephone exchangers, automatic controlling devices in the manufacturing process, and so forth. Several instruments in which relays, transistors and vacuum tubes are used.

have already been put into practical use after completion of the development stage. The parametron was invented in Japan in 1954 and proved to be a computing element as superb as these elements.

The parametron, as its name indicates, is a non-linear reactor utilizing the parameter exitation, and is used for amplification, memorization of information and standardization of phase and amplitude. It is similar to the memory elements which use the solid magnetic amplifier or rectangular hysteresis magnetic core and is recently being developed in America. However, it completely differs from them in its principle, and great hopes are placed in its future application, since it has been developed with the electronic techniques peculiar to Japan.

The parametron is simply manufactured by winding a coil around the new ferrite which is made by sintering the oxide iron after adding copper-zinc or nickel-zinc compound to it. The manufacturing cost is extremely low, and the product is of very small size (about 4 mm in diameter and 1 mm in thickness), but is durable almost indefinitely.

As it has advantages in that its action is stable and it requires no maintenance, it can be applied to electronic computers and electronic exchangers in which thousands of parametrons are used. It is true that parametron which is in practical use has slight disadvantages in that it consumes electric power of approximately 20 mV and its logical computing speed is 40 mmS, but research work is expected to increase its speed and reduce its power consumption to some extent. Moreover, compared with other electronic theoretical elements, it is highly advantageous and prospective in future that a single parametron possesses the maximum logical dividing number of 30 by which it can provide logical variables to as many as 30 independent logical systems.

Musasino-1 is the first enormous electric computer using parametrons and was completed at the Communication Laboratory of Japan Telegram and Telephone Corporation in February 1958. It uses about 5,000 parametrons and possesses memorizing capacity of 256 words by means of the core matrix system, and is expected to possess memorizing capacity of 1,024 words by March 1959. The computing speed is 1 mS (at 30 KC) or 2.5 mS (at 10 KC) in addition and 3.3 mS (at 30 KC) or 10 mS (at 10 KC) in multiplication. In other ways a computer, a PC-1 type of the same efficiency has been developed at Tokyo University since this spring and a revised PC-2 type is expected to be completed by March 1959. The trial manufacture of this type has already been developed by a private company for commercial purposes.

BELGIUM

THE ENTRE National de Recherches Métallurgiques (Belgium) has entrusted the Brassert Oxygen Technik A. G., in Zurich, the holders of which are the Austrian steelworks Vereinigte Oesterreichische Bisen-und Stahlwerke A. G., in Linz, and Oesterreichisch-Alpine Montangesellschaft A. G., in Donauwitz, with the commercial exploitation in countries other than Belgium and Luxemburg, of the new steelmaking process which has been developed in the steelworks of Arbed (Luxemburg) in collaboration with the Centre National de Recherches Métallurgiques. This process which is known under the name of the O.C.P. process, has been described in a communication presented at the International Iron and Steel Meeting held in Liege in June 1958.

To indicate the collaboration between the Austrian, Belgian and Luxemburg steelworks, the O.C.P.-process will be designated the LD-AC-process and the steel produced by this process will be marketed under the name of LD-steel. It will be possible to produce LD-steel from iron with any phosphorus content.

(*Continued from page 51*)

underground, and successfully operated.

5. Many factors influence the decision whether a particular waterpower is developed in the conventional manner or underground. Only a careful economic evaluation of the several possibilities can reveal the best solution.

6. Geological investigation of adequate scope and correct interpretation is essential to achievement of minimum construction costs.

7. The underground concept of development frequently permits much greater latitude in location.

8. The planned use of rock bolts can be a potent factor in economic construction underground in poor geological formations.

9. Underground power plants should be designed only in principle, pending entrance to the working area.

10. Experience based on numerous cases of underground development shows that well-planned projects can be economically built.

11. Operating experience has been good. Some failures have occurred due to inadequate allowance for controllable factors or improper design but they are very infrequent.

12. The Kemano, Bersimis I and Chute-des-Passes schemes, all in Canada, lead the world in capacity and in many other respects.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

Lift Slab Construction at Carleton

In establishing a new campus on a 130-acre site in Ottawa, Carleton University is employing some of the latest building methods and materials. Of the four buildings now underway, perhaps the most revolutionary construction is that used on Norman Paterson Hall, the arts building. It is being constructed by the lift slab method.

In the four-storey, 45,300 square-foot building, all floor and roof slabs were poured at basement level, one on top of the other, using only edge formwork and a special A. C. Horn Separating Compound to prevent the wet concrete slabs from bonding.

Steel columns provided the vertical framing and the slabs were hoisted into position by Youtz-Slick hydraulic jacks. Only one half of each floor could be raised with each lift, which averaged 350 tons. The slabs were 96 by 56 feet in size and varied in thickness. The roof slab, first to be lifted, was eight inches thick. The main floor slab (second level of the building) was 11 inches; the other two, 10 inches each.

A three-foot-wide construction joint between the individual lifts was filled in using normal concrete shuttering after the slabs were in place.

Under favourable conditions, a considerable saving of time is possible with lift slab as compared to conventional methods since concrete can be poured directly into the slab forms without the necessity of hauling it above ground level. This saving applies also to reinforcing steel which can be put in place on the ground for all levels. Another possibility, not yet exploited to any extent, is the raising of large quantities of building materials and other supplies as the slabs are lifted.

The slabs had to be designed for the sum of two moment conditions, the first being dead load moment with no column restraint, which condition would exist during the lifting of the slab; the second, live load moment with full column restraint. Wind stiffness was provided by poured concrete shear walls eight inches thick. They were poured through slats and sleeves left in the slabs for this purpose.

Reinforcing steel was made up of straight bars ranging in size from ⅞ to ½ inch thick, to permit the free run of electrical conduits and pipes in the central part of the slab. Stair openings and duct openings were left in the middle strips.

The first row of 10 by 10 inch wide-flange columns was set back six feet from the edge of the slab. The columns were plated into a box section to provide stiffness against buckling for the lifting particularly of the first slab.

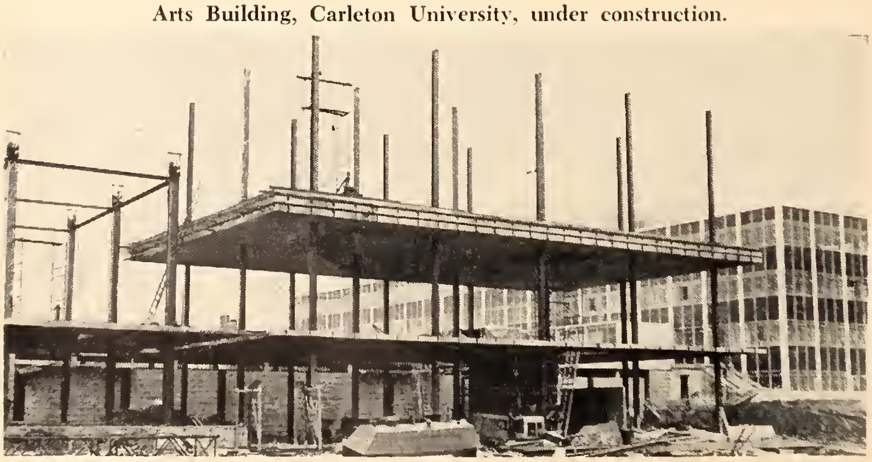
Inset steel collars cast into the slabs provided keyholes into which lifting rods could fit, as well as providing large bearing areas for the heavy slabs. The collars are supported by wedges which bear on shear plates welded to the face of the column. Small wedges were inserted into the top of the collar to provide column restraint and these and the support wedges below were finally welded to the column.

An interesting structural feature on the south side of the building is the main stairway which is supported on one side by Stressteel rods attached to cantilevered beams at the roof. The landings of the stairway are cantilevered in two directions from these supports.

Being constructed at a cost of $1,300,000, the arts building will be completed next summer. Other buildings are science, $2,500,000; library, $1,000,000; and a field house for athletics, $88,000. These three will be ready for occupancy early in the new year.

For 16 years since its founding, Carleton has been housed in a small red brick building in a residential area of Ottawa. Increasing enrolment and the need for more adequate facilities for the study of engineering, arts, science, commerce, journalism and public administration will force the university to relocate on its Rideau River campus as soon as possible.

Arts Building, Carleton University, under construction.



Correction

In the October, 1958 issue of the *Journal* page 67, *International Passamaquoddy Tidal Power Project*, by G. Millar, the statement was made that Dexter P. Cooper was a Canadian hydraulic engineer.

After extensive enquiries, it has been discovered that although Mr. Cooper spent much of his lifetime in Canada, and is buried in Canada, he was in fact born in the United States.

St. Lawrence Seaway and Power Project

Progress by Ontario Hydro

With employment averaging 1350 persons for November, placing of concrete was finally completed on the power-house. Eight units were operating, with installation progressing on other units. Most of the dredging upstream was expected to continue until mid-December.

Progress by NYSPA

Employment was maintained at some 1750 persons during the month. Placing of concrete reached 99 per cent of completion, and excavation had reached 94 per cent of the estimated total. On the American half of the power-house, eight units were operating, delivering 50 per cent of the total capacity in firm power. Tailrace excavation had reached a total of 630,000 yards.

At the Long Sault dam, painting of gates, hoists and equipment continued, and installation of elevators was resumed. Removal of construction plant and buildings and general cleanup work were in progress in all areas.

Cleanup of channel improvement at Toussaints and Iroquois dam was completed, while final sweeping of the ship channel in the Sparrowhawk area continued.

Progress by SLSDC

A force of 300 persons was employed during the month, most of it on cleanup and removal of equipment. The spare lock gate will not be delivered until March. Dredging in stretches of the channel where high velocities obtain, will continue as long as weather conditions permit.

Progress by SLSA

Employment during November averaged some 2500 persons on bridge erection, dredging, testing of lock gates and general cleanup. Water had been let in to the Cote Ste. Catherine lock and the two Beauharnois locks. The installation of lock operating machinery on these three locks was nearing completion but testing and final acceptance would be carried on throughout the winter. Dredging operations will be continued as long as weather permits.

On the CNR rail diversion at Victoria bridge, erection of steel was completed from St. Lambert to and including the crossing over the St. Lambert lock, except for the last three spans. All approaches at the south end of the Mercier bridge were completed and the completed north- and south-bound lanes on the Valleyfield-Malone approaches were opened for traffic during December. Erection of the towers for the lift-spans on the St. Louis and Valleyfield bridges across the Beauharnois canal was proceeding and would continue during the winter months. Traffic was passing normally over the Valleyfield bridge but was detoured at the St. Louis bridge.

New Bridge Opened at Massena

Inauguration ceremonies were held on December 1 to celebrate the official opening of the new $7 million, 5,000 foot long high level highway suspension bridge crossing the south channel of the St. Lawrence at Cornwall Island. The bridge crosses the International Boundary and gives an overhead clearance of 120 feet for ships. The main suspension span is 3,840 ft. long, carried on two 232 ft. towers each standing on two piers.

The new bridge replaces the old south channel bridge of the Roosevelt International Bridge some 1,300 ft. downstream, which has been removed. A new bridge is to be built by Canada across the north channel between Cornwall and Cornwall Island.

U.S. Subsidy Threatens Canadian Ship Owners

A new U.S. shipping subsidy bid has Canadian Great Lakes shipowners worried. American Export Lines, Inc. has applied for a subsidy for vessels to run between Great Lakes ports and the Mediterranean, and to designate the run as a new 'essential trade route'. One such route between Lake ports and Europe has already been approved. Indications are that the request will be granted. Canadian shipping firms see this as a threat to their livelihood once the Seaway opens, believing subsidies will spread ultimately to the U.S. Great Lakes fleet.

Progress on Winter Navigation in St. Lawrence

Good progress during the past year towards ending the 'needless blocking' of navigation in the Gulf of St. Lawrence, is reported by Arthur Schmon, president of the St. Lawrence and Gulf Development Association. Positive results towards easing the problem were being achieved through navigational aids, aerial ice surveys and additional ice-breakers, he said.

Two new $2.5 million icebreakers are under construction. Expenditures for harbour improvements costing some $2 million at Seven Islands, Dalhousie, Rimouski, and improvements in ferry service from Baie St. Catherine and Tadousac are being made. The federal government has earmarked $13 million for a winter port at Father Point. Two shipping companies, possibly three, will run scheduled services from Quebec City to north-shore points during the coming winter.

Tentative Plans for Opening of Seaway

Tentative plans at the end of November for the opening of the Seaway in 1959 by Queen Elizabeth and Prince Philip call for the Royal Visit at Montreal on June 25, 1959. Leaving the royal yacht at Sept Iles, the party will visit Knob Lake and Quebec City and will then re-embark at Quebec and proceed to Montreal. The official ceremony will take place in the Cornwal area, and will be a joint ceremony with President Eisenhower. The Britannia's main mast and its radio aerial have been hinged 20 ft. from the top so they can be lowered to permit passage under the bridges along the seaway.

Canadian Pipeline Projects

Trans Canada Pipelines

Trans-Canada Pipe Lines Limited, which completed construction of its 2,290-mile natural gas line in October, 1958, ahead of schedule and under the estimated $375 million cost, is now delivering Alberta natural gas to homes and industries in an area along its route encompassing three-fifths of the population of Canada.

Trans-Canada is serving 11 distribution organizations and the expected maximum day demand during the 1958-59 heating season is estimated at 263,400 m.c.f, compared with 195,800 m.c.f. daily sales estimated in 1956, and estimated Canadian sales of about 820,000 m.c.f. daily in the fifth year of operation.

The Alberta export permit under which Trans-Canada is operating provides for the removal of a total of 4.35 trillion cu.ft, of gas, at a maximum daily rate of 620 million cu.ft., and an annual rate of 210 billion cu.ft. The main suppliers of gas include B.A. Oil, Hudson's Bay Oil and Gas, California Standard, Canadian Delhi Oil, Provo Gas Producers, Home Oil and Canex Gas. This gas reaches the Trans-Canada line through the Alberta Gas Trunk Line Company's gas gathering system.

Trans-Canada is now delivering Alberta natural gas to cities and towns, homes and industries from Regina to Montreal. Sales contracts are in effect with Saskatchewan Power Corporation, Plains-Western Gas and Electric Company; Inter-City Gas Limited; Greater Winnipeg Gas Company; Northern Ontario Natural Gas Company; Consumers' Gas Company; Union Gas Company of Canada Limited; Lakeland Natural Gas Limited; Augusta Natural Gas; City of Kingston, Ontario; Quebec Natural Gas Corporation.

In addition to the approximate cost of $375 million for the building of the Trans-Canada Pipe Line system, the project sparked an industrial chain-reaction which will result in the spending of many billions of dollars.

Natural gas producers who supply Trans-Canada receive more than $650 million for their product; the producers will spend more than $200 million in the next few years drilling more wells and processing the gas; a new Alberta petrochemical industry based on stripping the byproducts from the gas calls for initial expenditures of $100 million; Alberta Gas Trunk Line will spend $60 million in construction; distributing companies along the route will spend approximately $200 million, extending present systems or building new lines; new pipe mills have required a capital investment of $50 million, other plants making valve assemblies, wrapping material and other pipeline requirements have invested $50 million—making a grand total of more than one billion dollars placed in circulation.

The new natural gas industry will have an immediate and important effect on Canada's adverse balance of international trade. For instance, in 1956 Canada imported coal from the United States valued at $130 million. The use of natural gas should reduce this dollar outgo by at least $40 million a year on the basis of the 1956 level of coal imports. In 1956 Canada paid $12 million for sulphur imported from the United States. By 1960 the sulphur recovered from Alberta natural gas will supply Canadian requirements and leave a surplus for export. Canada has been paying $12 to $15 million a year for imported natural gas. Almost all this gas has now been replaced by Alberta gas.

Some statistics of the pipeline:

More than 700,000 tons of steel required at a cost of about $150 million; contract construction costs, about $120 million; freight charges, $22 million; 43,000 railway carloads of pipe and other material; 8,930,000 cubic yards of excavation required in making the ditch; 530 miles of rock excavation; 13,700 miles of wrapping material for the pipe; 298 railway and highway crossings; 107 lake and river crossings; the pipeline carries the energy equivalent of four St. Lawrence seaway power developments.

Northern Ontario Natural Gas: Conversion work was completed in mid-November, and full-scale gas service from Alberta began in two mills of Abitibi Power & Paper Company Limited. At the Sturgeon Falls mill, natural gas will be used to fire mill boilers to produce steam for the manufacture of various types of board. In Iroquois Falls, natural gas will assist in the manufacture of groundwood, unbleached sulphite, newsprint and paper-board.

A total of 805 million cubic feet will be sold annually to the Sturgeon Falls mill. Total annual consumption for the Iroquois Falls mills is 2,359 million cubic feet. Both mills will burn gas on a dual-fuel basis, and retain previous heat source facilities. This enables mill boilers to switch from one fuel to another, on short notice, or to burn any desired combination of coal and natural gas.

Saskatchewan Power Corporation: Opened at a ceremony on October 30 the $10.5 million plant, first substantially sized plant of its kind in Saskatchewan for the processing of casinghead gas, is one of the most important conservation measures to be undertaken in the province. Initial rated capacity is 25 M. c.f.d., which can ultimately be expanded to 45 M. c.f.d.

St. Maurice Gas, Inc.: A proposed natural gas pipeline from Montreal to Quebec City would connect with Trans Canada just west of Montreal Island, pass through St. Hyacinthe and recross the St. Lawrence at Trois Rivières, then follow the north shore to Quebec. Three branches would serve St. Jean, Granby, Magog, Sherbrooke, Sorel and Drummondville. A branch east of Trois Rivières would serve Shawinigan. The proposed pipeline would be built by Cartier Gas Corp., at a cost of between $15 and $30 million. Cartier is seeking franchises in these communities — one such franchise has been obtained in Granby.

Alberta Underground Storage Ltd.: This Company, sponsored by B.A. Oil, Canadian Hydrocarbons and Goliad Corp. has been formed to develop underground storage for liquid petroleum gases near Hughenden, Alta. Most economical storage for large volumes of LPG liquids is the caverns in underground salt strata, after removing the salt by washing out with fresh water. Initial capacity would be some 150,000 barels. Ultimately 14 caverns would have a capacity of a million barrels.

Gas Products Pipeline Planned: Pembina Pipeline Ltd., is planning to build a 1200 mile pipeline from Alberta to the Great Lakes to market surplus natural gas byproducts. It would handle from 100,000 to 150,000 barrels of by-products daily. Estimated cost of the project approaches $150 million. Foothills Products Pipe Line Co. has applied to the Alberta Conservation Board for permission to export the by-products. The scheme involves a line to Lakehead or to Superior, Wisconsin, another to the Pacific Coast, or a combination of east and west routes. Processing plants would be located at the two terminals.

The Year 1958 Reviewed

Neil J. McKinnon, President, Canadian Bank of Commerce.

"It now seems likely that the Gross National Production (for 1958) will have a value fractionally above $32 billion, or about 2 per cent higher than in 1957", said Neil J. McKinnon, president of the Canadian Bank of Commerce at the ninety-second annual meeting.

"Allowing for higher prices the volume of production was probably little changed from the previous year. Our export trade has been well maintained, consumer expenditures have increased moderately and capital investment has shown but a moderate decline. For a year which began amidst gloomy forebodings this cannot be considered as other than a reassuring performance," Mr. McKinnon said.

A few of the characteristics of 1958 reported by Mr. McKinnon are these:

It now seems likely that a level of about $8.5 billion may be achieved in capital investment—a decrease of less than 3 per cent from last year.

A drop in capital expenditures for manufacturing is offset by an increase in expenditures for housing, which this year are estimated to reach an all-time high of more than $1.5 billion. Completions may amount to 153,000 units.

Aggregate consumer expenditure exceeded $20 billion for the first time.

There are indications that aggregate exports should come close to the level of 1957.

Industrial production, affected by domestic and foreign demand, emerged from its downward phase. Although volume has been adversely affected through industrial disputes it has, nevertheless improved to a level which, barring further work stoppages by now should compare well with last year. Mineral production has been adversely affected by less favourable foreign markets and prices but there are signs of improvement in some of its constituents.

Total value of mining production for the past year is expected slightly to exceed that of 1957.

Indications are that farm net income this year may prove to be slightly below that of 1957.

Although the work now going on in resource development is not as spectacular as that of a few years ago it is soundly based and undoubtedly we shall continue to see in the years to come a steady and important development of natural resources including the vital field of energy.

Hon. Gordon Churchill, Minister of Trade and Commerce, Canada

In a year-end review, The Hon. Gordon Churchill reports: "Considering the severity of the impact of . . . adverse influences from abroad, the pace of economic activity in Canada has been remarkably strong."

Some notes from the Minister's report are as follows:

On the basis of nine-month figures it appears that Canada's Gross National Product for 1958 will exceed $3 billion, 2 per cent above the figure of 1957. Prices on average have increased by almost the same percentage. Overall production in volume terms has equalled the level of the preceding year.

Employment has held up well and by the last quarter jobholders numbered about the same as a year ago. Industrial employment has been running moderately lower but this has been offset by a further filling out in service occupations. The labour force has grown at a slower rate this year, reflecting a level of immigration less than half that of 1957. Unemployment has been higher but the percentage increase from the same date a year ago has been narrowing sharply.

Despite conditions of ample supply in world-commodity markets, Canada's sales abroad have not followed the downward trend of world trade at large. They have remained at about the same level as 1957. Substantially increased sales have been achieved for several commodities including wheat, beef and uranium, farm implements. Reduction of industrial exports has been relatively moderate.

Imports into Canada are about 10 per cent lower in 1958 than in 1957.

The merchandise deficit for the first ten months was reduced to $242 million, from $733 million for the same period of 1957.

Capital spending plans at mid-year provided for outlays of $8.5 billion in 1958. Overall capital outlays for the year may fall but little short of the record $8,700 millions spent in 1957.

It is estimated that housing starts in 1958 will approach the 160,000 mark.

Another factor having an important sustaining effect upon general activity has been the high level of consumer spending supported by rising personal incomes.

Of the industries which had previously suffered a decline, most have experienced some degree of improvement by year-end. In aggregate terms the pick-up in production to date has been quite moderate. There is, however, strong indication of further expansion in market demand. Reflecting this improvement and contributing to it is the fact that inventory liquidation is now coming to an end, though conditions vary from one trade to another.

In recent months new capital expenditure plans have been appearing in increasing volume.

What Goes On

New Asbestos Mill

A $36 million mining and milling operation at Black Lake, Que., will contribute approximately 10 per cent of Canada's production of asbestos and 7 per cent of the free world's supply. It was formally dedicated in October 1958.

Owned and operated by Lake Asbestos of Quebec Ltd., a wholly-owned subsidiary of American Smelting and Refining Company, the operations are expected to yield 100,000 tons of asbestos a year for at least twenty years, from open pit mining.

In the course of construction, Black Lake was shifted to a new basin, a river was diverted into a new channel, four dams were constructed. The asbestos deposit was at the lake bottom, under 27 million cu. yd. of mud and silt.

The 9-million mill, houses ultra-modern equipment to free asbestos fibre from the ore, and to grade, dry, and prepare fibre for shipment.

Saskatchewan Developments

A trial run at the Potash Company of America Plant near Saskatoon saw the first large extraction of potash ore come above ground from the mine workings some 3,300 feet underground. This was the first time potash has been mined in Canada. The first commercial rail shipment was to leave the plant in December.

First production of polyethylene flexible pipe rolled off the assembly line at the Weyburn plant of Western Wire and Cable Co. Ltd., in November.

A 15-million basic steel industry will be established north of Regina. Inter-provincial Steel Corporation Ltd., with president J. W. Sharp, will equip the new plant for 100,000 tons per year capacity. Completion is planned for the end of 1959.

British Columbia Power

British Columbia's economy will be bolstered in 1959 by $95,800,000 expansion program announced in December by B.C. Electric.

Biggest single expenditure during the year will be $22,400,000 for work on the second-stage development of the Bridge River hydro-electric project.

This project will provide 345,000 horsepower of additional electric generating capacity before 1961 to meet growing power demands. Total cost will be $56,500,000.

Another $18,100,000 will be spent in 1959 on the Burrard steam plant now under construction on the north shore of Burrard Inlet, near Ioco. This plant will have a generating capacity of 800,000 h.p. from four generating units before 1965. The plant is designed for a possible ultimate capacity of 1,200,000 h.p.

The gas turbine electric generating plant at Port Mann, just east of New Westminster on the south bank of the Fraser, will be completed in 1959. Expenditure during the year on this 134,000 h.p. plant will be $2,100,000.

CONFEDERATION—A Progress Report

Following the recent practice, Dr. I. R. Tait, chairman of the Institute's Committee on Confederation made a progress report to the December meeting of the Council. The following report to the membership is based on Dr. Tait's report.

The hope was expressed in the November account that the report of the sub-committee would receive the approval of all members of the Joint Committee. This hope has been realized. Council has been advised that complete unanimity of approval has been received from all fifteen members of the Joint Committee. Not one suggestion or request for a change has been received. On the contrary every member of the committee has sent with his approval his congratulations to the sub-committee for their excellent report.

The committee now is ready to take the next step, i.e., submit the report to the two councils for their approval and for the subsequent referral to the members at large.

Council has arranged for a plenary meeting to take place at Toronto on Saturday January 31, at which councillors will have an opportunity to express their opinions.

A copy of the report and supporting documents is being mailed to each councillor so that he will have time to study it carefully before the meeting at which approval will be asked.

It was recommended by the committee that if the two councils approve the report, they should then submit it to their memberships with a ballot asking for their approval or otherwise. The Council of the Institute agreed to the recommendation. The Canadian Council have not yet had an opportunity to meet to discuss it but will do so shortly.

Confederation has surely moved a long way towards becoming an accomplished fact. There is still a long way to go and care must still be taken to make sure that each step is a safe one, but with the emergence of the committee's report, it is evident that the principal obstacles have been surmounted. Shortly the decision will be in the hands of the members themselves.

Anniversary for Structural Engineers

The Institution of Structural Engineers of Britain celebrated fifty years of service at a jubilee meeting October 7 to 10, 1958.

Ben O. Baker, M.E.I.C., of Quebec, Que., councillor of the Engineering Institute, represented the Institute at the meeting and conveyed greetings to the Structural Engineers.

He attended the dinner given by president-elect G. S. McDonald, as one of twenty-three guests from many parts of the world. He also attended the annual banquet and ball, at which there were well over eight hundred present.

Mr. Baker reported on his discussions at the council meeting in November, and he presented a copy of the Jubilee Issue of *The Structural Engineer*, Journal of the Institution, for the use of the E.I.C. Library. He also presented to the Library a set of preprints of the papers given at the Jubilee Meeting. Their titles are listed

Ontario Agricultural College Receives the President

Dr. Kenneth F. Tupper, president of the Engineering Institute was a visitor to the Ontario Agricultural College, Guelph, recently, when he addressed the engineering students and staff on "The Role of the Engineer in the Development of Canada".

Engineers who gathered at the College for the occasion are seen in the photograph: left to right: A. H. Austin, of Armco Drainage, Guelph, secretary-treasurer of the Kitchener Branch E.I.C.; Dr. Garnet T. Page, general secretary; Dr. J. D. MacLachlan, president of the Ontario Agricultural College; Dr. Tupper; Prof. C. G. E. Downing, head of the O.A.C. Engineering Science Department; and L. J. R. Sanders of Galt, councillor of the E.I.C.

on Page 000 of this issue. There were three Canadian papers on the program.

President of the Institution during the Jubilee year was Professor Sir Alfred Pugsley. Secretary during the past twenty eight years has been Major Reginald F. Maitland.

Nominees for Office

Engineering Institute of Canada

A list of nominees for office, as reported by the Nominating Committee, appeared on page 102 of the October 1958 issue of the *Journal.* Since that time the committee has reported the selection for president as follows:

President .... John Jeffery Hanna .... Calgary, Alberta

E.I.C. Technical Conferences in 1959

Regional Meetings

A growing interest in regional technical meetings was seen during 1958. This year there will be still greater opportunity for E.I.C. members to take part in this important activity, with four regional meetings planned by the branches.

The *Journal* will publish advance information about these conferences, as well as programs and reports. There are a few corrections to be made to the list which was included in the November and December issues.

The Second Southern Ontario Regional conference, to be held in Hamilton, Ont., on March 14, with six branches participating, is advertised on this page. E. W. Hill, M.E.I.C., is general chairman of the Conference Committee.

A Technical Conference is tentatively planned for May at Sudbury, Ont.

The Western Regional Technical Conference, to be held at Banff, Alberta, October 2-3, 1959, will provide a good program including a forum on drainage and irrigation. W. A. Smith, M.E.I.C., of Calgary, is chairman of the Conference Committee.

The Ottawa Regional Meeting will mark the 50th anniversary of the Ottawa Branch. The dates for this conference are October 15-16, 1959, and *not* October 18-19, as previously listed.

Annual Meeting, 1959

Good progress is also being reported on the technical program of the 1959 annual meeting: June 8-10, Toronto, Ont.

The *Journal* will have advance information about the annual meeting in every issue.

Chairman of the annual meeting committee is E. R. Davis, M.E.I.C., of Toronto.

Don't Miss The

SECOND E.I.C.

SOUTHERN ONTARIO REGIONAL CONFERENCE

Where: Sheraton-Connaught Hotel, Hamilton.

When: Saturday, March 14, 1959.

Program: Noon Luncheon — Panel: "Engineer — 1965"
Afternoon: Engineering Papers — Reception and Cocktails —
Dinner and Guest Speaker — Conference Ball

For the Ladies: Luncheon and Fashion Show

YOU made last year's Conference such an outstanding success that the 1959 Conference should be even better.

All EIC and APEO members and their ladies are cordially invited.

PARTICIPATING BRANCHES;

London Kitchener Border Cities Niagara Peninsula

Toronto Hamilton

Watch for details; Plan now to attend

Elections and Transfers

On the recommendation of the Admissions Committee a number of applications were presented for consideration to the meeting of Council for December, and it was agreed that the following elections and transfers become effective:

Members: F. Csete, Montreal; C. L. Evans, Toronto; N. Freight, Edmonton; S. P. Hauck, Edmonton; M. A. Lazarovici, Calgary; A. J. G. Leighton, Victoria; A. B. Maslin, Galt; T. O. Orr, Montreal; R. E. J. Putman, Toronto; W. C. Seaforth, Toronto; P. H. Stewart, Montreal; C. Szoo; Montreal; P. S. Szypulin, Montreal; A. C. Tait, Toronto; J. A. van der Giessen, Vancouver; A. A. Waters, Toronto; F. J. Winterburn, Baie Comeau.

Juniors: A. Jex, St. Catharines; K. Nyhus, Drumheller; J. H. Pitts, Niagara Falls; R. J. Rhodes, Montreal.

Affiliate: P. R. Gendron, Ottawa; A. T. Johnstone, North Bay; A. La Bissonniere, Montreal; A. G. MacAulay, Montreal; O. G. Moffat, Hamilton.

Junior to Member: S. G. Frost, Ottawa; G. Gow, Liverpool, N.S.; J. H. Legere, Montreal; A. M. Mackay, Cochrane; G. H. Milne, Fort Erie; T. E. Pelton, Vancouver.

STUDENTS ADMITTED

Queen's University: F. L. Anderson; R. Arcand; M. Backa; S. Backa; D. B. Bailey; D. A. Barrington; W. J. Barrott; W. R. P. Blackwell; R. M. Borne; J. H. Boyle; R. J. Brabbs; J. E. R. Brankley; J. G. Brics; G. J. Brinkmeier; J. C. Brownell; J. C. Bunge; C. D. Byrns; B. L. Calder; J. J. Cameron; R. K. Campbell; G. F. F. Carscallen; W. J. Clark; H. R. Clarke; D. T. Cole; D. M. Coulson; W. A. Crago; W. R. Darker; W. A. Davis; J. W. Davison; C. J. Demeyere; J. H. W. Diamond; W. R. Dormer; N. A. Douglas; G. R. Dowden; K. G. Dunn; D. G. Durant; A. E. Earl; W A. Este; W. A. Evans; A. R. Ferguson; J. D. A. Ferguson; E. Farankovich; W. R. Fraser; R. J. Geddes; A. W. Gilliland; J J. Gribbon; C. R. Grubb; K. M. Haapanen; D. E. Halliwell; D. E. Haws; J. A. Hayes; J. E. M. Henderson; W. A. Henwood; R. S. Hicks; E. A. Hopkins; W. A. Jaruis; W. T. Jenkins; R. E. Johnston; N. L. Journeaux; J. N. Kendall; J. Kiuru; L. O. Koskitalo; A. S. Krausz;
C. Lal; B. D. Lamorie; J. G. Lawrence; R. L. Levasseur; G. G. Liesemer; J. T. Lightall; D. G. MacDonald; G. A. MacIntosh; J. H. MacKay; D. M. MacKenzie; J. C. McBean; W. R. McBride; R. L. McCabe; J. T. McDermott; S. C. McEachern; W. G. McGill; A. S. McIntosh; J. D. McLeod; A. C. Machin; J. V. R. Manning; E. E. Marcellus; G. F. Marsters; R. E. Marttila; S. A. Meer; J. R. Mills; R. A. R. Mills; M. E. D. Misner; M. Moziar; M. S. Myint; E. J. N. Niceforo; G. A. Nicol; D. A. Norman; D. H. O'Hara; L. F. Organ;
M. A. Pe; G. D. Pearson; W. M. Porobich; D. L. Pratt; J. S. Pritchard; W. R. Purdy; H. A. Redstone; E. R. Richardson; K. S. Roberts; K. W. Ross; K. Roth; J. E. Sexton; G. V. Sherwood; K. W. Sinclair; J. C. Singlehurst; G. J. Splinter; R.. R. Stucky; D. G. Tate; R. R. Tinline; R. H. Townsend; D. R. Turnbull; G. D. Vallee; W. E. Watt; H. T. A. Webster; L. E. Wells; M. K. Win; H. C. Wood; H. A. Woodgate; A. Yuchimenko.

University of Manitoba: R. D. Adams; R. R. Adamson; E. W. Anderson; R. Billinton; J. I. Bogdonov; A. A. Borger; C. W. Bright; D. W. Brown; D. G. Buchanan; J. D. Buchanan; R. J. Chase; W. R. Cooke; W. L. Cox; R. L. Curtis; D. Demedash; D. Duncan; D. A. J. Ennis; P. N. Feschuk; R. B. Finlay; J. G. Fisher; R. K. Forbes; T. R. Fox; R. D. Hamilton; R. A. Hay; W. G. Herrod; H. L. Hiley; S. S. Hodge; F. N. Houston; R. M. Hovey; R. M. Jell; R. J. Johannson; B. Klewchuk; S. J. Kustra; D. F. Lamb; J. N. Lewak; G. B. Little; J. G. Locker; A. C. Mackey; S. C. MacPherson; J. Mar; D. B. McKenzie; R. R. McKibbin; W. Miller; L. A. Morison; W. E. Muir; L. R. Nichol;
L. F. Pedrick; K. N. Posgate; G. A. Pratt; B. W. Prentice; J. D. Rathgeber; H. L. Rawn; B. Reid; W. A. Reid; D. Reitlo; J. F. Russell; R. R. P. Schriber; G. Schultz; D C. Sexton; J. H. D. Smeaton; W. Smitiuch; T. J. M. Sopchuk; S. Soudack; D. K. Strang; G. Tarapasky; R. H. R. Tide; A. J. Watts; B. C. Weir; W. A. R. Whitcomb; H. R. Wilcox; D. J. Wilson; W. P. Wolfe; R. R. Zimmerman.

University of Ottawa: G. Archer; M. Bastien; M. L. Bedard; C. Bolduc; M. J. G. Boucher; J. H Bousfield; J. L. Bouvier; G. C. J. Bradette; R. T. Brown; J. E. Brunet; G. Campbell; A. J. Cataford; B. J. M Cataford; W. H. Y. Cheh; R. Cleroux; M. Concil; M. Cossette; J. M. Fournier; J. N. Falardeau; J. Fernandez; A. W. J. Galipeau; P. R. Gareau; G. Garneau; R. Gaudreault; P. Gauthier; G. M. R. Girouard; P. Gravel; R. E. Hansen; D. M. Harris; L. Huard; P. Hubert; D. J. Kyriazis; L. F. Landry; R. Larocque; D. Layton; M. Leeviraphan; P. A. W. Keon; V. Kui-Dick Li; R. A. Lord; Y. P. Lum;
N. J. McKay; J. P. B. Mangione; J. L. Mathieu; J. Michaud; J. M. C. Morency; R. G. Morris; A. Paldi; A. Paradis; M. Patenaude; J. R. Plaxton; G. R. Quarrington; E. D. Rainboth; L. M. R. Rehel; R. L. Robinson; J. Rousseau; J. P. Roy; P. Sanscartier; A. O. Sauolainen; A. Selin; S. D. Shaffer; J. T. Shilhan; G. A. Smith; M. F. Smith; J. G. Soulard; R. J. Turkevich; F. C. Van Der Pryt; K. P. Wong.

Loyola College: C. M. Archibald; H. Backman; T. F. Bagg; F. P. Brais; R. P. Czarnecki; R. Dechene; J. J. G. M. Desaulniers; M. B. Goruk; N. Hornyak; J. W. Houghton; A. B. Hurtubise; T. Kobelansky; J. G. Lavoie; J. H. Le Cornec; P. D. Maguire; P. E. Mayers; C. E. Ohlson; J. Osman; R. S. G. Piedalue; D. P. Rannie; M. St. Onge; J. A. Sinclair; P. A. Tetro; E. M. Traczyk; A. Turmaine; J. C. Verby; I. E. Williams.

University of Toronto: B. M. Addison; D. J. Condos; L. L. Davis; J. A. Deakins; J. H. Fine; D. S. Frost; G. W. Haessler; G. E. Holmes; M. E. Hoshkiw; H. S. R. Judges; F. E. Krueger; B. P. Leschuk; R. R. McCleary; D. A. McTavish; A. B. Nicholson; R. T. Orlando; J. A. F. Roberts; T. B. Roberts; W A. Travnik; E. L. Umbrico; D. L. Valentine.

Nova Scotia Technical College: D.A. Church; F. J. Corcoran; J. P. Corcoran; J. A. Fowler; G. J. Greer; E. C. Gregoire; J. A. Hopkins; F. J. Kelly; J. D. Kelly; R. M. Lane; D. F. MacLennan; J. W. Ricketson; V. R. Savoie; H. E. Slaunwhite; F. M. Swanter; R. J. Wong.

Ontario Agricultural College: M. D. Brown; K. G. Edwards; A. B. Hall; G. J. Harvey; J. D. Horwood; W. A. Johnston; A. M. MacKenzie; D. H. Patterson.

Sir George Williams College: C. F. Farnworth; F. Fiksel; S. F. Pressoir; D. Sicuso; S. Slawner; H. J. M. Van Der Staay; R. O. Wills.

University of Sherbrooke: J. Demers; R. Dion; S. Lacroix; C. Mercier.

Dalhousie University: J. H. Hayward; R. M. Ritcey.

St. Dunstan's University: B. A. Gallant; C. H. White.

University of Alberta: E. G. Hrdlicka.

Mount Allison University: J., E. V. Foster.
McGill University: — A. C. Niderost.
Graduates: M. R. Ernesaks (B.S.Sc., civil, Toronto 1958); S. J. Smith (B.A.Sc., mech., Toronto 1958); J. J. Qualters (B.Sc., Loyola 1958).

Applications through Associations

By virtue of the co-operative agreements between the Institute and the Association of Professional Engineers, the following elections and transfers have become effective:

ALBERTA

Member: R. G. Durward; **Junior:** M. M. Andrews; **Junior to Member:** T. Covello.

SASKATCHEWAN

Members: C. R. MacPhail; M. P. Nicholaichuk; C. A. Noble; A. Porter. **Juniors:** R. N. Filson; D. J. Nevill. **Junior to Member:** N. E Cressey; A. A. Roesch; H. Schmidt; **Student to Member:** M. E. Famulak.

CORRECTION

Edward M. Bates, Winnipeg. Man.: incorrectly reported in the March 1. 1958 minutes as Member, should have been listed as Junior.

STUDENTS: E. A. Anderson; P. P. Balasch; H. D. Barber; F. T. A. Barlage; H. J. Bell; L. P. Benoit; J. F. Betemps; B. C. Beveridge; B. Breadner; V. B. Brown; R. R. Bryce; A. Charnish; E. A. Cochrane; J. R. Connell; W. J. Cooke; W. W. Crossley; W. R. Demetrick; L. Dinter; J. Ens; J. S. Farley; L. D. Federspiel; E. W. Filipowich; L. Flaman; D. P. Flathman; S. T. Flett; B. J. Foster; C. B. Foy; R. G. Glencross; R. G. Gorrill; O. J. Green; J. H. Hamilton; J. M. Hamilton; R. S. Hamilton; W. J. Harder; T. D. Harle; F. R. Hill; R. O. Houston; W. M. Hunter;
R. N. Jacobs; F. W. Jamieson; L. E. Johnson; T. W. Johnston; A. W. Kempthorne; M. G. Korol; D. J. Kot; A. E. Kovach; E. O. Kozey; J. W. Kramer; L. H. Lashyn; T. S. Lau; G. A. Ledingham; T. D. Lee; D. H. Linn; D. G. MacLennan; A. L. MacMillan; J. R. McClement; K. E. McCullagh; W. J. McDonald; D. J. McKay; W. W. McKinnon; P. Machibroda; C. P. Mah; D. V. Makuch; E. C. Mikulcik; R. M. P. Miller; J. L. Milne; H. J. Murzyn; D. D. G. Nunweiler; J. O. Ochitwa; W. E. Olauson; A. L. Opseth; H. W. Orr; E. G. Popadynic; M. L. Parsons; D. A. F. Park; W. C. Paynter; P. Pisio; P. P. Pospisil; C. A. Reed; G. K. Rever; R. J. Reynolds; J. E. Richert; K. J. Rieder; L. I. Riess; G. W. E. Roach; G. K. Robinson; K. N. Rockel; C. J. Runolfson;
A. P. Sander; R. G. Sanders; G. R. Schell; A. J. Schwinghamer; D. L. Sedgwick; T. J. Seymour; B. A. Sjoberg; G. C. Skorobohach; D. R. Smith; G. C. Sollid; W. Spak; B. J. Stolee; M. P. J. Swanston; J. K. Theil; W. F. Thiele; L. E. Trickey; G. H. Turnbull; J. W. Ulrich; E. W. Unick; A. M. Veroba; J. K. Walker; H. J. Wasylyk; D. D. Warner; N. P. Weber; H. T. Welch; L. D. Westgate; J. N. Wilson; W. J. Wishlow; G. W. Wortman; J. T. Wright; M. Yamakami; G. R. A. Zieglgansberger; J. G. Zbeetnoff.

French Government Scholarships

Several thousand foreign students are working in French institutions, universities and laboratories. The number of engineering and technical students, in particular, has greatly increased since the war. It has become necessary to organize and coordinate formal courses and practical work. The French Government has created a service to this end (Service de Cooperation Technique) and has endowed a great many scholarships, a number of which have been reserved for Canadian engineers or technical men.

Value of grants includes: as much as 75,000 francs a month for the standard period of six months; free return trip from France to Canada; free transportation in France for authorized trips; privileges normally reserved to University students, to the extent available (lodging and restaurant facilities, community activities, libraries, lectures, etc.); allowances for the purchase of technical books and for the cost of typing final reports.

Prompt action is suggested. Before filing a formal application, which must be made on an official form and accompanied by several detailed documents, a simplified procedure is suggested, namely, that you *write immediately a letter covering as briefly as possible the following points:* Name, address and telephone number; date and place of birth; Academic training or equivalent, (specify degree and specialty) and class ranking; practical experience; references (give name and telephone number of two persons); knowledge of French; program and duration of proposed "stage" in France.

This letter should be addressed in triplicate to: Mr. Raymond TREUIL, Chairman of the Comite France-Technique, c/o French Embassy, 464 Wilbrod Street, Ottawa, Ontario.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Frank P. Moran, JR.E.I.C., of the B.C. Forest Products, Vancouver, B.C., died on May 3, 1958.

Born at Burnaby, a suburb of Vancouver, Mr. Moran attended the University of British Columbia and graduated with B.A.Sc. degree in mechanical engineering from that institution in 1951. Employed with the B.C. Forest Products since his graduation, Mr. Moran designed and was responsible for the building of an all steel mobile spar tree. The prototype of this proved very successful. Mr. Moran was at the time of his death engaged in making minor improvements on this work.

Mr. Moran joined the Institute as a Student Member in 1948, transferred to Jr.E.I.C. Membership in 1953.

Professor G. V. Douglas, M.E.I.C., retired geologist, died on October 8, 1958 in Toronto. George Vibert Douglas was born in Montreal on July 2, 1892. He began his engineering career while serving with the Northumberland Fusiliers, and the Royal Engineers, during World War I. Discharged with the rank of captain, he was one of those selected to receive a Military Cross in 1918. Returning to a civilian status Mr. Douglas pursued his formal education at McGill University and graduated with B.Sc., and M.Sc., degrees in mining and geology from McGill University in 1920 and 1921.

In the next two years Professor Douglas had the opportunity to take part as geologist on the Quest, R.Y.S., which was Sir Ernest Shackleton's expedition to the Antarctic. After two years as assistant professor at Harvard University he was appointed chief geologist to the Rio Tinto Mining Company in Spain, later in Northern Rhodesia. The newly established Carnegie Chair of geology at Dalhousie University, N.B., was offered him in 1932. He accepted the appointment and gave twenty-five years to the advancement of geological interest and studies at the University.

Through his lectures to a wide range of audiences and through the Dawson Geological Club, which he founded in 1933, he made geology come alive. After his retirement from Dalhousie University in 1957 he lectured at the Extension Department, University of Toronto and carried on geological consulting work.

Professor Douglas joined the Engineering Institute of Canada as a Junior member in 1920, transferred to Associate Member in 1921, and to Member in 1940. He became a Life Member of the organization in 1957.

Wilfred S. Lawson, M.E.I.C., retired chief engineer, Department of Justice, penitentiaries branch, died on September 23, 1958.

Born at Barnsley, Yorkshire, on November 27, 1880, Wilfred Stelm Lawson attended Yorkshire College, Leeds, England. Joining the Canadian Pacific Railway on his arrival in this country in 1903, he worked with the Temiskaming and Northern Ontario Railway and the Canada Foundry Company, Toronto, for the first few years. With the latter firm he became assistant engineer, assistant bridge engineer with the National Transcontinental Railway, bridge department, 1913, and acting bridge engineer, 1915. He also served the Canadian Army for several years, retiring with the rank of major. Later a bridge engineer with the Canadian National Railway Company, he left the organization to accept an appointment as a bridge instructional engineer with the Department of Railways and Canals, Government of Canada, in 1921. A year later he was transferred to the work of structural engineer, Penitentiaries Branch of the federal government. Named chief engineer of the Branch in 1928, he retained this responsibility until his retirement in 1947. During World War II he took over the duties of acting superintendent of penitentiaries, with the award of an O.B.E. in 1946.

Mr. Lawson was a member of the committee of the Ottawa Branch of the Engineering Institute of Canada which was responsible for the erection of the Colonel By Memorial in Ottawa.

Mr. Lawson joined the Engineering Institute in 1907 as an Associate Member. He transferred to the status of Member in 1916, and attained Life Membership in 1942.

Lt. Col. Robert Bickerdike, M.E.I.C., of Montreal, retired consulting engineer died on November 8, 1958.

Robert Bickerdike was born in Montreal on September 30, 1869. He was educated in Montreal schools and at McGill University. He was awarded a B.A.Sc. degree in civil engineering in 1891, and an M.Eng. degree in 1895. While yet a student he was engaged in work as an assistant on surveys for the location of the Vaudreuil and Prescott Railway, afterwards known as the Montreal and Ottawa Railway. His first graduate work was as an assistant engineer in charge of the McGill College Observatory.

During the next few years he worked with the United Counties Railway, the Atlantic and Northwestern Railway, the Drummond County Railway, and the Montreal Harbour Works. He was a demonstrator of surveying at McGill University for a time; and was later associated with the Department of Public Works, the Department of the Marine, Province of Quebec, and the National Transcontinental Railway.

Colonel Bickerdike was employed in construction work for the Canada Starch Company at Fort William and Cardinal, Ontario, before the first World War.

Active in the militia at that time, he was involved in the work of recruiting. He went overseas and saw lengthy overseas service in France, winning the D.S.O. and Bar. He returned to Canada in command of the 87th Battery and on demobilization was transferred to the Royal Montreal Regiment. He was transferred to the Reserve Army in 1920. He carried on his consulting practice in Montreal for many years.

Lt. Col. Bickerdike joined the Institute as a Student in 1888, became an Associate Member in 1895 and a Member in 1900. He attained Life Membership in 1936. He was also a member of the Institution of Civil Engineers.

John Samuel Hunter, M.E.I.C., of Calgary, president and general manager of Hunter Drilling Limited, was killed in a plane crash, October 8, 1958.

Born in Metronne, Sask., on December 25th, 1921, he attended the University of Saskatchewan, obtaining a B.Sc. degree in civil engineering in 1948.

His career began with the Canadian Pacific Railway Company in the post of junior draftsman in 1947. Receiving his degree, the following year he became senior transitman, then operating assistant. Mr. Hunter left the Canadian Pacific Railway in 1957 to join Seaman Engineering and Drilling Company Limited as general manager. A year later he acquired the responsibilities of president and general manager of Hunter Drilling Limited.

He joined the Institute as a Member in 1957.

Lt. Col. R. Bickerdike

G. V. Douglas

NEWS OF THE
Associations and Corporation

Information received through co-operation of the provincial organizations.

QUEBEC

(From the Bulletin of the Corporation of Professional Engineers, December, 1958.)

New Report Features Actual Salaries

Actual rather than recommended figures and a series of job levels instead of grade definitions are the more apparent features of the "Report on Salaries of Professional Engineers by Levels of Responsibility", published in September. This Report supersedes the "Schedule of Salaries" which was last issued in June, 1957.

The Report is a factual account of salaries paid 6,309 professional engineers by 92 industrial and other organizations in Ontario and Quebec as of July 1st of 1958. The survey was conducted by the Quebec Corporation and the Ontario Association. The organizations approached in the survey were asked to identify the work performed by the engineers in their employ with a number of descriptions of typical engineering jobs. It was necessary that the positions match the descriptions and the appropriate responsibility level.

The elaborate level descriptions in the Report make it easier to match a given job. In addition, more emphasis has been placed on the extent of responsibility and the reference to the number of years of experience is only incidental.

ONTARIO

From *The Professional Engineer*, November, 1958, an abstract.

Five Needs of The Professional Engineer, by J. Herbert Smith, D.Sc., P.Eng.

As I see it, the primary distinction between the professional man and the skilled technician is the *perspective* developed in the professional man as a result of the academic discipline of his training. This perspective not only allows him to see his own contribution as an important integrated part of the whole economic and social structure, but demands for his personal satisfaction and development that his work can be so seen by both himself and his associates.

The problem management faces is to identify the specific needs that must be satisfied if the professional employee is to be an effective and productive member of the enterprise.

Summarized then, these are the five specific needs of the professional engineer that must be satisfied by the design of his job:

(1) He must have professional work.
(2) He must have opportunities for promotion as a professional employee and individual contributor.
(3) He must have financial incentives as a reward for improved performance and greater contribution as an individual contributor.
(4) His job must be supervised from a professional viewpoint.
(5) He must have professional recognition both inside the enterprise and the larger community.

BRITISH COLUMBIA

Annual meeting

R. E. (Ron) Wilkins, O.B.E., P.Eng., was elected president of the Association for the coming year. Results of the ballot were announced at the Saturday luncheon of the annual meeting held in the Empress Hotel, Victoria, on December 5 and 6. New vice-president is H. P. J. Moorhead, P.Eng., and elected to membership on Council were R. S. Cunliffe, P.Eng., (Civil); Frank Noakes, P.Eng., (Electrical); H. M. Wright, P.Eng., (Metallurgical); J. R. Giegerich, P.Eng., (Mining); and William Hall, P.Eng., (Forest). The remaining four members, to be nominated by the Provincial Government, were to be named by Order-in-Council early in the new year. Immediate past president, George C. Lipsey, P.Eng., will continue to serve, ex-officio, for another year.

R. E. Wilkins, P.Eng.

Two hundred and seventy-five members, and seventy-five visiting wives checked in at the reception desk during the two day session.

Guest speaker at the annual luncheon on Saturday was Dr. Brock Chisholm, C.B.E., former director-general of the World Health Organization. Speaking on "Our Increasing Responsibilities", he stressed the fact that two thirds of the world's people are suffering from lack of food. He stated that starvation, through improper distribution of food, is an even greater danger than the peril of suicidal war. Contributing to this danger is nationalism in every form, and it becomes necessary for survival to develop a maturity that will make it possible for all of us to function as members of the whole human race, regardless of our upbringing or place of birth, he concluded.

A new function this year was a reception for the deputy ministers of the Provincial Government.

On Friday evening a highly successful stag party was held in the Pacific Club when the annual barbershop harmony duel for the Killam Kwartet Kontest Kup — the only plush bottom copper plated grease cup in the world — was won by a quintet composed of A. C. Dalrymple, P.Eng., G. Griffiths, P.Eng., J. W. Milligan, P.Eng., F. R. B. McLean, P.Eng., and S. P. Oakes, P.Eng.

On Saturday evening the ballroom of the Empress Hotel was crowded to capacity by 340 of the members and their wives for the annual banquet and dance.

The fifth annual Awards Luncheon was held on Friday, when some 35 recently registered members received their certificates. Life Membership medallions were also presented to T. H. Crosby, P.Eng., H. J. MacLeod, P.Eng., W. I. Nelson, P.Eng., J. I. Preissner, P.-Eng. and C. E. Scanlan, P.Eng.

The Letson Memorial Prize for the best report on mechanical engineering was presented to Norman H. Booth, P.-Eng., of Trail, by G. M. Letson, P.Eng., on behalf of his brother. A signal honour was paid to R. W. Diamond, P.Eng., when the members approved a recommendation of Council and granted him an Honorary Life Membership for his distinguished contribution to the Association and to engineering in general.

Personals

News of the Personal Activities of Members of the Institute

C. E. Campeau, M.E.I.C. (B.A.Sc., Ecole Polytechnique 1941) former director of the City Planning Department of Montreal, is practising as a consulting engineer and consulting town-planner in Montreal. He is the Member of Parliament for Montreal-St. James, Montreal.

Jos. A. Grant, M.E.I.C., (B.A.Sc., mining, Toronto 1942) has retired as consulting engineer in Montreal and is permanently residing at Dewittville, Que.

Mr. Grant was associated with highway, airport, and building construction across Canada for many years. He was employed by the Sheraton Corporation in Canada and the United States in recent years.

Ernest A. Leja, M.E.I.C. (chem., Latvia 1930) managing director of Lundrigan's Concrete Limited in Corner Brook, Newfoundland, holds office as chairman of the Engineering Institute's branch in that city.

W. H. Eastlake, M.E.I.C. (B.A., Toronto, 1912) has retired as general manager of the wire and cable division of Northern Electric Company Limited, Montreal.

Joining Northern Electric before World War 1, he was on leave of absence, 1915 to 1918, with the British Munitions Company Ltd. After the war he returned to the company and in 1933 was appointed assistant general superintendent of the wire and cable division. He became works manager in 1938, manager in 1945 and general manager in 1953. He is a Life-member of the Institute.

Prof. D. G. Huber, M.E.I.C. (M.A.Sc., mech., Toronto 1942; Ph.D., Iowa 1948) associate professor of the mechanical engineering department at McMaster University, Hamilton, has been elected chairman of the department. He was with the University of Toronto previously, as assistant professor of mechanical engineering.

H. H. Moor, M.E.I.C. (M.A.Sc., chem., Toronto 1923) has been appointed deputy management development counsellor of Imperial Oil Limited in Toronto.

With 35 years of service with Imperial Oil, Mr. Moor is a former manager of the Edmonton refinery, and recent manager of the refinery at Imperoyal, N.S. He supervised the expansion in Nova Scotia, completed in 1957.

A. H. W. Busby, M.E.I.C. (B.Sc., mining, Birmingham, England, 1923) has been named consulting mechanical and electrical engineer for the Rhodesian Section, Anglo-American Corporation of South Africa Limited. In Canada, he was associated for many years with the Consolidated Mining and Smelting Company, Trail, B.C. He was superintendent of engineering research and development for the company from 1946. He went to Rhodesia in 1954.

Murdo MacLeod, M.E.I.C. (B.Sc., chem., Alberta 1933) former plant superintendent of Imperial Oil Limited's Imperoyal Refinery, has become manager of the refinery. Mr. MacLeod has an extensive service with the company in Calgary, Regina and Toronto. He went to the Imperoyal refinery in 1948.

R. I. Stevens, M.E.I.C. (B.Sc., elec., McGill 1935; M.Sc., elec., McGill 1936) works engineer at the chemicals plant of Canadian Industries Limited at Shawinigan, Que., has become supervisor of the company's ammonia works at Millhaven, Ont. He joined the company in 1939, and was for several years at Windsor works.

Z. C. Van Schwartz, M.E.I.C. (M.S./M.E., mech., Northwestern University, Valparaiso, Chile, 1932) has been appointed management consultant of C. A. Norgren Co. & Affiliated Companies, Denver, Colorado. His previous occupation was director, engineering, manufacturing, standards of Baldwin-Lima Hamilton Corporation, Hamilton, Ohio.

R. S. Segsworth, M.E.I.C. (B.A.Sc., mech., Toronto 1935) has accepted a post as assistant to the general manager of Ajax Electrothermic Corporation, Trenton, New Jersey. He was formerly associated with the General Engineering Company, Toronto in the research and development branch.

Eric C. Smith, M.E.I.C. (B.Sc., civil, Leeds, England, 1949) has joined Atomic Energy of Canada Ltd. as civil design engineer in the nuclear power plant division. He was formerly associated with the Hydro-Electric Power Commission of Ontario, Toronto.

W. B. Thomson, M.E.I.C. (B.Sc., civil, Saskatchewan, 1942), has been appointed a construction engineer for the South Saskatchewan river project, with headquarters at Regina. He was previously working on the St. Mary Milk River project, at Lethbridge, Alta.

Mr. Thomson resigned, due to this move, as chairman of the Lethbridge Branch, E.I.C. He had been a member of the executive for several years.

The 3,071ST Bridge

New Rivière des Prairies bridge, near Montreal, incorporates ten 225 ft. girders, each 70 tons; twenty of 212 ft. and many of smaller size.

• PERSONALS

A. P. Wiles, M.E.I.C., (B.Sc., engineering and physics, Saskatchewan, 1946), formerly with Ford Motor Company of Canada as research engineer, is presently employed by the R.C.A. Victor Company as a systems engineer in the new defense systems division.

John L. Aikman, M.E.I.C., (B.Eng., mech., McGill 1950), chief engineer with Thurso Pulp and Paper Co., Thurso, Que., is working as shift engineer at Montreal Children's Hospital.

Lieutenant Commander M. R. Kent, M.E.I.C., (B.Sc., mech., Manitoba, 1950), on December 15th became engineer officer of "H.M.C.S. St. Laurent" (destroyer escort), Halifax, N.S. His earlier posting was as project officer for naval ships repairs and conversions at Canadian naval headquarters in Ottawa.

G. F. (Bud) Coote, M.E.I.C., (B.Sc., civil, Alberta, 1940), manager of the Accurate Exploration Ltd., Edmonton District, was promoted to general manager, of the firm, at head office, Calgary. The appointment was made in April.

John R. Sutherland, M.E.I.C. (B.Sc., civil, Sask., 1953), has been promoted from project engineer to division engineer, at Rosetown, Sask.

S. K. McWalter, M.E.I.C. (B.E., chem., Sask., 1948), of the British American Oil Company has taken over the post of operating superintendent at the company's Port Moody Refinery, New Westminster, B.C., following service as senior project engineer at head office, Montreal East, Que.

Roger C. Egglestone, M.E.I.C., (B.Sc., petroleum, Alberta, 1955), of the firm of Sun Oil Company, has been transferred from Estevan, Sask., to Calgary. Now engaged in production engineering, he was earlier a field engineer.

Frank Ross, M.E.I.C., (Higher Nat. Cert., elec., Birmingham Central Technical College, 1947), a member of the switchgear and motor control department, Canadian Allis Chalmers Ltd., St. Thomas, Ont., has been promoted to sales engineer on electrical equipment for the Montreal district sales office. Mr. Ross was earlier connected with Bepco Canada Limited, and the Amalgamated Electric Corporation Ltd.

Lt. Col. A. C. Cluff, M.E.I.C., (B.Sc., from the Saskatchewan area, to Army mech., Queen's, 1936), has been posted headquarters, Ottawa, as assistant director of Works, (stores). In the Saskatchewan area he served as area engineer with the rank of major.

D. R. Robson, M.E.I.C., (B.E., mech., Nova Scotia Technical College, 1950), chairman of the Amherst Branch of the E.I.C. in 1955, is a consulting engineer with the firm of N. H. McFetridge and Associates, consulting engineers at Dartmouth, N.S. Mr. Robson has been until the present time, plant superintendent of the No. 2 plant of the firm of Enamal Heating Products Ltd., Amherst.

John J. Rowan, M.E.I.C., (B.Sc., civil, Ecole Polytechnique, 1935; B.Sc., mech., Massachusetts Institute of Technology, 1936), has been promoted from assistant refinery manager to manager of the Montreal East Refinery, Imperial Oil Limited, Montreal. Mr. Rowan was a member of the Sarnia Branch Council of the E.I.C. in 1952 and 1953.

Norman Lapierre, JR.E.I.C., (B.A.Sc., civil, Laval University, 1955), formerly field engineer for the Baie Comeau Company is at present employed as engineer and estimator for C. Jobin Ltee., general contractors in Quebec City. Mr. Lapierre is secretary of the Baie Comeau Branch, E.I.C.

James D. Kingston, JR.E.I.C. (B.Sc. Civil, Queen's, 1954), formerly job superintendant with Temiskaming Construction Limited at Chelmsford, Ont., is a newly appointed project engineer, Hill-Clark-Francis Limited, Kirkland Lake, Ont.

Mattio O. Diorio, JR.E.I.C. (B. Eng., Metall., McGill, 1957), of the Dominion Brake Shoe Company, Joliette, Que., formerly assistant works manager, has been appointed works manager of the Joliette plant. Mr. Diorio joined the company in 1954.

Gordon K. Hunter, JR.E.I.C. (B.Sc., civil, Toronto, 1950), an engineer concerned

Franki method offers solution to differential settlement problem

Problem

The Saskatchewan Research Council building is one of four new structures on the University of Soskatchewan Campus, constructed on Franki Caissons.

The site soil conditions posed the problem of the transfer of heavy column loads to a suitable bearing stratum below the excavated grade. High water conditions required the use of a foundation eliminating the difficulties of deep excavation. The overlaying clay was inadequate to carry loads transferred by spread footings. The most significant problem was to determine the depth at which foundations could be based, for although the bearing capacity of soil increased with depth, the elevation at which differential settlements could be held within permissable limits was not obvious.

Solution

The Franki base is made by ramming zero slump concrete into the supporting soil with blows of 140,000 foot pounds of energy. Twenty such blows are required to expel each 5 cubic feet of concrete in the base to obtain 120 Ton bearing capacity. Concrete is added in the base until the required blows are attained.

Thus the engineers were assured that uniform bearing was achieved under each caisson, thereby eliminating the possibility of differential settlement and, at the same time, securing a measure of the bearing capacity of each base.

No other foundation system can offer these advantages so economically.

Head Office: 187 GRAHAM BLVD., MONTREAL 16, P.Q.

QUEBEC OTTAWA TORONTO EDMONTON VANCOUVER

with the improvement of highways and transportation has been awarded an Esso Good Roads Scholarship. Formerly a senior project design engineer with the Ontario Department of Highways, he is now registered in a course in transportation engineering at the Institute of Transportation and Traffic Engineering, University of California.

P. J. Pride, JR.E.I.C., (B.Sc. Metall., Queen's 1956), has joined the Arvida works, Aluminum Company of Canada, technical division and will work as an engineer in the metallurgical development department. With the Aluminum Company since 1956 he was previously a development engineer and metallurgist in the remelt department at the Shawinigan smelter.

K. Linn MacDonald, JR.E.I.C. (B.Sc., mech., Manitoba, 1956), formerly an engineer with the Ontario-Minnesota Pulp & Paper Co., Fort Frances, Ont. has been appointed plant engineer, Canadian Splint and Lumber Corporation Ltd., Pembroke, Ont.

Edward L. Littlejohn, JR.E.I.C. (B.A.Sc., chem., Toronto, 1949), of the Union Carbide organization, Toronto, has been named as assistant to the president of the Visking Company, Division of Union Carbide Canada Limited. Mr. Littlejohn joined the organization in 1949, and has since 1956 been manager of public relations, Union Carbide Canada Limited, at Toronto. He will now be located at the Visking Company office and plant at Lindsay, Ont.

J. McGown, JR.E.I.C., (B.Eng., mech., McGill 1951), formerly road foreman of engines, Kootenay Division, of the Canadian Pacific Railway, Nelson, B.C., has been named master mechanic of the Revelstoke Division, Revelstoke, B.C.

A. W. Saunders, JR.E.I.C. (B.Eng., civil, McGill 1949), flight test engineer, Trans-Canada Air Lines, Dorval Airport, Montreal, has joined the de Havilland Aircraft of Canada Ltd., as a test pilot at Downsview, Ont.

Keith S. Preston, JR.E.I.C., (B.Sc. civ. & mech., New Brunswick, 1955), of the construction and maintenance department, Imperial Oil Ltd., has been appointed assistant resident engineer of construction with Dominion Tar and Chemicals Company Ltd., Hamilton, Ont.

G. B. Weld, JR.E.I.C. (B.E. mech., Nova Scotia Technical College, 1955; M.Eng., mech., Sheffield, 1957), has been appointed assistant professor of mechanical engineering, Nova Scotia Technical College, Halifax. Until his present appointment Mr. Weld was assistant to the director, National Research Council, Halifax, N.S.

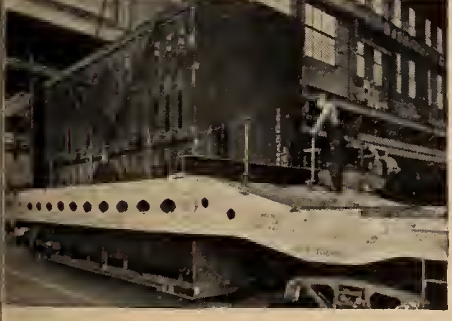
J. R. McMackin, JR.E.I.C. (B.Sc. Civil, New Brunswick, 1949), of Defence Construction (1951) Ltd., has been transferred from North Bay, to Camp Petawawa, Ont. Mr. McMackin has in each area been employed as a project engineer.

Claude Francoeur, JR.E.I.C., (B.A.Sc., civil, Laval 1955), formerly a project engineer on the Lake Ste. Anne reservoir project of the Perini Cartier Construction Company is now on the engineering staff, main office of the firm, Montreal.

Captain J. G. Forth, JR.E.I.C., (R.M.C., 1952; B.A.Sc., chem., Toronto, 1954), formerly officer commanding, First Airborne Troop R.C.E., Calgary, has been posted as second-in-command of 24 Works Company, R.C.E., Camp Borden, Ont. While stationed at Calgary, Captain Forth was responsible for the command, training, and control of the only airborne engineer unit in Canada.

Ross H. Curtis, JR.E.I.C. (B. Eng. elec., McGill, 1950), formerly sales engineer, R.C.A. Victor Company Ltd., Montreal, has been appointed manager, engineering products division, marketing dept., Calgary.

M.E.M. Gibson, JR.E.I.C. (B.A.I., civil, Trinity College, Dublin, 1954), was formerly field soils engineer, H. G. Acres &



• PERSONALS

Co., Labrieville, Que., on the Bersimis No. 2 project. He has recently accepted an appointment as design engineer with R. E. Winter and Associates, at Toronto.

R. E. Chamberlain, JR.E.I.C. (B.A.Sc. elec., University of British Columbia, 1953), of the Bailey Meter Company Limited, Montreal, has been transferred to Quebec City, Que. Mr. Chamberlain has relinquished the work of project engineer to become sales-service engineer in his new location.

Peter Glockner, JR.E.I.C. (B.Eng., civil, McGill 1955; M.Sc., structural Massachusetts Institute of Technology, 1956), has since then been employed as a design engineer for C. C. Parker, Whittaker & Company, consulting engineers of Edmonton, Alta. Early in 1958 he was appointed an assistant professor of applied mechanics, University of Alberta.

Flying Officer W. G. Williams, JR.E.I.C., (B.Sc., civil, Queen's 1955), is a construction engineer officer at the R.C.A.F. Station, Calgary, Alta.

Flying Officer Williams was formerly on the staff of construction engineering branch at Training Command Head quarters, R.C.A.F. Station, Trenton, Ont.

John S. Taylor, JR.E.I.C. (B.Eng., civil, McGill, 1949), who was assistant to general superintendent, reduction division, Arvida Works, Aluminum Company of Canada, is now technical superintendent, Beauharnois Works, of the same company.

Mr. Taylor served on the executive from 1955-56. Prior to his transfer he was vice-chairman of the Saguenay Branch of the E.I.C.

Richard Francis Critchley, JR.E.I.C., (B.Eng. mech., Saskatchewan, 1955), lately of Montreal, as production engineer for Dominion Engineering Company Limited is studying in Great Britain according to the provisions of an Athlone Fellowship. At present he is associated with the firm of Vickers-Armstrong (Engineers) Ltd., at Newcastle-upon-Tyne, Mr. Critchley will do post graduate work in the department of applied mechanics at the University of Sheffield in his second and final year in England.

F. D. Malloch, JR.E.I.C., (B.Sc., mech., Queen's, 1951), has transferred his services from the Department of Northern Affairs and National Resources to the Scarborough, Ont., firm of James Howden and Company of Canada Ltd. He is employed in the heat transfer division of that organization.

E. A. Beaumont, JR.E.I.C., (B.A.Sc., civil, British Columbia, 1949), formerly divisional engineer, location branch and district engineer, is now regional location engineer with Dept. of Highways, Prince George, B.C.

Donald S. Miller, JR.E.I.C., (B.Sc., mech., Queen's 1954), has resigned from the Royal Canadian Air Force to accept an appointment as lecturer, mechanical engineering department at Royal Military College, Kingston, Ont. He is pursuing post graduate studies leading to a masters degree in mechanical engineering. A former sabre pilot, he was stationed in Germany with the 4(f) Wing, R.C.A.F., at Baden - Soellingen, from 1955 to 1958.

J. H. Whelen, JR.E.I.C., (B.Sc., C.E., civil, U.N.B. 1952; S.M.; industrial management, M.I.T., 1954), has transferred his services from the economic planning and market research department of Canadian International Paper Company to Hygrade Containers, Ltd., Toronto division. His post is that of marketing manager.

J. P. Hartt, JR.E.I.C., (B.A.Sc. civil, Toronto, 1950), has accepted an appointment with the department of engineering teaching staff of Essex College, Assumption University of Windsor, Wind-

REFRACTORY CONCRETES

REGULAR SERVICE

CIMENT FONDU

For service temperatures up to 2450°F. High cold strength, and is ready for white heat service in 24 hours. Permits quick pouring of monolithic walls, roofs, hearths, any shape, size or form.

sor, Ont. Mr. Hartt's recent engineering experience was with the St. Lawrence Seaway Authority, civil engineering department at Welland, Ont.

W. B. McLachlan, S.E.I.C. (B.Eng. elec., McGill, 1958, has joined the junior engineer training program of the Ontario Hydro Electric Commission, at Thorold, Ont.

S. W. P. Wyszpkowski, S.E.I.C. (B.A.Sc. chem., Toronto 1958), is employed as a development engineer, for the Du Pont of Canada, textile fibres division, at Kingston, Ont.

C. A. Laferriere, S.E.I.C. (B.A.Sc. civil, Toronto 1957), formerly field engineer in building construction for the firm of Hill-Clark-Francis, Ltd., at Noranda, Que. has been named resident engineer in the field of municipal engineering, for Desjardins and Sauriol, consulting engineers, Pont Viau, Montreal.

Gilles Chartrand, B.A.Sc., chem., Ecole Polytechnique 1957), is employed as a technologist with the Shell Oil Company of Canada, Montreal.

Valmond Robichaud, S.E.I.C., (B.Sc. civil, New Brunswick, 1957), formerly an assistant engineer, Aluminum Company of Canada, at Shipshaw, Que., has been appointed assistant resident engineer, Department of Public Works, Trans-Canada highways division at Dartmouth, N.S.

J. S. Luffman, S.E.I.C. (B.Sc., civil, New Brunswick), is in charge of "Butler Buildings" for Fry's Engineering Co. Ltd., St. John's, Nfld.

Flying Officer R. H. Jones, S.E.I.C., (B.E. civil, Nova Scotia Technical College, 1958), is assistant construction engineering officer at the R.C.A.F. station, Clinton, Ont.

E. J. Jackiw, S.E.I.C., (B.S., mech., Queen's 1958), is now junior engineer at Horton Steel Works, Fort Erie, Ont.

Lieutenant F. J. Bradbrook, S.E.I.C., (B.E., civil, Nova Scotia Technical College, 1958), has been following the young officers training course with R.C.S.M.E., at Camp Chilliwack, B.C. since his graduation. He is presently posted at Camp Petawawa, Ont. where he is a headquarters lieutenant with 1 Field Squadron, R.C.E.

Norman Benoit, S.E.I.C. (B. Eng., elect., McGill 1958), is following a two-year training course with Canadian General Electric Company Ltd., Peterborough.

E. J. Stewart, S.E.I.C., (B.E., elec., Nova Scotia Technical College 1958), is an assistant engineer with the Canadian Pacific Railway, Montreal, communications department.

B. W. Sarjeant, S.E.I.C., (B.Sc. eng. civ. London, 1958), is design engineer with the firm of Read, Jones, Christoffersen, consultant engineers at Vancouver, B.C.

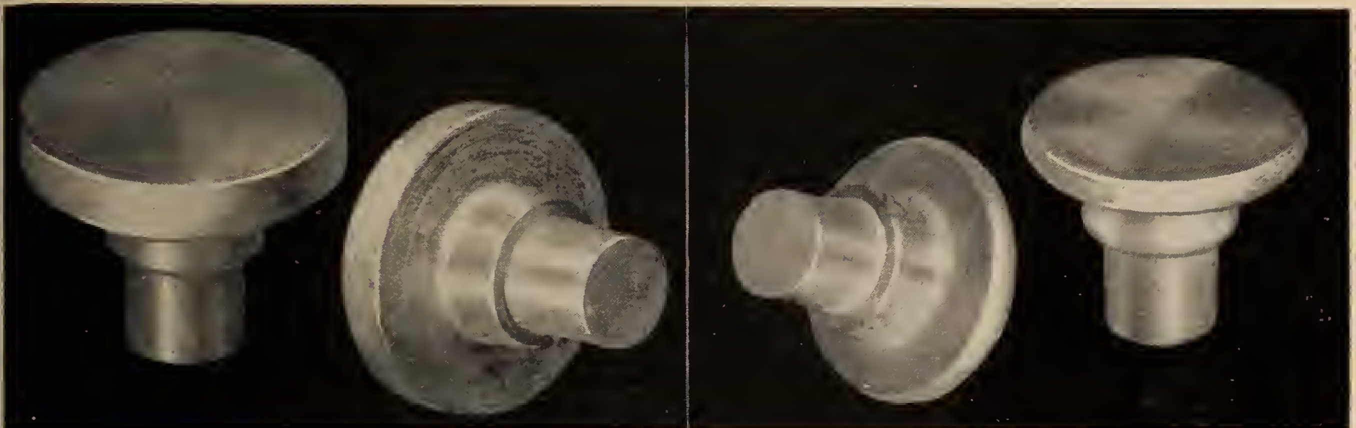
Kenneth E. Tingley, S.E.I.C., (B.Eng. elect., Nova Scotia Technical College, 1957), has left the Canadian General Electric Company Ltd., Peterborough, Ont., to work with the Linde Air Products, division of Union Carbide Canada. He has been assigned to the development laboratory at Newark, N.J. for a one or two year training period.

Murray E. Markanen, S.E.I.C., (B.Eng. civil, McGill, 1957), has left the firm of C. A. Pitts, General Contractor Ltd., seaway contractors at Cornwall, Ont., Mr. Markanen has joined a Brockville, Ont. company, Permanent Transit-Mix Concrete Ltd.

TO SAVE ON **FASTENERS**

Standardize your Specials

THROUGH STELCO COLD HEADING



Machined "Special" . . . slightly redesigned as a Cold Headed "Standard"

The simple Flat Head Shoulder Rivet shown on the left above (enlarged), was slightly amended as seen on the right, to permit production by cold heading instead of by machining. The elimination of scrap loss, combined with increased speed of production, brought a saving of 80% to the purchaser.

Pictured below are several other "specials" standardized by Stelco with considerable cost reduction.

57121.B

Result - 80% Savings!

Stelco's modern bolt-making facilities, plus the services of Specialty Fastener Representatives, offer you three ways to save on "special" fasteners —

FIRST — Many types of contoured parts can be produced by cold heading more economically than by machining. Not all savings are as impressive as the one illustrated above, but *cost reductions in the region of 40% are not uncommon* and are often accompanied by minor redesigning which adds to the strength of the part. Secondary operations, such as thread rolling or cutting, knurling, extruding, flattening, piercing, drilling, broaching, and bending are also provided for in Stelco's facilities.

SECOND — Stelco will carry as stock items your long-run repetitive "specials" — giving you a ready source of supply and the benefit of large-quantity prices.

THIRD — Your "special" requirement might already be in stock as a Stelco "Standard" — or possibly an existing "special" could meet your needs. In either case you would realise a saving.

Why not ask Stelco's Engineers to examine *your* "specials"? If they are adaptable to production by the cold heading process your cost reductions will be substantial. Any Stelco Sales Office is at your service.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings

BORDER CITIES

A. W. Malmberg, JR.E.I.C.,
Branch News Correspondent

ON OCTOBER 17, 1958, 160 members and guests of the Border Cities Branch of the E.I.C. honoured Dr. K. F. Tupper, O.B.E., president of the E.I.C. with a dinner and dance at the Essex Golf Club.

Dr. Tupper who had just returned from a visit to the U.S.S.R., spoke to the gathering on observations and impressions formed on his trip, which were both interesting and enlightening.

FREDERICTON

Lyle W. Smith, JR.E.I.C.,
Branch News Correspondent

AT A BRANCH MEETING on November 17, 1958 Mr. Cunningham of New Brunswick Telephone Company traced the development of transister tubes and their application in the telephone industry. He related some of the expected developments in the telephone industry and explained how they would be of service to the public. He also mentioned use of microwave networks and picture tube installations in telephone network.

SIR CLAUDE GIBB was the speaker at the meeting of October 28. Sir Claude is president of C. A. Parsons Co. Ltd., England, and his subject was "The Development of Nuclear and Orthodox Power Stations."

HAMILTON

W. A. H. Filer, JR.E.I.C., *Sec.-Treas.*
J. R. Currie, M.E.I.C.,
Branch News Reporter

AT THE NOVEMBER MEETING of the Hamilton Branch, on November 13, there was a panel discussion on the "Die Casting Process". The speakers were five representatives from four of the major Canadian producers of die castings. The panel chairman was N. J. Clark of Barber Die Casting Ltd. The other members were S. Bulmer, W. H. Weatherhead, and R. D. MacLean, all of the Die Caster's Section of the Automotive Parts Manufacturers Association. Mr. Clark gave a brief history of die casting in Canada, and the panel answered questions from the floor.

A technical session was held, followed by an informative film entitled "The Shortest Way".

The Hamilton Branch held its Annual Social Evening on November 28.

Members and guests were welcomed by Branch Chairman R. C. Mitchell, and L. C. Sentence introduced Dr. K. F. Tupper, president of the Institute. Dr. Tupper spoke briefly about activities of the E.I.C. in the international realm. He also gave a most interesting and informative talk about the recent trip to Russia made by Dr. Tupper and Dr. Page.

This event also marked the first official visit to Hamilton of Dr. Garnet Page in his new position as general secretary.

Earlier in the day Dr. Tupper and Dr. Page were taken on a tour of the nuclear research development at Mcmaster University by Dr. Hodgins and Dr. Thode, and on Friday afternoon the guests met with the Hamilton Branch Executive.

CORNER BROOK

E. R. Skanes, JR.E.I.C., *Sec.-Treas.*
H. A. Hinton, JR.E.I.C.,
Branch News Reporter

PROFESSOR D. L. MORDELL, dean of engineering, McGill University, spoke to the Corner Brook Branch, E.I.C. at their November 5 meeting. Subject of the address was space travel which, he said, is here now, insofar as it is technically possible within the limitations of our present knowledge. The recent American moon-rocket, although it went only about one-third the intended distance, was actually a very near miss. Many complicated problems remain to be overcome before manned space ships will be possible, but judging from the time taken for means of land, sea, and air travel to reach their present high state of development from the first steam carriage, a manned flight to the moon may be expected within ten years. Greatest need of this field, he said, is for men with better all-round education, not merely well-trained technicians. The problems that will be brought by the age of space travel now opening, will require independent creative thinking on the part of engineers, administrators, politicians, and men in many other fields.

KINGSTON

D. I. Ourom, JR.E.I.C.
Secretary and Branch News Reporter

MODERN INSTRUMENTATION in Control of Chemical Processes," was discussed by G. B. Hall, instrument engineer, Canadian Industries Limited, Montreal, at a meeting of November 4, 1958.

Mr. Hall outlined the uses and advantages of the various types of instruments available for the control of chemical processes. The discussion centred around the instrumentation required to control the operation of an ammonia plant. The limitations of materials were reviewed. and the desirability of duplicating key pieces of control equipment was discussed. The use and operation of the various pneumatic and electronic controller-recorders was described. The talk closed with a discussion of the application of automatic controls to processes.

MONTREAL

Dr. K. L. Pinder, JR.E.I.C.
Branch News Correspondent

THE NATIONAL FILM BOARD, Montreal, entertained members of the Montreal Branch on November 12.

The members were introduced to the functions and the background of the Film Board. The range of film types and the awards won by the Board were mentioned. The visitors (200 strong) were conducted through the different laboratories and recording studios.

NEWFOUNDLAND

R. L. Smyth, JR.E.I.C., *Sec.-Treas.*

Branch News Reporter

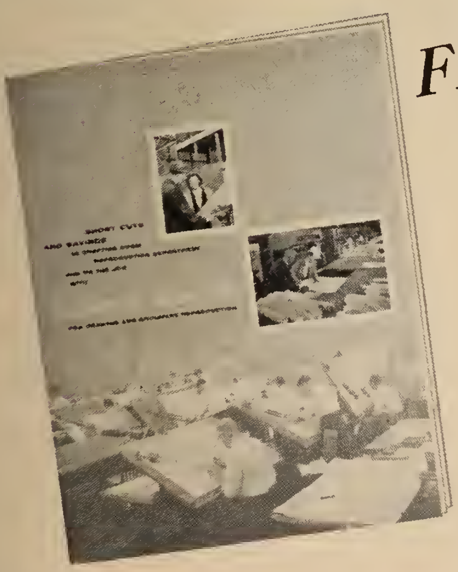
DEAN D. L. MORDELL, dean of engineering, McGill University, Montreal, was guest speaker before the Newfoundland Branch on November 2, 1958. In his talk, "An Engineer Looks at Space Travel". This lecture is reported elsewhere on this page.

SARNIA

R. F. Routledge, M.E.I.C., *Sec.-Treas.*
C. M. Stewart, JR.E.I.C.,
Publicity Chairman

PROFESSIONAL MANAGEMENT TODAY was the subject aired at a joint meeting with the Sarnia Branch of the Chemical Institute of Canada.

George E. Terris, vice-president of Payne Ross Ltd. of Montreal and Toronto, management consultants, was the speaker.



The meeting was under the chairmanship of J. H. Douglas. The speaker was introduced by M. Waghorne and thanked by N. Shipley.

TORONTO BRANCH

G. F. R. Norton, JR.E.I.C.
Branch News Reporter

D. S. Moyer, M.E.I.C., *Sec.-Treas.*

AN URBAN PLANNING CONSULTANT addressed the October 30 meeting of the Branch in a talk on "The Satellite City".

Mr. R. S. Dennison of Bromalea Consolidated Developments Ltd., dealt with the advent of the satellite city concept to fulfill human needs in areas of extensive urban development such as Metropolitan Toronto.

This was a joint meeting with the joint area committee. R. H. Self chaired the meeting. B. Hardcastle introduced the speaker and W. Sefton thanked the speaker.

Some guests at the Fifth Annual Engineers' Ball, Niagara Falls. 1958. In this group: D. A. Barnum, T. C. Keefer, A. W. F. McQueen. J. A. McLaren. C. T. Carson, B. H. Goodings, T. M. Medland, A.P.E.O., J. K. Picken, Mrs. Barnum, Mrs. Keefer, Mrs. McQueen, Mrs. Carson, Mrs. Picken, Mrs. Goodings.

At left, visit of F. S. Snow, C.B.E., past president of the Institution of Structural Engineers, London, to the Toronto Branch. From left to right: M. S. Yolles. W. P. Dumbleton. W. Sefton, J. L. Kellerman, T. Howarth, Mr. Snow, L. H. Fitzwilliam. A. Shuper. Professor A. Davidson, B. Hardcastle, and J. A. McLaren.

NOVA SCOTIA TECHNICAL COLLEGE

John Jay, S.E.I.C., *Correspondent*

PROF. MAX BAKER was a special guest at the regular monthly meeting of the executive of the Student Society. He was presented with a small gold penknife by John Jay, the student representative for the Engineering Institute of Canada. It was on the occasion of Prof. Baker's retirement as Faculty Advisor to the group and of Prof. Steeves' succession in this capacity.

PETERBOROUGH

G. M. Locke, JR.E.I.C., *Sec.-Treas.*

J. G. Hooper, M.E.I.C.,
Branch News Reporter

UNDERGROUND COAL MINING, its methods and problems were explained to members of the Peterborough Branch at a November 12 meeting, addressed by William H. Bowes. A stress analyst for the Civilian Atomic Power Department, Canadian General Electric Company, Peterborough, Mr. Bowes was concerned with an issue of current interest, "Men, coal and 'Bumps' at Springhill, N.S."

Mr. Bowes was introduced by John Pawliw and after a question and discussion period was thanked by C. W. Holman.

SAULT STE. MARIE

R. L. Wimperis, JR.E.I.C.,
Sec.-Treas. and Branch News Reporter

PROFESSIONAL RECOGNITION AND STATUS for engineers comparable with that enjoyed by other professions was discussed by Dr. K. F. Tupper, president, E.I.C., in an address to the Sault Ste. Marie Branch on November 11.

Introduced by W. Hogg, Dr. Tupper was thanked by L. F. Mason-Tulby.

While the members dined and listened to Dr. Tupper's address, the ladies dined separately with Mrs. Tupper, and later enjoyed card games. Following the president's address all joined in for the conclusion of the evening.

VANCOUVER ISLAND

J. A. Cowlin, JR.E.I.C., *Sec.-Treas.*

H. F. Coupe, M.E.I.C.,
Branch News Reporter

THE ANNUAL "LADIES NIGHT" was held at the Pacific Club, Victoria, on November 19. Cocktails and dinner followed by an address by Dr. G. C. Carl, director of the Provincial Museum, were enjoyed by members and their ladies.

Introduced by D. Watts, his subject "Island Explorations" covered field work carried out by the Museum staff on the west coast islands of British Columbia. The talk was illustrated with an excellent and very educational colour film entitled "The Sea".

VANCOUVER

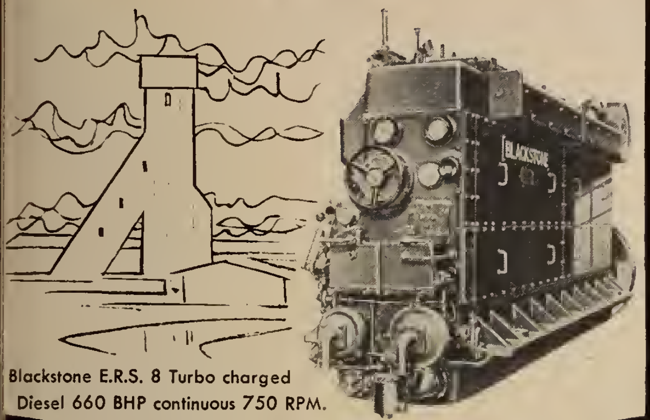
Branch News Reporter

Ronald Clough, M.E.I.C., *Secretary*

"SMALL BOATS" was the name given a lecture which introduced a variety of boats to assembled Branch members at a meeting held October 29. The authority was Vancouverite John Brandlmayr, consulting engineer, naval architect, and a senior partner of Spencer Boats Ltd.

On November 1 a field trip to "Spencer Boats Ltd." allowed numerous E.I.C. members to have a close look at the production of motorboats and sailboats designed by Mr. Brandlmayr.

On October 21 the Structural Section of the Vancouver Branch arranged a panel discussion on an always timely subject: "The Architect and the Structural Engineer-Relations of Scope of Work." The lively discussion between the panel members and the audience proved that while relations betwen the two professions are very satisfactory the ideas about the scope of work are not quite unanimous. The architects point of view was presented by Messrs. W. Leithead, P. Thornton and K. Gardner,—Messrs. B. Barrett, J. Read and A. C. Smith presented the structural engineer's case. Mr. W. E. Stone was the moderator.



Blackstone E.R.S. 8 Turbo charged Diesel 660 BHP continuous 750 RPM.

Calendar

American Inst. of Chemical Engineers

National meeting, Atlantic City, N.J., March 16-20, 1959.

National Association of Corrosion Engineers

15th annual conference, Chicago, March 16-20, 1959.

American Chemical Society

135th meeting, Boston, Mass., April 5-10, 1959.

American Inst. of Mining, Metallurgical, and Petroleum Engineers

National open hearth steel furnace, coke oven and raw materials conference, St. Louis, Mo., April 6-8, 1959.

International symposium on the physical chemistry of processed metallurgy, Pittsburgh, Pa., April 27-30, 1959.

American Society of Tool Engineers

27th annual meeting, Milwaukee, Wis., April 18-22, 1959.

National Research Council, Canada

Muskeg research conference 5th annual meeting, Winnipeg, Man., March 4, 1959.

Institute of Radio Engineers

National convention, New York, March 23-26, 1959.

Western joint computer conference (jointly with A.I.E.E.), San Francisco, March 2-6; Los Angeles, May 1959.

Joint conference on automatic techniques (jointly with A.I.E.E. and A.S.M.E.), Chicago, May 11-13, 1959.

American Society of Mechanical Engineers

Instruments and regulators division, Cleveland, Ohio, March 29 to April 2.

Gas turbine power conference and exhibit, Cincinnati, Ohio, March 8-11, 1959.

Aviation conference, Los Angeles, March 8-12.

Hydraulics conference, Ann Arbor, Mich., April 13-15, 1959.

Oil and gas power conference and exhibit, Houston, Texas April 19-23, 1959.

Management Engineering Conference (jointly with the Society for the Advancement of Management), New York, April 23-24, 1959.

Metals engineering conference, Albany, N.Y., April 29 to May 3, 1959.

Maintenance and plant engineering conference, Chicago, May 4-5, 1959.

Joint conference on automatic techniques (jointly with I.R.E. and A.I.E.E.), Chicago, May 11-13, 1959.

Design engineering conference, Philadelphia, May 25-28, 1959.

Semi-annual meeting, St. Louis, Mo., June 14-18, 1959.

Applied Mechanics Conference, Blacksburg, Va., June 18-20, 1959.

American Welding Society

Spring meeting and welding show, Chicago, Ill., April 6-10, 1959.

International Union for the Study of Electrothermics

Fourth international congress, Stresa, Italy, May 1959.

Building Research Institute

Eighth annual meeting, Pittsburgh, April 6-8, 1959.

The Society of Naval Architects and Marine Engineers

The society is receiving nominations for the four scholarships for graduate study which it has been offering each year.

The applications should be filed with the Secretary of the Society at 74 Trinity Place, New York, 6, before February 1, 1959.

Canadian Electrical Association

Eastern Zone Meetings, Quebec, Que. January 26-29, 1959.

R. C. E. M. E. Corps Association

The annual general meeting and annual dinner of the R.C.E.M.E. Corps Association was held at the R.C.E.M.E. School at Barriefield, Ontario, on Saturday, October 25, 1958.

Col. R. A. Campbell, OBE Director, Corps of Electrical and Mechanical Engineers, spoke to the meeting.

The following officers were elected as the 1958-1959 executive of the Association: president, Lt.-Col. E. D. Gray-Donald, M.E.I.C., Montreal; first vice-president, Major D. C. Ferguson, Toronto; Hon. Sec.-Treasurer, Lt.-Col. LeSueur Brodie, ED, Toronto. The immediate past president is Lt.-Col. J. K. Bradford, OBE, Toronto.

The annual dinner was attended by approximately 150 members including the following guests:—Gen. the Honourable A. G. L. McNaughton, P.C., C.H., C.B., C.M.G., Hon. M.E.I.C.; Brig. F. J. Fleury, C.B.E., E.D., Vice Q.M.G.; Major C. K. Johnston; Major W. Horan, C.D.; The Pay Corps Association; The Royal Canadian Engineers Association.

The guest speaker was I. N. MacKay, manager of engineering, Civilian Atomic Power Department, Canadian General Electric Company, Peterborough.

At the annual meeting of the R.C.E.M.E. Corps Association: left to right, Lt. Col. J. K. Bradford, past president, I. N. MacKay, guest speaker, Lt. Col. E. D. Gray-Donald, president, Gen. The Hon. A. G. L. McNaughton, and Lt. Col. A. G. Edward.

LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*HEAT EXCHANGERS: APPLICATIONS TO GAS TURBINES

Emphasizes design of heat transfer units in connection with gas turbines, so as to obtain an economical unit for various applications. The design of recuperative heat exchangers, regenerators, and air preheaters is presented along with related aspects as test arrangements, stresses and materials, cost, and the question of weight in aircraft units. (W. Hryniszak. Toronto, Butterworth, 1958. 343p., $10.00.)

*THE IMPACT OF HIGH TEMPERATURE TECHNOLOGY

Studies the present status of high temperature technology, and attempts to indicate possible future developments. Areas covered are nuclear power, propulsion, component equipment, aircraft and missiles, electronics, temperature measurements, high temperature process developments, and materials. A report written by graduate students under the guidance of the Harvard Business School Faculty. (V. P. Kovicik and others. Cleveland Heights, High Temperature Associates, 1958. 272p., paper $8.00.)

*BUILDINGS FOR RESEARCH

Discusses the requirements of good laboratory design and provides information on such factors as safety measures, waste removal, corrosion prevention, vents and chains, and modular units. This is followed by descriptions of research buildings in the fields of nucleonics, biology, electronics, and chemistry. A special section deals with atomic processes and equipment as they affect the design of the laboratory. A collection of articles published in Architectural Record since 1950. (New York, Dodge, 1958. 224p., $9.50.)

*ELECTRIC MACHINERY

A coordinated presentation covering transformers as well as both direct and alternating machines. Topics covered are types of windings, voltage relations, magnetic-field relations, energy losses, energy flow, efficiency, ratings, and basic torque relations. These principles are then applied to a detailed analysis of the performance of different types of machines. (C. C. Carr. New York, Wiley, 1958. 537p., $9.25.)

*BIOLOGICAL TREATMENT OF SEWAGE AND INDUSTRIAL WASTES VOL. II: ANAEROBIC DIGESTION AND SOLIDS-LIQUID SEPARATION

Papers dealing with current practices in the field of waste treatment. Part one is concerned with anaerobic digestion while part two discusses the separation of solids from waste water by sedimentation and flotation. Part three discusses elutriation, chemical conditioning, and vacuum filtration. The volume is made up of papers presented at the Conference on Anaerobic Digestion and Solids Handling, New York 1957. (Ed. by J. McCabe and W. W. Eckenfelder, Jr. New York, Reinhold, 1958. 330p., $11.50.)

*A HISTORY OF TECHNOLOGY VOL. IV: THE INDUSTRIAL REVOLUTION

A detailed account of the rise of modern industrialism. Six aspects are discussed: primary production; forms of energy; manufacture; static engineering; communications; scientific basis of technology. The volume is superbly printed and illustrated. (Ed. by Charles Singer and others. Toronto, Oxford University Press, 1958. 728p., $25.00.)

ELEMENTARY STATISTICAL PHYSICS

A fundamental treatment of statistical mechanics, intended for physics students, and also including stochastic processes and transport theory. The Gibbs method of ensembles is used, and the various applications of statistical physics covered are kinetic methods, the principles of detailed balance, the Boltzmann transport equation, thermal noise, and thermodynamics of irreversible processes and fluctuations. Negative temperature, magnetic energy, density matrix methods and the Kramers-Kronig causality relations are also included. Problems and worked examples are used to illustrate the text. (C. Kittel. New York, Wiley, 1958. 228p., $8.00.)

THEORY OF ELECTRICAL MACHINES

A text for final year electrical engineering students, treating the subject in a fairly general manner. The topics covered include electromotive force, windings, effects of load current in armature windings, transformers, synchronous machines, induction machines, a.c. commutator machines and d.c. machines. Purely design problems have not been discussed, but design fundamentals are covered in an appendix. (W. S. Wood. Toronto, Butterworth, 1958. 317p., $10.00.)

STORIES OF MEN AND MACHINES

A beautifully produced picture story of Czech industry published for the 1958 Brussels Exhibition. The photographs are excellent, and the accompanying text contains some charming anecdotes in English, by Ludvik Askenazy and other authors. (Prague, SNTL, 1958.)

*THE PRINCIPLES AND PRACTICE OF SURVEYING, VOLUME 1: ELEMENTARY SURVEYING, 9TH ED.

Various revisions have been made throughout this new edition including sources of maps and surveying information; European-type transits and levels; stadia theory; astronomical data and illustrative problems; circular curves; mine surveying; aerial surveying and photogrammetry. (C. B. Breed and G. L. Hosmer. New York, Wiley, 1958. 717p., $6.50.)

ENGINEERING SYSTEMS ANALYSIS

Intended as a text for undergraduates, the purpose of this volume is to show

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m.—5 p.m.; Saturday: 9 a.m.—12 noon.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

that methods and techniques of analysis used in one branch of engineering may actually be generalized methods which can be used to solve problems in any field of engineering.

The author commences with a definition and interpretation of engineering analogies. Other chapters cover mechanical vibrations; oscillations in electrical networks; dynamical systems and their characteristics; methods of solution for analogous systems and mixed systems; dimensional analysis and applications; principles of feedback and control; analog and digital computing machines.

Problems and references for further reading are also included. (R. L. Sutherland. Reading, Addison-Wesley, 1958. 223p., $7.50.)

*CREATIVENESS FOR ENGINEERS

Consists of two parts, the first of which discusses a philosophy to stimulate creativeness and to motivate the potentially creative person. The second part deals with a creative approach aimed at producing more effective reaction between the individual and his effort. Appendices provide means for practical application of these principles. A second edition of this book is now available. (D. S. Pearson. University Park, Pa., Pennsylvania State University, The Author, 1958. 122p., $3.75.)

SCIENCE STUDENTS' GUIDE TO THE GERMAN LANGUAGE

A grammar book for the use of science students studying German, based on the author's own teaching methods. Particular attention has been paid to special difficulties such as sentence structure and the participial phrase. The examples in the grammar and the passages for reading are taken from scientific writings, mainly in the fields of chemistry and physics, although passages from other fields are included. In addition to the basic grammar, the book contains many pointers useful for those learning to read German scientific texts. (A. F. Cunningham. Toronto, Oxford University Press, 1958. 186p., $2.00.)

THE PRINCIPLES OF SCIENCE

William Stanley Jevons played an important role in the development of modern symbolic logic. He pioneered in the construction of calculating machines, actually building a workable machine for the solving of logical problems; he used statistical data for studying economic trends; and initiated a new period in English economic theory with his contributions to the mathematical theory of economic utility, all this before his death in 1882. This is a reprint of the second edition of his book, his chief work on logic, and is a classic of logic and the scientific method. His logic is a simplification and correction of that of Boole. (W. S. Jevons. N.Y., Dover, 1958, 786p., $2.98.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Atomic energy

Britain uses atoms, London, Central Office of Information, 1958.

Selected readings on atomic energy. Washington, U.S. Atomic Energy Commission, 1958. 25 cents.

Canada. Minerals

Canada; map of principal mineral areas. Canada, Dept. of Mines and Technical Surveys, 1958. (Mines resources division and geological survey of Canada). 25 cents.

Iron ore and other raw-material sources for a primary iron and steel industry in Western Canada, by T. H. Janes. Canada, Dept. of Mines and Technical Surveys, Mineral resources division, 1958. (Mineral information bulletin MR 28). 25 cents.

Milling plants in Canada; metallic ores. Canada, Dept. of Mines and Technical Surveys, Mineral Resources Division, 1958.

City planning

Human considerations in urban development. Ottawa, Central Mortgage and Housing, 1958.

MEET THE AUTHORS

J. A. Thomas, M.E.I.C., Chief Engineer, civil division, The Shawinigan Engineering Company Limited, Montreal. *(Engineering Features of the Beechwood Development).*

Mr. Thomas graduated with a B.A. and a B.Sc. degree in 1936 and 1942 respectively, from Queen's University, Kingston, Ont.

He joined the Shawinigan Engineering Company in 1948 as hydraulic engineer, having had previous experience in the design of hydro-electric projects. In 1956 he was appointed chief engineer, civil division.

He is a member of the American Society of Mechanical Engineers, the Canadian Standards Association and the International Electro-Technical Commission.

R. E. Grout, M.E.I.C., Chief Engineer, electrical division, The Shawinigan Engineering Company Limited, Montreal. *(Engineering Features of the Beechwood Development).*

Mr. Grout received his engineering education at the University of Alberta (B.Sc., electrical, 1936).

He joined the Shawinigan Engineering Company in 1937 and has been engaged on the design of large hydro-electric generating stations and major transformer and switching stations. He was appointed chief engineer, electrical division in 1956.

He is a member of the American Institute of Electrical Engineers, and the Canadian Electrical Association.

W. S. McIlquham, M.E.I.C., Hydraulic Engineer, Dominion Engineering Works Limited, Lachine, Que. *(Beechwood Kaplan Turbines—Hydraulic and Mechanical Features).*

Mr. McIlquham holds an engineering degree from Queen's University (B.Sc., civil, 1923). After eighteen months of experience with the Bell Telephone Company of Canada, he joined Dominion Engineering Works Ltd., as hydraulics and design engineer. From 1942 to 1946 he served the Canadian army R.C.O.C. and R.C.E.M.E., and retired as a major.

Upon his release from the army he returned to the hydraulic department of Dominion Engineering Works.

L. M. Boyd, M.E.I.C., Chief Engineer, hydraulic division, Dominion Engineering Works Limited, Lachine, Que. *(Beechwood Kaplan Turbines—Hydraulic and Mechanical Features).*

Mr. Boyd graduated from Queen's University with a B.Sc. degree in mechanical engineering in 1934, and immediately joined the hydraulic division of Dominion Engineering Works Ltd., as design engineer. In 1940 he was transferred to the Longueuil division of the company as production engineer, responsible for the naval gun-mount production. In 1945 he returned to the head-office to organize a company-wide program of standardization. He was transferred back to the hydraulic division in 1947 as mechanical and production engineer. In 1952 he was appointed to his present position.

K. D. Sheldrick, Sales Manager, district operations, Bailey Meter Co. Ltd., Montreal. *(Methods and Trends in Automatic Combustion Control).*

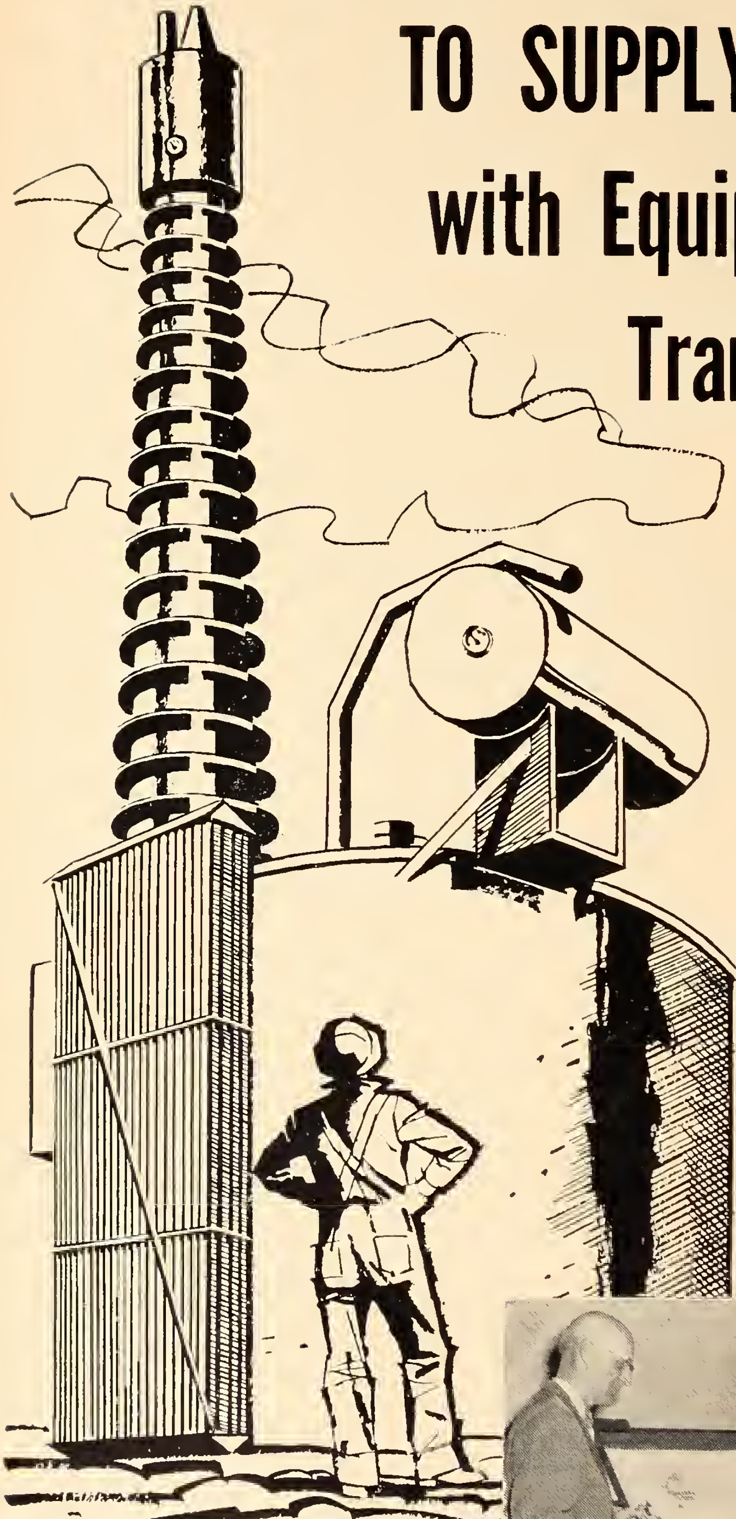
Mr. Sheldrick graduated in arts from the University of New Brunswick in 1927. After two years with the Nashwaak Pulp and Paper Co. Ltd., he attended an industrial course in instrumentation and combustion engineering for a one year period. From 1930 to 1941 he was engaged in sales and service engineering with the Bailey Meter Co. Ltd. in eastern Canada. In 1942 he joined the Canadian Army R.C.E.M.E., retiring with the rank of lieutenant colonel, commanding officer of the 3rd Technical Regiment, R.C.E.-M.E. (Militia) in 1946. He returned to the Bailey Meter Co., and held the post of manager for the firm's Montreal district office from 1947 to 1957. In 1958 he was promoted to his present position. He is a member of the Council of the R.C.E.M.E. Corps Association and chairman of the Corps History Committee.

J. R. Houghton, M.E.I.C., Assistant Works Manager, communications equipment division, Northern Electric Company Limited, Montreal. *(The Role of the Technical Assistant in Industry).*

Mr. Houghton is an engineering graduate from McGill University (B.Eng., mechanical, 1937). Upon graduation he joined Northern Electric Co. Ltd. as a telephone engineer. He subsequently occupied various supervisory positions leading to his appointment in 1951 as superintendent of manufacturing engineering in the communications equipment division. He was named engineer of manufacture in 1956. He is on the Board of Examiners of the C.P.E.Q., and chairman of the Professional Technicians' Committee of the C.P.E.Q. He is also a member of the Canadian Standards Association and the Institute of Administration.

We are indebted to the following for their contributions to the article *Fifty Years in Aeronautical Engineering:* H. C. Luttman, Secretary, Canadian Aeronautical Institute; R. D. Richmond, M.E.I.C., Chief Engineer, Special Weapons, Canadair Limited; F. R. Thurston, Acting Director, National Aeronautical Establishment; F. H. Keast, Chief Engineer, Orenda Engines Ltd.; Air Vice Marshal M. M. Hendrick, Chairman, Canadian Joint Staff, Washington; R. B. McIntyre, Assistant Engineering Director, De Havilland Aircraft of Canada Ltd.; W. H. Riggs, Vice-President, Manufacturing, Avro Aircraft Ltd.

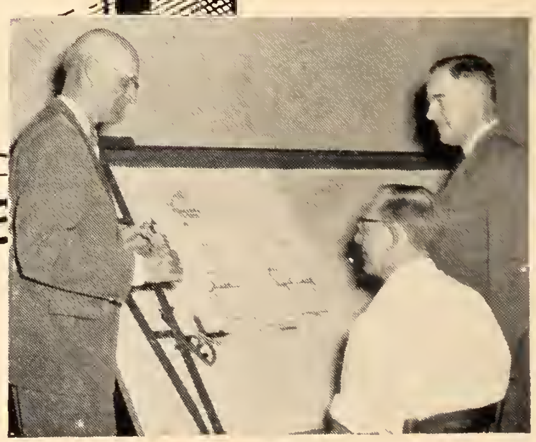
CANADIAN GENERAL ELECTRIC TO SUPPLY ONTARIO HYDRO with Equipment for E.H.V. Transmission Tests



Extra High Voltage power transmission over long distance is relatively new and possesses many unknown facets. To investigate fully its possibilities and thus provide economical transmission of power from remote generating stations, Ontario Hydro has initiated EHV Project Coldwater. The Coldwater Ontario Research Station, now in the planning stage, will uncover such characteristics of EHV transmission as corona losses, radio and TV interference and the best choice in the bundling, spacing and size of conductors.

Canadian General Electric has been awarded the contract to supply the transformers and bushings for this project. This contribution to an important research project is further conclusive evidence of the success of C.G.E.'s development-in-depth policy . . . a policy of continuous extensive research to help Canada's economy expand and Canadian technology progress.

Power Transformer Sales, Guelph, Ont.



Canadian General Electric designers confer on the preliminary outline of the new G-E transformers for Coldwater. The three single phase, 1667 KVA transformers will provide voltages in 2.5 KV steps from 205 to 605 KV, phase to phase. Relatively small, the tanks will be only 10 feet in height but the bushings will be 23 feet high and extend 18 feet above the tank cover.

FIFTY YEARS

OF

AERONAUTICAL ENGINEERING

A REVIEW OF CANADIAN PROGRESS

INTRODUCTION

by H. C. Luttman, Secretary, Canadian Aeronautical Institute

On the 23rd February 1909 the *Silver Dart* (Fig. 1), piloted by J. A. D. McCurdy, took off from the ice of Baddeck Bay in Nova Scotia and made a short and successful flight. The *Silver Dart* was built by the Aerial Experiment Association which was headed by Dr. Alexander Graham Bell; the other members of the Association were Glenn H. Curtiss,

• • •

This review has been written for *The Engineering Journal* by leaders in Canadian aeronautical engineering to mark the fiftieth anniversary of powered flight in Canada. Progress is recorded in the fields of: aerodynamics; structures and materials; propulsion; aviation electronics; ancillary services; and fabrication techniques.

Fig. 1 Above: The Silver Dart

an American engine expert, Lt. T. E. Selfridge, a U.S. Army expert on "aerodromics", and the two young Canadian engineers, J. A. D. McCurdy and F. W. (Casey) Baldwin.

The history of "first flights" is confused, partly because in the early days the definition of a "flight" was not clearly established—for example, a flight might not be recognized if it ended in a crash landing — and partly because everybody seems to have done their flying away from home. The first flight in England is credited to Col. S. F. Cody, who was an American citizen at the time; the first Englishman to fly was Henry Farman, who flew in France and whom everybody thought to be a Frenchman; and the first flight by a Canadian was made by Casey Baldwin at Hammondsport, N.Y. on the 12th March 1908. Despite the confusion, there is little doubt that the flight of J. A. D. McCurdy on the 23rd February 1909 at Baddeck was not only the first powered flight by a heavier-than-air machine in Canada but the first such flight made by a British subject in the British Empire.

The fiftieth anniversary of this historic event is being observed this year and it is interesting to look back at the progress in aeronautical engineering which has taken place in the meantime. From the *Silver Dart*, with a span of 49 ft., a gross take-off weight of some 750 lb., and an engine giving an intermittent 35 h.p., we have progressed to such aircraft as those appearing in Figs. 2, 3, and 4. Figure 2 shows the Canadair *Argus* maritime-reconnaissance aircraft, the largest aircraft ever built in this country, with a gross take-off weight of the order of 150,000 lb. Figure 3 shows the Avro *Arrow* fighter, capable of exceeding Mach 2—twice the speed of sound; the *Arrow* is powered by two Orenda *Iroquois* turbo-jet engines, each giving more than 20,000 lb. static thrust. Figure 4 shows the De Havilland *Caribou*, a fairly large utility transport with STOL (short take-off and landing) characteristics. All these Canadian designed and built aircraft are outstanding in their respective classes. Furthermore Canada has established a complete and almost self-sufficient industry to design and build the full range of aeronautical components and equipment.

Work has also been done in the new field of rockets and guided missiles but, with her relatively small resources of manpower, this country has made no effort to compete with others in this respect. If Canadian engineering achievements with manned vehicles offer any indication, no doubt the situation will be very different at the end of the next fifty years.

Aeronautical engineering is primarily mechanical engineering but it embraces almost every branch of engineering and touches almost every science. The sections that follow cover perhaps the major divisions of the subject. Each has been written by a specialist, who has endeavoured to cram fifty years of eventful and exciting development into the space allotted to him; he was indeed asked to get a quart into a pint pot.

AERODYNAMICS

by R. D. Richmond, Chief Engineer, Special Weapons, Canadair Limited

Reviewing the first fifty years of power flight in Canada from the time of the *Silver Dart* to the present, reveals the magnitude of the development that has taken place in the aeronautical sciences and their application. This growth is nowhere more evident than in the field of aerodynamics where research in theory and in the laboratory has made possible the rapid advances in performance and control of aircraft and missiles.

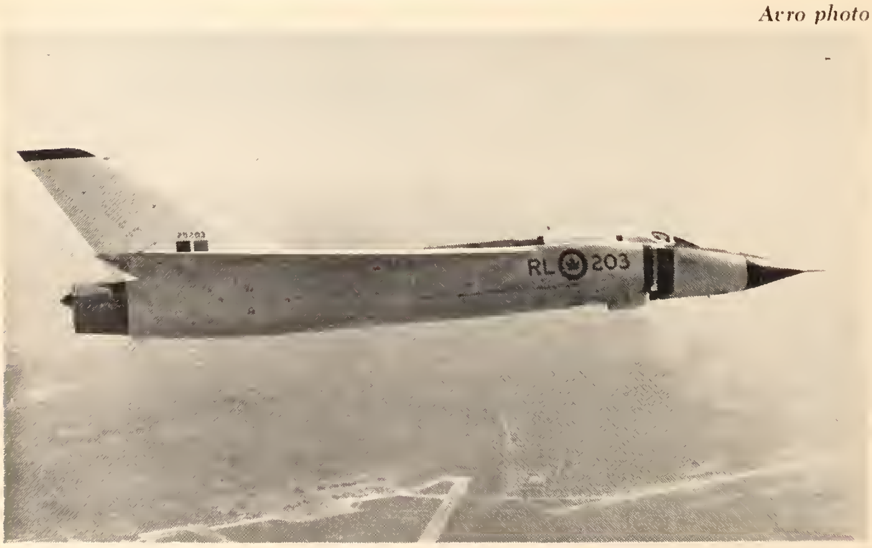
The earliest known Canadian research in aerodynamics, or in aeronautics, was undertaken by W. R. Turnbull. In 1902, seven years before the flight of the *Silver Dart*, he constructed Canada's first wind tunnel at Rothesay, N.B. (Fig. 5), and conducted tests on low-aspect ratio wings which he called "aeroplanes". Later from 1908 to 1911 Turnbull published three papers presenting his findings from theory and experiment on "aerial propellers". This work led to his investigation of the controllable pitch propeller on which he obtained several patents. These patents were subsequently licensed to the Curtiss Aeroplane & Motor Company, later to become the Curtiss Wright Corporation, who used them to develop the Curtiss Electric propeller, which is still currently in wide use.

In 1907 the "Aerial Experiment Association" was formed at Baddeck, N.S. for the purpose of conducting experiments in powered flight. The senior partner, Alexander Graham Bell, had become interested in this aspect of aeronautics through his experiments with kites. His work had attracted two young engineering graduates of the University of Toronto, Frederick W. Casey Baldwin, and J. A. D. McCurdy, and two Americans whose names became well-known in aviation, Glenn Curtiss and Lt. T. E. Selfridge of the U.S. army. The Association built a number of aircraft, the *Redwing* first flown by Baldwin, the *Whitewing* the first aircraft in the world to use hinged controllable wing flaps (ailerons), the *Junebug*, the *Cygnet II*, and the *Silver Dart*. Of these the *Silver Dart* piloted by McCurdy was the first airplane to be flown in Canada.

All the activity of this period, however, was not centred in the East. By 1907 the Underwood Brothers of Krugerville, Alberta, were conducting experiments and actually

Fig. 3 The Avro Arrow fighter aircraft

Avro photo



built an aircraft which had the appearance of a flying saucer; it never flew due to the lack of a suitable engine. Also, in 1910 Wm. Gibson near Victoria, B.C. built and successfully flew his *Twin-Plane* a configuration that consisted of two main planes in tandem.

From these early activities interest in aerodynamics as a science developed. Although several universities now have courses in aerodynamics, the University of Toronto, through the initiative of J. H. Parkin, was the first to offer one in their curriculum and to provide supporting experimental facilities. In 1917 he had established an aerodynamic research laboratory and constructed a wind tunnel having a working section of 4 ft. x 4 ft. with a velocity of 37 miles per hour. This was replaced in 1923 by a more efficient one having a velocity of 60 miles per hour which was used for many years in the instruction of students.

In 1949 this University formed the Institute of Aerophysics to train students and conduct research in the basic physics of gases, applied aerodynamics and ballistics in the field of supersonic flight. A supersonic wind tunnel having a working section of 16 ft. x 16 ft. for tests up to a Mach number of 3 was constructed for this purpose.

In 1929 the National Research Council built a wind tunnel in Ottawa with a 9 ft. diameter open working section giving a velocity of 230 ft. per second. This tunnel was the main aerodynamic facility available to government and industry until 1942. In that year a 6 ft. x 10 ft. closed working section tunnel having a velocity of 350 ft. per second was added and subsequently replaced the 9 ft. tunnel. It is now under the jurisdiction of the National Aeronautical Establishment and forms part of an aerodynamic facility that presently includes a spinning tunnel, a 10 in. x 10 in., a 16 in. x 30 in. supersonic tunnel (Fig. 6), and has projected a 5 ft. trisonic tunnel with operating Mach numbers from 0 to 4.5.

In 1951 the Canadian Armament Research and Development Establishment, a laboratory of the Defence Research Board, built an aeroballistic range capable of firing free flight models of missiles and aircraft up to a Mach number of 5.0. A smaller range capable of Mach 15 has since been added and others of different characteristics are planned. This facility, of great assistance in studying dynamic parameters, is not only unique in Canada but is one of few in the world.

De Havilland photo

Fig. 4 The De Havilland Caribou transport aircraft

The facilities are of course only the tools which have been used to develop aerodynamic knowledge. The application of this knowledge is manifest in the aircraft which have been designed or developed in this country.

The maximum speed versus time for some Canadian built aircraft is shown in Fig. 7. Although it is but one criterion, it is a good index of aerodynamic progress. The decrease in aerodynamic drag and the increase in wing loading which was made possible by the development of airfoils and lift increasing devices together made the largest contribution to this evolution.

This general summary narrates to some degree the Canadian development in the field of aerodynamics. It is not a static science, and to forecast the development for 50 years would be at least as difficult now as it was in 1909.

STRUCTURES AND MATERIALS

by F. R. Thurston, Acting Director, National Aeronautical Establishment

AT THE END OF the first 50 years of Canadian aviation, it has become a cliché to assert that these years have witnessed the greatest rate of scientific progress in human history and that a substantial part of this progress has been made in the aeronautical sciences of which Structures and Materials is a conventional subdivision. It is instructive, therefore, to remember that theoretical tools were available to the Aerial Experiment Association at the turn of the century for the solution of the structural problems that faced them and those who came after them. The natural philosophers of the 18th and 19th centuries had left behind momentous works on static structural stability, strength of materials, theory of vibration and theory of elasticity. These works, indeed, are to this day source references, and sometimes more, for the thousands of papers produced annually. In fact, the wealth of scientific theory that was available in 1909 has served as a placer mine for structures and materials research and development for 50 years and it is only in the last decade or so that new concepts and understandings have appeared, and these relate more to materials than to structures.

The essential theme of structures philosophy has always been and will continue to be the creation of structures of minimum weight and it is debatable whether the structures or the materials engineer has contributed more creatively to this enterprise. The structures analyst has tended to define his objective as the precise calculation of stresses in preconceived structures under known conditions of applied loading, environment, and constraint, and has added some sophistication by developing theoretical procedures for optimizing generic forms of design to provide minimum structure weight. In this, he has rather overlooked the more fundamental approach to his problem which lies in the determination of the least weight structure that will equilibrate a given system of applied loads.

The materials engineer has met, and partially solved, quite different problems. At the time the *Silver Dart* was built, the Hall process of producing aluminum metal had been known for 20 years, and duralumin alloy was available by the time of World War I. Since this time, several aluminum alloys susceptible to heat treatment have been developed and the course of structural developments has been most critically dependent on these materials. Many generations of aircraft have relied almost completely on the tensile aluminum alloys for primary structure and it is only recently in the more advanced-performance aircraft that parallel developments in high tensile and stainless steel and magnesium and titanium alloys are contributing to the solution of minimum weight or kinetic heating problems.

The theory of structural analysis has kept reasonable pace with the need for more refined analyses of aircraft structures. Up to about 1940 it was customary to analyze by what has come to be called Engineer's Theory. The essence of this process was to disregard the fact that the aircraft was a continuous three-dimensional elastic body and to make the necessary arbitrary assumptions to permit the analysis of the components separately by elementary shear, bending moment, and torsion equations. To this was added the development of methods based on the minimal principles and the principle of virtual displacements and these provided the analyst with powerful tools for the solution of statically indeterminate and structural stability problems. With the advent of electronic digital computers it has become possible to solve very large matrices very rapidly, and as a result it has become preferable to formulate two-dimensional problems in a tractable and more rational form and to solve them by numerical manipulation.

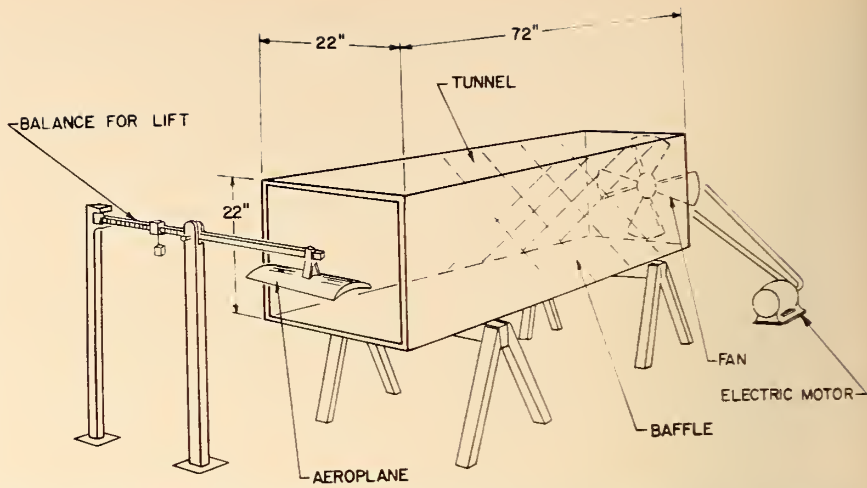


Fig. 5 Turnbull's wind tunnel 1902. Tunnel air speed: 10 mph (based on information from Turnbull's report "Researches on the Forms and Stability of Aeroplanes". Phys. Rev. Vol. XXIV March 1907).

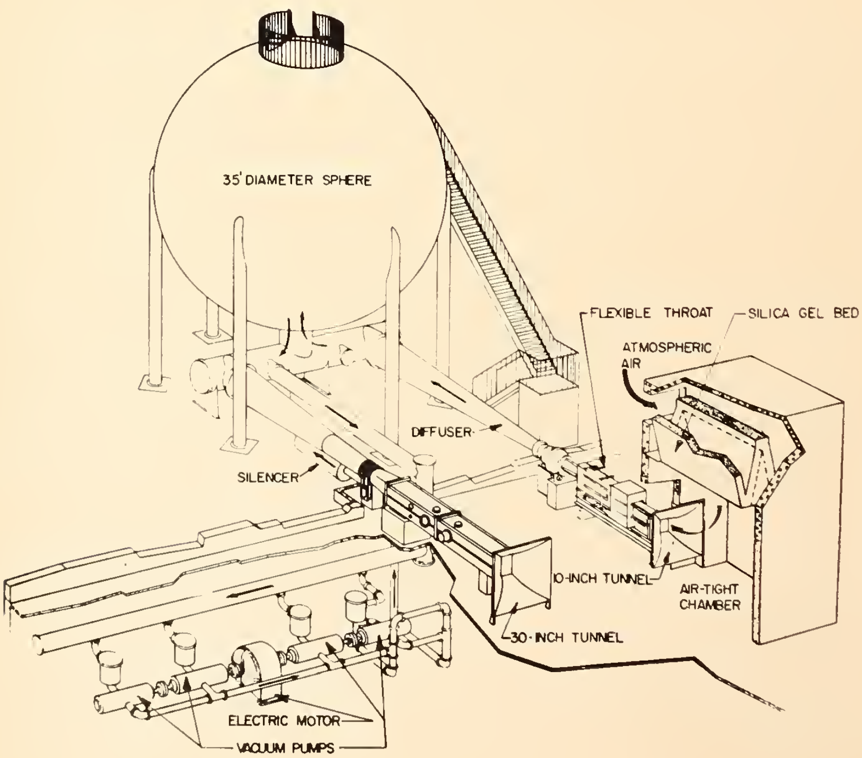
While these theoretical advances have done much to sustain the analytic art, some very great changes have taken place in the complementary field of structure testing. Both the precision and complexity of modern structure tests stem largely from developments in the instrumentation field which have led to a truly astonishing variety of transducers. These transducers are used both in flight testing to attest the accuracy of the applied loading and in the static structural testing in the laboratory to check the static strength and the validity of the assumptions of the analytic theory. Here again, however, the most extravagant process of load and structure verification is primarily a proof of the strength of the structure and does little to establish minimum weight design.

Fig. 6 High speed tunnels at the National Aeronautical Establishment. Tunnel capability: Mach 4 (NAE Rep.; "Symposium on High Speed Aerodynamics," Fig. 1, p. 68.



In recent years there has been a change in the importance of criteria from the concepts of structure static strength to criteria of aeroelastic stability and fatigue strength, and the change has involved a dependence on theoretical flutter prediction and flight flutter testing and expensive empirical studies of the fatigue resistance of structural components. These additional design considerations have added to the difficulty of designing for maximum structural efficiency.

The future of aircraft structure design is beset with new problems which are additive to those still unsolved. The kinetic heating problem is as challenging to the materials engineer as it is to the structural designer or analyst and, although some experience has been gained in the effects of programmed loading, the superimposition of programmed heating introduces a complexity which will need great efforts to resolve. Perhaps the greatest rewards are to be found in the study of high temperature resistant non-metallic or cermet type materials and in the application of high speed digital computers to structural analysis and weight control.

PROPULSION

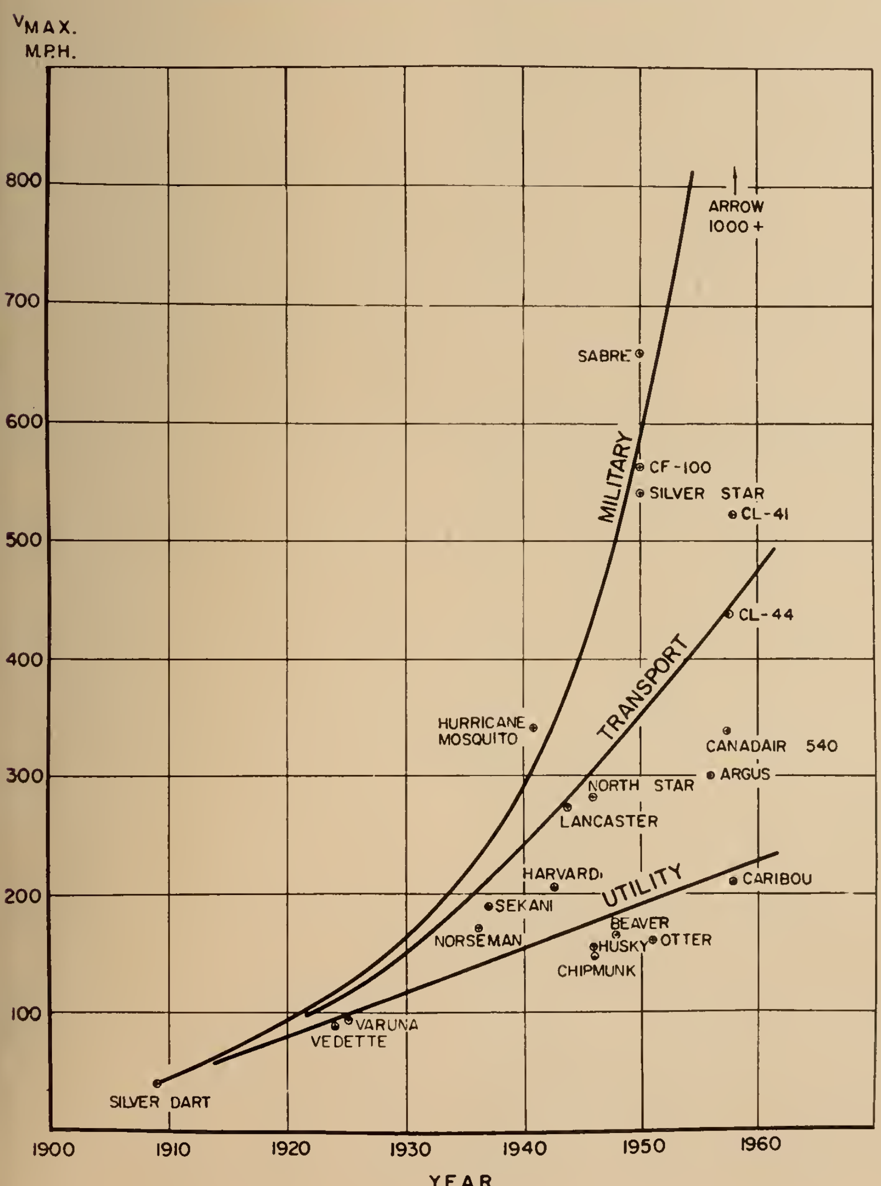
by F. H. Keast, Chief Engineer, Orenda Engines Ltd.

SOME WORDS WOULD BE appropriate with respect to the importance of aircraft propulsion in the affairs of the country. In all the branches of engineering there is probably none that approaches the aeronautical field in the necessity for the engineer to work so close to the bone. As weight is all-important there is no room here for large safety factors to cover ignorance. At the same time reliability is literally a life or death matter and the inspection methods applied must be of the highest quality. This means that knowledge must be precise on the part of the engineer with the minimum of "fluff factors" to cover ignorance. In fact, the aircraft industry, more than any other, can be taken as an index of the technological progress of a nation. At the bottom of the scale we have nations that consist of hewers of wood and drawers of water, and at the top end of the scale we have the precision engineering required of a country capable of designing aircraft.

How has Canada fared during the past fifty years?

In the early days of Canadian aviation, the name of W. R. Turnbull stands out and it was he who first imported, in 1906, an aircraft engine into Canada. This was a two cylinder "Duryea" engine (Fig. 8). This was actually for the purpose of driving airscrews to propel a hydroplane boat. The second step of providing the vehicle with wings was never achieved. The engine managed to destroy the propellers. This engine is now at N.R.C., Ottawa. It should also be mentioned that Turnbull did a good deal of important pioneer work on propellers and in fact invented the variable-pitch propeller. Another imported engine was the Curtiss engine (Fig. 9) of the *Silver Dart*, that made the first powered flight in Canada in February 1909. However, in the space available it is necessary to confine ourselves to engines designed and built in this country.

Fig. 7 Increase in maximum speed of Canadian built aircraft



We will skip quickly over the activities of the Underwood brothers, who drove model aircraft with elastic bands and weights on a drum which rotated the propellers, and also the initial efforts of W. W. Gibson, who in 1903 to 1904 used a window-blind spring in order to drive the propeller for his models. But Gibson, having bought a goldmine for $100 plus some chattels, managed to dispose of the mine for $10,000. This gave him the opportunity of continuing with an aero-engine of his own design which he had started a year or so earlier. In 1908, the 4-cylinder, 6-inch stroke engine was running, but was found to be of little use because of the high vibration. Even so, the completion of this engine was quite an achievement, since it was almost entirely handmade, a fact which was possible because of Gibson's earlier training as a blacksmith. His next engine was a 6-cylinder air-cooled motor and was arranged to drive two propellers, one in front of and the other behind the engine, in order to overcome torque reaction. Both propellers were 6 ft. in diameter and two-bladed. The front one rotated at engine speed and the rear one was geared to rotate at twice the engine speed in the opposite direction. It was completed in 1910 and ran extremely smoothly, developing 60 h.p. with a weight of 210 lb. The engine was installed in Gibson's *Twin-Plane* and had gravity feed from two fuel tanks, one on either side of the engine and well above. The aircraft made a short but successful flight on 8 September, 1910. Sixteen days later, it made a flight of 200 ft. which unfortunately ended in disaster, the machine suffering serious damage. The same engine was used for the Gibson *Multi-Plane,* which flew about a mile before landing on rough ground and suffering damage which forced Gibson to retire from aeronautics.

Canada was not involved significantly in the design and manufacture of aero-engines until 1943, when it was decided to look into the jet engine business and a Government technical mission was sent to the United Kingdom. In 1944, the National Research Council set up a cold weather test station at Winnipeg to test British jet engines. In the same year a Crown Company, Turbo Research, was formed and it was here that preliminary studies were made which led to the concept of the TR 4 (*Chinook*). The *Chinook* was an engine designed and built by the Gas Turbine Division of A. V. Roe Canada Limited which was formed in 1946 and later became known as Orenda Engines Ltd. It had a 9-stage axial compressor and single stage turbine with a specification thrust of 2690 lb. However the requirement for the engine changed before the engine was built. The TR 5 (*Orenda*) was ordered to give a thrust of 5500 lb. and the possibility of uprating to 6500 lb. At this time, great doubts existed in official circles of the ability of Canadians to produce such an engine. The competitors, in the U.K., were the Rolls-Royce *Avon* with 6500 lb. and the Armstrong Siddeley *Sapphire* with a similar rating. It was decided to proceed with the manufacture of the first three *Chinooks,* which really amounted to two engines plus one set of spares, in order to give the Canadian team an opportunity of testing an engine earlier than they could have if the *Chinook* order had been cancelled.

The *Chinook* design was really conservative; it had to be in order to provide an engine which would run and meet the specification, since the whole future of the Canadian aircraft industry hung on its fate. As a result of this, the *Chinook* produced a thrust of over 3000 lb., as against the 2690 lb. specification, and gave a promise of thrusts up to 3400 lb. As affairs in Canada seemed to work from one fiscal year to another, it was fortunate that the *Chinook* made its first run on 17 March, 1948. This ensured, for at least one year, the continuation of the engine industry in Canada.

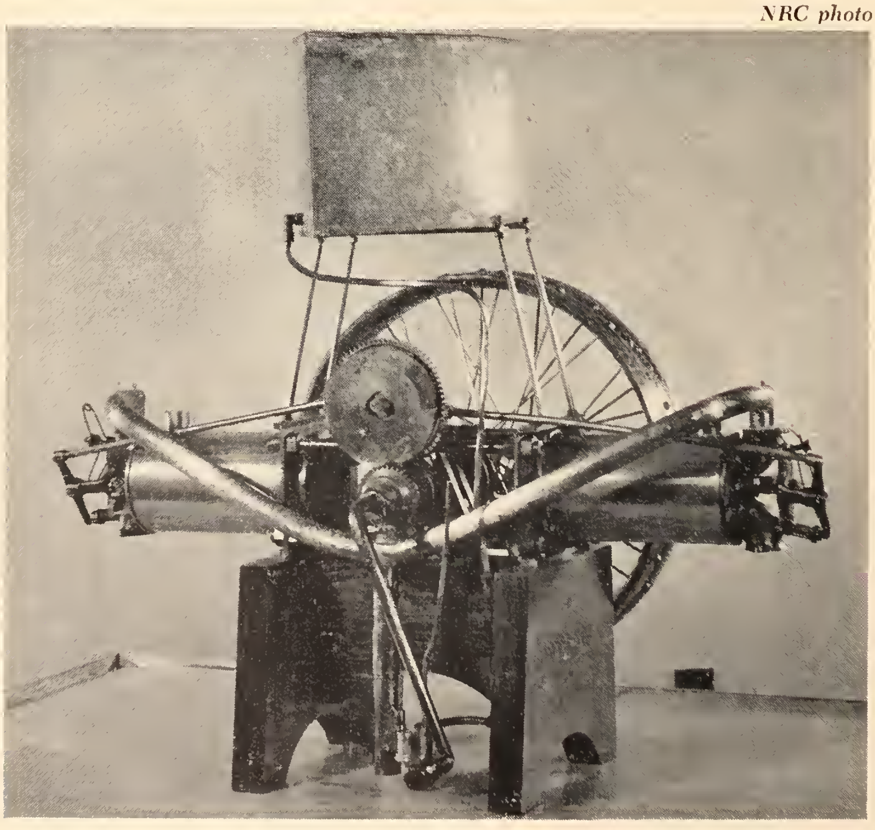
Less than a year later, on 10 February, 1949, the *Orenda* engine was first started on the bed. The engine exceeded its specification of 5500 lb. thrust very early in the development program and, in 1952, a factory specially built to produce the *Orenda* went into operation. The first production engines produced a thrust of about 6300 lb. This engine was known as the *Orenda* 2. The main defect in the *Orenda* 2 was rather sluggish handling, acceleration from idling to take-off being of the order of 18 seconds. After the first hundred engines, improvements were made to the compressor, which resulted in quite acceptable handling characteristics; this engine was known as the *Orenda* 8. Following this came the *Orenda* 9, which differed from the 8 mainly in its plumbing, allowing the engine to be used either as a starboard or port engine for the Avro CF100. (*Orenda* 8 had been handed engines.) In addition to the *Orenda* 2, 8, and 9, the *Orenda* 10 went into production in December 1952 to power the Canadair-built F86, later to be known as the *Sabre* V. This again differed from the 8's and 9's only in detail, having an aircraft-mounted rather than an engine-mounted oil tank and a bleed in order to provide an ejector action for scavenging the aircraft fuselage.

These early *Orenda* engines incorporated a single-stage turbine, which was heavily overloaded for the pressure ratio of the compressor. For some time it had been recognized that a 2-stage turbine was necessary in order to allow the *Orenda* to produce its full potential and, in March 1954, a 2-stage turbine was introduced giving rise to the *Orenda* 11 and 14 engines to power the CF100 and F86 respectively. Considerable compressor improvement had been developed on rig test during this period but its introduction awaited the 2-stage turbine. The net result of the 2-stage turbine and the compressor improvements was an engine which had a minimum guarantee of 7275 lb. thrust and a specific fuel consumption 15% lower than the single-stage turbine engines. At the same time, the weight was decreased from 2640 to 2360 lb. and fabrication methods were used for the turbine stationary parts as against the older method of casting.

Further engineering studies indicated that considerably more power could be produced from the *Orenda* engine. However no approval to put these measures into production was received on the grounds that, firstly, the F86 intake duct was limiting on mass flow, and, secondly, the CF100 was limited in altitude by buffet and not by power. Subsequent improvements in the CF100 removed the buffet ceiling completely and the air-

Fig. 8 The Duryea engine

NRC photo



craft became power-limited rather than buffet-limited. By this time, it was too late to change the engine policy and the potential 8500 lb. trust engine was therefore never undertaken. The *Orenda* finished up in its present form, producing an average of about 7450 lb. thrust. The number of engines produced for the R.C.A.F. was 3376 and for foreign countries 380 giving a total of 3756.

Some time in 1953, the *Arrow* concept was accepted and this time, in certain quarters of the Government, there was an idea that engines could be bought off-the-shelf. The aircraft engine industry in Canada did not accept this idea and believed that an engine could be produced which would give more thrust for less weight than any off-the-shelf engine. In this way, the *Iroquois* (Fig. 10) was born and in September 1953 this engine proceeded as a private venture. In December 1954 this engine was on the test bed and running. Government support followed. The *Iroquois* is an engine conceived to give 30% more thrust than the best U.S. competition for a considerably lower weight. The result is an engine which can give the *Arrow* better range and performance in any possible mission than could any existing engine.

This is what Canada can do in this age of precision engineering and technology; though it was a late starter, it has quickly established itself among the foremost of the world's aero-engine producers.

Fig. 9 The Curtiss engine originally installed in the Silver Dart

AVIATION ELECTRONICS

by Air Vice Marshal M. M. Hendrick, RCAF, Chairman, Canadian Joint Staff, Washington

It was not until shortly before World War II that there was any significant Canadian development in the field of electronics or electrical equipment for aircraft. Prior to that time, the RCAF had used World War I British pattern radio equipment in support of its photographic operations in the Canadian north, while most commercial operators and bush pilots had no radio whatever. In the late 1930's, the Department of Transport commenced to build the Trans Canada Airway, supported by low frequency radio ranges. This equipment however, came primarily from American factories. During the same period the RCAF used later pattern RAF equipment for its Army cooperation and fighter aircraft, but this equipment did not differ very markedly in design or sophistication from the late World War I types, nor was it possible to get spare components or industrial support in Canada.

The twin factors of obsolescent design and inability to depend on logistic support led the RCAF to initiate the Canadian design and fabrication of a family of radio equipments which marked the beginning of original work of this type for Canadian industry.

Fearing that the supply of crystals in wartime would be critical, equipments were designed to have the same frequency stability that crystals would provide but to be tuneable throughout the band. They were also designed to be readily tuned by "rule of thumb", with a minimum number of knobs and to have a single meter which, by switching, could monitor the circuits in the equipment. They were to be remotely controlled, to provide the normal types of transmission (CW, modulated tone and telephony) and to incorporate direction finding. In addition, they were designed for installation in aircraft and therefore had to be extremely light for their power and extremely rugged in terms of ability to withstand vibration, shock, temperature and altitude changes.

The first of these equipments were called AT1 and AR2 (Fig. 11), designed and fabricated by the Northern Electric Company. They represented as radical a departure from the previous equipments as the all metal monoplane did from the previous fabric-covered biplanes.

The first test flight of the prototypes was made in a Noorduyn *Norseman*, flying from Trenton to Montreal on 24 January 1940, and the equipment went on to prove itself and was made in large quantities to support the Commonwealth Joint Air Training scheme.

A ground transmitter was designed and built by RCA Victor and called the AT3 (Fig. 12). Though not as difficult an engineering problem as the airborne equipment, it nevertheless represented some very advanced thinking in terms of frequency control, frequency stability, and remote control. It was certainly the first Canadian transmitter to be controlled completely from a remote position by a telephone dial.

A companion airborne set called the ATR5 (Fig. 13) was designed and built by the Canadian Marconi Company particularly for Army cooperation aircraft — it was the first compact transmitter/receiver to be designed and built in Canada. These pioneer efforts represented the first and last time Canadian industry was given an opportunity to develop original electronic equipment for military use.

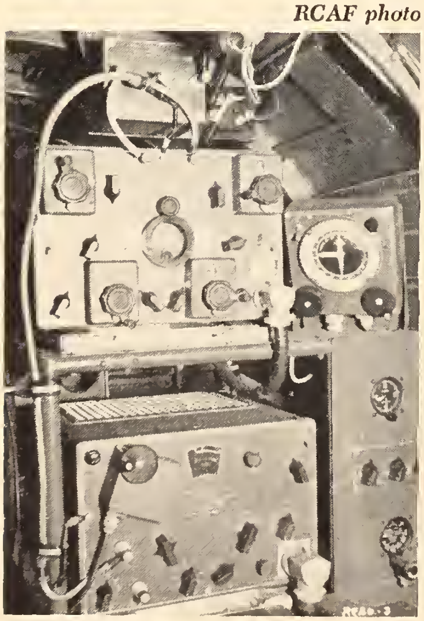
Once the vast resources of the United States were turned to the problem of producing the myriads of devices necessary for both civil and military use, the variety became so great that it was not economic for the Canadians to fabricate their own original equipment designs and the trend to purchase our requirements from the United States or to fabricate their patterns under licence set in and has been the standard practice ever since.

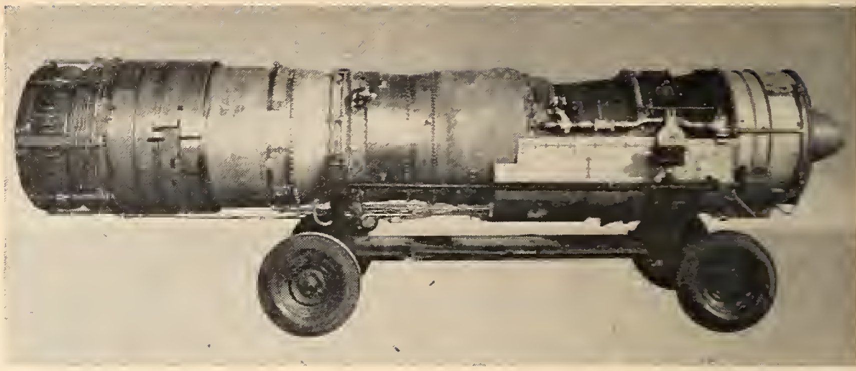
Canadian engineers also made significant contributions from the beginning of the war in the field of radar. Although these contributions were not necessarily ones of original design, they did involve the re-engineering of basic British designs and their fabrication in large quantities. Research Enterprises was the pioneer crown company which made the first early-warning radars in Canada. Enough of these equipments were fabricated to build Canada's early warning chain which remained in being for the duration of the war and then was immediately dismantled and abandoned.

At the same time, Canadian industry became involved in supplying airborne radars for the anti-submarine war. These were the famous ASV equipments (Fig. 14) designed and fabricated by the British in the first instance, and later manufactured to Canadian standards at home. A large number of these sets were constructed and about 150 patrol aircraft (of various types) were equipped with them at one time toward the end of the war.

Fig. 11 The first Canadian designed and built general purpose airborne radio transmitter and receiving equipment, AT1 and AR2, showing the transmitter with its universal tuning meter in the middle, the receiver with its remote control volume cable attachment to the tuning unit and the direction finding dial which controlled a loop direction finding attachment which use the aural null method.

RCAF photo





Orenda photo

Fig. 10 The Orenda Iroquois turbo jet engine

During this period, the National Research Council was one of the mainstays of Canada's radar effort. By modifying British designs and by original work of their own, they provided for the RCAF an IFF system and a beacon system, and toward the end of the war were working on original micro-wave radars (Fig. 15) which were intended to close the mouth of the St. Lawrence against submarines. These first micro-wave radars arrived too late for their primary role but they found their way into the role of tracking thunderstorms, and were used in pioneer work of what is now known as weather radar.

The beacon system was a 200 megacycle transponder, triggered by the airborne ASV equipment, which gave the aircraft distance and homing information. In 1946 the N.R.C. followed up this development by an airborne meter presentation attachment designed to operate with these beacons to meet the requirement then being generated by civil aviation for a pilot-operated navigation and fixing aid. The system was flight tested and proved excellent in measuring distances to 100 miles away and also in giving bearing, but it was subject to intense competition from other allegedly more sophisticated systems which were advocated very loudly by both American and British interests. The Canadian development was allowed to wither on the vine and it is interesting to observe that today no Canadian aircraft carries DME (distance measuring equipment) and we are still waiting for the installation of TACAN, which is the eventual outcome of those competitive systems promised in 1947.

The post-war build-up of our air defence system provided stimulus to the electronic industry in the logistic support, servicing, maintenance, and overhaul of the technical radars and communications equipment fitted in the CF100 and the *Sabre*. The radar gunsight in the *Sabre* was actually redesigned by the Canadian factory and an improved version, which gave greater performance for less complexity, was fitted in the later models of the aircraft.

A related activity, in which Canada has done some first class pioneer work in the last ten years, is in the field of the airborne navigational computation, which, though not electronic, is a combination electro-mechanical device to solve the dead reckoning problem. The "position and homing indicator" (PHI) and the R-θ computer are two cases, one for the single-seater and one for the multi-seated aircraft in which novel techniques were employed to produce reliability and accuracy in a minimum weight and size. The most complex example is the ANTAC system designed for the *Argus* anti-submarine aircraft.

During the last seven years, Canadian industry has branched into the airborne missile field with a training project sponsored by the Defence Research Board to develop the *Velvet Glove* air-to-air missile. Although the missile in performance was overtaken by advancing technology in the United States, nevertheless its development and testing in Canada proved the capability of the industry to design and fabricate the type of components required to meet the very rigid demands of modern missilry.

Since it commenced active original work in 1938, therefore, it is safe to say that the Canadian electronic industry has shown its ability to compete with the modern demands of military and civil aviation, but the opportunities to demonstrate this ability fully have been limited to the few cases where Canadian demand for numbers was large enough to support the project.

ANCILLARY SERVICES

by R. B. McIntyre,
Assistant Engineering Director,
De Havilland Aircraft of Canada Ltd.

THE AERIAL EXPERIMENT ASSOCIATION was founded specifically to construct an aircraft that could fly under its own power, carrying a man. The *Silver Dart* did just that — proving that man could guide himself about in an airborne vehicle. For a while this was quite enough; time was needed to learn about the art and science of flight itself. The technical step was great and the very adventure of flying was sufficient unto itself. In that period there was only one requirement for an aeroplane, namely, that it could fly.

As the techniques of aircraft design and operation improved, men soon combined imagination and ingenuity to direct the aeroplane into channels of usefulness both for military and civilian purposes. When people are asked to spend any length of time in a vehicle they expect to have safety devices, labor saving devices, and comfort. All this gave rise to ancillary services and accessory equipment. By definition, an ancillary service is subordinate to the prime functions of flying. The failure of any ancillary should not bring about catastrophic failure of the aircraft, but with the growth of ancillary services on today's large high-speed all-weather aircraft this may not be strictly true. Today we must regard many ancillary services as integral parts of the whole aeroplane and not merely as attachments put there as an afterthought.

An aeroplane consists, essentially, of an airframe, engines, ancillaries, and accessories. The ancillaries and accessories may be divided into those pertaining to flight, commercial or military use, and comfort. Thus an aeroplane's operational requirements dictate its necessary ancillary equipment and it is a fact that no modern aircraft can perform its proper function without the help of suitable ancillary equipment.

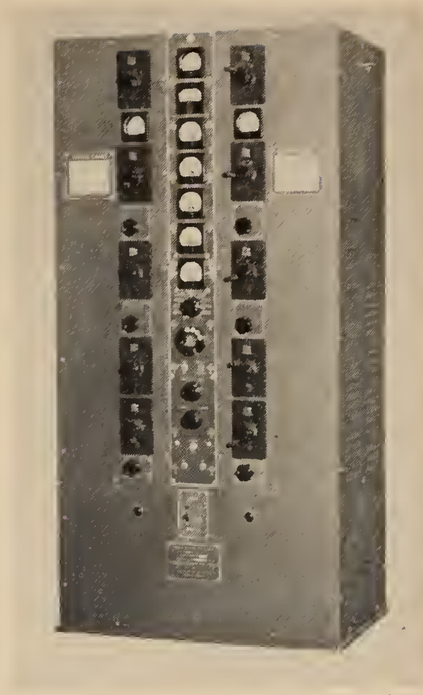
While the general term 'aircraft equipment' includes flight and engine instruments, navigation instruments, communication and navigation electronic equipment, these things are not usually regarded as ancillaries although in certain cases they derive their power from ancillary power services.

As aeroplanes grew in size and speeds increased, it became necessary to operate certain parts of the machine by a power source other than the pilot. Initially, it was a matter of relieving the pilot of distracting burdens, but later the work load exceeded human capability. In other cases the size of the aeroplane made the design of remote mechanical controls awkward, and power actuation was more desirable. The following is a list of some components operated by power on a modern large aircraft:

Main landing gear and doors; nose landing gear and doors; nose wheel steering; wheel brakes; air brakes; main wing flaps; cargo doors; armament system doors; windshield wipers. Such devices usually require only intermittent linear actuation.

As opposed to control or actuation there are other components or equipments which also require power. Such things as: engine starters; wing and tail de-icers; fire warning and extinguisher systems; lighting of all kinds (cockpit, cabin, navigation, landing, anti-collision, etc.); instruments (flight and navigation); electronic equipment (communication and navigation); windshield de-icing; automatic pilot equipment; cabin pressurization and air conditioning; galley services; armament systems. Obviously this list can grow with each additional end-use of an aeroplane, e.g., photographic survey work, agricultural work, etc.

Hence, we see that the majority of ancillaries involve us in considerations of powered systems. In certain obvious cases the aircraft designer has no choice but to use electrical power. In many cases there is a choice between electrics, hydraulics,

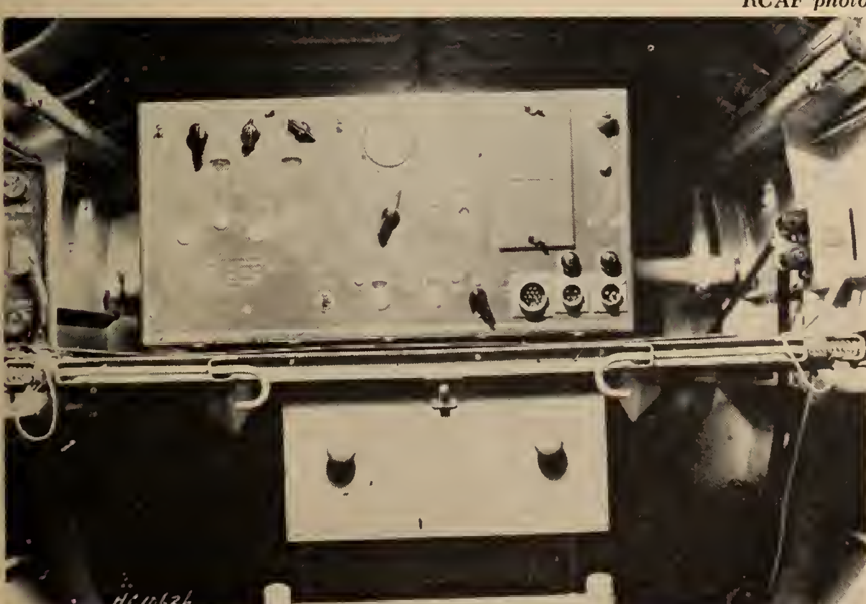


RCAF photo

Fig. 12 General view of the AT3 ground transmitter

Fig. 13 The first Canadian designed and built airborne transmitter receiver in one chassis, the ATR5.

RCAF photo



and pneumatics. Some aeroplanes have all three systems, each devoted to specific functions and occasionally one acting as a standby for another, such as a pneumatic emergency system on an undercarriage hydraulic actuation system. Today there are many specialist firms in the aircraft equipment field and the aircraft designer has a wide choice of electric, hydraulic or pneumatic equipment. The growth of this associated specialist industry has been of great help to the aircraft designers inasmuch as it has provided the aircraft firms with equipment to aircraft standards of safety, reliability, weight, and bulk at a reasonable cost.

The electrical system is probably the principal ancillary service on aircraft today. The growth of the aircraft electrical and electronic industry is a good index of this, and it is a fact that electrical power generation on aircraft has gone up rapidly in recent years. It is not unusual to find aircraft with total generated power output of several hundred kilowatts. Both DC and AC systems are used to supply starters, lighting, electronics, instruments, actuation motors and linear actuators, solenoids, heaters, cookers, air conditioners, and so on. While most aircraft use engine-driven generators or alternators, there is a development toward completely independent turbo-driven generators and alternators, particularly for the supply of constant frequency AC power. The use of DC rotating equipment becomes more difficult in high altitude jet aircraft.

Today, as for many years past, the battle is still waged on the relative merits of electrics versus hydraulics. There are some who favour the "one system aeroplane" which would, of course, have to be all-electric. However, the aircraft designer, who is always fighting the weight bogey, usually decides each issue on its own merits and, in most aircraft today, actuating power is supplied by both hydraulics and electrics. The pneumatic actuating system has gained much interest in the last few years in the U.S.A. although this system has a considerable history of development in the U.K. Many papers, by competent people, are available on the features and advantages of the various systems. In general, it can be said that high load actuators in the form of simple hydraulic jacks are consistently lighter than their electric-motor screw-jack counterpart even as an "installed" system.

On modern aircraft the power requirements are so high that it is important to decide on the general layout and types of powered systems at an early stage in the design. In other words, all systems (including the power plants) must be well integrated with the airframe. An example of this might be a jet propulsion engine compressor providing cabin air, cooled by a turbine which in turn drives an electrical generator and hydraulic pump.

Another major ancillary on modern aircraft is the cabin pressurizing and air-conditioning system. For many years both flight crews and passengers had to be contented with little or no comfort equipment and

Avro photo

seemed to get along quite well. Since 1945 there has been considerable work done by designers and builders at least to minimize the discomforts of flying. Cabin pressurization is more recent and has now graduated from being a simple provision for passenger comfort on piston engine aircraft, to an essential system on high-flying jets. The jet aircraft's cabin pressure system must have the ability to withstand failure of any sort, but it must be noted that current jet transports provide emergency oxygen equipment for crew and passengers. The equipment for pressurizing and conditioning is quite sophisticated and has been largely developed by specialist firms working closely with the aircraft builders.

The small high-speed turbine wheel is on the way to becoming the heart of modern aircraft accessory systems. It made its entry as a means of cabin conditioning and pressurization and is now the main component of much more far-reaching systems. The ancillary jobs of which the small turbine is capable are so diverse that it can be the means for generating electric power, refrigeration, hydraulic pumping, air compression, and the production of mechanical torque. In effect this will provide large aeroplanes with a "power station" independent of the main propulsion units, which offers advantages in efficiency, flexibility, weight reduction, and reliability.

This brief review can only highlight the main ancillary systems found in modern aircraft, but to engineers it should indicate how aircraft engineering has broadened in scope over the last 50 years. Mechanical, electrical, and electronic engineering have become as important to the aircraft designers as the structural, metallurgical, and aerodynamic aspects of flying machines. The airframe constructor undertakes to provide and be responsible for the complete vehicle. It is, therefore, natural that the aircraft designer should be critical of the elaborate standard of equipment current today. He persists in his plea for the reduction of equipment weight and bulk. The design gross weight of an aeroplane varies almost linearly with the combined weight of payload, crew and equipment, that is, the fixed items required to be carried. Hence, a 10% reduction in these fixed quantities gives about 10% reduction in all-up weight. On a long-range aircraft the payload, crew and equipment may total only, say, 20 to 25% of the gross weight so that it can be seen that a relatively small sacrifice on the fixed items can yield appreciable savings in all-up weight and initial cost. Reduction in bulk of equipment reduces total aircraft volume and results in lower drag and higher performance. Of course, advantage can only be taken of such reductions if they are known early in the design stage.

As already mentioned, the equipment designers have done a great deal toward reduction of weight and bulk, but it is expected that the conflict between operational amenities and aircraft performance will go on into the future. The aircraft designer must control the ancillary equipment situation since it is clear that such equipment has a large influence on basic aircraft design.

It would appear that aircraft and ancillary equipment engineers have made good use of their time over the

Engineering Features of the BEECHWOOD DEVELOPMENT

J. A. Thomas, M.E.I.C. *Chief Engineer, Civil Division,*

R. E. Grout, M.E.I.C. *Chief Engineer, Electrical Division,*

The Shawinigan Engineering Company Limited.

THE BEECHWOOD DEVELOPMENT is located on the St. John River in the Province of New Brunswick, about 110 miles above the provincial capital of Fredericton (Fig. 10). Perth and Andover, on opposite sides of the river, are some fifteen miles to the north; Florenceville is about twelve miles down river. There are bridges across the St. John River at each of these towns.

The St. John River valley, in this vicinity, runs north and south parallel to the International boundary and some eight miles to the east. The sides of the valley rise gradually from the banks of the river in pleasant fertile terraces.

Under a reference of 7th July, 1952, the International Joint Commission commenced a study of conservation and regulation of the St. John River. Its report published in 1953 recommended the Beechwood site for initial development on the main stem of the river, pointing out that it is centrally located with respect to system load centres and lies below the Aroostook and Tobique Rivers, both of which have some existing storage. Additional storage on the upper reaches of the river, when built, will benefit the Beechwood plant.

Hydrology

The St. John River basin lies in northern Maine and adjacent Quebec and New Brunswick. The watershed of the St. Lawrence River to the north and that of the Penobscot to the south adjoin the basin. The total drainage area is 21,600 square miles, making the St. John one of the largest rivers draining into the Atlantic Ocean. Sixty-five per cent of the drainage area lies in Canada and thirty-five per cent in Maine. The total fall of the river between the source and tidewater is 1,578 feet.

Below the Grand Falls site (Fig. 10) the river drops 287 feet to tidewater. The river here is broad and slow-moving with many shoals and islands formed by the deposition of materials carried in suspension down the swifter reaches. The profile suggests that power developments will have low heads and long headponds typical of peaking plants. Dam sites are primarily to be selected for foundation and abutment conditions rather than from any features of the river profile.

The mean annual run-off of the river at Pokiok, below the Beechwood site, is 1.56 c.f.s. per square mile, equivalent to 21 inches in the drainage area. Approximately two-thirds of this occurs in the months of April, May, and June, although there is often a flood peak in the fall. During the period of record the run-off has varied from a minimum of 0.2 c.f.s. per square mile to a maximum of 17 c.f.s. per square mile. The latter run-off as measured at Pokiok corresponds to the record flood of 238,000 c.f.s. at Beechwood in May, 1923. As may be surmised, the St. John River is very flashy and might be expected to present some difficulties during construction.

Power Potential of the St. John River

There are four power sites on the main stem of the river in New Brunswick, of which only two are developed. These are Grand Falls with an installation of 57,000 kw. at 132 feet head and the Beechwood plant to be described in this paper. The two undeveloped sites are Morrill, situated about halfway between Grand Falls and Beechwood, and Hawkshaw, some forty miles above Fredericton. Morrill is expected to develop 66,000 kw. at 53 feet; Hawkshaw, with a head of 55 feet, will produce 112,500 kw. Comparative estimates at an earlier date had shown Beechwood to be the most economical development.

Beechwood Installation

The studies made for the Joint Commission report showed that 102,000 kw. could be installed at an average head of 60 feet. Additional studies were made during the planning stage of the development which confirmed the proposed installation and established that three units should be installed with a rating of 36,000 kw. at a net head of 57 feet. These studies also confirmed that, in relation to existing storage and system load, only two units should be put in initially with space provided in the powerhouse for the third.

The value of capacity in a system combining thermal and hydro power is very high. The Beechwood plant will be operated essentially as a peak load plant during periods of low flow and the thermal plants will be base loaded. The reverse will be true during periods when the flow is equal to or greater than rated discharge.

Backwater Studies

The construction of the Beechwood dam produces a backwater effect which extends for many miles up the river. Since the countryside is well settled, extensive provisions were necessary to protect the banks over certain reaches and to compensate for flooded areas at others. In addition, the effect on the future site at Morrill must be determined.

Perth and Andover are principal areas affected by the backwater. It was apparent that, for a particular river level at this location, various flood flows could be passed depending on the number of sluice gates provided at the dam, coupled with the permissible drawdown. Hence, it was necessary to prepare the curves of Fig. 1, which shows the relationship between water levels at Perth-Andover and those of the forebay for various flows. Superimposed on these is the capacity curve for nine sluice gates and two regulating gates. Similar curves for various numbers of gates were used in the course of the study.

The flatness of the curves indicates at once that a comparatively large variation in level at the forebay for flows in the neighbourhood of 238,000 c.f.s. produces a much smaller variation in the corresponding level at Perth-Andover. Since the forebay must inevitably be drawn down, the backwater effect at points in between is not critical.

Further study along these lines indicated that nine sluice gates together with two regulating gates formed a satisfactory installation. The installation of a larger number of gates would reduce the backwater at the towns by only a fraction of a foot for a particular flood flow, or, on the other hand, would increase the flood capacity by only a small percentage for a particular level at Perth.

Backwater calculations were made by the step method to the Morrill site. The curves shown in Fig. 1 were interpolated by the unit-fall method.

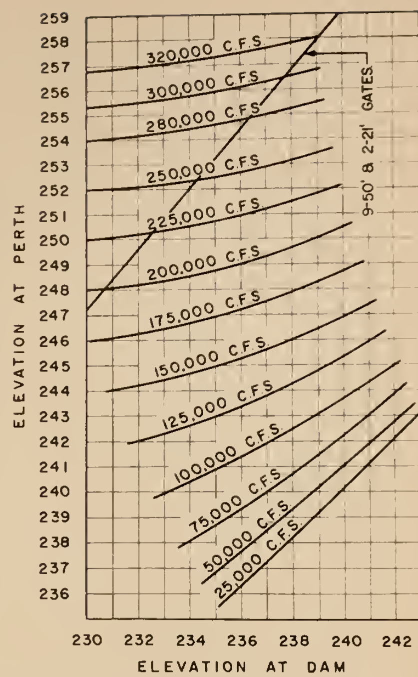

Fig. 1. Chart of backwater elevation between Perth and forebay.

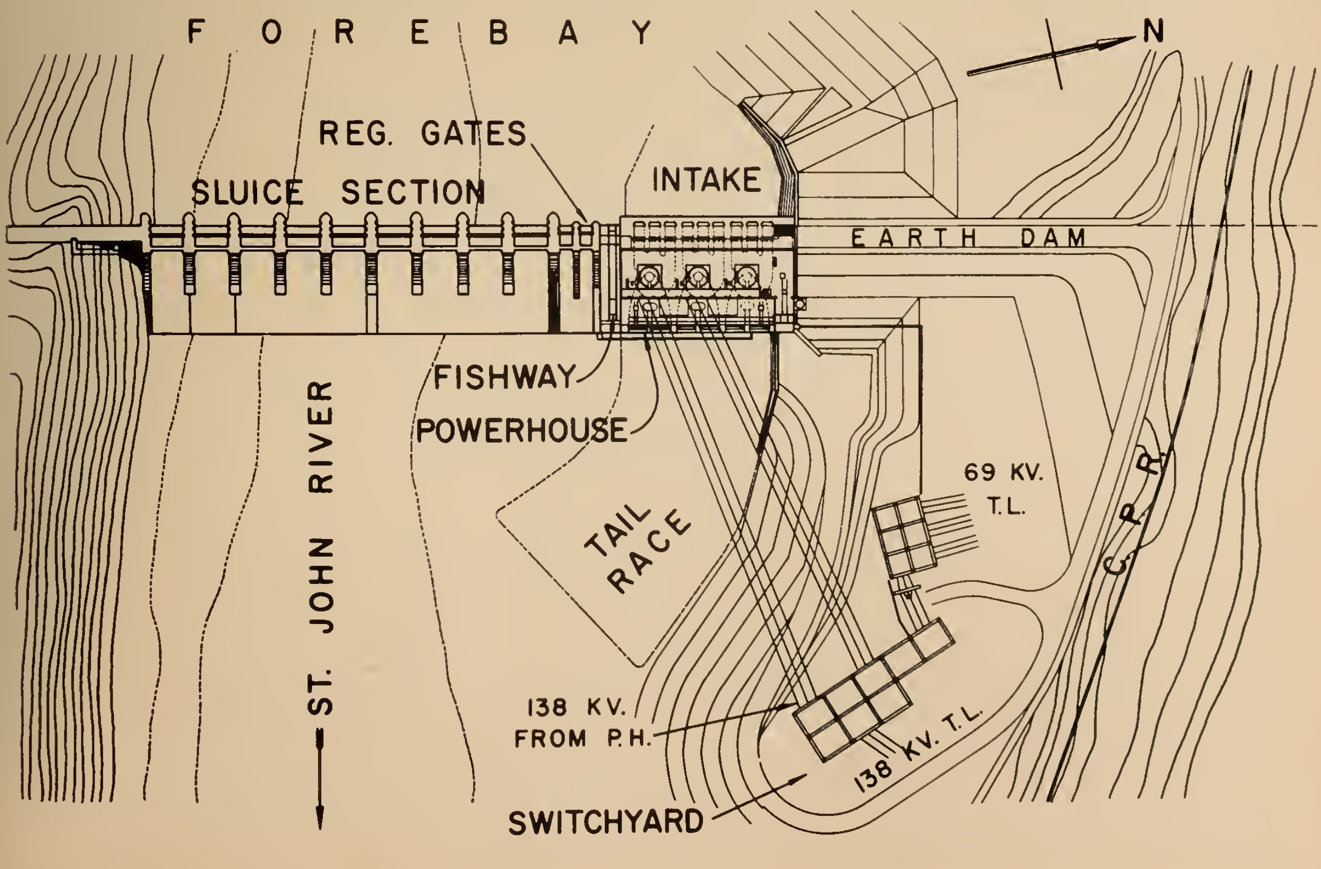
Description of the Site

Three locations of base line were investigated in the field. These lay in a reach some 800 feet long, and the bed rock profile was ascertained for each by diamond drilling. After some preliminary study, the middle or "K" line was selected as the base line for the development.

On the west bank the rock rises steeply to form an ideal abutment for the dam. Though overburden was rather heavy, there was no great problem in removing it. Rock, in the bed of the river near the west bank, is deep, at approximately elevation 142, and is overlaid with thirty to forty feet of silt. Towards the east bank it rises and remains generally

Fig. 2. General plan of the development.



horizontal at about elev. 170. The east bank of the river consists of overburden—a pervious mixture of silt, clay, and sand. Rock for the east abutment reaches elev. 248, the crest level of the dam, some 600 feet back from the original bank. Since the overburden is pervious, a cut-off wall was required to abut on the rock. Bumfrau Brook, which originally flowed along the bank, was diverted into the St. John above the base line.

The railway had to be diverted to a higher level on the east side of the river before construction. Highway grade changes and relocations, and extensive bank protection were also required.

Geology and Foundation Treatment

The topography of the preglacial valley of the St. John River near Beechwood has been largely modified by ice action during the last period of Pleistocene glaciation and by deposition of detritus during the retreat of the ice. Valley trains were established, subsequent stream action modified these deposits to a varying extent, and the river has cut down to its present bed, which consists of a bouldery alluvium of varying thickness. Terraces of mixed gravel and silty till frequently rise abruptly from the water's edge up to 70 feet. Above these terraces the hillsides are thinly covered with silty stony till ("potato dirt").

This silty till is well graded and was used for the impervious core of the earth dam that forms the closure to the east of the intake. The deposit was shallow, the moisture content of the in-place material was above optimum, and compaction was difficult during wet weather.

The gravel deposits in the river terraces produced excellent coarse aggregate for the concrete when 10 to 20 per cent of the lightweight particles were removed. Sink float processing was used to upgrade the gravel.*

Bedrock at Beechwood is a calcareous shale or argillite. Locally cleavage is so well developed that the rock has a slate-like appearance and evidence of bedding has been destroyed. Small dykes and stringers of calcite with or without quartz cut or meander through the argillite. The weathered surface of the rock varies from grey to greyish brown; on fresh surfaces it was dark grey, and in the zones of more pronounced cleavage, shiny jet black. In several locations drilling encountered zones containing water under artesian pressure in the bedrock and in the overburden of the river bed.

The most highly developed cleavage was found in the powerhouse area where the deepest excavation was required. During blasting operations the rock opened up along the cleavage planes, which added to the overbreak and necessitated an extensive bedrock consolidation program in the intake-powerhouse area as well as a close spaced pattern of curtain grouting along the upstream face of the intake.

At pier 12 a fault zone of variable width, generally of the order of 1 foot, was uncovered that had a north-south strike and dipped at 45° to the east. This zone was filled with brecciated argillite, unbrecciated calcite and minor gouge. The structure was open for the passage of water. Excavation for the draft tubes encroached on the faulted area and it was necessary to remove a part of the hanging wall that was unsupported and replace it with concrete.

Due to the solubility of the calcite and the openness of this fault, an extensive program of grouting was required to consolidate the material and seal off all water passages.

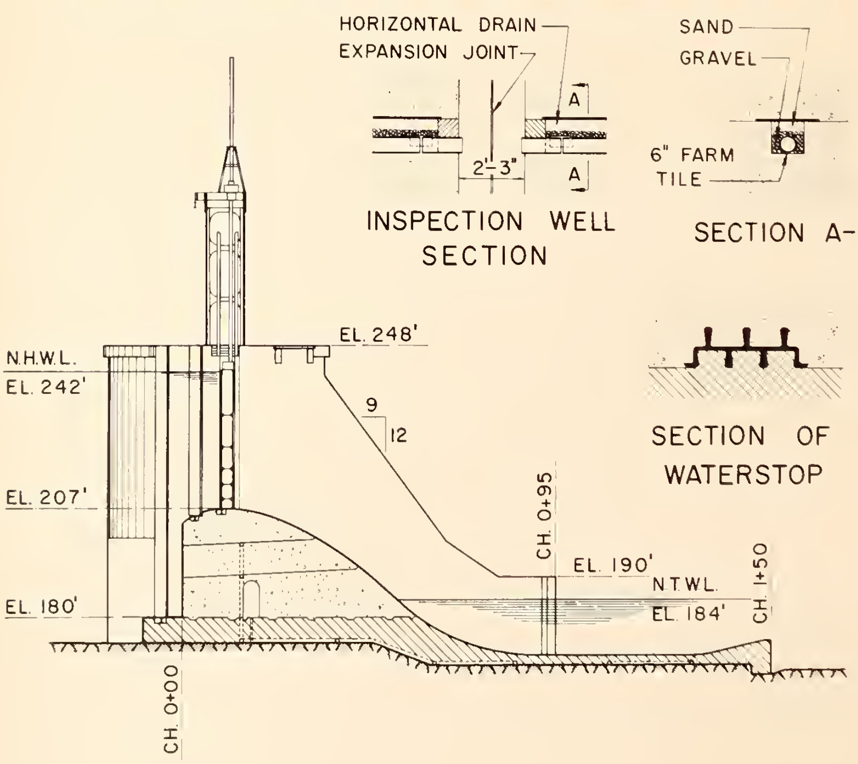
Extensive curtain grouting was necessary to establish a watertight cut-off extending to depth adjacent to the upstream face of the structures and along the upstream east retaining wall. Close spaced blanket grout holes to 20 feet depth were put down in the intake and powerhouse areas and under the east retaining wall to consolidate the bedrock distributed by blasting. In the fault zone at pier 12 both consolidation and curtain grouting were used.

In the western part of the sluice section the rock was relatively tight. A double row of curtain holes on 10-ft. centres to depths of over 100 ft. were required. East of pier 6 the rock was more open and three rows of holes with an effective spacing of 5 ft. were put down to a minimum depth of 100 ft. with test holes to 200 ft.

From pier 12 east across the intake, four rows of curtain holes were put down. The 45° east-dipping fault zone was grouted to 175 ft., below which it proved tight. Three rows of holes were vertical and one was inclined to the west, the effective spacing being approximately 2 ft. Both stage and step grouting was used in this area. Under the earth dam two rows of curtain holes were put down. Three rows of holes from 100 to 200 ft. deep were put down below the east retaining wall and extended downstream to the downstream face of the powerhouse.

In the intake-powerhouse area con-

Fig. 3. Typical section of sluice showing by-pass arrangements and seals.



*Heavy Media Processing of Gravels in New Brunswick, I. D. MacKenzie, Journal of A.C.I., Sept., 1958.

solidation grouting was carried out in two 10-ft. stages to a vertical depth of 20 ft. The primary pattern consisted of rows of holes on 10 ft. centres, the alternate rows being inclined 60° north and south. The second pattern consisted of holes intermediate between the first pattern with the alternate rows of holes dipping 60° east and west. Consolidation grouting to 20 ft. depth was also carried out under the core of the earth dam and under the east retaining walls.

Some 6,600 bags of cement were injected into the curtain grout holes and 3,500 bags of cement into the consolidation grout holes for acceptance of 11.3 and 1.5 bags per hole respectively.

Description of Structures

The final arrangement, Fig. 2, placed all the structures on a straight base line. On the west bank a concrete bulkhead section was poured against the rock, extending outward to the spillways which lie roughly in the centre of the river. The regulating gate section adjoins the spillways, and the fish hoist is between this and the powerhouse on the east bank. From the powerhouse to the east rock abutment there is a cut-off consisting of an impervious clay core blanketed by the local sandy material.

Spillways

There are nine spillways, each 50 ft. wide, with sills at elev. 207 corresponding to a normal forebay level of 242. Piers 15 ft. thick are raised to elev. 248, thus providing 6 ft. of freeboard. Two regulating gates each 21 ft. wide by 22 ft. high are also provided. The design allows the forebay level to rise to within 1 ft. of the top during an extreme flood.

For floods over about 100,000 c.f.s. the forebay is drawn down until a minimum pond level of elev. 230 is reached. After this, the forebay rises with the flood thus increasing the head over the sills. Table I gives some values of discharge capacity.

The historic flood is 238,000 c.f.s. or 17 c.f.s. per square mile. At maximum forebay level the run-off corresponding to the spillway capacity is 31 c.f.s. per square mile, which is considered a safe figure allowing for the flashy characteristics of the river.

The capacity of the two regulating gates is only slightly less than the rated discharge of two units; if load is lost on both units simultaneously, the gates can be quickly opened to control the forebay level.

Figure 3 shows the cross-section through the spillway. The sill shape

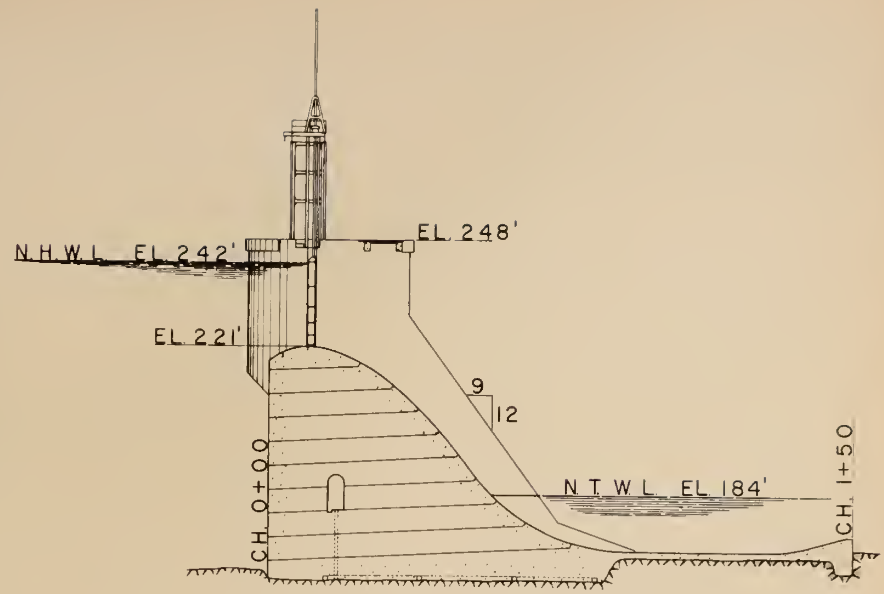


Fig. 4. Typical section of regulating gate.

is a scimimian parabola with vertex 10 ft. from the upstream face. Upstream of the vertex, the profile is a circle of 14 ft. radius with centre 9 ft. 6 in. from the upstream face, which is somewhat fuller than the theoretical true profile and is provided to allow for stop log gains and sill beams with clearance for working space in front of the gate. The complete profile was checked by model test to ensure that there is a positive pressure at all points on its surface.

A circle of 50 ft. radius joins the sills and aprons tangentially. The apron is a reinforced concrete slab of 18 inch nominal thickness extending some 150 ft. below the base line. At its lower end it sweeps up to a lip with a 10 ft. tangent length, making an angle of 14° to the apron surface. This lip serves effectively to prevent erosion of the rock at the toe of the apron, where there is quite a dissipation of energy. The apron elevations are varied to suit the elevation of bedrock except where the rock is very low. The drainage system is designed to prevent uplift on the slab due to high tailwater levels.

Expansion joints are provided on each side of the piers. Sills and piers are therefore designed to be separately stable, and reinforcing steel is placed through the horizontal pour joints to ensure safety of the sills against sliding. The sliding factor at the rock line for the composite structure (sills and piers) is kept low in view of the stratified type of rock.

The gates are 50 ft. wide by 36 ft. high, of fixed roller type, operated by individual screw hoists carried on steel towers and bridges. They are designed for an ice load of 5,000 lb./ft. width applied at any level from one to six ft. below the top of the gate. A monorail hoist, mounted on the upstream side of the towers handles the stop logs. The heating of the skin plates and gains of some gates for emergency winter operation is dealt with elsewhere in this paper.

To distribute the thrust of such large gates to the piers, presents a particular problem. Tower - type bedded parts were designed to support the gains, which are themselves completely formed in steel plate. Thus, mass concrete can be poured to embed the towers with no subsequent need to grout in the gains. The towers are also so designed that the load received by the gains is distributed deep into the mass of the piers. This results in an exceedingly strong arrangement and one not readily subject to concrete deterioration through spalling or erosion.

The two regulating gates are of similar design to those of the 50 ft. spillways. The sills were poured initially to the finished profile and are shown in Fig. 4.

Inspection Tunnel

An inspection tunnel in the dam, from the west bulkhead to the powerhouse, will permit inspection for leakage at or below the rock line and allow any necessary additional grouting to be done. Six-inch diameter pipes at 5-ft. centres are embedded in the concrete from the floor of the tunnel to the rock. Through these pipes a hole was drilled two to three feet into the rock foundation. Escape shafts are provided at three points along the tunnel rising to the tops of piers, and a portal is formed in the west bulkhead. All drains lead to the inspection tunnel which is provided with a sump and two 360 U.S.g.p.m. pumps operated by water level control.

Closure

The closure scheme to raise the water level in the forebay formed part of the design of the spillways. The sills were poured initially to elev. 180, the approximate level of the bed of the river and the piers to their final level. Stop log gains were built into the piers at the upstream and downstream limits of the sill. Three sets of steel logs were provided for the upstream gains while timber stop logs, reinforced by needle beams, were used in the downstream gains. The scheme called for closure of the openings in groups of three commencing at the west end and proceeding eastward. The flow of the river was to take place over the remaining sills. Of the final group of three, the first was to be concreted separately, then the remaining two simultaneously. Sufficient stop logs were available from the three sets so that these last two could be kept unwatered while the water was passed over the seven completed sills. The final closure was to take place at lower flows in late November or December.

Unwatering Scheme

The scheme for construction called for a cofferdam extending out from the west bank to enclose an area so that five sills and six piers could be poured. On completion, the cofferdam was demolished and the spring flood passed over the uncompleted sills and the remaining section of the river to the east, augmented by some bank excavation for the powerhouse. After the spring flood, a cofferdam was extended eastward from a section which sealed against a completed pier. This cofferdam enclosed an area to permit the pouring of the remaining sluices and part of the regulating gate section. This was to be completed before the fall flood together with a final cofferdam enclosing the powerhouse area, built to seal on the west regulating gate pier.

The St. John River is extremely flashy and calculated risks were necessary in reducing cofferdam heights so that the yardage could be placed and the necessary concrete poured between spring and fall floods. It was decided to provide for "between flood" flows of 40,000 c.f.s. and floods, either spring or fall, of 200,000 c.f.s.

Other conditions during the construction period included provision for passing the log drive and also the salmon run.

During the summer of 1954, while the design studies were progressing, very high summer flows were being recorded with peaks of over 90,000 c.f.s. This caused some concern to the engineers, but the flows during the actual construction period were con-consistently among the lowest ever recorded for the river. These extremely fortunate conditions led to some deviations from the original construction scheme.

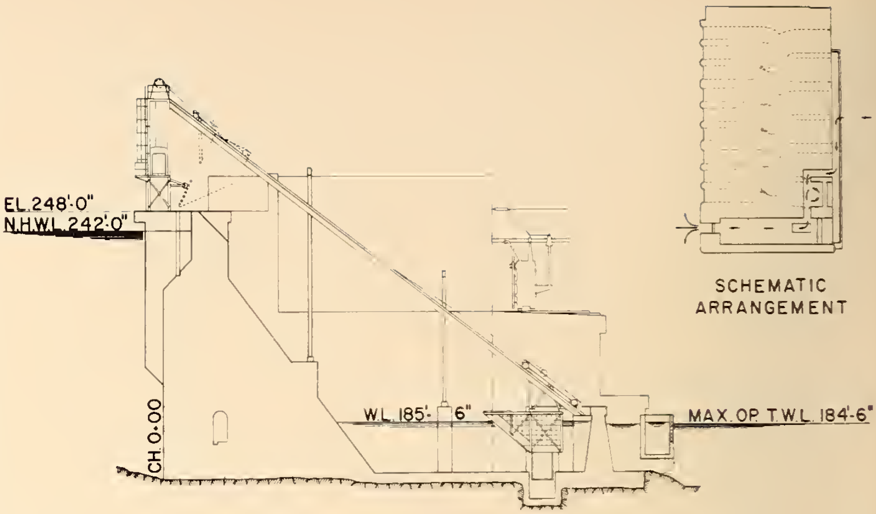

Fig. 5. Fish hoist arrangement.

Bubbler System

To reduce ice formation, a bubbler system is installed on each gate. Four nozzles equally spaced across the gate 12 ft. below the surface discharge air bubbles which raise relatively warmer water to melt any surface ice. Two 100 c.f.m. compressors supply the air.

Fish Passing Facilities

Each year, from May to November, the Atlantic salmon run up the river to spawn in the shallows of tributary rivers, principally the Tobique. Though the run is not of commercial significance, the value as game fish is great. It was therefore necessary to design facilities to get them over the dam at Beechwood.

During the run the salmon swim against the current, and this characteristic has been used to guide them. Since the flow from the draft tubes of the turbines forms an ideal attracting current, it is usually best to have the fish passage near the powerhouse.

A fairly conventional fish ladder is in use at the Tobique plant of the Commission, and it was at first proposed to build at Beechwood a similar reinforced concrete structure of alternating drops and rest pools conforming to a 1 in 12 slope. However, to build such a structure on the material of the east bank and to control settlement so as to maintain the slopes would be difficult and expensive, and an alternative method was designed. (Fig. 5).

Experience at Tobique showed that a gallery along the downstream face of the powerhouse above the draft tubes, with openings in its outboard wall, attracts the fish into the passages. This was incorporated in the Beechwood powerhouse as a gallery 8 ft. wide with three openings, each 6 ft. wide, provided with stop logs to produce a drop of 9 to 12 in. in the water surface to attract the salmon. At No. 1 unit the gallery turns in under the draft tube deck and leads to a rest pool formed in the west bay adjacent to the hoist. Adjustable louvres at the entrance and exit control velocities and deter the fish from returning downstream.

A flow of 12 c.f.s. was selected with provision for adding additional

Table I. Values of Discharge Capacity

Forebay Elevation	*Flood Gate Discharge c.f.s.*	*Regulating Gate Discharge c.f.s.*	*Total c.f.s.*
230	180,000	4,000	184,000
242 (normal)	345,000	14,700	359,700
247 (extreme high)	410,000	20,000	430,000

water if more than one opening should be in use along the collecting gallery.

The fish hoist consists of a cage which is pulled up an inclined trackway. The cage is 10 ft. square at the bottom with a sloping front end. (Fig. 6). The sides are wire mesh except at the bottom where plates extend up one foot to form a watertight compartment. A door on one side is automatically raised before the cage starts its upward trip. The cage is tipped on arrival at the upper level to pour the water and collected fish into the forebay.

In the down position the cage rests in a water filled basin with intake located so that the current attracts the fish into the cage. A wire mesh gate at the entrance closes with the door of the cage so that, when the cage is raised, the fish cannot pass into the basin. The gate opens when the cage returns.

The hoist was satisfactorily put into operation in August 1957; in ninety days, 1,127 fish passed over the dam. Operation can be automatic on a timed cycle, but at present the cage is controlled manually.

Logging

Both pulpwood and sawlogs must be passed over the dam at Beechwood. However, the characteristics of the river are such that the drives take place at the ebb of the flood. Hence no log chute is provided, the logs being passed over the open spillways or flushed through a regulating gate. Directing booms are stretched in the forebay and attached to anchors embedded in the piers.

Powerhouse (Fig. 7)

The powerhouse is an integral design; i.e., intake and powerhouse are combined. In this case the downstream wall of the intake constitutes the upstream wall of the generator room.

The units have concrete semi-spiral cases fed by a three-gate water passage. Trash racks are placed in the entrance and head gates, each with its own hoist, just downstream. The emergency gates, of which there is only one set, are dropped in the trash rack gains during repairs. The head gates can be removed by bringing them to the upstream face of the gate slot and transferring the lift from gate hoist to gantry.

The powerhouse has settings for three units, of which only two are installed initially. Since the unit spacing is 70 feet, it was possible to place the office and control buildings on the transformer deck between transformers, resulting in a very compact arrangement. Entrance to both buildings is reached from a balcony at elev. 218, 12 ft. above the generator room floor.

The superstructure is steel-framed with reinforced concrete walls. The walls of the powerhouse are 10 in. thick; those of the office and control building are 8 in. thick. All are poured with no expansion joints, and experience to date has revealed only a few hair-line cracks on the lines of the columns.

The large size of the units necessitates large generator room volumes. When the coldest part of the winter is reached, the available flow is low and hence the units will be operated at reduced loads. Calculations showed that it would not be possible to heat the space with heat from the units. Electrical heat was added, minimized by using light-weight pre-cast roof slabs of high insulating value. On this a bonded roof was laid.

The east end of the powerhouse consists chiefly of the retaining wall against which the east cut-off dam abuts. The main entrance is also at the east end of the downstream wall, the approach being just inside the retaining wall. The entrance opens directly on the repair bay.

East Cut-off Wall

Figure 8 shows the section of the earth fill dam which forms the cut-off. The compacted clay core and pervious blankets are of local material. As the core approaches the powerhouse retaining wall, it is widened out to increase the length of the leakage path along the concrete face. The blanket material is so pervious that toe drains are not necessary.

Compaction was done in 6-in. layers using a sheepsfoot roller. The rock foundations were grouted and smoothed with concrete for deposit of the core.

The roadway to the intake extends along the top of the dam, which is covered by a 3-ft. layer of gravel. The upstream slope is covered with 3 ft. of rip-rap and the downstream slope with 1 ft. of coarse gravel.

Powerhouse Auxiliaries

The powerhouse crane has a capacity of 175 tons on the main hook and 25 tons on the auxiliary hook. It is a conventional overhead travelling type with the operating cab at the upstream end of the bridge.

The gates, racks, and emergency gates are serviced by a 60-ton gantry crane on the intake. This gantry has unequal legs, the upstream legs being supported by tracks at deck level while the downstream tracks run on rails laid at the level of the gatehouse roof.

Provision has been made to move the transformers inside the powerhouse using a fixed hoist located over the roadway at the powerhouse entrance. The transformer is run out on a rail car, slung, and lifted by the

Fig. 6. Fish skip being raised to forebay.

hoist. The rail car is then run to one side and the transformer lowered to tracks provided at the repair bay level.

The various service auxiliaries in the powerhouse consist of strained water supply, fire pump, governor oil and air pressure systems, general service air, circuit breaker air pressure supply, oil filtering system, etc.

The portable oil filter used for filtering the transformer insulating oil is mounted on a four-wheel trailer suitable for towing on the highway. This unit includes a heater for heating the incoming oil to 80°C., a filter for removing solid matter, and a vacuum chamber for drying and de-aerating the oil. The unit has a capacity of 450 I.g.p.m. and requires 64 kw. for operation. Although this filter was supplied as part of the equipment for Beechwood it may be used readily for other transformers on the N.B.E.P.C. system.

General service air is provided by a portable electrically-driven compressor with a capacity of 160 c.f.m. free air at 100 p.s.i. Electrical outlets are provided at intervals around powerhouse and intake so that the installation of piping runs has been avoided.

Turbines

The turbines of this development are described elsewhere.* They are the Kaplan type rated at 45,000 h.p. at a net head of 57 feet and 109.1 r.p.m. At the time of installation, these were the largest of their kind manufactured and installed in Canada.

Single Line Station Diagram

Figure 9 shows the single line diagram for the generating station and high voltage switching stations. Power is generated at 13.8 kv. and is transformed to 138 kv. through the unit transformers. It will be noted that high voltage switching only is provided. There are no low voltage circuit breakers between the generators and the unit transformers. Transmission line No. 103 to Fredericton is connected to the 138 kv. bus. A tie transformer has been installed between the 138 kv. and the 69 kv. buses, and three 69 kv. lines are connected to this 69 kv. bus.

The 138 kv. bus is sectionalized by means of a disconnecting switch. In order to make full use of these two bus sections at this stage of development, the second unit has been connected temporarily in place of the third unit. On the 138 kv. Fredericton line No. 103, a bypass switch has been installed around the line circuit breaker to provide for breaker maintenance. On the 69kv. Fredericton and Tobique lines, No. 20 and 37 respectively, a line paralleling switch has been installed to permit maintenance of either of these line breakers with the other breaker in service.

A manually-operated disconnect switch has been provided in the low voltage bus between each generator and unit transformer to permit isolation of the generator for testing and maintenance. Power for station service is taken from units 1 and 2 to separate station service transformers through 13.8 kv. disconnect switches.

System Diagram

Figure 10 shows the connection of the Beechwood generating station into the New Brunswick Electric Power Commission transmission system. The 138 kv. line to Fredericton continues on to the Grand Lake generating station and Moncton. The 69 kv. lines No. 20 and 37 connect into the existing 69 kv. transmission lines between Fredericton and the Tobique Narrows generating station. The 69 kv. line No. 55 extends to the Canadian border to form an interconnection with the Maine Public Service Company.

Main Power Apparatus

Each totally-enclosed water-cooled generator is rated 40,000 kva., 0.90 power factor, 13.8 kv., 109.1 r.p.m. The stator coil insulation is Class "B", with the major insulation of asphalt-bonded mica tape. The field poles are provided with non-continuous amortisseur windings. The generators are of overhung design; i.e., the combined thrust and lower guide bearing is installed below the rotor, and there is no upper guide bearing.

Each three-phase unit power transformer is rated 40,000 k.v.a., 13.8-138 kv., Type OFW, 60°C. temperature rise. The transformers are connected low-voltage delta and high-voltage star with solidly grounded neutral. Full capacity off-load taps are provided at 141.45, 144.9, 148.35 and 151.8 kv. on the high voltage windings. Two separate oil-to-water heat exchangers are provided for each transformer. Each heat exchanger is capable of dissipating 80% of the transformer losses at full load with a maximum cooling water temperature of 20°C.

The three-phase tie transformer between the 138 kv. and 69 kv. buses in the switching station is rated 22,500/30,000 kva., Type ONS ONP, 55°C. rise, connected star-star with solidly grounded neutrals, and is provided with a 12.47 kv. delta-connected tertiary winding. This tertiary winding is not used at present, and one corner of the delta is grounded externally. This transformer is provided with on-load tapchanging gear having a range of ± 10% on the 138 kv. windings.

The 138 kv. windings of these transformers are designed with full 650 kv. impulse withstand level. This level was chosen due to operating conditions; voltages as high as 155 kv. may be experienced at the sending end of the 138 kv. system. Lightning arresters with a maximum line-to-ground voltage of 145 kv. rms are provided at each transformer.

The indoor sections of the 13.8 kv. buses between the generator and transformers are rated 2500 amp. and were fabricated on the job. The outdoor sections of this buswork to the transformers were factory-assembled with the three phases housed in one circular enclosure. This section includes a baffle with bushings to form a seal to prevent condensation of moisture in the outdoor section. The impulse withstand level of all sections of the low voltage bus is 110 kv.

The 138 kv. circuit breakers are three-pole, high-speed, air-blast breakers, rated 800 amp., with a symmetrical interrupting capacity of 2500 Mva., and a total interrupting time of 3.5 cycles. The 69 kv. circuit breakers are also air blast breakers and are rated 800 amp., 1000 Mva., 3.5 cycles. Separately mounted 138 kv. and 69 kv. oil-filled current transformers are installed on the line and transformer sides of these circuit breakers. The impulse withstand level of the 138 kv. bus, circuit breakers and current transformers is 650 kv.

Station Service Distribution

Power for station service is distributed at 575 volts. Each of the two station service transformers is rated 750 kva., 13.8 kv.-575 volts, Type ONS, 55°C. rise, three-phase, connected delta-delta, and is provided with off-load voltage taps only. These transformers are installed outdoors on the downstream deck of the powerhouse with the unit power transformers. These transformers are connected to the 13.8 kv. generator buses through disconnecting switches which are capable of breaking the transformer magnetizing current.

The main station service switchboard is of self-supporting, totally-

*Beechwood Kaplan Turbines: Hydraulic and Mechanical Features. L. M. Boyd and W. S. McIlquham. The Engineering Journal, 1959, Feb., p. 56.

enclosed, dead-front construction, and is installed at one end of the low voltage bus tunnel. Air circuit breakers are used throughout for 575-volt power distribution and for starting the 125 h.p. governor oil pumps. Duplicate radial feeders are provided from the main station service switchboard to sub-distribution switchboards located at each generating unit, and in the gatehouse, service bay, and switching station. A separate sub-distribution switchboard is provided in the powerhouse at each generating unit, and each 70-ft. generator bay is supplied with auxiliary power for motors and lighting on a unit basis. Interlocks are provided throughout the station service power distribution system to prevent parallelling of the two main power sources. Single-phase dry type distribution transformers, with 115/230 volt secondaries, are installed for the power supply for lighting, heating and fractional horsepower motors as required in each of the sub-distribution areas.

The total connected load on the station service distribution system is approximately 3,360 kva. Normally, this load is split and supplied from the two station service transformers. In times of emergency this load may be supplied from one transformer only, and demand ammeters have been provided to enable the transformer loading to be regulated.

Control, Metering, and Relaying Equipment

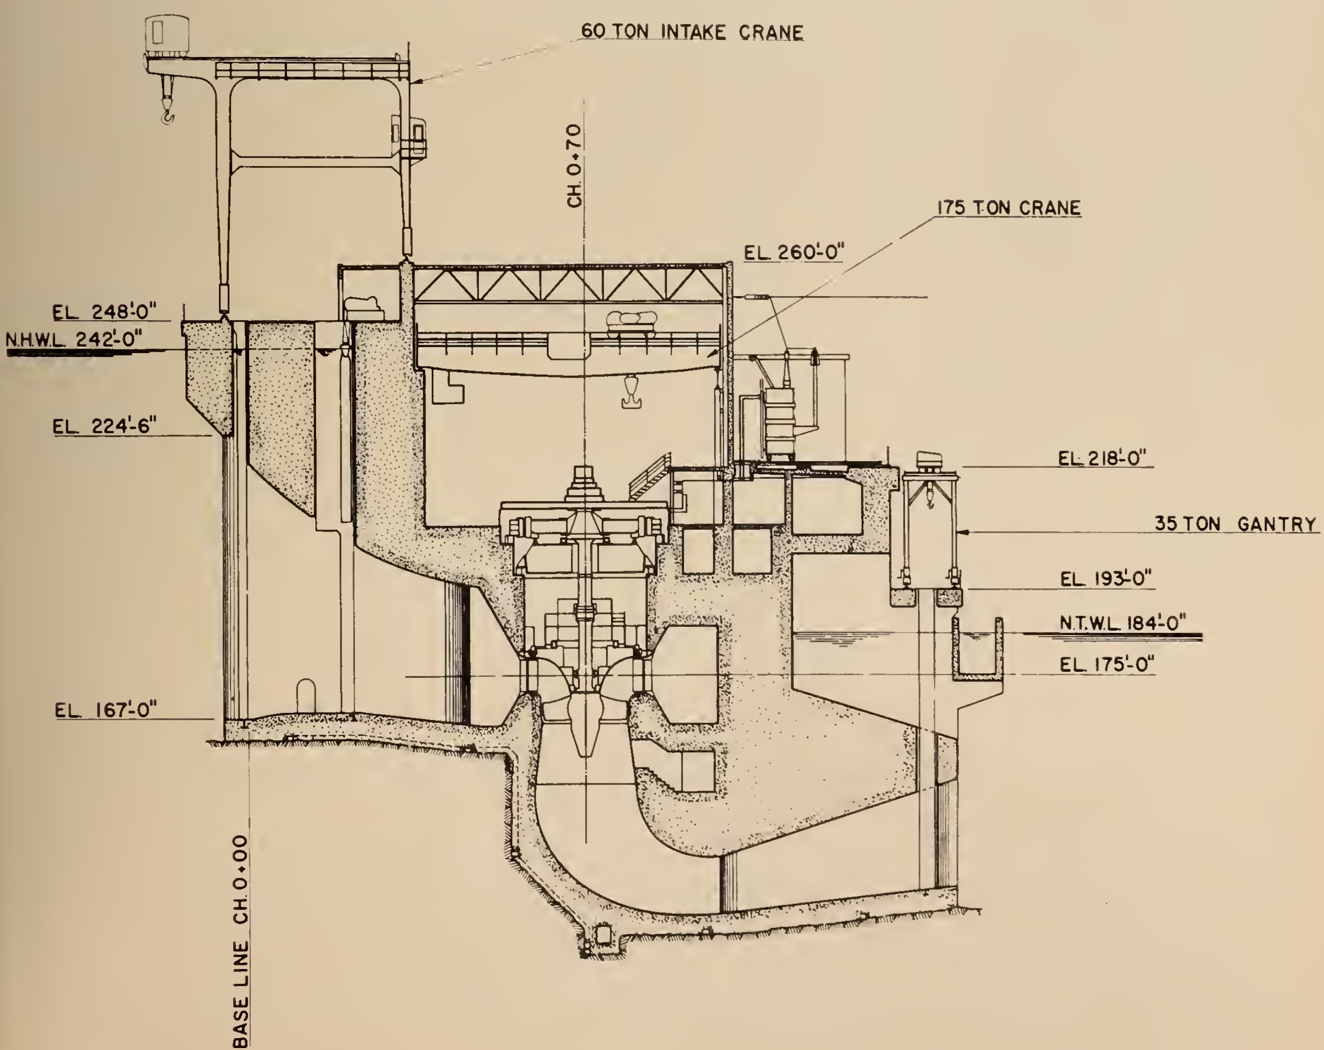
The control equipment is located in two general areas in the powerhouse. The main control, metering, and relay equipment is in the control room on the downstream side of the powerhouse, and the apparatus for generator and turbine control is on the generator room floor.

The control circuitry has been designed so that this station may be operated by a minimum staff. Consequently, all normal operating functions concerning the starting, stopping, and loading of the generators may be performed from the control room by the operator.

In general, all devices and indicating instruments required for the control of generation, synchronizing, and line switching are located on the benchboard in the control room. Two duplex switchboards are provided in the control room. The front panels of these duplex boards contain control equipment and instrumentation not directly associated with the control of generation or the transmission system. The rear panels contain the protective relay equipment for the generators, transformers, and transmission lines. The operator's desk in the control room contains a keyboard for the communication system, switches for the powerhouse signal system, and the station load and frequency control equipment associated with the electro-hydraulic governors.

A generator field cubicle consisting of four cells is provided for each generator and located on the generator room floor. Three of the cells contain the generator and main exciter field circuit breakers, the automatic voltage regulator with its rheostat in the main exciter field circuit, the generator and

Fig. 7. Typical section of powerhouse.



turbine bearing thermometers, and miscellaneous electrical equipment for the turbine and generator control circuits. One cell contains relays and auxiliary devices for the electro-hydraulic governor. Automatic braking has been provided for stopping the units as part of the automatic shutdown sequence.

It is not the purpose of this paper to give a detailed description of all the various features of the control and protective circuits in the powerhouse and switching station, but certain features of more than passing interest are described in some detail.*

Electro-Hydraulic Governors

The turbines for this development are provided with electro-hydraulic governors. Wicket gates and turbine blades are controlled by a hydraulic system which receives its signal from a frequency-sensitive electrical network rather than from a speed-sensitive mechanical element. Briefly, the voltage from the permanent-magnet generator mounted on the generator shaft is fed into a resistance-capacitance circuit which is resonant at system frequency (60 cycles per second). Any deviation above or below normal frequency is thus detected; a raise or lower signal is given to electronic tubes, which in turn power the electrically-operated control valve of the hydraulic servo-system. The actual circuitry of these electro-hydraulic governors incorporates a large number of auxiliary control and protective devices. The disposition of the various components is as follows.

The regulator cubicle, which forms one cell of the field cubicle on the generator room floor, contains the following equipment: the electronic regulator, including the power tubes; relays for protective features, gate locking and gate limiting control; frequency relays; relays for the selection of the damping; rheostat for the speed droop setting; rheostat for the speed-no-load gate setting.

The actuator cabinet on the generator room floor contains the electro-hydraulic control valve which provides the link between the electrical and mechanical systems. The actuator cabinet also contains the following auxiliary equipment: gate position potentiometers; gate limit control mechanism and indicator; gate lock mechanism controls and indicator; electrical tachometer; gate position indicator; start-stop pushbuttons.

*A complete tabulation of protective and alarm functions for generators, transformers, transmission lines, and auxiliary equipment in the station was given with the original paper. A copy of this (Fig. 12) may be obtained from the editor of the Journal.

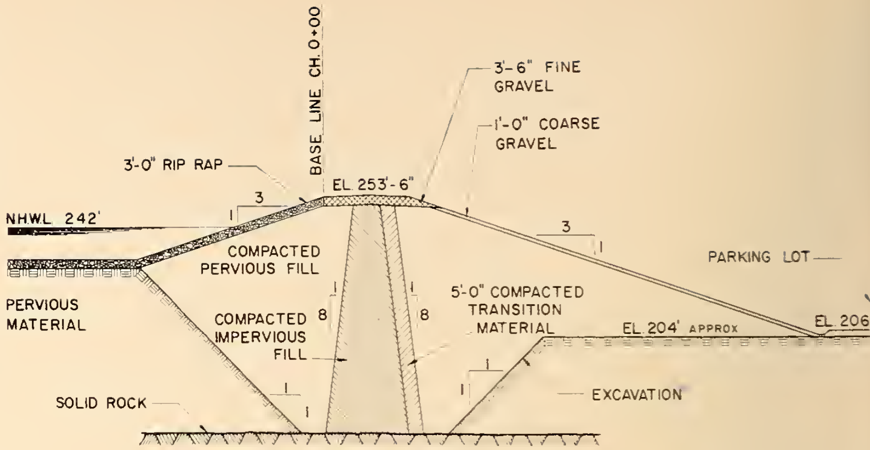


Fig. 8. Typical section of earth dam.

The controls for each governor which may be required by the station operator during normal operation are located in the control room on the benchboard, duplex board, or on the operator's desk. These controls are grouped as follows:

On the benchboard: calibrated rheostat for the power setting for the unit when on individual operation; calibrated rheostat for the frequency setting for the unit when on individual operation; selector switch to adjust the service damping; switches for the control of the gate limit and actuator lock; stop button for complete load rejection; indicating instruments for gate position, gate limit position and tachometer.

On one panel of the duplex board: selector switch and indicator for either individual or joint operation whereby the unit may be operated independently or on station control; selector switch and indicator for the selection of either no load or service damping; balance instrument for the regulating network.

On the operator's desk: All generators in the station may be operated on a station basis, that is, joint operation. The three rheostats required for joint operation are located on the operator's desk and are as follows: a calibrated rheostat for the power setting for the station; a calibrated rheostat for the frequency setting for the system; a calibrated rheostat for the regulating capacity, i.e., station droop characteristics.

Electro-hydraulic governors were selected for this installation only after considerable thought had been given to the requirements for load and frequency control on The New Brunswick Electric Power Commission system. At present, the two units at Beechwood represent approximately 23% of the total generation of the N.B.E.P.C. system with its interconnections. The choice of electro-hydraulic governors was based on the ease with which the operating characteristics of the governors may be adjusted to meet the daily and seasonal requirements for regulation. For each individual governor, the separate adjustment of the speed droop and damping ensures that the proper response may be obtained. Joint operation is readily provided by electrical interconnection of the individual governors within the station and gives a simple and effective control of all units in service. On joint operation, the total power output, frequency, and regulating characteristic for the whole station are easily adjusted with one set of controls, and the units will share the load at all times, even when operated isochronously, that is, with zero speed droop on flat frequency control. It is hoped that these two units, equipped with electro-hydraulic governors, will assist considerably in maintaining system frequency closely without the installation of additional frequency control equipment.

Supervisory Control of the Tobique Narrows Generating Station

The second item of interest is that supervisory control equipment has been installed at Beechwood to exercise remote control of the Tobique Narrows generating station some 17 miles upstream. This supervisory control and telemetering equipment together with the associated power line carrier equipment, was installed prior to the on-power date for the first unit at Beechwood. This enabled The New Brunswick Electric Power Commission to staff the Beechwood generating station with the operators from Tobique.

The supervisory control equipment is installed in the control room at

Beechwood and forms two front panels of one of the duplex switchboards. This supervisory control equipment contains a total of 24 points and gives the operator at Beechwood complete remote control of the Tobique station with its two generators and two 69 kv. transmission lines as follows:

Start and stop each of the two generators (which are provided with automatic synchronizing and speed matching); control the kw. loading on each generator; control and position indication for each of the line circuit breakers; receive alarm indications of abnormal conditions in the Tobique station; raise and lower the Tobique regulating gate.

In addition, "as-called-for" telemetering is provided to give the operator at Beechwood the following instrument readings from Tobique: generator volts; generator kw. and kvar. loadings; turbine gate and load limit positions; headwater and tailwater levels; 69 kv. bus volts.

Continuous telemetering of the Tobique total kw. output is provided at Beechwood, together with an integration of this reading, to give the total kilowatt-hours generated. The equipment at Beechwood also includes a device for retransmission of the Tobique kw. generation to the system dispatch office in Fredericton.

Communication System

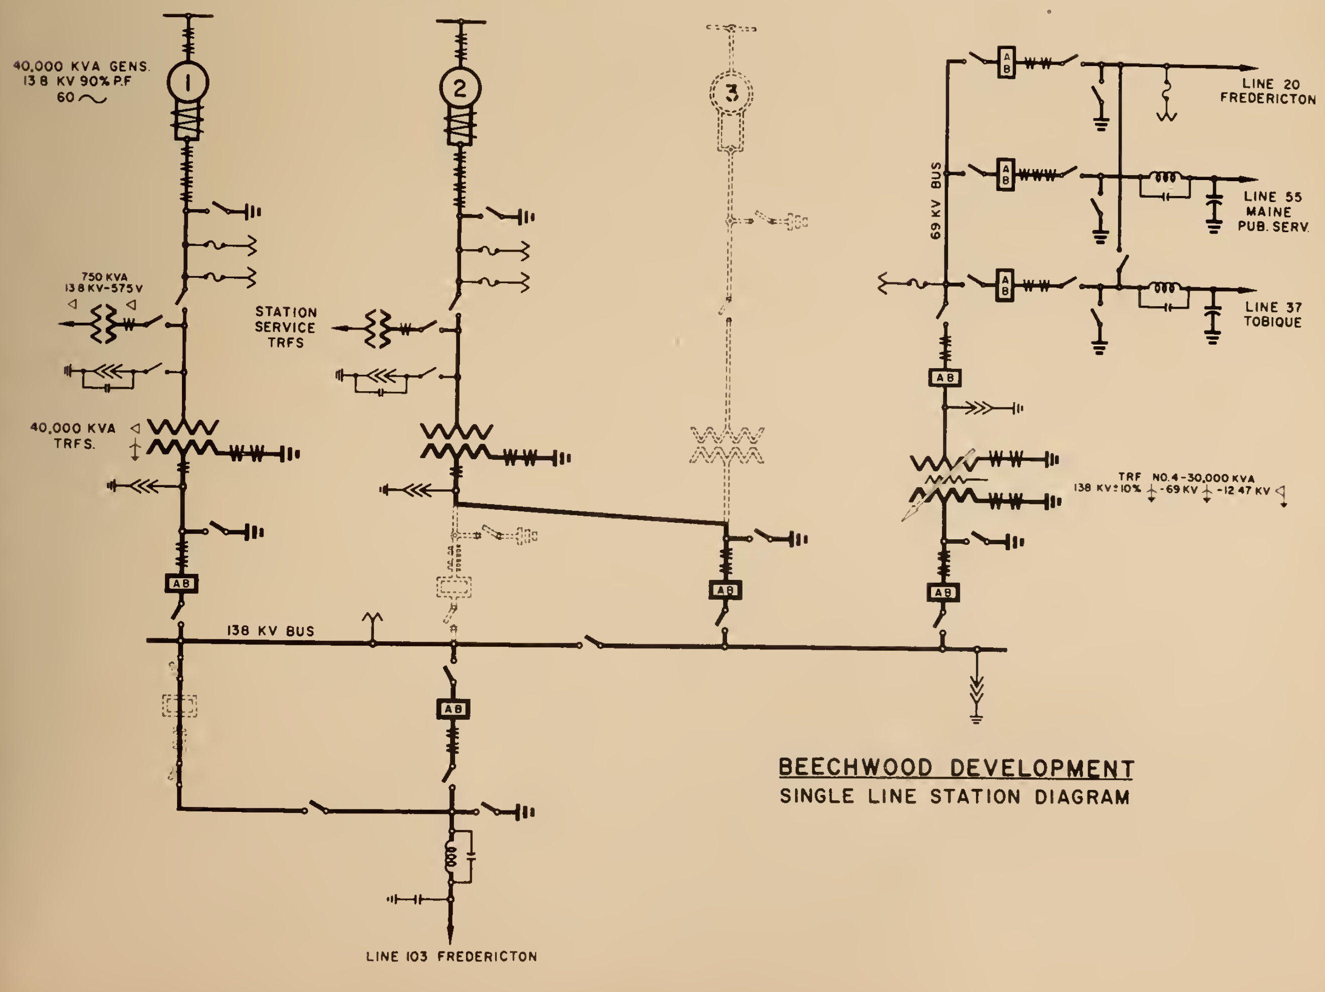
The third item, of interest to power utility engineers, concerns the N.B.E.P.C. communication system, of which Beechwood is the hub for the Upper St. John River Valley. Prior to the system expansion in the years 1956-58, of which the construction of Beechwood was a part, the N.B.E.P.C. relied on commercial telephone service between the various points on their system, except for some mobile F/M radio installations. After considerable study, which included the system expansion for possibly the next 25 years, it was recommended that the N.B.E.P.C. install and operate their own private communication system.

The recommended system utilizes power line carrier for all major links between stations, and is required to provide the following facilities: duplex voice channels for load dispatching, system operation and distribution operational traffic; continuous telemetering; supervisory control; relay protection.

The mobile F/M system is used for local distribution traffic during normal periods, and as an emergency standby to the carrier system when necessary. The commercial telephone system is not regarded as a back-up service to the privately owned carrier system. During severe storms the land lines are considered to be more subject to outages due to mechanical failue than are the power system transmission lines. Delays caused by prior calls on the commercial system could be a factor affecting the restoration of service on the power system in times of trouble.

It will be realized that a large number of carrier frequencies will ultimately be required for such a communication system. In order to accommodate all of the functions required for present and future use, single sideband carrier was selected for this application after considerable study. This choice was based on the need to conserve the number of frequencies required in the 50-200 kc. band, and to avoid interference with

Fig. 9. Single line diagram.



existing carrier installations at present operated by others in the Maritime area.

This communication system is basically a number of radial links emanating from the Fredericton dispatch office. The radial system was chosen as it offered the following advantages: the concentration of approximately one-half of the carrier sets at Fredericton localizes the maintenance to a considerable extent; a point-to-point conversion does not tie up intermediate carrier links unnecessarily; a high degree of privacy is obtained; a great degree of flexibility is obtained which permits future changes both as to frequencies and equipment in the communication network; as new links are established, they may be commissioned without interfering unduly with the carrier sets previously installed.

At both Fredericton and Beechwood, automatic dialling and PAX equipment is installed for all traffic in any direction so that the station operator in the control room is not required to perform the duties of a telephone operator. Fully automatic dialling is possible between all points on the system. A priority circuit is provided to enable the operator to take precedence over all calls and to cut into existing calls at will.

The Beechwood Generating Station is a secondary hub for this communication system for the Upper St. John River Valley. At Beechwood at the present time there are three radial carrier links installed as follows:

Beechwood/Fredericton. This carrier installation provides duplex voice communication and continuous kw. telemetering of both the Beechwood and Tobique outputs.

Beechwood/Tobique. Provides duplex communication supervisory control of the Tobique Station from Beechwood, and continuous kw. telemetering of the Tobique output.

Beechwood/Maine Public Service Company. Provides duplex communication and line relay protection.

All carrier circuits operate with phase-to-ground coupling on the transmission line. Many of the coupling capacitors are supplied with potential devices for synchronizing and metering.

All single sideband equipment is of the "reduced carrier" type operating with magnetostrictive oscillators. The equipment has a maximum output of 20 watts for the transmitter upper sideband and 0.8 watt for the carrier.

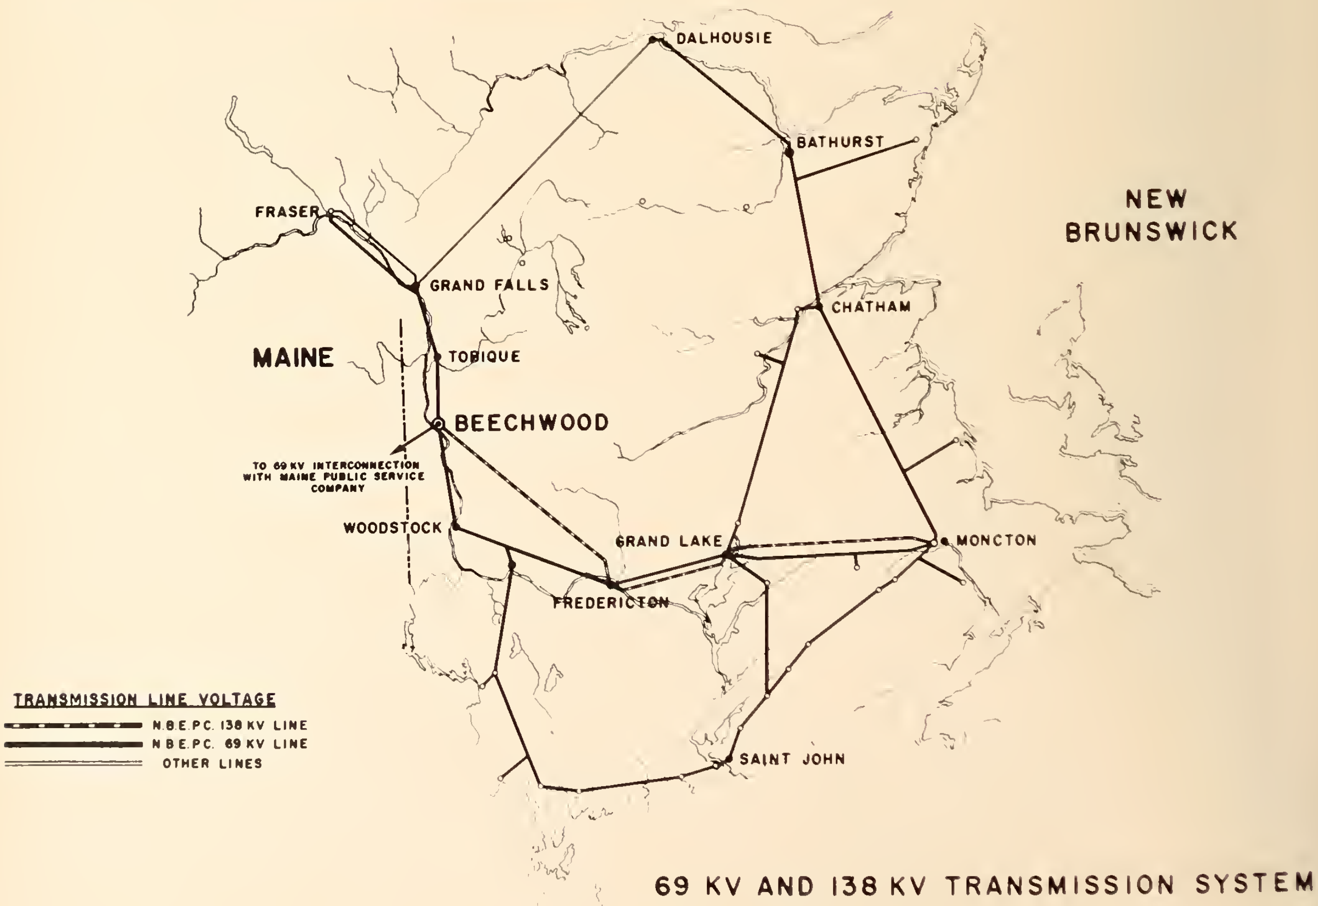
Draft Tube Evacuation and Spinning Reserve

The fourth item of interest is the provision for the evacuation of the water in the draft tube for the automatic "motoring-generating" changeover scheme.

In principle, this scheme has been provided so that either unit, when not required for kw. generation, may be operated as a synchronous condenser with an automatic spinning reserve feature. The unit will revert to generator operation automatically when required by system frequency conditions.

To explain this operation, assume that a unit is operating as a generator. To change over to synchronous condenser operation, the operator in the control room must first close the turbine gates, using the manual control switch. The operator then moves a selector switch to the "motoring" position. Two solenoid-operated valves, size 6 in. and 2 in. respectively, then open and introduce compressed air

Fig. 10. 138 kv. transmission system.



into the draft tube to depress the tailwater to a level below the runner blades. At this point the 6 in. valve closes. The 2 in. valve remains in the circuit to regulate the water level and admits additional air to make up any air leakage. The unit is now connected to the system, is running as a synchronous condenser, and may be used to supply reactive power if required. Should a sustained drop in system frequency occur to approximately 59.5 cycles for some three seconds (adjustable within the range of 1-5 seconds) indicating a deficiency of generation on the system, then a signal is given to the electro-hydraulic governor which opens the turbine gates fully. The air in the draft tube is carried out by the incoming water, and the full out-put of the generator is made available to the system in some few seconds. Upon restoration of system frequency to 60 cycles, normal governor action takes over and regulates the unit loading and frequency automatically.

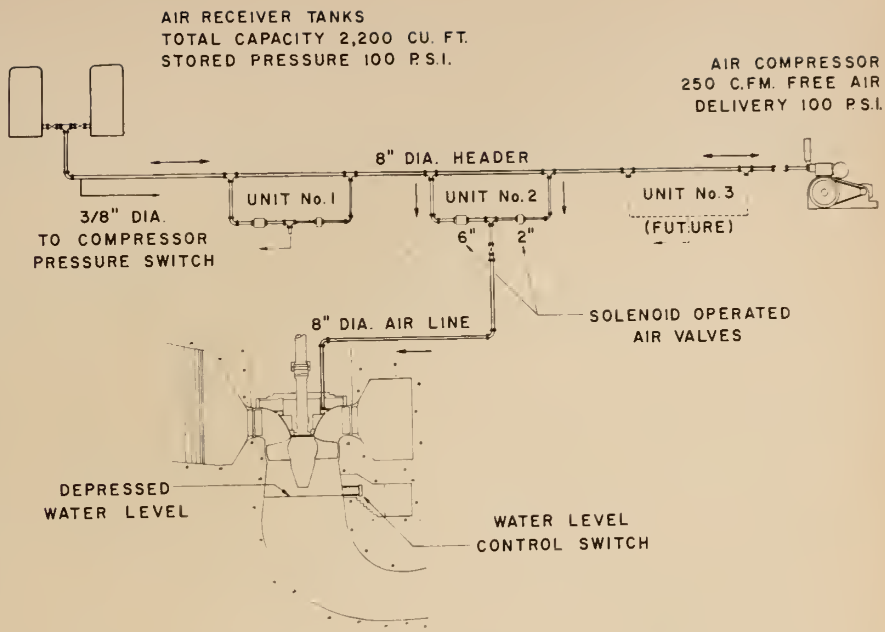


Fig. 11. Schematic diagram, piping and valves draft tube water depression system.

With this scheme a unit cannot be motored until the compressed air storage tank is fully charged, which requires approximately one hour. If the compressed air in the storage tank is insufficient to depress the draft tube level fully, a pressure switch on the tank actuates a "do not motor" warning in the control room.

The schematic diagram of the piping and valve arrangement for the draft tube water depression system is shown in Fig 11. The system is supplied by a 250 c.f.m. compressor discharging at 100 p.s.i. Air storage is provided by two receivers with a total volume of 2200 cubic feet. The volume stored at 100 p.s.i., when expanded to the draft tube pressure of approximately 12 p.s.i., is 20% greater than that required to depress the draft tube water level clear of the runner. This additional capacity is required to compensate for any loss of air due to leakage or due to the churning action of the blades during the initial blowdown.

The units are served by an 8 in. diameter header which runs the length of the station in the piping gallery. The air is discharged at each unit through the 6 in. and 2 in. quick-opening solenoid-operated air valves referred to previously. The air is passed from the valves through an 8 in. airline to the turbine head cover, through which it is admitted to the draft tube. These solenoid-operated valves for each unit are controlled by a water level switch attached to the draft tube liner adjacent to the draft tube access door. This switch contains four electrodes set at elevations 156 ft. 2 in., 156 ft. 6 in., 156 ft. 9 in. and 157 ft. 0 in. When the water level is depressed to elevation 156 ft. 6 in., the 6 in. valve closes and air continues to be supplied through the 2 in. valve, which is controlled in the "close" and "open" positions by the electrodes at elevation 156 ft. 2 in. and 156 ft. 9 in. respectively. The lowest part of the runner hub is at elevation 158 ft. 3 in. The electrode at elevation 157 ft. 0 in. is used for alarm purposes. The time required to depress the water level in the draft tube is a little less than one minute.

Protective Relaying

The protective relaying for the 138 kv. and 69 kv. transmission lines should also be mentioned as an item of interest. As noted previously under "Communication System", the construction of Beechwood was a part of the system expansion in the years 1956-58. During this period, the first 138 kv. transmission lines were placed in service between Beechwood, Grand Lake, and Moncton. In planning the protective relaying for this new high voltage transmission system, emphasis was placed on the need to standardize the protective relays for all new 138 kv. lines. In addition, it was necessary to equip many of the existing 69 kv. lines with new protective relays, as these lines would now operate in parallel with sections of the 138 kv. system. The same emphasis was placed on standardizing the protective relays for these 69 kv. lines. Extensive studies were made to determine the types of relays best suited to these applications. The types of relays thus selected, together with the basic relay circuitry, were then applied to all new 138 kv. lines and revisions to the 69 kv. lines on the N.B.E.P.C. system. Subsequent to this study, it was found necessary to depart slightly from these principles of standardization and utilize two types of distance relays, the selection of the relay type being dependent on the length of the line

Thus the 138 kv. line at Beechwood is provided with the following protective relaying: 3-stage directional reactance-measuring distance protection for phase-phase faults; 3-stage directional reactance-measuring distance protection for phase-ground faults; directional inverse-time overcurrent standby protection for phase-phase faults; directional inverse-time overcurrent standby protection for phase-ground faults.

Similarly, the three 69 kv. lines at Beechwood are provided with the following protective relay equipment: 3-stage directional reactance-measuring distance protection for phase-phase faults; directional inverse-time overcurrent protection for phase-ground faults; non-directional inverse-time overcurrent standby protection for phase-phase faults.

These relaying schemes were selected and specified for several reasons.

(continued on page 73)

BEECHWOOD KAPLAN TURBINES

Hydraulic and Mechanical Features

W. S. McIlquham, M.E.I.C., *Hydraulic Engineer, Hydraulic Division,*

L. M. Boyd, M.E.I.C., *Chief Engineer, Hydraulic Division,*

Dominion Engineering Company Limited

THE GENERATING equipment of the Beechwood development of the New Brunswick Power Commission consists of two vertical Kaplan turbines each rated at 45,000 h.p. under a net head of 57 feet at 109.1 r.p.m. Provision has been made for the addition of a third unit. These machines with a throat diameter of 18 ft. 4 in. are the largest Kaplan turbines in operation in Canada. They are also the first load responsive adjustable blade turbines to be designed and built by the authors' Company.

HYDRAULIC FEATURES

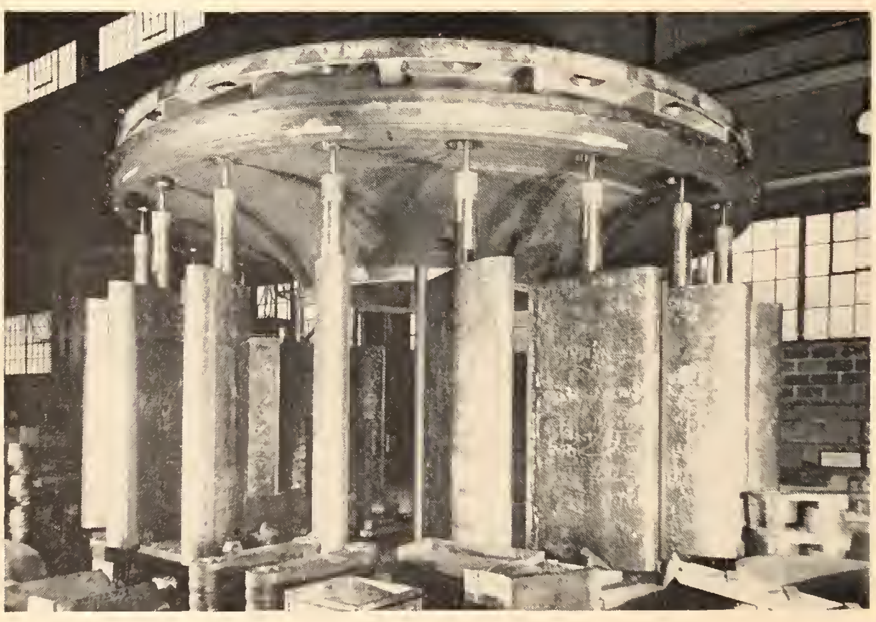
Model turbine equipment was tested in the hydraulic laboratory to determine the characteristics of the turbine to be manufactured for Beechwood. Several model runners and associated equipment were made and tested. The information obtained is presented in the form of curves plotted from the model tests.

Hydraulic Laboratory—Test Stand No. 1

Figure 1 shows model turbine test stand No. 1 with Kaplan type runner assembled.

In this open tank arrangement is installed a semi-volute case with a short intake section, a 10-vane stay ring, 20 wicket gates, elbow type draft tube and the model Kaplan runner designed for the Beechwood turbine. Under a head of 10 feet in the test stand, the performance characteristics of the model turbine are determined by measuring the discharge by means of a weir, the torque by means of a torque meter and the RPM by means of an electronic counter.

Lowering head cover into position on wicket gates



Characteristics of Kaplan Model Runner D-141-5

On the hill chart of Fig. 2 the performance characteristics of the model turbine, as determined by the tests carried out in test stand No. 1 (Fig. 1.) are consolidated and plotted.

On the abscissa is ϕ, the speed ratio, i.e.

$$\phi = \frac{\text{linear velocity at the throat diameter of the runner}}{\sqrt{2gh}}$$

and on the ordinate, HP_{11} (at best efficiency), i.e. unit horsepower or horsepower for a runner with a throat diameter of 1 foot operating under a head of 1 foot.

The model testing is done with a runner having a throat diameter of 16.326 in. and the HP_{11} values are calculated and plotted.

The rated horsepower for the Beechwood turbine is calculated from Fig. 2 as follows:

Rated horsepower

$$= HP_{11}\,(D)^2\,(H)^{3/2}$$
$$= 0.31\,(18.333)^2\,(57)^{3/2}$$
$$= 45{,}000 \text{ HP}$$

The test procedure is with the runner blades locked in the hub as a fixed blade runner, and several tests are required to obtain the performance as a Kaplan. In this instance six separate tests were run as indicated by the lines marked "A" = 0.50 to "A" = 3.00. This "A" dimension is a measure of the pitch or angle of the runner blades.

The lines for wicket gate angles and runner "A" dimension show these values to obtain best efficiency at the corresponding ϕ and HP_{11}.

Contours of best efficiency are plotted.

The Ns or specific speed lines are calculated by the formula $Ns = 153.2\phi \sqrt{HP_{11}}$ and are plotted as a ready reference.

Runaway Characteristics with Data for Beechwood

On the hill chart Fig. 3 are plotted the runaway speed characteristics of the model runner.

With the runner blade pitch or "A" dimension as the abscissa and the wicket gate angle as the ordinate, contours of runaway phi are plotted by the full lines. These contours show that the maximum runaway ϕ is obtained with the runner blades at 1.5 "A" dimension and approximately 49° wicket gate angle.

On the right hand side of this chart are tabulated data relating to Beechwood turbine operation.

(1) "Normal speed. ϕ versus H, turbine at 109.1 r.p.m." Here the effective heads and the corresponding ϕ values are tabulated for the turbine operating at the normal speed of 109.1 r.p.m.

Thus, in order to synchronize the turbine, the runner blades will be at the flat angle or at "A" dimension 0.50 and depending on the head the wicket gate angles required will be approximately 6° for 65 feet head and 11° for 35 feet head, at speed no load.

(2) "Runaway speed, turbine on cam, ϕ versus H". Here, for the effective heads tabulated, the corresponding ϕ values at runaway vary with the wicket gates and runner "A" dimension maintained on cam relation. This variation in the ϕ at runaway is shown by the broken lines.

The r.p.m. at runaway can be calculated by the ratio of the normal ϕ to the runaway ϕ. For Beechwood, the estimated maximum runaway speeds as calculated are as follows:

	Runaway Speed	
Head	*On Cam*	*Off Cam*
ft.	*r.p.m.*	*r.p.m.*
65	210	240
57	191	223

Hydraulic Torque on Runner Blades—Model

On the hill chart Fig. 4 are plotted the hydraulic torque characteristics on the blades of the model runner. In order to obtain the torque on the runner blades, special hydraulic controls and mechanical linkage were assembled in the runner hub. The required data were obtained from the tests by photographing instruments arranged on a panel, indicating: servomotor pressures, runner blade movement and wicket gate movement. With the runner blade "A" dimension as the abscissa and the wicket gate angle as the ordinate, contours of hydraulic torque are plotted at runaway ϕ for a head of one foot.

Zero torque indicates that the runner blades are in hydraulic balance.

The maximum torque tending to open the runner blades was obtained with the runner "A" dimension at 1.70 and the wicket gate angle of 50°.

Hydraulic Torque on Runner Blades — Beechwood

On Fig. 5 is shown the hydraulic torque on the runner blades of the Beechwood turbine under variation in head, for normal operation and at runaway, as calculated from the model test data.

(i) Normal operation on cam (109.1 r.p.m.). The variation in torque for the full range in power or runner "A" dimension is shown by the two full lines (1). At the design head of 57 feet the runner blades are very close to being in hydraulic balance for the full range in power.

(ii) Runaway operation *on* cam. The variation in torque for the full range of runner "A" dimension is shown by the two broken lines (2).

The magnitude of the hydraulic torque tending to open the runner blades under the rated head of 57 feet shows a maximum 12 times greater at runaway r.p.m. than at normal r.p.m.

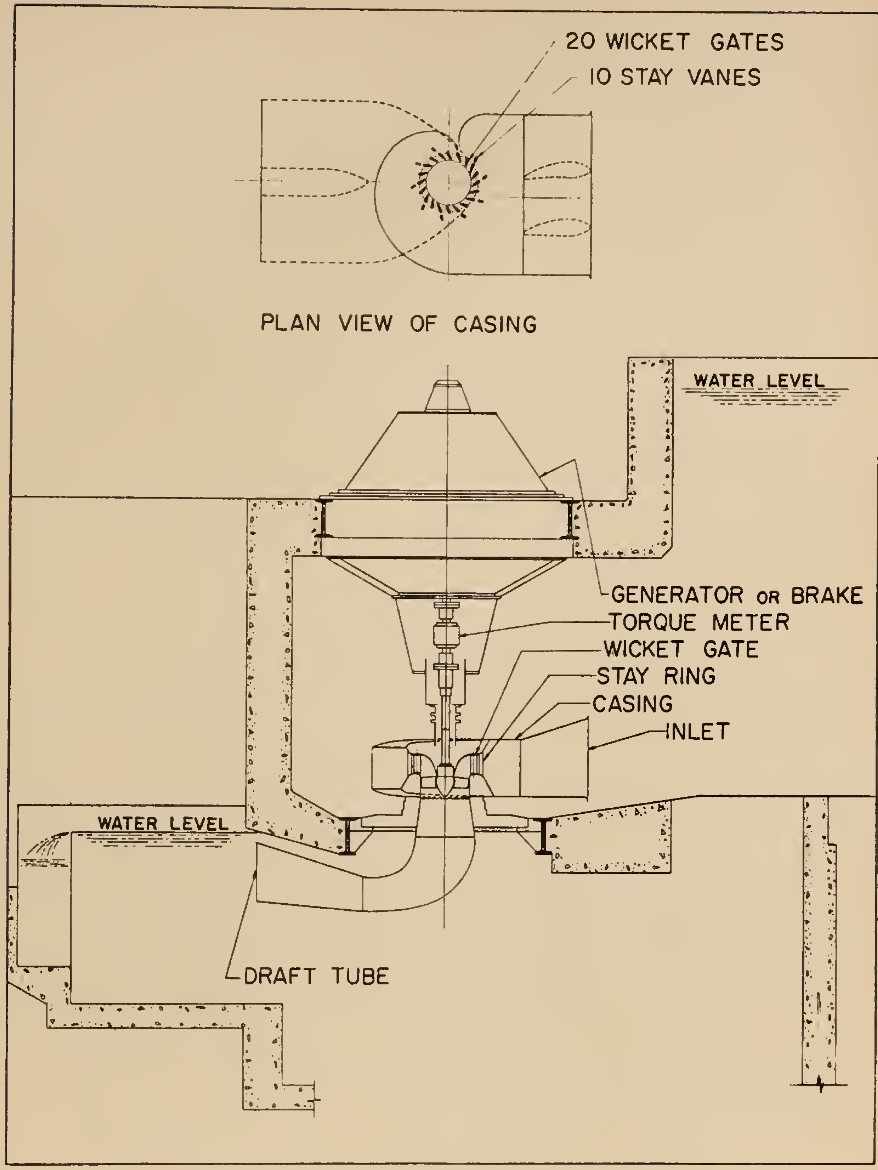


Fig. 1. Hydraulic laboratory—test stand no. 1.

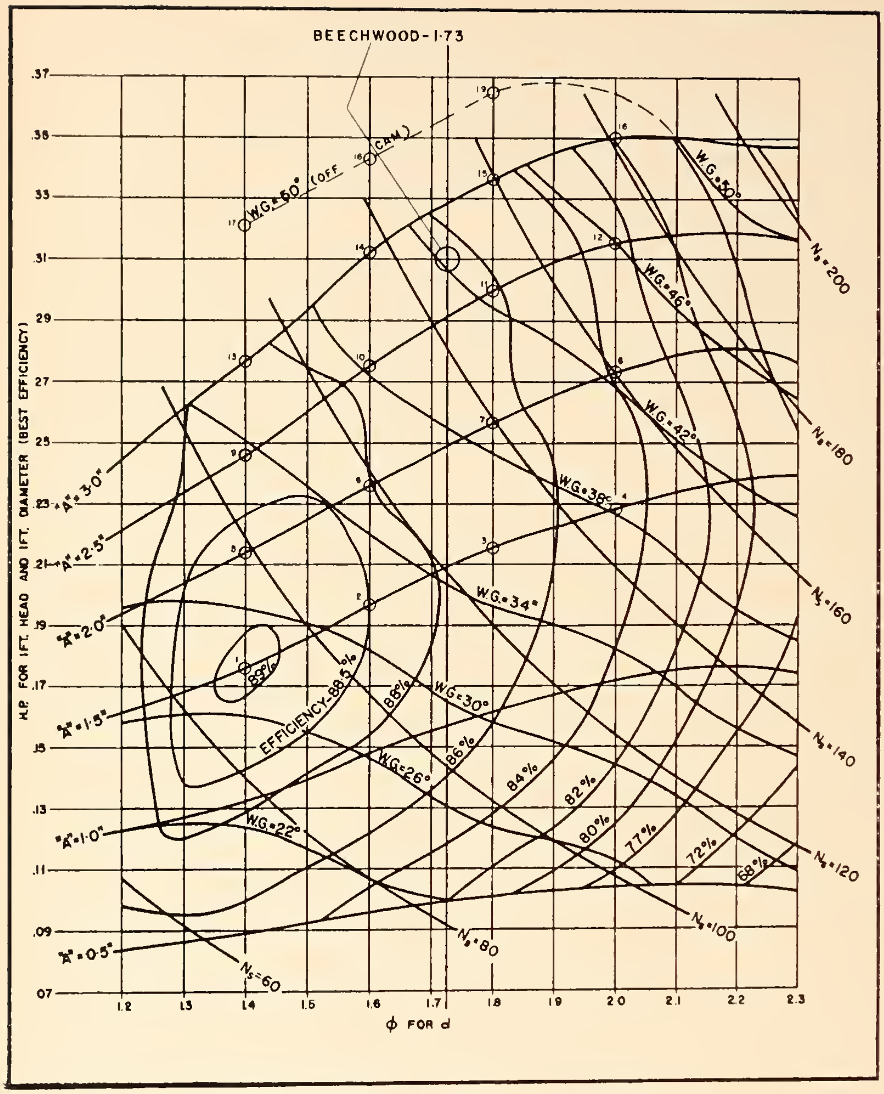

Fig. 2. Hill chart—model Kaplan runner.

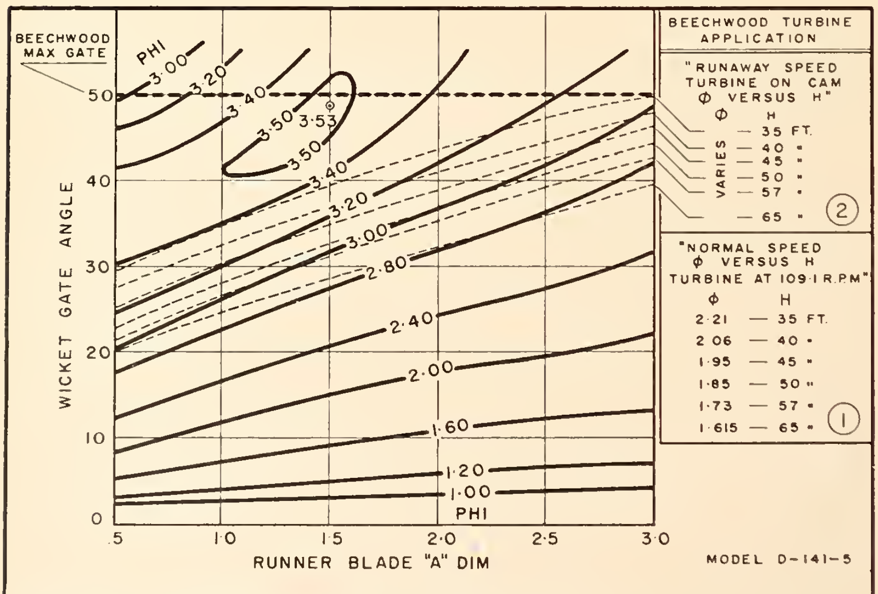

Fig. 3. Runaway speed ratio—model runner.

(iii) Runaway operation *off* cam. The maximum torque for full gate (50°) and the runner "A" dimension to produce maximum ϕ is shown by the top full line (3).

Beechwood Turbine Setting

Figure 6 shows the turbine setting; i.e., the elevation of the runner in relation to the tailwater elevation and the total head. The variation in the effective head as shown was estimated from the change in the tailwater elevation.

The sigma factors were calculated by the formula

$$\sigma = \frac{h_b - h_s - h_v}{H}$$

as detailed on Fig. 6. It will be noted that, for the turbine rating at 57 feet head the sigma factor is 0.8. This is based on the elevation of the runner axis 168.13 and the tailwater elevation at 180.7.

Sigma and Cavitation Characteristics of the Model Runner

In the cavitation laboratory the model runner was tested to obtain data showing:

(1) The sigma characteristics by measurements.

(2) The cavitation phenomena by photographs.

The photographs showed the model runner in operation over a sigma range from high values where no cavitation phenomena are visible to low values including that at the sigma break, i.e. the break in the $HP_{11} - \sigma$ curve, and beyond the break. The cavitation phenomenon showed clearly as it developed from incipient to a maximum with the change in sigma.

On the hill chart Fig. 2 the points (HP_{11} ϕ) at which the sigma and cavitation characteristics were tested, are identified by numbers (1 to 19). Points were selected to show the HP_{11}—σ curves, i.e. the change in HP_{11} with the change in σ.

Colour photographs were superimposed on the sigma curves to show the appearance of the runner in operation at the values of sigma indicated. The photographs were taken in colour to give better contrast and definition, and to facilitate the study of the cavitation phenomena and the effects of changes in blade design.

Beechwood Turbine—Estimated Performance

Figure 7 shows the estimated h.p. —efficiency curve at the rated head

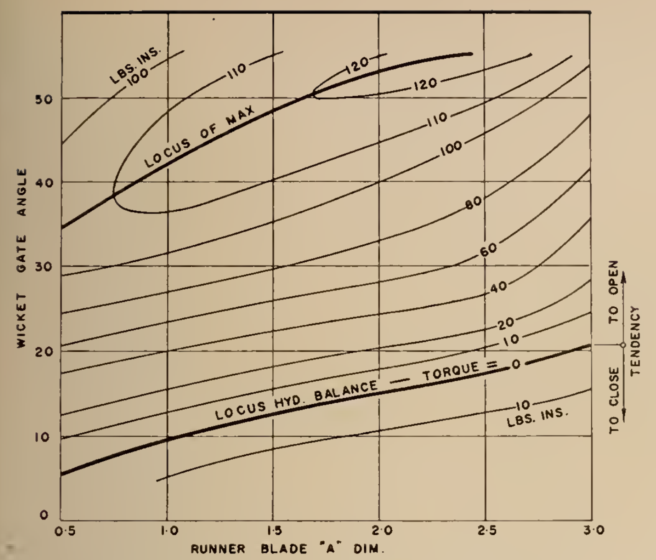

Fig. 4. Hydraulic torque on the blades of the model runner.

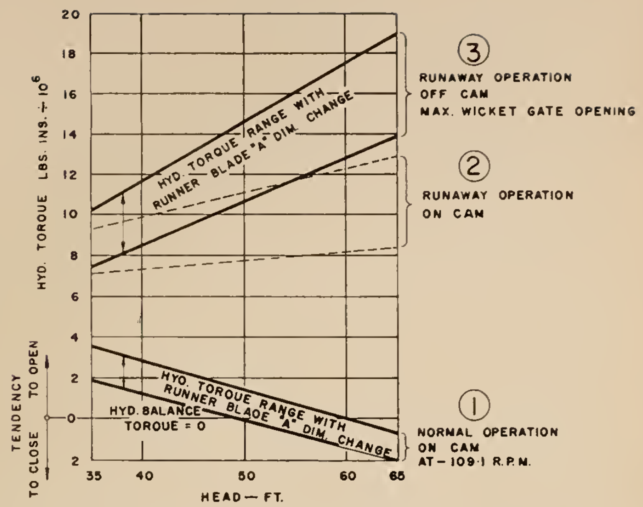

Fig. 5. Hydraulic torque on the runner blades estimated for Beechwood.

of 57 feet. Superimposed photographs showing the appearance of the model runner operating under equivalent field conditions of h.p., ϕ, and sigma, indicated the absence of visible cavitation phenomena for Beechwood operation.

Model Equivalents for Beechwood Turbine Performance

Figure 8 shows the model equivalents of HP_{11} and efficiency and the sigma curves which apply to the Beechwood turbine at rated head of 57 feet, i.e. $\phi = 1.73$. The sigma value at this head is 0.80.

MECHANICAL FEATURES

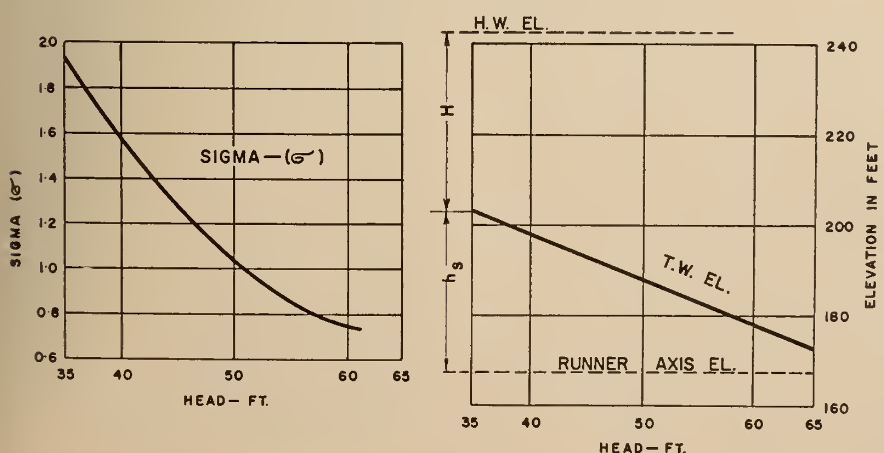
The mechanical design was largely conventional, with several minor departures. Throughout we drew heavily upon our experience with fixed blade turbines and manually controlled adjustable blade wheels.

Of particular interest are the selection and distribution of various materials throughout the machine. Steel castings, steel weldments, and iron castings all have their own merits and limitations. At the time of designing for Beechwood, all materials were becoming readily available. With our own steel and iron foundries, and with the extensive fabricating facilities of our associates to draw upon, our designers were not restricted. For each part the selection was based upon what were considered to be the most suitable inherent qualities. As will be seen, all three materials were freely used.

General Description

A concrete casing of the semi-spiral type leads the water from the upstream face of the power house to the turbine distributor. A concrete elbow type draft tube discharges the water into the tailrace.

Fig. 6. Beechwood turbine setting.



A cast steel stay ring of 7 ft. 4 in. distributor width with ten welded steel stay vanes carries the superimposed loads of the concrete, machinery, and hydraulic thrust, and directs the flow of water into the wicket gates. Twenty cast steel wicket gates control the speed of the unit.

The head cover is of cast iron in three main parts, the outer, inner and lower sections. The outer and inner sections are further sub-divided to facilitate manufacture and handling. The bottom ring is of cast steel and divided into sections.

Cast iron servomotors mounted in a fabricated steel pit liner operate the wicket gates through a conventional arrangement of links, levers, and a cast steel operating ring.

The throat ring is partly spherical in form, of pressed fabricated plate steel construction, machined in sections for handling. A cylindrical upper portion permits withdrawal of the runner. The spherical lower portion hugs the runner, minimizing leakage past the blade tips.

The draft tube liner is the simple conical type of fabricated steel extending 22 feet below the centreline of the turbine distributor.

The runner consists of five cast steel blades with integral trunnions mounted in a cast steel hub. Bronze bushed bearings carry the hydraulic and mechanical loads. A system of links and levers guided by a crosshead operates the blades under forces supplied by the blade servomotor mounted in an enlargement in the main shaft at the generator flange. The whole mechanism is flooded in a light oil topped up through the oil head. The runner is protected by a welded overlay of 18-8 stainless on the back of the blades in areas subject to cavitation and on the tips of the blades by a one-half inch stainless steel strip welded into position.

The shaft is of steel with integrally forged coupling flanges on each end including an enlargement at the generator end for the blade servo cylinder. An undercut enlargement near the lower flange provides a journal for the main bearing. Carbon segments, running on a stainless sleeve on the shaft, seal the head cover against leakage.

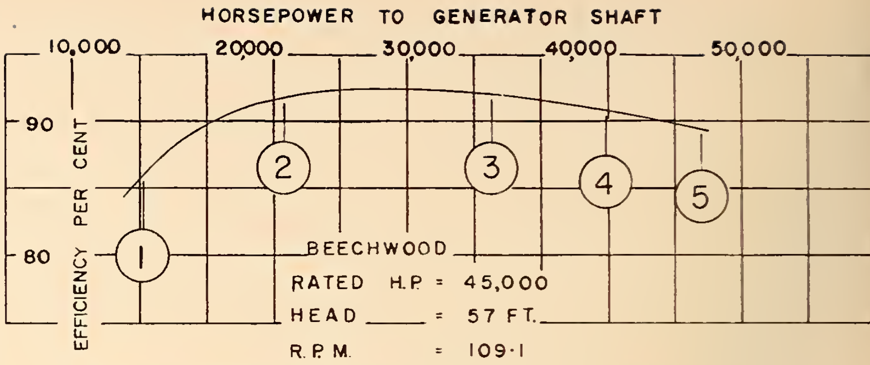


Fig. 7. Beechwood rating, HP-eff. curve HP_{11}-eff. and HP_{11} curves.

An oil bearing of the self-lubricated type with self-contained sump mounted in the lower head cover centralizes the wheel. A.C. and D.C. sump pumps protect the bearings against any water which leaks into the head cover past the shaft seals.

The oil head is mounted on the exciter frame above the generator. Oil from the governor is conducted through the governor oil piping and a system of stuffing boxes, and co-axially piped within the generator shaft to the blade servomotor. Movement of the blades is carried by means of a rod within the co-axial pipes in the generator shaft to the oil head where it is transmitted to the governor through a series of quadrants and cables. A small reservoir of oil at the top of the head maintains a static pressure on the oil in the runner hub.

Each unit is regulated by an electro-hydraulic governor. The gates are operated by the main servomotors in response to a speed-sensitive governor. The blades in turn are actuated by the blade servomotor, in response to movements of the wicket gates, through a cam in the actuator. The cam is three-dimensional, allowing manual adjustment of the cam action to suit seasonal changes in the effective head on the turbine.

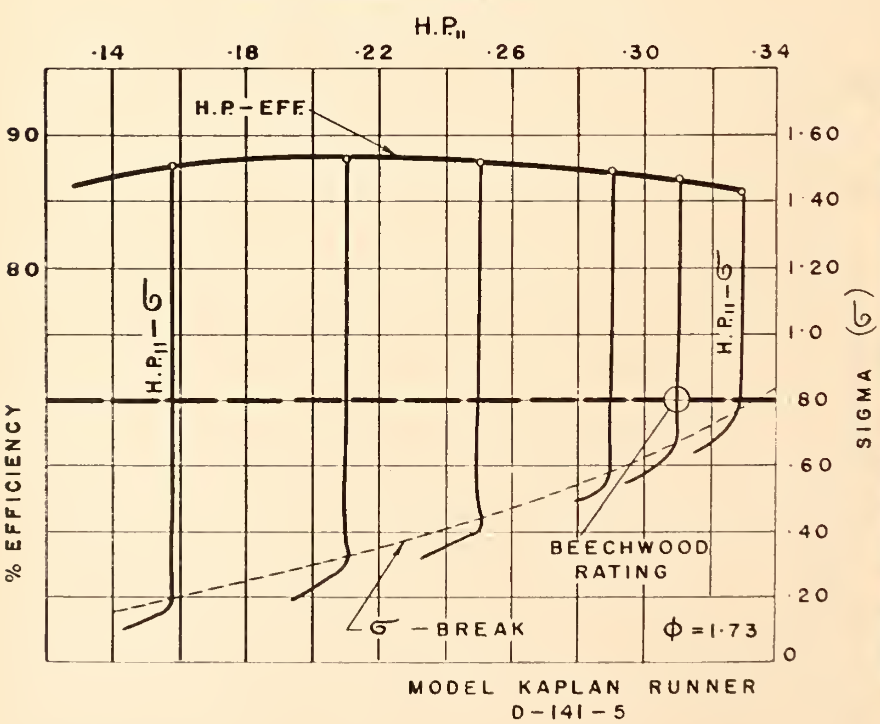
Unique Design Features

From the above description, the unit may be considered as rather conventional. However, several innovations were incorporated in the design.

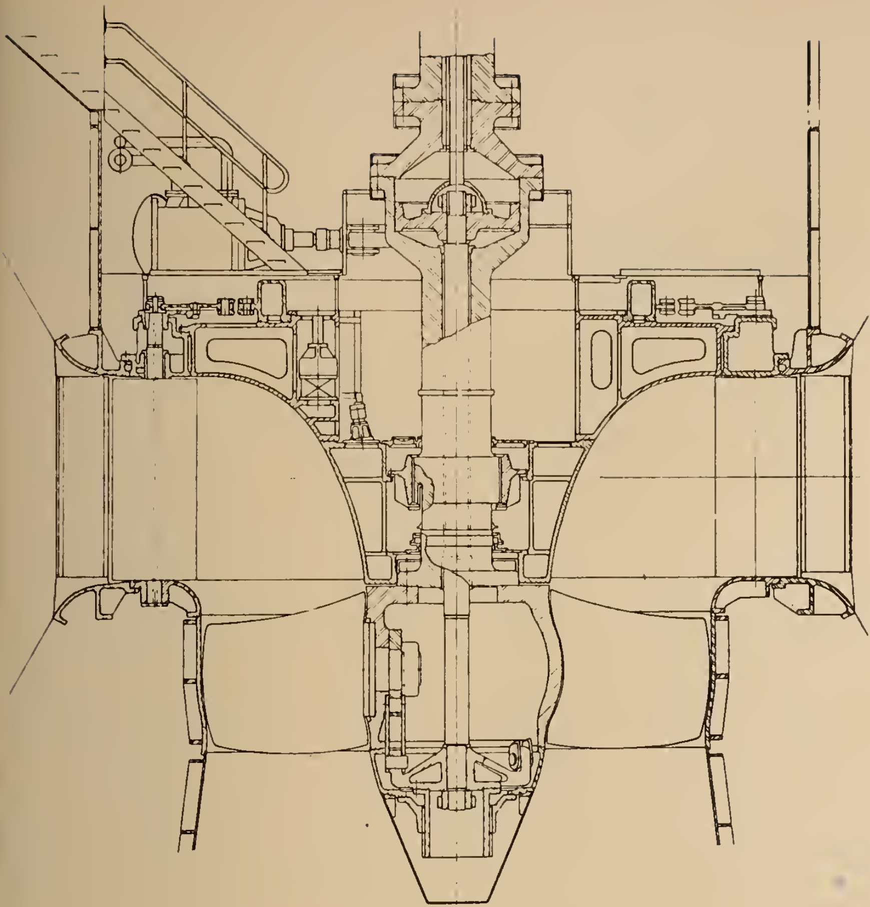
The crosshead in the runner hub, which prevents rotation of the spider under lateral forces of the levers and yet permits vertical motion in response to the blade servomotor, is a steel involute spline operating in a mating bronze guide. These splines were machine cut with conventional stock gear cutters. They provide an illustration of an application where advantage can be taken of the low cost and high precision inherent in gear cutting operations.

One of the most successful innovations was the design of the seals between the wheel blades and the hub. Kaplan wheels have long been plagued by leakage at this point. The problem is to keep the lubricant in the hub and water out by means of a packing which will not set up objectionable braking torque on the relatively large diameter of the blade trunnions. The problem is complicated by the fact that the packing is inac-

Fig. 8. Beechwood equivalents at rating.



Turning runner in shop after installation of blades



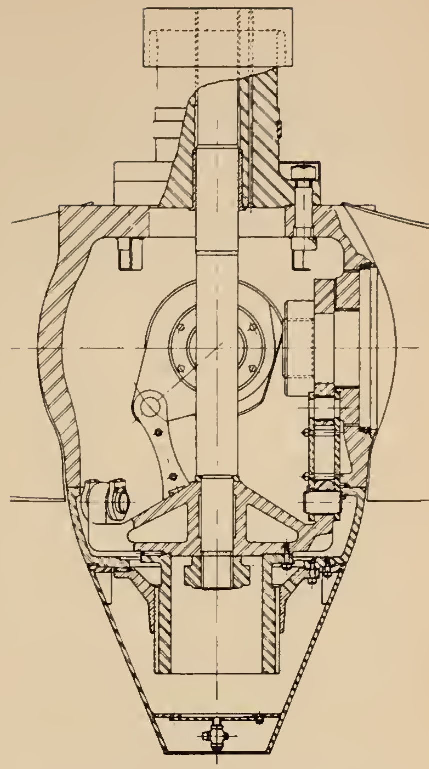


Fig. 9. Beechwood turbine — sectional elevation.

Fig. 10. Beechwood turbine hub section.

cessible and not easily adjustable. Furthermore, the design must permit replacement of the packing without the tedious and costly dismantling of the wheel.

Many existing designs were reviewed and discarded after elaborate laboratory tests. It was found that in most arrangements the packing was very sensitive to adjustment, and the margin between acceptable limits of leakage and friction was small. Further, the swelling of the packing due to absorption of oil or water usually quickly altered the original adjustment and friction became prohibitive.

The solution finally accepted was simple. Two round rubber rings placed between the blade and hub, separated by a lantern ring vented to the lower side of the blade, provided the seal. The design might have been further simplified by the use of a single ring, but the complex variation in water pressure around the blade stem defied laboratory analysis and the two-ring design was selected as being good insurance of performance.

The round rings under very slight initial compression gave surprisingly low friction. The arrangement provided ample space for swelling resulting from absorption of oil and water. It also provided for easy replacement without removing a blade by the use of a simple vulcanizing kit. The seal has met every expectation from the point of view of both friction and leakage. There has been no evidence of water in the hub, and in the early stages oil make-up was limited to one gallon a week.

The blade bearing design is not usual in North American practice. Each blade is carried on a single journal while the bending moment of the water load on the blade is resisted by two opposed thrust faces acting parallel to the axis of the blade. Advantages of this design are not conclusive. The short blade stem arrangement offered some gain in foundry practice and provided more space in the centre of the hub. It was also the arrangement successfully used in the past in several manually-controlled adjustable-blade propeller wheels.

The oil head was conventional in every respect, and we were surprised when trouble developed in two forms. An unpleasant bumping was felt in the head during certain phases of governing, and air sometimes entered the governor oil lines. Air entry was found to be due to a vacuum produced at the head by the unusually low level of the sump. The cause of the bumping was traced to an unbalanced thrust in the head due to different packing diameters in the oil lines leading to the blade servo. This thrust reached, under certain oil pressures, a value of 13,000 lb. uplift. Through a flexing of the exciter supporter beams, this uplift produced a movement estimated as 0.045 in. which registered on the feedback to the governor as a false blade movement. The prompt governor response and resulting change of thrust on the head caused sharp movements and hunting of the blades until a neutral position was obtained. A short series of sharp bumps on the platform was the result.

The existing head was replaced by a new design with balanced packing diameters to eliminate the deflection caused by changing oil pressures. Low-pressure oil lines were led to lantern rings between two sets of packing in each gland to prevent entry of air at sub-atmospheric pressures.

We still wonder why this trouble has never been reported before. Perhaps these problems are always pres-

Methods and Trends in

AUTOMATIC COMBUSTION CONTROL

K. D. Sheldrick, *Sales Manager, District Operations,*

Bailey Meter Company Limited

Automatic combustion control is defined, and examples are given of basic control layouts for oil- and gas-fired boilers, with some methods used in combination fuel firing. Further examples include controls for a large-capacity unit and simplified control systems for package boilers. Components common to these systems are reviewed. New trends in techniques have emerged: (a) as regards solution of the control problem; (b) as regards presentation to the operator. Two fields of research are discussed briefly, and their significance for future controls mentioned. The paper finally examines some of the human factors involved.

AUTOMATIC COMBUSTION Control may be defined as an automatic system which: (1) proportions fuel and air supplies for optimum overall economy throughout full operating range; (2) maintains steam pressure constant; (3) assures correct gradient of pressure conditions from combustion chamber through to stack; (4) notifies and records operating faults; and (5) incorporates centralized means for manual control and smooth transfer to automatic. It may also provide furnace purge, and fan and flame failure interlocks. The automatic control of boilers includes several other problems such as feed water control, steam temperature control, etc., which, however, may not be dealt with in a paper confined to combustion control.

Figure 1 is an automatic combustion control layout typical of applications to oil-fired boilers of capacities 15,000 to 250,000 lb./hr. Fuel and air supply are regulated in parallel from steam pressure, but with a refining correction of fuel from the ratio between air flow and metered oil input.

The area meter, transmitting either pneumatically or electronically, is the oil metering device employed, and where there is continuous oil return two transmitters are arranged for subtraction. This is the preferred arrangement when burning oil alone, but for the smaller boiler capacities, provision of the oil meter is often avoided by applying to air supply a refining correction from the steam-flow/air-flow relation of the boiler meter, as is commonly done with pulverized coal firing for all capacities. The controls for air supply may be applied to either forced or induced draught or both in parallel, but in all cases, except pressurized units, the proper balance between forced and induced draughts is secured by adjusting one of these factors from a controller responding to the draught in the combustion chamber.

Fig. 1. Control applied to oil firing.

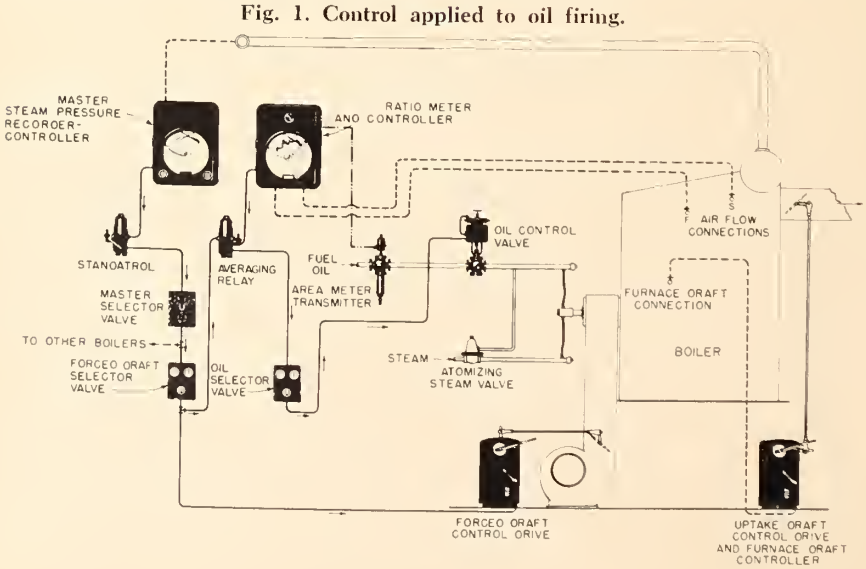

Figure 2 is a diagram of correct doctrine in the application of control to a gas fired boiler.

Gas flow and air supply are primarily regulated in parallel from steam pressure. A refining correction incorporating reset applied to gas flow from the ratio between metered air flow and metered gas flow assures precise proportioning for peak economy, and affords safety by virtue of a positive and rapid response in limiting gas admission to match air flowing.

Especially in oil refineries and chemical plants with supplies of by-product gas we encounter combination fuel firing with the requirement to use as much gas as possible. Figure 3 is typical of the solution applied to this problem on several boilers varying in size from 60,000 to 100,000 lb. hr. in three different refineries in Montreal East.

The master control signal is admitted to two computing relays for each boiler. In the first this is correlated with the output of a gas main pressure transmitter to determine the signal sent to the gas flow control valve. In the second the output from the transmitter measuring gas flow to the individual boiler is subtracted from the master control signal to determine the signal sent to the oil flow control valve.

The cams of the positioners of the oil and gas valves are characterized so that 1-lb. increments of the master pneumatic signal produce equal B.t.u. admission whether at the oil or gas valve. Such an increment, passing to the uptake damper control in the basic parallel response of the control system, will secure correct basic air response for either fuel. By properly correlating the proportional band adjustment of the first computing relay, the appropriate suppression on the gas main pressure transmitter, and the range of the master signal, maximum available gas usage is secured.

The proportional band adjustment for the second computing relay is selected so that reductions effected in oil input will, on a B.t.u. basis, closely match the increases in gas flow, and vice versa.

The normal variations in B.t.u. content in the gas and oil, and in pressure drops across the control valves, obviously limit the accuracy of the calibration of the responses of this gas-oil switching system, but the steam-flow/air-flow controller of the main combustion control system stands continuously ready to add a refining signal to modify total air supply, if needed.

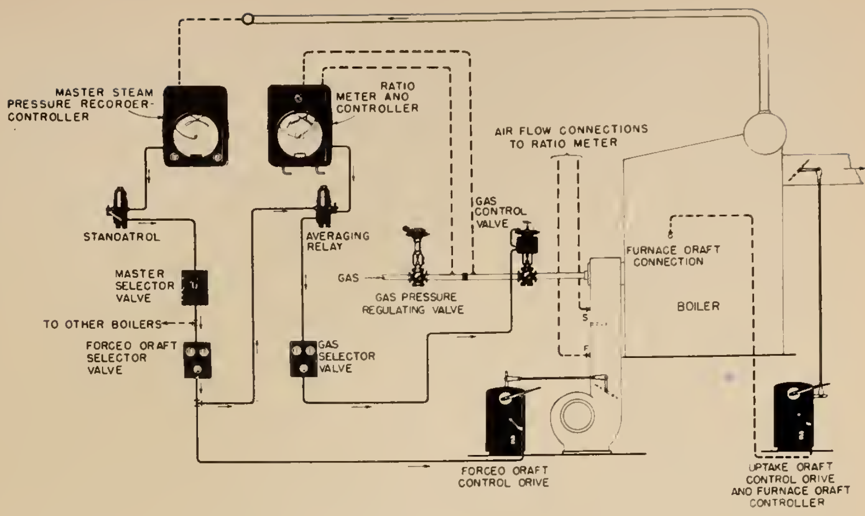

Fig. 2. Control applied to gas firing.

This scheme is easily added to existing control systems of correct design, and can yield highly lucrative reduction in gases lost to the flares.

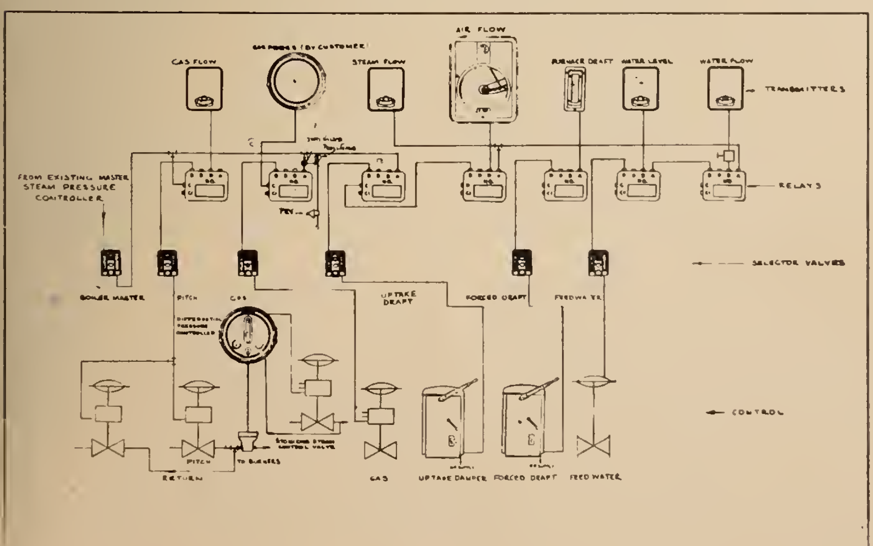
When burning oil and gas simultaneously, the complication of requiring two fuel measurements and their addition render it most practical to initiate the refining correction from the steam-flow/air-flow relation and to apply it to air. Figure 4 illustrates an installation where positioning one selector switch permits selection of steam-flow/air-flow correction when burning oil and gas simultaneously, or of gas-flow/air-flow correction when burning gas alone.

With normal refinery gases and oils, the cumulative effects of difference in excess air requirements and difference in flow effects of the products of combustion for the two fuels, make it practical to operate with little or no biasing of the corrective signal established by the steam-flow/air-flow controller, for the full range of proportions of the two fuels.

Frequently, however, we encounter a third fuel to be burned in combination, which has an entirely different B.t.u. content. The final check on excess air proportioning must in such cases be a recorder of % oxygen and % combustibles in the flue gases. As the curves of 0_2 content versus excess air percentage for the whole possible variety of fuels are almost coincident, analysis of 0_2 content provides continuous knowledge of excess air available in the furnace. This information may be used for either manual or automatic correction. The % combustibles pen, by detecting unburned gas in the flue gases, serves to detect faults in mixing, and in fixing the practical limits to excess air reduction. A smoke density recorder also often justifies itself from the savings that accrue when guidance is available to reduce excess air closer to the economical limit. For all multiple fuel firing, including solid fuels such as pulverized coal and bark, there is a definite trend to include continuous analysis for 0_2 and combustibles and to record smoke density. In a great many cases, e.g., refinery CO boilers and for auxiliary bark burning, 0_2 recording is quite indispensable.

For combination fuel firing, good control system design requires for each application careful examination of unit design, of fuel availabilities, of facilities for air measurements, and of suitability of the damper systems for their control purpose. Figures 3 and 4 illustrate methods adapted to specific problems and it should be ap-

Fig. 3. Control of gas and oil firing in combination.



preciated that, though alternative approaches may be offered, there will usually be one arrangement and choice of components that can excel all others in performance.

With the availability of Western gas in varying quantity, combination fuel firing will increase, and excellent answers to its problems, based on both refinery and past Western experience, will be forthcoming.

Figure 5 exemplifies the complement of components required and presently being built for a large high-pressure high-temperature boiler in Western Canada, with choice of firing pulverized coal, gas or oil (future).

At the other extreme in capacities fall the packaged steam generators for which simplified package control systems, as illustrated in Fig. 6, are available. These controls are of the simplified parallel or ratio variety, normally without a secondary refining correction. To merit the title of combustion control system, however, the damper drive and oil flow control valve must include means for characterizing their travels so as to achieve efficient fuel - air ratio throughout the whole operating range. In the system illustrated, this important function is accomplished by shaping cams in the air-operated positioning relays appearing on both forced draught damper drive and oil flow control valve.

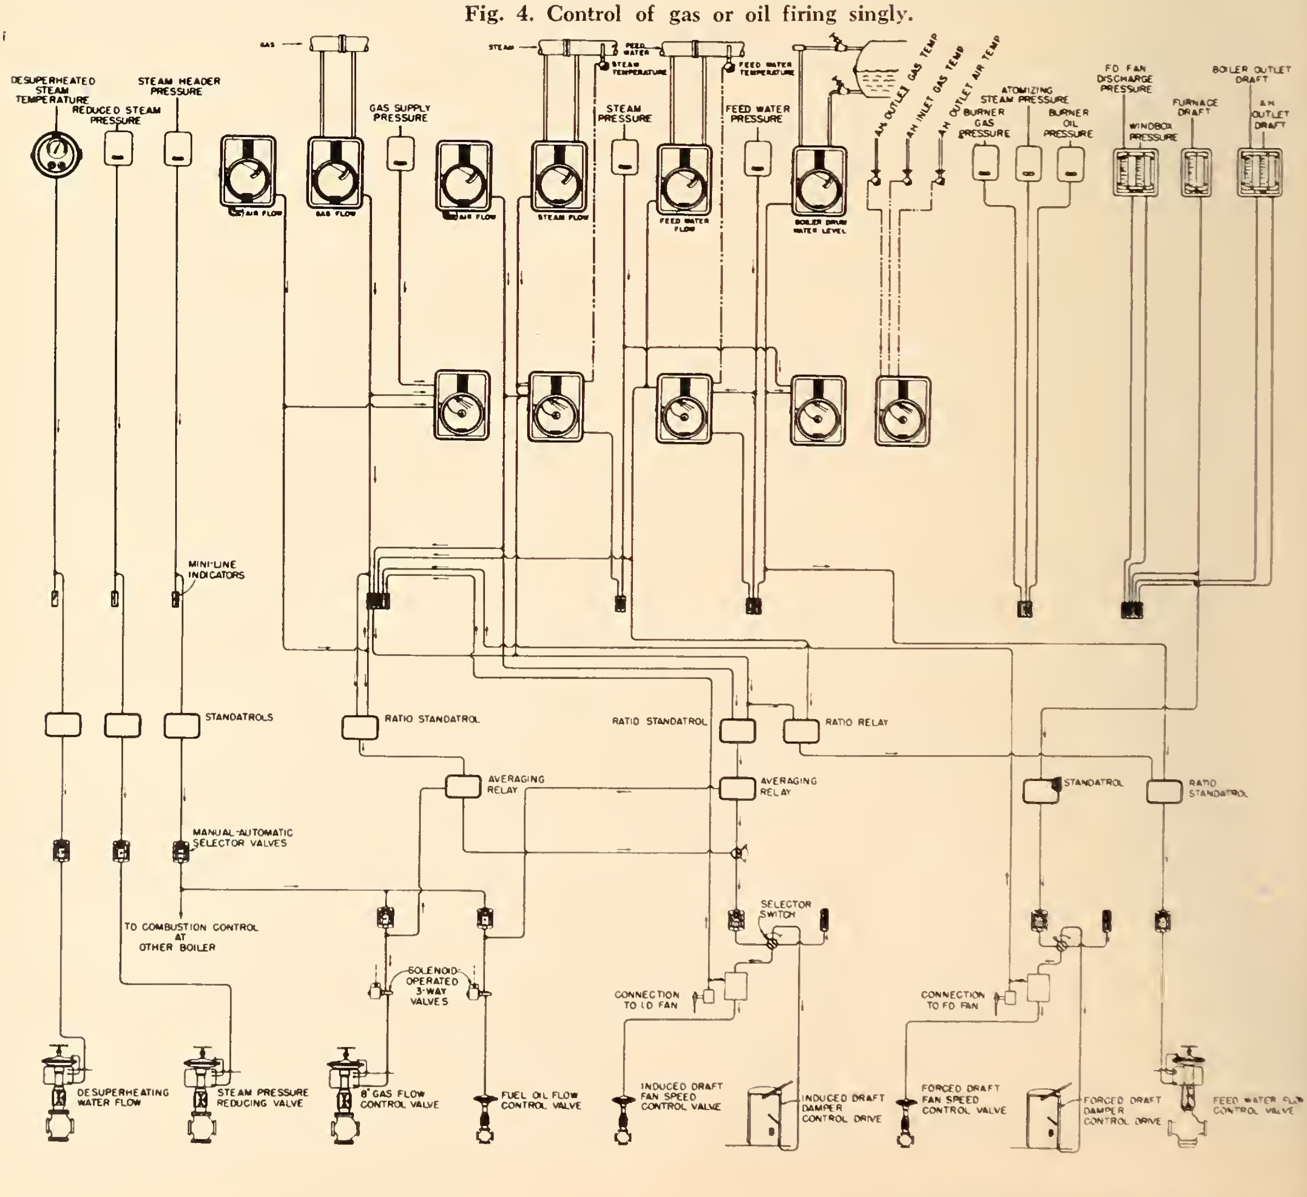
These package control systems incorporate interlocks for fuel shut-off from flame failure, from low water level, and from high steam pressure, and protective devices to assure low fire start and a safe minimum permissible fuel supply.

A tendency, shown two years ago, to specify fully automatic ignition for industrial package units fortunately appears to be waning for the causes which had always inclined boiler and control manufacturers against it. It involves an undesirable complexity of electrical switchgear and relays, which is normally not warranted, and which makes fault tracing by the user impractical, and results in unnecessary outage.

Having now viewed schematic control arrangements typical for a wide range of capacities, let us take a look at the components. (See Fig. 4.) To generalize, we find an increasing tendency toward local measuring devices transmitting a signal which may be used for indication, recording or controlling or any combination of those functions. Data continuously essential to the supervising operator are presented on grouped miniature indicators, operating faults declaring themselves by deviation from acceptable pointer pattern, drift from set point or alarm.

Data necessary only for loading history, efficiency calculations, preheater performance, etc., is recorded in related groupings on universal multiple-pen intermediate-size recorders, economically grouped on a panel that

Fig. 4. Control of gas or oil firing singly.



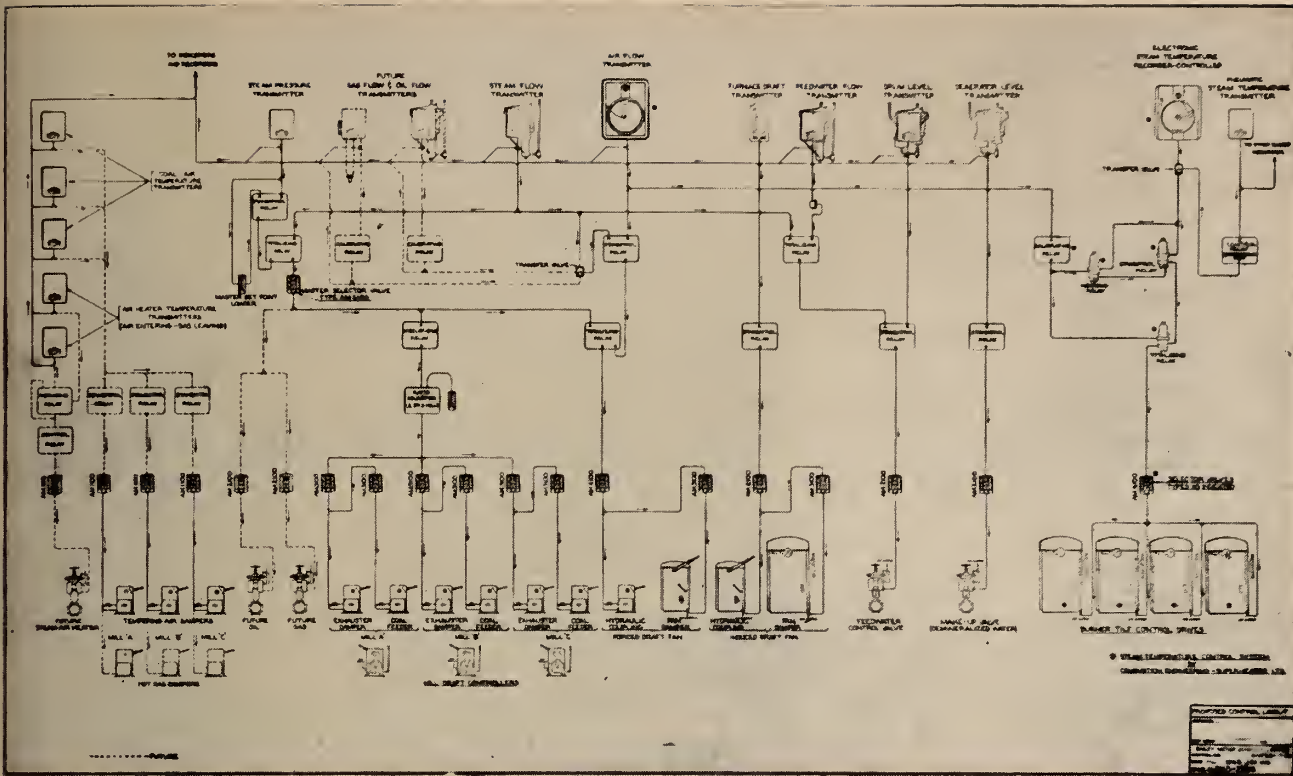


Fig. 5. Control components for a large boiler with three alternative fuels.

may, if necessary, be relegated to the background.

The signals that are to determine automatic control enter computing relays which provide proportional band, reset action, the addition of the refining correction, acceleration, and other functions as required. A given signal may be used simultaneously for two or more control purposes by introduction into separate computing relays, for example, the steam flow signal employed in the computation of the steam-flow/air-flow refining correction of the combustion control, in balance against the feed water flow signal in three-element feed water control, and as one element in steam temperature control. These computing relays need not be mounted in the control board, but may be racked elsewhere.

The outputs from the computing relays next pass to panel- or console-mounted selector stations which provide centralized manual automatic selection and bumpless transfer.

Control is finally effected by the power drives and valves connected to receive the signals from these selector stations.

Two important changes which emerge from this general consideration constitute trends in technique. One concerns the solution of the control problem, and is the adoption of the building block method employing standardized interchangeable and independent components. The other concerns data presentation and permits increased supervision per operator, by concentrating only indications of the essentials and the selector stations within reach of the operator, with the recorded factors in secondary prominence.

Perhaps the most important single factor in the success of the building block method is the achievement of a true universal recorder of intermediate size, precision built, with interchangeable plug - in components, dowelled, precalibrated and packaged. Figure 7 illustrates the exterior view, Fig. 8 the four positions for plug in components. Figure 9 shows the three most common standard components, namely, pneumatic and electronic receiving elements and the integrator. The pneumatic element can receive a standard pressure signal ranging from 3 to 15 or 3 to 27 psig. proportional to any factor such as flow, temperature, pressure, level, etc. The electronic receiving element is available in a wide range of measuring circuits including Wheatstone bridges, impedance bridges, potentiometric circuits suitable for voltage range spans from 2 mv. d.c. and up, etc., as required for the wide variety of factors to be recorded.

A multitude of receiver combinations are offered from these three components alone. Universality is completed by the availability of several further plug-in components such as the pneumatic controlling element, pneumatic transmitter, and direct-connected pressure element illustrated in Fig. 10.

An ingenious new inking system eliminates the mixing of recording inks by crossing records, and requires annual instead of daily attention. The reduced size of the receiver coupled with the new degree of record definition provides clarity of observation and interpretation for multiple rows of receivers on the same panel, resulting in a degree of panel economy unequalled by other methods.

Figure 11 illustrates the trend in technique of data presentation as described above.

As might be expected, current design often mixes former and new techniques as physical conditions and economy dictate best for any given plant. Pneumatic transmissions may intermingle with direct-connected instruments, and selector stations and miniature indications may fall on an inclined shelf integral with the recording panel.

In marine practice the same trends both in method and in data presentation are to be observed. In fact, space limitations and shock specifications imposed by naval design shared with central station needs in shaping their

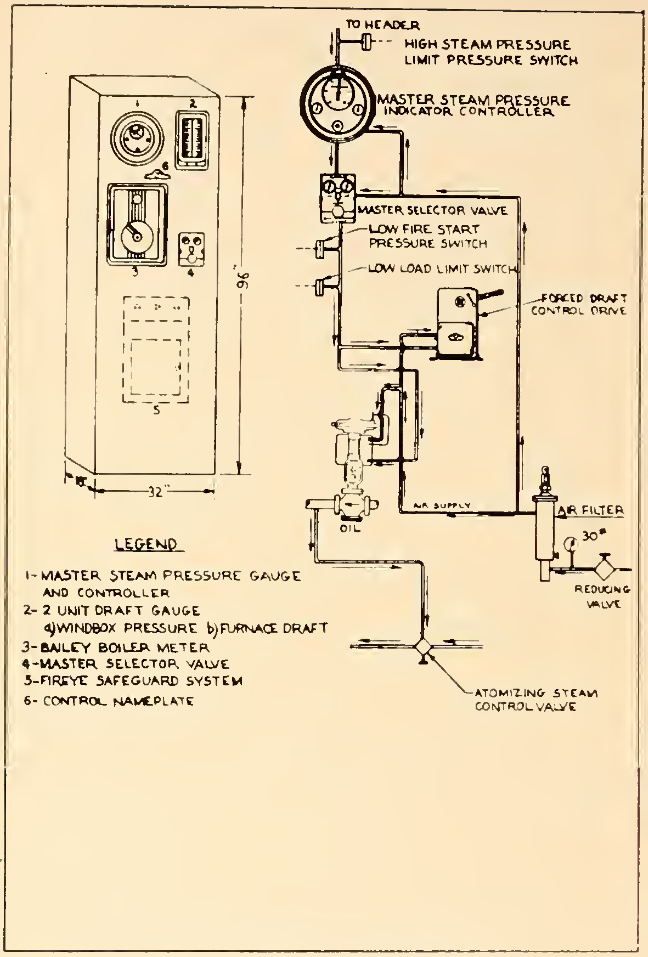

Fig. 6. Package boiler control.

Fig. 7. Intermediate size universal receiver.

evolution. As operating results from automatic operation have become more widely known, there has developed an insistent demand in the new marine construction for guiding and recording performance. It is to be expected that present fuels will persist for some time in both merchant marine and naval boilers.

If in any doubt as to the importance to warships of extending their fuel potential, contemplate for a moment the Battle of the *Bismark*, when Sir John Tovey, Commander in Chief of Britain's Home Fleet on H.M.S. *King George V*, after four days and nights of chase and search, himself came near to having to quit the area without bringing the *Bismark* to action, because he was approaching the limit of his fuel tanks, and when the destroyer *Mashona* was sunk after the same action, because she had overstayed her fuel supply and was condemned to a slow speed return to base.

For this reason, those who ponder naval tactics will find it difficult to believe that atomic plants will not inevitably power both submarines and the larger surface vessels. The added techniques for instrumentation and control as required for differing types of reactors, their steam generating and auxiliary systems have already been successfully worked out.

Electrical combustion control is again receiving attention in research and development departments in an effort towards improvement. The search continues for a simple electrical power unit capable of speed and precision comparable with that of the hydraulic or pneumatic power cylinder. The convenience of electrical signals for admission to printout and computing circuits adds some stimulus to this research.

The trend toward centralizing essential and related data in compact form has extended itself in steam electric generating stations to include the combining of control centres for boilers, turbines, auxiliaries, and (where applicable) load dispatching, in a single control centre. The results have been a decrease in supervisory and maintenance cost and improved performance through better coordination.

Obviously, in the control of the combustion process we have for some time been close to the possible optimum in economy, reliability, and flexibility. There still remains one area where an advance is being made. As in the past, its potential in the large steam electric generating station has provided the justification for its investigation. On the larger units fractional percentages in efficiency represent many thousands of dollars, and small variations in the efficiency of boiler, turbine, feed heating, and condenser systems continually occur and are often difficult to analyze. There is also the fact that on interconnected power systems, large savings reward the most economical incremental loading, and planning this demands precise determination of unit performance.

It became apparent, therefore, that an auxiliary complement of instrumentation might yield the desired results. Of this, one part would have to be of the highest possible precision and coupled to a computer with analogue record for performance monitoring. The remainder would be comprised of numerous primary measurements connected with selective fast scanning, digital printout, and programming for fault analysis and system study.

Where design of operating guides and controls had required rugged reliability and repeatability under continuous operation without instrument outage, this auxiliary instrumentation must be free for frequent removal from service for calibration checks, and the service of the scanning and programming equipment need only be intermittent. Moreover introduction of this auxiliary equipment could permit further simplification of the basic instrumentation provided to guide the operator. Also the user's need for large departments for result determination, interpretation and record could be eliminated. Figure 12 schematically illustrates this approach, which is already adopted in some plants in the U.S.A. and under study for others.

The success of this approach involves meeting several further requirements than does the application of computers in business, and progress is being made in three main fields of activity.

(1) proper selection of, and improved precision in primary measurements;

(2) the development of a high quality continuous performance computer with lock out on component failure; and

(3) considerable improvement in existing data programming equipment to increase operating time and reduce maintenance.

Performance determining equipment, as illustrated in the centre group of Fig. 12, may deliver continuous information of boiler, turbine, and heater cycle efficiencies, turbine heat rate, cost per M.w.h. output, etc. and deviations of the same from standard.

Figure 13 is a simplified schematic of one method of derivation of typical information. Standard electrical signals proportional to selected accurate measurements, and certain manually set signals derived from known data and tests, enter computing and comparison circuits whose recorded outputs represent performance and deviation from standard.

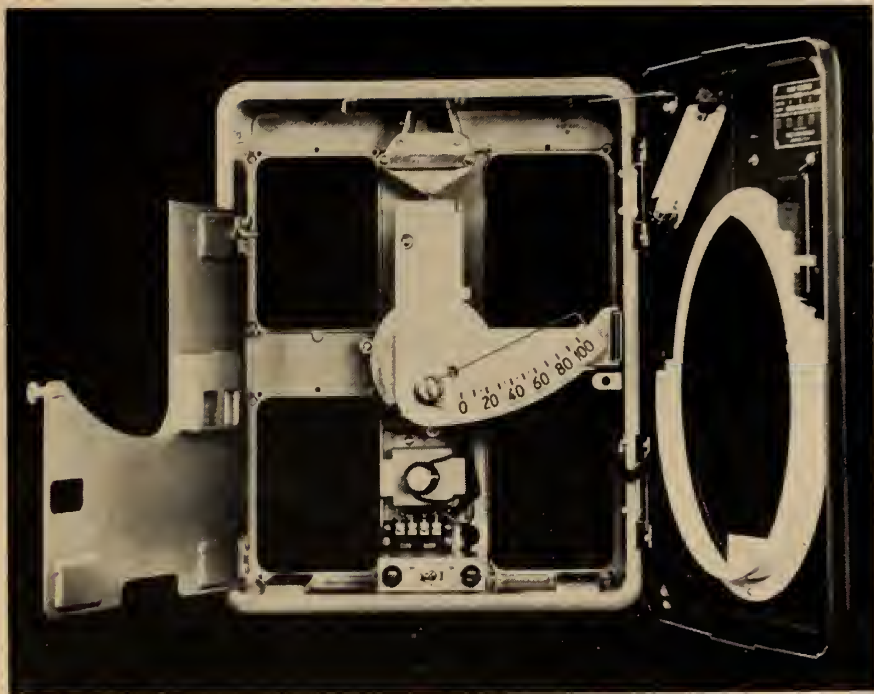

Fig. 8. Positions for precalibrated plug-in components.

For boiler performance determinations, the recognized accuracy of the heat balance method has pointed the way to the selection of feed water flow, excess air percentage, and the appropriate water, steam, and gas temperatures as the correct basic data. Questionable steam measurement at high pressures and temperatures, where steam table values have been based more on extrapolation than determination, may be completely avoided. Typical problems of precision are the wick effect of thermometer wells and choice of representative sampling points for flue gas temperature and analysis.

The fact that errors in determination of heat losses in flue gas, ash, and radiation show up in boiler efficiency calculations at approximately one tenth their own percentage, contributes to precision.

The test equipment represented by the group at the right of Fig. 12 may be designed for any studies intended whether simple or complex. Figure 14 illustrates components of a system

Fig. 9. Pneumatic and electronic receiving elements and integrator.

Fig. 10. Pneumatic transmitter, pneumatic controller, and pressure element.

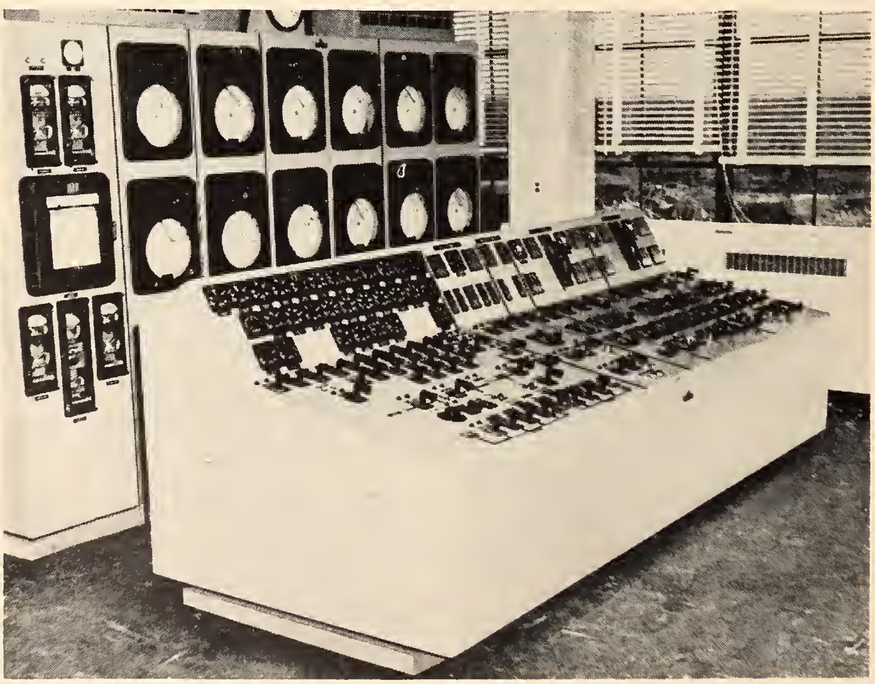
designed to analyze the operation of a large steam generator. At the touch of a button, analogue scanners connected to accurate measuring devices, begin to gather sequentially selected data. The analogue signals, certain preset data, commands to the computer, and necessary distinguishing symbols are digitized, properly sequenced, and punched in code on continuous tape for transmission by teletype to a remote electronic computer for processing.

In Fig. 14 the digitizer is the cabinet at the left, the control console is in the centre with the tape perforator mounted above it, and the teletype transmitting equipment appears at the right.

Having been automatically coded in the form suitable to the computer, it can be quickly processed mathematically and the results sent back to the boiler site by teletype.

In the past, when proving out a new steam-electric unit and determining optimum operating conditions, the requisite analyses have often required weeks of work by a team of test specialists. This new method of data gathering and processing shortens this to minutes, provides performance data of a type previously unobtainable, and is expected to solve problems that hitherto defied analysis. As it need be used only intermittently and for short periods, one assembly of equipment can be connected to test any boiler that has the necessary primary measuring elements. Likewise it can be moved from plant to plant. On large and complex units, a permanent installation for frequent test may, however, be justified.

Fig. 11. Mini-line approach: console and background panel.



Until reliable synchronized and related information and the effects of variables are capable of rapid computation, a complex process cannot be thoroughly understood and the potentials from the control of its components cannot be evaluated. Important need for probing additional data points and analyzing their relations may have completely escaped attention. However, scanning and digital printout alone achieve little. It is when they become a means to the prompt examination of immediately processed test and fault calculations, and there is a continuous presentation of computed performance and deviation, that the objective may be achieved.

A whole vista of possibilities opens out for good data scanning, if coupled with system analysis and performance computing, for large boilers, for a broad range of equipment associated with them and for many continuous flow processes. The example of the past would suggest that simplified forms of this equipment might be expected to find a place on boilers of intermediate capacities for design studies, boiler trials, and for operating guidance.

Engineering Personnel

The most important factor in control development being engineering

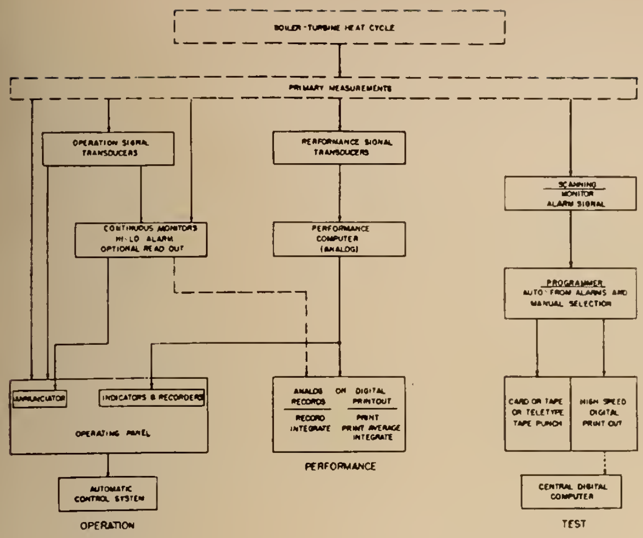


Fig. 12. Schematic of instrumentation arrangement for operational guidance, performance determination, and test.

Fig. 13. Schematic of analogue type performance determination.

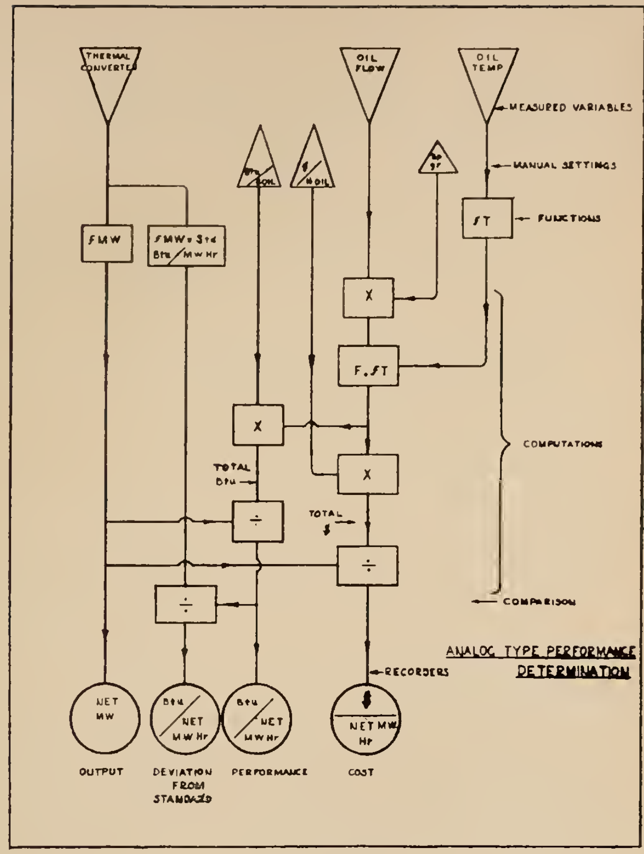

Fig. 14. Equipment for digital printout, programming, and teletype transmission to electronic computer.

personnel, it is fitting that we should appraise them and note their direction.

Biologists and students of prehistory have proved one billion years of life and at least two hundred thousand years of human occupation on this planet, and that nature laid down much of the earth's resources of fossil fuels (coal and oil) at least two hundred million years ago.

Modern man, multiplying unrestrained at a rate which could shortly outrun the earth's supply of chemicals essential to life, such as phosphorus, seems bent on exhausting the energy resources. He is beginning to pillage the energy stored in uranium ores with equal abandon.

In an age which is certain to be looked back upon as one of irresponsible waste, the instrument engineer and technician have made conservation their profession.

Two trends developing among Canadian instrument personnel merit attention, one inviting correction, the other gratitude.

The economics of manufacturing specialized products for large as compared with small markets, and the forces affecting the training and employment of technical personnel have tended heavily to develop far too great a dependence upon the re-

(Continued on page 79)

The Role of the TECHNICAL ASSISTANT in Industry

J. R. Houghton, M.E.I.C. *Assistant Works Manager, Northern Electric Company Limited, Montreal*

A GREAT DEAL HAS been said in recent years on the use of technicians or technical assistants in engineering work, and particularly their relationship with professional engineers in carrying out such work for industry.

The use of technical assistants in industry warrants study and discussion by engineers. It should be interesting to all of us because the great majority of engineers are now employed in industry of one kind or another. The real interest is probably not so much the present role of technical assistants but rather how technical personnel ought to be used in engineering industry and what action can be taken to improve their position in the future. There has been a tremendous growth in industry, particularly in the technical aspects, and the engineering profession has not long been widespread in industry. The prospects for industrial expansion in Canada and the increasing technical complexity in all branches of industry present a definite problem in the efficient assignment of scientists, engineers, and the various levels of technical personnel to technical work. Whether or not there has been a shortage of engineering and technical personnel, there is no doubt of the future shortage problem unless we find ways to improve the utilization of technical manpower and to establish working assignments which challenge the potential of each of the levels of technical skill available to industry.

Dr. James Killian* stated not long ago that the expansion of industry will only be possible if there is an adequate supply of scientists, engineers, and technologists. He said that the shortage was perhaps not a general shortage of numbers as much as a shortage of specific talents and skills, that is, a shortage of the more highly talented. This shortage is probably accentuated by the inadequate use of the talent available.

Though technically trained men are used in many industrial fields—in production, inspection, sales, purchasing as well as in engineering departments this discussion is limited to the use of technical assistants on engineering work, and the subject regarded from the point of view of the engineer and the administration of the engineering function in industry.

*Former president, Massachusetts Institute of Technology; special assistant to the President of the United States.

DEFINITIONS

The first difficulty is that of defining technical assistants, technicians, technologists or whatever other term may be used for this overall group of skilled people working in the engineering areas of industry.

Technical assistant can be considered as covering a wide range of personnel whose skills extend from craftsmen to professional engineer.

A comprehensive definition developed by the Conference of Commonwealth Engineering Institutes is: "an engineering technician is one who can apply, in a responsible manner, proven techniques which are commonly understood by those who are expert in a branch of engineering or in those techniques especially prescribed by professional engineers. The techniques employed demand acquired experience and knowledge of a particular branch of engineering combined with the ability to work out details of a task in the light of well-established practice".

More simply, technical assistants in engineering are those who, although not professionally qualified, are capable of undertaking assignments which require more formal education and more theoretical knowledge than is required by the skilled craftsmen. On the other hand, the technical assistant is particularly useful on these assignments because of the practical skills and abilities which he has. Technical assistants' work then involves some of the knowledge of the professional engineer and the skills of the craftsmen.

The classical distinction between engineering and technical work is that the engineer plans while the technical assistant makes and does; the engineer creates, the technical assistant applies.

LEVELS OF TECHNICAL ASSISTANT

It is obvious from these attempts to define technical assistants and their assignments that a very broad field is involved; a tremendous variety of jobs which require various levels of skills and of training and of educational background. Some skilled craftsmen graduate into technical assistant assignments. For example, a toolmaker may demonstrate a flair for drafting and design or for technical trouble-shooting and bring his toolmaking and metal-working skills and training into use to good advantage in these fields even although his educational background may be high school or technical school graduation or less. On the other hand, technical assistants with an educational background of junior or technical college of one type or another may be capable, for instance, of undertaking the detailed design and prove-in of complicated electrical test facilities, relieving the design engineer for the more fundamental planning and circuit development engineering.

JOB DESCRIPTION

To me, this is the principal area for discussion and for improvement. Those of us who are involved in administering engineering work in industry must develop better ways of defining or describing the different types and levels of technical assignments involved in carrying out the engineering departments' work. This is primarily job description, but with a difference because it is necessary, with increasing technical content of the assignment, to define the skills and characteristics of the man required to perform the job as well as to describe the job itself. Only in so tackling the problem can we subdivide job assignments to get full efficiency from the various available levels of technical personnel.

A fundamental point is that this job description or work assignment analysis involves defining both the technical skills and the educational background which are required for a technician to meet the needs of the various levels of work in an engineering department.

This is quite a difficult problem, perhaps particularly in Canada, where industry is relatively young and technical education is certainly still very young. Not only is there a need for more technical institutes at the post-high-school level or junior colleges but there is also a need for a national educational standard; that is, some means of comparing technical education and training, such as the National Certificate system in England, which has become so well known in this country in recent years. Such a system not only provides for the recognition of the educational background of a technical assistant but also provides the means for a technical assistant to progress from one level of education to another in a planned and recognizable manner. But this takes time and there are other things which can be done in the meantime.

ENGINEERING ORGANIZATION IN INDUSTRY

In order to bring some of these statements into focus, let me discuss briefly the organization of some of the engineering functions in my company, which is fairly typical of manufacturing industries, at least in the problems involved. The company, which requires a large engineering and technical staff both in the engineering design and in manufacturing, is organized on a divisional basis and there are several engineering departments associated with the divisions. In common with other companies, we have developed a fairly detailed technique for evaluating different levels of work and types of jobs, but there is still difficulty in deciding just which jobs can truly be classed as technical assistant to engineering work. Taking as the criterion the higher levels of technical work, however, there is at present a ratio of technical assistants to engineers of approximately 1:1 throughout the engineering departments. This compares with a ratio of approximately 1:2½ in 1949. We have put a lot of study in recent years towards increasing the direct support of technical assistants to engineers, but we still have a long way to go. Some studies suggest that, within the next ten years, this ratio will have changed to nearly 2 technical assistants for each engineer.

To illustrate, the manufacturing engineering organization in one of our larger manufacturing divisions is responsible for: (1) determining the methods of manufacture which shall be used for each product; (2) providing the facilities for manufacture; (3) developing the manufacturing shop layouts and issuing manufacturing instructions and specifications; (4) developing each new product and the facilities involved into a production unit; (5) cost-reduction engineering throughout the manufacturing shops; and (6) the provision of engineering and technical advice, assistance and trouble - shooting throughout the manufacturing shops.

The organization includes methods engineering for manufacturing and associated with the trades groups (toolmakers, electricians, millwrights, etc.); mechanical design (machines and tooling); factory engineering; and electrical test facilities design.

Much of this work involves top level engineering. It requires both the specific knowledge and skills of the professional engineer and his broad analysis and appreciation of the relationship of the engineering problem to the overall business problems. Much of the work however can be, and should be, handled by technically-trained men associated with the engineers. There is a wide variety of work, and hence the opportunity to make use of a variety of skills and levels of training either independently or in combination. Some of the categories of technical work have been selected to illustrate the functions of technical assistants and also the background of experience and education which is considered desirable.

TECHNICAL ASSISTANT ASSIGNMENTS – MANUFACTURING

A. *Technical Assistant, Grade 1— Shop Methods*

Functions — (1) Assists engineers on routine technical problems encountered during manufacturing. (2) Follows up delays in paper routines involving shop layouts and checks these against standards for errors. (3) Gathers information on shop outputs, material handling routines, shop equipment, as directed by engineer.

Educational Requirements—Graduation from high school (junior matriculation) with practical technical experience equivalent to 3½ years of training (equivalent to 7 to 10 years' service), must have mathematical ability and interest in science.

B. *Technical Assistant, Grade 2— Manufacturing and Inspection Layouts*

Functions — (1) Prepares layouts for manufacturing and inspection processes. (2) Calculates quantities of raw material needed and determines dimensional requirements. (3) Calculates weight of plating surface areas, etc. for manufactured parts. (4) Determines manufacturing sequence and equipment to be used and specifies particulars such as speed and feeds for production equipment. (5) Decides sequence and number of inspection operations and specifies packing methods. (6) Conducts shop tests on practicability of revised layouts.

Educational Requirements—Graduation from technical school plus 5½ years of planned training (equivalent to 11-16 years of service).

C. Technical Assistant, Grade 3—
Product Planning

Functions — (1) Analyzes new drawings to determine if parts are to be made internally, sub-contracted or purchased. (2) Recommends internal manufacture if savings are evident. (3) Assigns manufacturing routine and makes a preliminary estimate of tooling costs. (4) Analyzes quotations from purchasing dept. and designates source of supply on items to be manufactured outside. (5) Deals with engineers, manufacturing groups, tool design, and purchasing.

Educational Requirements—Graduation from technical school plus 6½ years of planned training (equivalent to 13-20 years' service).

D. Technical Specialist, Grade 4—
Shop Methods

Functions — Investigates and settles technical problems in the production shop and expedites material flow when technical problems are limiting feature. Handles portions of development projects. Works under minimum guidance from engineers.

Educational Requirements—Graduation from technical school or Junior Matriculation with additional related technical courses with 5 to 6 years planned training (equivalent to 15-18 years' service).

TECHNICAL ASSISTANT ASSIGNMENTS–FACILITIES DESIGN

A. Technical Assistant, Grade 1—
Test Facilities Development

Functions — (1) Assists engineers in the development and improvement of electrical test equipment. (2) Prepares and modifies specifications for less complex equipment units under engineering supervision. (3) Proves in test equipment and uses laboratory equipment such as meters, oscilliscopes, bridges, analyzers, etc.

Educational Requirements—Graduation from technical school plus added courses in radio and electronics, or three years' course at Ryerson Technical College, or equivalent, plus 3 years of planned training (equivalent to 6-9 years' service).

B. Technical Assistant, Grade 2—
Test Facilities Design

Functions — (1) Develops and designs test equipment for process and final inspection under the supervision of senior engineer. (2) Compiles instructions on technical description of equipment. (3) Investigates shop complaints regarding the need for or the use of test equipment.

Educational Requirements—Graduation in electronics from a technical college similar to Ryerson, plus 4½ years of planned training (equivalent to 9-15 years' service).

C. Technical Specialist, Grade 3—
Die, Jig, Fixture Design

Functions — (1) Designs complex dies, jigs, and fixtures as required in the manufacturing of intricate parts for telephone equipment and apparatus. (2) Works under minimum guidance from engineers.

Educational Requirements—Graduation from technical school with additional formal study on mechanical subjects such as tool design, metallurgy, etc., or holders of technical certificates such as HNC from the U.K., plus 8 years of planned training (equivalent to 15-20 years' service).

Some typical technical assistant assignments have been described to bring out some of the problems involved. Many of these jobs which can be handled by the top qualified technical assistants are very close to the function of the professional engineer in the field, in fact, it is difficult to develop the difference in a straight job description. The difference exists —first, in the narrower field of specialization of the technical assistant, and, second, the broader approach to the problem by the engineer as compared with that of the technical assistant. There is thus the complication of the amount of skill, ability, and actual training of the particular engineer or technical assistant assigned to a given area. It must be recognized that the younger less-experienced engineer or "engineer in training" may be less competent than a senior technical assistant in handling a particular job. In his early years, an engineer must undertake work which might be described as of technical level in order to gain the necessary practical experience to develop his full potential. He can and does learn from technical assistants. Thus we find overlapping of assignments in an engineering department, between engineers and technical assistants, and therefore overlapping of grade ranges.

Truly to perform the engineering function requires a full professional engineering education and the ability to apply this knowledge creatively. To do this an engineer must add practical experience to his fundamental knowledge. The successful engineering technical assistant requires high skill in at least one technical specialty and, as he succeeds to higher level work, he must add to his practical skills a continuously higher level of education. The degree to which a technical assistant approaches professional status is difficult to define and is really a matter of individual ability. A measurable level of technical education is needed, and means should be available for technical personnel to add progressive stages of such education and to obtain tangible recognition for it.

FUTURE ROLE OF TECHNICAL ASSISTANTS

There seems to be no doubt that we will need more engineers and more technical assistants in industry in the future. Fifty years ago, the ratio of technical personnel to others in industry was 1 in 300; now it is more like 1 in 50. This trend is increasing as a result of technological improvements in products and in manufacturing processes. In my company, the current ratio of technical employees to total is 1 in 20 and analysis indicates that 10 years from now this ratio is likely to be 1 in 12.

If we accept the fact that there is a need for scientists, engineers, and technical assistants, we ought to discuss what action can be taken to help fill this need. Specifically, what can the engineering profession do to assist in improving the supply and the calibre of technical assistants for engineering work? What ideas do engineers have and what steps can they take to bring these ideas into action? Both at E.I.C. and at C.P.E.Q. there are committees studying this problem. Also the A.P.E.O. recently acted to encourage the recognition and establishment of standards for various levels of technical assistants.

It seems there are three areas in which to work.

(1) There is the work which can be done in industry by engineering departments and administrators. This involves analyzing the sources of people who can be developed into technical assistants of one level or another. Sources which exist now are the high schools, technical institutes, and such technical colleges as are already in operation. A principal source is existing industrial staff who can be developed to become capable of handling technical work. Industry is already doing a lot of training to improve the abilities of its employees for technical work, but on predicted needs for the future much more training or training of much greater

numbers is needed. However, engineers can only do this if they can justify the costs to management.

Industry is eternally interested in avoiding any unnecessary expenses. If we honestly believe that we can improve the efficiencies of our engineering departments by making greater use of technically skilled people, then we must demonstrate to management that the costs of developing technical assistants are justified by the resultant savings.

There are many ways of developing technical assistants. Internal training programs can rotate employees through desired experience and give them specific courses in the technical skills required. Tuition refund plans enable employees with suitable qualifications to take evening studies in desired subjects. We have a long way to go towards the use of the system of part-time day release for educational study, which is very common in the U.K. through the National Certificate system.

(2) A second means of augmenting the supply and the calibre of technical assistants exists through improving and making available more facilities for evening study. A pressing need here is for the development of a standard of comparison for evening study courses so that credits can be given of recognized status.

(3) The third area for action, particularly in Canada, is technical education and training at technical institutes. In all recent Canadian conferences on educational matters, and also in the study work done by organizations such as the Industrial Foundation on Education, it is generally agreed that there is a need for a decided increase in the number of technical colleges of the post-high-school level in the various provinces of Canada. Quebec has an excellent set of technical institutes but is low on facilities for education between the level of these technical institutes and the university level. In Ontario, Ryerson Institute is the best example of the higher level technical college and there are other institutes of this type beginning to operate or under organization in at least three other cities. There is no question but that Canada will need more university graduates, and therefore more universities or radical expansion of existing ones, but at least the universities exist, whereas to fill this sub-professional gap it is necessary to bring into existence many technical colleges or institutes. If the engineering profession really believes this future need for technical assistants exists we ought to be able to help analyze the need and we should be able to assist in organizing the means to fill the need.

CONCLUSION

I have attempted to outline some thoughts concerning the role of technical assistants in engineering industry, from my own experience, and have attempted to be practical. Perhaps the points I have tried to make can be summarized:

(1) Certainly there is a growing need in industry for well-trained technical assistants.

(2) There is a need to develop a system of recognized status for technical assistants.

(3) This recognition should provide a stimulus for technical assistants to continue to improve their level of competency.

(4) Improved educational facilities are required to provide for this improvement in status.

The aim should be to provide education and training to develop all technical personnel to their maximum potential. The engineering profession has a definite interest, and should be able to assist in improving the future assignments of both technical assistants and engineers in carrying out engineering work.

We are constantly reminded that the rate of technological progress is increasing dramatically and that more thought must be given to these problems of increasing our capacity for engineering and scientific progress.

BEECHWOOD *(continued from page 55)*

The reactance relay for distance measurement is unaffected by arc and tower footing resistance. The relay scheme adopted may be extended and carrier relaying utilized if required in the future. Three-phase, high speed reclosure may be added if required. These relays may be applied to parallel lines having appreciable mutual coupling by cross-connecting the current transformers in the parallel lines. For the phase-ground fault relays, a scheme of sound phase compensation is used to ensure correct selection of the protected zones.

Of interest in connection with the relay installation at Beechwood is the relaying for the 69 kv. tie line with the Maine Public Service Company. The relay scheme is as listed above and, in addition, carrier relaying was added to give instantaneous clearance at both ends of the line for faults over the entire length of the line. This installation has an international aspect, and required the coordination of the following apparatus by the several engineering groups concerned.

(i) Identical protective relays were supplied for the two ends of the line. These relays are of the same type and manufacture, and were supplied by American and Canadian manufacturers respectively.

(ii) High speed, three-phase reclosing relays of different manufacture, but having similar dead time intervals, were supplied at each end of the line.

(iii) Identical carrier installations were provided for the two ends of the line. These two carrier installations were engineered in the Montreal office of the supplier. The equipment was manufactured in Europe and supplied through the Canadian and American offices respectively.

(iv) Different circuit breakers were employed on the two ends of the line. The circuit breaker at Beechwood is an air blast breaker of European design and Canadian manufacture. The breaker at Flo's Inn near Presque Isle on the American end of the line is a bulk oil breaker of American manufacture.

It is pleasing to report that extremely satisfactory collaboration was achieved among all parties concerned in this rather interesting sample of international cooperation on the technical level.

ACKNOWLEDGEMENT

The engineering design of the Beechwood Development authorized by The New Brunswick Electric Power Commission through the Honourable Edgar Fournier, Chairman. Mr. J. L. Feeney, M.E.I.C., then chief engineer and now a member of the Commission, and Mr. R. C. March, project manager, represented the Commission during construction. Mr. R. E. Tweeddale M.E.I.C., now chief engineer, acted as liaison engineer during the preliminary studies.

Dr. R. E. Heartz M.E.I.C., president of The Shawinigan Engineering Company Limited, directed the studies and design of the project.

INSTRUMENTATION IN INDUSTRY

PULP AND PAPER

This is the second in the series of articles on instrumentation in twelve Canadian major industrial groups. It deals with instrumentation in Canadian Pulp and Paper mills at various plants across Canada, producing sulphite, pulp, paperboard, kraftboard, bleached kraft, crepe wadding, newsprint, and fine and specialty papers.

In the entire Canadian pulp and paper industry it has been determined by the instrumentation committee of the CPPA that the value of instruments used today is close to $23 million or some 1½ per cent of its total capital investment. There are almost 60,000 instruments in use. The largest number used by any one company is 3,000 and the smallest number used is one. Specialty paper mills are the most highly instrumented, while newsprint mills use the fewest with 1 unit per ton of capacity.

Statistics of the Industry

Canada's Pulp and Paper Industry is one of the few leaders in manufacturing which can boast of a yearly output valued at more than a billion dollars. Four-fifths of the total output moves abroad. Almost a third of the U.S. wood fibre requirements comes from Canada. Pulp and paper accounts for about 5 per cent of Canada's gross national product. In 1957 the 6.4 million tons of newsprint, 10.2 million tons of wood pulp and some two million tons of paperboard and building papers was valued at almost $1.4 billion.

There are eighty pulp and paper companies operating some 130 mills in eight provinces, and employing some 335,000 workers in forests and mills. Canada has 26 companies making newsprint. They operate 146 newsprint machines in 42 mills with a combined capacity of six million tons yearly. Paperboard plants turn out 900,000 tons a year, valued at $125 million. Output of wrapping papers and fine papers at another 900,000 tons, valued at some $135 million yearly, is produced in 28 mills.

During 1958 the industry as a whole operated at about 80 per cent of capacity at mid-year, a new low for the operating ratio, but showed a modest recovery during the last half of the year. The overall demand for the industry's products declined about 5 per cent from the previous year.

From replies to a questionnaire recently circulated by *The Engineering Journal* among Canadian pulp and paper manufacturing companies, the following information as to the extent and practices of instrumentation in their respective mills is summarized. The information given, it is hoped, will not only be of value to instrument engineers within the pulp and paper industry itself, but will be usefull to other industry groups whose instrumentation will be covered in articles of this series in subsequent issues as a comparison with their experience.

Power is Metered or Checked

Power consumption by pulp and paper mills, including use for driving machinery and for electric-steam boilers, represents a greater portion of total production cost than obtained in most other industries. It is therefore generally found that both input of purchased power and output of developed power are metered or checked. In cases where the local utility serves few other customers, of course, this metering is less than necessary.

Steam Power Plant Instruments and Their Uses

Widespread use of instruments is found in the steam power plants for combustion control on thermal units, and for flow, feedwater, furnace temperature, gas and air flow. Some steam plants have automatic pressure recorders, steam flow meters on main steam lines and de-superheater controls on some of them, liquid level recorders, level controls on water tanks, timer controls, etc. The larger mills often have typical combustion control on main boilers and minimum base loading control on others, while elsewhere turbine flow meters and level controls for pressure reducing etc. are used. A recent innovation is continuous watch over the furnace by TV.

Capital costs per mill for steam-plant instruments only, exclusive of installation costs, vary from between $1,000 up to as much as $100,000 for a medium-sized fully automatic mill. On larger mills steam-plant instruments may represent an investment of $185,000 and even more in some instances.

Instruments are used by all companies reporting on steam processing plants for process control, and pressure reducing stations are frequently found throughout the plants. In some smaller plants heating is taken from steam mains. In no case did replies indicate separate plants were maintained for heating and power.

Who Specifies the Requirements?

The practice for determining instrument requirements for steam boiler plants appears to be to rely on the experience of the Company's engineering staff, and or the instrument section of the control dept. and, occasionally, of mill personnel. For boiler house system design, advice is sometimes sought from instrument vendors, particularly in special cases. Here, it depends on the size of the mill and the complexity of the instrumentation desired.

Instrumentation in Processing Plants

Most of the mills reporting, regardless of size or end-products, had been established 30 to 40 years ago. From their replies it was evident that prior to 15 years ago instruments were not widely used except in the boiler plants. It has been only during the postwar period that most of them have invested heavily in instrumentation for processing, and particularly during the past five years. One of the oldest newsprint mills in Canada, however, reported process instrumentation had been installed in its original plant 44 years ago.

Instrumentation is used in large up-to-date paper mills in their processing for measuring or controlling temperature and pressure, flow, acidity or pH, stock consistency, level humidity, differential temperature and pressure, position, fuel and wire guiding, weight, flow ratio, basis weight, moisture of paper, speed and speed ratios. Control of the cooking cycle in digesters is effected by the control of temperature and pressure, while the proper liquor charge is controlled by measurement of level. In washers, control is effected by control of flow and the consistency of the stock. Level recording of the various stock chests is the basis of control in the screen room, with flow controls for the supply of alum, sodium silicate, etc.

On the paper machines there is a speed recorder, and level-control on the head-box, with control of dryer temperature by temperature or pressure. Consistency is also recorded and regulated. In the Bleach Plant there is measurement and control of water, gas, stock, level, etc., and SO_2 and oxygen are also recorded and controlled, Beta meters are used for basic weight testing. In the chemical recovery plant there is flow control of waste liquor to evaporators and pressure, temperature and level control over furnaces. One new papermill uses a recording spectrophotometer and electric peak-load controllers.

Most Instrumentation for Process Control

As a general rule about 75 per cent of the investment in instruments, in terms of dollar value, is for process control, with the balance of 25 per cent being for measurement, divided roughly as follows: flow 30 per cent; level 25 per cent; pressure 15 per cent; temperature 15 per cent and miscellaneous 15 per cent. It is not unusual for a large paper mill to have as many as 1,500 controlling instruments installed.

Requirements of and uses for processing plant instruments in the case of small installations are generally determined by the Company's own staff. Control systems are designed usually by the staff or the Company's engineering office. Instrument manufacturers are often called in for advice, while consultants are generally called in for larger installations.

Time and Money Saved by Instrumentation

Replies to a question as to time, money and material savings effected by instrumentation disclosed a reluctance or inability to give definite information. One of the largest newsprint and sulphite pulp mills made the following comment: . . . "Very little savings in manpower cost; in most cases instruments are employed to control variables that a man could not control; most savings are the result of decreased equipment 'downtime', quality, uniformity elimination of safety hazards, etc. In fuel consumption it is estimated that as high as 30 per cent savings may have resulted over hand-firing, as well as due to the safety of automatic control. No records are easily available to permit estimates of money savings in general.

Repair, Parts and Servicing

To the enquiry as to who is responsible for instrument maintenance, replies disclosed that in most cases it is the instrument engineer. Where no instrument engineer is employed, or if he is absent, the plant engineer, or the control engineer or superintendent, is responsible.

Instruments are almost entirely purchased outright. One large pulp and newsprint mill rents on a very small scale, while others only rent temporarily for experimentation.

To the question "Do you carry complete replacements or repair parts", replies varied considerably. There is no indication that plants in remote locations tend to carry a larger stock of replacements and repairs than those closer to the sources of supply. Larger plants generally carry mostly repair parts in stock, and get the most necessary replacement units wherever possible. A few companies with several plants carry complete spare units in stock when possible or at least for the ones subject to frequent failure.

Servicing, replacing, repairing and calibration of instruments appears to be done predominantly by the plant staffs. This, of course, applies to minor servicing. Major jobs are customarily sent out to the maker for service. Even some larger papermills do their own servicing and replacements entirely, with exception of refilling of their thermometer bulbs.

The Instrument Crew

The size of the servicing crew varies from one instrument engineer with a head tradesman, five qualified mechanics and two to four apprentices, in the case of a large modern mill with many controls and measuring devices, to an instrument foreman and four men, assisted, when necessary, by electrical, mechanical or pipefitting crews, in the case of a smaller plant.

One pulp and paper producer with several mills, who has doubled his investment in instruments in the last five years, gives a 'rule-of-thumb' for servicing larger plants as "One man per each 250 units", which, in his case, works out at 1 foreman and a 5-man crew and shop facilities costing from $1,000 to $2,000, for each mill. The maximum number of instruments taken care of by one man as determined by a CPPA survey is 600, while the minimum number is 63. The average number of instruments per serviceman as recommended by ISA is 200 units.

Capital and Upkeep Costs

Initial cost of instruments, exclusive of installation, is estimated by a company with several mills at from 4 to 6 per cent of *total* capital outlay for a paper mill; 2 to 3 per cent for pulping; 6 to 8 per cent for bleaching; 2 to 5 per cent for steam, and overall 1 to 5 per cent.

One comparatively small but almost fully automatic plant 'guesstimated' its overall investment in instruments amounted to close to $1 million. Another company with two large mills gave capital cost for instruments and meters at $10,000 and for combustion controls at $8,000 in each plant. Another medium-sized "Kraft Mill" estimated its investment in instruments at close to $360,000, while still another company with two large pulp and paper mills reported capital cost of instruments including installation at between $1.5 and $2.25 million.

Upkeep cost on instruments seems to average $20 per unit annually for service and about $120 per unit for overall cost including replacements, which would in the case of some large mills run into very high figures. One large pulp and paper mill estimates its total cost for upkeep runs at least to $50,000 per year which, considering its capacity, appears to be moderate. Another large western mill's upkeep averages over $100,000.

Annual instrument cost for one large mill including servicing and maintenance but excluding new installations, runs around $13,000 for material and $23,000 for labour. Another medium size plant with up-to-date instrumentation spends $10,000 yearly on repair parts and $50,000 on labour; while a smaller mill reported $10,000 per year for replacements *and* labour. Still another company, with two large mills, reports cost of annual upkeep at $20,000 for instruments and $60,000 for maintenance.

Average Write-Off Two Years

Time required to recover initial cost of instrumentation varies widely, according to the process. A possible general average from a small number of replies appears to be around two years. Some companies replying stated all their instruments are justified on capital cost recovery within two years or less. Certain instruments are purchased for quality control only, which is, at times, an intangible value.

Commenting on the percentage reduction in manufacturing costs of various products through instrumentation, some companies replied that their plants would not be operational without instrumentation, and consequently no comparison with manual operation was possible.

One large manufacturer of pulp, paper and allied products pointed out that most instrumentation serves as quality control, or to increase operating efficiency as compared to manual labor. He estimated production per man-hour had increased and quality control had improved to the extent that, in general, instrumentation would save its value in one or two years. This, however, did not apply to measuring controls.

Who Specifies and Purchases Instruments?

Specifications are drawn up for instruments in processing plants and their installation in almost all cases by company's own staff of engineers. Consultants are frequently called in for advice, design and specifications on special installations, or in the case of new processes in the manufacturing plant, though even here some plants cling to the practice of relying on the advice of vendors.

There is no set procedure for purchasing instruments. Sometimes purchasing is done through the local purchasing department on specifications drawn up by the instrument engineer. In other cases specifications are drafted by the control dept. and orders are placed by the instrument department through the Company's purchasing agent. In the majority of cases purchasing is done through the central purchasing department.

Summing Up

Replies to a request for general comments on the importance of control and instrumentation in present operations, and for suggestions as to future trends, brought out some interesting opinions. The opinion of some companies appears to be that operation at the efficiencies required in order to stay competitive is impossible today without instrumentation.

It was generally felt that control and instrumentation could be increased in present operations to better the quality of products. Processes are being continually checked for further applications of instrumentation where these can improve production and quality. One reply stated . . . "without automatic controls in our big boilers it would be impossible to maintain efficient operation under sudden load changes." Other replies pointed out that more and more controls are being used in every department of the pulp and paper industry. Few controls displace men, but only relieve routine. "It is doubtful if the quality control or safety precautions would be effective if automatic controls were not employed," said the technical director of a large paper mill. "Most phases of the pulp and paper making industry will continue to require the operator's mind to direct and temper the control system, so as to produce the desired product. Thus a '*fully* automatic plant' is not in the foreseeable future. The processes are not yet predictable enough from scientific data for complete automation."

The Technical Superintendent of a western mill made these comments: "Future trends seem to be for more transmitter - receiver installations which is necessary for miniature instrumentation. Electrical and electronic instruments are competing well with pneumatic types. The trend to digital readout is not noticed in Pulp and Paper, but possibly will be soon. The general trend of instrumentation and automation would seem to require the training and development of a class of mechanic or technician able to service electronics, hydraulics and pneumatics."

Better Planning Needed As Well as Automation

Reasons for automation in the past in mills producing writing and printing papers shipped in sheet or roll form have been to produce more per time unit; to obtain greater uniformity of product; to reduce cost of product; and to make the product available to many.

The automation program must correct a maximum number of defects where they originate. It must make defects in the paper reel visible to the cutter through better signals. It must improve early identification of the best tonnage by sorting or converting for automated flow on end of the paper machine to finished flow. It must sidetrack off-standard tonnage for inspection.

Today automation is established practice in roll-rewinding controls, sheet cutting, loading, laying off sheets, counting, trimmers with automatic size of cut, setting, ream wrapping and carton packaging machines. Each of these operations require above average intelligence, which in turn requires a higher-paid worker. The jack-of-all trades 'millwright' of the past is fast disappearing, and being replaced by specialized maintenance crews.

Changes in planning and layout are needed too. Each delay represents extra placing and pick-up of tonnage representing man power and or machine energy. Good planning and clear directives are essential once such automation equipment is installed. How far a mill goes with future automation will still depend greatly on the future requirements of its customers, and on improvements in automation attained by the converters and the printers.

Organization of An Instrument Department

The rapid growth of instrumentation has, no doubt, induced pulp and paper mills, like many other industries, to organize a specified group to look after automatic control equipment. Most mills have found it expedient to combine maintenance with other functions such as trying out of experimental or temporary installations and carrying out a testing service.

This instrument group must be a

separate entity, with the chain of authority defined so as to conform with provincial laws and Union jurisdiction. It will be under supervisory authority, which is customarily shared 50/50 between control superintendent and the plant engineer or Engineering Dept., dependent on management opinion. Work of this instrument section extends across mill-department boundaries. It must never become an appendage to any of the processing groups, but must be a department with equal status to any other department in the mill. It must supervise new and modified circuits as well as attending to routine operation and servicing. The group needs a place to work, tools and machinery, test apparatus, spare parts, and instruction files and records. A rule-of-thumb for the workshop area including office space would be an average of 50 square feet per instrument unit, but not more than a maximum of 100 sq. ft.

Next under the control superintendent or plant engineer comes an instrument foreman. Under him come the technicians whose duties are to find faults, repair them, recalibrate, relocate, install, test and use instruments as instructed by the foreman. All these technicians are trained to handle certain common general duties.

Each technician in the group specializes as or in at least one of the following; process trouble shooting, analysis and start-up; electronic measuring and control; combustion control and boiler instruments; fluid dynamics, heat balances, etc; gas and chemical analysis; mechanical repairs; calculating machines; watchmaking, and lathe operation.

Equipment

Providing a basic tool kit for each man will pay off. An enterprising workman will add his own tools to the kit. A small precision lathe is a 'must'. Equipment should include a drill-press, bench guider, oxyacetylene equipment and a pressure-calibration bench, dead-weight testers, manometers, and thermometers for calibration standards. The watchmaker needs all the tools of his trade and a workbench for his job. An engraving machine is useful also for cutting name plates.

The office accommodation may be an area set off or partitioned from the shop area or it may be only 'desk room' with file cabinets and a library shelf containing instrument catalogues and text books. Files should include specifications and histories of each instrument from which to establish a maintenance schedule and to requisition spare parts. Cardex filing systems are found to be most satisfactory.

Instruments are getting more rugged and more reliable every day, and are taking on more difficult tasks and becoming more involved. To meet this change instrument departments must expect their duties to be upgraded. Education is listed as the top qualification for apprentices, followed by aptitude, initiative and tact in that order. The technician starting out today should have at least a senior matriculation education. The head of an instrument department who is not an engineer will be overlooked in promotion if he does not develop technically.

The more remote the mill, the better the training program for instrument technicians should be. Skilled men are in short supply and personnel have to be recruited and trained. About a third of Canadian pulp and paper mills have regular training programs, and a few have study periods on Company time for apprentices. An apprentice should be trained to read instruments and to know their limitations. Each should be taught how to switch instruments from automatic to manual control, and not to touch anything except set points.

About a third of Canadian pulp and paper mills have scheduled maintenance of instruments, while in another third of them maintenance is on a demand basis only.

Current Sulphite Mill Instrumentation*

Questionnaires were sent out in 1957 by Bowaters Newfoundland Pulp and Paper mills to some 20 Canadian pulp and paper mills across Canada, as reported in a recent issue of "The Canadian Pulp and Paper Magazine". Answers gave an indication of the extent to which instrumentation was being utilized at that time. Questions dealt mainly with types of instruments and controls used in various applications, and the problems encountered.

Only four of the mills reporting instrumentation in the melting of raw sulphur use a modified on-off or actually limit control. Biggest obstacle with types other than a temperature bulb in the molten sulphur tank is excessively high maintenance, and the constant attention required.

Of all mills questioned, the majority use a Glen Falls type of rotary burner and automatic burner-level control seems almost standard. Most mills have some form of measurement or control of SO_2. Most mills had found that by using suitable condensers on the sample line, the problems of moisture entrained in the gas could be handled fairly well.

From replies to this questionnaire it was gathered there was as yet no entirely satisfactory method of measuring acid or Baumé density. Only two mills had a record of this important variable, and they experienced high maintenance, which made it almost impossible to keep the unit in service.

On storage tanks, recovery towers and accumulators most mills record, and in some cases control, pressure, level and temperature. On pressure and livel measurements some form of liquid purge or sealing fluid is needed.

In digester operation the main variable that determines the rate of cooking is temperature, and this is regulated by controlling the flow of steam manually or automatically. Seven of the 20 mills reporting used manual cooking control, while the balance used automatic control with either steam flow or temperature program-cams being used. The desired steam flow or temperature is plotted against time in the form of a cam, and the controller then automatically controls the steam valve to give the desired values.

Fifteen of the 20 mills questioned used acid circulation systems either wholly or partially. Control of digester relief was fairly standard, fifteen using pressure set-point type of control. On the question of measuring digester level half the mills recorded it and the other half merely observed it with gauge glasses. Maintenance was fairly high for measurement devices with those who measure it the DP cell seems the most widely accepted instrument.

One very evident feature of the replies was the similarity of installations throughout the mills questioned. Practically all mills were found to be on the same general level of instrumentation, with few showing any great deviation from the average. This indicated there had not been as much development here in recent years as in some other industries or even in other sections of the paper industry. The survey showed conclusively that the major problem was one of maintenance, keeping instruments operative in an extremely corrosive envir-

INTERNATIONAL NEWS

SWEDEN

NEW RADAR SIGHTS. The 8000-ton Swedish cruiser *Göta Lejon* is said to be the first naval vessel in the world to be equipped with radar sights of a novel 'thinking' type, which will considerably increase the efficiency of her AA artillery. Part of an almost completely automated firing system, the radar sights operate on a signal, giving the horizontal attitude of an attacking aircraft, received from the ship's reconnaissance radar, which covers a wide horizontal and vertical field. The sight then automatically fixes the vertical position of the aircraft and locks the guns on the target, at the same time calculating the necessary lead. One or more guns can be controlled simultaneously, and are fired manually from the fire-control centre. The equipment, designed and made by the Dutch electronics firm Hollandsche Signaal Apparaten, is to be introduced on most destroyers.

LARGEST HEAT EXCHANGERS. The Alfa-Laval Group reports an order for several plate heat exchangers of an entirely new design, claimed to be the largest of their kind in the world, for a new aluminium producing plant in Guinea. The order, worth over $400,000, includes equipment for a total heat exchange area of some 54,000 square feet; heat savings are estimated at about $10,000 a day. The exchangers are used for cooling hot process solutions and heating and concentrating the cold used aluminium salt solutions. The plant, to be the largest aluminium producer in the world, is being financed by American, British, French and Swiss capital, and was designed by French engineers. The former French territory has large deposits of high-grade bauxite.

RUSSIAN TECHNICAL TRANSLATIONS. Recent Soviet achievements in many fields of science and technology have aroused great interest in other countries, but because of the language barrier few engineers outside the U.S.S.R. have been able to follow these developments at first hand. Now, however, the Production and Engineering Research Association, with the support of the Department of Scientific and Industrial Research, is making complete translations of *Stanki i Instrument*, one of Russia's leading technical journals. The English version will be published monthly from January 1959 under the title *Machines and Tooling*. This will cover research and development over a wide field of production as well as improvements in equipment and methods based on operating experience. Subjects include: tool design; ceramic tools; automation; induction heating; hydraulic mechanisms; machine controls; metal fabricating and finishing techniques; production in plastics; and many others.

THERMONUCLEAR CONVENTION. The Institution of Electrical Engineers has arranged for a Convention on Thermonuclear Processes to take place in London on 29th and 30th April 1959. The proceedings, held in conjunction with The British Nuclear Energy Conference, will be opened by Sir John Cockcroft, of the U.K. Atomic Energy Authority. Papers will be presented and discussed, and Sir George Thomson, Master of Corpus Christi College, Cambridge, will deliver a closing contribution. Subjects will include basic principles of thermonuclear processes, British work in the field, the possibilities of direct conversion from nuclear to electrical energy, and reviews of related work in the U.S.A. and U.S.S.R. Further particulars from the Secretary of the Institution.

AVIATION NEWS. Rolls-Royce jet and turbojet engines are to be made under licence in Germany by the M.A.N. engineering firm in Munich, to power civil and military aircraft still on the drawing boards in the reorganized Messerschmitt and Heinkel factories . . . The three 140-ton *Princess* flying boats (the world's largest), 'cocooned' since 1953, may be used by a new British company on a commercial passenger service between Britain, Rio de Janeiro, the Canadian Great Lakes, and a point in the U.S. . . . The balloon *Small World*, in which four persons recently attempted a crossing of the Atlantic from the Canary Islands to South America, had a 53,500 cu. ft. envelope of Terylene double-proofed with neoprene and contained in a hemp cord net made by a Ministry of Supply technician at Cardington.

UNITED STATES

HIGH-SPEED WIND TUNNELS. Conventional aerodynamic tunnels in which many problems have been solved, notably in the laboratories of the National Advisory Committee for Aeronautics (NACA), have been made obsolete by the advent of jet and rocket propulsion. The following are some of the recent installations in the U.S. which operate in speed ranges of the order of 2,500, 3,750, 15,000, and 32,000 m.p.h. North American Aviation Inc. has built the first privately financed 'trisonic' tunnel at Los Angeles, Calif. This single installation can be operated at subsonic, transonic, and supersonic speeds. The height of the actual 44-ft. long test chamber can be increased by a hydraulic mechanism from 3.5 ft. (supersonic range) to 6 ft. (subsonic). Operating air is stored at high pressure in eight steel spheres. In addition to the usual measuring equipment, the tunnel is fitted with cameras and data processing equipment. The Convair Division of General Dynamics Corp. has a tunnel at San Diego, Calif., which can operate from Mach 0.5 to Mach 5. Working on an intermittent cycle, power from an 8,000 h.p. motor is used to produce effects equivalent to the use of a 150,000 h.p. motor in a conventional tunnel. The stored energy is released for periods of up to two minutes, with an average of 30 seconds. Air is compressed to 85,000 psi. in six reservoirs with a total capacity of 116,500 cu. ft. The Lockheed Missile Systems Division tunnel at Sunnydale, Calif., for tests on the *Polaris* missile, can reach speeds of 15,000 m.p.h. and temperatures of 10,000°C. in a test chamber some 44 ft. long, 2 ft. high, and 6 ft. wide. An electrical charge of 20 million kw. is used to raise the temperature of a small quantity of compressed air at one end of the tunnel to 10,000°C. and the pressure to 4.9 million psi. The duration of the test is kept to 1/25th sec. to avoid melting the walls of the tunnel. To study the effects of placing a space vehicle in orbit and conditions of re-entry into the earth's atmosphere, another installation, Hotshot II, uses an electrical discharge to produce the effects of speeds up to 32,000 m.p.h.

past 50 years. The properly equipped aeroplane is a useful tool in today's world.

FABRICATION TECHNIQUES

by W. H. Riggs, Vice President Manufacturing, Avro Aircraft Ltd.

THE PAST FIFTY YEARS of aviation in Canada have brought about many changes in manufacturing. When the *Silver Dart* flew on 23 February, 1909, aviation in Canada consisted of a few ingenious individuals across the country who, in their backyards and sheds, were trying to invent and build machines of various kinds, that they hoped would fly. Their techniques were the "do it yourself" kind required to produce the wire, wood, and fabric contraptions of the day.

From these beginnings, an industry developed. Laminated wood sections replaced the solid wood members, and assembly fixtures were introduced to hold laminations during glueing operations. Plywood replaced fabric coverings, and steam pressure chambers were used to form wood panels. Metal tubular frames followed, requiring welding and control of welding processes.

Though wood was used extensively even during World War II on such aircraft as the *Mosquito* and *Cornell*, it was the introduction of the all-metal aeroplane that resulted in the most outstanding fabrication developments.

Light alloy materials were introduced, such as aluminum, with steel castings and forgings for greater strength at critical points. The machine and sheet metal shop replaced what had been mainly a carpentry operation. Heat-treat furnaces and process tanks changed the condition of these new alloys to permit forming operations, and provided a corrosion-resistant surface to the metals.

The quantities of aircraft required during the war years brought about new techniques which were aimed at quantity production. Routing processes were developed using a rotating cutting tool to cut sheet metal to the shape of a template. The rubber press was introduced to form these parts on form tools. Rubber presses of up to 15,000 tons capacity (Fig. 16) are at present in use in the industry. Stretch forming presses were developed to stretch and form sheets of material over large form blocks.

Methods of assembling these parts were improved with the introduction of hand-operated power tools. These included rivet guns and drills with portable heads to permit access to difficult work areas.

Because an aeroplane has many areas that restrict the number of men who can work at one time, extensive use of component assembly jigs was introduced. The structure was broken down into sections and these sections sub-divided into sub-assemblies. This permitted wider distribution of the labour force, and provided interchangeability of the various components. This breaking down of the work into specialized jobs has brought about the use of some six hundred classifications or trades within the industry today.

Rapid developments of the post-war supersonic age emphasized new problems in fabrication techniques. The problem was to reduce fabrication and development time in order to put the aircraft into service use in the shortest possible time. A reference to the production of Canada's Avro CF100 and Avro *Arrow* interceptors will illustrate this change of approach.

In the early development of the CF100, a number of prototype or development aircraft were built using many hand made parts, and parts made with tooling of limited production life. As these aircraft were going through their development stage, it was necessary to enter into a production tooling program before delivery of service aeroplanes. This delay was now prohibitive and, to overcome the problem, stable production tools and assembly fixtures were introduced at the start of the development program of the Avro *Arrow*.

Other improved techniques included the use of glass cloth on which parts were drawn to scale, providing a direct transfer of tooling and part dimensions to the shop. Full-scale master models of components provided an accurate reference for forming parts affecting critical outside surfaces. Metal to metal bonding and honey-comb construction were introduced into the design of the aircraft. This process is done in the autoclave (Fig. 17) where parts and bonded assemblies are cured under pressure and heat after application of adhesive.

Present supersonic aircraft require numerous heavy machined parts. This introduced heavy machining techniques such as skin milling (Fig. 18), where large wing skins are milled from solid billets of metal, eliminating design and assembly of numerous detail parts. Chemical milling is now under development where metal is reduced to shape by chemical action, replacing some machining operations. Electronic and tape operated lathes and mills that are presently being developed will make the machining operation a completely automatic process and will eliminate the requirement for much of the present-day tooling.

Another important development has been the need for control over the flow of thousands of parts through manufacturing and assembly stages. Canada's Avro *Arrow* has 38,000 parts, all of which must meet a predetermined schedule of production in order that assembly of the finished aircraft will not be interrupted. This control must also be exercised over 'bought-out' equipment such as air-conditioning, electronic and armament installations. The scope of this control can be further realized when we consider that over 650 companies and thousands of outside workers share in the production of today's supersonic aircraft, producing parts and assemblies to meet one over-all schedule.

COMBUSTION CONTROL

(Continued from page 69)

search, designs, products, and publications of our great friend and neighbor to the south.

This condition is of course not confined to the field of instrumentation but is widespread in light manufacturing, both mechanical and electrical. In the present state of Canadian markets, those who can should be planning new scope for the inventiveness of engineers at home, wider latitude for manufacturing in Canada, and support of university training that will inspire initiative and development.

Those engaged in engineering in all its phases are accustomed to understanding cause and effect, adding one and one to make exactly two, and assessing what is true. They tend by nature and habit to honesty, and are well qualified to exercise these talents beyond their profession, in the world around them.

They have become increasingly aware of the significance of what their effect has been and can be in raising the level of human welfare. There has been a trend, shared by instrument personnel, toward increased participation and leadership in affairs on community, provincial, national, and international levels.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

The Year 1958 Reviewed

Ontario Hydro

New stations and additions to existing plants, representing more than 800,000 kilowatts of capacity were placed in service by the Hydro-Electric Power Commission of Ontario in 1958. At year end, nine projects totalling 2.3 million kilowatts of capacity were under development.

Demand climbed above 5 million kilowatts for the first time. The Commission's total capacity reached 5.76 million kilowatts.

Capital construction expenditures were $200 million. St. Lawrence and Niagara river developments were the largest projects in the program.

Robert H. Saunders-St. Lawrence Powerhouse: 7 units placed in service, with nine more to come into service progressively in 1959; Ontario Hydro to receive 950,000 kw., at capital cost of $300 million.

Sir Adam Beck Niagara Generating Station No. 2: 2.2 million kw. now derived from Niagara River, with installation of 15th and 16th units.

Richard L. Hearn steam plant, Toronto: expansion continued; four units totaling 800,000 kw. are being added, with two units going into service in 1959. Ultimately, in 1960, capacity will be 1.2 million kw.

Lakeview thermal generating station: site west of Toronto is being prepared; installation designed for ultimate capacity of 1.8 million kw. at cost of $250 million; excavation to commence in 1959; two 300,000-kw. units to be in service by 1962. A second similar plant is planned for the Toronto-Hamilton area.

Northwestern Ontario: expansion in 1958; new hydro stations went into service at Whitedog Falls on the Winnipeg River and Caribou Falls on the English River.

Port Arthur: a 45,5000-kw. development at Silver Falls on Kaministikwia river is being built.

Thunder Bay coal fired plant at Fort William: construction started; initial capacity, 100,000 kw., at estimated cost of $26 million; power available in 1961; provision for enlargement to 1 million kw.

Red Rock Falls development on Mississagi river: preliminary construction in progress for completion in 1961.

Otter Rapids project on Abitibi River, near Kapuskasing: a start made on 131,000-kw. development; power scheduled for fall of 1961. Fifth unit of Abitibi Canyon station to be completed early in 1959, adding 45,000 kw.

Extra High Voltage Transmission: studies under way to determine economy of transmitting power from potential northeastern hydro sites capable of 1.8 million kw.

Nuclear power: Construction resumed in July on Nuclear Power Demonstration plant at Des Joachims, Ont.; to be in operation in 1961. Ontario Hydro is also involved in design and development phase of full-scale nuclear plant. First phase may be in 200,000-kw. range.

Frequency Standardization: ten-year program close to completion.

Rural expansion: 920 miles of line added.

Public Works, 1958

The activities of the Department of Public Works continue to expand in dollar value and in variety of projects, Deputy Minister H A. Young reported to the Canadian Construction Association meeting in January. Estimates for the current fiscal year are of the order of $240 million, and the indication is that expenditure will exceed 90 per cent of this. The Department also spent some $37 million on behalf of other government departments.

Of this latter category the Deputy Minister mentioned these: construction in N.W.T. and the Yukon, buildings and highways, largely projects for the Dept. of Northern Affairs and National Resources; a road program in national parks for the same department; roads to resources; marine work for Transport and National Defence Departments; work in the national parks sections of the Trans Canada Highway.

Housing comes under Public Works through Central Mortgage and Housing Corp. More than half the number of housing starts of all kinds during 1958 received Federal aid of some sort. Sixteen cities have undertaken redevelopment and renewal studies with assistance under the National Housing Act.

Winter construction is a concern of the Department. Besides programming maintenance and interior work on buildings started earlier, the Department scheduled 375 small harbour and river projects for the current winter. It continued work on as many marine projects as possible and is carrying out building of some 65 small post offices.

The Department is using models in studying problems of harbour development. The first major one related to Port Aux Basque and there are other model studies going on. The testing laboratory of the Department is moving into a new building.

An inter-departmental investigation of special interest is studying harbour developments extending from the Head-of-the-Lakes to Father Point. A similar study preceded the current harbour development at St. John's, Nfld., where the final cost will be some $12 million.

A study being carried on will report on the feasibility of a causeway across Northumberland Strait, between Prince Edward Island and New Brunswick. Another proposal under study is development of a new Arctic town at Frobisher Bay for the Department of Northern Affairs.

Deputy Minister Young said that activities of the coming year could not then be forecast. But the intention was, he said: to maintain the tempo, to pursue the program of federal buildings in small centres, to continue the highway program in Northern Canada and to expand the program of harbour improvements for navigation.

By means of a new 23-mile railway extension from Nimpkish, Vancouver Island, Canadian Forest Products Ltd., can haul logs to Beaver Cove. From there the logs are towed in booms to the company's processing plant at Vancouver. One of the nine major bridges on the new extension is shown above.

What Goes On

Iron Ore Outlook

An improvement in demand for iron ore is predicted for 1959 by M. S. Fotheringham, president of Steep Rock Iron Mines Limited, though iron ore is not at present in short supply.

Preservation and expansion of export markets is the industry's problem, Mr. Fotheringham says, with competition becoming increasingly keen for both the American and European markets. He estimates Canadian output could reach 96 million tons, 70 million to go to the United States, 16 million tons overseas, and 10 million consumed in Canada.

New Brunswick Prospect

The New Brunswick department of industry and development has forecast business in 1959. In the separate industries these trends are predicted:
Food industries: an increase in sales by 3 to 7 per cent;
Pulp and Paper: domestic sales higher by 3 to 10 per cent; exports increasing, or equaling those of 1958;
Metal mining: improvement in domestic sales by from 3 to 10 per cent and in export by 10 per cent; new interest in N.B. deposits;
Construction: sales to equal those of 1958, with housing starting slowly;
Merchandising: a gain in sales and improvement in profit.

Exploration in N.W.T.

Permits to explore more than a million and a half acres of the North-West Territories for oil and gas were acquired recently by six major oil companies.

Successful tenderers were Texaco Exploration Company, Champlain Oil and Refining Company, Canadian Husky Oil Limited, Imperial Oil Limited, Sun Oil Company, Mobil Oil of Canada Limited. The permit area runs along the Mackenzie River south-east to north-west some thirty miles each side of Norman Wells.

This brings to 76.5 million acres the area of northern Canada now under oil and gas permits.

Anniversary at Cornwall, Ont.

The Howard Smith Paper Mills Limited celebrated the 75th anniversary of its Cornwall division in November, 1958.

In 1883 the first sheet of paper was made; production of paper in 1903 was 3,000 tons; estimated production for 1963 is 112,000 tons.

In 1958 a new, larger soda recovery plant went into operation, and five major projects were announced, including a sixth paper machine.

Shawinigan Water and Power

All six units of the Beaumont power development will be in operation in 1959, Shawinigan Water and Power Company reported to its shareholders in November.

The 246,200-kw development on the St. Maurice River in Quebec was opened in September, 1958, with construction three months ahead of schedule and two generating units ready for regular operation.

St. Lawrence Seaway

At the end of 1958, construction of works under the St. Lawrence Seaway Authority jurisdiction had progressed to a stage which assures that all channels, locks and ancillary structures will be available to shipping at the opening of navigation next spring, subject, in part, to a restricted depth of twenty-four and one half feet until June 1, when the specified minimum depth of twenty-seven feet will be available throughout.

Completion of production and clean-up dredging to full depth and width in some channels was retarded by the early arrival of winter and by a shortage of dredging equipment. Production dredging remains to be done in these locations:
Turning basin at Montreal harbour: This work now expected to be completed at the end of the 1959 season. Until then ships may turn at the Longue Point Anchorage.
South Cornwall channel: Completion is scheduled for October 31, 1959. However, a safe channel of 450 ft. width and 27 ft. depth will be available at the opening of navigation.
North Cornwall channel: The use of this channel is not required in 1959. Work is scheduled for completion in late summer 1960.
Thousand Islands Section: Completion scheduled for July 1, 1959. Except for a half-mile stretch at Brockville Narrows which has been in use at width of 280 ft. during past years, a safe channel of 450 ft. width and 27 ft. depth will be available at opening of navigation.

Twenty-seven footh depth will be available in all channels after June 1 and, prior to that date, in all channels except the following where these conditions will govern:
Lake St. Louis: a 24½ ft. minimum depth at lower end of lake.
Lake St. Francis: a 24½ ft. minimum depth at a point ten miles below Cornwall.
Upper approach to Iroquois Lock: a 25½ ft. minimum depth.
Welland Ship Canal: navigation will be restricted to half channel widths in two short reaches. Available depth will be 27 ft.

Applied Physics at the Ontario Research Foundation

Dr. B. W. Schumacher, head of Department of Physics

The Ontario Research Foundation has recently enlarged considerably the staff and facilities for work in physics. A new Department of Physics is under the direction of Dr. B. W. Schumacher.

The new department is staffed and equipped so that, with the help of the longer established departments in the Foundation, it will be able to serve industry by (1) the study of materials and processes using modern physical methods; (2) the development of new instruments and techniques to meet the ever-changing needs of industry, and (3) the study of physical phenomena which will ultimately form a basis for new applications.

In the study of materials the physicist often joins forces with the chemist and metallurgist; in the development of instruments he enters the field of engineering. However, the approach of a physicist differs often from the approach of the other scientists. It may be more fundamental and therefore yield complementary information of value.

Some of the facilities at the Ontario Research Foundation laboratories are described below. A few of the characteristic features of physical methods are given with emphasis on the kind of information derived.

An electron microscope (Type Elmiskop I by Siemens) is the most recent addition. This instrument is installed in a room which is dust free and free of static electric charges. Its purpose is to get pictures of small objects or the details of surfaces which are beyond the reach of the optical microscope. These pictures reveal details of small objects beyond the wavelength of light. They convey, however, no information about the internal structure of these objects.

The resolution of the Elmiskop I is better than 12°AU, and due to its high beam voltage of 100 kev. relatively thick objects may be examined. For instance, some metal films may be observed directly, dispensing with the usual replica technique.

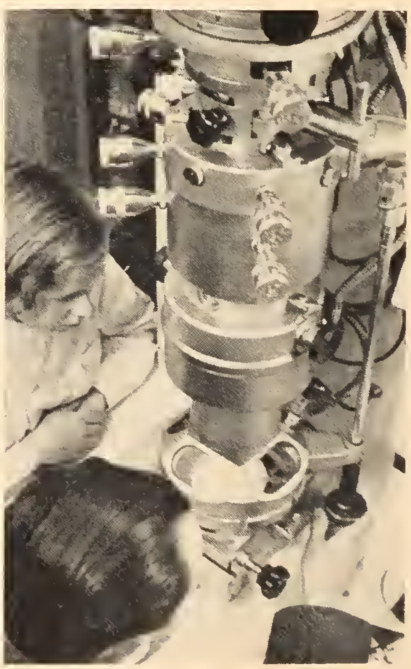
The Elmiskop I includes an *Electron Diffraction Camera*. The diffraction picture — whether taken by electrons, X-rays, or light — tells something about the structure of the diffracting substance although the elementary units of that structure are too small to be directly visible. But a limit is reached again, and one has to resort to another method if direct information as to chemical composition is required. To overcome this limitation a new method for getting an additional chemical analysis with an electron probe is under development at the Ontario Research Foundation.

Diffraction techniques do not give information about the elementary units of periodic structures like crystal lattices; they give only the average or ideal structure. Nevertheless, with all the refinements of the method, a surprising number of statements about these structures can be made.

X-ray Diffraction

The older method of X-ray diffraction with all its refinements is constantly employed. Various cameras suitable for any kind of crystal analysis and a recording diffractometer with Geiger counter are used. The X-ray laboratory is under the supervision of Dr. Ursula Martius. X-ray diffraction basically gives information as to the crystal structure of elements and compounds. Many of these structures are well known to-day and tabulated in a reference file issued by the ASTM. One of the very frequent applications of X-ray diffraction analysis is the indentification of an unknown compound by comparing its structure which is characteristic, like a fingerprint, with the structures on file. This kind of identification always yields the compound, i.e. it shows whether Fe, FeO, Fe_2O_3 or $FeSO_4$ are present. It might be called a molecular chemical analysis. Furthermore, X-ray techniques can be used to determine grain orientations, grain sizes, and of course unknown crystal structures. However, X-ray diffraction does not provide information as to shape, surface appearance, etc.

Electron microscope



In addition to the diffraction analysis, the available instrumentation is capable of *elementary* chemical analyses using X-ray fluorescence. In this analysis one observes the characteristic spectrum emitted from each of the chemical elements of a sample if bombarded by other, harder X-rays. This is similar to and complements optical spectroscopy or, for instance, the analysis by means of an ultra-violet lamp. The X-ray fluorescence is limited in its applications to elements with atomic number of 13 (Aluminum) or higher and to specimens of a fairly large size, say ¼ inch square. The Ontario Research Foundation is at present actively developing a method for covering the lower number elements also, by means of a microprobe less than one mil in diameter.

The Foundation does not now make radiographic pictures of large objects. However, microradiographs are made and have been used in several applications, for instance, locating precipitations of cobalt in a metallographic specimen and in the analysis of ores and minerals.

The electron microscope and X-ray laboratory is supplemented by a most complete *microscopy laboratory* which has been described previously.* It is based on standard instrumentation, and staffed by specialists. Using a standard colour photometer one of the staff recently showed a novel way of measuring the thickness of surface films on metals. Surface studies by the Tolansky interferometer method have led to valuable industrial information. All these laboratories are supplemented by excellent photographic facilities.

Infrared Spectroanalysis

The infrared spectrophotometer and laboratory, directed by Miss E. M. Kirby was recently expanded by a double-beam Perkin-Elmer spectrometer.

Infrared spectroanalysis provides molecular chemical analysis. The specimen, in this case, does not need to be present in the form of a crystalline substance. It can be in solution, or in a solid or gaseous form. The instruments determine some of the vibrational or rotational energy levels of the molecules. The related "absorption spectrum" can be used to identify the molecules present, or structural units in the molecules, even differentiating between isomers. This technique is especially useful in the analysis of organic substances but is not restricted to them.

In addition to the infrared spectrometer there are instruments for absorption spectroscopy in the ultraviolet and visible range of the spectrum, e.g. a Carry double-beam spectrophotometer and instruments for flame photometry.

It is not easy to draw a line where physical methods stop. The number of inspection methods is almost unlimited, since every physical constant that can be measured can be used for analytical purposes as well; for example thermal expansion, heat of solution, refractive index, etc. There is the relatively new method of vapour phase chromatography which differs basically from those methods listed above.

Vapour Phase Chromatography

Equipment for vapour phase chromatography is installed in the air pollution laboratory under the direction of Charles Newbury. The instruments provide an analysis by separation. The compounds in a mixture are separated due to their vapours requiring different lengths of time to be carried through an absorption column by a stream of dry gas, usually helium. The arrival of each component at the outlet is noted by a detector and recorder.

The unit has a separation efficiency equivalent to a distillation column of at least 4,000 theoretical plates, and recent developments promise an increase in this number to 100,000 using a sample as small as 10^{-8} grams. Consequently, this instrument is used to separate close boiling mixtures such as isomers. Not only will vapour phase chromatography give analysis of organic liquids, but it can determine the presence of natural gas in soil samples, indicating pipe leakage, or the percentages of hydrogen, oxygen and carbon-monoxide in 0.1 milli-litre of gas collected in the degassing of a steel sample.

Ontario Research Foundation will from time to time install new instrumentation to meet new problems as they arise. Important as these instruments are, they do not overlook the supreme importance of imagination, skill and experience of the scientific staff.

*A model Metalographic Laboratory, Majka, S.J. **Can. Metals** 19, No. 3: 54-58, (pt.1); No. 4: 56-63, (pt.2). 1956.

Hydro-Electric Progress in Canada, 1958

A maximum record was established in Canada in 1958 in the amount of new hydro-electric generating capacity brought into service in one year.

This is reported in the bulletin (No. 2625) published January 2 by the Water Resources Branch of the Department of Northern Affairs and National Resources, Ottawa.

The net total of new capacity installed was 2,485,040 hp. The previous high record was 1,758,450 hp. installed in 1954.

Ontario's total of new capacity was 1,301,800, the highest of the provinces; total for Quebec was 900,000 hp. The total installed capacity of water power plants in Canada is now figured at 22,376,048 hp.

The Bulletin is free of charge, available from the director, Water Resources Branch.

McMaster University Engineering Faculty

Progress is reported on several goals of McMaster University, Hamilton, Ont. There are students in the first two years of four-year degree programs in chemical, electrical, mechanical and metallurgical engineering, and engineering physics. First year of the civil engineering program commences in 1959. (*Engineering Journal*, Sept. 1958, Page 107).

There were eight members of the academic staff on campus by September, 1958; it is hoped to add eight more in 1959. Challenging positions are therefore open in all the named branches of engineering. Office and research space will be ready for occupancy in April, 1959. A personal interest in engineering research is a requirement, because a graduate research program is being developed.

Construction of the new Engineering building is proceeding well, for occupancy April 1, 1959.

Laboratory equipment is being purchased. Equipment already procured includes a Bendix digital computer, nuclear magnetic and electron spin resonance equipment, complete fluid mechanics laboratory, photomicrographic equipment and metallography laboratory. A one-megawatt nuclear reactor will commence operation in April. Associated with this there will be a single crystal neutron diffractometer. In chemical engineering, facilities make possible long range programs and mass transfer and radiation engineering. Electrical engineering has laboratories for servomechanisms and experiments on antennae. A new 50,000 lb. per hr. boiler can be used as an experimental facility. An adjacent steam turbine will allow realistic experiments on thermal power generation. A vacuum casting and melting laboratory will be the first of its kind in Canada.

Western Zone Technical Conference

October 2, 3, 1959, Banff, Alberta

On the recommendation of an E.I.C. Zone A. councillor's meeting held in Calgary, October 18, 1958, E.I.C. Headquarters has approved the holding of a Western Zone Technical Conference at the Banff School of Fine Arts on Friday and Saturday, October 2 and 3, 1959.

The main features of this conference are; a series of twelve technical papers with as many as possible dealing with the various economic and engineering aspects of Western Canadian Developments, a Forum on Irrigation and Drainage and a program for the ladies. Why not mark these dates on your calendar today and reserve a few days from your holidays so that you and Mrs. Engineer can attend the first Western Canadian Technical Conference?

Your help in obtaining suitable technical papers for the Conference is needed! You are invited to submit summaries of proposed papers to the Papers' Committee Chairman, Professor J. B. Mantle, c/o College of Engineering, University of Saskatchewan, Saskatoon, Sask. If you know of some engineer who could possibly contribute a paper you might inform the Papers Committee at an early date. The following deadlines are in effect:

May 15, 1959 — last date for submission of summaries and abstracts

July 1, 1959 — selection of papers complete

Sept. 15, 1959 — last date for submission of manuscripts.

W. A. SMITH, M.E.I.C.
General Chairman,
Western Technical Conference

International Yard and Pound

Letter to the Editor

It would be appreciated if you would publish the enclosed announcement on the international yard and the international pound. The text is self-explanatory but it may be of interest to recall the following facts of local concern to Canada.

In 1951 "An Act Respecting Units of Length and Mass" (15 George VI, Chapter 31) defined the Canadian yard as 0.9144 metre, which is in exact agreement with the joint announcement. The same Act defined the Canadian pound as 0.45359243 kilogram which is slightly discrepant with the ratio being established for the international pound. This difference is insignificant in all measurements except those of the very highest precision. Nevertheless steps are being taken toward the amendment of the Canadian legislation to make the Canadian pound 0.45359237 kilogram and so legally equal to the international pound. The ratio 0.9144 was chosen because it leads to a yard which is approximately half-way between the present imperial (United Kingdom) yard and the U.S. yard. It has the added advantage of making one inch exactly equal to 2.54 centimeters. The ratio used in the Canadian legislation of 1951 to relate the Canadian pound to the international kilogram was the originally accepted ratio between the pound and the kilogram. Through the years the imperial (United Kingdom) pound and the U.S. pound have become very slightly different and the ratio used in the joint announcement makes the international pound approximately the average between the imperial pound and the U.S. pound.

L. E. Howlett,
Director, Division of Applied Physics,
National Research Council,
Ottawa, Canada.
29 December, 1958

Announcement on the International Yard and Pound

The directors of the following standards laboratories —

Applied Physics Division, National Research Council, Ottawa, Canada; Dominion Physical Laboratory, Lower Hutt, New Zealand; National Bureau of Standards, Washington, United States; National Physical Laboratory, Teddington, United Kingdom; National Physical Research Laboratory, Pretoria, South Africa; National Standards Laboratory, Sydney, Australia;

have discussed the existing differences between the values assigned to the yard and to the pound in different countries. To secure identical values for each of these units in precise measurements for science and technology, it has been agreed to adopt an international yard and an international pound having the following definitions:—

the international yard equals 0.9144 metre;

the international pound equals 0.45359237 kilograms.

It has also been agreed that, unless otherwise required, all non-metric calibrations carried out by the above laboratories for science and technology on and after July 1, 1959, will be made in terms of the international units as defined above or their multiples or submultiples.

CONFEDERATION — A Progress Report

At the January meeting of Council held in Toronto on the 31st, sound support was given to the report on Confederation presented by the Institute's committee. Councillors right across Canada from British Columbia to Newfoundland approved the following resolution:

"That this meeting of the Council of The Engineering Institute of Canada receives and now approves with appreciation the report of its Committee on Confederation (dated 6 Nov. 1958), instructs the general secretary to circulate all members of The Engineering Institute of Canada the ballot suggested in Dr. Tait's letter of January 9, 1959, in a form to be agreed upon by the Joint Committee and by Council, and requests its Committee on Confederation to continue its good work until the proposed Provisional Council is appointed."

The next step will be to send a report and a ballot to every corporate member of the Institute. This ballot, if favourable, will authorize Council, in collaboration with the Canadian Council, to set up a Provisional Council whose duty it will be to prepare all the final details for final presentation to the corporate membership for approval.

With the January meeting of Council, Confederation has taken a great step forward.

Scientific and Technical Manpower

The Department of Labour of Canada is at present conducting its annual survey of men and women in the scientific and technical fields. The purpose of this survey is to bring up to date the records of these professional people which have been maintained by the Department since 1942 and, as well, to provide information on Canada's manpower resources in these fields for use in research.

The survey is designed to help answer a number of important questions about scientific and technical professionals. What kind of jobs do these people move into on graduation and how does this picture change as they become older? What are the typical career patterns of those in the various engineering and scientific fields, both in terms of salaries received and types of work done? How many and what kinds of engineers and scientists eventually become research workers, teachers, administrators and executives? To what extent do they feel that their professional qualifications are actually used in different types of work?

The current survey is part of a program in which one-third of the people in scientific and technical professions will be approached each year. By these means, all those registered will be covered in a three-year period. Those surveyed each year are selected in a manner which permits the information secured to be used as a statistical sample representing the whole group.

This year's survey is the third conducted by the Department since the present program was inaugurated. In the previous two surveys, some 34,000 engineers, scientists, architects and veterinarians were mailed questionnaires. In 1959, it is planned to get in touch with an additional 23,000 professionals in scientific and technical fields.

For the 1958 survey, statistics were tabulated for a group of more than 11,000 respondents with regard to their 1957 earnings, employment and education. Engineers represented 55 per cent of those covered and natural scientists 38 per cent, the remainder being architects and veterinarians. For those with bachelor's degrees only, it was found that the median salaries for engineers ranged from $4,630 for 1957 graduates to $10,605 for those who graduated in the period from 1920-1924. For scientists, the range of median salaries was $4,400 for 1957 graduates to $8,450 for those who graduated prior to 1915. At all levels of experience, salaries paid by industry were higher than those paid by government or universities. Industry was also the largest employer, with 82 per cent of the engineers and 52 per cent of the scientists, followed by the federal government which employed 9 per cent of all engineers and 21 per cent of all scientists. The Department of Labour issued a preliminary release of these data last year and will be putting out a final report shortly.

There is a rapidly growing need in Canada for information of this sort and this survey provides the major source of such data. The Department of Labour's efforts, however, can only be of real value if the coverage of professions is extensive and information on registrants is maintained on an up to date basis.

The Institute fully endorses the maintenance of the national register of scientific and technical professions and the survey program being undertaken and asks that all members who have received the questionnaire form this year co-operate by giving prompt and accurate returns to the Department of Labour, Ottawa.

Annual General and Professional Meeting

The Engineering Institute of Canada

Royal York Hotel,

Toronto,

June 8-9-10, 1959

The Engineering Journal will have advance information about the meeting in every issue.

2nd SOUTHERN ONTARIO
of The Engineering

Sheraton Connaught
Saturday,

YOUR RESPONSE AND ENTHUSIASM

shown last year has demanded that a second Southern Ontario Regional Conference be held. It is again sponsored by the E.I.C., and all Southern Ontario E.I.C. and A.P.E.O. members and their ladies are urged to attend. Comprehensive plans have again been made by a special Hamilton Branch Conference Committee for your pleasure and convenience.

The program will be stimulating for both engineers and their ladies and will afford the opportunity to make many new friends. Seven E.I.C. branches are participating to ensure the success of this Conference. They are Toronto, Hamilton, Niagara Peninsula, Kitchener, London, Sarnia, and Border Cities.

11.00 a.m. MEZZANINE FLOOR — **REGISTRATION**
Advance registration forms and hotel accommodation forms will be mailed to all members.

12.15 p.m. CRYSTAL BALLROOM — **MEN'S NOON LUNCHEON**
Prior to and during the informal noon luncheon, delegates will have the opportunity to renew old friendships and make new acquaintances.

1.00 p.m. CRYSTAL BALLROOM — **PANEL DISCUSSION**

What's on the Horizon for John Smith, B.A.Sc., Class of '65?

L. S. LAUCHLAND, M.A.SC., M.E.I.C., P.ENG.,
Professor and Head of Department of Engineering Science, University of Western Ontario.

S. D. RENDALL, B.A.,
Superintendent of Secondary Education, Department of Education, Toronto.

L. D. DOUGAN, B.A.SC., P.ENG.,
Vice-President, Operations, Polymer Corporation Ltd., Sarnia.

MODERATOR

H. L. SHEPHERD, B.A.SC., M.E.I.C., P.ENG.,
Manager, Salary Administration and Personnel Development, Canadian Westinghouse Co. Ltd., Hamilton.

What can be more vital to our profession or our way of life than the engineers who will join our ranks a few years hence? What knowledge and skills will they require? How should they be trained? What will be expected of them in their work? The panel will examine and discuss these related problems whose successful solution demands the attention and efforts of all of us.

2.40 - 5.00 p.m. — **TECHNICAL PROGRAM**

6.00 p.m. SHERATON ROOM — **RECEPTION AND COCKTAILS, AS GUESTS OF HAMILTON INDUSTRY**

7.00 p.m. CRYSTAL BALLROOM — **CONFERENCE BANQUET**

8.30 p.m. CRYSTAL BALLROOM — **EVENING GUEST SPEAKER**

Why Buy "Made in Canada"

STUART ARMOUR Economic Adviser, The Steel Company of Canada Ltd., Hamilton, Ont.

Mr. Armour is one of Canada's foremost economists. His subject affects each one of us as an individual and also as a member of our community. The economic problems facing our country are complex but their solution depends on the actions of individual people.

9.30 p.m. CRYSTAL BALLROOM — **CONFERENCE BALL. DANCING TO CHRIS LOVETT AND HIS ORCHESTRA**
Dress informal. Corsages for the ladies.
Refreshments available.

All E.I.C. and A.P.E.O. members and their

REGIONAL CONFERENCE

Institute of Canada

Hotel, Hamilton

March 14, 1959

THE SPECIAL LADIES' PROGRAM

permits your lady to accompany you and ensures that her day will be just as enjoyable as yours. The Hamilton Branch E.I.C. Auxiliary and the Wives of Professional Engineers will be hostesses during the special afternoon program.

Arrangements have been made by these ladies to provide dressing accommodation in their homes for the visiting ladies who will not be staying overnight in Hamilton. The Brittany Suite will also be available to the ladies throughout the Conference.

TECHNICAL PROGRAM

2.40 p.m. Future Trends in Extractive Metallurgy

DR. L. M. PIDGEON, B.A., B.SC., PH.D., P.ENG.,

Professor and Head of Department of Metallurgical Engineering, University of Toronto

Dr. Pidgeon is a recognized authority on extraction methods of light metals and initially developed the dolomite-magnesium extraction process which has been adopted universally. Dr. Pidgeon's talk will be on new trends and techniques and will deal particularly with energy requirements in the metallurgical extraction field.

3.30 p.m. Outstanding Problems in Microwave Engineering

DR. G. B. WALKER, B.SC., PH.D.,

Electrical Engineering Staff, Assumption University, Windsor.

Dr. Walker is a recent arrival from the U.K., where he acquired extensive experience in the field of microwave transmission. This new field of engineering will be of interest to all engineers particularly now that we depend so much on this medium of communication in our own country.

4.10 p.m. Recent Developments and Research in Fan Design

J. BARRY GRAHAM, B.SC.,

Research Director, Buffalo Forge Co., and Canadian Blower and Forge Company.

Prior to his association with his present companies, Mr. Graham was on the staff of U.C.L.A. at the Los Alamos Atomic Laboratory. Every engineer can produce air. Mr. Graham also knows how to move it and by the very latest methods.

2.40 p.m. Corrosion in the Chemical and Petroleum Industries

STAN V. ANTENBRING, B.SC., M.E.I.C.,

Chief Construction Engineer, Imperial Oil Ltd., Sarnia, Ont.

The cost of corrosion to Canadian industry runs to many millions of dollars annually. Mr. Antenbring will discuss causes, effects and remedies for this most serious drain of maintenance dollars that faces us all no matter what our field of engineering.

3.30 p.m. Current Problems in Municipal Engineering

W. A. WHETEN, B.SC., M.E.I.C., P.ENG.,

Dep. City Engineer, City of Hamilton

Mr. Wheten will explain how demands of a rapidly growing city are successfully met with particular reference to sewage disposal, water distribution and pollution, road construction and maintenance. Mr. Wheten has had considerable experience in this type of work in different parts of the world.

4.10 p.m. Power and Canada

R. A. H. HAYES, B.SC., M.E.I.C., P.ENG.,

Vice-President, Sales, H. G. Acres & Co. Ltd., Niagara Falls.

Progress in Canada has closely parallelled our development and utilization of power and will continue to do so. Mr. Hayes has personally had a hand in the design and construction of many of our largest power developments. It would be difficult to obtain a speaker more qualified to present a paper on this interesting subject.

For the Ladies!!

11.00 a.m.	Brittany Suite	Registration and coffee hour
1.00 p.m.	Sheraton Room	Buffet Luncheon
2.30 p.m.	Sheraton Room	Fashions for '59

The entire Ladies' Program will this year be held in the Sheraton-Connaught Hotel. See above for some of the special arrangements that have been made to ensure that the ladies have a pleasant and enjoyable day.

ladies are cordially invited. Plan NOW to attend.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Dr. Charles Camsell, M.E.I.C., former deputy minister of mines, and a past-president of the Engineering Institute, died on December 22, 1958, at the age of 82.

Born at Fort Liard, N.W.T., in 1876, he was the son of Captain Julian S. Camsell, Canadian Rifles, a chief factor in the Hudson's Bay Company. He received his early education at St. John's College, Winnipeg, and his B.A. degree at the University of Manitoba in 1894. Later he took post-graduate work in geology at Queen's University, and at Harvard and Massachusetts Institute of Technology.

Dr. Camsell spent the early years in exploration and study of the northwest.

These early adventures were published in 1954 by Ryerson Press in the book "Son of the North", an autobiography.

From 1894 to 1900 he travelled in Mackenzie River basin and in the region west to the Pacific Coast, taking part in geological survey work at Great Slave Lake, Great Bear Lake and the Coppermine River basin. During part of 1901 he was exploring the Moose River basin on James Bay for the Algoma Central Railways; in 1902 he traversed the woods buffalo country between the Peace River and Great Slave Lake, and acted as geologist to the Canadian Northern Railway Company in western Ontario and northern Manitoba in 1903. In the following year he joined the permanent staff of the Geological Survey, travelling from Dawson to the mouth of the Mackenzie River and exploring the Stewart and Peel Rivers. The year 1906 saw his activities

Ottawa Journal Photo
Dr. Charles Camsell, M.E.I.C.

transferred to British Columbia, where he worked for five years on economic problems. In 1914, in charge of exploratory work for the Geological Survey, he traversed the country between the Athabaska River and Great Slave Lake. From 1918 to 1920 he was in charge of the Vancouver office of the Geological Survey of Canada. In 1920 he was appointed Deputy Minister of the Federal Department of Mines, later the Department of Mines and Resources. He also became Commissioner of the Northwest Territories. He retired in 1946 as deputy minister, but held the post of Commissioner of N.W.T. for some time.

Dr. Camsell served on the E.I.C. Council in 1929 and 1930, and was president in 1932. He was president of the Canadian Institute of Mining and Metallurgy in 1947, president of the Royal Society of Canada in 1931, president and one of the founders of the Canadian Geographical Society. He held membership and offices in a number of other scientific and learned organizations.

Among his academic honours may be noted the degrees LL.D. which he received from Queen's University in 1922 and from the University of Alberta in 1929. The Royal Geographical Society awarded him the Murchison Grant in 1922 and the Founders Medal in 1945. The Institution of Mining and Metallurgy, London, presented him with its gold medal. The R. B. Bennett Empire Prize for 1945 was awarded to him for a paper presented to the Royal Society of Arts. The Professional Institute of the Civil Service awarded its medal to Dr. Camsell in 1946.

Gordon S. Stairs, M.E.I.C., chief engineer of the Nova Scotia Department of Highways and director of its new research and planning branch died suddenly in Toronto on October 5, 1958. He had been in Ontario on a study of the highway research program.

Born at Selma, Nova Scotia on August 31, 1889, he received his engineering education at Dalhousie University and at the Nova Scotia Technical College. He graduated with a B.Sc. degree in civil engineering in 1911.

During the early years of his career, he was employed on various engineering projects, by the Western Canada Power Company, Stave Falls, B.C. and by A. V. White, consulting engineer in Toronto.

Gordon S. Stairs, M.E.I.C.

In 1917 he was commissioned as a lieutenant in the Royal Canadian Engineers. After World War I he returned to Nova Scotia to be assistant engineer with the Halifax Works Department. Later he was town manager and engineer in Wolfville and in Windsor, N.S. Between 1928 and 1934 he served L. E. Shaw Limited and the Dominion Bridge Company Limited. He became resident engineer with the Department of Highways in 1934.

During World War II he served the Royal Canadian Air Force for five years in the Maritimes and Central Canada. In 1945 he returned to the Highways Department as division engineer of construction. He was appointed chief engineer two years ago.

Henrik Mugaas, M.E.I.C., civil engineer died at his home in Meaford, Ont., on August 4, 1958.

Mr. Mugaas was born on April 28, 1894 in the town of Evanger, Norway. He attended schools in Bergen, and technical high school at Darmstadt, Germany. After more technical training at Bergen, Mr. Mugaas began his career there. Coming to Canada toward the end of the 1920's, he worked on surveys for transmission lines.

From 1935 to 1943 he was with the Lamaque Gold Mines Ltd., Val D'Or, Que., as chief surveyor of the company. In 1943 he joined the R.C.A.F., and upon his release in 1946, he returned to the Lamaque Mining Co. at Bourlamaque, Que.

In 1951 he moved from Val D'Or, Que. to Meaford, Ont. where he worked on the general hospital, new public utilities, and also public and high schools.

In 1952 he accepted a position with the Department of National Defence on army construction. He also served the Central Mortgage and Housing Corporation for several years in the Maritimes.

John R. White, M.E.I.C., project supervisor, chemicals division of the Products Department of Canadian Industries Limited, Cornwall, Ontario, died in August 1958.

Born in Saskatchewan in the town of Parkside on September 2, 1916, he graduated from the University of Saskatchewan with a B.E. degree in mechanical engineering in 1938.

For two years he held various posts with the Saskatchewan Power Commission and the P.F.R.A. Moving East at the end of 1939, he worked with the Consolidated Paper Corporation, Three Rivers, Que. From 1940 to 1947 he was employed in the engineering departments of Defence Industries Limited and Canadian Industries Limited, as draughtsman, quantity surveyor, and assistant project engineer. In 1948 he was named estimating engineer of the Department of Development for the chemical division of Canadian Industries Limited, Montreal. In 1955 he was transferred to the Cornwall plant of the company.

• OBITUARIES

James Emmett Flynn, M.E.I.C., project engineer with Narod, Dawson & Hall, died recently in Vancouver.

He was born in Victoria, B.C., on January 4, 1914, studied forestry engineering at the University of British Columbia, graduating with a B.A.Sc. in 1942.

Upon graduation he joined the H. R. MacMillan Export Company as instrumentman on logging operations, becoming in 1945 survey chief on extensive topographic surveys on logging operations. In 1947 he joined Bloedel Stewart & Welch Ltd., as resident engineer for the construction and development of pulpwood resources in connection with establishing a new pulpmill. From 1949 to 1951 he was associated with Columbia Cellulose Co. Ltd., on the construction of a pulpmill at Prince Rupert, B.C.

Later he worked for the Central Mortgage & Housing Corporation and Defence Construction (1951) Ltd.

He joined Narod, Dawson & Hall, contractors for the construction of the Deas Island Tunnel, in 1957 as a project engineer.

Wing Commander D. G. Joy, M.E.I.C., former district director of air services, civil aviation at Winnipeg, died at York Mills, Toronto on October 30. He had been active in military and civil aviation from 1915 until his retirement from the Department of Transport in 1951.

Douglas Grahame Joy was born at Barrie, Ont., on February 16, 1887. He studied mechanical engineering at the University of Toronto, School of Practical Science, 1906 to 1910.

In the early part of his career he was associated with the Ontario Hydro-Electric Power Commission.

In World War I he served overseas with the Royal Flying Corps, winning the Air Force Cross. He had been one of the first graduates of the Curtiss Wright Aviation School in Toronto in 1916. He retired from the R.C.A.F. with the rank of Wing Commander in 1922.

In 1920 he returned to the Power Commission, but went into engineering contracting in 1922.

He joined the Department of Transport, Government of Canada, civil aviation branch, in Toronto in 1930. He was inspector of civil aviation in that area until after World War II.

Posted to Winnipeg then, he was district controller of air services concerned with the civil aviation, radio, meteorological and airways engineering divisions.

George Agar, M.E.I.C., retired vice-president and assistant to the president, Canadian Vickers Limited, Montreal, died on June 22, 1958.

He was born at Barrow-in-Furness, England on August 8, 1893, and attended technical school and mechanical engineering courses there

He was first associated with Vickers Ltd. in Barrow-in-Furness, as an apprentice. In 1913 he became a marine engine draughtsman. In 1917 he came to Canada and was appointed assistant chief marine engineering draughtsman and designer for Canadian Vickers Limited, Montreal.

By 1949 he had attained the post of executive engineer and assistant general manager of the company. Later, promotions were those of vice-president and executive engineer, and vice-president and assistant to the president. He retired in 1957.

Thomas O. Whillans, M.E.I.C., who retired in 1956 from the Government of Canada Patent Office, died on October 16, 1958.

He was born at Hurdman's Bridge, Ontario on November 22, 1890. He graduated from Queen's University with a B.Sc. degree in mechanical engineering in 1917.

Following graduation, he joined the Imperial Ministry of Munitions at Welland, Ont. From 1919-1920 he was a mechanical engineer with Pedlar People Ltd., Oshawa. In 1921 he joined the Canadian Patent Office as assistant patent examiner. In 1951 he was appointed assistant commissioner of patents with the Patent and Copyright Office of the Secretary of State Department. He was among those awarded a Coronation Medal in 1953 by Her Majesty Queen Elizabeth.

Harold Frederick Bush, M.E.I.C., general engineering supervisor at the Bell Telephone Company of Canada, Montreal, died on December 4, 1958.

Born in Ottawa on October 2, 1899, he attended primary and secondary schools there. In 1918, his university education was interrupted by World War I, in which he served in the Canadian Army Service Corps. Returning to McGill University upon his discharge from the army, he obtained a B.Sc. degree in electrical engineering in 1922.

Following his graduation he was for some time employed as engineer with the Hydro-Electric Commission of Ontario, at Ottawa. In November 1922 he joined the general engineering department of the Bell Telephone Company as an engineer. During the following twenty-three years he worked in the engineering department.

In 1946 he was appointed staff engineer in the headquarters staff engineering group where he played an important role in the decision to introduce microwave radio relay systems in Canada.

Mr. Bush was a member of the American Institute of Electrical Engineers, of the Canadian Standards Association and the Canadian Radio Technical Planning Board.

Calendar

Canadian Institute of Mining and Metallurgy, annual general meeting, Montreal, Que., April 13-15, 1959.

Operations Research Society of America, seventh annual meeting, Washington, D.C., Spring, 1959.

Institute of Environmental Engineers, third annual meeting, Chicago, Ill., April, 1959.

Symposium on the Chemistry of Cellulose, Tashkent, U.S.S.R., April, 1959.

Metal Powder Association, national meeting, Detroit, Mich., April, 1959.

American Institute of Electrical Engineers, early 1959 conferences; American power conference, (with ASME) Mar. 31-Apr. 2; railroad conference (with ASME), Chicago, April 7-9; electric heating conf., Philadelphia, Pa., April 14-15; electrical problems in the cement industry conference, Allentown, Pa., April 16-17; recording and controlling instruments conference, Philadelphia, Pa., Apr. 20-21.

American Society of Lubrication Engineers; national meeting, Buffalo, N.Y., April 21-23.

International Association of Geodesy; international symposium on instruments, Washington, D.C., Spring, 1959.

Aero Medical Association, Los Angeles, April 27-29, 1959.

International Association for Hydraulic Research; eighth congress, Montreal, during week of August 24, 1959. Information about participation is available from Leo Roy, c/o Quebec Hydro-Electric Commission, 107 Craig St. W., Montreal 1, Que.

Fifth World Petroleum Congress; The Coliseum, New York, May 30 to June 5, 1959. Congress Secretariat, 527 Madison Ave., New York 22, N.Y.

National Industrial Production Show; (also a display by British Manufacturers organized by the British Board of Trade, and the Birmingham Exchange and Engineering Centre), Toronto, May 4-8, 1959.

Chemical Institute of Canada; conferences of the protective coatings subject division, Toronto, Feb. 19, Montreal, Feb. 20, 1959.

American Society for Quality Control, Toronto Section; sixth annual forum, Hart House, University of Toronto, March 7, 1959.

American Meteorological Society; national meeting, Chicago, Ill., Mar. 24-27, 1959.

American Society for Metals, Montreal Chapter; 1959 educational lecture series, January to March. H. Neville Mason, P.O. Box 371, Station H., Montreal, Que.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

BRITISH COLUMBIA

Consulting Engineers Division

Some suggestions for stimulating B.C. payrolls through the increased use of B.C. products were presented to the Provincial Cabinet by the Association of Professional Engineers of British Columbia.

In a Brief prepared by the Consulting Engineers Division of the Association, it was pointed out that direct benefit would accrue to B.C. manufacturers, contractors and suppliers if engineering projects involving the use of public money employed permanent residents of the province as the prime consulting engineers. Among the advantages cited are the familiarity of B.C. professional engineers with local conditions, building codes, and business practices. Because of this local knowledge they design for and specify locally available products and services, to the general economic advantage of the province.

The brief was presented on behalf of the Association by President R. E. Wilkins, P.Eng., Past President George C. Lipsey, P.Eng., D. H. Drake, P.Eng., and Registrar J. A. Merchant, P.Eng.

ONTARIO

Annual Meeting of A.P.E.O.

Andrew W. F. McQueen, P.ENG., M.E.I.C., of Niagara Falls, Ont., is the 1959 president of the Association of Professional Engineers of Ontario. He took office during the annual meeting on January 24. He succeeds C. T. Carson, P.Eng., as head of the organization.

In business life, Mr. McQueen is president of H. G. Acres & Co. Ltd., consulting engineers. At present the firm is undertaking two large hydro-electric projects in West Pakistan. A member of the A.P.E.O. since 1938, he has served on the Executive Council during the last two years, and last year was the Association's first vice president.

He is a graduate (1923) in civil engineering from the University of Toronto, and received the professional degree C.E. from his alma mater in 1932.

Elected first vice-president for 1959 is Dwight S. Simmons, general manager of manufacturing, Imperial Oil Ltd., Toronto. The second vice president is John W. Holmes, design engineer, Canadian General Electric Co. Ltd., Peterborough.

The following councillors were also elected, two for each of the five engineering branches, in addition to one appointed for each branch by the Lieutenant-Governor-in-Council.

Civil branch: Tullis N. Carter, vice president and general manager, Carter Construction Co., Toronto, and William A. Clarke, chief engineer, Ontario Dept. of Highways, Toronto. The appointed representative is V. S. Murray, also of Toronto.

Chemical and Metallurgical branch: Thomas H. Adair, assistant director of engineering and metallurgy, Ontario Research Foundation, Toronto, and Edmund P. Lewis, senior chemical engineer, Polymer Corp. Ltd., Sarnia. One councillor to be appointed.

Electrical branch: Robert L. Hicks, engineer, distribution planning and design dept., Toronto Hydro-electric System, and Gordon M. McHenry, consumer service engineer, Ontario Hydro-electric Power Commission, London. The appointed representative is Dr. J. Herbert Smith, Toronto, president of Canadian General Electric Co. Ltd.

Mechanical, Aeronautical and Industrial branch: Donald L. Angus, a partner in the consulting engineering firm of H. H. Angus & Associates Ltd., Toronto, and Lawrence C. Sentance, manager of the Defence Apparatus Division, Canadian Westinghouse Co. Ltd., Hamilton. The appointed representative is Dr. G. Ross Lord, head of the mechanical engineering department, University of Toronto.

Mining branch: William E. Bawden, chief engineer of mines, Ontario Dept. of Mines, Toronto, and Dr. Marc Boyer, Deputy Minister, Canadian Dept. of Mines and Technical Surveys, Ottawa. The appointed representative is Dr. George B. Langford, head of the department of geological sciences, University of Toronto.

The new Executive Council convened at the Association's annual meeting which held Saturday, January 24, at the Royal York Hotel, Toronto.

Science Teacher Honoured

The newly established award to Ontario's "maths and science teacher of the year" has been won by H. E. Totten who is head of the mathematics department at Toronto's Forest Hill Collegiate.

Mr. Totten was selected over 17 other teachers nominated across Ontario by the various districts of the Ontario Secondary School Teachers Federation. Presentation was made at the annual meeting.

T. R. Loudon Receives Award

A pioneer in Canadian aviation, Prof. Thomas R. Loudon, P.Eng., of Toronto, received the Association's highest honour, the Professional Engineers' Gold Medal.

The citation reads: "The Professional Engineers' Medal is presented by the Association of Professional Engineers of Ontario to Thomas Richardson Loudon, B.Sc., C.E., P.Eng., Professor Emeritus of civil and aeronautical engineering, University of Toronto, who as professor of civil and aeronautical engineering, has made a valuable contribution to the professional and educational life of his country".

Students Receive Awards

Recipient of student awards of the Association were: A. M. Hale, a graduate of University of Toronto, who is employed by Preston Woodworking Machinery Co., and H. R. Whiteley of Ottawa, a graduate of Queen's, who is in England on an Athlone Fellowship.

Gordon Churchill, Guest Speaker

Trade and Commerce Minister Gordon Churchill paid tribute to the work being done by Canada's engineers both at home and abroad. He addressed the annual meeting.

"Canadian engineering firms", he said, "are already capitalizing on Canada's reputation overseas. Against the toughest competition, contracts are being secured in overseas countries in such diversified fields as frequency conversion of electrical plant, pulp and paper consulting engineering, bridge design and mining development".

Canadian firms competed recently, he said, for major contracts to provide defence telecommunications systems for NATO countries in Europe, radio broadcasting equipment for Latin American countries, and airborne navigation systems for use in the United States, Europe and Japan.

Personals

News of the Personal Activities of Members of the Institute

Rt. Hon. C. D. Howe, P.C., Hon. M.E.I.C. (B.Sc., Massachusetts Institute of Technology 1907) has been elected to the board of directors of RCA Victor Company Limited.

D. C. Turner, M.E.I.C. (B.A., chem., McGill 1932) staff assistant, Canada Starch Company, Cardinal, Ont., has been elected chairman of the Brockville Branch of the Engineering Institute.

J. W. G. Scott, M.E.I.C. (B.Sc., civil, New Brunswick 1949) partner in the firm Turnbull & Scott, Saint John, N.B., is the choice of the Saint John Branch of the Institute as chairman for the current year.

E. Bodmer, M.E.I.C. (mech., Switzerland 1944) is the new chairman for the Baie Comeau Branch of the Institute. He is associated with the Quebec North Shore Paper Company.

R. E. Wilkins, M.E.I.C. (B.Sc., civil, Queen's 1936) has been appointed assistant to the president of B.C. Engineering Co. Ltd., Vancouver. He was formerly superintendent of civil engineering design for the company. He is president of the Association of Professional Engineers of B.C. and the Military Engineers' Association of Canada.

James W. Kerr, M.E.I.C. (B.A.Sc., elec., Toronto 1937) has been appointed president and chief executive officer of Trans-Canada Pipe Lines Limited. He is the former vice-president and general manager of the Canadian Westinghouse Company's apparatus products group, at Hamilton.

H. T. Miard, M.E.I.C. (B.A.Sc., civil, British Columbia 1933) has been appointed deputy minister, Department of Highways, of British Columbia. He has been with the Department since 1947, most recently as assistant deputy minister.

D. C. Turner

J. W. G. Scott

E. Bodmer

Rear Admiral/(E) B. R. Spencer, M.E.I.C. (Royal Naval Engineering College, England, 1929) has been promoted from engineer in chief to chief of naval technical services at National Defence Headquarters, Ottawa.

W. A. Friebel, M.E.I.C. (B.Sc., elec., Manitoba 1933) has been named manager of utilities of the City of Saskatoon. He is the former city engineer.

C. A. Stollery, M.E.I.C. (B.Sc., civil, Alberta 1941) has been elected to the board of directors of Royalite Oil Company, Limited. He is vice-president of Poole Construction Company Limited.

A. W. Purdy, M.E.I.C. (B.Sc., civil, Queen's 1949) has accepted a position as district sales manager for the Canada Cement Company Ltd. at Calgary, Alta. He was formerly district sales manager for the Maritime Cement Company Ltd., at Moncton, N.B.

D. C. Macpherson, M.E.I.C. (B.S., Queen's 1924) is vice-president of the firm C. E. Macpherson Limited, Kingston.

E. J. Cole, M.E.I.C. (B.Sc., civil, Saskatchewan 1944; B.A., physics, Sask., 1946) has been promoted from assistant city engineer to city engineer of the City of Saskatoon.

A. J. McIntyre, M.E.I.C. (B.Sc., elec., Manitoba, 1947) has joined the St. Lawrence Corporation Limited, Three Rivers, Que., as assistant plant engineer. He was formerly assistant project engineer with Hanright and Company at St. Catharines, Ont.

M. E. J. O'Loughlin, M.E.I.C. (B.A.Sc., chem., Toronto 1947) of Imperial Oil Limited has been transferred to the Halifax refinery as plant superintendent.

Allan G. Moffat, M.E.I.C. (B.A.Sc., Toronto 1944) was appointed manager of Haddin, Davis and Brown (Manitoba) Limited, late in 1958.

A picture of Mr. Moffat was included

J. W. Kerr

in the November 1958 issue page 96, with an incorrect caption. The picture is repeated in this issue.

Rev. J. E. Page, S.J., M.E.I.C. (B.Sc., civil, Manitoba 1945; M.Sc., community planning, Manitoba 1958) former staff member of St. Paul's College at Winnipeg, is now a theology student at the Jesuit Seminary in Toronto.

E. R. Graydon, M.E.I.C. (B.A.Sc., civil, Toronto 1935) of the Dominion Bridge Company Limited, was recently named manager of the Ontario division. He was formerly chief engineer of that division.

A. M. Thomson, M.E.I.C. (B.Sc., civil, Saskatchewan, 1948) has been appointed technical sales representative for construction chemicals in Alberta and British Columbia for Dewey & Almy Chemical Division, W. R. Grace & Co. of Canada Limited, Montreal.

T. M. Claughton, M.E.I.C. (H.N.C., elec., Oldham, England 1943) until recently with the Montreal Engineering Company Limited, will be for approximately one year with C. A. Energia Electrica de Venezuela, Maracaibo, Venezuela.

M. d'Amours, M.E.I.C. (B.A.Sc., elec., Laval 1945), former superintendent of operations, Quebec Power Company, has been named general superintendent.

Gordon Barnholden, M.E.I.C. (B.Sc., chem., Saskatchewan, 1948) former plant manager, Canada Creosoting Company Ltd., Calgary, has been appointed superintendent of the company's British Columbia operations.

G. W. Redwood, M.E.I.C. (B.A.Sc., mechanical sciences, Cambridge 1946) succeeds R. I. Stevens as works engineer of the Shawinigan plant of Canadian Industries Limited.

E. W. Blackmore, M.E.I.C. (B.Sc., McMaster Univ., 1940), formerly products superintendent at the Toronto tar plant of the Dominion Tar and Chemical Company is presently assistant works manager at the Hamilton tar plant.

P. A. Brett, M.E.I.C. (B.Sc. elec., Manitoba, 1948), is district manager at the Winnipeg office of English Electric Canada, and John Inglis General Engineering Division.

R. M. Ferguson, M.E.I.C. (B.Sc., civil, Alberta 1946) is assistant chief engineer for Canadian Brown Steel Tank Company, Brandon, Manitoba.

H. M. Sherwood, M.E.I.C. (B.Sc., chem., Alberta 1933) has been promoted to sales manager, textile fibres division of Canadian Industries Limited, Montreal.

W. G. Muir, M.E.I.C. (B.Sc., mining, Nova Scotia Technical College 1931) is mine manager for Dominion Rock Salt Company Ltd. at Goderich, Ont.

J. M. Ferguson, M.E.I.C. (B.Sc., civil, Saskatchewan 1946) has been transferred to the head office of Mannix Co. Ltd. in Calgary, Alta.

Walter J. Francl, M.E.I.C. (Dipl. Engr., mechanical and agriculture, Vienna 1948) has been appointed chief design engineer of the municipal engineering department for the Edmonton office of Stanley, Gimble Roblin Ltd.

T. J. Boyle, M.E.I.C. (B.Sc., civil, Saskatchewan 1937) is assistant engineer of bridges, Canadian Pacific Railway Company. He has been a special engineer on matters connected with the St. Lawrence seaway affecting the C.P.R.

Kaljo Tammik, M.E.I.C., (B Sc., civil, Gothenburg, Sweden) has recently been appointed design engineer with M. M. Dillion & Co. Ltd., London, Ont.

P. J. G. Carrothers, M.E.I.C. (B.A.Sc., chemical and textiles, British Columbia 1944; S.M., M.I.T. 1952) an associate scientist for the Fisheries Research Board of Canada, at Vancouver has been transferred to the biological station at Nanaimo, B.C.

Dale A. Bailey, M.E.I.C., (B.E. civil, Sask., 1953; M.S.C.E.. Purdue 1958) has taken over a post with the Federal Department of Public Works, Regina, Sask. In his new work he is resident engineer, highways division.

A. L. Gourley, M.E.I.C., (B.Sc., mech., Queen's, 1946), is teaching at the Perth & District Collegiate Institute, Perth, Ont. Mr. Gourley was formerly with Phillips Electrical Company, in Brockville, Ont.

G. Y. Sebastyan, M.E.I.C. (B.Sc.E., civil, Michigan, 1953; M.Sc.E., Michigan, 1958), has joined the construction branch of the Air Services, Department of Transport, Ottawa.

Major W. E. Blake, M.E.I.C. (B.Sc., civil, Queen's 1947) is a military observer for U.N. in India and Pakistan. He was formerly at the First Canadian Infantry Division headquarters.

Louis Mathys, M.E.I.C. (M.Sc., mech., Federal Institute of Technology, Zurich, 1942), is in Cuba as chief engineer for the acid and metal recovery plant of Krebs S.A. Paris.

W. D. Alexander, JR.E.I.C., (B.Sc., M.E., mech., Manitoba 1950) has recently been released from the Royal Canadian Horse Artillery. He is assistant professor in the mechanical engineering department at the University of Manitoba.

N. W. E. Lee, JR.E.I.C., (M.Sc., civil, Purdue, 1954), of Hunting Technical and Exploration Services, has been transferred to Montreal. He is the company's project engineer and general representative in Photographic Survey Corporation (Quebec) Ltd.

• PERSONALS

G. Montambeault, JR.E.I.C. (B.Sc.Eng., mining, Laval 1952) has been transferred to the Copper Cliff works of Canadian Industries Limited, as project engineer.

Pierre Lefrancois, JR.E.I.C. (B.A.Sc., che., Ecole Polytechnique 1956) is doing post-graduate studies in industrial administration at the Carnegie Institute of Technology, Pittsburgh, Pa.

G. A. Metcalfe, JR.E.I.C. (B.A.Sc., civil, Toronto 1951) a maintenance engineer with the Department of Highways of Ontario has been transferred from the Chatham district to the Ottawa district.

Armand Couture, JR.E.I.C. (B.A.Sc., 1953, civil, M.S., Laval) is a transportation engineer in the Montreal office of the Foundation of Canada Engineering Corporation Ltd.

F/L A. V. Rugienius, JR.E.I.C. (B.Eng., chem., McGill 1951) former project officer for the directorate of aircraft engineering at R.C.A.F. headquarters, Ottawa, is studying at the College of Aeronautics, England.

J. Edward Henderson, JR.E.I.C. (B.Sc., civil, Queen's 1955) has completed research work under an Athlone Fellowship. He has a position as assistant to the turbine erector, Warsak hydro electric project in West Pakistan.

Lee Morrison, JR.E.I.C. (B.E., geological, Saskatchewan 1957) has been appointed exploration geologist for Benguest Consolidated, Inc. at Baguio City in the Philippines.

J. Shumiatcher, JR.E.I.C. (B.Eng., mech., McGill 1950) formerly field manager for Canadol Construction Ltd., Calgary, has become general manager of the firm.

J. M. Bentham, JR.E.I.C. (B.Eng., civil, McGill 1947), has been appointed engineer of track, Canadian Pacific Railway Company.

R. F. J. Falconer, JR.E.I.C., (B.A.Sc., civil, Toronto, 1955), is a project engineer with James F. MacLaren Associates, consulting engineers in Saint John, N.B.

Raymond Hebert, JR.E.I.C., (B.A.Sc., civil, Ecole Polytechnique, 1953), has been town engineer and assistant manager for the Town of Seven Islands, Que., since August, 1958.

W. D. Goodings, JR.E.I.C., (B.Sc. civil, Queen's 1951) is with Proctor & Redfern, consulting engineers of Toronto as resident engineer at Brantford, O.W.R.C.

R. C. Hermann, JR.E.I.C., (B.A.Sc., civil, U.B.C., 1952), has been appointed supervisor of construction cost in the accounting section of the general engineering department of the Aluminum Company of Canada Limited, Montreal.

George V. Cox, JR.E.I.C., (B.Eng., civil, McGill, 1956), is with the O'Brien Engineering Company Ltd. in Nassau, Bahamas.

L. J. Eibner, JR.E.I.C., (B.Sc., civil, Manitoba, 1948), until recently western division engineer for Laminated Structures Limited, Vancouver, has been transferred to the Montreal branch of the firm as sales co-ordinator.

Jan Dlouhy, JR.E.I.C., (B.Eng., chem., McGill, 1954; Ph.D., McGill, 1957), has joined the technical department of Cyanamid of Canada Ltd., Niagara Falls, Ont. as a senior engineer.

R. P. Malis, JR.E.I.C., (B.Sc., civil, Manitoba, 1954), until recently resident engineer at the Kootenay National Park for the Department of Northern Affairs and National Resources, has been transferred to Ottawa, Ont. as an administration engineer.

W. J. Monkman, JR.E.I.C., (B.Sc., elec., Alberta, 1949), is a design engineer with the Electrical Group of the Boeing Aeroplane Company, Renton, Washington.

Thomas V. Stephens, S.E.I.C. (B.Sc., elec., New Brunswick 1957) has been transferred to Esquimalt, B.C. as a lieutenant on the staff of the manager of electrical engineering of H.M.C. Dockyard.

Douglas W. Ferrier, S.E.I.C. (B.Sc., civil, Alberta 1957) has joined Associated Engineering Services Ltd., Edmonton, Alta.

Jean-Claude Hebert, S.E.I.C. (B.Sc., mech., Ecole Polytechnique 1958) is with the Canadian Broadcasting Corporation as assistant Quebec regional engineer.

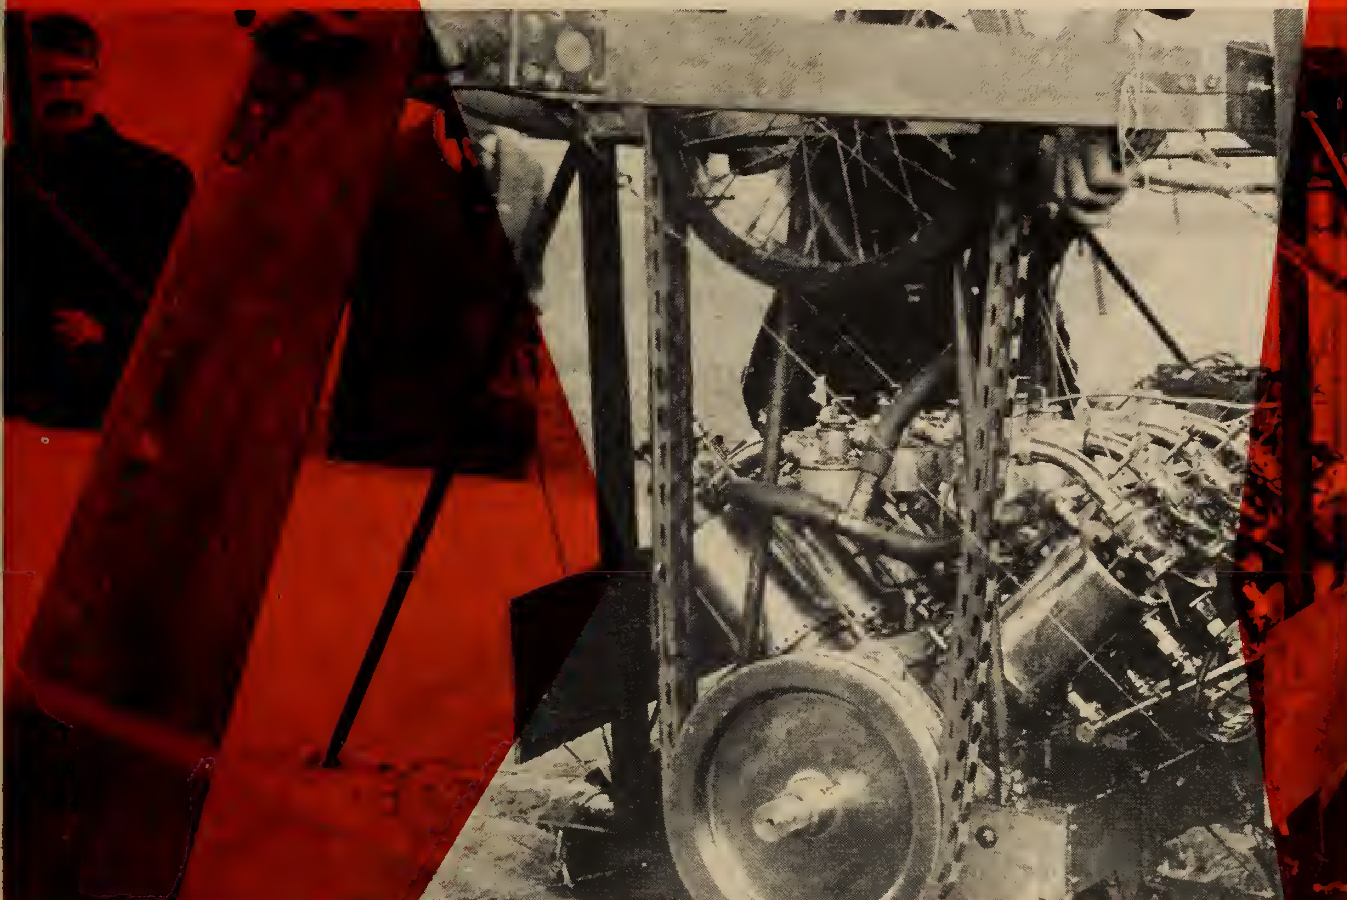
Paul E. Tremblay, S.E.I.C. (B.A.Sc., mechanical and electrical, Ecole Polytechnique 1958) is doing post-graduate studies in London, England under an Athlone Fellowship.

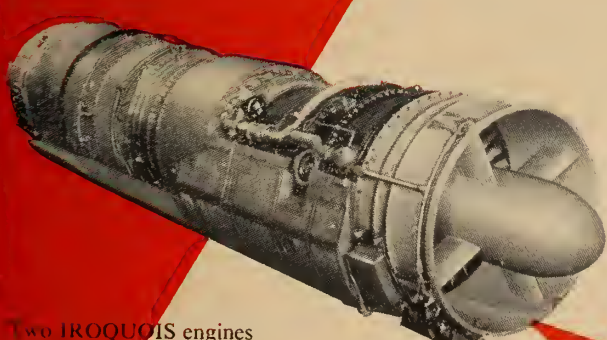
David G. Hobart, S.E.I.C. (B.Eng., mech., McGill, 1958), is studying economics at Pembroke College Cambridge, England.

F. T. White, S.E.I.C., (B.A.Sc., eng. and bus., Toronto, 1957), has joined International Business Machines, Toronto as system analyst.

Harold Norrish, S.E.I.C. (B.A.Sc., civil, British Columbia, 1958) is an assistant project engineer with the Greater Vancouver Sewerage and Drainage District.

Jean F. Riel, S.E.I.C. (B.A.Sc., mech., Ecole Polytechnique 1958) is at the State University of Iowa, for one year of study in hydraulics.





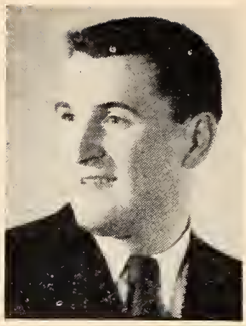
• PERSONALS

Paul P. Steinhubl, S.E.I.C., (B.E., civil, Saskatchewan 1958) has been appointed assistant district engineer with the Saskatchewan Municipal Road Assistance Authority.

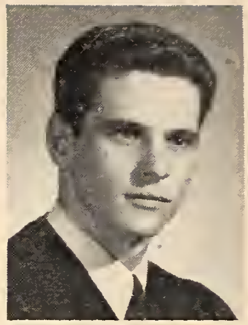
Jean Paul Voisine, S.E.I.C., (B.S.A., elec., Laval 1958), is working as an electrical engineer for Canadair Ltd. in Montreal.

P. J. Blanchard, S.E.I.C., (B.Sc., C.E., New Brunswick, 1958), is attending the University of Michigan.

D. G. Turner, S.E.I.C., (B.Sc., elec., Manitoba, 1958), is employed as scientific officer with the Defence Research Board, Canadian Armament Research and Development Establishment, Valcartier, Que.



J. C. Hebert



P. Tremblay

B. de Cardaillac

W. S. Wilkinson, S.E.I.C., (B.E., chem., Nova Scotia Technical College, 1958), is working for the Shell Oil Company of Canada.

R. B. Swansburg, S.E.I.C., (mech., Acadia, 1953; B.E., mech., N.S.T.C., 1955), has joined Kenwood Mills Ltd. as a sales and service engineer in Arnprior, Ont.

J. H. Bertin Tremblay, JR.E.I.C., (B.A.Sc., chem., Laval 1958), is employed in the Quebec Department of Health.

Gilles N. Theberge, S.E.I.C., (B.Eng., civil, McGill 1958), is assistant engineer for Canadian Pacific Railway at Farnham, Que.

Flying Officer D. R. Bundy, S.E.I.C., (B.E. mech., Saskatchewan, 1958), is a radar officer at R.C.A.F. station in Lac St. Denis, Que.

Wm. D. McGilvray, S.E.I.C., (B.Sc., mech., Saskatchewan, 1958), is with the Steel Company of Canada Ltd., Hamilton, Ont.

Bertrand de Cardaillac, S.E.I.C., (B.Eng., elec. (comm.), McGill, 1957) is with the chief electrical engineer of Asbestos Corporation Ltd.

Paul R. Bennett, S.E.I.C., (M.Sc., mech., Queen's, 1958), is employed as instrument engineer with the Spruce Falls Power & Paper Co. Ltd., in Kapuskasing, Ont.

Vincent G. Beckie, S.E.I.C., (B.Sc. Geological, Sask. 1958) is working with the groundwater section of the water rights division, Department of Agriculture, Province of Saskatchewan.

Seaforth M. Lyle, S.E.I.C., (B.Eng., elec., McGill 1958), is doing post graduate work at McGill University in the field of analogue computers.

J. Martino, S.E.I.C., (B.Sc., mech., Man., 1958), is employed as a reactor-mechanical engineer with the maintenance and power branch, Engineering Services Division, Atomic Energy of Canada, Deep River, Ont.

Claude Maillet, S.E.I.C., (B.Eng., communication, McGill, 1958), is now serving as a lieutenant in the RCEME Corps, Canadian Army (R).

R. Kenneth Cox, S.E.I.C., (B.Eng., civil, McGill, 1958), has become assistant engineer for W. D. Laflamme Ltd., contractors, Hull, Que.

INSTRUMENTATION

(Continued from page 77)

onment. If anything could be done to reduce this by better selection of alloys or other materials for instrument components it would be a step in the right direction, the survey concluded.

Trend Toward Automation in Stock Preparation

The stock preparation department in a paper mill furnishes stock to the paper machines, proportioned as to fibres and chemicals necessary to develop the varied sheet characteristics needed. The method of preparation may be manual, semi-automatic or automatic.

Comparative air-dry tons of stock furnished per man-hour since the beginning of automation, including colouring, broke-pulping, purchased pulp slushing and handling from storage, average as follows: *manual* 0.538 furnished per man-hour; semi-automatic, 1.53 tons furnished per man-hour; and fully automatic, 1.83 tons furnished per man-hour. This comparison shows there has thus been a decided increase in output per man-hour as the stock preparation moved toward automation.

Reasons for this continuous progress include a) increased labour costs; b) the need for improved uniformity free from human error, and c) the high cost of buildings, storage and equipment, particularly in mills where space is at a premium. Complete automation of stock preparation is a next step in the manufacture of a quality product at a minimum cost.

Advantages of Electrical Equipment

Although, currently, in most mills up to 90 per cent of the control systems are pneumatic, electronic devices enter into modern production systems and processes in many phases. Where put into service through carefully designed circuits and selected components, they provide a valuable and rugged controlling medium. Reluctance, in the past, to use such equipment arose from fears that delicate components and mysterious circuits would call for constant vigilance by skilled mechanics.

Electronic control devices are dependable in their performance under the most rigid standards. "The Building Block" method of circuit assembly, using sealed-in components, brings a new strength and reliability to industrial electronic applications.

Due to the fact that standard electronic control panels with the same basic assemblies can be used in so many places in one paper mill, spare parts inventories can be kept low.

There is one disadvantage in too wide a use of electronic devices, however, which may become a boomerang. When the equipment becomes too old and breakdowns call for service and replacements, there may be a lack of specialists to do the repair work on old and obsolete types of equipment, now superceded by more efficient and up-to-date models.

Modernization Needed

In the United States a special survey was recently completed of business needs for modernization in industry. The cost to replace obsolete facilities for all manufacturing was assessed at $34.8 billion. Of the total, needs for modernization in the pulp and paper industry was set at $2.655 billion.

Since roughly one-third of the United States' wood-fibre requirements comes from Canada, expenditure for modernization in Canadian pulp and paper mills might require an outlay of some $1.32 billion, assuming a similar age of manufacturing capacity as that of the pulp and paper plants in the United States.

The U.S. survey referred to determined that of the pulp and paper manufacturing capacity in the U.S., 49 per cent had been installed prior to Dec. 31, 1945; 17 per cent had been installed between that date and Dec. 1950; while the remaining 34 per cent of capacity had been installed between December 1950 and December 1957.

While no similar survey has been published for Canada, based on government figures for production of wood pulp at the end of each of these periods a rough comparison can be arrived at. Such a comparison would indicate that some 55 per cent of Canadian manufacturing capacity in the pulp and paper industry had been installed prior to 1945; another 20 per cent between then and late 1950, with the remaining 25 per cent installed between Dec. 1950 and December 1957.

In other words, a somewhat larger proportion of Canadian pulp and paper machinery and equipment than that of the industry in the United States may be presently in need of modernization, though what proportion of this modernization would be for instrumentation can only be surmised.

KAPLAN TURBINES

(Continued from page 61)

ent but usually to an unobjectionable degree, and in this case were aggravated by an unusually flexible oil head support and very sensitive blade response.

Another point of interest is the method by which pressure is maintained on the oil in the runner hub. The hub is connected through a central pipe in the main shaft to a small reservoir at the top of the oil head. Relative elevations of the oil head and hub ensure that static oil pressure within the hub always exceeds the water pressure of the tailwater under all conditions including shutdown. Proper sealing of the hub would make this feature unnecessary, but it was felt that it provided an extra insurance in case leakage of any type should develop.

We believe that Beechwood was the first application of an electrohydraulic governor in Canada. Our Company is neutral on this subject and installed this type of governor at the request of the consultants. It is felt that any advantages are more in the dispatching field than in mechanical governing. Its application will undoubtedly be followed with great interest.

Aside from the oil head problems mentioned, the units had no more than the usual run-in problems. The turbine performed smoothly over full gate range. Governing of the gates and blades was smooth and responsive.

In a paper given before the joint E.I.C.-ASME meeting in 1956* it was stated that 20% of the installed hydro capacity in the United States is of Kaplan design. The comparable figure in Canada at that time was less than 1%. Though conditions in Canada and the United States vary considerably in many basic respects, it is reasonable to assume that the number of Kaplan installations will sharply increase as undeveloped power sites become fewer in number and many sites have to be reconsidered. The Beechwood Development may be considered as an important step in this trend.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute

and abstracts of the papers presented at their meetings

AMHERST

G. R. Pond, JR.E.I.C., *Sec.-Treas.*

TIDAL POWER STUDIES undertaken for the Annapolis River dam were discussed by J. D. Conlon at a branch meeting on December 12, 1958. Mr. Conlon is chief engineer, Maritime Marshlands Rehabilitation Association.

General interest prompted a brief but rigorous investigation of the tidal power potential as well as the plant which could utilize the rock fill causeway, the main river control sluices and the temporary flow bypass structures which the Annapolis River dam, presently under construction for marshland protection and a highway bridge replacement will comprise.

BAIE COMEAU

G. W. Scott, M.E.I.C., *Correspondent*

DR. J. L. LUSSIER, of Quebec North Shore Paper Company spoke at the meeting of October 31, 1958.

Dr. Lussier discussed operation studies carried out in the woods department of the Quebec North Shore Paper Co. The greater part of his discourse covered the statistical analysis of evidence accumulated as the result of woods operations' studies. These analyses determine the most economic policy to be followed in a given set of operational circumstances. The talk was supplemented with statistical equations and diagrams.

THE ANNUAL GENERAL MEETING was held on November 20.

In his report the retiring chairman, V. M. Wallingford, said that following the inaugural banquet held in December 1957 which was attended by the Institute's president and general secretary the branch had had a most successful year.

The following executive was unanimously elected at the general meeting: Chairman, E. Bodmer; secretary, L. A. G. Tellier; treasurer, T. G. Rust; executive members, G. W. Scott, P. Suttie, J. M. Pope; representative for Labrieville, G. Laboissiere.

A dance which was attended by 60 members and guests followed the business of the meeting.

BELLEVILLE

D. A. Law, JR.E.I.C., *Correspondent*

J. R. MILLS, vice-president, Foundation Company of Canada, spoke at the branch meeting of December 8.

His talk on the Dew Line was followed by an excellent coloured film.

For the construction of this defence project advance parties, supplies, equipment and prefabricated buildings were landed by plane to establish campsites. Fuel, heavy equipment and structures were transported by ship during the short Arctic summer.

CENTRAL BRITISH COLUMBIA

A. F. Joplin, M.E.I.C., *Correspondent*

THE ANNUAL MEETING was held in Vernon, December 5, 1958.

An interesting prelude to the meeting was a dedication ceremony held at the "lookout" over Kalamalka Lake, seven miles south of Vernon. A monument was erected to commemorate the work of pioneer engineers, amongst whom is A. E. Ashcroft who was responsible for the design and construction of the Vernon irrigation district.

Similar plaques and cairns were erected at Oliver, Penticton, Kelowna and Revelstoke as a project of the Central B.C. Branch in connection with British Columbia's Centennial. Dedication ceremonies will be carried out at these centres. The engineers honoured by these plaques are:

Oliver: F. H. Latimer, in charge of South Okanagan Land Irrigation Project, 1905-1940; *Penticton:* A. H. McCulloch, engineer in charge of construction of Kettle Valley Railway which reached Penticton in 1914; *Kelowna:* F. W. Groves, in charge of development of water storage and irrigation 1908 till 1948; *Revelstoke:* Major A. B. Rogers, C.E., who was in charge of construction of C.P.R. through the Selkirk Mountains, 1880-1885.

CAPE BRETON

H. M. Aspinall, M.E.I.C., *Correspondent*

A SOCIAL EVENING and dance was held by the Branch on November 17 with about 40 couples attending. It was a very successful evening socially.

CHALK RIVER

C. A. Crawford, M.E.I.C., *Chairman*

THE CHALK RIVER PROJECT was discussed by three A.E.C.L. speakers on November 19. They were: Dr. D. A. Keys, scientific advisor to the president; Dr. G. C. Butler, head, Biology Division; and Dr. J. M. Robson, head, Nuclear Physics Division.

The members and ladies found the information most interesting. Dr. Keys' talk was a history of the project.

Dr. Butler explained the two uses of biology in atomic engineering: the use of pile products, and the determining of the effect of radiation on life. According to J. M. Robson, the physicist now has more dependence on the engineer, as new devices are developed.

Bishop A. H. Sovereign (right) retired bishop of the Anglican Church in the Yukon and N.W.T., officiated at the dedication of a plaque at Kalamalka Lake. At left is E. R. Gayfer, branch chairman.

• BRANCH NEWS

EDMONTON

I. G. Finlay, M.E.I.C., *Correspondent*

THE SOUTH SASKATCHEWAN RIVER DAM was discussed at a meeting of the Edmonton Branch on November 26. The speaker was R. Peterson, soil mechanics engineer, P.F.R.A.

Mr. Peterson discussed the history of the project, described the reservoir, irrigation, power and water supply scheme. His familiarity with the plan from soil observations to cost and status of construction made this a most informative session for the record audience of this year, 117.

KITCHENER

John Runge, M.E.I.C., *Correspondent*

PRESIDENT K. F. TUPPER visited the branch on November 24, speaking to the members about his observations during a recent visit to Russia.

KINGSTON

D. I. Ourom, JR.E.I.C., *Correspondent*

NEW DEVELOPMENTS in explosives and blasting techniques were described on November 25 by John Bell of Canadian Industries Limited, Montreal.

Mr. Bell discussed the use of millisecond detonating relays, the use of nitrocarbonitrates as blasting agents, and the recent introduction of ammonium nitrate and fuel oil mixtures. A film, "Blasting a New Niagara" illustrated the blasting techniques required during the construction of Sir Adam Beck No. 2 development.

LONDON

G. W. Chorley, M.E.I.C., *Correspondent*

THE ANNUAL VISIT OF THE PRESIDENT to London was on November 26. President K. F. Tupper was the luncheon guest of E. Rippingille, Jr., president of G. M. Diesel Ltd., together with Dr. E. V. Buchanan and the executive of the Branch.

Mrs. Tupper was entertained at lunch by the executive of the Engineers Wives Association. In the evening a cocktail party was given in their honour, and a dinner meeting was held.

In the afternoon Dr. Tupper addressed the engineering students at the University of Western Ontario.

NIAGARA PENINSULA

D. A. Barnum, M.E.I.C., *Chairman*

A JOINT E.I.C.-A.P.E.O. MEETING was held in Niagara Falls, on October 16, chaired by the E.I.C. branch. C. Bruce Hill, president of E.T.F. Tools Limited, spoke on Educational and Technical Advances in Russia.

JOHN FISHER was the speaker at a joint A.P.E.O.-E.I.C. meeting held at St. Catharines, Ont., on November 18. This meeting was chaired by the A.P.E.O. branch. Mr. Fisher's subject was Building a Greater Canada.

PRESIDENT K. F. TUPPER and Mrs. Tupper, with General Secretary Garnet T. Page and Mrs. Page, were guests of the Branch on November 27. The executive met for discussions with the visitors, and for dinner at the Niagara Falls Club.

THE BURLINGTON SKYWAY was the subject of a talk on December 4 by H. W. H. Casperd. This was also a joint meeting, chaired by the E.I.C. branch. A full description of the planning, building of the Skyway was given by Mr. Casperd, supervisor of field engineering and J. T. Gregg, supervising bridge engineer.

NORTHERN NEW BRUNSWICK

Stewart K. Henry, JR.E.I.C.,
Branch Correspondent

A GENERAL MEETING of the Northern New Brunswick Branch was held on November 18, with 20 engineers present.

P. J. Delicaet was elected vice-chairman, by acclamation. It was announced that R. C. Eddy would represent the Branch on the E.I.C. Nominating Committee, and that A. W. Rowe and R. W. Rankine were appointed branch auditors. Membership of the branch nominating committee was also announced. The branch annual meeting was planned for May 29, 1959.

John A. McLaren, E.I.C. field secretary was a guest at this meeting. A delicious lunch was served by compliments of the Connolly Construction Limited.

MONCTON

V. C. Blackett, M.E.I.C., *Sec.-Treas.*

THE ENGINEERS WIVES ASSOCIATION of the Moncton Branch held a pot luck supper meeting, on November 13, arrangements for which had been made by Mrs. H. L. Purdy, social convenor.

The president, Mrs. Wesley M. Steeves, chaired the meeting. The guest speaker, Dan Billing, co-ordinator of civil defence for southern New Brunswick was introduced by Mrs. Anne Nason, and gave a brief outline of the work being carried on by Civil Defence.

Mrs. H. L. Purdy, Mrs. Anne Nason, Mrs. V. C. Blackett, and Mrs. Wesley M. Steeves, executive of the Engineers' Wives Association, Moncton Branch.

The secretary-treasurer's report was read, and Mrs. J. W. Ward was named to the executive. Mrs. M. F. K. Leighton who had attended the 72nd annual meeting of the Institute in Quebec City, spoke of work being done in other wives' branches across Canada. Mrs. G. J. Gaudet, Mrs. R. C. Gillespie and Mrs. C. O. Lockhart, transferred back to Moncton, and Mrs. R. F. MacKenzie and Mrs. J. A. Baxter were welcomed as members.

A CHRISTMAS DANCE AND BUFFET SUPPER held on December 5 at the Brunswick Hotel, was enjoyed by members and their wives. It was sponsored by the Wives Association.

Buffet table decorations were supplied by Mrs. D. A. Foster. Each lady received a corsage. Prize winners during the evening were Mr. and Mrs. R. C. Gillespie, Mr. and Mrs. H. J. Crudge and Mr. Jack Veness.

Music was provided by the Maurice Stevens orchestra.

J. A. MCLAREN, eastern field secretary of the E.I.C., visited Moncton on November 13, and was the guest at dinner of the branch executive. Later, there was a conference at which Mr. McLaren explained and emphasized certain Institute services available to the membership. He referred particularly to the library at Headquarters. There was a lengthy discussion regarding *The Engineering Journal*. The executive were unanimous that the most desirable articles were those dealing with major Canadian engineering works, either under construction or recently completed.

NIPISSING, UPPER OTTAWA

D. W. Briden, JR.E.I.C., *Sec.-Treas.*

LADIES NIGHT, November 7, 1958, was the occasion of the visit to the branch of President and Mrs. K. F. Tupper and General Secretary Garnet T. Page.

The event took the form of a dinner and dance held at the Golden Dragon restaurant, North Bay, Ont. Dr. Tupper spoke to the eighty-four members, wives and guests present about his recent trip to Russia. It was a most enjoyable and interesting evening.

• BRANCH NEWS

OTTAWA

Arthur H. Graves, JR.E.I.C.,
Publicity Chairman

ALAN HAY, M.E.I.C., general manager F.D.C., and Walter B. Bowker, information division, F.D.C., spoke on "The National Capital Plan" on October 9, 1958. Approximately 60 persons attended.
J. W. KERR, M.E.I.C., vice-president and general manager, apparatus products, Canadian Westinghouse Co. Ltd. addressed the joint meeting (with A.I.E.E.) on October 16, on "Some Impressions of the U.S.S.R." Attendance exceeded 100 persons.
REGULAR LUNCHEON, November, 1958, was addressed by C. K. Hurst, M.E.I.C. on "Interesting Sidelights of Ripple Rock". Attendance, 75 persons.
LT. COL. J. I. THOMPSON, C.O. Army Survey Establishment spoke at November 20 meeting on "Topographical Mapping in Canada". Attendance was 50.

SARNIA

LEROY D. SMITHERS, president and general manager of Dow Chemical Co. of Canada, spoke to the Sarnia Branch of

Clair Huston, Leroy D. Smithers, Chairman R. A. McGeachy.

the Institute on November 20.
Mr. Smithers was the final speaker in the Branch's eight-week professional Development course.

SUDBURY

F. Jackson, M.E.I.C., *Correspondent*

PRESIDENT K. F. TUPPER, visiting the branch on November 10 with General Secretary Garnet T. Page, attended a dinner dance.
Dr. Tupper, introduced by W. J. Ripley, M.E.I.C., talked about Engineering in the U.S.S.R., and made other observations of his recent trip.

UNIVERSITY OF MANITOBA

Brian K. Laxdal, S.E.I.C.
Student Chairman

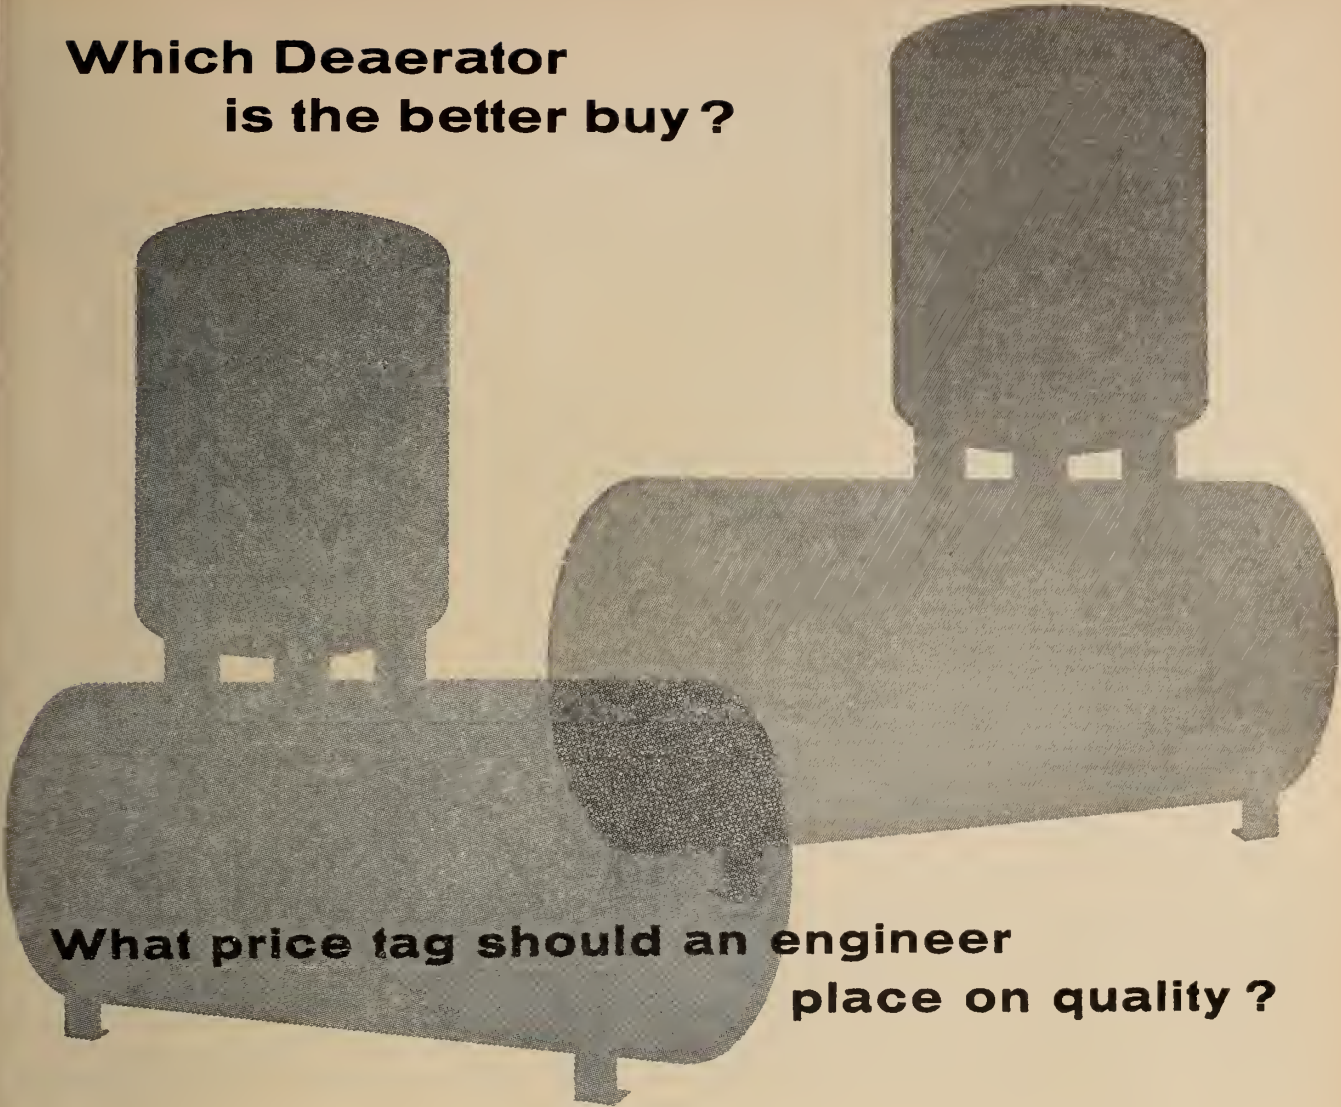
EACH THURSDAY at 12:30 to 1:30 p.m., in the Engineering Building, films and speakers as follows, have been presented to the University of Manitoba, Student Section.
Oct. 2–Operation Bluejay, (Attendance 200); Oct. 9–Dawn's Early Light (200); Oct. 23–Strange Case of Cosmic Rays, (200); Oct. 30–Skywatch on "55", (200).
Nov. 6–Speakers: H. F. Brehaut, Manitoba Bridge and Engineering Works; M. J. Davies, chief geologist, Manitoba Department of Mines and Natural Resources.
Nov. 13–Investment panel–sponsored by Winnipeg Chamber of Commerce; panel members: E. Jackson, moderator; L. Cemeron, mutual investments; J. MacKnight, stocks and bonds; S. Scott, life insurance.
Nov. 20–Dr. K. F. Tupper, president E.I.C.; Nov. 27–film, Phoenix Tower, (200).
Membership drive, Nov. 4-8; approximately 80 new memberships resulted.

WINNIPEG

P. M. Abel, JR.E.I.C., *Correspondent*

THE RIPPLE ROCK explosion was discussed at a meeting, November 20, by the technical service manager, explosives department, Dupont Company of Canada, R. S. Harding.
The meeting (attended by 70) first saw the excellent colour film prepared by Dupont which deals with the project. Afterwards, the meeting was conducted on a question and answer basis.
PRESIDENT K. F. TUPPER and Mrs. Tupper, with General Secretary Garnet T. Page were guests of the branch on November 19, 20,. 1958.

Which Deaerator is the better buy?



What price tag should an engineer place on quality?

These two medium sized deaerators look alike. We designed both. They have the same outlet capacity, carry similar guarantees and meet the ASME code. But one costs $2000 more than the other.

Which is the better buy?

Obviously, you would want to know more about each unit in order to make a sound decision. Construction to ASME standards and basic guarantees are but part of the quality story. The higher priced unit, for example, has far heavier shell plate, more tray area and spilling edge, superior shell reinforcement, stainless instead of carbon steel baffle, anti-flash downtake. All of these features, we have found, are important to continued top performance.

As one of the world's largest and most experienced manufacturers of deaerators, we believe we know which unit is the better buy. Extra margins of strength and capacity — wisely selected — are not luxuries but sound investments that eliminate downtime and expensive field repairs.

That is why we recommend *quality*, and why thoughtful engineers insist on *quality*. If you are considering the purchase of deaerating equipment we are prepared to help you evaluate *all* the features that mean *true economy* in service. Ask for Bulletin 4650 on the "Why and How of Deaeration".

Write for these five bulletins on Deaeration—the problem, types of deaerators and applications.

Toronto, Canada.

Montreal Winnipeg Vancouver

News of Other Societies

C.C.A. Meets at Montreal

The 41st annual meeting of the Canadian Construction Association was held at the Queen Elizabeth Hotel in Montreal, January 18-21, 1959. Over a thousand delegates were welcomed by the Hon. Sarto Fournier, mayor of Montreal. J. Eric Harrington, M.E.I.C., vice-president, Anglin Norcross Quebec Limited, was elected president of the Association for the coming year.

Association President, Harold J. Ball of Kitchener, noted that the volume of construction had continued to rise in 1958, while many other industries had experienced a decline in activity. As Canada's largest industry construction had thus played a key role in our country's overall economic stability. "The upward trend should continue in 1959 to a total of perhaps $7½ billion," he predicted. "Because of improved techniques the construction dollar will give relatively more value than ever before, increased costs notwithstanding. The industry still has almost unlimited scope for further advances."

Noting increased wintertime construction and virtual elimination of shortages as outstanding achievements in the past year, he voiced the impression Canada had now reached a stage where there was a definite *surplus* of contractors. In spite of record volumes there would be a "buyer's market" with bitterly keen competition being a standard condition.

Committee Reports

Apprenticeship Committee chairman, H. C. Nicholls, reported a 4 per cent increase in registration of indentured apprentices during 1958 or to 8,593, in eight provinces having apprenticeship agreements with the Federal Government. This growth however was at a diminishing rate compared with the 9 per cent increase in 1956 and the 7 per cent increase in 1957.

Chairman D. H. Jupp of the Business and Contractor Relations committee reported progress in the development of bid depositories had been limited, although establishment of such arrangements in Ottawa last September for plumbing and electrical trades was highly significant.

Chairman Robert Hewitt of the Construction Equipment Committee reported the publication of a revised edition early in 1958, of the CCA "Rental Rates on Contractors Equipment" schedule.

Chairman V. L. Leigh of the Housing Committee drew attention to the record breaking total of more than 150,000 completions in 1958. Cost and availability of land were more of a problem than actual construction costs. Land prices for NHA units had risen roughly 5½ times as much as building costs during the 'fifties'.

Chairman G. F. Lipsett of the Labor Relations Committee reported submission of a Brief to the Minister of Labour.

Chairman A. Blake Robertson of the Legislation committee reported on follow-up activities arising out of the brief submitted to the Minister of National Revenue in December 1957 relative to Department policies on reporting income. Although the department had not adopted the Association's first submission a number of related matters were clarified and agreed upon.

Chairman W. A. Marshall of the Sales Tax Committee drew attention to the fact that federal sales tax exemptions on material and equipment available to junior governments tended to discourage them to set up their own forces to carry out work normally going out to competitive tender. He urged the present discrimination against contractors be removed. A major sales tax hardship existed, he pointed out, in the different tax treatment given to competing materials.

Chairman Ray Brunet of the National Joint Wintertime Construction Committee, stated that although volume and employment this winter should be greater this winter than in 1957-58, upwards of one third of those unemployed were construction workers. He expressed hope all those having authority over the initiation of construction work would also plan *now* and in ensuing months so projects would be scheduled to provide employment *next* winter wherever possible.

On the second day's morning session delegates heard addresses by Major-General H. A. Young, Deputy Minister of Public Works, and President R. G. Johnson of Defence Construction (1951) Ltd. General Young's remarks are reported in another section.

Defence Construction

R. G. Johnson, president of Defence Construction (1951) Limited told delegates that in 1958 DCL had awarded contracts to the value of $90 million, compared with 58 million in 1957, while it entered 1959 with work outstanding valued at some $69 million. DCL expects expenditures on defence contracts in 1959 may be nearly doubled those of 1958, or nearly $100 million.

A total of $86 million was the present estimated Canadian contribution towards engineering and construction on Colombo Plan projects with which DCL is associated. Up until the end of 1958 Canadian expenditures on these projects amounted to $54 million.

NUCLEAR CONGRESS 1959

Forty sessions will be held during the five-day Nuclear Congress, 1959, which begins April 5 at the Public Auditorium in Cleveland, Ohio. The Engineering Institute is one of the twenty-nine sponsoring societies. The Congress will be comprised of the Fifth Nuclear Engineering and Science Conference, the Seventh Atomic Energy Management Conference, the Seventh Hot Laboratories and Equipment Conference, and the Atomfair.

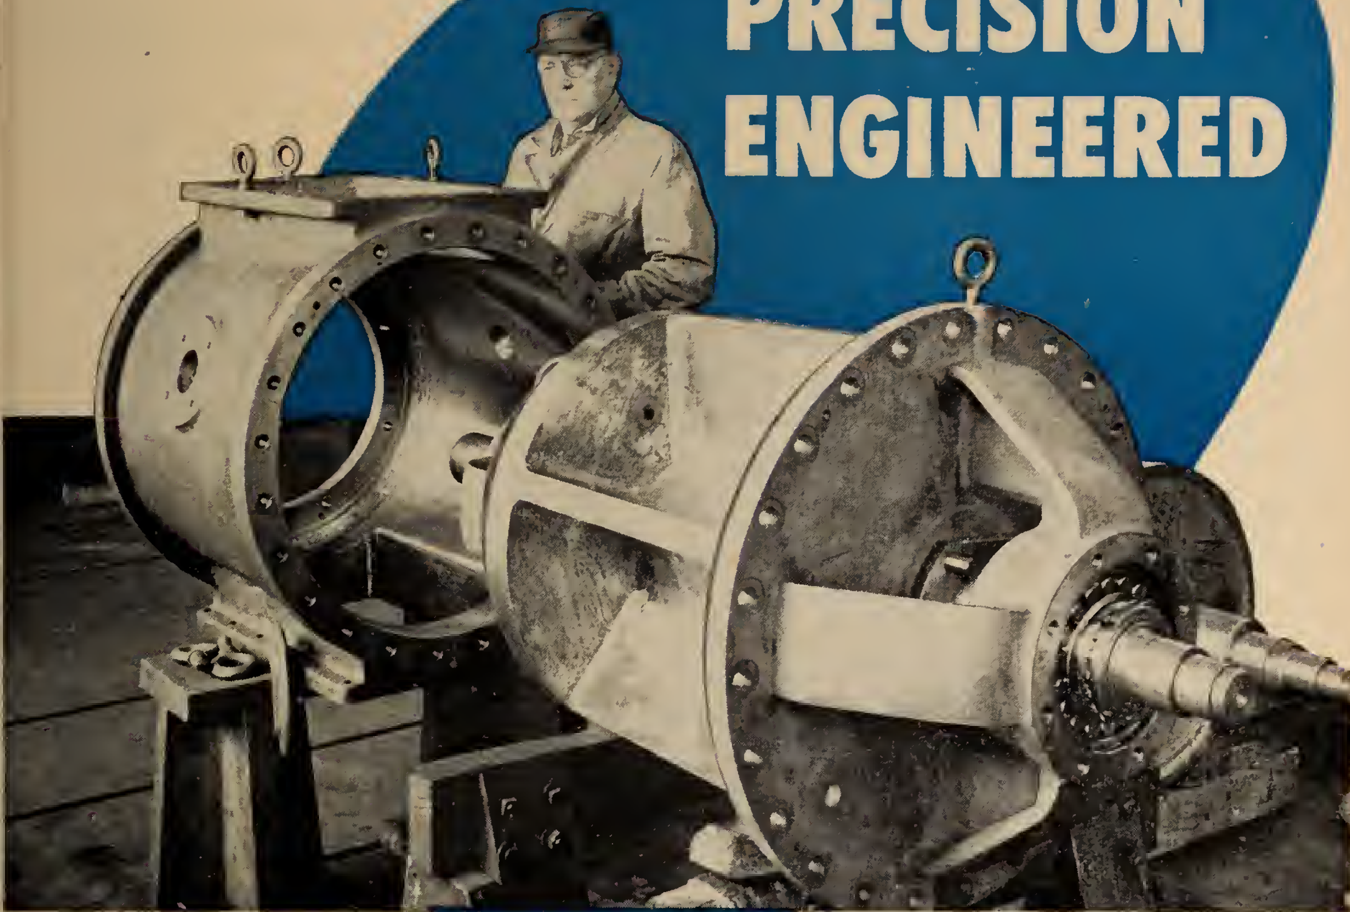
Nuclear Engineering and Science Conference

There are 24 sessions scheduled in the Nuclear Engineering and Science Conference. Their subjects are: Waste Disposal; Nuclear Research Test and Training Facilities; Simulation and Experimental Instrumentation; Water Supply; Nuclear Instruments; Nuclear Component Design; Health Physics; Heat Transfer; Reactor Instrumentation; Chemistry and Chemical Processing; Power Reactor Design; Instrumentation; Nuclear Fuel Processing Plants — Design and Practice; Radio Tracers in the Process Industries; Reactor Physics; Fuel Technology; Isotope Application; European Power Reactor (A), (B) and (C); Fusion Processes; Metallurgy and Materials 1, II; Reactor Operating Experience and Maintenance.

The Atomic Energy Management Conference consists of a series of discussions on the broad application of nuclear power and influence, and the potential of the nuclear field on the sociological and economic structure of industry.

The seventh conference on hot laboratories will deal with the highly technical details of the development of equipment and operation of laboratories for atomic energy.

The Atomfair, which is open for the whole five days duration of the Congress from 9:00 a.m. to 5:00 p.m. is an exhibit by major manufacturers of the latest products, components and services for the peaceful uses of atomic energy.



LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

CABMA REGISTER OF BRITISH INDUSTRIAL PRODUCTS FOR CANADA, 1958-59

There are over 3200 British products listed in the sixth edition of this most useful Register. More than 4000 British firms interested in export are listed, with information on their products, address and Canadian distribution arrangements. Canadian associated companies of British firms are listed separately. (Canadian Assoc. of British Manufacturers and Agencies. London, Iliffe, 1958. 653p.)

THREE STEPS TO VICTORY

This volume, sub-titled "A Personal Account by Radar's Greatest Pioneer" is the history of the development of Radar and its wartime use. Other inventions are also described: I.F.F (Identification, Friend or Foe); Oboe; Gee and Rebecca-Eureka. (Sir Robert Watson-Watt, M.E.I.C., London, Odhams, Toronto, Nelson, Foster and Scott, 1957. 480p., $6.50.)

*PRINCIPLES OF ELECTRONIC INSTRUMENTS

The first part of the book deals with instruments to measure electrical quantities by electronic methods. The second part deals with non-electrical measurements by electronic instruments, such as velocity, time, sound, light, pressure and temperature, and radioactivity. Emphasis is placed on the circuits of instruments rather than their use, and on circuits designed to operate at relatively low frequencies. (G. R. Partridge. Englewood Cliffs, N.J., Prentice-Hall, 1958. 393p., $11.00.)

THERMODYNAMICS OF ENGINEERING SCIENCE

The aim of this volume is to give undergraduate students a basic knowledge of thermodynamics and its applications.

The first eleven chapters can be considered as an introductory course.

The remaining chapters are on applied thermodynamics and cover compressors, turbomachinery, internal combustion engines, gas turbines, refrigeration and heat pump, jet propulsion, etc. (S. L. Soo. Englewood Cliffs, Prentice-Hall, 1958. 620p., $12.65.)

MATTER, EARTH, AND SKY

The latest book by this popular author, this volume covers the field of the physical sciences in non-technical language, with a wealth of diagrams and illustrations.

The first section discusses the field of "classical physics" illustrated by things familiar in everyday life such as the motion of a pendulum, waves, the flight of a tennis ball, etc. The second section deals with microcosms, the world of modern physics and chemistry, molecules, atoms and nuclear energy. The final section is concerned with things much larger than man, the interior of the earth; the oceans; the solar system; the stellar systems and the history of the universe. (G. Gamow. New York, Prentice-Hall, 1958. 593p., $10.00.)

*PRINCIPLES AND APPLICATIONS OF RANDOM NOISE THEORY

The author indicates how to formulate difficult noise problems, derive their solutions, and obtain proper physical design and interpretations. The book discusses probability theory, random noise analysis, random processes, engineering systems, correlation functions, power spectral, density functions, and optimum filters. (J. S. Bendat. New York, Wiley, 1958. 431p., $11.00.)

PULP AND PAPER MANUAL OF CANADA, 1958

This edition of the Manual contains a review of the industry in 1957, and also contains statistics of paper production. The papers in the second section deal with the use of hardwood and methods for keeping the moisture content of air low.

By far the largest part of the Manual is a trade directory, with a classified listing of machinery supply and service companies, trade names, and foreign companies represented in Canada. (Gardenvale, P.Q., National Business, 1958. 469p.)

*TECHNOLOGY OF COLUMBIUM (NOBIUM)

A summary of the present status of knowledge of columbium. The seventeen papers included study this metal from the standpoint of economic and supply aspects, properties, extractive and physical metallurgy, analytical problems, and various specialized aspects. The papers were presented at a symposium sponsored by the Electro-Chemical Society, May 1958. (Ed. by B. W. Gonser and E. M. Sherwood. New York, Wiley, 1958. 120p., $7.00.)

FLAVOR RESEARCH AND FOOD ACCEPTANCE

Based on four one-day conferences organized by Arthur D. Little, Inc., this volume can be called the authority on one of the basic factors of food product success, that is, flavour.

The chapters are all by experts in the field, and contain references for further reading. (New York, Reinhold, 1958. 391p., $10.00.)

*CASTILLA'S SPANISH AND ENGLISH TECHNICAL DICTIONARY. VOLUME 1: ENGLISH-SPANISH; VOLUME 2: SPANISH-ENGLISH

An extensive dictionary primarily concerned with the fields of engineering technology, although commercial and legal terms are included as are words of importance in everyday language because of the continual use they receive. Abbreviations and commercial terms are also included, while those used only in the pure sciences are in general excluded. (New York, Philosophical Library, 1958. 2v., $45.00.)

FUNDAMENTALS OF THERMODYNAMICS

The book presents an introduction to thermodynamics and its application in modern engineering problems. The first three chapters cover the basic laws of thermodynamics, following chapters cover: the pure substance (steam); vapour power cycles; vapour refrigeration cycles; the perfect-gas system; gas compression cycles; gas power cycles; gas and gas-vapor mixtures; steady flow of fluids; flow through pipes and ducts; heat transfer. A new two-colour Mollier chart is included. (C. M. Leonard. Englewood Cliffs, Prentice-Hall, 1958. 376p., $8.00.)

*CALCUL DE L'ECOULEMENT EN CONDUITES SOUS PRESSION OU A SURFACE LIBRE D'APRES LA FORMULE DE MANNING-STRICKLER

An extensive compilation of tables for the calculation of water flow in pressure conduits, and in channels with free surface, both open and covered. Under each of the main classes the tables are subdivided by cross-section — circular, ovoid, trapezoidal, etc., and figures are given for small dimensional changes over a wide range of size and shape. Graphical representation is a feature of some sections and numerical examples are given. (P. A. Arghyropoulos. Paris, Dunod, 1958. 326p., 3800 fr.)

• LIBRARY NOTES

*THE ENCYCLOPEDIA OF CHEMISTRY (SUPPLEMENT)

Intended to bring the original 1957 volume up to date, this supplement gives strong emphasis to the impact of nuclear phenomena on chemistry. Some of the topics given consideration are porphyrins, plasma, propellants, cermets, dosimetry, fluoridation, resonance, jet propulsion, liquid state, as well as many others. (Ed. by G. L. Clarke. New York, Reinhold, 1958. 330p., $10.00.)

*JET PROPULSION

The author attempts to explain concepts from the fundamental engineering laws rather than from an equation standpoint. Emphasis is given to the aerothermodynamics of gas systems, and topics discussed include the diffuser, nozzle, Fanno line, isothermal, normal shock, and oblique shock flow. The flow through each engine component and the components themselves are discussed, as are the combined performance characteristics of engines and air frames. (W. J. Hesse. Toronto, Pitman, 1958. 567p., $9.75.)

*TECHNICAL DRAWING, 4TH ED.

A thorough revision of a well known text. Areas which have been given particular attention in this edition include geometrical constructions; dimensioning and notes; threads, fasteners, and springs; shop processes; engineering graphics; structural drawing; topographic drawing; welding representation. The majority of the illustrations have been redrawn, and the format of the book has been enlarged to permit clearer illustrations. The entire volume has been revised to reflect the latest American Standards. (F. E. Giesecke and others. Galt, Brett-Macmillan, 1958. 844p., $7.50.)

*FLUID PRESSURE MECHANISMS, 2ND ED.

Studies the mechanism of hydraulic and pneumatic machinery, particularly from the viewpoint of their essential principles. Among the changes made in this edition are the inclusion of new material on slide valves, jacks with force limitation, special couplings, and synchronization systems. The chapter on servo systems has been substantially revised. (H. G. Conway. Toronto, Pitman, 1958. 235p., 32/6.)

*ENVIRONMENTAL SANITATION

Emphasis is placed on planning for the small community of less than 5000 persons. Among those aspects given consideration are control of communicable disease; location and planning in relation to sites for camp, industrial, housing, and similar uses; water supply sources, construction, treatment, and distribution; waste-water treatment and disposal; swimming pools and bathing beaches; food, insect, rodent, and noxious weed control; hygiene of housing. Empirical formulae and rules of thumb are applied when they are advantageous. (J. A. Salvato, Jr. New York, Wiley, 1958. 660p., $12.00.)

FEDERATION INTERNATIONALE DE LA PRECONTRAINTE: PROCEEDINGS OF THE SECOND CONGRESS

All the papers presented at the second congress of the Federation held in Amsterdam in 1955 are contained in this volume.

The five sessions considered: Function of grouting and anchorages in the behaviour of prestressed elements; Experience and problems concerning the manufacture and the use of steel for prestressing; Progress of precast prestressed work in the factory and the assembly by prestressing on the site of precast units; Moment distribution in statically indeterminate prestressed structures beyond the elastic phase; Influence of plasticity on the strength and instability of thin prestressed shells. (F. I. P. London, Cement and Concrete Assoc., 1958. 990p., £5.)

POWER TRANSFORMERS FOR HIGH-VOLTAGE TRANSMISSION

Written by the Chief Designer of the Transformer Department of Bruce Peebles and Company, this book shows some of the work being done at that company, and illustrates some of the factors to be taken into account in the design of transformers. (D. McDonald. Edinburgh, Bruce Peebles, 1958. 95p.)

DYNAMIC DECADE

The discovery of oil in Alberta has made a great difference to the economy of that province, and indeed to that of the whole country. This is the history of the search for oil in Alberta, the bringing into production of Leduc, Redwater, Pembina, etc. The author discusses methods of transporting and marketing oil, natural gas, pipe lines, production figures, etc. He considers the effect oil has had on Alberta's economy, the new industries it has attracted, and the problems which have been created. (E. J. Hanson. Toronto, McClelland and Stewart, 1958. 314p., $5.00.)

EXPERIMENTELLE UNTERSUCHUNGEN AN VERSCHIEDEN STARK KONVERGENTEN, SCHLANKEN ROTATIONSKORPERN BEI MAFIG HOHEN UBERSCHALLGESCHWINDIGKEITEN

This study starts with an explanation of the selection of bodies to be measured, the measuring of equipment used, the measurement of forces etc. Following this, the theory giving the main differential equation of the special flow; the release of the linear differential equations for supersonic speed; the calculation of pressure distribution etc. The results of measurements are given, taking into account tenacity. (H. R. Voellmy. Zurich, Leemann, 1958. 82p., 17 Sw. Fr. Mitteilungen aus dem Institut fur Aerodynamix No. 24.)

REFLEX KLYSTRONS

This survey of the current knowledge on reflex klystrons commences with a general introduction and the historical background. The topics covered include: cavity resonators and output systems; electron dynamics of the reflex klystron oscillator; load effects; engineering aspects; representative and unconventional reflex klystrons. The final chapter is devoted to future trends in the field. Many bibliographic references are included. (J. J. Hamilton. Toronto, Ryerson, 1958. 260p., $9.00.)

• LIBRARY NOTES

VEHICLE SPEEDS ON ONTARIO HIGHWAYS

An analysis of the speeds of 8499 motor vehicles on the highways of Ontario, based on information gathered at 16 sampling stations, on the open highway, on 2-, 3-, and 4-lane highways. Much of the material is presented in the form of graphs. (H. M. Edwards. Kingston, Queen's University, 1958. 65p., mimeog. Some reports available for distribution.)

°ENGINEERING MATERIALS

This volume is divided into three parts, the first of which deals with various kinds of aggregates, cements, concretes, bituminous materials, stone, timbers, glass and plastics. The second part deals with properties of metals and alloys including alloy steels, wrought iron, cast iron, malleable cast iron, and nonferrous metals and alloys. It concludes with the preservation and testing of materials. The authors are a group of engineering materials professors in American universities. (Committee on Engineering Materials. Toronto, Pitman, 1958. 616p., $8.50.)

°EFFECT OF SURFACE ON THE BEHAVIOR OF METALS

Four papers, the first of which deals with the preparation of surfaces for examination and with modern methods of examining the topography and structure of surfaces. This is followed by a paper that shows how the treatment that a surface has received affects its future chemical behaviour. A summary of the present state of knowledge on the relationship between surface condition, frictional resistance and wear is then given and followed by a paper on the influence of the surface on the physical properties of metal. These papers comprise the lectures given at the Institution of Metallurgists Refresher Course, 1957. (London, Iliffe for the Institution of Metallurgists, Toronto, British Book Service, 1958. 100p., $4.50.)

ENGINEERING DRAWING AND DRAWING OFFICE PRACTICE, 2ND ED.

Apart from a few minor corrections, the only change in this edition is the inclusion of an introductory chapter of recommendations and comments on British Standard 308, Engineering Drawing Practice, issued in 1953.

The book is intended for students, and starting from first principles covers all that is necessary for a good groundwork in engineering drawing. (P. S. Houghton. Toronto, British Book Service, 1958. 277p., $4.50.

NUCLEAR POWER YEAR BOOK 1958/59

The review articles in this second edition of the Year Book cover British nuclear power in 1958; nuclear instruments in 1958; progress in fuel element design; thermonuclear research at Harwell; uranium mining prospects. There are seven international and forty-one national atomic energy authorities listed. The technical data section has been expanded, in particular the reactor physics chapter has been enlarged, and material included on nuclear constructional and coolant metals. The isotope section has been enlarged, and the isotope tables contain data on 1391 nuclides.

This is a useful volume. (Ed. by W. Davidson. London, Rowse Muir, 1958. 570p., £3. 3. 0.)

BRITISH NARROW GAUGE RAILWAYS

A factual account of the few narrow-gauge railroads still operating in Britain and two which are not, including the only cog-wheel railway, that up Snowdon Mountain, and the only underground one, that in Glasgow. The gauges on the fifteen lines described range from one foot three inches to four feet. Details are given on construction, rolling stock and traffic. Illustrations, many of which are by the author, add to the interest of this fascinating book. (R. B. Jones. Toronto, Macmillan, 1958. 110p., $3.50.)

°HANDBOOK OF AUTOMATION, COMPUTATION, AND CONTROL. VOLUME 1: CONTROL FUNDAMENTALS

This volume, the first in a series of three, provides information which forms a foundation for the later volumes. It covers mathematics as applied to control, such as sets and relations, Boolean algebra, probability, and statistics. This is followed by a compilation of the latest techniques of numerical analysis, as well as comparisons of the various techniques; material on information theory, smoothing, filtering, and data transmission; thorough treatments of feedback control theory and of operations research. Emphasis is placed on practical methods of applying the theory. (Ed. by E. M. Grabbe and others. New York, Wiley, 1958. Various paging, $17.00.)

THE UPPER ATMOSPHERE

An account of the phenomena of the upper atmosphere being studied during the International Geophysical Year, outlining present day knowledge of the subject. The techniques used in investigation are described, including sound and radio waves, balloons and rockets. Methods of finding the speed of rockets and their positions, and of interpreting their signals are discussed. (H. S. H. Massey and R. L. Boyd. London, Hutchinson, 1958. 333p., 63/-.)

°THE SCIENCE OF HIGH EXPLOSIVES

Stresses the physical chemistry of detonating explosives. The fundamental principles and information necessary for technical applications is given, including commercial blasting, demolition, shaped charges, fast particles, shock and blast wave propagation, impact loading, strength, penetration, and conditions for explosion of materials. Procedures for computing thermo-hydrodynamic properties and products of detonation are also presented. (M. A. Cook. New York, Reinhold, 1958. 440p., $22.50.)

• LIBRARY NOTES

°AUTOMATIC MEASUREMENT OF QUALITY IN PROCESS PLANTS

Papers covering two aspects of the field: those that survey the experience gained with the control instruments now in use, and those that explore the potential plant application of analytical techniques currently used only in the laboratory. Specific topics include techniques for gas stream analysis, spectrometric methods, liquid stream analysis, new techniques for fluid stream analysis, and measurement of various physical properties. (Society of Instrument Technology. Toronto, Butterworth, 1958. 320p., $9.50.)

TRANSATLANTIC TELEPHONE CABLE

The papers presented at the January 1957 joint meeting of the Engineering Institute of Canada, Institution of Electrical Engineers and American Institute of Electrical Engineers have now been issued in a bound volume. The eleven papers cover the design, manufacture and installation of the first transatlantic telephone cable, together with a discussion of the papers, and an index. (Ed. by W. K. Brasher. London, I.E.E., 1957. 125p., I.E.E. Procs., v.104, 1957 pt.B, suppl. no. 4.)

ECONOMIC AND SOCIAL IMPLICATIONS OF AUTOMATION: A BIBLIOGRAPHIC REVIEW

Over one third of the 610 references in this bibliography are annotated. In addition to general references and a list of bibliographies, the listings cover the following topics: manpower and employment; society and government; selection, training and job requirements; human relations; collective bargaining; management; office automation; case studies. The purely technical aspects of automation are not covered. (G. Cheek. East Lansing, Michigan State University, Labor and Industrial Relations Center, 1958. 125p., mimeog., $1.25.)

PARKING

A survey of the parking problem and possible solutions, this volume commences by discussing parking habits and needs. It then considers various types of parking—curb, metered and off-street, and the best arrangement of parking lots and garages. Statistics are quoted, and most of the material is illustrated with diagrams. There is a useful bibliography. (R. H. Burrage and E. G. Mogren. Saugatuck, Conn., Eno Foundation, 1957. 401p.)

°YEARBOOK OF THE HEATING AND VENTILATING INDUSTRY, 1958/59

This new edition contains papers on environmental radiation in winter and summer, ventilation problems associated with the use of radioactive substances, and the future of electricity for space heating, as well as an index to heating and ventilating literature published during 1957. A buyers' guide, a list of trade names, and manufacturers' addresses are given for those firms located in Great Britain. (London, Technitrade Journals, 1958. 422p., 12/-.)

Your extra measure of protection against corrosion...

JENKINS

STAINLESS STEEL VALVES

Dependable, economical Jenkins Stainless Steel Valves come in a wide range of patterns and alloys to meet the needs of almost all corrosive services. You get more value for your valve dollar with Jenkins.

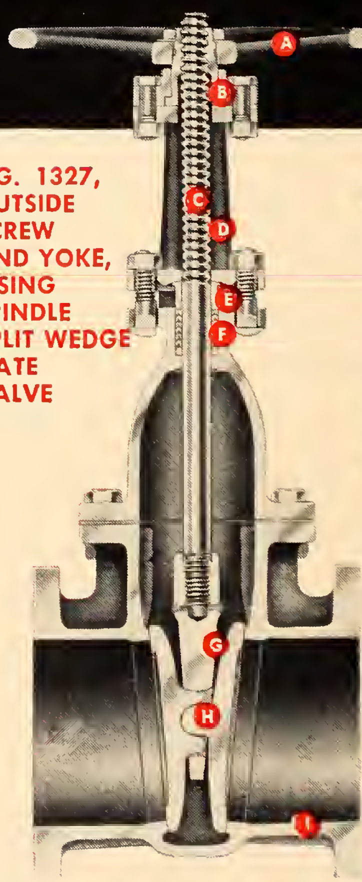

FIG. 1327, OUTSIDE SCREW AND YOKE, RISING SPINDLE SPLIT WEDGE GATE VALVE

- **A** High-Strength, Malleable Iron Wheel. Designed for firm, cool grip and easy operation.
- **B** Easily Renewable Yoke Bushing. Made of bronze for ideal thread engagement, with stainless steel spindle to prevent seizing or galling. Bushing of stainless steel optional.
- **C** Spindle. Long thread bearing surfaces with correct lead for easy, tight closing.
- **D** Yoke Bonnet. Liberal space between yoke arms for easy access to packing box. Precision machined flanged face assures uniform contact with gasket for a tight body-bonnet joint.
- **E** Two-Piece Gland. Gland flange and gland follower, eliminates binding of follower in case gland bolts are tightened unevenly.
- **F** Packing. Of chevron-type Teflon in large packing box. Prevents leakage.
- **G** Husky Wedge Carrier. Connects wedge to spindle, raises or lowers it.
- **H** Split Wedge. Ball-and-socket design automatically adjusts to tapered seating surfaces for positive shutoff.
- **I** Body. Through-port design for full, free flow.

MEET THE AUTHORS

William Cumming Leith, M.E.I.C., mechanical Research Engineer, Dominion Engineering Works Limited, Montreal. *(Cavitation Damage of Metals).* A graduate of University of B.C. (B.A. Sc., mech., 1948, M.A. Sc., 1949). Mr. Leith is at present studying part-time for a doctorate degree at McGill University.

Since 1955, he has been engaged in the study of cavitation damage in diesel engines. For the past six years he has been in charge of the Mechanical Research Department at Dominion Engineering Works Limited. He is a member of the ASME Cavitation Committee on the standardization of magneto-striction testing.

J. E. Cousineau, P.Eng., M.E.I.C., Surveys Engineer, Hydraulic Section, Power Development Division, Quebec Hydro-Electric Commission, Montreal. *Some Aspects of Ice Problems connected with Hydro Electric Developments.)*

Graduating from the Ecole Polytechnique (B.A. Sc. civil, 1941), Mr. Cousineau was employed by the Quebec Streams Commission until 1948 when he joined the Quebec Hydro-Electric Commission serving as resident engineer on heavy construction. In his present position he is responsible for surveys in connection with the investigations of rivers for the establishment of storage dams and hydro plants.

During the course of his work he has had considerable experience concerning ice problems affecting hydro-electric developments and has devoted ten winter seasons to actual field observations.

L. A. C. Walford, M.E.I.C., (A.M.I. mech., E., Great Britain), Partner, Wiggs, Walford, Frost & Lindsay, Toronto. *(Power Requirements for Commercial Air-Conditioning Systems).*

Mr. Walford joined the engineering staff of the Aluminum Company of Canada at Arvida, during construction of that plant. He was engaged as an engineer for the International Paper Company and G. Lorne Wiggs, Consulting Engineer. In 1940 he served as a technical officer on the Joint Inspection Board of the United Kingdom of Canada in New York, Washington, and Ottawa until 1945. Returning to his previous employer, G. Lorne Wiggs as chief mechanical engineer, he entered into partnership of Wiggs, Walford, Frost & Lindsay in 1947, taking charge of the Toronto office in 1954. A registered professional engineer of Quebec and Ontario, Mr. Walford is a member of the American Society of Heating & Air Conditioning and a Fellow of the Royal Society of Arts.

Robert N. Boyd, M.E.I.C., Supervising Engineer of design services with Du Pont of Canada, Montreal, Que. *(Buildings for Chemical Plants.)* Mr. Boyd graduated from the University of Toronto (B.A. Sc., (honours) mech. 1939).

Joining Du Pont of Canada in 1941, he was associated with the design of the nylon spinning plant at Kingston, Ont., and the nylon intermediates plant at Maitland, Ont. He was appointed supervising engineer of design in Montreal in 1954 and supervising engineer of design services in June 1957.

Mr. Boyd is a registered professional engineer in the provinces of Quebec and Ontario and a member of the American Society for Testing Materials.

Dr. J. M. Zarzycki, M.E.I.C., Chief Engineer, Canadian Aero Service Limited, Photogrammetric Engineers, Ottawa, Ont. *(Photogrammetry in Highways and Railways Engineering.)*

Dr. Zarzycki graduated from the Faculty of Civil Engineering and Geodesy of the Warsaw Technical University with a degree in geodesy. He received his doctorate degree in Technical Science in 1951 from the Swiss Federal Institute of Technology. He has served on the faculty of the Swiss Federal Institute of Technology and later acted as a scientific collaborator to the Wild Company, one of the world's leading manufacturers of photogrammetric and survey instruments. Offered a Post-doctorate fellowship by the National Research Council he travelled to Canada to work with the Division of Applied Physics of National Research Council.

A member of the Professional Engineers of Ontario and Quebec, he is presently Chief Engineer with Canadian Aero Service Limited, Photogrammetric Engineers in Ottawa.

Paul Joseph Beaulieu, S.E.I.C., Division of Administration and Awards, National Research Council, Ottawa, Ont. *(What Happens to Applicants for National Research Council Scholarships in Science and Engineering.)*

Graduating from St. Boniface College in the general, arts course in 1951 Mr. Beaulieu studied actuarial mathematics and statistics at the University of Manitoba, (B.A., 1951, M.A., 1954).

Mr. Beaulieu also attended the Sorbonne, Paris, where he studied mathematics and probabilities.

At present Mr. Beaulieu is employed by the National Research Council, Ottawa in the Division of Administration and Awards.

CAVITATION DAMAGE OF METALS

W. C. Leith, M.E.I.C. *Mechanical Research Engineer,*

Dominion Engineering Works, Limited, Montreal

Cavitation damage of metals can be observed on a magnetostriction-type of accelerated cavitation machine with a Fastax camera taking 8000 pictures per second.

A brief description of the mechanism of cavitation is given with some typical examples of cavitation damage to machine parts in service. The magnetostriction apparatus which is used to compare the relative resistance of materials to accelerated cavitation damage is described. Weight loss variations and correlated bubble formation patterns on test samples are shown for a range of vibration amplitude, temperature, and pressure.

Cavitation damage of metals in diesel cooling systems can be reduced by controlling the dominant liquid characteristic (temperature, pressure or wettability) at a stabilized cavitation level while the increased metal resistance of stainless steel welded overlay on cast steel runners is more practical for hydraulic turbines.

CAVITATION IS A well known hydraulic phenomenon which may be associated with its destructive effects in hydraulic turbines and diesel cooling systems, although its advantages have been utilized in numerous ultrasonic devices such as flaw detectors, cleaning baths, and navigational echo-sounders. It should be emphasized that cavitation refers to the formation and collapse of vapour bubbles, while cavitation damage refers to the destruction of the guiding surface at the point of bubble collapse.

CAVITATION IS THE CAUSE

Cavitation can be described as a hydro-dynamic phenomenon which relates to the formation and collapse of vapour bubbles in a flowing liquid. These bubbles form in regions where the local pressure is reduced below the vapour pressure at that temperature; and conversely these bubbles start to collapse as soon as the local pressure increases above the vapour pressure. The mechanism of cavitation inception under measurable and reproducable conditions which are suitable for observation has been studied most successfully by Knapp[1] who correlated the measured history of an actual vapour bubble to the classical analysis of Rayleigh[2]. The collapse of a spherical bubble in an incompressible liquid was considered assuming isothermal compression, but neglecting viscosity and surface tension. The excellent agreement of the experimental results to the theoretical postulations confirmed that the kinetic energy of bubble collapse was absorbed elastically in the water and given back largely undiminished in the rebound effects. The formation of cavitation bubbles at vapour pressure conditions is common experience and it implies that water has no tensile strength, while the breaking strength of water between its molecular layers has been estimated by Frenkel[3] at 150,000 p.s.i.

CAVITATION DAMAGE THE EFFECT

Cavitation damage can be described as a conjoint action of mechanical-chemical effects, that is, a mechanical repeated stressing of a metal surface in the presence of several possible chemical reactions, a mechanism which is similar to corrosion fatigue. The separate, distinct impact force at the collapse of a cavitation bubble produces a stress concentration on a very small area, and may cause plastic deformation and strain hardening if the severity of cavitation attack produces a mean shearing stress greater than the yield strength of the metal. Severe plastic deformation can initiate etching of the grain boundaries without much actual removal of metal. Cavitation damage will proceed as a mechanical fatigue action, accompanied and perhaps accelerated by electro-chemical corrosion between the crystals in the plastically deformed area.

ACCELERATED VIBRATORY CAVITATION MACHINE

The need for rapid evaluation of metals resistance to cavitation damage has prompted the commercial application of the magnetostriction effect under controllable and reproducible conditions. The magnetostriction effect is a broad term applied to ferromagnetic materials which exhibit a change in physical dimensions when subjected to a magnetic field; or conversely, a change in magnetic properties occurs when the physical dimensions are altered by an external force. The most significant change is the 'Joule effect' or the change of length along the axis of the applied magnetic field when the field is varied. Nickel contracts in length at a decreasing rate in an increasing magnetic field until a maximum or saturation value is reached. All ferro-magnetic materials are temperature-sensitive, the material losing its magnetism as the temperature rises until the Curie point is reached, where all magnetic properties cease.

The magnetostriction apparatus consists of a high-frequency oscillator which produces a resonant longitudinal vibration of a nickel tube at its natural frequency when subjected to an alternating magnetic field. In the apparatus used by this author the nickel tube vibrates at 6500 cycles per second and each end has an amplitude of 0.0034 inch. The test button which is ⅝ inch diameter, is screwed into the lower end of the tube. The test button is immersed ⅛ inch in distilled water which is maintained at a constant temperature by a water bath. The tube is cooled by a water spray on the inner wall, and a vacuum aspirator removes the excess water from the bottom of the tube. The vibration amplitude is calibrated for some indicated output from the resistance strain gauge which is cemented on the vibrating nickel tube. Tentative specifications for a standardized vibratory cavitation test were proposed in 1956 by Robinson, Holmes and Leith[4], so that various laboratory tests results could be correlated to field experience.

Incubation Period

There appears to be an incubation period or a time interval at the beginning of each test during which considerable plastic deformation of the test surface takes place without any apparent weight loss. The incubation period is well defined for rolled metals and welded overlays, but not for cast irons. The incubation period is of great interest to designers of hydraulic machinery, especially for seal rings and turbine runners. The incubation period for rolled metals appears to have a linear relationship with the corrosion-fatigue limit of the metal. For a given metal, the incubation period is independent of the vibration amplitude, but the weight loss after two hours is dependent on the amplitude.

Cavitation Intensity and Vibration Amplitude

The effect of vibration amplitude on cavitation damage has been studied to determine approximate degrees of cavitation resistance for various metals. Figure 5 shows the vibration amplitude necessary for cavitation damage of welded stainless steel overlay type 308, which can be regarded as the threshold value of the metals resistance to cavitation attack. The

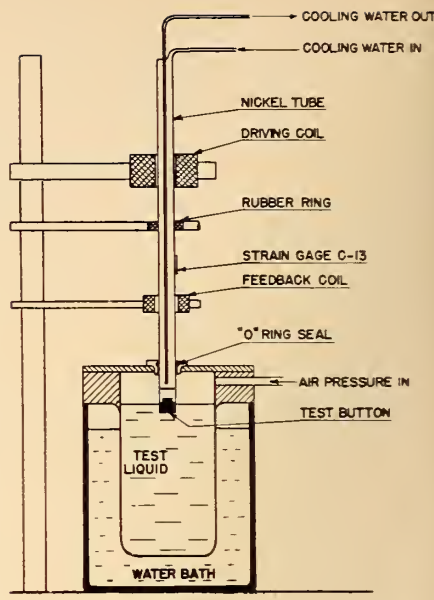

Fig. 2. Schematic diagram of nickel tube assembly.

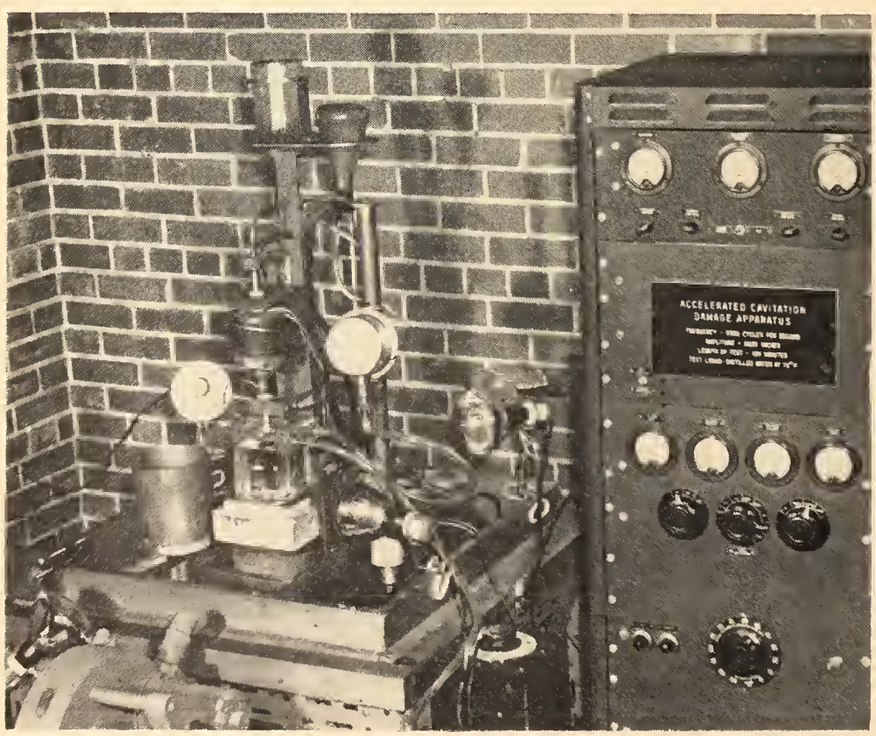
effect of vibration amplitude on this magnetostriction apparatus can be compared to the effect of flow velocity in a water tunnel, since they both show the threshold value of the metals resistance, below which no metal is removed despite some plastic deformation, but above which the rate of metal-removal accelerates rapidly with increased cavitation intensity.

Fig. 1. Accelerated cavitation machine with Fastax camera.



HIGH-SPEED PHOTOGRAPHY OF CAVITATION BUBBLES

A Fastax camera, which takes up to 8,000 pictures a second on 16 mm. film, has been used to photograph the cavitation bubbles on the test button as it oscillates up and down in distilled water at 6500 cycles per second. The cavitation bubbles are usually viewed at the usual projection speed of 16 frames per second which slows down the action 500 times. The film is pulled past the aperature in a continuous motion and a rotating prism exposes each frame in turn. A Goose control unit provides the regulation of the camera speed, besides a remote control operation and synchronization of the camera with an event being studied. The unit acts as a time-delay mechanism to limit the camera voltage to 130 volts during the first 0.070 sec., and then releases the higher voltage necessary to obtain the higher picture rate. This time-delay action prevents tearing of the film perforations by the sprocket during the initial period of high starting torque. The central area on the test

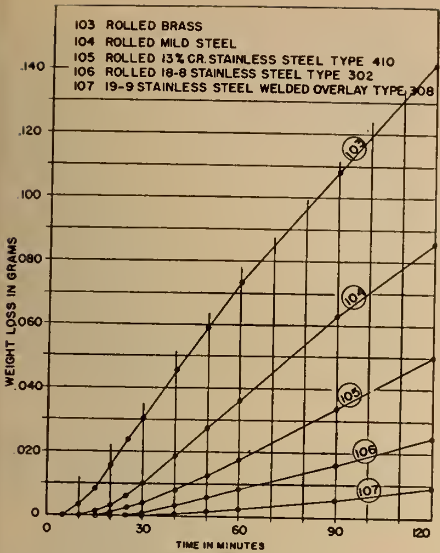


Fig. 3. Cavitation damage of typical metals.

button where the cavitation bubbles oscillate is the low-pressure zone during the upward motion of vibrating nickel tube, and the size of this central bubble pattern corresponds to the size of the damage pattern in all cases.

Effect of Vibration Amplitude

High-speed photographs of the cavitation bubbles show that only one central bubble forms at the low amplitude of 0.001 inch. As the vibration amplitude is increased to 0.003 inch, a continuous formation of small bubbles grows from the outer edge of the test button and these bubbles enlarge as they move radially to the central mass of oscillating bubbles.

Effect of Pressure

High-speed photographs of the cavitation bubbles show that the total area of the test button is covered by a blanket of oscillating bubbles at high vacuums near 0.5 p.s.i. absolute pressure. The size of this oscillating-bubble pattern is decreased as the pressure is increased, as the same work input is concentrated over a smaller area.

Effect of Temperature

High-speed photographs of the cavitation bubbles show that the bubble size increases with water temperature as expected by the decrease in the surface tension and the increase in the vapour pressure, but the cavitation damage is a maximum at 120°F where the maximum number of oscillating bubbles are observed.

CAVITATION DAMAGE IN HYDRAULIC TURBINES

Hydraulic turbines utilize the change of momentum of water as accomplished by the guiding surface of the runner vanes. The shape of these vanes is designed for specific operating conditions where the velocity of water is continuous across the flow area and cavitation is avoided by maintaining the local pressure at critical areas above the vapour pressure of the water. Since most hydraulic machinery is not operated continuously at the design conditions, metals with a high resistance to cavitation damage are used at critical areas. Cast steel runners with welded stainless steel overlay on the critical areas is common practice, since field repairs can be done in the turbine pit with a minimum of outage time. Stainless steel deposited by manual welding using stick electrodes 3/16 inch diameter require only one pass to provide sufficient metal for the 1/8 inch finished overlay thickness. Certified manual welding deposits stainless steel E308 with analyzed alloy contents of about 17% chrome and 9% nickel, and it deposits stainless steel E301 with about 16% chrome and 6% nickel as shown in Fig. 10.

Intensity of Cavitation Attack

Field experience with hydraulic turbines has provided three relative intensities of cavitation attack which have been based on the observed damages to the original cast steel runner, mild steel welded overlay and stainless steel welded overlay. The threshold value for each metal's resistance is considered to refer to a minor pitted condition after one year of operation, which would include the strain hardening and etching of the metal surface, without much actual metal removal.

(1) Minor pitting on the original cast steel runner.

(2) Severe pitting on the original

CAVITATION DAMAGE IN DIESEL ENGINES

The modern diesel engine, especially for the competitive market in transportation facilities, has a water-cooling system which is designed to operate at increased but stabilized cavitation levels, and this requires higher liquid pressure and chemical additions to minimize the formation of cavitation bubbles. These chemical additions include corrosion inhibitors to prevent initial chemical pitting, detergents to eliminate foaming, and wetting agents to provide an adhering liquid film on the metal by depressing the surface tension at the liquid-metal interface. The recent design trends toward higher speed and increased thermal and mechanical loading in diesel engines has intensified the degree of cavitation damage, and many operators have reported that cavitation control by chemical additions is impossible to maintain without skilled workers.

Three instances of cavitation damage in diesel engines which have been corrected after extensive research are: (1) water-cooled cylinder liners; (2) water-cooled nozzle sleeves; (3) oil-lubricated connecting rod bearings.

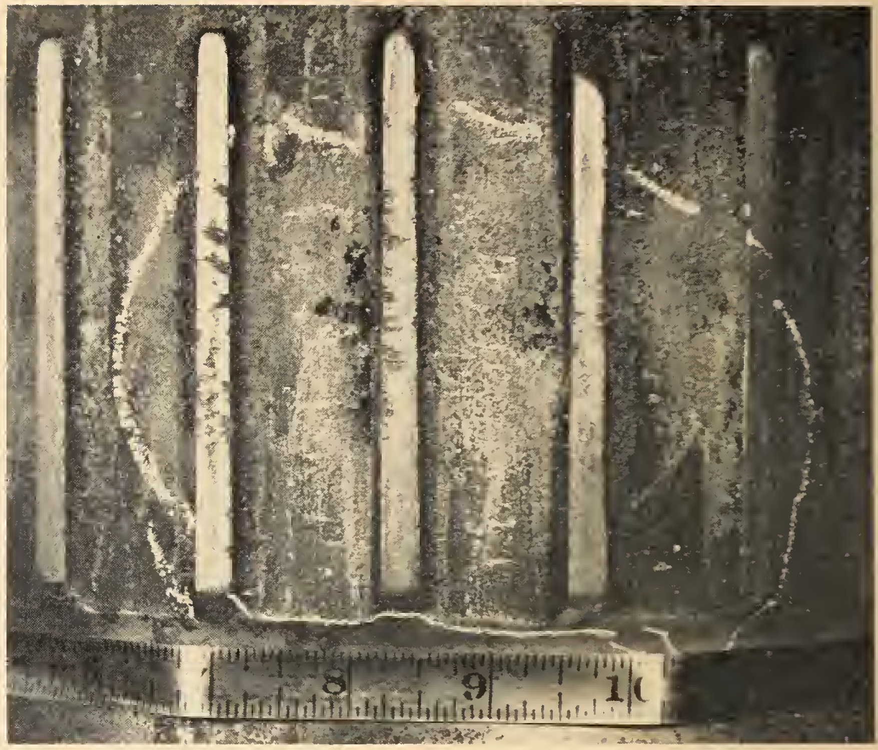

Fig. 12. A cavitated diesel cylinder liner.

Water-Cooled Cylinder Liners

Cavitation combined with corrosion in the water cooling system of diesel engines has caused unusual damage on the water side of alloy cast iron cylinder liners. The pitted areas have the typical honeycombed appearance of cavitation damage and they appear free of corrosion products. It had been usual to consider the internal wear as the major problem in cylinder liners, but chrome plating has extended the service life of the internal bore considerably. In some older diesel engines, the cylinder liner erosion was traced to unusually high water velocities at convergent-divergent water passages, where the locations of the water inlet and outlet were primary factors. The recent serious increase in cylinder liner erosion could not be

Fig. 13. Cross-section of a perforated liner wall.

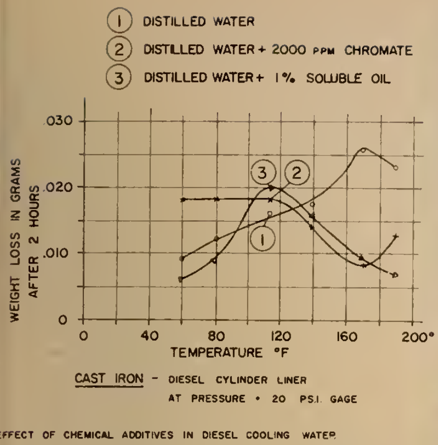

Fig. 14. Effect of chemical additives in diesel cooling water.

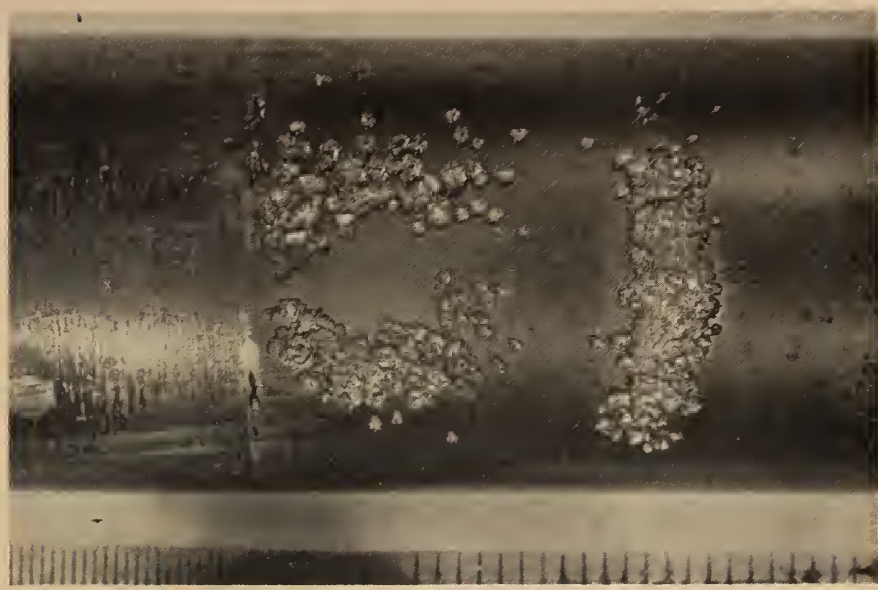

Fig. 15. A cavitated nozzle sleeve.

attributed to a flow condition, and further investigation revealed the presence of a major vibration problem. A vibration analysis revealed that pulsating vibratory forces from the piston side thrust were creating a forced vibration of the cylinder wall, similar to the ringing of a bell. The resonant vibration reaches a maximum amplitude at the middle of the water jacket, where the cylinder liner gets the least support from the engine block.

The worst pitted area is located on the water side of the liner exactly where the "side slap" of the piston takes place during the power stroke, which is 90 degrees from the crankshaft axis. The circumference of the liner vibrates with four nodes at 45 degrees from the crankshaft axis, and as expected, these areas are free from erosion. The side thrust from the piston distorts the liner into an oval shape, and the elastic properties of the cast iron permits the liner to vibrate alternately along the major axis and then the minor axis of the distorted elliptical shape.

Fig. 16. A cavitated connecting rod bearing.

Water-Cooled Nozzle Sleeves

Cavitation damage on the water side of bronze nozzle sleeves was noticed first in the Rocky Mountains where maintenance shops service diesel locomotives at 4,000 feet elevation above sea level. The nozzle sleeve is made of highly cavitation-resistant aluminum bronze, and is rolled into the cast iron cylinder head at each end. The eroded area appeared in a band around the sleeve on the discharge side of an annular flow passage where there was a convergent-divergent flow condition. Since the reduction of the atmospheric pressure at 4,000 feet elevation is about 10%, the cavitation problem was solved by increasing the back pressure in the pump return line by 5 p.s.i. On new diesel engines, the flow passage around the nozzle sleeve was corrected, and the increased back pressure in the pump return line is still recommended for diesel locomotives operating in the mountains.

Oil-lubricated Connecting Rod Bearings

In a reciprocating piston, there is a maximum side thrust on the crank pin bearing during the power stroke, which can cause oil separation on the unloaded side of the bearing. The cavitation bubbles can form in the low pressure zone at oil separation, and the bubbles collapse when the piston passes bottom dead-centre. Our test results show that the rate of cavitation damage is nominal as long as the lubricating oil is below 200°F., but the rate of cavitation damage accelerates rapidly above 200°F.

CONCLUSIONS

Diesel cooling systems remind us that vapour bubbles can be formed by cavitation and nucleate boiling although cavitation usually results from a pressure gradient and nucleate boiling usually results from a temperature gradient. Cavitation damage of metals in diesel cooling systems can be reduced by controlling the dominant liquid characteristics, (temperature, pressure, or wettability) at a stabilized cavitation level, while the increased metal resistance of stainless steel welded overlays on cast steel runners is more practical for hydraulic turbines.

SOME ASPECTS OF ICE PROBLEMS

connected with Hydro-Electric Developments

J. E. Cousineau, M.E.I.C. *Surveys Engineer,*
Hydraulic Section, Power Development Division,
Quebec Hydro-Electric Commission, Montreal.

THE HARNESSING of streams located in a cold climate cannot be fully taken advantage of if curtailments of power generation result from adverse ice conditions. The rivers of Canada are exposed to a severe winter climate. In the Province of Quebec, the St. Lawrence River and its numerous tributaries forming the southern network of streams now undergoing intense hydro-electric development, present their quota of difficulties incurred because of ice conditions. This paper deals with some of the aspects of the various ice problems pertaining to some existing and proposed developments within this network.

Streams often differ considerably in their characteristics, among others, the temperature of the water has a great effect upon the ice formation and the seriousness of ice problems. The formation of ice or the presence of an ice cover over a stream is not necessarily an indication that the mass of water is at the freezing point. Some rivers are cooled down to the freezing point whereas others retain a good part of their heat content throughout the winter period. Streams that are cooled down to the freezing point are most favourable to the formation of the three main types of ice, namely: surface or sheet ice, frazil ice, and anchor ice. Hence, water temperature measurements are of utmost importance and should be the key move in tackling all ice problems.

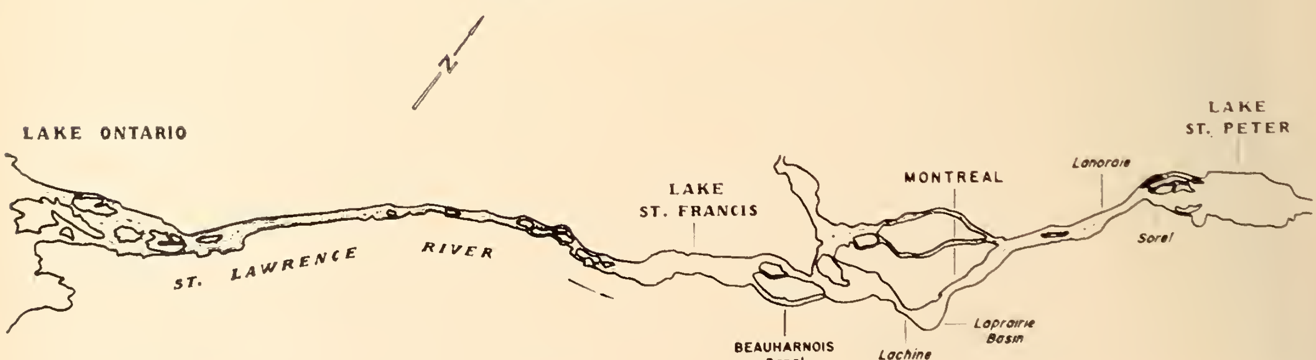
Firstly, the behaviour of a river whose mass of water is actually cooled down to the freezing point at the approach of winter will be discussed, then, briefly, the behaviour of a stream that does not cool down to the freezing point.

The freezing of the St. Lawrence River from Lake St. Peter to the foot of the Lachine Rapids, which occurs in very much the same way each year and offers a wide variety of phenomena, has been described by several authors. The following review is in the light of the present author's observations during the past ten years.

With the advent of cold weather, the water temperature in this stretch of the river gradually falls to the freezing point, and drift-ice appears over the surface. Sheet ice appears over areas of slack water, frazil forms in the more turbulent sections, and anchor ice grows in rather shallow but fast water. Slush-ice may also occur, depending on weather conditions. Owing to the fast current of the river, these ice flows are carried downstream into Lake St. Peter and there come to rest at a section near the lower end where the average velocity of water is from 1.0 to 1.25 feet per second. The converging shores at the outlet of the lake and the low velocity of water together with the water at the freezing point as well as the favourable weather conditions combine to form an ice bridge from which the ice-pack starts its travel up-stream. A packed ice cover then extends all the way up to the foot of Lachine Rapids covering the entire water surface.

The cover which forms over gently flowing sections, as in the case of Lake St. Peter, is relatively smooth; that is to say, only slight telescoping takes place as the drifts of ice pack up-stream. Thence, the cover becomes

Map of the St. Lawrence River.



more and more rugged as it extends over a faster current (Fig. 1). When the pack reaches a section of the river where the velocity becomes so high that the drift-ice is carried under the cover, a "hanging dam" forms. Such sections are found in the narrows at the head of Lake St. Peter and opposite Lanoraie, as well as in the Harbour of Montreal and at the foot of the Lachine Rapids. While a hanging dam is in the process of formation, backwater is created in front of the pack. The effects of this are a raising of the water level up-stream as well as an increase of the cross-sectional area of the river and a corresponding decrease of the average water velocity. According to this process the pack has been observed building upstream in sections of the river flowing at a rather high velocity. Even the Lachine Rapids were nearly surmounted by the pack on two occasions in the course of the past three winters, which is a phenomenon of recent occurrence.

Thus, from the outlet of Lake St. Peter to the foot of Lachine Rapids, smooth ice covers, rugged packed ice covers, and hanging dams alternate with one another. The passing of the pack at a certain point is characterized by a raising of the water level as the pack approaches the point and then a lowering of the water surface after the pack has passed. When a series of shoves occurs (i.e., when the pack advances and recedes, passing the same point many times during the formation and consolidation of a hanging dam to its full size) the water level at that point fluctuates giving the hydrograph a saw toothed form. It is possible to determine the time at which the pack has passed a point by examining the hydrograph for that point. The size to which a hanging dam will grow is dependent on the average velocity that the pack must overcome to travel up-stream without ice being carried under the cover, and this velocity is influenced by the weather conditions.

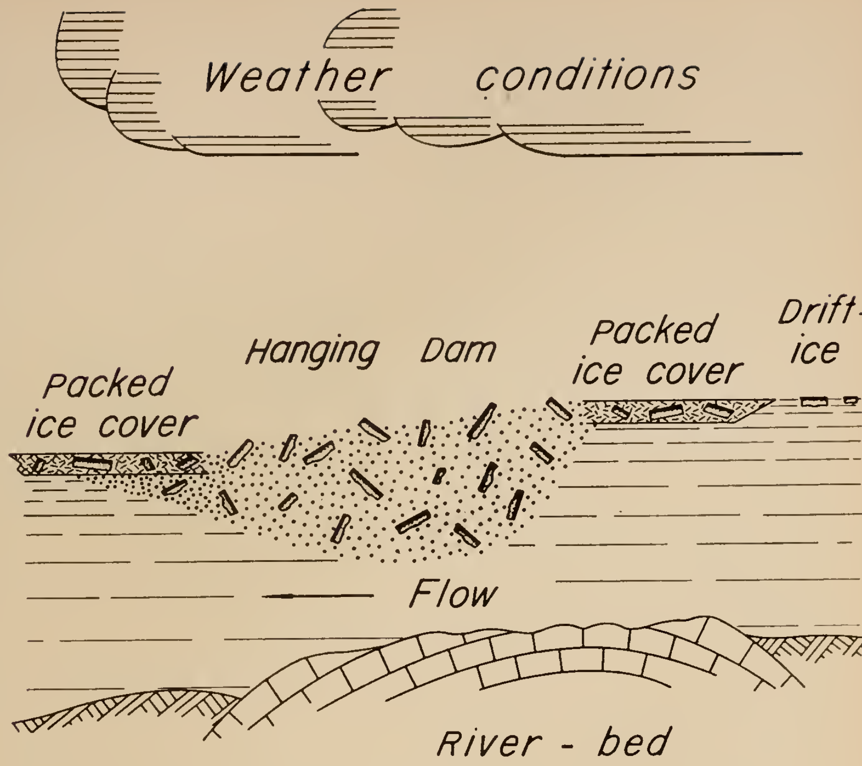


Fig. 1

The maximum average velocity against which an ice cover will pack up-stream without ice being carried underneath has been established, for all practical purposes, at 2.25 feet per second. It must be emphasized that the term maximum average velocity infers the existence of ideal conditions which may be defined as follows: the temperature of water must be at the freezing point and the atmospheric temperature down to at least zero degree Farenheit or better still sub-zero weather prevailing. Any departure from such ideal conditions must be associated with a lower average velocity. Therefore, the travel of the pack up-stream without ice being carried underneath is not governed by the average velocity of water alone; although the latter may well be under 2.25 feet per second, nevertheless a hanging dam will form. The more remote the departure is from ideal conditions, the lower the average velocity will be that the pack can overcome and the larger the hanging dam required to provide the lower velocity. As a matter of fact, the largest hanging dams and the highest water elevations in this stretch of the St. Lawrence River are associated with the milder winters and not with the colder ones. As evidence, Figs. 2 and 3 show the advance of the pack along the same stretch of the St. Lawrence River extending from the head of Lake St. Peter up-stream past Lanoraie but under different conditions.

In the first instance, namely, under ideal conditions, the pack advanced a distance of 25 miles in one day, i.e. from December 29th to the 30th of the 1947-48 winter freeze-up period; the temperature of water was at the freezing point and sub-zero weather prevailed. Under such circumstances the pack made fast progress and the ice cover that formed consolidated rapidly. Although ice forms more readily under ideal conditions, it must be realized that once a cover is formed, the latter acts as an insulator in preventing further formation of ice save for the growth of the cover itself. The result is that less ice will form and the slopes will be smoother if the freeze-up occurs under ideal conditions.

In the second instance, namely, under the most adverse conditions, the pack advanced along the same stretch of 25 miles but this time the journey took 21 days, i.e. from December the 30th to January the 20th of the 1948-49 winter freeze-up period; the temperature of water was at or very close to the freezing point but the atmospheric temperature was well above the zero mark most of the time. Large quantities of ice formed and packed, but as the cover could not consolidate on account of a marked departure from ideal conditions, a series of shoves occurred. The pack advanced and receded many times; the hanging dam grew larger and the slope became steeper than it did in the first case.

It is obvious that, under ideal conditions, a packed ice cover will form and consolidate more readily and that the pack will advance against a higher average velocity. The departure from ideal conditions may be brought about chiefly by a rise in atmospheric temperature or by a rise in water temperature or by both at the same time. In a stream where the mass of water is actually cooled down to the freezing point at the freeze-up period, it is almost invariably the rise in atmospheric temperature that brings about the departure from ideal conditions, the temperature of water remaining at the freezing point. Hence, the rate of formation and consolidation of the ice cover is dependent on the daily degree-days below the freezing point. Likewise ,the average velocity against which the pack can travel up-stream, forming a relatively smooth ice cover is subjected to the degrees of frost. Hence it is that during freeze-up period a hanging dam may form at a section where the average velocity of water is well under 2.25 feet per second.

The author has made an analysis of the data obtained on ice conditions of the St. Lawrence River over the nine winter-periods previous to 1952 and has endeavoured to show that an atmospheric temperature of 20° F. is very close to that at which the formation of ice or the growth of the ice cover is at a standstill, and consequently, that at least 12 degrees of frost are required at all times during the winter to ensure the stability of the ice sheet.

The amount of ice formation depends on the amount of heat liberated by the water. Therefore, the temperature gradient between the water surface and the atmosphere is by far the most important factor in producing ice. Hence, the number of degree-days below the freezing point in any period will be the measure of the quantity of ice formed. When the temperature of air is above the freezing point, heat passes from the air to the water. Heat is then absorbed by the water with a reduction in the proportion of ice. The amount of ice thus lost is also measurable by the degree-days above freezing.

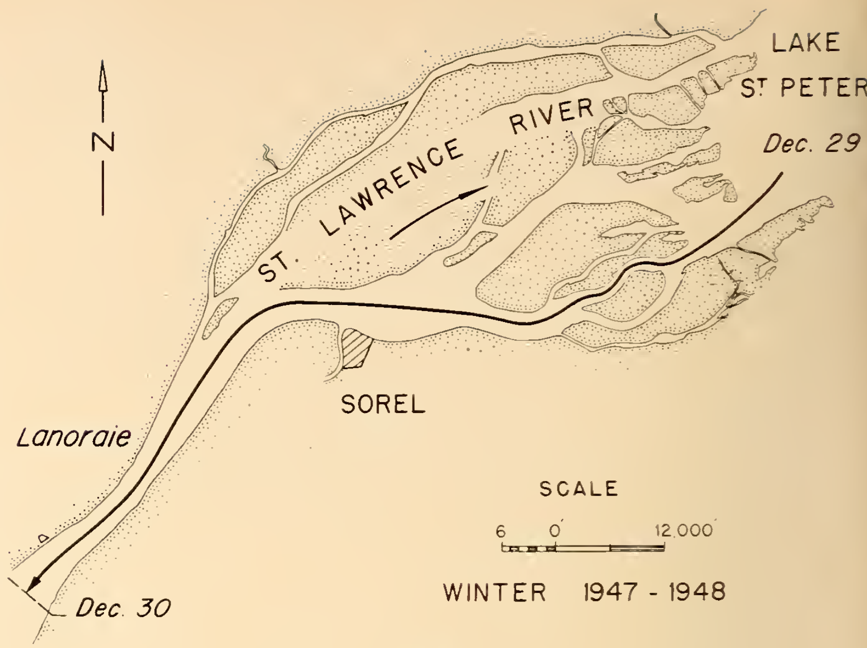

Fig. 2

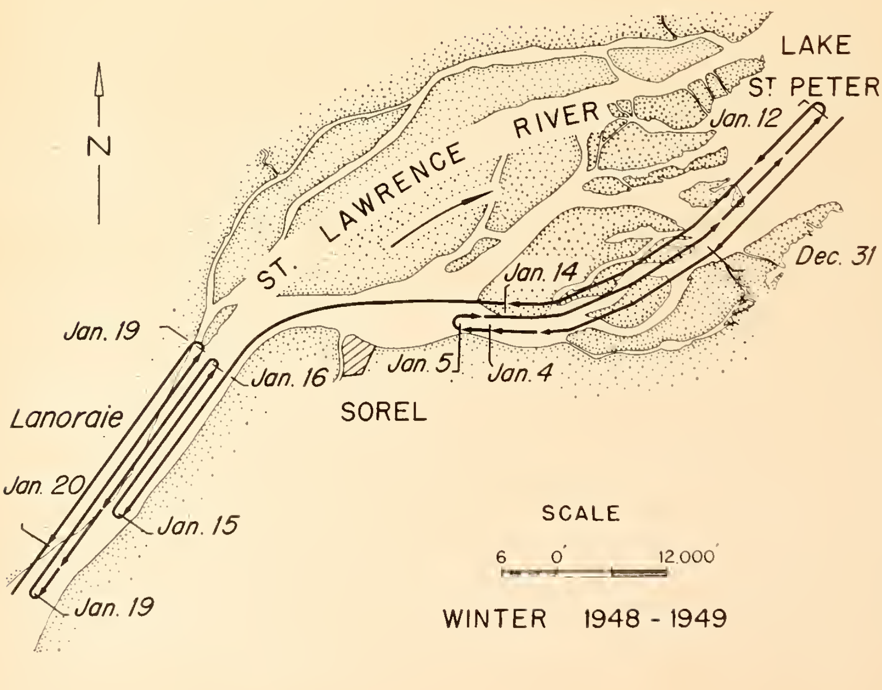

Fig. 3

Once an ice cover has formed and has consolidated to some extent, it is often advisable that pertinent information be made available with regard to its stability, especially at the beginning of the winter period. For such purpose a graph has been devised that can easily be prepared from day to day showing at a glance the stability of the cover (Fig. 4). According to the way the graph is prepared, it is of best value during the early stage of the winter season.

The graph shows the accumulated average of the degree-days from the date the ice cover formed. The only data required are the daily degree-days with reference to the freezing point with which the cumulative degree-days are obtained, and the accumulated average worked out daily from the date the cover is formed. The diagram indicates along the X-axis the period from the day the ice cover formed until the day the break-up occurred, and along the Y-axis the accumulated average of the degree-days. The horizontal lines limit the regions of ice cover conditions. When the accumulated average of the degree-days is above 15 the stability of the cover is good; when the average falls between 15 and 12 the ice cover conditions become fair; when the accumulated average drops to and below 12, shoves and even a break-up are most likely to occur. Hence, open water conditions are back when the average is down to 10. The application of this formula will give reliable indications provided that the average velocity of water at freeze-up was low enough to allow the cover to form quickly and without ice being carried underneath under prevailing conditions, and that the velocity after consolidation of the cover does not exceed 2.5 feet per second.

On streams that are cooled down to the freezing point at freeze-up period, base-load hydro plants located so that they must use the flow as it comes without being able to store any of it must be provided with a fore-bay of sufficient cross-sectional area to ensure a flow unhindered by adverse ice conditions, thereby averting the possibility of floods up-stream and a loss of head at the plant.

Of course, there may exist some natural or artificial features to safeguard a run-of-river plant against flooding up-stream when a loss of head occurs at the plant due to a hanging dam forming in the forebay. Such features may consist of a very large lake, say, the size of Lake Ontario on the St. Lawrence River or a proportionally smaller lake on a smaller stream, near the forebay and at the same elevation. In this instance, the reduction in flow due to the formation of a hanging dam would not suffice to raise the lake by an appreciable quantity before the winter period is over. Also a diversion channel, similar to that which by-passes the Beauharnois Canal, could provide an effective safety-valve.

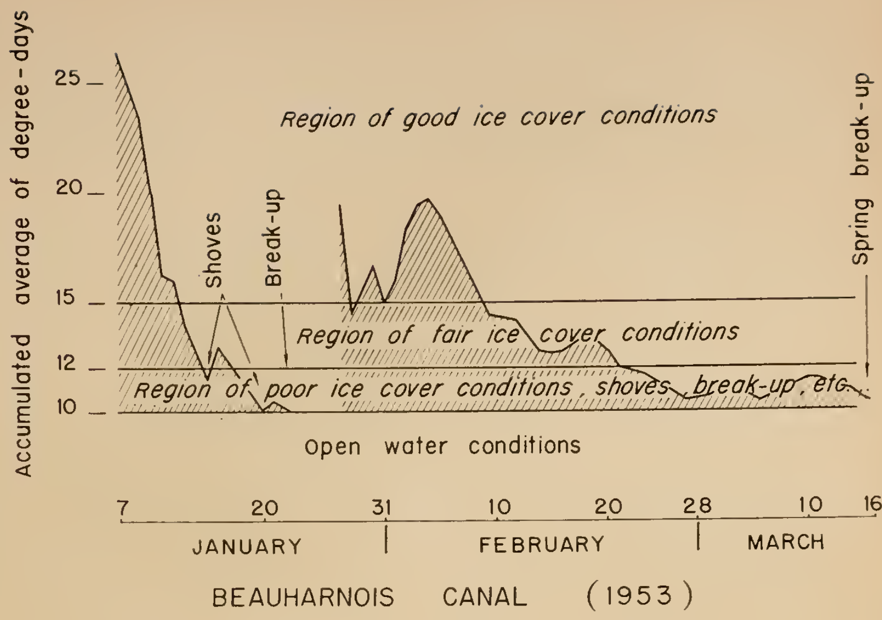

Fig. 4

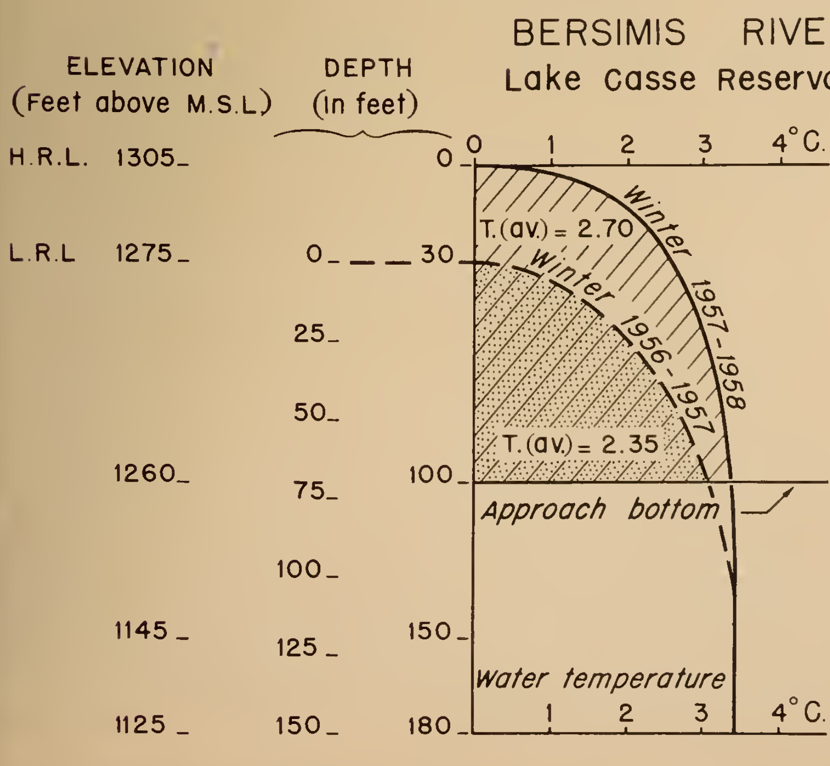
On the other hand, in the Lachine Section of the St. Lawrence river a base-load run-of-river plant would be provided with a sea-like lake capable of cushioning a rise in water level but could be provided with a by-pass. Here the flow must pass as it comes and consequently ice conditions obviously would be a big problem unless sufficient cross sectional area could be provided in the forebay to permit the formation of a smooth packed ice cover.

As previously stated, a stream whose mass of water is actually cooled down to the freezing point is most likely to accelerate the formation of all types of ice. The Lachine section is typical of such a stream. Ice could not be disposed of simply by letting it run through the plant, as an operation of this sort would soon clog the openings. Besides, a good ice cover must be formed and held up-stream to prevent further ice formation and avoid the recurrence of ice jams downstream in the Laprairie Basin that would flood the tailrace and drown out the units. This danger will always be present as long as the St. Lawrence river is allowed to freeze over below Montreal Harbour.

In this connection I fully concur with the opinion of Mr. Herbert L. Land, chief engineer of the St. Lawrence Ship Channel, who told a meeting of the World Ship Society (27 February 1958) that "Winter navigation in the St. Lawrence River inasmuch as the ice has run all the way to tide-water will not be possible for a long time to come with existing methods of combatting the ice menace".

A smooth packed ice cover is unquestionably the best protection with

Fig. 5



which a plant can be provided against ice troubles. A good ice cover on a forebay puts an end to the formation of ice of all types save of course, for the growth of the cover itself; it acts as an insulator. In the light of observations carried on the St. Lawrence River in the Soulanges and Lachine Sections, and also below the Lachine Rapids downstream to the head of tide-water, the cross-sectional area of the forebay at Lachine should be such that the average velocity of water would not exceed 1.5 feet per second at freeze-up period and 2.5 feet per second after the cover is well consolidated and until Spring break-up.

Such velocities may seem low but it must be borne in mind that in this particular section of the river: firstly, the temperature of water actually drops to the freezing point; and secondly, ideal conditions seldom exist at freeze-up time, though, if this is the case at the beginning, such conditions rarely prevail throughout the freeze-up period.

When conditions are such that even under a velocity of 1.5 feet per second the ice cover will not advance nor consolidate, then the chances are that the drifts of ice may run freely through the plant. But when a cover will form readily under a velocity of 1.5 feet per second or higher, then the disposal of ice through the plant becomes more and more hazardous as the velocity increases. In the author's opinion, the use of heat and compressed air to prevent trouble from ice cannot be relied upon in so mighty a river as the St. Lawrence.

In contrast to the St. Lawrence River the Bersimis River, a tributary of the St. Lawrence flowing into it between Forestville and Baie Comeau on the North Shore, is to a great extent never cooled down to the freezing point.

Under natural conditions, the Bersimis river appeared in winter like any other stream covered with an ice sheet save for a few open rapid stretches. Its development called for the establishment of two power plants Bersimis No. 1 and No. 2. The design of Bersimis No. 1 required an eight-mile supply tunnel by-passing a nine-mile gorge plus an eight-mile stretch of the river, whose intake was located on a tributary stream the Desroches river. The valley of the latter forming the approach to the tunnel provided a restricted section for the flow. At first sight velocities were found unduly high and consequently a certain volume of excavation was deemed necessary for the following reasons: (a) to reduce the loss of head; (b) to prevent erosion of the banks and ensuing pitting of turbines.

As regards the formation and maintenance of a probable ice cover, precise water temperature measurements were the key move. They were taken during the winter period 1952-53 when the river was still under natural conditions and brought to light the fact that at the head of the gorge the temperature of water of the Bersimis River never dropped to the freezing point, but averaged during the coldest winter months from 0.10 to 0.37 of a degree Centigrade above the freezing point. Nevertheless, an ice cover formed from the head of the gorge up-stream. The ice cover was tested and found to be very poor, hardly strong enough to support a man and dotted with small air holes. It is noteworthy that this river, lying between the 49th and 50th parallels of latitude, where the winters are without doubt much longer and colder, was never cooled down to the freezing point. This is indeed one special feature that accounts for the large difference in ice problems encountered from one river to another.

Furthermore, No. 1 development called for the creation of a reservoir from the head of the gorge up-stream which meant raising the level of the river by 160 feet (from elevation 1,145 to elevation 1,305 above mean sea level). The mass of water would then lose its turbulence and also its uniform temperature to assume the water temperature gradient characterizing deep quiet waters. That is to say, the upper layer of water would undoubtedly be cooled down to the freezing point and then the temperature of water would be warmer with depth, tending towards a temperature of 4° C. near the bottom, at which temperature water attains its maximum density. As the reservoir was to be created along a river and lakes having rather steep banks, the resulting storage was relatively deep in proportion to the area. These conditions were most favourable to the conservation of a good part of the heat content in the mass of water. As a matter of fact, subsequent water temperature measurements effected at various reservoir elevation have indicated that the higher the water elevation, the higher the temperature of water (Fig. 5).

At a reservoir elevation of 1,275, the upper layers of water entering the approach to the tunnel averaged 2.35 deg. Centigrade while at full reservoir elevation of 1,305 it averaged 2.75

POWER REQUIREMENTS FOR COMMERCIAL AIR CONDITIONING SYSTEMS

L. C. A. Walford, M.E.I.C.

Wiggs, Walford, Frost and Lindsay, Consulting Engineers

IT IS NOT MUCH over a quarter of a century since the vogue for air conditioning entered this country. Hardly had it been properly introduced, when the second phase of world conflict put a stop to its infant growth. Even in the first few years after 1945, the number of air conditioning installations could not be called large, but of recent years the growth of the industry may be termed phenomenal. Not only is a large proportion of the commercial structures being built with integral conditioning but many existing buildings are now being equipped with this amenity to comfort.

Apart from the effect of this on the air conditioning industry, both as to the manufacturer of equipment and the installer, it affects very closely the electric generation and distribution authorities, financial institutions, and the municipalities in so far as water treatment and distribution systems, and sewage and drainage collection and disposal are concerned.

It is the purpose of this paper to examine the electrical load imposed by air conditioning, and it is to be understood that the remarks are confined to commercial air conditioning systems, that is, those systems which are installed, in the main, to provide creature comfort. Industrial systems are another matter entirely, and beyond the scope of this paper.

In approaching this subject, it has been considered that it would be found interesting to know something of the factors which contribute to the total electrical load, something of the magnitude of this load and something of the current consumption during operation.

The term *air conditioning* is perhaps one of the most frequently misused terms in the English language. The definition of *air conditioning* to be found in the Guide of the American Society of Heating and Air Conditioning is "It is a process by which simultaneously the temperature, moisture content, movement and quality of the air in enclosed spaces intended for human occupancy may be maintained within required limits." In this definition the word "simultaneously" is most important; there are many installations which perform only some of the duties enumerated. These are not air conditioning systems in the fullest sense of the word.

If temperature and moisture are to be controlled within required limits, it is fundamental that in periods of high external temperature and relative humidity a capacity to cool and dehumidify is required and in periods of low external temperatures a capacity to heat and humidify is required. This is true only to a certain degree, since it will be readily understood that the effect of the external temperature is of significance only at the skin of the building, that is, at the side walls and the roof. Provided the effects of external variations in temperature are offset at the places where they occur, their effect on the internal spaces of the building is nil and the load in these spaces is always a cooling load. This internal cooling load is dependent upon:

1. Density of human occupation.
2. Lighting intensity.
3. Machine load.

To derive the total cooling load of 1,000 sq. ft. of office space the following design data have been assumed:—

Outside dry bulb	95°F.
Outside wet bulb	75°F.
Inside dry bulb	74°F.
Inside relative humidity	45%
Lighting	4 watts/sq. ft.
Occupancy	12 persons/1000 sq. ft.
Exterior wall factor	0.16 B.t.u./sq. ft./deg. difference
Double glazing	0.65 B.t.u./sq. ft./deg. difference
Fenestration	30%

An area of 1,000 sq. feet will accommodate twelve people comfortably, which represents, since it is assumed that these people are moderately active office workers, a sen-

In approaching the subject, it has been considered that, since air conditioning requires the use of considerable quantities of power, it would be found interesting to discuss the factors of a system which contribute to the electrical load, and useful to know something of the magnitude of the load and something of the current consumption during operation.

In this paper has been brought together the substance of two lectures given before the Canadian Electrical Association and the Montreal Chapter of the American Society of Heating and Air Conditioning Engineers.

sible cooling load of 2,400 B.t.u. per hour and a latent cooling load of 3,000 B.t.u. per hour.

To obtain what is considered to be good office lighting to-day requires about 4 watts per square foot and creates a cooling load of some 13,600 B.t.u. per hour.

The use of electric office machines is now almost universal. This is of the order of 0.7 watts per square foot and imposes a further cooling load of about 2,400 B.t.u. per hour.

These loads constitute what is known as the internal heat gain and are present at all times when the building is occupied. Their total is 21,400 B.t.u. per hour or 1.78 tons refrigerating effect.

Outside air for ventilation purposes is required for the comfort of the occupants of the space, a reasonable quantity for each office worker being 20 c.f.m. This air must be warmed or cooled as dictated by the outside conditions prevailing at the time. When outside conditions are at the design dry and wet bulb temperatures there is a quantity of about 1,000 B.t.u. per hour per person of heat present which must be removed. This cooling load is variable from day to day over the cooling season, but the peak for any particular project is reached when the design conditions laid down are attained.

Now if the 1,000 sq. ft. of office space under consideration is rectangular, having an exterior wall of 20 feet by 13 feet high, with westerly exposure, and an interior depth of 50 feet, the cooling arrangements must compensate for the heat transmitted through the window and wall structure by reason of the difference between the inside and outside dry bulb temperatures and the heat transmitted through the glass by solar impact. This quantity of heat will be of the order of 8,000 B.t.u. per hour and will depend on a number of circumstances; ratio of glass area to exterior wall area, wall construction or orientation of the building, outside shading and inside shading, among others.

The total of these two variable quantities, i.e. ventilation load for 12 persons and external load, is of the order of 20,000 B.t.u. per hour or 1.66 tons refrigerating effect.

BUILDING	A	B	C	D	E	F	G	H	J
RATIO NETT. TO GROSS AREA %.	72·5	77·22	73·2		65·64		68·55	70·25	63·23
TONS PER 1000 SQ. FT. NETT.	3·30	3·07	3·25	3·26	3·00	4·09	3·44	3·85	3·17
HP/1000 SQ. FT. NETT.	6·30	7·01	6·45	5·04	5·45	7·29	4·95	6·03	5·07
HP/1000 SQ. FT. GROSS.	4·55	5·41	4·72		3·58		3·40	4·24	3 21

Fig. 1.

For the hypothetical area of 1,000 square feet under consideration, therefore, the total cooling load is

Internal load	1.78 tons
Ventilation and external load	1.66 tons
A total of	3.44 tons

If the structure has only one floor then a roof load of about one half ton must be added for a net area of one thousand square feet.

It is to be noted that the whole of the 1,000 square feet has been considered to be air-conditioned space. In dealing with a building however, it is extremely unlikely that the whole of the space enclosed by the exterior walls will be air conditioned. The gross area of a building is that of the superficial area of the ground upon which it stands multiplied by the number of floors. The net conditioned area is the total area of the conditioned spaces within the building. Over a number of buildings the ratio of net to gross area can vary considerably as may be seen in Fig. 1.

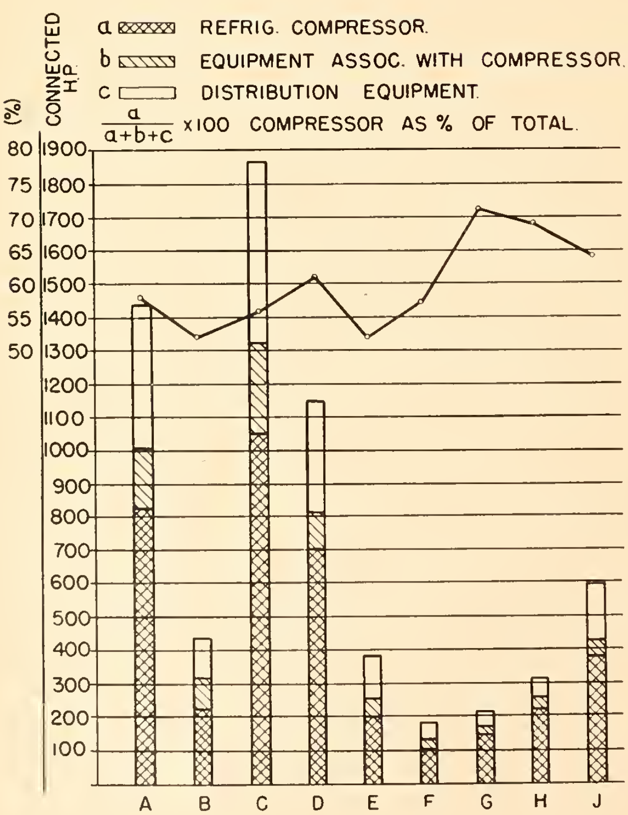

Fig. 2. Left

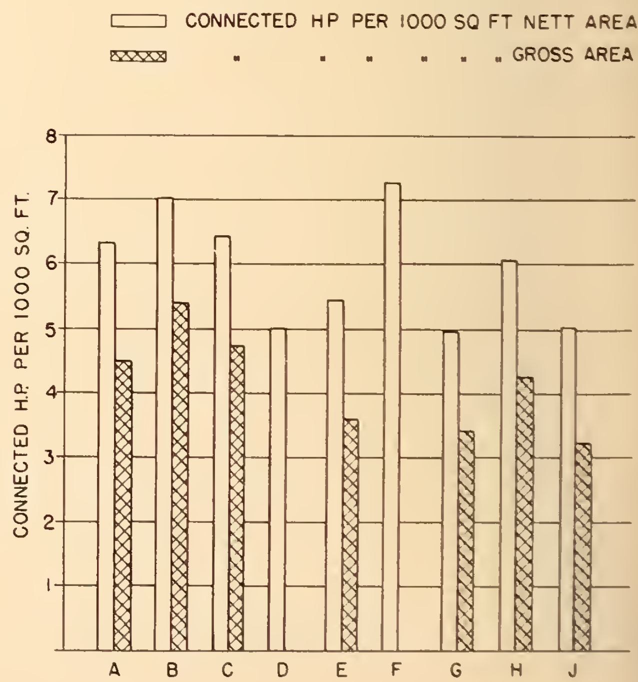
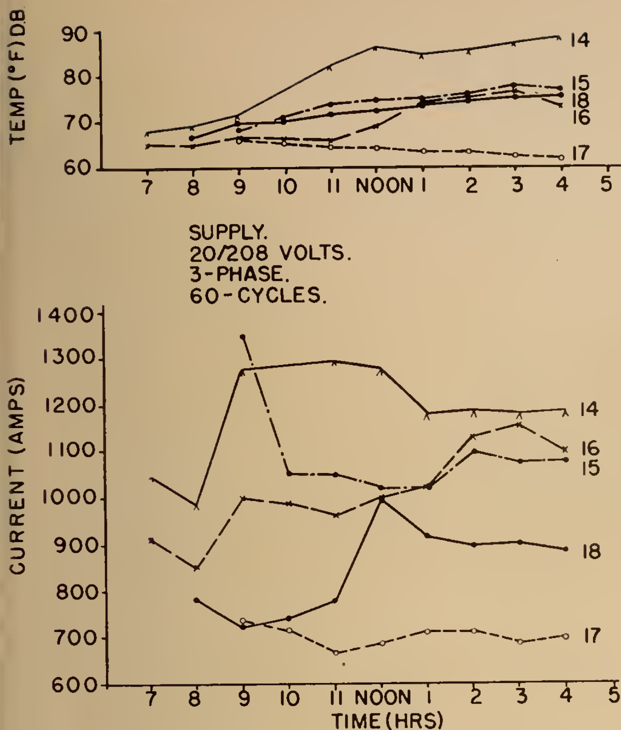
Fig. 3. Right





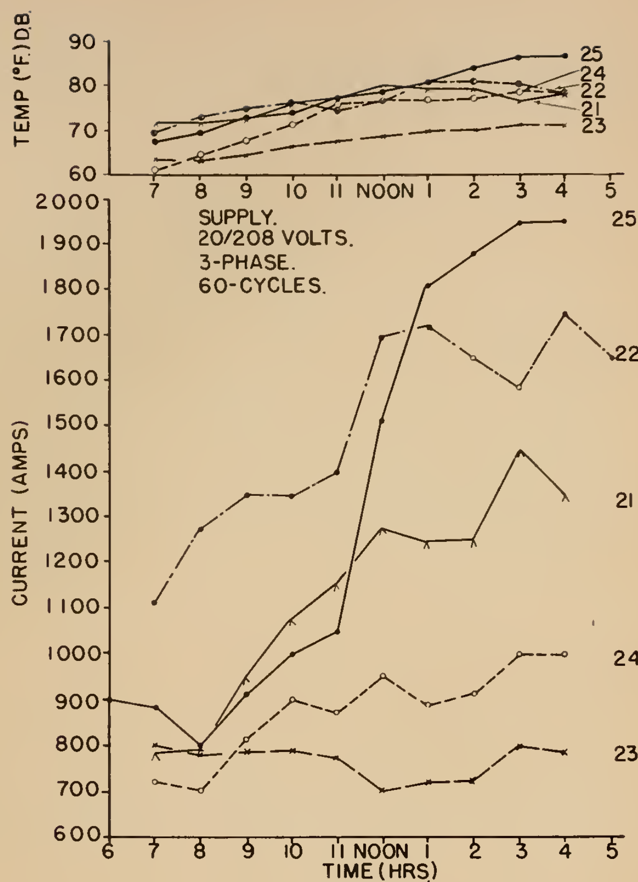


Fig. 4. Left

Fig. 5. Right

Actual tonnages per 1,000 sq. ft. net area for a number of fully air conditioned buildings are also to be found in Fig. 1. It will be seen that these figures are close to that of 3.44 tons evolved earlier, which figure may therefore be found useful for a quick estimation of a load.

It requires power to obtain refrigerating effect and power to distribute this effect to the occupied spaces. In comfort conditioning, one ton of refrigeration is obtained by the expenditure of one horse power, more or less; the figure varies usually between 0.89 and 1.1 h.p. per ton.

In close association with the refrigerating compressor are the condenser water pumps and the cooling tower. It appears that no useful figure can be obtained to relate the motor horsepower required for this associated equipment to that of the refrigeration compressor. The variation in this ratio is dependent upon both the selection of the equipment and the relative positions of the various machines within the building.

In the larger installations it is usual to use the refrigerating machine as a means of chilling water. The chilled water may be pumped to finned tube cooling coils installed in the air conditioning units, to similar coils included in under-window units, and/or to radiant coils in ceilings or walls. Power is also required to distribute air cooled by the medium of the chilled water in the coils installed in the air-conditioning units to the occupied spaces in the building. Here again it is not possible to relate within narrow useable limits the horsepower required for distribution purposes to that for the compressor. For each building a number of conditions are present which render it different from any other building. Among these different conditions are:

(1) Geographical location of the building.
(2) Orientation of the building.
(3) Ratio of superficial area to perimeter.
(4) Ratio of net to gross floor area.
(5) Ratio of window area to outside wall area.
(6) Density of occupation.
(7) Light intensity.
(8) Extent of use of business machines.

For eight installations Fig. 2 shows the connected horsepower required to bring reasonable comfort to the occupants. The total is divided into three parts, the cross-hatched lower portion being the horsepower of the refrigerating compressor, the single hatched portion the equipment intimately associated with the compressor and the unshaded portion the distribution equipment.

Facilities, such as spacious lounges, kitchen and cafeteria to be found in the two buildings (A) and (B), are to be found together in building (D). The total of (A) and (B) are brought together in (C). A conditioned area within a non-conditioned building gives different characteristics to those to be found in a fully conditioned structure; (F) is such a case and is shown for purposes of comparison. (A) employs medium pressure under-window units with a conventional interior zone in which air is admitted to the occupied space through a perforated metal pan ceiling from a supply plenum above it. (B) embraces a number of conventional systems.

Both (D) and (E) employ radiant heating and cooling together with conditioned air distribution. In proportion, (D) employs the radiant method to a greater extent than (E). The installations in G, H, and I are all of the high pressure under-window type, with conventional interior zones. Superimposed on Fig. 2 is a percentage line which indicates the refrigeration compressor as a percentage of the total connected horsepower. Whilst this percentage varies widely, it may be seen that the horsepower of the compressor is only about 60% on the average of the total horsepower required.

Figure 3 shows the connected horsepower required for the air-conditioning plant of the same eight buildings re-

(Continued on page 82)

Buildings for Chemical Plants

Robert N. Boyd, M.E.I.C.

Supervising Engineer, Design Services, Engineering Department, Du Pont of Canada Limited

THE SELECTION of suitable types of construction for the buildings needed to house chemical plants presents many interesting problems. The desired objective is, of course, the lowest long term cost. To achieve this, it is necessary to consider factors such as first cost, maintenance cost (which is particularly important if the process is corrosive), fire resistance, heating cost as influenced by degree of insulation, necessary interior finish to minimize dust accumulations or to permit hosing, weather resistance and appearance. The subject is of considerable importance to expanding chemical manufacturers such as Du Pont of Canada, whose investment in plant buildings, exclusive of building services is over $17,000,000.

This paper covers a number of the more important factors by describing, with costs, several types of construction used by this company to meet the various conditions imposed by their processes. The characteristics and limitations of these constructions will be discussed and some of the forward thinking in this field will be reviewed.

Housing Corrosive Processes

The first type of problem involves the provision of low cost non-flammable housings for wet processes of a corrosive nature. Such processes are frequently designed for a minimum room temperature of about 40°F. so that water used in the process and for floor washing will not freeze, no matter how low the ambient temperature may be. A specific example would be the adipic acid refining section of the nylon intermediates plant at Maitland, Ontario. This process involves the handling of acids, the fumes of which are highly corrosive.

Fig. 1. Photo of Kingston Bldg. 5 completed.

As shown in Fig. 3, the ground floor construction which was selected comprised acid proof brick on a concrete slab of earth. Some might expect sufficient heaving of the floor slab due to frost action to crack the brittle joint material used with the acid proof bricks. No noticeable movement has been experienced however during the four years this building has been in operation, due to the careful attention that was paid to the drainage of the sub floor area. This was accomplished by the provision of about two feet of gravel fill under the slab and the installation of perimeter weeping tile drains.

The determination of the allowance to be made in the structural design for future alterations and expansions to such a building is always a problem. While the project engineer has some ideas on the direction of future expansion, technological advances may impose structural loads never imagined during the original design. The policy followed is to steer a course between the Scylla of tight design, permitting no changes without structural alterations and the Charybdis of wasteful overdesign.

The walls selected are of ribbed asbestos-cement board, bolted to steel girts. Because of the specified room temperature of only 40°F., an economic evaluation showed that thermal insulation for the walls and roof could not be justified. The experience with this wall construction has been quite satisfactory. The asbestos-cement board, while brittle, has not suffered excessive mechanical damage, and it has quite good corrosion resistance. A minor drawback, however, has been the need of frequent maintenance painting of the steel girts.

The suspended floors are of reinforced concrete protected with acid proof brick where dictated by process requirements. The roof deck is also of reinforced concrete, because it is, in some measure, an operating and maintenance floor for the equipment located on the roof. No roof covering is used over the concrete deck.

The cost of this building was $1.00 per cubic foot. This figure, in common with all other units quoted covers the direct cost of the structure, factored to an E.N.R. construction cost index of 300. The figure does not include "indirect" charges such as engineering, contractor's profit, and payroll insurance, and it does not include building services, such as lighting, heating or plumbing. While the cost of this building may seem high, it should be noted that its primary function is to support much heavy equipment and piping and that its role of weather protection is of secondary importance.

Fig. 2 shows the finished appearance of this building.

Fig. 2. Photo of completed Bldg. 216.

Dry Storage Construction

The next problem is of importance to all segments of industry. This is the provision of very cheap, dry, unheated storage space where no corrosion is expected.

This particular problem was solved recently at the nylon yarn plant in Kingston by the selection of a prefabricated building having metal wall and roof covering which was erected on a floating slab foundation. Because of the impervious nature of the clay soil on which it was constructed, particular attention was paid to drainage of the sub floor area. As with the last example, a two foot layer of gravel fill was provided under the floor slab together with perimeter weeping tiles.

Fig. 1 is an interior view of the completed building. This structure

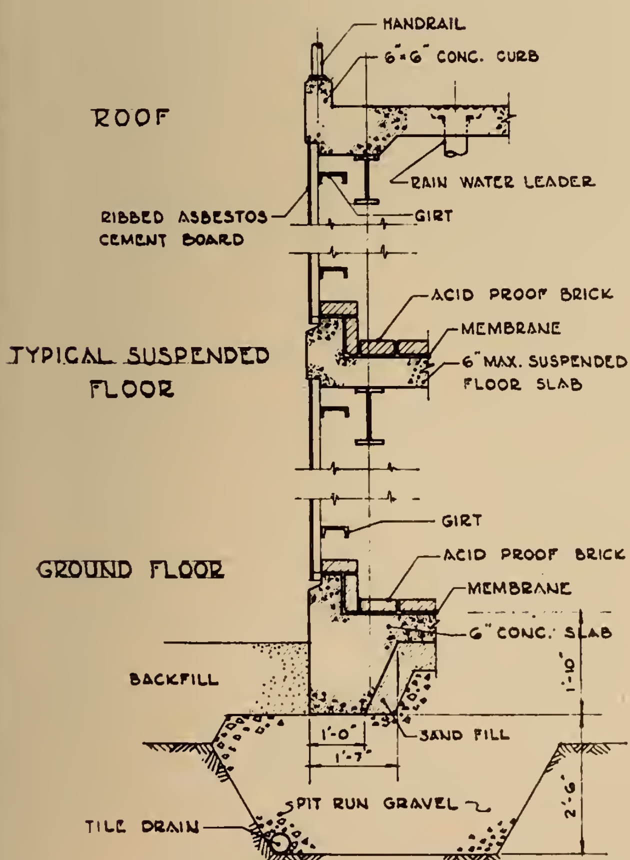

Fig. 3. Sketch of N.I. Construction (Bldg. 216) showing corrosive net process heated to 40°F.

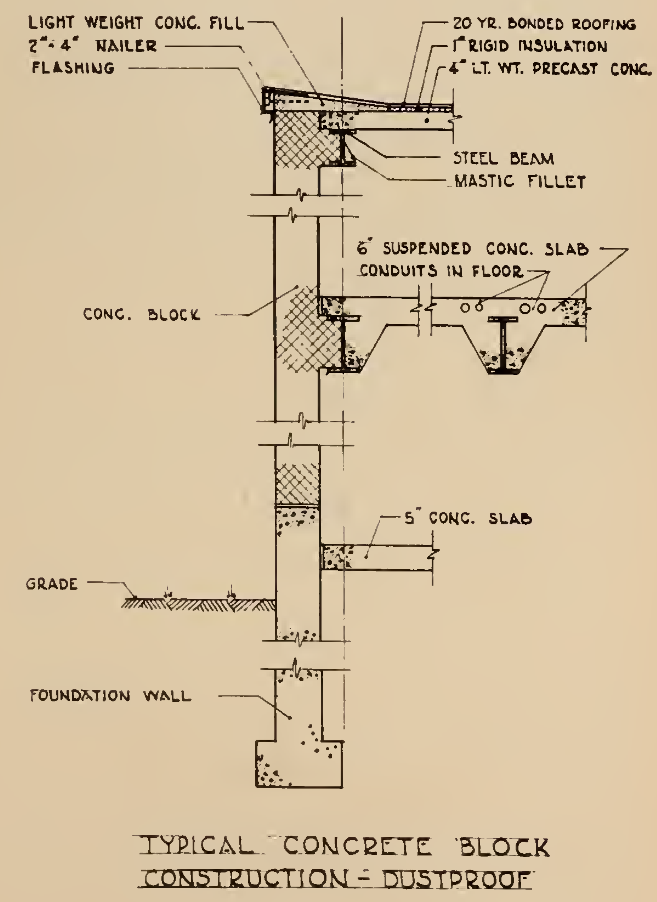

Fig. 4. Sketch of Dope House Construction

which had a floor area of 5600 sq. ft., cost 26c per cubic foot. In comparing this figure with others quoted, it should be recognized that this prefabricated building was engineered and erected by the supplier on a lump sum contract and the owner's indirect field expense and engineering charges were insignificant. This puts this particular unit cost on a considerably different footing from the other unit costs whose basis was described earlier.

Dustproof Construction

The selection of a suitable type of construction for the dope house at the commercial explosives plant at North Bay presented some interesting problems. The dry ingredients for commercial explosives are known as dopes and a typical dynamite may contain six or eight different dope ingredients which are needed to give the desired combination of properties. These dopes, comprising such materials as pulps and meals, are weigh batched in the dope house.

For this operation it was necessary to provide a noncombustible low cost structure with a dustproof interior finish to aid in housekeeping. Because some of the dope ingredients are moderately corrosive, a fair degree of corrosion resistance was desired. Since the building was to be heated to 40°F. only, very little thermal building insulation could be economically justified.

The construction selected, as shown in Fig. 4, included steel frame and concrete block walls. In areas requiring protection of the concrete floors against corrosion from ammonium nitrate, asphalt bridge planking was laid on an impregnated glass fabric membrane. This material which consists of a mixture of asphalt, fibre and mineral filler, is available in various thicknesses and sizes.

To prevent dust accumulations everything possible was done to eliminate horizontal ledges within the dusty part of the building. For example, beam flanges were covered with a mastic fillet or the beams were encased in concrete. Much of the electrical conduit was cast in the concrete floors. The ventilating ductwork was even carried on the outside of the building, in order to eliminate it as a potential location for dust accumulations.

The finished building cost 65c per cubic foot. This fairly high cost resulted partly from the special process requirements of corrosion resistance and dustproofing and partly from the rather heavy and extensive equipment supports that were necessary.

Dry Manufacturing

Also required, at the explosives plant, was a building of some 15,600 sq. ft. to accommodate equipment for the manufacture of shells and boxes. This is a dry operation with a room temperature of 70°F. The lowest cost construction was desired. As shown in Fig. 5, the construction selected comprised a steel frame with a flat roof and insulated wood stud walls covered with aluminum siding and lined with ⅜" plywood. The floor is again of floating slab construction. Because of the paper and wood materials used in this process, it was considered desirable to sprinkler this building and this, in turn, permitted the use of low cost flammable con-

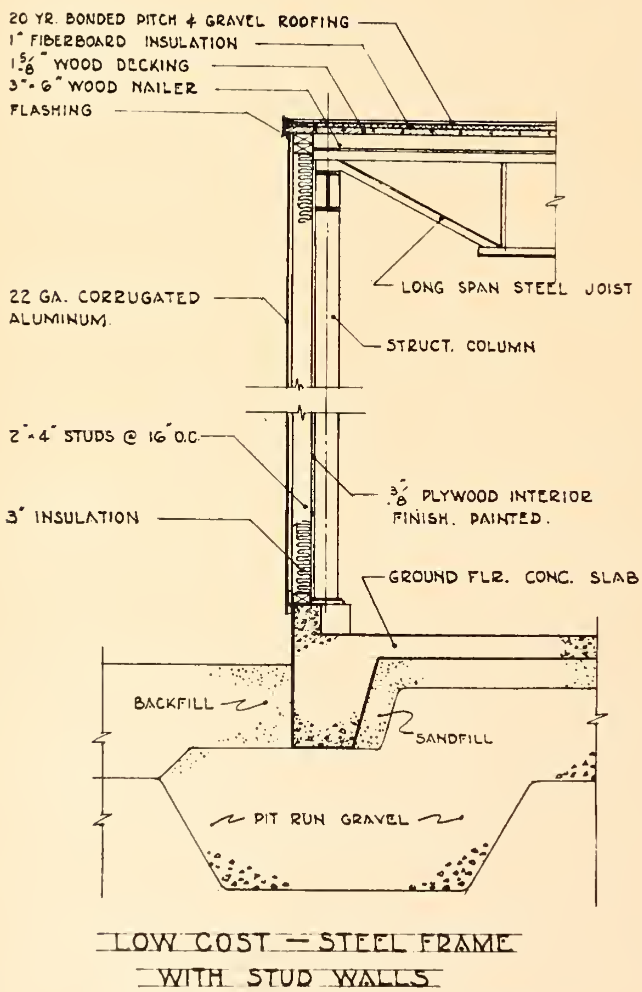

Fig. 5. Sketch of Shell and Box Factory.

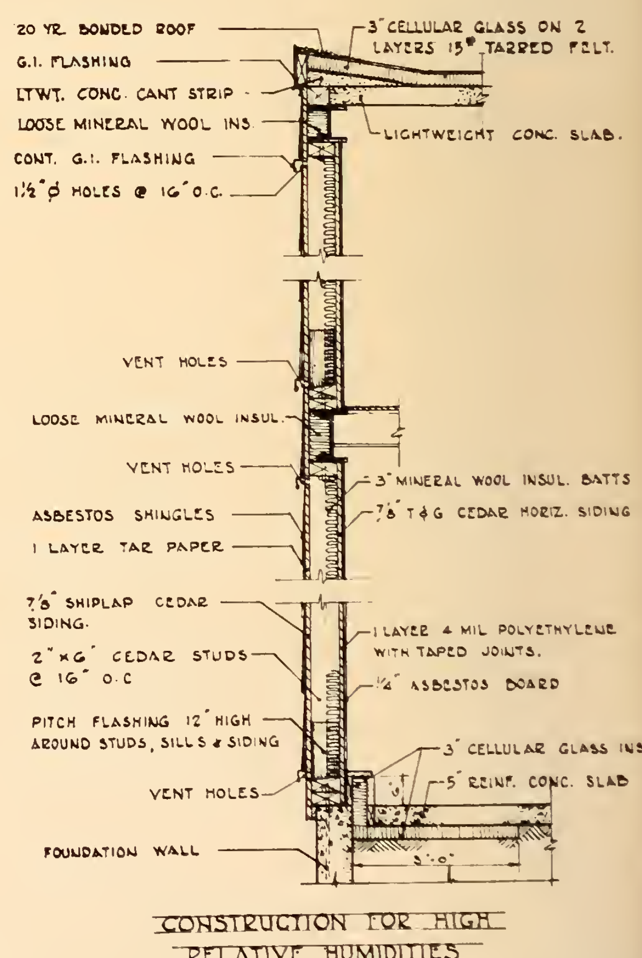

Fig. 6. Sketch of Kingston Wall.

struction materials which might not otherwise have been selected. The cost of this structure at 28c per cubic foot appears to be quite satisfactory when it is remembered that walls and roof are insulated.

Humidified Areas

At the nylon yarn plant in Kingston, many of the operations are carried out in areas maintained at a relative humidity of around 70%. Since the operations are clean and dry and involve no corrosive materials, the main problem results from the high relative humidity. The plant layout anticipates expansion of the humidified areas so most of the outside walls of these areas are of temporary construction. In the early days, before the importance of good vapour sealing was appreciated, extensive rotting occurred in the wood studs and sheathing used in these temporary walls. The solution to this problem, as shown in Fig. 6 involved a three pronged attack. First, a vapour seal of polyethylene film was provided on the room side of the wall, in order to minimize the flow of vapour into the wall. Second, vent holes were bored at the top and bottom of every stud space in order to dissipate, by gravity circulation, any water vapour that might penetrate the wall. Third, cedar studs and sheathing were used and a mopping of hot pitch was specified at the bottom of each stud space, in order to minimize rotting should condensation occur under highly unusual conditions. The wall is well insulated to keep the inner surface above the room dew point of approximately 60°F. in order to prevent condensation at this point.

The roof construction for these humidified areas also presents a problem. Since a built-up roof is by its nature a very good vapour seal, any water vapour that penetrates the roof insulation will be trapped and will eventually condense. The original roof construction used as a vapour seal two plies of roofing felt well mopped with hot pitch. The insulation was of cork, which was covered with a 20 year bonded roof. After a few years' operation, condensation began to appear on the underside of the roof deck in cold weather indicating that the roof insulation was losing its effectiveness. On investigation, it was found that the cork over much of the area was completely soaked with water which had passed upwards through the relatively permeable vapour seal that had been provided.

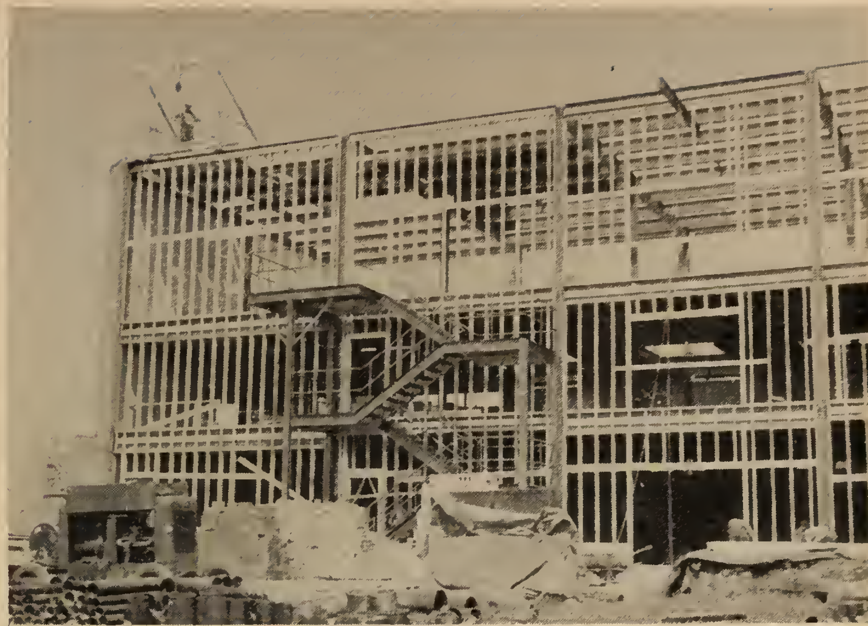

Fig. 7. Photo of Kingston under construction.

The solution to this problem, as shown in Fig. 6, was to use an impervious insulating material consisting of cellular glass. This construction has been completely adequate for the period of more than ten years that it has been in use at the nylon plant.

Fig. 7 shows a typical temporary wall under construction for a humidified area at the Kingston works. Because of the need of gravity circulation to remove moist air from the stud space, no headers are used between vent holes.

What of the Future?

These examples highlight some of the factors which have been considered in the selection of suitable housings for chemical plants. Experience has shown that these constructions are effective, but what of the future?

Sandwich wall constructions, such as mineral wool between aluminum, are becoming of more interest as their cost is reduced through improved installation techniques. Prefabricated sandwich panels should be of particular value for semi-permanent walls, because of their expected low cost, high salvage value and speed of erection.

Another subject for further investigation is the critical evaluation of prefabricated buildings for various applications. While several good makes are available, they are not necessarily cheaper than low cost custom built buildings. More information must be developed on the best applications for each of these types.

Still another area, is the use of advanced engineering and construction techniques. Plastic design, of which the first example on the North American continent is in a commercial building located in Kingston, Ontario, will lead to more economical structures. There is a place, in the chemical industry, for structures of precast and prestressed concrete. These structures, in addition to being economical, also provide excellent corrosion resistance in some environments which are highly corrosive to structural steel. On the construction side, experience with cylindrical paper tube forms for column piers has been excellent. It is thought that foundation costs can, in some instances, be further reduced by using these forms with auger drilled holes. Other techniques that should lead to cost reductions include the palletizing of construction materials, the use of stud welding for fastenings and the use of road pavers for construction of large floor slabs.

Because of the numerous interrelated factors, the selection of the best construction under any set of circumstances must be based on experienced judgement; because of rapid advances in design and construction techniques, what is best today may be completely outmoded tomorrow.

PHOTOGRAMMETRY IN HIGHWAYS AND RAILWAYS ENGINEERING

This paper discusses the application of photogrammetric engineering methods and electronic computers to highway and railway location problems. It describes the steps usually followed in location work and illustrates each phase of the work with practical examples. The techniques used in air photo analysis, ground and photogrammetric surveys, and methods of computing earth work quantities for estimates and pay purposes are described.

J. M. Zarzycki, M.E.I.C. *Chief Engineer, Engineering and Photogrammetry Division, Canadian Aero Service Limited*

TODAY'S RAPID development of vast areas of Canada represents a continuous challenge to the engineering profession. As we plan new highways and railways, the engineer has the difficult task of locating the best route and producing the best possible design in a very limited period of time. Not so long ago, the "classical" method of location was to travel the area on foot and examine the terrain from high points or to fly over it in an airplane and select a preliminary route. Only limited information could be obtained, and the route selection was done without detailed knowledge of topography, geology, soils and drainage. Alternative routes, more desirable than the one staked on the ground, were often overlooked.

The problem of route selection was always a challenge to the photogrammetric engineer. To meet this challenge the photogrammetrists have developed, during the last few years, precision aerial cameras, plotting instruments, and new advanced interpretation and compilation methods. Modern photogrammetric instruments have been combined with electronic computers to provide more speed, economy and precision in computation of excavation quantities. Today photogrammetric methods are being more and more widely used by highway and railway engineers.

Photogrammetry, a branch of civil engineering, is the science of obtaining various survey information by means of special types of photographs and interpretation procedures. It develops data heretofore collected laboriously on the ground. Its aim is to reconstruct precisely the measurements of two or three dimensional objects from photographs, and to obtain geological, soil, forestry and all geographical information of the photographed area.

Photogrammetric surveys for highway and railway location and design proceed in five steps:

(1) Reconnaissance survey of the entire area between terminal points to determine all feasible routes.

(2) Reconnaissance survey of these routes, in more detail, to determine the best route.

(3) Detailed reconnaissance of the selected route to produce a "paper location" of the semi-final line.

(4) Detailed survey of the semi-final route for the preparation of accurate cross sections and large scale topographic plans of selected areas. for major culverts and bridge sites. overpasses and clover leafs.

(5) Detailed survey of the route after construction for the purpose of determination of pay quantities.

How these surveys are carried out is described below.

(1) Reconnaissance Survey of the Area

After the traffic study is completed and the terminal points of the railway or highway are determined, the work of the photogrammetric engineer begins. Through a stereoscopic study of small scale aerial photographs (scale 1 in. = 1 mile, or 1 in. = 3333 ft.) the photo interpretation specialist provides the location engineer with reconnaissance information concerning geology, soil, drainage, land use and topography. From careful study of all pertinent factors over a broad area, several feasible routes are selected. The results of this study are presented in the form of a report in terms familiar to the location engineer. These results are keyed to a map or photo index and contain a general interpretation of the engineering significance of the data.

Since Canada is covered by aerial photographs made for the Federal

Fig. 1. An example of a photo analysis.

Fig. 2. The outlined strip on this reconnaissance map has been chosen to be re-photographed as the selected route. The new photograph will be used for detailed photo analysis and the preparation of accurate topographic plans *(32.5% reduction from original drawing).*

or Provincial Governments, the preliminary reconnaissance survey can be undertaken at any time of the year. The time necessary and costs involved are only a small fraction of time and costs for a reconnaissance survey on the ground. Furthermore, through the examination of a broad area, it is possible to study all alternative routes.

(2) Reconnaissance of the Alternative Routes

After alternative routes are selected, each one is studied in detail.

All the pertinent information needed by the location engineer for his study and choice of the best route can be provided by photogrammetry. In areas covered by National Topographical Series maps at a scale of 1 in. = 1 mile with 25 ft. or 50 ft. contours, it will be necessary for the photogrammetric engineer at this stage to conduct only a more detailed photo analysis of each route. A general study of grades and the extent of excavation and fill required can be conducted by the location engineer with the help of existing Federal Government topographic maps. This detailed study of the aerial photographs will provide information concerning drainage, general requirements for bridges and major culverts, the amount of rock excavation and location of gravel and aggregate materials needed for highway construction work. The aerial photographs will also provide valuable information about land use and property boundaries.

When the available aerial photographs are out-dated or of poor quality, it is advisable to fly new photographic coverage along each alternative route. This is particularly recommended when reconnaissance type maps must be prepared for areas lacking Government topographic maps. Photographs for this purpose are usually taken with a 6-in. focal length lens at altitudes of 30,000 or 20,000 feet above the ground giving a scale of 1 in. = 5000 ft. or 1 in. = 3333 ft. respectively. To obtain a stereoscopic coverage, the pictures are taken with 60% forward overlap and approximately 30% side overlap between the flight lines. The terrain can be viewed in three dimensions by using a simple stereoscope. These aerial photographs, which provide an up-to-date picture of the ground, are very useful in conducting more detailed photo analysis of each route. Furthermore, as these flight lines are planned to follow each alternative route, the compilation of 25 ft. contour reconnaissance maps will proceed more easily, faster, and less expensively than by using existing photographs. Reconnaissance type topographic maps compiled from aerial photographs show contours, drainage,

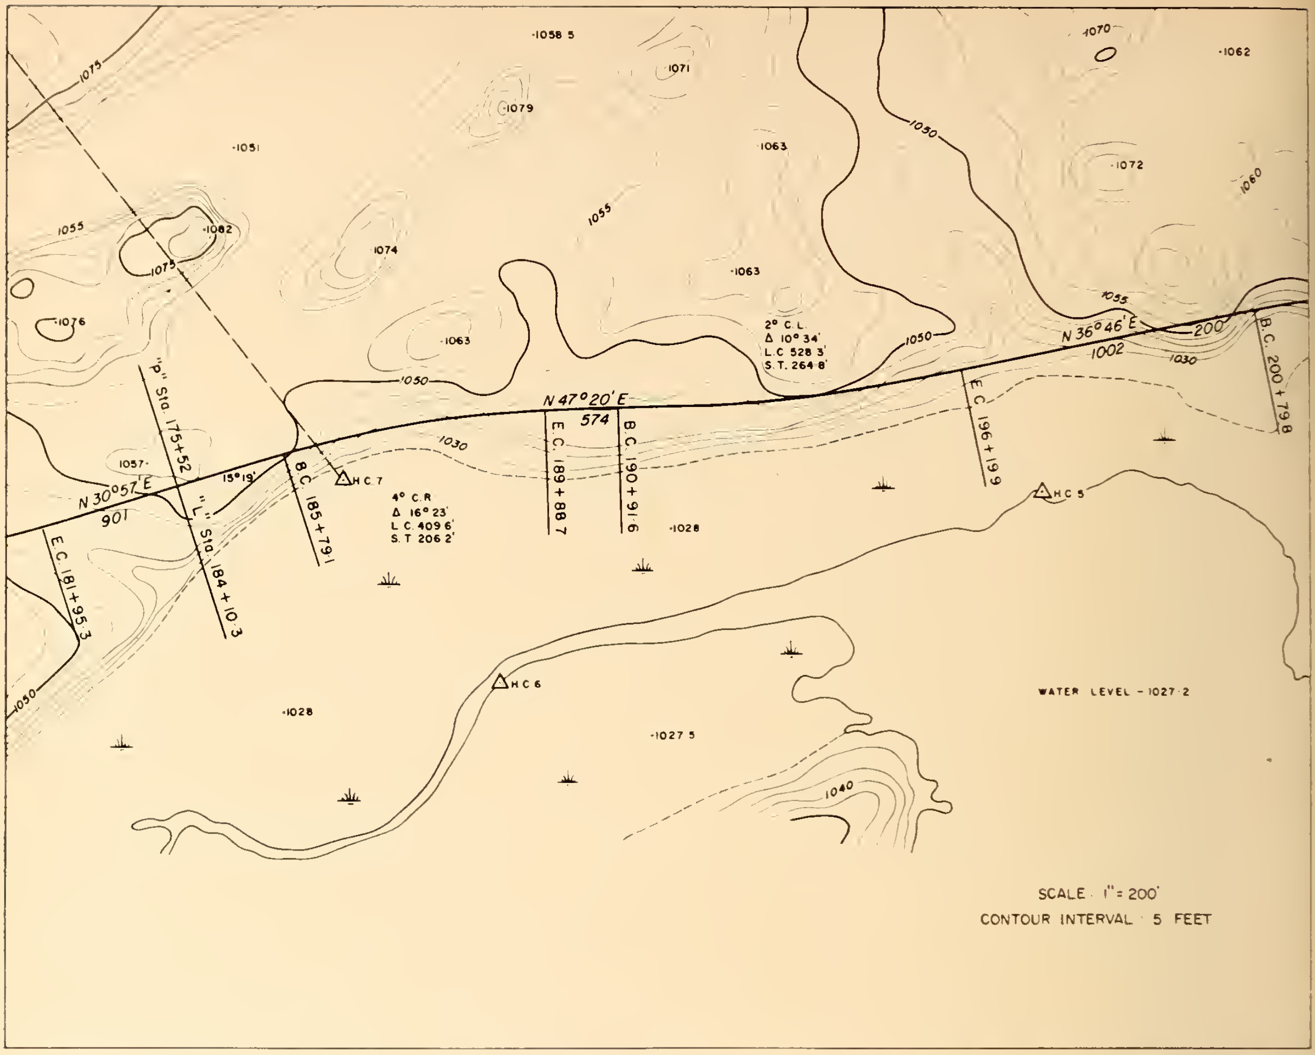

Fig. 3. The semi-final line is projected on a detailed plan as shown. This plan is used by ground survey crews in staking the centre line of the railway. *(32.5% reduction from original drawing).*

Fig. 4 The Kelsh stereo-plotter allows the operator to view an exact optical model of the photographic terrain. Contour lines and planimetric features can be traced off directly.

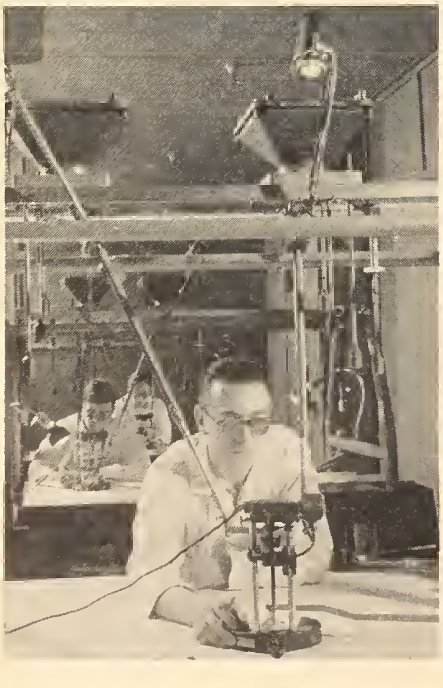

Fig. 5. The completed photo contour map. This is not a mosaic with superimposed contour lines but is a true orthographic projection.

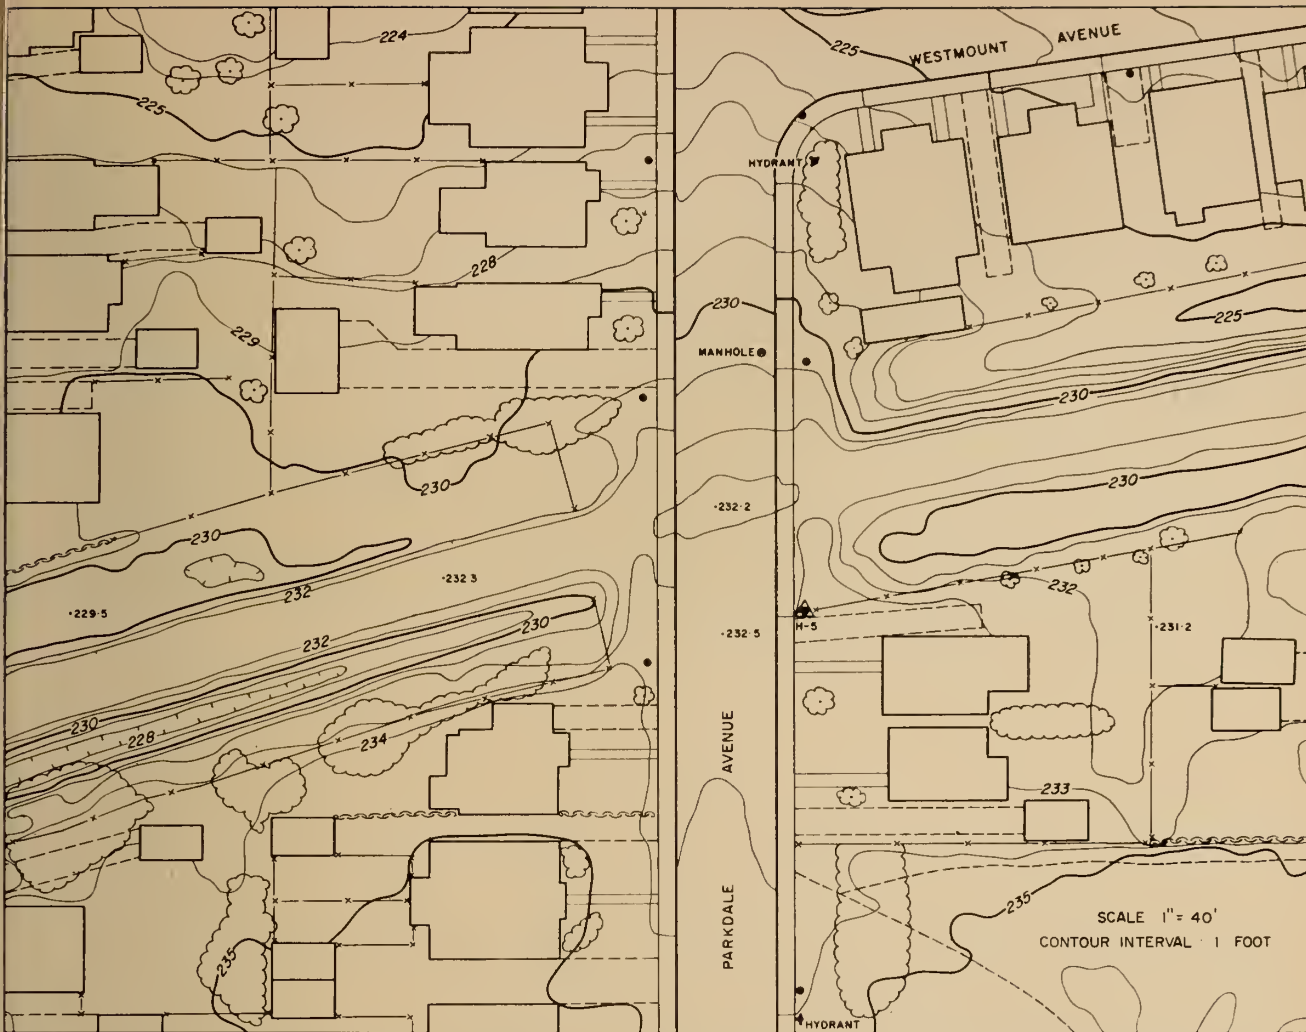

Fig. 6A. Large scale engineering plan of a portion of the proposed Queensway in Ottawa. ***(32.5% reduction from original drawing).***

roads, railways, county and township boundaries, major buildings, cross country power lines, and other important planimetric details. Contours compiled photogrammetrically express the land forms with far more detail than would be possible to obtain by ground survey methods. The most useful scale for the reconnaissance type maps is 1 in. = 1 mile or 1 in. = 2640 ft., and the contour interval 25 ft.

In most cases it is advantageous to prepare an uncontrolled mosaic from the high level photographs of each route. The scale of the mosaic should be approximately the same as the scale of the reconnaissance type topographic map. An uncontrolled mosaic is obtained by matching aerial photographs together to an approximate scale. The photographs are not corrected for the tip and tilt of the aerial camera at the moment of exposure. Therefore, an uncontrolled mosaic will show horizontal displacements of planimetric details due to tilt of the aerial camera and also due to the relief of the ground. Although accurate measurements cannot be made from mosaics, they serve a useful purpose. For example, the results of the air photo analysis and other pertinent location data can be conveniently shown on the mosaic. Such a presentation of engineering facts is very useful in discussions with laymen unfamiliar with engineering drawings.

Not only do the aerial photographs provide a vast amount of information over a broad area, but these studies can be carried out in the office without involving ground surveys, and therefore can be kept confidential. This is important to the location engineer and the administrator. Thus it is possible to eliminate in the planning stage property owners' concern and speculative real estate transactions. Consequently, the right-of-way can be secured for a more reasonable amount.

(3) Detailed Reconnaissance or Preliminary Survey of the Selected Route

The steps outlined in the previous paragraphs have brought the location engineer to the point where he can select one strip and be confident that he has selected the most practical and economical route. All this preliminary reconnaissance was completed substantially without setting foot on the ground.

In the location of the semi-final centre line of the road or the "P" line within the selected strip, photogrammetric methods especially developed for this purpose are of great assistance. The first step is to secure large scale aerial photographs of the entire route. These photographs shall be suitable for compilation of topographic maps portraying 5 ft. contour intervals at a scale of 1 in. = 200 ft. In relatively flat areas it is recommended that 2 ft. contour intervals be used. The width of the mapped strip is usually one mile, but it varies according to the topography. The scale of the aerial photography taken for compilation of 5 ft. contours is usually 1 in. = 1000 ft. The mapping plane's altitude, and consequently the

Fig. 6B. Aerial photograph taken from an altitude of 1800 ft. The area shown in Fig. 6A is outlined on the photograph.

Fig. 7. A field crew on location in Northern Quebec using the Telluro-meter, electronic instrument for distant measurement.

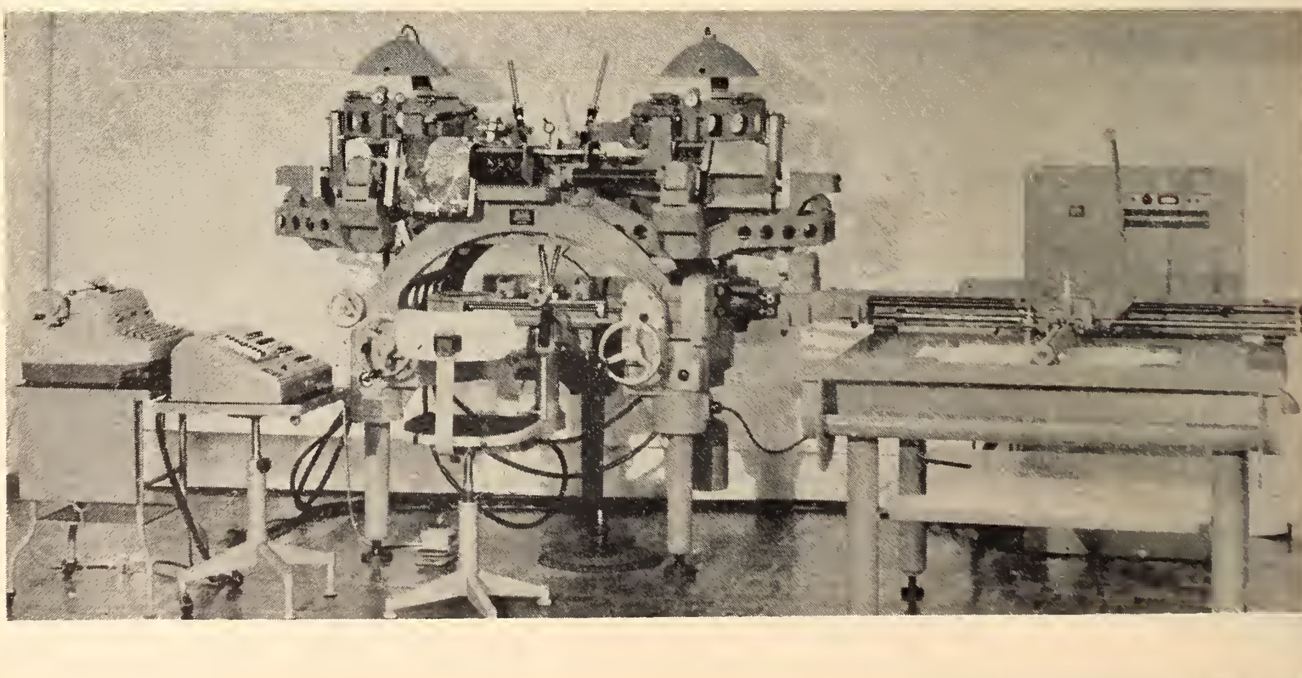
scale of the aerial photography for a given vertical accuracy, depends largely upon the type and quality of the lens in the aerial camera and upon the type and accuracy of the stereo-plotting instruments to be used for compilation. Therefore, the final recommendation as to the scale of the aerial photography and compilation methods should be made by the photogrammetric engineer responsible for the project.

To provide the location engineer with necessary information for the location work, the photogrammetrist will conduct a detailed photo analysis, establish vertical and horizontal ground control, and compile accurate topographic plans.

The detailed photo analysis will call the attention of the location engineer to specific or unusual situations and will provide information concerning rock and soil types, approximate depth of bedrock, location of possible sources of gravel and aggregate materials, location of quarry faces and outcrops, direction of dip of bedding plains, and the location of areas subject to slide. The photo analysis data are field checked before they are submitted to the location engineer. These field checks are of great importance and should be an integral part of the detailed photo analysis. The purpose of the field check is to sample necessary keys and to prove the validity of the information obtained from aerial photographs. The land use data are also obtained from aerial photographs by functional classification of the land along the proposed right-of-way.

The results of the photo analysis are presented in the form of an an-

Fig 8. A Wild A-8 Autograph with attached electronic coordinate printer. The tape immediately below the picture contains data on the coordinates of cross-sections obtained with the A-8 instrument. The second tape represents the program for electronic earthwork calculation.



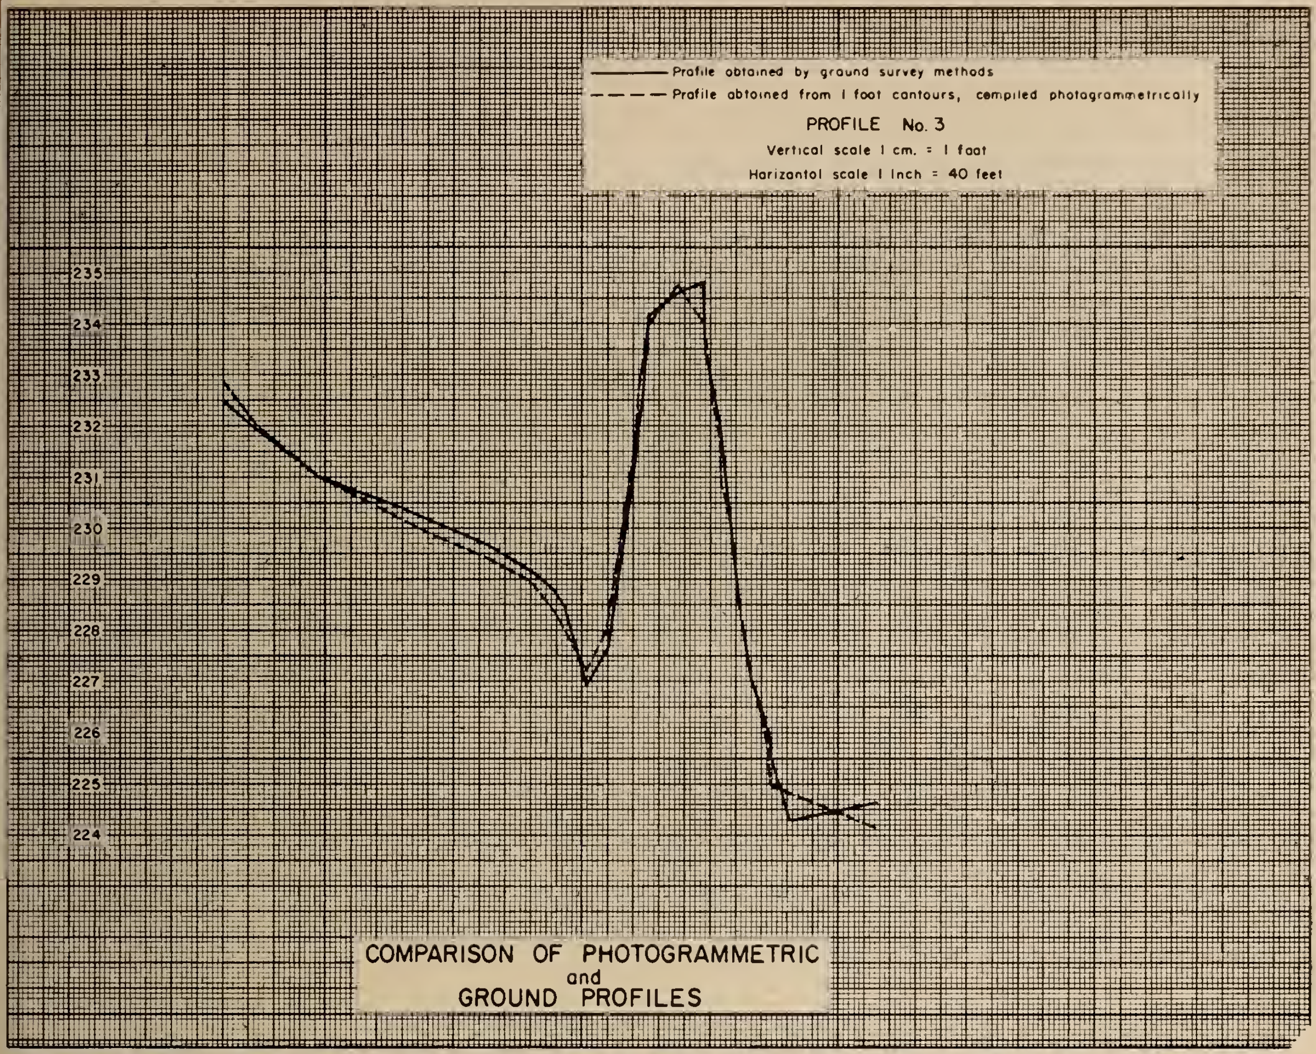


Fig. 9 (A). Comparative study of profiles surveyed by standard ground methods and by photogrammetry. The maximum deviation was found to be 0.5 ft. and the average deviation 0.2 ft. *(32.5% reduction from original drawing).*

notated mosaic with overlays showing soil, geology, borrow materials and land use classifications. This graphical presentation is accompanied by a written report discussing the engineering significance of the data. Based on the information provided by photo interpretation, the design engineer can lay out a more effective boring program and thus reduce substantially the time and cost of soils investigation.

The topographic plans required for location of the preliminary or semifinal line can be compiled most economically by photogrammetric methods. It is necessary to establish vertical and horizontal control on the ground for the purpose of "levelling" and "scaling" of the aerial photographs for this compilation. Careful planning of the ground survey is very important since it will not only influence the accuracy of the topographic plans but also will be of great assistance in staking of the centre line on the ground. The approach followed on large railway projects in Northern Manitoba and Quebec is to run accurate traverses and levels close to the proposed centre line as determined from preliminary photo interpretation and reconnaissance maps. Bench marks and traverse stations should be permanently marked approximately every mile and described. In addition, position and/or elevation of points readily identifiable on the aerial photographs should be established so that accurate topographic plans can be compiled.

In connection with ground control survey, the new electronic distance measuring device, the Tellurometer, is very useful. This instrument, which was developed in South Africa, measures distances from 1,000 ft. to 30,000 ft. with an accuracy of 2 inches. The only power supply required is a 6-volt automobile battery. The equipment consists of a "master" and a "slave" station, each weighing approximately 30 lb.

After the ground control is established, the topographic plans are compiled, using stereo-plotting instruments such as the Kelsh plotter or Wild A-8. Planimetric details such as roads, railways, streets, buildings, streams, rivers, water bodies, power lines, permanently marked traverse stations and other pertinent details are plotted from aerial photographs together with contour lines. The most useful scale and contour interval for the detailed reconnaissance type of plans is 1 in. = 200 ft. with 5 ft. contours. In flat areas 2 ft. contours are recommended. This plan covers a strip between one-half to one and one-half miles wide and thus gives the location engineer detailed information over a large enough area.

The standard accuracy of the topographic plans generally accepted is as follows.

Horizontal Accuracy — 90 per cent of all well-identified features shall be plotted to within 1/20 inch of their correct relative position. In urban or

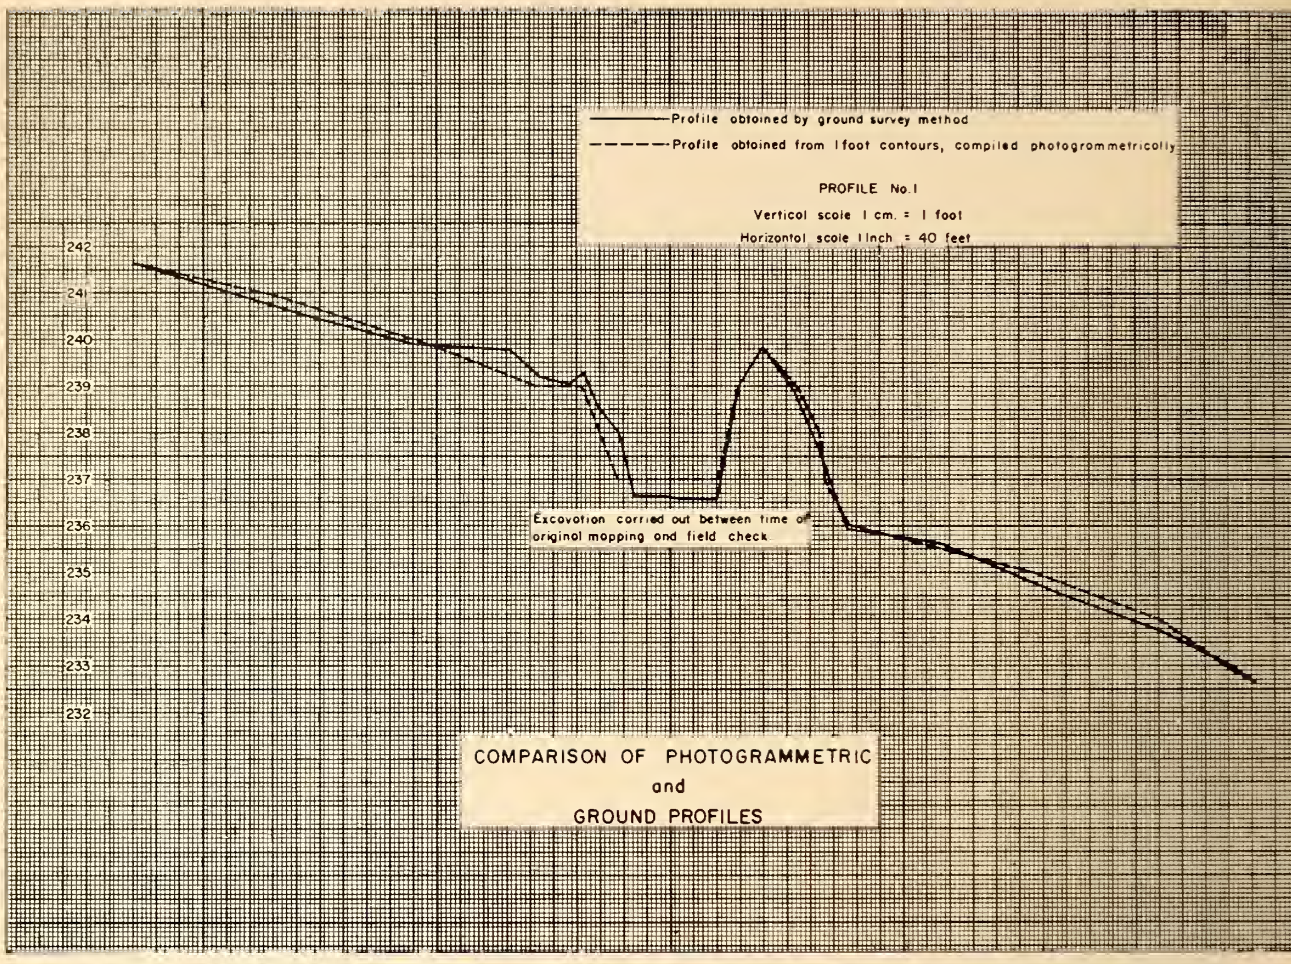

Fig. 9 (B). Comparative study of profiles surveyed by standard ground methods and by photogrammetry. The maximum deviation was found to be 0.5 ft. and the average deviation 0.2 ft. ***(38.3% reduction from original drawing)***

heavily developed suburban areas, the horizontal accuracy required is 1/40 inch. In these cases the plans should be drafted on a stable material, and not on linen. The maximum error should not exceed twice these specified accuracies.

Vertical Accuracy — 90 per cent of all contours shall be accurate to within one-half the contour interval. The maximum error should not exceed one full contour interval. This vertical accuracy can be maintained except for areas covered with heavy trees and heavy undergrowth. In such areas, the aerial photos should be annotated for the engineer to show different zones of vertical accuracy, according to density of tree cover in the area.

The topographic plans, together with the result of the photo analysis, provide the basis on which the design engineer can determine a number of feasible routes for the railway or highway. The engineer can project the centre line on these and determine grades, bearings of the tangents and coordinates of the P.C.'s, P.T.'s and P.I.'s. He can also compute preliminary excavation quantities and classify the excavated materials. Computing machines may also be useful to provide information on cut and fill for each tentative route. Using these data, the centre line can be transferred easily from the plans to the ground. The staking of the semi-final centre line on the ground will proceed more rapidly since it will not involve any extensive basic survey work and will eliminate the necessity of running trial lines. Ground survey conducted previously for the purpose of establishing control for photogrammetric mapping forms the skeleton from which the new centre line is surveyed. Experience shows that the final line of the railway or highway does not vary by more than 100 ft. from the semi-final line determined by using information supplied by photogrammetry. Very often these variations amount to 20 ft. or less.

The photo contour map should be considered also for location work. This new technique is a result of an ingenious combination of photogrammetric principles and was developed by R. W. Towill. The photo contour map shows both contour lines and a photographic image of all planimetric and cultural details of the area. It is not a mosaic with contours superimposed, but a true orthographic projection. In compiling this map each aerial photograph is corrected for tip, tilt, scale, and topographic relief. The correction for the relief is made for each contour interval. The location and design engineer will find this new map of great assistance in solving many problems because of the wealth of information it provides; it gives him continual reference in the field.

(4) Detailed Survey of the Semi-Final Route

After the semi-final or "P" line of the highway or railway has been transferred to the ground from the topographic plans, the possible borrow-pit sites and the right-of-way are photographed at a very large scale. If the route is covered by heavy timber or dense undergrowth the right-of-way should be cleared before the photography is taken. These photographs are used for compilation of detailed topographic plans at 1 in. = 20 ft. or 1 in. = 40 ft. or 1 in. = 50 ft. with 1 ft. contours and also for determination of cross sections and excavation quantities.

The necessary ground control for compilation of the detailed plans can be easily established at the time when the semi-final centre line is staked on the ground. These large-scale plans have been found very useful for detailed design of multi-lane highways, bridges, clover leafs and major culverts. The plans may be prepared for the entire right-of-way or only for selected areas.

In addition to planimetric details usually shown on the 1 in. = 200 ft. or 1 in. = 100 ft. plans, these large-scale plans also show culverts, sanitary and storm sewers, telephone poles, hydrants, curbs, and all structures, roads and railways, and all property lines visible on aerial photographs. Invert elevations for manholes, catch basins, and underground utilities can be added to the plans after a field editing. Plans of this type at a scale of 1 in. = 40 ft. with 1 ft. contours have been recently prepared by photogrammetric methods of the proposed Queensway in Ottawa. These plans are being used by the consulting engineers, for the detailed design, quantity estimates and solving of other problems encountered. To check the accuracy of these plans, profiles have been run on the ground and compared with the profiles obtained from contours plotted photogrammetrically. Figures 9A and B show this comparison, which establishes that the contours are well within the specified accuracy of 6 inches.

The same aerial photographs can be used for the determination of cross-sections of the terrain before construction and computation of slope stake data and accurate earth work quantities. For this purpose the precise stereo plotting instruments are coupled with a punched card or punched tape printer. The computations are performed by high-speed electronic computers. At the suggestion of the author the Wild Company, of Switzerland, has modified the A-8 stereo plotting instrument, adding an electronic printer which punches on a tape or card the XY coordinates and elevation of every point of the stereo model by simply pressing a button. When a profile or cross section must be established photogrammetrically, the stereo operator places the measuring dot on the ground along the cross-section to be taken and presses a button. At this moment the position and elevation of the point is registered on the tape. Every point along each cross-section and profile is measured and registered in this way. To compute slope stake data and the design quantities, this punched tape is fed to an electronic computer together with the design criteria and information covering type of materials along the route. The electronic machine computes the cut and fill quantities classified according to the type of materials, as well as vertical curves and the distance from the centre line and elevation of each slope stake. These data can be directly used for preparation of contract documents and for the detailed staking of the route. A graphical presentation of the cross-sections punched on tape is obtained by employing an Electro Dataplotter. This instrument (Fig. 11) draws the cross-sections at the required scales automatically from the punch tapes or cards. By using photogrammetric methods combined with electronic computers, the earth work quantities and slope staking data can be obtained much more quickly and cheaply than by using ground survey methods.

(5) Detailed Survey of the Route After Construction

This survey consists of the computation of progress and final pay quantities and preparation of plans and profiles of the route after construction.

The determination of pay quantities can be done by photogrammetric methods. After the road or railway is constructed, the entire route and the borrow pits are photographed at a very large scale. From these photo-

Fig. 10. A Kelsh plotter with a digital readout system developed by Canadian Aero Service engineers. The station number, distance from the centre line and the elevation of each point along a cross section are punched automatically on a tape.

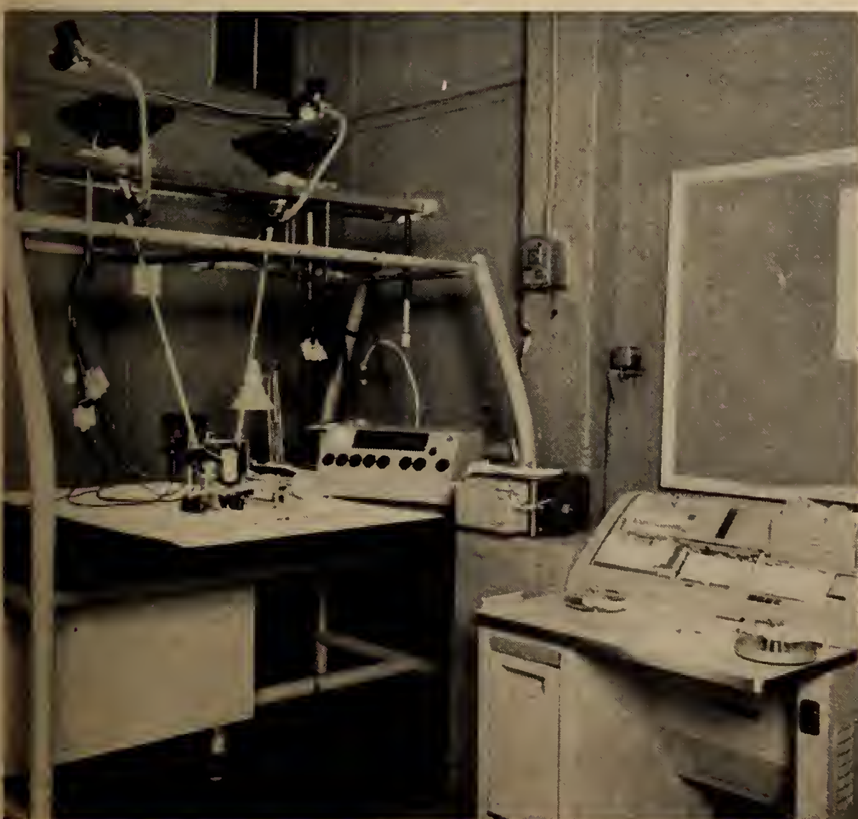

Fig. 11. The Electro Dataplotter for plotting of profiles and cross sections from punched tape or punched cards.

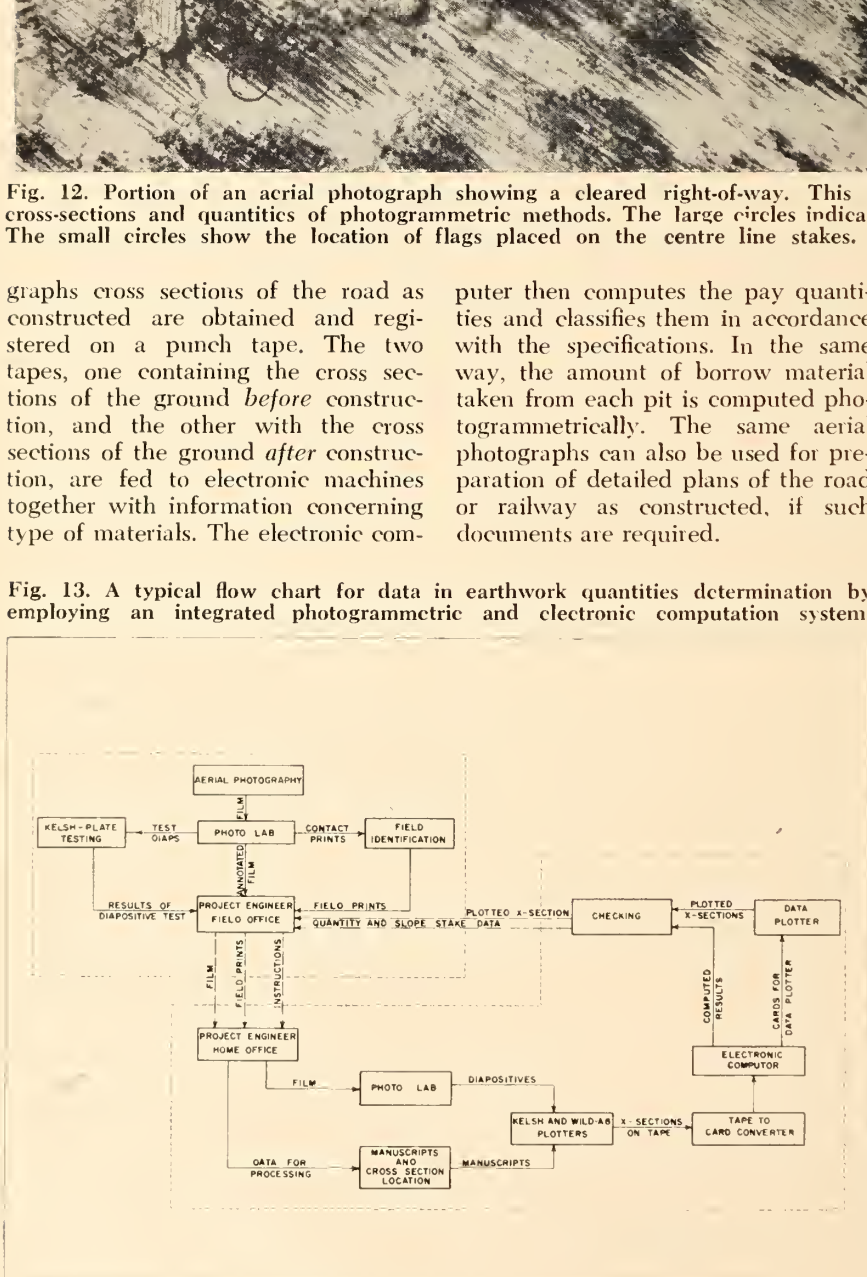
Fig. 12. Portion of an aerial photograph showing a cleared right-of-way. This was taken for the purpose of obtaining cross-sections and quantities of photogrammetric methods. The large circles indicate the location of permanent control points. The small circles show the location of flags placed on the centre line stakes.

graphs cross sections of the road as constructed are obtained and registered on a punch tape. The two tapes, one containing the cross sections of the ground *before* construction, and the other with the cross sections of the ground *after* construction, are fed to electronic machines together with information concerning type of materials. The electronic computer then computes the pay quantities and classifies them in accordance with the specifications. In the same way, the amount of borrow material taken from each pit is computed photogrammetrically. The same aerial photographs can also be used for preparation of detailed plans of the road or railway as constructed, if such documents are required.

Fig. 13. A typical flow chart for data in earthwork quantities determination by employing an integrated photogrammetric and electronic computation system.



The compilation of earth work quantities by photogrammetric methods offers many advantages:

(i) These computations can be done faster and less expensively than by ground survey methods.

(ii) By using photogrammetry a considerable saving of field engineering staff is achieved.

(iii) The cross sections obtained photogrammetrically reflect the shape of the ground more accurately than those surveyed on the ground. This is particularly true in areas of large cuts where the process of surveying cross-sections on the ground is incomplete and proceeds very slowly, which may result in delays in supplying the contractor with necessary information.

(iv) The computations are performed by a third and impartial group.

(v) The possibility of human error is practically eliminated because the cross-section data obtained in a stereo plotting instrument are directly punched on a tape and the computations are performed electronically.

(vi) The aerial photographs provide a rapid, convenient and indisputable record of the ground before and after construction, and many disputes can be settled in the office without the necessity of sending field crews to the area.

(vii) These photographs obtained

WHAT HAPPENS TO APPLICANTS FOR NATIONAL RESEARCH COUNCIL SCHOLARSHIPS IN SCIENCE AND ENGINEERING

Paul Beaulieu,* S.E.I.C.

Division of Administration and Awards, National Research Council, Ottawa.

SINCE 1917 the National Research Council of Canada has maintained a system of scholarships to assist graduate students in science and engineering who have shown promise of research ability. Altogether nearly 3500 awards have been held by a little more than 2000 graduate research students.

During the twenties the number of awards increased moderately from year to year, reaching a total of 592 in 15 years. The program suffered a severe setback during the depression of the thirties and it was not until the Second World War that it regained the level of the predepression years. In 1946, 30 years after its inception, the total number of awards granted had reached 1369.

Immediately after the war the annual number of awards began to increase rapidly. This was due partly to the fact that so many war veterans upon completing their bachelor's degree decided to continue studying for higher degrees. But it should be noted also that Canadians had become more conscious of the important role which science and engineering could play in the expansion of the country. In the eight years which followed the war, the Council awarded more scholarships than it had in the thirty previous years of its existence. In the last three years (1955-57), an average of 220 scholarships have been awarded each year.

The growth of this scholarship program has paralleled the development of facilities for graduate study and research in Canadian universities, and it has played an important role in the training of scientific personnel to meet the academic and industrial needs of the nation together with those of its public service. The annual expenditure for National Research Council scholarships has now passed the half-million mark.

SCHOLARSHIP COMPETITION

At present there are four types of scholarships offered in science and engineering. The bursary is awarded to those who have had no previous research experience and the studentship to those who have had one year or more of experience in research following graduation. Both these scholarships are tenable only in Canadian universities, and cover a working period of 8 months. They may be supplemented by an additional sum if the student works for a full year on his program. The other two types of scholarships are for study and research outside Canada. The special scholarship is given to those who have completed the requirements for a master's degree and desire to study in a field in which it is difficult to get the training in Canada, or to work under a world-famous scientist. The postdoctorate overseas fellowship may be held by those who have completed a doctorate degree and who wish to add to their experience by specialized training abroad. These last two awards are for a tenure of 12 months.

The scholarship competition is held annually in March. In each of the past few years over 500 applications

* Awards and Committee Services, National Research Council, Ottawa, Canada.

have been received. The members of the Honorary Advisory Council for Scientific and Industrial Research, better known by its short title—National Research Council—take direct responsibility for awarding all scholarships. This Council comprises representatives from Canadian universities and from all fields of science taken in a broad sense.

Each application stands on its own merit and a high standard of scholarship has been rigorously maintained. The numbers of awards are not limited by fields of research or by universities. The task of the Council is made more difficult by the fact that the universities recommend only their best students and hence they must select the very superior candidates from an already high calibre group. In recent years, close to half of the applicants were awarded scholarships. However, about 15% of these awards were not held for various reasons such as unforeseen financial responsibilities, changes in plans, sickness, etc. Over 80% of the scholarships awarded were for study in Canadian universities. In addition, it should be mentioned that many of the students who fail to receive a scholarship and a large number of others are supported under N.R.C. research grants made to members of university staffs.

Those responsible for such an important program are continuously concerned with what has happened to the scholarship holders over the years. Have these scholarships been a good investment for Canada? What has happened to the non-successful group of applicants? Are the methods of selection adequate? In an attempt to shed more light on such questions, this study was undertaken.

Totals	450	100	300	100	750	100

Summary A

WHO WAS STUDIED

Obviously, the group selected should be recent enough to reflect present-day operations and large enough to permit meaningful comparisons. Bachelor graduates of the 3-year period from 1949 to 1951 who had applied for a Council graduate scholarship in the years following their first degree were found to have these attributes.

This group is one of the earliest in which most students would by now have completed their training and entered upon careers in science. It also has the advantage of being the largest 3-year group available. Indeed there were more people by far who obtained a Bachelor's degree in science or engineering in these 3 years than in any other 3-year period in the history of Canadian universities, because of the war veterans who graduated in those years in addition to the normal student body.

All applicants for scholarships who had graduated with a bachelor's degree during this period amounted to a group of exactly 900. Current addresses for most of these people were secured from alumni associations, graduate schools which they had attended, and personnel officers of Government departments. Contact was established with approximately 98% of the group, and 96% of those who were sent letters responded to the questionnaire. Altogether, 846 people provided complete data.

WHAT WAS ASKED

Questions asked included: What university granted which degree, in what year, in what field of specialization? Present employment was asked for as at 1 July, 1957, together with name of employer, location of employment, position held, and annual salary effective at that date.

WHAT WAS ALREADY KNOWN

During the period 1949 to 1957 the Council received 1616 applications from the group of 900 students who form the basis for this survey; 80% of these applications were submitted in the four years following their bachelor's degree. About 36% of the applications were for a bursary, 45% for a studentship, and 19% for awards tenable outside Canada.

It should be pointed out however that 152 of these 1616 applications were submitted by students who were granted Research Council of Ontario Scholarships just prior to the date of the N.R.C. scholarship competition. Since it has been the practice not to duplicate these Ontario awards, these applications were not considered by the Council. However, in analyzing the returns of the survey these applicants have been included and considered as successful candidates.

Table I gives the distribution of

Total	846	477	62

applicants by region of bachelor graduation. Nearly 40% of the Canadian applicants for N.R.C. scholarships graduated from universities in Western Canada, where the population is 27% of the Canadian total. The percentage of applicants from Ontario was just slightly lower than the percentage of its population to the rest of Canada, while the percentage of applicants from Quebec and the Atlantic Provinces was considerably below the percentage of population in these provinces. It appears therefore, that Western Canada produces proportionately more graduate students who are interested in our scholarships. However, the graduates of Western universities have perhaps less opportunity for industrial employment in the home area and may thus be more easily influenced to continue their studies. Large eastern universities have probably a greater number of attractive scholarships to offer to their students than western universities.

The percentage of applicants from the Province of Quebec is lower than the percentage of its population but this is to be expected in the French-speaking universities of Quebec, where such excellent work is done in the humanities, law, and medicine, and where, until recently, science and engineering had not been given equal attention. Since 1945 the departments of science of French-speaking universities have expanded very rapidly and the trend seems to indicate that this growth will continue. The same thing is true in the Atlantic Provinces.

Of the 900 students in the survey, 512 were successful in winning one or more N.R.C. or R.C.O. scholarships. Excluding 65 R.C.O. scholarship winners, 447 or 54% of the applicants were successful in winning one or more scholarships from the National Research Council. The percentage of successful applicants from most of the universities is quite close to this over-all percentage.

These 447 successful applicants received a total of 798 N.R.C. scholarships or approximately 1.8 awards each. These 798 awards comprised 232 bursaries, 356 studentships, 85 fellowships (this category was consolidated with studentships in 1955), 67 special scholarships, and 58 postdoctorate overseas fellowships. The following is a breakdown of the 447 students by number of scholarships won. (Column A shows No. of N.R.C. scholarships won by an individual; col. B. shows no. of students who won 1, 2, etc. scholarships).

Category	*Level of education*	*Industry* %	*Government* %	*University* %
Working within 3 years of Bachelor graduation	The majority remained at the Bachelor level	76	17	7
Intent to do post-graduate study	Those who remained at the Bachelor's or Master's level	51	38	11
	Those who attained the Ph.D.	36	29	35

Summary D. Study/Job-Distribution

INFLUENCE ON ACADEMIC CAREER

Table II gives a distribution of the 846 reporting applicants, classified by highest degree and by year of obtaining highest degree; 477 or 56% have a Ph.D. degree, 290 (34%) went as far as the master's degree, and only 79 (9%) did not go beyond the bachelor's level.

Excluding the reporting applicants whose first application to N.R.C. was for a postdoctorate fellowship (14) and those who were still studying at 1 July, 1957, for a higher degree (82) the Summary Table A was derived.

This study shows that about three quarters of the successful applicants attained the Ph.D., and that a little less than half of the unsuccessful applicants also attained the Ph.D. Similar studies in other countries would be helpful in showing whether this Canadian experience was or was not unusual.

Female applicants

Of the 60 women in the survey, 52 have reported information. Of these 52 applicants 21 or 40% attained the Ph.D. degree. Excluding nine who were still studying for a higher degree, one obtains the distribution in Summary B, which can be compared to Summary A where male and female were grouped together.

Proportionately there were nearly twice as many women as men still studying for a higher degree. We note also that 51% of the women who have completed their studies have not attained the Ph.D. level as compared to 38% for men. This is to be expected as marriage has delayed or changed the plans of many women.

	Industry *U.S.* $	*Industry* *Canada* $	*Canadian Government* $	*Universities* *U.S.* $	*Universities* *Canada* $

Geographic Migration of Applicants Holding a Ph.D. Degree

How far you go depends on where you begin

Excluding those who were still studying at 1 July, 1957 (82), it is found that, among graduates of various Canadian universities who have applied for N.R.C. scholarships, there are highly significant divergences from the over-all proportion of Ph.D.'s. From Summary C the chi-square of 21.04 obtained in testing the homogeneity of ratios of Ph.D.'s to the number of applicants by region of B.Sc. degree, has a chance probability of less than 0.01.

The percentage of Ph.D.'s was highest amongst the graduates of Toronto and McGill. The percentage at the universities in the Western Provinces and the Maritimes was very close to the over-all percentage of 62%.

Number of years from the B.Sc. to the Ph.D.

From Table II can be drawn the following table which gives a distribution by the number of years from the Bachelor's to the Doctorate degree. It is assumed that Bachelor degrees are awarded at the end of May and that as many Doctorate degrees are awarded in the first 6 months of the calendar year as in the second 6 months so that the Doctorate degrees are considered to be awarded on 1 July of each calendar year.

No. of years from B.Sc. to Ph.D.	*Awarded B.Sc. in* *1949*	*1950*	*1951*	*Totals*
1.58—2.57			1	1
2.58—3.57	36	26	22	84
3.58—4.57	54	52	44	150
4.58—5.57	35	39	44	118
5.58—6.57	30	26	24	80
6.58—7.57	18	18		36
7.58—8.57	8			8
				477
Still studying	19	28	35	

It is expected that a good percentage of those who were still studying will eventually receive a Ph.D. degree. Therefore, since this table is open at the end, the median appears to be the most suitable measure of the average number of years required for the doctorate degree. We find that the median number of years spent to earn a Ph.D. was 4.6 years from the bachelor's degree.

Applicants who won at least one scholarship needed an average of 4.5

years to earn their Ph.D. The array follows:

No. of years from B.Sc. to Ph.D.	*Successful applicants awarded B.Sc. in* 1949	1950	1951	*Totals*
1.58—2.57			1	1
2.58—3.57	28	21	20	69

6.58—7.57	9	7		16
7.58—8.57	2			2
				334
Still studying	14	9	17	

Under existing regulations, a student may receive a maximum of four scholarships from the time he graduates to the time he completes his Ph.D. These scholarships cover the academic term and they can be supplemented by an additional amount during the summer preceding and also following the academic term. Therefore a student winning an award immediately after obtaining his B.Sc. may receive support for 4.3 years, which should on the average be sufficient time to complete his Ph.D.

On the other hand, unsuccessful applicants took more time, on the average, to complete their Ph.D.'s.

In fact, the median number of years required by unsuccessful applicants was 5.0, nearly 7 months longer than successful applicants.

No. of years from B.Sc. to Ph.D.	*Unsuccessful applicants awarded B.Sc. in* 1949	1950	1951	*Totals*

SUBJECT OF HIGHEST DEGREE

Table III gives a distribution of the 846 reporting applicants, classified by subject of highest degree, and by field of employment.

These 846 applicants were divided up as follows:

Subject of highest degree	*No.*	*%*
Chemistry	234	28
Life sciences	231	27
Physics	171	20
Engineering & Applied sciences	168	20
Mathematics & Statistics	42	5
	846	100

At 1 July, 1957, 56% of the reporting applicants had obtained a Ph.D. degree. In chemistry the percentage was 67%, compared with 61% in life sciences, 55% in physics, 45% in mathematics, and only 40% in engineering and applied sciences.

Of those who had not reached the Ph.D. level, 43% were successful in winning at least one scholarship. For each subject of degree the percentage of award winners was about the same as this overall percentage of 43. In fact a comparison by fields showed a chi-square of 1.98 and the chance probability of obtaining this figure is higher than 0.70.

However, the situation is different for those who have a Ph.D. degree. In this case a chi-square of 17.95 was found. The chance probability of obtaining this number is about 0.001. For Ph.D.'s, there are, therefore, highly significant over-all divergences in the percentages of award winners in the various fields of specialization.

The over-all percentage of Ph.D.'s who were successful in winning at least one scholarship was 70%. In chemistry it was 72%, in engineering and applied sciences 71%, and in mathematics 74%. In physics, however, the percentage was 83% whereas it was only 58% in the life sciences. Physicists received significantly more scholarships; students of the life sciences received significantly fewer.

Female applicants

Of the 52 female reporting applicants, 62% were in the life sciences and 24% in chemistry.

Subject of highest degree	*N.R.C. Award*	*Employed in*							
		Canada			*U.S.A.*			*Other*	*Total*

Table IIIB. Doctors

UNIVERSITY GRANTING PH.D. AND SUBJECT OF PH.D.

Table IV gives a distribution of Ph.D.'s by subject of Ph.D. degree and university granting Ph.D.

One observes at once the progress accomplished by the graduate schools of Canadian universities; 58% of the Ph.D.'s were given in Canada, 30% in the U.S., and 11% in the U.K.

A comparison by subject of degree and country awarding degree revealed a chi-square of 16.49, the chance probability of which is less than 0.05. There are therefore significant divergences from the above over-all percentages. Proportionately fewer people earned Canadian Ph.D.'s in mathematics and engineering. They preferred American universities in mathematics and U.K. universities in engineering. On the other hand, proportionately more people took Canadian Ph.D.'s in physics and fewer went to the U.S. Also, proportionately more people earned American Ph.D.'s in the life sciences with proportionately fewer going to the U.K.

One third of the 278 Ph.D. degrees taken in Canada were awarded by McGill University, and 27% by the University of Toronto. If we exclude these two universities we find that the American universities have awarded more Ph.D's than all the remaining Canadian universities.

The favourite American universities are Wisconsin, M.I.T., Cornell, and Illinois. One third of the 145 Ph.D.'s taken in the U.S. were awarded by these universities.

More than half of the 53 Ph.D.'s awarded in the U.K. were from Cambridge and London University.

Following are the universities which awarded the largest percentage of degrees for each subject of degree:

In the field of chemistry, 26% of the Ph.D's were taken at McGill, 12% at Toronto, 6% at New Brunswick, and 6% at Cambridge.

In physics, Toronto accounted for

	17	12	9	12	4	54
GRAND TOTALS	156	94	140	68	19	477

19% of the Ph.D.'s; McGill, 15%; British Columbia, 13%; and M.I.T., 5%.

In life sciences, 18% of the Ph.D.'s were awarded by McGill, 13% by Toronto, 5% by Wisconsin, and 5% by Cornell.

In engineering and applied sciences, 25% of the Ph.D.'s were taken at Toronto, 15% at McGill, 9% at Wisconsin, and 7% at London University.

In mathematics and statistics, Toronto awarded three of the 19 Ph.D.'s; and McGill, Princeton, Harvard, and Cambridge awarded two each.

COUNTRY AND FIELD OF EMPLOYMENT

Turning back to Table III, the 175 reporting applicants who are not classified as "employed" in Canada or the U.S. were divided as follows:

	Masters and Bachelors	*Doctors*
Studying science	82	
Postdoctorate Fellows in Overseas Labs		16
Medical Residents and Interns		12
Postdoctorate Fellows in Govt. Labs		6
Self-employed	10	6
Employed overseas	7	3
Housewives	10	3
Unemployed	4	8
Deceased	6	2
	119	56

Of those who had not reached the Ph.D. level and who were employed at 1 July, 1957, only 12% have taken up positions in the U.S. In Canada and the U.S., 51% were employed in industry, 38% in the Canadian government (Federal, Provincial, or Municipal) and only 11% in universities and other educational institutions.

The situation is quite different for those who attained the Ph.D. degree. Nearly one-third (30%) were employed in the U.S. In Canada and the U.S., 36% were in industry, 29% in the government, and 35% in universities. We must keep in mind that this distribution amongst industry, government, and university applies to a very special group of people — those who attained the Ph.D. degrees. It is very interesting to look at the distribution of all graduates of science and engineering of a given year. In 1957 the Department of Labour queried 2563 science and engineering graduates of 1954 and received replies from 1706 of them. Of these, 1425 were working and most of the rest were still studying. The distribution was 76% in industry, 17% in government, and 7% in universities and educational fields.

Summary D shows at once the difference brought about by the *intent* to study.

Table V. Reporting Applicants Classified by University of Ph.D. and Field of Employment

The study shows that the more postgraduate studying done, the more likely one is to end up teaching. The better education one has, the more one will seek interest in work, and the less importance one will attach to salary.

Although 41% of the employed applicants who have not attained the Ph.D. level have won awards, only 29% of those employed in Canadian universities were scholarship winners. On the other hand, 59% of the non-Ph.D.'s employed in American industry were scholarship winners.

Of the Ph.D.'s employed in Canada, 76% were scholarship winners compared to 61% for those employed in the U.S. This lower percentage of N.R.C. scholarship winners employed in the U.S. may be explained by the number of unsuccessful applicants obtaining support afterwards from U.S. universities. As Summary F shows, 60% of the unsuccessful applicants taking a Ph.D. in the U.S. have not returned to Canada. Also, the higher percentage of N.R.C. Scholarship winners employed in Canada may indicate a slight preference for N.R.C. awardees. Perhaps N.R.C. awards mean more in Canada.

COUNTRY AND FIELD OF EMPLOYMENT BY SUBJECT OF HIGHEST DEGREE

Again from Table III, a chi-square analysis of successful and unsuccessful scholarship applicants who earned a Ph.D. degree, by country of employment and subject of degree, shows highly significant over-all divergences: 60% of the unsuccessful applicants in chemistry were employed in the United States as compared with the over-all percentage of 30%. On the other hand, only 17% of the successful applicants in the life sciences were employed in the United States.

It appears that Canada loses proportionately more Ph.D.'s in chemistry than in any other field. Industry is responsible for this loss. In fact, in each of the fields of chemistry, physics, and life sciences there were more people employed in American industry than in Canadian industry.

It has been seen that 36% of the employed Ph.D.'s were in industry, 29% in the government, and 35% in universities. However, for each subject of degree there are highly significant divergences from these overall percentages.

Summary E shows the percentage

of Ph.D.'s in each field of employment by subject of degree.

As shown in Summary E, 57% of the chemists and 53% of the engineers were in industry, while 51% of the life scientists were employed in universities. On the other hand, only 11% of the life scientists were in industry and 19% of the engineers were in universities.

In other words, if one has a Ph.D. in chemistry or in engineering and applied sciences, chances are he will work in industry. If one is a life scientist or a mathematician, more than 50% of the time he will be employed in a university. As for physicists, in comparison to the over-all percentage, slightly more people were employed in the government and universities than in industry.

COUNTRY AND FIELD OF EMPLOYMENT BY UNIVERSITY GRANTING PH.D.

Table V shows that 70% of the "employed" Ph.D.'s were located in Canada. Divergences from this over-all percentage are found when looking at the country granting the Ph.D. degree. In fact 78% of those who received their Ph.D. in Canada were located in Canada, whereas only 49% of those who studied in the U.S. have come back to Canada. Of the 46 people who received their Ph.D. degree in the U.K., 87% have returned to Canada.

There are no significant differences in the proportion of those who remained in Canada amongst the Ph.D.'s from the various Canadian universities. However, of the nine Ph.D.'s given at the University of New Brunswick only four remained in Canada, while 16 of the 17 Ph.D.'s from Laval and Montreal universities were located in Canada.

Not quite a third of the Ph.D.'s from M.I.T., Cornell, or Illinois returned to Canada. However, 13 of the 14 Ph.D.'s from Wisconsin came back.

The Ph.D.'s from Canadian universities were nearly equally divided amongst industry, government, and universities, but there are significant divergences from this over-all distribution. Considering the following four groups of universities: Western Canadian universities, McGill and Toronto, other Ontario universities, and other Quebec universities plus New Brunswick, we obtain a chi-square of 13.65 the chance probability of which is less than 0.05.

Proportionately fewer Ph.D.'s from Western Canadian universities have entered industry and more have taken government positions. The same is true, to a lesser extent, of Ph.D.'s from Ontario universities (excluding University of Toronto). Proportionately more Toronto and McGill Ph.D.'s have accepted positions in industry and fewer were employed by the government. This is to be expected, since it is well known that industries concentrate their recruiting program on the two largest Eastern universities. The distribution of Ph.D.'s from New Brunswick and Quebec universities (excluding McGill) was close to the over-all distribution.

Of those who have received the Ph.D. from American universities, 43% were employed in industry, 40% were in universities, and only 17% were in the government, largely because a higher percentage of this group was employed in the U.S., and Canadian citizens are excluded from American government posts.

Of the Ph.D.'s from the U.K., 43% were working in the government, 35% were in universities, and 22% in industry.

INFLUENCE OF N.R.C. AWARDS ON LOCATION OF PH.D.'S

Summary F shows the distribution of award winners and unsuccessful applicants by country of employment and by country in which the Ph.D. degree was taken.

Nearly three-quarters of the scholarship winners in Summary F were located in Canada. The percentage was 82% for those who took their Ph.D. in Canada, 85% for those who went to the U.K., and only 54% for those who studied in the U.S.

On the other hand, 58% of the unsuccessful applicants who earned a Ph.D. were located in Canada. The percentage was 68% for those who received their Ph.D. in Canada, and only 40% for those who went to the U.S.

It appears that N.R.C. awards have a marked influence both in retaining Ph.D.'s in the country and in their

return to Canada after study in the U.S.

MIGRATION OF APPLICANTS

Of the applicants who attained the Ph.D. degree more than half were located in other regions than those in which they obtained their Bachelor's degree.

The highest percentage of migration of Ph.D.'s from region of Bachelor's degree was at the University of New Brunswick, 100%; Dalhousie, 82%; and British Columbia, 82%. On the other hand the lowest percentages were found at universities in Quebec: Laval, 0%; Montreal, 18%; and McGill, 33%.

Nearly two thirds of those who obtained their B.Sc. degree outside Canada and who have a Ph.D. degree have gone to the U.S. as compared to 29% for graduates of Canadian universities.

Of those who have not attained the Ph.D. level, only one third have migrated from the regions in which they graduated.

SALARIES

Of the 846 reporting applicants, 175 were not in regular employment (students, self-employed, overseas workers, housewives, etc.) and 671 were employed in either Canada or in the United States. Four of those employed failed to report salary, leaving 667 people on which to base a salary study.

Computing from Table VI, the percentage of applicants earning more than $7000 per annum is shown in Summary G.

In Canada, the gap between salaries in government and those in industry is apparent; it is much larger for Ph.D.'s than for masters or bachelors. Of course, Canadian citizens are not employed in American government posts but a comparison with American salary studies[1] shows that the spread between industry and government is greater in the U.S.A. than it is in Canada.

Canadian university salaries were much below salaries in the government and industry. Nearly one quarter of the Ph.D.'s employed in universities were earning less than $5000. The situation is reversed in Russia where a professional chair in a university carries the highest remuneration in the state.

Of the 667 reporting applicants, 40 had an income in excess of $10,000 and only 10 of them were employed in Canada.

Table VII(A). Salary Quartiles of Reporting Applicants by Field of Employment

The remainder of this section deals only with salaries of Ph.D.'s and it is important to remember that, on the average, these people obtained their Ph.D. degree only 2½ years ago. Table VII gives salaries for the 417 Ph.D.'s by country and field of employment.

As shown in Table VII (*a*), the median salary of Ph.D.'s employed in Canada was $6642. The median salary in industry was about $1000 higher than that in the government, which in turn was approximately $1000 higher than in the universities.[2] In the U.S.A., the median salary of Ph.D.'s was $8333, with industry more than $3000 higher than the universities. The difference between the median salary in American and Canadian industry was about $1600, while the difference between American and Canadian universities was only $400. In American industry, 25% of the Ph.D.'s were earning more than $10,125 per annum.

1 1957. National Survey of Professional Scientific Salaries. Los Alamos Scientific Laboratory of the University of California, Los Alamos, New Mexico.

2 These findings are in close agreement with the 1957 Survey of Professional Salaries for Engineers and Scientists, a confidential report published by the Division of Administration and Awards of the National Research Council.

Table VII (*a*) also shows that for those employed in Canada there was no significant difference in salary between scholarship winners and unsuccessful applicants. Scholarship winners working in the United States had a slight advantage over the unsuccessful applicants.

Table VII (*b*) shows that the best paid Ph.D.'s were the engineers, followed by the chemists and physicists. The median salary of engineers employed in Canada was $7281 compared to $9313 in the U.S. For chemists, the figures were $6926 and $8750, for physicists $6667 and $8250, and for life scientists $6143 and $6625. The discrepancies between disciplines are accounted for to a great extent by the percentages employed in industry. As Summary E shows, more than half of the engineers and chemists were in industry, while only one quarter of the physicists were so employed.

In Canadian industry, problems of supply and demand have resulted in salaries for the engineers being some distance ahead of those for chemists and physicists. Government salaries were more nearly equalized, but the salaries of life scientists were considerably below the others. In Canadian universities, salaries were also nearly the same but this time the salaries of chemists were considerably below.

In American industry the median salary for Ph.D.'s in physics was somewhat higher than those of engineers and chemists, while the life scientists were at the bottom. In American universities, the physicists and the mathematicians were the highest paid and, as in Canadian universities, the chemists were the lowest.

The median salary of life scientists in Canadian universities ($5850) was higher than in American universities ($5750); this is the only instance of a higher median in Canada than in the U.S.

DISCUSSION

The present study was exploratory. It raises many more questions than it answers, so it may perhaps be regarded as successful in its simple aim of probing *what* happened to our scholarship applicants, whether they obtained an award or not. A much more sophisticated study would be required to find out *why* these things happened.

Even so, it is evident that salary level, while important, is not the only consideration, nor even the principal factor in the complex decisions that these people have made. Canadian government pays its Ph.D.'s at a higher rate than the universities, and Canadian industry in turn pays a good deal better than the government. Yet the Ph.D.'s in question have distributed themselves about equally over these three fields of employment. The U.S.A. pays a good deal more money to people of this class than we do, yet more than two thirds of them preferred to work in Canada, instead of the other way about.

For so valuable a natural resource as young Ph.D.'s, any avoidable loss is serious, and merits study. But the view that this is a simple matter of supply and demand, and easy to manipulate by the device of raising salaries, is not supported by the present work. Gaps of several thousands of dollars will not always, nor even usually, prevent a good man from studying what he wants to study, working where he wants to work, or living where he wants to live. This is probably a very good thing, and one should perhaps be thankful that salary inequalities of this order have not succeeded in distorting the natural pattern. If our young scientists were influenced solely by money, they would all be engineers, happily at work in the industries of the U.S.A.

We must keep in mind, however, that Ph.D.'s in this survey have just begun their careers. Presumably they have chosen their field of employment after having determined where they would find the most interest in their work. However, later on in life, when they have experienced more the problems of supporting a family and maintaining their rank in a society where a lot of importance is attached to material well-being, several may sacrifice, to some extent, their interest, which was their primary motive, for more lucrative employment. It would not be surprising to find that in 10 years from now the pattern which was established at the start will have changed considerably and that salary will have been an important factor in explaining this change. Certainly interests may not have been genuine at first or may change later on. However, Ph.D.'s have spent a good number of years studying and it is reasonable to assume that, in most cases, their interests would be genuine by the time they reach the stage of employment.

Soil and Foundation Problems of the St. Lawrence Seaway Project

F. L. Peckover, M.E.I.C. and T. G. Tustin, Jr. E.I.C.

Soil Engineering Section, The St. Lawrence Seaway Authority, Montreal.

The Engineering Journal, 1958, Sept., p. 69

Carl B. Crawford, M.E.I.C.*

In view of the extensive use of soil mechanics principles in problems of design and construction of the St. Lawrence Seaway it is gratifying to see that these experiences are to be shared with the engineering profession. The authors have done an excellent job of compressing the highlights of their experiences into such a short paper. In doing this they have undoubtedly had to be ruthless in the elimination of detail.

One important practical problem which arises frequently in winter construction work involves the placing and compaction of soil during cold weather. Perhaps the authors would expand their comments to include details of this operation. Over what total area was it possible to work and at what rate was fill placed? Was the surface frozen between shifts and if so was the frozen material removed? Were chemical additives used?

The evaluation of Standard Penetration Tests is always of much interest and details on their application to the glacial till would be valuable. One would imagine a great variation in N depending on the size and distribution of boulders. How was the value corrected for silt content?

Perhaps it is not possible to do more than generalize on the discovery of water-bearing layers in dyke foundations but field experiences would be of general interest. Similarly the construction procedures adapted for cut-off trenches would be useful. Was sheet piling used and to what effect?

Supplementing the description of settlement observations at the Seaway it may be useful to report the development by the Division of Building Research of the National Research Council of an electrical gauge for measuring the compression of pre-determined layers of the natural soil beneath an embankment without interfering with construction. Details of construction are available from the Division. A series of concrete pads, placed on the natural ground surface before filling and then subsequently sounded by driving rods through the fill, together with a set of the gauges gives a complete picture of deformations at the base of the fill and through the subsoil.

Work by D.B.R. with the Seaway Authority and in other regions has illustrated the great value of the field vane apparatus for assessing the shearing strength of Leda clay. This device should however be used with caution. It performs in the field an undrained or quick-type shear test. It is possible therefore when used in a highly stratified or varied clay that local movement of pore water may occur completely changing the assumed conditions. Furthermore the results of vane tests should not be applied to long term stability problems in heavily over-consolidated clays since the assumption of no drainage does not apply and errors will be on the unsafe side.

It is hoped that the authors will be encouraged to publish further details of their work especially in connection with their experiences on "glacial till".

* Soil Mechanics Section, Division of Building Research, National Research Council, Ottawa.

The Authors

Placement and compaction of earth fills in winter on St. Lawrence Seaway construction was only done when unavoidable, and even then such fills were not allowed to remain in critical structures. The total depth of fill for dykes placed during freezing weather in any location was not usually more than 7 or 8 feet.

Provided they were compacted satisfactorily in every respect **before** freezing, fill layers which froze were allowed to remain in place. Chemical additives were not used. These would have had to be mixed with the fill material under heated conditions, adding considerably to the cost of the operation. References to their use can be found in highway literature.

Fill placement was usually in strips about 15 feet in width and approximately 150 to 200 feet in length, depending on weather conditions and the rate of placement. A typical operation with glacial till for dyke construction involved building each strip to the desired elevation before advancing to the next strip. In this manner, the amount of freezing was reduced to a minimum. The frozen surface of each new strip was removed before placement operations were commenced. Considerable judgment and experience are required to ensure a satisfactory job.

The operation is believed feasible only for fills for construction purposes, or those which can be strengthened on the surface or left standing for some months before use. Clay fills may be placed and compacted with less difficulty than granular fills.

In the great majority of instances the use of the standard penetration test was to indicate the relative density of the soil and the consequent difficulty to be expected in excavation and handling. For example, where scrapers were successfully used for excavation, penetration values were lower than where shovels were required.

There were indeed great variations in penetration values in till, as Mr. Crawford surmises. If a sharp increase in the number of blows during the test indicated a possible boulder, the result was discarded. Where a specific application of the test results was required, individual values were never used. There were usually a sufficient number of results available to plot against depth or even apply statistical analysis, permitting a conservative estimate of the average condition of the deposit.

Penetration values were corrected to compensate for the effect on the penetration resistance of the low permeability of the till, due to its silt content. This procedure is outlined in Reference (7) in the paper.

Practically all of the Seaway dykes were founded on glacial till, except at Beauharnois where a low dyke was built on marine clay. On till, foundation soils and water conditions were most effectively and economically investigated by test pits dug with a backhoe. Deposits below the reach of a large machine were usually considered as having a little influence on dyke performance.

Water-bearing layers encountered included coarse-grained alluvium in the river bed, and lenses of pervious material found within the till and sometimes at the till-rock interface. The alluvium, up to 4 feet in depth, was stripped off foundation areas before fill was placed. Pervious lenses in the till were exceptionally met and running sand was very rare. Cutoff trenches were therefore easily excavated under the impervious zone of the dyke, sometimes in conjunction with a deeper drainage ditch on the side of the cutoff next to the cofferdam. Cutoff trenches were backfilled with compacted impervious fill.

Sheet piling was not used as a cutoff in dyke construction. At Beauharnois, a small experimental installation of sheet piling was made through a thin layer of pervious till overlying bedrock, but it was not effective in reducing seepage due to the presence of boulders. A sheet pile wall was driven to rock along the existing power canal dyke, not to eliminate seepage but to offer resistance to piping which might develop through the foundation.

The authors are interested to hear of the development of special equipment by the Division of Building Research to observe the settlement of fills. Along with equipment already used to record the settlement of structures, this should add significantly to existing data on the settlement problem. At the same time, it is worth noting that simple field levelling on fills and structures throughout the course of a construction project can yield data which is most useful in dealing with numerous problems which cannot always be foreseen.

The points made by Mr. Crawford on the limitations of vane testing in assessing the strength of clays are well taken. The general remarks in the paper on this test are intended to apply only to the conditions in which used.

The comments of Mr. Crawford, who is engaged in the investigation of many Canadian construction problems involving soils and foundations, are appreciated, as is the opportunity to give more details on the points of interest which he raises.

POWER REQUIREMENTS FOR COMMERCIAL AIR CONDITIONING SYSTEMS

(Continued from page 57)

duced to the basis of 1,000 sq. ft. of both net and gross floor area. By neglecting (F) entirely and taking the total of (C) instead of the two separate buildings (A) and (B), the facilities provided in them become more or less comparable. The average of these six is shown to be 5.5 horsepower per 1,000 sq. ft. net area, and of the five for which gross areas are available, the average horsepower per 1,000 sq. ft. gross is 3.83. These figures appear to agree fairly closely with those quoted from United States sources which range between 3½ and 4 watts per square foot. Unfortunately, whether or not the unit area quoted is net or gross has not been indicated. The figures given above are fair to be used only in the vicinity of Toronto and Montreal areas. When it is considered that the variable portion of the load as established earlier is about 50% of the total, it will be conceded that geographical location and thence climate have considerable bearing on the horsepower required.

The operation of the air and water handling or distribution equipment is continuous throughout the year during the time of day when the building is occupied and the electrical load is uniform. No diversity factor may be applied to this load. However, the ratio of brake to name-plate horsepower runs about 90%.

The condenser water pumps and cooling tower fans also operate continuously, but considerable fluctuation in load will occur at the refrigeration compressor, even from hour to hour.

Figures 4 and 5 indicate how the dry-bulb temperatures may vary during the day and also how the current input to a compressor changes. The charts cover two typical weeks in July 1954. The wet bulb temperature has a much greater effect on the loading of the compressor than the dry bulb temperature. This may be seen particularly on the 21st and 25th. On the 21st at 2.00 p.m. outdoor conditions were 79° DB, 72° WB, whereas at 3.00 p.m. they were 76° DB, 76° WB, the current input increasing from 1245 to 1440 amp. On the 25th a sharp rise in the wet bulb temperature from 11.00 a.m. to 1.00 p.m. brought about a corresponding sharp increase in current. These typical charts seem to indicate that it is not possible to say at what time of the day a peak electrical load will be attained.

To summarize, a number of factors contribute to the establishment of the electrical requirements created by air conditioning. Of the total, about 50% is due to the internal load generated by lights, business machines and occupants, the remainder arising from solar and transmission gain and ventilation of air. The total load is of the order of 3.5 tons of refrigeration effect per 1,000 sq. ft. of net area at design conditions.

At such a load the total installed motor horsepower must be of the order of 5.5 per 1,000 sq. ft. of net area or 3.85 per 1,000 sq. ft. of gross area.

Only by comparison may figures be made to seem impressive. When it is considered that, prior to the advent of the fully air conditioned building, these same buildings would have been heated and ventilated, at least to the extent of toilet exhaust ventilation, at the expense of certainly not more than 0.5 h.p. per 1,000 sq. ft. of net area, it may be appreciated that air conditioning is having a very great effect on the electrical generation and distribution systems throughout the country.

INSTRUMENTATION IN INDUSTRY

FOODS AND BEVERAGES

CANADA'S FOODS and Beverages industry is the Nation's largest manufacturing industry. Selling value of its products at over $3.8 billion in 1956 represented 17.7 per cent of the value of all Canadian manufactures, while value added by manufacture amounted to 13.7 per cent of all manufacturing production. In 1956 this industry employed 183,000 persons; cost of materials used totalled $2.47 billion, and value added by manufacture amounted to $1.31 billion.

The leading industries of the foods and beverage group, in order of value of annual shipments, expressed in millions of dollars, was as follows in 1956; slaughtering and meat packing, 844.89; dairy products, 551.8; miscellaneous foods, 334.67; bread and bakery products, 306.8; the feeds industry, 250.95; fruit and vegetable preparations, 249.9; flour mills, 221.77; the brewing industry 215.9; fish processing, 169.93; and the distilling industry, 144.4.

Ten-year Increases in Foods Production per Employe

An analysis of statistics for the entire Canadian food industry shows that value added by manufacture per employe in constant dollars had increased in the case of some foods during the decade prior to 1957, despite wage increases which had almost doubled over the same period. This reflects more efficiency in production through mechanization and improved methods. The proportion of this increase in the value produced per employe which can be attributed to instrumentation and automation can only be surmised.

An analysis for each industry within the group shows gains during the ten years for slaughtering and meat packing; miscellaneous foods (mostly tea, coffee); fruit and vegetables preparations; and animal feeds. For the dairy, bakery, flour and cereals, confectionery and carbonated beverage industries there was little change in value added per employe in constant dollars, while for distilling, biscuits, sugar, and fish processing the value actually decreased.

Per Capita Food Expenditures

Retail food prices have been growing steadily over the past 10 years. However, all branches of the food industry have succeeded in minimizing higher costs through greater productivity. In 1955 the proportion of income spent on food ranged between 37.3 per cent for the lower income group and 18.7 per cent for the higher income group.

Food expenditures in 1947 in constant dollars accounted to 28.7 per cent of consumer spending on goods and services. In 1957, with rising incomes the percentage had declined to 25.7 per cent. Yet per capita food expenditures in constant dollars showed a steady increase. Since per capita food intake has not varied much in the past decade, the higher expenditure obviously is due largely to special facilities and services provided by processors and packers.

Computers in the Food Industry

In outlining instrumentation developments and uses in the first two articles of this series covering the chemical manufacturing and the pulp and paper industries, electronic computers were mentioned. Reason for this is that these industries deal mainly with bulk commodities, with a few large consumers and an established pattern of transportation and distribution which varies little from month to month and year to year.

In steel making, metal fabricating, oil, motor-vehicles and in the Food industry, however, there are a number of market areas to be serviced, many warehouses in which materials may be stored and a number of factories in which products may be processed. Here, the costs of transportation, storage, labor and raw materials in each of the different centres may vary. The market conditions in each centre may vary according to certain patterns which can partly be predicted. The problem to be solved is how to schedule production and transportation to obtain a maximum return on the investment. This is an 'operations research' problem.

Computations and calculations required to correlate and vast number of permutations and combinations possible to achieve maximum efficiency soon exceed the ability of the human brain equipped with a desk calculator. Thus the computer takes over. New concepts in management and in operations procedures have been developed. Expressions such as 'linear programing' and 'dynamic programing' are conceived and are developed to maturity by the computer.

There are three new keys to progress that food company management must try to turn. One is automatic warehousing, not only to solve labor and space, but also to improve customer service. Another is automatic data processing with electronic equipment to achieve fast, close control of sales and inventories. The third is the electronic computer that solves impossible problems. Properly manipulated it can take a complex set of facts and come up with simple answers to costly problems in processing, marketing and shipping.

"Electric brain" time can now be rented from major 'brain' manufacturers, at a cost of a few hundred dollars per problem. In some of Canada's largest cities there are large electronic computers installed by industries for their own work, such as Canadian Pacific Railway in Montreal. These computers can be hired on a time rental basis for solving other companies' problems.

Beyond the more common problems for computers, such as payrolls, paychecks, tracing freight cars, actuarial problems for insurance purpose, etc. there are two somewhat different problems involved in linear programming—one is the transportation problem, while the other is the general problem. The first of these revolves around distribution route scheduling, materials handling, sales area functions, crew scheduling, plant location factors, raw materials procurement, and the like.

The other problem is more 'general' than the transportation problem. Problems of this type involve all phases of product line, sales promotion, machine selection, building allocation, raw materials purchasing, process selection and labor use.

Electronic computers are now pinpointing best plant locations, precalculating process and control performance, handling accounting problems, forecasting sales and establishing optimum distribution operations.

What California Packing did with the Computer

Up to the minute facts on sales movement and inventories are essential parts of strategy decisions to counter unforeseen developments before they become cold statistics. California Packing, for example, a pioneer in the use of electronic business controls has achieved unusual results in this direction. Equipped with a pertinent sales analysis carried out by an electronic computer, management is able to have an overall concept of what is happening; to exercise closer control over inventories; to get a quick picture of where sales are headed; and to clear the desks of time-consuming paper work.

Besides these reports on sales and stock that executives receive each Monday morning, the computer is used to produce an inventory and sales report for each variety, size and package. It produces complete weekly rundowns on activities of each Calpak broker; and a similar weekly rundown for each buyer served by each broker. Clearly, the computer's major contributions to sales analysis are in terms of scope and capacity. Considering the amount of data that can be digested and assembled into useful information, no operating report or statistic need be considered so complex that it is impracticable to compile it.

Automatic Control in Food Plants*

A prime factor in boosting food plant productivity in America has been the dramatic switch in the past few years from manual supervision to automatic control. Electro magnetic monitors will operate through relays to activate electric, pneumatic or hydraulic servo-mechanisms to perform man-saving operations such as freezer loading, and recently developed static controls accomplish many functions formerly requiring high-speed relays with many multiple contacts.

X-ray level detectors assure proper container fill, while photo-cells are extensively used as "no-container-no-fill" devices, to monitor flow on conveyors. Through in-stream analysis, process instrumentation is rapidly achieving direct quality control of products right on the production line, where it operates most efficiently and economically. Control of process variables such as temperature, pH, pressure and flow is now virtually standard practice in efficiently operated food plants.

*Reproduced in part from an article in FOOD ENGINEERING, August, 1958.

Continuous automatic control of product quality factors is being achieved by triple-acting instrument systems that detect deviations from pre-set quality standards; apply instantaneous corrections and record results.

Density

Density of citrus concentrate is controlled by in-line refractory systems. Combining optical and electronic operation, they analyze the process steam 480 times per second in controlling and recording the blending of evaporation output and the required cutback juice.

Gamma-ray Transmission

Gamma-ray transmission is being used to control density of liquids, slurries, granules and powders. Another radiation device for use with small diameter pipes employs a source and detecting cell. Output signals can actuate valves, pumps or waters in a closed loop control system.

Viscosity

Consistency of apple-sauce is continuously controlled by a unit employing a hydraulically balanced flow bridge. This system is also applicable to baby-foods, tomato products and corn in cream style.

Better viscosity is being monitored in-stream by a spinning-bob viscosimeter that regulates addition of the dry and liquid ingredients to a blender.

Moisture

Moisture in free-flowing solids is controlled by an instrument operating on the capacitance-bridge principle. Another electronically controlled conveyor line unit measures and records moisture in cereals and baked goods, unaffected by variations in frequency or voltage. Nuclear-magnetic resonance of hydrogen atoms in water offers promise as an in-stream-control property.

Other Controls

Hydrogen's absorption of radio-frequency energy under controlled conditions give a 30-second moisture analysis. Infra-red spectrography is also a powerful tool for rapid identification and measurement of organic matter. Direct control of product quality is offered by a new unit that performs actual chemical analysis on the production line for sugars, protein, vitamins, salts and metals. X-rays are being used to regulate thickness of extruded materials such as dough. Rays do not contaminate the product or alter food values.

Particle size control is a unique application of a new in-stream instrument that charts size-frequency data for monitoring the operation of the size-reduction equipment. Instrument operation is based on difference in conductivity between particles and a fluid suspension medium.

Various Applications of Instrumentation

In an Ice Cream Plant: In a large U.S. ice cream plant an automatic bundler accumulates two half-gallon packages as they are conveyed from filler-wraps, and seals them in kraft paper. Then a coder imprints flavors on three sides. Sealed packages are conveyed to a freezing tunnel.

Actuated by electric motors and hydraulic devices, a new automatic pallet unloader automatically discharges cases to a conveyor at 25/30 per minute. It employs panel-mounted controls to regulate operating sequence:

Full pallets deposited at the loading station by lift truck are advanced to a dispersing table where a clamp holds all but the bottom tier. Bottom cases can move to discharge conveyor in simple file until all cases are unloaded. Empty pallets are automatically slacked.

A versatile liquid meter equipped with a 'memory' offers flexibility in quality control with less operator attention. Called a repeating autostop, it delivers the same quantity each time the valve is opened and shuts off automatically when a preset quantity is reached. Applications include batching of water, syrups and oils as well as production line filling of barrels or drums.

In a Sugar Plant: A large American sugar company is realizing great efficiency and economy by installing instrumentation costing more than $1 million. It has switched from its former batch operations which required considerable manual handling to a smooth fully mechanized continuous production flow. Multipurpose automatic timers cycle operations to level out production, open and close prime elements, control key factors and carry out additional centrifugal operations.

For melting, from a control panel sugars centrifuged from the mingler and vacuum pan are melted for subsequent refining into liquid sugars. There is control at this stage of flow rates and syrup density. The new robot timing changeover has brought greater uniformity in the proportioning of materials for more uniform quality at a labor savings.

In a Bakery: In a large new bakery a dual electrical system guards against plant shutdowns. A large console automatically draws materials from storage tanks, weighs and delivers them according to predetermined formulas.

Irradiation of Packaged Food: U.S. Army's new food radiations centre in California has a 24 million electron-volt liner accelerator which penetrates 6 inches of packaged food with ionizing radiation. The machine is the highest average-power accelerator ever built. Armed forces will need ready sources of imperishable perishables in the event of a fast moving atomic war.

TV Aids Flow Control: Industrial TV has been successful beyond expectations at a Hawaiian sugar plantation. Here the camera views flow and spread of sugar cane being conveyed from the washing plant to the mill. The picture is transmitted to the monitor where an operator regulated the volume of flow. The TV eliminated the need for a watcher.

Grocery store orders can be read photo-electrically, then converted to audible signals that go by phone to a central warehouse to be tape-recorded, decoded and fed into data-handling units. The system was 'nvented by IT & T.

Replies to Food Questionnaire

Replies received from various food industries to a questionnaire relative to instrumentation in their plants, were received from almost every type of food manufacturer.

With few exceptions these plants purchase their electrical power supply. The majority check consumption of power with their own instruments, yet one of Canada's largest meat packing industries with plants all across Canada relies entirely on the utility metering records.

Generally, separate steam plants for heating and power are not maintained. One flour and cereal manufacturer and a confectionery manufacturer who develop most of their own hydraulic power have separate steam plants. Another large meat packing company which purchases its power indicated that it produces steam separately in some of its several plants, while a supermarket chain which uses limited supplies of power makes its steam separately.

Main Purpose and Uses of Instruments

Instruments most commonly used are self-correcting feedback servomechanisms of the mechanical, electronic or electro-mechanical type, or those for continuously recording changes in physical or chemical phenomena (such as a recording pyrometer), or to display a physical or chemical phenomenon (such as a pressure indicator or pH meter).

The main purposes for which instrumentation is used is for achieving better quality, to provide continuous records of operations, to economize in fuel consumption, to regulate pressure or flow, to reduce labor and to provide central supervision for diverse operations, in that order of importance. They are used to count or measure, to provide supervisory warning, to determine rates of flow, to provide records for analysis, and less frequently to measure thickness, composition, to inspect material for flaws, and to measure other physical properties.

Types of instruments most commonly used are recorders for temperature, pressure, humidity, flow, superheating, density and level, and for controlling temperature, pressure, flow, density, consistency, levels, humidity, volume of liquid ingredients and electronic metal detection. They are used for toasting ovens, cookers, dryers, steam tempering, for air conditioning and refrigeration.

Comments from a Modern Processor of Canned Goods

The reply from one of Canada's largest manufacturers of processed food, — soups, canned vegetables, relish, pickles, etc. states "temperature control is used on continuous product heating processes, where a high degree of accuracy is required. Controllers are equipped with all or some of the following control elements: automatic reset, adjustable sensitivity, differential control. The heat-sensitive element (thermo-bulb) is in the heat exchanger effluent product pipe, and the controller operates the steam valve. Retorts are operated by similar controllers and differential control is not needed. The thermo-bulb is installed in the steam jacket of the retort. Pneumatic controllers are used for temperature control only."

"Besides a variety of pressure-reducing valves on steam and water lines, pressure controllers are used on long product lines as a safety device between two positive displacement pumps. The pressure-sensitive element is a stainless steel diaphragm in the product line. The pneumatic controller operates a valve to the run-off tanks. Differential pressure type flow meters cannot be used in food processing, since calibration is too complicated, and sometimes not possible without interrupting production, moreover these flow meters often do not meet sanitary standards."

"Tests with magnetic-type flow meters, with an electronic recorder-integrator, are of very recent date but look promising. They do not need calibration but do need very careful and complicated zero-adjustment. Positive displacement-type flow-meters have also been used recently. If the problem of wear can be solved, this type may be another step forward to solving the problem of flow control and metering in the food industry."

"Density control is effected by converting the weight of a constant volume of product into an air signal, which operates a mixing valve. Tests with radioactive penetration have been anticipated but not yet tried. Though no general way of measuring consistency is accepted, relative values are obtained by 'flow-bridge' instruments. However, tests must be made from case to case if this method is applicable. For level-control, besides the well-known float and electro-probe level controllers, radioactive sources and radiation indicators (geiger counters) are successfully used for level indication of high accuracy in storage vessels, where all other methods of level detection have failed completely".

Comments from Coffee and Cereal Producers

A prominent Canadian tea and coffee producer states that for coffee roasting, electronic controllers are used which complete the coffee roasting cycle automatically. These are basically potentiometer temperature recorders, with built-in control switches. Thermistor probe controllers are used on coffee pouch-making machines to ensure accurate heat control.

A flour, feed and cereals manufacturer has electronic recording temperature controllers on his toasting ovens, air operated controllers on his cookers, puffing guns, dryers and for wheat tempering. Thermo-hydraulic control is used on holding tanks for animal fats, molasses, shortening and hot water. For bin level indicators, proportioning, speed control, moisture meters etc. electronic controls and relays and 'electric-eyes' are used.

Purchasing of Instruments

Practically all replies indicated instrument requirements were determined by the company's own staff. In the case of a few producers operating a number of smaller, widely separated plants, assistance and advice is sought from consultants or instrument makers. For specifying and recommending instrument purchases the general rule is to rely on the Company's engineering department or plant maintenance department, — specifically the maintenance engineer or plant engineer. Purchases are finalized by the central purchasing department or plant, in most cases, though in some cases the engineering department, maintenance department, or both, make the decision.

Instrument Maintenance & Repairs

Few food firms report they have established a preventive maintenance program for instruments. Of those which have such a program, some are firms with a large capital investment and several large plants, while other firms are relatively small. The same is true of those who replied they had no such program. On balance the trend, if there is any, appears to be for larger firms to do preventive maintenance, while in smaller plants there is less occasion for it.

Answers to a question as to what system was used for handling spare parts or replacement units for instruments, indicated no predominent trend. Repair parts are stocked in most instances regardless of the size of the firm. The practice of stocking complete replacements was reported by several large firms conveniently located as to source of supply, while other firms with plants at remote locations do not carry replacements. Only one of the food firms circularized had found that instruments incorporating 'plug-in' features were particularly suitable for use in their plants. Most replies indicated a preference for instruments built on standard commercial lines or modified versions thereof, rather than for having them built to the purchaser's own individual specifications. All firms replying stated they purchased their instruments outright.

Investment in Instruments as Per Cent of Total Investment

As might be expected, there was a wide spread in the capital cost of instruments reported, as between the small firm or plant and the very large industry operating plants in many provinces. Answers ranged all the way from $10,000 for one medium-sized plant making chocolate and cocoa products, to $500,000 in the case of a large meat packing industry with several plants across Canada, or 2% of total fixed assets. A prominent chain of supermarkets has well over $100,000 invested in instruments, or between ¼ and ½ of 1% of total fixed assets.

Nor would it be easy or even possible to strike an average from the replies as to the cost of instruments in terms of the percentage of total capital costs of all plant and equipment. This is understandable because of the wide variation in instrument requirements for various foods and different processes and the extent to which firms have seen fit to adopt automation.

Another of the largest meat-packing firms with several plants, and with overall capital investment in plant and equipment of some $17 million, estimates the value of its instruments at around $100,000, — or three quarters of one per cent. A confectionery firm with one plant states its investment in instruments amounts to 'not more than one per cent of total capital investment'.

Some well-organized food processors treat their instruments as an integral part of each individual project. For example, instead of trucking a product from one building to another, it may be planned to pump the product. The necessary lines, pumps, tanks with pressure level and flow controllers or indicators are designed and estimated. Then total expenditures vs. the expected savings are evaluated. No records are kept on expenditures for instruments separately.

Maintenance and Repair Costs

The annual cost of instrument maintenance also varies widely, depending upon the extent of automation, on the setup of the maintenance crew, and, of course, the size of the plant. The lowest annual maintenance cost reported in terms of investment was that of a flour and cereals processor, whose annual maintenance was half of one per cent of the investment in instruments. A tea and coffee processor estimated his at three-quarters of one per cent. A supermarket chain estimated it at three per cent of instrument value, while a producer of canned specialties with some $50,000 or more invested in instruments thought his maintenance cost was five per cent of his investment in instruments.

Savings Realized through Instrumentation

A chocolate manufacturer states: "most of our instrumentation is of a fairly simple nature. Processes are largely batch type. Instruments primarily reduce supervision and ensure quality of product." A large canner with the most modern equipment, commenting on the time, money and material savings effected by instrumentation, had this to say . . . "Most of our processes would not produce acceptable products if controlled manually. Where manual control is possible and would produce equal results an economic study is made a part of the individual project, and no instrument or equipment will be purchased if a reasonable return on capital investment cannot be shown."

Another, a cereal food firm, points out quality control is very important and difficult to tag with a dollar sign. Without automatic process control industry could not remain alive in the present day competitive market. A firm which produces coffee, cocoa, cereals, gelatine desserts, and pectin from three large plants estimates that in its largest plant savings due to good instrumentation run as high as $200,000 yearly. A flour milling company states it reduces manufacturing costs by 10 per cent by instrumentation, compared with manual operation. A coffee and tea firm points out that one man can operate six coffee roasting machines with automatic controls, while with manual operation three men are needed for the same work.

Time Needed to Write-off Instruments

The general concensus of opinion expressed by firms answering this question seems to be "three years". A dessert, cereal and pet food manufacturer estimated 'three to four years'; a maker of canned specialties answered 'three to five years', while a fish processing, canning and freezing concern with six plants and a capital investment totalling $5 million

INTERNATIONAL NEWS

GERMANY

NEW OIL PORT. New oil tanker facilities built at Wilhelmshaven in only ten months consist of a 770-yard long jetty from shore out to sea, a 513-yard landing pier that can handle three tankers, and a 230-yard walkway from the end of the pier. Initially 60,000 dwt. tankers will have access through the 50-ft. approach channel, but dredging will later allow the passage of ships of 100,000 dwt. In a second stage, a duplicate pier will be built to increase unloading facilities to six tankers, and annual arrivals from 300 to over 700 vessels. A new 245-mile pipeline, the first major project of its kind in West Germany, will supply refineries, initially at 9 million tons a year, later up to 22 million tons a year. The port was built under considerable difficulties due to severe offshore conditions of wind and tide. A special platform with hydraulically-operated legs, built in Germany in co-operation with the U.S. patent holder, De Yong, of New York, was used for pile driving. The pile driver was so mounted that piles could be driven at any batter towards the platform. Steel piles for the jetty were up to 109 ft. long; bollard piles up to 139 ft. (*Deutsche Korrespondenz*, Bonn.)

SOLAR ENERGY. From studies by the Federal German Meteorological Service it is concluded that industrial use of solar energy is not practical with present techniques for Germany and countries in similar latitudes. However, diffuse sky radiation was found to be somewhat greater than direct solar radiation in these countries. Because of the lower angle of incidence, the effect of diffuse radiation is actually greater in winter than summer. It is recommended that planning for buildings and agriculture should consider site orientation to take advantage of sky-reflected as well as direct solar radiation.

CHEAP HEAT STORAGE. Originally patented in Germany 25 years ago, small heat storage stoves are now being produced in quantity to take advantage of cheap (half day-rate) electrical power during night off-peak hours. Austria, with 125,000 kw. in 1957, exceeded German stove installations (39,000 kw.), and Switzerland is another large user. The table-height stoves, about three feet long, have a magnesite or similar core containing heating elements and surrounded by a thermal insulator. Heated overnight to 300° - 700°C., the cores can supply heat at variable rates throughout the following day or rapidly for shorter periods (e.g., in churches) according to design and the rate of air circulation used. It is estimated that 1-kw. of installed power will heat a room of 300 to 450 cu. ft., depending on general thermal insulation. It is foreseen the sale of off-peak power will become more of a problem when nuclear power-plants are widely introduced. (*Deutsche Korrespondenz*, Bonn.)

EL SALVADOR

HIGHWAY DEVELOPMENT. The World Bank (International Bank for Reconstruction and Development) recently made a loan of $5 million to El Salvador towards a program to provide an all-weather road network through the Pacific coastal plain. This will help construct 21 feeder roads and additional work on the main Coastal Highway, opening up a large potentially rich area and improving communications in the south of the country. Design standards of 18 feeder roads are according to expected traffic; three will be secondary roads to connect with the Inter-American Highway.

UNITED NATIONS

ATOMIC ENERGY. The International Atomic Energy Agency (IAEA) has announced five meetings on peaceful uses of atomic energy during 1959. The first, 25-27 Feb. in Vienna, discussed techniques for determining the distribution of radioisotopes in the human body. In July, a seminar at Saclay, France, will review methods of training specialists in atomic energy techniques. A six-day conference in Warsaw on the application of large radiation sources in industry, especially chemical processes, is scheduled for September. In October, in Vienna, a symposium on radioactive metrology will aim to establish internationally accepted methods of standardization of radioisotopes. Finally, in November, a conference at Monaco will discuss radioactive waste disposal, supplementing the work of an IAEA panel set up in October 1958 to study disposal in the sea. Other international organizations are expected to collaborate (e.g., FAO, UNESCO).

UNITED KINGDOM

TRANSISTORS. The Institution of Electrical Engineers is to hold an international convention on transistors and associated semiconductor devices at Earls Court, London, 21-27 May, 1959, together with a scientific exhibition.

BURIED TRANSFORMER. A new type of buried distribution transformer has been successfully tested. Main advantage of the unit is that it can be installed easily at a load centre without the problem of finding new sites for transformers to reinforce existing supply networks. The unit is contained in a strong tank which can be buried in the ground with only a small ventilating pillar showing above the surface. The air-cooled, 500 kva., 11,000/433 v., three-phase unit uses Class C materials and is fully instrumented. As operating experience is gained, the rating may be increased to around 1500 kva.

GIANT VACUUM CLEANER. Designed by the originators of the vacuum cleaner, a mobile 'cleaner' weighing over 12 tons and more than 22 ft. long has been developed to remove flue dust and grit from large boilers and furnaces. Up to five tons of dust an hour can be extracted from a distance of about 100 ft. and moved by conveyor to disposal vessels. Used on underground flues in a steel plant, savings of 69% in man-hours have been obtained.

MAGNESIA FROM SEA WATER. First developed in 1937, a plant is now producing 150,000 tons of refractory magnesia a year from sea water, at a market price only 70% of that for imported material. Storage tanks totalling 8,000,000 gal. capacity are fed by centrifugal pumps through five pipelines. Calcium bicarbonate is removed before precipitation of the magnesia.

CONTINUOUS CASTING. Twin-strand steel billets and small slabs can be cast at least twice as fast, it is claimed, as by any other known plant on a modified continuous casting machine at Barrow-in-Furness. Two-inch square billets are cast at speeds of 220 to 360 inches a minute. Water sprays solidify the billet before it reaches the withdrawal rolls. Lengths up to 150 ft. have been obtained, though normal practice produces billets up to 30 ft. long.

SOME ASPECTS OF ICE PROBLEMS

(continued from page 54)

deg. as measured during the winters of 1956-57 and 1957-58 respectively. Excavation of the narrows therefore was carried out only to the extent required to reduce head loss and prevent erosion as no ice problem was anticipated and consequently there was no necessity to provide velocities to form and consolidate an ice cover, which meant considerable saving. Actually, whatever the velocity, no ice cover can form as long as a little turbulence is maintained. Should the flow nevertheless be completely stopped, then a cover would form to be melted as soon as operation of the plant is resumed.

The temperature of water at the foot of the gorge, under natural conditions, was sometimes very close to the freezing point, and from there downstream a solid ice sheet formed to the mouth of the river except at the rapid sections. To-day the water in the Bersimis No. 1 tailrace is at a temperature of 2.8 deg. C. when the reservoir is full. This temperature should never drop lower than 2.5 deg. C. above the freezing point at low reservoir level under normal operating conditions. Thence, the water flows to Bersimis No. 2 presently under development where it arrives at a temperature of 0.6 deg. C. after a turbulent 23-mile journey under obviously open water conditions.

Upon completion of Bersimis No. 2 the forebay will become a deeply embanked body of water flowing gently under an ice cover preserving its heat content. Under these new conditions water should reach the No. 2 plant at a temperature somewhat lower than that found at the outlet of No. 1 plant on account of the cold tributary waters between the two developments. In brief, ice will never interfere with the operation of the two plants due to the high temperature of water in winter.

Another example of an intake canal using "warm" water and flowing open the year round as at Bersimis No. 1, is the Shipshaw canal diverting the Saguenay river waters to the Shipshaw plant No. 2. It is 1½ miles long and the flow ranges from 36,000 to 46,000 c.f.s. under an average velocity of 4 to 5 feet per second. The temperature of its water, as observed during the coldest part of the winter of 1954-55, was 0.15 deg. C. above the freezing point at the entrance of the canal. Therefore, no ice problem is to be expected at the Shipshaw plant providing ice from the gently flowing head-pond upstream is prevented from entering the canal.

CONCLUSION

To sum up, rivers whose waters are cooled down to the freezing point are most favourable to the formation of ice of all kinds, and the best means of preventing ice from interfering with plant operation, especially if an important stream is concerned, is by providing a forebay with sufficient cross-sectional area to meet conditions other than the ideal. As regards streams whose waters are never cooled down to the freezing point, their ice problems are usually very easily solved. In resumé, the solution of the ice problem on one stream cannot be applied to any other stream indiscriminately.

PHOTOGRAMMETRY *(continued from page 70)*

at different stages of the construction are also of great assistance in observing erosion and drainage problems and indications of possible land slide, in addition, they will aid in anticipating future maintenance problems.

CONCLUSION

The development during the last few years in the field of photogrammetric engineering has undoubtedly influenced the thinking and the methods of the location engineer. Photogrammetry provides the engineer with data essential to location and design that, not so long ago, had to be collected laboriously on the ground. Information concerning rock and soil types, borrow materials, drainage and land use are obtained quickly from aerial photographs. Furthermore, accurate reconnaissance and detailed topographic plans together with cross sections, profiles, and earth work quantities are compiled photogrammetrically to an accuracy comparable to that of ground survey methods but considerably quicker and less expensive. The benefit of employing an integrated ground and photogrammetric survey together with electronic computations for the determination of pay quantities and slope staking data is not as much in dollars saved but in the convenience of having available a powerful tool which can conveniently take care of the fluctuating volume of surveys and which will provide insurance against costly delays of construction contractor's progress.

We agree with George J. Smith, of McElhanney, McRae, Smith and Nash, consulting engineers and surveyors, Vancouver, who urged the integration of large scale photogrammetry and ground survey in a recent speech. Addressing the Canadian Institute of Surveying in Ottawa, he said:

"It is believed we are facing major developments and improvements in survey instruments and techniques. These changes will be brought about by the rapidly rising costs of surveys using present techniques on the one hand, and on the other hand, by the probable savings made by the use of modern electronic and photogrammetric equipment. Present instruments are expensive, but it can be expected that continual development will lower their cost and raise their precision and degree of utility.

"One wonders what functions these new instruments will perform ten years from now . . . But one thing is certain: if they succeed in lowering the cost of surveying, their effect will be felt from now onward. And this can only be accomplished by the use of sound principles in the relationship of large scale photogrammetry and ground survey and their intelligent integration."

The advantage in using photogrammetric techniques in location work is not simply to substitute for ground methods but to afford economy, speed schedules, improve accuracy, and probably of overriding importance, to supply detail over a broad enough area that the engineer can sample all alternatives to produce the best possible design.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

National Aeronautical Establishment

By summer, 1960, the National Aeronautical Establishment of Canada will consist of:—

1. A flight research section and supersonic wind tunnel laboratory at Uplands airport, and
2. A structures section, subsonic wind tunnel, and hypersonics laboratory in the Montreal Road laboratories of NRC.

On January 1, 1959 the National Aeronautical Establishment became a Division of the laboratories of the National Research Council of Canada. In principle, the Establishment came into existence in 1951, charged with the responsibility for integration of government aeronautical research.

Then, nearly all of Canada's aeronautical research and testing facilities were located in the Ottawa laboratories of NRC and were administered by the Division of Mechanical Engineering. The aeronautical laboratories have since grown too large in scope and scale of operations; hence the decision to separate the aeronautical function as a new Division.

There was a parallel and related decision to proceed with the construction of the multi-million dollar supersonic wind tunnel at the NAE site near Uplands airport. Completion of this is scheduled for the summer of 1960.

While it is an intrinsic NRC division, responsible to the president of the Council, NAE has these aids:

The National Aeronautical Research Committee, which guides NAE in broad policy; made up of senior officials of the Defence Research Board, the RCAF, the Department of Transport, the Department of Defence Production, and the National Research Council;

A Technical Advisory Panel, at the technical level of operations; consisting of the director of NAE and representatives of the same agencies;

Associate Committees (being established) whereby industrial representatives can make their views and requirements in research and development known directly to NAE research engineers.

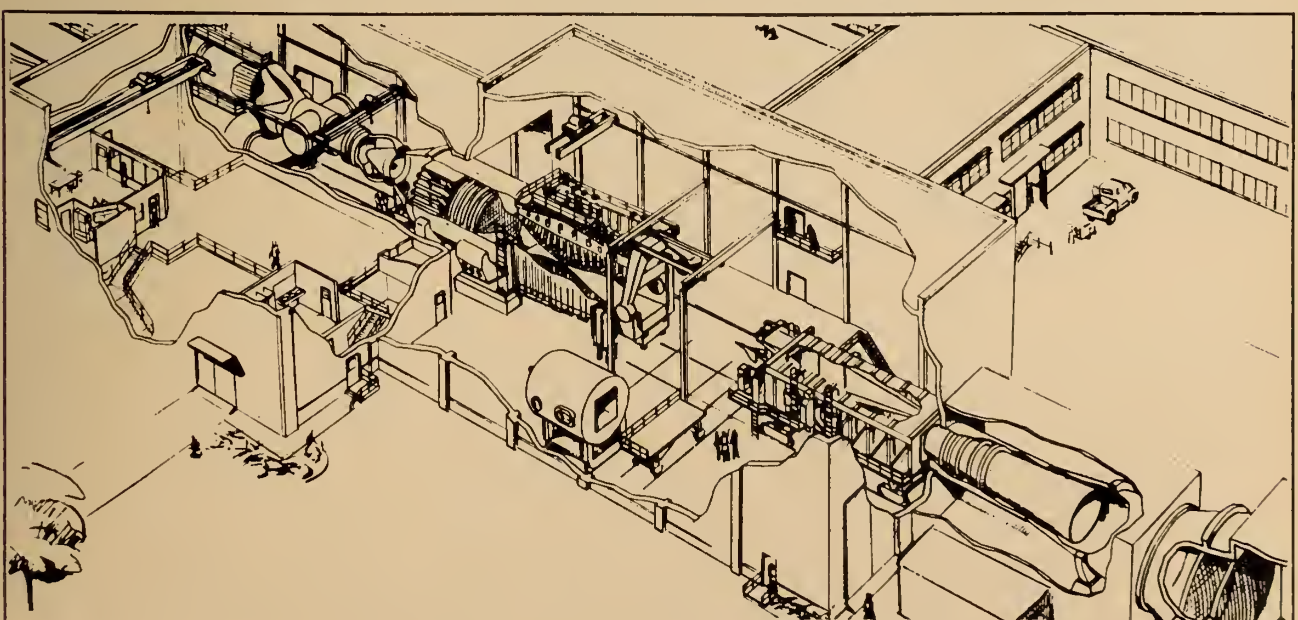
Frank R. Thurston, who was appointed acting director of NAE, is the former head of the structures laboratory of the Division of Mechanical engineering.

He has reported as follows on the research program:

The program of work of the NAE, has been affected by the various defence policy decisions that are pending with respect to air defence. Some of the program has been reoriented towards the more pressing problems of civil aviation. To this end, NAE has organized close technical liaison with the Department of Transport and is working on a variety of problems including vertical takeoff and landing, acoustic noise, runway roughness, air traffic control, airport lighting and a crash position indicator.

The new wind tunnel will greatly increase capacity for aerodynamic research. It will be used for work in a speed range up to a Mach number of about 4.5, and, at a later date by modifications and additions, to

Sketch of new high speed wind tunnel at the National Aeronautical Establishment.



Courtesy of Technical Art Associates, Toronto.

about Mach 15 and temperatures up to about 3000°K. The tunnel is a very advanced piece of equipment and compares favourably with tunnels of similar purpose anywhere in the world. Messrs. Dilworth Ewbank of Toronto have been retained as consulting engineers on design of the tunnel.

The flight research section of NAE has developed specialized equipment for the investigation of slipstream deflection and high lift devices applicable to aircraft design for short take-off and landing or vertical take-off and landing, and is flying contemporary Canadian-built aircraft in programs of research on dynamic stability and on engine reheat.

The structures laboratory has a program of research which includes structural dynamics and dynamic plasticity, structural fatigue with special reference to fatigue crack propagation and fail-safe design, problems of kinetic heating and, as an avenue of research quite new to the laboratory, the study and development of high-temperature-resistant non-metallic structural materials.

The change of the government's aeronautical laboratories to that of an integral, independent Division of the National Research Council, the acting director reports, comes at a time when there is much soul-searching regarding the future of Canada's aviation interests. The facts of the matter are, he says, that Canada will not cease to be an aviation-minded nation. The facts of our geography and distribution of our population preclude it, and the aeronautical sciences have not dried up or run out of potential advancement; they have simply been temporarily eclipsed by the need for a defence-motivated leap frog into astronautics.

"The result of this complexity in the aero-astro-nautical developments of the times is a challenge to level-headed planning", Mr. Thurston says, "and the newly created status of the National Aeronautical Establishment may well be taken as augury that the challenge has been accepted".

Moosonee, an Ocean Port

Moosonee, on James Bay, will be a major ocean port. Ontario's Premier Leslie M. Frost announced this in January, saying that Federal Government cooperation is contemplated. Ontario would proceed with the plan, in any event, so that Ontario will have an outlet on the sea lanes.

The plan is for a $5 million project, including dredging, the building of a dike and construction of docks. It would also involve the building of spur lines by the Ontario Northern Railway and the establishing of marshalling yards. Drilling is already being done to obtain information for location of the harbour.

These advantages have been cited in favour of the project:

The Ontario Northland Railway already connects Moosonee to Cochrane. Natural gas service can easily be extended from Cochrane. There are hydro-electric resources within 100 miles of Moosonee.

Benefits to be derived are headed up by these:

Northern Ontario's potential for development will get closer attention; a great agricultural area will become more accessible by rail and sea.

The port could be used as a supply base for northern defence and radar posts. Traffic in iron ore alone would justify the port, it is said. In the Belcher Islands there is an estimated 4.5 billion tons of iron ore. The new port will make possible its movement by rail to the industrial centre of Ontario, and by sea to other markets.

The Ontario Northern Railway is expected to launch a 20 to 30 million dollar modernization program.

What Goes On

Arctic Supply Operation

An arctic transportation operation of special interest was concluded last fall by the Department of Transport. It was a supply undertaking, by which 77,000 tons of supplies were delivered to defence radar sites, joint arctic weather stations and other outposts. It was the first Canadian sea-supply for DEW line sites in Foxe Basin, 200 miles north of the Arctic Circle. These previously had been served by United States shipping. The fleet also sailed to Mid Canada locations in Hudson Bay, to Frobisher and some 30 other outposts.

The fleet comprised 13 Department of Transport vessels, 22 chartered ships and 125 barges, landing craft and tugs. Throughout the summer they sailed from Montreal and Churchill to as far north as Eureka on Ellesmere Island.

The ships carried passengers to the posts, and the *C. D. Howe* had a special health and welfare mission. It was equipped to carry out medical examinations aboard. The icebreaker, *N. B. McLean* logged 15,500 miles on this voyage.

Soo Bridge

Discussions were held recently relative to the financing of the $18 million international bridge at Sault Ste. Marie. The projected bridge will be approximately 12,000 feet in over-all length, including the approaches from downtown Sault Ste. Marie, Mich., to the outskirts of Sault Ste. Marie, Ont.

Ontario Mineral Production

Mineral production in Ontario during 1958 reached $799 million according to a preliminary Government estimate. This is $50.3 million more than 1957 production.

Ontario's great increase in uranium production was alone more than enough to account for the over-all total increase. The uranium mines in the Elliot Lake and Bancroft areas produced uranium oxide valued at just under $222 million. Uranium held the top production figure. In second place was nickel, at $179 million, its production curtailed by reduction of world stockpiles and by work stoppages. Copper output was worth $72 million; gold production, $90 million; iron ore, $33.3 million.

Demand for Power in N.B.

New Brunswick is planning for the production and use of 600,000 hp. of electrical energy within the next few years. Production of the N.B. Electric Power Commission is now 226,000 hp. But demand is doubling every seven years and, in the immediate future the rate of new demand is expected to jump very sharply. Industrial growth, notably a $50 million oil refinery at Saint John, will demand greater quantities of power.

Ice Bridge for Trucking

An ice-bridge built near Edmonton made the news lately. Design was attributed to Dean R. M. Hardy, M.E.I.C., of University of Alberta.

The ice-bridge was built across the North Saskatchewan River by the use of plastic refrigeration pipes laid across the 150-foot main channel. Natural ice 2 feet thick was reinforced to a total depth of 3 feet.

This bridge allows direct truck transportation of sand and gravel into Edmonton, saving 3½ miles of the alternative route and saving $56,000 in costs.

Trans Canada-Pipe Lines Limited

Four compressor stations will be built by Trans Canada Pipe Lines Limited at an approximate cost of $13 million in 1959. Fifteen sales meter stations costing about $500,000, also will be put into operation.

Three of the new compressor stations will be built by the Northern Ontario Pipe Line Crown Corporation, at Ignace, Geraldton and Hearst, with design and engineering under the supervision of Trans-Canada. The fourth will be built by Trans-Canada near Maple, Ont.

Trans-Canada may now take 5.45 trillion cubic feet of gas from Alberta. The company's original permit from the Alberta Oil and Gas Conservation Board allowed the removal of 4.35 trillion cubic feet, which is under contract for delivery to distribution companies over the next 25 year period. The permit approved in January allows export from Alberta of an additional 1.1 trillion cubic feet during the next 22 years.

Garden City Planned

Webin Community Consultants, a division of Toronto Industrial Leaseholds (1957) Ltd., will convert 374 acres of land in North York Township into a garden city development of family-type rental housing. This land, south of Don Mills, is known as Flemingdon Park. It was acquired last June by Toronto Industrial Leaseholds (1957) Ltd., which is an affiliate of Webb & Knapp (Canada) Limited.

St. John's Harbour

A $13 million expansion of the harbour at St. Johns, Newfoundland, will be completed in the next 4 years. The port will then be able to handle an additional 250,000 tons of general cargo per year.

Main features of the plan are:

- Construction of a large finger wharf and adjacent marginal wharf, providing three additional berths to handle ships up to 10,000-ton capacity.
- Construction of about 2,200 feet of marginal wharves along the north shore to handle coastal shipping.
- The construction of a 617-foot marginal wharf for the ships of the Department of Transport.
- Provision of a boat basin for small boats, with a total berthing arca of 900 feet.
- Removal of harbour obstacles; provision of new mooring locations and tug service.
- Construction of service roads.
- A large modern terminal, built in conjunction with the new deep water berths and wharves in the west end of the harbour, will be linked to the railway yards.

Production Opportunities

A booklet published by the Department of Planning and Development of Ontario, gives a report on "Fabrication Gaps in Canadian Manufacturing Industry", as indicated by imports in excess of $1 million a year. Manufacturers may find here new opportunities for production or expansion.

O.W.R.C. Projects

As the Ontario Water Resources Commission approached the completion of its second full year of operation, March 31, 1959, Chairman A. M. Snider recently reported that OWRC was involved in municipal water and sewage projects throughout the Province having a total value of $30 million. These projects—24 water and 30 sewage—included those completed and in operation, those under construction, and those under OWRC-municipal agreement but still in the pre-construction stage. Water projects were valued at $7.7 million, and sewage $22.6 million.

All were built by the OWRC for the various municipalities and are being operated by or under the Commission's direction. Total value of OWRC projects now in operation is $4.2 million.

Canada Cement Anniversary

Canada Cement Company Limited is celebrating in 1959 fifty years of progress. These years have brought greater production, closer quality control and more economical operation.

Rotary kilns operating in the company plants today are up to 12 feet in diameter and 455 feet in length. Methods now involve high speed rotary quarry drills, large efficient electric shovels and large truck haulage units. Recent developments have added beams, joists, wall panels, roof and floor slabs, to an extensive list of concrete products for construction.

The company's annual capacity is 96 million bags of cement per year. The annual report, issued recently, predicted that in 1959 the plants will be operating at efficient rates, though at somewhat below capacity levels. This is based on preliminary estimates of construction volume.

Queen's University

A fifth year nuclear engineering course, has been available at Queen's University since last fall.

This is a one-year graduate program dealing with basic concepts of nuclear energy and with design of nuclear reactors and industrial applications of nuclear radiations. Information can be obtained from the dean of the faculty of applied science, Queen's University, Kingston.

A symposium on Plastic Design in Steel will be held at Queen's University, June 15-19, 1959. British, American and Canadian speakers are to give papers dealing with: fundamental concepts of plastic design, loads, single and multi-storey frames, connections, plastic behaviour, examples from Britain and the United States, design, foundations, and economics.

Information is available from Dr. H. W. Curran, Director of Extension, Queen's University, Kingston, Ont.

Tandem Accelerator, Chalk River

Atomic Energy of Canada Limited has in service a new, ten million volt atom smasher, known as the tandem accelerator.

It was designed and built by High Voltage Engineering Corporation, Burlington, Mass., and is the first machine of its type; its value is $1 million. It will be able to obtain information on the nuclei of heavier elements than could its predecessor, the Van de Graaff accelerator of 3 million volts.

The tandem accelerator consists of two Van de Graaff accelerators placed end to end, horizontally, in a 23-ton steel pressure tank, which is 34 feet long and eight feet in diameter. The tank contains nitrogen at a pressure of 225 pounds per square inch to insulate the accelerator, preventing escape of the electrical charge.

A beam of particles (for example, protons) is directed into the first of the two units where it is given an energy of five million volts. In the second unit, further acceleration of particles brings the total energy to ten million volts. The beam of particles is then directed against target material (such as magnesium or lead). The particles, penetrating the nuclei of the target atoms, revealing information about their structure.

A shielded building (150 ft. by 60 ft.) houses the accelerator. A separate building contains the control room, and closed circuit television permits observation of the operation.

E.I.C. — 1959

ANNUAL GENERAL AND PROFESSIONAL MEETING

The Committee on Technical Operations has arranged a technical program consisting of 43 papers and two panel discussions.

A strong annual meeting committee has been formed in Toronto, under the Chairmanship of E. R. Davis, M.E.I.C. The committee is working in close co-operation with Headquarters to round out the program.

The meeting will be in the new convention wing of the Royal York Hotel, with banquets in the beautiful Canadian Room.

Advance notice of the annual meeting and registration forms will be mailed to all members about the end of March. It is of special interest to note that the dates fall on a Monday, Tuesday and Wednesday. This is a departure from practice imposed by availability of convention bookings.

June 8, 9, 10, 1959, Royal York Hotel, Toronto

CONFEDERATION A Progress Report

There is little that has occurred on Confederation since the meeting of Council at Toronto. There has not been time to complete any of the steps that naturally follow the strong support given by Council to the report of the Joint Committee.

Your chairman has had conversations with the chairman of the Canadian Council committee leading to arrangements for the next meeting of the joint sub-committee.

The EIC members of the sub-committee are at work on a somewhat modified report for consideration of the joint sub-committee. It is proposed that the identical report to the membership will be used for the Canadian Council as well as the Institute.

It should be emphasized that it is not going to be a quick job to get from the committee unanimous agreement on the joint report, but there is every reason to believe it will be achieved within a reasonable time. Members must not expect to receive the ballot immediately, but they may be assured that every effort is being made to have it ready at the earliest possible time.

Engineering Careers

Letter to the Editor

The Engineering Institute of Canada is to be commended for its efforts to establish useful means of liaison between both the prospective Canadian technician and young engineering graduate and the opportunities in the broad field of Canadian engineering.

Had I personally as a youth the opportunity of reading a publication such as your recent edition of "Engineering Careers in Canada," I would have known where I was heading when I sought, and obtained a degree in electrical engineering. Fortunately, somewhere during that four-year course, I discovered that my aptitudes were those of a mechanic, rather than those of an engineer and, at graduation time, that the newspaper profession could be inviting to me.

For young people brought up in small communities and with little opportunity to travel, there is a great need for the broad picture in the choice of a career. That is where I consider your publication has its greatest value.

Enclosed is a tear sheet from the editorial page of *The Telegraph-Journal* containing editorial reference to your publication. The same editorial also appeared in our afternoon paper, *The Evening Times-Globe.*

J. G. Bruce,
Saint John, N.B.
Associate Editor,
The Telegraph-Journal, and
The Evening Times-Globe

Credit is Due

A picture of the *Silver Dart* appeared on page 33 of the February issue.

An apology to the National Geographic Society for failure to include a credit line under that picture, which they very kindly loaned for reproduction in *The Engineering Journal.*

Director of Technical Services

The general secretary of The Engineering Institute of Canada announces the appointment of J. Hance Legere, M.E.I.C., as director of technical services for the Institute.

J. H. Legere,
M.E.I.C.

Coming from Nova Scotia, Mr. Legere served five years with the Royal Canadian Corps of Signals. Demobilized in 1946, he enrolled at McGill University and in 1950 was awarded the degree of bachelor of engineering in engineering physics. Later he received a diploma in management and business administration from McGill.

Mr. Legere's industrial experience has been mainly in the fields of communications and electronic control. However, during the period 1954 to 1956 he was registrar of the Corporation of Professional Engineers of Quebec, and in 1955 he served as secretary treasurer of the Canadian Council of Professional Engineers.

More recently, Mr. Legere was chief engineer of Servomechanisms (Canada) Limited for two years, engaged in the design and manufacture of aircraft and industrial servomechanisms.

Periodicals in Engineering Libraries

The Engineering Journal has received confirmation of its importance as a source of reference in Canadian engineering and industrial circles.

In December 1958, the librarians of 75 leading Canadian engineering and industrial libraries were asked to complete a questionnaire, indicating which of sixteen periodicals they receive and retain. Sixty replies were received and tabulated.

Fifty librarians indicated that they keep *The Engineering Journal* on permanent file. The next highest technical publication was *Engineering News Record.* This was closely followed by *Engineering,* a British periodical.

The average retention figure for fifteen Canadian, British and American trade and technical periodicals was 24.6.

Bell Tower for U.B.C.

St. Andrews Hall at the University of British Columbia has a new 30-foot bell tower and bell, the gift of a New Westminster resident, Miss Annie Graham Hill, B.A., one of the university's earliest graduates.

The bell tower, built with funds donated by Miss Hill, commemorates her parents and step-mother. Her father, Arthur E. B. Hill, was a pioneer civil engineer, who helped to locate the C.P.R. Railway from Yale to Port Moody, and who helped to design and construct the first water supply system of New Westminster.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of Council on January 31, 1959.

Members: R. H. Abbott, Port Hope; R. M. Arner, Hamilton; D. L. Brignall, Hamilton; R. W. Gittins, Fort St. John; I. H. Lamb, Prescott; J. A. G. MacDonald, St. John's, Nfld; F. A. McCowan, Calgary; V. Milligan, Toronto; M. J. Morgan, Toronto; H. J. B. Nevitt, Sweden; R. J. Reeves, Hamilton; A. K. Rowntree, London; R. Sabljak, Vancouver; J. G. Spence, Kingston; R. H. Tanner, Belleville; N. Van Cleaf, Ottawa; A. L. Van Luven, Montreal.

Juniors: A. Alexander, St. Catharines; T. J. Gaffney, Sudbury.
Affiliates: H. D. C. Hunter, Victoria; C. G. Shaw, New Westminster.

Junior to Member: D. L. S. Bate, Toronto; E. W. Hill, Hamilton; J. C. Luscombe, Ottawa; J. I. McClelland, Trail; R. N. Payton, Hamilton; J. N. Schilizzi, Switzerland; K. D. H. Willcocks, Belleville.

Student to Member: J. M. Howes, Toronto.

STUDENTS ADMITTED

McGill University: E. Alzner, I. Alleslev, A. Amos, F. F. Angus, J. R. L. Atchison, P. E. Atkovitch, J. W. Atwood, J. O. Baatz, B. S. Basarke, J. D. Belcourt, D. L. Bercovitch, I. P. Bergeron, M. J. F. Bermingham, N. Berriman, C. H. Beuglet, R. L. Blackie, G. Bleier, G. D. Bonner, M. Boyer, R. Brousseau, M. L. M. Carle, I. A. Carson, R. C. H. Chen, W. B. Clarke, M. Cogan, A. J. Colman, E. G. Craig, W. Cupchik, N. Dion, G. A. Doig, M. Dorenfeld, J. R. Duckworth, P. A. Dupont, J. G. Dyke, R. D. Dyck, J. Egri, D. J. Ekanem, D. S. Elkins, F. H. Farmer, O. A. Fernandez-Cruz, G. R. Fitzbibbon, C. C. Flis, R. Fong, M. E. Fournier.
K. L. Fraser, Y. Freedman, A. J. Freyman, D. J. Galloway, S. B. Garfinkle, P. Gergely, F. M. Groundwater, L. Hamel, C. T. Harsora, E. C. Higgins, R. T. Holcomb, R. T. Horwood, D. U. Houghland, J. D. Hutchison, R. D. Japp, J. J. Kappel, P. R. Kemball, M. Kenney, M. Kiovsky, J. M. Klemka, H. P. Korman, L. Lahti, G. P. Laszlo, P. Lebeault, D. K. Lee, J. K. P. Lee, R. Y. M. Lee, R. Leibe, C. Loo, G. H. C. Lui, J. R. Mallamo, R. R. Martino, W. McCree.
D. W. McMullen, D. J. M. McVey, W. J. F. Meighan, C. Millar, L. Mincoff, G. N. Minns, P. J. Morrissette, T. N. T. Morse, R. H. Oldham, J. Opher, R. P. A. Pagotto, S. J. Polatshek, C. A. Potter, P. A. Preville, J. B. Quinlan, B. L. Rochester, A. D. Ross, C. A. Roy, D. J. Scholtz, D. G. Scott, L. Sebastien, D. T. Serbyn, H. T. Shrimpton, E. A. Silver, M. S. Sindhu, D. R. Smyth, L. Stein.
J. P. Stockhausen, T. D. Syme, R. G. Taylor, M. A. Tenander, R. B. Testa, N. Toye, J. M. Trischuk, T. Shang, S. R. Tumas, D. B. Uniat, R. H. Veach, D. A. Vivian, M. B. Walker, J. S. Watson, H. L. Wax, E. J. Weber, A. W. Y. Wong, T. F. Yung.

University of British Columbia: G. B. Allan, R. G. Auld, D. L. Birdsall, T. A. Bisaro, R. M. Boss, E. Bozgoz, D. W. Brown, D. A. Brundrett, A. F. Bygate, D. E. Chapman, H. R. Cherewick, A. T. Cooper, D. R. Crombie, G. D. Davidson, J. V. Davies, G. Doeksen, G. H. S. Duddy, R. A. Edgar, P. L. Eggleton, P. W. Elder, D. Erwin, G. A. Facca, D. L. Ferraro;
G. F. Fieber, D. M. Field, R. Gebauer, S. R. Greenwood, R. L. Hawkins, M. R. Higgins, R E. Higgins, T. J. Hirst, G. E. Hoar, W. H. Holland, H. Hooge, R. E. Horita, R. H. Hunt, H. Hussin, B. R. Isbister, G. A. Isbister, B. F. Jackson, N. A. Johnson, J. B. Kidston, W. L. Kilik, D. B. Kirk, A. V. Kouritzin, L. Kwan, V. S. Lamba;
M. Lambert, V. B. Lawson, O. H. Leiren, L. E. R. Lenoire, W. D. Little, E. J. Mazzuca, R. S. Moore, R. M. Murray, B. G. Mykvtiuk, D. W. Neilson, D. Nicholson, K. Oikawa, W. A. Olafson, W. V. Olson, M. H. W. Pau, T. P. Whittingham, E. J. Peterson, M. J. Polz, W. E. Reid, K. M. Richmond, L. A. Roosdahl, R. E. Rowlands, J. Saarma, R. V. Samol;
J. J. Sanderson, D. W. Saunders, E. H. Schroeder, R. G. Sexsmith, L. G. Shannon, H. A. Sharp, R. M. Sharp, J. Siiins, J. D. Smith, D. G. Strong, K. Teng, T. R. Tufts, R. M. Van Sacker, V. P. G. von Maydell, E. N. Walimaa, R. C. H. Werthner, T. M. White, P. A. Wiebe, A. W. Wild, L. F. Wolfe, P. Wong, W. D. Worobec, R. S. Zalkowitz.

University of Sherbrooke: J. Belleau, J. Bernier, P. Blais, Y. N. Boisselle, A. Breault, L. Chasse, R. Chasse, J. A. C. Cormier, M. Y. Demers, Y. Demers, D. Dumas, D. Gagnon, J. M. R. Gagnon, M. Labbe, P. Lacharite, P. Lambert;
L. Laplante, J. G. Lemay, J. R. M. Marcil, J. C. Moore, G. Morin, L. P. G. Morin, J. Morin, J. G. Nadeau, J. A. G. Richard, S. Richard, G. Teste, J. R. Tetreault, P. A. Tetrault, C. Tremblay, B. Vigneux.

University of Alberta: F. C. Astle, D. R. Ferrier, J. P. Ford, L. P. Haenni, A. Heidebrecht, R. L. Hemmings, M. P. Hermansen, W. F. Hobden, J. R. Hope, V. C. Jones, G. K. Leckie, D. A. Lindberg, P. Lukomskyi, D. G. Lunder, W. G. Maunder, R. B. Pinkney, P. T. Seabrook, K. J. Singleton, P. K. Symborski, T. H. Thomsen, E. I. Weleschuk, S. M. Zuk.

University of Toronto: R. T. Anthon, G. R. Bender, M. D. Davids, A. P. Fielden, D. K. Fountain, J. E. Garyfalakis, P. H. Griggs, B. M. Hersh, R. M. Korol.

University of Toronto: I. J. McGee, D. J. McLeish, R. J. Pau, R. Reio, A. A. M. Reed, V. Smiltnieks, D. R. Stemp, R. Taagepera.

McMaster University: I. C. Amery, P. I. C. Ernest, W. P. Gorrell, T. A. Hunter, R. E. Rowell, D. W. Weber.

St. Francis Xavier University: J. C. A. Beauchesne, P. Beauchesne, J. J. P. Bouvette, R. H. Burlock, J. R. Deschenes.

Queen's University: A. W. Armstrong, R. J. Balkwill, K. T. Bullen, A. G. Dyke, J. B. C. Roy.

Royal Military College: R. H. Brett, C. W. Dibden, M. J. Schelter, D. E. Woo.

University of New Brunswick: N. C. De Grace, G. A. Hatchard, R. J. Sharman, T. W. Walker.

University of Manitoba: F. P. Coinner, E. Romaniuk, R. T. Seepish.

Sir George Williams College: M. Chicha, I. Lindy, N. Vineberg.

Mount Allison University: T. A. Hiscock.

Waterloo College: H. S. Speers.

University of Saskatchewan: B. L. Vandall.

Nova Scotia Technical College: R. J. F. Swindles.

University of Alberta: K. C. Rainsberry.

Queen's University: E. R. Acton.

A.P.E.D.: J. A. Cummings.

Applications through Association

By virtue of the co-operative agreement between the Institute and the Associations of Professional Engineers, the following elections and transfers have become effective.

ALBERTA

Member: E. J. MacGinnis, J. D. Marshall; **Junior:** I. H. Barghshoon, J. D. Winkelaar, L. Davidson; **Junior to Member:** P. A. Clarke, F. C. Totino.

SASKATCHEWAN

Members: W. J. Keough, W. W. Petersmeyer, R. D. Lemmons; **Juniors:** V. K. Pedscalny; F. N. Trofimenkoff; **Junior to Member:** M. Barabas, B. K. Braaten, G. A. Gette, H. M. Hill, T. J. Manning, J. M. McNeil, V. L. Ryhorski, H. Solonginka, J. Stoffel, K. H. Thompson; **Student to Junior:** V. G. Beckie, A. C. Floyd, W. R. Hinz, W. E. Randall, A. G. Weimer, **Students:** A. W. D. Beck, D. V. Fowke, G. D. Genereux, D. L. Fraser, N. W. Ledray, J. W. McGuffin, W. F. Peterson, G. N. Steuart, M. G. Wilson.

QUEBEC

Member: I. W. G. MacCallum.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

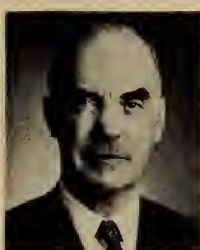
Dr. R. S. Jane, M.E.I.C., president of Shawinigan Chemicals Ltd. died on December 1, 1958.

Born in Cornwall, England, in 1898, Dr. Jane came to Canada in 1903. He graduated with a B.Sc. degree from the University of British Columbia in 1922. He was awarded an M.Sc. degree in chemistry in 1923 and a Ph.D. degree in 1925 by McGill University. He attended the University of London on a Wembley scholarship for the following two years. He received the degree of doctor of science from McGill University in 1958.

In 1927 Dr. Jane was named chief chemist at Shawinigan Falls, Que., with Canada Carbide Company. When that company became a division of Shawinigan Chemicals Ltd., he was placed in charge of plant research activities. In 1936 he was transferred to the research and development department in Montreal. In 1943 he was named director of the newly created industrial research department, Shawinigan Water and Power Company.

Three years later he returned to Shawinigan Chemicals Ltd., as director and vice-president in charge of research and development. He was appointed executive vice-president of the company in 1954, and president in 1956.

Dr. R. S. Jane, M.E.I.C.



J. W. McCammon, M.E.I.C.

He was elected president of the Chemical Institute of Canada for 1952-53.

J. W. McCammon, M.E.I.C., retired general manager and commissioner of the Quebec Hydro-Electric Commission, Montreal, died on December 4, 1958.

Mr. McCammon was born in Inverness, Que., in 1888. He attended McGill University, graduating with a B.Sc., degree in 1912, following which he served an engineering apprenticeship with the Canadian Westinghouse Company Limited, in Hamilton.

Between 1912 and 1929 he worked with Mackenzie Mann and Company in Montreal; as a manager of the hydraulic and electrical departments of the Canadian Fairbanks Morse Company, Montreal; and as contracting engineer and director, with the Charles Walmsley Company, Montreal. He joined the Beauharnois Light, Heat and Power Company in 1929 as assistant general manager. For nine years from 1934 he was a member of the Provincial Electricity Board and Quebec Public Service Board. It was in 1945 that he received the appointment to the newly created Quebec Hydro Electric Commission.

Mr. McCammon served with the Royal Canadian Garrison Artillery, the Seventh Canadian Siege Battery, and various British units, Royal Garrison Artillery, from 1916 to 1919.

Frank C. Tempest, M.E.I.C., who retired in 1956 as mechanical superintendent, Imperial Oil Company, Calgary, died on November 28, 1958.

He was born at Keighley, Yorkshire, England in 1891.

During World War I, he served as a dispatch rider for the 11th Canadian Field Ambulance, later transferring to the Royal Navy with commissioned rank. After the war he completed his education at the University of Alberta and late in 1922 he became draftsman for the Imperial Oil refinery, then under construction in Calgary. He was later promoted to engineer. About 1926 he was transferred to Royalite Oil Co., then a subsidiary of Imperial Oil Co., serving in Turner Valley as an engineer. In 1931 he was sent to the Tropical Oil Co., Columbia, S.A. where he served until 1938 as a refinery engineer. He rejoined the Imperial Oil Refinery at Calgary in 1940.

J. C. D. Taylor, M.E.I.C. of Winnipeg, Man., died on December 29, 1958.

Born in London, England in 1892, he attended Baltimore Polytechnic Institute, and studied civil engineering at the University of Philadelphia.

After working for a year with the Canadian National Railways, he joined the Manitoba Drainage Commission. Later he was municipal engineer for West Kildonan, Manitoba.

From 1924 to 1930 he served as superintendent with Canadian Engineering and Construction Company Limited. From 1935 until the outbreak of the second world war he worked on the design of the Winnipeg sewage treatment plant. During the war he was command engineer, No. 2 Air Command, R.C.A.F., on the design of water supplies and sewage disposal systems. In 1945 he was appointed hydraulic engineer of the City of Winnipeg.

In 1955 Mr. Taylor joined the firm of Haddin, Davis & Brown Limited, at Winnipeg.

Edward P. Innes, M.E.I.C., chief engineer, Canadian Canners Limited, Hamilton, Ont., died on August 22, 1958.

He was born at Simcoe, Ont., in 1910. He graduated from McGill University in 1934 with a B.Eng. degree in mechanical engineering. He joined Canadian Canners Ltd., taking charge of the engineering department. He was a director of Canners Machinery Ltd.

During World War II, he served with a technical liaison group at the British Ministry of Supply, London, and was promoted to major with the Canadian Army in 1944.

Marcel Guy Lanouette, M.E.I.C. died in July 1958.

Born in Montreal on September 13, 1913, he attended Ecole Polytechnique where he graduated with a B.A.Sc. (C.E.) degree in 1941.

From 1941 to 1945 he worked with the Canadian Broadcasting Corporation.

He joined the Lower St. Lawrence Power Company in 1945, where he was distribution engineer.

He was vice-chairman of the Lower St. Lawrence Branch of the Institute.

William James Edington, M.E.I.C., retired city engineer for the City of Moncton, N.B., died on September 25, 1958.

He was born on March 10, 1889 at Moncton. Graduating in civil engineering from the University of New Brunswick in 1919, he joined the city engineering staff. He became city engineer in 1948.

W. J. Edington, M.E.I.C.

In 1954 he retired from the post, but was retained by the city in an advisory capacity. He was engaged on a special engineering assignment at the time of his death. His service to Moncton spanned 39 years.

He served in the Canadian Expeditionary Force in the first world war.

M. J. Stanbridge, JR.E.I.C., of Winnipeg, was the victim of a traffic accident in the summer of 1958.

Born in Winnipeg, Manitoba in 1934, he attended Daniel McIntyre Collegiate and the University of Manitoba, where he was awarded his B.Sc., (Geol.) degree in 1956.

Personals

J. E. Sears, M.E.I.C. (civil, Queen's 1910) has retired from his practice as an Ontario Land Surveyor in the Huntsville area, Ontario.

H. Graham, M.E.I.C. (electrical, Bradford, England 1925) chief engineer, Public Utilities Commission, Victoria, B.C., has been elected chairman of the Vancouver Island Branch of the Institute.

H. Graham, M.E.I.C.

H. E. Seely, M.E.I.C.

J. E. Harrington, M.E.I.C., president of Anglin-Norcross Corporation Ltd., was elected president of the Canadian Construction Association for 1959.

W. J. Horner, M.E.I.C.

J. E. Harrington, M.E.I.C.

W. J. Horner, M.E.I.C. (B.Eng., mech., Saskatchewan, 1945) is chairman for the Kitchener Branch of the Engineering Institute for 1959. Mr. Horner is sales engineer with Sheldons Engineering Ltd., Galt, Ont.

E. Mason, M.E.I.C.

W. G. Small, M.E.I.C.

G. M. Young, M.E.I.C.

E. T. Harbert, M.E.I.C.

W. D. Barron, M.E.I.C., (B.Sc., mining, Queen's, 1943) has been appointed branch manager for the Province of Quebec, by T. McAvity & Sons Limited, Saint John, N.B.

Gilbert M. Young, M.E.I.C. (B.Eng., mech., McGill, 1934) has recently been appointed vice-president and general manager, Canadian Ingersoll-Rand Company Limited, Montreal.

E. T. Harbert, M.E.I.C. (B.Sc., mech., McGill 1923) formerly manager of engineering, Canadian Ingersoll-Rand Company Limited, Sherbrooke, Que., has been appointed works manager for the company.

W. A. Osbourne, M.E.I.C., (B.A.Sc., Toronto 1924) has retired as president of Babcock-Wilcox and Goldie-McCulloch Limited, He has been elected vice-chairman of the board of directors.

Ernest Mason, M.E.I.C. (Manchester Coll. Tech., 1922) chief design engineer of the Consolidated Mining and Smelting Company of Canada Limited, Trail, B.C., became a consulting engineer of the company on January 1.

Lloyd Williams, M.E.I.C. (B.A.Sc., elec., British Columbia, 1932) has been named assistant to the manager of the engineering division, Consolidated Mining and Smelting Company Limited, Trail, B.C.

W. G. Small, M.E.I.C. (B.Sc., civil, Saskatchewan, 1924) has been named chief instrument engineer, Consolidated Mining and Smelting Compay, Trail, B.C.

Hugh E. Seely, M.E.I.C., of Robertson-Irwin Limited, formerly of Hamilton, has been appointed manager of the Toronto district sales for the company.

P. E. Savage, M.E.I.C., has been appointed regional vice-president of the eastern region of the Dominion Bridge Company, Limited, in a reorganization of the Company creating four new regions. Each region will be controlled by a regional vice-president operating from the Montreal head office.

Mackenzie McMurray, M.E.I.C., is the new vice-president for the Ontario Region of Dominion Bridge Company, Limited.

E. A. Ford, M.E.I.C., has been named vice-president of the central region of the Dominion Bridge Company, Limited.

R. J. A. Fricker, M.E.I.C., will be regional vice-president of the western region of Dominion Bridge Company, Limited.

Robert S. Eadie, M.E.I.C., has been appointed vice-president and director of engineering, Dominion Bridge Company, Limited.

W. A. Osbourne, M.E.I.C.

W. D. Barron. M.E.I.C.

George H. Midgley, M.E.I.C., has been named vice-president and manager of the new marketing services group, Dominion Bridge Company, Limited.

G. H. Midgley, M.E.I.C.

P. E. Savage. M.E.I.C.

M. McMurray, M.E.I.C.

R. J. H. Fricker. M.E.I.C.

R. S. Eadie, M.E.I.C.

E. A. Ford. M.E.I.C.

Strang "meets" Pandjiris in Toronto

It's a daily encounter, as Kent Strang, a welding operator at our Toronto plant gets down to work with the highly efficient and versatile Pandjiris automatic welding manipulator, a portion of which is seen in operation above.

Both Strang and Pandjiris are "tops" in their respective fields — for in Toronto, as in 13 other Dominion Bridge plants from coast-to-coast, skilled operators work with up-to-date equipment of many types in the production of high quality platework for almost every Canadian industry.

Your inquiries will receive prompt attention at any of the plants listed below.

DOMINION BRIDGE COMPANY LIMITED. Plants: MONTREAL • OTTAWA TORONTO • SAULT STE. MARIE • WINNIPEG • CALGARY • EDMONTON VANCOUVER. Assoc. Company Plants: AMHERST, N.S.: Robb Engineering Wks., Ltd. QUEBEC: Eastern Canada Steel & Iron Wks. Ltd. WINNIPEG: Manitoba Bridge & Eng. Wks., Ltd. Divisions: Platework • Warehouse • Boiler • Structural • Mechanical.

Platework by DOMINION BRIDGE

• PERSONALS

J. M. Reid, M.E.I.C.

G. Eriksen, M.E.I.C.

D. R. Brown, M.E.I.C.

D. R. Brown, M.E.I.C. (B.Eng., mech., 1944; M.Eng., 1951, McGill) has been transferred to Monsanto Chemical Company, Dayton, Ohio, as a mechanical engineer in the research department, research and engineering division.

J. R. Burgess, M.E.I.C. (B.A.Sc., mech., Toronto, 1910) recently retired from the position of mechanical superintendent of Canadian Wallpaper Manufacturers Ltd., Leaside, Ont. He has since been engaged as a clerk of works for Marani and Morris on a project at London, Ont.

James M. Reid, M.E.I.C. (B.A.Sc., elec., British Columbia, 1951) has become district sales manager of the Pirelli Cables, Conduits Limited new sales office in Vancouver.

J. W. Demcoe, M.E.I.C. (B.Sc., civil, Manitoba 1939) is general superintendent of the Southern Ontario District, Canadian National Railways, with headquarters in Toronto.

J. H. Jackson, M.E.I.C. (B.A.Sc., civil, Toronto, 1947) is construction manager at Otter Rapids, Ont., for the Hydro Electric Power Commission of Ontario.

A. P. Wiles, M.E.I.C. (B.Sc., engrg. phys., Saskatchewan, 1946) has joined the defense systems division, of RCA-Victor Company Ltd., Montreal as systems engineer.

G. Eriksen, M.E.I.C. (civil, Oslo, 1925) is an engineer with the Ontario Water Resources Commission, Toronto.

B. Baribeau, M.E.I.C. (B.A.Sc., civil, Montreal, 1943) who was in Paris, France, as manager of European operations for Defence Construction (1951) Limited, has been transferred to Ottawa.

G. L. Wilson, M.E.I.C. (B.A.Sc., civil, Toronto, 1951) is deputy township engineer of the township of Etobicoke in Metropolitan Toronto.

E. R. Quinn, M.E.I.C. (B.Sc., mech., Queen's 1951) has joined Irving Pulp & Paper Ltd., Lancaster, N.B. as maintenance engineer.

John L. Kearns, M.E.I.C. (B.A.Sc., chem., Toronto 1945; Ph.D., Iowa State College, 1954) is associate professor of engineering science at the University of Western Ontario, London.

Wm C. McLean, M.E.I.C. (H.N.C., mech., Glasgow Royal Technical College, 1946) of Sarnia, Ont. has joined the Canadian Chemical Company, Edmonton, Alta., as maintenance engineer.

G. N. Hutchinson, M.E.I.C. (B.Sc., elec., Queen's, 1949) of Fort William, Ont., is now a maintenance supervisor with the Universal Cyclops Steel Corporation in Coshocton, Ohio.

O. Graham, M.E.I.C. (C.E., civil, Ecole Polytechnique 1921) is engineer superintendent with Desourdy Construction Limited, Ville Jacques Cartier, Que.

F. A. Lazenby, M.E.I.C. (B.A.Sc., civil, British Columbia, 1925) was recently appointed assistant chief engineer (executive) of B.C. Electric.

S. L. Kenez, M.E.I.C. (civil and general, Nador, Hungary, 1942) has joined the

City of Hamilton engineering department as roadway engineer.

K. H. Bjerring, M.E.I.C. (B.Sc., elec., Manitoba, 1934) has recently joined the staff of Stevenson & Associates, architects and engineers, Calgary, as a mechanical engineer.

H. W. Nasmith, JR.E.I.C., (B.A.Sc., British Columbia 1950; M.A., Washington University 1951) has joined the consulting engineering firm of R. C. Thurber & Associates Ltd. of Victoria, B.C.

Donald W. Rae, JR.E.I.C., (B.Eng., civil, McGill, 1956) has been named contract sales engineer for Horton Steel Works Limited in Montreal.

W. R. Lymburner, JR.E.I.C., (B.Sc., civil, Alberta, 1950) is a project engineer for Willis & Cunliffe Engineering, Victoria, B.C.

D. R. Gilham, JR.E.I.C.

W. R. Lymburner, JR.E.I.C.

G. T. Trotter, JR.E.I.C.

J. F. Preston, JR.E.I.C., (B.Eng., McGill 1950) resident engineer for the Du Pont Company of Canada (1956) Limited Maitland projects, has been transferred to the company's Sarnia projects.

G. T. Trotter, JR.E.I.C., (H.N.C.E., civil, London, England, 1957) has accepted a position as designer with Dominion Bridge Company Limited, at Winnipeg.

D. R. Gilham, JR.E.I.C., (civil, Portsmouth, England, 1955) is subdivision engineer in the township of North York, Ont. He was previously with the City of Hamilton.

J. Renchko, JR.E.I.C.

F. P. Linares, JR.E.I.C.

J. F. Preston, JR.E.I.C.

Francisco de P. Linares, JR.E.I.C., (mech., Barcelona, Spain, 1956) is presently with Massey-Ferguson Ltd., Toronto as industrial export sales manager.

J. Renchko, JR.E.I.C., (B.Sc., elec., Saskatchewan 1949) has accepted a position with Massena Electric Company, Massena, N.Y., as electrical engineer.

R. P. Baronet, JR.E.I.C., (B.Eng., mech., McGill, 1950) has become sales engineer at Peacock Brothers Ltd., Montreal.

• PERSONALS

J. Favron, JR.E.I.C., (B.Sc., mechanical and electrical, Ecole Polytechnique 1952) has accepted a post as air systems designer with Grumman Aircraft Engineering Corporation, New York.

F. E. MacIntyre, JR.E.I.C., (B.Sc., mech., Queen's 1949) is teaching at Glebe Collegiate Institute, Ottawa, as mathematics teacher.

R. G. T. Wilson, JR.E.I.C., (H.N.C., elec., Birmingham, England 1955) has joined the Foundation Company of Canada Ltd., as electrical engineer, on the Inco project at Thompson, Manitoba.

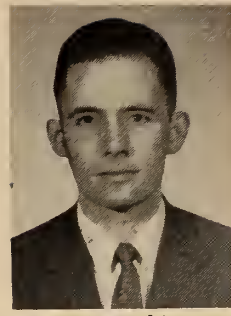
W. R. Coles, JR.E.I.C., (B.Eng., civil, McGill 1951) is in Geneva, Switzerland, attending the Centre d'Etudes Industrielles.

G. R. Begley, JR.E.I.C., (B.Eng., elec., McGill 1956) project officer for National Scientific Laboratories for ground controlled approach radar installations of the R.C.A.F., transferred in October 1958 to H.F. communications installations, employed by the Canadian government.

S. B. Smith, JR.E.I.C., (B.Eng., mech., McGill 1949; Eng.Sc.D., management engineering, Columbia 1958) is the manager of business policy and methods research, semiconductor division, for the Raytheon Manufacturing Company, Boston, Mass.

J. H. Westaway, JR.E.I.C.

S. B. Smith, JR.E.I.C.



A. M. White, JR.E.I.C.

S. G. Bruskiewich, JR.E.I.C., (B.Sc., mech., Saskatchewan, 1956) technical officer in the Royal Canadian Air Force has been transferred from France to headquarters in Ottawa.

A. M. White, JR.E.I.C., (B.A.Sc., mech., British Columbia 1949) has accepted a position with the Kaohsuiung Ammonium Sulfate Corporation Ltd., in Taiwan, China.

R. A. Plouffe, JR.E.I.C., (B.A.Sc.,) mech. and electrical, Ecole Polytechnique, 1951) of the Quebec branch of Canadian Westinghouse Company Limited, has been transferred to the company's Montreal office as manager, Agency and Resale, Eastern District.

A. H. Ruel, JR.E.I.C., (B.Sc., civil, Ecole Polytechnique, 1953) is now resident engineer for Beauchemin, Beaton & Lapointe, consulting engineers, Montreal.

W. C. Moffatt, JR.E.I.C., (M.Sc., mech., Queen's 1958) is at Massachusetts Institute of Technology to do post-graduate work in mechanical engineering.

J. H. Westaway, JR.E.I.C., (B.Sc., mech., Queen's 1952) former project engineer with Potash Company of America Ltd., Saskatoon has joined Dustbane Manufacturing Co. Ltd., Ottawa as manager, machine division.

C. V. MacLachlan, JR.E.I.C., (B.Eng., elec., McGill, 1950) is manager of the Public Utilities Commission at Ingersoll, Ont.

NEWS OF THE

Associations and Corporation

Information received through co-operation of the provincial organizations.

PRINCE EDWARD ISLAND

Officers Elected

The Association of Professional Engineers of Prince Edward Island announce new officers, as follows: president, L. A. Coles, Summerside; vice-president, R. D. Donnelly, Charlottetown; past president, C. W. Currie, Charlottetown; councillors, A. D. Cameron, J. L. Boomhower, C. H. Stewart, and W. S. Veale, all of Charlottetown.

QUEBEC

Engineering Activity in Quebec

Guillaume Piette, president of the Corporation of Professional Engineers of Quebec made some observations about engineering recently.

We can anticipate, he said, that in five year's time Quebec universities may graduate 1,000 new engineers per year as a result of the construction, by the provincial government, of the new Ecole Polytechnique, the establishment of a new School of Engineering at Sherbrooke and major additions to existing engineering faculties now underway or in the planning stages.

Mr. Piette said that in Quebec, more and more young men are turning to engineering careers, as witnessed by the tremendous increase in the enrolment since the end of the war.

The Corporation, he said, had undertaken an informal survey to determine the number and value of major engineering construction projects ($1,000,000 or more) undertaken, underway or completed in Quebec.

The survey uncovered some 150 such projects representing a total value of more than 2 billion dollars. Of these, roughly half, valued at one billion dollars, were in the Montreal area alone.

"This is far from being the complete picture," Mr. Piette emphasized. The figures represented only part of the engineering projects being worked on in 1958. There are probably many other projects of $1,000,000 or more. Moreover the sum of all smaller engineering projects might raise the total figure to well over $3 billion.

"And, of course, we have not taken into account the equally important but more difficult to measure achievements that are taking place in the fields of manufacture and production", he stated. "It is evident from the picture of the province's development in all fields of engineering during 1958 that most of our engineer members were very busy indeed".

ONTARIO

Annual Meeting, January

Speaking at the annual meeting of the Association, January 24, Col. T. M. Medland, executive director, stressed the need for an atmosphere "in which our engineers may grow professionally by providing technicans and clerical assistance that will enable the engineer to have time to think and to create". There was also room, he said, for increasing the awareness of professional attitude among the profession.

It is for every professional engineer who moves into management to remember that he still owes an allegiance and obligation to his profession and its members, and it is for the younger engineer to display a trust and confidence in those for whom he works," he stated.

BRITISH COLUMBIA

Councillors appointed

B.C. Government appointments to the council of the Association have been made since the annual meeting in December. These councillors are: C. B. Archibald, P.Eng., F. A. MacLean, P.Eng., O. Safir, P.Eng., and M. A. Thomas, P.Eng.

"Forward March"

Abstract of an editorial by President R. E. Wilkins, from "The B.C. Professional Engineer", January, 1959.

Last year we all recognized as being one of economic consolidation, and rightly so. This year there are many signs which indicate we must ensure that our professional development is such that we will be able to contribute our best to this inevitable and tremendous growth of our province.

During the past ten years the number of registered engineers within British Columbia has increased by 100 per cent. We now have 2,200 registered engineers and the potential addition, within two years, of another 700 who are now employed as engineers-in-training within the province.

A large number of these engineers will be participating as key men in the economic development of British Columbia and they can have a tremendous influence for good, perhaps a greater influence than any other segment of the community.

With this growth in our numbers and our influence, we must not lose sight of the fact that while our certificate of registration entitles us to certain rights and privileges it also imposes upon us very definite obligations and responsibilities. The extent to which our right to practice is respected by others depends both upon the deportment of the individual and the collective actions of our Association. We must strive continuously for a higher standard of individual competence, and greater stature and dignity for the Association.

Prior to 1949, the work of the Association was largely done by a comparatively small number of engineers who selflessly dedicated a large part of their time to developing the firm foundations upon which we have since built. We owe these engineers a great debt of gratitude.

Since 1949 there has been an ever increasing number of engineers who, by service in an expanding number of committees of the Association, have made many significant contributions. Thus, it is not necessary for a member to be elected or appointed to Council to be of service to the Association. At best, Council can serve as a registration body and formulate and execute action on matters of major policy. There is a vast amount of other work to be done by committees and individuals.

Each member of the Association has an obligation to share in the work of the Association and to contribute personally toward the enhancement of the practice of professional engineering within and without the province.

We have the organization; we have the strength; let us all march forward in unity and strive for a greater quality and pride in our profession.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings

BELLEVILLE

D. A. Law, JR.E.I.C., *Correspondent*

JOHN G. TODDS, manager, operations research, Northern Electric Co. Ltd., Montreal, addressed the branch on February 9.

Operations research originated with the military during World War II, and was adapted to industry in the early '50's. Management problems can be solved mathematically by using models fitted to raw data and manipulating relatively common formulae to fit the problem within specified limits.

BROCKVILLE

J. R. Eastwood, M.E.I.C., *Correspondent*

DR. KENNETH F. TUPPER, president of the E.I.C., was guest of honour at a meeting of January 21. The members enenjoyed hearing his reminiscences of a recent trip to Russia.

CAPE BRETON

H. M. Aspinall, M.E.I.C., *Correspondent*

THE ANNUAL BUSINESS MEETING took place on December 10, 1958, in Sydney.

Elections resulted in the following slate of officers: Chairman, W. L. Dodson; vice-chair., C. A. Campbell; secretary, H. M. Aspinall; treasurer, H. C. Maitland; executive members, R. Bradley, L. Boutillier, J. Laffin, R. Bezanson, P. Terry and J. Stevens.

This meeting also considered the setting-up of a scholarship fund for the benefit of engineering students in the area.

Activities for 1958 closed with a New Year's Eve party for members, wives and friends.

FREDERICTON

Lyle W. Smith, JR.E.I.C., *Correspondent*

DONALD SLACK, engineer, maintenance of way, Canadian National Railways, Atlantic Region, spoke at the meeting of January 19, 1959. He described the C.N.R. hump yard at Moncton, the initial cost of which will be $17 million. Great savings in operating costs will be effected by this installation, and speedier delivery of goods will result from ease of handling large volumes of traffic.

HAMILTON

J. R. Currie, M.E.I.C., *Correspondent*

CANADA'S AIRWAYS OF THE FUTURE were illustrated by Harold J. Connolly for members of the Branch attending a meeting of January 15. Mr. Connolly is director of the construction branch, Department of Transport, Ottawa.

Following a reception and dinner, the Branch reports for 1958 were given, and the installation of new officers took place. The officers: H. G. Seely, chairman; R. G. Stevenson, vice-chairman; J. R. Harbell, secretary; new executive members, P. J. McNally, M. M. Kennedy, H. K. Crean, and W. J. Hohn.

MONTREAL

K. L. Pinder, M.E.I.C., *Correspondent*

THE TECHNOLOGY OF WINE was considered by the Chemical Section at a meeting of December 3, 1958, with the help of guest speaker A. deChounac, director of research T. G. Bright & Co. Ltd., Niagara Falls, Ont.

Wine making being the first chemical engineering process, it merits historical study, Mr. deChounac believes. He described the making of Canadian wines, demonstrating with samples of Canadian champagne, and illustrating with a movie.

NIPISSING AND UPPER OTTAWA

D. J. Thornton, S.E.I.C., *Correspondent*

LOW TEMPERATURE Properties of Lubricants and Hydraulic Fluids was the subject of a talk given by A. G. "Bert" Almack, industrial sales manager of Imperial Oil Limited, Toronto, at a meeting of the Branch on December 9, 1958.

He covered: temperature vs. viscosity; hydraulic fluids, engine crankcase oils and automotive gear lubricants, and took part in an interesting discussion.

PETERBOROUGH

J. G. Hooper, M.E.I.C., *Correspondent*

PRESIDENT K. F. TUPPER, and Mrs. Tupper, Dr. Garnet Page and Mrs. Page visited Peterborough on January 15.

Highlights of the visit were: an afternoon branch executive meeting with the president; evening stag dinner for 65, Dr. Tupper giving his impressions of the Soviet Union and Dr. Page showing slides of their recent trip to Russia. In addition there was a cocktail hour and buffet supper for Mrs. Tupper, Mrs. Page and Mrs. Robertson, arranged by the Women's Auxiliary.

SARNIA

C. M. Stewart, JR.E.I.C., *Correspondent*

SARNIA engineers had the opportunity of hearing Dr. Kenneth F. Tupper, E.I.C. president, speak about Russia's strides towards industrialization, on November 25. Dr. Tupper spoke of possible reciprocal visits of Russian and Canadian engineers and scientists.

The visit of Dr. Tupper and General Secretary Garnet Page was made the occasion of a dinner dance, attended by some 100 members and their wives.

SUDBURY

F. Jackson, M.E.I.C., *Correspondent.*

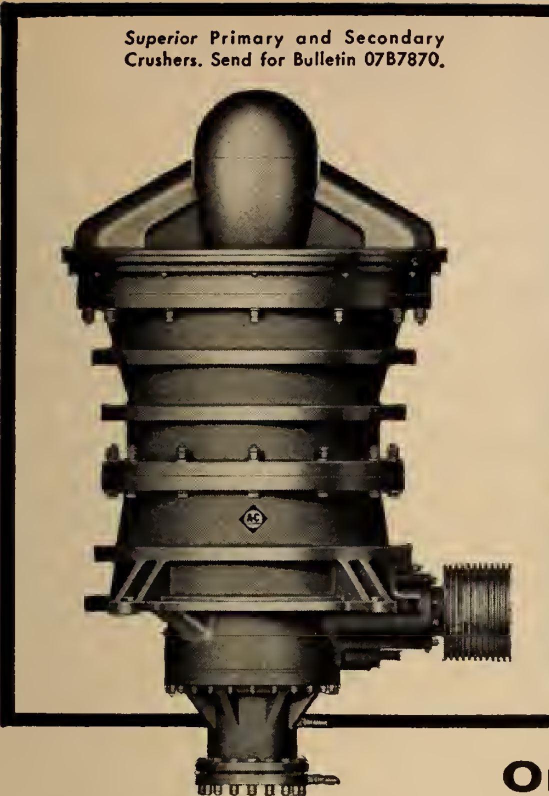
HYDRAULICS IN INDUSTRY was the subject discussed by C. F. Smith, manager, manufacturing division, Vickers, Sperry Ltd., at a branch meeting of February 12, 1959.

THE FIRST CENTRAL ONTARIO REGIONAL TECHNICAL CONFERENCE was announced by George Charlap, who is chairman of the organizing committee. The general theme is to be Engineering Outlook in Canada in the Next Twenty Years.

GRAHAM P. KEMP, M.E.I.C., sales engineer of Worthington Canada Ltd., talked to the members at a meeting of January 15 on Design and Selection of Pumps for Various Service. He had some advice for customers selecting pumps, and he answered questions after his address.

REGINA SECTION

THE WINTER FROLIC was held Friday evening, November 28, in the Shrine Temple ballroom. Jim Crate, social chairman of the Regina section was in charge of arrangements for the social season highlight. Ralph Cook, a member of the social committee, was master of ceremonies. Mrs. L. T. Holmes, social chairman of the Professional Engineer Wives, and her committee were in charge of decorations.

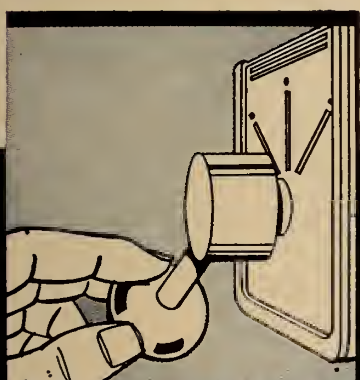


Superior Primary and Secondary Crushers. Send for Bulletin 07B7870.

Hydrocone Secondary and Tertiary Crusher. Send for Bulletin 07B7145C.

Only Allis-Chalmers gyratory crushers have exclusive

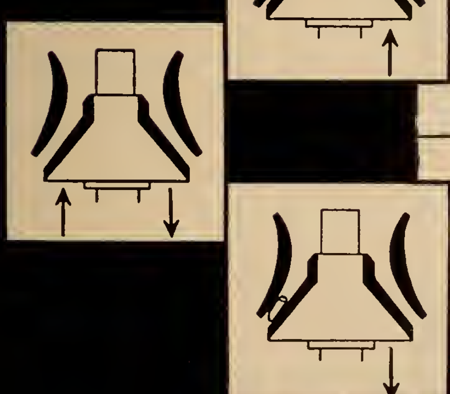
Hydroset mechanism...



HUNDREDS of crushing operators around the world have improved their plant efficiency and tonnage with Allis-Chalmers gyratory crushers equipped with *Hydroset* mechanism. This remarkable design feature has provided economy and convenience in crushing a wide range of materials — from andesite to zinc ore, and including the crushing of taconite in the world's largest crusher. No other gyratory crusher even approaches the time-saving advantages of "one-man, one-minute" product control offered by Allis-Chalmers crushers equipped with *Hydroset* mechanism.

"One-Man, One-Minute" product control

Hydroset mechanism raises or lowers the mainshaft hydraulically in less than a minute — at the flip of a switch.



Compensates for wear on mantle and concave ... saves hours of production time — with the flip of a switch.

Changes crusher settings in less than a minute — with the flip of a switch.

Clears crushing chamber in case of power failure or other emergency — with the flip of a switch.

Your nearest CA-C Sales Office will gladly give you all the details. Or write Canadian Allis-Chalmers Limited, P.O. Box 37, Montreal, P.Q.

CANADIAN ALLIS-CHALMERS

Superior, Hydrocone and *Hydroset* are Allis-Chalmers trademarks.

58-MM-2

Annual awards for engineering achievement were presented to Lloyd T. Holmes, deputy minister, Saskatchewan Department of Highways, Ken R. Pattison, city engineer, City of Regina and Karl W. Allcock, operating superintendent of the Saskatchewan Power Corporation.

TORONTO

Gordon F. R. Norton, JR. E.I.C., *Correspondent*

PAUL H. MILLS, Q.C., spoke at the meeting of November 20, on the subject of "Some Observations on Engineering Contracts."

Mr. Mills outlined two recent court cases, concerning construction contracts.

The speaker reflected for a short time, on his recent trip to Greece, and suggested that engineers who were retired, could find good use for their talent in assisting under-developed countries through the Colombo Plan.

The Branch welcomed as guests to this meeting the members of the A.I.E.E., Toronto Section.

THE ANNUAL MEETING of the branch took place on January 15, with 32 members and guests attending. Chairman Harvey Self moved the business along at a lively pace.

F. G. Gardiner, Toronto's super mayor, was the guest speaker, his timely subject: Suburbia Explodes.

STUDENTS NIGHT was held in Hart House on January 29, A. C. Davidson chaired the meeting which was arranged as a quiz contest. W. Larri was the moderator; the judges were E. Potter, M. J. Simpson, and M. Kitchen; timekeepers, G. Bonham, and R. Shaeff. In the final analysis the Mining engineers won out, with Engineering Business a close second, followed by the Mechanical boys.

VANCOUVER

J. J. Kaller, M.E.I.C., *Correspondent*

AT A NOVEMBER 19 MEETING organized by the Structural Section R. Clough, M.E.I.C., presented a lecture on Welding Failures. Mr. Clough used various examples of failure of welded construction to bring out many points necessary for the sound design of simple and complex welded structures.

ON NOVEMBER 26 branch members made a tour of the facilities of the B.C. Telephone Company, with particular emphasis on the B.C. portion of the trans-Canada micro wave system.

AT THE DECEMBER 3 MEETING, Peter Schearer, a Swiss engineer, working on a snow slide and avalanche problem at Glacier, B.C., gave a talk on Avalanche Observation and Control. The subject proved interesting to B.C. engineers, who sometimes have to contend with similar conditions. The Soils Group collaborated in this meeting.

OTTAWA

A. H. Graves, JR.E.I.C., *Correspondent*

W. L. KEAY, engineer in charge of sewage and drainage branch, Planning and Works Dept., City of Ottawa, discussed proposed new sewage disposal plant to be constructed at an estimated cost of $8,650,000. Approximately 70 persons attended, on December 4, 1958.

CENTRAL BRITISH COLUMBIA

A. F. Joplin, M.E.I.C., *Correspondent*

LES McLEAN spoke at a meeting on January 30, on the subject The Expanding Universe, The Amazing Universe. Interest was shown in Mr. McLean's subject by the many questions asked.

CHALK RIVER

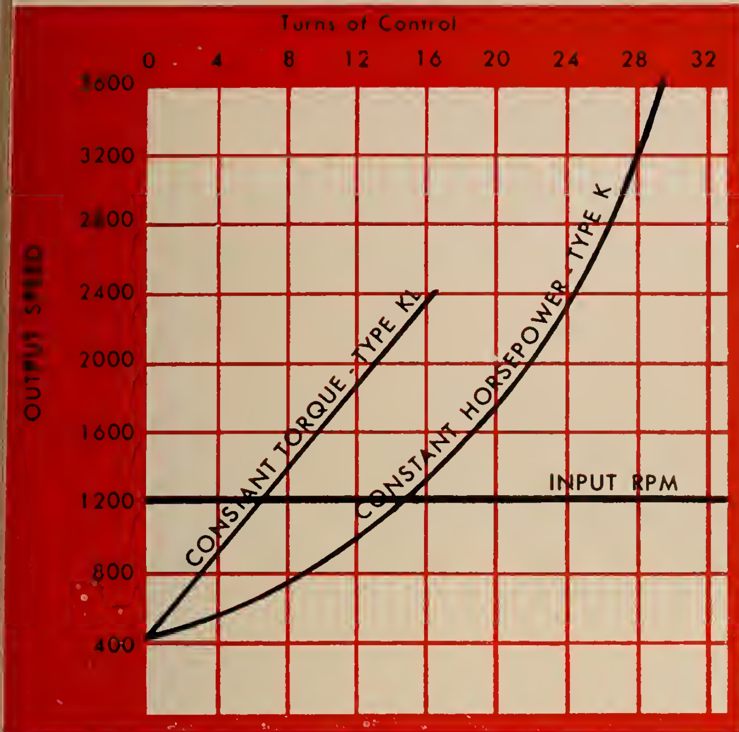
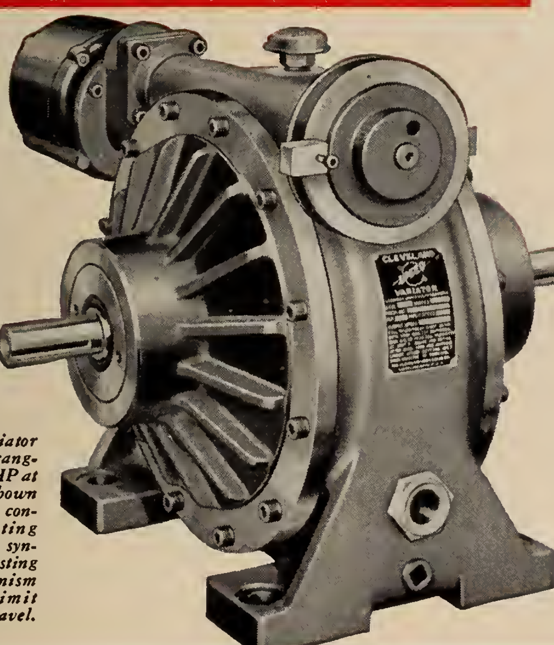
THE POLICY OF POLLUTION CONTROL and its effects on N.B. industry and citizens was the subject of a panel discussion at



CLEVELAND SPEED VARIATOR

Accurately Provides Dependable, Infinitely Variable Speed Control

Typical speed regulation curves for the Types K and KL Variators. Type KL offers a linear speed regulating pattern, often an advantage in automatic control applications. Output speed regulation of the Type K Variator follows a geometric progression pattern. Starting at the minimum output speed, each turn of the speed regulating wheel produces a fixed percentage increase in output shaft speed.



The Cleveland Speed Variator is available in 18 models ranging from fractional to 16 HP at 1750 input RPM. Unit shown at right, used in process control, has speed regulating worm driven by 75 RPM synchronous motor, with adjusting shaft indicating mechanism modified to actuate limit switches to prevent overtravel.

ANNOUNCED late in 1954, the new Cleveland Speed Variator met instant, enthusiastic acceptance. Engineers and designers of industrial equipment already have put thousands of units into use on such varied equipment as cigarette making machines, textile machinery, metalworking machinery, pharmaceutical equipment, transfer tables, conveyors and experimental and testing equipment of many types.

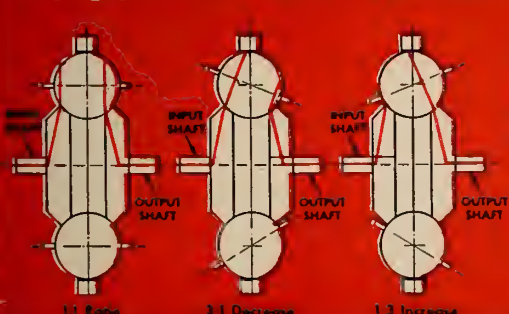
Infinitely variable, the Cleveland Speed Variator gives stepless speed over a full 9:1 range—from ⅓ to 3 times input speed. Output speed can be adjusted by either a hand wheel on the Variator or by manual or automatic remote control.

The Cleveland Speed Variator offers these major advantages:

1. An extremely compact unit with input and output shafts in line and rotating in the same direction.
2. Almost any input speed up to 1800 RPM can be used—either clockwise or counterclockwise rotation.
3. Rated for constant horsepower output over a 9:1 or 6:1 range; or for constant output torque over a 6:1 range.
4. Speeds infinitely variable over entire range of adjustment.
5. No slippage—positive torque response mechanism adjusts in direct proportion to the loads encountered.
6. Long life and minimum maintenance due to absence of belts or complicated linkages.
7. Ample bearing support for overhung pulleys on both input and output shafts.

Write for Bulletin K-200 for detailed description with photographs, sectional drawings, rating tables and specifications.

HOW THE CLEVELAND SPEED VARIATOR WORKS



Power is transmitted from input shaft to output shaft through alloy steel driving balls which are in pressure contact with discs attached to the two shafts.

Relative speeds of the shafts are adjusted by changing the positioning of axles on which the balls rotate (diagram, right, shows cutaway Variator with hand regulating wheel).

"It's the Drive That's on the Ball."

PEACOCK BROTHERS LIMITED

P. O. Box 1040 • Montreal

SYDNEY • TORONTO • SUDBURY • WINNIPEG • EDMONTON • CALGARY • VANCOUVER a meeting on December 15. The speakers were Dr. Bates, of the N.B. Water Authority, Alwin Cameron, provincial sanitary engineer, and Ronald Bemrose, superintendent of Oromocto sewage disposal plant.

The N.B. government has legislation covering waste disposal into rivers and coastal waters, Mr. Bates reported. New Brunswick can avoid the serious trouble encountered by other highly industrialized areas, Mr. Cameron said. Atomic pollution, in particular, would affect such important N.B. resources as fishing and the tourist industry.

Mr. Bemrose explained the operation of the Oromocto sewage treatment plant, which helps to prevent overpollution of the St. John river.

HALIFAX

W. J. Phillips, M.E.I.C., *Correspondent*

The annual meeting of the branch was held December 15, 1958. The following officers were elected: chairman, W. J. Phillips, vice-chair., H. A. Marshall, sec.-treas., J. E. Reardon; executive, J. G. Belliveau, J. R. Cameron, K. R. Mitchell, G. MacD. Haliburton, B. E. Langley, R. B. Webber, G. F. West, H. L. Archibald, C. I. Cameron, H. W. Doane

LAKEHEAD

R. L. Wimperis, JR.E.I.C., *Correspondent*

The annual meeting of the Branch was held on December 12. Reports from the chairman and the committees on finance, papers, entertainment and membership showed a successful year, with good attendance at meetings.

Elections resulted in the following list of officers: chairman, L. F. Mason-Tulby; vice-chair., N. Paoline; sec.-treas., R. L. Wimperis; executive, W. Hogg, W. B. Sproule, O. Dodson, K. R. Johns.

LAKEHEAD

G. O. Hanson, JR.E.I.C., *Correspondent*

T. C. Keefer, field secretary of the Association of Professional Engineers of Ontario was the speaker on February 9. His subject was the salary survey conducted in Ontario and Quebec. The salary survey will help to promote the professional status of engineers, removing one barrier in the employer-employee relationship.

D. B. McKillop gave a report of a meeting of Council of the E.I.C. in January. Mr. McKillop's belief was that Confederation could be accomplished within the next eighteen months. This was welcome news to the Branch. J. Ryhmes gave a brief report of a meeting of council of the A.P.E.O. which he had attended.

LETHBRIDGE

G. G. Campbell, M.E.I.C., *Correspondent*

A. E. Palmer, discussed Construction Methods in West Pakistan at a meeting of January 17, 1959. He has spent two years in Pakistan on a Colombo Plan appointment.

In construction of dams, roads, irrigation works and buildings, manual labour is used wherever possible, to relieve the 50 per cent unemployment figure.

Remarkable progress has been made in Pakistan to improve agricultural and industrial output. Paper and textiles have become, in a very short time, items produced there and exported. The main purpose of increasing exports is to enable Pakistan to buy food from other countries.

PETERBOROUGH

J. G. Hooper, M.E.I.C., *Correspondent*

The branch entertained the general secretary Dr. Garnet Page and Mrs. Page on December 10, 1958. While Dr. Page met with the members, Mrs. Page was entertained by the ladies' Auxiliary.

Dr. Page reviewed the work of the E.I.C., its purposes and objectives. Dr. Page also gave an interesting commentary to his film coverage of his

FLOOD CONTROL AND HYDRO ELECTRIC POWER IN THE FRASER RIVER was the subject of a panel discussion at a meeting on January 21, 1959. Moderator was: A. F. Paget, M.E.I.C., provincial water comptroller; panel members were: G. S. Andrews, T. A. J. Leach, and G. E. Simmonds.

The history of the Fraser River board was outlined. There was also discussion of surveying methods, hydrology of the watershed and flood control and power development schemes, which form parts of the recently completed Fraser River Board project.

CALGARY

Neil Carr, M.E.I.C., *Correspondent*

FISH AND POWER ON THE RIVERS OF B.C. was one subject discussed at a meeting of January 22, by the Hon. James Sinclair, president, Fisheries Association of B.C. W. F. McMullen, personnel manager, Canadian General Electric Co., Toronto, Ont., spoke on the subject of Changes in Engineering Utilization.

Mr. Sinclair spoke against damming the Fraser river. The combined potential of the Peace and Columbia rivers will provide adequate power for 20 years, in his opinion. The $80-million fishing industry could be doubled in the next 50 years, if the river is not developed for power, he said.

The role of the engineer is changing, Mr. McMullen said, now that he is beginning to have the aid of technicians, and the use of computer as a tool. His job is not to apply proven principles but to prove new ones, in the view of Mr. McMullen.

WINNIPEG

P. M. Abel, JR.E.I.C., *Correspondent*

NATIONAL RESOURCES PLANNING IN MANITOBA was summarized on January 29 by S. W. Shortinghuis, assistant deputy minister, Mines and Natural Resources, Manitoba. The speaker described the aims, problems and policy in the fields of forestry, fisheries, furs, water resources, flood and erosion control, big game, provincial parks, geologic surveys and mining, and soil surveys, etc.

The speaker also commented on the Arthur D. Little report, "Economic Survey of Northern Manitoba."

This was the annual meeting of the branch, at which reports of the year's activities were given. A new slate of officers was introduced by the new chairman, W. L. Wardrop.

• OTHER SOCIETIES

Association of Consulting Engineers of Canada

At the first phase of the annual meeting of the Association, held on February 16, C. C. Parker, M.E.I.C., of Hamilton, Ont., was named president for the coming year.

J. G. Frost, M.E.I.C., of Montreal, retiring president, was heartily congratulated upon his work. Vice-president of the Association is R. R. Duquette, M.E.I.C., Montreal; J. H. Ross, M.E.I.C., Toronto, is honorary secretary-treasurer. The Board of Directors is now composed of: C. C. Carruthers, M.E.I.C., Toronto; J. E. Dion, M.E.I.C., R. R. Duquette, M.E.I.C., J. A. Kearns, M.E.I.C., Montreal; N. H. Lawrence, M.E.I.C., Edmonton; A. D. Margison, M.E.I.C., J. H. Ross, M.E.I.C., Toronto; C. C. Parker, M.E.I.C., Hamilton. Ex-officio members of the Board are three immediate past presidents: J. G. Chenevert, M.E.I.C., Montreal; J. F. MacLaren, M.E.I.C., Toronto, and J. G. Frost, M.E.I.C., Montreal.

R. G. Gould, secretary for the past eight years has resigned. He is succeeded by Col. J. M. Muir of Toronto.

The second phase of the annual meeting will convene June 9, 1959, at the Royal York Hotel, Toronto.

Fifth Nuclear Congress
Cleveland, Ohio, April 5-10, 1959.

the most powerful data processing system in its field

First fully transistorized IBM computer, the new IBM Seven-O-Seventy provides remarkable operating features for both business and science. Capable of handling complex calculations and everyday accounting problems, the IBM 7070 saves time, work and money.

Transistor design reduces space requirements, lowers initial costs and keeps your operating costs low. Also, it can give you information on your business previously impractical to obtain because of the cost. This helps you make decisions faster and helps you plan the growth of your business on a sounder, more factual basis.

And unexcelled IBM services—ranging from program planning to personnel education—work for you, helping to speed profitable operation and bring a maximum return on your data processing investment. For more complete information on the new IBM 7070 call an IBM representative today.

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*MODERN SAFETY PRACTICES

Stresses the need for designing safety programs to conform to modern management practices and newly developed and tested concepts of safety organization and administration. The safety program is presented in four phases: the development of safe working conditions; job hazard analysis and personalized safety training; promotion of employee safety participation; enforcement of safety rules. Among other features, the book outlines consultative methods for safety engineers. (R. DeReamer. New York, Wiley, 1958. 357p., $7.00.)

*INTRODUCTION TO THE DESIGN OF SERVO-MECHANISMS

Gives a basic explanation of stability and feedback design, both single and multiple loop. The author attempts to provide a systematic approach to design problems and the principal performance requirements entailed such as harmonic response, time response, error coefficients, and noise response. Attention is also given to the common aspects of non-linear operation, and an appendix is included which covers servo-mechanism components. (J. L. Bower and P. M. Schultheiss. New York, Wiley, 1958. 510p., $13.00.)

EMPIRE AND COMMONWEALTH YEAR BOOK, 1958-9

The seventh edition of this useful reference work contains for the first time a cost of living index for Commonwealth countries, and a list of principal banks in all countries. The book is divided into three sections, the first of which contains miscellaneous information on Commonwealth organizations, trade, conferences, etc. The second section gives for each of the 80 countries and territories information on geography, climate, history, constitution, government, communications, area, population, education, trade, etc. The final section gives statistics on the production of raw materials and commodities in the Commonwealth. (Ed. by R. S. Russell. London, Newman Neame, 1958. 569p., 50/-.)

*ECONOMIC OPERATION OF POWER SYSTEMS

A presentation of new analytical and computing techniques that have resulted in significant savings for electric utilities. The author shows how matrix methods are employed to derive transmission-loss formulas, which form the basis for computational procedures utilized in digital computers. The application of analogue and digital computers to the problems of calculating transmission-loss formulas and generation schedules is also treated. (L. K. Kirchmayer. New York, Wiley, 1958. 260p., $12.00.)

DIE WISSENSCHAFTLICHE FACHBIBLIOTHEK

This volume is written mainly for Special Library librarians, who have no formal training. It serves as a methodical introduction to the work, and as a foundation for further development. It discusses the position and the operation of a library in an industry or a scientific institution, and gives the basic concepts and practices of daily library work. (J. Bramer and D. Vogel, Leipzig, Veb Otto Harrassowitz, 1956. 177p. DM 8,20.)

*KNOCKING CHARACTERISTICS OF PURE HYDROCARBONS

A study of a wide variety of pure hydrocarbons for the purpose of relating their structures and physical characteristics to their respective knock limitations in engines. Various engine types and operation procedures were utilized to take into account the effect of these variables on knock ratings. The study was developed under the American Petroleum Institute Hydrocarbon Research Project. (Philadelphia, American Society for Testing Materials, 1958. S.t.p. no. 225, 96p., $6.00.)

*THEORETICAL ELECTROMAGNETISM

Covers the following areas: electrostatics, magnetostatics, electromagnetic induction, Maxwell's equations and circuit concepts, electromagnetic waves, and a selected group of worked out problems in electrostatics. Vector methods are used throughout and the rationalized meter-kilogram-second-coulomb system of units has been adopted. (W. R. Myers. Toronto, Butterworth, 1958. 274p., $8.50.)

PROGRESS IN CARGO HANDLING, VOL. 2

The emphasis at the Third General Technical Conference of the International Cargo Handling Co-Ordination Association reported in this volume was on methods of improving the handling of merchandise on board ship. The papers and discussion in this section covered the handling of general cargo; research in cargo handling; the use of the pocket elevator; stowage; and container ship design.

The second symposium considered the marking of general cargo, and the handling of frozen meat. The third symposium discussed containers, and the fourth fruit handling. (Toronto, British Book Service, 1958. 306p., $12.75.)

*VISTAS IN ASTRONAUTICS. FIRST ANNUAL AIR FORCE, OFFICE OF SCIENTIFIC RESEARCH, ASTRONAUTICS SYMPOSIUM

The forty papers included in this symposium are presented under six major headings: re-entry problems of satellite vehicles, both dynamic and thermodynamic; tracking and communications for satellites and other space vehicles; environment and measurements, radiations in the high atmosphere; propulsion of space vehicles, including the plasma jet; orbit study and control; human factors in connection with space flight. (Ed. Morton Alperin and others. New York, Pergamon Press, 1958. 330p., $15.00.)

*THE PLASMA IN A MAGNETIC FIELD: A SYMPOSIUM ON MAGNETOHYDRODYNAMICS

Papers examining how magnetic fields influence and are influenced by plasmas. Section one deals with simplification of the orbit analysis of important configurations, while section two deals with the instability occurring at the interface between a plasma and a magnetic field. The concluding section deals with the transfer of energy between a magnetic field and a plasma. (Ed. by R. K. M. Landshoff. Stanford, Calif., Stanford University Press, 1958. 130p., $4.50.)

*AIRCRAFT AND MISSILE PROPULSION, VOL. 2

This volume, which is the second in a series of three, discusses the methods for analyzing and determining the performance characteristics of the gas-turbine power plant, the turboprop engine, the turbojet engine, the ramjet engine, and the liquid propellant and solid propellant rocket engines. Deriva-

tions of the principal equations are explained in detail, and a large number of exercise problems are included along with the answers. A considerable number of references are included at the end of each chapter. (M. J. Zucrow. New York, Wiley, 1958. 636p., $13.00.)

DESIGN OF AIR CONDITIONING SYSTEMS

Intended as a companion volume to the author's Design of Heating and Ventilating Systems, the emphasis in this book is on techniques of solving problems in air conditioning. Graphical solutions are given for many of the equations, and the use of the graphs will eliminate much calculation. The book covers psychrometrics, the cooling load, solar energy, comfort levels, air flow through ducts and fittings, the noise problem and panel cooling design. (F. W. Hutchinson. New York, Industrial Press, 1958. 336p., $7.00.)

ELECTRIC FURNACES

The industrial applications of electric furnaces are discussed in this volume which commences with a brief description of the three types: arc and induction for high temperature; induction and indirect resistance for low temperatures; and high-frequency capacitance heating and indirect-heat resistance furnaces for non-metallic materials. The industries considered include metal, glass, pottery and plastics. This is a most useful volume. (Ed. by C. A. Otto. London, Newnes, 1958. 248p., 35/-.)

LINEAR PROGRAMMING FUNDAMENTALS AND APPLICATIONS

Intended primarily for management, this volume presents the fundamentals of linear programming and its applications in non-technical language. After a brief introductory section, the second section considers methods used, including two developed by the authors, and a time-saving refinement, MODI, of another of their methods. In the chapters on applications, examples are taken from actual case studies. There is a useful bibliography, and the appendix contains a mathematical description of the Simplex Method, and a comparison of the Simplex and Modi Methods. (R. O. Ferguson and L. F. Sargent. Toronto, McGraw-Hill, 1958. 342p., $10.00.)

°BEMESSUNGSVERFAHREN, 16TH ED.

A manual of design procedures which are in accordance with the specifications and codes of the German Committee on Reinforced Concrete. It covers exterior forces on structures, bending, torsion, shear stresses, bond stresses, materials, flat slabs, special reinforcements, and various special cases such as roof slabs with glass inserts. The text is preceded by a list of the pertinent German (DIN) standards. (Benno Loser, rev. by Helmut Loser. Berlin, Wilhelm Ernst and Sohn. 1958. 351p., 26 DM.)

• LIBRARY NOTES

MINING EXPLOSIVES

Intended both for students and those engaged in mining and quarrying, this volume commences with a brief review of the history of explosives. The next six chapters describe the characteristics, composition and construction of blasting explosives and accessories. The next four chapters covers blasting in collieries, metalliferous mines, quarries and opencast workings. The final chapters deal with the storage and transport of explosives, and accident prevention. The text is illustrated with line drawings. The authors have had considerable experience in the field. (R. McAdam and R. Westwater. London, Oliver and Boyd, Toronto, Clarke, Irwin, 1958. 187p., $4.75.)

ELEMENTARY REINFORCED CONCRETE DESIGN, 2ND ED.

This new edition includes a comprehensive treatment of the load factor method of design permitted in the 1957 British Standard Code of Practice on the structural use of reinforced concrete in buildings. The Load Factor and Elastic Theory methods of design are compared, and chapters have been added dealing with retaining walls, prestressed concrete and beams of non-rectangular cross section.

The text is intended primarily for students. The topics covered include general structural mechanics, slabs and beams, columns and their footings, staircases and hollow tile floors. (W. Morgan. Toronto, Macmillan, 1958. 408p., $4.75.)

*PROGRESS IN SEMICONDUCTORS: VOL. 3

A selective review of current developments in the field of semiconductors that discusses the following topics: the magnetoresistivity of germanium and silicon; electronic conductivity of silver halide crystals; silicon junction diodes; lifetime of excess carriers in semiconductors; chemical purification of germanium and silicon; scattering and drift mobility of carriers in germanium; electronic processes in cadmium sulphide. (Edited by A. F. Gibson and others. New York, Wiley, 1958. 210p., $8.50.)

*REFERENCES ON FATIGUE

A list of references to articles published in 1957 dealing with fatigue of structures and materials. References are so arranged that sheets can be cut apart for filing according to any desired plan. Brief abstracts are included when readily available. (Philadelphia, American Society for Testing Materials, 1958. 64p. (s.t.p. no. 9-1) $3.00.)

*REPORT ON ELEVATED-TEMPERATURE PROPERTIES OF CHROMIUM STEELS

A graphic summary of the elevated temperature strength properties for chromium steels (12-27 per cent). It includes data on tensile strength, yield strength, elongation, rupture, and creep properties. Twenty-three alloys are covered ranging from 12 to 27 per cent chromium. (Philadelphia, American Society for

• LIBRARY NOTES

Testing Materials, 1958. 113p. (s.t.p. no. 228) $4.25.)

°COASTAL ENGINEERING, PROCEEDINGS OF THE SIXTH CONFERENCE, 1957

Papers dealing with wind, waves, and wind tides, with considerable emphasis on the hurricane; coastal sediment problems; coastal engineering problems; coastal structures and related problems; including breakwaters, wave absorbers, and sea walls. The theoretical aspects of the subject are covered as are specific problems in various localities. (Richmond, Council on Wave Research, Engineering Foundation, University of California, 1958, 896p.)

ON THE OLD LINES; LOCOMOTIVES ROUND THE WORLD, 2ND ED.

The author's personal record of the trains he has seen in thirty-seven countries. His photographs are nearly all of steam trains — he has little use for the diesel —and include coal burning, wood burning, narrow-gauge, wide-gauge, mountain railroads. Mr. Allen is fascinated by his subject, and so will his reader be. This second edition includes more photographs from Africa and Mexico. (Peter Allen. London, Cleaver-Hume, 1958. 190p., 25/-.)

STUDY OF SEVERAL AEROTHERMOELASTIC PROBLEMS OF AIRCRAFT STRUCTURES IN HIGH-SPEED FLIGHT

The emphasis in these reports is on dynamic aeroelastic effects. The first section deals with temperature within the structure, and stress and stiffness analysis of structures with temperature gradients. The second section considers aeroelastic phenomena, and discusses the determination of frequency response surface influences, flutter analysis, and panel flutter. This is a thesis written for the Eidgenossische Technische Hochschule in Zurich. (J. C. Houbolt. Zurich, Leemann, 1958. 108p., 12 Sw. Fr.)

°THERMODYNAMIC PROPERTIES OF WATER AND STEAM, 6TH ED.

Following preliminary material on the association theory of real gases, superheated steam, and the thermodynamic relations for dry saturated steam and boiling water, tables are given for the thermodynamic properties of water and steam up to pressure of 800-1000 a t a and temperatures of 1000°C. In setting up the tables for the high temperatures, the authors have extrapolated certain values from the experimental data available. The book is in four languages, English, French, Russian and German, printed in adjoining columns. (M. P. Vukalovitch. Berlin, VEB Verlag Technik, 1958. 245p., 20 DM.)

°CREATIVE THINKING

The major portion of the book is concerned with operational techniques of creative thinking, including group discussion methods and analytical or mechanical techniques that groups have found useful in stimulating new ideas.

Among those methods presented are the Gordon technique and brainstorming. The book concludes with descriptions of programs used by various corporations. (C. S. Whiting. New York, Reinhold, 1958. 168p., $3.95.)

GAS TUBES

Another in the basic electronics series issued by this publisher, this volume covers ionization in gases, gaseous rectifiers, gas tube voltage regulators, thyratrons and other types of gas tubes. The book is intended to explain the fundamentals of gas-tubes and their applications in electronics. (Ed. by A. Schure. New York. Rider, 1958. 72p., $1.50.)

LIGHT

Commencing with an explanation of the four concepts of the nature of light, corpuscular, wave, electro-magnetic and quantum, the book also covers in more detail reflection, refraction, the wave nature of light, the spectrum, both visible and invisible, optical instruments and illumination. (A. Efron. New York, Rider, 1958. 127p., $2.25.)

FUNDAMENTALS OF TRANSISTORS, 2ND ED.

This revised edition includes material on the theory, construction and operation of semiconductor devices such as surface barrier, intrinsic, drift, avalanche and spacistor types. The topics covered include semiconductor physics, the grounded base transistor, the grounded emitter and grounded collector transistors, transistor amplifiers and oscillators, and transistors at high frequencies. References are included. (L. M. Krugman. New York, Rider, 1958. 168p., $3.50.)

BASIC PULSES

A very basic "picture book" introduction to pulses, requiring some knowledge of electronics. It explains the composition, shaping techniques, measurement, generation and application of pulses, and is suitable for students, technicians and others wishing to study the subject at home or in class. (Irving Gottlieb. New York, Rider, 1958. 175p., $3.50.)

°PROCESS DYNAMICS

An examination of the characteristics of processes under unsteady-state conditions or in response to periodic disturbances. Those aspects treated include kinematics of materials handling; fluids in motion; forming, propulsion, and guidance; thermal process dynamics; mass transfer dynamics; chemical process dynamics. A special feature is the coverage given to methods for controlling process operations involving moving filaments, sheets and webs. (D. P. Campbell. New York, Wiley, 1958. 316p., $10.50.)

are Roy A. Nicholson Limited, Burlington, Ont. and Lord and Burnham Company Limited, St. Catharines, Ont. It is estimated that the film will last three winters and two summers on roof surfaces and five years on vertical exposures. It has been designed to withstand temperatures ranging from -60 degrees to 200 degrees Fahrenheit.

Hexagon Bolts. — The Steel Company of Canada, Ltd., Hamilton, Ont. has announced an important fastener industry simplification. The standard square head machine bolt and cap screws are being replaced in sizes ¼" through 1" diameter and 6" and shorter with a hexagon head and hexagon nut to be known as "Hexagon Bolts".

It is claimed that the advantages are improved quality, better appearance, lighter weight, easier and faster work on the assembly line. These new products will also simplify specifications and number of parts required for stock. For further details write to the company.

DuPont Sales — DuPont Company of Canada Limited has announced its sales in 1958 amounted to $81,680,000, an increase of 12 per cent over the previous year.

Railway Wage Agreement — Wage increases totalling nearly 10 per cent are included in the terms of a three-year agreement reached between the Canadian National Railways and 21,000 of its employes represented by the Brotherhood of Railway Trainmen. The agreement calls for wage increases in four stages and a number of rule changes. The employes affected are trainmen, conductors, baggagemen, brakemen, yardmasters, yardhelpers, switch tenders and yard-foremen.

Pirelli Expansion — Pirelli Cables, Conduits Limited has opened a new warehouse in Montreal, which has doubled the usable floor area to over 17,000 sq. ft. This new warehouse is one of a chain extending from St. John's, Newfoundland to Vancouver. In all branches heavy wire and cable stocks are kept on hand.

Dominion Bridge Change — Dominion Bridge Company, Limited recently announced that owing to the widening activities of its wholly-owned subsidiary, Standard Iron & Engineering Works Ltd., that organization will now be known as the "Edmonton Branch" of the parent company.

Esab Opens Canadian Office — Esab, a Swedish company, the founder of which, Oscar Kjellberg, originated the electrode and pioneered the craft of welding, has opened a Canadian office at 1215 Greene Avenue, Westmount, Montreal. There is also a warehouse branch at 222 Front Street East, Toronto. The name of the Canadian company is Esab Arc Rods Limited and it will be under the direction of Gustav Smith.

Water Resources. — The Ontario Water Resources Commission has announced the signing of preliminary agreement with three Ontario municipalities in regard to water and sewage projects.

Two agreements were signed with Mitchell whereby the Commission agrees to undertake the construction of sanitary sewage works as well as storm sewage works. The sanitary sewage system will involve the downtown residential and commercial area and the first stage of a sewage treatment plant.

An agreement with Leamington calls for construction of a storm trunk sewer system. In the township of Ancaster in the County of Wentworth, the OWRC will build water works for that township, including an elevated tank with a capacity of 750,000 gallons.

Underwriters' List — Underwriters' Laboratories of Canada, 7 Crouse Road, Scarborough, Ont. has commenced distribution of its September 1958 list of Inspected Appliances, Equipment and Materials. This supersedes the September 1956 edition and all supplements thereto. The new list consists of 230 pages and is 20% larger than the previous addition. For further information communicate with the Laboratories.

Construction Chemicals — A newly formed company, Construction Chemicals Limited, has been appointed Ontario distributor for the Dewey and Almy Chemical Division of W. R. Grace & Co. of Canada Ltd. President of the new concern will be Harold C. Pearson of Toronto, formerly of Westmount, Que. Mr. Pearson is retiring as vice-president of the Canadian Dewey and Almy division to form the new distributorship. He has had 45 years experience with Dewey and Almy.

Boiler Cleaner — Dow Chemical Company of Canada Limited has announced the development of a new technique for hydroxy apatite boiler scale removal. It is claimed that the process developed reduces downtime as much as 30 hours for high make-up industrial boiler cleanings.

The new technique makes use of chelating agents which are introduced into the boiler solution as a water solution and circulated at low pressures until the reaction is complete. For further details write to the company.

House Moving Equipment — Brantford Coach and Body Limited, Brantford, Ont. will be pleased to give further details of their equipment and method of moving buildings.

Recently they moved a two-storey triplex a distance of four city blocks in a very short time without a hitch. The house, measuring 50 ft. x 20 ft. x 26 ft. high and weighing 140 tons is, it is believed, the first occasion on which a Brantford Coach & Body designed and built Walking Beam Trunion did the job.

Write to the company for further details.

Paper Company Changes Name — The name of Mersey Paper Company Limited, Liverpool, Nova Scotia, has been changed to Bowater's Mersey Paper Company Limited.

Bowater's Mersey, Nova Scotia's second largest industry became a member of the Bowater organization in 1956. Current output is nearly 500 tons of newsprint a day from two machines.

INSTRUMENTATION, FOOD INDUSTRY

(Continued from page 86)

thought it took at least nine years or more to write-off his investment in instruments.

General Comments

"Where processes are varied and generally of an intermittent nature, operations do not lend themselves to complete automatic control", states the manager of a large canning industry. "In many cases processes are arranged for reversion to manual control where necessary, because of instrument failure, etc. With the coming automation in packaging, more accurate automatic temperature and quality control will be required."

"During past years many processes have been changed from batch type to continuous type of operation. The advantages are obvious and not achievable without many automatic control instruments. Simple and reliable flow measuring instruments for non-neutonian fluids are required. The existing type is still too inaccurate, too complicated and too expensive."

"In summary, the future of 'automation' in the food industry depends largely on further development of proportioning controls, applied to a wide variety and condition of food ingredients. It depends on parallel further development of automatic built-in quality control checks and corrective apparatus, and further improvement in sturdiness and reliability of instruments to avoid costly shut-downs of long continuous lines."

"Future trends are to a degree with us now", is the opinion expressed by a flour and cereal producer. "A punched card can start a process, operate it and shut it off when complete; in other words, push-button operation is today a reality. Without instrumentation and automatic process control of the food industry could not remain alive in today's competitive market. Greatly increased use of instrumentation is predicted as the food industry progresses toward more automation."

MEET THE AUTHORS

C. E. Frost, M.E.I.C., regional buildings engineer, eastern region, Bell Telephone Company, *(Quebec Labrador Tropospheric Scatter Radio System.)*

Mr. Frost graduated from McGill University in 1931 with a degree in civil engineering. He began to work for the Bell Telephone Company in 1937 until he joined the RCAF as a construction engineering officer in 1942.

In 1945 he returned to the Bell Telephone Company, and served as a member of the chief engineer's staff, and two years later was appointed special studies engineer. In 1951 Mr. Frost was appointed to the Regional Buildings Engineer's staff as construction contract engineer and was responsible for design and construction of structures to operate the first tropospheric scatter system installed anywhere in the world.

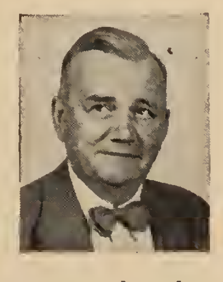
C. L. Emery, M.E.I.C., lecturer Queen's University. *(Design of a Functional Structure in or on Rock.)*

A graduate from Queen's University in 1936 (B.Sc. (honours), mining engineering) he received his M.Sc. there in 1958.

Mr. Emery has done mining, milling and field work in Ontario, British Columbia and Western United States. He has had experience in consulting, teaching and administration in high schools, technical institute and university.

At present he is doing consulting work in mining and structural design in Ontario.

Mr. Emery is a member of the Association of Professional Engineers of Ontario, of the A.S.E.E. and of the Canadian Institute of Mining and Metallurgy.



A. V. Corlett, M.E.I.C., Algoma Ore Properties Professor in Mining Engineering, Queen's University; and Head of the Department of Mining Engineering. *(Design of a Functioning Structure in or on Rock.)*

Professor Corlett received his B.Sc. degree in mining and metallurgy from Queen's University in 1922.

He has worked on oil well drilling in S.W. Ontario and Portuguese West Africa, on mining in Porcupine, on prospecting and exploration in Ontario, Quebec and Newfoundland. In 1936 he was mine manager in Western Quebec, and the Eastern Townships of Quebec for Aldermac Copper Corporation, later manager of the Normetal Mining Corporation. In 1958 he joined Queen's University staff and supplements his work by limited engineering consulting.

He is a member of the Professional Engineers of Quebec and Ontario and of the C.I.M., A.I.M.E. and A.S.E.E.

D. J. McDonald, M.E.I.C., area radio engineer, Toll Area, Bell Telephone Company, *(Quebec Labrador Tropospheric Scatter Radio System).*

Graduating from Queen's University in 1926 with a B.Sc. Mr. McDonald worked in various phases of transmission and radio engineering for the Bell Telephone Company of Canada.

His was the responsibility for direction of radio systems in the engineering of the "Pole Vault" system in Newfoundland and Labrador.

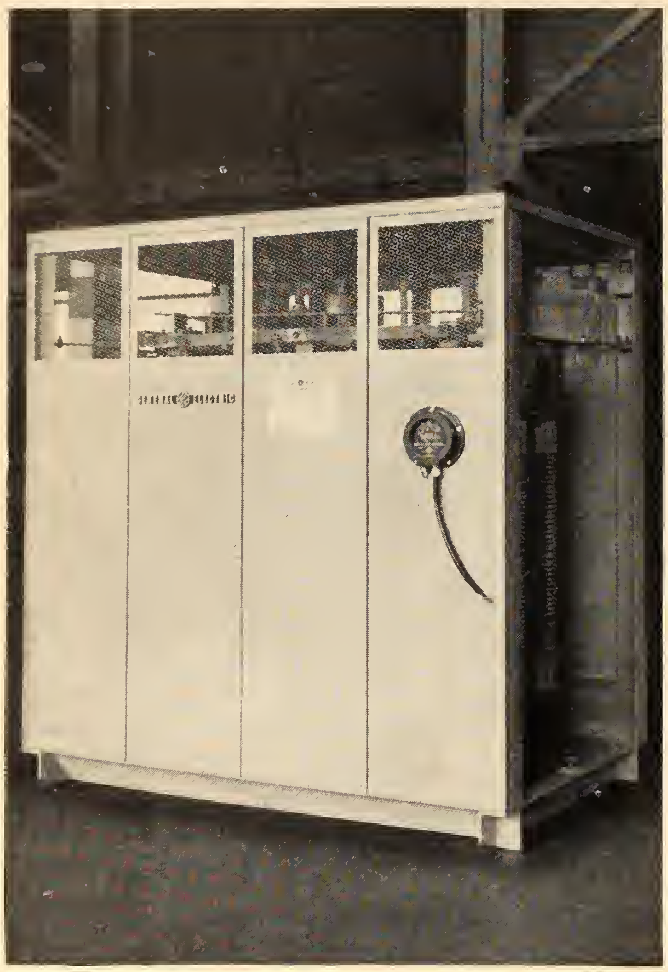
Mr. McDonald is a member of the Corporation of Professional Engineers of Quebec and the Institute of Radio Engineers.

R. G. Fuller, M.E.I.C., engineering and management consultant, Peacock Brothers Limited, Ville LaSalle, Que. *(The Free Piston Engine.)*

Mr. Fuller was educated in England where he was concerned with Power Generation and Utilization. In 1937 he went to the Far East for the British American Tobacco Company and was responsible for modernizing their extensive plants. In 1941 he was responsible for manufacture of naval equipment in Hongkong as director of Marconi's Wireless Telegraph Company (China) Limited. He joined the Brush Group in 1949 and after completing a world tour was appointed director of their engine export companies. Subsequently Mr. Fuller pioneered the Free Piston Engine for Associated British Engineering as director of their Canadian affiliate, and is now engaged in organizing a Free Piston Engine and Gas Turbine division for Peacock Brothers Limited.

Mr. Fuller is a member of many societies and corporations among which are: The Corporation of Professional Engineers of Quebec; Institute of Electrical Engineers (England), The American Institute of Electrical Engineers and the Canadian Chamber of Commerce.

The Engineering Institute wishes to extend its thanks to the following for their contribution to the paper appearing in this month's issue, *Deas Island Tunnel.* D. A. Young, M.E.I.C., assistant to vice-president, Foundation of Canada Engineering Corporation Ltd.; Per Hall, M.E.I.C., president "Fenco", Ltd.; T. Brøndum-Nielsen, Copenhagen; H. R. Kivisild, M.E.I.C., district engineer, "Fenco", Ltd.; A. T. Jeffrey, supervising electrical engineer, "Fenco", Ltd.; and O. H. Bentzen, project manager, "Fenco", Ltd.



Fully tested by the modern facilities of the C-G-E Power Transformer Works, Guelph, Ontario, a 1500 KVA, 13.8 KV, 80°C rise, open dry-type transformer stands ready for one-package shipment to its site where high and low voltage switchgear can be quickly and conveniently connected.

QUEBEC-LABRADOR TROPOSPHERIC SCATTER RADIO SYSTEM

D. J. McDonald, M.E.I.C., *Area Radio Engineer*
C. E. Frost, M.E.I.C., *Buildings and Structures Engineer*
Bell Telephone Company of Canada

The installation of a tropospheric scatter radio system to provide telephone and miscellaneous communication services to Schefferville and Goose Bay and to other locations in Northern Quebec and Labrador was undertaken by the Bell Telephone Company of Canada in association with Quebec Telephone. This paper is a report of the engineering and construction of the project with particular emphasis on the broad planning of the system and on the construction aspects. Part I deals with the communication systems engineering aspects; Part II deals with the design and construction of buildings, towers, roads, etc.

Part 1. Communication Systems Engineering

Goose Bay is a large military and civilian airport. It was served by a network of government-owned communication circuits for defence purposes but commercial communication service available to the public was limited to a single telegraph channel. The Canadian and United States Armed Services owned and operated local telephone systems for their own use, but service to the public was limited to lines important to the military establishments. There was urgent need for commercial telephone service in Goose Bay, for long-distance circuits, and for additional defence circuits; it was important that they be provided over routes widely separated from the existing government-owned systems.

Figure 1 is a map of the area showing main centres requiring communication facilities.

Schefferville, the northern terminus of the Quebec North Shore and Labrador Railway and the centre of the Iron Ore Company of Canada's mining operations, was given telephone service by the Ungava Telephone Company, an Iron Ore Company subsidiary. Long-distance circuits from Seven Islands were provided by a carrier system operating on open wire on the joint power and communication pole line built along the Quebec North Shore and Labrador Railway. The new requirement was for communication circuits for the Mid-Canada Line and other defence operations.

In addition to these established communities, there is activity at many other developing locations, such as the power development at Grand Falls on the Hamilton River, and the mining operations near Wabush Lake and Mount Reed. There is also need for communication north from Schefferville towards the Ungava Bay mining operations.

Planning Studies

The tropospheric scatter type of radio system, with its ability to span long distances between stations, is ideally suited for use to places like Goose Bay and Schefferville. Study indicated that the logical route for the facilities southward should be through Seven Islands, then served by Quebec Telephone. Negotiations were opened with the Royal Canadian Air Force concerning telephone service in Goose Bay, and with Quebec Telephone regarding the broad planning of the system.

The conclusions were that a central office and telephone plant would be installed in Goose Bay by the Bell Telephone Company of Canada to provide local service, and that long-distance circuits to Rimouski and Quebec would be provided by Bell Telephone and Quebec Telephone, each in its own territory. The conventional line-of-sight microwave type of system would be used for the long distance circuits from Quebec to Seven Islands, and the tropospheric scatter type of radio system from the vicinity of Seven Islands to Goose Bay and Schefferville.

This paper is concerned with the tropospheric scatter part of the overall project. For the rest, briefly, Lenkurt 74A microwave equipment operating in the 6000 Mc/s. band was selected for a 16-mile hop from the scatter station at Trouble Mountain to Seven Islands, and TD-2 microwave equipment (4000 Mc/s. band) for the part from Seven Islands back to Rimouski and Quebec.

There are six radio stations in the tropospheric scatter system. The station at the Seven Islands end of the system (Trouble Mountain) was in Quebec Telephone territory and was built and owned by them. The overall system was designed by the Bell Telephone Company of Canada, who acted as consultants to Quebec Telephone for the Trouble Mountain station.

Tropospheric Scatter Radio Propagation

The tropospheric scatter mode of radio propagation has been treated extensively in the technical journals. The most comprehensive single source of information is Proc. Institute of Radio Engineers, October 1955.

Radio signals in the upper VHF and higher frequency bands can be received at distances well beyond the visible horizon with sufficient power to provide reliable communication. The received signal varies extensively, the fading being of two principal types, fast and slow. The fast fading is caused by multipath transmission, and the rate of fading increases as frequency or distance is increased. Over short intervals of time the instantaneous signal has approximately a Rayleigh distribution. For example, a 20 db fade is expected about one per cent of the time and a 30 db fade for only 0.1 per cent of the time. The slow fading, for which a single cycle of variation may extend over a period of several hours, is generally independent of frequency and appears to be the result of changes in the average refraction in the atmosphere. The variation in hourly median values follows a normal probability law in decibels with a standard deviation of about 8 db[1].

In temperate latitudes the monthly mean signal is substantially higher in summer than in winter. In the 750 to 1000 Mc/s. frequency band the monthly mean signals for summer and winter may be 10 db higher and lower respectively than the yearly mean signal.

The radio transmission loss on long paths is higher than the line-of-sight path loss for the same distance. This, together with the wide fading range, makes it necessary to use high power transmitters, high gain antennas, and sensitive receivers to obtain reliable communication.

The generally accepted theory of tropospheric scatter propagation is that radio energy from a transmitting antenna is partly scattered by inhomogeneities in the lower atmosphere or troposphere. Some of it is re-radiated in all directions, a small part being back to the earth and in the same direction as the original beam from the transmitter. For a given antenna system and radiated power, the mean received power is dependent on:

(1) The distance between the transmitting and receiving stations.

(2) The angle to the horizon as seen from each station, looking in the direction of the path.

(3) The foreground clearance in the immediate vicinity of the antenna; that is, within the first few miles.

Referring to Fig. 2, A and B are the two stations and the antenna directional beam patterns are along the lines AC and BC.

The propagation loss or radio transmission loss increases with increasing distance between points A and B; this corresponds to increase in the angle θ. Further analysis shows that a positive horizon angle at either or both stations is equivalent to further increasing the value of θ and indicates why a positive horizon angle increases the transmission loss whereas a negative horizon angle reduces it.

Adequate ground clearance is required in the immediate foreground of the antenna for it to establish its full directional beam pattern.

It was planned to use tropospheric scatter radio equipment of the general type already used on defence projects in Northern Canada. Important characteristics are: (1) Operation in the 750 to 980 Mc/s frequency band. (2) Transmitters available with 2 kw. or 10 kw. output. (3) Frequency diversity receivers of the combiner type. (4) Parabolic antennas of up to 60 ft. reflector diameter. (5) Assurance of handling up to 130 voice channels with the promise of more.

System Planning Criteria

The planning of a communication system such as this requires compliance with certain criteria.

(1) Communication channels to service points in the territory must be by terminal or repeater stations at those points or, if located elsewhere, by branch systems extended to the service points.

(2) The system must provide the number of channels required now and must be capable of future expansion, preferably so that it can be integrated with a larger-capacity system if needed.

(3) The performance of the system should be adequate for the service to be handled. In this case the requirements were to be the same as for the continental long-distance circuits.

(4) Construction and operation costs must be reasonable.

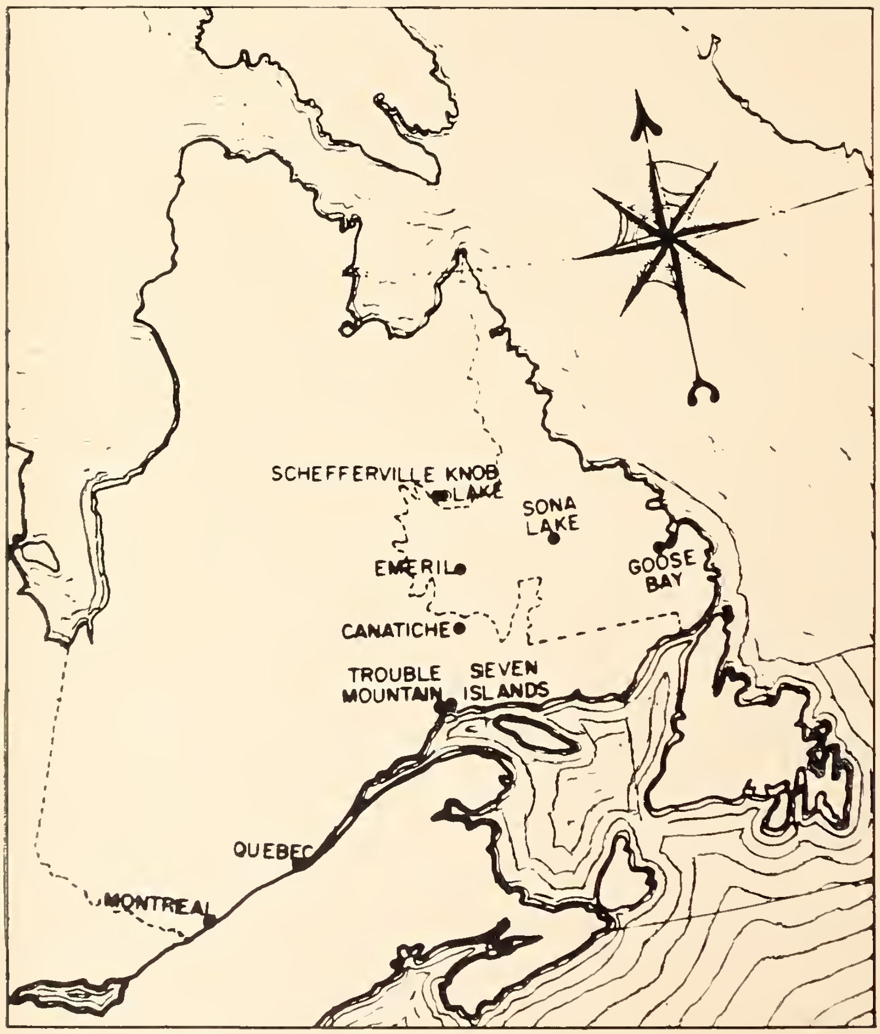
(5) Design and operation of the system must comply with regulations of the Department of Transport, which regulates radio stations in Canada.

(6) Where defence circuits traverse isolated regions, protection against sabotage and enemy action must be considered. The small number of stations in a tropospheric scatter radio system is an advantage.

Broad cost studies of tropospheric scatter radio systems and comparable line-of-sight microwave systems showed that the controlling factor is usually the nature of the access to the radio stations both for construction and for maintenance. If the sites for a line-of-sight system are accessible at reasonable cost from an established highway, then, in general, such a system can be built and maintained at lower cost than a corresponding tropo-scatter system. If access is by railway, the answer is not so clear because maintenance operations will depend greatly on the location and mode of operation of the railway.

Where access to the intermediate stations of a line-of-sight system is difficult and costly, the scatter system is usually cheaper to build and operate.

Fig. 1 Map of the area showing main centres requiring communication facilities.



Radio Frequency Allocations

The radio equipment for this project is designed to operate in the frequency band from 755 Mc/s. to 980 Mc/s. This overlaps the upper part of the UHF-TV broadcast band, which extends from 470 Mc/s. to 890 Mc/s., and the industrial, scientific and medical band from 890 Mc/s. to 940 Mc/s. Radio communication services in the latter band are not protected against interference from industrial, scientific and medical equipment. Control of interference to TV reception is a vital factor. International regulations require that the stations do not interfere with reception in other countries, and in this case the United States is of prime concern. In Canada, the stations are under the jurisdiction of the Department of Transport and control is exercised by issuing temporary radio station licenses subject to non-interference.

It is essential to separate the frequency assignments of the transmitters and receivers, operating at a particular station, by a substantial amount. Typical values for the equipment used in this project are 96 Mc/s. between the transmitter and receiver at one end of a relay section and 60 Mc/s. between the transmitter in one direction at a relay station and a receiver in the opposite direction at the same station. Because of the long-range propagation characteristics of the scatter mode, there are restrictions on how many transmitters in a multi-hop system may use the same frequency. These factors limit the number of separate systems which may terminate at a particular location or operate in a given territory.

Final System Plan

In Canada, tropospheric scatter systems in the 755 to 980 Mc/s. band are attractive only in regions of sparse population, remote from the United States boundary and where access to intermediate points is difficult and costly.

The preliminary planning established that the facilities should be tropospheric scatter from the vicinity of Seven Islands to Schefferville and Goose Bay and that the intermediate stations between Seven Islands and Schefferville should be close to the Quebec, North Shore and Labrador Railway. Still to be resolved were the number and location of these intermediate stations and the site of the station between the railway and Goose Bay; for the latter, Grand Falls on the Hamilton River was indicated as suitable. British Newfoundland Corporation Limited has done extensive preparatory work on the development of power at Grand Falls, where there will eventually be a substantial need for telephone service. For the stations between Seven Islands and Knob Lake, two basic plans were: one intermediate station with 10 kw. transmitters; and two intermediate stations requiring only 2 kw. transmitters. The latter plan was adopted, though overall costs for each plan were of the same order, mainly because:

(1) It is possible that the lower power transmitter need only be partially attended, and later unattended for at least part of the year.

(2) Two intermediate stations permit greater flexibility in establishing branches to other service locations.

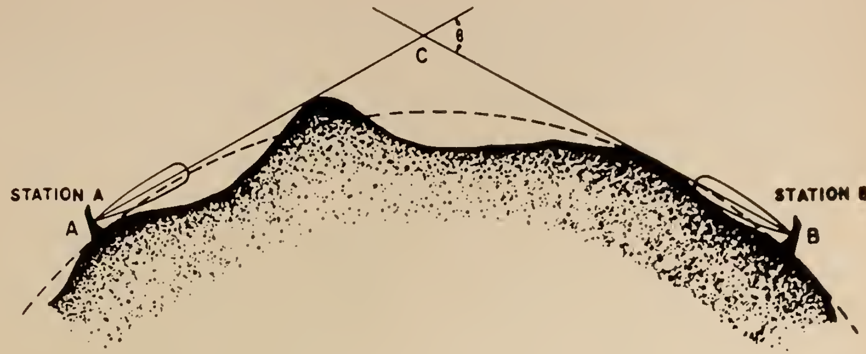


Fig. 2 Typical path profile: Tropospheric Scatter Radio System.

Site Selection

Site selection for a tropospheric scatter radio system is complex, comprising office study of maps and aerial photographs, field surveys, and further office studies. Many combinations were studied before reaching a final selection from the possible sites.

The prime criteria for the selection of sites are:

(1) Suitability for radio transmission.

(2) Feasibility of extending communication from terminals or other service points.

(3) Suitability for construction and maintenance of the radio station and associated facilities.

(4) Year-round access to the site.

Trouble Mountain

This is the southern terminus of the scatter system. The preferred location would be close to Seven Islands but the excessive positive horizon angle over the hills to the north made a site there impracticable. Trouble Mountain is 16 miles west of Seven Islands and closer to Clarke City. It is also a relay station on the TD-2 microwave system from Rimouski to Seven Islands, and a terminal station of the Lenkurt 74A microwave system between that point and Seven Islands.

The elevation of Trouble Mountain is 940 feet and the horizon angle towards the Canatiche station to the north is +18 minutes.

Canatiche

This site (elev. 2940 ft.) is 90.5 miles north of Trouble Mountain, 4 air-miles east of the Q, N.S. and L. railway. The railway here is in the Wacouna River valley and a suitable site must be at least 1000 ft. higher. The site chosen, from several, had the best radio performance commensurate with access and construction costs.

The horizon angles are -19 minutes south and -22 minutes north. An unobstructed view in all directions provides excellent potential for branch radio systems to serve neighbouring points.

Emeril

This site (elev. 2450 ft.) is 131.1 miles north of Canatiche, 5 air-miles east of the Q, N.S. and L. railway. It is the junction point for branches towards Schefferville and Goose Bay. The site had to be on a range of hills east of the railway to obtain satisfactory performance towards Goose Bay, and was selected, from three possibilities, on the basis of both radio performance and cost.

The horizon angles are: -13 min. towards Canatiche; -21 min. towards Knob Lake; -13 min. towards Sona Lake.

The horizon angle is favourable in all directions so this site lends itself to branches to other points.

Knob Lake

The site (elev. 1900 ft.) is 3 miles east of Schefferville and 118.4 miles north of Emeril, in a commanding position over the relatively flat country to the south. A road to within a few hundred feet of the site, together with favourable radio performance, made it an obvious choice. Horizon angle towards Emeril is -12 min.

Sona Lake

The site (elev. 1900 ft.) is 16 miles east of Grand Falls and about 3 miles east of the townsite which the British Newfoundland Development Corporation proposes to build for the power development. It is on the highest nearby hill, and is so much better in radio performance than any other readily-accessible point that it was an obvious choice.

Horizon angles are -12 minutes to the west and -10 minutes east. The distance from Emeril is 97.0 miles.

Goose Bay

The site (elev. 825 ft.) is on a hill 6 air-miles west of Goose Bay airport, and about 700 feet higher than the flat land on which the airport and town are built. A road to within ¾-mile of the site and the fact that there was no other suitable site nearby made the choice easy.

The horizon angle towards Sona Lake (137.4 miles) is +23 min.

TROPOSPHERIC SCATTER RADIO SYSTEM

The radio equipment operates in the frequency range 755 to 980 Mc/s. It is a broad band FM system with pre-emphasis and de-emphasis partly to equalize noise performance across the base band.

The receivers are designed for combiner-type diversity operation arranged for dual or quadruple diversity; the latter is used in this project (Fig. 3). Two antennas installed at a terminal are spaced 200 ft. apart to provide effective space diversity. In the transmitting direction, each antenna is fed from a separate power amplifier. One antenna is vertically polarized; the other horizontally. In the receiving direction, each antenna picks up both horizontally and vertically polarized signals and transmits them to four separate receivers. The outputs of the four receivers are combined, the baseband contribution of each receiver being proportional to the signal-to-noise ratio of the incoming signal.

The terminal station has two transmitters and four receivers in continuous operation, arranged to provide diversity and standby protection. If one transmitter fails, diversity is reduced from quadruple to the dual type but the system is still in service. If one receiver fails, diversity is again reduced but service is not interrupted. At a repeater station, the arrangement is two terminals back to back.

The broad baseband extends from 12 kc/s. to 800 kc/s. and is flat within ± 1.5 db. An order wire base band is available from 0.5 kc/s. to 12 kc/s.

The R. F. bandwidth of the receiver and of the exciter stage of the transmitter is 8 Mc/s. to the 3 db down points and the corresponding bandwidth for the power amplifiers is 6.0 Mc/s.

Intermodulation of a transmitter and receiver together is such that, when the system is loaded with uniform noise and fully deviated by noise peaks, the ratio of the noise per unit bandwidth being transmitted to that created by intermodulation in a blank space at any part of the baseband is greater than 42 db.

All units are designed to operate from either 120 volts single-phase or 208 volts 3-phase, four-wire, 60 cps. supply.

Transmitter

The transmitter includes an exciter stage and a 2 kw. or 10 kw. power amplifier.

The exciter unit consists of a modulating unit and a frequency multiplier and amplifier unit. The latter feeds into the 2 kw. or 10 kw. power amplifier. One modulating unit can drive two multiplier-amplifier units with the associated power amplifiers. The baseband input is 75 ohms, unbalanced, and the order wire input is 600 ohms or 150 ohms, balanced. The carrier frequency is crystal controlled to within ±0.003%. The exciter equipment is rack-mounted on standard 19-inch racks.

The 2 kw. power amplifier employs a klystron and is air-cooled. Power supplies, associated circuits, and the klystron, are mounted in a single cabinet, 5 feet wide, 3 ft. 3 in. deep, and 7 ft. high. The amplifier is designed for connection to a 50 ohm line through a 3⅛ inch coaxial cable flange. The power load is approximately 9 kva. An air-cooled dummy load is incorporated and a manual coaxial switch is provided for connecting to either the dummy load or the antenna.

The 10 kw. power amplifier is a liquid-cooled unit, the cooling system being separate from the radio equipment. The power supplies, klystron, and other amplifier apparatus are mounted in cabinets installed side-by-side to occupy a space 14 ft. 6 in. wide, 4 ft. deep, and 7 ft. high. The output connection is similar to the 2 kw. amplifier. The power load is approximately 40 kva. A liquid-cooled dummy load is incorporated with a manual coaxial switch to connect the amplifier either to the load or to the antenna.

Diversity Receiver

The diversity receiver unit comprises a conventional super heterodyne receiver, a pre-selector filter and a combiner unit. Four identical diversity receivers are required for quadruple diversity. The combiner outputs are connected in parallel and the contribution of each receiver to the total output is at all times proportional to the signal-to-noise ratio of the individual receiver.

The receiver, including the pre-selector, has a noise figure better than 8 db. The input impedance is 50 ohms unbalanced for connection to a coaxial line, and the base band output is 75 ohms. unbalanced. The diversity receivers are rack-mounted on 19-inch racks.

A unit, incorporating a recording meter, is provided at each receiver installation for the observation and recording of radio transmission. It may be connected to any one of the four receivers.

Antennas and Feed Horns

High gain antennas are required in tropospheric scatter systems. For the frequency band used in this project, the centre-fed parabolie reflector type is most satisfactory. Different antenna gains were required in the several relay sections and, as large antennas are costly, three sizes were provided, the reflectors being 30, 45, and 60 ft. in diameter. The reflector face of the 45-ft. and 60-ft. sizes is a square with the corners removed, and the diameter referred to is that of the inscribed circle. The ratio of antenna diameter to focal length of the parabola was kept constant to permit using the same feed horn design for the three sizes.

Expected gains of the antennas at 800 Mc/s. are as follows:

Reflector Diameter	*Gain with Respect to Isotropic*
60 ft.	41 db
45 ft.	38.5 db
30 ft.	35 db

Further information on the antenna reflector and feed horn support is given later in the paper.

The quadruple diversity plan calls for connecting one transmitter and two receivers to each antenna. Each feed horn must handle signals for a transmitter and receiver on one polarization, and for a receiver on the other polarization. To simplify the filters necessary to separate the transmitter and receiver connected to the same feed horn, the vertically and horizontally polarized signals should be isolated as much as possible.

The feed horn is a square-aperture waveguide horn to handle both horizontally and vertically polarized signals. The signal of one polarization is introduced by a waveguide feed at the rear of the horn. The cross-polarized signal, which is always a receiver signal, is extracted by a secondary feed terminated in a 1⅝-in. coaxial flange on the side of the horn. The isolation between signals of the two polarizations exceeds 35 db.

The face of the horn is closed by a fibre-glass window and the whole unit can be pressurized. A 500-watt heater is built into the rim of the horn for de-icing.

Radio Frequency Transmission Lines

There are two radio frequency transmission lines to each antenna (Fig. 3). One is a common feeder for the transmitter and one of the receivers. The other carries only a receiver signal. Two types of feeders are used, waveguide and coaxial line. The waveguide is WR975, a rectangular type with a 9¾ x 4⅞ in. cross section. The main runs are rigid, but sections of flexible waveguide are introduced at some of the corners to allow tolerance during installation and subsequent movement. The coaxial line is either 1⅝ or 3⅛ in. in diameter. Rigid coaxial line is used to a limited extent inside the buildings. The outdoor runs are all styroflex. Both the waveguide and the coaxial lines are pressurized.

The WR975 waveguide will transmit greater power than the 3⅛ in. coaxial line and also introduces less loss. In the 10 kw. transmitters, waveguide is required to handle the power in the transmitter feeder. The feeders for the 2 kw. transmitters are 3⅛ in. coaxial line, except at Sona Lake where waveguide was specified to avoid air transport of the heavy reels for the coaxial line. The secondary receiver feeders are all coaxial line.

Branching Filters

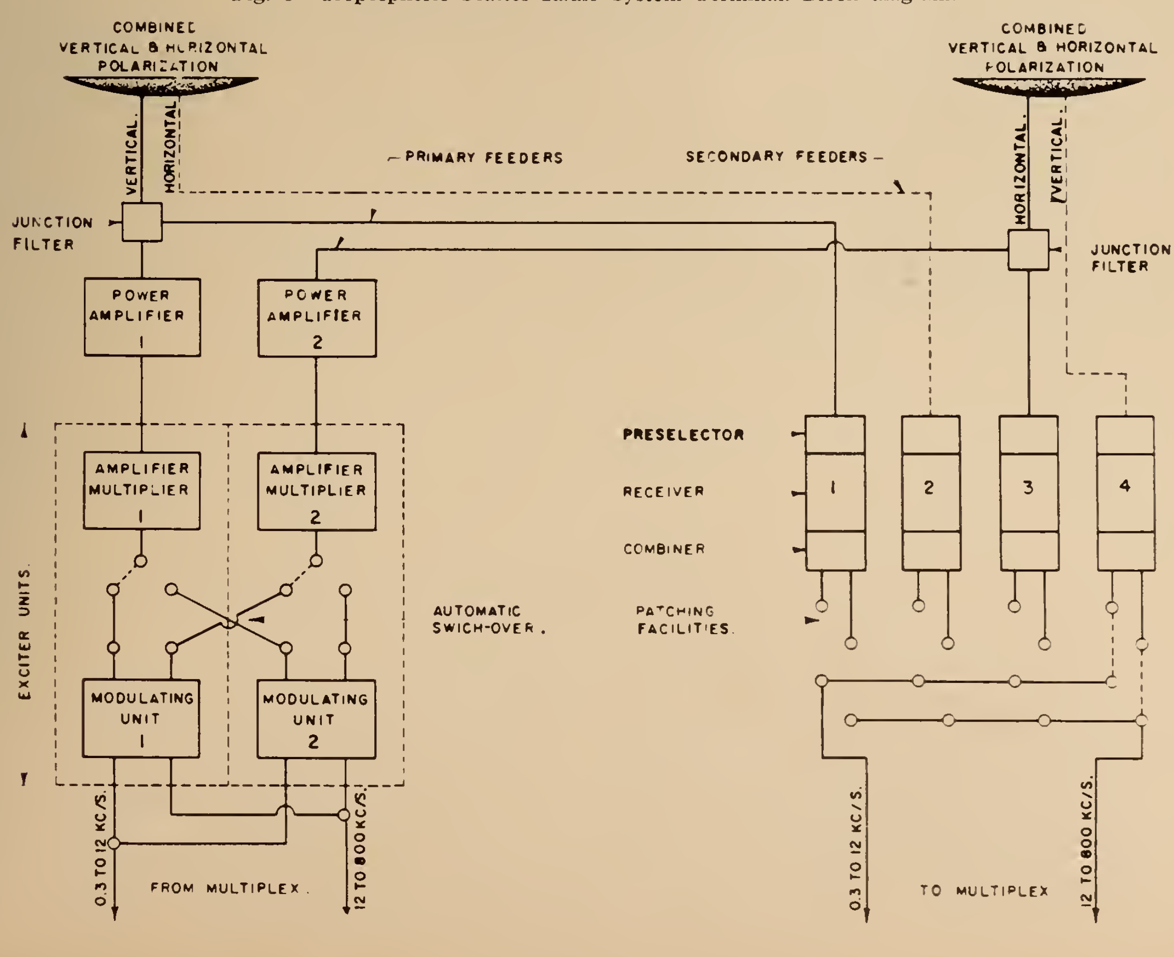
A transmitter and a receiver are connected to the common transmission line feeder through a branching filter (Fig. 3). The filter, in association with the receiver pre-selector filter, must protect the receiver against the high output power of the transmitter, and it must pass both the transmitter and receiver signals without excess loss or other impairment.

The filters consist of an assembly of 3⅛ in. coaxial line units silver-soldered together. The common feeder connects to the stem of a "T". Shorted coaxial stubs are bridged on each arm of the "T" and are adjustable in length to control the filter characteristics of the transmitter and the receiver branches.

Frequency Plan

The selection of frequencies for a multi-hop tropospheric scatter radio system was discussed earlier. Among other requirements, the frequency assignments must be compatible among themselves at each radio station and must also co-ordinate with the frequencies at all other stations where

Fig. 3 Tropospheric Scatter Radio System Terminal. Block diagram.



the receiver power may be sufficient to be a source of interference.

The minimum frequency separations permissible with the equipment installed in this project are: 96 Mc/s. between the transmitter and receiver frequencies in a common antenna; 60 Mc/s. between a transmitter and a receiver operating back-to-back at a relay station; 12 Mc/s. between two transmitters or two receivers operating back-to-back at a relay station.

Figure 4 shows the frequencies authorized for the project. In addition to the restrictions on frequencies within the particular project, the assignments must also co-ordinate with all other radio stations operating in the vicinity. This was of particular importance at Trouble Mountain and Goose Bay where there are many other radio installations.

There are four pairs of frequencies extending from 755 Mc/s. to 887 Mc/s. for the five relay sections. One pair of frequencies is assigned to the two sections, Trouble Mountain to Canatiche, and Sona Lake to Goose Bay.

Multiplex Equipment

The tropospheric scatter radio equipment transmits a broad base band from 12 kc/s. to 800 kc/s. and an order wire base band from 0.5 kc/s. to 12 kc/s., each band being available at all terminals and relay stations. The broad base band is subdivided into telephone channels on a frequency division basis using K and L1 carrier equipment.

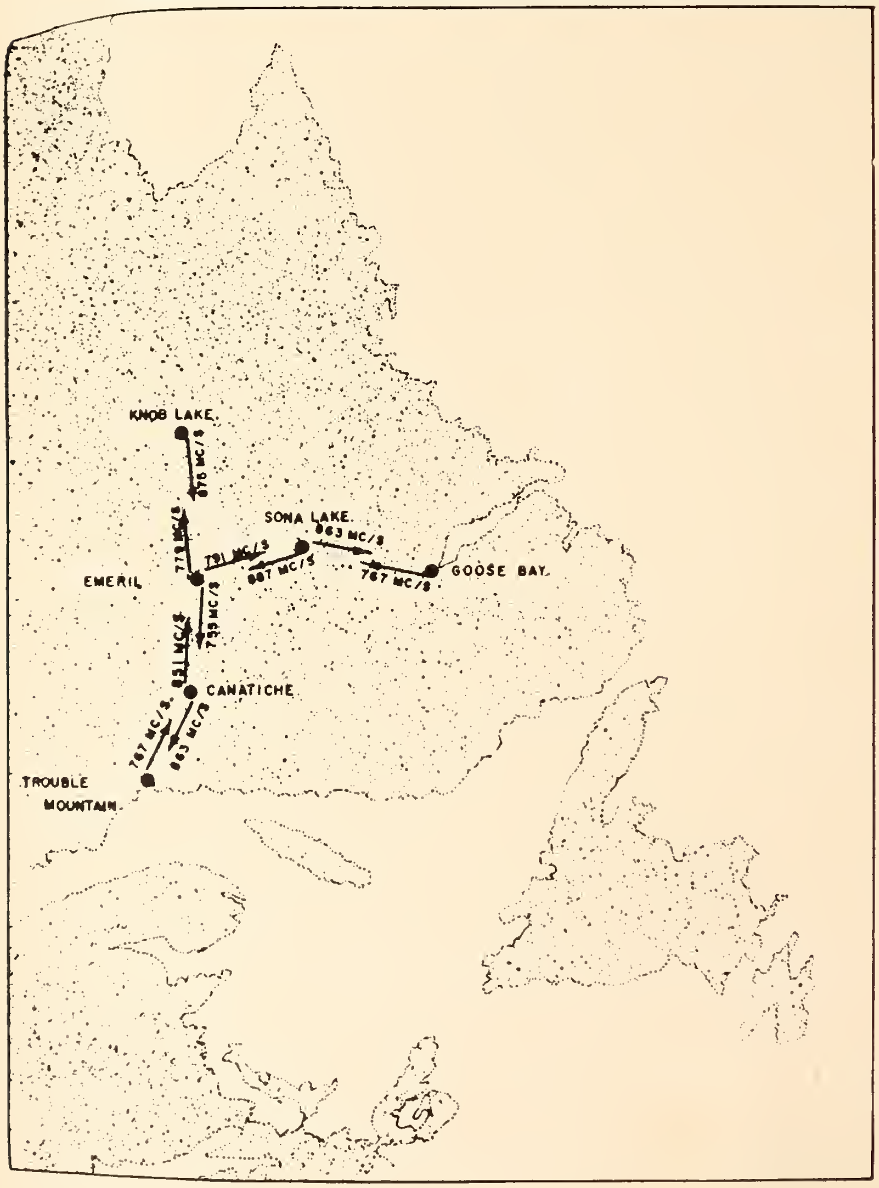
These types of multiplex were chosen for a number of reasons.

(1) The transmission performance objectives for the voice channels were the same as for long-haul circuits in the continental network where K and L carrier are used extensively.

(2) It is proposed to superimpose frequency shift carrier telegraph systems on the voice channels, thereby requiring high stability in the carrier frequency supplies. Provision is made to stabilize the carrier supplies at the several stations by means of a 64 kc/s. pilot transmitted over the system.

(3) L1 carrier is used on the TD-2 part of the overall project, and it facilitates the engineering and the operation and maintenance to extend the same type throughout.

Fig. 4 Frequency assignments: Quebec Labrador Tropospheric Scatter Radio System.



The K carrier equipment provides 12 voice channels in the band from 12 kc/s. to 60 kc/s. The L1 equipment can handle 600 channels, so only part of its capacity is used in this application. In the L1 equipment the voice channels are arranged in group banks of 12 channels each, and combinations of 5 group banks are put together to form super groups.

Super group No. 1 and part of super group No. 2 are being installed initially. These occupy the frequency bands from 68 to 308 kc/s. and from 312 to 552 kc/s.

The number of voice channels being installed initially in the several sections are as shown in Table I.

Table I. Number of Voice Channels Installed Initially

Section	*No. of Voice Channels*	*Type of Multiplex*
Trouble Mt. —Canatiche	108	L1
Canatiche—Emeril	108	L1
Emeril—Knob Lake	36	L1
Emeril—Sona Lake	60	L1
	12	K
Sona Lake —Goose Bay	60	L1

Only those channels necessary for service at the relay stations are brought down to voice frequency. Other channels are connected at carrier frequency to limit the number of conversions from voice to carrier frequency and vice versa. Where a block of 12 or less voice channels are adequate, the K carrier equipment is preferable to the L1 equipment. Initially, it is being installed only in the section from Emeril to Sona Lake.

Additional multiplex channels will be installed later. The critical units, limiting the maximum number of voice channels, are the transmitter power amplifiers in the radio equipment. The specifications called for meeting the performance objectives with 132

Table II. Path Data and Radio Transmission Performance

Site	Horizon Angle min.	Antenna Size ft.	Site	Horizon Angle min.	Antenna Size ft.	Distance Miles	Long Term Mean Path Loss—db	Long Term Median Fading Margin—db
Trouble Mountain	+18	45	Canatiche	−19	45	90.5	186.3	35.2
Canatiche	−22	45	Emeril	−13	45	131.1	186.5	35.0
Emeril	−21	45	Knob Lake	−12	30	118.4	182.4	36.1
Emeril	−13	45	Sona Lake	−12	30	97.0	176.4	42.1
Sona Lake	−10	60	Goose Bay	+23	60	137.4	204.5	30.5

channels on the 2 kw. system and 72 channels on the 10 kw. system. It is believed that realistic objectives are 200 and 100 channels for the 2 kw. and 10 kw. systems, respectively.

System Performance

Table II is a summary of the radio transmission data for each path in the system. In the compilation of the data, the following typical values were used for the various characteristics.

Radio frequency:
800 Mc.
Antenna gains:
60 ft., 40 db above isotropic; 45 ft., 38 db; 30 ft., 35 db above isotropic.
Feeder and filter loss:
10 kw., 2 db; 2 kw., 4 db
Receiver noise figure:
8 db
Receiver I.F. bandwidth:
8 Mc/s.

Primary Power Supply

The reliability of the primary power supply is a critical factor in the continuity of service of a communication system. There was no suitable commercial source of power at any of the troposcatter stations built by the Bell Telephone Company of Canada, so provision had to be made to generate primary power locally at each of them, together with adequate standby. As commercial power is available at the Trouble Mountain station, it was necessary only to install a standby source.

Power is provided at the radio stations by diesel engine alternator sets (Table III). Three sets are installed at each station, any one of which will handle the load. One set normally carries the load, the second is available as emergency back-up, and the third permits maintenance and repair work without interfering with the standby.

Normal operation of the engine alternators and switchover to standby is completely automatic. Remote manual control is also available. Alarms are provided for items such as low oil pressure, low fuel pressure, high water temperature, and overspeed. The alternator output is 208 volts, 3-phase, 4-wire and the normal frequency is 60 cps. As some units in the radio equipment are sensitive to variation in frequency, a monitor is provided to originate an alarm if the frequency varies.

Radio interference from the alternators and associated apparatus is controlled by suppressors and shielded wiring.

The electronic and domestic loads are supplied from separate circuits, protected individually. The circuits may be supplied from different alternators, but normally only one engine alternator set is in operation.

Maintenance of the engines is to be done at the stations. Expendable spares will be kept at each station, and larger spare parts will be stored at one location for the system.

The emergency standby at the Trouble Mountain station is a 60 kw. diesel engine alternator set.

Table III. Diesel Engine-Alternator Installations

Station	Engine Rating, kw. Initially	Supercharged	Alternator Rating, kw.
Canatiche, Emeril, Goose Bay	150	200	200
Knob Lake	100	—	100
Sona Lake	200	225	225

Communication for the Construction Phase

The sites at Canatiche, Emeril, and Sona Lake were not accessible from any commercial communication facilities. Goose Bay could be reached by telegraph but the service was inadequate for the needs of the project. Arrangements were made to serve these locations by a combination of teletype facilities and a private radio telephone network. A teletype circuit was set up from headquarters in Montreal to the construction office in Seven Islands. Private radio telephone stations operating in the medium- and high-frequency bands were established at Seven Islands, Canatiche, Emeril, Sona Lake, and Goose Bay. The transmitters are 100 watts output and all stations are licensed for operation on the same frequencies, 2804 and 5390 kc/s. Communication is point-to-point, messages being relayed verbally at intermediate stations.

Local communication was needed between the Canatiche and Emeril sites and their respective railheads on the Q.N.S. and L. Railway, and between Sona Lake station and the camp site by the lake where aircraft land. The Telephone Company's rural distribution wire laid on the ground or fastened to trees was used for this purpose and proved very satisfactory. At Sona Lake, VHF radio was operated for a period between the lake and the site, together with portable radio sets in the vehicles travelling between the two points, but it was not found necessary to continue this.

All transport to Sona Lake is by air and, to facilitate the operations, an aeronautical beacon station was installed. Since this air transport is in accordance with visual flight regulations, the beacon station was not essential, but its contribution to safety and efficiency warranted the installation. Experience has shown it to be very helpful.

The beacon operates at a frequency of 320 kc/s. and is adjusted for a radiated power output of 25 watts.

Maintenance Procedures

Warning of improper operation and means to carry out maintenance tests and adjustments were prime objectives in the design of the radio system and associated facilities. Alarms report the impairment of performance and the failure of certain components. In some instances, transfer to standby units is automatic in addition to the alarm. Test points allow checking operation while the equipment is in service, and units are readily removable for further investigation and repair.

Two broad guides were followed in planning for maintenance.

(1) All ordinary maintenance tests and repairs should be done without interrupting service. Normally two transmitters are in operation. If one is disabled or out of service for maintenance, the other should be in operation. Diversity is reduced from quadruple to the dual type but service is not interrupted. Similarly, if one or

two receivers are out of service, it is still possible to have dual diversity.

(2) It should be possible to carry out all tests and adjustments at a station without assistance from the adjacent station. Where tests are made in association with the adjacent station, they are to confirm the correctness of adjustment rather than being the condition for determining the adjustment.

Test instruments and other facilities at each station enable the staff to carry out all work required to put the system into service and to maintain it. It is expected that many repairs to units of equipment can be made at the station, though some will require special tools or techniques and will have to be returned to a central repair depot.

One tool which is most useful both in adjusting the radio equipment and in locating trouble is the "loop test set". It provides for extracting a signal from the transmitter, translating it to the receiver frequency, and feeding it into the receiver which operates on the same path. It facilitates adjusting the transmitter deviation and the receiver output level and also permits making noise and intermodulation tests on the equipment at a station.

The power amplifier klystron must be replaced occasionally, and a spare klystron carriage is supplied together with associated tuning coils and cavities. The defective one, together with its carriage, is moved out on casters and the spare substituted.

Essential instructions for operation and adjustment of the many units comprising the radio system, and for the overall line-up and maintenance, have been prepared in the form of Bell System Practices and have also been useful in the training of staff.

Operating experience is needed to establish standard maintenance procedures for equipment as complex as the tropo-scatter system. Some of the procedures are therefore temporary and will be subject to review.

Initial Test and Line-up of the System

The initial test and line up of the system will be carried out by the plant department staff. However, an engineer assigned to each station will advise the plant staff during the whole period. The system must be completely lined up in accordance with the instructions at the beginning. Otherwise, it is almost impossible to adjust it properly afterwards.

At the time of writing, the installation of the electrical and electronic equipment was practically complete and testing was under way. The system has now been through a complete lineup and break-in period and handles commercial telephone service.

Part II. Structural Design, Construction, and Transportation

Part II of this paper deals with the design and execution of the structures, works and buildings, associated with the Quebec-Labrador Tropospheric Scatter System. It is not the application of a recent engineering development, but the story of the adaptation of commonplace crafts and materials to meet an unusual situation.

The task involved the construction of a system of five stations. The system, spanning a distance of more than five hundred air miles traversed rugged northern terrain. The sites, except at Knob Lake and Goose Bay, were in totally uninhabited areas, on the summits of mountains to which there was no established access.

The design programme could not be undertaken prior to January 1957. The committed system service date was June 1, 1958, a period with but one summer season. This, combined with the effects of latitude and altitude, resulted in a construction season free of frost and snow of less than three months at all sites. A substantial part of this season would be taken up, at least at the intermediate stations, constructing access roads from the freight heads to the summits, over which the necessary construction materials could be transported.

Following the initial breakthrough, further time would be required to transport camp materials and to build the main construction camps, before starting work on the permanent structures.

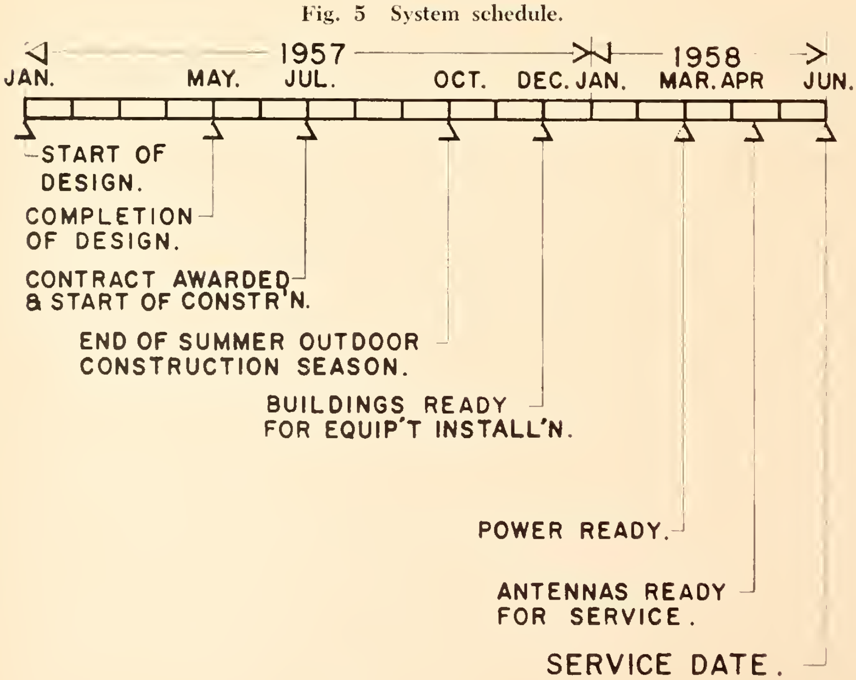
The system schedule (Fig. 5) demanded that the building areas required for the housing of the electronic equipment at all sites be completed, painted out, and dustfree by December 1st, 1957 to meet the start of the installation and test programme.

The situation at Sona Lake was further complicated by the fact that this site is accessible only by air. Preliminary estimates indicated that a gross of 2,500 tons of construction and support materials would be required at each site. The importance of holding this tonnage to a minimum need not be stressed.

The problem could not be resolved by a massive approach, even if such an approach were *economically* feasible. Overstaffing at the outset would result in a disproportionate period being spent constructing camp accommodation, so shortening the productive programme. The compact nature of the plant and the limited area occupied would restrict the number of concurrent work parties. This would preclude offsetting the overshortened construction period by merely adding workers.

Understaffing at the outset would lead to productive staff being diverted belatedly from the permanent works to construct camp accommodation for reinforcements.

Fig. 5 System schedule.



The optimum solution lay in the integration of the design, construction, and transportation concepts. In general, this involved the need to minimize weight commensurate with structural adequacy, and reduction of on-site labour by prefabrication, simplification of detail, and similar means. These ameliorating conditions had to be moderated by the realization that obvious advantages of prefabrication might be offset by less obvious disadvantages of prefab assemblies, difficult and expensive to transport, or requiring the transportation of small crews of specialist erectors or assemblers. It required full exploitation of work simplification and short cuts to intermediate programme objectives provided in the design, even if this meant digression from trade habit. Finally, one had to recognize the critical but basically ancillary role of transportation. The plan as visualized must be of adequate capacity, capable of immediate response to change of job pace and organizationally susceptible to such demands. It must have built-in deterrents to the tendency of project transportation organizations to become autonomous and to pursue their local efficiencies to the overall cost of the project.

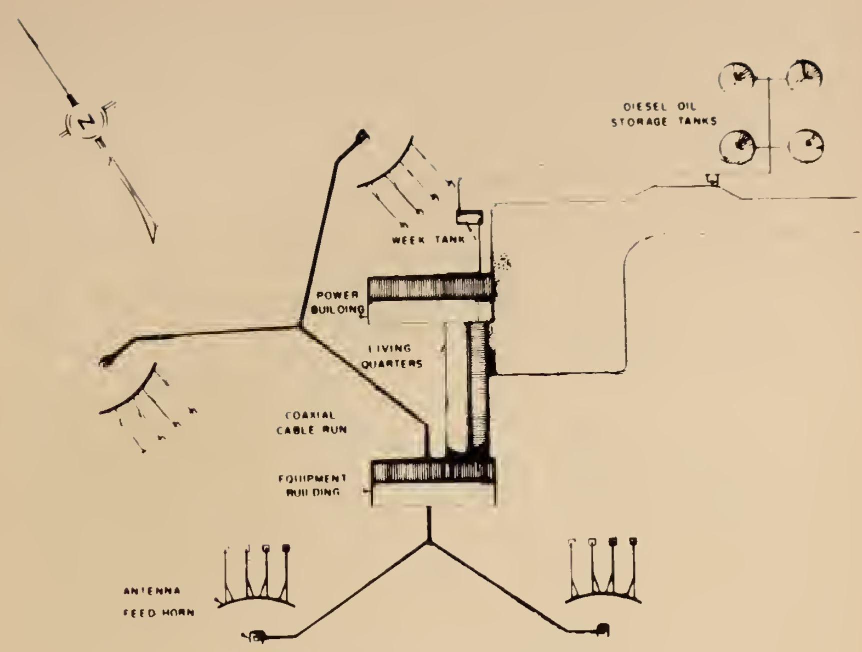


Fig. 6 Plan of the general layout.

DESIGN

The principal structural components required at each site were the buildings, the parabolic antennas, and the petroleum product storage facilities. A basic building design consideration in northern latitudes is whether related facilities are to be grouped under one roof, and closed in by one building form, or whether an open plan providing each separate facility with its own building may prove more advantageous.

In this instance four distinct main areas were: the radio equipment area, the diesel generator power room, the operators' living accommodation, and the garage.

The electronic equipment floor area requirement ranged from 1800 sq. ft. at the terminal sites to 2500 sq. ft. at the relay sites.

The power requirements also varied from station to station, from 100 kw. to 200 kw. However, the effect of this on floor space tended to become imperceptible.

With the electronic equipment and power room areas established, it was now possible to turn to consideration of the living accommodation areas.

The resident operating crew was set at seven, including the cook and houseman for the isolated stations at Emeril, Canatiche, and Sona Lake. To this number would be added any permanent personnel required to operate the heating plant, water and sewer facilities, the petroleum product installation, and similar services. Such personnel would increase the service facility requirement with a commensurate increase in support labour. A compact and highly mechanized plant requiring no additional personnel was indicated to offset the increase of support costs once the minimum personnel were exceeded.

A single roof design would eliminate interbuilding corridors, essential in such exposed locations; would simplify the water and sewer systems; and even more important, would present the possibility of meeting all heating requirements by recovering heat from the electronic equipment and the diesel generators.

A single floor plan was developed. Consideration of all factors led to it taking the form of a square U with the electronic equipment housed in one wing, the diesel generator room, water storage, and garage in the second wing, and the living accommodation area forming the base or tying member (Fig. 6).

Previous experience at exposed locations of comparable latitude had established the need to design against 120 m.p.h. winds, 90 lb. snow loads, and a temperature range from 40° to +90°F.

The system will be operated by personnel drawn, in rotation, from the Company's standing staff. These people have predominantly urban backgrounds, and provision must be made against mental as well as physical discomforts of living on a mountain top, confronted with the seemingly endless and empty wastes of the northland. This situation was met by developing the interior of the living accommodation wing along familiar and homelike lines. The basic floor plan was built around the customary living room, dining room, and kitchen core with bedrooms arranged bungalow-style along a central corridor.

With the floor plan developed and dimensioned, available prefabricated buildings could be studied and a choice made. A commercially-available stressed skin prefab was selected for all buildings required for the system.

Building Foundations

The building foundation design was controlled by the very short construction period available, the general lack of suitable aggregate, the need to hold weight down in view of the high transport costs, and the fact that all the buildings were founded on rock.

A free-standing wood post and laminated beam foundation was used under the equipment and living accommodation areas. The wing housing the generator room and garage was set on a concrete perimeter wall. A conventional reinforced concrete structural slab and girder floor was used in the diesel room. Individual concrete piers were provided for each generator unit. These piers were founded on rock, carried up through, and held free of the floor slab on fill.

Floors

Laminated wood floors were used in the equipment wing. The structure was designed to meet a uniform distributed load of 150 lb./sq. ft.

Principal factors contributing to the choice of this form of foundation and floor structure were:

(1) It is speedily erected of readily available and transportable materials.

(2) It does not require specialist labour.

(3) Construction is relatively independent of weather conditions.

(4) It can be held to minimum dimensions and weight as any future change in concentrated load can be met readily, without interior disturbance, by merely increasing the underpinning.

(5) It does not require the use of any equipment other than hand tools.

(6) It has a "U" factor of approximately 0.1.

An insulated wood beam and plywood deck floor was used for the living quarters. All lumber used in the foundation and floor systems was pressure-treated against rot. Its "U" factor was computed as approximately 0.1.

As previously mentioned, concrete slab floors were used in the diesel generator-garage wing as the schedule permitted a few weeks additional time for its construction. The advantages of this stronger, more permanent and fire-resistive construction for this application outweighed the additional cost and effort.

A four-thousand gallon reinforced concrete water storage tank was located in one corner of the diesel room. Founded on rock, it was carried up through the slab to a height of 3 ft. above floor level. The tank top formed a low mezzanine on which the station supervisor's office was constructed. Also by this means an area of the tank walls was exposed to the warm diesel room atmosphere as a precaution against freezing of the stored water.

Interior Finish

In keeping with the design approach previously mentioned, selection of materials for the interior finishing of the living accommodation wing was limited to those commonly used in medium range residential building. The kitchen, partially open to view from the dining area, is a slightly oversize version of the familiar planned kitchen encountered in such residences. Although presided over by a professional cook, it has none of the trappings usually associated with commercial or institutional kitchens. Individual colour schemes were developed for each room. Good quality domestic furniture, in harmony with the colour scheme, contributed to a cheerful, familiar and homelike atmosphere. The use of colour was extended to the work areas to offset monotony. Windows were generously proportioned and placed to take advantage of the vast outdoor panorama.

The windows were designed with a fixed sash and a permanently screened and louvered full-width opening immediately above the sill. This opening was closed on the inner face with an insulated gasketted hinged panel. This panel, closed, provides an insulated seal, and in its open or ventilating position acts as a draft deflector.

The windows, also designed by the owners' staff, were readily fabricated. They are draft free, do not require additional screens or storm sash, and remain frost free. This relieves the sense of claustrophobia which might otherwise be generated.

Conventional hardware was used throughout except on the exterior doors. These were fitted with bakelite handles to prevent damp hands freezing to them and shaped to provide a good grip for heavily-mittened users.

Heating and Ventilating

With the building design fairly well determined, maximum losses were computed and found to be 415,000 B.t.u. per hour under the most severe conditions expected. This, when combined with the ventilation requirements and the heat loss occasioned by drawing the diesel aspiration air directly into the power room, totalled less than the amount of heat which could be recovered from the electronic equipment and the diesel generators. This confirmed the feasibility of heating entirely by recovered heat and the practicality of a one-roof design. Detailed design on this basis could now proceed.

Principal considerations in the design of the heating, cooling and ventilating systems were:

(1) To provide adequate cooling systems for the operating elements, both mechanical and electrical.

(2) To ensure that individuality of unit cooling systems be maintained against the possibility of backup loss by the failure of a common element in the cooling system.

(3) To recover sufficient heat to meet all heating requirements.

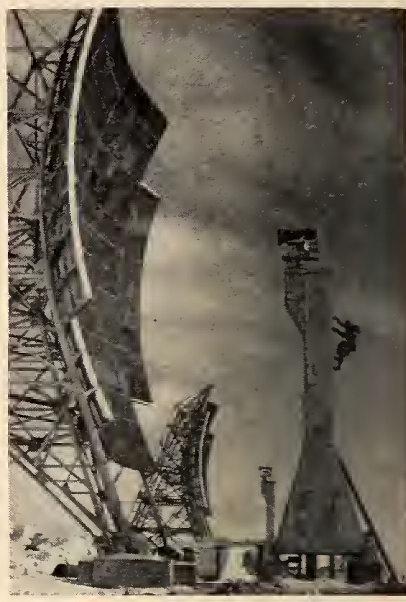

Fig. 7 View of the antenna and feed horn structures.

(4) To provide adequate ventilation.

To do this, two separate heat exchange plenum chambers were provided near the equipment requiring cooling; one in the power wing and one in the equipment wing.

The electronic equipment uses about 25% of the energy input; the difference is dissipated as heat. The greatest energy loss associated with this equipment is concentrated in the klystron units. The 10-kw. output klystrons with their 40 kw. input utilize both air and liquid cooling. The 2-kw. output units are air cooled and dissipate their heat directly to the room. The diesel generators provide the only other source of heat and are liquid-cooled.

The heat dissipated by the klystron blower systems is collected by large exhaust hoods covering the area occupied by the klystrons. This heat is ducted to a plenum chamber located in the equipment wing heat exchange room. Liquid cooling of the klystrons is by circulating a 50-50 solution of ethylene glycol and water through the body and collector of the klystron tube to a heat exchange coil in the plenum chamber. Each klystron is served by a completely separate pump, piping, and heat exchange coil, and is therefore independent of failure of its neighbour.

The diesel generator liquid cooling systems are similarly arranged. Each unit is connected by a separate piping system to individual remote radiators located in a common plenum chamber at the end of the power room.

With the heat largely concentrated in the two plenum chambers, it could be quite readily used or dissipated.

Four distinct duct systems were developed which permitted transfer of heated air from the power room plenum chamber to the power wing, the garage and the living quarters. Use of the heat recovered from the electronic equipment was limited to the heating of the equipment wing.

Ventilation of the power room is provided in summer by manually-operated propeller fans in the outside walls discharging directly to atmosphere. Power room comfort is maintained by these fans which provide 25 air changes per hour.

The equipment wing is ventilated in summer by a series of modulating dampers, bypasses, and thermostats which introduce outside air into the duct system, while exhausting the heated air from the heat exchange to outdoors. By this means equipment room temperatures can be held to within 12 degrees of outside ambient. All systems have humidifiers, smoke alarms, and controls for automatic heating and ventilation of the building areas as well as the cooling of the electronic equipment and diesel generators.

All sites are equipped with an automatic fire detection system.

As the stations will be attended continuously, fire-fighting will be manual. Each wing is equipped with portable CO_2 extinguishers, supplemented by a bulk supply of CO_2 stored in the garage in 50-lb. cylinders. These cylinders are manifolded together and fitted with a spray-nozzled 150-ft. hose that can reach all parts of the building.

Survival Huts

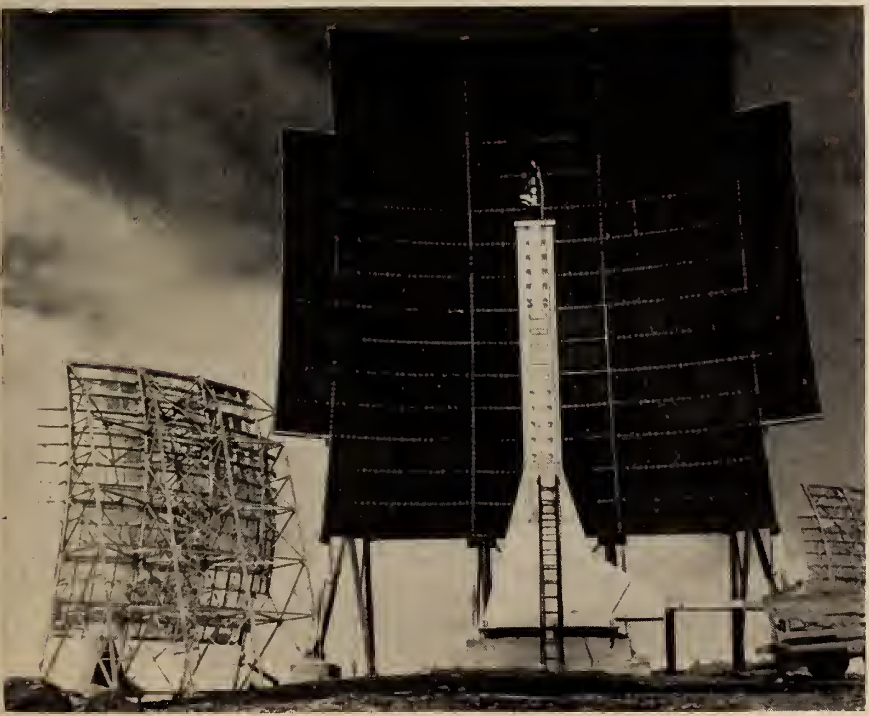
The buildings were made as fire-resistive as was economically feasible under the difficult conditions. However, they are not fireproof. Survival huts were built and equipped at each of the remote locations to afford shelter to a burnt-out crew until help could arrive. These insulated huts, of light wood and plywood construction, are completely fitted out with heaters, beds, cooking facilities, a small dining area, emergency food storage, and a small electrical generating set to supply electric light and power to operate an emergency radio.

In addition to their role as survival huts, they will be used to accommodate visitors, road and building maintenance, transport crews or other personnel on site for short periods.

Sewers and Water

Insulated septic tanks were used to dispose of sewage. The connecting sewers were spiral wrapped with electric heating wires and insulated to prevent freezing. These systems were all located in rock. Effluent disposal beds were created from backfill blanketed with moss. The disposal piping is not heated.

Fig. 8 Another view of the antenna and feed horn.



The rocky summits on which the relay stations are located have no readily available source of fresh water. Small ponds occurred at Canatiche and Sona Lake some 1500 ft. from the station and about 75 ft. below the summits. At Emeril a shallow well developed during construction at about the same relative position gives promise of meeting the station needs.

The water is carried from pump houses at the sources through electrically-heated piping to the 4,000-gallon inside storage tank previously mentioned. This piping is installed on the surface in insulated troughs. Automatic chlorination was incorporated in all systems.

Antennas

The next major structural components to be considered were the antennas. These were designed against the following conditions. Wind 120 m.p.h. with 3 in. radial deposit of ice; ambient temperature range -60°F. to 100°F. plus sun effect. Maximum permissible deviations under no-load conditions were set at $\pm \frac{1}{2}$ in. over the entire surface within the nominal diameter as measured from the focal point, but not to apply to small projections such as bolt heads.

It was further stipulated that maximum deflections be held to meet the most severe of the following conditions: (a) ± one inch to vertex with 100 m.p.h. wind and one inch radial deposit of ice; (b) ± two inches to lip with 120 m.p.h. wind with no ice. Under maximum load conditions of 120 m.p.h. wind and 3 in. radial deposit of ice, maximum developed stresses were not to exceed the elastic limit.

Antennas of 60, 45, and 30 ft. diameter were required. The 30 ft. size was available with modifications as a shelf item. The larger antennas required a different approach. Previous experience had indicated the desirability of designing large diameter antennas, for use under the severe conditions outlined, to transmit loads as directly as possible to the foundations. It is also considered advisable to utilize standard steel sections, conventional shop fabrication procedures, and drive-bolted field connections. Deflections of the antenna structure are more readily controlled if the feed horn is designed as a separate free-standing structure.

The design was successfully developed along these lines by Mr. Brian

R. Perry and his associates, Montreal consulting engineers, who also designed the foundations for the antennas.

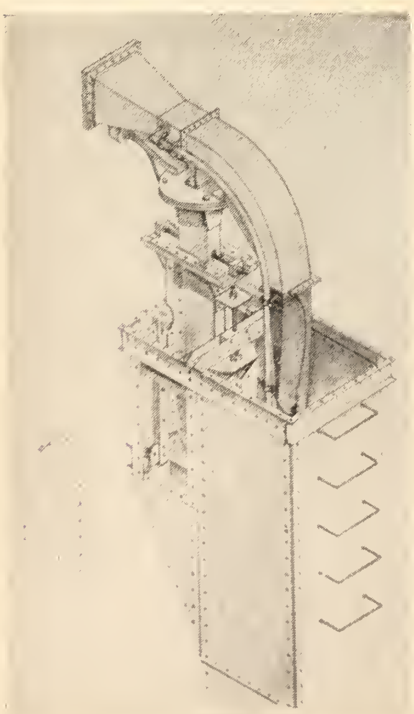
The fact that the traces of planes intersecting a paraboloid, and parallel to its axis, are themselves parabolic and mathematically identical regardless of their location on the paraboloid, permitted the use of essentially duplicate vertical trusses. This approach resulted in a satisfactory structure meeting all requirements and with the added virtue of great simplicity (Fig. 7).

The rectilinear shape of the structural backup also contributed to a ready means of checking the accuracy of the antenna surface in that it provided definite points to which the cartesian co-ordinates of surface check points could be referred.

The antenna surfaces were fabricated from 16-gauge galvanized steel plate bolted to the frame with ⅜ in. bolts on approximately 6 in. centres (Fig. 8).

Due to the weight of the structures and the multiple trusses, it was not considered practical to provide means of altering the orientation of the antenna. Nevertheless, ability to rotate the beam within a moderate range was desirable, not only to offset possible errors in orientation, but also to select the position for optimum transmission.

Fig. 9 Isometric view of feed horn tower.



The sweep required could be accomplished by varying the position of the feed horn (Fig. 9) 12 in. left or right of the horizontal axis, by tilting the entire feed horn tower about its base centre line. The base was provided with a simple jack screw and hinge mechanism. In addition the feed horn support was mounted on lead screws by which it could be adjusted ±6 in. along the axis of the antenna, with a similar arrangement for vertical adjustment.

Antenna and Feed Horn Foundations

All the antennas would be founded on rock. The foundations were individual concrete footings anchored into the rock for each of the vertical truss legs. The mass of these footings was the minimum necessary to transfer load from the anchor bolt assemblies to the rock anchor system, as bearing was not a controlling factor.

Fuel Supply

Since the power at all sites is provided by diesel-driven units, this necessitates an adequate supply of diesel fuel. Additionally there is the requirement for gasoline for vehicles and other mechanical equipment.

Principal considerations in the design of the fuel supply systems were: (1) type of fuel; (2) method of supply; (3) unloading facilities; (4) storage facilities; (5) on-site pumping and fuel handling facilities; (6) piping design.

Salient factors in the selection of the fuel were a low pour-point and low sulphur content. Type 1 Arctic Diesel with a pour point of -45°F. and maximum sulphur content of 1.0% was selected.

A commercial supply of fuel is available at Knob Lake and Goose Bay. Here no unloading facilities have been provided. The obvious means of supplying Canatiche and Emeril was the Quebec North Shore and Labrador Railway.

The trackside facilities are designed to unload one to three 10,000-gal. tank cars at one time without shunting or relocating the cars. A 25,000-gal. storage tank at each siding avoided the undesirable practice of unloading directly from tank car to tank truck and to overcome delay in car unloadings due to interruption of the truck haul.

The pumps are permanently piped and so connected that by operation of the valves they can be readily used either to unload from rail or airborne tankers or to load the tank vehicles used to transport to the summits.

Three sizes of tanks with the following characteristics were decided upon.

(1) Field fabricated 25,000 I.g. vertical tanks 20 ft. dia. by 12 ft. high.

(2) Prefabricated 5,000 I.g. horizontal tanks 8 ft. dia. by 15 ft. 6 in. long.

(3) Prefabricated 1,000 I.g. horizontal tanks 4 ft. 8 in. dia. by 9 ft. 10 in. long.

Tank farms were provided at each of the relay sites. These have a storage capacity of approximately 125,000 gal. per site, sufficient to carry the station for a year with safety.

To reduce maintenance, the pipe layout was designed to provide ample flexibility for all pipe movements without the use of flexible joints or couplings, and to provide maximum accessibility during inclement weather consistent with acceptable and economic piping practice. Precautions taken to minimize the hazard of losses due to pipe damage included the use of vacuum breakers and foot valves.

Site Layouts

With the number and dimensions of the major structural components determined, it was possible to develop the detailed site layouts. These were required by the start of construction as their relative positions are quite important.

The electronic criteria relating to the development of the site layout stipulated:

(1) A separation of 200 ft. between the axis of antennas facing in the same direction.

(2) The waveguides or styroflex lead-ins for a pair of antennas to be of the same length and not longer than 300 ft. from their respective feed horns to entry to the equipment building.

(3) Buildings and structures to be kept clear of the antenna foreground areas covered by a horizontal angle of 30° to the left or right of the vertical outer edges of the antenna reflectors.

In addition to the above, the location of the approach roads and their entrance to the site were governed by the electrical characteristics of the system.

To avoid signal interference by

vehicle ignition systems, the approach roads had to traverse the area overshot by the beams below a plane through the lower rim of the antennas, and inclined at an angle 10° below the horizontal.

Further, the roads were prohibited from areas in which the exposure to radiations from the antennas would exceed an intensity in excess of one milliwatt/sq. cm. There are indications that higher exposures may prove harmful to life.

The Canatiche and Emeril station sites were selected by office studies during the winter of 1956-57. Field information was limited to that procured by the siting party during brief visits and was of reconnaissance survey order. Nevertheless, the development of site plans could not be further delayed.

An aerial inspection by light aircraft flying at low altitude, was made to select the most likely routes for access roads to the Emeril and Canatiche stations in early 1957. Various possibilities were further investigated by walking over the selected routes, establishing traverses, securing some spot levels and notes on the topography.

Rough contour plans were prepared from this information, supplemented by data from maps and aerial photographs, and the usual computations associated with the estimating of road construction were made. As it was anticipated that the work would be done under a form of owner-managed cost-plus contract, it was considered that these methods would produce results of adequate accuracy.

CONSTRUCTION

The individual stations differ widely in ease of access and other factors affecting the task involved in their construction. Nevertheless, progress must be adjusted to overcome these variations, so that all reach the same state by the first fixed dates in the system schedule.

This frequently requires a distortion of the normal sequence of work, and contract arrangements must respect this fact.

The purchase of materials must be coordinated to secure desired system standardization, particularly of electrical and mechanical items, without undue resort to the closed specification.

Overall policies relative to wages and working conditions must avoid differences between neighbouring divisions of the work, which may cause discontent and high labour turnover.

A consolidated transportation control must be organized with facilities available to all elements, particularly in areas served only by chartered transport facilities. If expensive job delays are to be avoided, this transportation setup must be under the complete control of the organization directly responsible for field progress.

The best types of contract for the services of the various contractors must be selected, and the degree of direct control which the owner wishes to retain must be determined and organized.

Although the programme required that the system be ready for service by June 1, 1958, necessary test and lineup periods following the electronic equipment installation established secondary but critical intermediate points in the schedule. These required that: (a) the equipment areas be completed ready for the start of electronic equipment installation by December 1, 1957; (b) the station power plants be ready to deliver power at full operational level by March 1, 1958; (c) the antennas, feed horns, and waveguide installations be ready for full operational test by April 15, 1958.

May 1st was the earliest date by which the design programme could be completed and specifications prepared. From experience, July 1st was the earliest date for major work on the access roads following the spring breakup, and contracts must be awarded in time to start work by that date. Materials to be ordered by the general contractors must therefore be limited to those readily available. Consequently, all elements which required specific manufacture were listed from advance working drawings. To this list were added any items which were to be standard throughout the system.

Materials so identified were procured directly by the owners and issued to the job. They included the building shells, the antennas, feed horn towers and feed horns, waveguides, petroleum tanks, fans, motors, and controls for the heating and ventilating system.

The contracts for the erection of the antennas and the fuel oil tanks were arranged and administered directly by the owners. Issue items were listed in the tender calls to construction contractors, who were required to carry out the quantity surveys and purchase all other materials necessary for the construction work.

By this division of work, materials were made available in time, the desired degree of standardization was achieved, and the talents of the general contractor's staff were brought to bear at the earliest opportunity.

General policies relative to on-site pay and working conditions, developed to avoid disparity between sites, were set out in the tender calls. It was recognized that, if the labour response proved inadequate, they would have to be adjusted.

General Contract Arrangements

Unpredictable elements, which might seriously affect cost, prohibited the use of fixed price contracts. Detailed plans and specifications of the structures involved were available in time to tender. It was considered that these, plus an approximate delineation of the on-site freight handling and roadwork, provided sufficient information on which to base competitive tenders on a cost plus fixed fee basis. Competitive elements included the fee, offsite overhead, and the equipment rental rates. Responses were well grouped and highly competitive, confirming the feasibility of the method of tendering. The invitations to tender described fully the extent of owner management under which the work was to be executed.

Isolation pay or special incentive pay other than that inherent in the sixty-hour work week was not offered. No difficulty was encountered by the contractors when recruiting labour, although it was found necessary to offer a 70-hour week to steel erectors. An extremely small proportion rejected employment when informed of the dry rule, but the employers considered that the job gained more than it lost by these rejections.

Sona Lake

Sona Lake provided the only exception to the contract arrangements outlined above. The construction of this station depended entirely on transportation by aircraft. The station is on a mountain-top approximately four miles from the shoreline of the lake. The surrounding area is broken by ridges interspersed with extensive swamps and boulder fields. It is devoid of eskers or other fortuitous deposits suitable for the construction of a temporary airstrip. The lake presents the only feasible landing area.

The largest amphibious aircraft commercially available in Canada is the Canso. The largest commercially available aircraft which can be equipped with skis and landed on an unprepared area is the DC3, and study indicated it would be feasible to land this aircraft on the frozen lake. With the equipment which could be transported by DC3, an ice strip capable of accommodating larger freight planes, limited to wheeled landings, might be developed on the lake.

In view of the more economical rates and greater bulk capacities of the wheeled aircraft, which would largely obviate dismantling the construction equipment and diesel generators, it was decided to carry out an advance winter airlift during the late winter and spring of 1957.

A detailed plan for the construction of the site was developed by the owners from advance drawings and data available from previous projects. This included estimates of labour, camp size, construction equipment, fuel, diesel oil and gasoline requirement, food, camp supplies, and construction materials. In this instance, and in the absence of plans and specifications on which competitive tendering could be based, a contract was arranged with a selected contractor on a cost plus basis.

An advance party made up largely of contractor's personnel under the control of a Company transport foreman was sent to the site in early February. A small camp was established on shore at the proposed origin of the access road. A radio beacon was installed and a freight marshalling area cleared. A miniature bulldozer and jeep left on site by a previous engineering exploration party had been purchased and were used to assist in clearing a preliminary ice strip. Support of this partv was initially by the ski-equipped DC3. With the snow blanket removed, the ice thickness increased steadily until by early March the 34 in. required to land C46 aircraft was reached. It was not expected that the ice thickness would last beyond April 1st. A shortage of C46 aircraft and mild weather which flooded the airstrip, further reduced the transportation by heavy aircraft. However, with the assistance of the radio beacon and temporary strip lighting, round the clock flying was possible during good weather. The contractor's equipment, one of the permanent diesel generators, muskeg tractors, sections of the antennas, and fuel tanks too large to be transported by Canso were moved in first. With this accomplished, the programme was assured. However, heavy aircraft flying was continued as late as possible to take full advantage of the economies.

The entire air operation was carried out with but one mishap. This involved a C46 aircraft, carrying a six-ton tractor, which landed on the ice strip April 6th with its undercarriage up. The aircraft lost its propellers, air intakes, and other parts. The tractor stayed put, testimony to the efficiency of the transport group, and the crew were unhurt. The air operator was in a less happy position, but the entire construction party worked shift to jack the aircraft and make ready for the salvage party. This party arrived April 9th with necessary replacement parts, and the aircraft took off April 13, seven days after the accident.

By April 28th the ice had thinned until it would no longer support heavy aircraft landings. However, contact with the advance party was maintained with light ski-equipped aircraft until May 22nd. From then to June 9th when the first water landing was made, the advance party of twenty-four men was isolated.

It had been hoped to establish a winter tote road to the summit, transport the freight on hand, and establish the main construction camp. However, despite the use of muskeg tractors, the attempt was abandoned. Consequently the advance party limited their efforts during the spring period to improving the lake camp, the marshalling area, building a motor vehicle repair shelter, and generally getting ready for the summer operation. By the time the snow was gone, the Sona Lake programme was advanced sufficiently to keep pace with the other stations and maintain schedule.

A total of 500 tons was moved in during March and April. The heaviest lift was a 6-ton tractor. All material lifted during this operation was transported to Seven Islands by the north shore route and flown in from there.

Access Roads

It was proposed to bring the permanent roads only to "carriageable" grade of single pass width as their use would be limited to the domestic traffic of the permanent operating crew of seven plus the annual transportation of approximately 125,000 gal. of oil. The operational plan further contemplated equipping the stations with muskeg tractors and trailers to handle essential traffic during spring breakup and in winter when it might prove impractical to keep the roads plowed. Nevertheless, the start of transportation of materials to the summits, the establishment of construction camps, and the start of work on the stations proper could not be delayed until the access roads had been built. With about 12 weeks available before severe winter weather and 20 weeks before the electronic equipment areas must be ready for the installation programme, it was essential that tote roads be cut through to the sites at the summits as quickly as possible. Construction of the permanent roads would be carried on concurrently.

Summer Construction 1957

The tote roads were traversable only by tracked vehicles. Stone boats and heavy duty farm wagons were used as tows. However, platform-equipped heavy duty logging sleighs proved the most sucessful tow over the wet soil conditions encountered. A D4 tractor or equivalent towing such a sleigh could handle a six-ton load over the tote roads at an average speed of about two miles per hour. Winching was resorted to when required to overcome the typical sharp pitch to the summit. The tote roads, because of the high humus overburden and the light nature of the subsoil, cut through after relatively little use. Corduroying crews were kept busy continuously repairing the softer spots, but eventually sections had to be abandoned and bypassing sections made ready. The crews became expert at anticipating such spots and usually the bypass was located, cleared, and at least approaching readiness by the time the worn out section became impassable to freight.

Rock excavation and drilling equipment had been transported to the summits at the earliest possible date to prepare the foundation areas. Next, aggregate for the foundations (500 to 700 tons per site) was hauled distances of from four to seven miles. At times around-the-clock transport was needed to keep sufficient materials ahead of the construction crews. As the permanent roads advanced and could be used the slower tracked-vehicle haul was shortened.

With freight access and camps established on site, an effort was made to construct all foundations practically concurrently, as this was necessary if the concrete work was to be completed before cold weather set in. This work was dominated by the need to achieve an accurate orientation of the antennas and to maintain the relative positions of the other structures.

A relatively rainy summer hindered hauling aggregates over the tote roads, and the exterior concrete programme was not achieved. However, by freezeup in early October all major concrete work had been completed. Final small items such as pump bases and septic tanks were poured by early November. The usual devices of heated aggregates, tarpaulins, and hot air heaters provided all the protection required for this miscellaneous work. No extensive heated hoarding was needed.

The advance anticipated in the erection of the equipment wings with timber foundations and floors was realized.

The shells for the equipment wings were fully erected, the buildings closed in and interior work well in hand by the time the foundation work for the diesel wing was completed. Results varied slightly from site to site. However, by November 1st or approximately two weeks after the onset of severe winter weather, the shells of all buildings had been erected and closed in. The equipment wings at all sites were completed ready for the start of the electronic equipment installation programme by December 1, approximately twelve weeks from the start of construction.

The bases for the petroleum tanks had been made ready by the general contractors concurrently with the early foundation work and the steel plate transported to the sites in readiness for the erection crews. These tanks were assembled by field welding in the usual way. A travelling crew of nine men started the tank erection September 10th and completed the task, including testing, by the end of October. Associated pump, piping and electrical work was carried out by the general contractors.

Antenna Erection

The antenna erection crews were brought in during October. Erection was carried out concurrently at all sites. A typical erection crew comprised a foreman, a lead hand and ten erectors. All steel had been laid out on site before arrival of the erection crews. A mechanical crane was available at Goose Bay, but at all other sites a gin pole was used. Erection was unavoidably over the period from November until mid-February. Some of the winter's most severe weather occurred during this period. Temperatures dropped as low as -40°F, strong winds were fairly constant. Despite this a seven-day work week was maintained by all erection crews. The total lost time due to weather was less than 2%, and there was not a single lost time accident. The twenty antennas required for the system with their associated feed horn towers weighed 840 tons and included 26,808 structural members.

Construction of permanent roads was retarded by freight moving over them. Attempts to minimize this by parallelling tote roads were generally not feasible.

The construction of the Canatiche road proved much easier than had been anticipated. By the end of August a passable truck road had been constructed to about half a mile from the summit. Although the last half mile was the toughest, the prospect of easy truck access was tempting. It was decided to complete the road and let the construction materials accumulate at the rail side.

By September 23, with nine weeks to complete the equipment building, and the truck road still 2,000 feet short, work on the permanent road had to be suspended and toting resumed. Round the clock shift work was instituted to offset the time lost. The "building ready" date was barely met, with difficulty. This was the only, apparently more logical, attempt to build the access road first.

At Emeril, the ten miles of road had been corduroyed and the base laid by freezeup. However, about two feet of gravel was required to bring it to grade. It was expected that winter conditions would stop the work, but the gravel proved relatively dry and workable for the required period.

The road built under these conditions might well prove impassable during the spring thaw but this did not occur. It is not suggested that winter is the best time to build roads in comparable areas, but in this instance it proved practical.

The Sona Lake reconnaisance party found evidence indicating extensive gravel deposits, typical of this area. Construction equipment was scaled to meet this indication. However, it was later discovered that the showing was merely a minor pocket, and the entire area traversed by the road was otherwise devoid of gravel. A substantial deposit, three miles across the lake, could not be linked by road.

A raft was constructed from oil drums and powered with outboard motors. A 5-ton loader was transported across the lake to the gravel deposit, and about 600 tons of aggregate were ferried over during the summer. This was sufficient for all concrete work. The access road was corduroyed and ballasted with the fine sand available until freighting with tracked vehicles was possible. The construction of the station proceeded on schedule.

An ice road was opened across the lake during the following winter and 8000 yd. of gravel were hauled and stockpiled. There were too few trucks to carry on road construction during the winter, although no difficulty was experienced handling the gravel.

The contractors' heavy equipment was removed in April as the 1958 heavy airlift drew to a close. Distribution of gravel and final road grading was carried out by a small work party during the following summer, using equipment permanently assigned to the site for road maintenance.

At May 21, 1958, less than eleven months after the start of construction, the entire project was essentially completed; electronic equipment was installed and tested. The total force engaged on the construction and transportation work built up from zero in early July 1957 to a peak of six hundred (September 15th to October 15th), and then fell steadily to four hundred by January 15, 1958, when an even sharper decline began. At May 1958 less than one hundred were engaged dismantling camps, removing construction equipment, and clearing up minor tasks. All intermediate dates as well as the final dates of the construction schedule were met. Approximately 12,000 tons of material were marshalled and transported to the sites by rail, sea, and air. Air transportation cost over $600,000. Despite site-to-site variations from estimated, the cost of the construction and transportation programme should aggregate approximately one per cent less than the owners' original estimate.

ACKNOWLEDGMENT

The project proved a complex one which demanded the talents of many people. The authors welcome this opportunity to acknowledge the contributions made by their associates.

INTRODUCTION

by Per Hall, P.Eng., M.E.I.C

THE DEAS ISLAND Tunnel, a four-lane vehicular traffic facility, is now under construction near Vancouver for the British Columbia Toll Highways and Bridges Authority. The tunnel will provide a second, urgently needed, permanent crossing of the Fraser River and will form part of a major new freeway-type radial highway emanating southward from Canada's western seaport.

This crossing (Fig. 1) will open the way for the southerly expansion of the metropolitan area which, until now, has been channelled to the east between the two water barriers of Burrard Inlet and the Fraser River. It will augment the capacity of the existing Pattullo Bridge at New Westminster which has already become overtaxed, and will replace the present inadequate ferry service operating to Ladner, B.C. Complementing a new vehicular route the crossing will open large areas of land for residential and industrial development by offering fast, safe transit into and out of Vancouver.

In 1903 the first permanent crossing of the Fraser was established with the construction of a combined highway-railway bridge at New Westminster. Then in 1912 a ferry service was introduced at Ladner, instead of the bridge requested by a Delta Municipality citizens group. By 1925 the New Westminster crossing was inadequate for the traffic requirements and the Government took steps to ensure the future development of routes. As a result a private company undertook the construction of a bridge at Deas Island in 1933. This venture failed in that same year, and it was not until 1937 that the first new crossing, the Pattullo Bridge, opened to replace the highway portion of the New Westminster span.

By 1953, the Pattullo Bridge, purported to be capable of handling 3,000 vehicles an hour in one direction, was obviously near saturation. At this time, studies were initiated to determine the future need for highways and crossings. The resulting report recognized the overtaxing of existing facilities and the imperative need for additional crossings of the Fraser.

A subsequent study, prepared jointly by Foundation of Canada Engineering Corporation Limited and Christiani & Nielsen, recommended the construction of a four-lane tunsel at Deas Island. This was based on studies of possible locations at Port Mann, Annacis Island, Tilbury Island, and Deas Island, and on an analysis of traffic growth and future routes.

Physical Site Conditions

The area in which the tunnel is located is extremely flat, low lying, and bare of timber. It is protected from flooding by 6-foot dykes running downstream from Annacis Island to the mouth of the river.

Borings taken during preliminary studies indicated the presence in this area of a heterogeneous soil consisting of sand, silt and clay, with little uniformity of structure either in occurrence or in degree of compactness of the strata. The conditions suggested the possibility of considerable settlements for which allowance would have to be made in the design. However, a tunnel, unlike a bridge, would not impose any significant loads on the soil, and, therefore, would be a more suitable type of structure at this site.

The flow of the Fraser River, varying from 21,000 cfs. to 536,000 cfs. as measured some 60 miles upstream of the tunnel site at Hope, B.C., is markedly effected by tidal fluctuations in the Strait of Georgia. The tides and river discharge combine to give a water level range of 11 feet at the tunnel and a reversal of flow ranging from 7 fps. downstream to 3 fps. upstream.

The current in the river and the great variation in discharge combined with the nature of the bed material accentuate the scour and fill action normally observed in restricted channels at time of high water. In addition, material is transported in suspension while a bed load is carried along in the form of dunes.

A major consideration in the selection of the type and construction of a crossing at this site was that of providing adequate clearance for the navigation of ocean shipping moving up the Fraser to New Westminster. It was necessary to plan the crossing to provide not only the size of channel required at present, but also that which might be necessary at some time in the future. Since the channel in the Fraser must be maintained by extensive dredging it was also necessary to design the structure so as to avoid harmful changes in the existing scour and fill pattern.

Comparative studies of a bridge and a tunnel indicated that the tunnel could be built so as to avoid serious change in the hydraulic section of the river or dangerous reaction of the foundation soil.

In addition, the tunnel could be built more economically than a bridge and, in requiring vehicles to deviate only 80 feet from the horizontal as compared to 160 feet for the bridge, would provide for more economical passage of traffic.

As a result of the studies of traffic needs, site conditions, and the relative merits of a bridge and a tunnel, it was recommended that a tunnel be constructed under the Fraser River at Deas Island (see Fig. 8).

GENERAL LAYOUT and STRUCTURAL DESIGN

by T. Brœndum-Nielsen, P.Eng. and H. R. Kivisild, D.Eng.

THE APPROACHES at both ends of the tunnel are constructed as open troughs right out to the river banks to reduce as much as possible the length of the tunnel proper. Between each approach and the tunnel is a ventilation building. This general arrangement was found to provide an economical balance between the costs of the structure and those of the technical installations. The reduced length of closed tunnel made possible by this layout also affords a reduction in operating costs, as neither ventilation nor daytime illumination of the open approaches is required. All horizontal curves have been avoided to make passage of vehicles and inspection of traffic conditions easier.

Figure 2 shows a cross-section of the tunnel. There are four traffic lanes, each 12 feet wide, with a vertical clearance of 14 feet. The two-lane roadway for northbound traffic is separated from the southbound roadway by a longitudinal partition wall, the sides of which are sloped to improve acoustics. A bituminous road-surfacing has been chosen because of its smoothness, ease of repair, and sound-damping qualities. The two ventilation ducts, which run the entire length of the tunnel, are placed on the outer sides of the roadway tubes.

The subaqueous part of the tunnel consists of six precast reinforced concrete elements, each about 344 feet long, 78 feet wide, 24 feet high and weighing approximately 18,000 tons. The elements are cast in a dry dock excavated for the purpose near the site and later floated out and sunk in position in a trench dredged in the river bottom.

The tunnel elements are waterproofed with a 3/16 inch steel plate under the bottom slab and a bituminous membrane of the built-up type on the walls and the roof, except for a distance of 11 feet at each end of the tunnel elements, where a collar of 3/16 inch steel plate is used to facilitate the complete waterproofing of the tunnel at the joint between the elements. Steel plate waterproofing is also provided within areas of the roof where embedded parts penetrate the membrane.

The waterproofing membrane (asphalt with glass fibre reinforcing) is protected by a 4 inch thick layer of reinforced concrete under the bottom and on the top, and by 4 inch wood planking on the walls.

When an element has been sunk into its final position in the trench and temporarily joined to the element previously sunk, sand is jetted between the element and the bottom of the trench, and backfilled at both sides of the tunnel element. The river bottom is protected by means of articulated reinforced concrete mattresses covered by a layer of stone and rock, and rock protection is placed on top of the tunnel.

Approaches

Traffic requirements have determined the roadway geometry and thus the basic dimensions for the 1,800 ft. long approach on the Lulu Island side, which is shown on Fig. 3. The roadway drops 50 ft. over the length of this approach.

Both approaches and access roads are on extremely flat land, little developed and almost bare of timber.

Fig. 1. Map of Vancouver area.

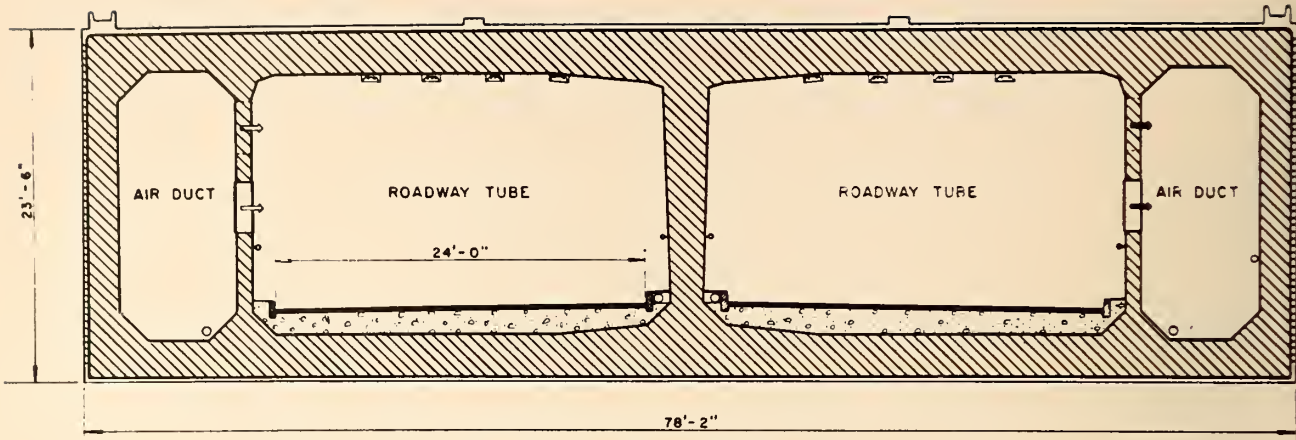

Fig. 2. Cross section of tunnel.

These factors favoured the adoption of the deep open approaches, which were designed as concrete troughs (Fig. 3 and 4).

A central wall running between the roadways for a distance of 420 ft. from the portals assists in ventilating the tunnel. This wall prevents the passage of vitiated air from one tube of the tunnel to the entrance of the other where it might be sucked into the tunnel.

Aluminum louvres are placed above the roadway for 310 feet in front of each of the two tunnel entrances and for 186 feet at the exits. By shading the roadway from direct sunlight, these louvres provide a transition, on sunny days, from bright sunlight to the lower light intensity in the tunnel.

Between each approach and the tunnel proper, a ventilation building provides a transition between the open trough and the closed subaqueous portions (Fig. 3 and 5).

Approach areas on both sides are a few feet above average river stage, but below high water stages. Although the north approach is behind the river dyke system, additional earth dykes encircle the approach area on both sides.

These dykes protect the approaches against crests of waves and surges and daily flood peaks. Under normal conditions the water is retained by the concrete walls of the troughs. If these walls had been built to retain maximum river stages, sections would have had to be increased considerably, with higher overall cost.

The mild climate with shallow maximum frost penetration depth (2.5 feet in normal soils) permitted the foundation of roadway troughs directly on the soil with bottom slab thickness varying for structural reasons only.

The troughs were designed as reinforced concrete sections. Two sections of approach structure were evolved, one being the gravity type trough used in the shallower parts and the other being one with cantilevered slabs extending into the earth to provide safety against uplift. (Fig. 5.) At the deepest portion the side walls are strutted.

Because of the heterogeneous nature of the subsoil, with lenses of sand, silt and clay, it was found advisable to divide the approach structure into 30 foot and 46.5 foot units connected by keys. The whole of the outer surface of the structure is waterproofed with an asphalt and fibreglass membrane, and the joints are provided with polyvinyl waterstops.

Basic dimensions of the concrete troughs give sufficient safety against uplift and excessive deflections. Since the trough dimensions are very sensitive to changes in stability requirements and soil properties, a whole range of conditions was investigated, and sliding was studied along various possible planes. Since the tunnel is located in a zone 3 earthquake area, various combinations of horizontal and vertical accelerations were considered. Because of the possibility of sand quickening under shock, a lowering of soil friction angle by vibration was taken into account. The combinations used were 0.21g with a friction angle of 30°, 0.1g with a friction angle of 20°, and gravity acceleration only with a friction angle of 15°.

As the main load in the structural design of side walls, a pressure of soil at rest combined with water to the crest of the troughs was considered. Reversal of stresses was checked by assuming only active soil pressure and a lowered ground water level. The calculated reinforcing was checked for forces acting during earthquakes.

In the main troughs, shear reinforcing was eliminated by increasing the thickness of the slabs. Longitudinal reinforcing was provided in gravity sections on the basis of subgrade drag theory and in the heavily reinforced units on the basis of the minimum required to distribute cracks as specified by building codes.

Ventilation Buildings

The ventilation buildings house the main fans for the tunnel and the necessary equipment for the control of the ventilation, lighting and traffic.

As already mentioned, it was considered necessary to divide the approach into relatively short units. For the same reason the ventilation buildings were made self-supporting so that they act as dams founded on slabs.

The walls on the river sides of the ventilation buildings retain earth and water. These forces are carried down to the base slabs by three longitudinal internal partition walls and by buttresses on the river side. These frames act in the same way as the buttresses of a buttress dam, although in this case they are working basically in tension.

Tunnel Section

The structural design of the tunnel section was made in accordance with the National Building Code of Canada.

The loads on the tunnel are: (a) weight of tunnel; (b) water pressure corresponding to high water level; (c) rock fill and sand deposits on the tunnel; (d) soil reaction; (e) frictional forces, i.e. vertical forces on the outer walls of the tunnel, caused by differential settlements of the ground below and outside the tunnel; (f) earthquake loads.

For ordinary loads, items (a) to (e), the allowable stresses were computed in accordance with the National Building Code of Canada.

The Hardy Cross moment distribution method was adopted in the analysis of the cross-sections of the precast tunnel elements. A number of cross-sections were analysed, a considerable number of load combinations being considered for each. In order to reduce the amount of calculation required, certain unit loading cases were chosen, for which the bending moments and normal forces were calculated. Any load combination could then be calculated easily by appropriately superposing the effects of the unit loading cases chosen.

The analysis proved that a uniform cross-section was appropriate for the entire length of the tunnel, and that even the reinforcement could be the same for all cross-sections, except for a few minor variations near the ends of the tunnel.

In the floating tunnel element, bending moments occur in the longitudinal direction. These were kept within permissible limits by an appropriate placing of the ballast and did not, therefore, necessitate additional reinforcement.

Differential Settlements

According to the subsoil investigations, the layers directly below the future tunnel bottom are mainly compressible silt. The influence of the settlements of these layers was investigated. Undisturbed samples were taken from the silt layers by means of thin-walled tube samplers and Oedometer tests were carried out on the samples extracted.

As the weight of the tunnel and backfill will be less than the weight of the soil dredged from the trench, the movement of the bottom of the trench will correspond to rebound when the trench is dredged, followed by some compression after the tunnel is placed. From the settlement calculations, it was found that the probable settlements would be 3 to 4 inches.

The tunnel was analysed as a beam on elastic foundation, loaded with a sinusoidal load having a maximum corresponding to rock fill plus 20 feet of sand, and a minimum corresponding to rock fill alone.

The tunnel structure was designed to be capable of following possible differential settlements without cracking. This called for a shallow cross-section, which was obtained by placing the ventilation ducts within the height occupied by the roadway tubes.

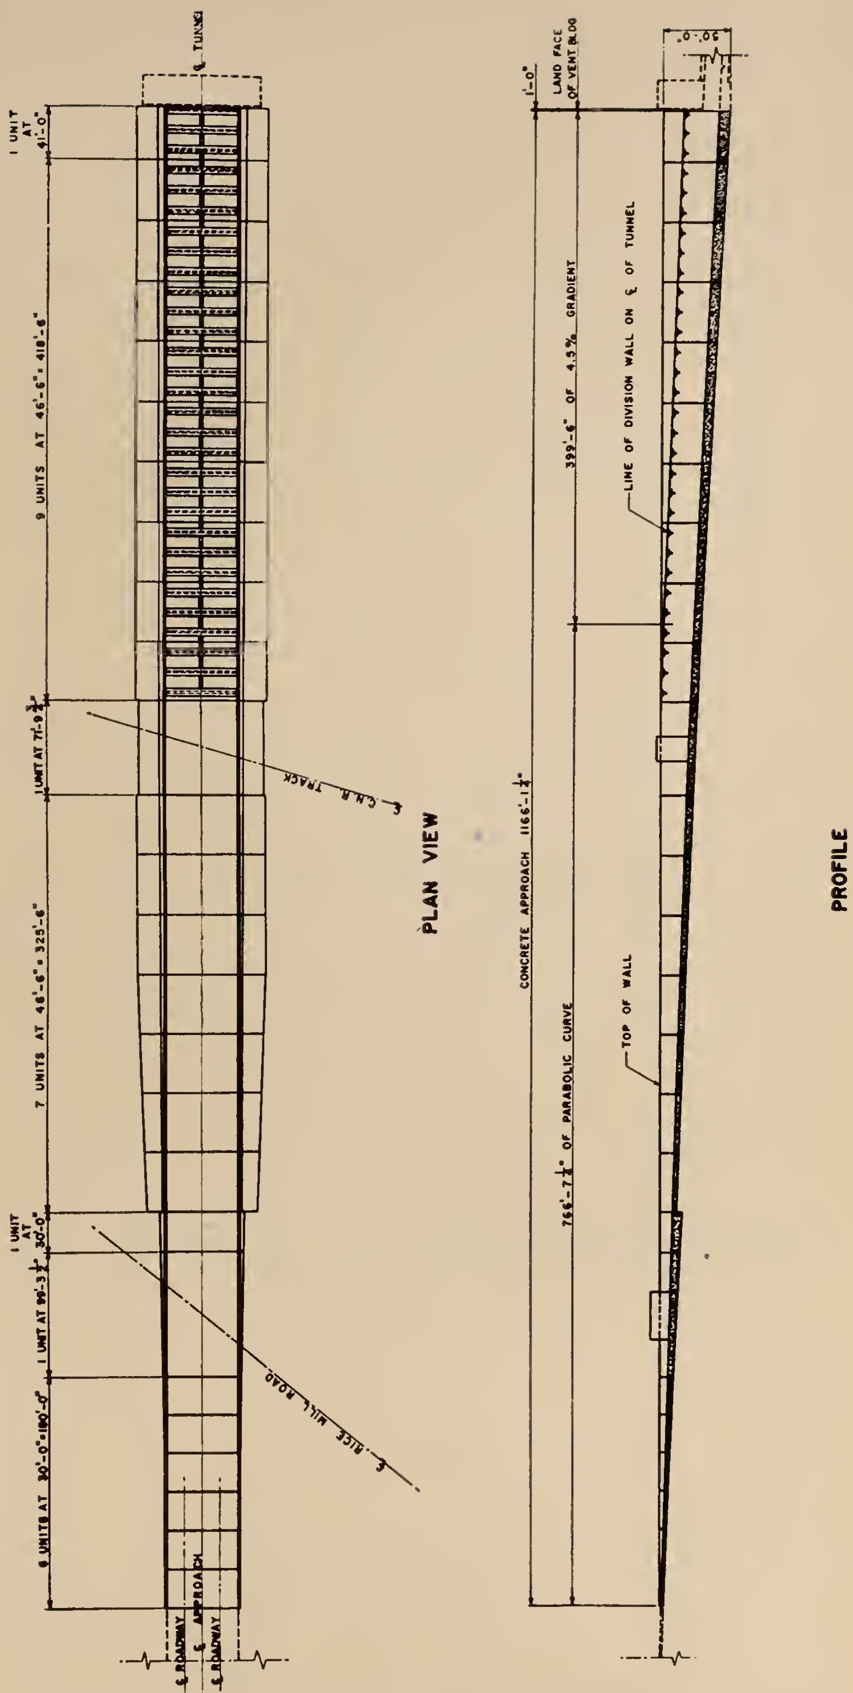

Fig. 3. Layout of Lulu Island approach.

The backfill on both sides of the tunnel represents a heavier loading on the silt than does the tunnel proper. This includes differential settlements which result in vertical friction forces between the backfill and the outer walls, with corresponding vertical shear stresses also transferred through the soil above the tunnel in the planes of the exterior lateral faces of the tunnel. These loads were taken into account in the stress analysis and were calculated by equalizing the elastic deformations of the cross-section and the corresponding settlements of the silt. Different distributions of the soil reaction beneath the tunnel were considered, and for each case the vertical friction forces and shear stresses were calculated. It was found, however, that the deformations of the cross-section and consequently also the stresses in the tunnel were practically independent of the assumed distribution of soil reaction.

Earthquake Resistant Design

The literature on earthquake resistant design of buildings is mainly confined to structures above ground level. Very little information is available on structures below ground level, and it is generally assumed that these suffer less damage during earthquakes than do structures above ground.

Since the Deas Island Tunnel is located in a zone 3 area, the effect of earthquakes on tunnels was studied thoroughly.

The conventional design procedure for structures exposed to earthquakes is to apply a horizontal acceleration to all parts of the structure. The acceleration of the masses of the different parts of the structure gives corresponding horizontal forces. The acceleration applied is often taken as 10 per cent of the acceleration of gravity but different values may be specified. The National Building Code of Canada specifies different values depending on the site and the type of structure.

By applying a horizontal acceleration to the earth mass, shear stresses will be set up in the soil. This method of approach corresponds, therefore, to shear waves transmitted through the medium. It is obvious that the shear stresses caused by the horizontal acceleration cannot exceed the shear strength of the soil, for if they did a failure would take place and the total energy of the earthquake would not be transmitted.

The maximum possible acceleration of shear waves will depend upon the shear strength of the medium through which the waves are transmitted. The maximum intensity observed on light geological formations is about 8 in the Modified Mercalli Scale, corresponding to an acceleration of 27 per cent of the acceleration of gravity.

During earthquakes, the stress changes take place so rapidly that no water can escape from the pores of the soil, which consists in this case of rather fine sand. The stress changes will result, therefore, in excessive pore pressures.

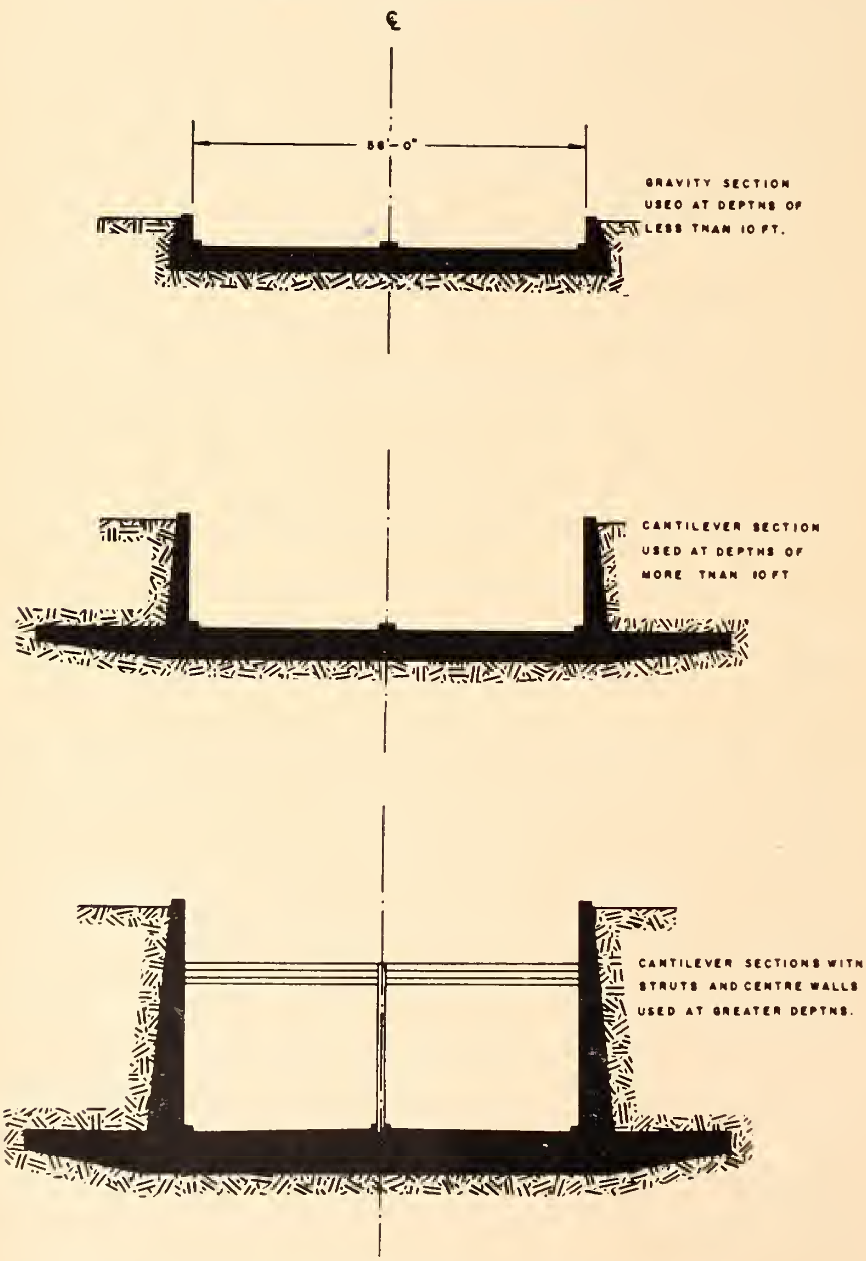
From theoretical considerations it was found that shear waves with an acceleration exceeding 21 per cent of gravity would cause failure in the soil. Thus the soil would not be capable of transmitting stronger shear waves.

The design was based, therefore, on a maximum acceleration of 21 per cent of gravity. For this acceleration, shear forces equal to 21 per cent of the overburden were assumed to be transmitted to the roof of the tunnel. In addition, an increase in the soil pressure on the outer walls of the tunnel, up to a value corresponding to the pressure from a liquid of the same density as that of the sand, was assumed.

The tunnel was so designed for this loading condition, corresponding to the failure condition in the soil layers, that the stresses exceed neither the yield point of the steel nor the compressive strength of the concrete.

Before it was finally decided to

Fig. 4. Types of approach units.



base the design on the above principles, an attempt was made to approach the problem in one of the following two ways:

A theoretical study of harmonic compression waves through an elastic medium showed that the effect of such waves corresponds to an increase in the soil pressure on the outer walls of the tunnel, which was in accord with the corresponding increase arrived at by the above considerations based on shear waves. Compression waves, however, do not cause shear forces on the tunnel (sidesway) and are consequently less dangerous than shear waves.

The results of a large number of earthquake tests on retaining walls backfilled with sand were studied. According to these experimental data, the increase in soil pressure on the outer walls of the tunnel would be smaller than the increase found by the theoretical shear wave considerations.

As a result it was found that the shear wave theory led to the most conservative design. Moreover, the structural analysis proved that a design based on this theory would require only slightly greater quantities of materials than would be the case were earthquake loading completely neglected. Consequently, it was decided to base the design on the shear wave theory.

Safety Against Uplift

For the completed tunnel, the factor of safety against uplift, under the most unfavourable conditions, is 1.16. All loads were checked during the construction period in order to reveal possible deviations from the design assumptions. If the frictional forces between the backfill and the outer walls were taken into account, the factor of safety against uplift would be 1.28.

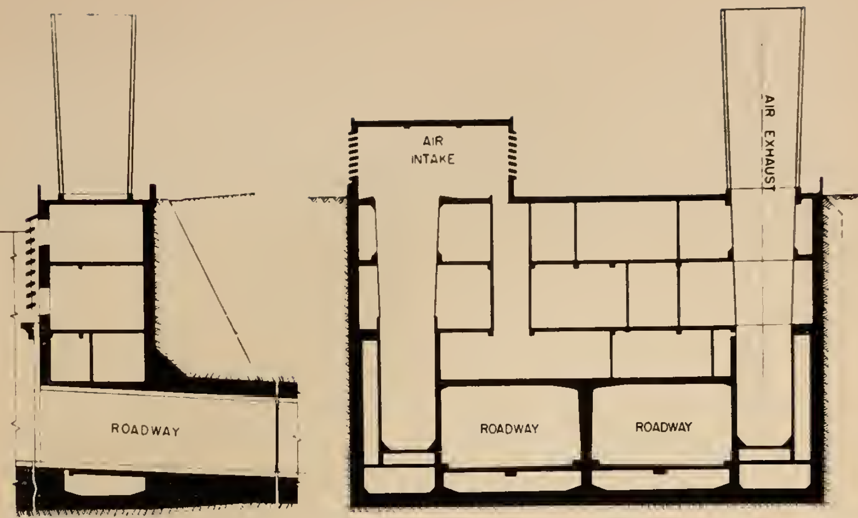


Fig. 5. Layout of ventilation buildings.

HYDRAULIC DESIGN

by H. R. Kivisild, D.Eng.

THE CROSSING is about 6 miles from the mouth of the Fraser River, and well within the tidal range which extends some 50 miles farther upstream. Normal tidal range is about 6 to 8 feet outside flood periods. Tidal currents are strong, reversing the flow during low discharge periods.

The river discharge is low during the winter, averaging approximately 21,000 cfs at Hope, B.C., with a minimum of 12,000 cfs. During the spring freshet, a discharge of 536,000 cfs has been recorded at Hope. A peak of 700,000 cfs is estimated to have a frequency of once in 1,000 years. At the site, outflow from various lakes between Hope and the site increases the discharge. This increase is again reduced by diversions to the North and Middle Arms a few miles upstream from the site.

During flood periods, river currents at the site are governed by discharge; during the winter months tides are the major cause of currents. Definite current patterns were established by velocity measurements and related to predict favourable periods for sinking operations.

The mildness of the climate precludes appreciable ice formation on the lower reaches of the Fraser River, except during the infrequent periods of low temperature. Local ice is not important, but ice floes from upstream may be up to 100 feet in diameter and a few feet thick.

Since the river current reverses during winter months, some salt water is carried upstream past the site. The salt water, being denser than fresh, takes the general form of a wedge, lifting the fresh water as it progresses upstream. The density of water on some days has varied from 1.00 at the surface to 1.02 at the bed. Obviously, this wedge had a special importance in planning sinking operations.

River Regime

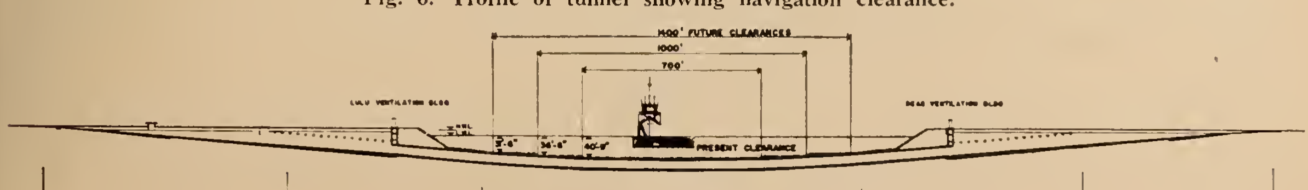
The current in the river, combined with the nature of the bed material, gives rise to considerable scour and fill action. A portion of the material is transported in suspension while the bed load forms dunes along the channel. These dunes have reached an amplitude of 15 feet with a length of 500 feet and may move downstream at a rate of up to 250 feet a day.

The river is constrained by dykes and revetments. Thus the shores are fixed. The only meandering is the shifting of the talweg and river bed contours from year to year.

Existing data on the river regime were supplemented by periodic soundings, bed load measurements, and trial trenches in the river bed. On the average the bed load samples were made up of 10% coarse sand, 80% medium sand, and 10% fine sand. Bed load was found to follow Schoklitsch's law for sedimentation.

For a study of tunnel effects on

Fig. 6. Profile of tunnel showing navigation clearance.



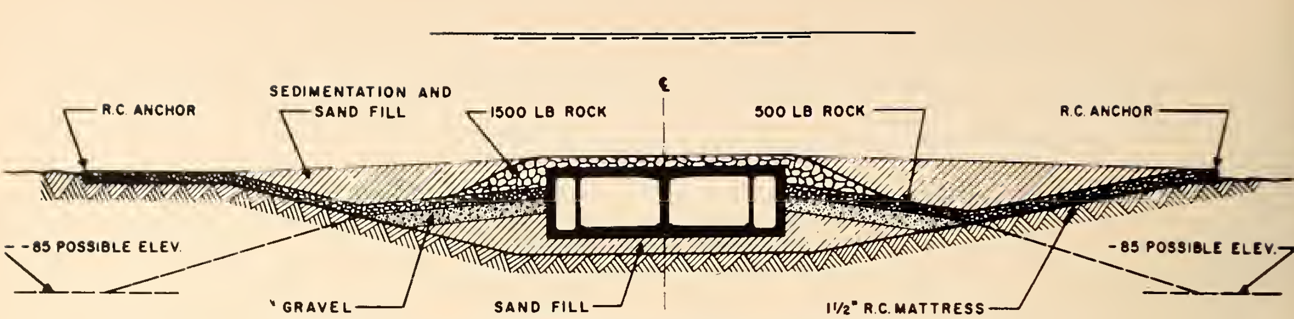


Fig. 7. Cross section of tunnel in place.

river regime, future river channels were estimated. These depend on various alternative river training programmes.

A certain amount of dredging is required to maintain definite depths and widths and also to provide a desirable course for any fairway. In addition to these corrective dredgings, continuous or periodic excavation of river bed material would be required if the section of the river with the planned fairways gets out of balance, and in the Fraser River the amount of dredging rapidly becomes very high.

Assuming the future characteristic discharge to be the same as at present, the maximum stable depth from low water will be about 28 feet for a 1400-foot fairway when the river is trained to that width and 37 feet for a 700-foot fairway inside the larger channel. Navigable depths are about 8 feet less than the average depths of stable fairways given above because of bed waves which reach 15 feet in the lower Fraser River.

Navigation

At present, the main river traffic of deep sea vessels past the site is directed to the Port of New Westminster, and amounts to some 400 vessels totalling about 2.5 million gross tons. Present navigation clearance is 22.5 feet below low water over a width of 300 feet.

For future navigation, the Department of Public Works has specified considerably larger clearances, which have been followed in the design (Fig. 6). The subaqueous tunnel is placed at a level to give the following clearances at minimum water surface elevation over the tunnel for a future channel: 31.5 feet over a width of 1,400 feet; 36.5 feet over a width of 1,000 feet and 40.75 feet over a width of 700 feet.

These estimated stable fairways fall within the clearances at the tunnel. The following clearances for navigation will be provided during various tide phases:

River Clearances

	Ord. Low Water	Ord. High Water
Tunnel Clearance		
1400 ft. width	33	39
700 ft. width	42	48
Stable Channel		
1400 ft. fairway	21	27
700 ft. fairway	30	36

The elevation of +3.5 feet GSC adopted for ordinary high water is reached practically daily for several hours and is thus a safe figure for navigation.

The Fraser River stable channels are comparable to those of the major navigable tidal rivers in the world, and the tunnel provides more than these clearances.

River Bed Protection

The tunnel and river bed upstream and downstream of the tunnel are protected by an apron. Its main purpose is to protect the tunnel itself against undermining, but it also provides a gradual guidance of river flow from the natural river section to the wider and shallower tunnel section and back to the river section, almost eliminating the effects of turbulence downstream.

Model tests showed that the depth of talweg is only mildly increased by the presence of the tunnel. On the basis of these tests, the only protection required was against the natural lowering of the river during flood periods. The blanket adopted (Fig. 7) was chosen because it could be placed in the river bed with a minimum of dredging and, as a flexible self-launching apron, would follow natural river bed contours.

On top of the tunnel and for 50 feet on either side, 1500 lb. stones are placed in double layers as protective armour over a double layer of 500 lb. rock and 5 feet of gravel. The heavy stones are required in this area because of the heavy turbulence encountered. From 50 to 100 feet from the tunnel the protection is made up of 500 lb. rock on a 1½ in. reinforced concrete mat. The mat extends for 15 feet under the gravel at the tunnel for anchorage and prevents the armour rock from sinking into the sand under the action of turbulence and pressure variations. At the extreme outside edges, the mat is attached to concrete anchor blocks, which also aided in the sinking and launching of the mats.

Bank Protection

Near the tunnel the shore protection below water level is basically the same as the river bed protection described above. Above water level for 600 feet, centred at the tunnel, rock armour on a gravel filter is used. Farther away from the tunnel, present guide banks are reinforced in some places by dumping rock.

Model of Sinking Operations

Hydraulic model tests were carried out at the Hydraulic Laboratory of the Technical University of Denmark in order to determine the drag effects on the tunnel element before, during, and after sinking.

Results confirmed previous calculations and supplied the important information that downward forces exist when the element is floating and upward forces when it is near the bottom.

Model Tests of the Layout

The final geometric layout of protective works was determined on the basis of model tests which were carried out in the Fraser River Model at the University of British Columbia under the direction of Professor E. S. Pretious. These tests gave flow and river bed conditions at the tunnel and showed the effects of the tunnel on the river regime.

The Fraser River Model has been discussed elsewhere. In general, it is a tidal, loose boundary model treating the lower Fraser River up to 56 miles from the mouth. Horizontal scale is 1:600 and vertical scale is 1:70.

The model bed for the Deas Island Tunnel erosion and sedimentation tests was moulded in the tunnel area to 1955 pre-freshet soundings and elsewhere to 1954 pre-freshet soundings. The hydraulic regime for verification and for normal maximum operating conditions was the 1950 natural tide period with freshet discharges. As an extreme case, a flood with a discharge of 700,000 cfs at Hope was also imposed. River beds with and without the tunnel were compared in both conditions mentioned.

The model test showed that the blanket design adopted, with armour at river bed level, gave the smallest scour effects for all alternatives. Tests indicated some local scour upstream of the tunnel to a maximum depth of 15 feet in extreme conditions. Downstream the influence of the tunnel was small, although it appeared to increase somewhat the tendency to shoal along the north bank.

At Kirkland Island Nose, the bed showed considerable scour, both with and without the tunnel when the 1000 year flood conditions were imposed.

After erosion tests, flow patterns were also studied. Flows before and after, both with and without tunnel, were practically identical, the only difference being a slight separation from the north shore downstream of the tunnel. Discharge distribution between the Main Arm and Ladner Reach was substantially unchanged. The tests showed no measurable drop of water surface elevation under any conditions.

Model Tests of the Blanket

Preliminary tests were run at the University of Alberta by Professor T. Blench, while the final series of hydraulic model tests to investigate the structure of the protective blanket was conducted under the direction of Professor E. S. Pretious in a glass-filled flume in the Hydraulics Laboratory of the University of British Columbia.

These flume tests could not be used to determine flow patterns or the effect of the tunnel on river levels. In the flume, the flow in the deepest channel, which was the section modelled, could not be redistributed sideways when restricted by the tunnel. In practice, the mild slopes of the blanket will redistribute the flow with only minor turbulence losses. Therefore, the more general phenomena were tested in the Fraser River Model, as already described.

As a first result, a run at 600,000 cfs showed that the protection with 500 lb. prototype weight was inadequate on top of the tunnel, and new protection with a prototype weight of 1500 lb. was substituted. It also became evident that downstream blankets could be shortened.

The blanket, as constructed, seemed stable under the 1000 year flood of 700,000 cfs at Hope with water surface at extreme low of 9 feet GSC at the site. Near the tunnel, 1500 lb. rocks were stable as were 500 lb. rocks at a greater distance from the tunnel.

At some stages in the tests, sediment collected on the apron but the shoals never rose above the crest of the tunnel. Furthermore, the flow in the tunnel area showed no harmful eddies in any of the tests.

Field Observations

Soundings at the site showed that the apron as built followed the design quite closely and, therefore, the effect on hydraulic conditions in the river regime could be expected to be the same as shown by model tests. This was verified by a series of field measurements.

During the construction of the protective apron, soundings were run at short intervals, as many as two a week towards the end of the construction period. The soundings showed considerable variation from natural conditions immediately after completion. The changes became less pronounced gradually and after the freshet the river bed was essentially the same as in the year before the placing of tunnel elements. The only change was the actual area of the tunnel mound.

Velocity measurements were carried out along the tunnel centreline which showed that the protection guides the flow as designed. Velocities did not increase except at the north bank and, after completion of the blanket, turbulence became negligible.

Flow distribution studies between the Main Arm and Ladner Reach showed no deviation from previous years.

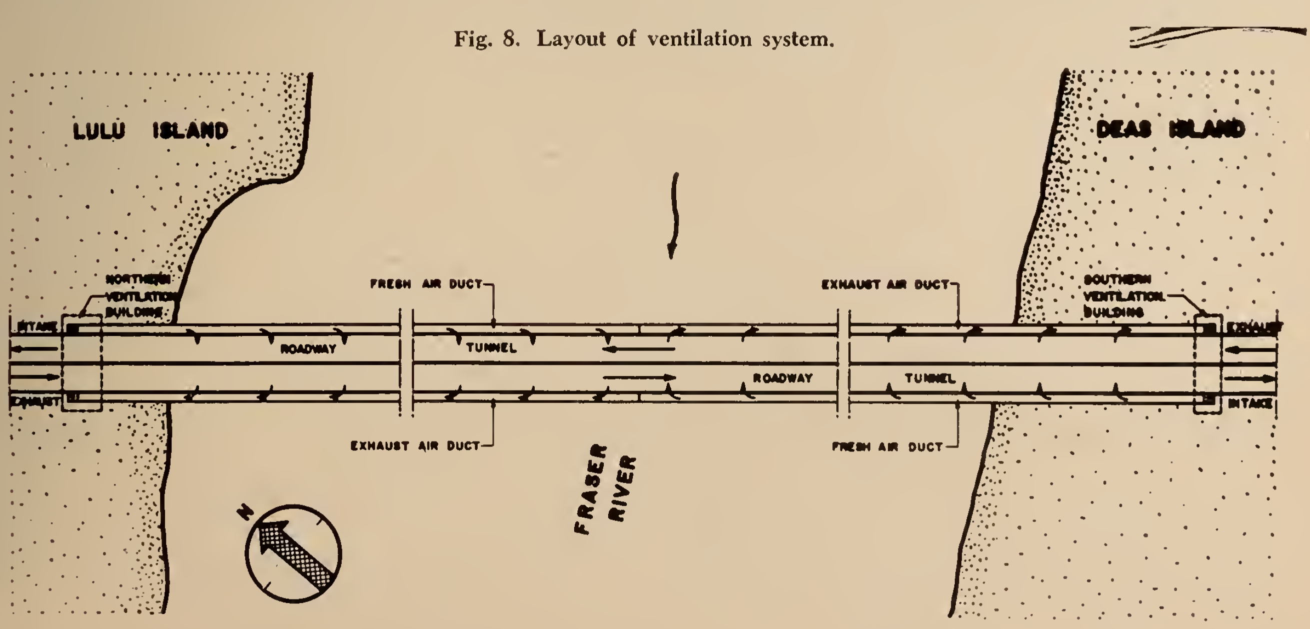
As was expected from the model tests, the tunnel was covered with silt on the southern half. On the northern half only the top of the tunnel is bare. No instability was observed anywhere on the blanket.

Relation of Studies to Design

As shown above, the variations in discharge, tides and water density affect the sinking procedures. However, a reliable method of forecasting the effects was devised by a combination of site investigations and theoretical studies.

Field measurements after construction showed that thorough hydraulic model studies make a reliable design of protective blankets possible.

Fig. 8. Layout of ventilation system.



TECHNICAL INSTALLATIONS

by A. T. Jeffrey, P.Eng.

THE BASIC DESIGN requirement is the provision under all anticipated conditions, of safe, rapid passage of vehicular traffic from portal to portal. This necessitates sufficient ventilation and lighting with adequate detecting and operating controls to govern traffic movement and ventilation and lighting programs under all possible conditions of carbon monoxide occurrence, fire, poor visibility, accident, wind and light. Such control necessitates the provision of the most reliable sources of power available, with alternative emergency sources.

Ventilation

Basic tunnel ventilation is provided by four reversible fans, capable of handling up to 1,000,000 cubic feet of air a minute, which create the main circulation of air in the semi-transversal ventilating system indicated in Fig. 5. The fans are located in the two ventilation buildings. (Fig. 5) Operation is controlled from a room in the northern building either by the automatic control system or manually by a tunnel operator.

During normal traffic conditions the air movement in the tunnel is the sum of the air movement caused by the mechanical ventilation and the air flow induced by the traffic.

For the mechanical ventilation fresh air is drawn into the tunnel through the entrance portal and exhausted laterally into the air passage over the first half of the tunnel. In the second half air is introduced into the tube and leaves the tunnel at the exit portal. The traffic air-flow velocity depends on the intensity and speed of the traffic.

As all four fans are reversible, the suction-pressure ventilation will be combined in case of fire so that smoke and heat will be removed from that part of the tunnel where cars are held up by the fire.

No spare fans are installed in the tunnel. When one fan is out of operation, for maintenance or any other reasons, a damper, located in the ventilation duct at the tunnel mid-point, can be opened and the other fan serving this duct can be used for ventilation of the full length of the tube.

The normal operation of the ventilation system is programmed by a master clock system adjusted for a 7-day period and over-ridden by carbon monoxide analysis and visibility indicators. The ventilation system may also be controlled manually by the operator. Fire ventilation is controlled automatically by the fire detectors.

Power

Under normal conditions, power is supplied by the British Columbia Electric Company at 12,500 volts from the north side of the river. This is stepped-down to 480 volts, which is the operating voltage for the tunnel motors and lighting, at a 450 kva-substation at each ventilation building.

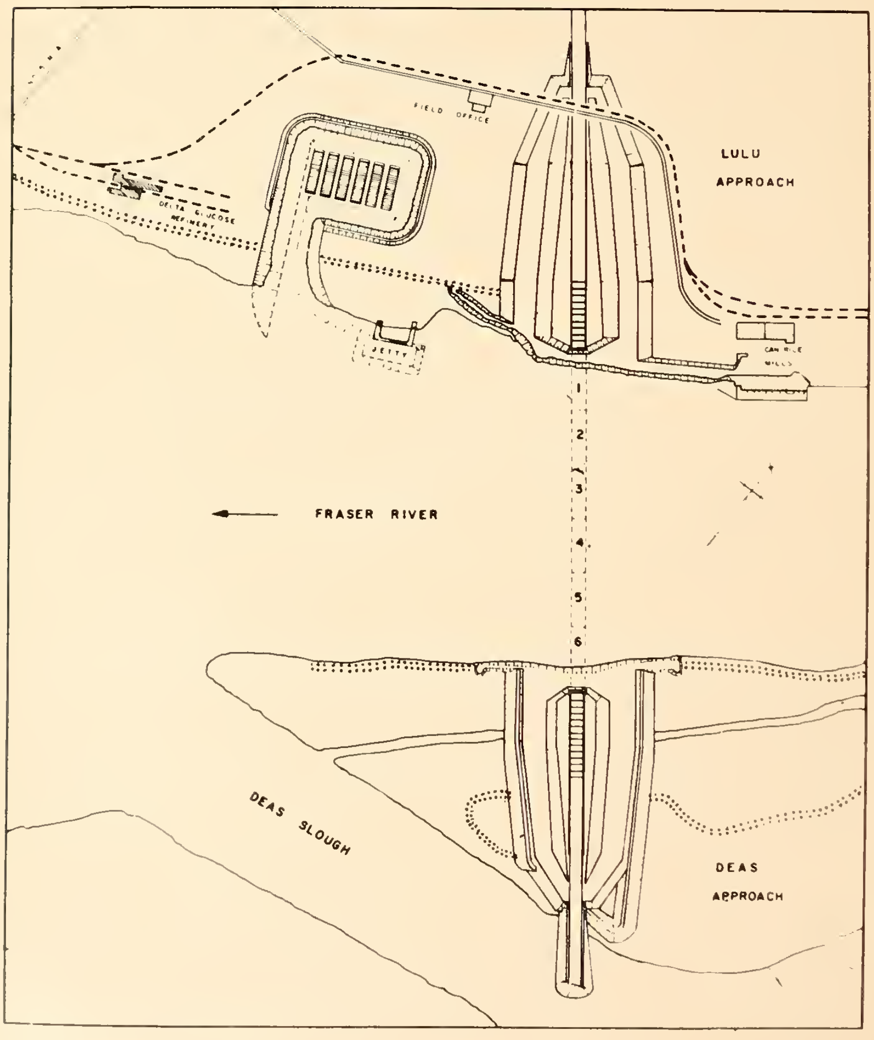
Should the normal power feeder fail, an automatic transfer is effected by means of interconnected oil circuit breakers at opposite ends of the tunnel to an alternate source of power at the south end. Should this second source also fail, the 150 kw. diesel generator is automatically started and put on the line. This will supply the ventilation motors at reduced speed, approximately half of the total tunnel light, all electric control circuits, and all the essential pumps.

During the 10 to 15 seconds it takes for the diesel generator to start, power is supplied to provide 12 kw. at 440 volts, 60 cycles, for minimum lighting requirements by means of a special motor generator set. The set consists of an A.C. generator, A.C. motor and D.C. motor, all on a common shaft. Normally the A.C. motor drives the A.C. generator. If power fails, the D.C. motor, supplied from a set of nickel-cadmium batteries, takes over well within 8 to 10 cycles thus ensuring no appreciable interruption of lighting.

Due to the long runs through areas of varying temperature, it was felt that condensation would occur within conduit runs. For this reason, it was decided that all power runs of 480 volts and lower would be made in TECK cable with a vinyl jacket over the armour to provide a maximum of protection against deterioration both of armour and of the rubber insulation.

The lateral runs to equipment located in the roof of the traffic section of the tunnel, which are fairly short,

Fig. 9. Layout of construction site.



are rigid conduit embedded in the concrete using RHRW insulated wire.

Control runs are made in multi-conductor type T insulated wire with a vinyl jacket over the bundled conductors.

Telephone wiring in the tunnel is by means of ALPETH type telephone wire with polyethylene insulation of the armour.

Lighting

Lighting of the tunnel is normally controlled by the programming clock. In case of extraordinary outdoor light intensity, this control will be overridden by photo-cells mounted at the tunnel entrance portal. The lighting will thus always correspond to the illumination on the approaches.

As this is an unlined tunnel with a normal concrete surface finish, reflector type waterproof fixtures have been used rather than some of the so-called tunnel types, which are designed primarily for tile-lined tunnels. Main tunnel lighting is provided by 430 and 800 milliamp 2-lamp fixtures.

Louvres over the tunnel approach for approximately 310 feet in front of the two entrances and 186 feet at the exits, provides proper transition between the levels of daylight and interior lighting. Immediately inside the tunnel entrance portal, the lighting level is of the order of 85 foot-candles, tapering off to approximately 10 foot-candles about 700 feet from the portal and 5 foot-candles in the remainder of the tunnel. This is designed to enable the eye of the average driver to adjust from the bright sunlight condition normally occurring on the highway to the relatively low level which is feasible in the tunnel. These levels and areas of lighting provide adequately for eye adaptation of a driver travelling at 60 miles an hour.

Power for lighting is provided at 440 volts primary, and the varying levels of illumination are obtained by automatically switching groups of lights.

Consideration was given to high voltage series circuits and alternatively to 400-cycle high-frequency lighting. In view of the somewhat limited length of this tunnel, it did not appear desirable to use either of these alternatives. The basic system is designed so that appreciably higher levels of illumination can be obtained in the future with the same fixtures, by modification of lamps and transformers, and by conversion to a 400-cycle power supply.

Safety and Protective Measures

Safety and protective measures for the operation of this tunnel were taken care of in a number of ways.

Carbon monoxide content of the air is continuously monitored at six points in each tube. A carbon monoxide content of less than two parts in 10,000 parts of air is normal throughout the tunnel. Any reading exceeding this will start up the fans if they are not operating, or increase them to full speed if they are not already in this position. The presence of smoke, visible exhaust fumes or fog, which is monitored continuously by visibility meters located at four points in each tube, will also result in an increase of ventilation intensity.

In case of fire in the tunnel, the control of the ventilation is taken over by the fire detectors.

The exhaust fumes from vehicles held up during periods of heavy traffic flow can cause an appreciable rise in the carbon monoxide content of the tunnel air and a decrease in visibility within a short time. However, use of "stop engine" signs avoids any appreciable increase in carbon monoxide content.

Traffic Lights and Control

Traffic flow in the tunnel is controlled from the control room by means of traffic lights spaced 150 feet apart, which normally show a green signal. At the entrances to the tunnel, key-operated buttons permit group operation of the lights by police or fire department. These switches may be over-ridden from the control room.

At the traffic signal positions there are also portable carbon dioxide fire extinguishers, telephones, and hose racks equipped with fog nozzles, for fire fighting purposes.

Suitable illuminated traffic direction signs, operated from the control room, are provided at the approaches to divert all traffic into one tube if the other tube is to be closed for repairs.

Photo-electric overheight indicators set at 13 ft. 8 in. above the road surface (maximum tunnel clearance) will be installed at the toll booths to sound an alarm if an "overheight" truck should pass.

A measure of traffic control is also provided by traffic recorders which are essentially magnetic pick-ups embedded in each lane at the tunnel portals. The recorder signals are fed to counters on the main control panel. The number of cars in the tunnel is approximately the difference in totals between the entrance and exit counters.

Fire Protection

Fire protection is provided throughout by means of a dry valve sprinkler system and electrical fire detection heads in the roof of the tunnel. The activation of any fire detection head will indicate, by means of an annunciator system in the control room, the presence of a fire within approximately 75 feet in any portion of the tunnel. In addition, the removal of

Fig. 10. Lulu Island approach during construction.

Fig. 11. Tunnel elements during construction.

one of the portable carbon dioxide fire extinguishers will indicate, by means of a pilot light, that an abnormal condition has occurred.

Telephones

Telephones connected to the control room are situated approximately every 150 feet, next to the fire alarms and fire extinguishers. These telephones are available for use by the general public or the tunnel operators. Pilot lights on the main control panel indicate which telephone is in use. A throw-over switch is incorporated in the main switchboard so that at night, when the tunnel operator is not normally present, all telephones can be connected to the nearest central fire or police station.

Loudspeakers

Traffic within the tunnel may also be controlled under emergency conditions by a loudspeaker system operated from the main control room. Speakers are located approximately every 50 feet throughout the tunnel so that communication with vehicle operators is possible throughout the tunnel.

Drainage

Drainage at the portals of the tunnel and at the mid-point is by suitable pumps which can be operated at full capacity by either the normal or the diesel emergency power supply.

The road gutters in the approaches and in the tunnel can be maintained ice-free by means of buried heating cables embedded in the upper asphalt coating and operated manually or by thermostatic control at the discretion of the tunnel operator.

Tunnel Maintenance

The electrical and mechanical equipment is located in the air ducts paralleling the roadways where possible. The equipment mounted in the traffic tubes is of watertight construction since the walls and ceiling will be washed down with water.

Two features of the control are especially interesting. Use has been made of various types of supervisory circuits to indicate malfunction or servicing requirements on automatic equipment. For example, on the visibility photocells high-sensitivity series relays are used to close an auxiliary contact and indicate lamp failure on the main panel board rather than having it show up as a false reading as smoke or fog condition.

Extensive use is made of graphic panels in the master control room, and all traffic lights and traffic control signs are indicated by suitably coloured pilot lights on the main control panel. On the traffic control system an innovation is the use of low-voltage remote-control wiring for all traffic signal control. Some 60 traffic signals require almost 120 miles of wire in their operation and, with this system, the majority of this wiring can now be handled by No. 16 low-voltage plastic-insulated bundled conductors.

CONSTRUCTION PROCEDURES

by O. H. Bentzen, P. Eng.

CONSTRUCTION of a tunnel like the Deas Island Tunnel is, in itself, an undertaking somewhat out of the ordinary. Although for the major part of the project conventional construction methods were used, there are several features which are unique and others which are of more than common interest.

Construction of the Drydock

The first major operation was the preparation of a drydock for the construction of the tunnel elements. Fig. 9 shows the layout of the construction site. After a thorough investigation, it was decided to build a dock large enough to permit construction of all six elements at the same time and to minimize its distance from the tunnel centreline, so as to keep small the distance over which the elements had to be transported. The floor of the drydock was 633 ft. x 384 ft., an area of about 243,000 sq. ft., while total excavation amounted to 450,000 cubic yards of material, making it one of the biggest ever constructed in Canada.

In constructing the drydock, the contractor chose to use an hydraulic cutter dredger instead of land equipment to remove the silt and sand. This turned out to be a very wise decision since the wet ground conditions encountered during the October, November, December, and January season would have made the use of scrapers and bulldozers impossible.

The general level of Lulu Island is around +3 ft. Geodetic Datum (GSC) while the high water of the Fraser River rises as far as 6 ft to 7 ft GSC. For this reason, before the dredger broke the existing river dyke to gain access to the drydock site, it was necessary to build temporary dykes around the area in order to prevent flooding of the island. These temporary dykes were built by means of drag-lines with as many as nine machines working at one time. They had a crown of about 10 ft. and a base of 50 ft. The material used was taken from the silt which overlies the area to a depth of about 5 or 6 ft.

Following the dredging and plugging of the passage to the river, the excavation was dewatered, the first part by open pumping. Two 12-inch pumps, each with a capacity of 4200 gpm, lowered the ground water to —7 ft. GSC. After that, a ring of wellpoints was installed at —5 ft. GSC. These wellpoints, spaced at 5 to 6 foot intervals, were 1½ inches in diameter and were connected to a 12-inch header. The pairs of 12-inch pumps hooked up to the system lowered the ground water to approximately —21 ft. GSC. The banks were then sloped to grade and the second ring of wellpoints installed. This ring consisted of 2-inch wellpoints also connected to a 12-inch header. The length of the risers on this ring was about 30 feet in order to take advantage of an impervious layer of soil lying about 35 feet down. The ground water was lowered to approximately —31 ft. or 32 ft. GSC, leaving 7 to 8 feet of dry sand above the water table. After the ground water level was stabilized, the daily pumping amounted to about 5,000 gpm.

Construction of Approaches

The second major construction undertaken was that for the two approaches and the ventilation buildings. The dewatering problem for these structures was a much greater one than for the drydock. At the drydock the ground water was lowered barely 30 feet, whereas in the approaches, the water table had to be lowered about 60 feet. In addition, the approach excavations were carried right out to the river bank whereas the drydock was some distance back from the river. The contractor for the drydock managed to keep the excavations dry by using only the lower ring of wellpoints and leaving only part of the upper one in on the river side as a precaution. However, the contractor for the approaches was faced with the necessity of putting in four rings of well-points of which he had to operate three at maximum.

The excavation of the Lulu Island approach (Fig. 10) was carried out by scrapers and bulldozers and the sand deposited on the future dykes on each side of the approach. For Deas Island, the top 20 feet of soil was removed by suction dredger, the dewatering equipment installed and the balance of the fill taken out by scrapers and bulldozers.

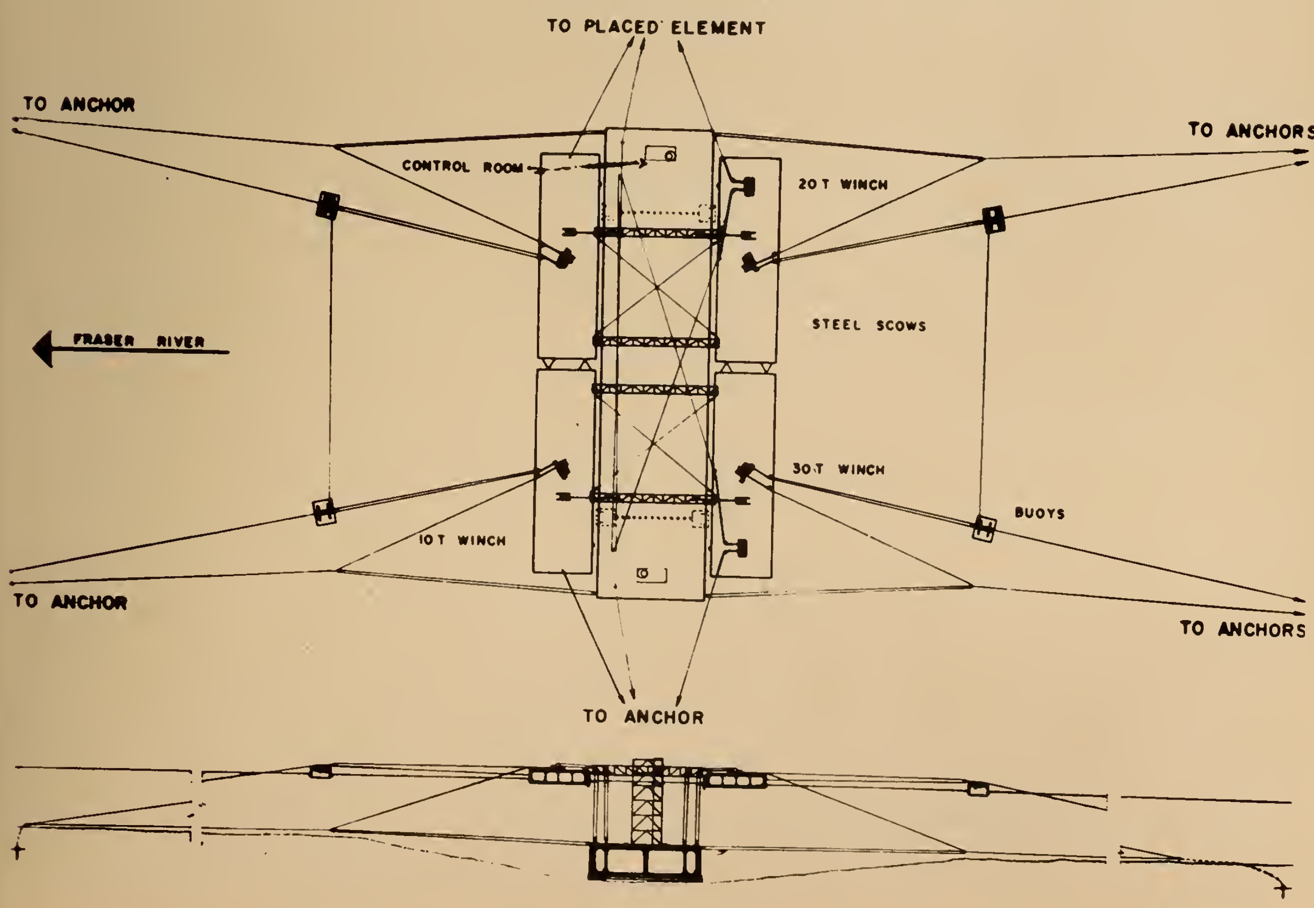
The dewatering of the Deas Island approach was carried out in a slightly different manner to that of the Lulu Island approach. Deep well pumps were installed on the Deas Island side in addition to the wellpoint system. The contractor decided to use deep wells because he had found indications from borings that a heavy layer of medium and coarse sand existed right down to approximately 100 feet below the surface. These deep wells were installed in the part of the excavation nearest the river and were served by five 14-inch and five 12-inch two-stage pumps.

As backfilling proceeded, after completion of the construction, the wellpoints from the dewatering system were withdrawn and the ground water was allowed to rise gradually. Water also was pumped into the approach structure in order to maintain the same level inside as outside so as to prevent lifting of the structure during this period. As soon as the water levels had risen to their maximum, the dykes facing the river were broken, at an appropriate stage of the tide, in order to provide room for the first tunnel element to be floated in and joined to the spout of the ventilation building seen in Fig. 5.

Construction of Tunnel Elements

The tunnel elements were constructed in the drydock by conventional methods, as has been mentioned in the section on the general layout and design of the tunnel. The ele-

Fig. 12. Floating rig.



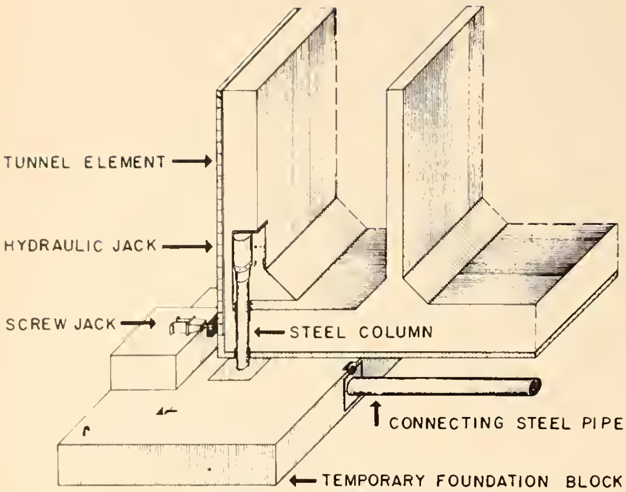


Fig. 13. Temporary foundation blocks.

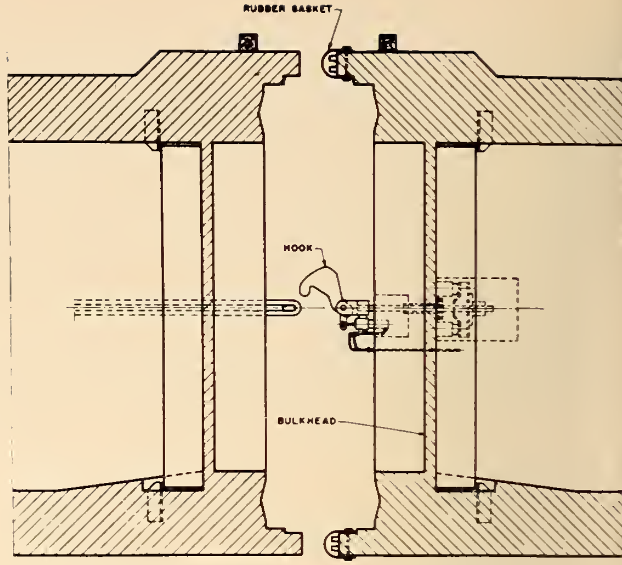

Fig. 14. Joint between tunnel elements.

ments are simply huge reinforced concrete boxes with temporary bulkheads at each end. Fig. 11 shows the elements under construction in the drydock.

Perhaps the most complex part of the element construction is the extensive waterproofing required, which has been described under "General Layout and Structural Design". The contractor had a certain amount of difficulty with curling of the steel plate forming the waterproofing of the bottom slab because of expansion and contraction caused by temperature variations. However, the contractor encountered no other difficulties in the fabrication of the elements.

After the elements had been completed, the drydock was flooded gradually by stages in order to test the watertightness of the concrete in the structures.

As construction of the elements and approaches neared completion, preparations were made for excavation of a trench in the river to receive the elements as they were placed. As has been indicated in the section on Hydraulic Design, it had been established by actual on-site tests, by hydraulic laboratory tests, and by theoretical studies, that a trench in the river bottom could be kept open long enough to permit the placing of the elements without too great a degree of silting. On the basis of the assumptions which had been made in the study of the excavation of a trench, it was decided to dredge only far enough in advance to permit of the placing of two elements without opening so much of the trench that redredging would be necessary. The assumptions were confirmed later by actual full scale tests at the site.

As the placing of the 18,500-ton tunnel elements had to be done to an accuracy of ⅛-inch, it was necessary to design very special floating equipment, special controls and special hydraulic equipment as well as to plan in detail the entire placing operation. An unusual feature is that there is access to the tunnel element before, during, and after the placing operation. In the normal procedure used for the placing of elements for a trench type tunnel this is not the case, and access is had only from the completed section of the structure when the temporary bulkheads are removed. In order to avoid delays in the execution of the complex placing operation and as time for the construction was running short, the special equipment and procedures to be used in the placing operation were designed by the engineer. Figure 12 shows a plan and a cross-section of the floating rig finally evolved for use in the placing operation and indicates to some degree the method of handling the element during the placing.

Primarily, the floating and sinking rig consists of four heavy steel scows, each 43 ft. x 150 ft., tied together by four steel trusses, the end ones supporting the heavy block and tackle used in lowering the elements and the central ones maintaining the proper distance between the scows. Winches are placed on top of the sinking rig scows, providing six drums for holding the entire rig in position, six winches for holding the element in the proper position, and four 10-ton electric winches used to control the lowering of the element through five-sheaved blocks.

The tunnel elements are lowered by admitting water to the ballast tanks within the ventilation ducts and then gradually slacking off on the supporting cables, permitting the element to sink gradually, always bearing the slope it will have in its final position. Within the elements themselves, two 8-inch electric pumps were installed and a complete piping system with valves was designed to enable the crew to fill or empty any ballast compartment to provide buoyancy as required during the operation.

The final accurate levelling of the element once it has reached the bottom of the river is accomplished by means of four 300-ton hydraulic jacks installed in the bottom of the tunnel element. The jacks, illustrated in Figure 13, are located approximately at the fifth points of the element, the two at one end of the element being connected so as give an effective three-point support to the element once it rests on the jacks. These jacks, which are controlled from inside the elements, operate 8-inch pistons which project through the bottom of the elements.

The temporary connection of the unit to the one preceding is accomplished by means of a hook and eye arrangement in the end of the tunnel unit, shown in Figure 14. The hook is capable of exerting a force of 150 tons by means of two hydraulic jacks inside the element. It is connected to the eye in the preceding element by hydraulic controls and, once in position, pulls the elements together in order to effect a temporary seal between the reinforced concrete collars, which form a temporary working chamber between the units within which workmen can complete the joint by connecting up the walls in both elements. One of the collars is equipped with an inflatable rubber gasket to ensure watertightness.

At the temporary jetty, for outfitting the elements prior to sinking, four concrete blocks, each 13 ft. square x 2½ feet deep, are suspended beneath it in line with the hydraulic jacks mentioned above. These blocks act as temporary foundations during the final levelling of the element and prior to the completion of the sand foundation which is jetted beneath the units. In addition, two access shafts and measuring towers, all electrical equipment, and special survey instruments were mounted on the roof of the element in preparation for the sinking operation as indicated in Fig. 15. Electrical power was provided by means of a diesel electric generator unit installed on one of the scows until such time as the element was in approximately its final position when a heavy armoured electrical cable was run from the shore to provide power for all electrical equipment.

When all preparations had been made, the sinking unit was warped out into its approximate position over the trench in the bottom of the river. With the tunnel element only a few feet from its final alignment, the sinking operation began adding about 400 to 500 tons of water and gradually slacking off the supporting cables. When the element had reached the bottom of the trench, it was aligned to within an inch or an inch and a half of its final resting place and the entire weight was taken up on the four hydraulic jacks resting on the temporary foundation blocks which had settled onto gravel pads previously placed in the bottom of the trench. At this point, between 1,000 and 1,500 tons of water ballast were pumped into the element and it was left in this position for twenty-four hours in order to obtain first settlement of the gravel pad foundations so that more accurate positioning could be accomplished the following day.

The next day most of the water ballast was pumped out again and the winches picked up most of the tunnel weight, leaving only about 10 to 15 tons to be supported on each of the hydraulic jacks. This provided a firm hold on the element but permitted accurate alignment in a lateral and longitudinal direction by means of the cables strung from the element to anchors in the river bottom. Accurate vertical positioning was accomplished by means of the hydraulic jacks so that in the end, the tunnel unit was in position within ⅛-inch of its theoretical vertical and horizontal position. The vertical positioning allowed for future settlement of the gravel pads, which had been calculated prior to the placing of the element.

Fig. 15. Preparations for sinking.

At this point, the element had been aligned longitudinally to leave between 1 inch and 1½ inches between the face of the reinforced concrete collar on the previously-positioned unit and the rubber gasket on the face of the collar of the element being placed. The gasket was brought into contact with the face of the adjacent concrete collar by means of the 150-ton hydraulically-operated hook, previously mentioned, which was engaged with the eye in the other element. As the full load was brought to bear on this hook, a firm connection was established between the gasket and the face of the element.

Once preliminary contact had been made between the two concrete collars, the water was bled from the space between the two bulkheads. As the water pressure inside the joint chamber was released, the full hydrostatic pressure on the free end of the element (about 3,000 tons) was no longer counterbalanced and forced the two units tightly together, effecting a complete seal of the joint.

Sand Jetting

As soon as practicable after making the temporary joint between the elements, sand was jetted between the river bed and the bottom of the unit. It is necessary to give complete support to the element in order to prevent the development of any extraordinary stresses in the unit such as would be caused by large void spaces beneath it. The sand was jetted beneath the element by means of a special gantry, pipe and nozzle arrangement. Sand was drawn from a scow moored near the jetting gantry, mixed with water, pumped through the pipe system and forced out through the nozzle into place under the element. From the 25 ft. pipe extending under the element, it was possible to jet sand under half the element from either side in longitudinal strips below the unit, the gantry being moved and the nozzle rotated as the work progressed to pack solidly all the space between the element and the river bottom.

Once the sand-jetting had been completed, the hydraulic jacks were released from their load and the entire weight of the element was carried by the sand. Then started the backfilling of the trench around the element and the installation of extensive protective works, as described in the paper on hydraulic studies and bed protection.

After a reasonable time for settlement of the tunnel units, work started on completion of the joint between units. This was effected by joining up and welding the steel plates forming the waterproofing at the joints, joining and welding the reinforcing steel, and completing the concrete for the walls, floor and roof.

At the time of writing, all tunnel elements have been placed, the backfilling and bed protection have been completed, and the joints between the elements have been finished. All that remains is the installation of the very complex mechanical and electrical equipment and controls required for the operation of the tunnel. The tunnel will be ready for opening in the Spring of 1959.

NEW LABORATORIES

of

THE PULP AND PAPER RESEARCH INSTITUTE OF CANADA

THE PULP AND PAPER Research Institute of Canada is supported jointly by the Federal Government, the pulp and paper industry, and McGill University, in Montreal. The two main functions of the Research Institute are to supplement the research carried out by individual companies in the industry, by acting as a fundamental research centre, and to train students whose advanced work in science and engineering is related to the industry. Research projects are carried out at the request of members of the pulp and paper and allied industries; facilities are available for non-routine tests and measurements required by industry; and a vast amount of technical and scientific information is gathered and distributed on an international scale.

The present organization developed from a branch of the Forest Products Laboratories of Canada, in 1913, and was housed in part of two old buildings at 3420 University Street, Montreal, at the south-east corner of the McGill campus. It became a joint enterprise in 1920, when the research activities of the Canadian Pulp and Paper Association were linked with McGill and the Government, and soon outgrew its facilities. The old buildings were demolished in 1927 and the present building on the same site was officially opened in 1929.

The work continued to develop, and during World War II included extensive research for the Government. In 1950, the program was extended and the Research Institute was reorganized as a non-profit corporation under Federal charter with a board of directors and a full time management. Dr. Lincoln R. Thiesmeyer has been president, and a director, since 1950. Subsequently, financial support was ensured through renewable contracts with sustaining members of the pulp and paper industry.

Soon after 1950 the operation had extended into other buildings, and the need for a larger, centralized headquarters was apparent. By 1955, plans for a new centre were made, and the Government had agreed to build and equip the new facilities at Pointe Claire, about 15 miles west of Montreal. The building was first occupied late in 1957 and was officially opened 18th September, 1958.

The new building, which is the main subject of this article, is the administrative headquarters of the organization and houses most of the research facilities of the Institute. However, the original site in Montreal is still in operation.

Work at McGill

In the Montreal University Street building, work continues on the postgraduate student program, together with some fundamental bench-type research and chemical engineering activity. The main library is also situated there.

The Physical Chemistry Division has equipment for X-ray diffraction measurements, radioactive counting, light-scattering, for molecular weight determination, a unique couette device for measuring the flexibility of fibres, and equipment for the study of macromolecules.

For the graduate research program, facilities include radio-tracer equipment for particle velocity determination; a hot-wire anemometer for gas-flow characterization; high-speed cinephotography; and a pilot plant for investigation of flash evaporation, fluidization, and particle technology.

Engineering Development

One of the principal engineering developments in recent years has been the Atomized Suspension Technique for treating waste fluids, which will be dealt with in more detail later in this article. Three pilot plant reactors are installed in the McGill campus building.

Comprehensive modern equipment is also available for viscosity and osmotic pressure determination, electrophoresis, paper- and column-chromatography, ultra-violet apparatus, and so on.

The new Building

The new building at Pointe Claire stands on a 90-acre tract of open land owned by the Institute. Cost of the building and equipment, contributed by the Federal Government, was two and a quarter million dollars, and the industry has provided apparatus and equipment worth a further half-million dollars.

Building Design

The building was designed with a view to the possibility of future expansion of any major section without interfering with any other part. The result is a structure of four two-storey wings joined at right angles to one another, with an adjoining single-storey wing housing the service departments. This arrangement allows the main departments to be extended vertically or horizontally, and the surrounding site is sufficienly large to accommodate any expansion foreseen at present.

The structural steel frame is fairly conventional, and floors are of concrete slab construction, designed for live loads of 100 pounds per square foot in the laboratories and considerably higher loads in the engineering areas.

The design of the foundations of the administration and laboratory wings is such that basements can be added by knocking out temporary walls at either end and removing the backfill which was placed in the excavation to prevent flooding. This plan provides for an economical extension of space if and when the municipality installs storm sewers.

Crawl space is provided beneath the other wings, and utility services are generally routed along corridors where there is convenient access to vertical service ducts.

The main electrical sub-station consists of a bank of three 500kva transformers which reduce the 12,000 volts supply to 600 volts. Distribution throughout the plant is at 550 volts, with inside dry type transformers being used at convenient locations for reduction to 110-220 volts. In a number of locations duct-covered bus bars carry the 550 volts, and access is through plug-in access doors. This provides for a very flexible arrangement, and enables the staff to carry out extensive rearrangement of heavy equipment with a minimum of disruption. Machines may be connected directly to the bus bars, or inside transformers may be plugged in to give lower voltage where required.

Heating is by forced hot water, which is circulated at 200-240 degrees Fahrenheit. The present heating installation consists of two 200 h.p. units for building heat and one 40 h.p. unit for domestic hot water.

Many of the process operations of the Institute require steam, and it is provided by a single 30 h.p. electrode-type electric steam generator. This unit allows considerable variation in pressure and demand, and was chosen partly for its versatility in this regard.

Conventional lighting is used throughout the building, the three main types being fluorescent, incandescent and mercury-arc. The intensity of lighting is good and lies in the range of 40-50 lumens at desk level.

The majority of the laboratory area is force ventilated, with exhaust through fume hoods on the roof. Of special interest are two experimental rooms, one of which provides for a relative humidity range from 10% to 90% at 73°F, and the other which provides for a temperature range of 55°F to 90°F at 50% relative humidity. These experimental rooms are serviced by unit air conditioners located in a service room adjacent to the laboratories.

The building is not equipped with automatic sprinklers, but uses a variety of commercial fire extinguishers selected for their suitability in handling the many different types of fire hazards which exist.

General Layout

The main entrance leads into the administrative wing, with offices, branch library, and printing and duplicating shop on the first floor. Above this are the executive offices, drafting and editorial services, and a woodlands research conference room.

The adjoining wing, at right angles, contains facilities for the physics, chemistry, and woodlands research departments. Extending from the end of this wing is a narrower one, leading to the services annex, and to which is attached the fourth, and shortest wing, housing the mechanical engineering development department, chemical pulping plant, refiner deck and stock preparation room, and the bleaching and small-scale pulping laboratory.

The service wing contains the boiler plant, machine shop, stores, and shops for pipefitting, sheet-metal work, and wood-working. A considerable amount of equipment is designed and built by the Research Institute, and the machine shop is very well equipped and capable of handling work to very fine tolerances.

Fields of Research

Briefly, the Research Institute is capable of dealing with problems affecting the pulp and paper industry from tree growth and nutrition to processing techniques and the development of processing equipment.

This involves fundamental research, which adds to the basic knowledge of many subjects and may lead to future developments, and current work on practical problems such as the life of

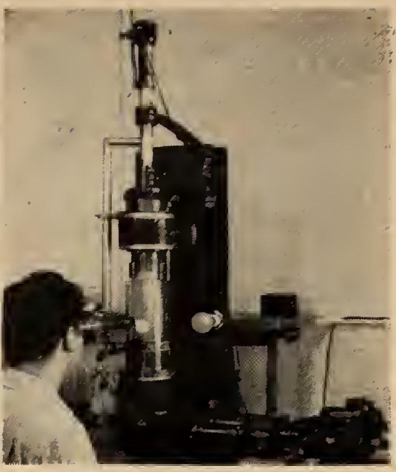

Fig. 1. Twin Couette apparatus for studying the hydrodynamic behaviour of fibres in liquids, and the flexibility and shear strength of wood pulp fibres.

paper machine wires, corrosion of digesters, power consumption for grinding processes, improvement of pulping processes, and so on. Some of these contributions to the operations of the industry will be discussed later.

Chemical Pulping

Many advances have been made in the chemical pulping field as the result of work done at the Research Institute. Much of the equipment of this department was designed at the Institute and includes four 2 cu. ft. pilot-scale digesters with preheating equipment and control of temperature, pressure, and pH. For preliminary investigations the Institute designed a microdigester which duplicates pilot-scale experiments on a small scale.

Pressure equipment includes two types of bomb digester. In one, chips are sealed in a heavy steel bomb which is heated by oil; the other version consists of a bomb which can be rotated above gas jets.

The main laboratory-scale equipment is completed by a bleaching plant and a precision guillotine chipper.

Wood chips for experimental purposes are stored in a special cold room and are sealed in plastic bags to retain the original moisture content.

Mechanical Engineering

The principal piece of equipment used for research into mechanical operations is a mill-scale 36-inch Bauer double-disk refiner. With an operating range of 600-1200 r.p.m., the refiner has a variable-speed feed belt and a capacity of 1-50 air-dry tons a day.

The department also has a Sprout-

Waldron stainless steel laboratory screen.

Physical Testing

Some interesting equipment has been designed and installed for physical testing and measurement. An Instron tester is used to measure the tensile strengh of fibres and cross-sections of wood. These can also be studied on a Vickers inverted projection microscope, which projects an image of the material on to a large inspection screen.

Designed at the Institute, and named after S. M. Chapman who developed them, are a smoothness tester for measuring smoothness of paper under printing pressures, and an electronic dirt counter. The latter looks something like a record-player turn-table and pickup; the paper sample is mounted on the rotating turntable and the 'pickup arm' has a photo-electric device in the head which scans the paper sample and automatically counts the contained specks of dirt.

Associated with this section is a special laboratory in which various controlled conditions of temperature and humidity can be maintained.

Another important piece of equipment is a scanning electron microscope which operates at magnifications up to 100,000 times. This is the first commercial prototype of an instrument developed at Cambridge University for making electron photomicrographs of wood fibres and similar materials. The scanning principle prevents the fibres from being burned during exposure.

Other Equipment

Among other specialized equipment used in the laboratories are two items which were originally developed by the Research Institute. A micocuvette uses ultra-violet absorption for the continuous measurement of lignin and other organic material in cooking liquors during chemical pulping. Also for use during cooking cycles is a special reference electrode with which continuous, high-temperature measurement of liquor pH can be made.

Photography and photomicrogaphy play a large part in the work of the Institute, and various forms of equipment are in use. The new photographic darkroom is comprehensively equipped and incorporates accurate temperature control.

Wood-Chip Slurries

One of the current fields of investigation which may be of particular interest to engineers is the hydraulic transport of wood-chips through pipelines, in the form of a slurry with water.

This work is still in the early stages, but a 528-ft. loop of 8-inch aluminum pipe has recently been installed, together with the associated auxiliary pumping equipment, for the study of this subject.

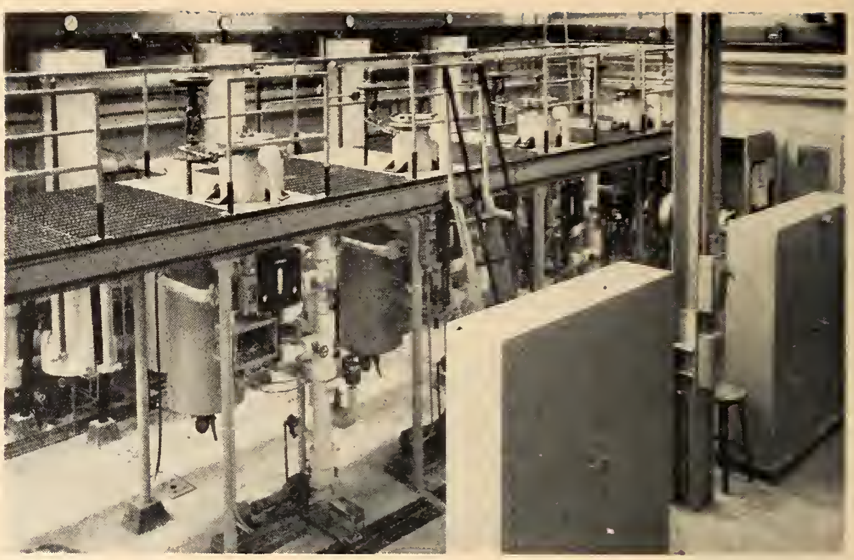

Fig. 2. 2 cu. ft. digesters used in pilot-scale studies of chemical pulping processes.

Atomized Suspension Technique

A development which promises to have far-reaching applications even beyond the pulp and paper industry is known as the Atomized Suspension Technique (AST). This was developed by Dr. W. H. Gauvin M.E.I.C., now head of the chemical engineering division of the Pulp and Paper Research Institute of Canada.

The AST has emerged from an original study of the possibility of recovering sulphur from waste sulphite liquors made during a severe sulphur shortage during 1951. There is no longer a shortage of sulphur, but the study has proved to be of great significance, and the technique has been patented.

Experimental Equipment

There are three pilot-plant AST reactors at the Research Institute building in Montreal, all of stainless steel construction. One is 8 in. i.d. by 10 ft. high; one is 12 in. i.d. by 15 ft. high; and the third, specially built for sludge treatment, is 5 ft. i.d. by 7 ft. high.

The results of three pilot-scale investigations are briefly described here.

Sulphite Waste—

The treatment of neutral sulphite semi-chemical liquors, in the 8-in. diameter reactor, gave a solid residue of sodium carbonate and sodium sulphate, steam, and a mixture of gases, particularly hydrogen, carbon dioxide, and methane. Results indicated that the technique might form the basis of a promising recovery process.

Sanitary Sludges—

From investigations into sewage sludges it was shown that these can be destroyed rapidly and continuously under atmospheric pressure. Low capital and operating costs are foreseen, and maintenance should be simple. Heating may be electrical or by oil, city gas, natural gas, or even waste flue gas. The first municipal-scale plant has now been built at Beaconsfield, Que., not far from the Pointe Claire headquarters of the Research Institute. For convenience, this plant is designed for electrical heating.

Refinery Effluents—

An aqueous refinery oil sludge was processed in the 8-in. reactor to determine if it could be separated into disposable or re-usable components. The products were steam, an essentially inorganic residue, a gas of excellent calorific value, and small amounts of oil.

Other Research Applications

The Atomized Suspension Technique is a particularly prominent example of the practical achievements resulting from the work of the Pulp and Paper Research Institute of Canada. Though there may be no other immediately apparent single comparable development, the work of the Institute over the years has had a considerable influence on the operations of the industry. In general this has amounted to an improvement in techniques and efficiencies of operation which has helped to keep the industry to the fore.

Woodlands Research

The growing and harvesting of woods and the development of improved species are regarded as a part of the overall manufacturing industry. Research into woodlands problems must be related to possible effects on mill practice.

The Woodlands Research Division is studying the nutrition of pulpwood species in the new laboratories at Pointe Claire, under controlled atmospheric and other conditions.

One current project is to evaluate a hybrid poplar grown by one of the paper companies. In addition to woodlands research the investigating team is concerned with grinding, chemical pulping, bleaching, physical and chemical testing of pulp, and the study of fibre characteristics.

Wire Life Study

In 1956 an investigation was started at the Institute, at the request of the newsprint industry, to find the causes of the short life of paper machine wires, which may be as little as four or five days. To study even the most likely of the many possible causes would be a long and costly process for the industry.

A research team with varied training and experience studied the problem in several mills and were able to select the most significant variables. These are: the drag load of the wire over the suction boxes; grit concentration in the headbox stock; wire speed, mesh, and length; and angle of wrap of the wire on the wash roll. Many of the findings can be applied immediately by the mills, and if any further research is indicated it can be restricted to these six variables.

Digester Corrosion

An earlier study by the Institute, in 1950, into the rapid corrosion of alkaline digesters was also directed at finding the principal causes from a large number of possible variables. The causes of both general surface attack and the more serious rapid local corrosion were found, and further work has resulted in the development of anodic protection against corrosion. This technique is being studied commercially in a pulp mill, following preliminary trials, and a commercial firm has been granted patent rights with a view to marketing the technique.

Power for Grinding

Although the Canadian newsprint industry, the largest supplier in the world, is fortunate in having cheap hydro-electric power and abundant softwood supplies, great economies could be achieved by only a small saving in the vast amounts of power required to produce groundwood, the principal component in newsprint. It is estimated that over 99 per cent of the power used is wasted in the form of heat.

The Institute has been engaged in a study of the mechanism of fibre-removal from wood by grinding. One of the findings has been that some deformation of the wood is necessary for fibre removal, but, at present, much grinding energy is needlessly used in repeated deformation of the fibrous structure by the grits in the stone. Further understanding of the fundamental process of fibre removal will doubtless produce results of value to this important section of the industry.

Fig. 3. A mill-scale 36-in. double-disc refiner, part of the complement of equipment for research in mechanical operations.

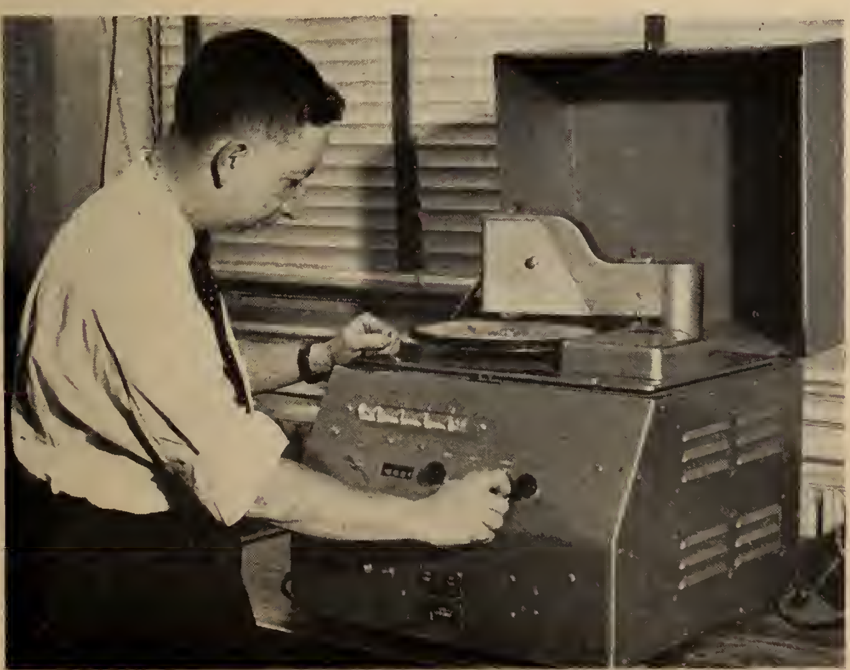

Fig. 4. The Electronic Dirt Counter. Paper sample rotates on turntable, is scanned photoelectrically, and dirt specks are counted electronically.

Pulpwood Holding Grounds

In 1952 the Institute was asked by the industry to investigate the problem of the forces existing in pulpwood holding grounds. This work has been under the supervision of Prof. R. J. Kennedy, M.E.I.C., of Queen's University, Kingston, Ont., and the first phase of the project was covered by a report published in *The Engineering Journal* (1958, January, p. 58).

A survey was made of installations and practice in eastern Canada, leading to a combined laboratory and field investigation. Methods of calculating the total force exerted by the water on the wood in a transverse holding ground, and the division of the force between the sjores and the boom system, were developed.

Fundamental Research

One of the most important functions of the Institute is to act as fundamental research centre for the Canadian pulp and paper industry. In this it supplements the various research organisations of individual companies.

Fundamental research is carried

out on a wide number of fronts each attempting to contribute to a broad background of theoretical knowledge from which the various problems arising in the manufacture of pulp and paper can be attacked.

It would be impossible to list here the multiplicity of fundamental projects currently active. A few well-spaced examples, however, will give an idea of the scope and variety of the program and of the way in which basic research is related to technological requirements.

Intensive investigations are being conducted in the Physical Chemistry Division into the hydrodynamic properties of pulp fibres in suspensions. The tendency of these fibres to flocculate results in unique flow characteristics which were, until recently, little understood, and which affect strongly not only the behaviour of the pulp throughout the entire paper-making cycle, but the quality of the finished sheet. Relating these fundamental properties to the properties of the sheet, can result in improved machine design and ultimately a better product.

The lignin macromolecule is undergoing special study. This complex and as yet imperfectly-understood substance is the chemical binding agent in wood, and further understanding of its colloidal and polymoric properties will contribute not only towards improved and more economical chemical pulping processes, but in the exploration of various possibilities of commercial lignin utilisation. Such basic studies of lignin and its derivatives has already suggested an increasing variety of technological applications of it as a dispersive alloid.

Related fundamental studies in the Division of Wood Chemistry are concerned chiefly with lignin's chemical structure and behaviour, with special regard to technical pulping and bleaching processes. Current pulping methods are so drastic that they destroy about one-fifth of the usable cellulose in the wood and reduce the viscosity of the remainder. It has been found in the laboratory that excellent pulp can be produced in a few seconds, a finding that may lead, after considerable development work, to high speed continuous pulping on a commercial scale.

Also having an important part in the basic research program are fundamental studies in mechanical pulping. Investigations are being pushed ahead into such fundamentals as stress-relaxation, in wood, the mechanical response of fibres to impact, energy loss during the deformation of a viscoelastic material—all of which have an important theoretical bearing on the mechanics of groundwood production and which could lead to new and more efficient mechanical pulping methods with higher output and less energy consumption.

In chemical engineering, basic studies are chiefly concerned with the technology and fundamental properties of droplets, small particles and finely-divided systems of various kinds. It was from research of this kind that the Atomized Suspension Technique described earlier was evolved.

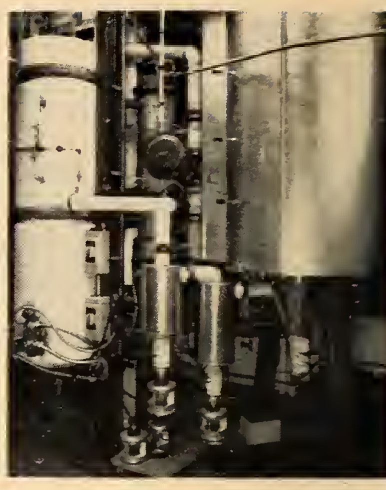

Fig. 5. Pilot-scale reactor for study of the Atomized Suspension Technique for chemical processing, newly-developed by the Institute.

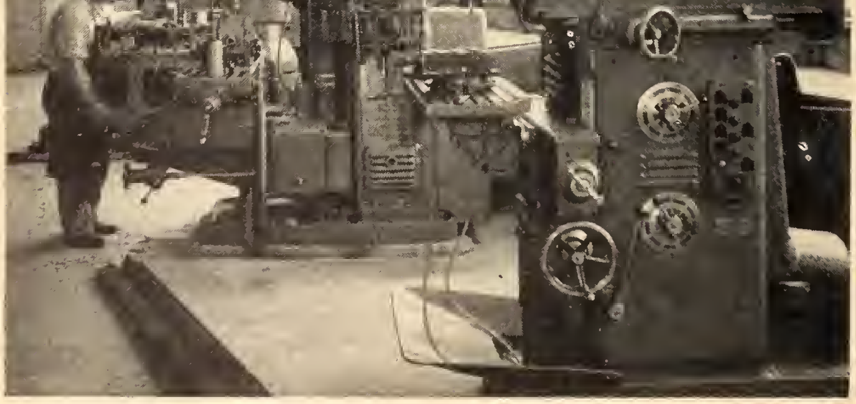
Fig. 6. Part of the well-equipped machine shop; an indispensable part of the research establishment. The Institute designs and builds much of its own equipment.



Some fundamental projects are carried out at a staff level, others by McGill University graduate students working toward doctoral degrees. Some are undertaken in the study of problems currently existing in the industry, others although their potential range of industrial significance is known, await direct application.

The pre-doctoral students participating in the basic research program are directly supervised by Institute scientific staff members who hold concurrent teaching posts at the University. Although most of the 250 who have so far participated have been organic and physical chemists with some chemical and mechanical engineers, the Institute hopes to broaden its area of co-operation with the University to include a wider variety of scientific disciplines such as metallurgy, pure physics, biology, biochemistry, and the new borderline science of biophysics.

Conclusion

The position to which the Canadian pulp and paper industry has advanced has been achieved through the joint efforts of researchers and operators within that industry and in others which supply raw materials and equipment.

The part played by the Pulp and Paper Research Institute of Canada is no small one, and it may well be greater yet as the Institute operates from its new headquarters and laboratories.

THE FREE PISTON ENGINE

R. G. Fuller M.E.I.C.

Engineering and Management Consultant
Peacock Brothers Limited, Ville Lasalle, Que.

BY DEFINITION, a free piston engine is one in which the movement of the pistons is controlled by the combustion and gas pressures instead of being confined to the repetition of a pre-determined motion governed by a mechanical linkage.

The free piston principle is as old as the gas engine and the first practicable engine developed by *Barsanti & Matteuci* in 1859 was essentially a free piston engine and was so described by its inventors. This engine was improved and put into commercial production by *Otto & Langdon*, who exhibited the engine at the 1867 International Exposition in Paris.

In this engine the piston operated in a vertical cylinder with the cylinder head at the base. The expanding products of combustion expelled the piston up the open cylinder. The stroke was limited only by gravity, friction and atmospheric pressure and the piston was returned to the firing position by gravity, assisted by the depression under the piston at maximum stroke and atmospheric pressure acting on the upper side. The energy in the falling piston was absorbed by rotating a shaft.

A modern diesel pile-driver operates on this same principle, but the energy of the falling piston is transmitted directly to the head of the pile supporting the cylinder head.

The *Humphrey* pump which was developed in 1906 is also an internal combustion free piston engine in which a column of water is substituted for the piston.

There are several well known boiler feed pumps and steam driven air compressors which are free piston machines. Although all these types are true free piston engines in that the stroke is un-confined by any mechanical linkage, in each case they are characterized by the use of only one piston, which in the internal combustion application is returned by gravity.

The free piston engines which are the subject of this paper are essentially different from the foregoing in that the piston is controlled and returned by gas or air pressure acting on the end of the piston remote from the combustion chamber. In practice this type of engine invariably uses two pistons operating in opposition with a common combustion chamber interposed between the two piston crowns; it has been the subject of commercial development since 1922.

Early Development

The development of gas generators can be traced back to the early work on turbo-charging by Dr. Buchi which has resulted in recent years in the development of the compound cycle in which mechanical power is taken off both a crankshaft and an exhaust gas turbine forming parts of the same system.

The free piston gasifier, however, owes its origin to *Pescara,* who built several types of free piston air compressor in the 1920's, the gasifier being a natural development from the free piston compressor, and a 950 kw free piston generating set was in operation in 1939.

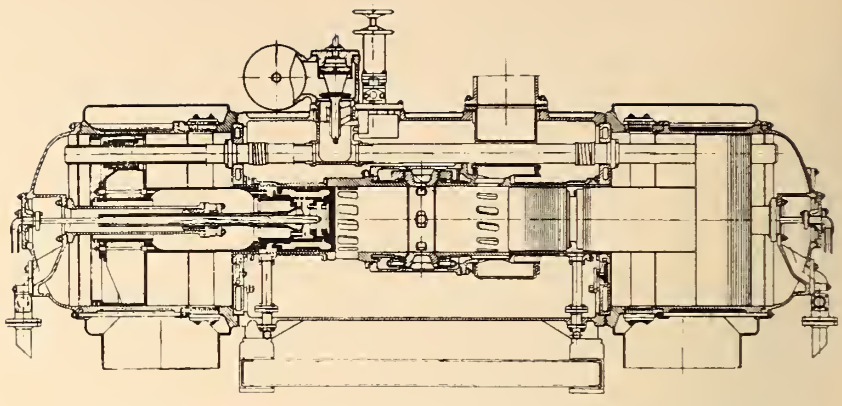


Fig. 1. Longitudinal section of GS. 34 Gas Generator 1250 gas H.P.

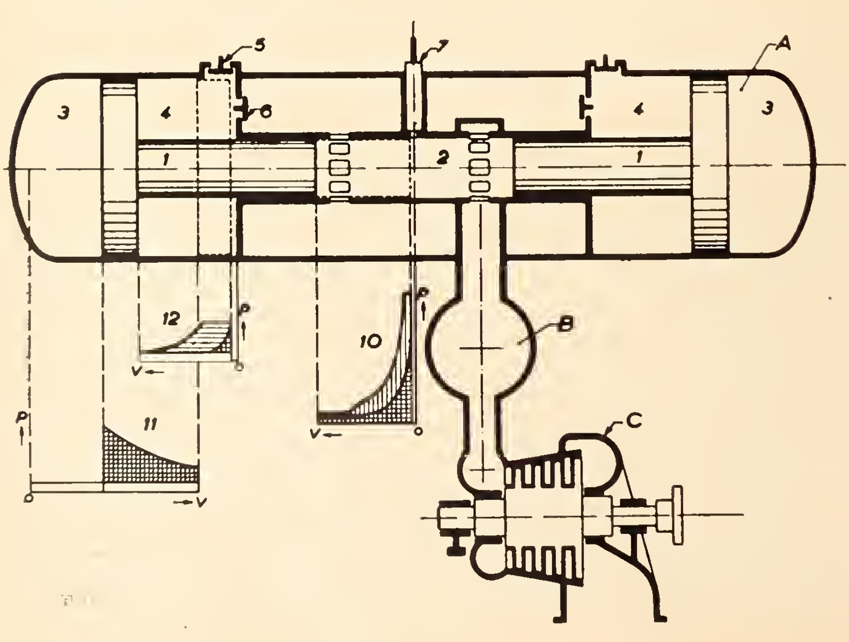
A prototype of the present 1250 GHP GS 34 unit was built in 1944, has been under continuous development since that time, and is now in regular production in both France and England.

In 1942 the Royal Navy initiated development of a smaller free piston gasifier of higher speed. This work was carried out at the Admiralty Engineering Laboratory in England, in conjunction with Alan Muntz. The latter have since continued the commercial development of this machine as the CS. 75.

An internal combustion engine can be considered to be a heat engine using air as the working medium, which air is expanded under the action of heat generated by the combustion of fuel in a closed cylinder. In a conventional engine the energy is converted into useful mechanical work in course of expansion by the movement of a piston and linkages connected thereto. The free piston gasifier utilizes the same heat energy, derived from the combustion of fuel to expand air in a cylinder in a precisely similar manner save that the process can be carried out more efficiently at much higher pressures. Instead of converting the energy directly into mechanical energy through pistons anl linkages, the working fluid is ducted away from the combustion part of the cycle which takes place in the "gasifier" and mechanical energy is extracted in a separate process by expanding the heated air and combustion products through a turbine.

Fig. 2. Diagrammatic sketch of a free-piston gas generator and gas turbine, showing pressure-volume diagrams of the engine, compressor and cushion cylinders. A) gas generator; B) gas collector; C) gas turbine. 1) piston. 2) engine cylinder. 3) cushion cylinder. 4) compressor cylinder. 5) suction valves. 6) delivery valves. 7) fuel injector. 10) p-V diagram of engine cylinder. 11) p-V diagram of cushion cylinder. 12) p-V diagram of compressor cylinder.



Logical Final Stage

The free piston gasifier turbine engine has been over 30 years in gestation largely due to the fact that it is the logical final stage in the development of the diesel engine, and as such had to await until high pressure turbo-charging and B.M.E.P.'s revealed the limitations of conventional crankshafts and bearings and provided the necessary incentives for their complete elimination.

Development has been broadly upon two lines, resulting in two basic types of free piston gasifier:—

(a) The outward compressing type in which the scavenge air is compressed during the outward firing strokes of the diesel piston.

(b) The inward compressing type in which the scavenge air is compressed during the inward or compression strokes of the diesel piston.

Advantages of the Inward Compressing Principle

Although the outward compressing type appears to offer advantages arising out of the phasing of the scavenge air pressure with port opening, in practice this is more than outweighed by difficulties in disposing of surplus heat and in assuring adequate lubrication.

All gasifiers presently in commercial production are therefore, based upon the inward compressing principle which enables a very simple and robust type of construction to be adopted.

This type of free piston engine is developed as a highly supercharged, horizontally opposed-piston, two-cycle uniflow engine in which each of the opposed pistons is rigidly connected by means of a rod or trunk to a compressor or cushion piston. The outer faces of these cushion pistons operate in closed chambers in which air is compressed during the outward or firing stroke of the diesel pistons, and the energy stored in the compressed air serves as a spring and returns the piston assembly to the firing position to complete the cycle. The inner faces of the cushion pistons function as scavenge pumps and compress air into the engine case surrounding the diesel cylinder.

Designed for Maximum Efficiency

It will be seen from this that the load-carrying bearings which are a limiting feature in the development of the conventional reciprocating diesel engine, are eliminated in the free piston engine and combustion conditions can therefore, be designed for maximum efficiency. The only mechanical linkage between the pistons is a synchronizing mechanism designed to keep the two pistons in step with each other. This mechanism also drives the fuel pump and other auxiliaries.

There are two basic classes of such free piston engines in production:

(a) *Air Compressors* in which the diesel cylinder is either naturally aspirated, or carries a very nominal degree of supercharge, the exhaust being either direct to atmosphere or against the modest back pressure of an elementary form of gas turbine arranged to drive the auxiliaries.

In the *Pescara* and *Mackay* compressors one of the two diesel pistons is connected to a compressor piston by means of a piston rod, the outer face of the compressor piston being arranged to deliver compressed air for the operation of pneumatic tools, etc. The inner face acts as a scavenge pump delivering air through valves into the engine case, from where it passes through scavenge ports into the diesel cylinder. The other diesel piston is connected to a cushion piston which operates inside a closed cushion cylinder; this serves to balance the forces acting on the opposite piston and to assist the return of the combined piston assemblies to the inner dead point position after each firing stroke.

This machine is thus non-symmetrical, and unlike the free piston gasifier, is not perfectly balanced, the synchronizing linkage being designed to transmit the out-of-balance output. The out-of-balance is in fact negligible when compared with conventional machines, and the machine is vibrationless in operation.

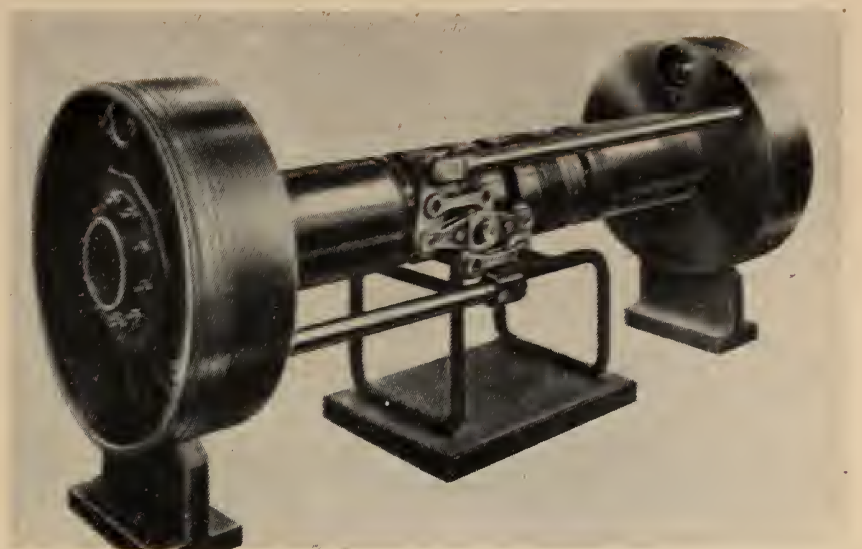


Fig. 3. Moving parts of GS. 34.

(b) The other class of free piston engine is the *Gas Generator*, or gasifier, which is of symmetrical construction, each diesel piston being rigidly connected to a cushion piston, as already described, and the entire output of the compressor cylinders is delivered to the diesel cylinder at a relatively high pressure. The air then undergoes a normal but highly supercharged diesel cycle, with combustion partly at constant volume and partly at constant pressure. The hot products of combustion are then discharged at a pressure slightly lower than that of the incoming air into a manifold connecting the gasifier to an exhaust turbine; the latter is the true prime mover.

The free piston gasifier is a logical development of the compound, turbocharged diesel cycle and is thus a very highly supercharged diesel engine. It replaces the compressor and combustion chamber of a conventional open cycle gas turbine, and operates at a much higher compression ratio and thermal efficiency than is ever likely to be obtained with an axial flow rotary compressor, or than can be usefully employed in a crankshaft engine.

Gas Thermal Efficiency

The free piston engine operates at a high thermal efficiency, the latter being defined as the work done per pound of gas delivered when expanded isentropically to atmosphere, divided by the heat input in the fuel for each pound of gas delivered. This gas thermal efficiency at the present stage of development is between 42 and 43½%, depending on the size of machine, and this, multiplied by the turbine and ducting efficiency, gives the brake thermal efficiency of the gasifier turbine combination, which is comparable with good diesel efficiencies, and nearly double that to be expected from a simple open-cycle gas turbine.

The Mechanical Features of free piston engines are characterized by a basically simple structure of generally cylindrical form, a feature which applies both to the main body of the engine and to the piston assemblies. Details of the two sizes of gasifier presently in production are shown in table I. The larger unit is designated as the GS.34 gasifier and is shown in section in Fig. 1.

Gas Load on Piston Crown

It will be seen from Fig. 2 that the loads produced by the gas pressures in the various cylinders are taken in a direct manner both in the body of the engine and by the piston assemblies. The gas load on the diesel piston crown is transmitted axially along a cylindrical trunk to the compressor piston, is absorbed by the inertia of the pistons themselves, and does not have to be transmitted through the body of the engine. Only the radial pressure loading in the combustion space has to be resisted by a hoop stress in the central zone of the diesel cylinder liner, which can be met by a very simple design. The outward momentum of the moving parts is taken by the cushion head, and as the cushion cylinder has a low ratio of maximum to minimum pressure, the maximum load to be transmitted through the body from one end of the engine to the other is relatively low.

The pistons are of generally symmetrical design as dictated by the gas loading on the piston crown. There being no wrist pin or bosses, none of the clearance or expansion problems normally associated therewith can arise. Similarly all loading is axial; there is no imposed side-thrust and the piston does not have to function as a cross-head as in the case of a conventional trunk piston engine. There being no crankcase, the danger of crankcase explosions is eliminated and the possibility of blow-by is minimized. As operating diesel engineers will know, amongst the main problems with modern highly stressed diesels are loading on the cylinder head studding and joints, and between the piston skirt and liner; the latter can be aggravated by the oil film breaking down due to the blow-by of small particles of carbon from the combustion space, or particles flung from the crankcase oil. These problems are largely eliminated in the free piston design.

Synchronizing Gear

There are the minimum number of constraints on the moving parts of a free piston machine. Each piston assembly, sliding in its respective cylinder is maintained in step with the other piston assembly by one set of synchronizing rods only. This synchronizing gear can take the form either of a lazy-tongs type of linkage as on the GS.34, a rack and pinion as on the CS.75, or a rocking lever and connecting rods as in the DAC compressor.

As has already been indicated, the synchronizing linkage is not required to transmit any load on a perfectly symmetrical engine other than that necessary to drive the fuel injection pump or other auxiliary equipment. The synchronizing linkage is therefore, made quite light not only to avoid a direct addition to the weight of the moving parts, but also because the compressor pistons themselves must be designed to carry the inertia loading produced by the synchronizing gear.

The moving parts of a 1250 GHP GS.34 gasifier are shown assembled in their firing position in Fig. 3.

The symmetrical construction of these engines makes them particularly insensitive to thermal distortions through rapid changes of load, and they can put on load from cold very rapidly. No energy is stored in the machine between cycles which therefore stops immediately fuel is cut off, and no damage can result from the dissipation of energy stored in rotating masses as is the case in conventional engines.

There is no vibration due to the reciprocating parts as the masses are made as nearly identical as is required and are in static and dynamic balance. The engines run with a remarkable absence of vibration and require virtually no foundations other than those required to support the actual static weight.

Care must, however, be taken that no extraneous vibrations are introduced by gas pulsations in the intake and delivery ducts of the machine. This can be achieved by correct design in the light of present day knowledge of gas dynamics and acoustical engineering.

The diesel cylinder discharges into a gas collector which smoothes the gas pulsations in the turbine manifold to a low value. The pressure variations in this gas collector at full load are of the order of plus and minus 4 lbs./sq. in. on a mean pressure of about 45 lbs./sq. in. The mean pressure wave has a fundamental frequency of about 10 cycles per second for the GS.34 and 18 cycles for the CS.75, and these frequencies are low enough not to constitute any hazard to the turbine blades the natural frequency of which, even in the first stage of a large turbine, is of the order of 1000 cycles per second.

Dephasing

A more constant rate of gas flow can be obtained in multiple installations by coupling gasifiers in pairs with a phase displacement of 180°. This is achieved by coupling the cushion ends of the two machines through a dephasing valve which consists essentially of a differential piston connected across the cushions which activates a valve, arranged in such a manner that cushion pressure is increased or decreased as necessary to keep the pistons displaced by half a cycle. In such a case, the engine cases would also be connected together in order to damp out cyclic fluctuations in scavenge air pressure.

A turbine constitutes an excellent silencer, and no other provision is required to silence the exhaust. The air intake casings around each compressor cylinder effectively silence the induction noise and reduce the air pulsations. The general level of noise produced by a free piston engine is somewhat less than that of a diesel engine of the same size and speed, and there is a notable absence of high frequency clatter arising from valve gear, etc. The noise level adjacent to free piston gasifiers has been measured at 95 decibels.

Characteristics

The characteristics of a free piston gas generator of the type under consideration are shown in Fig. 4. The curves, refer to the GS.34 but can be applied to the CS.75 by multiplying the speed by 1.8 and dividing the gas flow and power outputs by 3.

The speed of oscillation of a free piston engine is not an independent variable as it is on a crankshaft engine, and is principally determined by the mass of the moving parts and

Table I—Technical Data of CS. 75 and GS. 34 Gas Generators

Two types of free-piston gas-generator are at present available the GS. 34 of 1,250 gas h.p.* and the CS. 75 of 420 gas h.p. Their leading dimensions are given below:—

		GS.34	CS.75
Engine cylinder bore	in.	13.4	7.5
Comp. cylinder bore	in.	35.4	20.75
Overall length	ft.	13.75	7.5
Weight	tons	8	2.25
Stroke at continuous max. rating (C.M.R.)	in.	2 x 17.4	2 x 9.8
No. of oscillations at C.M.R.	cycles/min.	570	1,100
Mean piston speed	ft./min.	1,650	1,650
Gas temp. at C.M.R.	deg. C.	437	460
Gas pressure at C.M.R.	lb. per sq. in.	42.5	50
Mass flow of gas	lb. sec.	8.8	2.65
Gas h.p. at C.M.R.		1,250	420
Thermal efficiency into gas	%	43	42
Specific fuel consumption	lb./gas h.p. hr.	0.320	0.325
Volume compression ratio at C.M.R.		9.1	8.1
Compression pressure	lb. per sq. in.	1,000	1,000
Max. cylinder pressure	lb. per sq. in.	1,700	2,000
Heat to jacket cooling water	% heat input	14	17
Heat to piston cooling oil	% heat input	5	5

Present ratings of free-piston engines consisting of one gas-generator coupled to a turbine, with reduction gearing, are 1,000 shaft h.p. for the GS. 34 gas-generator, and 350 shaft h.p. for the CS. 75 gas-generator.

*The output of a gas-generator is usually expressed as "Gas h.p." This is defined as the power available from an adiabatic expansion of the gas down to atmospheric pressure.

the gas delivery pressure, and only to a secondary extent by other operating conditions such as the load and length of stroke.

The motion of the pistons is analogous to that of a weight on the end of a spring. In each case the frequency is determined by the effective stiffness of the restoring force. In the free piston engine, this stiffness is determined by the gas pressure in the various cylinders and it has an approximately constant value at any gas delivery pressure and increases with it.

As the frequency is proportional to the square root of the stiffness, the extreme range of speed from no load to full load is limited to less than two to one. This is because the stiffness due to the gas pressure varies over a range of less than four to one, which is approximately the range of the absolute pressure of gas delivery.

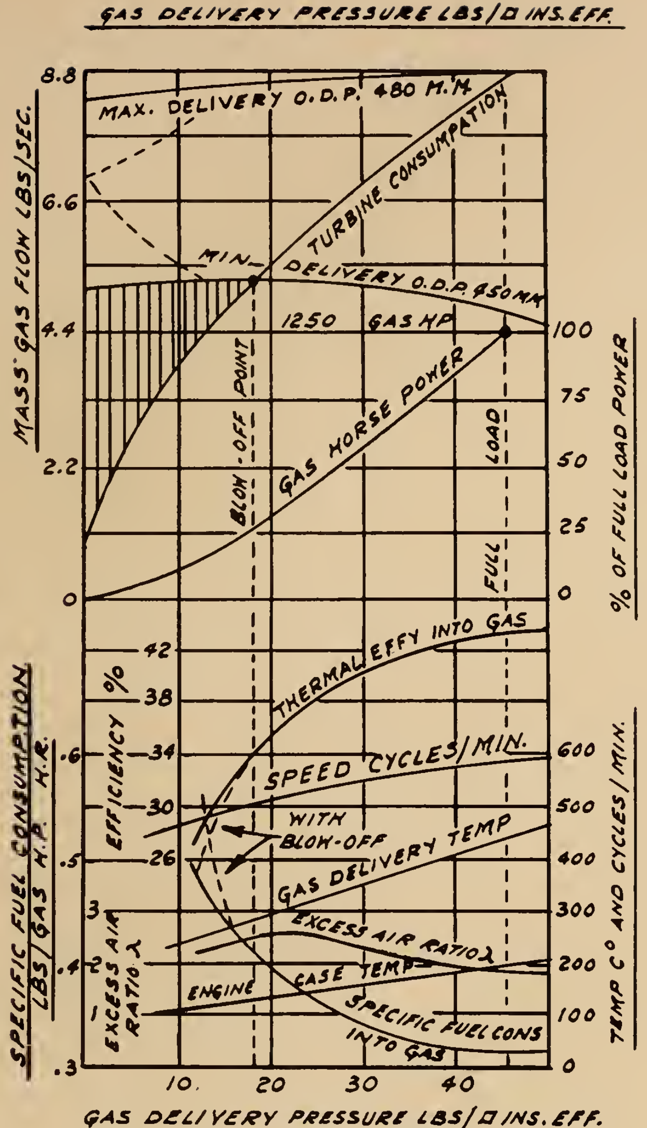

Fig. 4. Characteristics of GS. 34 gasifier.

Power Output

Basically, the power output is controlled by adjusting the fuel admitted which has the effect of varying the stroke, thereby altering the mass flow of gas. In the normal arrangement where a gasifier supplies a turbine, any increase in gas flow results in an increase of delivery pressure since the turbine behaves substantially as an orifice of constant area. At the same time the gas delivery temperature rises because of the increased work of compression.

The power output is proportional to the mass gas flow, the absolute temperature and the isentropic drop ratio, the latter increasing with the pressure ratio. Thus the combined effect of the three dependent variables is that the power varies over a wide range for quite a small change of stroke. For example, a drop in power of 75% from 100% to 25% is produced by a reduction in stroke of only about 20%. This effect is enhanced by the relatively large clearance volume in the compressor cylinder, which means that the percentage change in the delivery is greater than the percentage change in the rate of stroke.

Recirculation

The minimum permissible stroke is governed by the necessity of uncovering the scavenge ports, and which, in turn, determines the amount of fuel required when idling. This is compensated for and the part load performance and fuel consumption improved, by a system of "recirculation" whereby hot, compressed air from the engine case is fed back to the compressor intake. This has the effect of reducing the compression ratio and increasing the clearance volumes in the compressor ends, thereby reducing both the compressor deliveries and the cushion pressures, and which in turn slows down the speed of oscillation and reduces the mass gas flow to closely match the requirements of the turbine characteristics at part loads.

A by-pass valve may be also connected to pass some of the scavenge air direct from the engine case to the gas collector at low loads when there is more air available than is required to scavenge the diesel cylinder. This reduces the pressure drop across the diesel cylinder ports and reduces the pumping losses, which is reflected in further fuel economies. The mass gas flow can also be matched to turbine demand at light loads by throttling the compressor intakes.

A gas blow-off is provided to enable the gasifier to idle against a stopped turbine and to facilitate the starting up of gas generators in multiple installations, whilst others are already running on load.

The blow-off valve is customarily combined with a stop valve used to isolate the gasifier from the common manifold used in a multiple installation. This combination valve may be directly operated by the turbine actuated governor, and in the case of an electric generating set, an overriding servo valve may be directly operated by the main circuit breaker, which would take charge in the event of a sudden loss of load.

Stability

Stability is a function of the mean cushion pressure, which must be adjusted to suit the actual working pressure at the turbine stop valve in order to maintain suitable compression pressures in the diesel cylinder. The engine case pressure may be regarded as constant for any given load whereas the air in the cushion cylinder is compressed to several atmospheres and expanded again in course of each stroke. Thus for one part of the inward end of the stroke the cushion pressure is below that of the engine case whilst at the other it is above engine case pressure. Thus it is always possible to transfer air from the cushion cylinders to the engine case during one part of each stroke or from the engine case to the cushions during the other part of the stroke. Advantage is taken of this to automatically adjust cushion pressures by the use of a stabilizing valve between the balance pipe joining the cushions and the engine case. A spring-loaded differential piston, sensitive to the pressure differential between the cushion balance pipe and the engine case, is arranged to operate a piston valve which transfers air in either direction as required to compensate for changes in engine case pressure; which pressure is in turn controlled by the load demand on the turbines.

Fuel Injection

Fuel injection has to meet conditions peculiar to the free piston engine in that injection takes place over a period which includes inner dead centre when the pistons and all parts connected to them are stationary and there is no energy to continue the cycle other than that to be obtained from the combustion of fuel. Fuel injection in the GS.34 is, therefore, affected by means of an accumulator operated pump whereby fuel is metered and stored under pressure in a chamber which is vented to the injectors at a pre-arranged time, controlled by the delivery pressure, just before the inner dead point is reached. The fuel is expelled through the injectors by air pressure acting on the accumulator chamber. The injection operation is a function of the air pressure, fuel quantity and nozzle area, and is entirely independent of the pistons once the cycle has been commenced. The type of accumulator pump used in the GS.34 is illustrated in Fig. 5. Higher speed machines such as the DAC Air Compressor can use conventional injection pumps with mechanical delay. Controls are very simple and are centralized in a single hand wheel, the operation of which starts the set, governs its operation and shuts it down.

Initial movement of the wheel to the starting position admits air under pressure to a small, pneumatic cylinder which moves the pistons apart to their outer dead points. A "shot" of air is then admitted to the cushion cylinders, which serves to throw the two pistons together at full operating speed, raising the temperature of the entrapped air until the combustion of fuel causes the pistons to move apart and the machine is operating. Control of the set is then taken over by the hydraulic governing system operated by the power turbine energized by the gasifier. The air requirement for starting is very modest and of the order of 10 to 12 cubic feet.

The gasifier is stopped by cutting off the supply of fuel, either by means of the governor or by movement of the control wheel. Fuel may also be cut off by a simple mechanical over-stroke trip which is operated from the linkage in the event of the O.D.P. exceeding a safe limit, and by an overspeed trip on the turbine shaft connected to the same device. In the case of Marine applications of a type utilizing a unidirectional turbine with variable pitch propellers a single control can be arranged to co-ordinate turbine output with propeller pitch.

Performance and Economic Considerations

As has already been indicated, the thermal efficiency of converting fuel into gas is high, and is approximately 43% for the gas conditions which are now customary.

Losses are involved in converting the gas energy into mechanical energy, and typical figures are 1½% to 2% for pipe friction losses, etc., in the manifolding, and 1½% to 3% in the reduction gear, if used.

Turbine efficiencies vary with type and efficiencies of the order of 87% to better than 89% are obtainable with multistage axial flow turbines. Such efficiencies make possible an overall fuel consumption on heavy fuel better than .4 lbs./SHP /hour. Economies in weight and space, can be obtained by using small lightweight turbines running at speeds of the order of 30,000 RPM and upward and for some applications simple radial inwards flow turbines have advantages. Fig. 6 shows a 200 kw D.C. Marine auxiliary generator driven by a high-speed three stage axial flow turbine operating at 29,000 RPM and energized by a CS.75 gasifier.

The conversion losses are largely compensated for by a reduction of other losses. In a conventional engine,

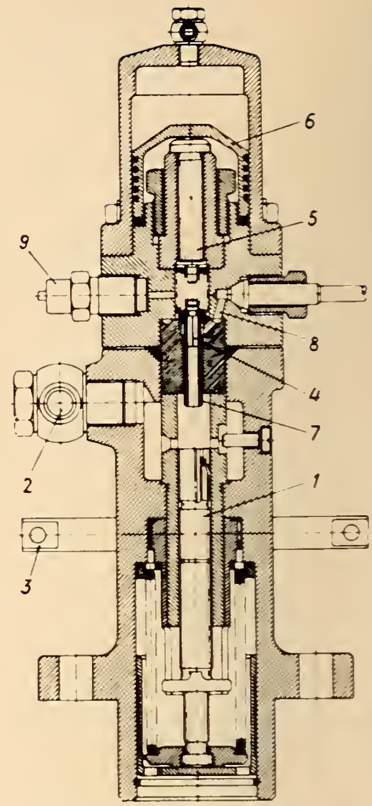

Fig. 5. Fuel accumulator pump (scale 1:5). 1) metering pump. 2) suction connection. 3) control rack. 4) non-return valve. 5) accumulator plunger. 6) air pressure plunger. 7) delivery valve. 8) fuel injection pipe. 9) safety valve.

as much as 25% of the mechanical power generated may be lost in overcoming friction, rather more than half of this being accounted for by bearing friction and windage, which is entirely eliminated in the free piston engine. According to tests carried out at the *Technical Hochschule* in Zurich (Eichelberg) the friction losses in a free piston engine amount to only 9.3% of the effective turbine output.

Comparable Heat Losses

The heat loss to the water jackets in a conventional engine can amount to 25% and an additional 6% or 7% may be lost through the lubricating oil. The heat losses in a comparable free piston engine approximate 19%, made up of 14% to the water jacket and 5% to the piston cooling oil.

It will be apparent from the foregoing that the overall efficiency of the gasifier and turbine is comparable with that of a modern high efficiency diesel engine operating at a thermal efficiency of the order of 37%.

The gasifier and turbine enjoy several advantages, particularly the ability to burn a very wide range of fuels, and in fact, the gasifier can be operated on anything from residual fuel and bunker "C" to kerosene and gasoline, the power output being directly proportional to the calorific value of the fuel used.

The gas in the manifold before the turbine stop valve contains approximately 80% unburned air, and advantage of this can be taken to burn additional fuel before the turbine, which has the effect of raising the gas temperature and increasing the mechanical output by some 40%. This feature can be usefully employed to temporarily increase the power output to meet peak loadings in certain applications, as for instance, traction, at the expense of a temporary reduction in thermal efficiency. The higher temperature levels will, however, necessitate a more expensive type of turbine blading.

The free piston engine and turbine being vibrationless, do not require massive foundations and the units, being comparatively small, do not call for heavy structural members or gantrycranes for maintenance purposes.

The power weight ratio and volume area occupied by an installation of given power compares favourably with other types of prime mover, and the fact that the gasifiers do not have to be in any particular alignment with the output shaft has advantages, particularly for marine propulsion and locomotive installations.

The cooling water requirement is low and is of the order of 7 gallons per installed horsepower per hour. The possibility of recovering heat from the turbine exhaust is of interest in some applications, as for instance, in the case of Heat pumps for space heating, and for the generation of hot water or steam.

Maintenance

Maintenance is very low due to the small number of moving parts and compares very favourably with other types of prime mover. Due to the use of low temperatures and pressures there is no corrosion or gummy deposit on the turbine blades, thus lengthening the time between inspection and overhauls. Based on actual experience with native labour in Tunisia the turbine section of a free piston installation need not be inspected under 25,000 hours running and no maintenance has been found necessary in this period.

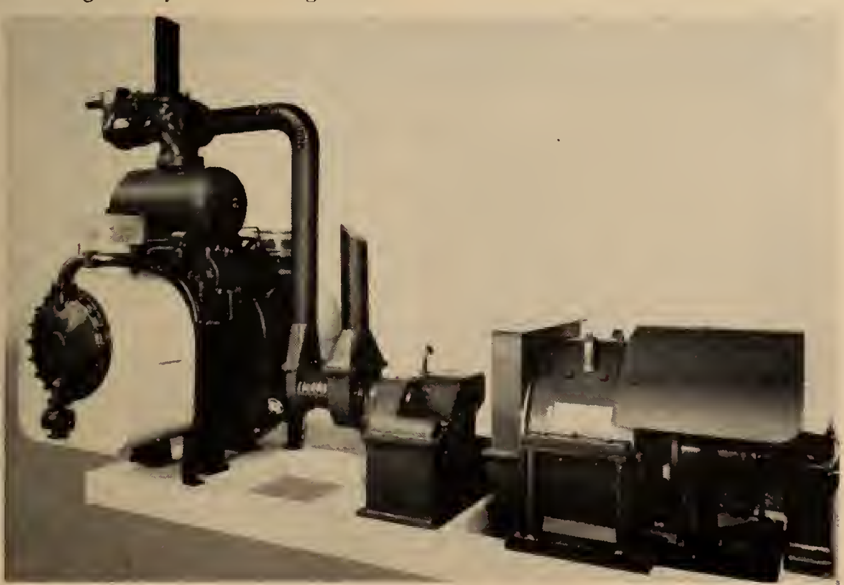
The moving parts are fewer and lighter than in corresponding diesel installations and there are no crankshafts or cam operated valves, load carrying bearings etc., and fewer and simpler pistons and rings.

Maximum maintenance weight to be handled on a GS.34 gasifier is only 550 lbs. for withdrawal of the piston assembly.

No additional head-room is required to facilitate dismantling and 3 ft. 6 ins. clear space at each end is sufficient to permit the drawing of the pistons etc. No valve grinding or fitting is necessary with free piston arrangement, and there are no tappets to adjust.

Complete stripping and rebuilding of a gasifier can be done by six men in one day, and ordinary service by two men in five hours. By providing standby gasifiers all maintenance and inspection work can be carried out in day shifts thus dispensing with night work.

Fig. 6. 200 Kw.D.C. Marine auxiliary generator driven by a high speed turbine and energized by a CS. 75 gasifier.



Liner wear is more evenly spaced over both the circumference and length of the wall than is the case with a conventional engine and no characteristic ridge is formed above the limit of travel of the top ring; neither is there the same tendency for bores to wear oval, there being an absence of the side thrust which is imposed by the angularity of the connecting rod in a conventional machine. The effect of heat transfer is also spread over a larger area of the liner wall due to the greater rate of the acceleration of a free piston compared with one confined by mechanical linkage. As has been shown, due to the absence of stored energy, the free piston engine is inherently non-destructive and offers advantages in unattended installations or where supervision is limited.

Rating

The rating of the free piston engine can be separated into the rating of the gasifier itself and of the complete gasifier-turbine set.

The gasifier rating is primarily a matter of the maximum loading of the diesel pistons for good endurance, the limit set on the piston stroke in relation to the outer mechanical limit of its travel, and the maximum permissable engine-case temperature.

The present continuous rating of the GS.34 is 1250 GHP but outputs of well over 1500 GHP have been sustained for considerable periods on test, so that the CMR may be considered to be conservative.

Two conditions can be considered for the derating of complete gasifiers/turbine sets viz:—

(a) with an "adjusted" turbine, the nozzle area of which is designed to suit site conditions.

(b) with a "fixed" turbine, the nozzle area of which is designed for other than site conditions of ambient and altitude.

The derating for an "adjusted" turbine is only about one-fifth for temperature and one-half for barometer, as compared with the derating for a conventional diesel engine.

Applications

Applications have covered a wide range and considerable experience has now been obtained in continuous operation both in central electricity stations and with Marine propulsion units.

Over 300,000 GHP of gasifiers are either in operation or in course of production, and an impressive number of operating hours have been accumulated.

Electrical Applications

Of the existing electrical applications, a 1200 k.w. installation has been running at Rheims since December 1951. A similar installation at Metlaoui, in Tunisia, has been running since 1953, operating 24 hours a day, burning residual fuel, and has now run something over 25,000 hours. The turbine was first inspected after 12,000 hours, and the blades and bearings were found to be in excellent condition,—and the very light deposit on the blades was found to be easily removed and confirms that no corrosion or deposition troubles should be experienced even when running on cheap fuels.

A 600 k.w. set was installed at the Cerveceria Modelo, Cuba, in 1953.

A 6000 k.w. installation was made at Cherbourg for the Electricity de France in 1955, and a similar installation at Tours.

A 3000 k.w. installation was made at Ajaccio, Corsica, in 1955.

During 1956 two 1500 k.w. sets were installed in Noumea and a further 1500 k.w. set for Companie des Phosphates de Gafca, at Redeyef, Tunisia. A 1500 k.w. set was installed in Lome (Senegal) two 3600 k.w. sets at Augusta, Corsica, and two 1500 k.w. sets for a cement Company at Chekka, Syria, a 4000 k.w. set for Egypt, and a further set for Pointe-Noire, Cameroons.

In addition the following sets are known to be on order and in course of manufacture.

2—4000 k.w. sets for Sicily.
1—1500 k.w. set for England.
6—6000 k.w. sets for Singapore.
2—3000 k.w. sets for Malaya.
2—6000 k.w. sets for Finland.
2—3,000 k.w. sets for Malaya.

It will be noted that many of these installations have been operating in remote parts of the world where they are maintained by native labour, and operating experience has been so satisfactory that in many cases repeat orders have been received, which would confirm that maintenance is low and well within the capacity of comparatively unskilled personnel.

The foregoing covers generating sets in regular commercial operation, and in addition, a number of sets have been supplied for experimental purposes.

Marine Applications

The largest number of marine installations are under the French flag, where the French Navy adopted a free piston gasifier turbine installation as standard for a class of fast minesweeper, which was first laid down in 1953 and now consists of 21 ships. The free piston propulsion system being free of vibration does not transmit any significant signal through a ship's hull plating to the sea which makes it particularly suitable for this application.

The 1100 ton coasters *Cantenac* and *Merignac*, in regular service since 1953 and 1954 respectively, have been in continuous operation and have achieved the best record for regularity of their fleet, with phenomenally low maintenance. It is particularly noteworthy that these ships are popular with both the deck officers, due to ease of manoeuvering and reliability, and with the engine room staff, due to ease of maintenance and acceptable engine-room conditions—to the extent that transfer is resisted to other ships in the fleet with conventional engine-rooms.

A 6000 SHP installation has been made in the converted liberty ship *William Patterson* by General Motors. This ship is in regular ocean service and has completed several transatlantic crossings. The weight of the propelling machinery and auxiliaries is 385.4 tons as against 463.8 for the original machinery of only 2500 SHP. Auxiliaries account for nearly 140 tons. Average speed on trials was 16.7 knots with six gasifiers, 15.4 with five and 12.3 with four operating. Final operating costs for this ship have not yet been made available but corrected fuel consumption for all services is understood to better .510 lbs/shp/hr as against .494 lbs/shp/hr for the sister ship with geared diesels. The Patterson uses commercially available bunker "C" and no special processing is required other than centrifuging.

The 1,350 ton 15 knot deep sea trawler *Sagitta* has now been 270 days at sea since being commissioned in January 1958. She is equipped with two GS.34 gasifiers feeding a 2000 SHP 8000 RPM unidirectional turbine driving a C.P. propeller through reduction gears. Fuel Consumption has averaged 7.2 tons per day using heavy oil. Two sister ships have since been ordered.

The *T. V. Morar* of 9,200 ton deadweight capacity and 2,500 SHP has been in regular service since the beginning of the year and has attracted much favourable comment from ship owners and others who have sailed in her.

The *T. V. Morar* is the first British vessel built specifically for free piston propulsion and her engine room is the first all British built marine installation of this type. The installation consists of three GS.34 gasifiers feeding a reversing turbine running at 5250 RPM and driving through reduction gears to a propeller at 115 RPM.

The ship is an ore carrier and is built to the maximum dimensions considered to be suitable for a vessel calling regularly at Port Talbot. The weight of the whole machinery is only 410 tons as against a total of 630 tons for the diesel sister ship which gives an increase in deadweight of about 200 tons. The use of free piston machinery could have permitted a reduction in engine-room length of ten frame spaces, but the vessel being an ore carrier, it was found to be unnecessary to make use of more than five. These five frame spaces give an increase in bale capacity of 12,411 cu. ft. over the sister ship and also allow an increase on 309 tons in water ballast capacity.

The *T. V. Morar* has a designed service speed of 11 knots. The fuel consumption of the MK 11 turbine intended for this vessel is 0.42 lbs. per SHP/hr using heavy fuel of 1,500 seconds viscosity. On trials, speeds of 12½ knots were achieved on three gasifiers and 9½ knots on two gasifiers with the third shut down.

Under construction are installations for a cargo ship of 2000 SHP for France, Fenwick & Co. Ltd., 4000 SHP for a dry cargo vessel building for Bolton Steamship Co. Ltd., a 4000 SHP installation for a cargo liner for British India Steamship Co. Ltd., and a 7000 SHP propulsion set for a new cargo liner building for Crest Shipping Co. Ltd.

Two 16,000 SHP installations are under construction for French vessels and seven 4000 SHP installations are being built for USSR and a 3,000 SHP installation is being built for a Whale Catcher in Holland.

In addition to these, a number of marine auxiliaries of 200 k.w. incorporating CS.75 gasifiers are being installed in ships in England.

Industrial Applications

In addition to the above applications, gasifier turbine installations have shown themselves to be suitable for other duties such as pumping water and compressing gas, and a pumping installation has been in operation in a Paris waterworks since 1955.

A free piston turbo compressor is particularly suitable for heat pump applications as the turbine can be designed for direct coupling at the most efficient compressor speed and all the heat can be recovered.

As a result of a survey of the most suitable power source, free piston gasifiers were selected for the 13,000 SHP gas compression plant in the new I.C.I. Synthetics Plant at Wilton, England. This installation consists of 13 GS.34 gasifiers feeding into a common ring supplying 6 turbo-compressors. A GS.34 Turbo-compressor is to be installed in Australia.

Rail Traction

The ability to burn cheap, residual fuels, coupled with the favourable torque characteristics of the turbine makes the gasifier turbine power unit very suitable for traction applications.

A 1000 HP locomotive incorporating a single GS.34 gasifier was built by Renault and has been in regular mainline service since 1952. The gasifier and turbine of this locomotive are carried on the main frame and the drive is transmitted to the axles by means of a gearbox and carden shafts. This particular locomotive has been burning a light furnace oil with a viscosity of 85 seconds Redwood at 100°F. and shows an appreciable economy against a diesel locomotive running on gas oil; this is accentuated by the fact that gas oil is taxed in France, as in some Canadian provinces, whereas furnace oil is not.

This locomotive has run well over 125,000 miles in normal operation and the experience gained has been used to design free piston gasifier locomotives of 2000 HP which are also built by Renault. A 2000 HP locomotive is also under development by General Motors in the United States and 3,000 BHP locomotives are being built in U.S.S.R. as a result of satisfactory operating experience with Free Piston Gasifiers.

It would appear that the low temperature and pressure to which the connecting ducting between the gasifier and turbine is subjected would lend itself to the design of a locomotive in which small, high speed turbines were mounted on the power trucks, where they could be directly connected to the axles through suitable gearing, as in a traction motor, the turbines being supplied fram gasifiers mounted on the main frame.

The CS.75 gasifier would appear to be particularly suitable for this application as their short length would enable them to be mounted transversely across the chassis and multiple units could be installed to deliver 3600 HP or more. Such an arrangement would facilitate maintenance by the replacement of individual gasifier units in rotation, with serviced units, and would greatly reduce the time during which the locomotive was out of service for maintenance purposes.

Automotive Applications

The gasifier turbine is also suitable for automotive applications, and at least four companies have small units in the range 100 HP to 250 HP under development which would be suitable for powering commercial vehicles and possibly private automobiles.

The low temperature gas turbine has special advantages in multiwheel drives where differentials can be dispensed with and for the steering of tracked vehicles. The turbine performs a similar function to a torque converter and for most applications variable speed transmissions can be dispensed with, and the turbines can also be designed to give up to 60% reverse torque which may also be used for braking purposes.

General

Applications to date have followed conventional lines, but the characteristics of the gasifier turbine unit lend themselves to applications where mechanical power is required to be taken from shafts at relatively high rotational speeds.

Turbine speeds can be matched to those of highly efficient rotary compressors for the delivery of process gas etc. An interesting application is the driving of a compressor associated with a heat pump which would also enable the heat content of the exhaust gas to be recovered. Other applications are the driving of high frequency generators in association with electronic apparatus, high frequency electric furnaces etc.

The quick starting feature offers interesting possibilities of designing large no-break mains failure standby sets of a type where the turbine rotor would substitute for the no-break flywheel.

In addition to straight gasifier turbine applications, there are attractive possibilities to be had from mixed cycle installations in which gasifiers are associated with steam installations.

The exhaust discharged from the gasifier-turbine contains approximately 80% of unburned air, which can be used under a boiler as preheated furnace air. This has the effect of raising the overall steam plant efficiency and the combined efficiency of a gasifier and steam plant can approach 33%. Such a combined cycle is of particular interest in Marine installations, as it enables a reduction to be made in boiler size, and enables the earning capacity of a vessel to be increased.

Conclusions

The free piston engine combines the advantages of the high thermal efficiency of the diesel engine with the torque characteristics of the gas turbine; it also eliminates most of the disadvantages associated with these types of prime mover.

The free piston engine is now out of the development stage and is firmly established, particularly in the fields of industrial power generation and marine propulsion, and its applications in these fields are expanding rapidly, particularly in the unit range from 1000 to 16,000 H.P.

The application of the free piston engine to road and rail traction is not yet out of the development stage, but the operating characteristics of this engine are such that it must become firmly established in this field also.

The free piston engine has numerous advantages over other prime movers for certain applications, and these include reliability and ease of maintenance with relatively unskilled labour, the elimination of vibration and resulting saving in foundations and structural supporting members, as for instance in ships, light unit weight and bulk, which lends itself to trans-shipment by air, and maintenance without heavy lifting tackle. The ability to burn a very wide range of fuels which includes residual oil, the ability to deliver a stalled torque, and the ability to deliver power at high rotational speeds suited for direct coupling to turbo-compressors, high frequency electrical generating apparatus etc.

Further improvements may be anticipated in specific output, the fuel consumption at light loads, and on widening the range of applications, particularly by the development of small lightweight gasifiers suitable for automotive applications.

No man is an Iland, intire of Itselfe
John Donne; circa 1625

THE SCIENCE and art of engineering has been divided and subdivided continuously since sappers first moved from military engineering into civilian service. The specialist in each branch finally discovers that his problems are not unique, but constitute the problems of engineers in other branches, so now a coalescence of engineering knowledge for the design and construction of the major projects is necessary. Civilization has reached a stage where it appears that men may again have to go underground and live as cavemen. The design and construction of underground excavations for the housing of power plants, warehousing, factories, bomb-proof record storage, and the accommodation of people as a civil defence project falls in the field of the civil engineer.

This paper is intended to point out the interdependence of civil engineers, geological engineers, and mining engineers in the design of these underground structures. The mining engineer, if he has any unique qualifications, is learned in the construction and support of underground excavations. He is inclined to take a pessimistic view of ground support surrounding underground excavations because he is seldom asked to work except in rocks that have been subjected to the tremendous geological disturbances which have brought about most orebodies.

The mining engineer is accustomed to working with stresses beyond those employed by most engineers and if he has learned nothing else he does know that there is no such material as "solid rock." There is a parallelism between structural members used by other engineers, and their counterparts used in structures underground. The mining engineer however develops his structures within a stressed mass. The behaviour of rock as a structural material is examined, in this paper, in relation to the stresses to which it is subjected in the peripheries of underground workings. The intention is to demonstrate the unique knowledge which is stock-in-trade for the mining engineer and its usefulness to reveal and either utilize or neutralize factors that affect the design of underground excavations. Foundations, open excavations, and closed excavations are considered.

Structural Elements in Excavations

The most obvious structural member in an excavation is the beam or arch overhead. The next feature observed would be the side walls, which may be considered as analogous to either pillars or abutments. The design problem at once apparent is that there is only one free face to the arch or to the abutment. The thickness is not revealed by observation. The other elements entering into underground structures are struts, or an assembly of contiguous struts that may be considered to form plates or slabs. These are usually measurable in dimensions because usually they are of different material from the primary material in which the excavation is being made. A dyke is an example of this structural element.

Physical Characteristics of Rock

There can be no intelligent design unless the physical characteristics of the materials entering the design are known. Rock is made up of mineral crystals or amorphous material, which may be crypto-crystalline. It is a material similar to concrete in that there are particles having varied physical constants in a matrix of other materials also having varied physical constants. The standard tests that have been devised for other construction materials are parelleled for the testing of rock specimens. The U.S.B.M. (United States Bureau of Mines) has designed and published a series of standard tests for rock specimens.[1] These are bulk tests. The data obtained refer to the average behaviour of the assemblage of minerals in the test piece which represents the rock under test. The tests are designed to be made on drill core which is the easiest and the most common way to get samples of the rock which will be involved in the construction. The orientation which the drill core had in the parent rock is important, though not included in the above reference.

Standard Tests. A length of drill core showing no visible defects is examined sonically to determine the velocity of sound, longitudinally and transversely, in the diamond drill core. The sonic measurements, and the density of the rock give a value for Young's modulus, shear modulus or modulus of rigidity, the damping capacity, and the derived function, Poisson's ratio. These characteristics are determined under conditions of no applied stress. Density is an important factor in these determinations and it will change with changes in the bulk modulus. The values obtained by sonic tests, apply only to the conditions of no stress and will be different for different degrees of stressing. They only serve to compare the characteristics in the unstressed state.

The strength in compression is measured by preparing a suitable cylinder of rock from a piece of diamond drill core and compressing it to failure. Auxiliary measurements at this time may include the use of strain gauges to find the axial and the lateral strains to give new measurements for the moduli and Poisson's ratio. The strength in tension is difficult to learn because apparatus to test the strength in tension is difficult to devise. A measure of the strength in shear is made by a transverse fracture test which determines the modulus of rupture, a characteristic having a value somewhere between the strength in shear and the strength in tension. The U.S.B.M.[1] specifies other tests having to do with hardness and abrasion resistance, but these do not appear to have any connection with support of underground excavations.

Time Effect. Laboratory studies not prescribed by the U.S.B.M.[1] have been made of stress-strain-time relationships. This introduces the phenomenon of creep and plastic deformation. Most rocks when compressed rapidly and released from pressure

Fig. 1. Photoelastic studies showing the stress fields around openings.

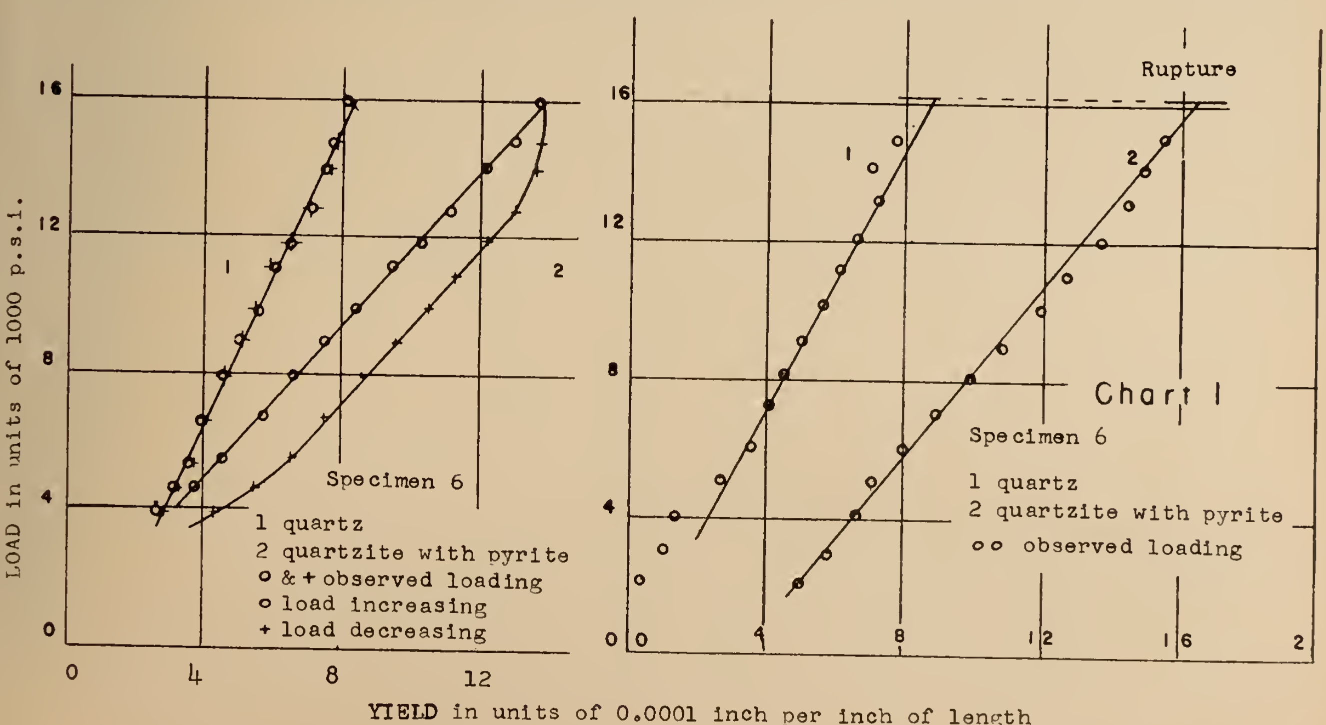
rapidly show a straight line stress-strain relationship and the strain is recovered. If the stress is applied slowly or is maintained at any level on most rocks there will be increased strain. If the stress is released quickly at the end of an elapsed time the stress-strain relationship will be nearly linear and nearly parallel to the line showing the rapid application of stress. Much of the residual strain remaining at the conclusion of the unloading cycle will be recovered at a rate decreasing with time. Whether all strain will be recovered with sufficient time or not depends on the behaviour of the rock minerals when stressed.

Behaviour When Stressed. It has already been stated that rocks are made up of an assemblage of minerals with varying physical characteristics. When the rock is stressed some minerals behave as elastic (Hooke solid) bodies, and others as plastic bodies (St. Venant solid), and others as viscous (Newtonian liquid) bodies. When the stress is first applied the elastic bodies behave elastically, and plastic bodies behave elastically up to the point where they, the plastic bodies, yield plastically, and the viscous portions behave elastically for a small amount of strain then proceed to flow to accommodate the pressure.

When the specimen is destressed the elastic particles are restrained from immediate recovery of strain by the surrounding viscous matrix and the plastically deformed particles remain plastically deformed. Stress bringing about a reversal of the viscous flow and arising from the elastic qualities of the Hooke's bodies is resisted by the viscous matrix but it yields and there is a slow recovery of the strain in the elastic bodies with the consequent readjustment of the viscous matrix. Eventually all the elastic strain will be recovered but the plastic deformation will not be recovered. These phenomena are shown in Charts 1 and 2.

Stresses Around Openings

The distribution of stresses around openings must be known to permit proper design to accommodate them.



These stresses around several standard shaped openings have been studied by many mathematicians and physicists in a manner referred to here as the classical treatment.

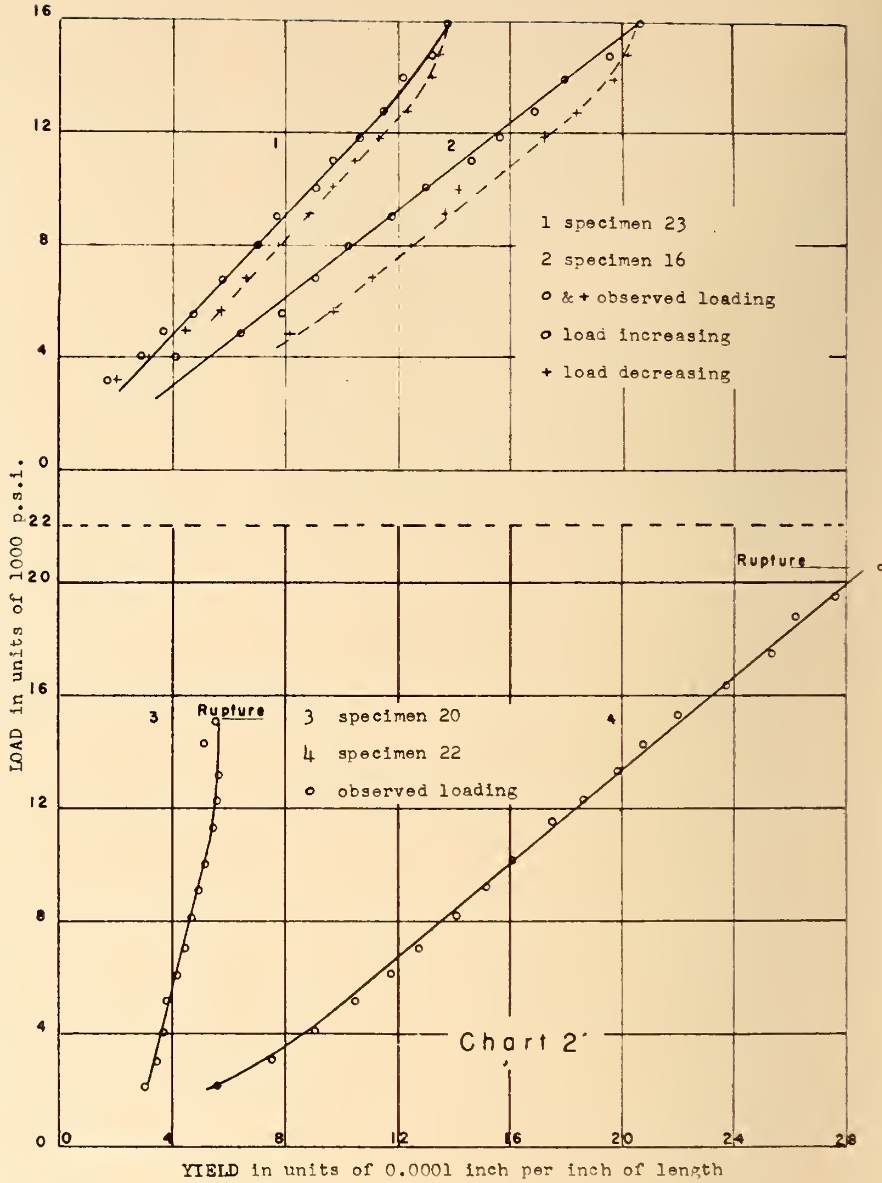
Classical Treatment. The first shape examined is the circle. Most books on mechanics of materials or behaviour of materials under stress, or theory of elasticity derive formulae to show the stress condition around openings of various shapes. Under conditions of unilateral compression the circle will display a tensile, tangential stress equal to the applied field at the diameter marked in the direction of the field of stress and at the diameter normal to the field of stress there will be a compressive, tangential stress of three times the applied field. The isotropic stresses are calculated by adding the effects of a unilateral field acting at right angles to the first field. The result is a uniform tangential compressive stress around the circumference and equal to twice the applied field.

Similar calculations are made for other shapes and the results of such calculations are shown in Chart 3, which is from R. I. 4192; Duvall.[2]

The mathematical treatment is supplemented by photo-elastic studies to show the stress fields around openings to confirm the mathematical findings and to examine fields about openings too irregular for reasonable mathematical analysis. The photo-elastic findings check the mathematical findings and the stress fields about different openings are shown in Fig. 1.

Pragmatic Treatment. The classical treatment describes the stress distribution around an opening in material that is isotropic. Rocks are aeolotropic, and controlled stress fields are not available. There are two types of stress to be considered in the field of an excavation in rock, and a third type which is a combination of the two. The first is superincumbent weight, and the second is orogenic stress.

Superincumbent Weight. The rock in which an excavation is to be made will be stressed and strained to a degree permitted by the Young's modulus and Poisson's ratio of the rock involved. An element of the rock at depth would be in a condition analogous to an apparatus consisting of a cube having movable diaphragms as boundaries and equipped with tensed springs pressing outward against each of the cube faces (diaphragms). The degree of strain in the springs would be a function of the weight carried above the elemental



cube. Dash pots, to prevent instantaneous release of strain, must be added to the system. When the balance attained by the system in the elemental cube is disturbed by an excavation all the strain due to the superincumbent weight acts as if it were concentrated in the elemental cube, and is a function of that weight. The elastic strain in the springs will be recovered as rapidly as will be permitted by the restraint of the dash pots which serve to simulate the viscous flow action of the matrix of the elastic particles of rock. There will be a release of upward stress and the superincumbent prism of overlying rock would seem to have no support. Support will be provided by contact between the walls of the prism and the surrounding rock in a manner analogous to the behaviour of granular material in a deep bin where the floor of the bin only has to support a small arc of the granular material. The rest of the weight is carried by the wall of the bin as may be seen by Jansen's formula, sometimes called Ketchum's formula.

The vertical pressure V in a deep bin is

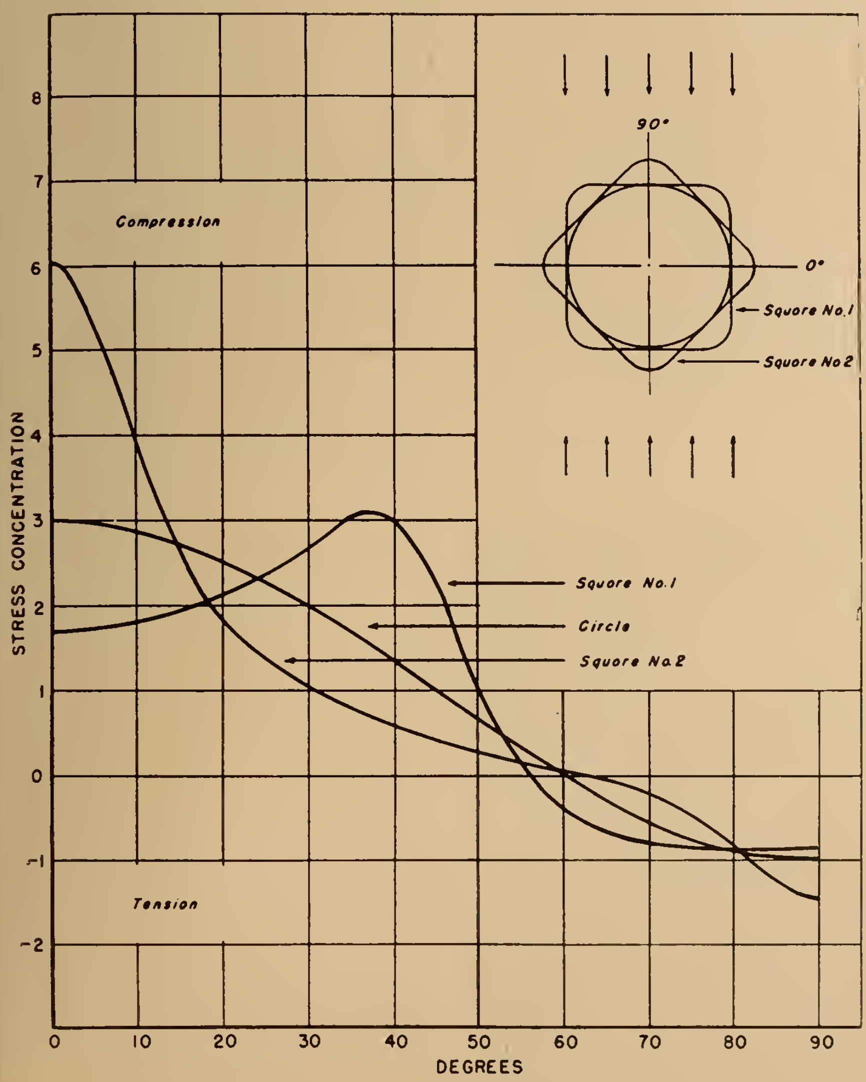
$$V = \frac{WR}{K\mu}\left\{1 - \epsilon^{-K\mu' h/R}\right\}$$

where h represents any height at which V is determined. It is the only variable and $\epsilon^{-K\mu' h/R}$ is a decaying function that rapidly approaches zero with increases in h, and V becomes constant with respect to h.

It is established that the roof (back) of an excavation will only be deformed in good time by the recovery of the elastic strain which was brought about by the superincumbent weight. Once the deformation has accommodated this elasticity the distance to the surface has no effect. The support will be supplied as a beam, but because rock is always weak in tension and usually has actual or potential discontinuities, the support is provided by an arch described by Evans[3], as the voussoir beam. The abutments, at the ends of the beam, will be stressed to accommodate the weight of the intradosal material and the horizontal stress that is already there, from Poisson's ratio for the rock, in the undisturbed ground. This stress will be in a direction controlled by the magnitude of these two components, and applied at the corners of the opening. The walls of the excavation may be considered to extend as the walls of the prism to the surface and, as pointed out above, will carry the superincumbent load. Consequently at the corners of the excavation the ordinary field of stress is increased by having to carry the stress from over the opening and the horizontal stress formerly in the rock. The application of stresses of different magnitudes and directions will either produce a failure in shear at the corners or be accommodated by an adjustment at the corners of the excavation to bring the various stresses in balance. The wall of the excavation will be acting as a plate with a body weight equal to the normal vertical stress field and an imposed load equal to the load over the excavation. These features have been analysed by Emery.[4] A similar reaction will take place in the floor section of the excavation.

Fig. 2. Successful application of rock bolts.

Chart 3



Orogenic Stresses. Probably no rocks with a geological history in the earth's crust have remained undisturbed since they were established. They have been subjected to warping and folding and to carrying great weights of superimposed rock. Some authorities estimate that as much as 24 miles of rock have been worn off parts of the Precambrian Shield in Canada. The phenomenon that gives the best appreciation of the extent of the stresses involved in crustal deformation is probably the reverse fault where the pressure being relieved by lateral thrust has been sufficient to shear the formations and slide one side of the shear over the other with a consequent lifting of all the rock above the member. Prior to the rupture by a thrust fault a horizontal segment of the earth's crust must be considered as a plate in a high state of stress, and an excavation in this plate will permit a rapid release of some of the elastic strain and some with a slower rate that will decrease with time. This stress may often be greater than the stress applied by the superincumbent load above the excavation. The process of accommodating the stress built into the rock will be the same as that of superincumbent stress.

Combined Stresses. A proper combination of superincumbent load stress and orogenic stress can result in a stronger structural member than either one would alone. Furthermore the resultant of the two stresses will always be greater than either principal stress. Morrison and Coates[5] examined the stress conditions in St. Venant solids and demonstrated that shear is resisted by the magnitude of the secondary stress involved in the shear. The beam over an opening may behave as the prestressed concrete beams used in construction do. The result would be firmer, stronger, wall boundaries for an excavation than if either one of the stress sources operated alone.

The physical characteristics that resist failure range from compression, the strongest, through shear which is intermediate, to tension which is the weakest. Rock is aeolotropic in its structure but in addition it is seldom continuous. It may be interrupted by bedding planes or by faults, which are obvious, or slips which are discontinuities in the rock. They may be microscopic in size or may not be developed, and the weakness would only be a place where a slip could occur under stress. These weaknesses may have any orientation, and intersecting planes. The result is that no rock design should assign any resistance in tension to a rock. It is usually safe to assign compressive strength and the most likely type of failure is in shear. Three types of failure may be recognized—fracture failure, plastic failure, and explosive failure.

Fracture Failure. This type of failure is most apt to be seen in rocks having high elastic moduli when they are compared to the compressive strength. It is not confined to the elastic bodies in the rock assembly. The viscous matrix components will fail in brittle fracture if the stress-strain rate is faster than can be accommodated by the rheology of the rock. The plastic failure is a failure in shear between small sub-divisions of the failing body. The result is a permanent set that is not recovered when the rock is destressed. The explosive failure is the release of stored up strain energy that occurs when stresses are concentrated in a part of the rock mass that is unable to accommodate them. The failure may be on a small scale, where brittle components of the rock fracture explosively to yield microseisims, or where the whole rock fails at once and produces rock bursts. There are several ways in which this energy may be concentrated in one portion of the rock mass. One manner that is easy to visualize is where a rock member with high moduli characteristics is under stress when surrounded by rocks with much lower moduli. The stress will be concentrated in the strong member which will carry it as a strut up to the point where violent failure takes place. This can work as well during destressing periods as during stressing periods. There will be a similar differential stress set up when the rock is being destressed and a crack may start. Recognition of the phenomenon of a crack tip being propagated through different types of rocks, fed by the strain energy of the rock so relieved, is recognized in the Third Theory of Comminution by Bond.[6] If the crack reaches the surface before it fades, spalling takes place.

One or all of these types of failure may be found in any type of working here considered, foundations, open excavations, and closed excavations.

Open Excavations. This term refers to openings in the surface which may be formed by stripping or digging.

Foundations. The most obvious cause of rock failure under foundations is the existence of either a weak clay, or shale, bed concealed below an apparently strong bed at surface. Under the weight of the foundation or under the different hydrodynamics induced by the existence of the structure the clay or shale or other weak bed will shrink or heave according to the controls available. This will result in an adjustment in the foundation and damage either by cracking or shifting in the structure. A second form of failure that may occur is due to warping of the bedded foundation rocks, or the presence of two types of rock formation with boundaries that are not parallel to the foundation plane. The two rocks will not have identical physical characteristics, and because of the varying thickness of one over the other there will be differential strains under identical pressures. These may be sufficient to cause cracks in the building. The stresses resulting from the application of a wall on a plane, in this case the surface of the rock, are examined in the Theory of Elasticity[7] and in other books on elasticity. A third, less obvious, source of failure is one that would result from the disturbance of the equilibrium existing on the upper side of a formation acting as a strut or plate in stress. The forces available in such a formation were exhibited in a marked way at the Marmoraton Mine, Marmora, Ontario, while the limestone was being stripped from over the orebody. At a depth well within the range of the height of many structures the differential pressure between the wall rocks and the pit bottom, where the superincumbent weight had been removed, permitted a condition of differential stress so that there were great upheavals in the floor of the pit. The pit was approximately 2400 feet by 1800 feet in area. "The area which was affected was a parabolic-like section at the north end of the pit having its focus on the centre line of the pit with the distance from the focus to the vertex being approximately 300 feet. There were two distinct upheavals which occurred approximately 300 feet apart. The apex of the upheaval reached an elevation of approximately 15 feet above the elevation of the pit floor."[8]

The conditions may have been aggravated by differential stresses set up as described above, when the elevation of the pit-bottom was approaching that of the underlying ore.

Fig. 3. An example of effective guniting at the McIntyre mine.

Failure in Open Excavations

The Marmoraton pit-floor failure is one type of failure. The most likely source of failure is in the walls of the excavation. Bedding planes, faults, and slips may have such an attitude that the walls will slide into the excavation. The other forces at work to bring about wall failure are those that every engineer has observed around an earth excavation. The phenomenon is extensively observed in soil mechanics. The difference between the behaviour of rock and soil is a function of the internal friction. If the rock, as a result of occurrences in its geological history, is minutely fractured or has incipient minute fractures it will behave as a soil. These fractures may result from man-made weakness. An example is the rock slide at Turtle Mountain, B.C.

Failure in Closed Excavations. The behaviour of rock in closed excavations is the usual field of investigation and control for the mining engineer. Rock is not an isotropic body and it is not subjected to isotropic stresses. If rock was isotropic, continuous, and subjected to isotropic stresses, no excavation would fail if the cover was thicker than the span of the opening. It has been pointed out previously that rock is aeolotropic and subjected to differential stresses. The elastic behaviour of rock makes it subject to failure in shear, and the shear planes will approximate 45° in direction to the applied force. The aeolotropic nature of the rock makes it improbable that this will be the only control. To a degree the failure, bit by bit, of the rock will result in a granular mass which is best analysed for failure in a manner analogous to the analysis used by engineers in soil mechanics. The rock is considered as fragments of elastic bodies subject to interface movement, which is restricted by the magnitude of the stress normal to the plane of incipient movement, and by the cohesion between the particles. This phase of rock mechanics is the subject of the paper by Morrison and Coates.[5] The evidences of failure by this agency are spalling, slabbing, and crushing.

Some rocks are sufficiently weak in shear to fail as plastic bodies and their failure is evidenced by a squeezing in of the walls surrounding an excavation. When this happens to an advanced degree the walls of the excavation will close the opening.

Support in Rock Structures

Rock may be supported in several ways. The first is to erect a framework against the walls and roof of the excavation to keep loosened rock from falling into the opening. The loosened rock takes up more space than rock in place so, at a reasonable height above the framework, support will be maintained against the unbroken back and an effective supporting arch maintained. Fracturing from elastic failure will be limited to a small amount of broken rock lying above the frame support.

Mining engineers have long recognized that the only satisfactory support for rock is rock, and the objective of another method of support is to make the rock self-sustaining by preventing the initial movement between rock components. The most recent practice in rock support involves the use of rock bolts which are anchored well behind the surface of the excavation and maintained in high tension. It is pointed out above that when a rock yields elastically the components are restrained from relative motion by the normal component of the pressure at the face of the potential slip. This is reinforced by the cohesion of the rock particles. The purpose of rock bolting is to increase this pressure normal to the slip planes that, if allowed to develop, would reach the surface of the excavation and result in a loosened rock. One phase of this manner of correction is analysed by Corlett.[9]

Fig. 4. Result of side pressure against a concrete lining in a small opening.

Another manner in which effective rock bolting improves the structural qualities of the walls in a rock excavation is by increasing the magnitude of the secondary stress which may prevent failure in the manner established by Morrison and Coates.[5] The failure between the adjacent rock particles is brought about by the ratio between the two principal stresses acting on the rock. If one of these, the stress in the direction of the rock bolt, is the lesser stress and it is increased by the bolt tension the ratio will be small enough to prevent failure. A third effect of the rock bolts is when the wall boundary of the excavation is in a condition of stability brought about by the proper balance of two directional stresses and it is behaving as a prestressed beam. The rock bolts will resist the tendency to destress by expansion into the opening and the prestressed condition will be maintained. It is clear that the maintenance of a high stress in rock bolts is needed to make them effective in any other manner than as a substitute for posts. Figure 2 shows a successful application of rock bolts. The structure in the foreground shows support by a framework.

The application of concrete as gunite is a third method used by mining engineers to preserve the walls of excavations. It is not widely used but has been used successfully under conditions that would make its successful application seem improbable. The gunite must be applied carefully on a thoroughly cleaned and scaled surface so it can form a bond with undisturbed rock. The result is that fractures are prevented from starting at the surface of the rock. An early description of extensive guniting was from the McIntyre Mine by Keeley[10] and that gunite is still operating effectively twenty-five years later (Fig. 3).

Plastic Failure. Plastic failure resulting in a rock that continues to yield permanently under pressure can, as pointed out above, completely fill an opening. When the plasticity is sufficiently developed it would seem that the only way the opening could be kept open would be to design a lining to resist isotropic pressures equal to the weight of the superincumbent rocks as one would design a pressure vessel to be submerged. Figure 4 shows the result of side pressure against a concrete lining in a small opening. The design of the lining resisted the vertical pressure more effectively than it did the side pressure. The method of placing the concrete made this probable.

Rocks that have plastic tendencies and fail plastically have been successfully held with gunite. Figure 5 is the picture of an excavation maintained in a yielding rock. The twisted columns have not moved relative to the gunited surface, which is undisturbed. The deformation of the columns was caused by the upheaval of the floor, which was not protected by gunite. A similar excavation in similar rock, made as a hoist room, held in an equally satisfactory fashion in the back, but the hoist was continually getting out of line because of the heaving in the floor. There may be, in addition to preventing initial movement in the rock, an added protection against the hydrodynamic action of water getting into the rock, or air getting into the rock, and causing the formation of new minerals requiring greater volume.

Policy or experience may dictate the use of massive concrete linings to maintain underground openings. Such linings must always be placed tightly against fresh undisturbed rock to be most effective. They have the disadvantage of requiring a larger excavation than would be needed for thin linings such as gunite, and the stress in the wall and roof members behaves as stress in such members behaves anywhere. It increases with the square of the span and in many underground designs one finds the span greatly increased, with the accompanying increase of stresses to be accommodated, and the strong rock which was taken out is replaced by concrete which is a much lesser structural material.

Explosive Failure. Explosive failure, referred to usually as rock bursts in metal mines or bumps in coal mines, often produces an amount of energy that cannot be resisted by artificial supports or by rock weakened by excavations. The only remedy available is to locate the excavation so it will not induce dangerous accumulations of strain energy in small bodies of rock. Great depth or wide openings are not needed to permit rock bursts. They have been known at shallow depths as a result of the inherent stresses built into the rocks during their geological history.

Fig. 5. Excavation maintained in a yielding rock.

CONCLUSIONS

Any excavation should be sited and designed only after a thorough examination of the proposed location by engineers and geologists. The field of the geologist would be a study of the lithology and geological history of the location area to determine the rock types and the extent of the tectonic forces involved. The geological study would involve surface examination and diamond drilling.

Diamond drill cores from the vicinity of a proposed excavation must be available to the designing engineer and proper teamwork between him and the geologist should provide some cores useful to both. Drill cores for the engineer must have definable orientations. He should determine the physical characteristics of the rocks, using the drill core as samples. He, if he has a proper background in rheology and structural engineering, can determine how the rocks will behave under the stresses imposed by the excavation. These factors will control the proper orientation, the permissable size, and the ground support needed, that will enter into the design.

ABSTRACTS

OF 1959 ANNUAL GENERAL MEETING PAPERS

Precast Concrete as an Aid to Winter Construction
A. W. Smith and C. R. Crocker
Placing concrete in winter is difficult, may be extra costly and be delayed. Studies, since 1954, by N.R.C. Division of Building Research include feasibility of using precast concrete to meet Canadian conditions. Results are reported in the paper. Precast concrete is widely used in Europe, almost exclusively in Russia, for commercial, industrial, and residential building. Northern countries are of special interest, with climates similar to many parts of Canada. Technical literature search was supplemented by visits to precast concrete manufacturers, consulting engineers, architects, builders, laboratories, in U.K., U.S.A., and Canada. Future for precast concrete appears to be good, once accepted. One problem: difficulty of joining structural precast members at low temperatures.

Littoral Drift in Lake Ontario Harbours
R. J. Kennedy and A. Brebner
Depth in many Lake Ontario harbours is maintained by annual dredging. At Cobourg, Ont., annual cost is over $50,000. Problem may increase greatly with larger seaway traffic. Movement of material by wave action along the shore (littoral drift) is a world-wide problem, but fundamental knowledge is lacking and particular solutions may not apply elsewhere. Since early 1958 a N.R.C. Associate Committee, with members from Dept. of Public Works, N.R.C., and Queen's University, have studied the problem. The paper deals with the continuing collection of field data: wind and wave records, rate of change of underwater contours, characteristics of beach material and its point of origin. A parallel fundamental laboratory study is intended to relate wave characteristics to the transport capacity for any given material.

The Humber Sewage Treatment Plant
R. L. Clark
The Municipality of Metropolitan Toronto is carrying out the first complete pollutional control program of its kind in Canada. The Humber Sewage Treatment Plant, one of three major plants in the scheme, will provide complete activated-sludge treatment to all sewage flows from the Humber River watershed, ultimately serving 800,000 persons or one-third of the Metropolitan area. Initial capacity will be 50-million gal./day, from 475,000 population. Paper describes planning for flow, treatment, and plant site. Details include main plant design, components, facilities, power supply, structure, architecture, hydraulic design, staff facilities. Construction methods and progress are reviewed, and plant costs presented.

The Use of Fly Ash in Concrete by Ontario Hydro
I. Mustard and C. MacInnis
A resumé of Commission experience with the use of fly ash as partial cement replacement. Particular properties of fly ash, its effect on properties of concrete, and a summary of Commission applications (Niagara, St. Lawrence, Whitedog and Caribou power projects). Purchase specifications, method of handling the ash, effectiveness in producing desired results, and how fly ash concrete compares with regular concrete for job control, handling properties, etc.

Experimental Studies of the Effects of Blasting on Structures
A. T. Edwards and T. D. Northwood
Controlled blasting was done near six buildings to determine ability to withstand ground-vibration damage. Three buildings in wet silty clay soil; others in well-consolidated glacial till. Blasts increased until damage occurred, in attempt to correlate damage with size of blast and distance from structure. Measurements of displacements and accelerations of the ground, and at points in the structure, were also correlated with size of charge, distance, and soil type. In silty clay, difficult to produce horizontal vibration, but large vertical motion occurred; damage always associated with large settlement. In till, both horizontal and vertical components were produced; damage associated with ground wave rather than effects such as settlement. Results compared with damage criteria now in use. Suggest peak acceleration gives best correlation with damage.

Hydraulic Problems in Connection with the Development of the St. Lawrence River
H. W. Lea
Maximum St. Lawrence River flow is only double the minimum, due to Great Lakes storage. Any regime changes must avoid up- and down-stream damage. On approval of the navigation-power development in the International Rapids section, in 1952, the International Joint Commission established three boards; to report on regulation of Lake Ontario within 4-ft. level range; to approve plans and construction by Power Entities; to ensure, after completion of work, that Commission Orders about levels and flows are complied with. Detailed criteria are in the paper. Operations are covered from Montreal to Lake Erie, with information about the work and financing of the various Canadian and U.S. authorities concerned.

Backwater Computations for the St. Lawrence Power Project
H. M. McFarlane and C. C. Gotlieb
First part outlines the need for backwater computations between the power dam and Lake Ontario as basis of hydraulic design for the power project; describes available data and selection of parameters to cover all expected flow conditions. High-speed electronic computer used to investigate large number of cases. Preparation of computer data, interpolation of computations, and final arrangement of interpolated backwater slopes are explained. Second part sets up basic iteration for computing water-level difference between two ends of river channel; presents new method of using iteration to calculate water levels in a net of islands. Main features of computer program, method of computer runs, examples of input data, and computer results are described.

River Control in the International Rapids Section
K. A. Henry
Unusual circumstances arose in the International Rapids

Section during St. Lawrence Power Project construction, where many agencies and their contractors were engaged in works affecting river conditions. Paper outlines need for overall control of operations affecting river conditions, and administrative arrangements made to achieve this. Actual field control system, and need for continued use of models as construction and design tool, demonstrated by description of handling some of problems involved.

Design and Erection Features of the Vertical Lift Bridges for the St. Lawrence Seaway
W. G. H. Holt

Detailed record of design and erection features of vertical lift bridges for the Seaway. Canal, railway, and design engineers collaborated for best design after study of existing bridges in Canada and U.S.A., and of proposed sites. Complete description of superstructure, in three sections. Structural: arrangement of tracks and roads, design, characteristics of towers and spans, counterweight construction, means of access. Mechanical: design; counterweight ropes, sheaves, balance chains; machinery and operating ropes; operating torques and speeds; houses; auxiliary engines; accessories. Electrical: design; motors and control equipment; wiring; lighting; bridge operation. Other data: erection procedures; material quantities; canal, rail, road traffic.

St. Lawrence Power Project — Rehabilitation
J. H. Jackson

Problem: extent of headpond flooding from construction of Barnhart powerhouse and Long Sault Dam; human factors; communities established over 100 years. Analysis: studies for new locations of communities, roads, railways, etc.; professional assistance retained by Ontario Hydro; part of Town Councils and Planning Boards. Solution: actual construction program—field organization, roads and services, house moving, other buildings, shopping facilities, rental housing, shoreline improvements, railway and highway relocation. General review of program and its impact on area and communities involved.

Roughness Coefficients for Water Supply Tunnels
J. B. Bryce

Two concrete-lined tunnels (5½ miles long, 45 ft. finished dia.) convey water for Sir Adam Beck Niagara Generating Station No. 2 from intakes on Niagara River to canal leading to powerhouse forebay. Twelve piezometer openings in each tunnel to determine tunnel performance, roughness coefficients, head losses. Paper describes tunnels, provisions for field testing, test procedures, and results. Also comparison with design values.

A Method of Determining the Power Potential of Rivers with Many Reservoirs and Power Plants
G. S. Cavadias

Determination of the power potential of modern hydro-systems is a complex problem, and methods available for its solution are not entirely satisfactory. Paper presents method based on earlier work. (D. Johnstone, J. W. Hackney) and considers total power production of the system as basis for computations. Productions and installations of individual plants are considered as well as total system power potential. Paper gives theoretical basis for computations, and an example of the method applied to typical hydro-system.

Tests of Hydraulic Turbines – An Appraisal
J. J. Traill

Describes 100-year improvement in turbine efficiencies and part played by systematic testing. Value of tests to purchaser and in subsequent operation of power project. Describes and compares four methods of measuring flow of water through turbine, including thermodynamic method, now used in improved form in parts of Europe. Discussion of tests of turbine models and relation of test results to results expected in the prototype.

Photography and Electronics as Tools in Hydraulic Work
I. W. McCaig

General: lag in application to hydraulic measurements of recent developments in photographic and electronic techniques. Examples: photographic techniques—electronic flash. Bersimis-Lac Casse intake; photographic recording—shape of Lake Ste Anne transition; high speed cinephotography—Warsak cofferdam. Electronic techniques: stress in pressure measurements—Upper Campbell Lake development, Bersimis-Lac Casse turbines; stability measurement—Bersimis No. 2 surge tank.

Electrohydraulic Governors at Beechwood Generating Station
P. G. Fazzari and G. H. D. Ganong

Development of large power networks puts severe requirements on regulating equipment. New Brunswick Electric Power Commission chose new ASEA electrohydraulic type governor for Beechwood station. Conditions will vary with wide seasonal river-flow range. Station would carry base load in spring and fall; act as regulating plant in summer and winter. Governor should meet present requirements and future centralized load-frequency control. Paper describes Beechwood governors: operation, electrical and mechanical construction, operating and protective features; reports tests to determine best fixed characteristics for regulation and overspeed control. Frequency charts show possibilities of equipment under various operating conditions.

Design and Construction of Whitedog Falls and Caribou Falls
N. St. C. Haines

Hydro-electric generating stations at Whitedog Falls (Winnipeg R.) and Caribou Falls (English R.) were designed and built by Ontario Hydro staff, are remote-controlled. Described: site selection, turbine capacity, electrical equipment, auxiliary equipment, unwatering procedure; also construction of two powerhouses, two concrete dams, eight small earth structures, 34 miles of main supply road; clearing some 20,000 acres of land.

The First Cyclone Fired Boilers in Canada and Some Aspects of their Early Operation
E. K. Akin

Cyclone fired boilers installed at Water Street plant of Nova Scotia Light and Power Co. Limited. Planning, selection, installation of units. Reference to other services and equipment (fuel handling, ash removal); special high level oil burners to boost steam temperature for hot starting. Boilers can burn bunker C oil as well as coal; quick change-over. Early problems and their solution. Performance tests to be made after mid-1959.

Some Considerations in Steam Power Plant Design
A. G. Christie

Growth of integrated electrical systems requires new look at design of steam power plants. Rising fuel costs and load justify large steam units with highest possible steam temperature and pressure. Re-study needed of hydro sites with water storage to determine availability for peak load service with greater capability than for base load. High efficiency of steam plants to offset obsolescence and fuel costs may lead to such combinations as gas-turbine/steam-turbine joint operation at supercritical pressures. Pumped storage has limited future. Use of low grade fuels must be encouraged. Problem of sulphur and ash in fuels; economic uses being developed for powdered coal ash. Fully automatic plants reduce labour but need competent operators. Design of new plants must consider changing practice in plant details: steam generator construction, water treatment, superheat control, air heater operation, vacuum pumps, cooling towers, etc.

Special Features of the Brandon Generating Station
A. C. Blue, E. M. Scott, W. P. London, P. A. Pasquet

The Manitoba Hydro-Electric Board thermal generating station located at Brandon on economic considerations, notably cost of lignite fuel from southern Saskatchewan mines. Four units total 132,000 kw.; simpler feedwater heating cycle than usual as low load factor expected. All plant water softened before use. Circulating water system unusual for Canada; includes large cooling tower operating in adverse weather. Experience in burning lignite in tangentially-fired furnace. Panel arrangement in central control room as used in U.S.A.; not previously in Canada. Both hot water and steam used for plant heating and pre-heating combustion air. Electrical systems are described.

Economics of By-Product Power Generation
W. P. London and W. M. Newby
Steam turbines of back-pressure or extraction type are among methods of recovering heat remaining after primary conversion of heat into electrical energy. This heat may be used to obtain 'by-product' power, and so improve overall economy of power production. Equipment is considered in detail; factors affecting economy; conditions favouring such installations. Application of back-pressure and extraction turbines to different industries; effects of the differences in processes. Contrast: in pulp and paper industry, power demand exceeds amount available as by-product of steam demand; in petrochemical industry, reverse is often true. Cycles involving gas turbines; when these may be economically feasible; examples of application.

Graphite in the World Nuclear Power Program
late Sir Claude D. Gibb, K.B.E., F.R.S. Presented by H. B. Topham.
Reasons for use in Britain of graphite-moderated reactors for Calder Hall, current and proposed nuclear generating stations. Details of new reactor-quality graphite factory at Newburn Haugh, Northumberland; plant installed; construction problems. Raw materials, their control, processes to make the special form of synthetic graphite required. Plant can produce 10,000 tons/yr. nuclear graphite, 5,000 tons/yr. commercial material, e.g., steel-furnace electrodes. Total capacity can be expanded to 40,000 tons/yr. First load of reactor graphite accepted 16 months after start of plant construction. Capital cost some $16,000,000.

H.Q. Computation Centre for the H.E.P.C. of Ontario
(A series of four papers on various aspects of Ontario Hydro's program to centralize and integrate its data processing by a large scale digital computer and a teletype communication network. Data to be captured on punched paper tape, transmitted by teletype to data processing centre, where output reports printed on high-speed equipment and mailed to various offices.)
(1) *The design of the data communication system* (W. H. Sanders). Equipment provided by several firms. Only numeric input was bought; rest is leased. Operating and control procedures; correction of errors.
(2) *The network between regional offices and head office, and the tape sorting operation.* (S. J. Crossman). Outline of the system from regional offices to head office, and automatic message sorting at the latter. Details of network and equipment; procedure followed.
(3) *The circuit logic of the tape message sorter* (J. Rywak). Electronic circuitry used to achieve desired operation of tape message sorter, of which functions described in paper (2). Circuitry is assemblage of basic logic elements including shift register composed of bistable transistor switching circuits, diode gate circuits, and binary to decimal conversion matrices. Detailed design of basic elements not discussed.
(4) *Communications between area offices and regional offices* (H. R. Davis). Communications between 99 area offices and 9 regional offices of Ontario Hydro provided by Canadian National Telegraphs. Each regional office has C.N.T. Autoscan unit which automatically sequentially selects associated area offices; can be operated manually. Regional offices have modified page printers, with tape reperforators and transmitters. Area offices have transmitter distributor and transmitter control unit. Methods of interconnection of offices, including telegraph signals.

Edmonton Installs Canada's First Oil-Filled Pipe Cable System
C. Z. Monaghan and W. J. Pardy
Plans to increase Edmonton power system capacity to meet load growth. New underground 72-kv. distribution system, radiating from new city power plant. Two circuits now in use. Described: requirements; oil-filled pipe cable transmission system; service conditions; design of components; cathodic protection. Installation: material handling; training personnel; excavation, laying, welding; testing; cable pulling, splicing, terminating, vacuum treatment, oil filling. Special problems. Operating experience.

138-kv. Undersea Cable Across Georgia Strait
T. Ingledow
Power link between lower B.C. mainland and Vancouver Island includes five 138-kv. submarine power cables laid in 1956 between mainland and Galiano Island, another underwater crossing to Saltspring Islands, an aerial link to Vancouver Island. Submarine cable, largest yet laid, is gas-filled galvanized wire armoured type, made in continuous lengths, longest 14.7 miles. Selection of routes; difficult crossing conditions; method of loading and operation of laying ship. Practical results.

Magnetic Amplifier Control for Reversing Hot Mill Auxiliaries
R. L. Duke and L. R. Hulls
Electrical machinery and controls can now reverse hot rolling mills in less than two seconds. Time taken by auxiliary equipment to return metal to the mill after a pass is nonproductive; selection of equipment important to reduction of time lag. Drive motors and control selected after analysis of mechanical requirements and limitations of auxiliary equipment, which generally involves control of large number of d.c. machines. Drive must be easy to maintain, reliable, and simple. Magnetic amplifier used to excite generator of Ward Leonard drive suitable for control of auxiliaries: mill tables, side guides, screws. Response of these closed-loop systems must be adequate for purpose. Current limit protection required; detailed analysis required for proper design.

The Interconnected Power Systems of Nova Scotia and New Brunswick
G. D. Mader, T. F. Clahane
Major power utilities of Nova Scotia and New Brunswick will be interconnected in March 1960. Project discussed from inception to completion, and beyond. Individual utilities were limited to 50 Mw. generating units; 100 Mw. units can be accommodated on collective system; increased efficiency, lower unit capital costs. Individual utilities: service areas, rates of load growth, thermal/hydro ratio in service. Single sideband power line carrier system used for communications, telemetering, and relaying; operation of interconnection, how charges are applied, various types of interchange energy. Future developments.

Industrial Uses for an Auxiliary Low Frequency Supply
G. L. Tiley and E. Oldfield
Problems associated with control of a.c. motors, particularly variable-speed variable-load reversing drives. How a low frequency supply can solve some of these problems. Speed control: two types of mine hoist drives incorporating low frequency features. Other applications of low frequency: inching of large motors driving ball mills; similar machinery periodically operated at slow speeds; unusual application for hard anodizing requires single-phase low frequency supply. Common methods of producing low frequency supply; limitations.

The Development of an Electronic Detector of Flaws in Paper
M. P. MacMartin and N. L. Kusters
High quality paper must be flawless, dirt-free. Checked by visual inspection of single sheets. After investigation of characteristics, electronic flaw detector built; should be able to check paper at several hundred ft./min. without damage. Description of detector. Reflected light variations measured

by photomultipliers; optical scanning system; variations operate sorting mechanism. Present model checks paper up to 300 ft./min.; speed could be raised.

Shock Hazards of 60-Cycle Electric Currents
A. R. Morse
Review of experimental work on shock hazard of electrical currents and their physiological effects on heart, muscles, lungs, brain. Dependence of effects on intensity, duration, wave shape, frequency of current. Particular emphasis on 60-cycle frequency. Significance of electrical resistance of human body in conjunction with direct and indirect effects of applied voltage.

Processing of Low-Grade Iron Ore Using Petroleum and Natural Gas
P. E. Cavanagh
Iron ore processing, iron and steel production, historically based on coal fuel. New techniques allow use of oil or gas as heat source and reducing agent to convert oxides into metallic iron. Use of oil and natural gas in concentration of low-grade non-magnetic ores; also for production of metallic iron at mine site. Advantages of using techniques in Canada, particularly in West and at Lakehead.

Voluntary Standards — Vital to Progress
J. A. Reid
Economic progress of Canada largely dependent on use of voluntary standards; examples. Many standards evolved, only recently have organizations guided formation of standards. Several such organizations in Canada; industry and government; Canadian Electrical Manufacturers' Association. Future progress depends on ability of industry voluntarily to modify existing standards to take advantage of new products and processes; to create standards for existing and new products. Responsibility of producer and user industry management.

Engineering for Export
R. A. Frigon
Engineering exports in form of consulting engineering services, equipment, and construction contrasting play increased role in Canada's foreign trade. Engineering opportunities abroad, and benefits to Canadian firms; challenging problems; prospects under programs of international organizations and foreign governments for accelerated development; opportunities abroad for design studies, resources surveying, construction, equipment supply, management services; solutions to export problems; assistance available from Department of Trade and Commerce and Trade Commissioner Service abroad; financing; dealing with large scale projects, joint ventures. Approaches taken by competing countries. Actual cases of recent engineering exports from Canada show what can be done.

Geological Features and Foundation Treatment at the Beechwood Development
In the introduction, a brief outline of the general geology of New Brunswick and Maine with particular reference to the St. John River water shed is given. The surface geology including the effect of the last period of glaciation at the Beechwood site is developed. The investigational drilling and testing program, the reason for choosing the actual site and assessment of rock conditions based on this work is considered in some detail.
During the construction period the geological problems encountered are explained and the methods of overcoming these problems are given. Detailed data on the drilling and grouting program carried out in each section of the development is presented. This includes available information on the effectiveness of this program. Cost data for construction period, drilling, testing and grouting, etc. is stated.

A Gas Turbine Power Plant for Locomotives
Some of the gas turbine locomotive developments are reviewed in relation to operating experiences in various parts of the world.
In the light of this experience and of some of the characteristics of operation in Canada, certain lines of development seem in one or more respects to be attractive. In particular, it appears to be important to determine the practicability of relatively high power mechanical transmission and it is essential for most purposes to evolve a prime mover with better part-load economy than is normally attained by the simple low pressure gas turbine.
Both of these questions are examined and some experimental data are presented for comparison with design assumptions, and proposals are then made.

INSTRUMENTATION IN INDUSTRY

METAL FABRICATING

METAL FABRICATING plants in Canada comprise some twenty diversified industries manufacturing products from iron and steel, and non-ferrous metals. End products include transportation equipment such as motor vehicles, railway rolling stock, ships and bicycles. They also include structural steel, sheet metal products, wire goods, boilers and plate, castings pipe, hardware and tools, machinery, heating and cooking apparatus, aluminum, brass and white metal products and electrical equipment.

Together, the 3400 plants operated by these industries employ 360,000 persons, who add a value of $1,530 million annually by manufacture and have a combined output with gross value of over $5 billion. The ten year post-war period from 1946 to 1956 was one of steadily rising production, during which time hourly wages in manufacturing industries almost doubled, as did the prices of most of the materials used in manufacture.

By comparing the values added by manufacture per employee in 1946 for each industry group, with the value added per employee in 1955, and expressing the latter in constant 1946 dollars, it is observed that output per employee sharply increased for some industries during the ten year period while others showed little change and a few industry groups showed modest decreases in output per employee.

Best gains were recorded by motor vehicles, smelting and refining, copper and brass and white metal products, miscellaneous steel industries, sheet metal products and farm implements, in that order. Other industries which showed reduced values of output per employee included non-ferrous metal products, aluminum products, wire goods, shipbuilding, boilers and plate, and machine shops.

This paper appears to reflect improved methods in processing, handling and distribution brought about by mechanization in those industries showing gains in production per employee. But how much of it has been due to automation and instrumentation can only be conjectured.

Automation Survey in United States*

Highlights from a recent survey, and forecast of automation in the United States, published in "Automation", has strong implications for automation and instrumentation in Canadian industries as well. "One of the most compelling forces pushing industry toward increased use of more instrumentation and automation", it points out, "is the life-or-death need for the United States to stay out in front of the international race for scientific supremacy". This applies equally to Canadian industry.

Of 2,300 plants in 20 U.S. industry groups the percentage reporting they now use automation and advanced instrumentation varied from a maximum of 33 per cent in the petroleum industry and 28.4 per cent in electrical machinery, down to minimums of 6 per cent in lumber and wood, textiles and food products. Per cent using automation and instrumentation in metal fabricating was 10.3 per cent.

What they will buy in 1959

Out of 2,700 plants reporting, percentages planning to buy various types of automatic equipment, incorporating advanced instrumentation were as follows: drive and speed regulation, 41 per cent; interlocked control of operations, 33 per cent; automatic measuring and gauging, 25 per cent; automatic weighing; 16 per cent; process sensing and control, 24 per cent; tape and punch card control, 15 per cent; computer control 4.4 per cent; automatic data processing 12.2 per cent; and remote control, 6 per cent.

Other information of interest from the survey: 83 per cent of the development of machine and process control systems is done by the industries themselves with their own engineering staff, 24 per cent use the services of instrument manufacturers and 21 per cent employ engineering consultants.

Replies to Questionnaire

Replies from Canadian metalprocessing firms to a questionnaire recently sent out by the Journal, show that with few exceptions these firms purchase their electric power from utilities. Exceptions are very large producers or those who are also primary producers. In almost all cases consumption of power was reported checked, though in a few isolated cases the checking was done at the suppliers meters.

Half the plants replying had separate steam plants for heating and power. One establishment with several plants developed its own hydraulic power and produced its own steam requirements separately. Another large producer purchasing power had its own steam heating plant in a separate building for convenience. Generally the larger industries using large amounts of energy are those having separate steam plants.

Main Purposes of Instruments

Plants were asked what were the main purposes of their instrument installations. All of those replying answered it was to achieve better quality; almost as many stated it was to provide a continuous record. About half those answering also included as reasons economy in fuel consumption and regulation of pressure or flow. Few replies gave central supervision or reduction of labour forces as purposes.

As to what instruments were used for, replies indicated, in order of frequency, the following main purposes: to count or measure; to control automatic processes; to measure thickness of materials; to inspect material for flaws; to provide supervisory warning; to provide records for analysis; to measure other physical properties; to determine rate of flow; to measure composition of materials. In the larger establishments with diversified products and a high value for fixed assets, all or most of the above purposes were mentioned.

Some of the larger plants used special instruments in their metal-testing and X-ray laboratories. Other plants used them for automatic cycle control of machine tools and for diversified electronic tests of parameters, barometers, etc. or for carrying out altitude tests at hot and cold temperatures. In another plant instrumentation was principally used in connection with steel heat-treating and pump tests.

*Reproduced in part from an article in the Feb. '59 issue of "Automation" by special permission of the Penton Publishing Co.

A large industry with several plants, producing its own primary materials, uses instrumentation for measurement of its own materials; for measurement of large d.c. currents and voltages used in electrolytic production; and in measurement and control of melting and casting temperatures; heat-treating; plant safety and cost-accounting.

Who specifies, recommends and purchases instruments?

All replies to the question "Who determines instrument requirements?" indicated this responsibility rested with the company's own employees.

Several plants indicated suppliers or manufacturers of instruments were also consulted, while independent consultants or staffs of affiliated companies were rarely asked for advice. Where packaged equipment is purchased with its own instrumentation, the company engineers have little choice.

Specifications for instruments where needed are customarily drawn up by the companies' engineering staffs, though occasionally the plant or maintenance department or production department prepare them. The plant electrical engineer is often the one directly concerned. Sometimes the requirements are merely outlined and the instrument manufacturers make the detailed recommendations.

The choice of the supplier is made by the central purchasing department in most instances, though it is occasionally left to the engineering or plant maintenance department. Sometimes the engineering production and maintenance departments make a joint decision.

Servicing and Maintenance

Servicing of instruments is generally done by company staffs, sometimes assisted by suppliers' representatives trained in the instrument suppliers' plants. In smaller plants there are frequently service contracts with independents and occasionally service is purchased as required. One of the largest metal processing concerns with several plants across Canada does its own servicing in its largest plant with some 60 engineers and mechanics, while in its smallest plant servicing is done by one full-time mechanic.

There was no evidence from the replies that preventive maintenance programs are the general practice, and it appeared to be the exception rather than the rule. One of Canada's largest electrical manufacturing concerns with several plants reported such a program in its larger plants but not in the smaller ones. Two of the largest auto and truck manufacturers also reported having a preventive maintenance program.

It appears the general practice to carry a stock of spare parts or repair parts, and for the larger establishments with several plants complete replacement units are kept in stock. Choice of these spares and replacements is sometimes based on the instrument supplier's experience, but more often the stock of repairs is built up through the company's own experience.

Instruments incorporating optional plug-in features do not appear to be particularly suitable for most plants replying. One large manufacturer of electrical appliances with many plants finds them useful but did not indicate whether they were used in smaller plants or in the larger plants where it might be expected they would be most adaptable. One large auto manufacturer finds them suitable.

Instrument requirements generally follow standard commercial lines.

Instruments are purchased outright as a general rule. Only two companies replying to the questionnaire indicated instruments were occasionally rented when required: a large appliance manufacturer reported 95 per cent of his instruments were purchased and the remaining 5 per cent rented. A boiler and turbine manufacturer rents 20 per cent of his instruments.

Investment in Instruments

Plants were asked to state (a) their total investments in instrumentation, (b) their investments in instrumentation over the past five years, (c) their annual maintenance cost for instruments, and the value of their fixed assets. Several branch plants owned by U.S. companies withheld data on fixed assets, and this information could not be readily determined from local records.

Investment in instruments varied from a maximum of $100 500 thousand by a manufacturer of motor vehicles and $350,000 in the case of an electronic device manufacturer, to a minimum of $5,000 for a wire and wire products, perforated metal and screen manufacturer. Apart from new industries established since 1953, other plants reporting had made between a tenth and a half of their investment in instruments within the last five years.

Annual maintenance cost on instruments varied between $20,000 for a smelter and refinery, to $150 for a crane manufacturer with fixed assets of $3 million. One of Canada's largest makers of steel products ranging from structural steel to boilers and plate work spends $400 yearly to maintain instruments used for boilers and heat-control only, valued at some $25,000. Annual maintenance costs vary between one per cent and 10 per cent of the cost of the instruments, with the majority falling between 3 and 6 per cent.

Instrument cost related to fixed assets

Investment in instruments expressed as a per centage of total investment in fixed assets varied widely. For the large structural and plate work manufacturer who only used instruments for boilers and heat treatment; investment in instruments represented one hundredth of one per cent. A plant making construction equipment, with fixed assets of $4 million had spent 6 10 of one per cent of its fixed assets on instruments. An auto and truck manufacturer's investment in instruments was less than a third of one percent of fixed assets. Apart from these plants the investment in instruments appeared to vary between one-fifth and one-half of one per cent of total value of fixed assets.

Recovery time for Instrument Investments

Estimates of time required to recover the original cost of instruments varied widely, from less than one year for a company producing electronic devices to between 6 and 8 years for manufacturers of heavy construction equipment and makers of electrical and mechanical appliances.

The plant for producing electronic devices regulates air and temperature by standard non-centralized electromagnetic devices, and measures product parts with precision instruments. It also carries out diversified and complex electronic tests of instruments without which production would be impossible.

A company with several plants making heavy engineering products such as boilers, plate and tanks, cranes, and doing structural fabrication, estimated a five year write-off. This company, however, only uses instrumentation on boilers and heating equipment.

Plants estimating a write-off period of 3 to 5 years use instruments for controlling automatic processes and for providing supervisory warnings. These are plants producing construction equipment, power-transmission, material handling equipment and bearings, etc. Another group which estimate a 6 to 8 years period for write-off have instrumentation for

(Continued on page 100)

INTERNATIONAL NEWS

FRANCE

FRENCH GOALS confidently expected to be achieved in 1959 are as follows:

STEEL—A record-breaking 15 million metric tons are to be produced.

GAS—The ten billion cubic feet natural gas reservoir at Lacq in the Pyrenees will be sending gas to Paris and Lyons for general use by November.

ELECTRICITY—Five new hydro-electric stations, including the big one at Vogelgrun on the Grand Canal of Alsace, will be put into service, and great progress will be made on the huge Roselend and Serre-Ponçon dams in the French Alps.

New production units will be added to almost all of the larger thermal power plants.

New centers will be built for the transformation of Lacq gas into electricity.

The fifteen locks of the Garonne river's lateral canal are to be equipped with an extraordinary installation for the production of electricity. Consisting of a series of small generators utilizing falls with no more than ten-foot water drops, they will furnish 20 million kw-h. a year. It is planned similarly to harness the Rance Estuary in Brittany.

The first large French nuclear center, "EDF 1", built primarily for the making of electricity, will be completed at Avoine, near Chinon in the Loire valley. It is to supply an annual 400 million kw-h. A sister center, "EDF-2," has now gone into construction nearby, and another nuclear electricity center, built within the framework of Euratom, will probably be constructed in the Ardennes region. (By 1971, atomic energy will account for 30 per cent of the country's total output of electric power.)

PETROLEUM—Oil production in Parentis (near Bordeaux), Gabon and the French Sahara is being increased, thereby reducing import needs from non-French sources.

The 375-mile pipeline joining the Hassi-Messaoud field in the Sahara to the Mediterranean port of Bougie in Algeria will be ready for use in October.

RAILROADS—The basic effort of S.N.C.F. (French National Railroads) will be to continue electrification of its lines. The equipment program for the electrification of the Paris-northeast triangle, serving the three principal economic regions of France, will be completed this year.

The French railroad network is expected to have a total of 4,375 miles of electrified lines by the end of the year, which will carry more than half its total traffic.

SHIPYARDS — French shipyards today are building the biggest tankers in Europe, and are designing and constructing ships (totaling some 500,000 deadweight tons in 1959) for French and foreign customers.

AIR TRANSPORT — In May, the "Caravelle" jet-liners will be put into commercial service.

PUBLIC WORKS — The large suspension bridge crossing the Seine at Tancarville near Le Havre, will be completed in July.

AGRICULTURE — The "phytotron," one of the most complete laboratories for agricultural research in the world, will be finished and ready for service at Gifsur-Yvette near Paris.

SPACE SCIENCE—At Nançay in the Cher Department. where a mile-long radiotelescope is already in service, construction of a second one is scheduled. These apparatuses permit "listening" to waves coming from outer space with an acuity never before obtained, it is said.

For the first time, French multistage rockets will be launched.

THE ATOM — Three new atomic piles will be added to the eight already in use, and construction will begin on three more. One of these will be a fast neutron pile cooled by liquid sodium, designed for the study of breeder reactors.

Most ambitious project will be the setting up of the Pierrelatte plant, in the Drôme region, where Uranium 235 will be separated from natural uranium. Its principal structure will cover 25 acres of the 1,500-acre site.

A plant for the extraction of Cesium 137 from atomic waste will be set up. (This product is of importance in industry and medicine, where it usefully replaces radioactive cobalt.) This is the first time recuperation of by-products from the combustion of uranium will have been accomplished in France on an industrial scale.

The center for the utilization of thermonuclear energy at Fontenay-aux-Roses will be greatly enlarged. Here, a new machine, called "Equator III," will be built.

France is constructing its first atomic submarine, and is perfecting its own A-bomb.

From *France Actuelle* March 15, 1959

SWEDEN

THE SWEDISH STATE POWER BOARD has during recent months celebrated its fiftieth anniversary. Later, five large power plants will be put into operation, two of which will be the biggest of their type ever completed in Sweden and even holding some world records, as to design and output.

Stenungsund, on the Swedish West Coast, will have a rock-encased steam-power station. Its initial capacity is 300 MW, but blasting out of two more rock halls is going on. With two more boilers and steam turbines, for which these rock enclosures are planned, the plant will produce 700 MW. The commissioning of the first stage of the installation is to take place on October 1.

Sweden's largest hydro-electric plant, Stornorrfors, which will have a capacity of 375 MW — 25 MW more than the Harspranget station above the Arctic circle — will be officially inaugurated on September 1 this year. The two first turbines have been running for some time, and a third is under installation. Two more water-power plants, Järkvissle and Langbjörn, having a capacty of 87 MW and 80 MW respectively, will start operating in the summer and autumn.

The fifth power station is the gas-turbine plant at Västervik, on the Swedish east coast. This plant will have a nominal rating of 40 MW and is to be taken into use commercially on October 1. It is of a new type for Sweden. The machinery was delivered by STAL.

At Stenungsund, each of the two machinery halls of the first stage, now completed, has the dimensions: 409 x 80 x 109 ft. Some 23,000,000 cu. ft. of rock have been blasted away, and more than half as much is still to be removed. The plant is to have double rotation turbines, said to be the world's largest, each consuming 34 tons of oil per hour. Its oil harbour can accommodate 60,000-ton tankers.

Stornorrforsen has three NOHAB turbines and ASEA generators. Their output is 125 MW each. They may be supplemented by a fourth unit later on. The tunnel area of 4,400 sq. ft. also constitutes a new record.

The most interesting feature of the Västervik plant, which is situated on an island, is that it will be automatically remote-controlled from the mainland. The two smaller hydro-electric plants feature interesting solutions of the dam-building problems, which have been tackled in entirely different ways. The former is a rockfill dam on a drainage bed, while the latter has been built according to the Concretor-Prome to slide-casting system. This method is also to be used for the Messaure dam above the Arctic Circle, which has a threshold height of 330 ft. and guards a reservoir containing 13 million cu. yards of water. One of the great advantages of the new Swedish dam-building system is that it cuts building time by 80 per cent.

Finally, it should be reported that during the jubilee year Swedish trunk-line cable-network builders will converge with their Finnish and Norwegian colleagues on their respective frontiers to connect up the three Scandinavian power systems with each other.

UNITED KINGDOM

FIRST BERYLLIUM PLANT. The first plant in Europe for the production of the metal beryllium in wrought forms is to be established at Birmingham, England, by the Metals Division of Imperial Chemical Industries Ltd., of Millbank, London, S.W.1. Designed to produce semi-fabricated forms of the metal, such as rod, tube and plate, and finished machined parts, the plant is expected to come into production by the end of 1959.

Its first task will be the execution of a production scale contract placed with I.C.I. by the United Kingdom Atomic Energy Authority as part of a development project. Spare capacity may later find additional outlets for this unusual metal, in which aircraft and missile designers are showing considerable interest.

Interest in beryllium as a nuclear engineering material has been intensified by the need for a metal which will perform satisfactorily in the higher operating temperatures envisaged in advanced nuclear reactors of the Calder Hall type. For the present programme of Britain's nuclear power stations, special magnesium alloy materials are used for sheathing (or "canning") the nuclear fuel. To increase the efficiency of this type of reactor, canning materials must be used which retain their strength at high operating temperatures. Because of its unique combination of attractive nuclear engineering properties, beryllium has been chosen by the Industrial Group, U.K.A.E.A., for the fuel canning in its Advanced Gas-cooled Reactor.

Outside the nuclear engineering industry, beryllium is likely to be of interest where a combination of light weight and high strength, or light weight and an unusual degree of rigidity is needed.

INSTRUMENTATION

(Continued from page 98)

automatic processes and supervisory warnings also, but in addition have instruments for thickness control and measuring and counting.

Comments given in replies

A manufacturer of cranes, boilers, plate and tank work states "considerable savings are effected with the aid of a smoke-density recorder, possibly as much as 5 per cent in fuel consumption. Steam-air flow instruments contribute towards perfect firing conditions, and aid staff in meeting widely fluctuating steam demands. Poor firing could lower efficiency by up to 10 per cent. Feedwater temperature, held to a maximum by visual observation of the instrument results in lowering boiler plate stresses set up by widely fluctuating temperatures of water entering the boiler, helps maintain smoother steam generating conditions and saves fuel".

"Oil pumping, heating and pressure gauges provide the staff with means to set up proper combustion conditions. Efficiency firing depends on maintaining maximum oil temperature and pressure. Savings from other quarters could be quickly eliminated if oil temperature and pressure get out of hand. Proper instrumentation enables the operating engineer to set up a necessary log-sheet of operations, and permits operating with less staff due to close control of shift routine".

"In the boiler room proper instruments kept in good order permit a closer watch on the staff at night on holidays and weekends—a great help when operating with minimum staff. Boiler operation could be simplified by direct boiler water analysis at the boiler. However there has been no improvement in boiler water testing for many years. A direct reading combination alkalinity-density and hardness instrument is still to be devised".

A maker of electronic instruments and controls comments that "numerical machine-tool control provides reductions in manufacturing costs of from 80 to 90 per cent. Other instrumentation is either essential to business or provides a minimum of 10 per cent reduction with the over-riding principle that it must pay for itself in one year".

"The importance of control and instrumentation in the process industries has not been sufficiently realized . . . numerical control in the machine-tool field will provide during the next few years the most amazing and exciting development in metal-working equipment that has occurred during the past decade . . . industries with foresight expecting to be in business five years hence must look to electro-mechanical types of control in the machine tool, process and nuclear reactor fields."

A manufacturer of compressors, drills, mine hoists pumps and pulp and paper equipment believes the trend today is towards greater instrumentation in many new fields. There is some danger, he thinks, that instrument makers have a tendency to work in too many extremely fine details in their instrumentation, sometimes overlooking the basic requirements and basic operating conditions.

A metal manufacturer turning out aluminum products remarks that instrumentation in his industry is mandatory due to the close tolerances which govern product quality — properties of strength, hardness, ductility, conductivity, corrosion resistance etc. It is also important in point of view of plant safety, efficiency research, inspection and testing. He anticipates this use will increase as new products and operations develop and as new instruments become available. Improvements in measuring equipment and techniques must keep pace with needs for greater accuracy. Such improvements will be a continuing trend in the future made possible by the increased use of electronics.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

International Nickel Manitoba Project

The new nickel mining project at Thompson, Manitoba, is scheduled to start smelter out-put in July 1960, and to come into regular full-scale production at an annual rate of 75 million pounds in 1961. With some 2,000 men engaged on the project during 1958, sinking of the 2,100 ft. mine production shaft and of the development shaft was completed. Related underground developments were carried forward.

Construction of surface facilities at the plant proceeded somewhat ahead of schedule. The production shaft headframe was readied for installation of the permanent hoists, the building for the mill and for the connected mine changehouse was completed, and work progressed on the smelter. The 500-ft. stack to disperse waste gases and to supply draught to the smelting equipment was finished. The compressor building and most of the service buildings were virtually completed. Yard grading, sewer, water and power distribution installations, and the construction of yard trackage, proceeded according to plan.

At Kelsey, 53 miles northeast of Thompson, construction of the power plant by Manitoba Hydro-Electric Board on the Grand Rapid of the Nelson River progressed satisfactorily.

The townsite situated astride the Burntwood River, two miles from the plant area, began to be transformed into the town of Thompson, which has been planned for an initial population of 8,000. Installation of the roads, sewer and water lines, and of the power distributing system, was on schedule. Construction has started on a water treatment plant and the town sewage disposal plant, and is about to start on the first of the four schools in the townsite and on a hospital to be operated by the Company.

Some B.C. Projects Proposed

In a list of industrial expansion projects proposed by British Columbia industries, and published by the British Columbia government, there are the following intentions expressed:

Primary steel: The Consolidated Mining and Smelting Company Limited was investigating the possibility of smelting pig-iron, using mine tailings from the Kimberley mine, which contain millions of tons of iron ore.

Flakeboard, fine papers: The Powell River Pulp and Paper Company Limited plans two new industries. The first would be a flakeboard mill with a capacity of 100,000 sq. ft. daily, and employing 40; the second, a fine paper mill employing 70 people.

Among projects under way, representing industrial expansion in the province, the following are listed:

Crown Zellerbach Canada Limited has a new corrugated paper box factory completed in 1959. Celgar Development Company will have a new pulp and lumber operation. The pulp mill will have a capacity of 500 tons daily, and will employ 325 in the pulp mill and 100 in logging and sawmilling. Completion is scheduled for 1960.

Wrights-Canadian Ropes Limited will complete in 1959 the expansion of a plant to manufacture a new product: prestressed wire rope. The plant's capacity will be 200 tons.

Air line: A new servicing base for turbine aircraft, with a new hangar and maintenance facilities, is to be completed in 1960.

Glass containers: Dominion Glass Company has underway a $4 million warehouse section, with main plant to follow.

CANADIAN DEVELOPMENTS
of 1958 will be reported in
THE ANNUAL REVIEW, 1958
May issue of
THE ENGINEERING JOURNAL

Private and Public Investment, 1959

The government has reported on the outlook for 1959 in private and public investment in Canada and summarized the results of a recent survey of capital spending intentions.

For the fourth year in succession, the minister of trade and commerce anticipates, capital investment in Canada will exceed $8 billion, a more than three-fold increase in a period of twelve years.

Intended outlays on construction and machinery, including repairs, are reported at 11.1 billion dollars. Within the total program, the principal increases appear in commercial and institutional building and government projects. Commercial construction will apparently go ahead more rapidly than ever. There is little change indicated in the rate of capital spending for a broad range of industry, including agriculture, forest and mineral extraction and processing, secondary manufacturing and transportation and communication. However, fuel and power industries have indicated a somewhat lower level of capital expenditure.

The minister of trade and commerce said that the rate of anticipated expenditures for 1959 indicates a continued expansion in industry. As a proportion of total national output, anticipated outlays for new plant and equipment compare favourably with levels in most post-war years.

What Goes On

Thermal Plant at Saint John, N.B.

Construction was due to begin in March 1959 on the new thermal electric generating plant in Saint John. The plant is estimated to cost 17 million dollars—a portion of the estimated $100 million program forecast for the entire district. Scheduled to be in operation for 1961, the plant is to be built in the Courtney Bay area of St. John.

Recent discussions indicate many other changes for that area.

Steep Rock Mines

On the "C" ore zone which the Company has leased on a royalty basis to Caland Ore Company Limited, Canadian subsidiary of Inland Steel, Steep Rock's President reports that the property is being prepared for open pit mining in 1960. Production from the Caland Mine is scheduled to build up from 750,000 tons in 1960 to a required minimum of 3,000,000 tons annually.

International Channel Improvements

Under an agreement between the United States and Canada, a cut-off channel will be constructed in the St. Clair River between Lake St. Clair and Lake Huron to eliminate the sharply curved channel known as the Southeast Bend. The cut-off channel will be six miles long, 700 feet wide, and will have a minimum depth of 27 ft. It will provide for two-way traffic in a straight line in place of the sharply curved channel and it will improve considerably ease of navigation in the St. Clair river.

The United States will pay for the construction work which will be done under the supervision of the U.S. Army Corps of Engineers. Canada's share consists in providing all the land required for the cut-off channel and in maintaining the channel after construction is completed. It passes almost entirely through Canadian territory, but Canada's sovereign rights over the area are protected by the agreement.

Ontario's $885.7 million budget

In the fiscal year ending March 31, 1959, the government will have carried out the largest works and service program in its history. In the provisions for the year 1959-60 there are these items among many others:

Education: An expenditure on education totalling $202.4 million; an appropriation of $1.2 million is being made for the introduction of a new and expanded system of aid to students of ability who are desirous of continuing their education beyond the secondary school level.

Highways. The appropriation for highways is $261.3 million. Among the important projects are: start on high-level bridge on Queen Elizabeth way crossing Welland canal at St. Catharines; acceleration of work on highway 401 to achieve its completion by 1963; work on the Rainy Lake causeway and on the extension of highway 120 west from Atikokan.

Mining. Total expenditure for assistance for the mining industry would be $6 million, including $1.5 million for mining access roads, and special payments totalling $3 million to mining municipalities.

Forestry. Appropriation for forest management, conservation and regeneration is $27.8 million, including $1.5 million for logging and forest-access roads.

Housing. Provincial cost of land assembly on rental-housing projects is provided by $6.5 million appropriation.

Hydro. Capital construction outlays in 1959 are estimated at $196 million.

Alberta's Budget for 1959

The total expenditure of the government will be $309.6 million. Some of the projects to be accomplished are as follows:

Agriculture: A sum of $705,000 has been provided for irrigation, drainage and flood control projects.

Education: $10.8 million are required to meet the basic needs of the University in Edmonton and in Calgary. Construction of the physics and chemistry building is to commence.

Public Works. Expenditures totalling $43 million are planned by the Department of Public Works.

Mines, minerals and oil. The sum of $1.9 million has been appropriated for the department to continue the administration of the development of natural resources.

Highways. Construction of highways, bridges and ferries will require the spending of $48.5 million. This includes $3 million for work on the trans-Canada highway and $4 million for roads to resources.

Developments in Saskatchewan

- A $1 million steel fabricating plant is to be built in Regina by the Dominion Bridge Company Ltd. Dominion Bridge expects to have the new plant in production before the end of 1959. The plant's main operation will be the fabrication of structural steel for buildings and bridges, but it will also warehouse a complete stock of steel supplies for Saskatchewan industries.
- A major expansion program being completed in May 1959 doubles the capacity of the Saskatoon Boiler Company Limited.
- The province's post-war industrial growth and its potential for future economic developments are being scrutinized by a group of Canadian and American research specialists. These consultants have been engaged by the Saskatchewan government to make an objective appraisal of the provincial economy and to suggest long-range programs to ensure the best development of the province's economic potential.

One phase of the research will be devoted to an analysis of resource development and expansion possibilities. The study will include industries based on forest resources, uranium, potash, clays, oil, natural gas and other minerals. Industries appearing to have favourable possibilities will be defined, and suggestions for promotional activities will be outlined.

- There will be a new industry in Moose Jaw which will involve an investment of about $500,000. A cold roll-form steel mill is to be established.

Need for Nuclear Power

"From 1965 onwards we hope nuclear electric stations will begin to supply some of our thermal requirements," Ontario Hydro chairman James S. Duncan said recently.

However, the production of nuclear energy at a cost that will compete with traditional methods of generation still awaits the solution of a great many engineering and technical problems, he said.

Inflation

Ontario Hydro chairman James S. Duncan, in a recent speech referred to inflation as a national problem which "dwarfs all others in its significance". The problem facing Canada, he said, is not one of runaway inflation, but one of gradual and progressive erosion of the purchasing power of our currency.

Canada's prosperity is largely based on foreign sales of basic commodities, such as newsprint, iron ore, copper, nickel, wheat and uranium. But natural resources are of value as an export only if they are competitive on world markets. If inflation is to be halted, it will, in Mr. Duncan's opinion be accomplished by the weight of public opinion. Sacrifices and discipline, imposed upon ourselves are necessary to safeguard the economic system and the way of life, he said.

Lift-Bridge at Burlington

The contract for construction of the $3.7 million vertical lift-bridge at Burlington, Ontario has been awarded to Bridge and Tank Company of Canada.

The largest and longest of its type in Canada, it is a combination railway and highway structure spanning the Burlington Beach ship channel. The new bridge will be 370 ft. long and 51 ft. wide. Massive towers from which the bridge will be suspended will be more than 200 ft. high. In raised position the bridge will give a clearance above water of 120 ft. for ship passage.

C.N.R. extends marshalling system

Another link in the chain of new marshalling yards being built across Canada for the Canadian National Railways will be provided at Toronto, if federal legislation is obtained. It will complement the three hump yards under construction at Winnipeg, Montreal and Moncton.

Algoma Bloom and Plate Mill

The only combination bloom and plate mill on the North American continent was completed and test rolling began in March 1959, by the Algoma Steel Corporation Limited, Sault Ste. Marie, Ont.

With this installation, Algoma has become one of Canada's leading heavy industries.

An electronic card program controls mill operations. This system in the mill can readily be expanded to include card control program for other mill functions such as speeds, reversal of drive, speed of mill tables, operation of manipulators, etc., or the entire mill operation.

For rolling slabs, the mill is fed with massive 30-ton steel ingots from soaking pits. Covers of the new pits can be removed by remote control. The ingot is automatically selected and lifted out, transferred to receiving table, automatically weighed and turned around.

In the rolling operation it is rolled into a bloom or slab. The blooms are transferred to other mills for manufacture of structurals or other products, or they may be re-rolled in the new mill into plate or tube rounds.

The huge mill is powered by two 4,000 hp. motors. It is used as a 2-high assembly for rolling slabs and a 4-high assembly for rolling plate. Industrial television is being installed.

The dual purpose mill has capacity to roll 500,000 tons of steel ingots a year and also to re-roll the resultant semis into 350,000 tons of plate and/or tube rounds.

In addition to increasing the Company's steel rolling capacity, this mill provides greater flexibility in operations. Its capability of producing tube rounds releases existing facilities for other production as required.

Projects yet to be completed by Algoma are: a large blast furnace turbo blower which, with the boiler recently completed, will allow retirement of all blast furnace blowing equipment more than 16 years old; a new and more powerful drive for the reversing roughing stand of the rail and structural mill; and a new continuous reheating furnace for the same mill, replacing old furnaces.

Investigations are now being made into the advisability of installing a universal beam mill at the steelworks to produce wide flange beams in sizes most used in Canada.

The Orenda Engine

The *Journal* has been informed of the following, as a discussion of the article titled "Propulsion", by F. H. Keast, *(Fifty Years of Aeronautical Engineering)* which appeared in the February issue of *The Engineering Journal*, Page 37.

(a) The ORENDA was designed to a very simple and clear specification which called for a maximum ground level static take-off thrust of 6,500 pounds;

(b) ORENDA No. 1 regularly achieved and sometimes exceeded the specified thrust of 6,500 pounds;

(c) This prototype engine established some kind of a record for reliability by completing 784 hours of rigorous "type test" type of running without being removed from the test stand. This was achieved after almost 100 hours of previous running and two partial strips for inspection but without any modifications. A further interesting fact is that this extraordinary run was terminated abruptly by a bolt and package of Schick injector razor blades being accidentally sucked into the engine intake.

CONDUCT OF TECHNICAL SESSIONS AT 1959 ANNUAL MEETING, E.I.C.

As a result of many comments from members attending past annual meetings and careful consideration by the Committee on Technical Operations, some changes will be made in the conduct of technical sessions. An outline of procedure adopted for the coming Annual Meeting is as follows:—

1. As far as possible, a session chairman will not take more than one minute for the introduction of the author.
2. *The author will be allowed 15 minutes for the presentation of his paper.* Each author is asked to make his presentation based on a summarization of his paper adapted to oral presentation. (Remember papers are to be preprinted and available well before the Annual Meeting). *There will be a warning signal under the control of the chair which will notify a speaker when he has one minute remaining. The speaker will be similarly notified when his time is up and must then close his presentation promptly.*
3. *Authors* will be provided with ten preprints of their papers as soon as possible and *are asked to invite prepared discussion* from those they think can contribute to the value of the treatment of which the paper is the broad framework. *The appropriate Engineering Division chairman should be advised promptly of the names of invited discussors* so that session chairmen can be notified. *The Engineering Divisions* of the Committee on Technical Operations *will also invite discussion on Annual Meeting papers.*
4. Discussors are asked to make known to the session chairman their desire to participate in discussion, at the first opportunity before the opening of the session.
5. Time will be allotted for discussion from the floor, if at all possible, but preference will be given to those who have indicated their desire prior to the opening of the session.
6. *The maximum time allotted for any discussion will be limited to 5 minutes and the warning-signal procedure noted in (2) will be utilized.*
7. *The author will be allowed not more than 7 minutes for verbal closure. The warning-signal procedure noted in (2) will be utilized. However, the author's written closure can be of such length as necessary to deal appropriately with the ensemble of discussions.*
8. *Session chairmen will close their sessions at the scheduled time.*

See annual meeting notice elsewhere in this issue.

News of the Institute and the Profession

COMMENT
CORRESPONDENCE
ELECTIONS
AND TRANSFERS

ROYAL VISIT — 1959

H.R.H. The Prince Philip has graciously consented to address engineers and scientists at a luncheon at the Royal York Hotel, Toronto, at noon on Monday, June 29th. Groups participating are

Canadian Aeronautical Institute
Canadian Council of Professional Engineers
Canadian Institute of Mining and Metallurgy
Chemical Institute of Canada
Engineering Institute of Canada

Applications for tickets should be made immediately to

Engineers and Scientists Committee
P.O. Box 62
Postal Station Q
Toronto 7, Ont.

The ticket allotment will be one to a person and the applicant must indicate his registration with one of the organizations participating. Tickets are non-transferable.

A cheque in the amount of $5.00, payable at par in Toronto, must accompany each individual application. Cheques should be made payable to the Engineers and Scientists Committee.

Distribution of tickets will be made on June 1st taking into consideration

(1) Order of receipt of application
(2) Fair distribution to participating organizations

CONFEDERATION

A Progress Report

The joint sub-committee on Confederation met again in Montreal on Tuesday, March 10. The report on Confederation was studied again and a few minor suggestions were made so that the report could be reissued as a completely unanimous joint report.

In the form which it is now being submitted to the Canadian Council and resubmitted to the Council of the Institute, it has been streamlined somewhat with the objective of making it clearer for final presentation to the membership.

The committee quickly reached unanimity on all points and since the meeting the report has been retyped and sent to the various members of the joint committee, all of whom have sent in their approval. Thus it is possible to report to the membership that the report in what the committee expects will be its final form is now complete. It will be submitted to the Council of the Institute at its meeting in Montreal in April and will be considered by the Canadian Council at its annual meeting in May. It will be submitted to the membership shortly thereafter.

The sub-committee believes that the report in its present form is clear and concise and that the members will have little difficulty in following it in every detail. It is the joint committee's belief that the report provides an adequate basis for the provisional council, now referred to as the Engineers Confederation Commission, to conclude all the planning necessary to bring Confederation to pass.

ANNUAL GENERAL AND PROFESSIONAL MEETING

The Engineering Institute of Canada

ROYAL YORK HOTEL, TORONTO,

June 8, 9, 10, 1959

TECHNICAL ACTIVITIES

Members will be interested to know about several new features for the technical program at the June 8-10, 1959, Annual Meeting in Toronto, which your Committee on Technical Operations has planned.

Thanks to the several active Engineering Divisions a well-balanced program of technical papers has been arranged. Many of the papers are tied closely to the basic theme of the meeting—BY THE RIVER TO THE SEA—but the remainder cover new developments of interest to engineers in every field of our profession. There is to be a half-day panel session, with five notable Canadian educationalists, economists and engineers, on "The Economic Impact of the Seaway". Another exciting feature will be a four-part symposium on the far-ranging "Headquarters Computation Centre for Ontario Hydro".

This issue of *The Engineering Journal* carries abstracts of all papers which will be included in the program. You will thus have a chance to know something about the technical papers to be presented, and know it in advance.

Moreover, annual meeting papers are to be preprinted and made available to members requesting them, at a nominal cost, well in advance of the meeting. They will also be available at the meeting. Any member can thus secure a copy of a paper in which he is interested in ample time to prepare a discussion and submit it either to Headquarters by June 1st, or to the chairman of the session at which the paper is being presented, prior to presentation.

The success of technical sessions depends on your attendance, on your contribution to discussions. Why not make the Annual Meeting in Toronto the best ever?

PLEASE REFER TO PAGE 93 FOR ABSTRACTS OF THE TECHNICAL PAPERS TO BE PRESENTED.

THE NEXT ISSUE OF THE JOURNAL WILL HAVE THE COMPLETE PROGRAM OF EVENTS OF THE ANNUAL MEETING, 1959.

The Speakers Panel

Conference Banquet

Southern Ontario Regional Conference

The second Southern Ontario Regional Conference was a complete success, with attendance equalling last year's. The conference was held in the Royal Connaught Hotel, on Saturday, March 14 in Hamilton.

Following the late morning registration, the luncheon at one o'clock featured a very interesting panel discussion that captivated the audience. The topic was "What's on the Horizon for John Smith, B.A.Sc., Class of '65". The moderator was H. L. Shepherd, manager, salary administration and personnel development, Canadian Westinghouse Co. L. D. Dougan, vice president, operations, Polymer Corporation, stated what Canadian industry needed and required of this young engineer. S. D. Rendall, superintendent of secondary education, Department of Education, Ontario, outlined what is now being done in the way of scholarships, bursaries, and education to help John Smith prepare for university. Lastly, Professor L. S. Lauchland, head of the Department of engineering science, University of Western Ontario, emphasized the academic education of the student engineer, and said that this education is subject to changing world conditions. Professor Lauchland summed it up very appropriately, "Engineering is a journey and not just an experience". An enthusiastic question and answer period followed.

The remainder of the afternoon was occupied with technical papers.

While the men were listening to these technical papers, the ladies were enjoying a fashion show under the capable direction of Mrs. Joyce Saunders, Program Convenor.

The conference banquet was held in the Crystal Ballroom with a capacity crowd. After a delicious turkey dinner, Hugh Seely, chairman of the Hamilton Branch, E.I.C., introduced the head table to those present. Dr. Garnet Page, general secretary of the E.I.C. expressed his satisfaction at being present for this conference.

Stuart Armour, economic advisor to the Steel Company of Canada Ltd., was guest speaker. His subject, "Why Buy Made in Canada" was indeed applicable to every engineer present.

An informal dance in the Crystal Ballroom concluded the conference.

E. W. Hill, M.E.I.C., very capably directed and organized the Conference for its second successful year.

Ladies Coffee Hour: Mrs. H. L. Hillgartner, Mrs. Joyce Saunders, Mrs. R. H. Stevenson, Mrs. J. M. Skinner.

Trophy for Engineers

The Clement Mathew Anson Trophy is an innovation for the annual Plumbers' Ball at McGill University. It was awarded for the first time this year to the department of engineering who made the best showing in the exhibits presented on the night of the ball. The winner was the metallurgy department, with a display of perpetual motion. Dr. L. Austin Wright of the E.I.C., substituted at the ceremony for C. M. Anson who was in London, England. Receiving the trophy was G. M. Desjardins, president of the McGill Engineering Undergraduate Society.

Dr. Anson is the one who thirty-three years ago founded the Plumber's Ball and was responsible for its being called by that name. At that time he was president of the Engineering Undergraduate Society. The ball was a challenge to those who doubted that the engineers could carry off a social function of quality. From that day it has been the outstanding social event of the whole university.

Staff Changes

Two members of The Engineering Institute staff left the employ of the Institute on February 28, 1959, for other positions.

They are: Henry P. Gatin, director of membership services, who has been at E.I.C. Headquarters since the fall of 1956; and John A. McLaren, eastern field secretary, whose service through the Toronto office had been available to eastern members since early 1958.

Elections and Transfers, for February, 1959, are listed on Page 133 of this issue.

NORTHERN ONTARIO REGIONAL CONFERENCE

of The Engineering Institute of Canada

Nickel Range Hotel, Sudbury, Ont.

Saturday, April 25, 1959

SOMETHING NEW

This conference is the first of its kind in this region sponsored by the E.I.C. All northern Ontario E.I.C. and A.P.E.O. members and their ladies are urged to attend. A special Sudbury Branch conference committee has made comprehensive plans and arrangements for your pleasure and convenience. The guest speakers, papers presentation, and social program will be stimulating and enjoyable for both the engineers and their ladies and the conference will present an opportunity for all northern Ontario members to meet.

12.00 - 1.15 p.m.	MEZZANINE FLOOR	REGISTRATION
12.00 - 1.30 p.m.	MEZZANINE FLOOR	BUFFET LUNCHEON, Men and Ladies
1.30 p.m.	BALL ROOM	GENERAL ASSEMBLY and welcome from the Sudbury Branch.
1.30 - 4.15 p.m.	BALL ROOM	CONFERENCE PROCEEDINGS

TECHNICAL PAPERS

Engineering Future of Canada in the Next Twenty Years

1. ENERGY—Nuclear, Hydro-Electric, Carbonaceous, Solar.
   J. L. OLSEN, *Canadian General Electric Co., Kingston.*
2. TRANSPORTATION—Land, Air, Water
   A. LIGHTBODY, *Assistant Manager, of Research, Canadian Pacific Railways.*
3. DEFENSE
   MAJ. GEN. W. S. MACKLIN, *Ottawa, Ont.*

Concurrently with technical session, an attractive Ladies' Program will be held at the Copper Cliff Club. Note: Arrangements will be made for dressing accommodation for visiting ladies.

6.00 p.m.	LOUNGE	RECEPTION AND COCKTAILS as guests of the Sudbury Branch.
7.00 p.m.	BALLROOM	CONFERENCE BANQUET. Evening guest speaker. DR. GARNET T. PAGE, *General Secretary of the Engineering Institute.*
9.30 p.m.	BALLROOM	E.I.C. REGIONAL CONFERENCE DANCE Dress informal.

All E.I.C. and A.P.E.O. members and their ladies and guests are cordially invited

PLAN TO ATTEND!!

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

Sir Claude Dixon Gibb KBE, FRS

One of the all time "greats" of the engineering profession died suddenly on January 15th, 1959 at the airport in Newark, N.J. He was Claude Dixon Gibb, Chairman and Managing Director of C. A. Parsons & Company, Limited, Newcastle-upon-Tyne, England.

Sir Claude was well known to Canadians and in particular to members of the Engineering Institute. He was a frequent visitor to Canada, and had a host of friends here. On two occasions he delivered lectures to a series of branches of the Institute, and it is noteworthy that he broke all attendance records at each branch. As a lecturer and a discusser of technical problems in his diversified field he was without peer or equal.

Sir Claude's health was such that for years he knew he was "living on borrowed time," but he carried on his duties as if nothing were wrong. He was always cheerful, interested in everything around him, helpful to other people, and charming in a way that brought him new friends and greatly enhanced old friendships.

Few engineers possess the breadth of his interests, his knowledge and his achievements. He was a great engineer and an outstanding industrialist. It was said by those who should know that although he was the chief administrator of his company, he was still the best engineer in the organization.

The Engineering Institute recognized his outstanding character and achievements by making him an Honorary Member at the Annual Meeting in Quebec in 1958.

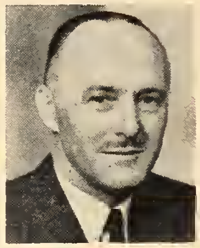
This distinguished gentleman was born in Adelaide, Australia in 1898. He was graduated from the South Australian School of Mines (Adelaide University) and later did post-graduate study at London and Durham Universities, to obtain his doctor's degree.

From 1917 to 1919 he was a pilot in the Australian Flying Corps, and in the second world war was Director General Armoured Fighting Vehicles and Chairman of the British Tank Board. In this post he led the team that developed the Centurion Tank. He developed and brought into production the British 17 pounder, and as well was responsible for all British weapon production.

After the first world war 1920-1923 he was senior research assistant in the engineering laboratory University of Adelaide. In 1924 he went to England and started his industrial training as a fitter at the Heaton Works of C. A. Parsons and Company Limited. In rapid succession he became chief engineer and director of the company (1929), General Manager 1937, Joint Managing Director 1943 and in 1945 Chairman and Managing Director, the position he held at the time of his death.

Also he was Chairman of the Reyrolle Company, and of the Nuclear Power Plant Company, Limited.

In 1945 he was honored by the King, with a knighthood, for his war work, and in 1956 he was made Knight of the British Empire for his outstanding contribution to the development of atomic power. He was made a Fellow of the Royal Society, for original research and design, new methods of manufacturing steam turbines and for his armament work.



Sir Claude Gibb,
KBE, FRS,
HON. M.E.I.C.

He has presented innumerable technical papers, and has received many awards for them, from many parts of the world.

Sir Claude was a great man. The profession is justifiably proud of him. It is tragic that he should have been cut off at so young an age, and the world deprived of his continued good works. Few men have made so deep a mark on industry and on their profession. The world is much better because of him and there is every reason to believe that his influence will continue for years by virtue of his good example.

"I shall not look upon his like again."

L. A. W.

Clive Joyce, S.E.I.C. died on November 15, 1958.

Born on May 28, 1933, he attended Queen's University, graduating with a B.Sc. (Hons) (Chem.) degree in 1957.

He was awarded his M.Sc. degree in chemical engineering at Queen's University in 1958. He had later started on research in fluid flow through porous media. He was on a National Research Council scholarship.

Alex. Alfred Plummer, M.E.I.C. died April 24, 1958.

He was born on September 19, 1889 in Toronto, Ont.

From 1904 until 1910 he was employed in railway, lumber and municipal engineering in Ontario and British Columbia, and from 1912 to 1913 he was partner and superintendent of Marshall, Plummer & Company, engineers and contractors. In recent years the firm was designated as A. A. Plummer Company Ltd., Vancouver, B.C.

Herbert Alcock Elgee, M.E.I.C. died early in 1958 in England.

He was born on December 7, 1867 in India and received his B.A. degree at Trinity College, Dublin. He also attended engineering school at Trinity College.

From 1902 until 1913 he was employed as engineer and agent for various harbour works in Singapore, South Africa and British Columbia. In 1921 he became chief engineer with the Back Bay Reclamation Scheme, India, returning to England in 1928.

Richard F. Davy, M.E.I.C. died on November 29, 1958 in Victoria, B.C.

Born in Toronto on November 7, 1875, he carried out extensive explorative surveys for the Canadian government in Quebec.

In 1928 he became assistant engineer with the Department of Public Works, Canada, and in 1941 retired from the Department at Victoria.

T. E. Gilchrist, M.E.I.C. of Peterborough, Ont., died on September 26, 1958.

Born in Ottawa, Ontario in 1888, he graduated from McGill University in 1910 with a B.Sc. degree.

He worked with the Canadian General Electric Company for many years in Peterborough. He had joined the Canadian General Electric Company in 1910 in the testing department.

James Walsh MacMahon, M.E.I.C. died on October 4th, 1958 in Montreal.

He was born in St. Catharines, Ont., on November 11, 1883. He graduated from McGill University with a B.Sc. degree.

Mr. McMahon was made a Life Member of the Institute in 1949.

John J. Murphy, M.E.I.C., of Ottawa, Ont., died on June 28, 1958.

Born in Halifax, N.S. on November 13, 1874, he had his early schooling there. Later he studied at the La Salle, Cambridge House Academies and Kings' College, and attended an engineering course 1892-93.

His early career included work in the Provincial Engineering Office, Halifax, and for the Nova Scotia Southern Railway. Later he was engaged in the Welland ship canal project at Port Colbourne, Ont. In 1928 he became assistant to lock engineer, Welland ship canal. In 1932 he was in the division engineers' office. His engineering service to the Welland canal and the Trent canal extend over many years.

Mr. Murphy had completed more than fifty years of membership in the Institute, having joined in 1890.

A. Q. Niazi, JR.E.I.C. died in 1958 in Pakistan. He was born in Pakistan on January 1, 1925 and from 1932 to 1940 attended Panjab University schools in that country.

In 1947 he went to McGill University, graduating in 1950 with a B.Sc. degree in civil engineering. In 1957 he served as sub divisional officer, P.W.D. (B.&R) in Lahore, West Pakistan.

Personals

M. J. des R. Tessier M.E.I.C.

W. J. Bichan, M.E.I.C.

W. J. Bichan, M.E.I.C. (B.Sc., mining, London 1932) of M. J. Boylen Engineering Services, is in Toronto after having spent two years in management of Advocate Mines Ltd, Baie Verte.

F. J. Slominski, M.E.I.C. (B.Sc., civil, Saskatchewan 1925) of Poole Construction Company Limited, Edmonton, has transferred from the Regina Branch. He is a vice-president of the company and district manager of the Saskatoon District.

M. J. desR. Tessier, M.E.I.C. (B.A.Sc., C.E., Ecole Polytechnique 1909) has retired as managing director of the Better Business Bureau of Quebec.

J. J. Kaller, M.E.I.C. (London, England 1950) has accepted the position of administrative engineer with the Corporation of the District of Burnaby, B.C.

V. M. Wallingford, M.E.I.C. (B.A.Sc., civil, Toronto 1944) is chief engineer of the Arbec-Campbell group of Companies, with office in Montreal. He leaves Baie Comeau, Quebec, where he was with Canadian British Aluminum Co. Limited, and Chairman of the local Branch of the E.I.C.

John Stephenson, M.E.I.C. has retired as plant engineer, National Steel Corporation Hamilton, Ont. He is now with the water works design division, City of Hamilton.

W. E. John Turke, M.E.I.C. (civil, Zurich, Switzerland, 1936) has recently been named a senior associate of the firm of Surveyer, Nenniger & Chenevert, Montreal. He has been in charge of structural design and of complete projects with the firm since 1941.

Jack Hahn, M.E.I.C. (B.Eng., elec., McGill, 1947) has become a senior associate of the firm Surveyer, Nenniger & Chenevert, Montreal. He is on the executive committee of the Montreal Branch of the Institute for 1959.

A. C. Davidson, M.E.I.C. (B.Sc., civil, 1935; elec., 1936; Manitoba; M.A.Sc., Toronto, 1949) has been elected chairman of the Toronto Branch of the Institute. He is assistant professor in the department of civil engineering at the University of Toronto.

W. J. Manning, M.E.I.C. (B.A.Sc., civil, Polytechnique, 1927) of the Department of Transport since 1940, has been promoted from chief of aids to navigation to the post of director, marine services.

A. Laing, M.E.I.C. (B.Sc., civil, McGill 1930) has recently been appointed chief of aids, marine services branch of the Department of Transport, Ottawa.

Carson F. Morrison, M.E.I.C. (B.Sc., civil, Saskatchewan 1925; M.Sc., structural, McGill 1927) has been appointed editor of *Canadian Consulting Engineer,* a Hugh C. MacLean publication. He will remain in his position of professor and head of the department of civil engineering, University of Toronto.

Alan Wyatt, M.E.I.C. (mechanical, R.N.E.C., Keyham, 1951) of Ontario Hydro is on loan to Atomic Energy of Canada Limited, working on the CANDU project, as design engineer, nuclear power plant division.

W. R. Astrop, M.E.I.C. (B.A.Sc., civil, Toronto 1950) of C. C. Parker and Associates, has been named assistant bridge engineer.

Douglas R. Wilson, M.E.I.C. (B.Eng., civil, McGill 1951) has been appointed section head, sewage and water department, R.C.A.F. headquarters, Ottawa.

F. De Francis, M.E.I.C. (B.Eng., civil, McGill 1951) has joined Harbour Steelworks Ltd., St. Sulpice, Que., as chief engineer.

Elson H. Hanson, M.E.I.C. (B.Sc., civil, Saskatchewan 1953) is a municipal engineer of the municipality of Fort Garry, Man.

Jack Hahn, M.E.I.C.

W. E. John Turke, M.E.I.C.

W. R. McEown, M.E.I.C. of the Department of Trade and Commerce has been named district inspector, electricity and gas, Toronto standards division.

Edward G. Taylor, M.E.I.C. (B.Sc., civil, Queens, Belfast, 1948) has been appointed chief utilities and roads engineer design division with the Directorate of Works (Army), Department of National Defence, Ottawa.

W. R. McEown, M.E.I.C.

W. E. MacDonald, M.E.I.C.

C. H. Davis, M.E.I.C. (B.Sc., Sir George Williams College, 1937) of the Bell Telephone Company of Canada has become equipment engineer, customer services, eastern area.

W. E. MacDonald, M.E.I.C. (B.Sc., mining, N.S.T.C. 1950) of the Dominion Coal Company Limited, has been appointed district superintendent, district No. 3, New Waterford, N.S.

Karl Pozsonyi, M.E.I.C. (dipl. civil, Budapest) has joined E. M. Peto Associates Ltd., Toronto, as soil engineer.

Morley M. Muth, M.E.I.C. (B.Sc., civil, Sask. 1956) has joined the design branch of the Manitoba Department of Public Works.

A. C. Davidson, M.E.I.C.

J. J. Kaller, M.E.I.C.

R. J. Coghlan, M.E.I.C. (B.Sc., mech., Saskatchewan, 1943) formerly resident engineer for Bailey Meter Company Limited, London, Ont., has been promoted to district manager for the company, in the Atlantic Provinces. His headquarters are in Halifax, N.S.

O. I. Johnson, M.E.I.C. (B.Sc., civil, Saskatchewan 1948) has been appointed maintenance superintendent, Kimberley fertilizer department of The Consolidated Mining and Smelting Company, Trail, B.C.

Donald P. Ryan, M.E.I.C. (B.Sc., mech., Toronto 1949) has been appointed Ontario district representative for Precipitation Company of Canada Limited, Toronto.

James E. Smith, M.E.I.C. (B.A.Sc., mech., British Columbia, 1949) has been appointed chief, Norden products sales, Canadian Pratt & Whitney Aircraft, Montreal.

Can you identify these

Dominating the skylines of Canadian cities, these buildings new and old reflect the nation's striking growth. Can you identify them? Like thousands of other well-known buildings from coast to coast, they contain steelwork fabricated and erected by Dominion Bridge Company Limited . . . testimony to the experience, enterprise and engineering skill of Canada's oldest and largest steel fabricators.

Alfred H. D. Haiblen, M.E.I.C. (B.Eng., elec., McGill, 1946) president of Jedwin of Canada Limited, has been appointed secretary-treasurer of O'Day Associates of Canada Limited, Toronto.

O. van Deurs, M.E.I.C. (M.Sc., civil, Copenhagen 1943) has taken up the position of county engineer of Lampton County, Ont.

Robert L. Higgins, M.E.I.C. (B.Sc., mech., Louisiana, 1952) until recently with Canadian Utilities Ltd., Edmonton, has gone to Keyport, Wash., as supervisory electronic engineer at a naval torpedo station.

Harold L. Steel, M.E.I.C. is the new chairman for the Amherst Branch of the Institute. He is chief draughtsman, structural steel division, of Robb Engineering Works Limited, N.S.

Frederick Krug, M.E.I.C. president of Canadian International Power Company Limited, and vice president of Montreal Engineering Company Limited, is this year's recipient of the Gano Dunn Medal of the Cooper Union Alumni Association.

R. D. Hall, JR.E.I.C. (B.Sc. elec. Alberta 1948) is the new chairman for the Lethbridge Branch of the Institute. He is utility engineer with the City Hall, Lethbridge, Alberta.

H. Orlando, JR.E.I.C. (B.A.Sc., civil, Toronto 1953) project design engineer with the Ontario Department of Highways, has been transferred from the Kingston region to London, Ont.

A. L. Adams, JR.E.I.C., (B.Eng., elec., McGill, 1951) has recently been appointed electrical superintendent of Mannesmann Tube Company Ltd., Sault Ste. Marie, Ont.

R. J. R. Welwood, JR.E.I.C. (B.Sc., mining, Queen's 1950) former mine captain, Stanleigh Uranium Mining Corp. Ltd., is now a research engineer, Panel mine, Elliot Lake, Ont.

R. F. Critchley, JR.E.I.C., (B.Eng., mech., Saskatchewan 1955) has gone to England on an Athlone Fellowship, and is with Vickers-Armstrong (Engineers) Ltd. at Newcastle.

C. A. Clements, JR.E.I.C. (B.Eng., civil, N.S.T.C. 1954) of the Hydro-Electric Commission of Ontario, construction division, has become design engineer at Ontario Hydro's head office in Toronto.

Ralph Neil, JR.E.I.C. (B.Eng., civil, N.S.T.C. 1957) resident engineer with the Department of Highways, at St. John's, Nfld.

Stuart F. Lyon, JR.E.I.C. (B.A.Sc., civil, Toronto 1954) is now working on construction of the Inter-American highway in Costa Rica.

R. F. Gurr, JR.E.I.C. (B.Sc., mech., Queen's 1954) is project engineer, works engineering department, at the Aluminum Company of Canada Limited, Kitimat, B.C.

Jules Leonard, JR.E.I.C. (B.A.Sc., civil, Polytechnique, 1952) has been named sales representative for Roxalin of Canada Limited, Montreal.

T. Argyropoulas, JR.E.I.C.

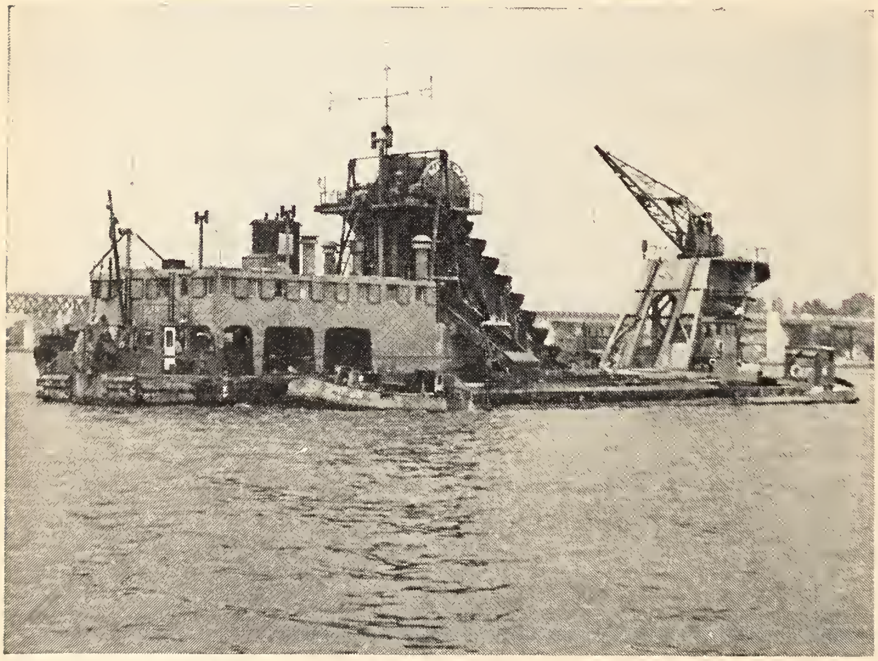
Joseph A. Baxter, JR.E.I.C.

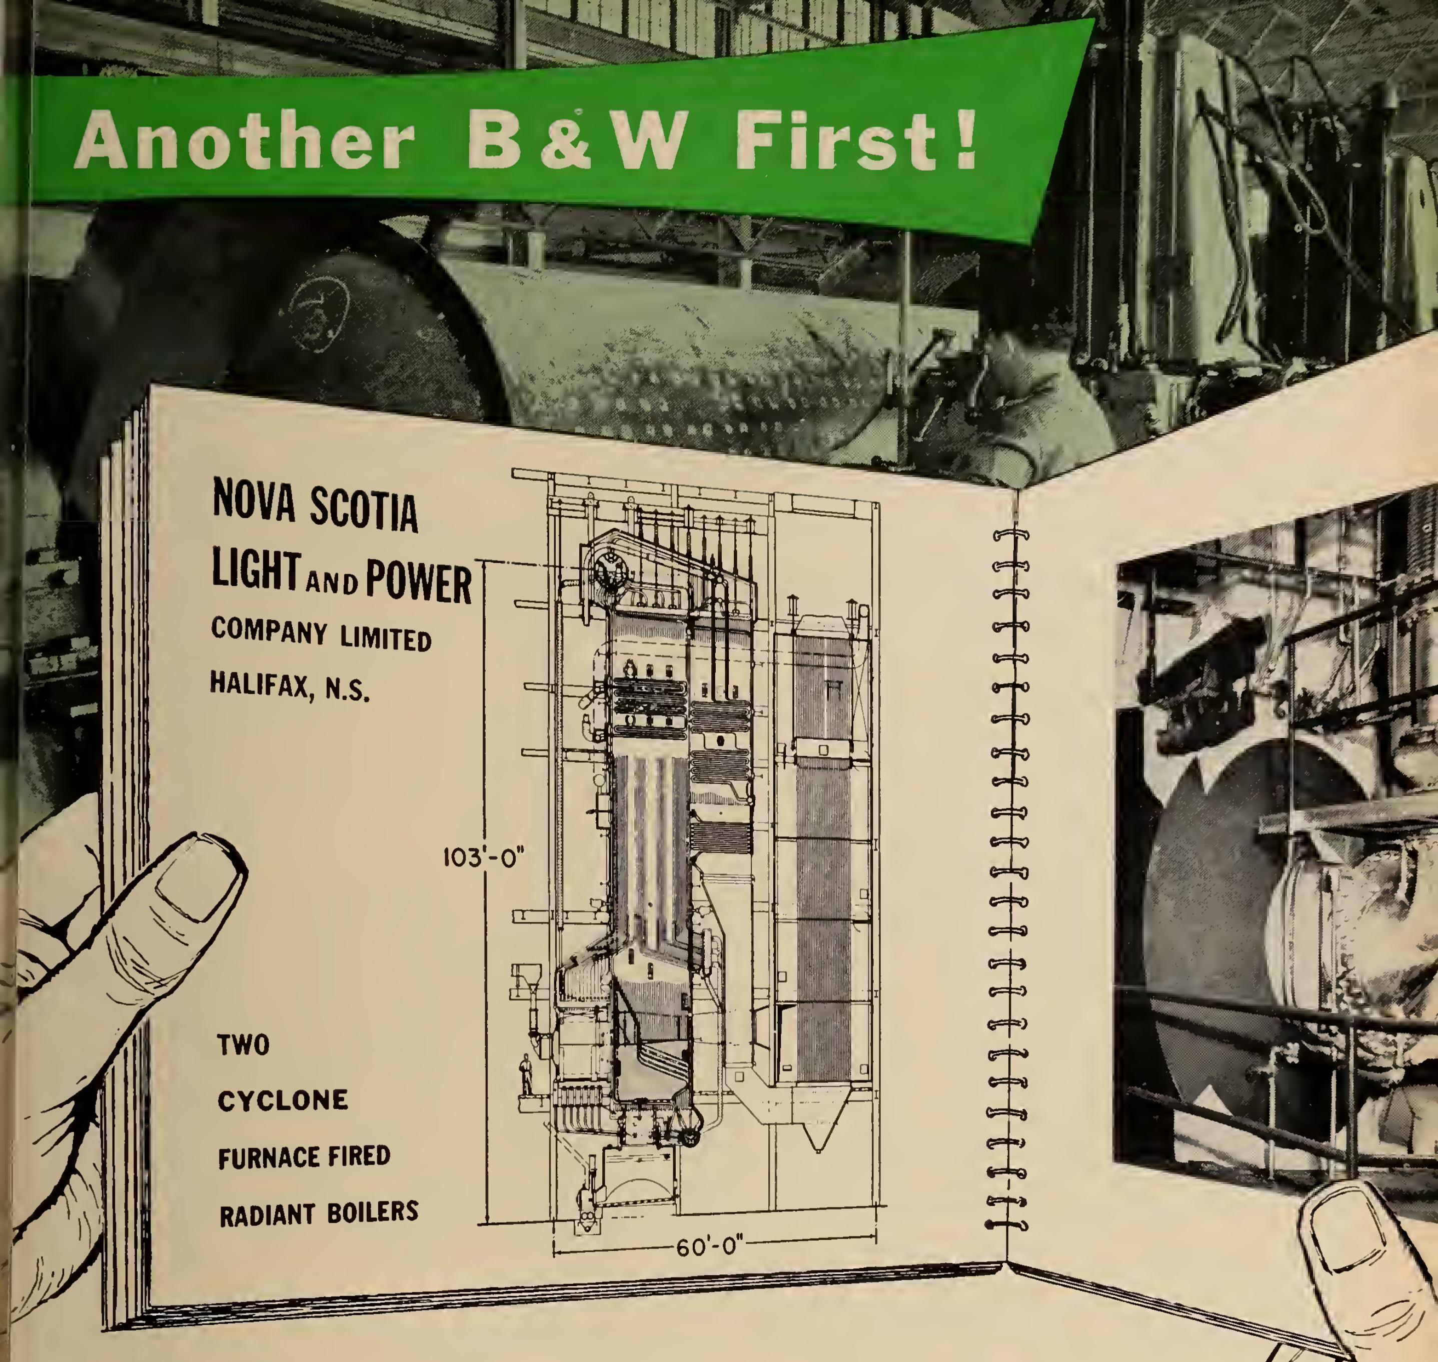
T. Argyropoulos, JR.E.I.C. (B. Eng., mech., McGill 1951) has joined Grumman Aircraft Engineering Corporation, Bethpage, New York, as systems analysis engineer.

David G. Turner, JR.E.I.C. (B.Sc., elec., Manitoba 1958) is a development engineer with the Defence Research Board, Canadian Armament Research and Development Establishment, Valcartier, Que.

Joseph A. Baxter, JR.E.I.C. (B.Sc., civil, New Brunswick 1957) has joined Gill and Company Limited, St. John, N.B., as sales engineer.

M. F. Pittuck, JR.E.I.C. (B.Eng., civil, McGill 1951) of Shawinigan Engineering Company Limited, Montreal, has





...designed – manufactured and erected by B&W in Canada

The first two Cyclone Furnace Fired Boilers in Canada are in successful operation at Nova Scotia Light and Power Company Limited, Halifax—designed to burn a wide variety of fuel, especially low grade coal, and fuel oil.

These modern pressure-fired units with fully drainable superheaters have a combined capacity of 900,000 lbs. of steam per hour at a superheater outlet pressure of 925 psi and a controlled steam temperature of 915° F. Their flexibility, ease of operation and dependability have been outstanding features.

These are the largest steam generating units in the Maritimes.

The foresight of Nova Scotia Light and Power Company Limited in the selection of B&W Radiant Boilers with Cyclone Furnace firing, to meet their power requirements, is a credit to their progressive management and engineering staff.

the meter with NO flow restrictions

now handling all these difficult liquids

Foxboro's first Magnetic Flow Meter went "on stream" in 1954. Today, this new-type meter has gained industry-wide application for precise, linear measurement of corrosive, viscous and other difficult process liquids.

The Magnetic Flow Meter is installed as simply as a length of pipe, with no straight runs required. It connects by standard electric cable to remote Foxboro Dynalog Electronic Recorder. Overall accuracy of the system is ±1%. And the meter even measures reversing flows.

With easy-to-measure liquids, or with tough ones like those listed below, the performance-proved Foxboro Magnetic Flow Meter provides flow measurement with no line restrictions. For complete details, write today for Bulletin 20-14C.

Joseph Ziegler, S.E.I.C. (B.A.Sc., mech., British Columbia 1958) is in Salt Lake City, Utah, where he is employed as a design engineer.

Lionel R. Simard, S.E.I.C. (B.Eng., civil, Polytechnique 1958) is city engineer with the City of St. Lambert, Que.

Specially Shaped Noranda Copper Tubing Provides Extra Strength for Etlin Electrical Connectors

Seamless, pure electrolytic copper tubing is produced by Noranda in a selection of special shapes for electrical solderless connectors. The H. B. Etlin Company, Toronto, one of Canada's major electrical equipment manufacturers, uses the heavy walled five-sided shape illustrated here.

Noranda seamless copper tubing is preferred because of its high mechanical strength as well as electrical conductivity. The tongues are fabricated from heavy Noranda Copper bus-bar for rigid clamping and low heat loss. Ampere range for these connectors is from 25 to 800 inclusive.

Fulfilling special product and component needs is standard practice at Noranda. Noranda technical service stands ready to serve you, your product and production needs—both present and contemplated—on any copper and copper alloy subject, size or shape. A call to your nearest Noranda Sales Office will bring whatever assistance or information you require.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings

BAIE COMEAU

G. W. Scott, M.E.I.C. *Correspondent*

Herbert J. Racey, exec. vice-president of Racey, MacCallum and Associates Limited, Montreal, was the speaker booked for the meeting of February 4. Neill Holloway of the engineering staff of Racey, McCallum substituted for him, giving the paper on Lessons Learned from Structural Failures.

Five cases were discussed: three of concrete structures which had failed because of insufficient protection from freezing in cold weather operations, and two of structural steel failures caused by a lack of provision for the resistance of lateral forces.

BELLEVILLE

D. A. Law, JR.E.I.C., *Correspondent*

R. L. Beck, M.E.I.C., application engineer of C.G.E., Peterborough, was the speaker on March 9. Progress in Atomic Energy was his subject.

The interesting talk, illustrated with slides, reported the application, requirements and economics of nuclear plants for the production of electric power, process steam and combined power and heat.

The fission cycle, thermal cycle, and the physical layout of atomic plants were discussed, and also the different British, American and Canadian approaches to nuclear power. There was a lively discussion period, indicating great interest.

BORDER CITIES

R. L. Kennedy, JR.E.I.C., *Correspondent*

Assumption University was the location and the subject of a panel discussion on January 15, 1959. In the university library, three speakers discussed the history, present standing and future plans of the newly formed university. They were: F. A. DeMarco, chairman of the staff of Essex College; W. H. Arison, chairman of the board of Essex College; and C. T. Carson, chairman of the Engineering Educational Committee.

The Ladies Auxiliary has a membership of 81, and an average attendance of 40 at meetings. The group celebrated their seventh anniversary at the annual dinner meeting this year. New officers elected are Mrs. C. M. Armstrong, president; Mrs. H. V. Chapman and Mrs. J. W. Brison, vice-presidents; Mrs. J. E. Sennot, recording secretary; Mrs. E. T. Rivington, corresponding secretary; Mrs. L. T. Raham, treasurer; Mrs. R. H. Darke, group convenor; Mrs. D. Servage, publicity; Mrs. J. D. Livingstone, Mrs. J. E. Dykeman and Mrs. J. M. Reid, councillors.

Four interest-groups are promoting friendship among the members. Seven general meetings were held during the past year.

Mrs. J. W. Brisson, Mrs. C. M. Armstrong, and Mrs. H. J. Chapman, of the Border Cities Branch Ladies Auxiliary.

EDMONTON

I. G. Finlay, M.E.I.C., *Correspondent*

A joint meeting was held by the Edmonton Branch and the Engineering Students Society, University of Alberta, on January 13. A film on the demolition of Ripple Rock was presented, by courtesy of the Federal Department of Public Works, to an audience of about 200.

The annual joint dinner meeting with the Association of Professional Engineers of Alberta was held on January 23. There were 200 present.

PRESIDENT K. F. Tupper visited the Corner Brook Branch (left) on February 16, the Northern New Brunswick Branch (below) on February 9, and the Halifax Branch (below, left) on February 12. He was accompanied by General Secretary Garnet T. Page. The pictures show:

***Corner Brook:* Mrs. Garnet Page, K. F. St. George, Mrs. Leja, Dr. Tupper, E. A. Leja, Mrs. Tupper.**

***Halifax:* Dr. I. P. Macnab, Dr. Tupper, W. J. Phillips, G. F. Vail, R. D. T. Wickwire; *Northern N.B.:* T. H. McSorley, W. S. Hosking, S. K. Henry, Dr. Tupper, D. C. McCallum, P. Dallien, L. L. Marshall.**

• BRANCH NEWS

FREDERICTON

Lyle W. Smith, JR.E.I.C., *Correspondent*

DR. K. F. TUPPER, E.I.C. president, visiting the branch on February 18, spoke about his Russian tour of last October.

Dr. Tupper was accompanied by Mrs. Tupper, and by General Secretary Garnet T. Page and Mrs. Page.

Welcoming the guests to New Brunswick were: Premier Hugh John Flemming, Public Works Minister J. Stewart Brooks, and Mayor William T. Walker.

Other items of interest announced were: award of life membership to S. W. Babbitt; E.I.C. award to fifth-year engineering student Mr. Gallant; and presentation of Athlone Fellowship to D. Hayward.

NOVA SCOTIA TECHNICAL COLLEGE

John Jay, S.E.I.C., *Correspondent*

THE ANNUAL TECH BALL, was held in Halifax and the exhibits, centering around a "space travel" theme, were judged by prominent engineers and their wives. For the first time, this year, a cup was presented by the Engineering Institute of Canada to the department displaying the best exhibit. J. D. Kline, past chairman of the Branch, presented the trophy to the winning civil engineering department. Their model of a domed city expressed their idea of a city for another planet. Other exhibits included models of rockets, space stations, and space costumes.

SUDBURY

Fred Jackson, M.E.I.C., *Correspondent*

MODERN ELECTRICAL CONTROL IN THE MINING INDUSTRY was discussed by Eric Oldfield, of Canadian Westinghouse Ltd., at a meeting on March 12, 1959. Means of electrical control of mining and reduction equipment were reported.

NIPISSING AND UPPER OTTAWA

D. J. Thornton, S.E.I.C., *Correspondent*

J. W. "WES" MCNUTT discussed the Russian Lumber industry, and the role of the engineer, at a meeting on January 14. He is the president of Wm. Milne Ltd., and Moose Lake Lumber Co., North Bay. His talk was based on a three week visit to Russia in 1956.

Nipissing and Upper Ottawa Branch, front, R. Prescott, Chairman J. S. Cooper, J. Warburton; back, G. M. Goodreid, R. S. MacLennan, P. Rebin, J. Rosborough.

PLASTIC PIPING FOR INDUSTRIAL PURPOSES was discussed by J. E. McEwen, M.E.I.C., on February 11. This monthly dinner meeting was held at Temiskaming, Que. Mr. McEwen is in the plastics division, of Rahn Metals Limited, North Bay, Ont.

He described some of the thermal molding operations by which resin becomes the finished product: e.g. setting, injection, or extrusion molding. Properties of polyethylene, polyvinylchloride and nylon were discussed and of the newly developed polypropylene, which seems to have unlimited possibilities. Uses and applications of plastic piping were demonstrated.

PERMANENT, ECONOMICAL, MODERN

for industrial, commercial, public and private building

CONTINUOUS

STELCOAT

GALVANIZED STEEL SHEETS

Preformed as

WALL PANELS • ROOFING • INSIDE PARTITIONS

PERMANENT . . . "Stelcoat" has the strength that only steel can give, and with normal care will provide long and satisfactory service.

ECONOMICAL . . . "Stelcoat" needs less structural support than other materials and lends itself to streamlined building methods.

MODERN . . . "Stelcoat" is efficient and versatile, to satisfy the colourful requirements of present day design.

Stelco's continuous galvanizing process bonds zinc to steel so tightly that the coating on "Stelcoat" Sheets will not flake, peel or chip, even when worked to the limits of the steel itself. "Stelcoat" Sheets are available flat, corrugated, fluted or ribbed, from all leading fabricators in Canada.

EASTERN TOWNSHIPS

Jean Bourassa, JR.E.I.C., *Correspondent*

EXIT AND RE-ENTRY PROBLEMS OF MISSILES AND ROCKETS were presented by Dr. G. B. Bull at a meeting of February 20, 1959. Dr. Bull is superintendent, aerophysics wing, Canadian Armament Research and Development Establishment, Valcartier, Que.

The speaker told of the problems encountered in aerophysics and of the Canadian research and achievements, from the first experiments at Baddeck, fifty years ago. The modest wind tunnel at the University of Toronto in the 1920's was described. There was also illustration and details of experimental work being done at CARDE on test models propelled in tunnels simulating space flights at very high speed.

At the Eastern Townships Branch meeting of February 20: Geo. M. Dick, Councillor Ben Baker, speaker G. B. Bull, Chairman G. P. Cote, and E. T. Webster.

SASKATOON SECTION

Roger Dupuis, M.E.I.C., *Correspondent*

STUDENTS PAPER NIGHT was attended by 31 students and 14 members. The Student Section was very successful in all phases of the arrangements.

Adjudication was in the hands of Dr. F. H. Edmunds, Department of Geology, University of Saskatchewan. After hearing four well prepared and ably delivered papers, he chose two winners, with wholehearted approval of the meeting: first, R. E. George; second, J. B. Franklin.

Their subjects were, respectively, "Run-in of Journal Bearings with Various Lubricants", and "Feasibility of Direct Current Transmission Lines".

UNIVERSITY OF NEW BRUNSWICK

Hans Foerstel, S.E.I.C., *Correspondent*

ENGINEERING WEEK the week of January 17-23, had these main events:

Wassail Dinner: traditionally, faculty members, president of U.N.B., chairman of E.I.C. Branch told their stories and jokes;

Social night: engineers entertain gals.

Hockey game: Foresters vs. engineers, with heavy losses, engineers won, 5-4.

Film night: Movies on the new Fredericton bridge, with comments by E. Donohoe of Intrusion Prepakt Co. Ltd.

Engineering Formal: apex of the week, well-attended; excellent music, crowning of the engineering queen.

PORT HOPE

D. A. Runciman, JR.E.I.C., *Correspondent*

HIGHWAY PLANNING AND URBAN TRAFFIC PROBLEMS were discussed by A. J. Freedman, municipal studies engineering, Dept. of Highways, at a meeting on February 11, 1959.

Factors to be considered in planning

• BRANCH NEWS

a new, or improving an existing road are: population density of the area; land use near the route, expected traffic density on the proposed road, and many others.

SAINT JOHN

H. K. Larsen JR.E.I.C., *Correspondent*

PRESIDENT K. F. TUPPER, president of the Institute, visited Saint John on February 19, accompanied by Dr. Garnet T. Page, general secretary. They were luncheon guests of the executive. They also attended a branch dinner, with Mrs. Tupper and Mrs. Page, at which members had the opportunity of hearing Dr. Tupper speak on the Institute's international affiliations and on his recent trip to the U.S.S.R. with Dr. Page.

SASKATOON, Ladies Auxiliary

Mrs. W. G. McKay, *Correspondent*

A NEW WOMEN'S GROUP was organized in Saskatoon: The Professional Engineers' Wives Club of Saskatoon.

Mrs. J. B. Mantle and Mrs. E. J. Cole were in charge of an organizational meeting at Clinton Lodge attended by about 50 members. A constitution was set up and the first executive was elected.

Honorary president is Mrs. Mantle. Mrs. H. McI. Weir was chosen as president; other officers are: vice-presidents, Mrs. E. Kent Phillips, Mrs. A. E. Beazely; secretary, Mrs. W. G. McKay, treasurer, Mrs. J. G. Trotter; convenors, Mrs. R. C. Strayer and Mrs. F. A. Gerard. Another meeting was announced for March 3.

SAULT STE. MARIE

R. L. Wimperis, JR.E.I.C., *Correspondent*

"A GIFT OF NATURE", a picturesque but non-technical film on hydro development in Ontario, was shown at a meeting on January 30. The film covers hydro developments historically, including some interesting film taken during the actual building of the earlier projects.

PROFESSOR E. KEMP, Professor of mining and geology, Michigan School of Mining and Technology, Sault Ste. Marie, Mich., was the speaker on February 26; his subject: Geologic Time.

Geologic time is figured by such methods as the rate of decay of Uranium or Carbon 14 in the bodies of old animals and plants. By this scale the earth was formed approximately 10,000 years ago.

TORONTO

G. Norton, JR.E.I.C., *Correspondent*

THE FUTURE OF METALS was the subject discussed by Dr. L. M. Pidgeon on December 11, 1958. Dr. Pidgeon is head of the department of metallurgical engineering, University of Toronto.

Big Wheels in the BLOCK BUSINESS

TIMBERLAND

Rollalloy BLOCKS

The line grooves of Timberland wire rope blocks are flame-hardened. Wire rope does not mark these grooves . . . groove retains its surface and shape—greatly extending wire rope life. All Timberland Rollalloy blocks are mounted on roller bearings. Housings cup around the sheaves and prevent cable fouling. Require only seasonal lubrication.

Buy the Block That Pays For Itself

Remember—these quality features not only ensure maximum safety and long life but return real dividends through savings in wire rope costs. Whatever your requirements, a Timberland engineer can help you get the proper blocks for the job.

Write or phone today for complete literature.

Head Office and Factory: WOODSTOCK, Ontario

BRANCH OFFICES: PORT ARTHUR, ONTARIO, NORTH BAY, ONTARIO, MONTREAL, P.Q.

He divided the 16 most abundant metals into four groups—precious, classical non-ferrous, modern non-ferrous, manufactured metals. He discussed each group in terms of the required capital structure, the complexity of the metallurgy, the marketing problems and the ratio of production cost to selling price. It was said to be possible that aluminum, iron, magnesium and titanium will prove to be the most widely used metals, particularly in view of the advent of atomic energy.

Dr. A. I. Johnson, Associate Professor, Department of Chemical Engineering, University of Toronto, spoke at the meeting of February 19, 1959. His subject was High Speed Photography in Chemical Engineering.

To illustrate the problem of observing phenomena, Dr. Johnson outlined some typical speeds: 22 ft/sec. for the four minute mile; 100 ft/sec. for a 70 m.p.h. train; and 3000 ft/sec. for a bullet. The phenomena which he was studying were in the order of 100 ft. per sec. in one case, and once every 1/300 of a second, in another.

Camera speeds vary from 16 to 6,000 frames per second. Time magnification results when high speed movies are shown at sixteen frames per second. For instance, pictures taken at 6,000 frames per second require 150 seconds of viewing for each second of exposure. Usefulness of the technique was demonstrated by pictures of circulation patterns in drops, formation of air bubbles, air atomization of liquids, nucleate boiling from a hot wire, and mixing of liquids.

UNIVERSITY OF ALBERTA

Elections of Officers for 1959-60 resulted in the following list of officers: President, Jim Ford; vice-president, Dennis Lindberg; second vice-president, Bob McKenzie; Secretary, Elgie McGrath; Treasurer, Rae Donald, social convener, Ron Bullen; sports director, Ray Speer.

WINNIPEG

P. M. Abel, jr.e.i.c., *Correspondent*

The Brandon Generating Station, its design, construction and operation was discussed and illustrated by four speakers from the Manitoba Hydro-Electric Board, on February 19, 1959. They were: A. W. Knight, engineer, J. Karras, engineer, J. Shipper, electrical constructional engineer, and S. C. Irving, superintendent; introduced by J. R. Rettie, manager, engineering and construction division.

The discussion included a general review of the civil, mechanical, electrical, and operating features incorporated into the Brandon generating station. This is a steam turbine station of 132,000 kw. capacity, recently completed and placed into operation by The Manitoba Hydro-Electric Board.

E.I.C. Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a meeting of council in February 1959.

Member: B. B. Babicki, Vancouver; R. Farrand, St. Johns, Que.; J. W. J. Lewis, Winnipeg; A. C. McDonald, Sarnia; O. G. Moffat, Hamilton; H. W. Moxon, Peterborough; R. J. Oliver, Ottawa; A. G. Patil, Montoursville, Penn.; G. L. Ray, Calgary; M. W. Shishakly, Montreal; T. R. B. Watson, Toronto.

Junior: G. A. Escher, Montreal; M. A. Fraser, Montreal; A. Galatis, Montreal; A. A. Palajs, Montreal; M. V. Price, Montreal; R. C. Stutchburg, Baie Comeau.

Affiliate: H. F. Neuman, Calgary.

Member: J. A. M. Bell, Montreal; R. T. Crawford, Calgary; L. Griffith, Texas.

Junior: B. H. L. Tache, La Prairie.

STUDENTS ADMITTED

University of Toronto: C. Alexopoulos; A. J. Barone; D. H. Blenkarn; R. M. Bodrug; P. I. P. Boulton; F. G. Bowyer; J. H. E. Cracknell; B. A. Didyk; J. M. Farley; R. D. Foster; G. D. Gamsby; H. M. Goodfellow; B. C. Gregory; R. E. Howard; R. R. Hudgins; W. P. Inksetter; W. F. Johnson; E. Kovacs; D. K. Laine; J. T. Lawrence; D. J. Morton; M. L. Pearson; M. G. Quaid; E. W. M. Rankin; J. B. Ridpath; D. C. Robinson; A. C. Shaw; L. W. Sobczak; T. H. Topper; W. S. Wei; I. M. Wilson.

E.I.C. ANNUAL MEETING, 1959

TORONTO, JUNE 8, 9, 10

LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

*SYMPOSIUM ON ELEVATED TEMPERATURE STRAIN GAGES

Fourteen papers and a panel discussion covering various types of strain gages, including resistance wire, metal-film, foil, and optical; gage alloys, bonding agents; and temperature compensation techniques. The symposium was sponsored by the Aeronautical Structures Laboratory, Naval Air Material Center in 1957. (Philadelphia, American Society for Testing Materials, 1958. (s.t.p. no. 230.) 163p., $4.50.)

GEOLOGICAL STRUCTURES AND MAPS, 2ND ED.

In this enlarged edition, material has been included which will be particularly useful to civil and mining engineers. The first section of the book consists of a survey of the principles of interpretation of geological maps, including sedimentary rocks; outcrops; folds; faults; erosion; igneous beds; drift deposits; oil bearing structures; borehole and shaft sections; location of concealed coalfields and planning the development of mine workings. The second section contains maps and exercises based on the text. (A. Roberts. London, Cleaver-Hume, 1958. 92p., 12/6.)

*PUNCHED CARDS: THEIR APPLICATIONS TO SCIENCE AND INDUSTRY, 2ND ED.

Beginning with an introduction to the use of a simple punched-card file, the book continues with case histories of punched-card applications including the Peek-a-Boo System, the Uniterm System, mechanized coding and searching techniques applied to the metallurgical literature, the Zato-coding System, and the use of punched-cards in linguistic analysis as applied to ancient texts such as the Dead Sea Scrolls. This is followed by fundamental considerations in coding and system design, future possibilities, and an annotated bibliography on the uses of punched-cards. (Ed. R. S. Casey and others. New York, Reinhold, 1958. 697p., $15.00.)

FUNDAMENTALS OF PIPE DRAFTING

Intended for drafting students with a basic knowledge of mechanical drawing who wish to develop skill in pipe drafting. It covers piping symbols and their representation; diagram drawing; controls; pipe and pipe fittings; specification of parts; detail drawing. The text includes problems and a glossary of piping terms. (C. H. Thompson. New York, Wiley, 1958. 66p., $3.50.)

GROUNDS MAINTENANCE HANDBOOK

This volume covers all aspects of maintenance from the selection of land to the methods necessary to keep the area in first class condition. It covers planning; the growth and maintenance of turf; planting and care of trees, shrubs and perennials; equipment maintenance and use; disease, insect and weed control; soil erosion; roads and parking areas; materials specifications; maintenance of picnic areas. The author is now a landscape artist with the Power Authority of the State of New York on the St. Lawrence Power Project. (H. S. Conover. New York, Dodge, 1958. 501p., $10.75.)

GENERAL THEORY OF ELECTRICAL MACHINES

Based on a graduate course given at Imperial College, this volume presents a general theory applicable to all types of electrical machines. The subjects covered include methods of analysis of machines; d.c. and a.c. machines; d.c. machines in control systems; a.c. operation of synchronous and induction machines; methods for generator and system analysis; the generalized rotating machine. A chronological bibliography covering the years 1923 to 1954 is included. (Bernard Adkins. Toronto, Ryerson, 1957. 236p., $9.00.)

WHO'S WHO IN WORLD AVIATION AND ASTRONAUTICS, 1958

There are over 3000 biographies in this second edition of a useful directory, which, in spite of its title, is concerned mainly with residents of the United States. The persons included are officials of aircraft, engine and associated industries, scientists, air force officers, government officials and others who have taken an interest in or contributed to aviation, astronautics and allied fields. (Ed. by M. E. Grambow. Washington, American Aviation Pubs., 1958. 497p.)

AGREGATS LIANTS ET BETONS HYDRAULIQUES, ACIERS ET METAUX USUELS

The first section of this volume deals with various kinds of aggregates for hydraulic concrete, hydrocarbon concrete, and concrete used for roads. The second section considers limes and cements used in construction, with standards for their manufacture and use. Mortars and hydraulic concrete are discussed in the third chapter, and steel and other metal used in construction in the last. The book contains a great deal of very detailed information. (J. Arrambide and M. Duriez. Paris, Editions du Moniteur des Travaux publics, 1958. 596p., 2475 fr.)

TABLES ABREGEES DE PUISSANCES ENTIERES

Tables prepared especially for use with calculating machines, giving whole powers of numbers higher than cube. These powers are given in the tables to ten, and sometimes to fifteen significant figures. The author explains the method by which the tables have been calculated in his introduction, and also explains their use. The tables have been printed

---

THE ENGINEERING INSTITUTE LIBRARY

The publications mentioned in these Notes are now available in the Library. Members of the Institute may borrow books, periodicals, pamphlets, etc. from the Library. The loan period is two weeks, excluding time in transit, and two items may be borrowed at one time. Library hours are: Monday to Friday: 9 a.m.—5 p.m.; Saturday: 9 a.m.—12 noon.

Because of a recent change in policy, publications (except periodicals published by other engineering societies) may no longer be purchased through the Library. If members have difficulty obtaining material locally, it is suggested they write to the Library, and the enquiry will be forwarded to an appropriate bookseller. For further information write to the Librarian.

by photographing the original handwritten sheets, to avoid error in composition. (P. Montagne. Paris, Dunod, 1958. 411p., 5,600 fr.)

PRECIS D'ELECTROTECHNIQUE A L'USAGE DES INGENIEURS

Translated from the English edition, Basic Electrotechnics, this volume is intended as a text for electrical engineering students, and covers basic electromagnetic theory. The topics dealt with include steady and alternating current theory, electrostatic fields, condensers and dielectrics, electrodynamics, the calculation of magnetic fields, Maxwell's equations and electromagnetic waves, generators and other apparatus. (B. L. Goodlet. Paris, Dunod, 1958. 354p., 3300 fr.)

CIRCUITS A RELAIS ET AUTOMATISMES A SEQUENCES

In this volume the author presents methods for the analysis and synthesis of relay circuits in calculating machines. The first three chapters contain a general survey of the subject, the operation of the machines, some examples of circuits, and an outline of coding and programming. The remaining chapters consider in more detail the two fundamental problems connected with this subject, the systematic simplification of logical functions and the establishing of contacts to satisfy a given system of logical equations. (P. Naslin. Paris, Dunod, 1958. 240p., 2700 fr.)

MESURES EN RADIOTECHNIQUE

Intended as a handbook for students, to bridge the gap between theoretical courses and actual practical applications, this text tries to give general principles rather than actual experiments. The eleven chapters cover: general characteristics of materials and of measuring instruments; circuits; low, and very high high frequency measurement; vacuum tubes; high frequency impedance measurement of radioelectric frequencies; transmitters; electromagnetic fields; receivers. (E. Fromy. Paris, Dunod, 1958. 784p., 9800 fr.)

*SCIENTIFIC USES OF EARTH SATELLITES, 2ND ED.

The present edition has been enlarged to the extent of almost being a handbook of earth satellites. Those areas most extensively revised are the orbit of a small earth satellite, insolation of the upper atmosphere and of a satellite, meteorological measurements and measurements of the earth's magnetic field from a satellite vehicle, ionospheric structure as determined by a minimal artificial satellite, and measurements of interplanetary dust. (Ed. by J. A. Van Allen. Toronto, Ambassador, 1958. 316p., $13.50.)

UNFIRED PRESSURE VESSEL CODE SIMPLIFIED

This latest edition is based on the A.S.M.E. Code and contains simplified charts for internal and external pressure; shell thickness, flanged and dished head thickness, flat head thickness, flat cover plate thickness and openings and reinforcements, external pressure on heads, stamping, head and shell volumes, welding qualification positions, new information on magnetic particle and penetrating oil tests, plate identification, nonidentified material, articles on Canadian pressure vessel requirements, the Code symbol and certificate procedure to follow to obtain them, and welded repair procedure. (R. Chuse. Leonia, N.J., 1958. 48p., $6.50.)

RADIO COMMUNICATION

The fundamentals of radio communication theory are presented in this text which is written at the undergraduate level. Some of the topics covered include: circuits; transformers; sound reproduction; radio transmission and reception; feedback; amplifiers; oscillators; modulation; radio waves; transistor amplifiers, etc. The book is written from the viewpoint of the engineer rather than the mathematician. (W. F. Lovering. Toronto, Longmans Green, 1958. 536p., $10.80.)

ELECTRONIC DIGITAL COMPUTERS: THEIR USE IN SCIENCE AND ENGINEERING

The emphasis in this volume is on the operation rather than the design of computers, and the capabilities and uses of the various types of machines are discussed. The author first considers functions, components, number representation, memory, input and output. Other chapters cover coding and programming, problem analysis and machine operation. There is a useful bibliography. (F. L. Alt. New York, Academic, 1958. 336p., $10.00.)

UPLIFT IN GRAVITY DAMS

The author's first publication on the subject of uplift was a letter which appeared in Nature in January 1942. He has since published several papers and reports, and this volume presents his latest theories. The first two chapters discuss the different theories which have been advanced for the calculation of the pressure of water infiltrating through the material of a gravity dam. In the third chapter, the various experimental approaches to the problem are considered, and the problems associated with these. The final chapter discusses the methods of reducing uplift pressure and leakage in dams by providing a waterproof screen. (Serge Leliavsky. Toronto, Longmans Green, 1958. 267p., $9.00.)

*THOMAS TELFORD

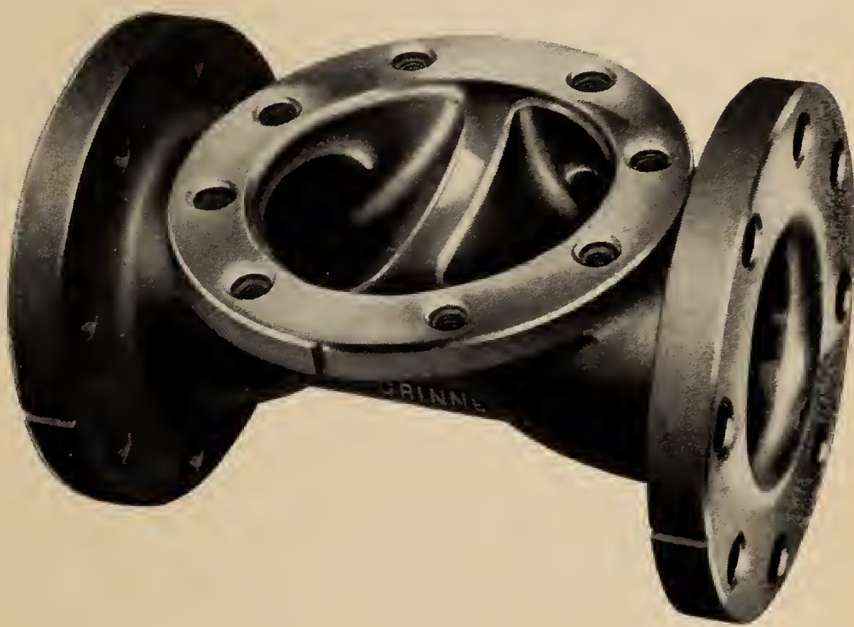
The story of a great Scots engineer who built bridges, roads, aqueducts, and canals. The author has written a more detailed account than has hitherto been available, and at the same time has tried to present a portrait of Telford as a man. In addition to his great engineering feats, Telford served as first president of the Institution of Civil Engineers, and occupies a significant place in the history of engineering. (L. T. C. Rolt. Toronto, Longmans Green, 1958. 211p., $5.00.)

*AXIAL FLOW COMPRESSORS

Beginning with a brief review of basic fluid dynamics and thermodynamics, the book continues with a discussion of two

Now... you can have Grinnell-Saunders* Diaphragm Valves of

Ductile Iron with Glass-Lined Bodies



Saunders — Reg. Trade-mark

After long research, Grinnell has available top quality, corrosion-resistant glass lined bodies for its line of rugged ductile iron valves.

EXTRA TOUGHNESS The greater toughness of ductile iron resists impact, torsion, line strains and thermal shock. Grinnell-Saunders valves of ductile iron handle severe service requirements where both internal and external impact shocks may be expected, and where piping stresses from rapid heating and cooling occur.

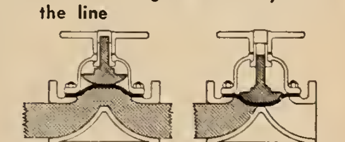
ECONOMY Approved and used by leading industries, ductile iron offers many of the benefits of cast steel at a lower price.

Of particular importance to users of Grinnell-Saunders valves is that ductile iron bodies can now be *glass-lined*—a procedure not practical with cast steel bodies.

WIDE SELECTION Body linings: glass, rubber, neoprene. Diaphragms: soft natural rubber, natural rubber, white synthetic rubber, neoprene, reinforced neoprene, butyl, Hycar, Teflon, Kel-F, PVC (polyvinyl chloride), polyethylene. Bonnet materials: ductile iron, grey iron. Bonnet styles: handwheel (non-indicating stem or indicating stem), chain wheel, lever for quick operation, and sliding stem for a wide selection of power operated topworks.

Important features of the Grinnell-Saunders Diaphragm Valve

- Diaphragm completely isolates operating mechanism from the fluid in the line
- Diaphragm lifts high for full, streamline flow in either direction
- Diaphragm effects positive, leak-tight closure
- Diaphragm easily replaced without removing valve body from the line



OPEN   CLOSED

GRINNELL-SAUNDERS DIAPHRAGM VALVES

Grinnell Company of Canada Ltd. • Edmonton • Montreal • Toronto • Vancouver • Winnipeg • Distributors in Principal Cities

pipe fittings • welding fittings • pipe hangers • valves • Grinnell-Saunders diaphragm valves • pipe prefabricated piping • heating specialties • water works supplies • Grinnell automatic fire protection systems dimensional cascades; pitch line design of compressor stages; calculation of losses, stage efficiencies, and characteristics; compressor testing and instrumentation; supersonic compressors. Extensive references are given. (J. H. Horlock. Toronto, Butterworth, 1958. 189p., $8.00.)

°SAMPLED-DATA CONTROL SYSTEMS

Discusses the basic theory of sampled-data control systems in particular and circuits, networks, computers, and system engineering in general. A general approach is provided to mixed digital-analog linear systems along with a thorough discussion of the z-transform method which can be applied to a wide variety of fields. Problems arising in feedback control systems are solved and discussed by means of application of digital computers. General applications of the z-transform method and the operational solution of linear difference equations are enumerated and clarified. (E. I. Jury. New York, Wiley, 1958. 453p., $16.00.)

PROCEEDINGS OF THE CONFERENCE ON THE PROPERTIES OF MATERIALS AT HIGH RATES OF STRAIN

This conference was held in London in 1957, under the auspices of the Institution of Mechanical Engineers. Twenty-two papers were presented on a subject which is becoming of increasing importance. The paper at the first session dealt with the deformation of solids at high rates of strain. The other sessions considered experimental techniques, metal working, impulse loading and stress waves, non-metallic materials, and basic properties of materials. (London, Institution of Mechanical Engineers, 1958. 268p., £3.3.0.)

°AMENAGEMENT, UTILIZATION ET PRIX DE REVIENT DES USINES HYDRAULIQUES

This book is the first volume of a treatise on hydraulic engineering. The first part deals with the general mechanics of hydraulic engineering, equipment, analyses of power systems, and the various aspects of electrical power. Then the integration of water power production into the total production of the country, and the problems of conservation of water supply are discussed. The last part deals with economic factors involved in the production and distribution of power. (H. Varlet. Paris, Eyrolles, 1958. 211p., 3,000 fr.)

°TOPICS IN ELECTROMAGNETIC THEORY

A unified treatment of topics in the field of electromagnetic theory and microwave electron tubes. The first chapter is devoted to periodic transmission systems and lays the groundwork for the following chapters which deal with propagation on a wire helix, concepts concerning coupling of modes of propagation, and anistropic media with particular reference to the ferrite. (D. A. Watkins. New York, Wiley, 1958. 118p., $6.50.)

°JUNCTION TRANSISTOR ELECTRONICS

An attempt to provide engineers with a co-ordinated source of information about the characteristics and circuit applications of transistors. The first half of the book deals with low frequency, linear applications and with background device physics and characteristics. The remainder of the book covers more general network analysis techniques, a greater variety of circuit applications, more complicated broadband and high-frequency circuits, and non-linear switching applications. Useful tables of transistor circuit formulas and a substantial number of numerical examples are included. (R. B. Hurley. New York, Wiley, 1958. 473p., $12.50.)

°INTRODUCTION TO THE THEORETICAL AND EXPERIMENTAL ANALYSIS OF STRESS AND STRAIN

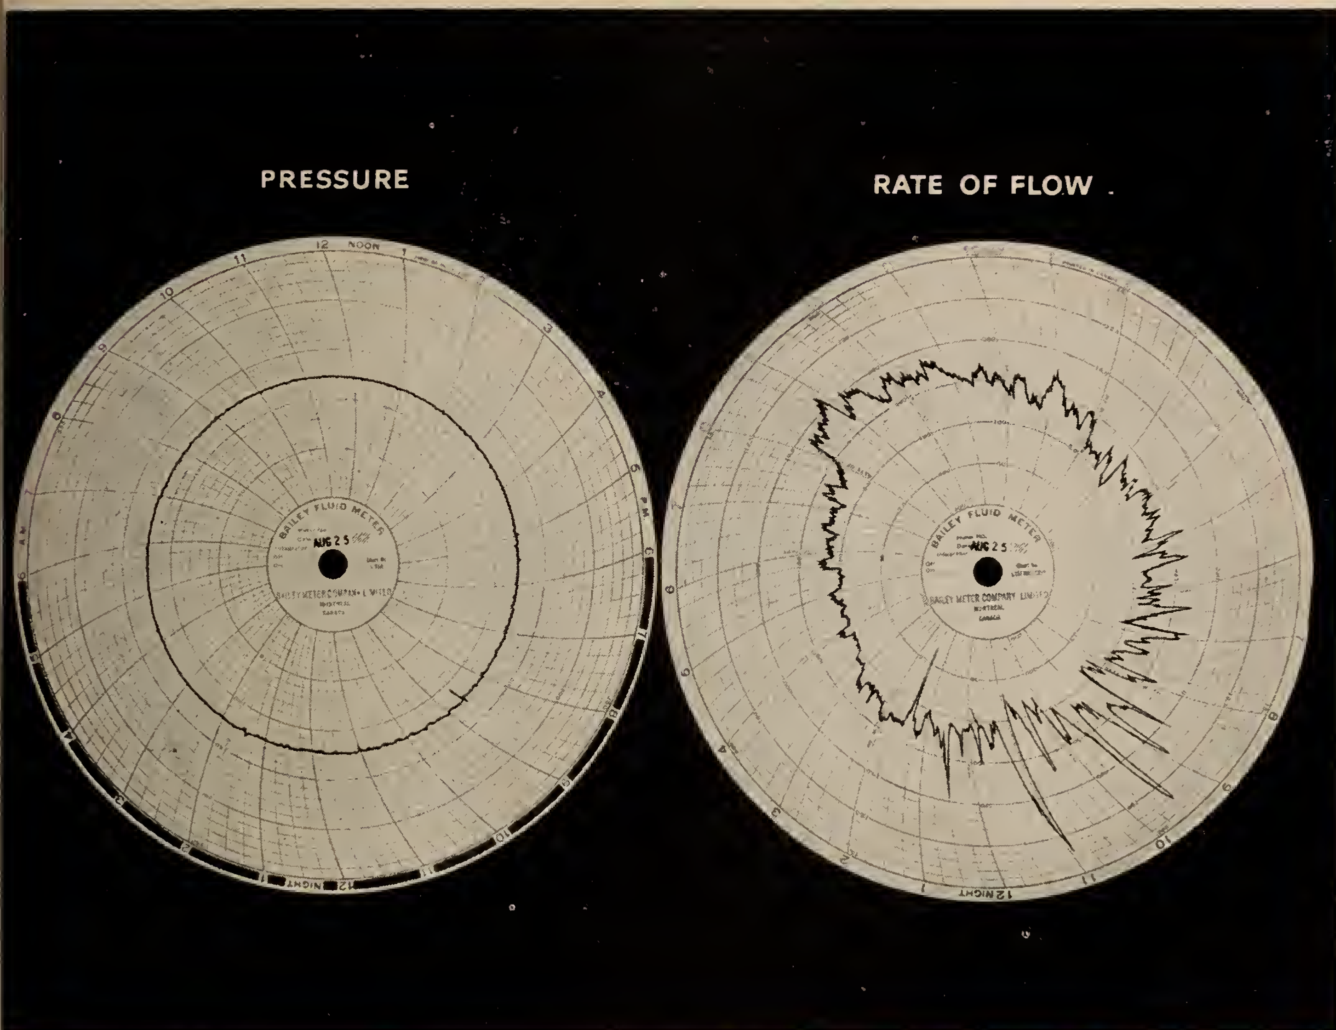
An introduction to the field of stress analysis that covers the theory of elasticity, dimensional analysis, mechanical strain gages, brittle coatings, and grid methods. The theory of elasticity is presented from the general three-dimen-

Edmonton depends on

Bailey!

Every hour of every day Edmonton's water works maintains a constant water pressure . . . and BAILEY does it!

The Bailey Air Operated Control System, automatically regulates two 15,000,000 Imperial Gallon capacity, variable speed, high lift pumps each fitted with a hydraulic coupling . . .



Here are the Pressure and Rate of Flow records from one of these high lift pumps. Note what happened at 10.55 p.m. on August 25th . . . the flow increased 10.2 M.I.G.P.D. (67% of pump capacity) almost instantaneously, and there was a momentary drop in pressure of only 5 psi!

During the 24 hours when these charts were being recorded only one variable speed pump was in operation . . . and its output represented approximately 20% of the total plant output.

Every minute of every hour, Edmonton's water supply depends on BAILEY!

Bailey Meter Company Limited

HEAD OFFICE: 1980 CLAREMONT AVE., MONTREAL

ENGINEERS AT YOUR SERVICE FROM COAST TO COAST sional point of view, and although the conventional parallelopiped approach is used, a rigorous theoretical development is given where necessary. Technical detail has been de-emphasized in favor of basic concepts which are applied to the solution of specific problems. (A. J. Durelli and others. Toronto, McGraw-Hill, 1958. 498p., $15.00.)

TIMBER ENGINEERING DESIGN HANDBOOK

Written by three senior officers of the Timber Mechanics Laboratory of the C.S.I.R.O., this handbook is intended primarily for Australian engineers and architects, but will prove valuable to all those interested in timber construction. It covers the use of timber as a structural material; design loads; design stresses for solid timber; the design of beams, columns, joints and trusses; glued laminated construction; the structural use of plywood; proof testing and preservation. The final chapter gives examples of timber structures, both in Australia and elsewhere. (R. G. Pearson and others. Melbourne, University Press and Commonwealth Scientific and Industrial Research Organization, Toronto, Macmillan, 1958. 248p., $5.00.)

*SEWERAGE AND SEWAGE TREATMENT, 8TH ED.

The sewage project is covered from its inception to design, construction, operation, and maintenance. In this revised edition, new material on oxidation ponds has been included, and the attention to practice in sludge treatment and disposal has been increased. Additional information is also given on the subject of stress-pollution prevention and the oxygen-sag curve. A review of the literature since the last edition in 1952 is presented and approximately half the illustrations are new or revised. (H. E. Babbitt and E. R. Baumann. New York, Wiley, 1958. 790p., $10.75.)

HOW TO TROUBLESHOOT A TV RECEIVER, 2ND ED.

New subjects in this revised edition include portable TV receivers, vertical chassis, and printed circuits. The volume is concerned more with the location of the fault in the receiver than its repair. (J. R. Johnson. New York, Rider, 1958. 150p., $2.50.)

METALLIC RECTIFIERS AND CRYSTAL DIODES

A comprehensive discussion of the principles and practices of metallic rectifiers and crystal diodes, their applications and practical possibilities. (Theodore Conti. New York, Rider, 1958. irreg. paging, $2.95.)

*INTRODUCTION TO A STUDY OF MECHANICAL VIBRATION, 2ND REV. ED.

Reviews the elementary theory of mechanical vibrations as well as some of the more important vibration problems encountered in practice. This edition deals in greater detail with vibration amplitude in rotary machines and with the principles of and the instruments for the measurement of vibrations. (C. W. Van Santen. Galt, Brett-Macmillan, 1958. 310p., $8.50.)

*PRESTRESSED CONCRETE: THEORY AND PRACTICE

Discusses structural analysis, design, and current practical procedures; tanks and pipes; bridge deck analysis; deformation of prestressed concrete and transmission length; overload, ultimate strength and partial prestressing; unit mold and long-line systems; the Lee-McCall, Freyssinet, Magnel-Blaton, Gifford-Udall, and other systems; friction; anchorage stresses; roads and runways. (P. B. Morice and E. H. Cooley. Toronto, Pitman, 1958. 394p., 57/6.)

*CAUSES AND PREVENTION OF CORROSION IN AIRCRAFT

Considers such aspects as causes and prevention of corrosion in engines; corrosion in electrical equipment; the electroplating process; anodic oxidation of aluminum and chromating of magnesium;

• LIBRARY NOTES

metallizing processes; paints, enamels, varnishes and resins for protecting aircraft components; non-destructive examination. (T. C. E. Tringham. Toronto, Pitman, 1958. 124p., 25/-.)

*AERODYNAMICS OF SUPERSONIC FLIGHT, 2ND ED.

Covers flow in a duct, two-dimensional flow, the oblique shock, approximate theories, supersonic wind tunnels, three dimensional flow, and performance calculations. This new edition contains additional material on the aerodynamic theory and the design of a simple supersonic wind tunnel as well as various revisions throughout the text. (A. Pope. Toronto, Pitman, 1958. 243p., $3.55.)

TECHNICAL BULLETINS AND PAMPHLETS RECEIVED

Architecture
Small house designs. Ottawa, Central Mortgage and Housing Corporation, 1958.

Asbestos
The Canadian asbestos industry, by E. J. Bonkoff. Toronto, General Research Associates, 1958.

Awards
Scott Turner; Hoover medalist 1957. New York, Hoover Medal Board of Award, 1957.

Construction industry
Should private firms plan public works? by Robert Moses. (Reprint from the New York Times Magazine of Nov. 16, 1958) (Some copies available in the EIC library.)

Foundations
Tables for the calculation of passive pressure, active pressure and bearing capacity of foundations, by A. Coquot and J. Kerisel. Paris, Gauthier-Villars, 1948. 960 fr.

Mathematics
Cours d'exercices sur le calcul mathematique: algebrique, differentiel and integral, by M. Laboureur. Paris, Librairie Polytechnique Ch. Beranger, 1955.

Graded examples in mathematics for national certificate students, by E. G. Shalders. Books 1, 2, and 3. London, Blackie, 1958. 5/- each.

New periodical
The first issue of Jl. of Engineering for Power, one of a series of new quarterly publications initiated by The ASME appeared in Jan. Other quarterlies to be issued by the Society during the year under the general heading, Transactions of the ASME, will be Jl. of Engineering for Industry, Jl. of Basic Engineering, Jl. of Heat Transfer and the long-established Jl. of Applied Mechanics.

Porous materials
Effect of temperature distribution on moisture flow in porous materials, by W. Woodside and J. M. Kuzmak, Ottawa, N.R.C., Division of Building Research, 1958. (Research paper no. 68) 10c

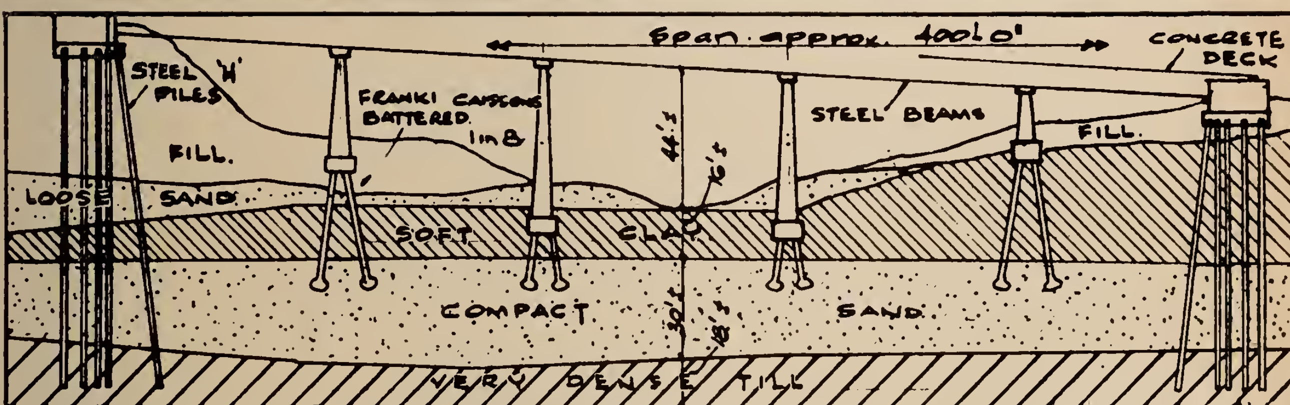
A possible force mechanism associated with the freezing of water in porous materials, by L. W. Gold. Ottawa, N.R.C., Division of Building Research, 1958. (Research paper no. 66) 25c

Sscholarships
Report on university support for science, engineering and medicine for the 42nd year of operation, 1958-59. Ottawa, N.R.C., 1958. 50c

Soil mechanics
Soil moisture tension and ice segregation by E. Penner. Ottawa. N.R.C., Division of Building Research, 1958. (Research paper no. 67) 25c

RANKI FACTS

Franki Caissons Overcome Don River Bridge Pier Foundation Problem



PROJECT:	Bridge
OWNER:	D.H.O.
LOCATION:	Don River and H'way 401—Toronto
GENERAL CONTRACTOR:	Steed & Evans Ltd. Maple, Ontario
NO. OF FRANKI CAISSONS:	112
WORKING LOAD:	100-tons
ERAGE CONCRETED LENGTH:	15'-25'
NO. OF STEEL-H PILES:	120
AVERAGE LENGTH:	72'

Problem

To arrive at the most practical and economical foundations for bridge piers which had to be built over 30' of compact sand topped by about 16' of soft clay. (See sketch.)

Solution

Franki Caissons were used for the pier foundations, obtaining high load capacity in the permeable sand layer, at economical depths.

For the abutments, with lighter loads and a considerable thickness of compacted fill to penetrate, Steel-H Piling was used. To obtain adequate bearing, the Steel-H piles had to be driven to the till.

This illustrates well the considerable saving in length and cost that can be achieved by using Franki Caissons where the soil is granular.

Literature — This series of job highlights, as well as other descriptive literature, will be sent to you upon request to Franki of Canada Ltd., 187 Graham Blvd., Montreal 16, P.Q.

MANITOBA

Public Relations

by R. W. Hutchinson, P.Eng.
From *The Manitoba Professional Engineer*, March, 1959, an abstract.

The public respect afforded the profession is proportional to the effectiveness of its public relations program. The engineering profession, perhaps more than any other, has a need for a solid public education program. Our very name "engineer" has a broad application used to describe anybody from a locomotive operator to a rocket scientist. Most of us do not deal directly with the public and hence our exact function is not clear to many people.

The responsibility of good public relations rests not only with Council and the public relations committee, but also with the membership at large. One of the most encouraging signs in recent years is the increased interest the professional engineer of Manitoba is showing in his Association. For example our Committee is at present offering a career advisory program for high school students. The response to our request for speakers has been most gratifying and this program is providing sound guidance for future engineers as well as helping many professional engineers to develop their ability to speak in public and enhance their profession.

QUEBEC

Results of the 1958 Salary Survey

The BULLETIN of the Corporation of Professional Engineers of Quebec features tables and graphs illustrating the findings of the survey it made last year.

These notes are given:

Median salary of Quebec engineers did not change from last year; it remained at $7,800, after experiencing increases in 1957, 1956 and 1955.

Average of the changes in income earned at the median level *by years of engineering experience* amounted to a 0.7% increase as against 5.1%, and 7.8% in 1957 and 1956 respectively.

Average of the changes in income earned at the median level *by each year of graduation or equivalent* amounted to a 4.6% increase as against 9.3% and 12.2% in 1957 and 1956 respectively.

Consulting remained the field of work where earnings are the highest; median income of engineers engaged in this field was $8100, and 25% of them had earnings equal to or greater than $12,000.

Engineers holding executive positions form the best-paid group; median income of these engineers was $10,850.

Figures clearly show that, as time progresses engineers 'migrate' from nonsupervisory work into work of a supervisory nature and eventually into managerial functions.

If we had to select a 'typical Quebec P.Eng.', using as the basis the information made available through the survey, the engineer selected would have graduated in the last ten years and would have supervisory responsibilities in industry.

BRITISH COLUMBIA

The University and You,

by G. E. Baynes, P.Eng.
An editorial in *The B.C. Professional Engineer*, February, 1959.

A committee of engineering graduates was recently established by the U.B.C. Alumni Association to discuss with the University the appointment of a new Dean of Applied Science. This committee consisted of Harold P. Moorhead, P.Eng., Rod Lindsay, Dave Brousson, Terry Lynch, Alumni Director John Haar, and the writer.

Our help to the University was almost significant and we believe that it will be difficult to replace a man of Dean Henry Gunning's calibre.

However, what we did learn about the problems of the University, and particularly of the engineering faculty, was most revealing.

There is no doubt that our university is suffering from a bulge in population. There are now 1,100 in Applied Science, all endeavouring to become engineers, and some with almost insurmountable handicaps. Some commute twice each day through our time-wasting traffic, others live in substandard basements or attics. Because of this congested living and travelling not more than ten percent of these students take part in any sport or club facility offered on the campus. Few of these young men ever really know their professors or know their university.

Our country has many resources, but perhaps the most important of all is the young man capable of advanced training. This training has never been easy, but there must be a limit to the frustrations that a young student can endure.

There is a real need for standard, student, living accommodation on the campus. The dormitories now under construction are the first of the men's residences and will only meet a small fraction of the requirements.

It is most vital that the teaching be maintained and the provincial budget be extended to meet this requirement. There is a need for more bursaries and scholarships to overcome the proposed raise in student fees.

Your university needs your interest and your help. We must ensure that talent is not lost or frustrated through removable circumstances.

ALBERTA

President Govier Comments

From *The Alberta Professional Engineer*, January, 1959, an abstract.

The engineer's role in the development of the natural resources of a country is one of great importance. It is his technical knowledge and skill which guides both the exploratory effort required to find the resources and the plans and designs for the subsequent development of them. Moreover, although perhaps less well appreciated, it is on the confidence placed in his honesty, integrity and ethics that projects for the development of resources are financed.

But the engineer's value is by no means restricted to his technical contribution. Projects for the development of natural resources require money, often in very large amounts. This money is made available by corporations, the general public, or from government, only when the project is judged to be worthwhile.

The judgment of the practicability of projects of this kind is ordinarily based upon valuation and feasibility studies prepared by professional engineers. These studies are accepted by corporation management, financial houses and security commissions primarily because of the confidence which is placed in the honesty, integrity and ethics of the Professional Engineers. Thus in the last analysis it is the professional qualities of the engineer which enable the projects incorporating his scientific and technical solutions to proceed. We in the profession must protect our good name not only by maintaining high technical standards but also by jealously guarding our professional ethics.

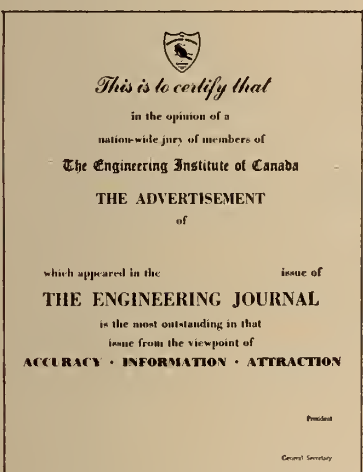
E.I.C. Advertising Award

First judging of "Journal" Advertisements Results in a "Tie"

In January of this year the Institute commenced the monthly award of certificates for the best advertisements in the current issues of the "Journal".

Each month, fifty readers are being asked to study the advertising pages to select the advertisement which is, in their opinion, the best from the viewpoints of ACCURACY — INFORMATION — ATTRACTION. The names of the judges are picked, at random, from the various provincial mailing lists — five names per province.

The judging of the advertisements in the January issue resulted in a tie in the number of votes for two advertisements — Dominion Bridge Co. Limited — a two-page advertisement on pages 78-79, and Peacock Brothers Limited (Rockwell-Nordstrom Valves), also a "double page spread", on pages 16-17. To each of these companies, a certificate of merit will be presented.



This is to certify that
in the opinion of a
nation-wide jury of members of
The Engineering Institute of Canada
THE ADVERTISEMENT
of
which appeared in the issue of
THE ENGINEERING JOURNAL
is the most outstanding in that
issue from the viewpoint of
ACCURACY · INFORMATION · ATTRACTION
President
General Secretary

E.I.C. CERTIFICATE
The certificate, which measures 8½" x 11½", is awarded each month to the advertisers whose advertisements are judged the best in the current issue. These certificates are completed with the name of the advertiser and the issue in which the advertisement appeared. All advertisements appearing in the "Journal" are eligible for the award.

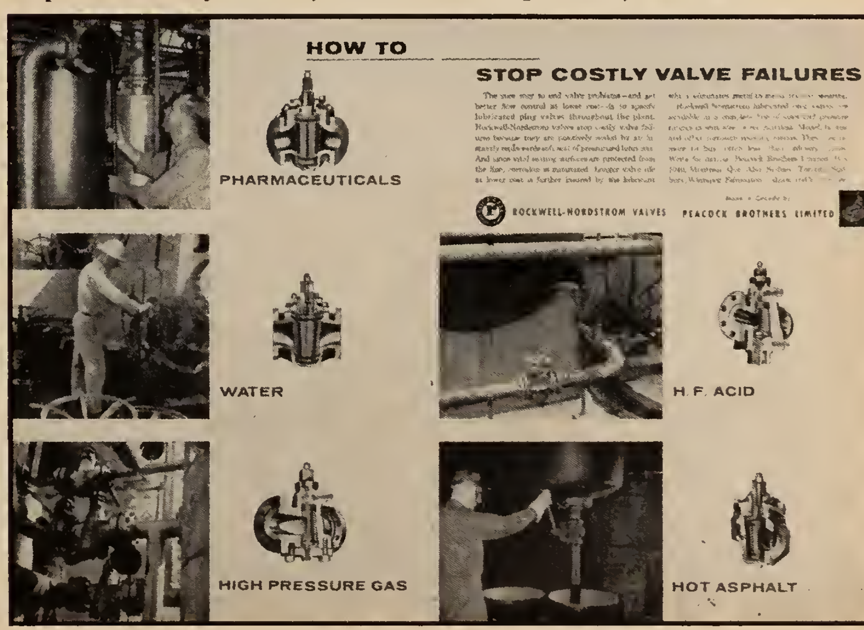
The main purpose of this judging is to gain a good cross-section of opinion as to the type of advertisement which has the strongest appeal and is of the greatest use to Canadian engineers. The various advertisers, and their agencies, will be kept informed as to the opinions of the judges — whose names will not be divulged — so that they will know the type of advertising message most acceptable to our readers.

This opportunity is taken to thank those readers who have already served as "judges" and to ask all who may receive a request to serve the Institute in a similar manner to return the questionnaires they receive within five days of receipt.

Congratulations are extended to the Dominion Bridge Co. Limited and Peacock Brothers Limited on the winning of the first Engineering Institute of Canada Certificate of Advertising Merit.

DOMINION BRIDGE ADVERTISEMENT
This advertisement, which appeared in the January issue of The Engineering Journal, tied for the greatest number of votes for the best advertisement in the issue. The jurors were fifty members of the Institute. The advertising agency, which placed the advertisement, is McKim Advertising Limited, Montreal.

PEACOCK BROTHERS ADVERTISEMENT
This advertisement for Rockwell-Nordstrom Valves tied for first position, with an advertisement of Dominion Bridge Co. Limited. Both advertisements appeared in the January issue. The advertisement was prepared by Marsteller, Rickard, Gebhardt & Reed, Inc., Pittsburgh, Pa., and was placed in the "Journal" by McKim Advertising Limited, Montreal.



awarded a $9,000,000 contract for production of height-finding radar equipment for the Pinetree radar line in Northern Canada to the Canadian General Electric Company Ltd. The equipment will be part of the integrated defence system of the continent. Most of it will be built at the Royce Works plant in Toronto, but some will be contracted to Canadian suppliers.

Nylon Automobile Parts — Almost 250 different items in some of this year's cars are made of "Zytel" nylon resin, according to Dupont of Canada Limited (Box 660, Montreal). The total weight of all parts made of this material and used in the average new car is less than one pound.

Nitrile Silicone Rubber — NSR-X5602, the first product in the new family of G-E Nitrile silicone rubbers, is now available from Canadian General Electric's Chemical Department, 940 Lansdowne Avenue, Toronto. It is intended for intermittent contact with high-swell fluids or continuous immersion in milder fluids. It is described as having "intermediate fluid resistance". NSR-X8701 available in March; NSR-X4803 is available in April.

RTV silicone rubber, recommended for electrical potting and encapsulating and for high and low temperature sealing and caulking is described in CBS-170, a new bulletin available from Chemical Materials Section, Canadian General Electric Company (940 Lansdowne Ave., Toronto).

Railway Operating Deficit — The Canadian National System shows operating revenues for January 1959 as $55,676,000; expenses, taxes and rents, $60,422,000; and a net operating deficiency $4,746,000.

Gate Valves — Crane Limited has initiated the manufacture of valves of top quality to meet A.W.W.A. specification, according to the company. To conform with various types of joints they are available in several types of end connections. For literature on Crane A.W.W.A. double disc gate valves, contact Crane Limited, 1170 Beaver Hall Square, Montreal.

New Chemical Plant — Expansion of its facilities in Eastern Canada is being made by Electric Reduction Company of Canada, Ltd. The next stage involves a multi-million dollar expenditure for plants to produce sulphuric and phosphoric acids, sodium phosphates and other products. These plants will be located at Port Maitland, Ont. Sodium chlorate expansions have recently been completed for the company at Buckingham, Que. and Vancouver, B.C.

Public Transportation System — Quebec Power Company has sold its 100 per cent ownership of shares of Quebec-Autobus Ltee, which operates the public transportation system in Quebec City, to Transport Regional Ltee.

New Ownership — Union Carbide Canada Limited and Shawinigan Chemicals jointly announce that Shawinigan Chemicals Limited has become sole owner of Canadian Resins and Chemicals Limited, through acquisition of Union Carbide Canada Limited's 51 per cent interest.

Union Carbide will continue to produce and sell plastics through its two divisions—Bakelite Company and Carbide Chemicals Company.

The acquisition will permit integration of Canadian Resins and Chemicals' operations with those of Shawinigan Chemicals, whose plants are in proximity.

New Grinder — Atlas Copco Canada Ltd., Montreal Airport, Quebec, has added a new 8 in. extra-heavy duty grinder to its line of pneumatic tools. Its patented non-wearing governor has no contact between rotating and stationary parts. The machine also has a safety coupling which disconnects the wheel spindle from the motor. Other features are a built-in lubricator, and exhaust silencer and special light alloy body parts.

New Control Plan — Canadian National Railways has implemented a new method of motive power control across its system. The innovation is expected to result in more efficient operation, considerable savings, and more advantageous placement of power.

Atomic Engine for A-Sub — Canadian Westinghouse Company Limited advises that Westinghouse Electric Corporation will supply the atomic engine to drive Britain's first atomic submarine, the Dreadnought. Agreement has been reached between Rolls Royce Limited and the American firm.

Change of Name — Linde Air Products Company, Division of Union Carbide Canada Limited, has deleted the words "Air Products" from its name. Since February 1st, 1959, this company is known as Linde Company, Division of Union Carbide Canada Limited.

Fibre Tubes in Overpass. — "Sonovoid" fibre tubing, a product of Sonoco Products of Canada Limited, is being used in the construction of the elevated portion of the Metropolitan Boulevard, Montreal. The order for the tubing is the largest the Company has received in any part of the world.

The elevated portion of the Boulevard is six miles long and approximately 700,000 ft. of 26 in. tubing will be used. The 60 ft. span which has been developed for this structure is another Canadian "first". The design and specification was prepared by Brouillet, Carmel and Boulva.

The "Sonovoid" slab system, which has many uses, utilizes void tubing to create a symmetrical system of cylindrical air cells, within the concrete slab, to remove mass and weight of non-working concrete at the neutral axis—it introduces a system of successive "T" beam sections to carry the load.

For complete information on "Sonovoid" and its applications, write to Sonoco Products of Canada Ltd., Brantford, Ont.

the engineering institute of canada

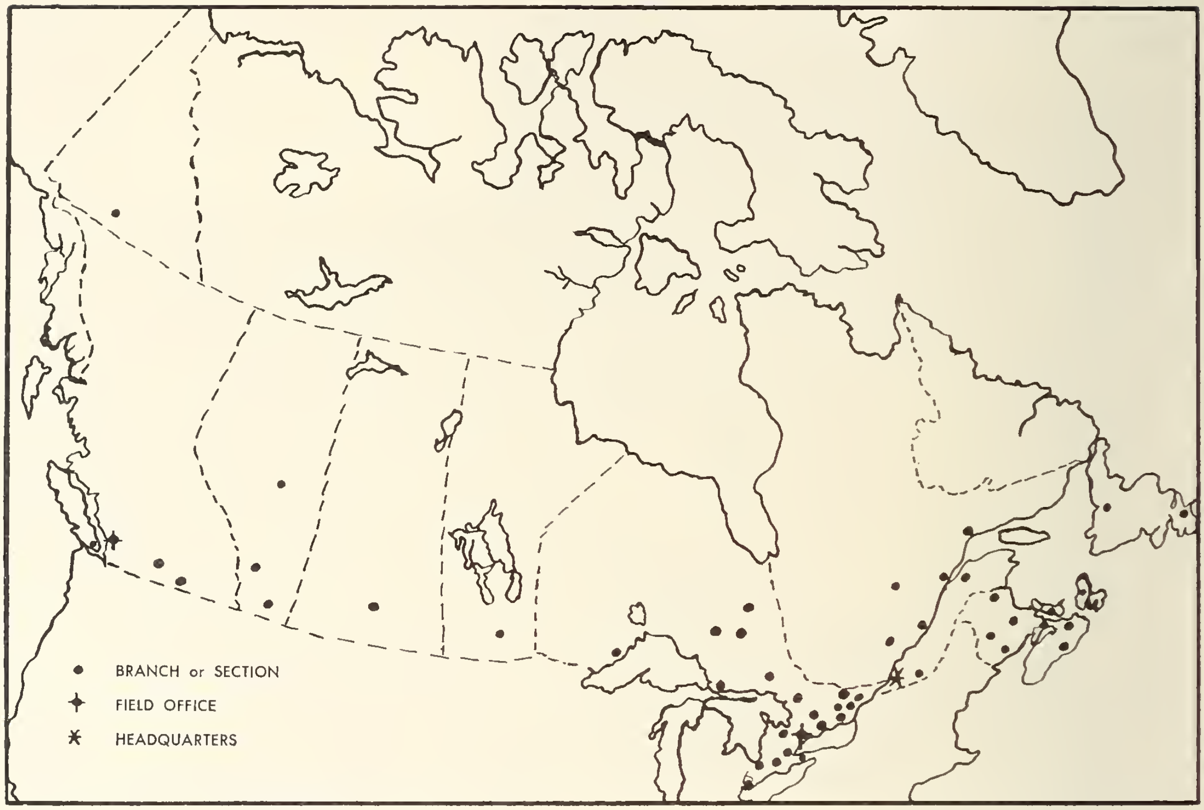
1958

REPORT OF COUNCIL

and reports of committees and branches

LISHED AS A SUPPLEMENT TO THE ISSUE OF *THE ENGINEERING JOURNAL* FOR APRIL NINETEEN HUNDRED FIFTY-NINE

The Engineering Institute of Canada



This institute has a voluntary membership of over 18,000 engineers, maintains 50 branches from Newfoundland to the Yukon, publishes the Engineering Journal and other literature, and has achieved international eminence as one of the front ranking engineering societies of the world. It is devoted to the following purposes:—

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

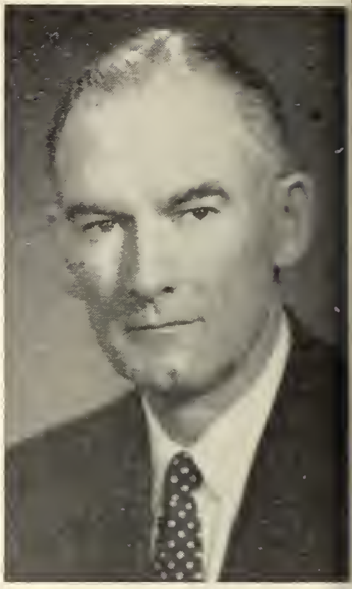
THE ENGINEERING INSTITUTE OF CANADA

annual report

for the year ended December 31 1958

contents

LETTER FROM THE PRESIDENT



LETTRE DU PRESIDENT

WITH THIS LETTER there is transmitted to each of the 18,542 members of The Engineering Institute of Canada the report of the operations of your Institute for 1958 — its 72nd year of service.

Please read this report carefully, because it contains, in an organized form, a statement of your Institute's activities and accomplishments for the year. These constitute a real record of achievement, and demonstrate vividly what the E.I.C. does for you, for the profession and for the nation, both at home and in the world scene.

When you have read the report, I trust that you will join with me in taking increased interest and pride in Canada's largest technical society — The Engineering Institute of Canada. I trust that you will also join me in expressing appreciation to the hundreds of members whose efforts have made this fine record of achievement possible. This includes the Past-Presidents, Council members, Committee members, the many local officers, faculty advisors, and our representatives on the technical committees of other societies and organizations. Our thanks are also due the staff, who have rendered good service in their respective capacities.

Nous transmettons ci-joint à chacun des 18,542 membres de l'Institut le rapport annuel de l'année 1958, la 72ème de son existence dévouée au service de la profession de l'ingénieur et du Canada.

Veuillez lire ce rapport avec attention parce qu'il relate, sous une forme concise et facile à interpréter, l'oeuvre accomplie par votre Institut durant l'année qui s'achève. Ce palmarès constitue un véritable record et montre sans équivoque ce que l' "Engineering Institute of Canada" est en mesure d'accomplir pour vous, pour la profession et pour le pays, tant au point de vue national qu'au point de vue international.

Je suis convaincu qu'après la lecture de ce rapport, vous voudrez prendre une part plus active à nos travaux, et que vous éprouverez des sentiments de fierté à être membre de la plus importante société technique du Canada, l' "Engineering Institute of Canada". Je suis sûr que vous vous joindrez à moi pour féliciter le grand nombre de nos membres qui, par leurs efforts, ont contribué à un essor aussi remarquable de notre Institut. Je pense à nos anciens présidents, aux membres du conseil, aux membres des comités, au grand nombre d'officiers de nos chapitres locaux, à nos représentants dans les facultés de génie et à tous ceux qui ont travaillé en notre nom avec d'autres sociétés professionnelles et techniques. Nous remercions aussi le personnel de l'Institut qui, dans l'exercice de ses fonctions, nous a rendu des services à signaler.

K. F. Tupper, M.E.I.C.,
President

The Engineering Institute
of Canada.

REPORT OF COUNCIL

ADMINISTRATIVE SERVICES

ACTIVITIES OF THE PRESIDENT

In the spring of 1958, Dr. C. M. Anson completed his presidential visit to a large number of branches. He interrupted his travel in this country for six weeks to represent the E.I.C. at the Conference of Engineering Institutions of the British Commonwealth, held in Australia and New Zealand, March 19 to April 2.

En route to Australia, on February 10, 1958, Dr. Anson unveiled the E.I.C. memorial to the late H. J. Cambie, a bronze plaque prominently situated in the Canadian Pacific Railway station in Vancouver, B.C.

Shortly after assuming the office of President for 1958-59 in May, Dr. K. F. Tupper represented the E.I.C. at the annual meetings of The Chemical Institute of Canada in Toronto and of the Royal Architectural Institute of Canada in Montreal, and at the Fiftieth Anniversary celebrations of the American Institute of Chemical Engineers in Philadelphia. Later in the year he represented the E.I.C. at the annual meetings of the American Society of Civil Engineers and the American Society of Mechanical Engineers in New York City. At the latter he held a reception for Canadian engineers and their ladies present at that meeting, and for officers and senior members of sister U.S. engineering societies.

In response to an invitation from the government of the U.S.S.R. and with the approval of the Canadian government and the E.I.C. Council, Dr. Tupper visited the U.S.S.R. for two weeks in October to discuss arrangements for the exchange of teams of engineers between the two countries. En route to the U.S.S.R. Dr. Tupper presented the greetings of the E.I.C. to the Institution of Civil Engineers, the Institution of Mechanical Engineers and the Institution of Electrical Engineers in London, The Société Royale Belge des Ingénieurs et des Industriels, in Brussels and the Danish Institution of Civil Engineers in Copenhagen.

After returning from the U.S.S.R., Dr. Tupper visited about one-half of the Institute's branches and student sections before the end of the year, covering most of Eastern, Central and mid-Western Canada.

COUNCIL

Council met 11 times in 1958, including one plenary meeting in May devoted to Confederation. The average attendance at Council meetings in 1958 was 24.

The Councillors in Zone "A" (Western Canada) met twice, in March and in October, to consider Institute problems particular to the Zone, and to prepare appropriate recommendations to Council.

COMMITTEES

The committees appointed by the Council continued to contribute to the efficiency of the Institute's operation. Not only do they study proposals which have been referred to them by Council, but in various ways each keeps in touch with situations and attitudes within its terms of reference and, when necessary, initiates considered action.

All standing and special committees were active during the year, their reports appear on pages 16 to 23 of this report.

FINANCE

The financial results for the year 1958 were somewhat disappointing. Expenditure exceeded revenue and consequently a deficit was incurred on the year's operations. The appreciable increases in administrative expenses arose chiefly through expanded activity at both the local and the international level. Total revenue was less than in the previous year due to a reduction in advertising revenue.

HEADQUARTERS

On January 1, 1958, Colonel L. F. Grant retired as Field Secretary after making a magnificent contribution to Institute activities for many years. Particularly noteworthy was his contribution to the very successful professional development programs operated by a number of branches, and which are due in large measure to his initial inspiration and guidance. Mr. John McLaren became Eastern Field Secretary in January, 1958.

May 30, 1958, marked the completion of twenty years of outstanding service as General Secretary by Dr. L. Austin Wright. On Dr. Wright's retirement on this date, he was succeeded as General Secretary by Dr. Garnet T. Page. Dr. Wright was retained by Council as General Consultant to assist and advise the President and General Secretary on request.

The Eastern Field Secretary

All but 7 of the 40 branches of the Institute east of the Manitoba border were visited. Visits have also been made to many of the engineering colleges, where calls were made on members of the faculty and talks given to student bodies about the work of the Institute, along with showing of films on current engineering projects. Considerable time was also spent assisting in the organization and operation of branch professional development programs.

Wherever possible stops were made to visit "orphan" members who by reason of distances from the place of branch meetings have little contact with the E.I.C. except through the Journal. Altogether, over 19,000 miles were travelled in connection with the work of the Institute.

Many calls were made on the Toronto office to assist in locating employment. In the earlier part of the year, many engineers found it necessary to seek positions and this office assisted them, in conjunction with the employment service at headquarters, by suggesting possible sources of new employment. Toward the end of the year, requests for employment service diminished considerably.

The Toronto office was used frequently for committee meetings of technical sections and professional development courses.

The Western Field Secretary

During 1958 the following Branches, Sections and unorganized groups were visited, some of them more than once:— Victoria, Vancouver, Chilliwack, Powell River, Kelowna, Penticton, Trail, Lethbridge, Calgary, Edmonton, Medicine Hat, Swift Current, Moose Jaw, Regina, Saskatoon, Prince Albert, Brandon and Winnipeg.

The impression gained on these visits is that, with one or two exceptions, the sense of isolation felt by Zone "A'" groups is decreasing.

This desirable trend can be ascribed to a variety of causes such as periodical Regional meetings of Councillors, more frequent visits by Institute Officers and staff; in other words, to better communications. It is also considered that the recent prominence of discussion on Confederation has tended to awaken interest and understanding in the National, rather than the Provincial character of the profession.

The Annual Meetings of the Associations of Professional Engineers in Alberta and Saskatchewan were attended by invitation and in both cases a warm welcome was received.

Two meetings of Councillors of Zone "A" were held during the year, one in Edmonton in March and one in Calgary in October. Both were fruitful and they appear to serve a very useful purpose.

At the Calgary meeting the decision was taken to hold a Zone "A" Regional Technical Conference at Banff on October 2nd - 3rd 1959 and Calgary has consented to act as Host Branch.

Assistance was rendered to professional development courses which are operating or being planned in Winnipeg, Edmonton, Calgary and Vancouver.

The employment situation for engineers in B.C. was very bad, compared to recent years, for most of 1958, though it has shown some slight improvement toward the end of the year. Many calls were made on the Vancouver office for help in securing employment.

MEMBERSHIP

The total membership at the end of 1958 was 18,542, representing a net increase of 991 over the previous year. The ratio of gains to losses was approximately 2.2:1. Gains include admissions and reinstatements. Losses include resignations, removals and deaths.

The continued growth in total membership was due in large measure to the efforts of the branch membership committees in recruiting candidates for corporate membership, and to the Student Representatives and Faculty Advisors who conducted drives for student membership.

Table I indicates the increases in the various classes of membership during the year and shows the losses by resignations and removals.

Deceased Members

During the year 1958 the deaths of members of the Institute (including four Honorary Members) have been reported as follows:

Honorary Members

Doane, Francis William Whitney, Halifax, N.S.
Gibb, Sir Alexander, Westminster, London, England.
Gray, Francis William, Victoria, B.C.
Pratley, Philip Louis, Montreal, P.Q.

Members

Addie, George Kyle, Quebec, P.Q.
Agar, George, Montreal, P.Q.
Allingham, Ralph R., White Plains, N.Y., U.S.A.
Altrogge, Alfred Joseph, Saskatoon, Sask.
Ballantyne, Norman Frank, Ottawa, Ont.
Bash, Kenower Weimer, Toronto, Ont.
Bickerdike, Robert, Westmount, P.Q.
Bush, Harold Frederick, Montreal, P.Q.
Camsell, Charles, Ottawa, Ont.
Clarke, Ernest R., Scarborough, Ont.
D'Aoust, Joseph Gilbert, Powell River, B.C.
Davy, Richard Frederick, Victoria, B.C.
Dickenson, John Goodall, Toronto, Ont.
Douglas, George Vibert, Toronto, Ont.
Edington, William James, Moncton, N.B.
Elgee, Herbert Alcock, Budleigh, Devonshire, England.
Faulkner, Charles Frederick Peter, North Surrey, B.C.
Flynn, James Emmett, Vancouver, B.C.
Forgie, James, Kew Gardens, N.Y., U.S.A.
Fowlie, Cecil Winston, Halifax, N.S.
Fry, Albert Edward, Montreal, P.Q.
Fulton, Edward Arthur, St. Louis, Missouri, U.S.A.
Furlong, Henry Walter, Wollaston, Mass., U.S.A.

Highgate, Robert Allen, Wallaceburg, Ont.
Joyce, Bruce Edward Clive, Bedford, N.S.
Valiquet, Joseph Georges Jean, Ottawa, Ont.

DISTINGUISHED FOREIGN VISITORS

During 1958 the Institute was pleased to receive many important visitors from abroad. Among them were:

Sir Arthur Whitaker, and Alexander McDonald, President and Secretary respectively of the Institution of Civil Engineers, of Great Britain.

J. M. Landis, President, American Society of Mechanical Engineers.

O. B. Schier II, and T. A. Marshall, Secretary and Senior Assistant Secretary respectively of the American Society of Mechanical Engineers.

L. R. Howson, and Wm. Wisely, President and Executive Secretary respectively of the American Society of Civil Engineers.

W. J. Barrett, President, American Institute of Electrical Engineers.

E. R. Needles, President, Engineers Joint Council, N.Y.

W. K. Brasher, Secretary, Institution of Electrical Engineers, of Great Britain.

All of the foregoing gentlemen, some with their wives, were guests at the Annual Meeting, Quebec. Others, who made our acquaintance on different occasions, included —

Frederick Snow, Past president, Institution of Structural Engineers, of Great Britain.

Ove Guldberg, Secretary, Institution of Danish Civil Engineers.

James Newby and Dr. H. V. Walters, both of the I.A.E.S.T.E. Committee of Great Britain, of which Mr. Newby is Executive Secretary.

Sir George Barnett, Head of factory inspection for the British Government.

D. P. R. Cassad, President, Institution of Engineers, India.

E. A. Nadirshah, past-President, Institution of Engineers, India.

Luis Giannattasio and James M. Todd, President and Vice-President respectively of U.P.A.D.I.

R. H. Richmond and E. D. McWalker, both of the State Rivers and Water Supply Commission of Australia.

CONFEDERATION

The following is a progress report on Confederation for 1958:

Council's special Committee on Confederation, working in collaboration with a similar committee appointed by the Canadian Council of Associations and the Corporation of Professional Engineers, has worked steadily toward the production of a definite plan for "Confederation".

On May 19, the Council held a plenary meeting in Quebec City to receive and discuss a report of the joint Committee. Council unanimously accepted seven of the eight clauses, and accepted the eighth clause in principle, subject to further discussions as a guide for future action by its committee. The committee was asked to prepare a statement based on its report and outlining the objectives of the new national body for presentation to and balloting upon by the membership of the Institute and the Associations and Corporation, after approval by the respective councils.

The chairman of the special committee reported to each meeting of Council to keep members of Council informed of progress made by the committee.

At the December Council meeting the chairman of the committee reported that the final report of the sub-committee had been circulated to all members of the joint committee, and that all members have reported that they approve the report in its entirety. It was agreed that a plenary meeting of Council be held at the earliest possible date after distribution of the joint report to members of Council, and this plenary meeting was arranged to take place in Toronto on Saturday, January 31st, 1959.

DIRECT SERVICES

ANNUAL AND REGIONAL MEETINGS

The 1958 Annual General and Professional Meeting was held in May at the Chateau Frontenac in Quebec City. Because of its location and historic interest, Quebec is a popular spot for such gatherings, and those members and guests who participated enjoyed a fine meeting. The total registration of 932 was not the largest on record, but the excellent spirit and enthusiasm shown through the many events will long be remembered.

Although the official duration of the meeting was three days, the program of business and committee meetings, technical sessions, conferences, and social events pretty well filled a five day period. 37 technical papers were presented, on a wide variety of subjects, and the general comment was that the professional meeting was interesting and well-rounded. Special conferences were convened for the deans of engineering, the branch officers, and engineering students. The employment and library services functioned at Quebec throughout the conference.

The social events were highlighted by farewell tributes to the retiring General Secretary, Dr. L. Austin Wright. He was the recipient of several beautiful gifts from the members, and from the twenty Presidents under whom he served. Hospitality was provided again through the courtesy of "Muriel's Room", and the Institute is grateful to the many Canadian firms whose generosity made this possible.

The schedule for future annual meetings is:

1959 Royal York Hotel, Toronto, Ontario, June 8-9-10

1960 Royal Alexandra Hotel, Winnipeg, Manitoba, May 25-26-27

1961 Hotel Vancouver, Vancouver, B.C.

1962 Queen Elizabeth Hotel, Montreal, Quebec, this will be the Seventy-Fifth Anniversary of the E.I.C.

Regional Meetings

The first E.I.C. Southern Ontario Regional Conference was held on March 15, 1958 at the Royal Connaught Hotel, Hamilton. This conference was organized by the Hamilton Branch with the Niagara Peninsula, Toronto, Kitchener, London, Sarnia, and Border Cities Branches participating.

383 engineers and their ladies attended this most successful conference, which combined excellent technical and social programs.

In line with the Institute's policy of expanding its program of regional conferences to bring this type of service to as many members as possible, plans were initiated in 1958 for the following regional conferences:

March 14, 1959	— Hamilton, Ont.
April 25, 1959	— Sudbury, Ont.
October 2-3, 1959	— Banff, Alta.
October 15-16, 1959	— Ottawa, Ont.
May 6-7, 1960	— Kingston, Ont.

In addition, the regular biennial regional conference for members of E.I.C. and the professional associations in the Atlantic Provinces was held at Digby, N.S., September 2-4. It was well attended and was highly successful. The 1960 conference will be held in St. Andrews, N.B. in early September.

AWARDS, HONOURS, MEDALS AND PRIZES

These awards were presented during the annual meeting to those recipients who could be present.

HONORARY MEMBERS

Armand Charles Crepeau, Sherbrooke, Sir Claude Dixon Gibb, Newcastle-upon-tyne, England, Philip Louis Pratley, Montreal, Que., Irving Richard Tait, Montreal, Que., Earle Oliver Turner, Fredericton, N.B., Leslie Austin Wright, Montreal, Que.

JULIAN C. SMITH MEDALS

Richard Edgar Heartz, M.E.I.C., Montreal, Que., Robert Edwards Jamieson, M.E.I.C., Montreal, Que.

ROBERT W. ANGUS MEDAL

Russell J. Kennedy, M.E.I.C., Kingston, Ont.

DUGGAN MEDAL AND PRIZE

Robert David, M.E.I.C., Montreal, Que., G. G. Meyerhof, M.E.I.C., Halifax, N.S.

LEONARD MEDAL

E. O. Lilge, M.C.I.M., Edmonton, Alta.

PLUMMER MEDAL

H. R. L. Streight, F.C.I.C., Montreal, Que.

ROSS MEDAL

Ronald George Griffith, M.E.I.C., Montreal, Que.

H. N. RUTTAN PRIZE

Wilfred Pegusch, JR.E.I.C., Vancouver, B.C.

PHELPS JOHNSON PRIZE

Donald Andrew Chamberlain, JR.E.I.C., Montreal, Que.

ERNEST MARCEAU PRIZE

Gilles Gagnon, JR.E.I.C., Montreal, Que.

JOHN GALBRAITH PRIZE

Charles Murray Stewart, JR.E.I.C., Sarnia, Ont.

MARTIN MURPHY PRIZE

Robert Donald Neill, JR.E.I.C., Fredericton, N.B.

BRANCHES

The inauguration of the Chalk River Branch in May, 1958, was memorable, for this was the fiftieth Branch to be established by the Institute. The fifty branches extend from Newfoundland to Vancouver Island, and provide technical and social programs to the many thousands of members in their areas. Financed in part by rebates of membership fees, the activities sponsored by the branches are the "life-blood" of the Institute.

Almost every branch received either President Anson or President Tupper in 1958, and the headquarters and field staff visited as many branches as possible, to ensure the best possible communications between the branches and the national officers and Headquarters. Headquarters and the field staff continued to work closely with branches by assisting with technical programs, professional development programs, administration matters, records, membership and admissions, stationery and mailings, and groups of engineers' wives.

A successful branch officers conference was held during the 1958 annual meeting at Quebec City. This conference put forward a number of useful recommendations and suggestions to the Council which have been most helpful in the formulation of acceptable policies and programs. Based on the recommendations of this meeting, both in 1957 and 1958, a draft manual for the operation of branches was proposed and circulated to all branches for comment before the final printing, which will be done in 1959.

The Officers, Council and staff wish to acknowledge the great amount of voluntary work done by the hundreds of branch officers and committee members in rendering direct local services to the membership, and for their co-operation in supporting the various national and international projects which depend in large measure on branch support for their ultimate success.

CERTIFICATES FOR MEMBERS

Approximately 190 members received E.I.C. membership certificates, available on request at a cost of $1.25. Later in the year Council decided that all Life Members would be presented with a special certificate of life membership. This new policy will be implemented in 1959.

CO-OPERATION WITH OTHER ENGINEERING AND SCIENTIFIC ORGANIZATIONS

In addition to the formal meetings between representatives of the member societies of such international organizations as UPADI and the Conference of Engineering Societies of the British Commonwealth, the E.I.C. maintains regular and extremely cordial contacts with the Institutions in the United Kingdom, and other Commonwealth societies, the Founder Societies in the United States of America, the representative national engineering organizations in Europe, the far East, and Latin America. These frequent exchanges of information and assistance have proven invaluable to the Canadian engineering profession.

At the national level, the Institute works closely with the Canadian Institute of Mining and Metallurgy, The Chemical Institute of Canada, The Canadian Aeronautical Institute, the Canadian Good Roads Association, and others on a number of important government-sponsored and inter-society projects.

There was no change in the operation of the seven agreements between the Institute and provincial registering bodies in 1958. These agreements have made it possible for administration to be simplified and have resulted in substantial savings and convenience to the members in the provinces concerned.

EMPLOYMENT SERVICE

Employment opportunities for engineers were less numerous in 1958 than during the previous five years, as shown on the following table:

1954	1955	1956	1957	1958
"Situations Vacant"				
228	181	190	297	366
No. of applicants "Situations Wanted"				
400	550	500	350	300

Geographical Distribution Situations Vacant 1958

Maritimes	9	Central Canada	250
Prairies	33	West Coast	8

In addition to the 366 engineers who advertised for employment in the Journal, the employment service assisted 230 unemployed engineers during 1958. The majority of these were recent immigrants to Canada, and others released from industries. Approximately 800 interviews were conducted during 1958 and 65 known placements were made.

1600 copies of the employment bulletin were printed every month — 1100 of these were sent to a standing list of employers of engineers; and 500 distributed to those seeking employment.

One hundred and sixty-five students from all parts of Canada registered for summer employment during January, February and March.

The scarcity of engineering jobs affected the graduating class of 1958. A canvass of the larger employers indicated that, although they were conducting campus interviews across Canada, the number of graduates required would be smaller than in the previous few years. Late in the year, some increase was noted in the demand for engineers. This was reflected by the fifty-five new positions listed in December.

ENGINEERING EDUCATION

3rd Biennial ASME-EIC Conference on Engineering Education

"How Should Industry Aid Engineering Education?" was the theme of the 3rd Biennial Conference on Engineering Education sponsored jointly by ASME and E.I.C. held at the University of Michigan, Ann Arbor, October 15-16, 1958. There were 117 delegates at the Conference of which 33 were from Canada. 11 Canadian universities were represented.

The Conference was divided into three sessions, which took the form of panel presentations followed by general discussion. Past-President C. M. Anson and President K. F. Tupper addressed the delegates at the opening dinner and closing luncheon respectively.

The first panel presentation was on the topic "The Philosophy of Co-operation between Industry and Higher Education". The second panel was on the topic, "Continuing Education by Industry in Industry" and the third panel dealt with "Support by Industry of Higher Education".

Committee on Engineering Education as recommended by the E.I.C. Education Conference, the Council approved the establishment of the E.I.C. Committee on Engineering Education. Seven members representing the universities and seven representing industry have been appointed, with Dean H. G. Conn as interim chairman. This Committee, which will meet for the first time during the 1959 annual meeting in Toronto, shall concern itself with matters of engineering education that come before the E.I.C., and detailed proposals for the scope of the committee will be reviewed for adoption.

Canadian Conference on Education—The E.I.C. was one of nineteen national organizations which sponsored the Canadian Conference on Education held in Ottawa in February. The Institute's representatives participated actively in the workshops on higher education, school buildings and equipment; and teachers—quality and quantity. It was generally agreed that the conference was successful in increasing the public's awareness of Canada's problems in education, in bringing together those concerned with these problems, in stating what some of the basis problems are, and in the establishment of a continuing organization to sponsor constructive action toward the solution of these problems. The Institute is a sponsoring member of the continuing organization of the Canadian Conference on Education.

Engineering Education Conference — The 1958 meeting was held on May 20, in conjunction with the E.I.C. annual meeting at Quebec. Attended by deans of engineering from degree-granting universities, it was chaired by Mr. J. Hoogstraten and was concerned primarily with preparing plans for a major engineering education conference in 1959.

The conference recommended specific terms of reference for the new 14 member Committee on Engineering Education being established by the E.I.C., and named seven academic members to the committee. The other seven members are to be selected from industry by the Institute.

The conference also agreed to place before the National Conference of Canadian Universities a proposal that they establish a committee of engineering educators within the N.C.C.U.

Finally, in the international realm, many useful discussions regarding engineering education were held during the Conference of Engineering Institutions of the British Commonwealth, and the V UPADI Congress and with experts from the the Organization for European Economic Cooperation who visited Canada late in 1958.

General

On a continuing basis, the Institute maintains a close and effective relationship with universities, appropriate agencies of the Federal and Provincial Governments that are concerned with education, with the Canadian Education Association and the Canadian Teachers Federation.

GOVERNMENT LIAISON

In 1958 the E.I.C. continued its close liaison with the Federal Government, working co-operatively with many agencies and departments on a day-to-day basis in the interests of Canadian engineering, and in helping to solve problems referred to the E.I.C. directly either or by virtue of the Institute's membership on committees and boards established by the government. The Institute learned with pleasure that the government had seen fit to appoint senior engineers to a number of important commissions inquiring into important problems affecting the nation's economy and resources.

The list of specific areas of Institute participation is long, including certain technical committees of the National Research Council, the Department of Trade and Commerce, the Department of Labour and the Department of National Health and Welfare; covering such areas as building research, the Colombo Plan, the United Nations Technical Assistance Administration, technical manpower, vocational training, and civil defence. On another level, the E.I.C. is in regular communication with the Civil Service Commission, the Department of External Affairs, the National Film Board and other agencies regarding vocational information, and the dissemination of knowledge about Canada's engineering achievements to other countries.

LIBRARY AND FILM SERVICE

Increased use was made of the library during the year, and the majority of the requests continued to come from members and other libraries in the Montreal area. An average of twenty-five requests were handled a day.

The total number of items circulated by the library during the year was 4,326, an increase of more than 1,000 over 1957. It is interesting to note that about twenty-five per cent of the loans were made to other libraries which have come to rely on the completeness of the Institute's collection. Of the 670 members who borrowed books from the library during the year, 433 were from the Montreal area. The remaining borrowers were distributed as follows: West Coast, 15; Prairies and Western Ontario, 71; Ontario and Quebec, 122; Maritimes, 28; U.S.A., 1.

During the year the library compiled sixty-one bibliographies of periodical articles for members. In addition numerous recommendations of suitable books were made, in letters, over the telephone, and to members visiting the library in person. Eighteen of the bibliographies compiled were in the field of civil engineering, ten electrical and eight mechanical. The remaining twenty-five covered a variety of topics from the "Antartic" to "Wood".

The library handled 319 members' subscriptions to 28 publications of 11 other engineering societies. The library staff also made over 7,000 photoprints, of which nearly 2,000 were sent to members in lieu of bound volumes of periodicals and of otherwise unobtainable papers and articles.

The library distributed over 800 free pamphlets to high school students requesting information on engineering as a career, and over 900 free copies of the Engineering Journal to high school students, undergraduates, and others expressing an interest in the publication.

One new film was acquired during the year, "Blasting a New Niagara". The total film circulation was 63.

Over 600 books were added during the year, bringing the total collection to about 6,300. The value of the volumes received for review in the Engineering Journal was $3,900, and that of those purchased was $800.

The library has exchange arrangements with organizations in thirty countries, including several behind the Iron Curtain, and nearly eighty percent of the 500 periodicals received in the library are acquired on this basis.

It appears that many members are not aware of the full extent of services of the E.I.C. library since most inquiries are largely in the fields of civil and electrical engineering, although the library contains material on all branches, much of which is not available elsewhere.

STATISTICS OF LIBRARY USE

	1957	1958
Mail enquiries	1430	1624
Phone enquiries	3052	3168
Persons visiting the library	2334	2654
Borrowers registered	488	670
Circulation		
Books	1892	2364
Periodicals	1184	1725
Pamphlets	163	237
Total	3239	4326
Parcels of books mailed out-of-town	270	432
Bibliographies compiled	63	61
Photocopies made	3135	7220
Members subscriptions to publications of other societies	338	319
Films circulated	60	63
Books acquired	421	621
Value of books acquired	$ 3723	$ 4747

TABLE II

PHOTOGRAPHIC EXHIBITS

Three exhibitions of photographs were displayed at the annual meeting at Quebec and were made available to the branches and universities across Canada for exhibition. Canadian photographs were submitted in large part by Canadian industrial advertisers in the Engineering Journal. Awards of merit were subsequently presented by the Institute to the exhibitors with the five winning entries. The other two were on the subject "Atoms for Peace", showing development in the peaceful applications of atomic energy in the U.S.A. and in the U.S.S.R. The "Atoms for Peace" exhibits attracted considerable attention, as they were displayed side by side and presented an interesting comparison.

The Canadian photographs submitted for competition at the 1957 annual meeting were shown at six universities in the early months of 1958. "Atoms for Peace" exhibits were shown by eight branches and one provincial association as well as by three Student groups at universities. At the end of the year advance bookings had been made which will keep the exhibits on tour continually until the end of April 1959.

PROFESSIONAL DEVELOPMENT

Engineer's Council for Development
E.I.C. Representation on E.C.P.D. Council

Institute representatives on the Council of E.C.P.D. were Colonel W. S. Wilson, Mr. G. R. Henderson and Doctor Otto Holden. Colonel Wilson's term of office expired during the year and he was reappointed for a three year period. Representatives of the professional development programs of Toronto, Hamilton and Niagara attended the two-day work session of the training committee of E.C.P.D. held in Pittsburgh on May 19th and 20th. The following is quoted from the 1958 Annual Report of E.C.P.D.

> "An excellent discussion of the "Canadian First Five Year's Program — for Young Engineers, by Young Engineers" was given by three young members representing the Professional development program group of the Engineering Institute of Canada. Steps are being taken to have their presentation published".

The Institute was also represented at the 26th Annual Meeting of the Engineers' Council for Professional Development at which representatives from the Toronto, Hamilton and Niagara branches of the Institute presented a similar demonstration to that which was given at the Pittsburgh meeting.

The following definition of engineering, submitted by the Recognition Committee was adopted at the Annual Meeting of E.C.P.D.
It reads as follows:

> "Engineering is the (learned) profession in which a knowledge of the mathematical and natural sciences gained by study, experience and practice, is applied with judgment to develop ways to utilize economically the materials and forces of nature for the progressive well being of mankind".

The following Institute representatives on E.C.P.D. committees were appointed for 1959:

Guidance	— D. A. Young
Education and Accreditation	— C. H. R. Campling
Ethics	— J. E. L. Roy
Recognition	— Guy Savard
Training	— George L. Schneider
Information	— Garnet T. Page
Planning	— L. Austin Wright
Student Development	— E. Muszinski

Preliminary plans were made to hold the 1960 annual meeting of E.C.P.D. in Montreal, early in October 1959.

Professional Development Programs

Following the successful operation of professional development programs in the Southern Ontario region, consideration was given to the formation of a national co-ordinating committee on professional development programs. This committee would provide, through Headquarters, guidance and assistance to branches of the Institute contemplating the establishment of professional development programs.

Professional development programs sponsored by the various branches are included in the branch reports. Sixteen branches planned or were operating professional development programs for the 1958-59 season.

PUBLICATIONS

1958 was the fortieth anniversary of The Engineering Journal and the Institute received many messages of congratulations, including a cordial greeting from the Prime Minister of Canada, on the successful completion of forty years of this outstanding service to Canadian engineers.

Recommenced in the fall of 1957 after over twenty years during which its publication was suspended, "Transactions of the E.I.C." was published on a regular quarterly basis in 1958, providing the sole Canadian medium for the publication of papers dealing with the results of research in engineering. The autumn issue dealing with "Ice" was supplied by special arrangement with the National Research Council of Canada, and has received wide acclaim.

For the second successive year the Institute published its unique "Engineering Careers in Canada", which provided up-to-date vocational information and descriptions of career opportunities to all first and final year engineering students in Canada, as well as to high schools and public libraries.

No historical biographies were published in 1958, but preparations were completed for the publication of an excellent biography of Sir Casimir Gzowski in 1959. The response to the first E.I.C. historical biography "Daylight through the Mountain" published in 1957, continued to be excellent, and further laudatory reviews were received.

In addition, a number of administrative publications, including a branch manual, a student section manual, supplements to the E.I.C. catalogue of films, a manual for councillors, a compendium of data about professional development courses, and several small brochures for students were initiated.

SPEAKERS FOR BRANCHES

In response to requests for assistance from certain branches which normally have some difficulty in arranging for their technical programs, Headquarters gave increased attention to providing speakers who address one or more branches.

In 1958 Headquarters arranged for 34 speakers to address a total of 49 branch meetings.

STUDENT AFFAIRS

As the result of the work of the Student Policy Committee there was increased interest in the formation of student sections. Two new sections were in the process of organization at the end of the year and requests for information and guidance were received from other student groups. Thanks to the efforts of student representatives and faculty advisors, 1310 engineering students jointed the Institute in 1958.

Grants to faculty advisors, amounting to $2250 were made during the year. These grants were authorized by Council to provide financial assistance for student member activities. In addition, grants were made to four branches at university centres for specific projects associated with students activities as authorized by Council.

Over 4,000 copies of the new pamphlet "Serving Canadian Engineers" were distributed at the universities. In addition, copies of "Engineering Careers in Canada, 1958" were distributed to all first year and final year engineering students.

The financial assistance of the Life Members is gratefully acknowledged. They contributed $500 to the Students Conference at Quebec and provided the necessary funds to increase the Student prize to $50.

E.I.C. slide rule tie clips were again presented to all engineering students who became Student members of the Institute.

TECHNICAL OPERATIONS

National

The report of the Committee on Technical Operations on page 22 summarizes the major areas of technical operations for the year. This part of the Institute's program has received a great deal of attention by headquarters, in view of its importance to the membership. In addition to advising on the technical contents of annual and regional meetings, the committee has assisted the Publications Committee considerably, and has aided the staff in their efforts to provide speakers to branches requiring such assistance.

The E.I.C. assists many agencies of government in technical matters and also co-operates with sister societies in Canada in technical activities of major importance. Examples of these are the Committee on Wintertime Construction of the Canadian Construction Association, a number of committees of the Canadian Standards Association, the Canadian Radio Technical Planning Board, and the Canadian Management Council.

International

Participation in the sponsorship of programs of international technical organizations, and their conferences, is an important aspect of the E.I.C. program. In 1958 the Institute took an active part in the Fourth Nuclear Engineering and Science Congress held in Chicago, March 17-21. This congress brings together engineers and scientists of many kinds for the purpose of exchanging new information in the field of nuclear energy. The Fifth Congress was held in Cleveland, Ohio, April 5-10, 1959, and tentative plans are that the Sixth Congress will be held in New York City, in the Spring of 1960.

The Second International Heat Transfer Congress will be held in the U.S.A. and in Europe in 1961. As one of the sponsoring organizations, the E.I.C. is active in the work of the preparatory committee.

Other international technical activities in which the E.I.C. is active include the ASME Committee on Air Pollution, The Column Research Council, The International Association for Bridge and Structural Engineers, the International Aviation Writers Association, The International Federation of Chemical Engineering, The International Electrotechnical Commission, and the Society of Technical Writers and Editors.

Finally, even though the Institute is not itself a member of the World Power Congress, since governments are the only members, numbers of Institute members and headquarter's staff took a leading part in organizing all phases of the sectional meeting held at the Queen Elizabeth Hotel, Montreal, Sept. 7-12. This meeting was attended by 1200 delegates representing 41 nations.

Exchange of Teams of Engineers between Canada and the U.S.S.R.

In January 1958, at the suggestion of the Ambassador of the U.S.S.R. to Canada, and with the approval of the government of Canada and the E.I.C. Council, negotiations were initiated with the object of arranging for exchange visits of teams of engineers between Canada and the USSR.

In June 1958, it became obvious that personal discussions would greatly facilitate the successful conclusion of these negotiations. The government of the USSR invited the President and General Secretary to visit the USSR as its guests while in that country, to discuss arrangements in principle concerning the proposed exchanges and, in addition, inspect typical facilities for engineering education and a number of representative engineering achievements.

The E.I.C. Council at its meeting on July 18th, 1958 authorized the President and General Secretary to accept this invitation, as well as approving the expenses involved in transporting these two officers to and from the USSR.

The President and General Secretary left Canada by air on September 20th and had useful visits with the officers of sister societies in the United Kingdom, Belgium and Denmark as they proceeded east. On September 27th they flew from Copenhagen to Moscow on a Russian jet aircraft, the Tu-104.

On the Monday after arrival, a meeting was held with the vice-chairman and senior staff of the Scientific and Technical Committee, and a program that would best accomplish the purposes of the visit was arranged, after a completely harmonious discussion and mutual agreement. Following this the President and General Secretary spent a strenuous two weeks following the program of engineering, scientific and cultural interests that had been arranged, and in completing the discussions concerning the exchanges of teams of engineers between the two countries.

The President and General Secretary left Moscow by Tu-104 on Saturday, October 11th arriving in Paris later the same day. After paying their respects to the offices of the Institute's sister society in France, they left Paris for North America on Monday, October 13th.

Prior to their departure from Canada, the President and General Secretary had received letters of encouragement and interest from the Secretary of State for External Affairs, Mr. Sidney Smith. Mr. Smith had advised all Canadian embassies concerned about their mission, and the officials at each embassy were most courteous and helpful.

It was agreed that the areas for an initial service of exchange would be petroleum refining, petrochemistry, oil production and drilling, electronics and communications, power stations and the mining and the benefication of ores. Several other areas were considered on a tentative basis.

The delegations are to be small, and the stay in the West countries from three to four weeks. The E.I.C. Headquarters is acting as the clearing house for the Canadian portion of the arrangements, and the Canadian government is kept fully informed.

Conference of Engineering Institutions of the British Commonwealth

This conference, which meets every four years, met from March 19 to April 2 in Sydney, Canberra and Melbourne, Australia. Representatives from Great Britain, South Africa, Ceylon, Pakistan, New Zealand, Australia, and Canada participated. The Canadian delegates were Dr. C. M. Anson, Dr. I. R. Tait and Dr. L. Austin Wright.

A report of the resolutions and recommendations of this Conference were submitted to the Council of the Engineering Institute of Canada in the fall of 1958 and approved. It is anticipated that the next meeting of this Conference will be held in Canada in 1962.

I.A.E.S.T.E.

The E.I.C. continued to act as the Canadian agency for the International Association for the Exchange of Students for Technical Experience. 1958 was the sixth year of such participation.

In January, 1958, Mr. E. C. Luke, Secretary of the Canadian IAESTE Committee and a member of Headquarters' staff, attended the tenth annual meeting of IAESTE in Madrid, Spain.

This was an excellent conference attended by delegates and observers from twenty-one participating nations. He reported that the annual IAESTE exchange involves about 6,000 students, and approximately 35,000 students have been exchanged since the association was formed in 1948. It is certain that this relatively young international movement has become a strong influence toward mutual understanding and goodwill among nations.

From the point of view of total numbers of students accommodated by Canada, 1958 was somewhat of a disappointment. There was an overall decrease of about 12% probably due to general economic conditions in Canada during the year. Many employers who had provided places in previous years were obliged to decline requests for the first time. 95 European students, from 11 countries, were provided with summer employment in Canada.

However, it is encouraging to report that 24 Canadian engineering students took advantage of the plan to visit and work in 10 different countries abroad. This was double the number of Canadian participants in any previous year.

The collection of funds to continue the Canadian IAESTE Travelling Bursaries was difficult in 1958, with the result that the amounts granted to Canadian students had to be rather drastically reduced. At its meeting in October, the Canadian Committee, after considerable thought, decided to discontinue the bursaries on a trial basis for 1959, to test the effect on Canadian participation.

Further useful work was done to foster the general growth of IAESTE in Canada. A strong effort was made to awaken the interest and enlist the future support of other organizations.

It is felt that real progress was made in this direction, particularly with the Canadian Institute of Mining and Metallurgy, the Canadian Metal Mining Association, The Chemical Institute of Canada, and the Canadian Chamber of Commerce. Their kind co-operation is gratefully acknowledged.

V UPADI Congress

The Engineering Institute was host to the V UPADI Congress in Montreal at the Queen Elizabeth Hotel from September 2-6. More than 100 engineers, representing 16 countries in the Western Hemisphere, were present.

Local arrangements for the congress were made by a committee of E.I.C. members, with Dr. I. R. Tait as chairman.

President K. F. Tupper was named President of the Congress, with representatives from Mexico, Brazil, and the United States as vice-presidents. Simultaneous translation in Spanish, Portugese and English was available at all plenary sessions.

In addition to the standing committee meetings, a conference on engineering education was featured. A program of investigation was proposed to establish uniform practices and procedures in engineering education throughout the Western hemisphere.

UNESCO

The Canada Council is the agency of government responsible for UNESCO matters in Canada. It has established a Canadian National Commission for UNESCO, representative of appropriate departments of government and national organization. The Institute is an official co-operating body of the Canadian National Commission for UNESCO, and as such it is consulted on all matters of interest to engineers that are part of Canada's participation in the program of UNESCO. The E.I.C. was represented at the first meeting of the National Commission, held in Ottawa in February.

VOCATIONAL INFORMATION

The vocational guidance activities of the branches, in various forms to suit local conditions, are reported in the annual reports of the branches.

In addition to the great amount of the work done by branches in local secondary schools, the Institute distributed the pamphlets: "After High School What?" and its French language edition "Science Genie", and "Careers in Natural Science and Engineering" published by the Federal Department of Labour. Approximately 1000 pamphlets and sample copies of the Engineering Journal were distributed.

The Institute publication, "Engineering Careers in Canada — 1958-1959" was placed in all Canadian high school libraries, most public libraries, and distributed to all first and final year engineering students at Canadian universities.

WIVES' ORGANIZATIONS

Although not an official activity of the EIC, the Institute attaches great importance to the activities of the engineers wives' associations.

During 1958, the activities of the Engineers Wives' Associations increased all across Canada. The aim of all groups is to welcome newcomers to their centres and to promote cordiality and friendship among the wives of the members of the Institute, and in many cases, among the wives of all members of the profession. Membership figures range from twenty to over three hundred in different cities.

Commencing in 1957, a "Wives' Meeting" has been held at the time of the Annual Meeting of the Institute, at which reports of the groups are presented, and ideas for future activities are exchanged.

Respectfully submitted on behalf of the Council

K. F. Tupper, M.E.I.C.,
President

Garnet T. Page, M.E.I.C.,
General Secretary

AUDITORS' REPORT

We have examined the balance sheet of The Engineering Institute of Canada as of December 31, 1958 and the statement of revenue and expenditure for the year ended on that date and have obtained all the information and explanations we have required. Our examination included a general review of the accounting procedures and such tests of accounting records and other supporting evidence as we considered necessary in the circumstances.

In our opinion the accompanying balance sheet and statement of revenue and expenditure are properly drawn up so as to exhibit a true and correct view of the state of the affairs of the Institute at December 31, 1958 and the results of its operations for the year ended on that date, according to the best of our information and the explanations given to us and as shown by the books of the Institute.

PEAT, MARWICK, MITCHELL & CO.,
Chartered Accountants.

MONTREAL, P.Q., MARCH 12, 1959.

TREASURER'S REPORT

As indicated in the report of the Chairman of the Finance Committee, expenditure exceeded revenue during 1958.

Revenue for the year showed a decrease of some $27,000 from 1957 and totalled just over $560,000. Expenditure increased some $54,000 reaching $595,000. There was a draw-down on reserves for pension payments and it was necessary to reduce accumulated surplus by the year's deficit of $32,000. In these circumstances, it was not possible to add to our various reserves during 1958.

Revenues from advertising at $325,943 in 1958 were $37,000 less than in the previous year. Increases in local activity arising from Confederation discussions led to greater direct service expense. At the international level — participation in the Commonwealth Conference of Engineering Societies and exchange discussions with the U.S.S.R., resulted in greater staff travel.

There has been a reduction in assets in 1958 mainly in the accounts receivable and securities investments. At the year's end the Institute's assets, according to the auditors' statements, totalled $429,830 whereas in 1957 they were $462,533.

T. W. EADIE, M.E.I.C.,
Treasurer.

REPORTS OF THE COMMITTEES

ADMISSIONS COMMITTEE

During 1958, the Admissions Committee held nine regular meetings. In all, 424 candidates were considered and 1310 Students were admitted:—

Applications for Corporate Membership	283	
Applications for Affiliate Membership	12	
Special Cases	46	
Applications for transfer	83	
Student admissions	1069	1493
Admissions through Provincial Associations:		
Applications for Corporate Membership	119	
Applications for Transfer	81	
Students	241	441
Total		1934

ROGER BRAIS, M.E.I.C.,
Chairman.

BOARD OF EXAMINERS

The Board of Examiners held three meetings during 1958, during which 26 candidates were considered.

Five candidates were admitted after verifying and assessing their qualifications. Four were accepted as Members and one as a Junior member. Twelve candidates were advised to qualify through the Provincial Associations concerned.

Two were advised to qualify through oral examinations and are still pending.

At the year end seven candidates were still under consideration.

A recommendation was made to Council and approved, concerning recognition of qualifications obtained through British Institutions.

J. L. DE STEIN, M.E.I.C.,
Chairman.

CANADIAN CHAMBER OF COMMERCE

Throughout the year, The Canadian Chamber of Commerce carried out its responsibilities in expressing the views of business on public affairs, in promoting improvements in Canada's trading position, and in promoting the right economic climate for business.

Highlights were the annual meeting, held in Montreal, October 6, 7 and 8, at which the Chamber's policies for 1959 were approved, and the presentation of these policies to the Prime Minister and Cabinet in Ottawa on January 9, 1959.

Following are the Chamber's official views on subjects which are of particular interest to the engineering profession:

A major new policy statement on labour relations holds that unions should register with the Department of Labour and comply with similar conditions, in so far as reporting is concerned, as companies incorporated under the Companies Act. The Government has been told that an amendment making this mandatory should be included in the Industrial Relations and Disputes Investigation Act expected to be up for revision at the forthcoming session of parliament.

The submission suggests that, while good industrial relations cannot be created by legislation, nevertheless to the degree that legislation may be necessary it should be designed to ensure a proper balance of rights and responsibilities of employees on the one hand and of employers on the other, with due regard to the public interest.

Dealing with trade, the Chamber says Canada's trade policy should be designed to encourage the continued development of the country's natural resources and at the same time step up industrialization. While the expansion of trade on a multilateral basis is in the best interests of the country, Canada cannot proceed further or faster in setting the example for freer trade between nations than is justified by the actions of the leading trading nations of the world.

The government is asked to completely revise the Customs Tariff and the Customs Act, which are outmoded, particularly in regard to many so-called "end use" and "class or kind" tariff items.

The Chamber also advocates that some form of financial machinery for longer-term credit facilities be made available to Canadian exporters, including engineering and construction, in order to enable them to be competitive with exporters of other countries who now enjoy such credit facilities.

Chamber policy also points to the need for gradual tax reduction which can only be achieved if spending is contained. The Government is asked to make a re-examination of the entire income tax structure in Canada because personal and corporate income tax rates are too high for a developing country.

Chamber policy also asks that the Government:—

1. Take aggressive action to ensure a greater and more continuous flow of desirable immigrants.

2. Re-examine the Canadian defence programme to ensure that adequate provision is being made for the vastly more expensive weapons of the future.

3. Complete as expeditiously as practicable the review being made of combines control legislation.

4. Recognize with respect to any regulation required at the national government level relating to energy resources that this regulation should be administered by existing agencies of the Government of Canada, augmented where deemed necessary.

5. Take the lead for the immediate establishment of machinery for interprovincial liaison and planning for the construction of interprovincial and other highways of national importance.

6. Give secondary industries in Canada every possible support exclusive of subsidies to encourage the export of finished goods.

7. Permit tenders for the Federal Government and the Crown Companies to be received in regional offices at a date and time that is simultaneous throughout Canada, after which they shall be forwarded to Ottawa to be opened.

F. G. Rutley, M.E.I.C.,
Representative

CANADIAN STANDARDS ASSOCIATION

During the year four meetings of the Board of Directors and sixty-two meetings of Technical Committees were held.

Publications issued during the year included 26 new standards, 4 issues of the "Quarterly Bulletin" and 4 issues of "CSA News". The "Bulletin" includes meeting reports, advice concerning new and current projects and newly issued specifications, while the "CSA News" provides up-to-date information on CSA standardization activities, lists of newly issued specifications and lists of new sustaining members.

The following new standardization projects were authorized by the Board of Directors:—

Hydraulic, electric and pneumatic installations on machine tools, plumbing fixtures, electrical insulation, design specifications for structural aluminum, surface finish of metals, explosion-proof enclosures, skelp, and steel farm fences.

Requests for several additional new projects are now under consideration by the Board.

173 standards reached various stages of development by the end of the year as follows:—

36 — Technical Council (Final authority for technical content)
7 — Sectional Committees.
37 — Specification Committees.
93 — Preliminary Development.

In addition there are revisions to 37 standards in various stages of development.

During the year the Association granted five licences authorizing use of the certification marks, "CSA STANDARD" and "CSA STD" indicating compliance with the provisions and requirements of published CSA Standards.

The CSA Testing Laboratory has equipped its thermal laboratory with the necessary facilities for the purpose of conducting extensive tests on gas appliances, equipment and accessories. The certification service thus provided has been integrated with the oil and electric certification services in order to provide the manufacturer with a complete and unified program for those appliances and equipment which utilize combinations (e.g. oil-gas, oil-electric, gas-electric, etc.) of fuel and energy sources.

The Laboratories have completed a successful year of operations and the number of applications for certification continues to increase.

It is with regret that we announce the passing of P. L. Pratley, M.E.I.C., who served as E.I.C. Representative on Technical Council. A successor had not yet been appointed at the end of the year.

CONFEDERATION

The Institute's committee is pleased to report that the year 1958 saw more progress towards Confederation than has been in evidence previously.

So far the members of the Institute have not been consulted but the councillors have had the opportunity to study the report put out by the Joint Committee and have given their approval of it. Also, the councils of the provincial organizations have approved it. It is expected the membership will be asked for their approval shortly.

The report is based on the eight clauses presented to the Plenary Meeting of Council at Quebec in May. There have been no changes in the basic principles or philosophy, but amplifications and interpretations of the clauses have been made a part of the report. Also, the report contains figures on income and expenditures for the National Body, which are used as the basis of the proposed initial fee for the National Body.

The report also proposes that the membership authorize the creation of an interim council to be known as The Engineers Confederation Commission, which will be charged with the task of drawing up the final agreement and the detailed by-laws and regulations necessary for the operation of the National Body. This Commission will represent both the associations and the Institute branches and will have on it representatives from every province and territory.

The Commission's report will be submitted to each corporate member of the Institute for approval. Similarly, the report will be submitted to the provincial bodies. When approval from the Institute membership and the Associations is received, the Commission will be dissolved and the National Body will take over. At that moment Confederation becomes a reality.

The general purpose of Confederation as proposed in the report is to "enable enlarged services to be rendered to the professional engineers of Canada." This will mean the elimination of overlapping activities, the addition of new interests and activities, the development of efficiency in society management, an increase in public recognition, and a reduction in costs and in individual fees.

Your committee wishes to emphasize the pleasure they have had in working with a similar committee appointed by the Canadian Council of Professional Engineers — together constituting the Joint Committee. In particular this applies to the members of the sub-committee who with their opposite numbers from the provincial groups, constituted the Joint Sub-Committee. These six members met several times throughout the year, in Toronto, Ottawa and Montreal. They have spent long and frequent hours in discussions, in deliberations, in the preparation of documents. At no time were they far apart in their ideas, and at the end of it all they were completely unanimous in their recommendations to their own committee and to the parent bodies.

This of itself was a great achievement and perhaps is the best guarantee that Confederation will accomplish its objectives.

It is almost necessary to take a few items from 1959 in order to adequately appraise the work of 1958. In January 1959, the Institute held a Council meeting at Toronto at which the report of the Joint Committee was considered at great length. This meeting finally passed the following resolution:

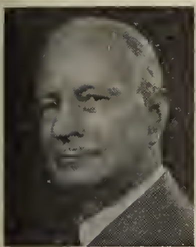
> "That this meeting of the Council of The Engineering Institute of Canada receives and now approves with appreciation the report of its Committee on Confederation (dated 6th November 1958), instructs the General Secretary to circulate to all members of the E.I.C. the ballot suggested in Dr. Tait's letter of January 9, 1959, in a form to be agreed upon by the Joint Committee and by Council, and to request its Committee on Confederation to continue its good work until the proposed provisional Council is appointed."

Since then the report has been revised slightly and once again has been approved unanimously by the members of the Joint Committee. It will be presented to the Council of the Institute in Montreal at the April meeting. After approval there, it is recommended by the committee that it go to the membership with a ballot asking for approval.

Your committee believes that the road to Confederation is now open. As already explained, there are certain steps yet to be taken, but it is not expected they will present any difficulties. When a report similar to this is being written for 1959, it may well record the realization of the long sought objective — Confederation.

Irving R. Tait, Hon. M.E.I.C.,
Chairman.

LIFE MEMBERS COMMITTEE



The number of Life Members within the Institute membership increases each year. The total grew from 751 in 1957 to 809 in 1958; 738 of these are in Canada; 16 in Great Britain and 49 in the United States. There are 7 in other parts of the Commonwealth and 2 are classified as foreign. 45 Life Members died in 1958.

The Life Members Committee again administered the funds collected during the annual appeal. The sum collected from December 1957 to November 1958 was $3,706.00.

Disbursements were made to assist the Institute in several of its activities. For example, $375.00 was made available to augment the Student prizes of the Institute, thereby making the prize $50.00 instead of $25.00 and $500.00 was donated to assist in meeting the expenses of the annual Students Conference held during the course of the annual meeting.

The committee, at its meeting on October 24th, 1958, considered making money available in the form of prizes or bursaries to assist worthy and needy students in meeting their university expenses. Realizing that substantial sums of money would be required to do this on an adequate basis, the committee has been canvassing some of the deans of engineering to get their reactions to proposals which the committee has been considering.

No decision has been reached as yet but favourable comments have been received in every instance. The deans emphasized, however, that as the cost of the university education is increasing steadily it becomes desirable, if not necessary, that the amount of money available should be increased substantially also. It is possible, that with the steady increase of contributions made by the Life Members something worthwhile in this field can soon be done.

The Life Members in the Montreal district had a social evening at Institute Headquarters on April 24th of 1958. It is hoped that a similar event can be arranged for 1959.

L. Austin Wright, Hon. M.E.I.C.
Chairman.

LEGISLATION COMMITTEE

The legislation committee held no meetings, as no matters were referred to it for study or recommendation.

R. B. Winsor, M.E.I.C.,
Chairman.

NOMINATING COMMITTEE 1959

Amherst, R. L. Alexander.
Baie Comeau, T. G. Rust.
Belleville, C. H. Lusk.
Border Cities, C. G. R. Armstrong.
Brockville, R. H. Wallace.
Calgary, A. W. Howard.
Cape Breton, C. N. Murray.
Central British Columbia, E. R. Gayfer.
Chalk River, H. V. Smith.
Corner Brook, K. Bulins.
Cornwall, J. M. Hawkes.
Eastern Townships, J. C. Davidson.
Edmonton, R. N. McManus.
Fredericton, I. M. Beattie.

Vancouver Island, Thomas Miard.
Winnipeg, T. E. Storey.
Yukon, J. R. B. Jones.

Chairman: W. K. Gwyer, M.E.I.C., Trail, B.C.

PAPERS COMMITTEES

During 1958, responsibility for the content of the technical program of the Annual General and Professional Meeting was transferred by Council from the Papers Committee to the Committee on Technical Operations.

There having been no other business placed before the Papers Committee, its activities have been restricted to providing all possible assistance to the Committee on Technical Operations during the period of transition.

J. H. Budden, M.E.I.C.,
Chairman

POLICY COMMITTEE

The Policy Committee was established in 1957, to serve as an advisory body to the council. It studies questions of major policy and prepares recommendations to guide council in its actions.

In 1958, this committee took an active interest in the Institute's new program of regional technical meetings, Zone "A" council meetings, the work of the field secretaries, publications, student affairs and annual meeting dates, and conducted a review of special funds now held by the Institute.

A. Deschamps, M.E.I.C.,
Chairman.

PRAIRIE WATER PROBLEMS

Once again this year the Prairie Water Problems Committee did not hold a meeting, but its members watched with interest certain developments in the prairie water problems.

Construction was continued on the Waterton — Belly River diversions. The Saskatchewan and Dominion Governments completed agreements and work was begun on the Outlook development on the South Saskatchewan. Construction work was continued on some of the St. Mary's — Milk River canal system so that more utilization of irrigation was possible.

A committee was formed by the Alberta Government to study the whole aspect of irrigation during the summer of 1958, and their report will undoubtedly have some impact on the future development and plans for development in Alberta.

The committee will continue a watching brief on the development of prairie waters, and hold meetings as necessary.

G. A. Gaherty, M.E.I.C.,
Chairman.

PROFESSIONAL INTERESTS

The activities of this Committee on Professional Interests have been largely suspended as a result of the discussions going on in regard to Confederation.

Any new agreements between the E.I.C. and the Provincial Associations or changes to the existing agreements have been held up until this whole matter is settled or clarified.

This committee has not carried out any other specific duties and stands ready to act when required.

E. B. Jubien, M.E.I.C.,
Chairman

PROPERTY COMMITTEE

The committee held one meeting, on June 30, 1958, at which the President and General Secretary of the Institute were present, with five members of the committee. Last year we reported that a large building might be erected to the north of the Institute premises on Mansfield Street, Montreal. The chairman had several meetings with the prospective owner of this building to the point that dates were discussed of the time an offer would be made for the property of the Institute. As a result of these discussions, it was recommended that a real estate valuation of our property be made on the basis of ascertaining not only the present market value but also the market value of the property in the light of real estate sales of property adjacent to our own. This valuation was made and, while it cost about

$400.00, your committee believed the expenditure necessary if the Institute were to consider an offer of purchase. While the urgency of making a decision has lapsed, the owners of the property to the north are still asking the Institute to place a price on our Mansfield Street property.

Several months ago the committee consulted two of the leading real estate agencies in Montreal, asking them if they knew of, or could locate, other premises which would be more suitable. So far neither one has made a satisfactory proposal.

There are several possible recommendations that your committee might eventually make. It must be pointed out, however, that the present location is an excellent one and that the Institute is presently occupying extremely low-cost space.

For immediate attention your committee recommend that, in order to overcome the present shabby appearance and serious overcrowding, the following steps be taken during the summer of 1959:

1. The Montreal Branch be requested to relinquish the auditorium and to rent meeting space in one of the many excellent assembly rooms available in Montreal. The branch now pay extra dues to the Institute for the use of the auditorium, and certain other services. Some of this revenue could be diverted to meet the extra cost to the branch.

2. The auditorium be turned into office space after proper plans and specifications have been approved.

The committee would like to point out that they consider the Headquarters building in its present form and condition to be inadequate for a professional body of the standing of The Engineering Institute of Canada. Any monies spent now to make the building adequate for present requirements may be only a temporary measure and, in making such expenditures, the future should be kept in mind.

F. G. Rutley, M.E.I.C.
Chairman,

PUBLICATIONS COMMITTEE

This committee acts in an advisory capacity to the editor on the general policy of the publications of the Institute, and makes recommendations and reports to Council on this work.

Five meetings were held during 1958, 100 technical papers were considered, and 55 were approved for publication.

The report on "The Engineering Journal" activities is best summarized by the following tabulation:

Item	1958	1957	1956
1. No. of copies printed	233,950	222,650	207,000
2. Average monthly circulation	19,034	18,106	16,909
3. Average number of pages	184	206	197
4. Average pages of editorial	91	103	100
5. Number of abstracts printed	40	107	———
6. Percentage return on readership survey	40	42	40
7. Percent technical papers of editorial content	36	34	———

Papers published during the year covered the branches of chemical, civil, electrical, mechanical and mining, and included special articles on engineering, ethics and engineering management topics.

This is the order of readership interest, as indicated by the sample readership surveys:

1. Technical papers.
2. Canadian developments.
3. Business and industrial briefs.
4. Abstracts.
5. Employment.
6. Personals.
7. Branch and Association News.
8. Library Notes.
9. Month-to-Month.

An author's page and a section on International News were added during the year.

The publication of Transactions of the Institute was actively pursued during 1958. Four issues totalling 183 pages were printed in total quantity of 54,000 at an average cost of $4500.00 per issue. The purpose of Transactions is to bring to the members papers by Canadian authors which would not otherwise be suitable for publication because of length, limited interest or technical complexity.

The publication has been well received since printing was resumed in September 1957, and is providing a much needed service for Canadian research and development, with resulting enhanced prestige for the Institute.

Comments and suggestions about Transactions are welcomed, and those engaged in the newer and more specialized branches of engineering are particularly invited to contribute articles and to participate in discussions.

The 1958-1959 issue of "Engineering Careers in Canada" was released in November. 12,500 copies were printed, and the majority have been distributed to universities, libraries, engineering societies, high-schools etc. As in the past, this activity is self-supporting.

Close liaison was maintained with the Committee on Technical Operations. This committee is most appreciative of the co-operation extended by CTO and particularly for their assistance in revising and up-dating the list of reviewers, which now includes over 100 authorities in various fields of engineering.

In view of the highly technical content of Transactions, consideration is being given to the formation of a special Editorial Review Board for this publication.

The committee wishes to express its sincere appreciation and thanks to all authors, correspondents, advertisers and members of headquarters staff.

H. A. Mullins, M.E.I.C.,
Chairman

STUDENT POLICY COMMITTEE

Since its inauguration, the Student Policy Committee has been endeavouring to ascertain how the Engineering Institute of Canada may best serve the undergraduate engineer.

Informal discussions with Faculty Advisers at several universities disclosed that protocol, rules and regulations vary considerably among the universities and this influences to a considerable degree the perogatives and scope allowed to a Student Section on each campus.

At the Annual Meeting in Quebec City, twenty student delegates from fourteen degree-granting universities attended a Student Conference where the Society's role in the student's education and career was outlined and considered. The enthusiasm of the delegates and their serious concern over the problems discussed were most encouraging and impressive.

Since the conference the Committee has been working with the Director of Membership Services in the preparation of literature to acquaint the student with the history of the Institute and a student section manual (not yet completed) that will serve as a guide for the organization of a section and the planning of a worthwhile program.

To date the Committee has largely functioned as a fact finding agency but it is now preparing recommendations for Council's consideration. It is our hope that through the suggested program, we will be able to stimulate the undergraduate's interest and enthusiasm while performing the services that he requires and expects from a national professional society.

C. G. Southmayd, M.E.I.C.,
Chairman.

TECHNICAL OPERATIONS

During the administrative year 1958-59, the Committee on Technical Operations was actively engaged in developing procedures, investigating possibilities for enhanced technical activities throughout the Institute, and planning the program for the 1959 Annual Meeting. The Committee met three times during the year. Much of the work was carried out by correspondence, although frequent resort was made to personal contact and telephone.

The six original Divisions (Chemical, Civil, Electrical, Hydroelectric, Mechanical and Mining Engineering) were active throughout the year. Committee and Division personnel totalled some 60 members of the Institute.

Council has approved the formation of a Management Division and a Bridge and Structural Engineering Division.

During the course of the year the guidance provided for authors of papers at Annual Meetings was extensively revised, to give effect to numerous suggestions arising from observations at such meetings. Significant deadlines were also materially advanced, to provide for:—

Receipt of title of paper and name of author or authors	October 31st
Receipt of abstract of paper	November 30th
Receipt of manuscript	January 31st

As of December 31st, 1958 about two-thirds of the abstracts had been received, for the 46 papers being submitted for consideration for Annual Meeting use. These cover all fields of engineering activity in Canada, although many are tied in directly or indirectly with the Seaway.

In addition it is planned to have a panel of five noted Canadian economists, educationalists and engineers discuss "The Economic Impact of the Seaway".

A questionnaire was submitted to the Branches, relative to their interest in the establishment of Branch Technical Discussion Groups informally organized to read and discuss papers presented elsewhere, and made available through Headquarters. Such papers might be selected from among those accepted for use in The Engineering Journal, or Transactions, publication of which would be delayed for an agreed period to allow of such discussion Groups. Any formal technical discussion arising from such reading would be co-ordinated and forwarded to Headquarters for reply by the author and, possibly, eventual publication in the "Journal". The response to this questionnaire has not yet been analyzed.

A number of proposals received by Headquarters for co-operation of one type or another with various international engineering organizations were submitted to the Committee for investigation. Advice was tendered in all such cases. In two cases, proposals were laid before Council for positive action. These were approved by Council, as noted. Assistance was given the Publications Committee in revision of the lists of reviewers.

Respectfully submitted on behalf of the Committee on Technical Operations.

F. L. Lawton, M.E.I.C.,
Chairman

REPORT OF TRUSTEES ON THE HARRY F. BENNETT EDUCATION FUND

Having been appointed Chairman of the Harry F. Bennett Education Fund October, 1958, it is with some diffidence that I undertake this report on the activities of this Fund for the calendar year of 1958.

Many applications for loans were received coming from most of the provinces. Of these, 57 loans were granted for a total of $11,750.00, repayments on outstanding loans were received in the sum of $4,164.50 and interest on the loans of $187.74 was also received.

The Fund had a cash balance of $570.51 as of January 1, 1958 and a cash balance of $1,828.11 as of December 31, 1958.

As on November 25, 1958 there were outstanding balances on loans of $26,906.50. While most of these loans were reasonably recent transactions, there were a number that had been unpaid for several years. It was the opinion of the Trustee that definite steps should be taken to collect these. Accordingly, appropriate registered letters are being sent to these borrowers.

The Trustees feel that more precise rules of procedure should be followed in both making and collecting loans and accordingly Procedures were agreed upon and respectfully submitted to Council.

O. Holden, M.E.I.C.

REPORTS OF THE BRANCHES

AMHERST: 1958 activities began February 3rd with a dinner meeting at the Fort Cumberland Hotel. The speaker was Lt/Col. M. C. Sutherland-Brown, D.S.O., C.D., B.Sc., P.Eng., M.E.I.C., speaking on the Alaska Highway and the Collapse of the Peace River Bridge. As former senior highway engineer with D.W.D., Lt/Col. Sutherland-Brown gave a very informative and interesting talk, well illustrated with slides and movies, including the actual collapse of the Bridge.

On February 17th a joint meeting was held with the Moncton Branch, in Moncton, N.B. The speaker was the Rev. Father M. W. Burke-Gaffney, P.Eng., of Saint Mary's University, speaking on "Sputniks".

On March 17th a counselling night was sponsored at Mount Allison University in Sackville, N.B., for the engineering students and each branch of engineering was explained by the panel comprised of qualified members.

The panel was chaired by H.W.L. Doane, Vice-President Atlantic Zone, E.I.C.

On November 7th, Mr. J. A. McLaren, Eastern Field Secretary, E.I.C. visited the branch and a dinner meeting was held. Mr. McLaren showed two very interesting films "The Blasting of Ripple Rock" and "Building Methods in the Artic".

At a Dinner Meeting on December 5th the election of officers took place and Mr. J. D. Conlon, Chief Engineer, Maritime Marshlands Rehabilitation Association, spoke on the study undertaken by his office on the proposed Tidal Power Project which was considered for incorporation in the Annapolis River Dam now under construction to reclaim marshland in the Annapolis Area of Nova Scotia.

Counselling was carried out by members at Career Guidance Nights at several High Schools in the area.

BAIE COMEAU: As our branch is new, we did not organize any Professional Development Courses last year, nor did we participate in Counselling in Schools.

We have been quite active the last two months investigating the general situation at Baie Comeau. Conditions here are quite different from branches in or near urban centres. We met with our secretary, Mr. L. A. G. Tellier, and discussed the general problem of building an appropriate organization.

We have no *Engineers' Wives' Association* at Baie Comeau. We are interested in such an organization, however, and will discuss it at the next meeting of the Executive Committee.

The branch is attempting to search out methods by which member engineers can help young students to enter the engineering profession.

BELLEVILLE: The account of the activities of the Belleville Branch during 1958 are as follows:

Eight meetings were held during the year including two plant tours. Meeting topics were "Health Problems in Industry", "Water Pollution and Sewage Disposal", "Development of the Industry and Industrial Research in the Uses of Plywood", "The Dock at Baie Comeau" and "The Dew Line".

Tours were made of the Pyrotenax and the Hinde and Dauch Paper plants in Trenton.

$25.00 prizes were given to the Grade XIII student in each of the local high schools who plan to enter engineering and has obtained the highest standing in English, Algebra, Trigonometry, Geometry, Physics and Chemistry. The award was broadened this year to allow a separate prize to be given at each school. David James and Jim Green were the winners at Belleville C.I.V.S. and Quinte Secondary School respectively.

The branch did not hold a Professional Development Course during 1958.

BORDER CITIES: Nine meetings were held by the branch during the year, of which two were joint meetings with the APEO. The program was interesting and varied and was well accepted by those attending. Discussion on the subject of professional development has led the branch to the conclusion that there is no need in the immediate future due to the proximity of Assumption College and other universities located in Detroit.

The branch has advised local schools of their willingness to participate in counciling services if required but there is no organized student guidance program.

The Engineering Wives Association held two general meetings during the year. The Annual Spring Tea was held at the home of Mrs. J. E. Mainwaring of April 12th and on April 29th members enjoyed a tour of the Canadian Rock Salt Plant at Ojibway. Other activities included a family picnic at Point Pelee on June 21st and a luncheon at the Lakewood Golf Club on Sept. 16th.

During the President's visit an afternoon tea was held in honour of Mrs. Tupper at the home of Mrs. C. M. Armstrong with members of the executive attending. Among the groups which are progressing very favourably are three bridge groups and a bowling group. The membership totals approximately 81 and averages an attendance at meetings of approximately half the membership.

BROCKVILLE: Seven meetings and one plant tour were held in 1958. The topics of the meetings covered such subjects as Responsibilities of Management, Engineering Aspects of Fire Underwriting, Pros and Cons of Automation, The Acoustics of the Shakespearean Theatre Stratford, Pitting Corrosion, Water Supply and Sewage Disposal Problems at Brockville, and Laying a Submarine Cable in Lake Maracaibo, Venezuela. Great difficulty was encountered in selecting dates for meetings that would not conflict with the arrangements made by the P.D. group. On occasion it was felt that both Branch and P.D. meetings would suffer unduly from having too many engineering meetings, and as a result joint meetings were proposed and branch attendance at two of the P.D. meetings has proved successful. The average attendance at meetings was 35.

The 1958-59 P.D. course is a series of 10 lectures on general aspects of law. The speakers are from the Law Faculty of Queen's University. The course has proved very popular, and there is an enrollment of 57 of which 30 are non-members of EIC.

The topics of the lectures are Buying on Credit, Criminal Law, Criminal Procedure, Wills and Estate Planning, The Courts and Litigation, Motor Vehicle Accidents, Companies, The Proposed Bill of Rights, Family Laws, and Real Estate Transactions. The average attendance has been 45. The Professional Development Committee feel that the success of this course will form a good basis for future courses with regard to organization, cost and planning. This is the third year the branch has had a professional development course.

A membership drive was held during the year and although considerable effort was put into it, the results were not too encouraging. There is a potential of 93 new members in the area but the results of correspondence and personal approach to these engineers is not yet apparent.

CALGARY: Four general technical meetings were held during 1958. All were of the "double" dinner type, starting at 5.30 p.m. with a very short business meeting and then the first speaker. The meeting would then adjourn for dinner. At approximately 8.00 p.m. the meeting would reconvene and a second speaker give a talk. The average attendance at these four meetings was approximately 85. The branch annual meeting, which is held in April, had Dr. O. M. Solandt, one of Canada's leading scientists as guest speaker and approximately 70 people attended.

The social functions of the year included the barbecue held for President Anson during his visit in January, the annual "Slide Rule Soiree" in February attended by approximately 320 people and the annual barbecue held in September.

The first part of the year saw completion of our first fully fledged Professional development course. The final eight meetings of the 15-meeting course were held in January through to April with approximately 350 members registered. Two courses, one on "Religious Philosophies" and the other on "Government" were held in the fall. Each course consisted of 5 lectures and had a registration of approximately 70 people.

The Student Guidance Committee worked with the General Guidance Committee of the Calgary School Board in providing counselling to high school students. An Engineers' Panel was provided for a student guidance meeting in March. The branch also provided refreshments for the students. Approximately 40 students attended the meeting.

The Engineers' Wives, with a membership of 225, again had a very active year. They had a Handicraft Group, three Bridge Groups and a Cultural "Coste House" Group. The general functions included a Pot Luck Supper, Annual Dinner and The Annual Membership Tea. The wives also made their Annual Scholarship award of $100.00 to a high school student who registered as a first year engineering student at the University of Alberta.

CAPE BRETON: During the year members received talks on "Metropolitan Surveys" "Coal Preparation", "An Engineer Looks at Space Travel" "Lubrication in the Operation of an Oil Refinery" and "A Visit to Australia". Average attendance at these meetings was approximately 35 to 40. On June 11th the annual lobster party was held at Alex LeDrew's summer cottage and on October 31st the Cape Breton branch executive members met Mr. J. A. McLaren, Eastern Field Secretary, for discussions on various phases of EIC activity. A social evening was held on November 17th for members, their wives and friends with an attendance of approximately 45 couples. Reports by the various committee chairmen and by the branch chairman, J. V. Palmer, were delivered at the annual Business Meeting on December 10th and the scrutineers reported the names of the branch officers elected for 1959.

The final event of the year was the highly successful New Years' Eve party attended by more than 100 couples.

The Professional Engineers' Wives Association was formed in 1957 to promote friendship among the wives and widows of the engineering profession. Five business meetings were held during the year with an average attendance of 20 from a total membership of 32. During the year a very successful tea was held at the home of Mrs. W. R. Lewis. Many of the members participated actively in the Mental Health Blitz.

CENTRAL BRITISH COLUMBIA: I am pleased to be able to report that in 1958 our membership has risen by nearly 15% over that of last year. This has been a continuation of the trend for the past few years and is, I hope, a measure of the growing importance of our branch in British Columbia.

Our Central British Columbia Branch covers a very large geographical area and it is, I feel, a credit to our members that attendance at the meetings have been so good and enthusiasm for our projects so high.

During 1958, British Columbia Centennial Year, the branch has brought close to completion the ideas promoted last year of honouring those engineers in British Columbia whose lives and endeavours have done so much to build this province as we know it today. Cairns commemorating them have been placed in a number of leading centres in the central interior.

A number of very interesting meetings were held during the year, in particular that which our President, Mr. C. M. Anson and wife attended. It was a great pleasure to have our President in attendance and I am sure his visit was very much appreciated.

I should like to extend my sincere thanks to the 1958 Executive, especially our secretaries and convenors who have done splendid work in arranging the meetings of the Institute during the year and carrying out those duties which befell them. I would like further to extend my good wishes to the incoming 1959 Chairman and executive and hope that our membership will give them the splendid co-operation which I have experienced in 1958.

CHALK RIVER: The Chalk River branch was inaugurated on May 9th, 1958 with a nominal role of 31 members. The boundaries of the Chalk River branch as approved by Council consists basically of the County of Renfrew less the Townships of McNab, Bagot, Blithfield, Admaston Horton and Ross.

Meetings were held on November 19th and December 17th at which interesting talks on the Chalk River Project were heard and a film entitled "Our Mr. Sun" was shown. During the year the Chalk River branch was host to the Nipissing and Upper Ottawa branches and the Peterborough branch and supplied guides for a tour of the plant. The Chalk River branch would be pleased to arrange and conduct visits to the Chalk River Plant A.E.C.L. at any time. Any branches interested in this tour please contact the branch secretary giving one month's notice if possible.

The branch is not yet engaged in student counselling activities nor has it encouraged the formation of an Engineers' Wives Association. In regard to the latter activity it is considered more advantageous to encourage members and wives meetings than to attempt to form another group, since there are many clubs and societies already operating in the Deep River area.

CORNER BROOK: Five technical meetings, one dinner meeting and two business meetings were held during the year. Subjects covered during the technical meetings were "The Application of Air to Industry", "Communications with Emphasis on Trans-Canada Toll Dialing Systems", "The Microwave System", "An Engineer Looks at Space Travel" "Wild Life in Newfoundland".

On June 27th, a dinner meeting was held at which Mr. W. S. Read spoke on "The Watson's Brook Power Development". A business meeting was held on January 28th and on November 6th, an executive dinner meeting was held with the visiting Field Secretary, Mr. J. A. McLaren. Attendance at all meetings was generally good varying from 12 to 25 members.

In general the Corner Brook Branch enjoyed a very good year in 1958.

CORNWALL: During the year 1958 our activities were maintained at the same high level as in previous years. We started off with a visit from our Montreal Vice-President Mr. Deschamps. The ladies were present and the two recipients of our bursary were presented with certificates at this time. The other meetings during the year were of varied interest with talks on the following:

- "Economic Advantages of Complete Year Round Air Conditioning"
  by Mr. N. K. Smith of Honeywell Controls.
- "Charting Arctic Waterways"
  by Mr. Mike Bolton of Canada's Hydrographic Services.
- "Conversion of Coal Fired Boilers to Oil"
  by Mr. G. Van Beek.

A visit to the Power Dam closed our season for the summer.

The Fall season opened in October with a talk on the "Modification of the Jacques Cartier Bridge" by Mr. Ross Chamberlain and in November Mr. Serge Stuken of Canadian Arsenals talked on the production of Ballistic Missiles. It will be seen that the topics were of a more general interest rather than purely technical. This is in many ways dictated by the rather varied interest of the engineers in our branch. Attendance at all talks was an average of 25 members.

Our membership has fallen off during the past year and many friends we had made during the construction of the Hydro Project have left.

No award of the Magwood Bursary was made this year because in the eyes of the bursary committee no student was eligible. All students who were previous recipients are doing well at their respective universities.

On April 2nd the Cornwall Collegiate and Vocational School held a career day programme. Members of our group addressed groups of students on mechanical, electrical and civil engineering.

EASTERN TOWNSHIPS: The branch held eight meetings during 1958. Most of these meetings were held at Le Club Social de Sherbrooke, and included a buffet supper sponsored by local commercial or industrial firms. Attendance at meetings was relatively high.

On January 10, Mr. R. L. Beck, engineer of the Civilian Atomic Power Dept., Canadian General Electric gave a talk entitled "Progress in Atomic Energy", illustrated with slides. Members of C.I.M.M. Sherbrooke Branch were our guests. J. S. Mitchell & Co., sponsored a buffet supper served before the meeting to almost 110 members and guests.

Mr. C. A. Peachy, President of the Corporation of Professional Engineers of Quebec addressed a joint meeting E.I.C. — C.P.E.Q. in February. A total of 121 engineers turned out to hear Mr. Peachey's "Plan for Unity", and enjoyed a splendid buffet-supper offered by Codere Ltée.

The first students' night organized for engineering students at University of Sherbrooke was held at the auditorium of the Faculty of Engineering on March 14th. Mr. Adrien Leroux, fourth year student won the first prize with a paper entitled "Power Factor Correction". At the end of the meeting, lunch was served at the Cafeteria, courtesy of Coté, Lemieux, Carignan & Bourque, Consulting Engineers.

On April 11th, C.I.M.M. Sherbrooke Branch invited members of the branch to a meeting sponsored by Forano Ltd. and featuring Mr. R. F. Shaw, Vice-President of Foundation Co. of Canada. Mr. Shaw gave a talk on the "Dew Line", illustrated with an excellent film in colour.

The annual meeting of the branch was held at Beauharnois, Que. on May 3rd on the occasion of a visit of Beauharnois Power Development and the adjoining Seaway Locks.

The Annual Golf Tournament took place at the Sherbrooke Country Club on September 27th. In spite of very inclement weather, 37 members participated. Mr. Roland Dugre from Asbestos, Quebec won the Fabi Trophy.

Mr. F. T. Matthias, Director of Engineering and Construction Division, Aluminum Co. of Canada, addressed a joint meeting E.I.C. — C.I.M.M. on Alcan's "Chute-des-Passes" Power Development. This meeting had been arranged by the Sherbrooke Branch of C.I.M.M. and sponsored by Hall Machinery of Canada Ltd. At the end of last year, the branch reached an agreement with C.I.M.M. Sherbrooke Branch whereby two meetings of the season would be joint meetings, and each of the branches would organize one meeting. This agreement was made in order to help the local branch of C.I.M.M. which has lost a few members following the closure of mining concerns in the Eastern Townships.

Finally a joint meeting C.P.E.Q. — E.I.C. was held on December 12th to honour Mr. Guillaume Piette, President of the Corporation. On this occasion, the president inaugurated the Eastern Townships Chapter of the Corporation. The officers of the new chapter are those of the executive committee of the branch.

EDMONTON: The Edmonton Branch held seven dinner meetings during 1958 with an average attendance of 80. A variety of speakers were heard at these meetings, their subjects ranging from nuclear power stations to development of Canada's north.

One field trip to the Premier Steel Plant on the outskirts of Edmonton was made in March.

One lecture meeting was held, the subject being the "Deas Island Tunnel". This talk was given by Mr. Lea of the Foundation Co. of Canada and was arranged by the Western Field Secretary.

The two highlights of the year were the annual family picnic, held in June, and the annual dance, held in November. Both of these functions were well attended.

A professional development program was begun in the Fall of 1958 and was offered in association with the department of extension of the University of Alberta. The detailed arrangements for this course were made by Mr. Jack Longworth, chairman of the Young Engineers' Committee, in co-operation with officials of the department of extension.

The program was divided into two parts. Three lectures on "Effective Reading" and two on "Public Speaking" were presented during October 20th to December 15th. The lectures were of one and one-half hours' duration and were held every second week. Five lectures on "Business Management" were planned and these commenced on January 12, 1959. The fee for the total series was ten dollars, or five dollars for each half. 64 members were enrolled for the first half of the program and 55 for the second half.

This branch did not carry out counselling in high schools in 1958.

The Engineers Wives' Club was again very active during 1958. 1958-1959 is the tenth season during which this Club has been in existence. A monthly meeting is held each month from September to April. As well as these monthly meetings, the following activities are carried out by smaller groups within the Club: Books, Bowling, Curling, Bridge, Handicrafts, Dancing and Public Speaking.

The membership at the end of 1958 was 353.

FREDERICTON: During the year the branch held eleven regular meetings most of which were dinner meetings with guest speakers.

A total of seven speakers and one panel discussion were heard on such varied subjects as:

1) Hydrology of the Saint John River.
2) The Organization and Operation of a City Engineers Department.
3) The Human Side of Engineering.
4) The New Steam Generating Station of Fraser Companies Ltd. in Edmundston, N.B.
5) Prospects for Thermal and Nuclear Power Generation in the Future.
6) Past and Future Developments in the Telephone Industry.
7) Problems of Water Pollution and its Control.
8) The Status of Confederation of the E.I.C. and Professional Engineering Organizations.

Of the seven speakers hear, five were from outside the Fredericton Branch and were:

Mr. A. H. Tweedie of the Royal Canadian Engineers.

Mr. T. Bellinger of H. C. Acres & Co. Ltd.

Mr. J. Cunningham of the N.B. Telephone Company.

Sir Claude Gibb of C. A. Parson's Co. Ltd., England.

Mr. D. O. Turnbull, Consulting Engineer.

The two branch members who delivered papers were Mr. J. L. Feeney and Mr. W. L. Barrett.

Social entertainment included a dance sponsored by the U.N.B. Engineering Society, a smoker for the graduating engineers at U.N.B. a lobster boil in June and the upriver meeting at Edmundston in September which included a dinner, dance and golf tournament.

This latter function, which combined social and technical functions was organized completely by the non-resident members and was a great success.

The ladies were invited to all the social functions with the exception of the student smoker.

HALIFAX: Membership in the Halifax branch increased by 42 and totalled 598 by the end of 1958.

The technical and social program for the year was a most successful one. Ten general meetings were held, in addition to a very successful showing of the pictorial exhibit "Atoms for Peace in the USSR". The two social events of the season were co-operative efforts with the Association of Professional Engineers of Nova Scotia and took the form of a joint Annual Banquet and a special meeting at The Pines in Digby.

The technical meetings were generally well attended with the notable exception being the February meeting with senior students at Tech.

For the first time in a number of years the branch closed the books showing black ink. This was done without prejudice to the general activities of the Halifax branch and as a tribute to the enthusiasm and support of the members.

It was necessary to appoint two new members to the executive during the year. In accordance with the requirements of the by-laws, Mr. R. B. Killam of Yarmouth replaced Mr. J. E. Clarke who was transferred from the branch area, and Mr. H. A. Marshall replaced Mr. W. J. Phillips who was elected Vice-Chairman at last year's election.

Headquarters this year emphasized the advantages of the formation of technical divisions in the various branches. After considerable discussion your executive decided and so advised headquarters that technical divisions would not be successful in our organization at this time. However it is gratifying to note that a number of Halifax branch members are on the National Committee on Technical Operations.

Careful consideration was given to the organization of professional development courses in the branch but after much discussion it was decided that professional development courses would not be organized in 1958. An opinion was expressed that the universities, The Junior Board of Trade and various private companies offered somewhat similar courses, and that the need was not as great as in previous years.

The branch was active in student affairs and is now ready to provide student guidance services to advance pupils at high-schools in the area.

The Halifax branch participated actively in the Maritime Professional Engineers' Conference at Digby and enthusiastically supports this worthwhile activity.

HAMILTON: The total membership at the year end was 471 members, a decrease of 31 from the previous year. There was a decrease in all categories except Branch Affiliates.

Hamilton Professional Development Program continues the success it has enjoyed for several years under capable leadership. The Director attended meetings of the Engineers' Council for Professional Development in Pittsburgh and St. Louis and, together with representatives from Toronto and Niagara Falls, outlined the programs being conducted in Canada. The program has a membership of approximately 150. A self-appraisal form is being prepared to assist members in determining their progress since graduation. A comprehensive reading list has been provided to the membership.

A varied and interesting program at eight meetings was held during the year, and included a field trip to the Parkdale Works of the Steel Co. of Canada. To change the format of the fall stag, a beer and oyster party was held in September on McNally's farm near Waterdown. This was a very successful occasion in spite of the beer strike. The Annual Engineers' Ball was attended by 140 couples and was one of the best balls we have had. The die casting section of the Canadian Manufacturers' Association provided an interesting panel discussion together with a film of the Die Casting Industry. President K. F. Tupper visited the Branch in November and addressed the membership on his trip to Russia . . . The 5:30 Dinner meeting appears to be gaining favor in many Branches. The program committees are commended for providing varied and interesting meetings.

The branch news editor provided coverage of all branch functions in both the Hamilton Spectator and the Engineering Journal.

The meeting attendance varied between 40 and 75. The efforts of the attendance committee are directed to the new members of the Branch through a phone squad.

Two very successful programs have been operated in the past two years. A course on the general subject of Law is presently being conducted by members of the Hamilton legal profession. 126 are registered of whom 59 are non-E.I.C. members. Interest is very high in this course.

The counselling committee maintained by the Branch has filled several speaking assignments. Members have been asked to assist in counselling McMaster engineering students. This program can have beneficial results to all concerned when in operation.

The first conference of a regional nature was held in Hamilton this year. Its success is now a well-known fact. 200 couples attended from all of Southern Ontario. The calibre of the technical papers was high. An interesting program was provided for the ladies. Many branches have inquired about the program to guide them in preparing their own conference.

We express sincere appreciation to all those who have been responsible for providing the many services rendered by the Branch in the furtherance of the engineering profession. Your work on the various committees is gratefully acknowledged.

HURONIA: The Huronia Branch enjoyed a fairly active year. The subject matter of our meetings was well diversified and maintained considerable interest among the members.

Counselling of high school students was carried out by a committee appointed for this purpose. This committee worked with members of the Canadian Institute of Mining and Metallurgy and extended their service to outlying areas of the branch through Institute members.

The desire to establish a professional development course has not yet been noted. It seems that the lack of a concentration of junior members in any one town of our area has hindered any movement in this direction.

KINGSTON: The program for the year was an active one beginning on January 14th with a paper on "A Ship Model Milling Machine" and finishing on December 9th with a ladies film night. In the intervening period the branch was presented with papers on "Vibration Problems in a Large Utility", "Air Pollution in Hamilton, Ontario", "Water Resources" "Some Aspects of Racing Yacht Design" and "Modern Instrumentation in Control of Chemical Processes". An informative and interesting panel discussion on engineering education moderated by L. F. Grant and consisting of D. M. Jemmett, D. L. Rigsby, V. S. Ready and R. W. T. Birchard was held on February 6th. A student paper's night was held on March 4th and the Joint CIC, KMS, EIC Dance took place on March 7th. The annual meeting and dinner was held on May 31st. The branch did not operate a professional development course during the year but some preliminary plans were made for a technical conference to be held early in 1960.

While the branch did no formal counselling during the year a panel discussion on engineering education served its purpose to some extent.

KITCHENER: The Kitchener branch was very active during the year, and thanks to a drive by the chairman and other members of the committee to ensure good turnouts at meetings, the season ended with a slight surplus. A very successful Students Night was held at Waterloo College.

The branch was successful in securing the services of Dr. Lord as the guest speaker and the good results obtained encouraged us to embark on a similar program with the Ontario Agricultural College next year. The program might be stimulated by instituting prizes for student papers or some other similar activity.

The branch continued to provide counselling services for high-school students in the area.

It has been found very difficult to arrange general meetings without coming into conflict with meetings of other local service clubs, and probably because of this, technical meetings are generally not well attended. On the other hand, social functions have been very successful.

It has been the experience of this branch that to ensure successful turn-out a great deal of spade work must be done. Speakers topics should be of a general and interesting nature and some device such as a telephone committee must be used to stimulate interest.

KOOTENAY: The executive has taken a great interest in the national affairs of the Institute this year, stimulated by the close approach to Confederation and also by the progress shown in the development of Zone Council Meetings under the leadership of our member and Vice-President, the late S. C. Montgomery, and by the Western Regional Conference to be held in Banff in 1959.

The Annual Meeting in Quebec City was attended by our councillor and late vice-president, distance preventing other members from participating.

Locally, we have continued to hold regular monthly dinner meetings with the exception of October and November. The meetings, continue to be well attended and appreciated.

We had a total of 7 dinner meetings, 1 smoker, 8 executive meetings and in addition we displayed the Russian and U.S. Panels on Atoms for Peace at a meeting of the Joint Technical Societies in this area.

The highlight of the year was our President's visit in April.

Our Scholarship Award of $50.00 was presented this year to engineering student Grant John of Trail.

We again participated in the Joint Technical Societies' program of vocational guidance for High School Students.

No professional development course was offered in 1958, although preliminary steps were discussed at our last executive meeting toward re-establishment of this course.

Membership has shown a slight decline since the year end of 1957. This is mainly due to deaths, transfer and one resignation.

LAKEHEAD: The Lakehead Branch enjoyed a successful year financially and more important still, the general membership showed a greater interest in the affairs of the branch.

A total of ten meetings were held during the year, two of which were social. The technical meetings were well attended but there was a decided preference for topics of a general nature which could be related to everyday life.

The Lakehead's annual dance held in March this year was an outstanding success with over eighty couples in attendance. The '59 dance committee have a high standard to emulate.
The branch was honored by having a visit from President Dr. K. F. Tupper and the general secretary, Dr. Garnet T. Page. A dinner dance was held in honor of this occasion and a good number of members and their ladies came out to hear Dr. Tupper speak on his impressions of Russia gained on his recent trip to that country.

The Lakehead boasts a very active Wives'Association and they repeated last year's success by sponsoring an excellent supper dance following the cocktail party given by the A.P.E.O. President, Mr. C. T. Carson, for the district engineers and their ladies. Mr. Carson was accompanied by his wife and daughter and by Col. T. M. Medland, executive director.

The ladies are not solely concerned with social activities and for the last several years have donated a bursary to be given to a deserving student as recommended by the Lakehead College of Arts Science and Technology.

LETHBRIDGE: Following is a statistical summary of Lethbridge Branch activities during 1958.

Number of regular meetings	4
Average Attendance	37
Number of special meetings	2
Attendance	40
Number of field tours	1
Average attendance	40
Number of executive meetings	5
Average attendance	6

The branch did not operate a professional development course during 1958.

In January the film "The Eighth Sea" depicting the St. Lawrence Seaway Project was shown to the members at the regular monthly meeting. A paper, suitably illustrated by slides on "Hydraulic Model Testing", was presented to the February meeting by C. D. Smith, Hydraulics Engineer for the P.F.R.A. at Saskatoon.

In March, the Branch was given a talk entitled "A Forward Look at the Telephone Industry" by Mr. H. J. Childs, Switching and Planning Engineer with the Alberta Government Telephones.

The October meeting took the form of a joint dinner meeting with the Association of Professional Engineers, which was followed by a panel discussion on "Professional Affairs". The panel consisted of Dr. Govier, President of the A.P.E.A.; A. E. McDonald , Executive Secretary of the A.P.E.A.; C. A. Stollery, Vice-President of the A.P.E.A.; and J. F. McDougall, Registrar of the A.P.E.A.

The highlight of the year was the noon luncheon meeting in November at which time the branch was honoured by a visit from President and Mrs. K. F. Tupper and the General Secretary of the E.I.C., Garnet T. Page. Following luncheon, a very enlightening field trip was taken to the Canadian Sugar Factories plant at Taber, Alberta.

The annual "Engineers Ball" was held in December, a successful climax to the year's activities. All the meetings were dinner meetings, and the branch was again fortunate in having Mr. and Mrs. G. Brown provide the dinner music, a tradition with the Lethbridge Branch for over thirty years.

The Ladies Auxiliary had a very successful and active year. Regular monthly meetings were held with bridge parties on alternative months, and guest speakers at the other meetings covered many interesting topics. The Highlights of the year were the tea and luncheon tendered Mrs. K. F. Tupper when she accompanied President, Dr. K. F. Tupper on his visit to Lethbridge in November, and the year end banquet held at the Flying Club in May.

LONDON: A Professional Development program was organized by the London branch for the 1957-1958 season. Two separate groups were active and total registration for group A was 13 with an average attendance of 6 while total registration for group B was 41 with an average attendance of 17.

The branch co-operated with the Guidance Dept. of the London School Board at their career exposition and assisted the association of Professional Engineers with a display booth at which high-school students could make enquiries about engineering as a career.

The Engineers' Wives Association organized 4 social events during the year and entertained the President's wife at luncheon on November 28th at which time they presented her with a souvenir coffee spoon of the city. Membership in the Wives' Association for the year was 146.

The branch generally enjoyed a very successful year.

LOWER ST. LAWRENCE: The Branch held two smokers at Rimouski early in the year, and on October 27th, the new executive was elected at a gathering of engineers from Rimouski and the surrounding area.

A ballot was held to determine the type of program to be organized for the coming season, and it was agreed that there would be two mixed social events, one technical meeting, one industrial visit to the North Shore and two smokers.

On October 20th, a special dinner meeting welcomed the Field Secretary, Mr. J. McLaren, and on December 13th the members and their ladies held an enjoyable dinner party.

MONCTON: Nine technical and social meetings were held during the year. In January, J. D. Cunningham, public relations officer, N. B. Telephone Co., gave an address on the future of the telephone.

A combined meeting of the Amherst and Moncton branches was held in February, at which, Fr. Burke-Gaffney spoke on space travel and related subjects. Nominations for 1958-59 branch officers were received at the March meeting. Also, at this meeting, slides were screened showing the pre-stressed girder bridge, under construction, connecting Shippigan with Shippigan Island. The annual meeting of the branch was held on May 26th. During the summer, a Saturday afternoon cruise on Shediac Bay, arranged by Lloyd Parsons, was cancelled at the last moment because of stormy weather. Instead, branch members were entertained at the shore cottage of Mr. and Mrs. Parsons. The fall season opened in October with an address on investments, stocks and bonds by W. A. Shaw, Moncton manager of Anglin, Bell and Co. In November, the branch heard G. G. Fisch speak on professional management today. On November 13th, the executive entertained J. A. McLaren, Eastern Field Secretary, at dinner and afterwards held a round table conference with him.

The branch membership now numbers one hundred, the largest in some years. The branch does not operate a professional development course and has no counselling committee for high school students.

We regret to record the passing of William James Edington, M.E.I.C., whose death occurred on September 25th.

The Engineers' Wives Association of Moncton branch, has a membership of sixty. Mrs. W. M. Steeves is the president and Mrs. V. C. Blackett the secretary-treasurer. Four social affairs and business meetings were held during the year, the first being a bridge at the home of Mrs. W. A. Purdy, on February 7th. The annual meeting was held on May 9th, at the home of Mrs. J. W. Demcoe, and officers for 1958-59 elected. Bridge was played after the business of the meeting had been concluded. On November 13th, a very successful pot-luck supper was held at the Y.M.C.A. The group was addressed by Dan Billing, Co-ordinator of Civil Defence for southern New Brunswick. On December 5th, a Christmas dance and buffet supper was held in the Brunswick Hotel, to which members of Moncton branch were invited.

MONTREAL: The activities of the branch are numerous, and only some of them can be mentioned in this report. This does not lessen the appreciation of the untiring efforts of all those who contributed to the successful program of the past season.

Special committees are now studying problems in evening education, French-English membership and branch communications. The committee on French-English Membership is of special interest, since it is unique to branches having bilingual or multibilingual membership. Its purpose is to determine whether the proportions of French speaking and English speaking members of the branch bear some reasonable relationship to the relative proportions of these two language groups in the total population of Montreal, and if not, whether any steps can be taken to bring the proportions more nearly in line with what it is felt they might be.

1958 activities included the annual meeting, students night, a National Film Board tour, a pre-summer social, a golf tournament, the annual dance, a smoker and talks on the "Ville Marie Project" and "Construction of Bersimis No. 2". The Professional Development Seminar consisted of a series of lectures on Management and Leadership, Organization, Planning, Forecasting, Control, Business Financing, Marketing and Advertising, Labour Relations, Chairmanship and Taxation. It was attended by approximately 45 members. The Junior Council held regular monthly meetings, and prepared interesting functions and meetings for the 1400 Junior E.I.C. members.

A Telephone and Publicity Committee operates in the Montreal branch. Its main functions are to contact and advise members by telephone and to write and edit reports on meetings and other functions.

A Special Studies Committee was formed to inquire into ways and means of improving the Branches programs and activities, and a Social Club Investigation Committee was given the task of determining the feasibility of organizing a social club for engineers and friends who could meet informally for luncheons and other planned activities. Student representatives were very active at the universities, and more than 100 students attended the Students Night.

The technical sections presented varied programs. Thirty-four interesting papers were presented, and a number of field tours were made.

In the course of the year the branch organized two forums to acquaint graduating high-school students with the profession of engineering, its challenges, its rewards and its responsibilities. Work also advanced on the preparation of a manual on student guidance which it is hoped may be made available to branches throughout Canada.

NEWFOUNDLAND: The branch had another successful year with good turnouts at monthly meetings, and a favorable financial situation existed.

During 1958 we held seven general and six executive meetings. The general meetings took the form of dinner meetings, and we were fortunate in securing prominent speakers for each of these occasions. Some of our speakers were Dean D. L. Mordell, M.E.I.C., McGill University, and Mr. J. A. McLaren, M.E.I.C., Field Secretary.

As in previous years, we had a students night at which three engineering students from Memorial University presented papers on the subjects of their choice. Mr. G. Moores was awarded the prize of $50.00 for his paper on Stock Market Trends.

The social highlight of the year was the annual dance in April.

NIAGARA PENINSULA: The 1958 program began on January 30th when a joint EIC - APEO meeting was held at Niagara Falls. On March 15th, many members attended the Regional Technical Conference at Hamilton, and in April members enjoyed a tour of the Atlas Steel Plant in Welland, followed by dinner.

The Niagara Peninsula Branch Annual Meeting, which is also the Annual Ladies Night, was held on May 9th. Following the reception and dinner an interesting talk on glass was heard. The pre-vacation program ended in June with a visit to the Huntley Generating Station at Buffalo, N.Y.

The 5th Annual Professional Engineers Ball was held on September 26th in co-operation with the APEO and was attended by approximately 200 couples. In October the branch listened to an interesting talk on Education and Technical Advances in Russia, and in October they were addressed on the subject "Building a Greater Canada".

The President's visit to the branch took place on November 27th, and on December 4th the final meeting was held at which a paper on the Burlington Skyway was presented.

The majority of EIC events in this region are held as joint affairs with APEO, and this arrangement has been most satisfactory.

NIPISSING AND UPPER OTTAWA: No professional development courses were offered by the branch in the past year. Counselling for high school students was carried out in 1958 and a "Student's Night" was successfully held in March with 29 Students in attendance at a dinner meeting. This event is again planned for next year.

Highlights of the year included the visit of President Tupper and General Secretary Page and a field trip to the Atomic Energy Plant at Chalk River.

Our Branch does not have an Engineers' Wives' Association, as such, but on the occasion of the President's visit, an afternoon tea was held by the wife of our Branch Chairman in honour of Mrs. Tupper.

NORTH EASTERN ONTARIO: This branch was in the process of reorganization during 1958, and no formal program of activities was carried out.

NORTHERN NEW BRUNSWICK: The branch held a total of eight meetings during 1958 including five general, two executive and the annual meeting. Attendance at the general meetings averaged about 40% and at the annual meeting about 60% of the active membership. Branch membership totalled 65 on December 31, 1958 as compared to 62 on the same date in 1957.

The first general meeting of the year was held in Dalhousie on February 21. The guest speaker was Mr. R. C. Eddy, M.E.I.C., of Bathurst, who gave an interesting talk on the Sematic Reaction, or S-R-Grid.

The second general meeting was held in Bathurst on March 28. Following a business meeting, the members saw the film "Our Mr. Sun", supplied by the New Brunswick Telephone Company.

The third general meeting was held in Newcastle on May 10. Guest speaker was Mr. H. D. Scully, manager of Nesbitt, Thomson & Company Ltd., Saint John, N.B. Mr. Scully gave a very interesting talk on the services rendered by an investment dealer and on the different types of securities on the market.

The annual meeting was held at the Country Club in Dalhousie on June 6, with the ladies present. A brief business meeting was held to provide for the installation of new officers. The guest speaker was Mr. E. A. Barks, Regional Meteorologist of the Atlantic Provinces. Mr. Barks gave an interesting outline of the development of weather forecasting in which he covered the growth and scope of the weather services of Canada.

The fourth general meeting was held in Campbellton, on October 1, The guest speaker was Mr. G. B. Lawson, who until recently was a design engineer with Fraser Co. in Edmundston and is presently associated with Fraser Co. sales division in Montreal. Mr. Lawson gave a very interesting and aptly illustrated paper on the new steam plant extension at Fraser Co's Edmundston mill, which produces pulp for the Fraser Co's paper mill in Madawaska, Maine.

The fifth and concluding general meeting of the year was held in Bathurst on November 18. Guest at this meeting was Mr. John A. McLaren of Toronto, the Eastern Field Secretary of the Institute, who was completing his first Maritime tour. Mr. McLaren's talk concerned the many functions of the Institute and he pointed out that one of his main duties was to bring the facilities of the Institute's Headquarters closer to the outlying Branches. Two films, entitled, "Ripple Rock", a description of the April 5 demolition and "The Eighth Sea", a description of the St. Lawrence Seaway Developments were then shown.

NORTH SHORE LOWER ST. LAWRENCE: The branch had a very active and successful year with the main activities being five dinner meetings and two field trips. Mixed dinner meetings are found to be especially successful and talks were heard on the following subjects: "The Canadian British Aluminium Development", "Arctic Construction", "Town Planning", "The Early History of Knob Lake Area", and "Aerial Photography for Engineering Construction". On March 21st a party of engineers made a field trip to Mile 84, Bell Telephone Site for installation of micro-wave scatter system. On July 19th a party of engineers made a field trip to the tanker "Imperial Edmonton" which is participating in an inovation of having an oil tanker remain in port to fuel ore carriers.

The program was very well supported by members and their guests and in general the branch had a very successful year.

NORTHERN NOVA SCOTIA: This season's activities commenced with an executive meeting on June 19 at which time arrangements were made for election of new officers and other matters were discussed.

The first general meeting was held on July 31 and Dr. Mordean Goodman, formerly professor of geology at Dalhousie University, was the special speaker. Dr. Goodman's address on the principle methods of geophysical explorations was well received by the small group present.

The ballots were opened at this meeting and the election of officers was announced.

A dinner meeting was held on Nov. 10 to welcome Mr. J. A. McLaren on his first official visit to this branch.

The group, consisting of fourteen members and Mr. McLaren, was entertained during dinner by bagpipes and Scottish dancing. After dinner two interesting films were shown, "the Demolition of Ripple Rock" and the "Construction of the Railroad from Seven Islands to Knob Lake". Mr. McLaren also addressed the meeting, outlining the functions of the E.I.C. Library and other services of the Institute.

The next meeting will be called early in February and the main thing on the agenda of that meeting will be a discussion of Confederation.

OTTAWA: The Ottawa Branch held 16 functions during 1958—10 luncheons, 3 evening meetings, one field trip, one dance, and the annual spring golf tournament. All but one of these were held jointly with other engineering groups.

Attendance averaged 80, with a maximum of 125. The field trip was attended by 75 people.

In May, the chairman and treasurer joined the President and General Secretary in launching another satellite of the Ottawa Branch, The Chalk River Branch.

Our most exciting task for the year was preparing for the celebration ceremonies and a banquet to mark the Fiftieth Anniversary of the Ottawa Branch. Under the chairmanship of Mr. R. F. Legget, a semi-centennial committee was set up early in the year, and the first fruit of this committee's labours was a banquet held on 17 January, 1959.

In addition to chairing this committee, Mr. Legget prepared, in collaboration with Mr. S. G. Frost, a history of the Ottawa Branch, published in booklet form as a souvenir of the Semi-Centennial.

PETERBOROUGH: Following a very interesting spring program, the Branch held a successful Golf Day on June 28th. The fall program consisted of four meetings at which speakers dealt with general subjects, a very successful field trip to AECL at Chalk River, and a "Pub" Night.

As in past years, the Branch has co-operated in student guidance where requested, but has relied on the various other organizations operating in the area to do the bulk of the planning.

The Engineers Wives Association organized a number of interesting events, and reported a very successful season.

PORT HOPE: During the year 1958 the branch held six meetings with an average attendance of 20, except on Ladies Night when more than 40 were present.

In January the branch received a talk on "Personality Development for Executives and Foremen", and in February the subject was "Do You Keep a Notebook?" A field trip to Toronto to view the hydraulic model of the St. Lawrence Seaway was organized for April and in October a talk on "Investment Outlook for 1959" was received. The year's activities ended in November with the showing of a film "Atomic Energy in Canada".

PRINCE EDWARD ISLAND: Five regular meetings were held during the year 1958, of which three were dinner meetings and one was a film and lecture night. These were held jointly with the Association of Professional Engineers of P.E.I. The fifth meeting was our annual picnic, which was held at Keppoch Beach at the cottage of the Chairman, C. W. Currie.

The annual meeting was held at Charlottetown on November 11.

There were no professional development courses conducted here but three short lectures were given to student engineers.

QUEBEC: Le point culminant des activités de la Section de Québec au cours de l'année 1958 fut sans doute la tenue de l'Assemblée Générale Annuelle de l'Institut dans nos murs. Plus de neuf cents délégués y assistaient. Le Comité Exécutif offre ses remerciements au Président du Comité d'Organisation, M. Ben O. Baker, et à tous les membres de ce comité dont les efforts ont grandement contribué au succès remporté.

Quatre conférences techniques ont été présentées cette année. La réunion conjointe du mois de janvier où l'on présenta des travaux sur quatre aspects différents de l'étude des satellites fut sans contredit la mieux réussie de l'année. Plus de trois cents personnes étaient présentes. L'assistance aux trois autres conférences fut d'environ vingt-cinq.

Le tournoi annuel de golf de la section, tenu le 15 septembre au club de golf Royal Québec, a été encore une fois l'événement social le plus populaire de l'année. Une soixantaine d'ingénieurs de Québec participaient avec leurs épouses aux différentes activités de la journée.

Le Comité exécutif remit au programme une partie d'huitres qui eut lieu au début de décembre. Malgré cette période de l'année moins propice aux activités de ce genre, une quarantaine de membres répondirent à l'appel.

Au début de septembre, le Conseil de la Section, de concert avec l'association des diplômés de Polytechnique, avait le plaisir de recevoir la visite de M. Robert l'Hermite, directeur des laboratoires des Travaux Publics et Bâtiments de France. Notre visiteur exprima son ardent désir de promouvoir des échanges de vues entre ses confrères de France et les ingénieurs canadiens.

C'est avec un vif plaisir que le Comité Exécutif souligne la nomination de M. Guillaume Piette, à la Présidence de la Corporation des Ingénieurs Professionnels de la Province de Québec, et aussi l'élection au Parlement Fédéral de Messieurs Maurice Bourget et Yvon Tassé, tous membres de la Section de Québec.

Grâce à la coopération du Ministère Provincial du Bien-Etre Social et de la Jeunesse, nos membres ont eu encore cette année l'opportunité de suivre des cours de perfectionnement en structures.

SAGUENAY: The Saguenay branch has just completed another interesting and active year. The executive met 11 times to discuss Institute affairs and to consider the activities planned by the various committees. As usual, all activities were run in co-operation with the Saguenay Chapter of the Corporation of Professional Engineers of Quebec. This arrangement has proven to be of mutual benefit. The meetings committee did an excellent job, organizing a total of 8 meetings in the course of the year.

not counting the annual meeting. These meetings covered a variety of subject material including physics, lubrication, mining, finance, instrumentation, metallurgy, sales, hydro-electric power systems and local history. Two of these meetings were organized jointly with the local branch of the C.I.C. In addition, there were three field trips. The Spring program of the professional development activities consisted of two subjects: "Experimental Design" and "Public Speaking". Each group held six meetings and total registration was 19 of whom it is estimated that 75% attended.

The Autumn program consisted of three courses, Investment Policy for the Individual, Statistics, and Great Books. The first two were held both at Arvida and Isle Maligne while the last course was held only in Arvida. Ten meetings are scheduled for the branch year. Registration is 44 and average attendance runs at approximately 80%.

With the co-operation of local branches of the C.P.E.Q. and C.I.C. a series of talks is held each year at local high-schools. The talks usually last about an hour and are followed by an informal question period. In 1958 a meeting was held at each nine schools and a total of 384 students attended. This program has been enthusiastically received by the school administrations.

SAINT JOHN: In addition to the annual meeting, the Saint John branch held four dinner meetings, four professional development meetings, two plant visits, a picnic and a Hallowe'en party.

The average attendance at the dinner meetings was 34 and talks were heard on:

"Broader Education for Engineers"
"A Forward Look at the Telephone Industry"
"An Engineer Looks at Space Travel"
"Professional Management Today"
"The New Thermal Power Plant in East Saint John"

The professional development series included the following subjects:

"Art and Architecture"
"The Saint John Exhibition"
"Saint John — Its Past and Future"
"Historic Fort LaTour".

There was no definite enrollment for this course but members' wives were invited to each meeting and the average attendance was 32.

At the executive meetings, seven of which were held, the average attendance was seven. In addition, the Board welcomed the eastern field secretary, John McLaren, in November to an executive luncheon at which twelve were present.

As usual, the plant visits proved to be very popular and the picnic and Hallowe'en party provided notes of variety which attracted several members to their initial appearance at our functions.

ST. MAURICE VALLEY: 1958 was marked by a 14% increase in E.I.C. membership in the St. Maurice Valley. This was due partially to existing members being transferred to the Valley and partially to a concentrated membership drive by the Membership Committee during the early part of the year. There were 9 general meetings held including the E.S.J.C. dance in May and the E.S.J.C. golf tournament held in August.

The year's activities began with a smoker and film night held in Shawinigan during February. This was followed by a mixed dinner meeting in Three Rivers in March. This was strictly a "Ladies' Night" with the T. Eaton Company supplying a speaker on "Home Decorating and Furnishing". The men again regained their domination however, with three members of the branch making up a panel discussion on cameras and photography, this meeting being held in Shawinigan during April.

At the end of May the annual dinner meeting and election of officers was held in Shawinigan, with Brigadier C. Wallis, a member of a management consultant firm as guest speaker. In the middle of June a joint field trip with the C.I.C. was held, with the group visiting the Beaumont Power Development of the Shawinigan Water and Power company some ten miles north of La Tuque. This concluded the Society's activities for the summer months with the exception of the annual E.S.J.C. golf tournament held in the Ii-8-Eb country club in Three Rivers in August. Some 130 golfers took part in the "Duffers Tournament" with approximately 170 members attending the buffet held in connection with the tournament and at which the noted sports columnist Baz O'Meara was guest speaker.

The regular fall activities resumed in October with a general meeting in Three Rivers at which Mr. L. F. Tsao, noted Chinese journalist, business man and former member of the United Nations Secretariat gave an extremely interesting insight into the present China situation. It was appropriate that the final meeting of the year, was without doubt one of the most interesting, with Dean D. L. Mordell, Dean of Engineering at McGill University speaking on "Satellites".

This year did not include a visit from the President with Dr. Anson having visited the branch in November 1957 and Dr. Tupper scheduled to arrive here in February 1959. There was no professional development course held during the year, although it is hoped, after the extremely successful one in 1957, to plan one for the fall of '59 or the early winter of 1960. No active counselling was carried out in the schools, however, a one year bursary honouring a life member of the branch, Mr. F. X. T. Berlinquet was given to Laval University and was awarded a St. Maurice Valley engineering student, Mr. Bernard Beland. The branch has retained its predominately male character with no Engineers Wives' Associations having been formed.

Six executive meetings were held during the year, with alternate meetings being held in Shawinigan and Three Rivers.

SARNIA: Ten meetings held during the year included a smoker, organized and run by the juniors of the branch, a dinner dance on the occasion of the President's visit, the annual meeting with the election of officers and seven meetings at which speakers were heard on the following subjects: "Investments", A Detergent Alkylate Plant", "Industrial Television", "Rocket Fuels", "Forestry Engineering and the Canadian Pulp and Paper Industry", "Safety and the Engineer" and "Professional Management Today".

During the year the membership of the branch increased from 158 to 165. The branch, in co-operation with the Provincial Association made arrangements for candidates to write professional engineers exams in Sarnia. A member was also provided to serve on the Harbour Advisory Committee which is assisting the city to prepare for the opening of the St. Lawrence Seaway.

The professional development course was most successful and consisted of a group of qualified speakers discussing "The Canadian Economy". Sixty engineers enrolled in the course and the average attendance at lectures was 45.

The branch was active in providing student guidance when requested by local high-schools. The Engineer Wives Association completed their second year of activity. The 75 members assisted in organizing the annual dinner dance as well as carrying out a varied program of their own.

SASKATCHEWAN: The branch had the pleasure of entertaining two Institute presidents in 1958. On both occasions the visiting officers sat in on the regular monthly meeting of the executive committee. Both presidents spoke to the engineering students at the University of Saskatchewan. They joined the membership at a social event in the evening and gave interesting talks on the general activities of the Institute. The branch being located so far from headquarters in Montreal, these visits by the President and the General Secretary have a unifying effect and we look forward to similar visits in the future.

The branch has been active in the organization of a Western Regional Meeting to be held at Banff in October. The Saskatchewan branch is pleased to co-operate with other branches in Zone A to arrange a useful technical program for this meeting. During the year the Saskatchewan branch was represented at two Zone A Council Meetings, one held in Edmonton on March 28th and the other in Calgary on October 18th. The branch was also represented at the 1958 Annual Meeting in Quebec City by Prof. J. B. Mantle. In accordance with the wishes of students at the University of Saskatchewan an officially recognized student branch of E.I.C. was set up during 1958. A regular section was also set up at Regina which had for many years been directly controlled by the executive. Establishment of this section makes the organization more consistent throughout the territory and the Regina section now has its own slate of officers and looks after its own affairs like other sections.

The Engineering Institute Prize for 1958 was presented to Mr. H. D. Barber of the University of Saskatchewan by President Tupper in November.

During the year the branch was visited by Commodore A. C. M. Davy, Western Field Secretary, and by Mr. Henry P. Gatin, Director of Membership Services at Headquarters. These visits improve communications between the branch and Headquarters and are most welcome.

SAULT STE. MARIE: The 1958 season got underway on February 14th, with a talk from the City Engineer on some engineering details, financing, and critical need of a road underpass currently being constructed. The next meeting on March 28th was a non-technical but very interesting talk on history of early Indians in the Sault area by Mr. C. Lawrence. Coloured slides and a display of Indian artifacts accompanied the talk. The May 2 meeting consisted of a field trip through the new Mannessman Seamless Tube Plant. Last minute failure of arrangements caused the cancellation of a mixed-social affair on May 30th. On October 2nd a film on the mid-Canada Early Warning System and a film on the Micro Relay across Canada were shown.

On November 11th we were honoured by the President's visit along with Mrs. Tupper and Dr. G. Page. The annual meeting was held on December 12th.

Attendance of resident members has averaged approximately 45%. Interest was shown by the ladies during the presidential visit in the formation of a ladies group. Progress on this matter will be reported in 1959.

SUDBURY: On January 16th Father Furlin of the Sudbury University spoke on progress in the establishment of a university at Sudbury. Dr. Bruce Wilson of the Inco Medical Service also gave an interesting talk on Civil Defense. On February 13th Mr. D. W. Grey spoke on "Forest Management" and one month later Mr. Lennox Lane discussed the Sudbury Parking Authority after which Mr. Hugh McGinn spoke on "Ignition Rectifiers". The program at the April

10th meeting for members and their wives consisted of a social evening after which a film on the "Dew Line" was presented. The annual meeting was held on May 8th and was followed by a film on "In Pursuit of Wisdom" presented by the University of Toronto. The joint meeting with the APEO was held on October 7th when Mr. John Fox addressed 105 members of both organizations. The October program consisted of a field visit to the Johns Manville plant in North Bay, and another field inspection tour to the mining property of Falconbridge at Fecunis Lake was held on the occasion of the visit of the President and the General Secretary. This latter trip was followed by a social evening. The program was terminated on December 11th when Bruce Hamilton addressed members on "Stainless Steel".

Seven executive meetings were held during the year but no professional development courses were organized.

The Education Committee carried out vocational guidance programs at eight high-schools in Sudbury and district.

Generally speaking the year's activities were very successful and the average attendance at the seven regular meetings was approximately 41% of branch membership.

TORONTO: Fifteen general meetings were held during 1958. They included the annual branch meeting, two plant visits, nine regular meetings and three special meetings, one a students night, the second a ladies night and the third the occasion of the President's visit. The annual meeting was held on Friday, February 17th, at the King Edward Hotel. The dinner was attended by 135 people and following dinner in the business section the guests were addressed by Prof. M. H. Hewer, Associate Professor in the Department of Mining Engineering at the University of Toronto. The subject of his talk was "The Construction of Hydro-Electric and Thermo-Electric Projects in Pakistan".

The final meeting of the spring session was a visit to Avro Aircraft Limited at Malton, where we were privileged to see the detail of the final assembly shops, the flight line of the Avro Arrow, and films of the first flight of the aircraft.

Fall activities began with a plant visit to Oranda Engines on Thursday, September 25th. Turnout to these plant visits was exceptionally good and a sincere vote of thanks is due Avro Company and their subsidiary organizations for the time and trouble expended in the organization of these extremely interesting plant tours. The nine regular meetings of the branch consisted of papers on the following subjects: "Forest Engineering and the Canadian Pulp and Paper Industry" by C. B. Davis, "From Icarus to Earth Satellites" by B. Etkin, "Education and Industrial Progress in Japan" by K. Piekarski, "The Cost of Housing" by R. F. Legget, "The Iron and Steel Industry in Russia", by P. E. Cavanagh, " 'Ripple Rock' Devil Beneath the Sea" by R. S. Dick Harding, "Satellite City" by Roger B. Dennison, "Some Observations on Engineering Contracts" by Paul H. Mills, "Some Observations on the Future of Metals" by Dr. L. M. Pidgeon.

The attendance at regular meetings varied from 50 to 200 with the average attendance about 100.

Several joint meetings were held by the E.I.C. The first was the meeting on Saturday, March 1st which was held in conjunction with the Royal Canadian Institute, the meeting of October 30th was held in conjunction with the joint area committee which is made up of the E.I.C. and the I.C.E. The meeting of Thursday November 20th saw members of the Toronto section of A.I.E.E. invited as special guests. Toronto branch members in turn were invited to join A.I.E.E. members at their supper club meeting held at Hart House the same evening.

Students night was held at Hart House on Friday, February 7th. The program took the form of the $64,000 Question and master of ceremonies was Prof. L. E. Jones. 28 students participated and prizes of more than $100 were distributed.

Ladies Night was an informal buffet dinner and dance at the Boulevard Club on Friday, November 28th. 250 people attended. The President's visit was held in Hart House on January 7th. Guests and members were given the opportunity of meeting and talking with the President and his associates, at the conclusion of the business meeting.

In addition to the meeting program of the Toronto branch, both the joint I.E.E. - E.I.C. Committee and the Joint Area Committee (Civil) conducted similar meetings of more particular interest to the electrical and civil engineering fields. Considerable interest was shown in these programs especially that of the joint Area Committee, where meeting attendance is comparable to the attendance at the general branch meetings.

Professional development courses organized by the branch are operating actively on a three-year basis. The enrollment is 130. The Toronto E.I.C. Wives Auxiliary had a very satisfactory year and now have a mailing list of 230. Several interesting meetings were held during the year and the group was instrumental in entertaining the wives of the visiting English engineers who visited Toronto last spring.

Counselling activities by the E.I.C. Toronto branch is done at the request of Career Counsellors of which there are many in the high-schools of metropolitan Toronto. Speakers are provided where requested and the branch co-operates in the distribution of the booklet entitled "Engineering Careers in Canada".

The branch wishes to express its appreciation for the help given to the various activities of the Toronto branch of E.I.C. by the Eastern Field Office at 160 Eglinton Avenue East.

VANCOUVER: The Vancouver branch held 17 functions of various kinds during the year. Activities began on January 22nd with the joint meeting with the professional association. This meeting took the form of a panel discussion on "Engineering Ethics" and was well organized and executed. The professional development course began on January 29th and on February 4th the annual get-together with the members of the student section of the Vancouver branch was held. The President of the Institute visited the branch on February 10th and this was one of the highlights of the year. The Structural Engineering Section presented a film on "Construction of the Nelson Bridge over Kootenay Lake" on February 18th and the following week in a joint meeting with the association, the branch toured the new plant of LaForge Cement Company of North America. The March 11th meeting was held jointly with the provincial association and Wing Commander A. L. Bocking spoke on "Air Defence in North America". On March 18th the Structural Section again presented a film on "Construction of the Pontchartian Bridge". On March 22nd members and their families visited the Stanley Park aquarium and were given a behind-the-scenes tour. The annual branch meeting was held on April 16th and Dr. Chris Riley spoke on "The History of Mining in British Columbia". The Seattle chapter of the American Society of Civil Engineers entertained members and their wives royally on May 17th and in June the branch viewed a film entitled "The Powerful Horseshoe" dealing with the Niagara Development and enjoyed a field trip to C.P.A. where the new Bristol Britannia was open for inspection.

The fall program consisted of an interesting talk on small boats by John Brandlmayr, an illustrated talk on "Welding Failures" by R. Clough, an illustrated talk on "Avalanche Defence" by Mr. Peter Schaerer and a field trip to one of the sites of the B.C. Telephone Company Micro-wave System. One of the major events of the season was the annual ladies night, formal, at the Hotel Waldorf.

VANCOUVER ISLAND: The branch had an interesting and active season and the general program was well received by the members. Professional development courses were not organized as it is felt that there are sufficient night-school and college courses available to members wishing to participate in such activities. The branch provides counselling services when requested by high-schools but has not organized a formal counselling service. The branch supports an Engineers' Wives Association which has just completed an active and successful season.

WINNIPEG: The affairs of the branch were carried out in a commendable manner by those responsible for operation of activities.

The situation in respect to the attendance at meetings has improved.

During the year we were fortunate in that two Presidents visited the branch. In the spring, Mr. Anson was here and paid a visit to the students section at the University of Manitoba and in the fall Dr. Tupper was with us for two days, during which he met with members of the branch. He had luncheon with the president of the University and afterward addressed a gathering of the students and in the evening had an interesting meeting with the Branch Management Committee.

A professional development course was not organized this year. There was diversity of opinion regarding the kind of course to be given and these did not become sufficiently reconciled to permit the carrying out of this feature of branch function in 1958.

During 1958, which was the fifth full year of operation, five meetings of the civil section were held and the section executive convened on six occasions. Two plant visits were made and one social event held.

At the general meetings an average attendance was forty-two. Plant visits appeared to have more appeal as fifty members attended each of these. The section membership is now two hundred and twenty-five.

The Electric Section held six general meetings, with an average attendance of 42. Three plant visits were made and the overall average attendance was 59.

The membership increased during 1958 to 183. However, as a result of the survey taken near the end of 1958, a cutback reduced the number on the mailing list to approximately 100.

The attendance is increasing somewhat, but there remains much room for improvement.

The student section holds monthly meetings during the academic year and the subjects dealt with are varied in substance and in methods of presentation. Films are used extensively, but the section and the branch endeavour to obtain speakers for student meetings.

The approximate membership of the Student Section is 350, with an average attendance of 200 at regular meetings.

Eight regular meetings of the Brandon section were held during the year. The regular meeting date has been the third Monday of each month and has taken the form of a supper meeting, with a guest speaker.

Average attendance for the year has been approximately 17 — the lowest attendance being 12 and the highest being 37. The largest attendance was on the occasion of a tour through the newly-opened Brandon Thermal Electric Station. This was the only field trip of the year.

Five executive meetings were called during the year. The chief function of the executive meetings was to line up programs of adequate interest for the regular general meetings.

During the year this section again experienced a considerable turn-over in membership. The number of names on the mailing list has remained fairly constant with about fifty notices of meetings sent out each month. However, the prime task of the section appears to be the problem of creating sufficient interest in the new residents to fill the gaps left by those who have been moved away.

The Winnipeg Branch held six regular meetings, with an average attendance of 70 and the Management Committee met six times and had interesting meetings with Dr. Anson and Dr. Tupper and with the General Secretary, Garnet T. Page.

YUKON: Membership in the branch is small, and most corporate members are also members of the professional engineers association, hence the majority of our meetings are joint meetings. The program consists of monthly meetings, and each summer a field trip is organized to some project of special interest. Meetings are generally in the form of a dinner followed by a talk or films of interest to all. The subjects covered in 1958 included construction, soils engineering, and general topics.

ONTARIO DIVISION:

A Statutory Meeting of the Ontario Division was held in Hamilton on March 15, 1958, at the time of the Regional Conference. Several important matters were discussed and the new officers for 1958 were installed. They were:

Chairman	— M. A. Montgomery
Vice-Chairman	— H. R. Sills
Treasurer	— G. R. Turner
Secretary	— J. G. Hall

Members of Board of Managers:
Dean Conn, P. Buss and E. R. Davies

A Statutory Meeting of the Ontario Division was held in the Royal York Hotel in Toronto, on January 24, 1959. It was attended by 16 members.

The Treasurer's Report showed a balance at the end of 1958 of $101.14.

It was noted that three Regional Conferences are scheduled for this year in Ontario, namely in Hamilton, March 14, Sudbury, April 25, and Ottawa, October 15, 16, 1959.

It was decided to hold a meeting of the Ontario Division in Hamilton at the time of the Hamilton Regional Conference, on March 14, 1959.

The officers for 1959 are:

Chairman	— H. R. Sills
Vice-Chairman	— W. J. Ripley
Treasurer	— G. R. Turner
Secretary	— John G. Hall
Board of Managers:	Dean Conn, P. Buss, E. R. Davies

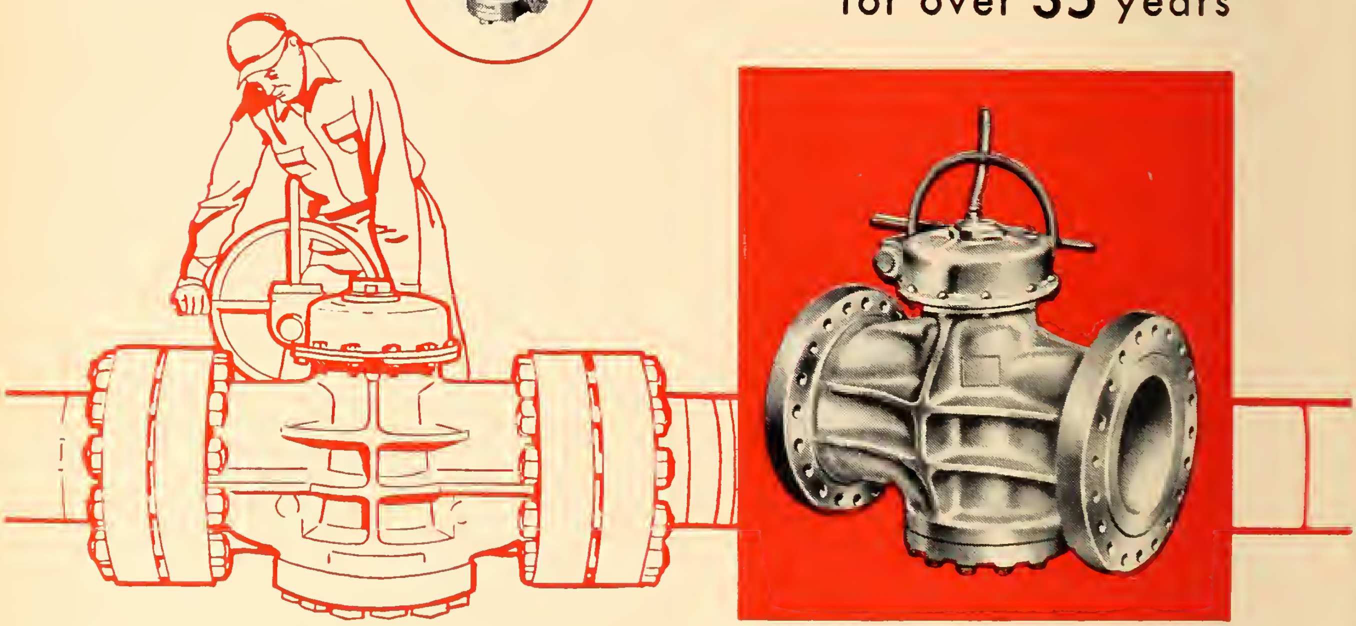
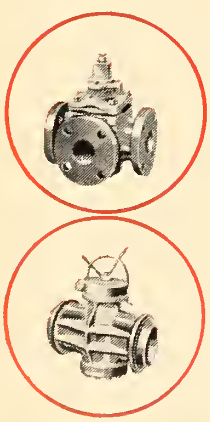
ROCKWELL-NORDSTROM VALVES . . .

manufactured and stocked in CANADA for over 35 years





Manufactured under license in Canada by Peacock Brothers Limited and stocked in warehouses across the country, Rockwell-Nordstrom valves are available in a wide range of types, sizes and pressure ratings. Dependability is proven by thousands of trouble-free installations in many industries from coast to coast.

Rockwell-Nordstrom lubricated tapered-plug valves are ideal for oil, gas, water, slurries, corrosive and erosive fluids. They provide tight shut-off and quick, easy operation. When properly lubricated and adjusted, they will not leak or stick. Sizes to 34"; pressures to 15,000 lbs. test. Ask for Bulletin PNV-965, Peacock Brothers Limited, P.O. Box 1040, Montreal 3, Que.

CANADA IN 1958

THE CANADIAN ECONOMY, which did not suffer from the 1957-58 recession to the same extent as that of the United States, experienced a modest recovery in the last three-quarters of 1958. Government spending cushioned the effects of the recession but inflationary pressures did not subside.

Though employment on farms and in construction was steady and in the service industries it was stronger, it was some 6 per cent lower in manufacturing and 5 per cent lower in mining. The nation at year-end faced a repetition of the serious winter unemployment situation experienced the previous year, despite a cut in immigration to half the numbers entering in 1957.

Though exports showed little change from the previous year, a sharp reduction in imports brought a substantial cut in Canada's trade deficit. Even with a lower crop yield due to prairie drought, the year-end saw a 12 per cent drop in wheat in storage for export and carry-over. Petroleum production was down 10 per cent of capacity. Electrical manufacturing showed a drop of 7½ per cent due to weakness in sales of 'consumer durables', and motor vehicle sales were down 14 per cent, compared with 1957. The physical volume of construction remained unchanged with buoyant house building compensating for lower industrial construction. But electric power production showed a rise of 7 per cent, retail trade was vigorously maintained, inventory liquidation was believed to have run its course, and 1958 saw continuation of the drop in the consumer debt burden.

Outlook for 1959

Looking ahead to 1959, economists predicted a continuation of the modest recovery experienced in 1958, with private investment slightly lower, federal expenditures maintained and provincial expenditures somewhat higher. They foresaw a gross national product of $34 billion, up 5 per cent in value terms over 1958, though showing little improvement over 1958 apart from continued rises in prices and population. There was increasing concern about the stability of export markets due to the effects of Russian competition and the European common market, as well as to possible further U.S. quota restrictions on imports. The still-unsettled freight rate problem, temporarily solved by the 17 per cent increase granted last year, they pointed out, would remain a lively issue.

Further Expansion—no boom

Trade minister, Gordon Churchill, in a year-end message told Canadians the nation's gross national product at slightly over $32 billion, was up 2 per cent from 1957. The rise had been entirely in prices, however, with volume of production unchanged. Employment held up well, and while the number of jobless also increased, the percentage rise was 'narrowing' sharply from that of a year ago. Personal savings increased from 7 per cent in 1957 to about 9 per cent in 1958, with much of this in liquid form.

Summing up, he found most industries that had suffered in the economic decline had improved by year-end. The rise was moderate but there was "strong indication of a further expansion in market demand." Despite Canada's sensitivity to world market influences, the extent of contraction in the Canadian economy was of much smaller dimensions than that in the United States.

Employment covered in Review

Employment in the mining, petroleum, electric power, transportation construction and heavy manufacturing industries but excluding civil service and armed services, covered in the following review, represents more than 40 per cent of Canada's civilian non-farm labour force, or the effort of some 45 per cent of all paid workers. Those not included are employed in such industries as clothing, textiles, food, beverage, retail trade, printing and publishing, tobacco, rubber and leather footwear, and all service industries.

Sources of information used for each industry are confined to records of production supplied by the Dominion Bureau of Statistics, from financial reports, press statements and from government information releases. In addition, comments and forecasts of industry leaders are quoted, though no general forecasts are made by the Engineering Institute of Canada regarding the outlook for 1959.

THE CHEMICAL INDUSTRY

British American Oil's $25,000,000 gas processing and sulphur plant, officially opened in October, 1958, is one of the largest suppliers of natural gas to the Trans-Canada Pipe Line. The plant is 13 miles southeast of Pincher Creek, and approximately 35 miles from the Alberta Rockies. The 350-foot incinerator stack, right, is visible for many miles.

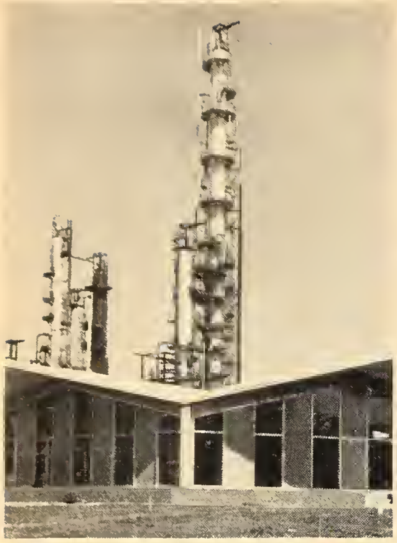
Table I.—Manufacturing Statistics—1957
Chemicals and Allied Products Group

Type of Production	Establishments	Employees	Selling Value of Factory Shipments
			Millions of Dollars
Coal Tar Distillation	11	528	$13.7
Heavy Chemicals	53	10,167	215.8
Compressed Gases	55	1,706	24.3
Fertilizers	45	3,042	83.8
Medicinals and Pharmaceutical	210	8,185	140.1
Paints and Varnishes	129	6,329	131.1
Soaps and Washing Compounds	138	3,650	118.9
Toilet Preparations	91	2,242	49.8
Inks	32	966	16.9
Vegetable Oils	11	656	61.0
Adhesives	29	627	13.7
Polishes and Dressings	47	836	22.3
Plastics (Primary Only)	29	3,452	91.8
Miscellaneous	261	12,215	220.2
Total	1,140	54,601	$1,203.4 Million

PRODUCTION by the Canadian chemical industry in 1958 attained a new record value estimated at some $1,290 million or 7 per cent higher than in the previous year. The increase in physical volume was close to the average postwar growth rate. The demand for heavy chemicals was strong due to greater uranium ore processing, and capacity for sulphuric and nitric acids and sodium chlorate production had been expanded to serve this growing market. Sales of medicinal and pharmaceutical preparations and detergents increased, as did the consumption of paints. Output from new plants recently placed in operation replaced imports such as titanium oxides and petroleum cracking catalysts.

Measure of the Industry

The Canadian chemical industry is one of the largest in Canada in terms of value of production, and one of the nation's fastest growing industrial groups. It annually ships goods from Canadian factories valued at more than $1,250 million of which about $200 million is exported. In



This skyscraping absorber deethanizer, over 200 ft. high, is the tallest unit processing tower ever built in Canada. It is a vital part of Imperial Oil's $28,500,000 petrochemical plant at Sarnia.

Glass lined beer tanks for Molson's Brewery.

addition, imported supplies valued at nearly $300 million supplement Canadian production in the domestic market.

There is a dense concentration of about 1,200 chemical products plants in Ontario and Quebec, though western provinces now have 15 per cent of the total number of plants.

In terms of value of product, chemical production exceeds the clothing industry and approximately equals the value of output by the entire electrical products group. The value of chemical products added per average employe on an annual basis is presently over $11,000—the second highest, next to petroleum refining, among all Canadian manufacturing industries. Production of chemicals represents more than 5 per cent of the gross national product, compared with 3½ per cent in the prewar years and more than double chemicals' share in the 'twenties'.

Capital Investment

Capital expansion during 1958, while large compared with a few years ago, was lower than in either of the previous two years. New investment declined by an estimated 10 to 15 per cent below the $149 million invested in 1957, and included large sums required to complete various projects announced or initiated the previous year.

Only a few of the new plants in operation in 1958, such as those producing epoxy resins, organic phosphates, and inorganic fluorine derivatives constituted initial entry into domestic commercial manufacture. A plant to produce hydrogen peroxide was started up and progress was made on facilities for making high-density polythene and polyacrylonitrile for the first time in Canada.

The use of chemical processes to upgrade waste or by-products was also expanded: lignin chemicals in Quebec; urea from coke oven gases, waste nitrogen and blast furnace gas in Ontario; sulphur from sour natural gas in Alberta. The output of sulphur from Alberta and B.C. sources tripled between 1956 and 1957, and increased still further in 1958. Elsewhere most new capacity added or nearing completion was for chemicals already being produced, such as sulphuric acid chlorine, caustic-soda, sodium chloride and ammonia.

Outlook—Improved Production—Pause in Expansion

Announcement of relatively few large projects recently suggests a further decline for 1959. Though some sectors of the industry see their capacity presently overbuilt, industry leaders see no evidence the decline will be either sharp or prolonged. Though the supply of technical personnel is adequate at present, the long-term outlook is causing concern and further support by the industry in donating funds for education will need to be more widespread.

The effect of the 1957 58 business contraction was moderate and of short duration. There is strong indication the gains in production rates during 1958 will continue. Having added substantially to its productive capacity, the chemical industry should be in a good position to respond to improved economic conditions during 1959.

RUBBER PRODUCTS

CANADA'S SUPPLY of synthetic rubber is produced at Sarnia, Ontario, by Polymer Corporation of Canada Ltd., while the nation's supply of natural rubber is all imported. Polymer, with employment of 1,600 persons, produced 132,000 long tons of synthetic in 1958, or practically the same tonnage as in 1957. Synthetic production is more than 80 per cent in the form of Buna-S, followed by Butyl, neoprene, Buna-N and other types, in that order.

Total consumption of rubber in 1958 by types, based on preliminary reports, in millions of pounds, was: natural, 84; synthetic, 102.4; and reclaimed, 33.36. Consumption of natural was 12 per cent lower than in 1957 while synthetic and reclaimed were down some 8 per cent each. The trend towards the use of more synthetic and less natural rubber continued, with percentages used as follows: natural 37.3 per cent; and synthetic 47.5 per cent.

In 1957, latest year for which a full report is available, factory shipments by the rubber products industry were valued at $326 million, or 8½ per cent below those of the previous record year. Employment stood at 22, 178 persons. Materials used were valued at $144.24 millions. Production was almost entirely in Ontario and Quebec, with factory shipments valued at $265.8 and $59.7 million respectively.

COMMUNICATIONS

AND

TRANSPORT

TELEPHONE

DURING 1958 the Bell Telephone Company, which owns more than two-thirds of all Canadian telephones in operation and accounts for 66 per cent of the employment and 70 per cent of the gross revenue received by Canada's fifteen main telephone systems, continued to develop and improve its services.

There was however a slight levelling off in growth from the number of telephones installed at 185,000, compared with 190,000 installed in 1957. There was, on the other hand, a 4 per cent increase in volume of long distance calling over the previous year, to some 186 million conversations, while total conversations, local and long distance, at some 8.6 billion was higher by 8 per cent than in 1957.

At year-end the Bell System had a total of more than 3,140,000 telephones in service. The list of people waiting for service was reduced during the year from 18,000 to 10,000 and unfilled orders for individual in place of two-party lines from 34,000 to 11,000. Construction to improve the service involved capital expenditures exceeding $180 million.

A Bell Telephone plant craftsman inspects a perforator, one of the many intricate machines required to provide direct distance dialing service at Toronto and Guelph during 1958.

The Industry in 1957

In 1957, the most recent year for which complete statistics are available, Canada's fifteen largest telephone systems represented 96 per cent of total telephone investment. They operated 93 per cent of Canadian phones and earned 96 per cent of the telephone revenue. By the end of 1957 the number of telephones operated by these 15 systems had increased 7 per cent to 4.51 million. There were 1,625,900 telephones on individual lines; private branch exchange and extension phones numbered 1,121,264 and 2-party lines totalled 1,263,700. Pay stations 58,233.

Property and equipment was valued at $1.877 million; revenue totalled $439.5 million or 10 per cent higher than in 1956. Net income amounted to $53.16 million. Employees totalled 61,831, whose wages amounted to $213.8 million.

Next to the Bell system, British Columbia, Alberta, Manitoba and Saskatchewan systems in that order recorded the largest number of conversations, while Avalon Telephone Co. showed the largest number per telephone, followed by Alberta, Edmonton Automatic, Fort William municipal and Manitoba systems, in that order. Bell, New Brunswick, Quebec, Northwest and Okanagan systems were below the Canadian average of 1,766 calls per telephone.

Rate Increase Allowed

At the end of November 1958 the

Federal Cabinet confirmed new rates for Bell service approved earlier by the Transport Board. These went into effect December 1 and are designed to produce $8.6 million of additional yearly earnings.

TELEGRAPH

Perhaps the outstanding development during 1958 was the announcement at the Commonwealth Trade and Economic Conference held in Montreal, of the acceptance, in principle, to proceed with plans for a Commonwealth round-the-world telephone cable system. Canada had submitted some engineering, operating and administration proposals which contributed to the resolution of the many problems involved and the decision to go ahead with such a challenging project.

The first leg of the round-the-world cable will be in service toward the end of 1961 with the completion of a Canada-U.K. trans-atlantic cable engineered to provide 60 telephone channels. The first contract for the manufacture of one major section of this cable was signed in September by C.O.T.C. and Submarine Cables Limited, London, England. This contract, which amounted to 2½ million dollars, covers the 400 mile Gulf of St. Lawrence link between Corner Brook, Newfoundland, and Grosses Roches, P.Q. The engineering and planning of this project continues to be a major activity of the Corporation.

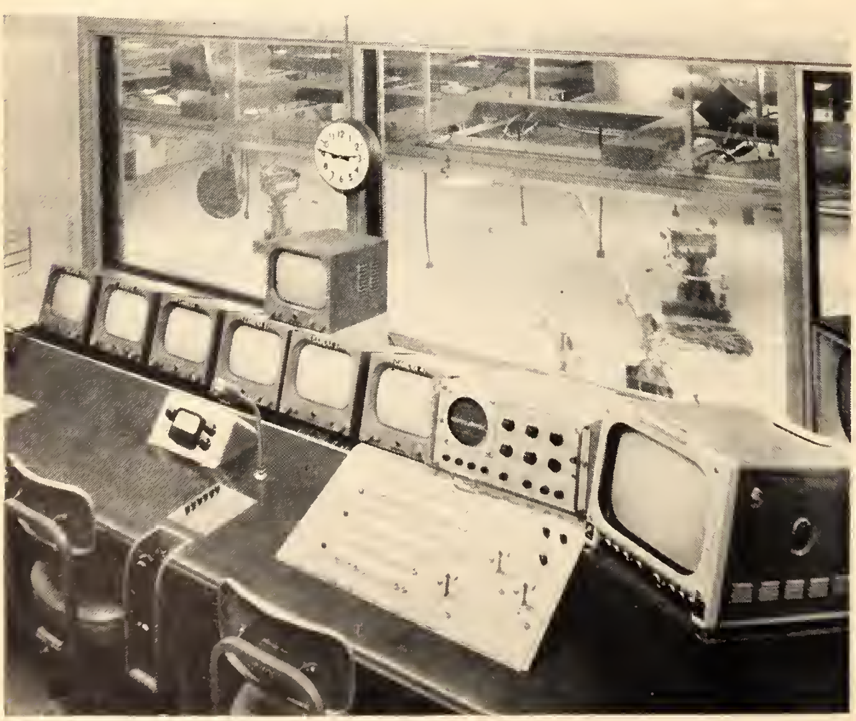
Operating revenues of Canadian telegraph and cable systems in 1957, last year reported in full, rose 10 per cent to $44.8 million from $40.7 million, largely on the strength of sizeable increases in revenues of the Canadian Overseas Telecommunication Corporation and the Eastern Telephone and Telegraph Company. Due to a 16.6 per cent increase in operating expenses however, net income dropped 16½ per cent to $5.304 million from the record high of $6.35 million attained the previous year.

Number of telegrams transmitted reached a 10 year low of 19,163,723, down 6.1 per cent, while messages received from the United States at 2,126,964 were 4.7 per cent under 1956. Number of cablegrams however reached a new high of 2,580,745, 6.2 per cent more than the previous year. Money transfers totalling $25.6 million were 5.3 per cent higher than in 1956.

Total pole line mileage increased 317 miles to 48,375 and wire mileage 8,778 miles to 451,669 during 1957. Major changes were 703 miles of pole line added by C.N.T. and a decrease of 465 miles by Dominion Government Telegraph Service.

A sugar-scoop antennae is hoisted into place along the Trans-Canada Telephone System's microwave network. The 3,900 mile communications skyway was completed by the telephone companies on July 1, 1958.

Montreal-TV studio 42. Video control room view of production desk.



A total of 5,070 offices were maintained for receiving and sending messages compared with 4,934 in 1956. Number of employees engaged advanced to 11,159 from 10,833, while their earnings rose to $37.72 million from $34.7 million. The average annual salary rose to $3,380 compared with $3,204 the previous year.

Of the 11 companies in the group, Canadian National Telegraphs and Canadian Pacific Railway Company between them earn 82 per cent of the total revenue, transmit 99 per cent of the telegrams and 41 per cent of the cablegrams.

RADIO AND MICROWAVES

1958 saw completion of the first Trans-Canada Microwave system, capable of transmitting television programs coast to coast in Canada. The year also saw completion of many of the Tropospheric Scatter Microwave links and other radio linkages serving the northern defence establishments.

HIGHWAY TRANSPORT

In 1957 according to the latest published full report of the Motor Transport industry, there were 2,062 "for hire" freight carriers in Canada, with a total investment of $180.28 million in property, vehicles, etc. Their total revenue rose to $259.06 million that year, compared with $233.5 million in 1956. The average number of persons employed totalled 26,338. Net operating revenue totalled $11.79 million.

Other News of the Industry

Highlights of the Canadian Trucking Association meeting at Saint John in February 1958 included a demand for new legislation on trans-border trucking, and notice that the CTA would continue to oppose the railways' entry into the highway transport field.

In July a start was made on construction of the CPR terminal for Dench of Canada, Ltd., at Edmonton, estimated to cost $250,000 for 12,000 ft. of floor space, with provision for piggyback service. Construction was also started on a $1 million Mack truck centre in Toronto.

Faced with higher operating costs, transport operators will have to increase rates in 1959 to meet them. Wage negotiations between 65 transport firms and the Teamster's Union will add some $10 million for about 7,000 employees. Interprovincial trucking firms have already applied to the QTB for a 17 per cent hoist in rates effective January 1959.

Promising Future for Truckers

A bright future for the industry lies in the fields of bulk tank haul for milk; truck handling of bananas from New York; and tank-truck haul of flour, vinegar, cement, grain, sugar, chemicals and acids. An application has been filed with the OHTB for carrying liquor in glass-lined tank trucks. In addition, truckers stand to benefit from the opening of the seaway.

'Containerization' will help cut handling and distribution costs. This and "piggyback" are fast-growing trends. Truckers are taking a hard look at materials handling costs, and there has been a noticeable change in terminal handling of traffic. A system of trailer interchange, started in Ontario during 1958, is destined to be widely adopted. For truckers in any province operating across the international boundary has come the suggestion for a joint U.S.-Canadian body, through which common transportation problems could be evaluated and solved.

Burlington Bay Skyway, near Hamilton, Ontario, a 4½ mile long elevated highway. This four-lane skyway eliminates a major traffic bottleneck on one of Canada's most heavily-travelled roads.

RAILWAY TRANSPORT

Freight traffic in 1958 for all Canadian railways dipped for the second year in succession, to some 64 billion revenue ton miles, or 10 per cent below the 71 billion ton miles carried in 1957. Passenger-traffic also turned downward after three years of improvement, finishing the year with a total of some 2.5 billion revenue passenger miles, 12 per cent under the 2.925 billion passenger miles of traffic for 1957. Revenue carloadings dropped to 3,750,000 or 7 per cent under the 4,037,381 cars loaded in the previous year.

The year 1958 saw orders for rail cars cut in half from the huge orders placed in 1957 totalling close to 10,000 cars. With carloadings down 7 per cent and earnings squeezed, railways were placing the bulk of their new equipment dollars into completion of their dieselization programs scheduled for completion in 1961. Little change is expected in 1959.

Both of Canada's two major railway systems face a growing problem in the unprofitable commuter service, though the bulk of it is handled by the C.N.R. Efforts to attract off-peak traffic have failed. Equipment and personnel stand by all day for 4 hours, at most, of actual work. Commuters and their local authorities are unwilling to pay more. If fares are upped to pay the cost most commuters will abandon using the service.

Canadian Pacific Railway

Despite a decrease of some 10 per cent in freight traffic in 1958 from the previous year, the Company continued replacement of steam with diesel motive power and was using some 950 diesel units by year's end, doing about 95 per cent of its total rail work with diesels. Further improvements to switching yards, signalling and maintenance of way were made. A four-year contract for relining 1,865 feet of main line tunnel through the Rockies east of Field, B.C. was completed in June. Timber lining was replaced with concrete.

Installation of centralized traffic control was completed from Glentay to Trenton and will be extended to Toronto. The Company acquired control of Smithson's Holdings, Ltd., which wholly owns Smith Transport Ltd., and now owns or controls trucks over almost 10,000 route miles from coast to coast.

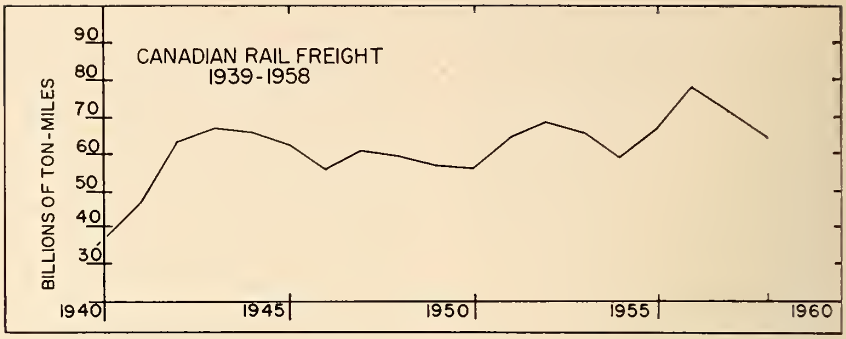
'Piggyback' service was introduced for licensed 'for hire' trucking firms between Montreal and Toronto. This service was extended in 1958 to New Brunswick, to the Lakehead cities and to Western Canada. Plans are underway to extend it to the Pacific coast. Gratifying results were obtained from the wider use of self-propelled 'Dayliners', but increased use of automobiles and buses and improvement of rural highways have all but eliminated passenger traffic on many branch lines.

A two-year dispute regarding the employment of firemen on diesels in freight and yard service, was settled last May. The findings of the Kellock Commission were accepted by both the Railway and the Brotherhood of Locomotive Firemen and Enginemen, modified as to seniority.

Early in 1958 a new subsidiary, Canadian Pacific Oil and Gas, Ltd., was incorporated to assist in development of the Company's oil and gas rights. CPOG has signed a contract for sale of gas to Trans-Canada Pipelines.

In September Canadian Pacific joined with other railways in applying to the Board of Transport Commissioners for a general 19 per cent increase in freight rates, to meet the cost of wage increases recommended by a Conciliation Board. A judgment was rendered in November awarding a 17 per cent freight rate increase. On November 26 an appeal by eight Canadian provinces against the award was disallowed, and the 17 per cent increase took effect December 1.

While ocean passenger carryings by the Company's three liners between Canada and Britain were satisfactory, a world-wide depression in ocean freight rates was reflected in diminished earnings by seven owned and four chartered cargo vessels. A replacement for one of the passenger-cargo liners is on order and when it enters service in 1961, it will be the largest of the fleet. The 'Empress of England' replaced the retired 'Empress of Scotland' as the Company's cruise ship out of New York last winter.



Canadian National Railways

Like other Canadian railways, the C.N.R. felt the impact of general business conditions in 1958 on its traffic in terms of decreased revenue, tonnage and patronage, while costs of wages and materials continued upward. Estimates indicated year-end tonnage figures for revenue freight handled would be down about 10 per cent below 1957, with a loss of 9 million tons compared with 1957. Freight revenues would be down about 8 per cent. Chief decreases were recorded in coal, iron and steel ores and concentrates, autos and parts, pulpwood and crude oil. Increases occurred in vegetables and in lime and plaster.

Due mainly to a 50 per cent drop in immigration and a decline in military movements the upward trend in passenger revenues over the past three years was reversed and showed a drop of 12 per cent from the previous year. Revenues of the C.N.R. telegraphs continued to improve and were further augmented through acquisition of the Northwest Communication System and the Yukon Telegraph Company. Total increase in communications revenue amounted to some 15 per cent.

Nevertheless the Company continued active construction of branch lines. A line from Optic Lake to Chisel Lake in Northern Manitoba will be completed in 1960. In Quebec, tracklaying had been completed on the second 66-mile section between Cache Lake and Lac Chigoubiche. This new line will stretch over 133 miles between St. Felicien and Cache Lake. When coupled to the 161 mile line opened in 1957, between Beattyville and Chibougamau, it will form a 294 mile arc through Northern Quebec which will be opened late in 1959.

Elsewhere new methods, materials and equipment were being put to use to consolidate and improve services. A major speed-up in freight schedules, new equipment and schedules in passenger service, the opening of the Queen Elizabeth Hotel in Montreal, and new communications facilities were highlights of the year's program. Construction was also commenced on a new headquarters building just south of the Queen Elizabeth and Central Station.

Work continued on the huge classification Hump Yard west of the city of Montreal, scheduled for completion in 1961. Another four-year project was undertaken for a new Hump Yard two miles in length outside St. Boniface, Manitoba, across the Red River from Winnipeg. The project, to cover 628 acres with over 100 miles of trackage, will be capable of classifying up to 7,000 freight cars daily.

All train operation in the Atlantic Region and on the south shore of the St. Lawrence west to Montreal is now completely dieselized, as well as most of the operations in northern Ontario, Quebec and British Columbia. By year-end more than 80 per cent of freight train miles were dieselized.

Part of the Frederick G. Gardiner Expressway. Shown are the Humber River bridges, T.T.C. underpass and C.N.R. overpass, constructed by Foundation Company for the Department of Highways of Ontario. The Municipality of Metropolitan Toronto, Toronto Transit Commission and Canadian National Railways, Consulting engineers were Lakeshore Expressway consultants and Canadian National Railways.

Extension of centralized traffic control to the entire main transcontinental line is well underway. Signalling on four subdivisions will be completed by mid 1959, with another five sub-divisions scheduled for complete signalling by early 1960. CTC will be in operation on 40 subdivisions when the program is completed.

Progress continued on establishment of a mocrowave system between Sydney and St. John's for TV and general communication service for operation in 1959.

To find ways of increasing wages while volume of revenue traffic was depressed a general freight rate increase of 3.6 per cent was authorized to take effect on January 15, 1958, but was finally disallowed. Faced with wage increases recommended by a Federal conciliation board a general rate increase of 19 per cent plus 25 cents per ton on coal and coke was applied for. A rate increase of 17 per cent with 22 cents per ton on coal and coke was granted effective December 1st, and a wage settlement was effected with non-operating unions.

Other News

The official opening of the Pacific Great Eastern's northern terminals at Dawson Creek and Fort St. John took place on October 1st, with the inaugural train being operated from Vancouver to the Peace River. Some $80 million dollars had been spent on equipment and track.

Quebec Cartier Mining Co. awarded contracts in September for a 193 mile railway to a point 300 miles north of Shelter Bay on the St. Lawrence. Included in the project will be a huge concentrator for pelletizing up to 8 million tons of iron ore annually, and a 60,000 h.p. power development to provide power. Cost of the project will ultimately reach $300 million.

A matter of lively concern in Alberta at year-end was selection of a route by the Federal government for their proposed $70 million railway to the Northwest Territories, Pine Point on the south shore of Great Slave Lake. Of various routes open for selection the shortest and likely the cheapest would be from McMurray, about 250 miles. But a second possible route is possible from Grimshaw. Just across the Alberta-B.C. border lies the northern railhead of the PGE running from Vancouver which might be a take-off point. Saskatchewan would like the line to start from Radium City. Alberta's claim is expected to have the advantage.

WATER TRANSPORT

Volumes of freight handled in foreign and coastal shipping services at Canadian ports last year showed sharp declines from 1957. Freight handled in the first nine months at 102 million tons was close to 14 per cent lower than the 118 million tons handled in the same period of 1957. Shipping handled in foreign service dropped to 51.2 million tons from the 67 million tons in the previous year. Volume in coast service was steady at 51.2 million tons compared with the 51.5 million tons the previous year for the same period. Though shipments of grain improved 50 per cent over those of past years, movements of iron ore, coal, lumber and petroleum showed sharp declines.

Lake Traffic Sharply Down

Freight cleared through Canadian canals in the 1958 navigation season was also sharply lower. Cargo tonnage through all Canadian canals amounted to 20.56 million tons vs. 36.4 million in 1957, with biggest losses in coal, iron ore, petroleum and iron and steel, partly compensated for by an increase of over a million tons of grains. Tonnage through Canadian and U.S. locks, including the Sault Ste. Marie Canals, amounted to 75.45 million tons compared with 110.8 million tons in 1957. Biggest drop was in downbound iron ore and upbound coal, partly balanced by downbound grains and crude petroleum.

Number of vessel passages through the Welland Canal totalled 8,496 compared with 8,903 the previous year, while vessel passages through U.S. and Canadian locks at Sault Ste. Marie numbered 16,249 compared with 21,044 in 1957. Vessels passing through St. Lawrence canals showed little change at 10,978 compared with 11,282 in 1957.

Ocean Rates

The year 1958 saw ocean freight rates fall to about the same level as they were fifteen years ago—a level where many ship-owners barely covered operating costs. This condition forced many owners to lay up their vessels. Between January and December almost seven million gross tons of shipping was laid up, about 2 million tons of it tanker tonnage. In addition about two million gross tons were broken up.

More Cargo in the North

Canada hopes to handle all waterborne cargo in the Canadian North during the navigation season of 1959, according to Federal Transport Minister George Hees. The United States now handles only one military operation in Canada's Arctic waters, he said. Full support when required has been promised for the $200 million iron ore development at Hopes Advance Bay in Ungava. Backers had requested icebreakers, weather service and navigational aids to assist shipment of iron concentrates via Greenland. More than 100 units of ship-to-shore landing craft have been provided and breakwaters, causeways and beachheads established.

Winter Shipping in the Gulf

That record amounts of cargo will be handled by ports in the lower St. Lawrence and Gulf region during the winter 1958-59, was predicted by the Lower St. Lawrence and Gulf Development Association. In 1957, winter shipments amounted to a total of 19 million tons vs. 3.3 million tons in 1953. By 1970 a volume of 45 million tons is expected —most of the record tonnage expected will be newsprint, bauxite and aluminum ingots. New elevators at Baie Comeau will be in operation by late 1959 and if used on the same basis as those at Montreal, viz. five times their capacity during the year, grain handled could amount to 75 million bushels within a few years or 2 million tons of cargo.

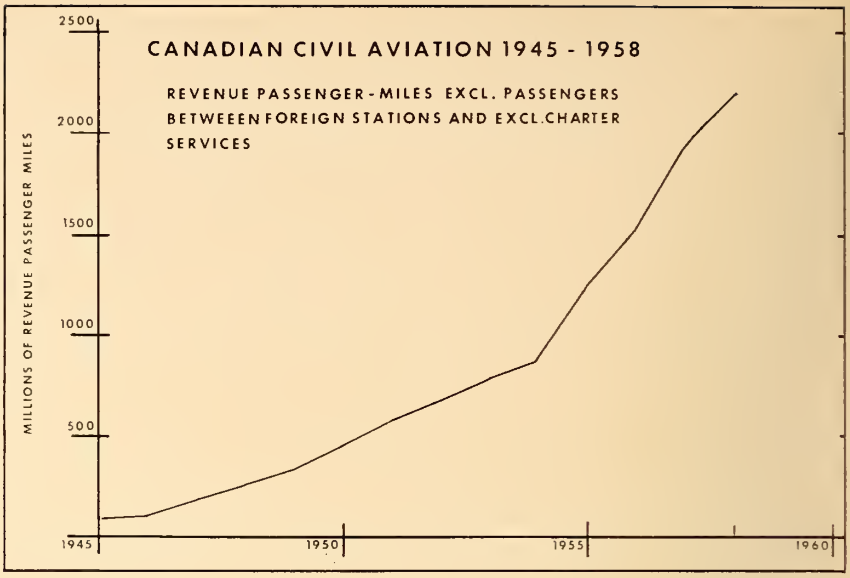
Other News of the Industry

On May 21 the Royal Commission on Coasting Trade recommended in their final report that Canadian ships should not be given any special advantages over those from other members of the Commonwealth.

In October the 8,300 ton auto-ferry William Carson began daily round trips between Sydney and Port au Basques. New piers with freight and passenger facilities were completed at Port au Basques and Sydney. The Sydney freight shed was extended and 250 ft. were added to the shed at Port au Basques.

An experiment at Lakehead ports in December 1958 raised hopes of a slightly longer shipping season and even limited movement of ships all winter. Two ships loaded with 9,000 tons of cement were kept ice-free in the Kaministiquia River during a

25° below zero cold spell with surrounding ice two feet thick. This was the first practical use of a bubbler system in Lake Superior, and cost some $5,000 to install, including $3,000 for an air compressor, $500 for polyethylene piping, $1,000 for electrical service and $500 for labour.



AIR TRANSPORT

THE RAPID GROWTH in Canada's commercial passenger air transport over a ten year period to the end of 1957 continued through 1958, but at a slightly slower pace. Based on reports for the first 9 months of 1958, revenue passenger miles were some 15 per cent higher than in 1957, to a probable 1958 total of 2.20 billion passenger miles. Cargo traffic showed a drop of some 20 per cent during the first half of the year but improved during the second half.

Trans-Canada Airlines

Trans-Canada Airlines, which carries 80 per cent of the nation's domestic air travel and 25 per cent of its air-freight, reported a 17 per cent increase in passenger traffic, to a new record of 1.63 billion revenue passenger miles. Carriage of mail, express and freight for the full year remained at close to the same levels as for 1957, with some 10 million mail ton-miles, 2.5 million express ton miles and 12.68 million freight ton miles.

During the year TCA expanded its activities to meet the heavy demand for air travel, and provided the greatest capacity in its history of more than two billion seat-miles, 19 per cent over that of 1957. Its fleet at year-end numbered 47 Viscounts, 18 other Turbo-props, 11 super-constellations, 21 DC-3's. Four more Viscounts and one super-constellation will be delivered early in 1959. TCA and other IATA carriers introduced an economy class fare for Atlantic travel. Tourist fares were reduced 20 per cent.

By 1961 TCA will become the first intercontinental airline in the world to operate an all-turbine fleet. Construction of a $20 million overhaul and maintenance base was commenced at Dorval to provide service for TCA's future fleet of DC-8 jetliners.

TCA's Atlantic services during 1957 carried 107,054 passengers and handled 243 million passenger miles, 3.86 million ton miles of freight and 1.78 million mail ton miles. This compared with 328.7 million available seat miles and 45.7 million available ton miles.

Canadian Pacific Airlines

CPA, whose domestic air service in Canada is limited to routes of lower traffic density, sought authority in 1958 from the Air Transport Board to fly five transcontinental routes in Canada. In January 1959 the ATB authorized one return non-stop transcontinental flight daily from Montreal to Vancouver.

CPA's Pacific services during 1957 carried 55,914 passengers and handled 215.6 million passenger miles, 3.2 million ton miles and 0.516 million mail ton-miles. This compared with 407.2 million available seat-miles and 42.6 available ton-miles. To its fleet of 8 DC6B airliners, CPA added 6 Bristol-Britannia turboprop aircraft during the year to fly its intercontinental routes.

Ground Facilities and Services

During 1958, Dorval, Malton, Winnipeg and Vancouver airports received delivery in March of Decca MR-75 Shoran Surveillance Radar, while Canadian Pacific Airlines received delivery at Vancouver of its first electronic flight super DC6B simulator. In May, Department of Transport announced $20 million would be spent at Malton for offices and four aeroquays for jet service, in addition to two already built, while a $4 million contract for runways would be completed in 1961. Kelowna would get a 5,000 foot runway.

Very high-frequency omnirange radar installations were announced in July, to be operative between Kenora and Lethbridge, while further sites would be selected in the Maritimes. In August, TCA announced it would receive its first DC8 simulator in September 1959 for installation at its $20 million Dorval overhaul base. With plans for the new passenger terminal at Malton readied and bids to open in December, the facilities there, it was said, would be ahead of anything yet devised for the jet age.

ATB approval was given for TCA to serve Brussels and Zurich in March; in May for CPA to stop at the Azores; in May for Wheeler Airlines to serve Great Whale from Montreal; in August for Nordair to serve Frobisher from Montreal with three flights weekly; in October for Western Pacific and B.C. to amend their services to Prince Rupert and other B.C. airports. Sabena was granted one-stop service from Montreal to connect at New York for flights to Moscow, while Aeroflot will make two flights weekly from Moscow to New York.

Special Flying Services

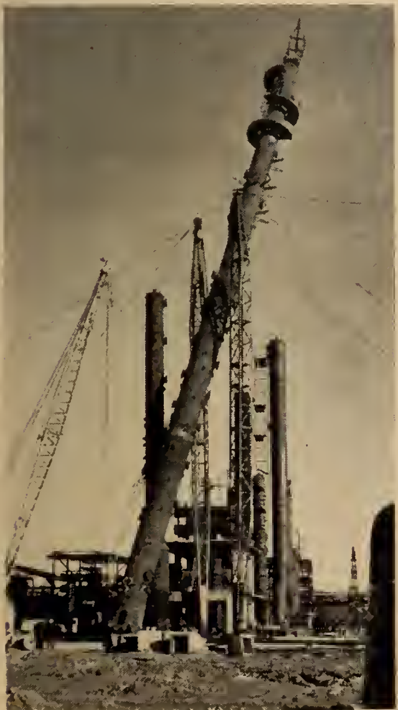
Northern operations, not included in any of the above statistics of nonscheduled services, take in aerial surveys, spraying of forests for budworm control, exploration and geological air surveying for mineral and petroleum resources and special airlifts for construction and mining equipment, rescue and mercy flights and various charter services, such as the servicing of radar station personnel in the northern radar warning lines.

The number of privately-owned aircraft operated in Canada has been increasing rapidly during the past three years, and at year-end totalled 2100.

CONSTRUCTION

THE CONSTRUCTION Industry leads all other industries in Canada in the number of persons it employs and in the value of production. New highs have been recorded in volumes of work done for every year since the end of World War II, though the gain for 1958 over the previous year was only between 1 or 2 per cent compared with the 10 per cent and 20 per cent gains in the two previous years of 1957 and 1956 respectively. Value of construction work performed by contractors at 76 per cent of the total in 1958, remained at about the same proportion of the total volume experienced in recent years.

Erection view of Canada's tallest unit processing tower . . . shop fabricated and field assembled by Horton Steel Works Limited; erected by Canadian Bechtel Limited at Sarnia, Ont.



Approximately 614,000 workers earn about $2.37 billion annually, or a third of the value of work done. They install or use new material or equipment annually worth $3.4 billion. The construction industry's program today represents some 22.3 per cent of the nation's gross national product, compared with 16½ per cent a decade ago.

Annual Report for 1958 based on 'Intentions'

The annual DBS report for 1956-58, containing the most recent statistics available, contains final data for 1956, preliminary data for 1957, and estimates of the intended program for 1958 based mainly on "Private and Public Investment in Canada, Outlook 1958", gathered from a survey undertaken during the previous fall by the Department of Trade and Commerce, revised in June 1958. Preliminary final statistics for 1958 are not published in time to be included in this Review. For 1957, however, the actual figures turned out to be some 4 per cent higher than the 'intentions'. Value of work performed in 1956-1957-1958 by categories, is shown in Table I.

Summaries of investment intentions by sectors of the Economy, as reported by the Department of Trade and Commerce for 1958 and 1959, are shown in Table II. Values of construction performed in each province during 1957-58 are shown in Table III.

As a further, more up-to-date indicator of new work undertaken in 1958, a summary by categories of contract awards during that year for each category of construction, as compiled by the MacLean Contract Guide, appears in Table IV. This statement, issued monthly, shows total cumulative contract awards compared with those of the previous month and year. It is closely watched by the industry as an indicator of trends. Because only three-quarters of all construction is done by contract, however, no record of work done with *day labour* by railways, utilities, communications, industries or governments is included. The annual volume of construction recorded in Tables I, II and III, moreover, includes carry-overs from preceding years, while values in Table IV are total current 'awards' only for the year noted.

Highlights of Building Construction in 1958

Building construction in 1958 showed an increase of some 8 per cent over the previous year. This was mainly due to the 33 per cent increase in housing, though institutional construction was also higher than 1957 by some 10 per cent. Commercial building showed little change, but industrial construction dropped sharply by 25 per cent.

Though the federal building program undertaken the past two years began to slow down through completions during 1958, this was compensated for by the beginning of an upsurge in civic buildings, city halls, provincial government buildings, homes for the aged, city auditoriums and the like. These added to the continuing heavy program for university buildings which will average $20 million over a 10-year period, and the seemingly insatiable demand for schools and hospitals, kept building construction at a high level.

A partial list of the more conspicuous building completions during the past year would include — the Queen Elizabeth Hotel and the addition to Ecole Polytechnique in Montreal; the addition to the Royal York Hotel, Bank of Canada Building and

Confederation Life Building, at Toronto; second men's residence at Queen's University, Kingston; engineering science building at Western University, London; a $7 million tube-mill and a courthouse at Hamilton; and mine buildings and housing development at Elliott Lake.

Notable among new buildings started during the year were the Place Ville-Marie project at Montreal; a 30-storey office building for Prudential Insurance and the 20-storey Trusco Office Building at Toronto; and a chemical and geological survey building for Department of Mines and Technical Surveys in Ottawa.

Continuing under construction were administration buildings for airports at Dorval, Malton, Winnipeg, Halifax and Edmonton, as well as a 13-storey office building for Shell Oil and the Mackenzie office building at Toronto; the Trade and Commerce building at Ottawa; a Sports Centre at Montreal; the T.C.A. Jet Maintenance Base at Dorval, an Exhibition Building at Calgary; the Blooming Mill at Algoma; and the Goodrich Tire Distribution Centre at Toronto.

More than $35 million was spent in the far north for moving the town of Aklavik to the new site at Inuvik and for townsite projects at Forts McPherson, Simpson and Smith.

View of "Mr. Klimax" Marion 7800 dragline with its 35 yard bucket. A truck is parked beside the dragline showing comparative size.

Engineering Construction in 1958

Engineering projects as a whole showed only a moderate gain in volume in 1958 over the previous year. Highway construction at over $1 billion was some 7 per cent higher than 1957; electric power construction, waterworks and sewage, railways and communications, and other engineering showed little change from the previous year; construction of dams and irrigation works showed a small increase. Gas and oil facility construction showed a substantial gain.

Apart from the progress on Canadian power developments (reported in the foregoing section on Power); highway developments by provinces; and the crude oil and natural gas pipelines and Defence Construction projects covered elsewhere in this section, some of the outstanding engineering projects completed or underway during 1958 were as follows:—

Excluding terminal buildings, work completed or under way during the year on clearance, runways, etc., amounted to some $6 million, bringing the total outlay since World War II to a cumulative total of $32 million at year-end on 150 major airports in Canada.

New projects undertaken during the year are listed under 'Civil Aviation'. The objective is to prepare runways for take-off and landings of 150 passenger jetliners.

Bridges

Prominent among bridges were the New Brunswick Island $1 million bridge, started last August; the Burlington Skyway at Hamilton, opened last September; the floating bridge over Okanagan Lake at Kelowna, opened last August by Princess Margaret; alterations to Victoria Caughnawaga, Jacques Cartier and Mercier bridges at Montreal to provide clearance for seaway traffic, substantially completed during the year; work started on the Nun's Island bridge over the St. Lawrence from Verdun to the South Shore; the rebuilding of the Peace River bridge in northern B.C. where piers were completed and a $4 million superstructure contract was under way; the new Second Narrows Bridge at Vancouver, two spans of which collapsed last summer; a C.N.R. bridge over the St. Maurice River; the Autoroute bridge over the Riviere des Prairies; and a bridge over the Exploits River in Newfoundland.

Tunnels

Major tunnelling projects included the four lane, mile-long, $17 million Deas Island Highway Tunnel under the Fraser River south of Vancouver to be opened early in 1959; and the half-mile tunnel under the straits of Georgia on the B.C. coast, successfully blown up in April removing Ripple Rock, long a hazard to navigation; the proposed $201 million tunnel for

The Craw River Valley Bridge, one of the major building projects on the second half of C.N.R.'s new $35 million Chibougamau branch line.

the Toronto subway, approved last fall but not commenced at year-end. Highway tunnels are also proposed under Mount Royal at Montreal estimated to cost $97 million.

Railway Projects

Completion of Pacific Great Eastern's extension to Dawson Creek and Fort St. John on October 1st was the highlight of the year in railway construction. In September contracts were awarded for a 193 mile iron ore railway 300 miles north of Shelter Bay on the Gulf of St. Lawrence by Quebec-Cartier Mining Co. In Manitoba the C.N.R. was pushing a 52-mile line into base-metal territory at Chisel Lake, 400 miles north of Winnipeg—while in Quebec construction of the second section of the Chigougamau branch from St. Felicien to Cache Lake continued. Pending at year-end was a decision respecting commencement of a $70 million, 400-mile rail extension from Waterways, Alberta to Pine Point, N.W.T., jointly by the C.P.E. and C.N.R. to be assisted by a Federal grant.

In communications, Canada's 3,900 microwave network from coast to coast was opened for operation on July first.

Pipeline Construction in 1958

Canadian pipeline construction in 1958 amounted to some 4,200 miles, for the third largest season in Canadian petroleum history. Completion of the last of the 'big-inch' lines, the 30 inch Trans Canada gas line from Lakehead to Toronto, was the outstanding job in 1958 in variety of problems and terrain, as well as the record number of 12 spreads which worked on a continuous section of 853 miles. With this line in the ground, the basic mainline distribution pattern of Canadian oil and natural gas has been set up, and there can be no more transcontinental pipelines of the same magnitude in the foreseeable future.

Crude oil lines were marked by only two main-line jobs: the Swan Hills-Edmonton line and Interprovincial's four short loops, between them totalling 207 miles of line. The remaining crude oil construction was gathering system work, amounting in all to 375 miles, as shown in Table II. The total of natural gas lines, 3,600 miles, compared with last year's all-time record of 4,300 miles (Table VI).

The outlook for 1959 is for lower volume and much smaller diameters of pipe, since the number of communities remaining to be served along the routes of the main lines is diminishing and the long laterals are mostly laid. However, services for new houses and industrial and commercial buildings in Toronto and Montreal will provide a firm foundation. Some 2,000 miles of gas lines may be laid next year, as well as another 500 600 miles of oil lines.

Head Gates for Beauharnois Hydro-Electrical development, Beauharnois, Que.

Materials

The year 1958 witnessed the virtual elimination of shortages of materials which in the past had hampered construction operations. Material prices however, in spite of the recession, in most instances held at 1957 levels or showed increases.

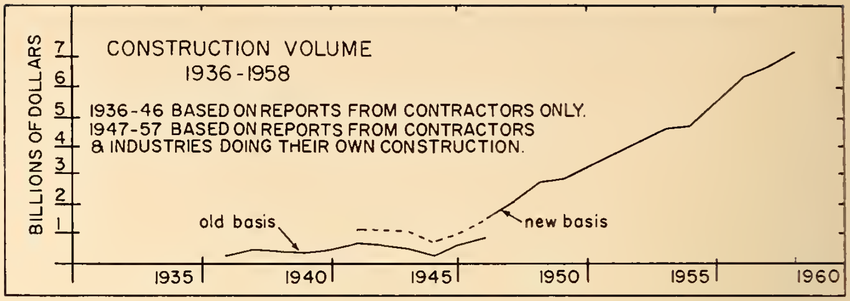
Additions to capacity for materials production over recent years should tend to hold prices steady in the coming year, though labour demands and strikes may result in some price increases.

Lumber prices remained close to the 1957 average during the first half of the year but rose 1½ per cent in the second half; cement, gravel and sand were up 2 per cent; brick, tile and stone prices were lower but gained 1½ per cent the second half; paint and glass showed little change; lath, plaster, insulation, plumbing and heating equipment prices were up slightly; roofing and electrical equipment prices were down 15 per cent and 12 per cent respectively, and other material prices remained steady. The composite price index showed little change.

The demand for laminated 'glulam' timber was maintained, with school, church, and recreation buildings making up for the drop in the industrial building. Total shipments of sawn lumber during first 10 months of 1958 were about the same as in 10 months of 1957. Exports for the same period were up 8 per cent while domestic shipments were some 3½ per cent lower than in 1957.

Bookings of fabricated structural steel held up well, and suppliers foresee an 8 10 per cent increase ahead for 1959, due to enlarged capacity. Advances in welding techniques have reduced weights and saved on erection. Production and shipments of cast iron pipe and fittings were below those of 1957 by 10 per cent and 5 per cent respectively, and of steel pipes, tubing and fittings down 11 per cent and 21 per cent respectively from 1957.

Producers sales of products made from Canadian clays valued at some $40 million were 20 per cent higher than in the previous year, while sales of concrete brick were double, concrete blocks up 25 per cent, concrete pipe up 42 per cent and ready-mix concrete up 33 per cent compared with 1957.



Climate Effect—Research

The effect of Canada's rigorous winter climate on the behaviour and endurance of various building materials is being ably and widely studied and publicized by the Division of Building Research, National Research Council, at Ottawa, established in 1957. The effects of low temperatures on soils, muskeg, masonry, wood products, concrete, plastics, plaster, bituminous materials, paints, and insulation are observed at seven different test sites across Canada.

Trends

Canadian architects are realizing that today's trend is toward more simple exteriors, in better taste than the oppressive over-ornate buildings of the past. The swing is towards acceptance and widespread application of the newer uses of concrete as a building material. Prestressed concrete is gaining popularity in bridges, and in buildings as well, though more slowly. Prestressed members are being produced at reasonable cost.

The lift slab method is gaining recognition, due to savings in forms and shoring costs. Walls are being poured on the ground and tilted into position. This saves on placing reinforcement and on mechanical and electrical work. With another method large *suckers* lift prefab units and deposit them where desired. *Thin-shelled* architectural structures of concrete are making their appearance where scaffolding and forms can be used often to reduce over-all cost. Concrete curtain wall panels are rapidly replacing metal panels.

Coloured buildings too, are gaining favour with architects even at extra cost. Coloured porcelain enamel on a metal base to modernize exteriors of old buildings is finding widespread use due to its weather resistance, though subject to corrosion on a steel base if the porcelain gets chipped. Anodized aluminum, stainless steel with baked-on coatings, ceramic-face glass units, glazed brick tile and ceramic veneer in colours are alternatives, though appearance, as well as comparative costs for installation and maintenance, must be compared.

In heating and air-conditioning, the growth of heating by natural gas is having a sharp impact on boiler, furnace and unit heater selection. On large buildings the trend is towards grouping of temperature control instruments on a large central panel to save legwork. Full air-conditioning installations are fast becoming a 'must' to attract and hold tenants. Wide interest is being shown by home-owners in the plumbing and heating trades campaign to publicize advantages of remodelling older homes for greater comfort, convenience and style in their plumbing and heating appointments. The heat-pump, too, is already finding its place in many homes for heating in winter and cooling in summer.

Another far-reaching trend is the growing use of electronic computers in the construction industry. Already widely used for road and highway quantity calculations, and for stress design on bridges, they are now coming into use for determining the best gradients at which to build the road. Combined with aerial photography they determine the best vertical and horizontal alignments.

For estimating, computers can already correlate cost-experiences, classify them and extract therefrom cost data to be applied to estimating new work. Computer manufacturers predict in ten to twenty years from now the engineer's prime responsibility will be delineation of the problem and the study of the fundamentals.

Table III—Values of Construction by Provinces—1957-58, in $ Millions

Preliminary—1957		Intentions—1958	
Building	Engineering	Building	Engineering
420.7	477.4	408.4	417.1
315.3	392.5	344.5	460.2
146.0	207.7	172.4	200.2
180.9	178.4	185.7	159.7
1,421.3	977.4	1,546.0	1,159,5
894.0	676.8	957.4	678.7
85.7	73.8	87.9	64.9
80.2	62.9	111.6	69.0
8.4	8.3	10.2	11.6
55.1	39.2	49.2	41.9
$3,607.7	$4,094.4	$3,873	$3,263

He will then turn the design, detailing, scheduling, cost control and preparation of the bid over to modern electronic equipment.

The trend to better illumination, both outdoors and in offices and homes, as outlined in the Review published in the Journal issue of April 1958 (p. 94), continues apace. The average lighting level of 10 to 100 foot-candles in 1952 has grown to a range of 100-200 today and is expected to double again by 1968 as lighting technology improves. Westinghouse engineers have revealed a long forward stride in the use of 1,500 cycle power instead of the standard 60-cycle, with power conversion efficiency near 95 per cent at rated load.

Table IV—Contract Awards in 1958—In Millions of Dollars

Province	Residential	Commercial	Industrial	Engineering	Total
British Columbia	104.38	94.35	14.86	56.18	269.78

DEFENCE CONSTRUCTION

Since its establishment in 1950, Defence Construction (1951) Ltd. has completed construction valued at over $1 billion for Canada's national defence. Much of this expenditure has contributed to the development of Canada's north.

In 1958 D.C.L. awarded defence contracts to the value of $90 million compared with $58 million in 1957. The year 1958 opened with uncompleted work outstanding valued at $28.6 million, while work outstanding at year-end was valued at approximately $69 million. In view of the substantial increase in awards in 1959 and the additional work expected for National Defence in 1959, it is anticipated that expenditures on defence contracts in 1959 may be nearly double those of 1958, or nearly $100 million.

Northern Development

As in previous years, 1958 again saw large projects undertaken in the north, such as paving a section of the North West Highway System (Alaska Highway), the construction of the new Peace River Bridge and the large refuelling facilities program at Frobisher, Churchill and other sites. The contract for paving the first 51 miles of the Alaska Highway is nearly complete, while the new Peace River Bridge is expected to be ready for traffic next fall.

Under an agreement between Canada and the U.S. four refuelling bases are being built in Frobisher Bay, Churchill, Manitoba, Namao and Cold Lake, Alberta. Funds for design and construction are being provided by the U.S.A.F. In recent months D.C.L. awarded construction contracts to the value of $25 million for these refuelling facilities. Work is already under way at Frobisher Bay and Churchill. The Frobisher Bay contract was awarded in the amount of $10.8 million. During last summer some 9,000 tons of initial stores were shipped there and work was started immediately.

Air Defence Program

Turning to future defence construction activity—D.C.L. looked forward to participating in a start in 1959 this year on the new aspects of the air defence program, which call for the introduction of Bomarc, *Sage*, and the extension and strengthening of the Pinetree radar control system. The Bomarc guided missile is designed to be used in defence against hostile bombers. The Bomarc missile is an airplane, it has wings and stabilizers and air keeps it aloft. It is guided from the ground with the aid of the same radar system as that used in guiding manned interceptor aircraft. Unlike conventional aircraft the Bomarc is launched from a vertical, tail-down position by the blast of a rocket engine.

Two Bases

It is proposed to establish two Bomarc bases in Canada, to be located in northern Ontario and Quebec areas. Additional Bomarc bases may be located in Canada in the later development of the program, but priority is being given to these two bases. The government decided to incorporate SAGE, or semi-automatic ground environment, in the Canadian air defence system. Expected to be in operation by early 1962, SAGE, an electronic computing centre, will serve as the brains of the air defence system, and will be integrated as part of the North American SAGE system under Norad. The government has also approved the extension and strengthening of the Pinetree radar control system. Several additional large radar stations will be constructed.

Erection of structural steel for engine test house at T.C.A.'s new turbine maintenance and overhaul base at Montreal's Dorval Airport.

NATIONAL DEFENCE

THE NAVY IN 1958

Consolidation of technical training, maintaining increasingly complex naval equipment, armament and machinery and the setting up of a team to study the feasability of acquiring nuclear submarines, were high on the list of R.C.N. activities in 1958. At year-end the Navy had 47 warships in commission, three R.N. submarines under its operational control and a further 6 ships under refit.

Major additions to the fleet in 1958 were two destroyer-escorts, one frigate, 43 CS-2F anti-submarine aircraft, and the last of the *Banshee* jet fighter procurement program. *Banshee* fighters were fitted with the air-to-air *Sidewinder*, while anti-submarine helicopters were fitted to carry homing torpedoes with a kill capability.

A new Naval Technical School was opened at Esquimault, B.C. to serve as a primary source of highly skilled personnel to operate and maintain the increasing amount of technical equipment. Training advances included formation of a cadet training squadron on the Pacific Coast with the primary task of training cadets from service colleges, universities and HMCS *Venture*.

Today's sailor is a technician and specialist. Here a petty officer of the engineering branch operates a throttle valve in the engine room of a Tribal class destroyer escort.

THE RCAF IN 1958

Elements of air Defence Command stood ready on a 24-hour-a-day basis throughout the year to detect and attack any hostile aggressor. Keeping these elements in top operational form were several NORAD exercises.

In September, Prime Minister Diefenbaker announced that an integrated weapons system which includes the *BOMARC* missile and SAGE (semi-automatic ground environment) would be introduced into the Canadian air defence system by 1961. Also approved was the extension and strengthening of the Pinetree radar control system. Two *Bomarc* bases will be built in the general northern Ontario and Quebec areas and others may be located elsewhere in Canada.

Runway barriers were installed at seven Air Defence Command bases in Canada during the year. The barrier will prevent aircraft up to and including the CF-100 from becoming damaged by overshooting the runway on landing.

Overseas, some 6,000 members of Canada's European-based Air Division continued to retain their high operational standard. Simulated combat exercises were carried out during 1958 among the R.C.A.F.'s four fighter wings and with other NATO countries. Canadian aircrews again won top honours from aerial marksmen of other NATO air forces during the air firing competitions at Cazza, Franee.

In July, a ceremony held at Winnipeg marked the closing of the original NATO aircrew training scheme begun in 1950. Final intakes of NATO aircrew personnel were nearing completion of their courses at year-end. Replacing the original plan, training was continuing for limited numbers from Norway, Denmark and the Netherlands. Since the inception of the original scheme, the R.C.A.F. has graduated more than 5,500 aircrew from 10 NATO countries. With the reduction in training, two of the Command's bases—Claresholm and London were closed during the year.

1958 was a busy year for Air Transport Command as its aircraft airlifted nearly 14 million pounds of cargo and more than 70,000 passengers. During the year more than 180 scheduled round trips were made to Europe in support of No. 1 Air Division and the UNEF in the Middle East. In addition, nearly 650 replacement troops were airlifted from Montreal to El Arish and 675 were returned. on special U.N.E.F. rotation flights.

Late in 1957, the R.C.A.F.'s two *Comet* aircraft were put into scheduled Trans-Atlantic service, and since that time have made 28 round trips.

THE CANADIAN ARMY IN 1958

From the four corners of the globe where its members are working to maintain world peace, the Canadian Army looked back at year-end on another year of progress and achievement.

As the year ended Canadian soldiers were serving in Europe, the Middle East and the Far East in support of Canada's increasing commitments to NATO and the United Nations. In June observers were sent to Lebanon for duty with the United Nations Observer Group. Canadian troops serving overseas at year-end totalled some 6,500, the majority with Canada's NATO brigade group in Europe and with U.N.E.F. in Egypt. Late in November all U.N. observers were withdrawn from Lebanon.

At home and abroad the Army embarked on a gradual but general reorganization in 1958 to meet the changing concepts of war and the advent of the *space age*.

The Government decided in October to equip the Army with the U.S. *Lacrosse* surface-to-surface guided missile. A battery of four launchers and associated fire control equipment will be put into service. Half the battery will be assigned to the 4th Canadian Infantry Brigade in Germany while the other will be located in Canada.

The 1st Canadian Infantry Division ceased to exist as an active unit last January, and the field force was reorganized into four independent brigade groups. In line with the new tactical concept that the brigade is the basic fighting formation, the activation of a new armoured regiment was announced in November. Each brigade group in the Regular Army now has an armoured regiment in support.

Planning for the future also gave birth to the Directorate of Combat Development, which will develop new doctrines and techniques and assess these by modern scientific methods.

New equipment introduced during the year included prototypes of the *Bobcat*, a new armoured tracked carrier featuring speed and mobility, essential factors for survival on the atomic battlefield. Amphibious as well as armoured, the vehicle affords complete protection against the thermal effects of atomic explosions and can carry troops across all types of terrain.

Also in the field of nuclear warfare, an Army officer came up with an invention, since adopted as standard equipment by the Army, for a safer, more practical and more economical method of testing the instruments used to measure radioactive fall-out and contamination.

The first full-scale field use of a tellurometer, a battery-powered *echo* timing instrument that accurately and precisely measures the distance between two points, was made in the far north last summer by Army Engineers surveying 60,000 square miles of unmapped tundra. Several other military survey parties, from the Army Survey Establishment, took to the field to help the mapping of Canada.

The Army's communications link with the United Kingdom was boosted in October with the opening of a new 30-kilowatt radio transmitter near Ottawa, equipped with an electronic *memory* device which automatically sets the multitude of controls after a master switch is turned on.

Symbolic of the ground-air co-operation necessary in the air defence of North America is this photo of swift CF-100 "Canuck" interceptors on a sweep over the domes of an R.C.A.F. radar station.

CANADIAN ARSENALS IN 1958

CANADIAN ARSENALS LIMITED, a Crown-owned company whose function is to produce arms and ammunition for the Armed Services, continued to effect improvements in manufacturing techniques.

The Company has nine Plants located in Ontario and Quebec, and among the major production facilities recently installed are the following:

Artillery cartridge cases, previously manufactured from brass, are being replaced by steel cases. The cases are cold deep-drawn and subsequently zinc plated. The plating is performed in a Lasalco plating and chromating unit which performs fourteen separate operations automatically. This unit is located at the Dominion Arsenal Division in Quebec City. Heat treating of the steel cases is also carried out automatically in an Ajax continuous submerged electrode salt bath furnace.

At the Small Arms Division of the Company, at Long Branch, Ontario, extensive use is made of broaching machines in the production of the 7.62 mm FN Rifle*, 12 broaches effecting some 37 operations previously performed on 150 milling machines. This rifle is capable of being fired single-shot, semi-automatically, or fully automatically at 650 rounds a minute.

At the Explosives Division in Valleyfield, Quebec, a program of reconstruction of wartime temporary facilities was proceeded with, and new facilities for the manufacture of rocket grains were completed and brought into production. A building housing crystallizing equipment was used in the manufacture of RDX high explosive. Protection is afforded on three sides by sand-filled timber barricades which are believed to be the highest in the country.

New army personnel troop carrier, "Bobcat".

---

*"The F.N. Rifle" *Engineering Journal* of March 1958.

GOVERNMENT WORKS

Federal Department of Public Works

DURING THE FISCAL year 1957-58, latest year for which a record of DPW is available, construction and repairs were done on 263 wharves, breakwaters and other harbour facilities of which 188 were completed. A total of 1,488 smaller projects were undertaken. Dredging was carried on in 328 locations involving removal of 9.5 million cubic yards.

World's largest Waterspheroid, standing 132 ft. above ground level at Red Deer, Alberta.

Contracts for construction of 292 Federal buildings and other premises occupied by Government departments were awarded. Work was still in progress at March 31, 1958, on 122. Construction was started on the DPW administration, the National Gallery and The Finance Building, all in Ottawa.

Expenditures are shown in Table 1.

Sewage and Water Projects

Worthy of mention among sewage and waterworks projects were Metropolitan Toronto's East Don Sanitary Trunk Sewer, completed in 1958; and Montreal's Decarie-Rainbault \$10½ million Collector Sewer, 8½ miles long and 13½ ft. in diameter along Queen Mary Road, to be completed in late 1959. The Conestoga flood control dam in Ontario was completed in January 1958.

In Ontario alone the Ontario Water Resources Commission, set up in April 1957, has already committed itself to \$23 million for construction on behalf of municipalities requesting water and sewer projects. Its objectives are to insure maintenance of safe water supplies and to make it possible for municipalities to finance water and sewer treatment works. Six waterworks and three sewer projects costing \$1½ million are in operation, as well as a 30-mile water supply line costing \$3.7 million from Lake Erie. Under construction are some 25 additional projects which will cost another \$20 million.

Expressways

Among municipal projects for expressways completed or under way were the \$1 million Parkway at Montreal over Mount Royal, opened in September; the 35-mile 80 100 ft. wide Metropolitan Trans-Island Boulevard across Montreal Island, to cost \$31 million over a six year period; The Ontario Highway's Dept. 'Queens Way' through Ottawa; a 6-lane expressway from Vancouver to Blaine, Wash., which passes through the Deas Island Tunnel under the Fraser River; the Don Valley Parkway and the F. G. Gardiner Expressway at Toronto, opened in August.

Highway Construction in 1958

Total road expenditure at all three levels of government in 1958 was estimated by The Canadian Good Roads Association at \$1,044.6 million on highways, roads, streets and bridges—a 7 per cent increase over that of the previous year. Of the total, federal expenditure totalled \$115.66 million, provincial expenditure totalled \$668.97 million (including subsidies of \$86.45 million to municipalities), while municipal expenditures totalled \$260 million in addition to provincial subsidies.

Federal expenditure of $115.66 million was divided as follows: National Defence Northwest Highway System, $10.11 million; Northern Affairs and National Resources, $28.14 million, Public Works, (including Trans Canada Highway Grants) $60.8 million; Federal District Commission, $1.6 million; Railway Grade Crossing Fund, $15 million.

Net current and capital expenditures by provinces in 1958 on highways, roads and bridges, with expenditures on construction only for each shown in brackets, were as follows: in millions of dollars: P.E.I., $4.06 ($2.58); Nova Scotia, $27.28 ($14); New Brunswick, $23.45 ($12.44); Quebec, $150.9 ($106.28); Ontario, $257.58 ($181.43); Manitoba, $35.62 ($4.83); Saskatchewan, $32.9 ($8.71); Alberta, $57.98 ($11.46); British Columbia, $79.2 ($14.74). Newfoundland's budget, not yet approved, was expected to total $10 million.

A breakdown of construction progress for each province during 1958 by categories such as mileages of grading, base course, paving, etc., as reported at the C.G.R.A. Convention in October, was published in the November issue of the Journal under 'Roads Roundup', pages 120-123.

Of the three levels of government, according to C.G.R.A., statistics on municipal road and street expenditure are the least reliable. Previous expenditures prior to 1958 had been substantially underestimated. Efforts now under way will improve the accuracy, but more reliable data is needed on urban road and street finance before a clear picture can be gained.

Highway Traffic Statistics

Vehicles on Canadian highways in 1957 totalled 4,459,595, double the number registered in 1948. Each registered vehicle travelled an average of 8,253 miles in 1957, compared with 7,942 miles in the preceding year. In 1957 all motor vehicles travelled an estimated 36.8 billion miles, compared with 33.6 billion miles in 1956.

Canada's mileage of surfaced roads rose from 131,000 in 1945 to an expected 252,000 miles by the end of 1958. For the first time since World War II there was evidence builders of intercity highways and rural roads were catching up with traffic demands. Urban traffic gets more and more congested however. More than half of Canada's population live in cities, but municipal expenditures amount to only one quarter of the total national road and street budget.

Federal 'Roads to Resources' Program

Of national importance was the Federal governments proposal last year to spend $115 million over seven years on roads in the Northwest Territories and the Yukon. British Columbia, Alberta and Saskatchewan signed agreements with Ottawa last fall under the program. Initial projects commenced in 1958 included the $20 million Cassiar-Stewart Highway, while starts were made by Dept. of Northern Affairs on the Mackenzie Highway from Alexandra Falls to Yellowknife. Construction will start in 1959 on 400 miles in the Yukon from Flat Creek northerly to Fort McPherson and on the Clinton Creek Road northwesterly from Dawson. Several bridges to replace ferries along the Whitehorse-Dawson road were undertaken during the winter.

Government Works

Apart from the many and diverse services performed by federal, provincial and municipal governments, the end-product is in the form of construction of highways, buildings, airports, navigation canals or channels and other forms of public works. Public accounts from the Federal Government and each of the ten provinces are not published until a year or more after the end of the fiscal year.

Capital investment intentions during 1958 by government departments, housing and institutional services, exclusive of Crown Companies, commissions, authorities, administrations and the like, were expected to amount to $3,592 million or 38 per cent of the total Canadian investment, compared with 32 per cent in 1957. Direct government outlays at all three levels of government during 1958, exclusive of privately-owned housing and institutions, were expected to amount to $1,515 million, according to revised forecasts in June 1958, or 17.7 per cent of the total Canadian investment, compared with $1,405 million or 16.7 per cent of the total Canadian investment in 1957.

The total of direct government outlays in 1956, last year for which full statistics of all government expenditure are available, was shown in the Trade and Commerce "Private and Public Investment Outlook" at $1,300 million. Deducting therefrom the $163.5 million spent by the Federal Department of Public Works, including highways, the same year (as shown in detail on Table I) leaves $1,137.5 million presumably spent by provinces and municipalities.

Expenditures during 1956 by provinces and municipalities on highways and streets totalled some $820 million, leaving some $317.5 million spent the same year on other categories of public works and publicly-owned institutions. A summary of public works expenditures from Provincial Public Accounts the same year showed a total of some $150 million for provinces alone. The difference of $167.5 million would thus appear to represent public works expenditures at municipal levels.

Foundation Co. of Canada develops high-speed tunnelling methods without the use of explosives. Start of operation on 11-ft. diameter 2½ mile long Humber Valley Trunk Sewer for the Municipality of Metropolitan Toronto.

P.F.R.A.

The Prairie Farm Rehabilitation Administration, or P.F.R.A., was set up in 1935 during the severe drought and depression years of the 'thirties' to aid farmers in the dry belt of the three prairie provinces. The Act establishing it was amended in 1937 to increase its scope and authority. Its head office is at Regina, with regional offices at Kamloops and Winnipeg and 18 district offices in four western provinces. It is administered through the Federal Dept. of Agriculture. Its two primary functions are water development and land utilization within the 105 million acre area under its supervision.

Larger Irrigation Projects in 1957-58

During 1957-58 expenditures under special votes were: surveys and engineering, $1.77 million; St. Mary River project, $1.62 million; Bow River project, $1.67 million; land protection and reclamation in Manitoba, $337,190; Buffalo Pound project, $440,515; South Saskatchewan project $259,600; Red Deer project, $71,800; construction on other miscellaneous projects, $22,855 and surveys and construction on Assiniboine and Qu'Appelle Rivers, $249,582.

On the St. Mary project the East Ridge Dam and the Belly river division canal were completed. Repairs and alterations were made on a number of works already in operation. Almost 170,000 acres were under irrigation in 1957.

On the Bow River project, enlarging of the original facilities were completed. Capacity of Lake McGregor reservoir was increased. Water was delivered for the first time in 1957 to the West Block of the project, which received 3,073 acre-feet of water during 1957.

On the South Saskatchewan River development sufficient information was gathered in 1957 to permit proceeding with construction. Extensive drilling investigations of site foundations was undertaken and silt sampling and stream flow measurements were continued. At outlook a 171 acre experimental farm to study techniques, practices and crop yields was in operation with water pumped from the river. (Though not noted in the 1957-58 report, agreement was reached in July 1958 between the Federal Government and the Province of Saskatchewan to commence construction of this project on a cost sharing basis.)

No New Trend in Dustbowl

Saskatchewan and Manitoba farmers fear they may be headed for a cycle of drought like that of the 'thirties'. The Red River valley last September suffered the most acute water shortage in 25 years, while around Saskatoon farmers were watering their cattle by tank-trucks. Winter snowfall has been below normal during winter 1958-59. But scientists of the climatological section of the Meteorological service of Canada see no recurrence of the pattern that preceded the dry years of the 'thirties'. Although occasional dry years may come, moisture seems to be getting better instead of worse over the long-haul, they say.

Engineering Services to Foreign Nations

Canada's consulting engineers and architects are continuously designing and supervising new buildings, housing, manufacturing plants, and heavy engineering developments for power, pipelines, airports, smelters and refineries, harbours and transportation facilities. These are translated by Canadian construction firms into the nation's industrial potential at a rate valued at more than $7 billion annually. Here is a vast store of 'knowhow' available to younger nations.

Many Canadian engineers—mining, civil, electrical, mechanical, atomic and chemical, are active as consultants in foreign countries all over the world. Vast power and electric traction systems in such countries as Mexico, Spain, Venezuela and Brazil have been designed and built by Canadians. Brazilian Traction is operated today from Toronto by Canadian management.

In addition to the work being carried out by Defence Construction, Ltd. in commonwealth countries under the Colombo Plan, Canadian general contractors are taking a growing and lively interest in bidding on foreign projects. For example, one such firm is currently installing a 40,000 k.w. nuclear research reactor in India, while another is associated with a local firm which was low bidder on a multi-million dollar hydro-electric and irrigation project in Latin America, in competition with a dozen American and European construction firms. Pulp mills have been designed and built recently by Canadian engineers in thirteen foreign countries.

Canada's trade commissioners all over the world can obtain full information about these projects and the firms which are designing them and carrying them out. A further direct source of information is the Engineering and Equipment Division, Department of Trade and Commerce, Ottawa, Canada.

Canadians are welcomed in foreign lands because foreign nations understand Canada has no political aspirations and no 'strings' are attached to their services.

Table I—Expenditures by Federal Dept. Public Works Fiscal Year 1957-58.
in millions of dollars

	Dredging	Construction and Improvements	Repairs and Maintenance	Staff Sundries	Total
	$	$	$	$	$
Public Buildings	—	55.43	7.28	30.41	99.13
Harbours and Rivers	7.30	21.98	2.99	1.57	33.85
Trans Canada Highway	—	62.20	—	—	62.20
Administration, etc	—	—	—	8.10	8.10
TOTAL 1957-58	7.30	139.62	10.27	46.09	203.28
TOTAL 1956-57 FOR COMPARISON	6.68	104.20	9.88	42.74	163.50

Canadian Engineers in Southeast Asia

The Canadian Colombo Plan Administration of the Department of Trade and Commerce has been endeavouring since its inception in 1951 to assist the commonwealth countries in Southeast Asia with their economic and industrial development. Substantial progress in certain fields has been made by many of these countries, including Pakistan, India and Ceylon, through the assistance given by Canada but a tremendous amount of work remains to be done.

The Colombo Plan Construction Program, which is part of the over-all Plan, is managed by Defence Construction (1951) Limited on behalf of Trade and Commerce. During the past 5 years, through Canadian engineers, contractors and manufacturers, it has supplied Pakistan and India with the complete design and specifications for structures and equipment, as well as construction equipment, permanent equipment, building materials, construction management, supervision, superintendence, training and the technical services necessary to instal hydro-electric developments ranging from 12,000 to 240,000 kilowatt stations, and thermal steam plants of 10,000 to 20,000 kilowatt generating capacity.

They have also supplied similar services for transmission lines and a 300 metric-ton per day cement plant in West Pakistan. In Ceylon, Canadian engineers and contractors have contributed their knowledge and energy to complete successfully a fish refrigeration and by-products plant capable of processing 25 tons of fish every 24 hours.

The total Canadian contribution to the construction program up to the present time approximates $86 million of which approximately $73 million has been committed. A general distribution of the commitments is as follows: engineering services $6 million; permanent equipment $43 million and construction services, including construction equipment, $24 million.

INDUSTRIAL PRODUCTION

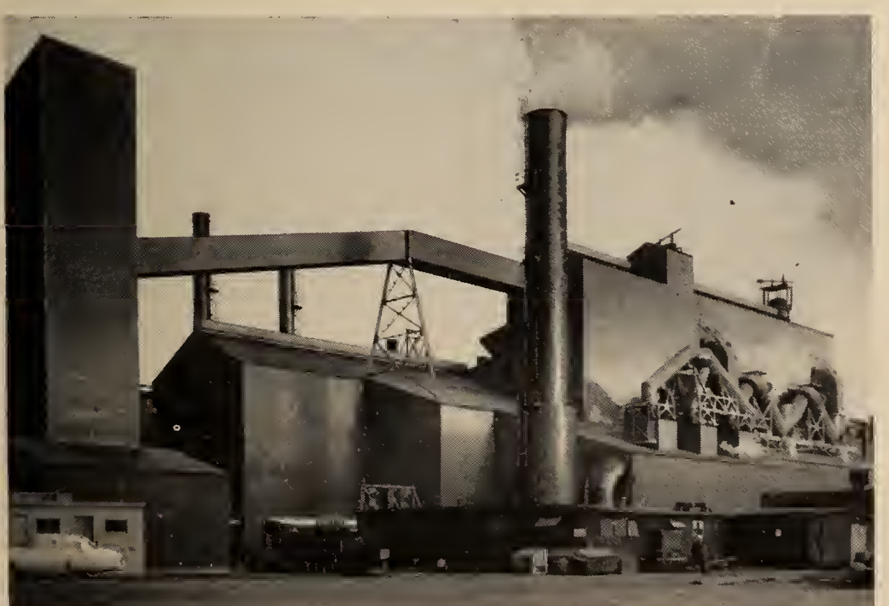
IRON AND STEEL

CANADA'S PRIMARY steel production for the full year 1958, at some 4.25 millions tons of ingot, showed a decrease of 13½ per cent compared with the 4.92 millions tons produced in 1957. Production for the year averaged 73 per cent of rated capacity, in spite of a strike at Stelco, Canada's largest producer, which had dropped total output close to 50 per cent of capacity in September and October. Production of pig iron at some 3.06 million tons for the full year was 18 per cent below the 3.73 million tons produced in 1957.

Canadian steelmakers finished the year at close to 90 per cent of rated capacity, the highest operating level since early in 1957. With orders on hand at year-end indicating a high operating level for the first quarter of 1959 at least, they saw a fair chance of overall domestic demand holding at a high level through most of the year.

Farm implement orders were at a new high level; steel demand for heavy industrial construction programs was strong; demand from appliance manufacturers was improving and the automobile industry showed signs of early recovery. On the other hand, new railway car business was almost at a standstill; while a depressed oil industry and a sharp drop in demand for pipe, casing, etc. had sharply reduced the markets for steel plate.

Two L-D Oxygen Steel-making furnaces at the Algoma Steel Corporation, Limited are housed in the large building shown here. It is equivalent to a 10-storey structure spread over the length of a city block.



Production Statistics for 1958

Of the 3.73 million tons of crude iron ore charged to blast furnaces 75 per cent came from foreign mines and 25 per cent from Canadian mines. Of the 1.78 million tons of sintered or pelletized ore used, 46 per cent came from Canadian mines and 54 per cent from the industry's own processing. Scrap used totalled 132,100 tons. Of the 3.06 million tons of pig iron produced, 429,494 tons was shipped for sale and the balance retained for the industries' own use. Pig iron production averaged 71% of the industry's annual capacity of 4.25 million tons.

Charges to steel furnaces of 4.75 million tons included 2.61 million tons of pig iron, 1.17 million tons of produced scrap and 0.97 million tons of purchased scrap. Of the 4,254 million tons of ingot made, 3.797 million tons was basic open-hearth (including 19,736 tons of alloy steel) ingot; and 0.457 million tons electric. Of the 90,684 tons of steel castings made, 15,971 tons was open hearth, 74,695 tons electric and 18 tons other production.

Disposition of Steel Castings

Based on reports from consuming industries for shipments of the 90,685 tons of castings, distribution was as follows, in tons: exports, 1,545; to automotive industries, 586; agricultural, including farm implements, 1,801; mining, lumbering and quarrying, 14,787; petroleum, 1,187; national defence, 47; public works and utilities, 2,964; railway operating, 17,978; railway rolling stock, 30,523; shipbuilding, 1,255; and miscellaneous, 5,476.

Production during the year of rolled steel products was made up of 3.46 million tons of all hot rolled products, 1.258 million tons of cold rolled products and 114,866 tons of all alloy products. Total shipments amounted to 3.42 million tons, of which 1 million tons was for further processing; 4.71 million tons of carbon products of which 1.47 million tons was for further processing, and 114,947 tons of alloy products of which 93 tons was for further processing.

Disposition of Rolled Products

Disposition of rolled steel products was as follows: in tons: to wholesalers, 319,470; exports, 222,605; automotive industries, 175,200; agricultural including farm implements, 90,238; construction, 601,200; containers, 321,258; merchant trade, 323,095; mining and lumbering, 76,600; defence, 3,710; pressing and stamping, 182,277; public works and utilities, 23,833; railways, 319,000; railway rolling stock, 71,285; shipbuilding, 15,327; pipes and tubes, 461,300; and miscellaneous, 3,044.

Capacity

Iron blast furnace capacity at year-end totalled 4,248,875 tons annually, with 76.3 per cent in 9 furnaces in blast, 16.9 per cent in 4 banked furnaces; and 6.8 per cent in 2 furnaces blown out. Annual steel furnace capacity as of January 1958 at 6,303,000 tons was for ingots; basic open hearth, 4,497,000 tons; electric, 706,000 tons and oxygen, 710,000 tons. Steel casting capacity totalled 390,000 tons.

Activities of the "Big Five" Primary Producers

Steel Company of Canada, Canada's largest producer of ingot, with annual ingot capacity of 2.4 million tons, brought its new number 2 blooming mill into operation at Hamilton early in 1958, raising its total annual rolling capacity to five million tons of steel.

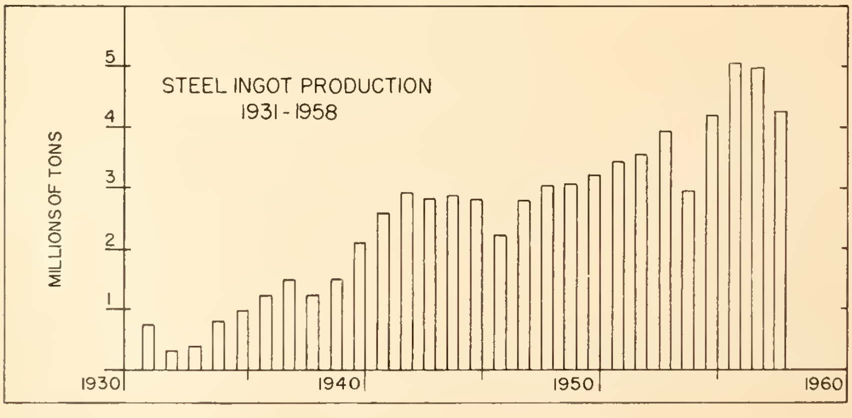
That, however, is double its current ability to produce steel, for to fully utilize the new $25 million plant would normally require as well a doubling of coke-oven, blast furnace and open hearth facilities. Planning in this direction is now under way. Estimates of their costs are difficult to make, but Stelco officials think capital expenditure might ultimately reach a further $1.6 billion.

Stelco officials see no reason as yet to modify their prediction made to the Gordon Commission in 1956, that Canadian steel consumption would double to 14.3 million tons annually by 1980. Assuming some 83 per cent of this to be domestic production, (vs 70 per cent at present) the entire Canadian steel industry would have to double ingot capacity over the next 22 years to about 12 million tons a year.

Algoma Steel Corporation

Canada's second largest producer with capacity of 1.3 million tons is in the final stages of a 10-year modernization and expansion program. Preliminary engineering is complete on a new plant to make heavy structural steel beams up to 24 inch widths on a 75 acre site on the U.S. side of the St. Mary's river. This $25 million project will be carried out in three separate stages over several years.

With completion in 1959 of two new plants—combined blooming and wide-plate mill and an oxygen steelmaking mill, the major post-war expansion costing some $170 million will have come to an end. This ten-year period will show a 62 per cent expansion in Algoma's steel capacity. The existing 600,000 ton operation it started with will also have been fully rehabiliated.



The new ore bridge of Algoma Steel Corporation, Limited has a bucket capacity of 22½ tons, making it one of the largest of its type in existence. Large bucket capacity and the fast operating speed of the bridge have reduced ship unloading time.

Blast furnace facilties have been expanded and modernized. No. 6 furnace has been enlarged to a capacity of 1500-1600 tons daily. Fifty per cent of the greatly expanded coke oven capacity has been built since 1953. The combined blooming mill and wide plate mill will start operation early in 1959. The new plate mill will greatly increase Algoma's market potential in flat products. Long term steel supply arrangements with Mannesmann Tubes, among the most modern pipe mills on the continent built next door to Algoma, has opened a big market for 'tube rounds' for casing. Ingot product in 1958 amount to 961,535 tons.

Dominion Steel and Coal Corporation

For Dosco, Canada's third ranking steel ingot producer with close to one million tons annual capacity, the last big addition was the opening of a sixth open hearth furnace at Sydney in mid-1957, raising capacity from some 700,000 tons yearly to about a million tons.

Most recent capital additions other than the new open hearth furnace include soaking pits at Dominion Iron and Steel, a $4 million plant for Canadian Steel and Graham Nail division in Toronto, a new rolling mill finishing building at Canadian Tube and Steel products in Montreal and a new plant for Canadian Bridge at Montreal.

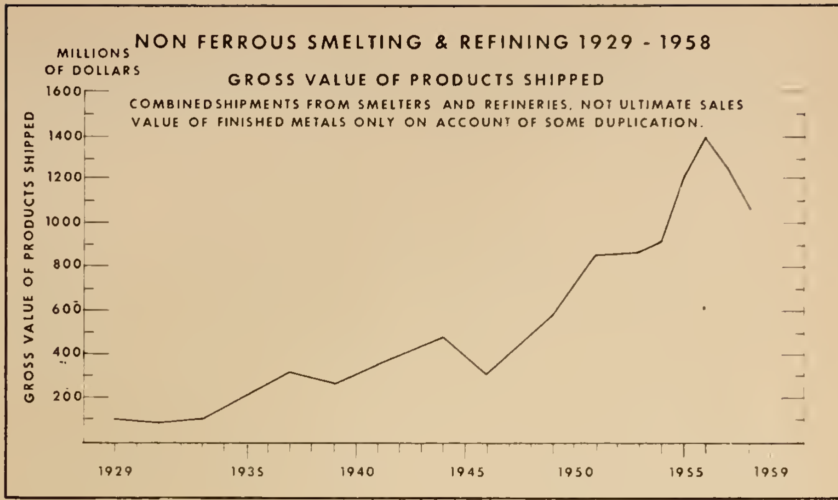
The year 1958 was one of widespread changes. In September 1957 control of the Company had been taken over by A. V. Roe, Canada, Ltd. management reorganization revolved around in the division into four operating divisions:—production, fabrication and manufacturing, mining and transportation. Currently, capital expansion is limited, reflecting the lower steel demand. Tonnage of ingots produced in 1958 has not been reported.

Dominion Foundries and Steel Corporation

Dofasco, with an annual capacity of at upwards 900,000 tons, added 45 coke ovens in 1953, bringing total to 105 ovens and making the company self-sufficient in coke supply. The company also opened its anhydrous ammonia manufacturing plant, built by North American Cyanamid. It is spending $4.5 million on new equipment, including two boilers and boiler house to provide the extra steam needed for the new ovens. Ingot tonnage for 1958 has not been disclosed, but it is expected to be considerably below 1957 production.

Atlas Steels

With annual capacity of some 240,000 tons of specialty steels, operated at about 40 per cent of capacity in February last year, but recovered to 55 per cent of capacity by mid-year. Value of production based on the first 9 months indicated value of shipments for 1958 would reach some $30 million or 31 per cent below 1957. The decline last year was mainly due to reduced requirements of the automobile industry, which accounts normally for half of the company's sales tonnage and 35 per cent of the sales dollar.



Construction of a 3-storey 39,000 sq. ft. administration building, started in October 1957 was completed in June last year, to promote the use of stainless steel for construction in Canada. This steel is produced by Usines Gilson, S.A. of Belgium, a company in which Atlas acquired a 30 per cent interest in 1957.

Other Developments in 1958

Elsewhere in Canada, a start was made last year on a new pipe mill at Contrecoeur, Quebec by Steel Company of Canada. New steel finishing capacity was installed in Western Canada. Construction of a small basic steel mill is being planned by U.S.-Canadian interests south of the St. Lawrence River at Varennes east of Montreal. It will have annual capacity of some 100,000 tons of semi-refined steel. Part of the output will be sold as pig iron with the balance being made into ingots. Capital cost is estimated at between $7 and $12 million, will use the Strategic-Udy process and will be built by Koppers Co., Inc.

General view of the structural steel preparation aisle at Mount Dennis plant. Material is cut, drilled and cleaned in one continuous operation and is then ready for assembly and subsequent painting.

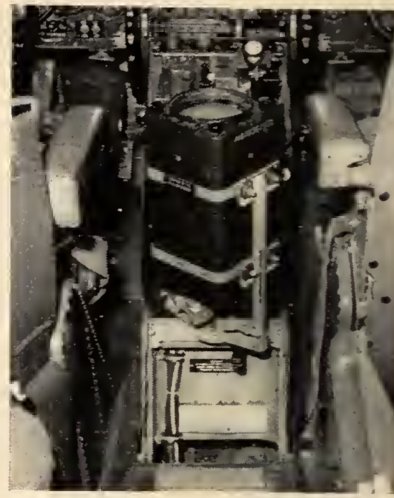
IRON CASTINGS

Production of iron castings, pipes and fittings during 1958 amounted to 691,268 tons or 7 per cent less than the 743,716 tons produced in the previous year. Shipments during the same period at 568,322 tons, however, were only 3 per cent less than 1957 shipments in the same period. Cast iron pipes and fittings alone showed a 2.3 per cent increase, so that the drop in volume was entirely in the area of general castings and castings for use in producers' own plants. The industry covers operations of iron and steel works chiefly occupied in making commercial iron castings or iron and steel pipe and tubing. Some machinery, boilers, engines, stoves and furnaces, etc., were made as secondary or minor products. Some iron foundries have not been included in the Iron Castings Industry, but are classified to other special groups such as manufacturers of agricultural implements, stoves, etc.

SMELTING AND REFINING

The gross value of the output from the Canadian Smelting and Refining Industry in 1958 amounted to some $1.18 billion, down 8 per cent from production the previous year valued at $1.28 billion. This was due largely to the lower production of base metals from Canadian mines.

The industry includes only firms engaged primarly in the smelting of non-ferrous ores or concentrates and in the refining of metals recovered therefrom. The smelting of imported ores is included. Secondary smelters, which treat scrap metals, are not included. The list of metals covered includes copper, nickel, lead, zinc, aluminum, magnesium, titanium, molybdenum, tungsten, cobalt, antimony, bismuth, cadmium, selenium, tellurium and precious metals.



The weather radar scope in Trans-Canada Air Lines' Super Constellation aircraft.

BRASS AND COPPER PRODUCTS

Shipments by the Brass and Copper Products Industry during 1958 were valued at some $163 million, about 12 per cent less than the value of shipments the previous year of $179.2 million, and 33 per cent lower than the shipments in 1956 valued at $244.1 million.

In 1956, according to the latest full report available 108 foundries and 46 fabricating plants reported under this industry. Total employment stood at 9,220; 5,368 persons in Ontario, 2,952 in Quebec; 560 in Alberta and New Brunswick; 191 in British Columbia and 149 in Manitoba. Wages and salaries paid totalled $34.73 million, fuel and power cost $2.4 million, materials used cost $173.6 million, value added by manufacture totalled $69.5 million, and gross selling value of products amounted to $244.1 million. Ontario plants accounted for 55 per cent of the output and Quebec plants for 40 per cent.

ALUMINUM PRODUCTS

The year 1957-58 witnessed a change for the aluminum industry, with strong demand and rapid expansion of capacity being succeeded by over-supply and keen competition. Aluminum Co. of Canada's 620,000 ton annual capacity in the Saguenay and Kitimat areas, which operated at full capacity in 1956, was cut back to some 590,000 ton rate of output in two stages during 1957-58. Production rate was again cut back at the end of 1958 for a third time, to 500,000 tons yearly.

Apart from some 90,000 tons of ingot used in the Canadian aluminum products industry, production of ingots from both companies, Alcan and CBA, is exported. Alcan's Canadian market for products is improving, and consideration is being given to enlarging its rolling capacity at Kingston. CBA is participating jointly with Phillips Electrical Co. at Brockville in building a cable mill, while Alcoa may also enter the Canadian fabricating industry. Best gains are expected in sales of aluminum sheet.

Installation on B-47 Aircraft for Iroquois engine flight-test. Designed and built by Canadair Limited.

THE MACHINERY INDUSTRY

Based on preliminary reports for the first 10 months of 1958, value of shipments by the industrial machinery industry fell about 25 per cent below the value of shipments in 1957, and was 42 per cent lower than the value of $471.2 million shipped in 1956.

In 1956, latest year for which a full report is published, there were 414 establishments employing 37,520 persons, 23,000 of whom were employed in Ontario and 11,000 in Quebec, and who earned $142.1 million. Fuel and power cost $4.33 million and materials used cost $213.15 million. Valued added by manufacture was $274.4 million and gross selling value totalled $471.2 million. Values of production for some of the principal items manufactured were as follows: conveying and materials handling equipment $50 million; construction machinery and parts, $46 million; compressors and pumps, $31 million; engines and parts, $25 million; pulp and paper industries machinery and parts, $25 million; transmission equipment and bearings, $22.6 million; and all other products $271.6 million.

FARM IMPLEMENTS

This industry covers only firms which produce agricultural implements as their main product. Some other firms in other groups produce implements as a major part of their production, but are excluded from farm implement statistics on employment and value of products. Preliminary reports of shipments during 1958 indicate an increase of some 35 per cent over the previous year, to a value of some $150 millions.

Sales of farm implements and equipment in 1957 to Canadian customers, including imports but excluding exports amounted to $149.3 million, a 12.6 per cent decrease from the previous year. This value is at wholesale prices, and an estimated mark-up of 20 per cent should give a reasonable figure for dollars spent by farmers, according to the industry. In 1957, tractors, haying and harvesting machinery were the major lines responsible for the over-all decline in sales.

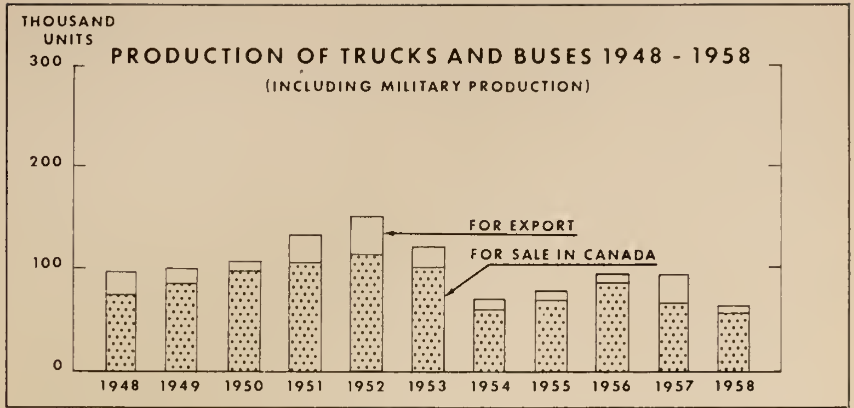
MOTOR VEHICLES

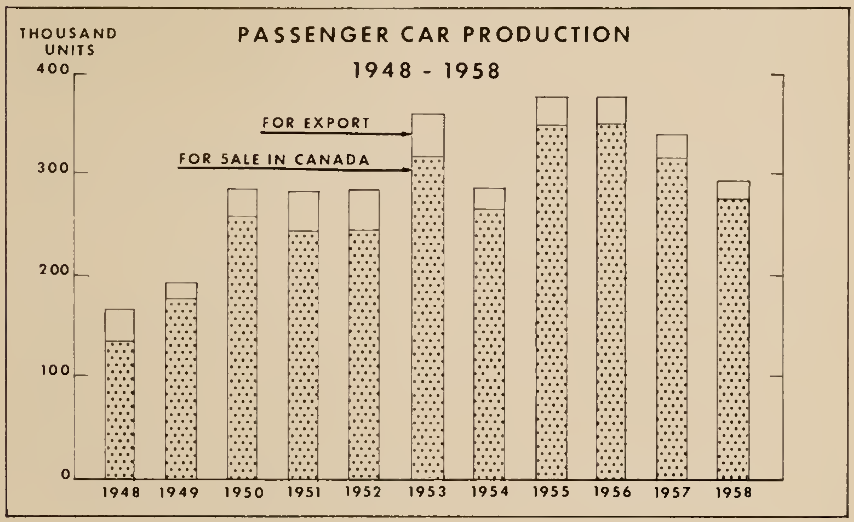
Canadian production of motor vehicles in 1958 at 355,465 units was 12½ per cent below the 411,492 vehicles produced in 1957. Passenger car production at 297,025 was 12 per cent lower and commercial vehicle production at 58,370 was 18½ per cent lower than in the previous year.

Factory shipments of made-in-Canada passenger cars at 298,344 units and Canadian-made commercial vehicles at 61,281 units were 12 per cent and 15 per cent respectively below shipments in 1957. Slightly more than half the commercial vehicle shipments were those maximum gross vehicle weight of 6,000 lbs. and less. During the last quarter, however, sales exceeded production by some 15,000 units.

Standing of Manufacturers

General Motors of Canada was the leading producer in 1958 with 158,712 vehicles, followed by Ford of Canada with 89,267, Chrysler of Canada with 44,131 and Studebaker of Canada at 4,514. Sales of British and European cars in 1958 at 69,439 passenger cars and 6,116 commercial vehicles accounted for 18.7 per cent of the total volume of Canadian sales. This compared with 11.9 per cent in 1957 and 8.4 per cent in 1956.





RAILWAY ROLLING STOCK

Sales of railroad equipment in 1958 to Canadian railways by the 30 firms which produce it were valued

at some $342 million or 11% below the value of shipments made in 1957, the best year the industry ever had, and 1 per cent below the value of shipments in 1956.

In 1957, the most recent year fully reported, 30 establishments employed 27,909 persons, 12,649 of whom worked in Quebec, 5,959 in Ontario, 4,822 in Manitoba, 2,635 in the Maritime Provinces and 1,844 in Alberta and British Columbia. Total earnings amounted to $104.16 million; fuel and power cost $4.42 million; cost of materials used was $241.83 million; valued added by manufacture was $140.47 million and gross selling value of products was $386.72 million.

The number of various types of equipment produced were as follows: passenger cars, 25; box cars, 5,169; gondolas, 1,050; flats, tank cars and refrigerator cars, 497; all other types of freight cars, 3,734; all valued at a total of $99 million; standard gauge diesel-electric locomotives, 521, valued at $94.4 million; forgings, castings, brakes and shoes, and repair work, $155 million; all other products including value of uncompleted cars after deducting during 1957, $42.1 million. Imports during the year were valued at $29.8 million, while exports were valued at $12.8 million. Most of the equipment was a carry-over of orders placed in 1956.

SHIPBUILDING

The year 1958 was a disappointing one for the shipbuilding industry. The report of the Royal Commission on Coasting Trade, made public in May, recommended that marine industries in Canada should be dispensed with rather than helped. In addition, there was a scarcity of orders placed for commercial vessels. Production activity was centred on the fitting-out and completion of the remaining destroyer-escorts in the 14-ship RCN program commenced eight years ago. The last four are due for completion in 1959; one each in February and June and the final two in November. Four service ships were built for the Federal Government and some fifteen commercial vessels, as shown in Table I.

The level of employment in the shipyards is steadily falling and further declines are expected. The 15,000 production workers employed at the peak of the naval program in 1951-52 had dropped to some 10,000 by year-end. However, orders were placed early in 1958 for six new vessels at a cost of $10 million and for conversion of two wartime tank-landing craft for carrying cargo to DEW line sites in the Arctic. In November, Defence Production Minister Raymond O'Hurley announced allocation of six new destroyer-escorts for the RCN, for completion in 1962-63

AIRCRAFT AND PARTS INDUSTRY

The year 1958 saw a falling off in aircraft production from the value of production of $424.44 million reported for 1957, the record peacetime high in value of production. Though figures are not available for the year, industry leaders have estimated a drop of some 5 per cent below 1957.

The industry's third largest manufacturing group in terms of employment and ninth in terms of sales, is subject to many rapidly-changing factors which make predictions for the future difficult. Its prospects will depend on implementation of a production-sharing agreement for defence equipment with the United States.

Achievements in 1958

As a year of achievement by the Aircraft industry, 1958 had some outstanding highlights; the first flight of the *Arrow* on March 25;** completion of Belgium's order for 50 Mark CF-100: full production by Canadair of the CL-28 *Argus* Maritime Reconnaissance aircraft continued, with about half the order completed; commencement of production for the CL-44 military transport, with expected follow-on with CL-44C Canadair Liner; completion of *Sabre* production at Canadair in October, with a total of 1,815 produced; and a production line started for the CL-66, turbo-prop version of the former piston-engined Convair 440 liner, with its derivative the Canadair 540 which will follow.

The end of July saw the first flight of DeHavilland's *Caribou*, while production continued on *Beavers* and *Otters;* and CS2F-1 Trackers were still being assembled for the Royal Canadian Navy. Canadian Pratt and Whitney continued production of engines and overhaul of Sikorski helicopters; Rolls Royce of Canada extended facilities for overhaul of "Dart" turbo-props, while turboject-powered DC-8's and Vickers Vanguards will be going into service with TCA. Bristol Aero-Engines (Western) Ltd., opened new facilities for overhaul and repair of CPA's "Bristol Proteus" turbo-props.

Though the missile field did not enjoy an encouraging year, the *Sidewinder* is being carried as armament on RCAF Navy *Banshee* jets purchased from the United States. Late in the year it was announced an order had been placed for *Marten Lacrosse* short range ground-to-ground missiles for the Canadian Army.

**Production of The CF105 "Arrow" was discontinued in February 1959.

ELECTRICAL MANUFACTURING

Preliminary estimates indicate the 1958 output of Canada's electrical manufacturing industry will have a value of some $1.13 million, 7½ per cent below the production during the previous year valued at $1,222 million. The heavy capital goods section or apparatus division of the industry had a sharply reduced volume of new orders from the nation's utilities and industries. Spending emphasis in the appliance field showed an increasing trend towards soft goods and services, and away from such durables as electrical appliances.

In the electronics section, sales of consumer products such as radios and TV sets held up well, during the first half year, though decreased demand in the second half resulted in a drop of some 10 per cent below that of the full year of 1957.

In the engineering products sector of electronics, defence orders continued to fall off for the second year. Commercial requirements of engineering products during the first half of 1958 almost equalled demands for defence. But at the year-end the engineering section found itself in a state of "suspended animation". This was largely due to government decision to abandon the Astra five control system for the CF 105 Arrow, and to a delay in orders for commercial requirements for communications system, until needs for circuits for purely defence purposes are determined.

Demand for Apparatus

At the end of 1958, Canadians had available to them a total of 26,154,-000 horsepower of electrical generating capacity, an increase of 2,736,-000 horsepower or 8 per cent over 1957's year-end figures. This augurs well for the long-term future, for it indicates the confidence of the utility industry in having available generating capacity to meet the anticipated demand for more and more electrical power.

It is recognized that utilities and heavy industries—the consumers for apparatus—cannot expand on a balanced incremental basis year by year. It appears that the apparatus segment of the electrical manufacturing industry can look for no rapid upswing in demand for its products over the next 12 months. The trend points toward a five-year apparatus segment unless distracted by international emergencies.

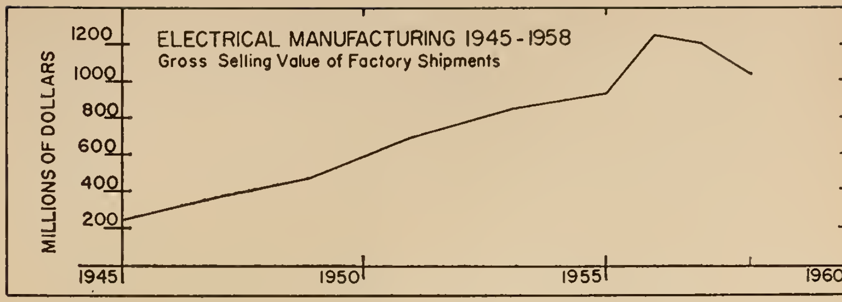
While high Canadian wage rates militate against the industry in many of its product lines, leaders in the Industry believe that certain types of Canadian-built electrical apparatus could compete successfully in the export market. Export sales in these products have been lost over past years, however, due to lack of a Canadian equivalent of the extended credit terms offered by government-supported agencies in the United States, Britain and West Germany.

Representations were made last year by the industry to the Federal government, asking for the establishment of export-import banking facilities to make available to Canadian exporters credit terms and conditions equivalent to those in the countries against whom the industry is competing.

The Appliance Market

Industry sales of major appliances during 1958, showed more pronounced strength in the second half of the year than in the first. While refrigerator and television set sales were down 5 and 10 per cent respectively, the increases in industry sales of ranges, wringer washers and automatic laundry equipment (up 9, 8 and 15 per cent respectively) more than offset these declines and produced a total increase for this group of consumer goods of some 2 per cent. This picture was in sharp contrast to the major appliance market in the United States where 1957 was a poor year and 1958 a worse one.

Much of the strength in appliance sales and consumer goods in general can be traced directly to Government monetary policy and its effect upon the housing program.



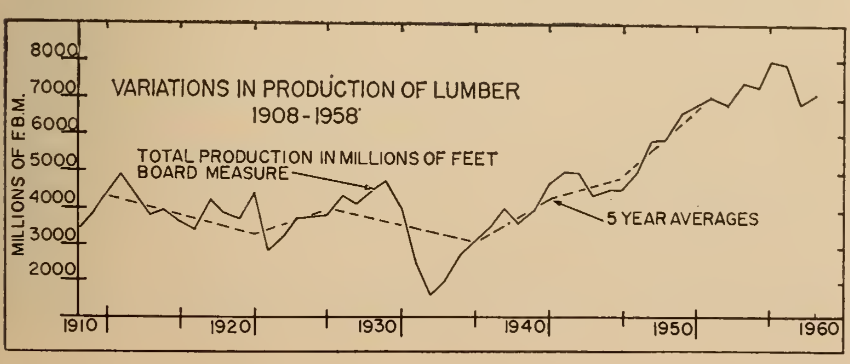
Lighting

Electric lighting in all of its many uses in modern electrical living showed continued progress during the year, and promised significant advances in the future. While the year's progress in light source developments were reviewed at The National Technical Conference of the Illuminating Society in Toronto, the most important report was the presentation of the findings of researches through the ten years on the quantity of illumination needed for every day seeing tasks in commerce, industry, and the home.

On the sound scientific basis of these studies, technical committees of the Illuminating Engineering Society are preparing new recommended footcandle values, substantially higher than those formerly used. In some cases the new values are two to three times the old. The putting into practice of these higher recommended footcandle values will greatly increase the amount of electricity used for lighting.

There is better lighting in Canada's new office buildings, factories and shopping centres. Fluorescent lighting continues to forge ahead. A recent development which has contributed to this is the introduction of the Power Groove fluorescent lamp, with a wattage rating as high as 200 watts.

Developments have been introduced which contribute to greater safety on our streets and highways. The four-lamp headlight system used on new cars has greatly improved night driving visibility. On streets, there has been a distinct trend to fluorescent lighting; the result is better lighted streets with far less glare.



Electronics

Canada's electronic equipment industry is continuing to show every sign of growing into a full-fledged giant. A large part of electronic equipment business is devoted to defence, but the commercial electronics business has also gone through rapid expansion.

In the commercial electronics field, controls for automation of factories and industrial processes will take a major share of future electronics expenditures. Companies within the industry have continued to carry out investigations of the Canadian market potential for computers and industrial television, with a view to full-scale entry as soon as economic circumstances are favourable. Some of the brightest prospects for the industry lie in these areas, along with general communications and industrial control systems.

The recent changes which have taken place in government control of the broadcasting industry should serve to increase demand for broadcasting equipment which decreased in 1958 as a result of the slowing down of the issuing of licenses. While industry volume of mobile radio was reduced in 1958 due mainly to reduced investment in capital equipment, the new Department of Transport regulations permitting increased use of two-day mobile radio by business vehicles should continue to have a stimulating effect over the next few years.

Nuclear Power

Developments in the field of electric power generation from nuclear sources continued to attract world-wide attention in 1958. The year saw a trend toward concentration on fewer reactor types. Britain continued work on several large nuclear power stations using graphite moderator and natural uranium fuel. The U.S. will concentrate on the three reactor types. Canada's efforts continue with the heavy-water moderated type of reactor which she has pioneered. These moves to concentrate effort and experience should hasten the advent of economic nuclear power.

The heavy-water moderated reactor still appears to be by far the most suitable type for economic application in large central stations in Canada. The major advantage of this type of reactor is its low fuelling cost, combined with freedom from the need for chemical reprocessing of spent fuel to recover unused uranium 235 and plutonium. The fact that large supplies of natural uranium are available in Canada and other countries is also of great importance. Enriched fuel on the other hand is, in the main, obtainable only from the U.S. with attendant political and price controls.

There are several important areas in Canada (e.g. southern Ontario) in which nuclear power should become competitive within the next 5 or 7 years. There are few undeveloped waterpower sites available within economic distance of the large load centres.

The year saw formation by Atomic Energy of Canada Ltd. of a new division known as the Nuclear Power Plant Division, to help advance development of nuclear power to a stage at which the utilities and industry can continue development on a normal commercial basis.

Progress on Canada's Nuclear Power Demonstration Reactor (NPD) has been excellent. Construction activities were resumed last summer, and with rock excavation completed, the building substructure is now being poured. This 20,000 kw prototype plant will be commissioned early in 1961. There is no doubt that experience with NPD will prove incalculable for Canada's power reactor program as well as contributing generally to reactor technology.

CEMENT AND CONCRETE PRODUCTS

Canadian manufacturers of Portland cement during 1958 produced 6,316,569 tons or 1½ per cent more than the 6,248,718 tons produced in 1957. Shipments during 1958 at 6,157,817 tons were also 1½ per cent higher than those in 1957.

Concrete Products

During 1958, concrete products shipped (with comparative quantities shipped in 1957 for each item following in brackets) were as follows: concrete brick, 136.6 million (94.1 million); cinder concrete blocks 13.4 million (9.75 million); haydite and slag concrete blocks, 19.8 million (17 million); concrete chimney blocks, 724,900 (834,669); cement drain pipe, sewer pipe, water pipe and culvert tile, 669,676 tons, (453,225 tons); ready mix concrete, 6,520,134 cubic yards, (4,966,161 c.y.).

GLASS AND PRODUCTS

Factory shipments of glass for 1958 are not recorded separately by months. For this reason no records for 1958 are available. Though it is doubtful that glass shipments in 1958 greatly exceeded the $90.8 million value recorded for 1957, the flat glass section of the industry experienced its best year to date, mainly due to record housing construction.

In 1957 factory shipments at $90.82 million were 4.3 per cent higher than in the previous year. Imports were valued $47.9 million compared with $50.4 million in 1956. Exports totalled $1.15 million compared with $1.5 million in 1956.

CLAY AND PRODUCTS

The clay products industry is divided into two sections for statistical purposes. Production from domestic clays, including building brick, structural drain and roofing tile, stoneware, sewerpipe, pottery and refactories, in 1957 came from 119 plants which employed an average of 5,700 persons, whose earnings amounted to some $13.8 million. Process supplies cost some $1.03 million and gross selling value amounted to $34.9 million. Ontario plants accounted for 27 per cent of the total employment. All provinces except Prince Edward Island produce clay products.

Production from imported clays includes electrical porcelains, sanitary ware, sewer pipe, tableware, artware, floor and wall tile, and fire clay blocks and shapes. Production in 1956, last year for which full data are available, came from 37 establishments employing 2,131 persons; 1,200 in Ontario, 744 in Quebec, 162 in Alberta and British Columbia. Net value of production was $14.2 million and gross selling value of products amounted to $20.95 million.

THE LUMBER INDUSTRY

Production of lumber in Canada during 1958 at some 7.017 billion board feet showed an increase of about 1.4 per cent compared with the 6.76 billion feet produced in 1957. Production in British Columbia showed an increase of some 550 million feet, while in the rest of Canada production dropped by some 300 million feet.

During the first ten months exports, which represents about half of production, were about 6 per cent higher than for the same period in 1957. About 80 per cent of these exports were to the United States, compared with the 40 per cent that went to the U.S. ten years ago. Only 12 per cent of exports went to the United Kingdom and 6 per cent to other Commonwealth countries, however, compared with 40 per cent and 12 per cent respectively ten years ago. This would indicate that the industry is not doing enough to encourage exports to other countries.

In the domestic market the use of lumber was greatly influenced by increased government spending and by the sharp increase in housing construction.

The mills range in size from the giant mills on the Pacific Coast, cutting up to half a million board feet per shift, to the small mills which only turn out a carload of lumber in ten days. The larger mills are concentrated around Vancouver, New Westminster, and the lower mainland of British Columbia as well as on Vancouver Island, along the Ottawa Valley, Georgian Bay, Rainy River, and the Coast of New Brunswick.

MINERAL RESOURCES:

THE YEAR 1958 was another encouraging one for Canada's mining industry as a whole, in spite of the troubles facing many of its segments. The total value of production for all minerals, including petroleum, at $2.12 million was 3 per cent below that of the previous year's value of $2.19 billion. Improvements during the last half-year made the outlook brighter than had seemed possible at mid-year for many of the leading minerals.

Iron Ore

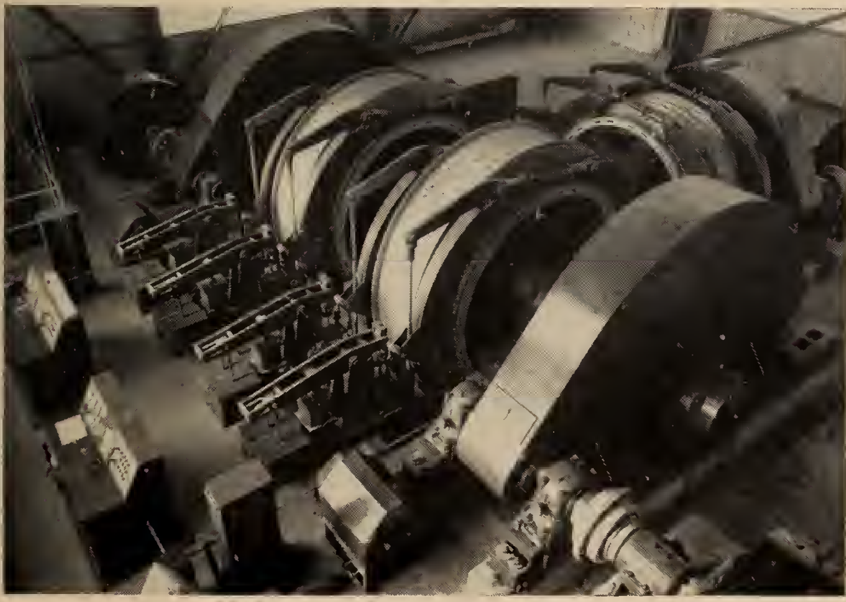
Canada's production of iron ore amounted to some 16 million tons, compared with slightly over 20 million tons in 1957 and 22 million for 1956. Since productive capacity far exceeds the 6 million tons of Canada's ore consumption, the bulk of output must be exported, and in 1956 more than 80 per cent of exports went to the United States. Last year U.S. imports of Canadian ore dropped to around 8 million tons, reflecting the sharp drop in U.S. steel production resulting from the recession.

Newcomers in 1958 were Hilton mines in the Ottawa Valley and Canadian Charlson near Steep Rock, both of which will ship concentrates. Hilton has a capacity of 600,000 tons of pellets yearly while Charlson's capacity is 25,000 tons yearly from Haematite bearing gravels.

Elsewhere, Iron Ore of Canada will show a production of some 8 million tons for 1958; Steeprock, though output was sharply reduced, is gearing ing for a steady annual production of 5½ million tons. Algoma Ore Properties set a new record in 1958 and expects to turn out 2 million tons of highgrade sinter in 1959 from its enlarged plant; Caland Ore near Steeprock will not be in production before 1960. Cyrus Eaton's Ungava Iron Ores reached a decision at year-end to spend some $200 million to develop its property for production of 5 million tons of pellets yearly, mainly for European markets.

The decision of United States Steel to develop its Quebec Cartier project in Ungava marked another important milestone in Canada's ore picture. Work is underway for building a 193 mile railroad, a power plant and a concentrator to produce 8 million tons of high grade pellets annually, at a cost of $300 million. Lowphos Ore Ltd., near Capreol, whose 600,000 ton concentrator is ready to produce, deferred commencement of production early last year because of the slack ore demand.

The friction hoist room at Steep Rock Iron Mines Limited, Ontario.



Uranium

Canada moved up to second place, ahead of South Africa, in world uranium production during 1958, more than doubling the 1957 output of 12.9 million pounds to reach a record total of 28 million pounds of uranium oxide in 1958. This increase in productivity will continue through 1959 and reach its peak in 1960, which will be the first full year of continued capacity operations for all plants now operating or planned.

Canada's strong position in uranium potential is due to reserves presently estimated at some 375 million tons of ore, 95 per cent of which is in Ontario and the balance divided between Saskatchewan and the Northwest Territories. All of the planned 19 milling plants, with combined capacity of 43,000 tons daily, were operating prior to mid-1958, but some have yet to reach capacity production.

New Production

In the Beaverlodge field alterations to the Lorado custom plant delayed attainment of full capacity and efficiency until early 1959. In the Bancroft area of Ontario, Canadian Dyno Mines went into operation in May, and expect production at rated capacity of 1,000 tons daily by the end of 1958.

In the Elliott Lake area Milliken Lake Uranium Mines built its milling rate up to capacity of 1,000 tons daily by year end. Stanleigh Uranium Mining Corporation commenced production early in 1958 and attained a rate of more than 2,000 tons daily in the fall, with expectation of 2,600 tons a day by mid-1959. Stanrock Uranium which went into production early last year was up to a rate of 3,000 tons daily by year-end. Northspan has all its milling plants in operation and has been producing precipitates at contract rates for the last half of 1958, still obtaining some of its ore from Algom. Canmet attained capacity operation in October.

Nickel

Canada's production of nickel in

1958 totalled 278 million pounds, down 26% from the 376 million pounds produced in 1957 which was nearly three quarters of the Free World trade. The oversupply situation observed in 1957, was aggravated last year by a recession in industry, a sharp decline in defence requirements, particularly in jet engines, and a drastic curtailment of steel production.

Canada still accounts for about two-thirds of the Free World's output and expansion plans underway will ensure that this ratio will not be materially changed. Capacity in Canada in 1959 will total 392.5 million pounds, out of a Free World total of 549 million pounds. Of this, Inco's Sudbury plant's capacity is 310 millions, Falconbridge 55 million and Sherritt Gordon 27½ million pounds.

During 1958 Canadian production totalled 376.26 million pounds, due to Inco going on a 4-day week last summer and later to a strike at its Sudbury plants starting September 24 which lasted almost three months.

With defence applications for nickel decreasing, producers are co-operating with industry to encourage greater consumption, and to use nickel in as many new products as possible. The most promising prospects are in the fields of stainless steel, supersonic aircraft, turbines, machine tools, atomic energy and space vehicles.

Copper

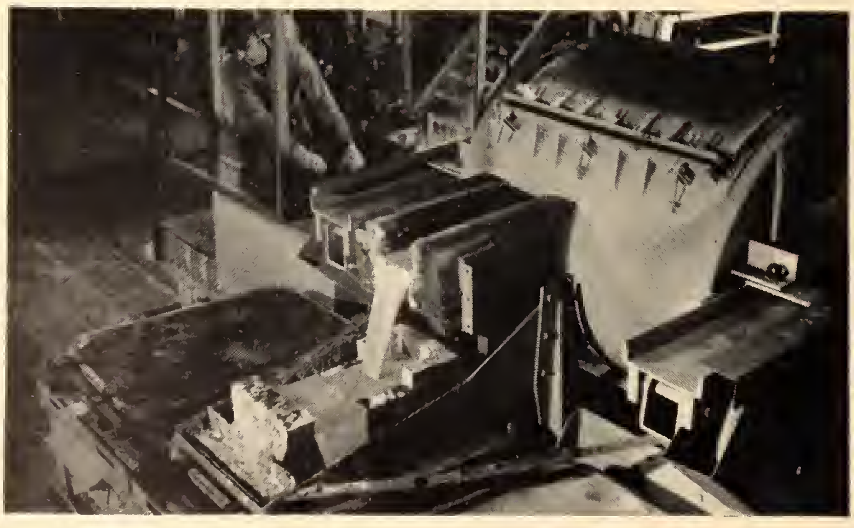
Canada in 1957 was the Free World's fourth largest producer of copper after the United States, Chile and Rhodesia. Record production of 353,293 tons was recorded in 1956. In 1957, production dropped slightly to 346,000 tons.

The free-world copper market held considerable encouragement at year-end. World production was down considerably last year, Northern Rhodesia mines with a combined output of 1,000 tons daily were strikebound for seven weeks. These, coupled with the Inco strike, took near 100,000 tons off the market. Copper prices have recovered from a low of 24 cents per pound in June to 29 cents at year end. Stocks of the metal have been reduced by a healthy margin. Consumption increased rapidly during the last four months of 1958 in the United States.

Geco Mines and Gaspé Copper mines were primarily responsible for the higher Canadian output last year. Geco attained production late in 1957, and average over 3,500 tons of ore daily. Gaspé Copper, which lost production of some 10,000 tons during 1957 due to a strike, produced steadily in 1958.

One new producer, Merrill Island Mining Corporation, started up its mill early in 1958 in the Chibougamau area. Copper-Rand Chibougamau Mines will go ahead with mill construction and will probably take ore also from Bouzan and Chibougamau-Jaculet. Hudson Bay Mining and Smelting closed early in 1958, but it is expected to re-open early in 1959. Other closures included Quebec Copper and Rainville Mines, whose grades were too low at 1958 price levels, and Goldstream for the same reason. Heath-Steele Mines in New Brunswick, Nickle Rim Mines and Min-Ore Mines also closed down.

New Inco Refining Process. Casting nickel sulphide anodes, one of the steps in International Nickel's new nickel refining process that marks a step forward in the Company's program to obtain maximum recovery from the ore it mines. The process is in commercial operation in a section of Inco's nickel refinery at Port Colborne, Ont.



In the Mattagami area of Quebec exploration has uncovered several new prospects, including the Watson Lake property of Mattagami Syndicate, sponsored by Noranda, McIntyre and Canadian Exploration. Craigmont mines and Bethleham Copper Corp. in British Columbia are investigating large low-grade deposits.

Lead

The outlook for lead is obscured by worldwide oversupply, lower demand and by U.S. import quotas based on 80% of average exports to the U.S. for years 1953/57 inclusive. On the other hand delayed cutbacks now being imposed are beginning to take effect. World mine and smelter production, which increased some 5 per cent in 1957, will show a reduction of 10/12 per cent for 1958. An attempt has been underway at a meeting in Geneva, attended by representatives of lead and zinc producing and consuming countries, to stabilize markets for these metals . . . Nineteen major producers from as many countries are financing research to expand present uses and develop new applications.

Canadian production for the first half of 1958 was only slightly off from 1957, but showed a substantial drop during the second half. Output for the full year amounted to 185,000 tons valued at $42.1 million or some 20 per cent below 1957.

Canadian exports of lead in ore and concentrates during the first half of 1958 were at about the same rate as in 1957, though refined exports were off some 7 per cent. However, the U.S. quota imposed on October first allows 12,000 tons more to enter the United States than was exported to that country in 1957. The largest reduction in Canada's imports of tetrethyl lead, due to the opening in 1957 of Ethyl Corporation of Canada's plant in Sarnia, helped to increase the balance of exports since that time.

At Consolidated Smelters' Pine Point Mines on the south shore of Great Slave Lake, large deposits of lead-bearing ores have been outlined, as well as in the Pelly and Highland river areas of the Yukon. In the Snow Lake area of Manitoba, Hudson Bay Mining is developing the Chisel Lake mine, where drilling has outlined nearly 4 million tons of ore. Heath-Steele Mines and Brunswick Mining in New Brunswick, and Sunshine Lardeau and Silver Standard in B.C., were closed down during 1958.

Zinc

Free World productions of Zinc in 1958 at 414 million tons was down only some 7% below the total for 1957, yet production still exceeded consumption by more than 20%. There were some cutbacks in Australia and the United States, which reduced their outputs 13% and 23% respectively below the 1957 figures. Canada and Mexico, the other two major producers both produced more than in 1957 during the first eight months, and for the full year their production was about the same as in 1957 or slightly higher. Between them, the four major producing nations mentioned above account for just short of one half of the free world's zinc production.

An intensive research program has been set up under auspices of the American Zinc Institute and process has already resulted in finding new applications for the metal, especially in the zinc alloy field. A new process has been perfected for smelting zinc in a blast furnace by Imperial Smelting Corporation.

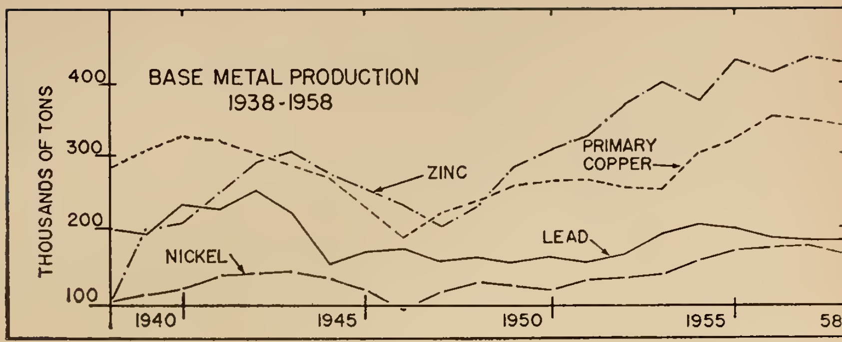
Gold

Free World production of gold in 1958 was close to the output of the previous year, when production was valued at $1.02 billion. South Africa maintained its leadership with an output of 17 million ounces, while Canada's output at 4.53 million ounces was slightly higher than in the previous year. Increase in Canadian gold production in 1958 was due principally to the high grade mines in the Red Lake area. During the year production at Norlartic mines was revived, while Bralorne, Campbell Red Lake, Cochenour-Williams and Barnat improved their outlook by developing new and higher-grade ore bodies. There was little prospecting done, and for the longer term the outlook for gold mining in Canada is clouded by the lack of new mines being developed.

Cobalt

World supplies of cobalt continue to accumulate and demand appears to be falling off. Little improvement can be expected until new uses are discovered, until the demand for high-temperature alloys increases, until U.S. stock become diminished, and business conditions improve. The U.S. is still stockpiling and lower-priced metals are replacing cobalt in certain standard uses, such as for permanent magnet alloys.

International Nickel, Falconbridge and Sherritt-Gordon are the big producers in Canada, with production in 1957 of 2.4 million lbs., 777,000 lbs., and 172,000 lbs. respectively. Total 1958 production was 2.52 million pounds. The Inco strike and decreasing U.S. demand considerably reduced the Canadian exports below the 1957 record.



Platinum

Though the demand for platinum up to two years ago greatly exceeded the supply, the position was reversed in 1957. The United States offers the main market, the oil industry being the largest consumer of platinoids, used as a catalyst for making high-octane gasoline. With the reduced oil production on the American continent the past two years the industry has cut back its purchases of platinum.

Most of Canada's production at 144,565 ounces comes from nickel producers, and with the long strike last fall at Inco production fell considerably below that of 1957. Canadian exports have fallen still further during the past two years.

Silver

World silver markets continued relatively stable in 1958, and prices are unlikely to drop below the current rate of 91 cents an ounce to consumers. Though business is recovering from the recession of the past two years, the effects included a drop in silver consumption for the arts and industry, though a 16 million ounce increase in 1957 for coinage largely compensated for the drop in arts and industry usage.

Canada's 1958 production was 31 million ounces compared with the 30 million ounces produced in 1957.

Consolidated Smelters, leading producer, with a 10.9 million ounce output in 1957, produced somewhat less in 1958. Torbrit Silver Mines in Northern B.C. had a slightly lower output. Hudson Bay Mining remained at about the figure of 1.5 million ounces the previous year. The combined output of Geco and Wilroy, new producers in 1958, just about compensated for the decreased production from "Smelters" and Inco.

Magnesium

Throughout 1958 there was an oversupply of magnesium, although the business upturn during the last quarter brought in new demand, bettering the outlook for 1959. World production may be below the record output. The U.S. produced 81,263 tons in 1957, with Russia in second place at 60,000 tons, while Canada produced 8,097 tons followed by Norway, Italy and France in that order. Canada's 1958 output amounted to 5,800 tons.

Canada uses only 12 per cent of her production, exporting the balance. A stiff tariff shuts off export to the United States. European demand has been steady and has improved in recent months, but the Japanese market has disappeared due to the collapse of the U.S. titanium market in connection with which magnesium was used.

Magnesium metal is finding new uses in many domestic and industrial products and in defence, notably for missiles and jet engines. The supply is unlimited, since in addition to many large deposits it can be extracted from salt water of the oceans. Canadian exports in 1957 were valued at $4.5 million. Last year the amount was substantially lower.

Lithium

With the supply of lithium still ahead of demand by a wide margin and with U.S. chemical processing capacity at double current production, lithium faces a difficult period over the next few years in establishing itself as a civilian commodity. Though most of the production is dependent on government purchase for defence purposes, such as rocketry and satellites, producers are concentrating efforts to build their future on civilian demand. In 1957, 30 million pounds out of the 42.2 million pounds produced went to the Atomic Energy Commission and other government agencies.

Canada's only producer is Quebec Lithium, which produces some 165 tons of lithia concentrate daily. The entire output is exported to the United States and in 1958 it totalled 3.94 million pounds valued at almost $2 million. Brazil, Southern Rhodesia and the Belgian Congo are also producing nations.

Barite

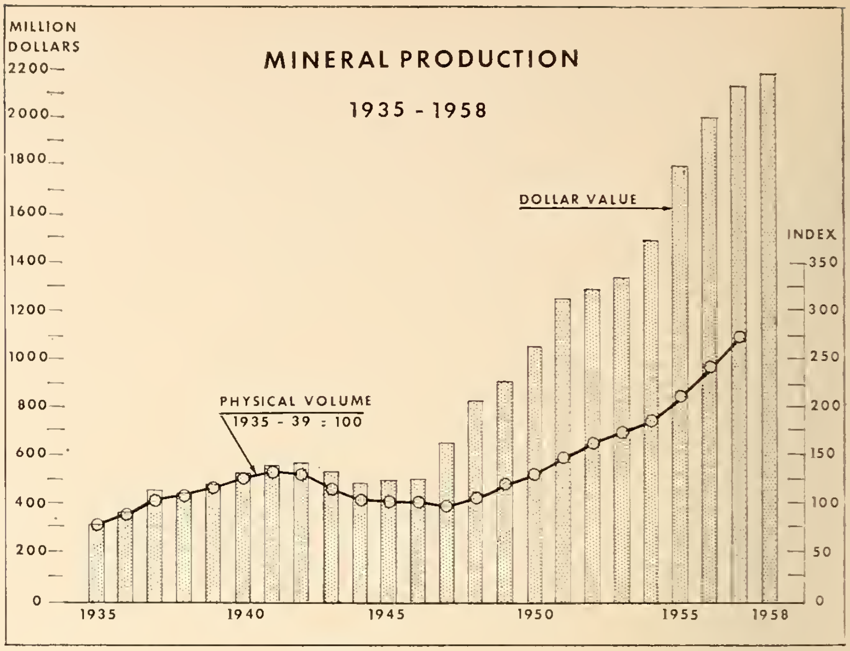
More than three-quarters of barite production is used to make "drilling mud", a weighting agent in drilling oil wells. The drop in exploratory well drilling in the United States and particularly in Canada, and the 20 per cent cutbacks in consumption last year created a problem for barite producers. Prices, however, have remained relatively steady. The United States is Canada's best customer and in 1957 took 77% of Canadian barite production.

Canadian barite production last year dropped to 180,000 tons, compared with 228,000 tons the previous year. Production for 1959 increased to 201,000 tons. There are three producers—Magnet Cove Barium Corp. in Nova Scotia, Mountain Minerals, and Giant Mascot Mines in British Columbia. Magnet Cove is the largest and produces some 90% of Canada's output.

Fluorspar

In spite of a drop in consumption and production in the U.S. the world's largest user of fluorspar, the world outlook improved in the latter half of 1958, except in Canada. No exports were made by Canada last year. U.S. stockpiles, which took all available Canadian exports in 1956 and 1957, were filled more than a year ago.

Canadian production in 1958 was valued at $1.55 million, considerably below that of 1957. Mexico, due to her low cost production, can sell competitively in Canada. About 10,000 tons were imported from that country in 1958, about 75 per cent of Canada's total fluorspar imports. There are three Canadian producers, Newfoundland Fluorspar Ltd., St. Lawrence Corporation of Newfoundland, Huntingdon Fluorspar Mines in Ontario.



Tungsten

Demand for tungsten has fallen sharply reflecting near termination of U.S. government supply contracts and a slower tempo of business. The use of tungsten has shifted gradually from high speed steel to tungsten carbides. Expansion for the latter is continuing. The opening of new fields, such as jet and rocket transportation, electronics and nuclear energy, however, give promise of a growing market for tungsten alloys.

Canadian production in 1958 was 691,000 lbs. of concentrate, compared with nearly 2 million lbs. in 1957. Canadian Exploration Ltd., Canada's sole producer, completed its contract with the general Services Administration of the U.S. last June

Table 1—Preliminary Estimate—Value of Mineral Production by Provinces ($ Millions) in 1958.

and its tungsten mining and milling operations at Salmo, B.C. were suspended. Exports were well below 1957. Imports of tungsten ores, on the other hand, were almost double those of 1957. Atlas Steels Ltd. of Welland, largest Canadian Consumer, uses some 80% of the total ferrotungsten and scheelite used in Canada.

INDUSTRIAL MINERALS AND FUELS

Potash

Culminating 10 years of research and development, first production of potash took place in Canada 15 miles west of Saskatoon, producing 168,000 tons in 1958. Potash Company of America reached the potash horizon at 3,335 ft. in July. The concentrating plant will handle 4,000 tons daily to produce 600,000 tons of muriate of potash per year. Another company, International Minerals and Chemicals Corp. (Canada) Ltd., has nearly half completed its shaft at a cost to date of $7 million, and will start production this spring at 400,000 annually.

Sulphur

Within two years Canada will become the world's second largest producer of sulphur and its products. Two new plants, Jefferson Lake Petrochemicals of Canada Ltd. in the Fort St. John area and B.A. Oil Co. at its recycling plant at Pincher Creek, Alberta, were in production during most of 1958. Two more plants for recovery of sulphur from sour natural gas will be in operation this year. Total output for 1958 amounted to 99,645 tons.

Lime

Demand for lime was at an all time high in 1958 as a result of requirements by the construction industry and uranium production. With three new plants completed or under construction, production at 1.6 million tons exceeded that of 1957 by 20 per cent.

Coal

Coal production at 11.4 million tons in 1958 was 12 per cent below that of 1957. This was largely due to reduced industrial production, the railway dieselocation; inroads of natural gas and to the shut-down at Sydney by Dominion Steel and Coal Co. last summer to reduce its stockpile. New Brunswick stockpiles had risen threefold to 100,000 tons.

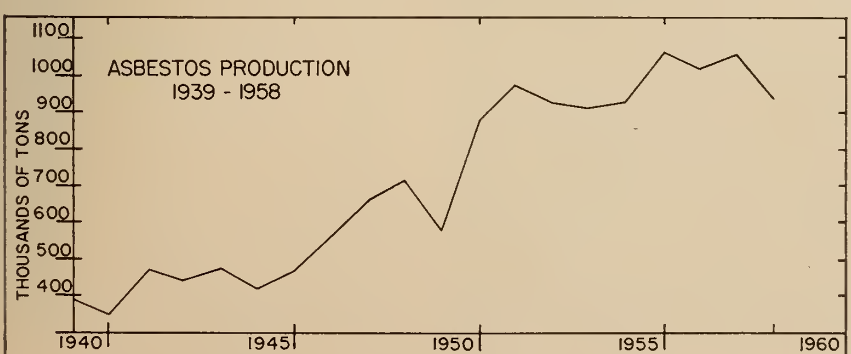
Asbestos

The Asbestos Mining industry in Canada is steadily moving forward to greater productive capacity, in the firm belief that there will be steady growth in world asbestos consumption over the next quarter century. In 1957 Canada produced just over half the world total of 2 million tons. Europe was the second largest producer by continents, at 575,000 tons including a probable 500,000 tons by Russia, followed by Africa, Asia, Australia and New Zealand, and South America in that order.

Productive capacity was up by some 15 per cent in Canada last year due to three new producers, Lake Asbestos of Quebec, National Asbestos Mines and Carey Canadian Mines, all in the Eastern Townships, and another 15 per cent increase in capacity is expected by 1960.

The recession last year caused a market decline in both Canadian production and exports. Output for the year totalled 942,000 tons compared with 1,061,419 tons in 1957. Exports, which account for some 90 per cent of production, declined more than 30% below the 1957 level.

While search for new deposits continues unabated, particularly in British Columbia and the Yukon, only potential new producer at present is Advocate Mines in Newfoundland. The Company has an agreement that may result in a 3,000 ton per day production by 1962.



Gypsum

Gypsum produced in Canada in 1957 totalled 4 million tons vs. 4.86 million tons in 1956. A year long strike at Canadian Gypsum Co. was settled in October.

Salt

Production of salt in 1958 amounted to 1.86 million tons, slightly higher than that of 1957.

PETROLEUM

Canada's crude oil production in 1958 dropped below that of the previous year for the first time, recording a total of 165 million barrels, a 10 per cent drop below the 182 million barrels produced in 1959. Gross value at $403.4 million was 9 per cent less than in 1957. Alberta, the province with the largest output of some 113 million barrels compared with 137.4 million barrels the previous year, showed the sharpest loss of 20 per cent. Saskatchewan, with an output of 45 million barrels, showed a gain of 21 per cent over the 1957 production of 36.86 million barrels. Manitoba production at 6 million barrels showed little change from the previous year, while production from British Columbia and the N.W. Territories at 1.5 million barrels also showed little change.

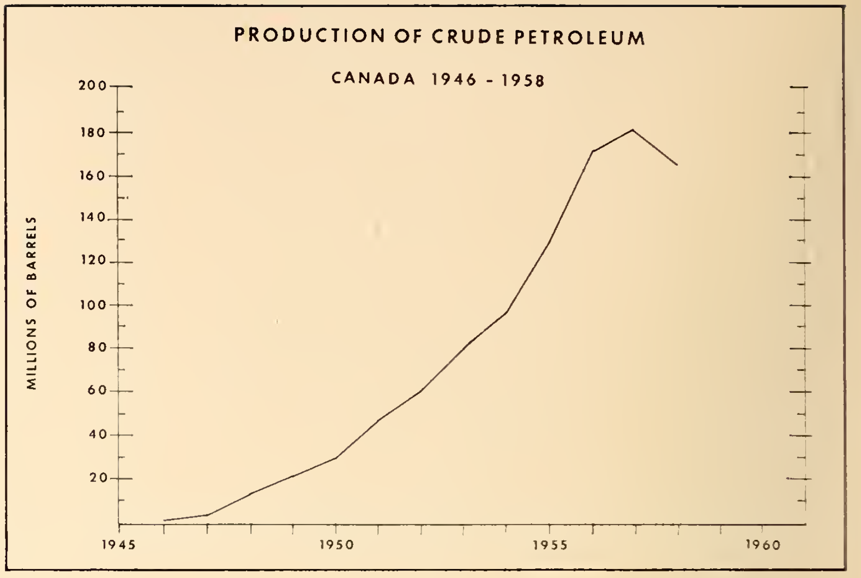
Domestic Market Steady — Export Down

Though the domestic market remained strong on all fronts, the overall decline was due to the drop in exports, mostly those to the west coast. Transmountain throughput for the year showed a total of only 12.6 million barrels against 40.4 million in 1957. Exports from Saskatchewan and Manitoba together added up to 18.6 million barrels against 14.2 million in 1957—a gain of 4.4 per cent.

The net loss of export markets was thus 23.4 million barrels, which left a modest increase of 3.9 million barrels in Canada's domestic consumption of Canadian crude. This was primarily due to diversion of crude runs to Ontario refineries, wherever possible, from the Montreal refineries which operate on imported crude, mostly from Venezuela. It was also due to a changeover to domestic crude by the Sun Oil refinery at Sarnia, which heretofore had been using imported mid-continent oil.

Drilling

Though total completions for the year were down to some 2,400 wells, 16 per cent below the previous year's total of 2,963, they were higher than in any year prior to 1955. The most noticeable difference to previous years was the reversal of trends in Alberta and Saskatchewan. Alberta completions, at 1,550, showed a 10 per cent gain over 1957 while Saskatchewan completions at 800 were 35 per cent below the previous year. Manitoba showed only 85 completions against 224 in 1957, while B.C. and North West Territories at 75 completions showed a drop of 18 per cent. Footage drilled of some 12.5 million feet was only about 9 per cent below the 13.8 million feet put down in 1957.



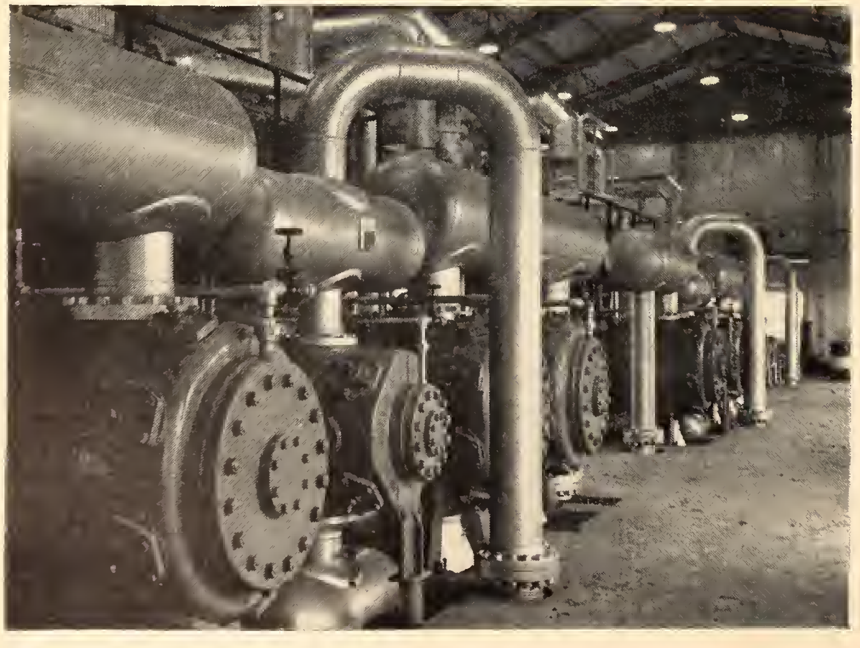
Exploration

Exploration activities were also curtailed. The year 1958 ended up with some 1,100 crew-months for both oil and gas exploration, 20 per cent below the 1,389 crew-month total of the previous year and the smallest aggregate of work since 1949. The trend marks the inevitable decline in the number of new prospective areas to be explored as the western sedimentary basin becomes more nearly saturated with geophysical records. The outstanding problem is now muskeg as wildcat activities move northward. Muskeg research is a dominant element in future exploration methods and policy. Vehical development depends heavily on the research program for leads as to types of equipment suitable for use in muskeg.

Crude Discoveries

Though 1958 was not an outstanding year for finding new oil pools of importance; quite a number of new finds were recorded which assisted in bringing reserves up to an estimated 4 billion barrels. Best discovery during the year was in the Slave Point area in Northern Alberta where six oil accumulations have already been found in an area of 12,000 square miles. The Swan Hills-Whitecourt-Red Earth-Kaybob, Virginia Hills-fields are all in this area. An active search program was being concentrated there during the winter of 1958-59.

Interior view showing huge 2000 h.p. gas compressors at the Steelman gas plant located 2 miles north west of Steelman, Sask.



Less Development Drilling

The steady trend towards wider spacing of wells, with minimum spacing of 80 acres in fields with good porosity and permeability has sharply cut the amount of drilling required to develop a given area. Likewise increased rig and crew efficiencies have reduced drilling time and hence the number of rigs needed.

Refining

Additions to crude refining capacity in 1958 totalled 61,000 b/d, divided between British Columbia, Ontario and Quebec. Cracking capacity additions totalled 27,800 b/d, divided between British Columbia, Quebec and Ontario, in that order. Capacity now includes 834,550 b/d for crude refining in all Canada and 363,715 b/d cracking capacity as shown in Table 1.

Though domestic crude runs to Canadian refineries were sustained due to substitution of domestic crude from Ontario refineries for imported crude from Montreal refineries total refining operations were down some 10 per cent compared with 1957. This was due to the general business and industrial recession which showed only modest improvement as the year came to a close. Total runs of crude in Canadian refineries amounted to some 230 million barrels, compared with 239 million in 1957.

Refineries under contract for completion in 1959 and 1960 total 440,000 b/d capacity for crude, asphalt and aviation gasoline, and 50 million c.f.d. capacity for gas processing. Ad-

ditions are divided by province as follows:
Alberta 33,800 b/d; Saskatchewan 3,000 b/d; Manitoba 6,700 b/d; Ontario 35,000 b/d; Quebec 24,000 b/d; Maritimes 38,000 b/d; and Alberta some 50 million c.f.d. gas processing capacity.

Moderate Improvement seen for 1959

Alberta producers started the new year with nominations at 383,715 b/d, vs. 365,860 b/d in December, featuring a reduction for Transmountain and an increase for Interprovincial. Observers predict the upward production trend in crude production will be resumed in 1959, gaining possibly 5 per cent over the 1958 daily average for an increase of some 25,000 b/d, or a total of some 171/173 million barrels for the year, regaining at least half of the lost volume last year. This assumes no increase in west coast shipments for export, but also assumes U.S. import quotas will have no adverse affects on the current volume going to northern states.

Refining operations, they forcast, will improve moderately to some 250 million barrels. Exploration will settle down at around 1,000 crew-months unless there is a material change in the market outlook. Drilling activity will decline only about 10 per cent below the 1958 level. With any increase in the oil market or further gas export the completion total could recover to 2,500 wells and footage to 13 million feet.

NATURAL GAS

Canada's natural gas industry in 1958 experienced the most exciting year in its short history. Vast developments in all its phases were seen, from exploration and development drilling and completion of gas-processing plants by producers in British Columbia, Alberta and Saskatchewan, to the arrival in late October of Alberta gas in the central provinces, replacing all imports, and extension of gas mains in many eastern municipalities.

Though not looked upon as an improvement for new discoveries, several important new finds were made. The most promising was the huge Berland River field in the foothills of Alberta, 160 miles northwest of Edmonton, with a 600 foot Devonian D3 payzone. The initial open-flow potential of the discovery well was 400 million cubic feet daily, the highest rate ever recorded in Western Canada. Another promising find of gas was at Panther River, 200 miles to the southeast of Berland at a depth of 9,000 feet.

Production up 40 Per Cent

Production of natural gas enjoyed a tremendous increase in 1958, to an estimated 400 billion cubic feet compared with the 1957 total of 286 billion. Principal factor in the big increase was full-year operation of Westcoast Transmission's main line to the British Columbia interior and Vancouver and the export market to Pacific States.

Adding the volumes of gas already contracted for between Trans Canada and its eleven major utility customers between Regina and Montreal, totalling some 263 million cubic feet per day, to Westcoast's current contracts of some 400 million, makes doubling 1958's total production within four or five years appear a distinct possibility, even assuming completion of no further export pipelines within that period. This means looping programs or complete new lines must be nearing completion by that time to double capacity for the next period of expansion.

Big Year for Pipeline Construction

The year 1958 was the third largest in Canadian pipelining history for natural gas. The bulk of it occurred in Eastern Canada, where a total of some 1,100 miles of mainline were laid most of it between Lakehead and Toronto. This was made up of some 1,000 miles of laterals and gathering lines and an estimated minimum of 1,200 miles of local distribution systems or a total of 3,340 miles. A detailed breakdown of pipeline locations and mileages is shown in the sections dealing with Construction. The oil men should be able to hold their industrial customers and sign up new ones, but it is the domestic consumption where the real fight will occur.

Three More Pipeline Systems Projected

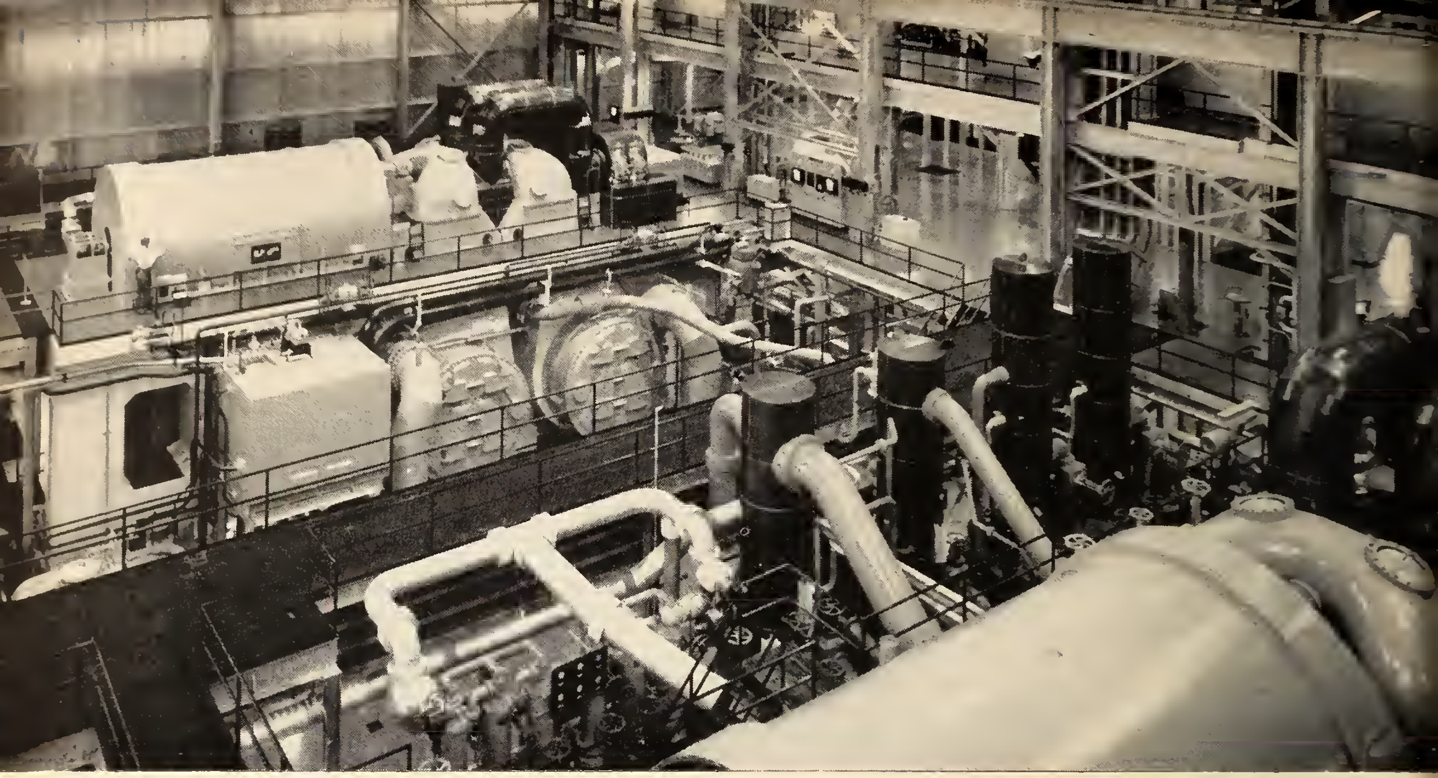
Two new pipeline projects are still awaiting approval to draw on the rapidly growing 'wet gas' reserves of southwestern Alberta for supplying the rich markets of California and the Pacific Northwest. One of these, sponsored by Westcoast Transmission, would provide a second Canadian link from southwest Alberta to feed through the Crows Nest Pass into the Pacific Northwest-El Paso system, already supplied by Westcoast from northern British Columbia fields.

Another alternative project, the Alberta and Southern, proposes a $300 million pipeline linking up a huge gathering system from Peace River to the U.S. Boundary, to be built by the Alberta Trunk Line to serve Pacific Gas and Electric territory in central California. The two large distributors of gas in Alberta, Northwestern Utilities and Canadian Western Natural Gas, are partners in the venture. Its approval could introduce more competition for the vast foothill gas reserves so far uncommitted to Trans Canada, with better wellhead prices and a higher load-factor market for producers.

Major gas discovery of 1958 was made at Berland River, Alberta, 160 miles northwest of Edmonton, where the jointly-held British American Oil well, probably the world's largest gas well, was brought in.

The Alberta Conservation Board in October advised these two pipeline organizations to re-submit their applications in January after reducing by 25 per cent the volumes they proposed to export, implying export permits would then be approved. No permits are yet received from the Board of Transport Commissioners nor from the F.P.C. at Washington.

Another multi-million dollar project is taking shape to market by-products separated from Alberta Natural Gas, to cost between $100 and $150 million. It would carry the products by pipeline in liquid form westward to Vancouver and eastward to the Canadian Lakehead ports or to Superior, Wisconsin.



POWER PRODUCTION AND DISTRIBUTION

AN ALL-TIME record was established in 1958 in the amount of new hydro-electric generating capacity brought into operation in any one year. A **net** total of 2,557,040 h.p. of new capacity was installed, after making allowance for the dismantling of 6,360 h.p. of existing capacity. The previous record was in 1954, when 1,785,450 h.p. of new capacity was completed.

Ontario Led, with Quebec Next

Largest single addition came from the first nine units of Ontario Hydro's Robert H. Saunders — St. Lawrence generating station, — the Canadian half of the International Powerhouse at Cornwall, producing 675,000 horsepower. Quebec's completion of the final three units of the Bersimis 1 development 300 miles northeast of Montreal added 450,000 horsepower.

Ontario provided the largest annual increase in hydro generating capacity for any one province, with 1,301,800 horsepower added during 1958, bringing that province's total installed capacity to 7,126,566 h.p. This, however, was lower than the Quebec total of installed capacity of 9,879,857 horsepower, which included the addition of 900,000 horsepower during the year.

The Department of Northern Affairs and National Resources forecasts addition of another two million horsepower in 1959 and some 2,600,000 in succeeding years. Of this Ontario expects to add 600,000 horsepower in 1959 and 360,000 more in succeeding years. Quebec's plans next year call for another 1,300,000 horsepower and more than 1,400,000 h.p. thereafter.

New thermal electric stations or extensions of present installations were proceeding in nine provinces as well as in the Yukon and Northwest Territories.

A Third of Canada's Power Resources Developed

The total installed capacity of water-power plants in Canada at year-end was listed at 22,470.040 horsepower, which represents 33 percent of total resources. In addition to these hydro-electric developments the building of new thermal-electric plants and extensions increased in 1958 in some provinces, notably British Columbia, Manitoba and New Brunswick, in that order. If this additional thermal capacity of some 662,000 h.p. is added, as well as some 3 million h.p. in service prior to 1958, the grand total of available power, both hydro and thermal is more than 26 million h.p. (Table I)

British Columbia

In British Columbia a total of

Calgary Power Ltd., Wabamun Power Plant. This view overlooks the generator of the first unit installed at the Wabamun steam plant. Beyond is the second 350 ton turbo generator which was commissioned late in 1958, giving the plant a total capacity of 144,000 kw.

189,700 h.p. of new hydro-electric capacity was installed during the year, while a further 35,000 h.p. was under construction for 1959 operation with another 475,000 h.p. in the planning or development stage.

The B.C. Power Commission completed the first stage of its Strathcona development on Vancouver Island near Upper Campbell Lake, where the initial installation of 42,000 h.p. was placed in operation in July. The 175 ft. earth fill dam here provides 800,000 acre ft. of storage. The Ash River development near Port Alberni was nearing completion and will be in operation by mid-February 1959.

The powerhouse, five miles below the storage dam at Elsie Lake, is below an 11 ft. diam. tunnel and wood-stave pipeline, and contains a 35,000 h.p. unit under a head of 700 ft.

The British Columbia Electric Co. Ltd. continued work on the final phase of its Bridge River development on the Mainland, for completion in 1960, when combined capacity of four plants will reach a total of 692,500 h.p. The final phase includes a second storage dam, to be called Mission Dam, a new powerhouse and a 16½ ft. diameter lined tunnel 12,700 ft. long. This dam, now under construction, will be 188 ft. in height, will raise the head at Bridge River No. 1 to 1,356 ft. and increase the capacity from 248,000 h.p. to 276,000 h.p. Another interesting feature is the deep grout curtain through the permeable material underlying the dam.

On Vancouver Island the company's 2,300 h.p. Goldstream plant, built early in the century, was dismantled.

The Aluminum Co. of Canada installed a seventh unit of 150,000 h.p. at its Kemano plant. An eighth unit comprising a turbine and generator of similar capacity had been delivered, but installation is being deferred for the present.

In the thermal-electric field, the B.C. Power Commission installed two 25,600 single cycle gas turbines at Chemainus, one late in 1957 and a second in January 1958; two regenerative cycle 24,000 h.p. gas turbine units were also being installed here for completion in January and February 1959. A 600 kw. diesel plant at Chetwynd near Dawson Creek will be in operation in January 1958; at Prince George seven diesel units with total capacity of 6,480 kw. were transferred to inactive plant and two more 3,000 kw. units are planned for operation in December 1959 and February 1960.

Elsewhere the following thermal installations were completed: 4,200 kw. in six diesel units at Quesnel and 1,800 kw. at Dawson Creek in three diesel units. In active prospect for early completion in 1959 or 1960 are 6,000 kw. in two diesel units at Dawson Creek, a 1,000 kw. Diesel unit at Smithers and a 100 kw. diesel unit at Alert Bay.

The British Columbia Electric Co. continued work on the Port Mann Gas Turbine plant near New Westminster, for operation early in 1959. The four 33,500 h.p. turbines will operate with natural gas as a preferred fuel or oil as a standby. The plant is designed to be remotely controlled from the load despatch office 15 miles away, from where 470,000 hp. of hydro power is already under remote control.

At Ioco on Burrard Inlet the company had commenced work on a steam plant designed for ultimate capacity of six units of 211,000 hp. each. The first unit is planned for operation in January 1961 and another in October, with the rest to follow as required by load growth.

Alberta

There were no new hydro-electric units installed in Alberta during 1958. Calgary Power Ltd. deferred work on extensions to its Spray and Rundle plants until 1959, where a 62,000 hp. unit and a 40,000 hp. unit will come into service respectively in 1960. Stream flow studies are under way on Brazeau River, a possible site for a future development.

In the thermal-electric field, Calgary Power doubled the capacity of its natural gas-steam station at Wabamun, by bringing into operation a second 66,000 kw. unit in October. Northland Utilities Ltd. is studying hydro sites on the Heart River near McLennan and on the Fridette River near Uranium City.

Northland Utilities Ltd. replaced a 500 kw. unit with a 3,000 kw. gas-diesel unit, while Canadian Utilities Ltd. placed in operation a 10,000 kw. gas turbine unit at their Sturgeon Plant. The city of Edmonton brought into service a new 10,000 kw. gas turbine unit at its municipal thermal-electric plant. The City of Lethbridge added a 10,000 kw. gas turbine unit to its municipal station, while the city of Medicine Hat built a 4,000 kva. substation.

Saskatchewan

An agreement was reached in July 1958 between the Federal government and the Province of Saskatchewan for joint construction of the South Saskatchewan River project. A hydro-electric installation of some 200,000 hp. will be included in the development.

The Churchill River Power Co. continued construction for addition of a 7th 19,000 hp. unit at Island Falls, expected to be in operation by July 1959. The Saskatchewan Power Corporation added a 66,000 kw. steam turbine to its Queen Elizabeth thermal station at Saskatoon. Capacity of the Kindersley station was increased by 20,000 kw. in two gas turbine units.

Manitoba

The Manitoba Hydro - Electric Board is building its Kelsey generating station on the Nelson River at Grand Rapid. Five or six units under a 50 ft. head are proposed, each of 42,000 hp. Two are scheduled for operation in July 1960 and three more during 1961. Installation of a 6th unit is being considered. The plant will supply power to the International Nickel mining development at Moak, Mystery and Thompson Lakes. Some 10 per cent of the powerhouse and 5 per cent of the main dams were completed by year-end. The diversion channel and sluiceway structures were nearing completion, and the 250,000 c.f.s. flow of the river was expected to be passing through the sluiceway by that time.

Thermal-electric projects underway in 1958 included completion of four steam turbine units each of 33,000 kw. at Brandon, while the Board's Selkirk generating station will place one 66,000 kw. in service in December 1959 and a second at mid-1960. The pumphouse structure on the Red River near Cook's Creek was completed for supplying cooling water to condensers. The Board's program is based on an expected increase in power demand through the winter of 1961-1962.

The Commission purchased four diesel generating units aggregating a capacity of 1,825 kw. and the distribution system at The Pas in December last. A new generating station was completed by year-end with two diesel units totalling 1,750 kw. and two of the units of the purchased equipment were being installed with them, bringing capacity to 3,150 kw.

The city of Winnipeg continued

with repair work at Pointe-du-Bois and Slave Falls power stations and completed two substations in the Winnipeg area. The Department of National Defence added one 1,136 kw. diesel unit at Churchill.

Ontario

Ontario's total of 1,301,800 hp. of new capacity installed during 1958 was the highest among the provinces. In addition, new capacity under construction is expected to add over 600,000 hp. during 1958 and some 360,000 hp. over succeeding years.

By year-end nine 75,000 hp. units were installed in the Ontario-Hydro's Robert A. Saunders - St. Lawrence Generating Station, with a capacity of 375,000 hp. The remaining seven units are scheduled for service by November 1959. The upstream earth fill cofferdam had been blasted on July 1st, 1958, and the headpond raised to within 4 ft. of normal operating level.

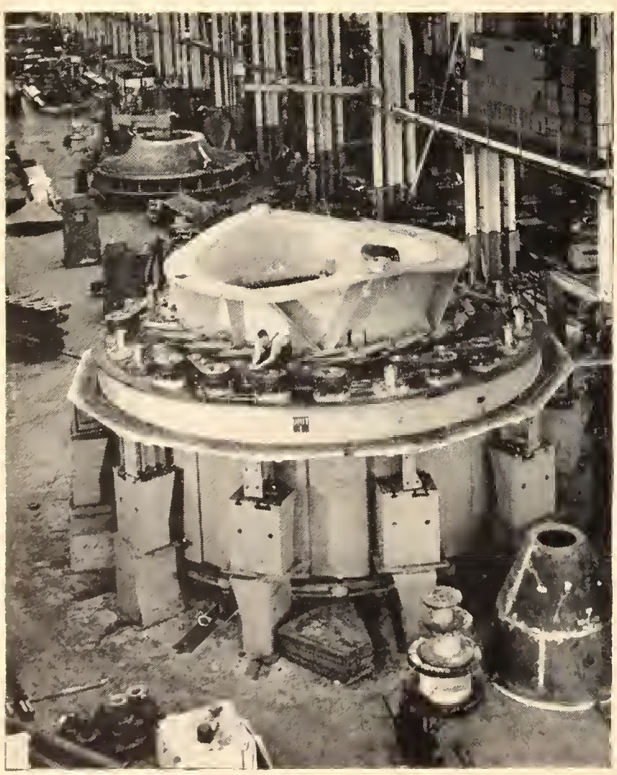
At the Sir Adam Beck - Niagara Generating Station the Commission completed development of the power resources on the Niagara River with the placing in service of the last three units of the pumping-generating station and of the last two additional units at the main station. Each of these units is rated at 105,000 h.p. Each of the six pumping-generating units has a capacity of 47,000 hp. at maximum discharge.

In February 1958 the first of three 27,000 hp. units was placed in service at the Whitedog Falls plant on the Winnipeg River. The other two units were placed in service in March and June respectively. A similar development at Caribou Falls on the English River with three 34,000 hp. units was placed in operation early in October.

Late in 1957 the Commission completed works for diverting water from Lake St. Joseph on the Upper Albany River system to Lake Seul in the English River System. This water provides additional power at Ear Falls, Manitou Falls and Caribou Falls on the English River, and the six plants on the Winnipeg River in Manitoba. The two provinces have an agreement for sharing the additional power produced in Manitoba.

One additional unit was also added during the year at Manitou Falls on the English River, and at Alexander and Cameron Falls on the Nipigon River. These additions have added some 62,500 hp. to the Commission's installed capacity.

Construction was also started during 1957 at Silver Falls on the Kaministiquia River, of a 60,000 hp. single unit generating station. By the end of 1958 a tunnel had been excavated and partly lined, and 30 per cent of the powerhouse structure was built. When placed in service next September it will be remotely controlled from the Port Arthur transformer station.



Shop erection of a 200 h.p. turbine for the Beauharnois Development of the Quebec Hydro-Electric Commission.

A new generating station with two 26,500 hp. units on a head of 93 ft. will be built at Red Rock Falls on the Mississagi River, for operation in 1961. By year-end first-stage cofferdams had been built and the headpond area partly cleared. Further upstream on the James Bay watershed another generating station was under way at Otter Rapids 23 miles from the Abitibi Canyon Plant, to be placed in service in 1962. The powerhouse, integral with the dam and sluice structures, will house four 60,000 hp. units. The Commission also plans to increase the output at Abitibi Canyon with a fifth 66,000 hp. unit.

During 1958 the Commission also undertook construction of two new thermal electric stations, the Lakeview Station west of Metropolitan Toronto and the Thunder Bay Station at Fort William. A third station is planned for the Hamilton area. Good progress was made on enlarging the Richard L. Hearn Generating Station to 1,200,000 kw., or three times its present size.

Studies were continued with Atomic Energy of Canada Ltd. and other interested agencies regarding development of a large-scale reactor for production of energy from nuclear resources. Plans for a 200,000 kw. nuclear station are being developed. Meantime construction was resumed at Des Joachims on the Ontario side of the Ottawa River. Work on this 20,000 kw. nuclear station had been temporarily suspended in 1957 to permit changes in design.

Apart from the activities of the Commission, the Great Lakes Power Co. placed in operation in October at Gartshore Falls on the Montreal River, a generating unit of 30,300 hp. capacity under a 115 ft. head. The company is also going ahead with its Cat Falls development on the Michicopoten River for initial operation in June 1959. This plant will have one 30,300 hp. unit under a 95 ft. head.

Quebec

In the Province of Quebec, installation of hydro-electric facilities totalling 900,000 hp. capacity was brought into operation. In addition, new capacity currently being built will add some 1,300,000 hp. during 1959 and more than a million hp. in later years.

Hydro-Quebec completed its 1,200,000 hp. Bersimis I project by adding units 6, 7 and 8. Each unit is rated at 150,000 hp. under a head of 785 ft. At Bersimis II, 23 miles downstream, where there will be five 171,000 hp. units under a head of 377 ft., three units are scheduled for operation late in 1959 and the remaining two late in 1960.

At Beauharnois the Commission continued construction of the third and final section of the powerhouse which will contain ten 73,700 hp. units with provision for a seventh. Initial operation with two units is expected in April, with a third to follow in June and a fourth in September. Completion is planned for 1961 with total capacity of 2,234,700 hp. The Commission also built a storage dam at Lac St. Anne on the Toulnoustouc River, a tributary of the Manicouagan. Studies were also underway regarding the development of the Lachine Rapids section of the St. Lawrence, and of the Carillon Rapids on the Ottawa River.

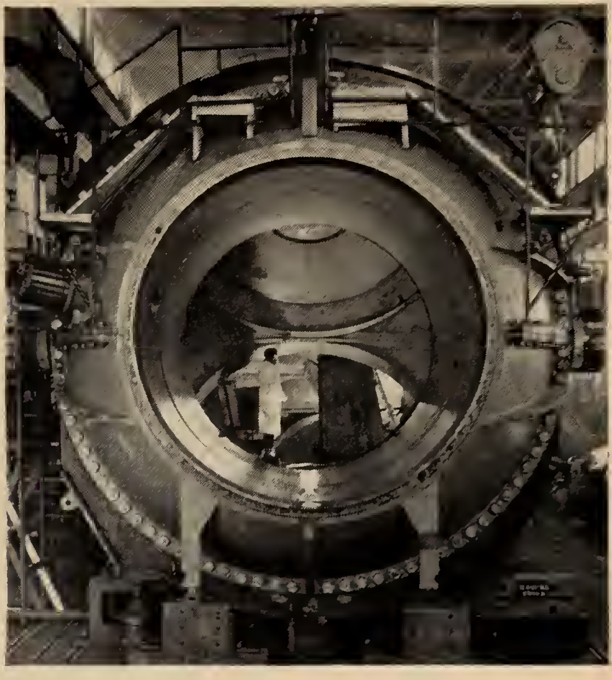
The Shawinigan Water and Power Co. brought into operation the first four 55,000 hp. units operating under 125 ft. head at its Rapide Beaumont plant on the St. Maurice River. Units 5 and 6 were placed in service in November-December. The Manicouagan Power Company completed its McCormick Dam No. 2, an extension to its plant at First Falls near Baie Comeau. The last two 60,000 hp. units were placed in service in March, bringing total plant capacity to 292,400 hp.

Quebec Cartier Mining Co. commenced a development on the Hart Jaune River last October, to supply power to its immense iron ore project in the Lac Jeannine area. A storage dam will impound 54 million cubic feet of water. Plans call for development of 66,000 hp. five miles downstream, in three units under 130 ft. head, with provision for two or three units at the storage dam at a later date.

The first of the five 200,000 hp. units at Aluminum Co. of Canada's Chûte des Passes project on the Peribonka, operating under a head of 625 ft. is expected to be in service by August 1959. The Company has indefinitely postponed a project to divert water from Manouane Lake into the Bonnard River, a tributary of the Peribonka.

The James MacLaren Co. Ltd., is building for completion in 1959 a 50,000 hp. plant on the Lièvre River at Dufferin Falls. The plant will have two 25,000 hp. units under a 62 ft. head.

Hollinger Hanna Limited is studying a possible 180,000 hp. development on the Aux Pekans River in the headwaters of the Moisie.



Foot bore straightflow valve for Bersimis No. 2 development under construction in the John Inglis plant.

The Gatineau Power Co. completed conversion of its equipment from 25 to 60 cycles at Paugan and Farmer's Rapids. Last remaining 25 cycle plant at Chelsea will be converted early in 1959.

Extensive repairs were completed on the Gouin Storage dam on the Upper St. Maurice and on the Allard Dam on the Upper St. Francis River.

Omitted from reported 1957 installations was a completion by Smelter Power Corporation, totally owned subsidiary of Nickel Mining and Smelting Corporation, which placed its 42,000 hp. hydro plant on the Chicoutimi River. (273 ft. head) in service in May, 1957.

New Brunswick

The New Brunswick Electric Power Commission placed in service in January 1958 the second of two 45,000 hp. units, in the thermal-electric field, at its Beechwood development. The NBEPC has currently under construction a 50,000 kw. steam plant at Saint John, expected to be completed next July. The Bathurst Power and Paper Co. completed addition of a 6,540 kw. unit to its steam plant at Bathurst, while the Fraser Company Ltd. added in mid-October a new 12,500 kw. unit at its Edmundston steam plant.

Nova Scotia

The Nova Scotia Power Commission purchased and dismantled two small plants on the Sissiboo River. In June construction was started on two new developments to replace them, 12,000 hp. in one unit at 125 ft. head at Weymouth Falls, and 8,000 hp. in one unit at 85 ft. head at Sissiboo Falls. Both will be in operation late in 1959. The Clearland plant on the Musquash River with its 330 hp. was dismantled. The Commission proposes two new plants on the Sissiboo at Riverdale and Wreck Cove with capacities of 8,000 hp. and 55,000 hp. respectively.

The Nova Scotia Light and Power Co. completed its new 73,000 hp. development in three units at Windsor Forks in December. Two more projects are in active prospect at Lequille and Alpina with 7,500 hp. and 6,500 hp. capacity respectively. During the year the Company was adding a 45,000 kw. unit to its Halifax steam plant for 1959 operation, while the Seaboard Power Co. was adding a 16,000 kw. unit to its plant at Sydney, with operation expected by September 1959.

Prince Edward Island

The Maritime Electric Co. is installing a 10,000 kw. unit at its Charlottetown plant for operation late in 1961.

Newfoundland

The Bowater Power Co. completed in March at Cornerbrook a 12,000 hp. development in two units under a 526 ft. head. United Towns Electric Co. added a 3,600 hp. unit to its hydro plant at Lookout Brook in November, while construction was commenced at Pitman's Pond on a 1,200 hp. plant in one unit under a 70 ft. head. Newfoundland Light and Power Co. Ltd. expected to complete in December 1958 a new 17,000 hp. development in two units under a 307 ft. head at Rattling Brook near Norris Arm. At its Manihek Rapids development in Labrador, Iron Ore Co. of Canada will add a new 19,000 hp. unit under 35 ft. head in 1960.

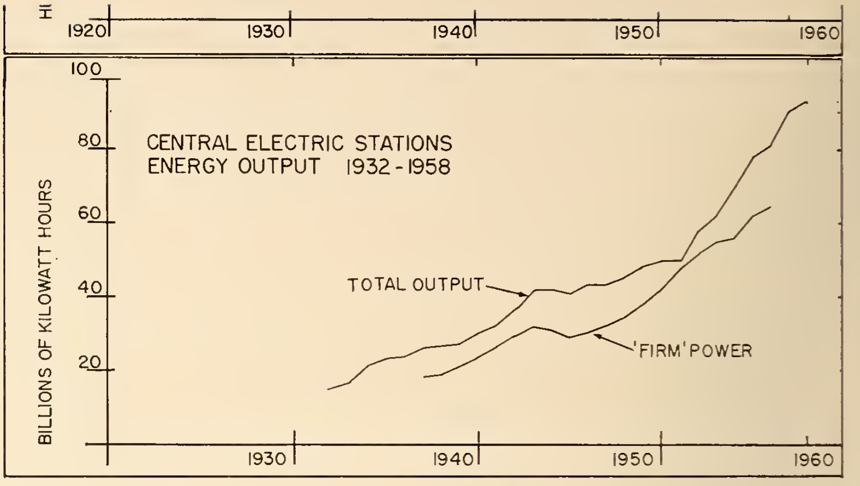
Yukon and Northwest Territories

At the Federal Government's Northern Canada Power Commission Whitehorse Rapids development on the Yukon River the first 7,500 hp. unit was placed in service in November, and a second similar unit at year-end. Provision is made for a third unit. On the Snare River in the N.W.T. the Commission plans a second development of 9,200 hp. in one unit, 8 miles downstrtam from the existing Snare River Plant.

Installation of thermal plants during the year included a 600 kw. unit at Fort Smith, (replacing 2-100 kw. units); a 150 kw. diesel unit in New Aklavik (now named 'Inuvik') to augment the two existing 375 kw. units as required. The Commission also commenced an extension to the existing Fort Simpson plant for addition of the 100 kw. diesel unit formerly at Fort Smith. The Yukon Hydro Electric Co., which is allied with Yukon Hydro Co. Ltd., installed a 150 kw. diesel plant at Haines Junction, Y.T.

Columbia Settlement Near

At the end of the year there were signs that the long controversy on Columbia River power may be approaching a settlement. Acting Prime Minister Howard Green announced early in December that "steps are to be taken at once to complete an agreement with the United States which will make possible the co-operative development of the River." This co-operation would be based on control of projects in Canada, he said.



This hinted that power from the Canadian stretch of the Columbia might have to be under a joint federal-provincial authority. It implied Canada will keep the regulation of flow in its own hands, possibly through a federal authority.

The Government also re-asserted agreement on flows and downstream benefits should be worked out by the International Joint Commission, rather than through diplomatic channels.

Expressing delight at Canada's readiness to negotiate, U.S. officials interpreted Mr. Green's statement as indicating Canada had abandoned the idea of diverting the Columbia into the Fraser watershed.

Other Developments

Ottawa is firmly opposed to any early development of power in the Peace River Canyon, as proposed by the Wenner-Gren group with Premier Bennett's backing, believing it will be most valuable 25 to 30 years from now. Federal authorities have never seriously feared that development of the Peace River might interfere with development of the Columbia. They believe it would not be feasible for private interests to dam the Peace Canyon unless they have an immediate market for most of the 4 million hp. potential. A market for so much power could not be found without export, and Ottawa has a veto over all power exports.

World Power Conference

Following the articles and reports on proceedings of the World Power Conference in September 1958 in Montreal, covered fully in the October 1958 issue of The Engineering Journal, there is little more to add regarding developments in nuclear power after so short a lapse of time. These developments were covered in articles commencing on pages 63, 75 and 85 of that issue.

TABLE I—Power Installations for 1958-1959-1960 and Planned for future years.

	Installed in 1958		Scheduled for 1959		Scheduled for 1960		Planned for 1960 or future years	
	Hydro hp.	Thermal kw.	Hydro hp.	Thermal kw.	Hydro hp.	Thermal kw.	Hydro hp.	Thermal k2.
British Columbia	192,000	228,000	35,000	145,600	475,000	340,000	(a)	340,000
Alberta	..	103,000	..	..	120,000		..

Less dismantled	6,360							
NET TOTAL	2,557,040							

Footnotes—(a) Excluding Mica Dam and diversion of Columbia, and 4 million hp. on Peace River.
(b) Excluding Lachine Development.
(c) Excluding 4 million hp. at Grand Falls.
(d) Excluding 4 million hp. on Yukon and Nass Rivers.

PULP AND PAPER INDUSTRY

CANADA IS THE largest exporter of pulp and paper in the world. More than four-fifths of the total output moves abroad. Some 92 per cent of newsprint production is exported and 90 per cent of the pulp manufactured for sale also goes to foreign markets. With an annual volume of production valued at $1.4 billion, pulp and paper accounts for 7 per cent of the output of all Canadian industry. At current values the industry represents an investment of some $3 billion.

Production in 1958

Total wood pulp produced last year at 9.907 million tons declined almost 3 per cent from the 1957 level and by 5 per cent from the all-time high established in 1956. Canadian newsprint output for the year at 6.095 million tons was 5 per cent lower than in 1957. The productive capacity of the newsprint mills in 1958 was more than 7 per cent higher than in 1957. Thus by mid-year the operating ratio had dropped to the lowest level of postwar years.

Both in Canada and the United States, most of the recent additions to newsprint capacity have been completed. However, in 1959 operating ratios for the newsprint industry in Canada will continue to reflect the reserve capacity which was created in the last twelve months.

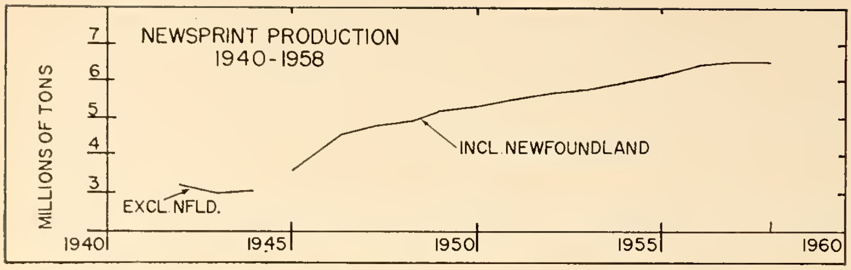
Paperboard production in 1958 surpassed the all-time record levels reached in 1956, and increased more than 6 per cent over 1957. Demand for fine paper was well maintained, with both production and consumption higher than in the previous year. Production of wrapping paper exceeded the record level established in 1956.

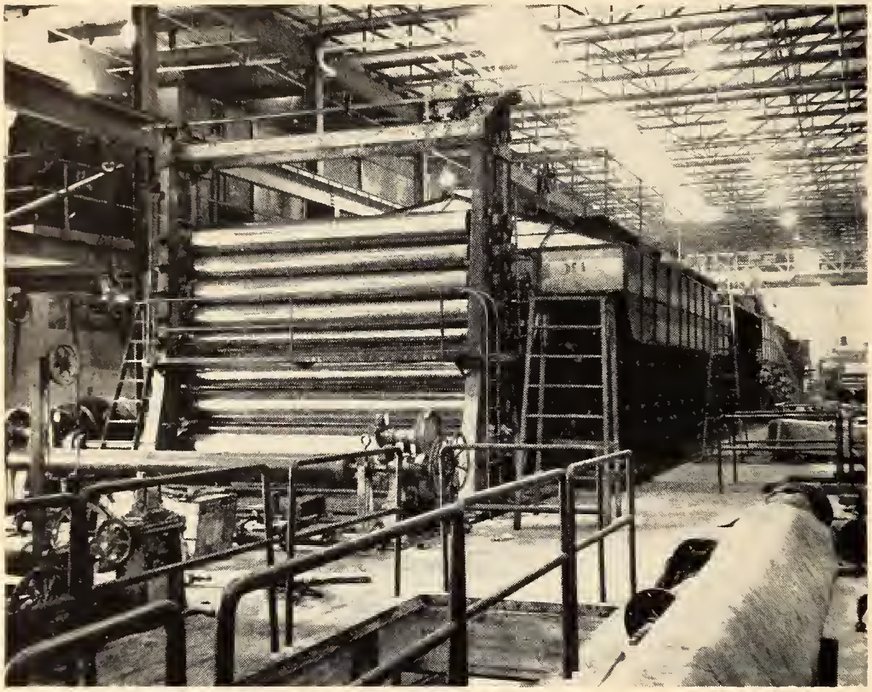
Technically, the industry continued to progress satisfactorily, with research programs underway both in the mills and in the woods. The budworm epidemic appears to have been halted, and productivity of the woods worker increased again. Today west of the Rockies it takes 1.3 man-days to cut and move a cord of wood to the mill, as compared with 1.8 man-days a decade ago—a 27 per cent reduction.

Industry Statistics

There are 80 pulp and paper companies, operating 130 mills in eight provinces. Almost a third of the United States' wood fibre requirements comes from Canada, which exports annually to the U.S. 1.8 million cords of pulpwood, 1.9 million tons of pulp and 5.2 million tons of newsprint, close to 2 million of which is eventually repulped for paperboard or other products. Of the total pulp and paper output 45 per cent comes from Quebec, 26 per cent from Ontario, 13 per cent from British Columbia and 16 per cent from five other pulp-producing provinces.

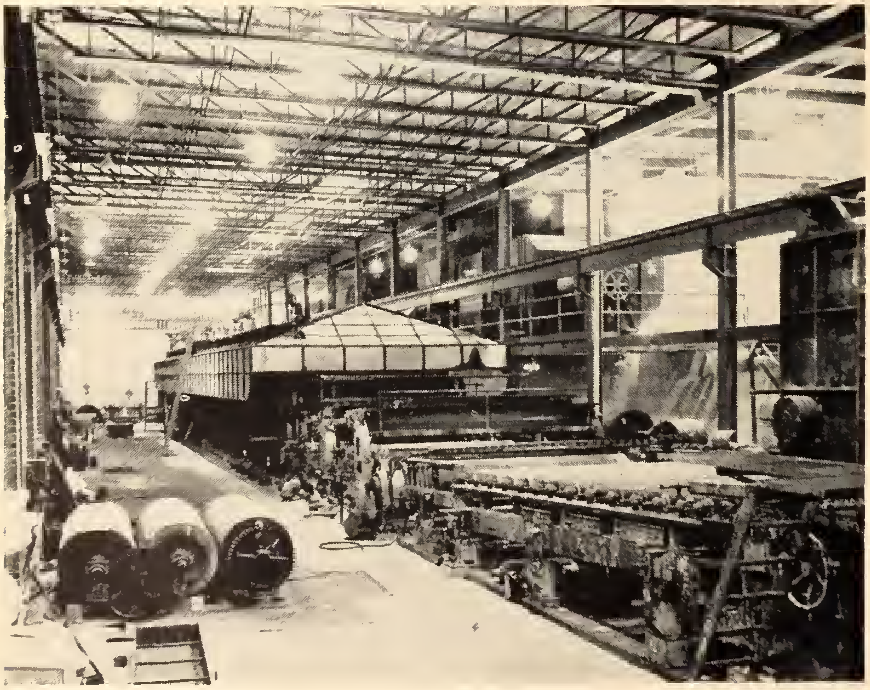
There are 26 companies making newsprint, which operate 146 newsprint machines in 42 mills. In addi-





Installation of No. 3 paper machine room. View from the dry end or calender stack. Donohue Brothers Ltd., Clermont, Que.

Installation of No. 3 paper machine room. View from the wet end or Fourdrinier end. Donohue Brothers Ltd., Clermont, Que.



tion to pulp and newsprint the mills have an annual output of 1.9 million tons of paperboard; book, writing, wrapping, tissue, cleaning, industrial and other papers; building papers and board, and hardboard and other pulp products. Next to newsprint, the paperboard plants are the largest producers, making 900,000 tons annually. Canada also produces more than 250,000 tons per year of fine papers from 15 mills.

Including 95,000 woods workers, pulp and paper creates employment for some 335,000 workers. Even excluding its seasonal workers totalling some 270,000 pulp and paper is one of the largest employers in the land.

Technical Sessions

Among technical subjects discussed at the annual C.P.P.A. meeting were factors affecting Fourdrinier wire life. In papermaking the soupy pulp flows on the moving wire mesh screen where the water drains away. Pulp fibres felt together into a wet sheet. With today's high speed of paper machines replacement of Fourdrinier wires has risen alarmingly. An industry-wide task force had been studying the problem.

Another session dealt with chemical pulp problems. Chemical pulp is produced by cooking wood chips in an acid or alkaline solution. Exports are valued at some $275 million annually. A paper was presented on advances in the design and operation

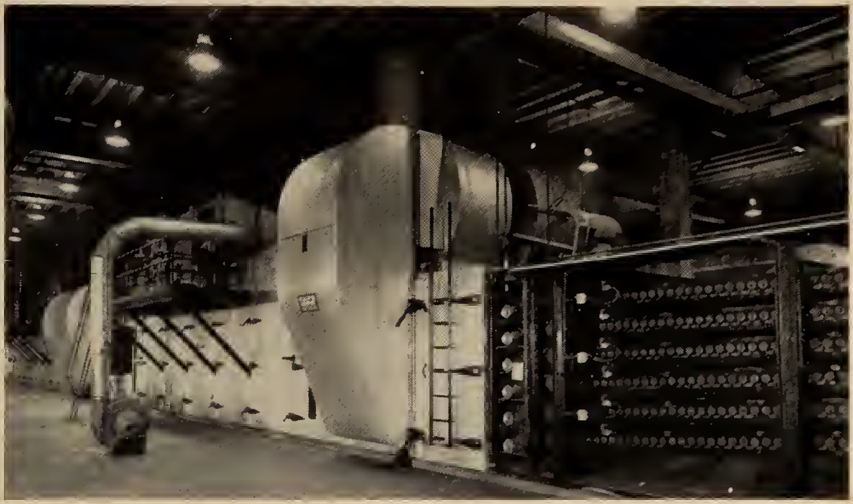
Towering 250 ft. above the wild woodlands of Northern Quebec is the largest differential surge tank of its kind in North America. This was erected for Price Brothers and Company Ltd., pulp and paper manufacturers.

of chlorine dioxide generators for bleaching the pulp. Another paper dealt with purity and bleachability of pulps.

Discussions on fine paper manufacture included a paper on research into factors that allow paper to curl, and another dealing with pitch-dispersal chemicals that permit production from resinous woods such as jackpine. Paperboard production problems were discussed, such as the large quantities of steam used in papermaking, alkaline pulping of poplar and a new technique for continuous rather than batch-pulping of northern hardwoods.

Another session dealt with handling and storing of raw materials, palletization, trials of a special pulpwood railway car, and a case history of an industrial truck driver's training program were subjects of addresses. A boxboard session discussed packaging, sizing, quality control and uniformity. A session on pulp blending discussed a magnetic stock proportioning control system, as well as stock flow and measurement through orifices. In a session on mechanical engineering, subjects included methods of getting more pulp from a given amount of wood, electrical engineering, and alkaline pulping of hardwoods.

A session on paper drying was devoted to infra-red radiation in papermaking; bark disposal, new processes of bark utilization, and use of bark to generate steam. Discussions related to static rectifiers, fundamental chemistry of wood, drying and ventilating and operating problems of paperboard production as well as testing and quality control.



Infeed section Coe tunnel dryer for softboard at Prairie Fibreboard Limited, Saskatoon, Sask.

Table I—Canadian Pulp and Paper Production and Exports—1957-1958

Preliminary 1958 figures

	Production		Exports	
	1958	1957	1958	1957
Gross value of output	$1.4 billion	$1.4 billion	$1 billion	$1 billion
	Tons	Tons	Tons	Tons
Total wood pulp	9,906,712	10,176,707	2,213,701	2,232,185
Dissolving and Special Chemical	306,551	341,411	248,789	291,523
Bleached sulphite paper grades	553,775	583,300	349,191	384,736
Unbleached sulphite	1,558,383	1,754,162	209,424	297,036
Bleached sulphate	1,118,627	882,970	880,669	716,353
Unbleached sulphate	833,862	775,391	259,362	256,020
Other chemical	235,463	244,823	32,343	41,311
Groundwood	5,234,675	5,516,713	226,498	237,697
Newsprint	6,095,553	6,396,501	5,609,024	5,907,393
Containerboard	485,845	455,495	50,058	57,402
Boxboard	420,258	390,063	26,497	22,262
Total paperboard	906,103	846,008	76,555	79,664
Fine paper	254,068	252,086	15,873	16,270
Coated paper	30,960	29,450	1,227	1,202
Other printing paper	91,641	80,925	63,820	54,590
Special papers	128,367	124,800	3,785	5,218
Wrapping paper	287,930	269,177	28,720	18,836
Building papers and boards	320,000	272,000	15,000	23,300

RESEARCH AND SCIENCE

John R. Kohr

At the concert: "Ma, what's the book the conductor is reading?" "That's the score." "Oh? Who's ahead?"

SCIENCE IN CANADA has always been a concerted effort rather than a competitive sport; and this is still true in 1958-59, both internationally and internally. Internationally, we don't crave a place in the race into space at a quickening pace just to save face; and internally, we have become a nation where even distillers make exhortation toward moderation!

The score of science in Canada—and I make it a point not to say "Canadian Science"—is composed of thousands of research notes, conference proceedings, annual reports, technical journals, science lectures, and even television shows; the orchestration is provided by federal and provincial government laboratories, by independent research organizations, and, increasingly, by universities and by industry.

At the last count, in 1957, industry alone employed some 4,500 professionally trained scientists—the number had doubled in the short span of two years! — and some 3,500 technicians. Multiply these figures by some 40 hours a week for some 50 weeks a year . . . and you'll hear the wheels of progress hum . . . to the point where this symphony of science will begin to sound almost like the Flight of the Bumblebee. No wonder that the voice of the "vocal soloist", the lone inventor, is nowadays seldom heard in the land.

However, this marathon musical metaphor was not meant to end on a sour note but rather with the three "leitmotivs"; expansion and improvement of research facilities; focus on higher standards of education in the sciences; and, finally, increasing emphasis on supra-national aspects of science.

Postdoctorate Fellow from India, using vacuum apparatus to concentrate biological materials without having to apply heat. The commonly used heating method would decompose these "Thermolabile" substances. Work of this type is done in the fermentations and enzymology section, Division of Applied Biology, National Research Council, Ottawa.

Expansion and Improvement of Research Facilities

Increasing interest of industry in research-development is shown by investment in new or extended research facilities, which amounted to $12.8 million in 1957. This is more than 20% of the estimated value of all facilities used for research up to 1955. Indications are—from the size and number of industrial laboratories opened in 1958—that this rate of growth will be kept up for several years to come. This means, roughly speaking, that during the 'fifties, Canada will have experienced an industrial research expansion equivalent to that of the entire half of the century!

Government research laboratories are beginning to show a more—shall we say, conservative—rate of growth. This is not surprising if one considers that in Canada large and powerful research organizations in government departments dealing with natural resources had already existed long before industrial research in this country was able to get going. Long-range plans for veritable networks of government research laboratories, conceived shortly after World War II, have now been largely put into effect by the Department of Agriculture, Atomic Energy of Canada Limited, Defence Research Board, Mines and Technical Surveys, and the National Research Council of Canada.

Notable additions are: the new forest products laboratory of the Department of Northern Affairs and National Resources; the new testing laboratory of the Department of Public Works; the telecommunications laboratory of the Defence Research Board; a plant biochemistry annex to N.R.C.'s Prairie Regional Laboratory; and the Fire Research Laboratory of N.R.C.'s Division of Building Research.

The Fire Research Laboratory is unique in Canada. Almost half of its 550,000 cubic feet consists of a huge, 40 ft. high hall that houses two enormous furnaces, the one for research into fire resistance of walls, the other for fire resistance of floors. Cost of the laboratory, including equipment: a cool million dollars. Cheap, if one compares it with the 44 million dollars damage caused by 25,560 fires in 1958, in Ontario alone! Invaluable, if one considers the 450 persons injured and the 155 lives lost by fire in 1958, in Ontario alone! (Totals for Canada not yet available at time of writing.)

In the provincial field, an example of healthy growth was given by the Alberta Research Council which recently added to its facilities at the University of Alberta a large laboratory and pilot plant financed by the Alberta government to the tune of some $750,000.

Focus on Education in Science and Engineering

Talking of the University of Alberta reminds me that many other universities in Canada have launched a building program that reveals both the grasp of, and the reach for, benefits yet to be derived from higher education in *all* fields. In these plans, the biological, chemical, medical, physical, and engineering sciences are not being overlooked, to put it mildly. At Ottawa University, for instance, a million-dollar chemistry building has followed hard at the heels of a similar electrical engineering building, to be followed in turn by a million-dollar biology building. And on the brand-new campus of Carleton University, only a few miles away, the Henry Marshall Tory Building for Science and Engineering is nearing completion.

In the Maritimes, the biggest single step in expansion of facilities at St. Francis Xavier University recently culminated in the opening of a Chemistry and Physics building, erected at the approximate cost of—you've guessed it — a million dollars. (Could it be that the fascination exerted by this "round figure" has something to do with its pleasant plumpness?)

At Dalhousie University, erection of the Sir James Dunn Science building has been made possible through a gift by Lady Dunn of nearly two million dollars. (To explain this extra munificence, it may be worth while recalling for a moment that Dalhousie's present chancellor is, among other things, a professional engineer!)

Mount Allison and the University of New Brunswick have also made tremendous strides both in the enrolment of science and engineering students and in the corresponding provision of new facilities.

I have dealt here with the Maritimes at some length because I want to exemplify the gradual achieving of a healthy balance in these provinces between education in the natural sciences — where the low number of scholarship holders, for one thing, had indicated a significant lag behind the central and western provinces—and education in law and the humanities, in which the Maritimes had always enjoyed a Canada-wide reputation for their "export of brains".

But of all science building projects in Canada, by far the most magnificent, both in conception and in execution, is the new Ecole Polytechnique on the campus of the Université de Montréal. Built at a cost of nearly ten million dollars, it takes care of an enrolment of nearly a thousand students, making allowance even for

Not all pieces of equipment used in scientific research are as complex as this apparatus operated by a technician of N.R.C.'s Division of Applied Physics. ***Photo by Malak, Ottawa***

Teamwork is of increasing importance in most scientific developments. A valuable member of the team is this drafts-"man". ***Photo by Malak, Ottawa***

the enrolment being doubled within the next ten years. Could there be a finer symbol for the emergence of what I may call—if you'll pardon the bilingual "jeu de mots"—*le génie canadien!*

"Engineering is becoming ever more popular among the students in the French(-speaking) high schools and classical colleges (of Canada). The major industrial developments in Eastern Canada catch the eye and the mind of young French Canadians as they never did before. This, coupled with the normal increase in the school age population will soon result in a much greater participation of French Canada in national economic development. The new facilities of Ecole Polytechnique come at a good time to cater to the coming generation, which rightly sees the opportunities where they lie." (*The Engineering Journal,* January 1958, p. 89, in the first of a series of articles on Engineering Faculties in Canada.)

Preparing samples for testing of the physical properties of ice, in the snow and ice laboratory of the Division of Building Research.

Emphasis on buildings, and their cost, is of course merely a macroscopic and grossly materialistic measuring stick: a laboratory, to a team of scientists, means no more and no less than what an auditorium means to an orchestra; for, basically, buildings are merely a shell, to make a good performance resound in all its glory. Scientific apparatus—just like musical instruments—often involve major expenses, too: think of the computing centre at the University of Toronto, the nuclear reactor at McMaster University, the wind tunnel at the University of British Columbia; the financing alone, of these modern monumental "teaching aids" often involves separate contributions from various government and industrial sources.

Skilled hands remain one of the most valuable assets of any scientist. Photo shows grain fertilization experiment of the Department of Agriculture Research Laboratory, Winnipeg.

With some industrial corporations assuming an ever increasing share and constantly growing interest in higher education, it is gratifying to note that the golden age of the individual benefactor is far from being a thing of the past; not perhaps as flamboyantly enthusiastic as some seventy-five years ago, when Louis Agassiz founded the first outdoor laboratory, for which John Anderson—a tobacco merchant in New York—donated an island (complete with a solid fifty thousand dollars for operating expenses), while a Mr. Charles G. Galloupe contributed a yacht, and François de Pourtalès took care of building a harbour, to say nothing of Quincy Shaw who gave Agassiz a hundred thousand solid dollars "to be used for whatever seemed best". Still, McGill University recently was left a whole mountain, Mont St. Hilaire, with no strings attached. And another industrialist has converted his summer estate into a haven for tired, but far from retired, leaders of Canada's academic world, so that they would find time for some undisturbed fish . . . pardon me, philosophizing.

Supra-National Aspects of Science in Canada

The most significant, and perhaps the most satisfying, symbol of advances of science in Canada is its increasing international recognition. Here are some variations on the theme.

The International Geophysical Year, officially concluded on 31 December 1958, was undoubtedly the most valiant effort at international scientific collaboration ever to be made; in all fairness it must be admitted, however, that some parts of this far-reaching program assumed undertones of nationalistic competition; the Canadian I.G.Y. program became thus doubly remarkable: not only for the extent and diversity of its operations but also for its "down-to-earth" detachment from any motive that was not rigorously scientific. Even the removal of Ripple Rock—an eminently practical engineering project — was made to serve I.G.Y. scientists for explorations in geodetic theory.

A large-scale Postdoctorate Fellowship scheme, now in its twelfth year of operation, has been expanded so that it now welcomes to Canada some of the world's most brilliant young scientists, to work not only at the National Research Council but also at various other Government laboratories and even at universities.

Canadian scientists are being asked in ever increasing number to serve on missions for UNESCO; to participate in international expeditions (last year, for instance, to study aborigines in faraway Central Australia); and to help with the Colombo Plan, both as experts abroad and as mentors for Colombo Plan Fellows whose training requirements may range from learning how to build and run a nuclear reactor to studying the latest techniques of food and drug inspection.

Similarly, excellent liaison between Canada's Technical Information Service and its counterparts abroad was pointed up last summer when, for the first time, the European Productivity Agency seconded one of their bright young men to T.I.S. for a six-month study of its operation all across Canada.

On the other hand, Canadians continue to learn new and unusual approaches to scientific and technical problems from visiting experts: a striking example is the work done by a Swiss specialist during the past two winters on avalanche control in the Canadian Rockies, under the joint auspices of Canadian railways and N.R.C.'s Division of Building Research.

Some Canadian developments, such as the cobalt teletherapy unit, are being exported to many countries; the advances Canada is making in photogrammetric research have lead to substantial contracts between various underdeveloped countries and Canadian aerial surveying firms.

The two "Atoms For Peace" conferences may be cited as typical examples of large-scale meetings outside Canada, where Canada was able to contribute both her scientific contingent and by her popular exhibits. Speaking of exhibits, Canada's photo display at the "International Exposition on the Teaching of Sciences" held this winter at the Sorbonne, Paris, was so well received that Canada's Department of External Affairs has been asked to make it available in other European cities.

Canada has become a favourite "host country" for World Congresses, such as entomology, genetics, biometrics, and the World Power Conference. The largest scientific gathering ever to be held in Canada will take place when the Ninth International Botanical Congress will meet, 19-29 August 1959, in Montreal.

Montreal, Ottawa, and Toronto are among the cities now frequently chosen for annual meetings of scientific societies with headquarters outside Canada; e.g., the Institute of Radio Engineers and the Society of Chemical Industry. Eminent Canadian scientists have achieved the signal distinction of serving as presidents of international scientific organizations — although their nationality had, of course, little to do with the fact that they were chosen; they simply were considered best suited to hold the position.

Some scientists in Canada have also started to play a leading role in such supra-national endeavours as the proposed redefinition of the International Metre in terms of wavelengths rather than material standards. Moreover, in an agreement among Commonwealth nations and the United States a single value for the standard inch will become effective as of 1 July 1959: instead of the U.S. inch of 2.540005 centimetres or the British inch of 2.539996 centimetres, the inch adopted in Canada in 1951, measuring an "even" 2.54 centimetres will be accepted; again, the Canadian inch will be accepted not because it's Canadian but simply because it's easier to handle.

To the superficial observer, this may sound like straining at a gnat; but, contrary to popular opinion, this is precisely how progress is being made in the natural sciences; and yet, although "Science is Measurement", the progress of science itself is, fortunately, beyond all material measure . . . in Canada . . . as well as in the rest of the world.

Summer student—releasing weather balloon for the Department of Transport in one of Canada's Arctic outposts.

ST. LAWRENCE SEAWAY AND POWER DEVELOPMENT

THE OFFICIAL opening of the St. Lawrence Seaway marks the realization of a project conceived more than a century ago. As early as 1825 the Hon. Robert Young of Montreal began agitation for a deep waterway and seven years later his views received support in a widely publicized article "The Concise View on Inland Navigation". The professional engineer enters the story in the person of Thomas Coltrin Keefer, M.E.I.C. first president of the Canadian Society of Civil Engineers (1887) later the Engineering Institute of Canada. Thomas Keefer planned and supervised scores of waterway projects mostly for the improvement of traffic conditions on the Canadian rivers.

Looking downstream at the remains of Toussaints Island in the foreground. Ships which will bypass Iroquois Dam in the centre distance will be raised through Iroquois Lock and pass through what was formerly Toussaints Island. In this photograph the island has been excavated, flooded and the rim dyke is being removed by dredges.

In a series of books and in scores of pamphlets, articles and addresses around the middle of the century, Keefer put forth his views on the use of Canada's waterways. The St. Lawrence was to him a broad passage into the heart of a virgin continent whose commerce sooner or later must take to the seas. His remedy for falls, rapids, portages and other natural obstacles on the St. Lawrence system was to cut more and more canals so that ships of all nations navigating without interruption could pick up cargoes on every cove on the Great Lakes.

The Welland Canal

In 1913 the Canadian Government undertook a project which would ultimately form part of the completed seaway. The new Welland Ship canal fourth and largest of a series of four canals built in Canada to connect Lakes Erie and Ontario, was commenced in that year. Work was suspended in the fall of 1916 but was resumed after World War I and was completed in 1932 at a capital cost of $130 million. The last eight miles of channel are now being deepened to 27 feet. But a newer Welland canal costing some $75-100 million will be needed within 10 years. If the Seaway is to carry its full potential and pay for itself in 50 years, it is expected that tolls will enable Canada to build this duplicate soon enough to allow full development of traffic.

It was Mr. R. A. C. Henry, M.E.I.C., then chief engineer of Beauharnois Light Heat and Power Company who made the imaginative and far sighted proposal that the difficulties of power development in the Soulange section should be overcome by the construction of a canal between Lake St. Francis and Lake St. Louis to take the full flow of the St. Lawrence.

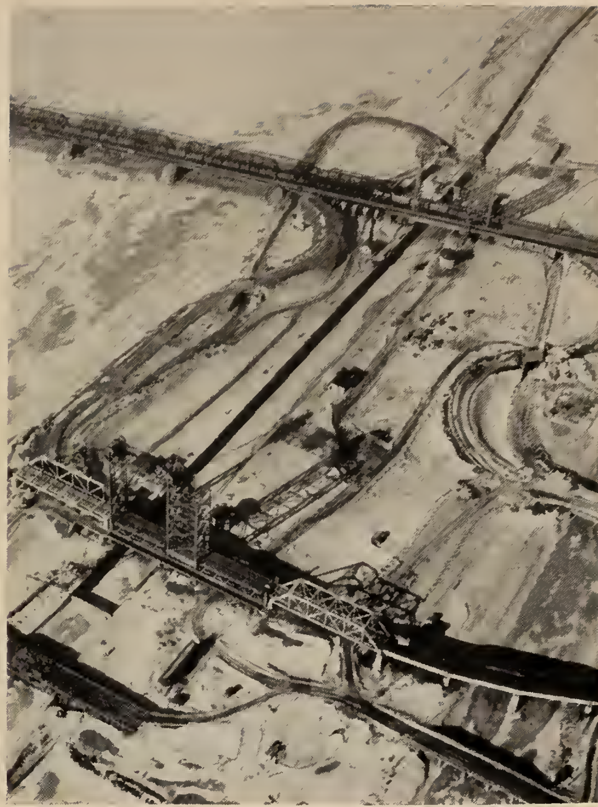
Beauharnois

The Beauharnois development, now owned and operated by Hydro Quebec, is one of the largest plants in Canada with one million three hundred and fifty thousand horsepower at present in store. When completed it will produce over 2,000,000 horsepower. Located in the Soulange section it was commenced in 1929 with the proviso that the power canal would later be improved and deepened and widened to the dimensions necessary for use as a navigation channel for the Seaway. The power canal is 16 miles long and is now being dredged to a 27 ft. depth throughout. Two locks have been installed by Canada's Seaway Authority.

Plans for the construction of the seaway proper, however, involved agreement in detail between Canada and the United States, and it was not until 1954 that the men and machines on each side of the border could actually begin their huge task.

Opening Ceremony

The ceremony last September at the powerhouse on the International Boundary was a tribute to the perfect co-ordination that has marked the four-year construction period of the St. Lawrence Seaway and Power Project. Premier Leslie Frost of Ontario and Governor Averill Harriman of New York State jointly pressed a switch to start eight generators delivering power on a commercial basis on September 5th, the exact date set four years previously for first delivery of power and partial opening of navigation through the new locks. The opening of the complete seaway on schedule will be the crowning achievement of this co-ordination between the Joint Commission, the Board of Control, the Joint Board of Engineers, the four Authorities and the many contractors and suppliers.



New approach to an old bridge: work began in 1958 on the construction of a new, alternate approach to the Victoria Bridge. This will provide an uninterrupted flow of road and rail traffic once the St. Lambert Locks of the St. Lawrence Seaway are in operation.

Raising a Bridge

The smooth operation of the intensive four-year program was marked by many impressive engineering accomplishments. Outstanding among these was the raising of the southern half of the 2½ mile Jacques Cartier highway bridge over the St. Lawrence at Montreal harbour to provide adequate overhead clearance for seaway vessels. The roadway profile was changed by jacking the spans and building up the bridge piers on which they rested to increase the clearance by 50 ft.

A further 33 ft. was gained by replacing one of the original deck-truss spans with a new through-truss span built on falsework on one side and slid laterally into place, pushing the old span on to falsework on the other side. Translation of the trans-channel span took place on October 20, 1957, closing the bridge to traffic for less than five hours on a Sunday morning. Jacking of the bridge was completed on July 2, 1958. The designer of the original bridge, the late Dr. P. L. Pratley, M.E.I.C., also designed this modification which fully preserves its artistic and practical value.

New Locks

Canada has built five of the seven new locks on the seaway between Montreal and Prescott that replaced 21 on the old system. The smooth working of the gate machinery in the new locks is another notable achievement. It takes only six minutes and causes a minimum of water disturbance to fill or empty a lock 80 ft. wide with a usable length of 768 ft., providing a lift of 6 ft. This is half the time taken in the Welland Canal locks built some 25 years ago.

The two American locks were opened to navigation for ships of 14 ft. draft early in July, and by the close of navigation a total of 5289 vessels had passed through these locks and through the Iroquois Lock on the Canadian side. By year-end work on the remaining four Canadian locks, St. Lambert, St. Catherine, and the Upper and Lower Beauharnois locks was completed,

Rolling lift bridges for the St. Lawrence Seaway Authority at Cote St. Catherine and Iroquois.

with the exception of machinery installation and testing of the lock gates, expected to be ready for the opening of navigation in 1959.

Rail Bridges

Early in October 1958 a 212 ft. 1,500 ton rail-highway lift span, assembled a mile east of the upstream entrance to the Beauharnois canal, was loaded on two scows and towed on three tugs to the site of the Valleyfield railway bridge crossing the canal. After one existing span had been removed and stored on pile supports the new lift span was raised by pumping out the scows and let down to exact position on the bridge piers. Later another 212 ft. span was towed 8 miles down the canal and installed on the N.Y.C.-St. Louis rail bridge.

International Powerhouse

Works of the power project also have been brought into effect with a notable smoothness of transition. One example of this has been the shortening of the customary dry-out period on the Canadian generators in the International Powerhouse, permitting the first two to be placed "on-line" within one week following the raising of water in the headpond.

The flooding sequence of June 30-July 5, 1958 was carried out with remarkably little dislocation of river traffic. At 4 a.m. on June 30, 1958 shipping was cut off between Cornwall and Prescott, Ont. on existing 14-ft. draught canals. At midnight stoplogs were placed in the closure structure after the last downbound vessel had cleared. At 4 a.m. July 1, gates of the Iroquois dam were opened to pass 310,000 cubic feet of water per second, then at 6 a.m. the tunnel ports of Long Sault dam were progressively closed.

At 8 a.m. on July 1 cofferdam A-1 above the Long Sault Rapids between Sheek and Barnhart Islands was placed with some 35 tons of explosive, releasing a 30 ft. wave which slowly inundated 30,000 acres of land creating an international lake 35 miles long and 5 miles wide at its widest point. At 9 a.m. the cofferdam at Ogden Island near Waddington, N.Y. was bridged.

With filling of the pool completed July 4, power production was commenced with two units on the Canadian side while navigation was resumed on July 4. By the end of that month seven units were producing power—three on the Canadian side and four on the U.S. side. At year-end eighteen units were in operation, nine in each half of the powerhouse.

INSTRUMENTATION IN INDUSTRY

POWER FIELD

IN THE PRODUCTION and distribution of electricity, instrumentation is an inherent part of the business, and some of the most exacting instrumentation systems in operation have been developed for, and are in use by, the electric power companies. The variety of types of instruments runs the gamut from simple indicating and recording instruments to precise electronic and hydraulic devices governing the speed of generators with amazing accuracy and complex switching devices which isolate a fault on a transmission line in a wide flung distribution system and, in less time than it takes an electric light to extinguish itself, transfer entire areas to alternate sources in the power grid.

A very large proportion of the fundamental equipment in many of the companies reporting consists of automatic, remote and supervisory control systems. One company operates ten hydro plants from a central control room operated by one man, and has a steam plant operating with a centralized system which allows the control and operation of two 66 MW units utilizing the services of one attendant per shift.

Reason for Instrument Installations

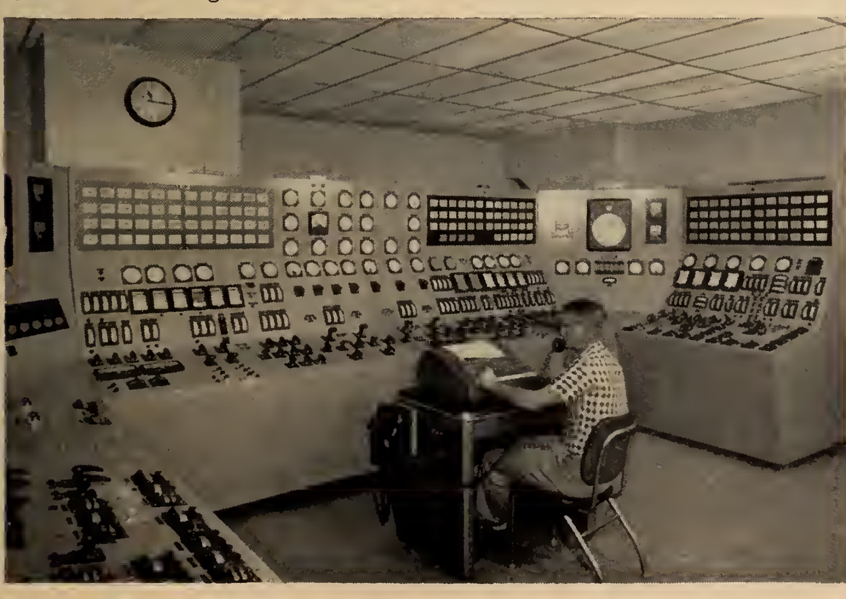
While it is generally true that a large amount of instrumentation is required in the production and distribution of electric power, it is interesting to note that the most important reason given by respondents for advanced instrument installation was to reduce the labour force. By using remote control relay systems, and automatic switching and protection equipment, they have been able to give a higher order of reliability in service with a shrinking labour force. Comments indicated that this trend will continue, probably at an accelerated pace, as labour becomes more expensive, and as reliability of electronic control devices improves.

With increased use of remote control, there is a general trend towards more recording instruments to give an accurate record of performance preceding, during and after troubles and faults occur. Other major reasons for investment in further instrumentation were for purposes of central supervision, for regulation of operating variables and for telemetering.

Uses of Instruments

Generally speaking, in the electric power industry, instruments are used to measure, regulate, protect, provide supervision and to provide records for analysis. Measurement is incorporated in the many metering instruments, and involves measurement of current, voltage, power, phase, speed, frequency, etc. Regulating instruments include both mechanical and electronic instruments, and include very sensitive systems such as those used to control turbine speed at modern hydro generating stations. The standard power frequency is taken so much for granted that many people lose sight of the fact that half the nation is timed by electric clocks which rely on extremely close control of generator speeds at power stations for their very high order of accuracy. Supervisory use of instruments includes those applications in which operating parameters are relayed to a central supervision point for control, and analysis of records obtained by use of continuously recording instruments enables engineers and technicians to do a better job of interpreting faults and equipment breakdowns, as well as providing continuous records of peak loads, miscellaneous faults, etc.

Calgary Power Ltd., Wabamun Power Plant. The nerve centre of the plant is the control room. All main equipment is controlled from here, including the equipment for automatically controlling the heat cycle of the steam generator. Instruments on the *console* are grouped for maximum clarity and convenience for the operator. The right half of the control panel shown in the photo regulates operation of the recently added 66,000 kilowatt unit. Section to the left commands the performance of the original installation.



Who Determines Instrument Requirements?

In the overwhelming majority of companies responding, the power companies' employees themselves determine the company's instrument requirements. Forty percent of the respondents indicated they also use consultants to specify their instrument while in isolated cases this work was performed by the staffs of affiliated companies, or by the engineering staffs of instrument manufacturers. In every case, the actual specification and recommendations for types of instruments to be purchased was done by the company's engineering department.

Who Buys the Instruments?

It was apparent from answers received that this question depends very largely on the internal organization of the companies involved. There appears to be a trend in some companies to appoint men with a technical background to their purchasing department, and then make them responsible for actually selecting the supplier who can produce to the specification supplied by the engineering department at the most favorable price. In the vast majority of cases, however (83%) the engineering department itself specified the actual brand of equipment, and the purchasing department acted in a passive role in bringing the equipment into the plant.

Servicing

Ninety-two percent of the companies responding to the questionnaire serviced their instruments themselves, and some reported fairly extensive instrument shops equipped to do a wide range of instrument repairs. Some of the companies maintaining their own instrument shops also purchased repair service as required, and this seemed to be more common where electronic control equipment with sensitive, and sometimes elaborate, test installations are required. One medium sized company with a great deal of modern control instrumentation does not operate an instrument shop, and buys all of its instrument service requirements as needed.

Preventative Maintenance

Respondents were split evenly on this question—half of them used an organized system of preventative maintenance, and the other half made repairs as failures occurred. The two largest companies reporting used a system of preventative maintenance, but there was no clear-cut pattern with regard to size of company in the remaining group—some of them did and some did not.

Remarks contained in answers to the questionnaire indicated that this is a field in which considerable research and investigation is required. Many companies who did not operate a system of preventative maintenance indicated that they had never attempted to isolate the cost elements involved in such an operation. There seemed to be a general fear that such systems grow by Parkinson's Law and become prohibitively expensive, whereas in actual fact the details of any such program are extremely flexible, and must be tailored to the individual needs of companies concerned. One company scheduled a yearly preventative maintenance check of all instruments associated with each generator in a multi-generator power house, and records over the years had shown this to be good economics. They fitted their program into natural breaks in generator service, and were able to make use of instrument technicians who would probably have been used with less than one hundred percent efficiency otherwise. They pointed out that their preventative maintenance program tended to equalize the workload in the instrument shop, and to lessen the incidence of all-out emergencies.

Spare Parts Practices

More than fifty percent of the respondents maintain a stock of spare parts built up through their own operating experience. Nearly forty percent stock the spare parts recommended by the equipment manufacturers. Some of these thought the practice somewhat expensive, and deplored the tendency by some instrument companies to "pad" the lists of recommended spares to bolster their sales and profit. They feel that good spares lists, conscientiously recommended by instrument manufacturers as a result of their own statistical experience, were a real asset to users of instruments, especially where new types of instruments are involved. They felt that instrument manufacturers interested in the long term picture could do an excellent service by providing "essential" lists of recommended spare parts.

Only a limited number of companies kept spare supplies of complete replacement units. This tied in with the preference for plug-in units. Apparently such units are not popular with the power companies, where many of the installations are permanent in nature, and where versatility is not so important as in manufacturing industries. A few did indicate a preference for the advantages of plug-in units where faults are concerned, especially with electronic instruments where faults may occur in cycles, and where repair time is difficult to estimate. A few spare plug-in units, especially where there is standardization of common elements, makes for a high degree of reliability of service in these cases, and there was some indication of a trend in this direction.

Instrument Specifications

The overwhelming majority of companies reporting preferred to use standard commercial lines for their instrument requirements. A few indicated that they usually have their more complicated control instruments built to their own specifications, and a few others preferred to modify standard instruments, with the engineering usually done in their own engineering department, and the modification usually done in their own instrument shops.

As would be expected in the field of electrical power supply and distribution, almost all of the companies own their instruments outright. A few companies reported rental of a small percentage of their requirements.—mostly computers and other costly equipment which are not used on a full-time basis.

Statistics on Instrument Usage

Capital investment in instrumentation was not given by about half of those responding, but the majority of the remainder reported investments in the range $100,000.00 - $500,000.00. One firm reported investment in instrumentation as between $5,000.00 and $25,000.00, and five reported instrument investment in excess of $500,000.00. Statistics on annual maintenance costs was also not well reported, but several indicated their annual expenditure to be in the order of $8,000.00 - $10,000.00 and one firm indicated an annual maintenance expenditure of $100,000.00.

Thirty-five percent of those replying reported an investment in instruments of over $200,000.00 during the past five years, and a large number reported investment of from $5,000.00-$50,000.00 over the same period of time. Recovery time for instrument investments was long, as might be expected in this industry. The majority of those reporting did not expect to recover instrument investments in less than 9 years, and many indicated much longer recovery times.

INTERNATIONAL NEWS

AUSTRALIA

SNOWY MOUNTAIN PROJECT. Progress is reported by the Institution of Engineers, Australia.

In the case of three contracts, assigned in late 1958, remarkable progress on the actual work of the contract has been achieved during the first six months.

Tooma Contract: This contract provides for the construction of the Tooma Dam and Tooma-Tumut Tunnel together with four small dams to divert water from secondary streams into the tunnel. The contractor, Thiess Bros. has opened up the Deep Creek Adit from which the tunnel will be driven in both directions. As at December 31, 1958, excavation of the adit was complete and advances of 3,100 and 2,100 ft. had been made upstream and downstream respectively. A drift from the tunnel for the raising of the Deep Creek intake shaft had been completed, and 300 ft. of excavation of a construction drift for the Tumut heading of the tunnel.

Tooma Dam will be of zoned earth and rock-fill construction, 230 ft. in height with a maximum base width of 1,200 ft. Excavation of the diversion tunnel for the dam is well advanced with 1,300 ft. out of a total length of 1,500 ft. completed. Excavation of the abutments and cut-off trenches of the dam site are well advanced.

T.2 Contract: This contract was awarded to the Joint Venture of Kaiser, Perini, Morrison, Raymond. It is for the construction of T.2 Diversion Dam, T.2 Power Station and the associated headrace and tailrace tunnels.

An extensive construction camp and housing area is being set up by the Contractor at the junction of the Tumut Tiver and O'Hares Creek some 5 miles downstream of the power station site. The direct road connecting the power station and the tailrace portal is also under construction.

The access tunnel to the power station site has been excavated for a distance of 2,000 ft. out of a total length of 3,600 ft. from the portal towards the machine hall.

A construction adit, 500 ft. in length, to provide access to the downstream end of the headrace tunnel and the surge tank has been completed, and excavation of the three miles long headrace tunnel has advanced 400 ft.

At the downstream end of the tailrace tunnel, open cut excavation is in progress and work has commenced on the tunnel portal.

Tantangara Contract: This contract provides for the construction of a concrete gravity dam 150 ft. in height together with the ten mile long Murrumbidgee-Eucumbene Tunnel. It was awarded to Utah Aust. Ltd., and Brown and Root Sudamericana Ltd.

The contractor is driving the tunnel from two faces at opposite ends and, at the end of December, the Murrumbidgee heading had advanced 3,300 ft. and the Providence heading 3,400 ft. Weekly advances of between 300 and 350 ft. are currently being achieved at each face. Excavation of the control shaft at the intake end of the tunnel adjoining Tantangara Dam has been completed.

At the dam site, stripping of the dam foundations is well advanced, grout hole drilling is in progress, and grouting of foundations has commenced.

Construction of the cofferdam for the river diversion channel was completed and the river diverted on the 20th November.

Aggregate and concrete batch plant is under construction and stripping of the quarry site from which coarse aggregate will be obtained is in progress.

Stripping of the stilling basin is also in progress.

UNITED NATIONS

SOLAR, WIND AND GEOTHERMIC ENERGY development is reported in a United Nations study on new energy sources.

The report (Doc. E/3218), prepared at the request of the UN Economic and Social Council, was to be considered by the Council's session, Mexico City on April 7.

The progress achieved, says the study, is the result of efforts by government agencies, manufacturing firms, individual inventors, universities and other organizations in various parts of the world.

Besides detailing technical and other developments in use of energy from the sun, the wind and the earth, the report puts forward a suggested agenda for a future international conference on new sources of energy.

In a summary of recent developments, the report says that direct conversion of solar energy to electricity by means of solar batteries and by thermo-electric converters is rapidly being advanced. Work also continues, though at a slower rate, on use of solar energy in steam-raising, air conditioning, refrigeration and water distillation. Less progress appears to have been made in developing solar heat storage, solar engines and use of solar furnaces for industrial production.

A significant feature of recent developments has been the increasing attention given to new materials, such as plastics, suited for use in solar equipment.

In the field of wind power, the past two years have been a period of "consolidation and of transition from experimentation to applied research and commercial use." In underdeveloped countries, wind power surveys have led, in a few cases, to the installation of the first modern wind power plants.

The linking of large wind-power plants to local or country wide grid systems is being explored, most of the work on this being done in Europe, it is noted.

As regards geothermic power (natural steam and hot water) the report notes that production of electricity from this source—limited two years ago to Italy—is being started in other countries. The greater interest in geothermic power is also reflected in the search for and discovery of new geothermic fields.

INDIA

WATER UTILIZATION. The chairman of the Central Water & Power Commission, Government of India, has recently published a paper on master plans for integrated water utilization (*J. Inst. Eng. (India)*, v.38, n.7, pt. 1, 1958). India has a geographical area of 806 million acres, of which land utilization statistics are available for only 719 million acres. In 1955 316 million acres were under cultivation, but only 18% of this area had irrigation facilities; about 40% of a further 87 million acres now classified as 'barren' is cultivable with irrigation.

There are great contrasts between flood and drought in the country, since annual rainfall varies from 5 in. to over 100 in., according to region. (Cherrapunji in Assam gets some 500 in. of rain a year.) On the one hand floods may destroy rich agricultural areas, on the other, nearly 30% of the land has a rainfall of less than 30 in. a year. At the same time the growth of population, and hence the need for more crops, is exceptionally great. From 362 million in 1951, it is estimated that the population by 1975 will be 492 million. Studies and surveys are proceeding towards the ultimate development of the necessary irrigation and water-control projects.

Hydro-Electric Power — The true potential of India's water resources for the production of electric power has to be related to the other aspects of flood control and irrigation schemes, and much survey work on individual sites is involved. However, current studies by the Central Water & Power Commission indicate an economic hydro potential of about 40 million kw. at 60% load factor. In addition there are large resources just beyond the northern boundaries of India, of which the most spectacular is on the Brahmaputra River, just inside Tibet, with a head of about 7500 ft. This could give 30 million kw. at 60% load factor for the mutual advantage of India and China.

Estimated maximum future demands for the whole of India are (in million kw.): 1960-61, 4.2; 1965-66, 7.2; 1970-71, 11.1.

Development Costs — It is estimated that the cost of irrigating 50 million acres of land, and generating and distributing 15 million kw. of power will total the equivalent of some $9.6 billion, exclusive of utilization costs. This is based on $64 for storing and distributing water to irrigate one acre, and $425 to generate and distribute 1-kw. of hydro power.

In recent years foreign technical and economic assistance has contributed to the overall planning for the water and hydro-electric developments. The largest aid has come from the United States, with considerable help also from the United Kingdom, Canada, West Germany, and others. Canada has made by far the largest contribution under the Colombo Plan. Assistance includes the provision of equipment and technical advisers, and of technical training facilities both in India and in the contributing countries.

WATERPROOFING MUD. About 300 million people in India live in villages where most of the houses have mud walls. These are badly damaged by rains during the monsoons. The Central Building Research Institute has developed methods of waterproofing and protecting the mud walls from erosion. One method uses a plaster of mud and 'cut-back' (bitumen diluted with kerosene and paraffin wax); another consists of painting the normal dry mud wall with a slurry of cement, hydrated lime, and fine sand mixed with soap solution. Cost is said to be within the reach of the ordinary villager.

BRITAIN. This large-screen projector can prevent "radar blindness". Six controllers are sitting at a large scale table plan of the airways round an airport as film is projected from above, by the Kelvin Hughes rapid processing projector, six seconds after the scene has been picked up by a radar set. Previously, each operator would have sat at his own cathode ray tube, and fed information to a central control system.

U.S.S.R.

SOVIET SPACE ROCKET. Abstract of an article by V. Chichakov, M.Sc., in the Soviet Press.

The Soviet rocket was intended to fly into outer space and to reach the second cosmic velocity (11.2 km — 6.959 miles — per second) or to exceed that velocity. The scientific apparatus of this huge flying laboratory was designed to study some specific features of outer space and chiefly that near the moon. These tasks were stated in the first announcement issued immediately after the rocket successfully got into the orbit set by calculation and the instruments.

The rocket headed for the moon, when the moon was in its "last quarter" phase. At that time the moon was almost perpendicular to the radius of the earth's orbit and ahead of the earth (in relation to the orbital movement of our planet).

The space projectile launched from the earth consecutively imparted to each of the subsequent stages of the rocket an ever increasing velocity, until, finally, the last stage acquired the velocity which until recently seemed fantastic and unattainable and which, as the calculations have shown, has enabled this body to move independently of the earth, breaking the fetters of the earth's gravitation. Together with the velocity the earth had at the moment of the rocket's launching, the imparted velocity became sufficient for the rocket to become a satellite of the sun which governs the movement of all the planets, comets, and meteoric and other bodies of our solar system. The rocket passed very close to the moon (at a distance of less than two diameters of the moon). It is this proximity which made it possible to receive the fullest data on the magnetic field of the moon and its radio activity. All the other scientific tasks of the space rocket were carried out independently of the rocket's nearness to the moon. These were general tasks of studying outer space. Now the rocket has completely established itself on its orbit around the Sun. That orbit is almost circular. It lies beyond the orbit of the earth and is about four times nearer to the earth than the earth's closest big planet, Venus.

It should be borne in mind that the information about the movement of the new planet will still be amplified. The impact of the planets of the solar system upon its movement will be studied. More accurate calculations of the position of the new planet in outer space are to be made in future.

Canadian Developments

NEWS OF MAJOR ENGINEERING DEVELOPMENTS IN CANADA

Civil Defence

Canada's civil defence organization now has a consolidated communications system stretching from St. John's, Nfld., to Victoria, B.C., as a result of circuits established by the communications organizations comprising the Trans-Canada Telephone System.

The new National Attack Warning System was turned over to civil defence authorities on April 1. The network provides inter-communication between all 10 provincial capitals and 19 other major Canadian cities or target areas, as well as the five air defence command control centres in Canada. A single control officer can give or receive messages to all or any one of the 34 stations on the system.

Existing long distance telephone circuits could be utilized when required. When not in use, they serve as regular long distance circuits.

Key centre for the 34-point network is at St. Hubert, Que., where the senior warning control officer works closely with air defence command headquarters. Any alert received by the base is immediately passed on to the civil defence officer who can then order the communications system energized by alerting The Bell Telephone Company of Canada at Ottawa.

Kept abreast of all new developments by the air defence command personnel at St. Hubert, the senior warning control officer can then report detailed information to the coordinators at the provincial capitals or direct to any other city on the network. In the event of a local attack for emergency the coordinator at any point can relay details back to the control centre at St. Hubert.

While 34 points were established on the network at the time of the turn-over, the facilities can be easily expanded to other centres virtually anywhere in Canada.

McAvity's 125 Years in Business

T. McAvity & Sons Limited is celebrating its 125th birthday in 1959.

The Company, now described as the second-biggest industry in the Maritimes (i.e. second to the DOSCO operation), started in 1834 in Saint John, N.B., as a hardware and drygoods business. It soon branched into the working of brass for ship parts needed in the shipbuilding industry in Saint John.

This early growth was accomplished by founder Thomas McAvity and his six sons. The business is still a family-owned enterprise, headed by President G. Clifford McAvity.

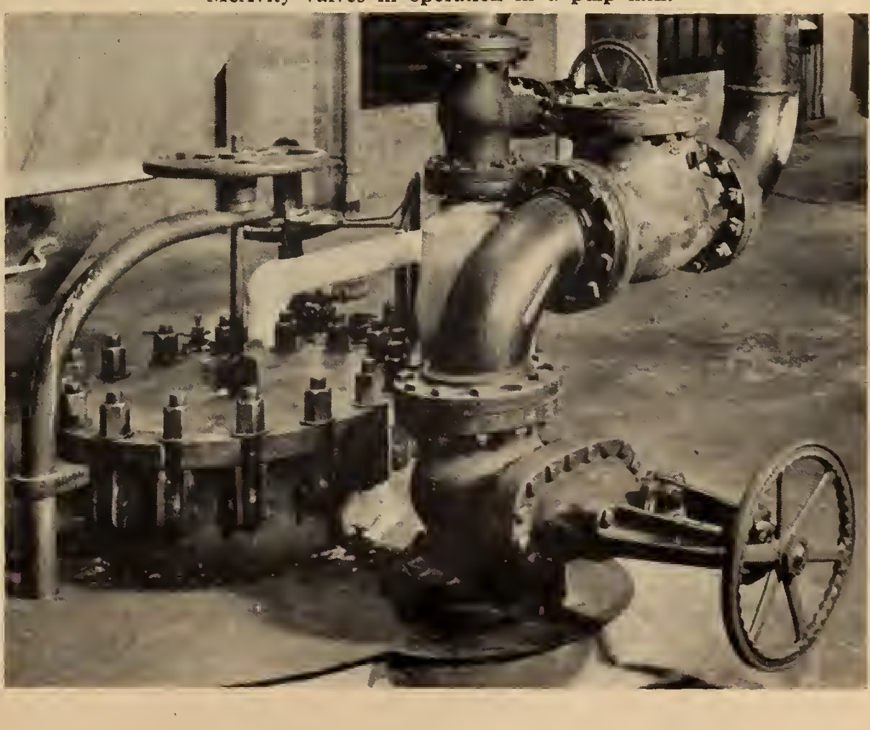
The brass and iron foundries began modestly, but grew rapidly. In 1879 the first valve was produced. Now, with 550 employees, the company is marketing across Canada, supplying valves in bronze, iron, steel, and aluminum for all services, pressures and temperatures. These products are fabricated in the 10-acre Saint John plant, along with fire hydrants, and corporation brass for municipalities.

The range of products has expanded, steadily and profitably. The largest expansion has been seen since World War II.

This adaptability has been of special service in the pulp and paper field. Metallurgical research and technical control of alloys allowed the company to provide high-nickel alloy castings and nickel-containing stainless steel cast valves able to withstand acid conditions occurring in that industry, and in others.

Extending applications for special purposes, McAvity entered the atomic energy field, to design, develop and manufacture special stainless steel valves of a type not previously made in Canada. They are used in the NRU reactor, the Canada-India reactor, and the current NPD project. Pressure ratings vary from low to 1,750 p.s.i., and temperature con-

McAvity valves in operation in a pulp mill.



ditions have been known to reach 550°F.

McAvity products will be found as far west as Vancouver, used in the fields of general contracting (buildings), municipal contracting (water and sewage systems), power developments, shipbuilding, mining, plumbing and heating, railways, and the petroleum industry.

The plant in Saint John includes brass, iron and aluminum foundries, as well as machine and assembly shops.

In the iron foundry, castings weighing up to 1,200 pounds are produced regularly, while occasionally a casting weighing as much as 4,000 lb. has been produced. Mechanization of the foundry has been undertaken when necessary. New foundry installations handle over 70% of output.

Branch offices and warehouses are located in Montreal, Toronto, Winnipeg and Calgary, and there are resident representatives and salesmen at strategic points across Canada, as well as distributors and jobbers. A Western manufacturing plant, T. McAvity and Sons (Western) Limited, Medicine Hat, Alta. is manufacturing fire hydrants, valves, and water works specialties.

What Goes On

Foreign Trade Service

As part of the efforts of the Department of Trade and Commerce to promote trade between Canada and other countries, a series of booklets is being produced providing up to date information on trade opportunities in various areas.

The basic material is compiled by a Trade Commissioner in the territory concerned, and the booklets are designed for distribution to interested Canadian manufacturers and exporters.

Copies are available from the Foreign Trade Service, Ottawa, on request. Venezuela, Rhodesia, Nyasaland, and Ireland have been dealt with in the series.

B.C. Budget for 1959

From the British Columbia budget presented in February to the legislature, these items can be noted.

The Pacific Great Eastern Railway: Having extended its regular passenger service last October to Dawson Creek and Fort St. John, the PGE railway made a substantial operating profit in 1958. Allowance was made in the budget for further improvement required in the line to handle the increased traffic.

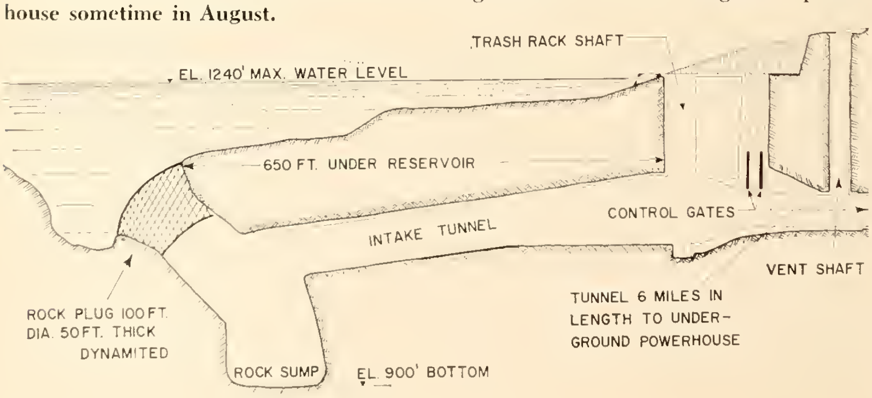
British Columbia Toll Highways: The Deas Island tunnel, forming part of the Fraser delta system, is expected to be in operation by the middle of 1959. Work has started on the highway connecting the Deas Island tunnel with the Oak Street bridge.

The Forest Industry

British Columbia's forest industry is experiencing a "surplus market condition" for its products because demand "has not yet fully materialized" for the output of its expanded mills.

President Peter T. Sinclair of Crown Zellerbach Canada Limited made this statement recently. He called for the utmost vigilance in 1959 in resisting operating cost increases and for more vigorous marketing activities.

Chute-des-Passes. A milestone on the Aluminum Company of Canada Ltd., 1,000,000-hp. Chute-des-Passes power project in Northern Quebec was successfully passed when explosives shattered a 30,000-ton rock plug and dropped the pieces into a pit dug out of the tunnel floor below. Removal of the plug cleared the way for water from the reservoir to enter an intake tunnel. There a temporary concrete barrier behind the control gates prevents premature flooding of the six-mile long power tunnel which will deliver water to electric generators in an underground powerhouse sometime in August.



RCAF Anniversary

This year the RCAF celebrating its 35th anniversary, has these milestones to recall.

Formed on April 1, 1924, it grew from 323 members to 906 in eight years.

Reduced in membership and operation during the depression, during World War II the RCAF grew from 4,061 men and a handful of outdated aircraft to a force of 206,000 men equipped with craft of the latest training and operational types.

The RCAF reverted to a peacetime footing. The few units retained resumed the prewar activities of aerial photography and air transport, including mercy flights. There was a search and rescue organization fulfilling the commitment to International Civil Aviation Organization.

The RCAF received its first jets in 1948, Vampires.

The RCAF transport element, assisting UN Forces in Korea, flew 600 round trips, to Japan, carrying personnel and freight.

The RCAF undertook training of aircrew for other NATO nations and Canada contributed a 12-squadron air division for NATO's integrated forces in Europe.

1953 saw the CF-100 go into squadron service with the RCAF for duty with Air Defence Command.

Emphasis placed on early warning and interceptor control system, produced in 1954 the Pinetree Line, jointly built. The two other warning lines went into operation in 1957.

An early 1959 announcement said the DEW line operational positions were to be manned by the RCAF.

Today the RCAF operates 40 regular force and auxiliary squadrons, 21 of them being regular force fighter and interceptor units. In Canada, nine CF-100 all-weather squadrons are on round-the-clock guard, and overseas four CF-100 and eight F-86 squadrons are serving with NATO. On this continent, under NORAD, the RCAF and the USAF operate as one to protect North American airspace, while retaining their individual identities. Three squadrons equipped with Argus and Neptune aircraft are protecting the coast lines east and west.

The introduction of the BOMARC missile and SAGE into the Canadian air defence system brings the RCAF to the "doorstep of the missile age".

Concrete Pipe Specifications

There is a new revision to the A.S.T.M. specification designated as C76-57T for reinforced concrete pipe conduits. D. H. Perkins, managing director, Ontario Concrete Pipe Association, commented on this recently, and information is available from his office at 60 Harbour St., Toronto 1, Ontario.

Oil Transportation Study

Cost of transporting Alberta viscous crude oil by pipeline may be favourably affected by a study being made by Alberta Research Council scientists.

Some Alberta oil which tends to adhere to the pipe wall requires high-cost pumping power. But pilot model tests, and computations, show that if water is introduced into a viscous oil pipeline, it forms a moving layer between the oil and the pipe wall. The oil is transported in a moving pipe of water, or in a "lubricated" pipe, and therefore needs less power. The water, with a relatively low viscosity, occupies the region of maximum frictional resistance at the pipe wall.

Further tests with the small scale pipeline may be followed by field tests in co-operation with an operating pipeline company.

Air Control

The Department of Transport's most recently established area control centre is located at Goose Bay, Labrador. Its purpose is to provide traffic control service to aircraft, civil and military, which operate in the north-easterly latitudes.

Goose Centre works together with the RCAF, who operate approach control and tower units, to provide traffic control service. It also provides control services to aircraft which operate on a controlled airway originating at Gander, Nfld., and terminating at Frobisher, N.W.T. In addition, oceanic control service is provided for the area between Greenland and Labrador.

Halifax Redevelopment

The housing project at Mulgrave Park, in Halifax, is described by Earl A. Levin, in the January issue of *Habitat* as "part of a redevelopment program which may be the most important experiment in urban redevelopment so far undertaken by any Canadian city." The full program involves not only housing of 350 families at Mulgrave Park, but redevelopment of a part of the city's business district, with financial assistance from the Federal Government under the National Housing Act.

The area to be vacated and later redeveloped contains a mixture of rundown commercial and residential buildings, covering about ten blocks of the business section. The 351 dwelling units will be contained in two eight-storey apartment blocks, one four-storey walk-up, and the balance in three-storey buildings containing apartments and maisonettes. The final form of the commercial redevelopment has not yet been determined. Cost of acquisition and clearing of land will be shared by Halifax and Federal governments.

B.C. Forest Survey

The British Columbia government Forest Service has produced and published a report, "Continuous Forest Inventory of British Columbia", which gives some new statistics of interest to government and to the forest industries.

In the province forestry is the primary industry, accounting for 40 per cent of the economy, and dedicated to sustained forest production.

The 118 million acres of commercial forests is equal to the total commercial forest area of the twelve western states of the United States.

Today, the government reports, the concept of sustained-yield is the industry-wide concept of operation, with more than 5 million acres of productive forest land managed by private industry. The Crown manages another 32 million acres.

Industry and Education

Evidence of the increasing interest of industry and commerce in higher education is observed by the Industrial Foundation on Education (170 University Ave., Toronto 1).

The giving plans of companies have been analyzed, with the cooperation of the companies, and a report is available. It will serve as background information for the guidance of any companies interested in setting up new, or modifying existing, programs of financial assistance to higher education.

The 127 companies reporting represent a fairly complete cross-section, and provide over fifty per cent of the total amounts contributed directly to universities by industry and commerce in 1957.

Of the total grants contributed to higher education in the survey group, the allocation to capital expenditure and unrestricted use represented the largest proportions—58.5% and 14% respectively. Other allocations were: student aid, 10.1%, special applications, 6.1%, research, 5.1%, and scholarship supplementary grants, 4.3%.

With the number of employees used as a measure of company size, the average amounts of grants of all companies was found to be $15.00 per employed person.

Copies of the report can be obtained from the Foundation at cost of $2.00 each.

Microwave link. Reflectors now completed at Cape North, N.S., and Red Rocks, Nfld., by Canadian National Telegraphs are part of the link to go into service in June, bringing Newfoundland into the cross-Canada microwave network. The system will provide three channels of communication into Newfoundland from the mainland, one each for Canadian Broadcasting Corporation television programs, for C.N.T. telephone and telegraph service, and for use as a standby. In the opposite direction, there will be one channel for commercial traffic and one standby which can be used for TV on occasion.

News of the Institute and the Profession

COMMENT
CORRESPONDENCE
ELECTIONS
AND TRANSFERS

CONFEDERATION

There have been no developments since the report which appeared in the April *Journal*. However, a comprehensive report is shown in the annual report of the Institute which has been printed and circulated to all members.

R.C.E. Corps Reunion

There will be a "once in a lifetime" Dominion wide reunion of the Corps of the Royal Canadian Engineers in Toronto on June 12, 1959. This is an officers' reunion, and a testimonial dinner to the Colonel Commandant, Brigadier J. L. Melville, C.B.E., M.C., C.D.

Information can be obtained from W. K. Clawson, P.O. Box 217, Sta. K., Toronto.

The date has been arranged to tie in with the E.I.C. annual meeting in Toronto when many Sappers will be on hand.

Another event is the D-Day Ball, of the Officers Wives Auxiliary, 2 Field Engineer Regiment, R.C.E., on Thursday, June 11, 1959.

President's Tour

President Kenneth F. Tupper, continuing his tour of the Branches, visited Cape Breton on February 13. In the photograph; William Dodson, branch chairman, Dr. Tupper, past chairman Vince Palmer, and Councillor M. R. Campbell.

Eighty members and wives and friends attended a dinner held on this occasion.

Annual General Meeting, E.I.C.

Notice is hereby given, in accordance with the by-laws, that the annual general meeting of the Engineering Institute of Canada for 1959 will be convened in the Concert Hall of the Royal York Hotel, Toronto, Ont., on June 8, 1959, at 10.00 a.m.

Elections and Transfers

A number of applications were presented for consideration and on the recommendation of the Admissions Committee, the following elections and transfers were effected at a Meeting of Council on March 21, 1959.

Member: M. L. Bassan, Montreal; B. R. Boardman, Toronto; O. Brody, Montreal; J. F. Godsell, Saint John; Harris-Lowe, Queenston; G. J. Hebert, Cap de la Madeleine; R. W. Karle, Brazil; M. O. Kellogg, Toronto; J. Leitersdorf, Hamilton; R. F. McCune, Montreal; D. J. McDougall, Montreal; T. J. F. Pavlasek, Montreal; H. R. Switzer, Montreal; J. C. Thompson, Montreal; E. W. Weaver, Sudbury.

Junior: A. H. Banani, Elliot Lake; D. L. Bertrand, Sherbrooke; D. G. Quinlan, Sorel; A. D. Taylor, Sault Ste. Marie.

Junior to Member: W. N. Brown, Quebec; C. A. Dagenais, Montreal; W. D. Dawson, Montreal; M. B. Ferman, Montreal; J. Granger, Montreal; A. G. Hoyt, Trenton; S. Narvey, Toronto; J. M. Rosborough, Temiskaming.

Student to Junior: J. M. Robic, Montreal; D. Rudberg, Montreal.

STUDENTS ADMITTED

University of Toronto: B. L. Allan, G. N. Bird, D. E. Blachford, G. C. Bonham, E. C. Budicky, D. B. Coveney, J. H. R. Crumb, I. G. Cumming, W. D. Farwell, J. I. Fisher, J. F. Green, R. G. Hannaford, W. R. Hayworth, R. M. Herod, M. K. Ho, D. M. Kaminker, G. A. Look-kong, V. Lum, W. H. Mak, F. J. Reinders, S. B. Urving, P. Woon.

Nova Scotia Technical College: S. M. Bishop, W. J. Campbell, W. Chan, B. J. Cutcliffe, H. K. Giddens, D. L. Greenwood, R. G. Hache, E. A. Hachey, Y. K. Leung, R. L. McClare, A. N. S. O'Rourke, D. J. Skinner.

Saint Mary's University: P. B. Carroll, M. P. Chan, D. J. Chiasson, A. K. Connors, J. G. Flemming, G. W. Hill, F. G. Mason, H. A. L. McGuire, J. V. Nolen, G. P. Pothier, R. L. Sheehan, R. E. Wayland.

Laval University: R. Caron, R. Doucet, M. Garon, G. Lamontagne, C. Martel, P. Michaud, R. M. Pelletier, A. Thivierge.

University of New Brunswick: D. W. Betts, J. J. Gorman, N. M. Hoyt, G. R. Marquis, A. Venczel.

University of British Columbia: C. G. Meckling, W. S. Rodenchuk, L. J. Trabert, R. V. M. Zahar.

University of Manitoba: A. Boychuk, G. G. Duncan, B. K. Stinson, T. M. Syposz.

University of Alberta: T. R. Horn, R. W. Patterson, H. G. Tym.

McGill University: F. J. Miller, A. Robinson.

St. Francis Xavier University: T. P. Kieser, M. A. Pettigrew.

Mount Allison University: T. Havas.

Cambridge University: C. D. Thompson.

University of Saint Joseph: V. Leger.

Student of A.P.E.O.: A. Gonnsen.

University of Toronto: H. B. Lett, M. A. Mann.

Application through Association

By virtue of the co-operative agreement between the Institute and the Associations the following elections and transfers have become effective.

SASKATCHEWAN

Members: F. D. Hamblin, R. Hood, B. D. Olafson, W. Stemmler, J. J. White; **Juniors:** P. J. Bonser, A. W. Cliteur, G. E. Cummings, E. H. Gerretsen; **Junior to Member:** D. B. Dundee, M. Kesmarky, E. M. Misfeldt, J. B. Street; **Student to Member:** J. W. MacNeill; **Student to Junior:** N. J. Antaya, B. L. Kilpatrick, J. E. Lovecky, D. E. Mortin; **Students:** R. A. Baumgartner, K. A. Birch, D. G. Charrett, A. Jmaeff, R. G. Lightfoot, D. J. McCuaig, W. Nemanishen, P. A. M. Poliquin, S. M. Quilty, K. J. Serdula, R. S. Sins (Miss), W. A. Tapuska.

NEW BRUNSWICK

Member: J. J. Pader.

SEVENTY THIRD

ANNUAL GENERAL AND PROFESSIONAL MEETING

OF

THE ENGINEERING INSTITUTE OF CANADA

JUNE 8, 9, 10, 1959 ROYAL YORK HOTEL TORONTO, ONT.

REGISTRATION

Advance registration through E.I.C. Headquarters closes May 23.
Registration opens 3:00 p.m. June 7, and continues at 9:00 a.m. June 8, 9 10, 1959.

ACCOMMODATION

The Royal York Hotel is headquarters, with 500 rooms reserved for E.I.C. members and guests.

TECHNICAL PROGRAM

The technical program is listed on the following two pages.

LADIES' PROGRAM

There's promise of a "new and different" program of activities for the ladies attending the meeting; also:
9.30 a.m. daily, Ladies' Coffee Hour
9.30 a.m. Tuesday, Engineers' Wives Meeting.

TORONTO DIARY

Events for all four days at the Royal York Hotel are listed on the back page of this program.

Preprints of many of the above papers are available from Headquarters, 2050 Mansfield Street, Montreal, at a cost of 50 cents per paper.

ANNUAL EIC MEETING

SUNDAY, JUNE 7

9:30 a.m. Education Conference (Deans) Branch Officers' Conference
10:00 a.m. Council Meeting
12:30 p.m. Joint Luncheon, all conferences
2:00 p.m. Continuation of Conferences
3:00 p.m. Committee on Technical Operations
8:30 p.m. Atomic Energy Film

MONDAY, JUNE 8

9:30 a.m. Education Conference continues
10:00 a.m. Annual General Meeting
12:00 noon Muriel's Room
12:00 noon Authors' Luncheon
2:00 p.m. Students' Conference
3:30 p.m. Policy Committee
6:30 p.m. Reception Muriel's Room
7:00 p.m. Dinner
9:00 p.m. Open House

TUESDAY, JUNE 9

7:45 a.m. Authors' Breakfast
9:30 a.m. Professional Development Committee
10:00 a.m. New Council Meeting
10:00 a.m. Consulting Engineers, Directors
11:30 a.m. Professional Development Lunch
2:00 p.m. Professional Development Forum
2:00 p.m. Students' Conference, cont'd.
2:00 p.m. Plant Visits
2:30 p.m. Consulting Engineers, Annual General Meeting
7:00 p.m. Consulting Engineers, An- open to all.
9:00 p.m. Muriel's Room, Refreshments
9:30 p.m. Cabaret—entertainment

WEDNESDAY, JUNE 10

7:45 a.m. Author's Breakfast
9:00 a.m. Joint ASME-EIC International Council
12:00 noon Muriel's Room, Refreshments
12:30 p.m. Luncheon, prizes and medals
2:30 p.m. Faculty Advisers' meeting
6:30 p.m. Muriel's Room, reception
7:30 p.m. Annual Banquet
After Banquet—informal reception
10:00 p.m. Annual dance
10:00 p.m. Open House, Muriel's Room

THE ENGINEERING INSTITUTE OF CANADA

NEWS OF THE
Associations and Corporation

Information received through co-operation of the provincial organizations.

ONTARIO

President McQueen Comments. From "The Professional Engineer" March, 1959, an abstract.

"We cannot help but continue with the building both of ourselves and our profession." They, of course, go hand in hand, because if we enlarge on our own capacity for life we automatically build and extend the engineering world which is so dear to us.

Twenty-five years ago the aim of the A.P.E.O. was to have all engineers become members of the Association and so be licensed to practice under the Act. It may be said that this objective has now been achieved. The present task of the A.P.E.O. is to make their members act like professional people. We must grasp clearly the essential features of professional conduct. Our code of ethics is excellent but on examination it can hardly be said to require more of us than a standard of performance. If we continually build ourselves, developing our essential integrity and that inner something which is in each of us, we must go beyond the simple requirement of the Code. The mainspring of professional behaviour is, in part, simply love of one's work, so that our best is freely given, and in so doing, deep pleasure and satisfaction is obtained.

QUEBEC

Officers Elected

W. J. Riley P.Eng., of Montreal, was elected president of the Corporation of Professional Engineers of Quebec at the Annual Meeting held at the Chateau Frontenac, Quebec. He succeeds Guillaume Piette, P.Eng., of Quebec City.

J. G. Chenevert, P.Eng., Montreal consulting engineer, was elected vice-president and O. S. Gislason, P.Eng., of Arvida, was made honorary secretary-treasurer of the Corporation.

New members elected to the Corporation's Council are: Gilles Sarault, P.Eng., consulting engineer of Quebec City, A. J. Groleau, P.Eng., Area Plant Manager, The Bell Telephone Company of Canada, Montreal, and H. J. Racey, P.Eng., consulting engineer of Montreal.

Other councillors include Arthur Piche, P.Eng., Guillaume Piette, P.Eng., immediate past president, of Quebec City, and G. N. Martin, P.Eng., of Montreal.

William J. Riley is chief engineer of Sperry Gyroscope Company of Canada Ltd.

Born in Chicago, Ill., he received all of his education in Montreal. Mr. Riley

W. J. Riley, P.Eng.

graduated from Loyola College High School in 1937, and entered McGill University's engineering faculty where he remained until 1940 when he answered the call to arms. During the war years, Mr. Riley served with the Royal Canadian Artillery in England and North Western Europe and retired with the rank of captain in 1945. He was awarded the Military Cross and the Canadian Forces Decoration. He returned to McGill in 1945 and in 1948 obtained a degree of bachelor of engineering with honours in Mechanical Engineering.

He joined International Harvester Company Ltd. as product engineer responsible for the design of engines in the company's truck division of Chatham, Ont.

In 1950, he joined Canadian General Electric Company at Montreal as quality control engineer and the following year was made divisional engineer of the Montreal works. He was promoted in 1952 to the post of manager, engineering, of CGE's Montreal works and the same year he became assistant works manager.

In 1953, he joined Sperry Gyroscope (Ottawa) Ltd. as works manager and remained there until 1955 when he was called to the Montreal plant as chief engineer of Sperry Gyroscope Company of Canada Ltd.

In his present position, he is responsible for development engineering, product engineering and quality control in connection with instrumentation and controls.

Mr. Riley is a councillor of The Engineering Institute of Canada, a member of the American Management Association, The Canadian Aeronautical Institute and the Society of Automotive engineers.

Until last year, he was a member of the Canadian militia and retired to the supplementary reserve with the rank of major.

ALBERTA

Registrar Appointed

The Association of Professional Engineers of Alberta appointed Ivan G. Finlay, P.Eng., registrar of the Association. It is the first time the position is to be filled by a full time appointee.

Mr. Finlay was born and educated in Alberta, graduating from the University of Alberta in 1950 with the degree of Bachelor of Science in Electrical Engineering. He subsequently joined the Electrical Inspection Branch of the Province of Alberta and in 1954 was appointed assistant chief electrical inspector. In 1956 he was promoted to the position of chief electrical inspector.

He has been active in technical affairs and is a member of the executive of the Edmonton Branch of the Engineering Institute of Canada. He is also a member of the Edmonton Electric Club and the International Association of Electrical Inspectors.

Annual Meeting

The annual meeting of The Association of Professional Engineers of Alberta took place in the Palliser Hotel, Calgary on April 3rd, 1959.

Technical papers on the program were: "The Impact of New Developments in Chemistry" by Dr. P. E. Gishler; "New Developments and Applications in Physics" by J. M. Dewey; "Advances in Mathematical Techniques and the Development of High Speed Computers" by Dr. R. G. Racicot; "Social Implications of Recent Scientific Advances" by Rev. F. S. Morley, and "The Engineer of the Future" by John H. Fox.

Engineer-Senator

J. A. Buchanan, P.Eng., has been appointed Alberta's new senator.

Mr. Buchanan came to Edmonton in 1910 after graduating in civil engineering from the University of Toronto. He was a surveyor, and later entered the construction field. In 1931 he organized the Buchanan Construction Co. Ltd., of which he is president.

OBITUARIES

The sympathy of the Institute is extended to the relatives of those whose passing is recorded here.

James A. Dick, M.E.I.C. died on January 20th, 1959.

He was born on July 27, 1882 in West Calder, Scotland.

From 1906 until 1938 he was mainly employed in railway and contracting engineering in Ontario and with the Gatineau Power Company in Ottawa.

During the war he was assistant director of civil engineering maintenance for Department of National Defence (Navy) retiring as director from that position in 1954.

Edward Ponsonby Corner, M.E.I.C. of Kenogami, Que., died on January 6, 1959.

Born on March 10, 1888, in Georgetown, British Guiana, he received his training as a mechanical engineer in Glasgow, Scotland. In 1919 he was sent to the British West Indies by Fawcett Preston where he was the agent for sugar machinery.

He came to Montreal during 1930 where he was Quebec representative for Hamilton Gear and Machine Co. Ltd. until his retirement in 1954. Afterwards he was employed as gear specialist with the Canadian International Paper Co., at Kenogami, until 1956.

John A. MacArthur, M.E.I.C. died on December 11, 1958.

He was born April 15, 1902 in Glasgow, Scotland and received his B.Sc. degree in engineering from the University of Glasgow in 1924.

Mr. McArthur came to Canada in 1929. He joined the Abitibi Power and Paper Company Ltd. at Fort William, Ont., after varied experience with chemical, engineering and shipbuilding work.

From 1944 he was connected with Sherbrooke Machineries Ltd., Longlac Pulp and Paper Company Ltd., in Toronto, and with the Stadler, Hurter and Company of Montreal.

In 1954 he founded his own consulting firm with Alfred Malkin in Montreal.

Gordon Wesley Parkinson, M.E.I.C., chief of the PFRA design division, died on January 23, 1959.

Born at Mount Sicker, B.C., he graduated from the University of Saskatchewan in 1929 as an engineer, and later received his master's degree at LeHigh University in Bethlehem, Pa.

After working for various construction firms, he became instructor on the staff of the Saskatoon technical school from 1936 until 1939, later becoming lecturer and assistant professor at the University of Saskatchewan.

During the Second World War, he carried out research work for the National Defence Department in connection with floating docks and airfields built of ice. In 1946 he left the University to join the PFRA. His most important work there was in the South Saskatchewan River project for which he was in charge of engineering design.

Walter C. Griesbach, M.E.I.C., consultant engineer for the Foundation Company of Canada Limited, died February 16, 1959.

He was born in Collingwood, Ont., on July 23, 1891. He graduated from Queen's University in 1912 with a B.Sc. degree in civil engineering.

Following his graduation he became assistant engineer with the Department of Public Works of Canada, and in 1918 joined the Foundation Company of Canada with whom he was chief engineer until 1958.

He was awarded the Gzowski Medal of the Engineering Institute, and was the inventor of the multi-cylinder pneumatic caisson.

Joseph Henry Bower, M.E.I.C., died on January 1, 1959 in Toronto.

He was a graduate of the University of Toronto in 1914 with a B.A.Sc. degree.

He was at one time secretary to the Hydro-Electric Enquiry Commission, and in 1949 he became superintendent to the hospital for sick children in Toronto. He retired from this position in 1957.

R. G. Smalley, M.E.I.C., died in Vancouver, B.C. on September 13, 1958.

He was born in London, England on November 21, 1907 coming to Canada in 1910 and to Vancouver in 1930. He worked with Wilson Engineering Corp., Cambridge, Mass., and studied structural engineering.

He joined the Western Bridge & Steel Fabricators Ltd., in 1938 as assistant chief draughtsman. He was chief draughtsman from 1951 until the time of his death.

Earlier he had worked in structural engineering at Port Arthur, and with other organizations in Vancouver. He held a commission in the R.C.N.V.R.

John A. Shaw, M.E.I.C. of Hudson Heights Que., retired C.P.R. engineer, died on December 29, 1958.

He was a graduate of McGill University in 1899 with a science degree in electrical engineering. He worked for the Montreal Light, Heat and Power Company as assistant for the next five years.

In 1904, he joined the Canadian Pacific Railway Company and in 1915 was appointed general electrical engineer for the company. His subsequent duties included the supervision of mechanical installations in company plants and office buildings. He retired in 1946.

Joseph Nicholas de Stein, M.E.I.C. died on January 19, 1959, in Regina, Sask.

He was born in St. Petersburg, Russia. on August 28, 1880, and received his engineering degree in Germany, at Stuttgart University.

In 1905 Mr. de Stein joined the Grand Trunk Pacific Railway in Canada. About 1920 he established his own business, now known as the Western Drafting and Blue Printing (Western Branch) Instruments Ltd., in Regina, Sask. He retired from the firm in 1951.

He was a member of the Regina town planning commission when it was formed in 1930.

Dr. John A. Stiles, O.B.E.,M.E.I.C., died in Ottawa on November 29, 1958. Since 1919 he worked with the Boy Scout Movement, first as assistant Dominion commissioner. He was appointed Dominion commissioner in 1930. He retired in 1946 as chief executive commissioner.

A graduate of the University of Toronto, he was awarded the O.B.E. in 1935 and in 1946 was honoured with the degree of Doctor of Science by U.N.B.

His work before 1919 was that of dean of applied science at University of New Brunswick.

E.I.C. ANNUAL MEETING 1959

ROYAL YORK HOTEL, TORONTO, JUNE 8, 9, 10.

John Jeffery Hanna

PRESIDENT

THE ENGINEERING INSTITUTE OF CANADA

1959 - 1960

JOHN JEFFERY HANNA, M.E.I.C., of Calgary, Alberta, president-elect of The Engineering Institute of Canada is an engineer who has been associated with Alberta's oil industry for over thirty-five years.

Mr. Hanna is a graduate of the University of Toronto, having received the B.A.Sc. degree in civil engineering in 1914. His work has been continually in the West since he joined the engineering department of the City of Calgary, in 1914.

He served with the Canadian Engineers in the Expeditionary Force, from 1914 to 1919, attaining the rank of Captain.

Returning then to work for the City of Calgary, he was assigned special engineering work for two years on natural gas and general engineering. Then during 1920 and 1921 he was resident engineer for the City on the Hillhurst Bridge.

Mr. Hanna was with the Lethbridge Northern Irrigation District in 1921, and was resident engineer on the Old Man River flume.

His service for Imperial Oil Limited at Calgary Refinery was accomplished in the positions of construction engineer, mechanical superintendent, assistant refinery manager, and refinery manager.

Mr. Hanna's membership has been a considerable asset to the Institute and particularly to the Calgary Branch. He has served on many committees, as chairman and as councillor. With his membership dating from 1917, he is one of the most interested and best informed members of the Institute.

The Association of Professional Engineers of Alberta has received his support as a member of council, as vice-president and as president. He was its representative to the Dominion Council in 1955.

Mr. Hanna has actively participated in student guidance and educational reform for many years in Alberta. For both the Calgary Branch of the Institute and the Chamber of Commerce he has acted on local committees on education. He sat on the Professional Engineers Committee on Counselling and Education when a brief was submitted to the Senator Cameron Royal Commission.

Other services have also claimed Mr. Hanna's attention: he has been a member of the Chamber of Commerce for 18 years, a councillor and a committee chairman; a member and director of Rotary International, Calgary Club. He is chairman of the Finance Committee of the Calgary Branch of the Canadian Red Cross Society. He is in his second term as an alderman of the city of Calgary.

NEWLY ELECTED OFFICERS OF THE INSTITUTE

At the Annual Meeting, three vice-presidents and thirty-six councillors will take office, and will serve with others whose terms of office continue. The complete list of Council members will appear in the June issue.

R. B. Chandler, M.E.I.C., of Port Arthur, Ont., is elected a vice-president of the Institute representing the Province of Ontario.

Mr. Chandler has recently been appointed a member of the Lakehead Harbour Commission by the Federal Government. He retired as manager of the Public Utilities Commission of Port Arthur in 1954, having held that office from 1945. He then became a member of the Commission, and is now its chairman.

Earlier, from 1917-1923, he was with the C. D. Howe and Company, Port Arthur, as designing and supervising engineer, and as a consulting engineer and partner. He had completed his engineering studies at the University of Toronto in 1912, receiving a B.A.Sc. degree.

F. L. Lawton, M.E.I.C.

R. B. Chandler, M.E.I.C.

C. V. Antenbring, M.E.I.C., elected vice-president of the Institute to represent the Western Provinces, is president of Cowin & Co. Ltd., Winnipeg.

Mr. Antenbring studied at the University of Manitoba, graduating in 1926 in civil engineering.

He joined Cowin & Co. Ltd., in 1927 as a designer of reinforced concrete.

He is a former chairman of the Winnipeg Branch, and a former councillor of the Institute. He is also a past-president of the Association of Professional Engineers of Manitoba.

F. L. Lawton, M.E.I.C., chief engineer, power department, Aluminium Laboratories, Montreal, is elected a vice-president of the Institute, representing the Province of Quebec.

Mr. Lawton has acted in an engineering capacity on a number of major hydro-electric developments and projects.

He graduated in 1923 from the University of Toronto in electrical engineering. For the first eighteen years of his career he was successively with The Canadian Westinghouse Company, the Quebec Development Company, the Duke Price Company Limited, and its successor, Saguenay Power Company Limited. In 1941 he joined the Aluminum Company of Canada Limited as assistant chief engineer, and was named to his present post in 1948 with Aluminium Laboratories.

Mr. Lawton has served the Institute as a councillor, and he is a past-chairman of the Saguenay and Montreal Branches.

Nicholas Gritzuk, M.E.I.C., has been elected a councillor to represent the Yukon Branch of the Institute.

Mr. Gritzuk's experience has been in the Canadian North, in either the mining industry or associated with it, since 1934. After gaining a degree, B.Sc. (honours), in metallurgical engineering from Queen's University in 1945, he returned to the Central Patricia Gold Mine in northern Ontario. However, in 1946 he received the appointment of metallurgical and mill superintendent for a new Yukon venture, now United Keno Hill Mines Limited. In 1952, with the development of an associate company as an asbestos producer in northern British Columbia, the transport division of United Keno Mines Limited and Cassiar Asbestos Corporation Limited was established, based at Whitehorse, Yukon. Mr. Gritzuk was made manager of this function and a wholly-owned equipment sales subsidiary—the Territorial Supply Company Limited.

Commander P. F. Fairfull, M.E.I.C., superintendent of the Graving Dock at Esquimalt, B.C., has been re-elected to represent the Vancouver Island Branch on the council of the Institute for another two-year term. (Commander Fairfull's biography appeared in the June 1957 issue of the *Journal* in connection with his first election to this office.)

P. N. Bland, M.E.I.C., will represent the Vancouver Branch on the council of the Institute for a two-year term,

Mr. Bland has been since 1949 chief engineer of Canadian Sumner Iron Works Ltd., Vancouver. Mr. Bland joined the engineering profession through the Association of Professional Engineers of B.C. in 1933. He had worked with Sumner Iron Works in Vancouver and Washington for ten years. Since 1931 Mr. Bland's work has been with the Canadian Sumner Iron Works Limited, with the exception of a three-year period. His first appointment as chief engineer was made in 1937.

Mr. Bland served the B.C. Association as a member of the Board of Examiners, as a member of the editorial board and as a member of Council. He is a past chairman of the Vancouver Branch, E.I.C.

H. R. Hatfield, M.E.I.C., of Penticton, B.C., has been elected to represent the Central British Columbia Branch on the Council of the Institute.

Mr. Hatfield graduated from the University of British Columbia in 1928. In 1930 he joined the Interior Contracting Company Limited, at Penticton, working with this company until 1958, and attaining the post of president and superintendent. He is now a consulting engineer.

During the war years he spent a year with the R.C.A.F., and he acted from 1941 to 1945 as service and works engineer in the R.C.E. at Petawawa, Barriefield and Chilliwack.

Mr. Hatfield is a former chairman of the Central British Columbia Branch.

A. F. Brooks, M.E.I.C.

S. Barkwell, M.E.I.C.

A. F. Brooks, M.E.I.C., superintendent nitrate plants, Warfield Department, Chemicals and Fertilizers Division, of The Consolidated Mining and Smelting Company of Canada Limited, has been elected councillor of the Kootenay Branch of the Engineering Institute.

Mr. Brooks received his education in Montreal. He graduated from McGill University with a degree in chemical engineering in 1950, after having served with the R.C.A.F. from 1939 to 1945. While in the air force he was engaged in technical armament work in Canada and the European theatre; he attained the rank of Flight Lieutenant. Mr. Brooks joined Cominco at Trail, B.C. and in 1951 he became a research engineer in smoke and fume control work. He was assistant superintendent, phosphate plant, Warfield Department from 1956 to 1958 .

Mr. Brooks has been active in Professional Development Course programs of the Kootenay Branch. He was Branch chairman in 1955.

A. Howard Douglas, M.E.I.C., of Saskatoon, professor and head of the civil engineering department, University of Saskatchewan, Saskatoon, past chairman of

P. F. Fairfull, M.E.I.C.

N. Gritzuk, M.E.I.C.

P. N. Bland, M.E.I.C.

H. R. Hatfield, M.E.I.C.

the Saskatchewan Branch, 1949, has been elected to serve as a councillor for the Institute, representing the Saskatchewan Branch.

Mr. Douglas is a graduate of the University of Saskatchewan, 1931, with a degree of B.E. in civil engineering. He worked in the field of contruction and structural design with contractors, and in the bridge branches of the Ontario and the Saskatchewan departments of highways. He served for 4½ years with the construction engineering branch of the R.C.A.F. in Ottawa. He joined the staff of the College of Engineering at the University of Saskatchewan in 1947, and took over his present position in 1953.

He is a member and past president of the Association of Professional Engineers of Saskatchewan.

Stewart Barkwell, M.E.I.C., will be a councillor of the Institute representing the Winnipeg Branch.

Mr. Barkwell is a graduate of the University of Manitoba, 1940, with a B.Sc. degree in electrical engineering.

He joined Canadian General Electric that year. He spent three years in industrial engineering at the G.E. armament plant, at Peterborough, Ont. After service with the RCEME he returned to CGE power transformer section in design engineering. He joined the apparatus sales department in Winnipeg in 1950 and in 1955 was appointed utilities sales engineer.

Mr. Barkwell has been active with the E.I.C., serving five years on the executive of the Winnipeg Branch Electrical Section and as chairman of the Section in 1956. In 1957 he was appointed to the Electrical Engineering Division of the Committee on Technical Operations.

T. H. Newton, M.E.I.C., will be a councillor of the Institute representing the Edmonton Branch. He is the immediate past-chairman of the Branch.

Mr. Newton is president of T. H. Newton Engineering Ltd., Edmonton, and a graduate in civil engineering from the university of Alberta, class of 1948.

Earlier he has worked with Main, Rensaa and Minsos, Edmonton, and with the Lee Oil and Natural Gas Company, Edmonton.

D. B. McKillop, M.E.I.C., councillor-elect for the Lakehead Branch, graduated from Queen's University in 1929.

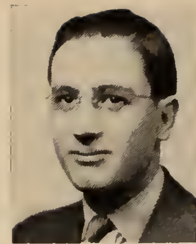
Since that time he has been employed in various capacities with the engineering department of Canadian National Railways.

He has recently been designated as Fort William representative on the Lakehead Harbour Commission soon to be established for the administration of a $7 million harbour facility being developed in conjunction with the St. Lawrence Seaway Development.

F. A. Orange, M.E.I.C., has been re-elected to a second term on the Council of the Institute, representing the Sudbury Branch. Mr. Orange is a design engineer with International Nickel Company at

D. B. McKillop, M.E.I.C.

F. A. Orange, M.E.I.C.



A. L. Furanna, M.E.I.C.

H. A. Gadd, M.E.I.C.

Copper Cliff. A biography appeared in the June 1957 issue of *The Engineering Journal* in connection with his first election to this office.

A. L. Furanna, M.E.I.C., has been elected a councillor of the Institute representing the London Branch.

Mr. Furanna is a graduate of Queen's University, 1939, with a degree of B.Sc. in electrical engineering. He has been associated with the Public Utilities Commission of London, Ontario since 1940, with the exception of three years of wartime leave. He was appointed chief engineer in 1949, which position he still holds, with that of assistant general manager.

Mr. Furanna's contribution to the work of the E.I.C. has been extensive: member of the executive, secretary-treasurer of the London Branch, vice-chairman, chairman, 1949, and chairman of the Profession Development Course.

Harry A. Gadd, M.E.I.C., will be the councillor representing the Port Hope Branch.

Mr. Gadd's engineering education was taken in England, including an engineering course at Rugby College of Technology and mechanical apprenticeship at British-Thompson-Houston Company, Rugby. Mr. Gadd came to the Canadian General Electric Company Limited in Toronto in 1923 and has been employed since that time by C.G.E.

Here his activities have included manufacturing, sales and engineering assignments. He is now manager, plastics engineering, C.G.E. plastics plant at Cobourg, Ont.

J. W. Dolphin, M.E.I.C., will be a councillor of the Institute representing the Kingston Branch. He is a former branch chairman.

J. W. Dolphin is head of the department of civil engineering, Royal Military College of Canada at Kingston. He is a graduate of the University of British Columbia, 1937, with a degree of B.A. Sc. in civil engineering.

Until the beginning of World War II he was employed by the Hydrographic Service. During the war he served the R.C.A.F. as a works officer and later as a navigator. When he returned to Canada in 1946 he was appointed lecturer at the University of Manitoba. Upon obtaining an M.Sc. degree from the University of Minnesota in 1948 he was named assistant professor of civil engineering at the University of Manitoba. In 1952 he joined the staff of R.M.C.

J. W. Millar, M.E.I.C., is the new councillor representing the Nipissing and Upper Ottawa Branch of the Institute.

Mr. Millar received the degree of B.A. from the University of B.C. in 1926 and that of B.A.Sc. in mechanical engineering from the same university in 1927. He had been associated with the Canadian Pacific Railway earlier, and after his graduation he worked until 1943 with C.P.R. in western Canada. From 1938 to 1943 he was general locomotive foreman at Vancouver. In 1943 he received the appointment of inspector of the Department of Railways of the Province of B.C. He later worked with the Pacific Great Eastern Railway. In 1948 he accepted his present position as chief mechanical engineer of the Ontario Northland Railway, North Bay, Ont.

W. G. Mitchell, M.E.I.C., chief design engineer, Canadian Bridge Division, Dominion Steel and Coal Corporation Limited, Walkerville, Ontario, has been elected to Council. He will represent the Border Cities Branch.

Mr. Mitchell received the bachelor degree in engineering from Trinity College, Dublin, Ireland in 1925. After several years in the London offices of Dorman Long and Company, he came to Canada in 1929 and joined Canadian Bridge as a draughtsman. Mr. Mitchell was chief draughtsman for the company for a number of years before being appointed to his present position.

He served the Border Cities Branch E.I.C. as chairman in 1956.

J. W. Dolphin, M.E.I.C.

J. W. Millar, M.E.I.C.

W. G. Mitchell, M.E.I.C.

T. H. Newton, M.E.I.C.

J. S. Waddington, M.E.I.C.

R. H. Self, M.E.I.C.

R. Harvey Self, M.E.I.C., will be a councillor representing the Toronto Branch for a three-year term. As comptroller of buildings and plants for the Board of Education of the City of Toronto, he is in charge of the architectural, engineering, and maintenance and custodial work of buildings of the Board, which he joined in 1955.

Mr. Self graduated from the University of Toronto in 1938 with a B.A.Sc. degree in civil engineering. He joined Ontario Hydro in 1940 after two years with various companies. Later, in 1943-1945 he was on loan to the Department of National Defence at Ottawa. In 1951 he was appointed generation construction engineer for the Ontario Hydro. In 1954 he was appointed the rehabilitation engineer for the St. Lawrence Seaway project in charge of the rehabilitation program on the Canadian side.

Mr. Self is the former chairman of the Toronto Branch of the Institute. He has also been a member of committees of the Institute.

J. S. Waddington, M.E.I.C., has been re-elected a councillor of the Institute to represent the Brockville Branch of the Institute. A biography of Mr. Waddington, division manager of Phillips Electrical Company, appeared in the June 1957 issue of *The Engineering Journal.* This was in connection with his first election as councillor.

A. D. Janitsch, M.E.I.C., has been elected a councillor of the Institute representing the Belleville Branch.

Mr. Janitsch is associated with Stephens-Adamson Mfg. Co., of Canada Ltd., Belleville, and is a former sales engineer of the company.

T. N. Davidson, M.E.I.C.

P. W. Gooch, M.E.I.C.

H. Chaput, M.E.I.C.

J. E. Hurtubise, M.E.I.C.

He is a mechanical engineering graduate of McGill, B.Eng., 1940. He worked first for Frost & Wood Co. Ltd., at Smiths Falls, Ont., before going to Belleville in 1942.

C. A. Crawford, JR.E.I.C., will represent the Chalk River Branch on the council of the Institute.

Mr. Crawford is a mechanical engineering graduate of University of British Columbia, B.A.Sc., 1951. He is a design engineer in the research engineering department of Atomic Energy of Canada Limited, Chalk River.

Hector Chaput, M.E.I.C., councillor-elect for the Ottawa Branch of the Institute, is equipment manager, Ottawa Transportation Commission.

He graduated from Queen's University in 1941, with a B.Sc. degree, after which he completed the C.G.E. test course. He served with the R.C.A.F. as a signals officer and pilot.

After service with the English Electric Company as a design engineer, he was appointed to the Ottawa Transportation Commission staff in 1949 as an electrical engineer.

Mr. Chaput is a past chairman of the Ottawa Branch of the Institute.

T. N. Davidson, M.E.I.C., of Montreal has been elected a councillor of the Institute representing the Montreal Branch. He has earlier served the Branch as a member of the executive, program chairman and as a member of various committees.

Mr. Davidson attended Queen's University where he received a B.Sc. degree in electrical engineering in 1941. Upon graduation he became associated with the Canadian National Carbon Company in Toronto, leaving in 1942 to enlist in the R.C.N. where he served as an electrical officer.

He joined Northern Electric Company in Montreal in 1945 and is presently assistant superintendent, plant engineering in the headquarters staff organization of the Company.

P. W. Gooch, M.E.I.C., will be a councillor of the Institute representing the Montreal Branch for a three-year term. Mr. Gooch was educated at Upper Canada College, the University of Toronto, faculty of applied science and engineering.

He graduated in 1936 with a degree of B.A.Sc. and in 1937 obtained the degree of M.A.Sc. His first engineering work was with DeHavilland Aircraft of Canada, after which he worked from 1939 to 1941 with DeHavilland Aircraft Company, Hatfield, England. From 1941 to 1947 he was with Canadian Vickers Ltd., Aircraft division and Canadair Ltd. in various positions. Since 1947 he has been with Canadian Vickers Ltd. industrial division and his present position is chief engineer. Mr. Gooch was chairman of the Montreal Branch of the Institute in 1958. He had served earlier on the Branch executive and as a member of Branch committees. He is also a member

V. Jepsen, M.E.I.C.

A. S. Mitchell, M.E.I.C.

of the Institute's Committee on Education.

Jacques E. Hurtubise, M.E.I.C., will be one of the representatives of the Montreal Branch on the Council of the Institute.

After obtaining a bachelor of arts degree, professor Hurtubise entered Ecole Polytechnique, Montreal where he graduated in 1934. He took a post-graduate course in soil mechanics at the Massachussets Institute of Technology in 1939, and subsequently obtained his M.Sc. degree at Ecole Polytechnique.

He was a member of the teaching staff at Ecole Polytechnique from 1934 to 1937, after which he was employed by consulting engineers. He returned to Ecole Polytechnique in 1939, first as assistant professor and subsequently as associate professor and professor of civil engineering.

Professor Hurtubise has been active as a consultant. Since 1953 he has been acting as a consultant for the St. Lawrence Seaway and the Joint Board of Engineers.

A. S. Mitchell, M.E.I.C., has been elected councillor representing the Eastern Townships Branch of the Institute.

Mr. Mitchell graduated from McGill University in 1938 with honours in metallurgical engineering. He has worked for the International Nickel Company at Copper Cliff and the Consolidated Mining & Smelting Company at Trail and Yellowknife, N.W.T. and in 1941 he joined the Union Screen Plate Company of Canada (Limited) at Lennoxville, Que., as a plating engineer. He is presently works manager of the Lennoxville, Que., plant.

Mr. Mitchell is a former treasurer of the Eastern Townships Branch.

Viggo Jepsen, M.E.I.C., will represent the St. Maurice Valley Branch of the council of the Institute for a two-year term.

Mr. Jepsen joined the staff of the Consolidated Paper Corporation in 1936 in Grand'Mere and remained there until 1955 when he was transferred to the head office in Montreal. He became assistant chief engineer, the position he now holds.

Mr. Jepsen was born and educated in Denmark. He came to Canada in 1928 and was connected with the preliminary investigations for hydro-electric developments of the Upper St. Maurice River and the construction of the Rapide Blanc dam and power house. In 1932 he worked for Jas. A. Ogilvy Ltd., Montreal as sales engineer and early in 1936 he transferred to the Canadian Copper Refiners Ltd. at Montreal East as design engineer.

He is a past councillor of the Institute representing the St. Maurice Valley Branch from 1947 to 1949.

Jean R. Menard, M.E.I.C., of Rimouski, Que., will be a councillor of the Institute representing the Lower St. Lawrence Branch. He is a past chairman and secretary of the Branch.

Mr. Menard is a graduate of Ecole Polytechnique, class of 1943. He was with the Canadian Army, serving overseas with the R.C.E.M.E. during the war. In 1946 he was discharged with the rank of captain.

He joined the Department of Public Works of Canada in the Quebec District. In 1948 he was transferred to Rimouski.

B. M. Monaghan, M.E.I.C., of Seven Islands, Que., is re-elected as councillor representing the North Shore Lower St. Lawrence Branch.

Mr. Monaghan was the first chairman and has been councillor of this Branch since it was inaugurated late in 1958. He is chief engineer of the Quebec North Shore and Labrador Railway.

He graduated from the University of Saskatchewan in civil engineering in 1946. He went to Seven Islands after a few years in surveying for the Department of Mines and Resources. He has been a location engineer for the railway and assistant chief engineer.

A. B. Sinclair, M.E.I.C., superintendent of the hydro-electric department of Price Brothers and Company, Kenogami, Que., has been re-elected a councillor of the Institute representing the Saguenay Branch.

Mr. Sinclair's biography was published in the June 1957 issue of the *Journal*, on the occasion of his earlier election to this office.

S. B. Cassidy, M.E.I.C., communications and electrical contractor will represent the Fredericton Branch on the Council of the Institute for a second term.

A biography of Mr. Cassidy appeared in the June 1957 issue of the *Journal*, on the occasion of his election to this office.

Charles Miller, M.E.I.C., will represent the Baie Comeau Branch on the Council of the Institute.

Mr. Miller is general manager of the Manicouagan Power Company, Baie Comeau, Que.

Graduating from Queen's University in 1930, he worked with the Saguenay Power Company Ltd. at Arvida, Que. He was assistant resident engineer for a project at Shipshaw, and he was chief engineer of Aluminum Power Company Limited in 1944.

In 1945 he went to the Beauharnois Light Heat and Power Co., Beauharnois. He joined the Ontario Paper Company in 1947, working on construction of a development of the Manicouagan Power Company. Later he worked as a consulting engineer in Montreal. He was the project manager of the Canadian British Aluminium Company Development at Baie Comeau, Que. He received his present appointment this year.

Mr. Miller is a former chairman of the Saguenay Branch of the Institute.

J. R. Menard, M.E.I.C.

N. F. Stewart, M.E.I.C.

M. C. Collins, M.E.I.C.

L. L. Spurr, M.E.I.C.

T. C. Higginson, M.E.I.C., president of Eastward Industries Ltd., Saint John, N.B., has been elected to represent the Saint John Branch on the Council of the Institute for the next two years.

Mr. Higginson is also Maritime manager of the Automatic Sprinkler Company of Canada, Limited, vice-president and managing director of Country Club Heights Ltd., and vice-president of the Saint John Board of Trade.

He was born and educated in Montreal. He joined the Automatic Sprinkler Company of Canada in 1928, becoming manager of their interests in the Maritimes in 1946. At the same time he formed Eastward Industries Ltd., and in 1952 he entered the housing and development field.

R. D. T. Wickwire, M.E.I.C., will represent the Halifax Branch on the Council of the Institute.

Mr. Wickwire is with the Nova Scotia Power Commission, Halifax. He is a mechanical engineering graduate of Nova Scotia Technical College class of 1946.

He has been serving on the Council of the Institute since last year, after having been active in the affairs of the Institute in Halifax.

Lawrence L. Spurr, M.E.I.C., will be a councillor of the Institute, representing the Amherst Branch.

Mr. Spurr is employed as the outside plant supervisor for the Canadian Broadcasting Corporation at their international shortwave transmitter in Sackville, N.B.

Mr. Spurr is a graduate of Acadia University and of the Nova Scotia Technical College, receiving a degree in civil engineering in 1947. He worked for the Nova Scotia Power Commission as a resident engineer until 1953, when his service with the C.B.C. started.

Norman F. Stewart, M.E.I.C., of the contracting firm, County Construction Co. Ltd., Charlottetown, will be on the council of the Institute, representing the Prince Edward Island Branch.

Mr. Stewart studied at Dalhousie University and at Nova Scotia Technical College, gaining his degree of bachelor of engineering, civil, in 1951.

He had earlier served in the Canadian Army (Active), 1940-1943; and in the R.C.A.F. (air crew) from 1943-1945. He served as a flight engineer, and was discharged with the rank of flying officer.

He is a past chairman of the Charlottetown Branch of the Institute, and a past president of the Association of Professional Engineers of P.E.I.

Marshall C. Collins, M.E.I.C., will represent the Corner Brook Branch on the Council of the Institute.

Mr. Collins attended Clarkson College of Technology at Potsdam, N.Y., graduating in mechanical engineering, B.Sc., 1928.

He went to Central America and worked for some years for the United Fruit Company. Returning, he worked on heavy construction jobs, and he joined International Paper Company in 1935 at the Philadelphia plant of a subsidiary. He transferred in 1936 to a newsprint mill at Corner Brook, Nfld. He remained at this plant when ownership passed to Bowaters Newfoundland Pulp and Paper Mills Ltd. He became assistant chief engineer, 1940, chief engineer, 1948. He is now resident development engineer, responsible for long term planning.

C. H. Conroy, M.E.I.C., will represent the St. John's, Nfld., branch on the Council of the Institute.

Mr. Conroy is chief engineer of the Department of Public Works (Nfld.).

He studied at St. Bonaventure's College, at St. Francis Xavier University, and at Massachusetts Institute of Technology. He received the degree in electrical engineering in 1928.

He worked as an electrical engineer for International Power and Paper Co. Ltd., at Corner Brook and Deer Lake, and in 1934 joined the Department of Public Works.

A. B. Sinclair, M.E.I.C.

Charles Miller, M.E.I.C.

S. B. Cassidy, M.E.I.C.

T. C. Higginson, M.E.I.C.

Personals

G. G. Meyerhof, M.E.I.C. (D.Sc. 1954, civil, London) has accepted an invitation by the Council of the Institution of Structural Engineers, London, England, to become the Institution's representative in Eastern Canada. He is head of the department of civil engineering, Nova Scotia Technical College, Halifax, N.S.

W. L. Wardrop, M.E.I.C. (B.Sc., elec. and civil, Manitoba, 1939, 1947) consulting engineer in Winnipeg has been elected chairman of the Winnipeg Branch of the Institute.

G. N. Martin, M.E.I.C. (B.A.Sc. C.E. Polytechnique 1934) of Dominion Bridge Company Limited has been appointed general Manager, boiler division, for the company with office at Lachine, Que.

W. G. Holt, M.E.I.C. (B.A.Sc., mech, Toronto 1936) has been appointed general manager, mechanical division for the Dominion Bridge Company Limited with office at Lachine, Que.

Thomas Dembie, M.E.I.C. (B.A.Sc., civil Toronto 1936) of Dominion Bridge Company Limited, has been appointed chief engineer in the Toronto plants of the company.

Duncan N. Smith, M.E.I.C. (B.Sc., civil, Indiana) has been appointed chief design engineer in the Toronto plants of Dominion Bridge Company Limited.

Malcolm D. H. Dickson, M.E.I.C. (M.A., civil, Cambridge, 1945) has been made vice president of Newton, Dickson and Associates Limited, Toronto.

Charles J. Ward, M.E.I.C. (B.Sc., ceramic, Saskatchewan, 1936) has been appointed assistant city building inspector for the city of Regina.

Philip T. Nash, M.E.I.C. (B.Sc., mech., Queen's 1945) of Trane Company of Canada Ltd., at Windsor, Ont, has been appointed special projects engineer with the company in Toronto.

John W. Forster, M.E.I.C. (B.Sc., civil, Alberta 1944; M.Sc., Iowa, 1947) has gone to Madison, Wisconsin, to work as a hydroelectric engineer for Hydro Electric Planners.

L. F. Bresolin, M.E.I.C. (B.A.Sc., chem., Toronto, 1950) is process engineer with the Cities Service Refining (Canada) Ltd. Trafalgar refinery, at Burlington, Ont.

Walter A. Byskal, M.E.I.C. (B.Sc., civil, Manitoba, 1953) is a project engineer for Mannix Co. Limited on railroad construction at Chisel Lake, Man.

John C. Robinson, M.E.I.C. (B.Sc., civil, Manitoba, 1956) is assistant regional construction engineer for Central Mortgage and Housing Corporation at Winnipeg.

C. D. McKinney, M.E.I.C. (B.Sc., elec., New Brunswick, 1944) of Shawinigan Water & Power Company has since 1958 worked as superintendent of the Joliette line and substation district, Joliette, Que.

Thomas A. Miller, M.E.I.C. (B.Eng. chem. McGill, 1944) has been transferred from Winnipeg, Man., to Montreal as senior engineer with the Trans Canada Airlines.

Edward N. Reed, M.E.I.C. has been appointed general manager, Parking Authority Of The City Of Ottawa.

Captain B. Yarymowich, M.E.I.C. (B.A.Sc. chem. Toronto, 1949) formerly with the Canadian Army Staff College in Kingston, Ont., has been posted to Montreal as staff captain (administration) at H.Q. Quebec Command.

W. L. Wardrop, M.E.I.C.

G. N. Martin, M.E.I.C.

James C. Leahey, M.E.I.C. (B.Eng. elec., McGill, 1935) is general manager of British Timken (Canada) Ltd., at Toronto, Ont.

H. A. Davis, M.E.I.C. (R.M.C., 1926 B.A., econ., Carleton) is employed in the Department of Finance, Ottawa in the analysis division of the Treasury Board (Defence and Works). He is concerned with construction activities of Departments of National Defence and Public Works.

John C. Robinson, M.E.I.C.

C. D. McKinney, M.E.I.C.

R. T. Bogle, M.E.I.C. (B.A.Sc., mech. British Columbia, 1940) of English Electric Canada has been appointed general manager for the company.

W. T. Bennett, M.E.I.C. (B.S., mech. Tufts, 1924) chief engineer with Canadian International Paper Company, has been appointed vice-president, engineering, for the company.

A. C. Abbott, M.E.I.C. (B.Sc. mech., B.Sc. elec., McGill, 1925, 1926) of The Shawinigan Water and Power Company and

M. D. H. Dickson, M.E.I.C.

Duncan N. Smith, M.E.I.C.

formerly vice-president, distribution, has been appointed vice-president with broader responsibilities in the Company.

W. R. Way, M.E.I.C. (B.Sc., elec., McGill, 1918) of The Shawinigan Water and Power Company, formerly vice-president and chief engineer, has been appointed vice-president with broader responsibilities in the Company's affairs.

Stanley T. Murray, M.E.I.C. (B.A.Sc. chem., Toronto, 1950) was recently appointed town engineer of Aurora, Ont.

Norman J. Allison, M.E.I.C. is assistant division manager with Interprovincial Pipe Line Co., western division, Edmonton, Alta.

Donald R. McLeod, M.E.I.C. (B.Sc. civil, Manitoba, 1947) has accepted the appointment of assistant deputy minister with the B.C. Department of Highways, Victoria, B.C.

Christopher R. MacPhail, M.E.I.C. (B.Sc., civil, Queen's, 1957) has been appointed resident engineer with Isumi, Arnott and Sugiyama, Saskatoon, Sask.

R. T. Bogle, M.E.I.C.

John W. Forster, M.E.I.C.

A. C. Abbott, M.E.I.C.

W. R. Way, M.E.I.C.

Thomas Dembie, M.E.I.C.

G. G. Meyerhof, M.E.I.C.

• PERSONALS

Gordon C. Wallace, M.E.I.C. (B.Eng. Liverpool, 1947) has accepted a post as senior design engineer, civil/structural, with Dorr-Oliver Inc., Stamford, Connecticut.

Kurt M. Lissel, M.E.I.C. (B.Sc., civil Saskatchewan, 1950) has been promoted to earth materials section engineer for P.F.R.A. on the South Saskatchewan River Development.

John A. B. Brenan, M.E.I.C. (B.Sc., elec., New Brunswick, 1949) of the New England Telephone and Telegraph Co., Portland, Maine, has been transferred to the company's branch in Boston, Mass.

D. B. Furlong, M.E.I.C. of Producers Pipelines Ltd., Regina, Sask., has been elected president and general manager of the company.

Important "links to"

big savings in lime recovery

• First, an Allis-Chalmers lime sludge kiln recovers lime at approximately half the cost of new lime. Second, the patented chain system for heat recovery in Allis-Chalmers kilns saves up to 40% of fuel costs. Third, the efficiency of this heat recovery system minimizes dust loss to a point that 10% extra capacity can be realized.

For complete information, call your C-A-C representative, or write Canadian Allis-Chalmers, P.O. Box 37, Montreal, P.Q.

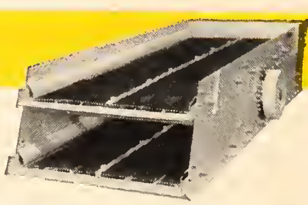
The carefully designed chain system in the feed end of an Allis-Chalmers kiln accelerates drying three ways:

1. Direct transfer of heat from chains to sludge.
2. Material is lifted into path of hot gases.
3. Flow of gases is directed over sludge bed under suspended chains.

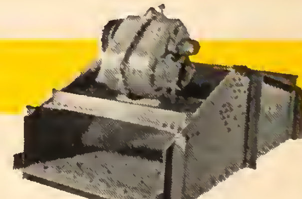
CANADIAN ALLIS-CHALMERS

58-PP-1

Low-Head is an Allis-Chalmers trademark.



Chip Screens — Accurately balanced mechanism assures removal of highest possible percentage of chips, dust, dirt. Chip travel is uniform, stratification rapid.



***Low-Head* pulp screens** handle high consistencies, save water and power. Maintenance is simple. Mechanism can be removed as a unit.

J. James Chilibeck, JR.E.I.C.

J. N. Schilizzi, JR.E.I.C., (mechanical, Paris 1950; London, 1951) project engineer, plant engineering department, at the Aluminum Company of Canada Ltd. Arvida works, is transferred to a post as technical advisor for the Middle East, for L'Aluminium Commercial, Zurich, Switzerland.

Leo I. Rotgaus, JR.E.I.C. (B.Eng., mech., McGill 1956) has joined Winer & Chazonoff Contractors Corp., Montreal, as project engineer.

P. Yachinec, JR.E.I.C. (B.Sc., elec., Alberta 1946) has been appointed general manager for Sinclair Radio Labs Limited, Toronto.

Pierre Thiviere, JR.E.I.C. (B.A.Sc., Polytechnique 1956; M.Sc., thermodynamics, Birmingham, 1958) has joined Canadian Pratt & Whitney Aircraft Company Ltd., Montreal, as an analytical engineer.

R. Marchand, JR.E.I.C. (B.Sc., elec., Manitoba, 1954) is now with the R.C.A.F., Air Materiel Command, engaged in telecommunications maintenance.

B. I. Shulakwych, S.E.I.C. (B.Sc., mech., Manitoba 1957) until recently with Dominion Engineering Company Ltd., Montreal, is doing post graduate work at the University of Toronto in business administration.

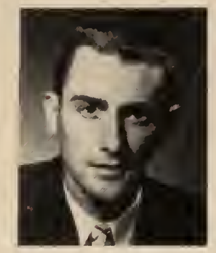
H. K. Beatty, S.E.I.C. (B.Eng., elec., Nova Scotia Technical College 1957) trainee engineer in Canadian General Electric Company Limited, has joined the outside plant engineering department of N. W. Engineering, Downsview, Ont.

R. E. Whitten, S.E.I.C. (B.Eng., civil, Nova Scotia Technical College 1958) is now employed by Foundation Company of Canada, Montreal.

Alfred N. Leung, S.E.I.C. (B.Sc., civil, Manitoba 1958) is doing post graduate studies in highway engineering at the University of Alberta, Edmonton.

K. M. Ferguson, S.E.I.C. (B.Sc. mech., New Brunswick, 1958) is now employed as assistant rubber plant manager with Pirelli Cables, Conduits Ltd., St. Johns, Que.

Alvin W. Kruger, S.E.I.C is a draftsman-computer with Ceepee Oil Co. Ltd., Regina.



A. C. Floyd, JR.E.I.C.

Max Deitch, JR.E.I.C.

• PERSONALS

H. W. Walford, S.E.I.C. (B.Sc., civil, New Brunswick 1958) is doing post-graduate work at the National College for Heating, Ventilating, Refrigeration and Fan Engineering in London, England, under an Athlone Fellowship.

M. P. Paidoussis, S.E.I.C. (B.Eng., mech., McGill 1958) is with General Electric Co. of England, Ltd., Erith, Kent, under a nuclear engineering overseas training fellowship.

F/O David Greenfield, S.E.I.C. (B.A.Sc., civil, Toronto 1958) is at present taking the R.C.A.F. maritime navigation course at Summerside, P.E.I.

James Broughall, S.E.I.C. (B.Sc., chem., Queen's 1958) is a junior chemist with the Canadian International Paper Company, at Gatineau, Que.

Colby Burns, S.E.I.C. (B.Eng., civil, Saskatchewan 1958) is with the City of Regina, Sask., as assistant roadways engineer.

C. R. W. MacPhail, S.E.I.C. (B.Sc., civil, Queen's 1957) has become a field engineer with Izumi, Arnott and Sugiyama, Regina, Sask.

Robert Desrosiers, S.E.I.C. (B.A.Sc., civil, Laval 1957) is with Laminex Products Limited, Quebec, Que.

John H. Morrish, JR.E.I.C. (B.A.Sc., civil, Toronto, 1952) formerly of Montreal has been appointed division engineer with the Canadian Pacific Railways, Schreiber Division, Schreiber, Ont

Max Deitch, JR.E.I.C. (B.Eng. elec., McGill, 1952) has recently been appointed product manager, high tension switchgear, of Canadian Line Materials Ltd., Toronto, Ont.

P. Vink, JR.E.I.C. (B.Sc., civil, London, England 1955) is employed by De Leuw Cather and Company Ltd. in Toronto, as a junior engineer.

Benedict Chan, S.E.I.C. (B.Sc., mech., Manitoba 1957) of Otis Elevator Co., New York, has been appointed an engineer trainee in the executive office of the company.

Clifford H. Laurence, S.E.I.C. was transferred early this year by the Shawinigan Water & Power Company from the production plant department Shawinigan, Que., to the electrical repair department, Three Rivers.

Norman J. Antaya, S.E.I.C. (B.Eng., elec., Detroit 1958) has joined the Saskatchewan Power Corporation, Regina, as assistant distribution engineer.

M. J. Minor, S.E.I.C. (B.Sc., elec., Manitoba 1958) is plant engineer with the Hydro Electric Commission of Ontario, at Seven Sister Falls generating station.

R. D. Thibodeau, S.E.I.C. (B.A.Sc., chem., Toronto 1958) is at Assumption University of Windsor, where he is studying towards a masters degree.

Benoit St. Laurent, S.E.I.C. (B.Sc., civil, Laval 1958) is with the Department of Highways of Quebec.

NEWS OF THE BRANCHES

Activities of the Fifty Branches of the Institute and abstracts of the papers presented at their meetings

BAIE COMEAU

G. W. Scott, M.E.I.C., *Correspondent*

WINTER NAVIGATION was discussed by Dr. Huet Massue, M.E.I.C. on March 25. Dr. Massue is general manager of the lower St. Lawrence and Gulf Developments Association.

Dr. Massue's observations and analysis gave a clear indication of the enormous industrial developments to be expected along the north shore of the lower St. Lawrence during the next ten years particularly east of the Bersimis River, where the Hydro Electric and mineral resources of this area have yet to be fully exploited. A final conclusion of Dr. Massue's analysis was the necessity for all-year-round navigation in the lower St. Lawrence.

CAPE BRETON

H. M. Aspinall, M.E.I.C., *Correspondent*

RADIO-ISOTOPES—Some of their Industrial Applications was the subject discussed by Frank L. Martin on March 31st, 1959. Mr. Martin is research metallurgist, Dominion Iron & Steel Company.

Mr. Martin discussed the use of radioactive tracers in the study of water flow and gas flow; and in some industries. Some examples were the examination of a sheet metal for a thickness uniformity, study of origin of non-metallic inclusions in steel products.

The great interest of the audience of thirty-five members and guests was demonstrated by the brisk questioning following the talk.

CENTRAL, B.C.

A. F. Joplin, M.E.I.C., *Correspondent*

DR. K. F. TUPPER was guest at a dinner meeting with Mrs. Tupper and with Dr. and Mrs. Garnet T. Page on March 19. Dr. Tupper talked about the work of the E.I.C. concluding with interesting remarks on his and Dr. Page's visit to Russia. Dr. Tupper was present at the dedication of a memorial plaque in honour of pioneer engineers and especially F. W. Groves who from 1908 until 1948 was primarily responsible for the design and maintenance of irrigation work in the vicinity of Kelowna. This plaque is located on the shores of the Okanagan Lake near the Kelowna Memorial Museum.

CORNER BROOK

H. A. Hinton, JR.E.I.C., *Correspondent*

LABOUR UNIONS were the subject of a paper by F. J. Fitzpatrick on March 12. Mr. Fitzpatrick is solicitor and assistant secretary, Bowaters Newfoundland Pulp & Paper Mills, Ltd. He outlined the legal relationships between employers and unions as well as some of the regulations governing them individually.

Mr. Fitzpatrick thinks it is time for some revisions of our labour legislation perhaps along the lines of the so called "Right to Work" laws of some states in the U.S.A. A long lively question and answer period followed, centring chiefly around the current loggers' labour dispute in Newfoundland.

EDMONTON

I. G. Finlay, M.E.I.C., *Correspondent*

DR. R. E. FOLINSBEE, Head, Department of Geology, University of Alberta gave a talk titled "Our Fuelish Hopes" on February 17. In a general review of the fuel situation in Alberta, Dr. Folinsbee pointed out that new exploration techniques had accounted for a marked increase in reserves of oil and gas in the last ten years. However, these reserves are minute as compared to those in the Middle East and this in conjunction with the ease of production in the Middle East areas make future for the industries in Alberta somewhat cloudy.

The merits of additional pipeline construction would appear to be doubtful under the circumstances he said and in view of the fact that discovery of new oil or gas fields seems to be reaching a maximum with present techniques.

DR. JOHN T. DEUTSCH, Head of the Department of Political Economy of the University of British Columbia, was the speaker on March 13. His subject was the role of the engineer in Canadian development.

E.I.C. PRESIDENT K. F. TUPPER, visited the branch on March 30, when he reviewed the affairs of the Institute and announced the Western Technical Conference to be held in Banff next October. Dr. Tupper told of his impression formed in his travels across Canada of the vast potential of natural resources awaiting development. He was accompanied by general secretary Garnet Page, Mrs. Tupper and Mrs. Page.

Dr. Page presented an E.I.C. prize in engineering to Robert K. Teshima fourth year student in engineering physics at the University of Alberta.

The engineers wives club of Edmonton and the wives of the executive of the Edmonton Branch entertained Mrs. Tupper and Mrs. Page at cocktails and dinner on March 30.

FREDERICTON

Lyle W. Smith, JR.E.I.C., *Correspondent*

ROBERT LYNCH, speaking at a meeting of March 16, pointed out some of the changes which have taken place during his twelve years with the Department of Public Works of New Brunswick highway division. Modern highway practice was being used in New Brunswick. Using a cost comparison, over ten years, Mr. Lynch said that although the cost had gone up considerably the standard of highway has risen even more.

HAMILTON

C. A. McCurdy, JR.E.I.C., *Correspondent*

A. E. BERRY, M.E.I.C., General Manager and Chief Engineer of The Ontario Water Commission spoke on February 19, about the program of O.W.R.C. Following a buffet luncheon, Dr. Berry opened his remarks by stating the scope of the commission. The commission though given very wide powers in 1957 is reluctant to use the more extreme powers.

Some of these powers are, action against community if it is not providing satisfactory water service to its consumers, aiding neighbouring municipalities to work jointly to solve mutual problems of water resources and action to prevent pollution of Ontario's waters. The commission will place in use in 1959 its new laboratory.

LAKEHEAD

G. O. Hanson, JR.E.I.C., *Correspondent*

NOEL DANT spoke at the meeting of March 31, on the subject of the direction the future expansion of the Lakehead will take, due to the influence of the Seaway. Mr. Dant is director of the Lakehead planning board. His interesting and informative talk was heard by about forty members of the branch as he outlined some of the problems confronting this area. There are many opinions as to the effect of the seaway, and Mr. Dant feels that a few years of operation are needed before the full potential could be assessed. One opinion is that the first ten years of the seaway will belong to eastern Canada while the second decade of operation will bring major changes to the Lakehead area. A lively discussion period followed Mr. Dant's talk.

LETHBRIDGE

G. G. Campbell, M.E.I.C., *Correspondent*

PLASTICS was the subject discussed on February 20, by Jack Burkell, process engineer supervisor, of C-I-L, Edmonton.

The location of the polythene plant in Edmonton was mainly due to the gas field supply, and the properties of the gas. The main problem in production of polythene is that temperatures are critical, and pressures of 30,000 p.s.i. are required.

MONTREAL, Junior Branch

R. D. Hatfield, S.E.I.C., *Correspondent*

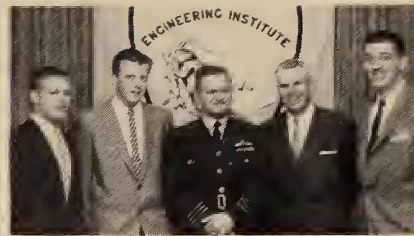
STUDENTS NIGHT was on January 28, with four speakers, two from Ecole Polytechnique and two students from McGill University. A successful turnout of over 100 students was the result. Two of the papers were given in French and two in English, the topics being directly concerned with the students' studies and summer employment.

Five of the Montreal Student Guidance Committee members: Howard Tinkler, Florian Leroux, Herb Moore, Don Young and Jack Hahn.

NIPISSING AND UPPER OTTAWA

D. J. Thornton, S.E.I.C., *Correspondent*

WING COMMANDER HAROLD J. M. LONDEAU spoke at the meeting of March 11 on the subject "The Engineer in the R.C.A.F." The speaker is from R.C.A.F. Headquarters, Ottawa. As in previous years the branch was host to the Grade 13 students from North Bay, Sturgeon Falls and Temiskaming who intend to follow an engineering career. The dinner meeting was attended by about 100 members and their student guests. Wing Commander Londeau discussed the various requirements of an engineer in the Air Force and the fields in which today's engineer might expect to be working in the future. An Air Force film was shown after which there was an informal discussion.



Don Farnsworth, Erlend Skolseg, Speaker Wing Cmdr. H. J. M. Londeau, J. S. Cooper, chairman, and Ron Granger, at meeting of Nipissing and Upper Ottawa Branch.

OTTAWA

D. R. Grimes, JR.E.I.C., *Correspondent*

A SUMMARY OF MEETINGS since January is as follows:

50TH ANNIVERSARY DINNER JANUARY 17. Approximately 170 people attended the dinner celebrating the 50 years of the Ottawa Branch of the Institute. At the Anniversary Dinner greetings to the Branch were given by Hon. Howard Green, Minister of Public Works and His Worship Mayor George Nelms. There were anniversary comments from some senior members of the Branch and greetings to the branch from Dr. K. F. Tupper, President of the Institute. The branch was founded in January 1909 when thirty-five persons attended a meeting which elected Col. W. P. Anderson as chairman. Since that first meeting membership of the branch has climbed to more than 1,000, including some 300 student members.

LUNCHEON MEETING February 5th.

At this meeting Col. W. A. Capelle, M.E.I.C. spoke about the Canadian Army in Gaza. He said Israeli and Arab border incidents have been practically eliminated by the United Nations Emergency Force guarding the Gaza strip. Col. Capelle gave highlights of his recent year's duty with Canada's contribution of 900 men at the UNEF camp at Rafah in the Sinai area.

PAPERS NIGHT—Junior Section,

The Junior Section of the branch arranged Papers Night on February 27, at which seven papers were given and at which three judges had the difficult problem of selecting winners who were as follows:

IN THE JUNIOR SECTION,

First—K. Burn of National Research Council for his paper Techniques of Measuring Moisture Content of Soils by Using Radioactive Materials.

Second—F. Marchand of Marchand Electric Company for his paper "Automatic Controls in Machines".

STUDENTS SECTION

First—J. Therrien of Ottawa University who gave a slide illustrated talk on "Tellorometer".

Second—P. Lemay of Ottawa University who spoke on "Some Aspects of Application of Nuclear Magnetic Resonance".

VISIT TO BUILDING RESEARCH CENTRE February 19. Sixty members took part in a tour of the Building Research Centre National Research Council on February 19. To start the tour R. F. Legget, Director of the Division spoke on the broad field of building research in Canada, stressing that portion of the Division's work which was being carried out in various parts of the country. The tour included visits to laboratories engaged in work on building materials (concrete, masonry and paint), soil mechanics and snow and ice. In addition visits were paid to the acoustics and structures laboratories as well as to laboratories engaged in work on thermal insulation and vapour permeability.

LUNCHEON MEETING, March 5.

Russell Smart, Barrister, Ottawa spoke on Patents of Invention. Patent protection is vital to both inventor and manufacturer said Mr. Smart. Patents form a medium of exchange in industry and result in a freer exchange of technieal knowledge between different members.

PETERBOROUGH

J. G. Hooper, M.E.I.C., *Correspondent*

BUILDING IN THE FAR NORTH OF CANADA was discussed by Robert F. Legget, on March 12, 1959. Dr. Legget is Director of Building Research, National Research Council. His audience numbered one hundred and forty members and guests. If Canadians move into that vast area to mine or drill for oil they will have to learn how to adapt themselves to it Mr. Legget said.

The new site for Aklavik, is an example of a planned northern Canadian settlement. Buildings are constructed on wooden piles. The piles are not driven into the ground; holes are bored by steam, the posts are inserted, and the perma-frost is allowed to freeze around them.

ST. MAURICE VALLEY

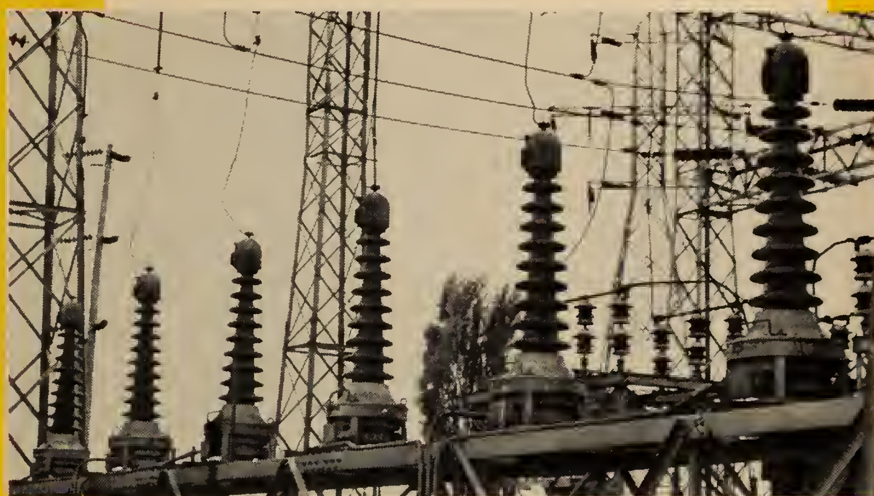
E. A. Love, JR.E.I.C., *Correspondent*

A SUMMARY OF BRANCH MEETINGS is as follows:

SATELLITES. A talk by D. L. Mordell, Dean of Engineering, McGill University, December 2, 1958.

Dean Mordell outlined the possibilities of limited space travel by human beings within the next 15 years and possibly sooner.

HOME BUILDING, some Do's and Dont's, were given by Bert Prime, editor of



"Canadian Builder' on January 15. Mr. Prime's talk dealt primarily with the present trend in house building which he has observed across Canada. Mr. Prime suggested that prospective home builders should investigate the various aspects of home building very closely before they become financially involved and he noted the excellent advice that was available to them from the C.M.H.A. A short question period followed.

DINNER MEETING A visit of the president to the branch was marked on February 26, 1959 with a cocktail party and dinner. Mr. Tupper was accompanied by general secretary Garnet Page.

TORONTO

D. R. Abbey, M.E.I.C., *Correspondent*

TWO MEETINGS were held by the Toronto Branch, March 5 and March 19 speakers were E. B. Danard, Babcock-Wilcox and Goldie McCullock Limited, Toronto and Dr. Lapp, project engineer, missile division, de Havilland Aircraft of Canada Limited, Downsview, Ont.

Mr. Danard said that the engineer is always searching for better and more efficient ways to accomplish results. In the thermal power field, this may be done by means of increased cycle efficiency. He outlined the advances in steam generation technique ending with an outline of a plant generating at 4500 p.s.i.

Dr. Lapp commented that Canada entered the air age five years after the Wright Brothers flew at Kitty Hawk, but by present indications a longer wait will occur before Canada enters the space age. The speaker showed how space flight is calling on the ingenuity of all engineering disciplines. For example missilry, is one of the activities which generated the systems engineer. Dr. Lapp reviewed the situation with respect to rocket fuels currently used, possible future trends, and the exotic fuels still on the horizon.

CORRECTION. In a report of the Branch annual meeting, March issue, page 108, attendance was given as 32, whereas the correct attendance figure was 324.

VANCOUVER

J. J. Kaller, M.E.I.C., *Correspondent*

GORDON W. SPRATT, M.E.I.C., operations manager with MacDonald & MacDonald Ltd., inspecting and testing engineers spoke on Concrete Admixtures on January 22. Admixtures are used in producing concrete in difficult or specific conditions. In Vancouver less than 20% of total production of concrete is without admixtures. Properties of these chemicals were given and results to be expected from using particular admixtures were described.

PROFESSIONAL DEVELOPMENT COURSE

The Program is as follows: February 4—Principles of Management, February 11—Business Forecasts and Planning, February 18—Organization Problems, February 25—Industrial Engineering—Tools and Applications, March 4—Business Accounting and Finance, March 11—Corporate Investment Policy, March 18—Management and Labour, March 25—Management Consulting.

YUKON

E. W. King, M.E.I.C., *Correspondent*

SPECIAL GUEST at the meeting of March 26, 1959 was Dr. Kenneth F. Tupper president of the Engineering Institute, who spoke in detail of the international affiliations of the E.I.C. He also spoke in some detail of the trip to Russia taken by himself and Dr. Page in late 1958.

This was a dinner meeting with approximately 70 present. At the conclusion of the meeting a film was shown which demonstrates reconnaissance of the road from Dawson City to Fort McPherson which was carried out in 1958 by Federal Department of Public Works engineers.

LIBRARY NOTES

ADDITIONS TO THE INSTITUTE LIBRARY • REVIEWS • BOOK NOTES • STANDARDS

BOOK NOTES

Prepared by the Library, The Engineering Institute of Canada

*Book notes marked by an asterisk have been provided through the courtesy of the Engineering Societies Library in New York.

THE CHEMICAL KINETICS OF ENZYME REACTION

A general account of the subject, bringing together some of the main results and concepts developed on the physical side. The first eight chapters deal with general principles, basic kinetic laws, mechanisms, hydrostatic pressure etc. The remaining chapters cover individual enzyme systems. The book will be primarily of interest to those in the biological and physical sciences. The author is Professor of Chemistry at the University of Ottawa. (K. J. Laidler. Toronto, Oxford, 1958. 419p., $9.00.)

AN INTRODUCTION TO FLUID DYNAMICS

Intended primarily for students in mathematics and theoretical physics, this volume concentrates on fundamental dynamical principles and their applications to fluid flow. The topics covered include the theory and properties of the perfect fluid, Bernoulli's theorem, irrotational flow, velocity potential, forces on a body in a uniform stream, discontinuous flow, design of wing profiles, slender-body theory, etc. (G. Temple. Toronto, Oxford, 1958. 195p., $3.75.)

ELECTRONIC AVIGATION ENGINEERING

Avigation is "the science or art of conducting aircraft in flight from one point to another". Electronic avigation engineering covers radio and electronic aids to aviation. The systems are grouped in four classes, according to use in long-distance flights, short flights, approach and landing zone, and the airport zone. The equipment described includes: direction finders, consol, navaglobe-navarho, decca, delrac, radux, loran, radar, inertial systems, distance measurement, tacan, fixed-beam and radar low-approach systems, ground magnetic loops, etc. Many references are included for further reading. (P.C. Sandretto. New York, International Telephone and Telegraph Corp., 1958. 722p., $9.50.)

***ELECTRIC LIFTS, 4TH ED.**

Various aspects of design and installation of elevators are covered, including drives, roping systems, motors, variable voltage equipment, brakes, gearing, cars and guides, gates and doors, floor leveling, and control systems. In this edition new illustrations are given for more recent equipment and the text has been rewritten to conform with recent practice. (R. S. Phillips. Toronto, Pitman, 1958. 411p., 63/-.)

***SOLID PROPELLANT ROCKETS; AN INTRODUCTORY HANDBOOK: SECOND STAGE**

This second edition contains additional chapters covering new developments and recently declassified information, including new applications, propellant technology, hybrid rockets, and safety. A particular feature of the volume is the extensive bibliography of over 800 items dealing with solid propellants. (A. J. Zaehringer. Wyandotte, Mich., American Rocket Co., 1958. 306p., $8.00.)

THE PHYSICAL CHEMISTRY OF STEELMAKING

The proceedings of a conference held at M.I.T. in 1956, summarizing present knowledge in the field, and including the results of recent fundamental research and its application to current problems. The subjects covered at the sessions were: liquid metals and properties of solutes in liquid iron and steel; equilibria of reactions in liquid iron and steel; behaviour of metal oxides and of components of iron and steelmaking slags; slag-metal equilibria in blast-furnace and steel-making furnace systems; kinetics and slag-metal reactions; reaction rates in iron and steelmaking processes; solidification of castings and ingots. (J. F. Elliott, ed. New York, Wiley, 1958. 257p., $15.00.)

***FUNDAMENTALS OF ADVANCED MISSILES**

Gives the basic principles determining the performance of guided missiles, ballistic missiles, and space vehicles. Discussed are kinematics of flight, application of fluid mechanics to aerodynamics and propulsion, dynamics, properties of microwaves, application of infrared radiation, radar, guidance, and guided-missile systems. Information is presented from the point of view of theory, experimentation, and typical examples encountered in practice, rather than detailed design of missile types. (R. B. Dow. New York, Wiley, 1958. 567p., $11.75.)

***INDUSTRIAL HYGIENE AND TOXICOLOGY, VOL. 1: GENERAL PRINCIPLES, 2ND ED.**

An extensive treatise on industrial health. Revisions in this volume cover such areas as noise and its environmental implications, heat and its control, ionizing radiation exposures and the inhalation and ingestion of radioactive gases and aerosols, human engineering and industrial safety, industrial sanitation, air pollution, and illumination. (F. A. Patty, ed. New York, Interscience, 1958. 830p., $17.50.)

EDITORIAL NOTES FROM CONCRETE AND CONSTRUCTIONAL ENGINEERING

The main purpose behind these essays is to encourage engineers and scientists to explore beyond technical problems, and to point out the pitfalls besetting those who have not developed an inquiring and logical mind. The essays are concerned particularly with civil and structural engineering, but can be read with profit by most engineers. (H. L. Childe. London, Concrete Publications, 1958. 83p., $1.75.)

***REINFORCED CONCRETE FUNDAMENTALS**

Emphasis is placed on the physical behaviour of reinforced concrete members and the approved ultimate strength theory. Included are enough details of ultimate strength design for practical use, information on the American Concrete Institute Building Code requirements, and a comparison between ultimate strength and working stress analysis. Additional features of the book are a thorough treatment of slabs, working stress methods in detail, and an emphasis on anchorage length as well as moment in its coverage of bend points for steel. (P.M. Ferguson. New York, Wiley, 1958. 604p., $11.50.)

OUR FOREST HERITAGE

The first part of this interesting book is the story of the development of forestry and recreation in New Hamshire, where an intelligent conservation programme has been pursued for the last sixty years. The author's personal reminiscences in the second part cover woods operations in New Hampshire and Canada in the early part of this century. (W. R. Brown. Concord, New Hampshire Historical Society, 1958. 341p., $5.00.)

***NATURAL AERODYNAMICS**

A study of the physical principles and processes of fluid motion. Topics discussed include vorticity, viscosity, boundary layers, wakes and turbulence, buoyant convection, plumes and jets, air waves, and clouds and fallouts. Much of the material contained is of interest to the person working with air pollution problems. (R. S. Scorer. New York, Pergamon, 1958. 312p., $9.00.)

°LINEAR PROGRAMMING AND ASSOCIATED TECHNIQUES

A bibliography containing over one thousand items up to the year 1957. Particular emphasis is placed on applied fields such as production scheduling and inventory control, while certain parallel fields as game theory and linear inequalities are somewhat restricted. Abstracts or annotations are given for most of the items listed. (Vera Riley and S. I. Gass. Baltimore, Johns Hopkins University, for Operations Research Office, 1958. 613p., $6.00.)

°COATED ABRASIVES—MODERN TOOL OF INDUSTRY

Describes how abrasives are manufactured and the various factors involved in their effective use in the metalworking, woodworking, glass and plastics industries, and in applications ranging from heavy material removal to fine polishing. Many recent advances are covered including new automatic machinery and various applications such as strip scouring, pre-plate finishing, and contour finishing. (Coated Abrasives Manufacturer's Institute. Toronto, McGraw-Hill, 1958. 426 p., $9.80.)

°DESIGN AND CONSTRUCTION OF ASPHALT PAVEMENTS

Discusses such aspects as types of asphalt pavements, petroleum asphalts, mineral aggregates, design and construction of hot-mix asphaltic concrete pavements, asphalt pavements and bases employing liquid asphalts, surface treatment and seal coats, and reconstruction of old pavements. A feature of the volume is the appendix on laboratory-mix design of asphaltic concrete. (J. Rogers Martin and H. A. Wallace. Toronto, McGraw-Hill, 1958. 305p., $13.25.)

°ENGINEERING VIBRATIONS, WITH APPLICATIONS TO STRUCTURES AND MACHINERY

Introduction to the analysis of technical vibrations of linear and nonlinear systems with particular emphasis on the transient state of motion. Classical analytical methods are used where feasible as are approximate methods, including the phase-plane graphical method for the solution of transient problems and the Ritz averaging method for solving steady state nonlinear problems. Attention is given to the physical aspects of vibration problems, and nonlinear relationships are introduced where possible. (L.S. Jacobsen and R. S. Ayre. Toronto, McGraw-Hill, 1958. 564p., $12.00.)

°GLASS ENGINEERING HANDBOOK, 2ND ED.

A handbook on the composition, manufacture, properties, and applications of glass as an engineering material. In addition to coverage of the more commonly known glasses, there is information on photo-sensitive glass, glass-ceramics, electrically conducting glass, glass in electronic circuit components, and glass-reinforced plastics. Specific aspects given treatment are stress testing and strength determination, radiation conductivity emissivity, and high energy radiation effects. An extensive section is devoted to fibrous glass. (E. B. Shand. Toronto, McGraw-Hill, 1958. 484p., $12.00.)

°NONLINEAR PROBLEMS IN RANDOM THEORY

In the first comprehensive study of the application of random theory to nonlinear processes, a top-rank mathematical analyst examines the role of nonlinear processes in physics, mathematics, electrical engineering, physiology, and communication theory. He demonstrates how random processes — in space as well as in time — enter into the study of statistical mechanisms, a useful approach to new research in gas and plasma theory, for instance. (N. Wiener. New York, Wiley, 1958. 131p., $4.50.)

°ELEMENTARY MATHEMATICAL PROGRAMMING

Intended as an intermediate approach, the subject is presented in relatively nonmathematical terms. Following a general treatment of the distribution, simplex, and approximation methods, the complete solution and analysis of two typical industrial problems is presented: a manufacturing and a blending problem. The applicability of high-speed computers for solving problems is then discussed, and available computer programs are indicated which will accomplish the solution of mathematical programming problems. The remainder of the book illustrates the details of various problems solved by programming. (R. W. Metzger. New York, Wiley, 1958. 246p., $5.95.)

°ESTIMATING CONSTRUCTION COSTS, 2ND ED.

A practical text outlining various methods of preparing estimates. This edition has been expanded to include more information on bonds, insurance, and depreciation of equipment, as well as new information on stone masonry, house carpentry, interior finish, millwork, wallboard, lathing, plastering, painting, glass, glazing, roofing, plumbing, and electrical wiring. Costs data has been brought up to date throughout. (R. L. Peurifoy. Toronto, McGraw-Hill, 1958. 446p., $11.20.)

FBI REGISTER OF BRITISH MANUFACTURES, 1959

The classified Buyers' Guide lists the products and services of over 7,500 members of the Federation of British Industries under some 5,400 headings. Other sections give the addresses of companies, trade associations, trade marks, and proprietary names. (F.B.I. London, Iliffe, 1959. 1139p., 42/-.)

ASRE AIR CONDITIONING-REFRIGERATING DATA BOOK. VOL. 1: REFRIGERATION APPLICATIONS

The first of a projected four volume series of Data Books to be issued during the next three years, to cover all phases of the industry. This volume deals with the use of refrigeration in the storage, processing, handling and distribution of foods and beverages; low temperature applications in the fields of medicine, metallurgy and cryogenics; industrial applications including ice manufacture, skating rinks, concrete dams, foundations, liquid cooling and photography; refrigeration piping systems.

These volumes grow out of the ASRE Applications and Design Data Books. and they will be revised in rotation. (P. B. Christensen, ed. New York, American Society of Refrigerating Engineers, 1958. irreg. paging, $12.00.)

°GROWTH AND PERFECTION OF CRYSTALS

Reports of an international conference held at Cooperstown, New York in 1958, on crystal phenomena, polymer crystallization, and crystallization of simpler molecules. Organic, inorganic, and polymeric substances are investigated from the standpoint of crystal perfection, formation and structure of whiskers, presence of dislocations, and the mechanism of crystal growth from the melt, solution, and vapor. Several papers emphasize the differences and similarities between polymer and ordinary crystallization. A special feature is the bringing together of literature on whisker phenomena dating back to 1574. (Ed. by R. H. Doremus and others. New York, Wiley, 1958. 609p. $12.50.)

°MAGNETIC AMPLIFIERS: THEORY AND APPLICATION

The fundamentals of magnetism, electromagnetism, and electromagnetic induction are discussed in the preliminary chapters. This is followed by a description of the theory, operation, and application of saturable reactors and magnetic amplifiers in both feedback and non-feedback cases. Present commercial and industrial uses are presented in detail as are the advantages and disadvantages of the magnetic amplifier. (S. Platt. Englewood Cliffs, N.J.. Prentice-Hall, 1958. 238p., $7.00.)

°FUNDAMENTALS OF DIGITAL COMPUTERS

Following a discussion of fundamentals the author explains computer arithmetic applications, binary counting, and special codes; computer circuitry, including the various gates and the circuitry utilizing them, various storage systems found in modern computers; computer programming, including specific examples of programming applied to commercial units; comprehensive descriptions of representative commercial computers. A concluding section deals with servicing and maintenance factors. (M. Mandl. Englewood Cliffs, N.J., Prentice-Hall, 1958. 297p., $9.00.) *(Continued on Page 184)*

E.I.C. CERTIFICATE OF ADVERTISING MERIT

The fifty members of the Institute who were asked to judge — from the viewpoints of ACCURACY — INFORMATION — ATTRACTION — the advertisements in the February issue of the *Journal*, voted strongly in favour of the four-colour insert advertising cable manufactured by the Canada Wire and Cable Company Limited.

Each month, fifty members are being asked to scrutinize the current issue of the *Journal* and to select the advertisement which they consider to have outstanding merit. This method of judging the advertisements is part of a continuous effort to improve the content of *THE ENGINEERING JOURNAL* and to assist the advertisers in presenting their advertising messages in a manner pleasing to the readers.

The advertisement in the February issue which received the second highest number of votes was a double page spread (on pages 12 and 13) released by General Electric Company Limited of England. This advertisement is headed "The Power of Johannesburg".

Front

Back

Winning Canada Wire and Cable Company Insert

This four-colour insert appeared on pages 97 and 98 of the February 1959 issue. It was voted best in the issue—from the viewpoints of ACCURACY — INFORMATION — ATTRACTION — by a large majority of the jury made up of fifty members of the Institute. The advertisement was prepared by Walsh Advertising Company Limited, Toronto.

• BRIEFS

New African Companies — The incorporation of two new companies, Ghana Aluminium Products Limited and Nigeria Aluminium Products Limited is announced by Aluminium Limited of Canada.

Saltbath Furnace — Canadian General Electric announces that the new Ajax submerged-electrode saltbath furnace was to be demonstrated at the National Industrial Production Show of Canada, Toronto, May 4-8.

C-I-L Today — This was the name of the film which was the feature of the annual staff functions of the company in Montreal and Toronto last January; the theme: "Time for testing our competence." Members of staff had the opportunity of meeting the new president, Peter C. Allen.

New Catalogue — Now available from Air Reduction Canada Limited and dealers from coast to coast is a fully illustrated 60 page "General Welding, Cutting and Accessories Catalogue." Copies available from the company, 905 Hodge Street, Montreal 9.

Brick Floors — A 4-page bulletin—"The Embeco Method for Setting Floor Brick", published by The Master Builders Company, Ltd. describes brick floor installation with corrosion-resistant and wear-resistant joints. For free copy write for Bulletin E-27B, The Master Builders Company, Ltd., Toronto 9, Ont.

ASEA Journal — Volume 31, 1958 features an article about a stacker crane with a lifting height of 21 ft., capacity of 2 tons. It has proved to be invaluable in the handling of goods in stores and warehouses.

• LIBRARY NOTES

(Continued from page 149)

°OPERATIONS RESEARCH FOR INDUSTRIAL MANAGEMENT

Presents recently developed operations research techniques used for executive decision making with emphasis on simulation studies. The application of operations research methods is considered in relation to financial allocation, transportation problems, inventory control and production setups. Descriptions are also given for game theory, linear programming, flow techniques, and matrix algebra. The use of electronic computers in relation to operations research is discussed. (D. N. Chorafas. New York, Reinhold, 1958. 303p., $8.75.)

°BOILING WATER REACTORS

A brief history is given of the boiling water reactor concept and of the early experiments at Argonne, including the development and operation of the Experimental Boiling Water Reactor. The various Borax experiments are then described in detail as is the General Electric Company's Vallecitos plant. In addition a thorough explanation is given of the physics underlying the design of the various reactor plants. The book concludes with a discussion of present and future research and development programes on boiling reactors. A volume in the Atoms for Peace presentation set. (A. W. Kramer. Reading, Addison-Wesley, 1958. 563p., $8.50.)

°FLUID FUEL REACTORS

Three basic types of fluid fuel reactors are studied. The first is the aqueous homegeneous reactor. Such factors as nuclear characteristics, properties of aqueous fuel solutions, technology of aqueous suspensions, chemical processing, and design and construction are treated. The second is the molten-salt reactor, with consideration of the chemical aspects, construction materials, nuclear aspects, and heat-transfer systems. The last type presented is the liquid-metal fuel reactor with treatment of such factors as reactor physics, composition and properties of liquid-metal fuels, construction materials, chemical processing, and engineering design. A volume in the Atoms for Peace presentation set. (Ed. by J. A. Lane and others. Reading, Addison-Wesley, 1958. 979p., $11.50.)

°PHYSICAL METALLURGY OF URANIUM

A comprehensive treatment that studies uranium in terms of fundamental properties and mechanisms. Among those aspects studied are radioactivity and nuclear reactions, crystallography, physical and chemical properties, mechanical properties, deformation, recrystallization and grain growth, transformations, diffusion in uranium systems, radiation damage to uranium, thermal-cycling growth, and metallography. An appendix provides phase diagrams for binary uranium alloy systems. A volume in the Atoms for Peace presentation set. (A. N. Holden. Reading, Addison-Wesley, 1958. 262p., $5.75.)

°PROJECT SHERWOOD: THE U.S. PROGRAM IN CONTROLLED FUSION

This is the first unclassified report on the controlled thermonuclear effort in the United States. Beginning with the basic principles involved in a fusion reaction, it continues with the various methods now being studied to control thermonuclear energy with the hope of eventually producing net power. Methods such as pinch, stellarator, magnetic mirror, and molecular ion ignition are explained. A volume in the Atoms for Peace presentation set. (A. S. Bishop. Reading, Addison-Wesley, 1958. 216p., $5.75.)

RADIATION BIOLOGY AND MEDICINE; SELECTED REVIEWS IN THE LIFE SCIENCES

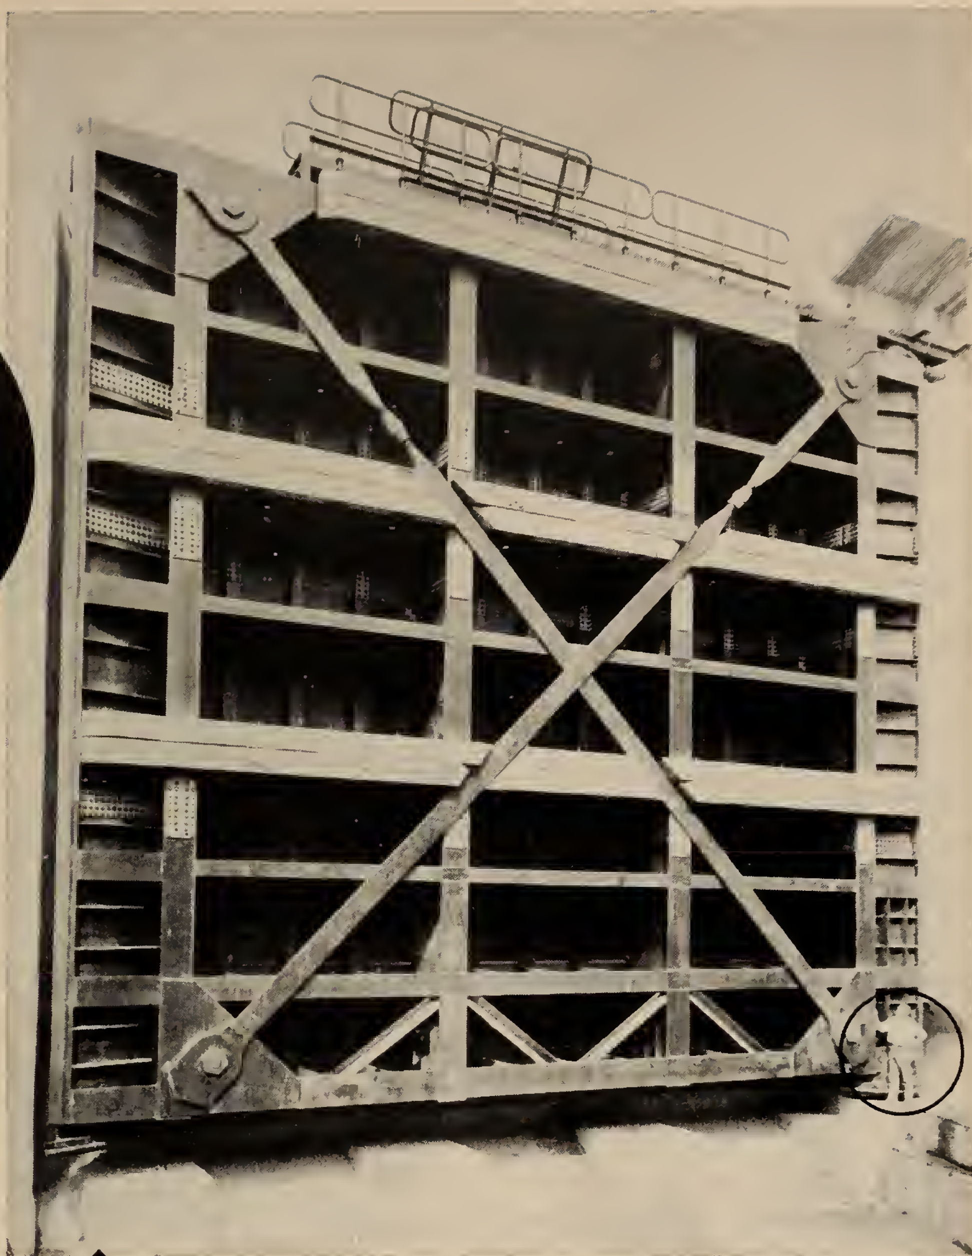
An introductory chapter summarizes the history of the use of radiation in diagnosis, therapy and experimental biology, and discusses the impact of the atomic age on growth and aging, ecology, etc. The next group of chapters deals with the effect of radiation on cells and organs, mutations, mathematical biology, and the effect of radiation on mammals. Four chapters deal with radiation safety. The remaining fourteen chapters are concerned with the uses of radiation, including radioisotopes in medicine and agriculture, accelerators in medical research, tracer applications and radiobiological dosimetry. The volume is concerned with work in the U.S., and is a volume in the Atoms for Peace presentation set. (W. D. Claus, ed. Reading, Addison-Wesley, 1958. 944p., $11.50.)

°THE SHIPPINGPORT PRESSURIZED WATER REACTOR

All aspects of the design and construction of the Shippingport reactor are discussed. Among the topics included are the factors entering into the selection of plant design parameters; reactor design, fuel element development, and core construction; radioactive waste disposal system; electrical and mechanical components used in the reactor plant; shieldings of the reactor plant and waste disposal facilities; hazards evaluation; a description of the turbine-generator plant; training of personnel. A volume in the Atoms for Peace presentation set. (U.S. Atomic Energy Comm., Division of Reactor Development, Naval Reactors Branch. Reading, Addison-Wesley, 1958. 588p., $9.50.)

Canadian Vickers Limited, Montreal, have supplied 12 Upper Mitre Gates and 14 Lower Mitre Gates for St. Lawrence Seaway Locks, in which all joints were field assembled with Stelco High-Strength Bolts, using a total of about 170,000 pieces, ¾" and ⅞" diameter.

Illustrated here is a 110-ton Upper Mitre Gate in the St. Lambert Lock.



Seaway Lock Gates field assembled with STELCO HIGH-STRENGTH BOLTS

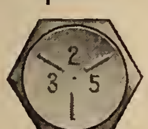
This unusual application for high-strength bolts offers striking evidence of the versatility of this technique in the field fastening of joints in all types of structural steel assemblies.

Stelco High-Strength Bolts require only one third the installation time of rivets. They also provide greater strength both in tension and in shear, are easy to remove for structural alterations, and are re-usable if desired.

High-strength bolting permits favourable working conditions in the field, with a minimum of equipment. A bolting team normally comprises two men, but if necessary the bolts can be installed satisfactorily by one man working alone.

For complete information, contact any Stelco Sales Office. A free technical manual is yours on request.

Every bolt head marked . . . every shipment certified.



All Stelco High-Strength Bolts are guaranteed to conform to ASTM Specification A-325. A certificate to this effect is issued with each shipment and every bolt is identified as shown.

NATIONAL DIRECTORY OF THE CANADIAN PULP AND PAPER INDUSTRIES, 1958-59.

In this edition, the statistical reviews of the industry have been brought up to date; the mill listings section is arranged by province from west to east, instead of alphabetically. The directory also includes a classified list of manufacturers, lists of paper and pulp mills classified by product, Canadian organizations in the industry, government departments, etc. (J. N. Stephenson, ed. Gardenvale, National Business Publications, 1958. 518p., $5.00.)

°CHAMBER'S TECHNICAL DICTIONARY 3RD ED.

A new edition of a standard reference work encompassing the fields of science, engineering and manufacturing. New terms have been added, while older terms have been revised where necessary to include new aspects. (Ed. by C. F. Tweney and L. E. C. Hughes. Galt, Brett-MacMillan, 1958. 1028p., $7.50.)

°SODIUM GRAPHITE REACTORS

Placing emphasis on the Sodium Reactor Experiment (SRE), such aspects are covered as the reactor and its shielding, cooling, and fuel-handling systems; nuclear, heat-transfer, and transient characteristics; design and development of components; installation of equipment and operation of the plant. In addition information of a general nature is included dealing with the origin of the sodium graphite concept, the technologies of sodium, graphite, and zirconium as they relate to sodium graphite reactor design, and fuel element development. A volume in the Atoms for Peace presentation set. (C. Starr and R. W. Dickinson. Reading, Addison-Wesley, 1958. 288p., $6.50.)

°SOLID FUEL REACTORS

Reviews the basic concepts, present status of development in the United States, and the technical outlook for five projected solid fuel nuclear power reactor types. These are the fast-neutron power breeders, heavy water reactors, gas-cooled reactors, organic moderated and cooled reactors, and a thermal reactor for recycling plutonium. The information presented ranges from well-established experimental, theoretical, and developmental results to analyses intended to provide direction for future work. A volume in the Atoms for Peace presentation set. (J. R. Dietrich and W. H. Zinn, eds. Reading, Addison-Wesley, 1958. 844p., $10.75.)

°THORIUM PRODUCTION TECHNOLOGY

The entire process of thorium production is studied, beginning with the extraction of thorium from ores to the fabricated thorium slug ready for cladding, prior to use in the reactor. Emphasis is placed on the separation of thorium from impurities, its reduction to metallic form, and fabrication of the metal. In addition sections are included on physical and chemical properties of thorium, health and safety aspects of thorium production, and analytical and metallurgical testing procedures. A volume in the Atoms for Peace presentation set. (F. L. Cuthbert. Reading, Addison-Wesley, 1958. 303p., $6.50.)

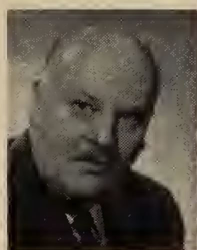
MEET THE AUTHORS

L. G. Brazier, PH.D., B.SC., M.I.E.E., director of Research and Education, and director of British Insulated Callender's Cables Limited *(Capacitor Developments in Great Britain).*

Dr. Brazier was educated at London University, served as pilot in Royal Flying Corps and R.A.F. during the war, 1917 to 1919. From 1923-1925 he did mathematical research at Royal Aircraft Establishment on aircraft structures and elastic stability. In 1925 joined Callender's Cable & Construction Company Limited and after their amalgamation with British Insulated Cables Limited was appointed manager (Research). In 1950 he was appointed director of the company, and became director of Research and Education in 1954.



P. A. Sporing, O.B.E., M.SC., managing director of Telegraph Condenser Company Limited *(Capacitor Developments in Great Britain).*

Mr. Sporing was educated in London and Zurich Universities and in 1923 joined the Telegraph Condenser Company Limited of which he became managing director in 1938. He is Director of Telegraph Condenser Company (Canada) Limited and Chairman of British Dielectric Research Limited. Mr. Sporing is the author of numerous patents relating to capacitors.

J. B. Birks, B.A., PH.D., reader in physics, Manchester University *(Capacitor Developments in Great Britain).*

Dr. Birks was educated at Wallasey Grammar School and Queen's College, Oxford. He worked from 1940-45 with Telecommunications Research Establishment and then successively held positions on the faculties of the University of Glasgow, Rhodes University, Grahamstown, South Africa and Manchester University.

Gerald Nadler, assistant professor of industrial engineering, Washington University, Saint Louis, Mo. *(Measuring Human Motions for Designing Machines.)*

Professor Nadler attended the University of Cincinnati and received his B.S.M.E. from Purdue University in 1945, his M.S.I.E. in 1946, and his Ph.D. in 1949. Since 1947 Professor Nadler has taught industrial engineering at Purdue and Washington Universities and also is available as a consulting industrial engineer. He belongs to a number of engineering societies in the United States and is registered with the professional engineers of the State of Missouri.

Jay Goldman, assistant professor of industrial engineering, Washington University, Saint Louis, Mo. *(Measuring Human Motions for Designing Machines.)*

Dr. Goldman attended Duke University where he obtained his B.S.M.E. in 1950, Michigan State University, M.S.M.E. in 1951, and Washington University, D.Sc. in 1955. Dr. Goldman has been teaching industrial engineering at Washington University since 1956 and is also a consultant industrial engineer. Among other societies Dr. Goldman is a member of the American Institute of Industrial Engineers.

R. M. Bremner, P.ENG., A.M.I.C.E., in charge of construction and planning at the University of Toronto. *(3,500 Ton University of Toronto Building Moved 250 Ft.)*

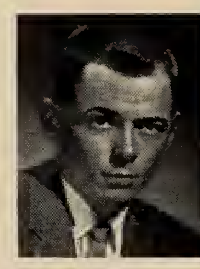
Mr. Bremner graduated from the Royal College of Science & Technology in Glasgow. While in Scotland he was involved in the design and construction of many heavy industrial schemes.

Mr. Bremner came to Canada in 1954. He was responsible for the supervision and design of the foundations and ancillary work for the first civilian sub-critical reactor in Canada.

He is a member of the Association of Professional Engineers of Ontario and of the Institution of Civil Engineers.

Jules O'Shea, JR.E.I.C., Canadair Services Ltd., Pilotless Aircraft Division, Boeing Airplane Co., Seattle, Washington. *(A Typewritten Grammatical Word Counter).*

Mr. O'Shea graduated from the Ecole Polytechnique in 1957 with a B.A. Sc. in electricity and mechanics. He has worked with the control group of the missile system section of Canadair Ltd. to adapt the Sparrow II to the Arrow interceptor. Mr. O'Shea's speech at the Annual Students' Night in Montreal about his electronic device, which he built as a hobby, won him first prize.



Robert J. McTavish, JR.E.I.C., field engineer with Dravo of Canada Limited, Toronto, Ontario *(Construction of Foundations for Vernon Narrows Bridge.)*

Mr. McTavish graduated from the University of Toronto with a B.A. in civil engineering in 1955. He joined Dravo in 1955 and worked on marine and shaft sinking projects in Canada and the United States until mid 1958. Since then he has been employed in Dravo's estimating department in Toronto.

Mr. McTavish is a registered professional engineer in the Province of Ontario.

M. P. MacMartin, assistant research officer electrical engineering section, Radio and Electrical Engineering Division, National Research Council, Ottawa, Ontario *(The Development of an Electronic Detector of Flaws in Paper).*

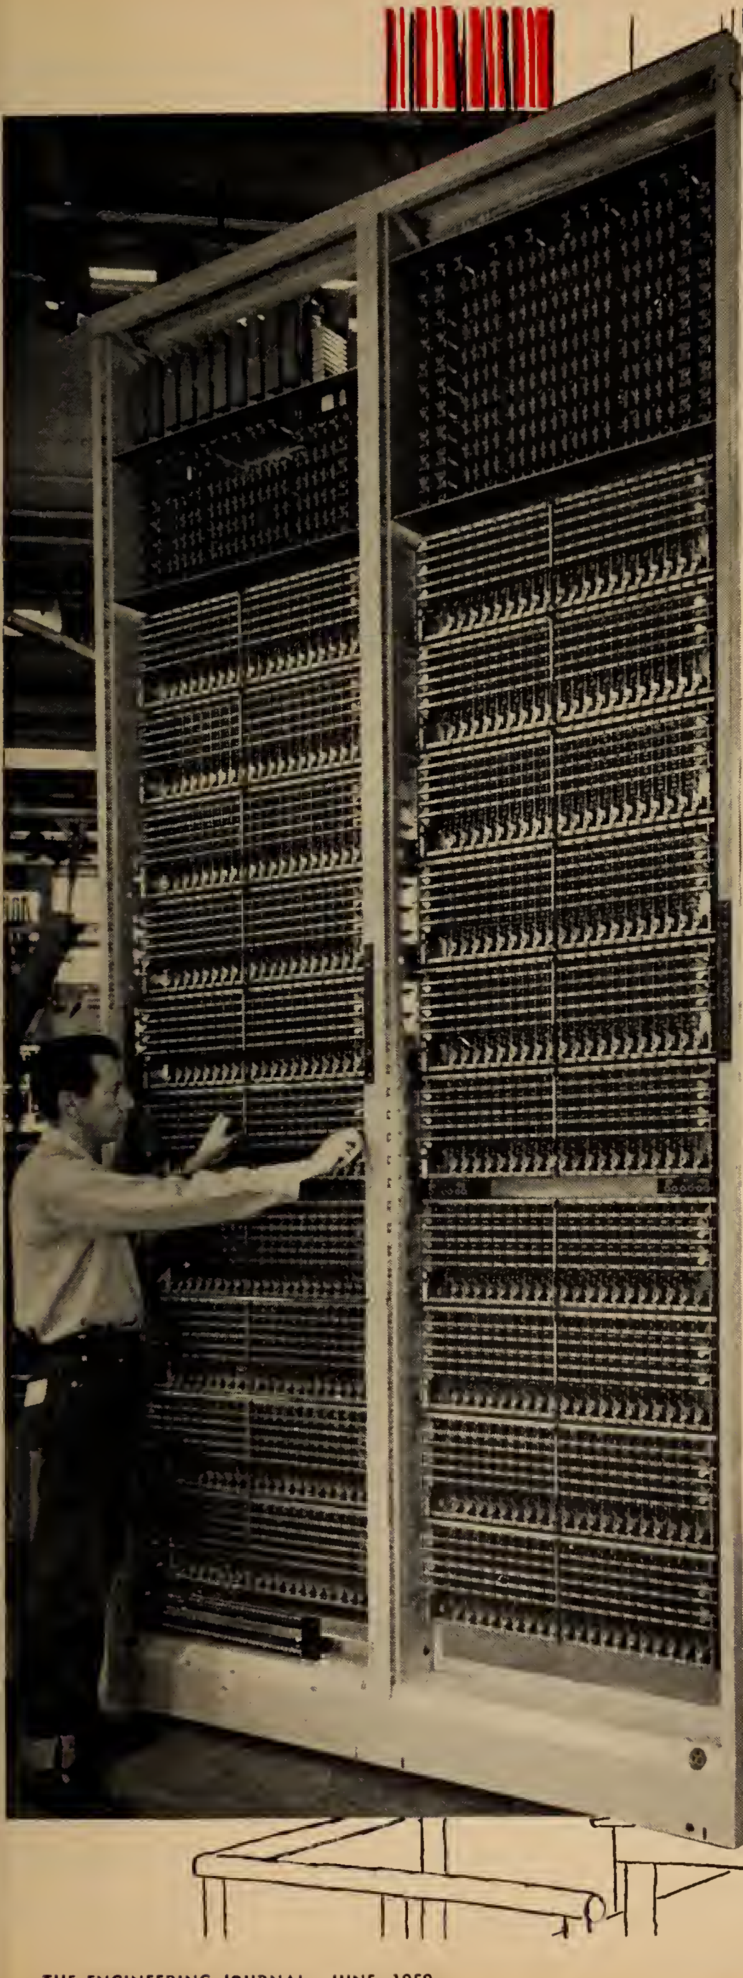
Mr. Martin graduated from Queen's University in 1950 with a B.Sc. (Hon.) in electrical engineering.

He has been working in the Electrical Engineering Section of N.R.C. since then.

N. G. Kusters, head, electrical engineering section, Radio and Electrical Engineering Division, National Research Council *(The Development of an Electronic Detector of Flaws in Paper).*

Mr. Kusters was born in Belgium and obtained his B.Sc. in mechanical engineering in 1937 and in electrical engineering in 1938 from the University of Louvain. His M.Sc. in mechanical engineering was obtained from M.I.T. in 1939.

We are indebted to the Faculty of the Ecole Polytechnique for their co-operation in the preparation of the paper which appears in this issue.



Message from the President

IF WE, as Canadian engineers, are not happy with the world, and in particular Canada, as we find it today, then let us remember that we are largely responsible for what we find.

We took the knowledge which research scientists had discovered for us, and as applied scientists and engineers used this knowledge to produce new materials, to improve processes, to reduce labour, and to find and develop new reserves of natural resources and raw materials.

If we now find that we have a surplus of goods, of labour and of natural resources let us not blame the politicians or economists or foreign competitors. Let us admit that we were too much absorbed with the problems of today and did not sufficiently plan for those of tomorrow.

We believe in private enterprise, in individual initiative and in acceptance of responsibility for our acts. Let us then prove our leadership by using our knowledge, experience and ability to look forward and to push ahead into new fields of endeavour for the future.

But let us lead not only in material things. We have been given education and training in how to get on with people, in how to manage large organizations and in how to conserve time and energy. Let us use some of our talents and time to assist in the solving of many of our community problems and in promoting cultural enterprises and in other public service. Only as we do this will we be recognized as truly members of a profession.

I sincerely appreciate the great honour which you have paid me in selecting me as President of the Institute. It is an office which over many years has been filled by very distinguished engineers. I shall earnestly endeavour to follow in their footsteps to the end that the prestige and service of our organization may be further enhanced. I look forward to your assistance and support and to the opportunity of working with you.

J. J. Hanna

J. J. HANNA, M.E.I.C.

ECOLE POLYTECHNIQUE
NEW ENGINEERING BUILDING

Specially written for this issue in collaboration with the University authorities.

The design and construction of these new quarters make an interesting engineering story. The main purpose of this article is to record the services, equipment and other facilities which are housed in the establishment.

FOUNDATIONS AND CONSTRUCTION

At the end of 1954 work started on the clearing of the rough, wooded, hillside site adjoining the grounds of the University of Montreal at the north-west end of Mount Royal. Excavation, which proceeded during 1955, revealed problems due to fissured and crumbling rock, and work proceeded until sound bedrock footings could be reached.

Figure 1 shows the plan of the building, which is conceived in four zones, subdivided into eight wings (A to H). Construction started in May 1955 with the foundations of wing A, and the first concrete pile at the north-east corner of this wing was driven to a depth of 35 feet before reaching solid rock. The rock under wings B, C, E, F, G presented no undue difficulties, though fissures and water-courses were present, but the base under H slopes rapidly to the west so that the two inside piles of the west wall are supported on a massive concrete slab. The wing D was perhaps the most 'awkward' since adjoining piles may be based on rock at depths which vary by 10 to 15 feet.

After establishing base lines, the wings A, C, and G were built separately, followed by the connecting wings B, D, E, F, H. Interconnection was made without any error. Wing G. was required at the very beginning to permit the installation of the heating system in the Boiler Room.

The reinforced concrete structure is fairly straightforward, but is generally very rigid and strong to deal with the loads imposed by equipment in various laboratories. The design takes into account the many large and small, steady and intermittent, known and unknown forces which occur in the building.

Of particular interest in the construction are the torsion-supported concrete canopy over the front entrance, the two circular staircases in the entrance hall, prestressed concrete tanks in the hydraulic labora-

Since its founding in 1873 l'Ecole Polytechnique has been prominent in the training of French-speaking engineers. Affiliated to the Université Laval de Montréal in 1887, the School has been an affiliate of the Université de Montréal since 1920 and could be regarded essentially as the engineering faculty of that body. It is constitutionally separate from it, having its own board of Governors and its own administrative officers. Through its contract of affiliation with l'Université de Montréal, it shares in the academic life of the campus and its degrees are given by the University. The curriculum leads to the degree of bachelor of applied science in the field selected by the student during the third year of his 5 year course. The curriculum and degrees are naturally fully recognized and particularly so by the Government of France as the equivalent of the courses and degrees of the major French schools: Polytechnique of Paris, Ecole des Ponts et Chaussées, Ecole Centrale, Ecole supérieure d'électricité, etc. With the financial assistance of the Government of the Province of Quebec, l'Ecole Polytechnique is now housed in entirely new quarters on the campus of the Université de Montréal.

tory, and a prestressed concrete base for the building structures laboratory.

In the old laboratories difficulty had been experienced with cracking of the walls and base of the hydraulic test tanks and channels. The new facilities were carefully designed in prestressed concrete, using cables in tension. The task was complicated by irregularity of the shapes involved and interruptions by expansion joints and openings.

The structural test laboratory at Lehigh University has a test base of 78 inches of reinforced concrete. Though loads in the Polytechnique laboratory will be comparable, it was necessary to avoid extensive and difficult excavation in hard rock, and consequently a 52-inch thick slab of prestressed concrete has been incorporated. Using a retarding agent and pouring at night to benefit from low temperatures, a strength of 8000 p.s.i. at 28 days was obtained. Vibration effects are localized by mounting the slab on a foam rubber cushion enclosed in a non-permeable membrane to avoid the deleterious effects of water.

HEATING SYSTEM

From the functional plan of the building (Fig. 1) the ideal location for the boiler room was the wing G. Consequent on this, the mechanical engineering department was also situated in the same wing. The installation of the heating and ventilating services was influenced by the aim of making the whole building a potential laboratory; that is, the students should be readily able to see the function of the whole scheme of distribution.

The total volume of the building is nearly 8.2 million cubic feet, and the floor area is 457,184 square feet. (Corridors, restrooms, stairways and elevators not included.)

Heating

The heating system is divided into eight zones. The two furthest zones (wings A, B, C) are heated by steam with differential exhaust and exterior temperature controls. The pump room and control panel are in wing B. The six zones in wings D to H have forced-circulation hot-water heating with external temperature controls. The heat exchangers and circulating pumps for this system are in the boiler room, and each zone has an exchanger fed with steam at 5 p.s.i., water temperature being controlled bv a three-way valve. Each feed pump is driven by an electric motor, and there is a standby steam-turbine pump which can feed two zones at a time in an emergency.

In addition to zone control, all lecture rooms are fitted with valves and thermostats to prevent local overheating when rooms are occupied; this also reduces fuel consumption.

In the wings A to E 'Wallvector' radiators are installed, and these are extended wall-to-wall in the administrative section of C for better appearance. Heating in wings F, G, H, which contain the chemical, metallurgical, mechanical and hydraulic laboratories, is by cast iron radiators

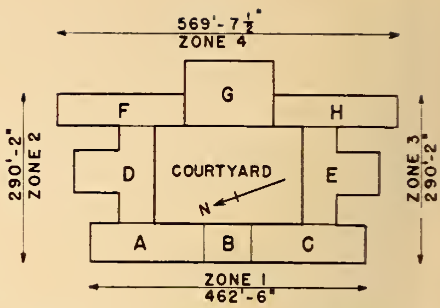

Fig. 1 — General plan of building.

or convectors. The main entrance and students' entrance are heated by ceiling air vents or cabinet installations, all separately controlled.

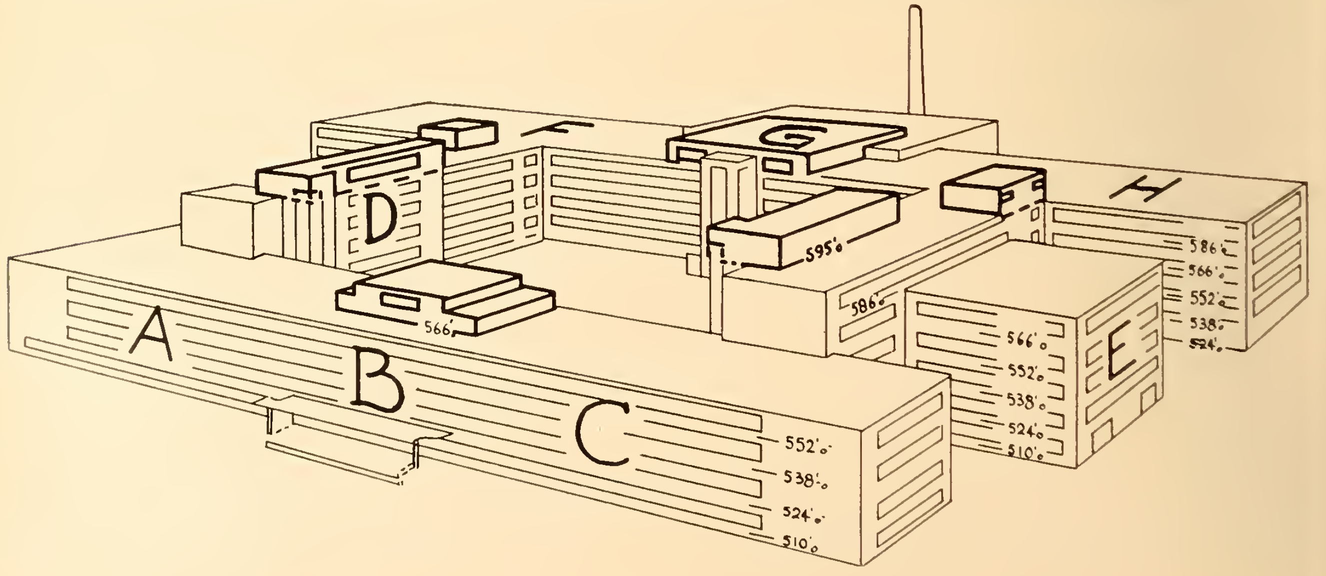
None of the piping is concealed in the permanent structure, but is readily accessible, where hidden, through removable panels. Most of the piping in wings D to H is open.

An unusual feature of the system is the use of wrought iron for most of the steam and water heating pipes. The main return pipes for steam condensate are of IPS brass, silver-soldered to 'Wallseal' unions. Some 14,900 square feet of steam radiation (E.D.R.) and 52,400 square feet of hot water radiation (E.D.R.) are installed.

Snow Removal

The ramp leading to the central courtyard is kept free from snow and ice by buried pipes through which heated glycol is pumped. The system is started manually, but temperature control is automatic. To prevent snow accumulating on the

Fig. 2 — General layout of building, showing position of penthouses for ventilating equipment (bold outline).



windows facing the yard, a somewhat simpler and slower-acting melting system is incorporated.

A sump in the courtyard is covered by steel plates which can be heated by steam at 100 p.s.i. Snow in the yard is pushed on to this, where it melts and is drained away.

Boiler Room

For heating the building and the ventilating air there are two water-tube boilers, each giving 25,000 lb. steam per hour at 100 p.s.i. Only one of these is needed in normal operation. A third boiler, giving 9000 lb./hr. steam at 250 p.s.i. and 50°F. superheat is linked to the heating system by a 250/100 lb. reduction valve. Steam from this boiler is supplied to specific laboratories.

The automatic burners operate on Bunker 'C' fuel with steam atomization, and use light oil for cold starting. There are two burners per large boiler; one for the 9000 lb./hr. unit. The oil is preheated and fed by electrically-driven pumps, with steam-operated pumps as a standby. Main oil storage is in two 15,000 Imp. gal. tanks, and there is one 1000 Imp. gal. tank for light oil. These boilers using oil as fuel can be easily converted to gas or coal.

All condensate from the heating system is received in a steel tank, whence it is pumped to a degasifier which uses live steam (or, if necessary, turbine exhaust steam). This unit, with a capacity of 35,000 lb./hr. at 160°-220°F., helps to prevent corrosion by removing oxygen and other non-condensable gases from the feedwater.

Feed pumps are electrically-driven with steam turbine standby. Each of the two large boilers is supplied by a pump of 35,000 lb./hr. capacity at 150 p.s.i.; the pump for the high-pressure boiler has a capacity of 12,000 lb./hr. at 300 p.s.i.

Combustion Control

A control panel centralizes instruments for recording steam delivery, water flow, combustion temperature, carbon dioxide, steam pressure, feedwater temperature and pressure, and ultimate steam temperature for the boiler with superheat.

All necessary safety controls are incorporated and oil, air, and feedwater are regulated automatically. A pump for each of the three feedwater lines injects the required amount of chemical water-treatment solution from a central tank. Quantities of solution (injected through solenoid-operated three-way valves) are controlled by steam usage through a mechanism linked to the combustion controls.

Fig. 3 — The torsion supported concrete canopy over the front entrance.

Domestic Hot Water

Two hot-water storage tanks (Monel), each of 1325 U.S. gal. capacity, have a reheat rate of 2160 U.S. gal./hr. at 40° to 140°F. using steam at 15 p.s.i. Two circulating pumps supply all hot water taps in the building.

In the summer, or when the steam boilers are not operating, a 342 kw./550 v. submerged-electrode boiler is used. This does not add to electricity costs, since the normal overall summer consumption is well below the minimum basic charge for electrical supply.

Temperatures at strategic points in each building zone, and the hot water feed and return temperature and pressure, can be read and adjusted if necessary at a central console in the boiler room.

Exhaust Stack

The octagonal stack, of radial brick faced to match the building exterior, is 150 feet high and six feet in diameter at the top. It is fitted with an external ladder, lightning rod, and air navigation beacon.

VENTILATION

The problem of ventilating such a large building was solved by considering the various wings A to H (Fig. 1) as separate units; each of these has a different function and type of occupation. Architecture and construction were also taken into account.

The final plan placed operating equipment in six penthouses built on the roof and situated as shown in Fig. 2. The areas served from these penthouses are noted in the table.

Ventilating Plan (Fig. 2)

Penthouse	*Area served*
B	Library
D	A; D (part)
F	D (part); F (part)
G	F (part); G; H (part)
H	H (part); E (part)
E	E (part); C

From these penthouses 68 different ventilating circuits operate: (i) 17 circuits of air feed and return, with some recirculation, for lecture rooms, drafting rooms, and administrative offices; (ii) 15 circuits of heated 100% fresh air, all evacuated to atmosphere, particularly for removal of fumes from chemical, metallurgical, and other laboratories (these 32 circuits, i and ii, can displace some 282,000 cu. ft. of air per minute); (iii) 36 circuits for exhaust of stale air from all toilets, dark-rooms, fume chambers in laboratories, etc., with total displacement of 113,000 cu. ft./min.

Ventilation for lecture rooms and offices is conditioned in winter only. The chemical laboratories can select rates of 10, 20, or 30 complete changes an hour, according to need. The library air is controlled for humidity to protect the many books and periodicals.

Most of the air circulation is at conventional rates, but wing C is supplied (from penthouse E) at a maximum of 4,000 ft./min. This system will be used for study by mechanical engineering students.

The dining area and students' quarters on the first floor of wing C are supplied with 100% fresh air. This can be heated by a novel 'thermowheel' exchanger, which can recover 60% to 80% of the available heat from the stale exhaust air. The system will be used for laboratory studies.

All ventilation is controlled centrally from the boiler room, using a high-frequency signal system instead of conventional cable connections to the penthouses. This system is described further under Electrical Equipment. The control program takes into account the time of occupation of the various rooms and laboratories.

Noise and vibration from the penthouse installations are practically eliminated by the use of rubber mountings and cork bases under the machinery.

Fig. 4 — Outside storage tank of propane gas.

WATER AND SERVICES

The City of Montreal provided a 16-inch pipeline from the reservoir at the top of Mount Royal (elev. 655 ft.) via the Mount Royal cemetry which adjoins the upper limits of the Polytechnique grounds. This pipeline delivers water at 45 p.s.i. to a header with the necessary valves from which one eight-inch line runs to the University grounds and a similar line enters the Polytechnique building between wings G and H. Here two centrifugal pumps boost the pressure to 80-100 p.s.i.

Instead of the conventional hydraulic distribution systems incorporating air reservoirs, circulation is controlled by a centrifugal pump driven by a variable-speed electric motor to meet any fluctuations in demand. Should there be any failure in the 500 U.S.g.p.m. pumps or the 20 h.p. motors, a bypass gives direct supply from the 45 p.s.i. source. There is thus no need for a separate storage tank.

In an emergency, the large quantities of water in the storage tanks for the hydraulics laboratory can be pumped into the central heating system.

Water Distribution

Hot water circulation is conventional, all pipes being accessible through doors in cavity walls or false ceilings.

In the laboratories, there are two hot and cold water circulations; one for the use of the laboratory equipment and the other for domestic uses, and they are specially identified to avoid the possibility of siphoning contaminated water into the main supply. (The City of Montreal will not accept the use of vacuum breakers.)

All hot and cold water piping is of copper, class K.

Waste and Drainage

Laboratory waste which may be chemically contaminated is discharged through Duriron piping. The system has been designed to minimize the amount of this material required.

Three parallel 15-inch drains join a 24-inch main running in front of the building and eventually down to the city mains on Maplewood Avenue. The 15-in. drains run: (i) from wing F through D and A; (ii) from H through E and C; (iii) from G via the central courtyard, whence run-off is collected, and out through B. This drain also takes in any overflow from the hydraulic laboratory.

Special Laboratory Services

Special services include steam, compressed air, vacuum, distilled water, and gas.

Steam — The chemical and thermal machines laboratories are supplied with steam at 250, 100, and 15 p.s.i. Several other laboratories have 100 and 15 p.s.i. supplies.

Compressed Air — All requirements for compressed air are supplied from the boiler room by two compressors of 180 cu. ft./min. capacity (40 h.p. motors) and one compressor giving 365 cu. ft./min. (75 h.p. motor). An intermediate cooler is provided, plus a special cooler for dehumidifying the air.

Vacuum — Continuously-available vacuum of 25 in. Hg is provided in laboratories from a central system in the boiler room. Two 280 cu. ft./min. vacuum pumps are driven by 20 h.p. motors.

Distilled Water — A central automatically-controlled gravity-fed supply of distilled water is provided from the penthouse on wing F. Capacity is 10 U.S.g.p.h. from a 26 kw. heater, with storage for 300 U.S. gal. in a tin-lined tank. All piping, unions, and valves are of polythene.

Propane Gas — The demand for gas, which is seasonal, is not enough to justify the cost of a link to the gas mains on Maplewood Avenue, and therefore propane gas is used for laboratory supplies. From a 7000 U.S. gal. storage tank outside the building, 30 U.S.g.p.h. can be vaporized at 20 p.s.i., with automatic operation. Gas in the main distribution lines in the building is at 20 p.s.i., but between these lines and the laboratory outlets are safety and reduction valves to give a supply at 6 oz./sq. in.

ELECTRICAL SERVICES

The provision of adequate electrical supplies for an engineering school such as this presents more problems than does the design for a large commercial or public building. Different laboratories have widely differing needs, and there must be considerable flexibility to meet new demands which may arise.

Main Supply

The main supply comes from two 12 kv. Hydro-Québec lines. The 2500 ft. link between these lines and the internal sub-station is by: (i) 1000 ft. of underground line beneath the Polytechnique grounds; (ii) 1500 ft. of overhead line following the route of the 4 kv. lines that supply the University. This latter installation involved lowering the 4 kv. lines by some 10 ft. and adding the 12 kv. line above them without interrupting the existing supply.

Unit Substation

The unit substation is under the electrical laboratories in wing D and consists of Metalclad type equipment divided in three sections:

i) Potheads, disconnects, air breakers and Hydro-Quebec measuring equipment are grouped together in the first section. From this section, 12 kv. busbars supply the transformers.

(ii) Two main transformers for lighting and power supply are 3-phase, 12000/550 v., 1500 or 2000 kva. capacity, with convection or forced cooling. These transformers supply 2000 amp. busbars.

(iii) Three transformers and voltage regulators supply the electrical, electronic and physics laboratories, and provide 220 v. 3-phase power. The equipment is: a 3-phase, 500 kva., 12000/550 v. transformer with 54 kva. induction voltage regulator; a 3-phase, 225 kva., 12000/220 v. transformer with 25 kva. regulator; and a single-phase 200 kva., 12000/110-230 v. transformer with 20 kva. regulator.

This transformer station, totalling 5000 kva., was specially designed for Ecole Polytechnique and should meet demands for several decades to come.

The station is illuminated, and windows of special shatter-proof glass permit inspection of the main components.

Direct Current Supply

Direct current is supplied to the laboratories from sixty 685 amp.-hr. lead oxide accumulators, which are maintained by a 400 amp., 125 v. charger with silicon rectifiers.

Distribution

The main distribution boards are in the electrical engineering laboratory above the transformer station. There are five boards for distribution from the five transformers; one board for d.c. supply; one for Hydro-Québec recording instruments; and one board for supplies at variable voltage and frequency.

There are seven secondary boards for lighting supplies, each comprising three single-phase 550/110-220 v. transformers at 75 or 100 kva., according to load in the section concerned. One secondary board for power supply delivers 350 h.p. to the boiler room, 350 kw. to electrical steam generators, 600 h.p. to the hydraulics laboratory, and an estimated 750 h.p. to the gas dynamics laboratory. This board is supplied simultaneously by two busbars, with a switching system to distribute the load evenly between the two transformers.

Lighting

Lighting represents about 40% of the total cost of electricity, and particular attention was paid to its design and installation. Adequate illumination and accessibility were the main considerations, but appearance was not neglected.

Lighting levels are (in foot-candles): lecture rooms 40; drafting rooms 50; laboratories 30. Altogether, some 3800 incandescent lamps were required, of which 600 were of one type for the lecture rooms.

The corridors, administrative offices, and library are lit by rapid-start fluorescent lamps. Those in the library are recessed in the ceiling beneath white reflectors and are covered with transparent glass panels which incorporate translucent honeycombed diffusing strips to give an even, shadowless distribution of light. This is one of the first installations of its kind in the country.

The access roads are lit by reflectors similar to those designed for aircraft runways or bridges, mounted only three feet above ground level.

Fig. 5 — The accumulator room.

Laboratory Supplies

All laboratories have supplies of 550 v. 3-phase; 220 v. 3-phase; 110-220 v. single-phase; and 125-250 v. d.c.; usually via a separate board for each department. These boards are also connected by two 200-amp. lines to the secondary board in the electrical engineering laboratory which provides variable voltage and frequency.

In addition, different voltages are supplied for individual requirements; for example, the engineering physics department has a 12 v. d.c. supply, and physical chemistry has a source at 1000 c.p.s.

Remote Control

An interesting feature is the system used for remote control of services. Because of the distances involved, ventilating installations are in six separate penthouses, and the exterior lighting is divided into three sections (rear parking lot, central courtyard, and access roads), each supplied from different points. Centralized control is achieved by the use of carrier waves, thus eliminating the considerable lengths of cable necessary in conventional systems.

An alternator in the electrical laboratory imposes frequencies of 2965 and 3803 c.p.s. on the entire 550 v. and 110/220 v. system. This output is coded and controlled manually or automatically, according to an established schedule, from a console in the boiler room. Relays at any point in the distribution system receive the coded output and accept or reject it according to conditions, thus starting or stopping the various ventilating circuits. Seventy-two relays may be installed at present, with provision for a further thirty-six.

Intercommunication

Rapid communication is essential in such a large building, and two distinct systems have been installed to augment the heavily-loaded regular telephone facilities.

(1) *Calling System* — There is a loudspeaker network over which the central telephone operator can make announcements, either generally or to local speakers. Musical notes at 800 and 2000 c.p.s. will be broadcast

over the general system to announce the start and finish of class periods; these operate from the central timing unit.

(2) *Internal Telephone* — Offices in the front section of the building, including administration, and those of department heads are connected by an automatic telephone system. In addition, each department head or his secretary can reach his staff by a local telephone circuit.

THE ENGINEERING LABORATORIES

The move by Polytechnique into its new quarters coincides with the introduction of a revised program of studies leading to full specialization courses. *(The Engineering Journal,* Oct. 1958, p. 93.) The eight fields of engineering now offered and which are described in the above reference, are: civil, mechanical, electrical, chemical, metallurgical, mining, geological, and engineering physics.

Some of the laboratory facilities and equipment available to the students of these various fields will be described in the remainder of the present article.

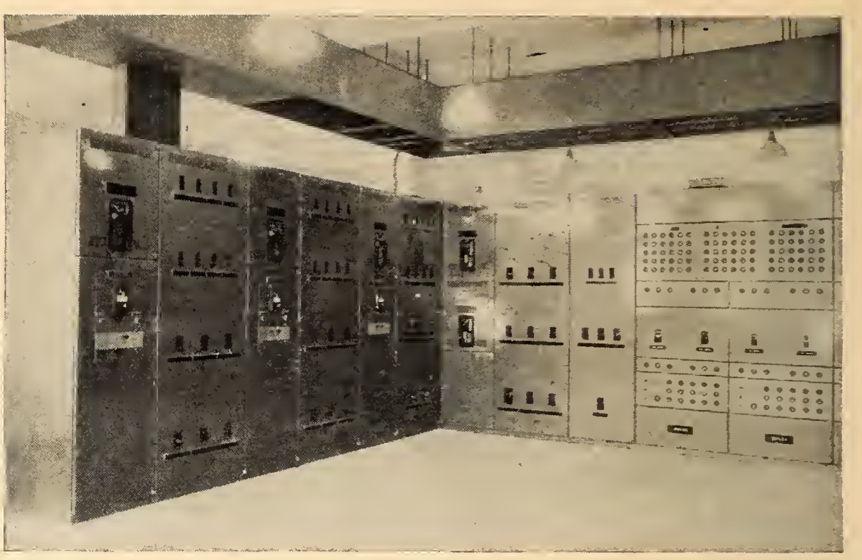


Fig. 6 — A section of the main board. Left: three regular tension panels; at the back: the continuous current panel; at right: the panel for variable tension and frequency.

CIVIL ENGINEERING

The civil engineering department has four divisions: surveying, sanitary engineering, hydraulics, and public works.

Division of Surveying

The laboratories of the surveying division, which cover 3400 sq. ft., are subdivided into three groups: survey, geodesy, and photogrammetry and cartography. The first deals with the theory and operation of instruments, and includes a test bench for transits and theodolites. The geodesic laboratory includes equipment for standardization of chains and checking of levels.

The photogrammetry laboratory which is being established will be equipped with a Multiplex machine and various stereoscopes. Easy access will be provided to the roof, from which astronomical observations may be made and an opportunity given to the students to familiarize themselves with the various instruments.

A maintenance and repair shop is provided.

Division of Sanitary Engineering

Equipment is now being ordered to establish the laboratory with the necessary instruments for research and advanced studies pertaining to water purification and sewage treatment. Both the chemical and bacteriological aspects can be studied with the equipment at hand. For the study of the hydraulic problems encountered in Sanitary Engineering, the facilities and modern equipment of the Hydraulics Laboratory are readily available.

Division of Hydraulics

The hydraulics laboratories occupy the first three floors of wing H, covering some 27,000 sq. ft.

Six pumping units have a total capacity of 18,000 U.S.g.p.m., and four of these units can be operated in parallel. All pumps in the laboratory are supplied from prestressed concrete storage reservoirs with a total capacity of about 150,000 U.S. gal. The construction of these reservoirs has been mentioned earlier.

Four different turbines are available for study: a 10 h.p. vertical unit with interchangeable wheels; a 30 h.p. horizontal turbine for cavitation studies: an impulse turbine with a capacity of 6 h.p. under 250 ft. head; and a horizontal Francis unit of 9.7 h.p. under 100 ft. head. The various hydraulic circuits are provided with flow-measuring equipment such as Venturis, Dall tubes, and Pitot tubes.

Two steel measuring tanks mounted on weigh-scales, each with a capacity of 40,000 lb., are used for accurate calibration of the flow-metering equipment and also for efficiency tests on a vertical pump and other equipment.

Several test channels have been provided in the laboratory. A prestressed concrete channel on the second floor is 185 ft. long, 8 ft. wide, and 6 ft. deep, with observation windows in one of the vertical walls; it is being equipped with a motor-driven carriage which runs on accurately aligned rails. This channel will be used to calibrate current meters and for testing ship models, and models of hydraulic structures. Two glazed channels, equipped with weirs and supplied by constant-level reservoirs, will be used for studies of flow in open channels and also for testing scale models. A channel, 75 ft. long, will be utilized for the study of sediment transportation. Two tilting flumes will also be provided.

In addition to an instrumented wave tank, seven other test channels are provided in the laboratory: intake and discharge flumes for the vertical turbine and others for the study of density current, stability of earth dams, and three small steel channels with weirs.

Division of Public Works

Four laboratories are grouped together in the Division of Public Works. These are: soil mechanics, highway materials, concrete and construction materials, and structures.

Soil Mechanics — This laboratory has been expanded considerably during the past twenty years and much work done in the relatively new field of soil mechanics. The present laboratories are well equipped to continue this teaching and research work, complemented by field studies and research on methods of measurements of soil properties "in situ".

Apart from the standard equipment required for the identification and classification of soils, apparatus is provided for the study of permeability, capillarity, frost action and compaction. Various types of triaxial compression machines, direct shear machines and oedometers are also available for work on the shear and consolidation characteristics of soils. Some of this equipment has been developed or modified in the laboratory in order to carry out research work in this and other related properties.

Highway Materials — This laboratory adjoins those of soil mechanics and is provided with all the equipment needed for the study of the physical and mechanical properties of the materials commonly used in the construction, maintenance or repair of roads. One section is concerned with the study of bituminous mixtures, with the aid of Marshall apparatus.

In conjunction with the soil mechanics laboratories, research work is carried out on soil stabilization and on frost action.

Concrete and construction materials — The laboratories for testing concrete and construction materials are well equipped for a variety of tasks. Materials tested include cement, aggregates, mortar, concrete, masonry, wood, structural steel and so on.

An efficient concrete mixer of a capacity of 5 cu. ft. and a high-frequency vibrator are available. Concrete test beams and samples can be cured in a room (25 ft x 10 ft x 9 ft high) in which the temperature and relative humidity are accurately controlled.

A cold room (18 ft x 8 ft x 9 ft high) has also been installed for research work on concrete and construction materials. The temperature can be controlled to $\pm 1°F$ and can be lowered to -60°F. The high-capacity refrigerating unit can be also connected to a mobile chamber in which tests of structural units can be made at low temperature.

A freezing and thawing unit capable of running tests according to the four ASTM methods is under construction.

Apart from the standard apparatus for cement and concrete testing, the available equipment includes various types of extensometers, high precision comparators, creep and shrinkage measuring devices, and apparatus for the determination of dynamic moduli of elasticity of concrete and other construction materials.

Structures — A wide variety of tests may be performed in this laboratory. A universal testing machine of 220,000 lb capacity equipped with a pulsator may be used for either static or dynamic loading. The laboratory is equipped with another universal testing machine of 100,000 lb capacity, a 400,000 lb press for compression tests and a 1,100,000 lb press capable of accommodating specimens up to 16 ft in height.

Tests on structures of various shapes may be carried out on the prestressed concrete testing bed. This bed is 60 ft long, 19 ft wide, and 54 in thick. Three-inch diameter bolts of special alloy steel are embedded in pairs in the concrete, the distance between pairs of bolts being 5 ft longitudinally and 4 ft in the transverse direction. Structural steel frames may be fixed to the bolts by means of special adapters so that structures up to 60 ft long can be tested. The structural elements may then be loaded by hydraulic jacks fixed to the steel frames. These jacks can operate in any chosen direction. Both static and dynamic tests may be carried out and on account of vibrations the bed rests on a special dampening foundation. The testing bed is designed for vertical loads of 500 tons or horizontal loads of 750 tons at points 8 ft above the top of the bed. A 10-ton travelling crane services the testing bed. The capacities of the high-precision hydraulic jacks which form part of the test equipment range from 2.5 tons to 100 tons. A range of steel sections for building up the loading frames completes the equipment for this work.

Various types of extensometers are available and using electronic measuring instruments coupled with special strain gauges, an accuracy of 1/1,000,000 in./in. may be attained.

Fig. 7 — A section of one of the well designed laboratories.

MECHANICAL ENGINEERING

Under the new program of studies, mechanical engineering is a separate course whereas, from 1943 to 1958, there was only a partial specialization in an option called mechanical-electrical engineering.

Equipment

The equipment brought by the department from its previous quarters includes a Diesel engine, other internal combustion engines, an air compressor, a steam engine, blowers and ducts, a refrigerated chamber, and various pieces of machinery. A recent, and valued, acquisition is a steam turbine with condenser and associated equipment with which many experiments can be carried out.

As mentioned in the sections dealing with heating and ventilating, the boiler room and other equipment in the new building will be used for extensive studies by the mechanical engineering department.

Further new equipment will include installations for advanced studies in gas dynamics, and new internal combustion engines with complete instrumentation.

Additional facilities will be installed as required, and the aim of the department is to provide those who wish to proceed to the Master's or Doctor's degree with all the equipment that is found in other schools of engineering.

Laboratories

The laboratories and offices of the mechanical engineering department are situated on two floors of wing G, which also contains the boiler room, and part of wing F (Figs. 1 and 2). A comprehensive series of instruments is provided for the observation and control of the boilers and all the other equipment which has been described earlier.

Adjoining the boiler room on either side are two 2675 sq. ft. laboratories, one for the study of gas dynamics, the other containing the Diesel and gasoline engines, compressors, and similar equipment. Opposite the boiler room are a store for equipment and tools, and what is now known as the research laboratory, to be used for future expansion.

At mezzanine level in the boiler room are the hot water storage, electrical heater, and circulating pumps, with facilities for studies of heat transfer. Adjoining the mezzanine at the same level are two laboratories each of 2675 sq. ft. area. The first of these will house equipment for the study of ventilation, air conditioning, refrigeration, and heat transfer, with appropriate controlled-condition chambers. The second area will contain the new steam turbine, condenser, and pumps, together with further ventilation and refrigeration apparatus.

Across the corridor from these laboratories are the departmental offices, which extend partly into wing F, a room for storage and calibration of instruments, a design section, and a lecture seminar room.

ELECTRICAL ENGINEERING

The new course in electrical engineering up to the B.Sc. degree combines both the fields of electrical power and communications (electronics), in contrast to many courses which tend to provide specialization in either field.

Laboratories

The electrical engineering laboratories occupy most of wing D, the transformer sub-station being at the lowest level. The equipment in this sub-station has been described under Electrical Services, as have many of the other facilities which will be available for study.

On the higher floors are laboratories for electrical machines and measurements, and communications. The entire fourth floor is devoted to electronics and electronic-physics, particularly for research and post-graduate studies. Part of the fifth floor is to house an electronic computing centre.

ENGINEERING PHYSICS

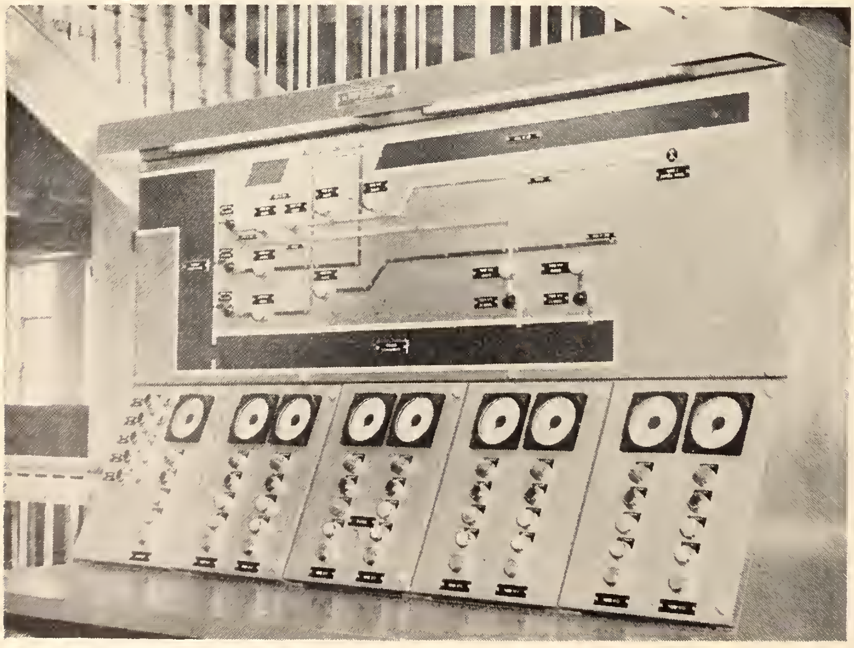
Instruction in engineering physics is a new departure for the Ecole Polytechnique. The approach is more fundamental and analytical, and rather less technological, than in the classical fields of engineering. The curriculum includes physical chemistry, thermodynamics, heat transfer, nuclear physics, metallurgy, nuclear engineering, solid state physics, and the study of electronic computers.

Laboratories

The engineering physics laboratories are equipped for the study of all necessary aspects of modern physics, and a physical measurement centre will provide such apparatus as: optical spectrometer, X-ray diffractometer, mass spectograph, electron microscope, and so on. Some of these facilities may be shared advantageously by other departments such as physics, chemistry, metallurgy, mining, and geology.

The laboratories of the electrical engineering department are also available to engineering physics students for work in fields of common interest.

Fig. 8 — Central control console for operating pumping units and motor-operated valves.



CHEMICAL ENGINEERING

The chemical engineering department includes a general chemistry section as this department has to supply all the chemistry courses needed for chemical engineering and for other branches of engineering.

Chemistry Laboratories

The chemistry section includes laboratory facilities that will be used by all the students during their initial training and later by students in certain branches of engineering. The largest laboratory of this section is the general chemistry laboratory which covers an area of 6,200 sq. ft. and which can accommodate easily 120 students at one time. The other principal laboratories of this section are those of physical, organic and analytical chemistry which total 8,600 sq. ft. To serve this chemistry section, there are the necessary preparation rooms, balance rooms, work shops, stores and also some research laboratories having a total area of 5,000 sq. ft. This section also includes the Montreal laboratory of the Department of Mines of the Province of Quebec.

Chemical Engineering Laboratories

The chemical engineering laboratory which is the most important of this section has a floor space of 40 by 60 ft. with an average height of two floors but with a raised section of 16 by 15 ft. giving a height of three floors. At first floor level runs a mezzanine floor with a central opening of 27 by 40 ft. This arrangement will accommodate pilot plant size industrial equipment such as heat-exchangers, distillation columns, absorption columns, evaporators, driers, filter presses and so on.

The chemical engineering section also includes a laboratory for industrial control and the study of recording instruments, a research laboratory in unit operations and a high pressure equipment laboratory. There is also in this section a large laboratory for applied chemistry with two smaller laboratories, one for analytical work and the other for instrumentation analysis. The usual service rooms as work shops, stores etc. are also provided in this section.

Two special laboratories have been reserved for work on corrosion and the roof of the rear wing of the building has been prepared to install benches for an atmospheric corrosion site. About 20,000 sq. ft. are available for benches on which test panels of metals and coatings will be studied.

Space has been also allocated for a physical measurement center which will be under the direction of the department of physics and chemistry. This center has already been referred to under engineering physics.

All the laboratories of the chemical engineering department have the usual necessary services as gas, vacuum, compressed air, etc. plus a three rates ventilation system that will satisfy any requirements.

METALLURGY

The great developments in the extraction and processing of metals in the Province of Quebec have laid particular emphasis on the operations of the new department of metallurgy, and facilities have been provided for undergraduate teaching and for postgraduate study and fundamental research in the various fields.

Laboratories are organized for studies in the three main phases: extractive metallurgy, metal working, and fundamental metallurgy.

Extractive Metallurgy

The extractive metallurgy laboratories, which are in addition to those for mineral treatment belonging to the department of mining engineering, include a general laboratory and special labs. for mineral refining and metal extraction. Part of the main laboratory is used for chemical treatment of minerals.

The laboratory used for work on the extraction of metals is equipped with furnaces heated by electric arc, oil, gas, electrical resistance, and vacuum furnaces. It also contains the equipment required for the extraction of metals, such as zinc, by the electrolysis of aqueous solutions or such as aluminum, by the electrolysis of fused salts.

Refining and Treatment

The refining and further treatment of metals is carried out in several laboratories, including the electrolysis section. Melting and casting are mainly done in the furnace rooms mentioned above.

For the metal treatment experiments the facilities are planned to include equipment for forging, laminating, extruding, wire-drawing, and welding.

In the heat-treatment section are furnaces with controlled atmosphere, high- and low-temperature furnaces, annealing furnaces, and soaking furnaces.

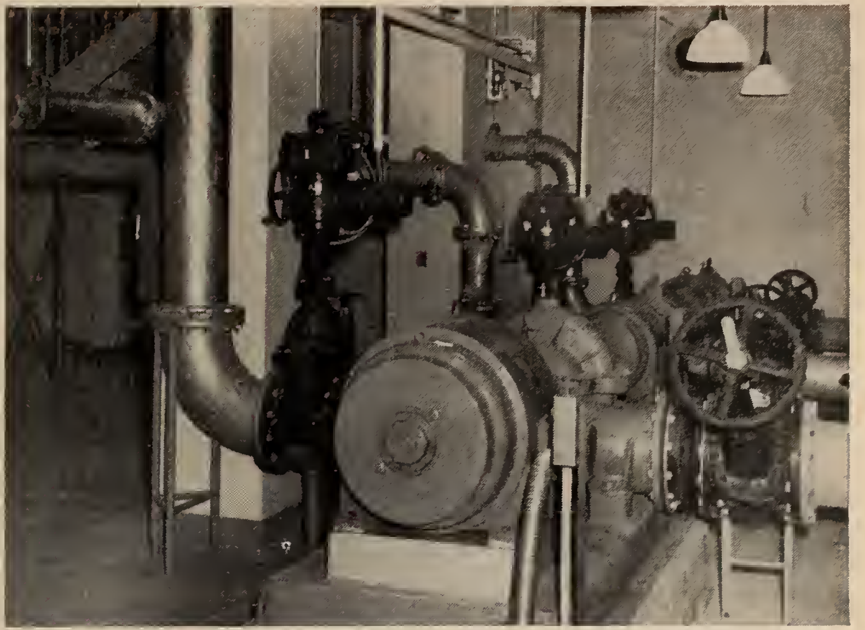


Fig. 9 — Three pumping units having a total capacity of 10,000 U.S. g.p.m.

Fundamental Metallurgy

In the field of fundamental metallurgy, chemical problems are investigated in the extractive metallurgy laboratory. Facilities are provided for physical metallurgy, pyrometry, and microscopy. Another section is equipped for investigations by ultrasonics, X-rays, gamma-rays and radioisotope tracers.

The equipment necessary for this work includes polishers, microscopes, and metallographic apparatus, and an electron microscope is to be added. For radiography, generators of X-rays and gamma-rays are to be provided.

Special Features

To assist in the efficient operation of the laboratories several features have been given special attention. To deal with the dust and fumes which are an inherent problem in metallurgical operations, special drainage is provided in certain of the floors so that they can be flushed down with large quantities of water, and correct ventilation and exhaust have been carefully studied.

A flexible general layout is provided by the use of specially-constructed interior walls which can easily be removed and equally readily rebuilt.

MINING ENGINEERING

Mining engineering, which originally formed a partial specialization with metallurgy, later with geology, is now the concern of a separate department. Instruction is given in such field subjects as surveying, excavation, drainage, and mine management, as well as in the extractive processes essential to the mineral industry.

The new course takes into account the importance of mineral dressing and the department is equipped to study the various processes in addition to the facilities of the department of metallurgy.

Laboratories

The various sections of the mineral dressing laboratories cover a total area of some 12,600 sq. ft. One section is concerned with crushing, screening and sampling; another deals with methods of separation and concentration by gravity, jigging, Wilfley table, Humphreys, spiral, etc. Electrical separation by dry and wet methods, electrostatic precipitation, flotation, and other means are studied.

Cyanide extraction and similar processes using aqueous solutions are housed in a separate room fitted with driers, storage and settling tanks, filters, and so on. A group of continuous-analysis equipment enables the student to follow the course of the various processes and to make necessary adjustments.

The laboratories are fully equipped for the complete study of such problems as ore enrichment, and more extensive facilities than previously will be available for work on the 'new' and rarer metals.

GEOLOGICAL ENGINEERING

In addition to teaching the new specialized course, the department of geological engineering provides facilities for students of geology from other departments and for part of the course of the Faculty of Geology at the University of Montreal.

Essential for the study of geology, the department has gathered an extensive and varied collection of rock and ore samples, maps, and photographs, which are housed on either side of the department's own library.

Laboratories

The general mineralogy and geology laboratory is used for the elementary study of rocks and minerals. It can accommodate 100 students. In the crystallography, mineralogy, and petrography laboratories, crystallography is studied by use of crystal models and optical goniometer. Rocks, eruptive and metamorphic ones in particular, are studied with binoculars and petrographic microscopes, in thin sections, by polarized light.

Similar facilities are provided in the laboratory for the evaluation of mineral samples from the principal mining centres of Canada and elsewhere. Here, ore specimens are studied by polished sections under the ore microscope and by microchemical tests.

For the study of sedimentation, equipment includes binoculars, petrographic microscopes, precision balance, hot plates, evaporating baths, filters and a centrifuge. The same section is also used for Stratigraphy, Historical Geology and practical Paleontology, including the identification of fossils which involves the use of small drills and tools for removing the fossils and preparing them for examination.

Adjacent to the department's library is a map room with all facilities for map storage, examination and tracing.

Lectures and labs in Physiography, Structural Geology and Geology of Canada are given in a class-room having access to the map room.

Geophysics

Equipment now in use for instruction in geophysics includes dip-needles, magnetometers, Geiger counters, and scintillometers. Further equipment for a proposed research program will be bought or made locally.

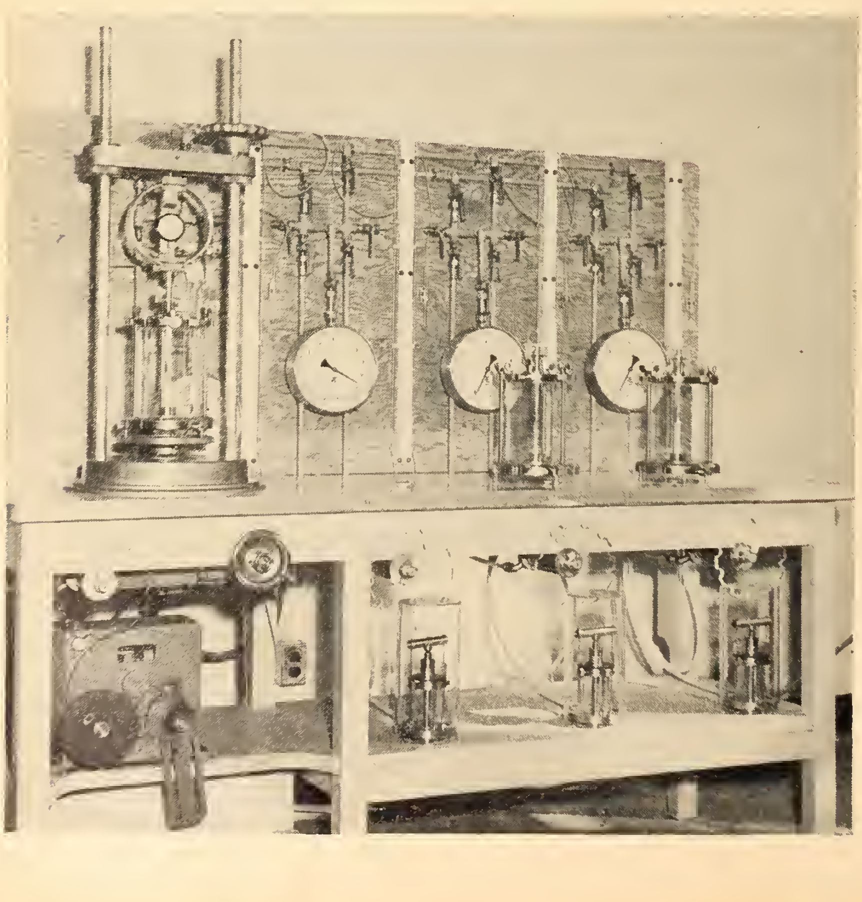
Research

Each professor in the department has his own small laboratory for personal research or work by one of his students. Other rooms are also available for graduate students.

The main research laboratory features the latest apparatus for the study of minerals and other crystalline materials by means of X-rays, diffraction, and spectro-fluorescence. Refractive indices are measured by the double variation method, with provision for monochromatic illumination, universal and heated stages.

Other equipment includes balances of a wide range of sensitivity, a Vreeland spectrometer, an isodynamic separator for magnetic minerals, a microscope for microphotography, etc. Equipment for the study of clay minerals by differential thermal analysis and various other research instruments are to be ordered in the near future.

Fig. 10 — Triaxial compression apparatus.



The Library

The library is an important feature of the Ecole Polytechnique and occupies a select position on two floors of the north-east end of the main entrance wing. The total area occupied is some 26,000 sq. ft.

On the first floor of the library, entered from the main hall, a central aisle extends the full length. The reception counter and administrative offices are near the entrance and opposite a room with table space for 32 persons, and containing the current year's issues of up to 1000 periodicals. Adjoining this is the general reference system, used for locating required publications.

In the middle section, about one-third of the total area, bookshelves run at right angles from either side of the aisle, with room to walk round the outer ends. Space is provided for five years issues of periodicals preceding the current year; earlier issues are stored on the second floor. The books are classified by the universal decimal system, and the shelves are marked for quick identification of the various sections. There is space for about 35,000 books.

At the far end of this floor is the reading room, which can seat 96 persons. This area is far enough away from the reception counter to avoid any disturbance to the readers, and the floor and ceiling of the library are insulated to minimize noise from people moving around.

A door in the library leads to part of wing D, in which is a room for reading microfilms, a bookbindery, and rooms for library staff.

The Second Floor

A metal staircase leads from the main library to the second floor, which also has a central aisle and is fitted with removable bookshelves, permitting considerable flexibility of arrangement.

In addition to issues of periodicals earlier than those held in the main library, this floor is used for storage of official publications from various countries and other volumes that are referred to less frequently. About

IMPREGNATED PAPER CAPACITORS

PAPER, IMPREGNATED with oil or other suitable insulating impregnant, remains the principal dielectric material used for power capacitors, and also for many radio capacitors. Over the last fifty years major improvements have been made in the quality of capacitor paper tissue, and of the oils and other impregnants. Despite the development of many synthetic dielectric polymers, few of them can compete economically with impregnated paper in the power capacitor field.

Among electrical components the capacitor can claim a respectable antiquity. The first capacitor antedates the first dynamo and the first cable by more than a century.

It was in 1746 that Pieter van Musschenbroek of Leyden wrote to his friend Réaumur, "I wish to inform you of a new, but terrible experiment, which I advise you on no account personally to attempt. I had suspended by two blue silk threads, a gun barrel, which received electricity from a glass globe. From the opposite end of the gun barrel hung a brass wire, the end of which entered a glass jar, which was partly full of water. Suddenly I received in my right hand a shock of such violence that my whole body was shaken as by a lightning stroke. The vessel, although of glass, was not broken, nor was the hand displaced by the commotion; but the arm and body were affected in a manner more terrible than I can express. In a word, I believed that I was done for". Thus the first capacitor, the *Leyden jar*, was accidentally discovered.

From those early days when electricity was but a toy, through the pioneer researches of Faraday, Franklin, Kelvin and others, to the modern electrical and electronic industries, the capacitor has remained an almost inevitable component of electrical experiments and electric equipment.

Today the manufacturer of capacitors supports an industry with an annual production of $20 million in Great Britain, of $79 million in the U.S.A., and of $9 million in Canada. The capacitors range from the massive capacitor banks, such as that at Sorel, Quebec installed for power factor correction, as shown in Fig. 1, to the miniature tantalum oxide capacitors less than the size of a pea used in transistor circuits.

As in other fields of engineering endeavour the rapidity with which new types of capacitors are being developed, and new scientific techniques are being applied to capacitor design, is greater than at any previous time. The object of this paper is to present a broad account of current capacitor research and development in Great Britain.

Paper Research

Research is in progress on the fundamental properties of cellulose papers, and on new types of "paper" using man-made fibres such as polystyrene, polyethylene terephthalate (Terylene), polytetrafluoroethylene (P.T.F.E.) and nylon, in combination with glass fibre or cellulose. A complete pilot-scale paper-making machine enables experimental papers to be made in the laboratory. Detailed studies are made of the electrical properties (permittivity, power factor, insulation resistance, breakdown strength, etc.), the physical properties (uniformity, density, porosity, transparency, mechanical strength, surface texture, shrinkage, effects of temperature and humidity, etc.) and of the chemical composition of experimental papers and of paper obtained directly from the suppliers. In this manner new types of paper with improved properties are being developed.

The *Talysurf* instrument is used for recording the surface texture of the paper i.e. the hills and valleys of the paper surface. A light stylus traverses the specimen paper and the surface profile irregularities are magnified and recorded. Fig. 2 is a typical record showing the differences in surface texture of different papers.

It has been shown by tests and microscopic examination that impulse breakdown of an oil/paper dielectric tends to occur at points where the paper is thinnest, even though these thin areas are so small as to be only one or two mil. in dimension. The paper is, of course, purchased on the basis of its average thickness, though its electrical performance is determined by these microscopic areas of minimum thickness. Thus the *Talysurf* records give a clear demonstration of the volume of paper which is being uselessly purchased.

Oil Research

Mineral oil is still the principal impregnating liquid used in paper capacitors. Fundamental studies of the properties of oil have resulted in the development of improved types of insulating oil. Apart from the usual measurements (permittivity, power factor, viscosity index, insulation resistance, electrical strength, acidity, water content, thermal conductivity, and so on) the molecular constitution of an oil is studied by means of ultra-violet and infra red spectrometry.

Mineral oil is a complex mixture of different hydrocarbons, which can be divided into three main groups, paraffinic, naphthenic and aromatic. The composition of the oil depends on its natural source and on its method of refinement. By the ultra-violet and infra-red spectograms just mentioned it is possible to determine the relative proportions of the paraffins, naphthenes, and aromatics, and also the detail structure within these groups.

A thorough investigation has been made of the evolution and absorption of gas by oils, when subjected to high electrical stresses. The "gassing" qualities of an oil have an important influence on its behaviour as a capacitor impregnant, and it is hence essential to have a quantitative measure of this property. The evolution or absorption of gas, with the oil under electric stress is measured by means of the "gassing cell".

It has been found that as the aromatic content of an oil is increased, its tendency to evolve gas is reduced. On the other hand, as the aromatic content is increased, the oil becomes more susceptible to degradation by heat and electric stress. By adjustment of the aromatic content combined with the addition of appropriate anti-oxidants, it is, however, possible to constitute an impregnant in which both properties are satisfactory.

Other Impregnants

Similar work is in progress on the chlorinated diphenyl impregnants (Aroclors). Since the decomposition products of these materials are toxic and acidic, and hence can corrode the capacitor electrodes, leads and cases, care is required in their utilisation if the high reliability and long service life achieved with oil impregnants is to be maintained. The one attractive feature of chlorinated diphenyl, compared with oil, petroleum jelly or other non-polar impregnants is its relatively high permittivity, which enables the size of the basic capacitor to be reduced by a factor of about 40% or more. The increased permittivity is due to the polar nature of the chlorinated diphenyl molecules, and this results in increased power factor, relatively large variations in capacitance with temperature, and reduced insulation resistance, compared with mineral oil.

Other high-permittivity polar impregnants employed or studied as alternatives to the chlorinated diphenyls include castor oil, fluorinated aromatic compounds and the organic amines.

Ionisation Studies

A major factor determining the ultimate breakdown under stress of an impregnated capacitor is the ionisation discharge occurring in gaseous "voids" in the dielectric. During the last few years, extensive studies have been made of ionisation phenomena, and other long-term deterioration effects, in paper capacitors.
